ACR/ARHP 2009 Annual Scientific Meeting Overall Needs Assessment

Submitted by Joel A. Block, MD, Chair & Brian F. Mandell, MD, PhD, Immediate Past-Chair on behalf of the Annual Meeting Planning Committee.

Rheumatologists need in-depth knowledge of the most recent developments in rheumatology to ensure the highest standards of patient care and safety. They rely heavily on the ACR/ARHP Annual Scientific Meeting to meet this need.

The ACR/ARHP has created a forum for physicians and health professionals to receive the most relevant and timely information at the annual meeting. In addition to the presentation of the latest peer selected clinical and scientific abstracts, invited speakers will provide clinical, practice and quality focused, education delivery, and basic scientific information in various formats including, didactic lectures, debates, and interactive sessions, such as poster tours, Meet the Professors and Workshop sessions.

Sessions and topics are chosen for presentation at the annual meeting by the AMPC, a diverse group of individuals with representation from full-time clinical practice, academic, and institutional environments, as well as the international rheumatology community. The selection of the annual program proceeds after a systematic review of feedback provided by the ACR membership and past meeting attendees. Feedback on content needs is solicited annually after the Annual Scientific Meeting. Attendance at individual sessions is recorded, and the content areas of highly attended sessions are offered again the next year. The charge of the AMPC is to produce a meeting that communicates the latest important science, evidence-based clinical recommendations, and experience derived management strategies in the rheumatic diseases.

Clinician representation on the AMPC expressed a need for more discussion of practical management issues, in a forum that could accommodate a larger proportion of the attendees. Several innovations have been added in the last two years to meet those needs. These include the Curbside Consults – Ask the Professors session, and additional Medical Aspects lectures. This year, a series of Clinical Management sessions, such as a Thieves' Market, Radiology Pearls and management of difficult issues, will be added.

Workforce assessment indicates that pediatric expertise is not universally available. Therefore, a specific pediatric rheumatology curriculum is integrated into the annual meeting to provide pediatric updates to adult rheumatologists, in addition to providing a high-level educational program to pediatric rheumatologists.

As new practice guidelines are developed, formal presentations are provided to alert the membership and explain, in an open forum, the data supporting the guidelines and propose approaches for implementation; similarly, as new technology relevant to musculoskeletal diseases is adopted clinically, such as ultrasound, workshops and talks are provided to facilitate their utilization in attendees' clinical practices. Training program directors are surveyed formally and informally regarding education gaps as they relate to curriculum development. Results of the in-training examination and other evaluations are, and will be increasingly utilized to support content development at the annual meeting. For instance, assessment of competence and skill in synovial fluid analysis of trainees and staff has reinforced the need to offer workshops continuously on synovial fluid analysis at the annual meeting. Workshops are offered on skin score because it was recognized during the conduct of clinical trials in patients with scleroderma that clinicians were not uniformly measuring the progression of the disease, and obtaining a skin score at the time of examination provides a standardized measure for recording progression or response to treatment. Focus groups have been added to our toolbox of approaches to assess the educational needs of our attendees.

The basic science of rheumatology is a rapidly advancing field, and is covered extensively in the schedule. Basic Science Symposia, State-of-the-Art Lectures, a series of Immunology Updates for the Clinicians, and a Basic Science pre-meeting course are offered. The science curriculum is developed by a sub-committee of the AMPC consisting of U.S. and internationally prominent basic scientists.

We will continue to expand our efforts to poll the membership regarding their needs and desires, as well as vigilantly continue to review quality and pay-for-performance initiatives to guarantee that the needs of the rheumatology community and of our patients are consistently met.

About ACR/ARHP Education

ACR/ARHP Program Objectives

The American College of Rheumatology and the Association of Rheumatology Health Professionals, a division of the ACR, are organizations of physicians, health professionals and scientists serving members through programs, including education and research. Through these programs, the ACR and the ARHP foster excellence in the care of people with rheumatic and musculoskeletal diseases.

The 2009 ACR/ARHP Annual Scientific Meeting programs have been independently planned by the ACR Committee on Education, the ACR Annual Meeting Planning Committee, the ARHP Program Committee, the ARHP Advanced Practice Skills Training Course Task Force and the ARHP Clinical Focus Course Task Force.

This program is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather are intended to present the opinions of the authors or presenters, which may be helpful to other healthcare professionals. Attendees participating in this medical education program do so with full knowledge that they waive any claim they may have against the ACR for reliance on any information presented during these educational activities. The ACR does not guarantee, warrant or endorse any commercial products or services.

Program Objectives

At the conclusion of the 2009 ACR/ARHP Annual Scientific Meeting, participants should be able to:

- identify recent developments in the diagnosis and management of patients with rheumatic diseases
- outline new technologies for the treatment of rheumatologic problems
- describe potential challenges to the delivery of care to patients with rheumatic diseases and specify possible solutions
- utilize new research data to improve the quality of care of patients with rheumatic diseases

CME Credit and Certificates of Participation

Physicians

The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to sponsor continuing medical education for physicians. The following activities have been approved for 52.75 *AMA PRA Category 1 Credit(s)™*: the Basic Research Conference, the Clinical Research Conference, the Review Course, the ACR/ABIM MOC Learning Session For Recertification, the ARHP Clinical Focus Course, the ARHP Advanced Practice Skills Training Course, the ACR Scientific Sessions including the ACR Workshops and the ACR Meet the Professor Sessions. Physicians should only claim credit commensurate with the extent of their participation in the activity.

Health Professionals

As a division of the College, the Association of Rheumatology Health Professionals offers a Certificate of Participation.

The ARHP designates the Clinical Focus Course, the ARHP Advanced Practice Skills Training Course, the ACR/ARHP Scientific Sessions, the ACR pre-conference courses, the ACR Meet the Professor and Workshop sessions for hours of participation.

International Physicians

International physicians, who register as part of a group and require *AMA PRA Category 1 Credit(s)™*, must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers, and e-mail address. The information will be used to verify your meeting attendance.

Meeting Evaluations

Computers are available on-site for you to complete your CME/ Certificate of Participation application and meeting evaluation form online during the meeting. In addition, you can complete the evaluation and print your certificate after you return home. Paper CME application forms will not be available.

Conflict of Interest/Disclosure Statement

As an educational provider accredited by the Accreditation Council for Continuing Medical Education (ACCME), the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all speakers and moderators participating in an ACR sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Speakers, moderators and abstract authors submitted their disclosure online prior to publication. Disclosures for invited speakers are listed in the program book indices and online. These disclosures are listed by presenters' last name in numeric format according to the list above.

Abstract author disclosures are published online as well as in this supplement. Disclosures for the Late-Breaking Abstracts are published online and in the December issue of *Arthritis & Rheumatism*. Any individual who refuses to disclose relevant financial relationships will be disqualified from being a planning committee member, a presenter, or an author of a CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Antibodies against An HSP Epitope Suppress Autoimmune Arthritis by Modulation of Cytokine Regulation. Y. Naparstek, G. Katzavian, R. Meyuhas, A. Hershko, E. Moallem and R. Ulmansky, Hadassah University Hospital, Jerusalem, Israel

Purpose: We have previously shown that resistance to Adjuvant Arthritis (AA) is due to the presence of anti-heat shock protein (HSP) antibodies, directed at peptide 6, a 16 amino-acid surface epitope.

Method: In this work we have studied the effect of antibodies against peptide 6 on various models of autoimmune arthritis and the mechanism of their anti-inflammatory effect.

Results: Active vaccination with peptide 6 as well as passive vaccination with monoclonal anti-peptide 6 murine and chimeric monoclonal antibodies suppressed significantly murine adjuvant and collagen arthritis. Incubation of murine and human mononuclear cells with the protective antibodies induced the secretion of IL-10. The antibodies bound to a surface molecule on human cell membrane and induced upregulation of IL-10 mRNA, via a cAMP associated pathway. The level of anti peptide 6 antibodies in the serum of patients with rheumatoid arthritis was significantly lower than in healthy controls. We have recently developed a humanized anti-peptide 6 antibody devoid of immunogenic epitopes. This antibody has similar immunomodulatory effects as those of the murine and chimeric antibodies.

Conclusion: We conclude that HSP contains protective B-cell epitopes exposed on its surface, and that natural and acquired resistance to autoimmune arthritis is associated with the ability to develop an antibody response to these epitopes. These antibodies cross react with a macrophage surface receptor and modulate cytokine production. Lower levels of anti peptide 6 antibodies in patients with RA suggest that they play a role in protection against human autoimmune diseases as well. The monoclonal humanized anti-peptide 6 antibody, as well as active vaccination with peptide 6, may serve as new therapeutic tools for suppression of human arthritis by skewing the immune system selectively towards an anti-inflammatory response.

2

A Therapeutic Vaccine Arrests Disease Progression in the Collagen Type II (Bovine) Murine Model for Rheumatoid Arthritis by Altering Cytokine Environment. Daniel Zimmerman[1], Eyal Talor[2], Patricia Taylor[3], Sean O'Neill[4], Alison Bendele[5] and Kenneth Rosenthal[6], [1]CEL SCI Corporation, Vienna, VA, [2]CEL, Vienna, VA, [3]Northeastern Ohio colleges of Medicine, Rootstown, [4]Washington Biotech, Columbia, MD, [5]BolderBiopath, Bolder, CO, [6]Northeastern Ohio colleges of Medicine, Rootstown, OH

Purpose: The collagen type II (bovine) (CIA) induced arthritis murine model is often used to evaluate treatments for rheumatoid arthritis (RA). Following initial induction, the disease progresses into a more classical cell and cytokine mediated pathogenesis. We will use this model to evaluate a new therapeutic vaccine for RA

Method: Male (7-8 week old) DBA/1J mice with CIA induced arthritis were either untreated or treated with the CEL-2000 L.E.A.P.S. experimental therapeutic vaccine or etanercept (Enbrel). CEL-2000 vaccine consists of 2 peptides of human origin, a segment of the beta 2 microglobulin molecule referred to as peptide J and a peptide (254-273) from human collagen Type II. Disease was induced by 2 immunizations of bovine type II collagen on day 0 (in CFA) and day 21 (in ICFA). The mice were scored daily for an Arthritic Index (AI) score. Therapy was initiated when the mice (n=8) had a group mean AI score of 3.5 +/- 0.1 and range of 1-6. CEL-2000 vaccine 33 or 100 nmole was administered on day 0 and 7 of therapy and etanercept 3 mg/kG was administered every other day for the 28 days unless otherwise noted. Mice were evaluated at least 3 times a week for **A**) footpad swelling and **B)** AI score. At the termination of the study, tissue sections were evaluated for **C**) histopathological parameters including 1) inflammation, as evidenced by accumulation of eosinophils, basophils, neutrophils and macrophages, 2) cartilage destruction 3) bone resorption, and 4) pannus membrane formation in the synovial

space. **D)** Sera, collected at the start of therapy and 10 days later, were evaluated for levels of 22 cytokines / chemokines, as measured by the RayBiotech protein array.

Results: By all four parameters there was a statistically significant ($p \leq 0.05$ or better depending on the day of therapy and parameter being considered) benefit of the CEL-2000 vaccine therapy and to a lesser extent for etanercept therapy. CEL-2000 caused an increase in IL-12p70 and IL10 and reduction in disease associated serum levels of TNF-a, IL-17, IL-6, MCP-1 and IL-12p40. A number of cytokine changes were also seen with Enbrel although to a lesser degree

Conclusion: CEL-2000 vaccine administered as a therapy arrested the progression of RA disease and its efficacy was demonstrated by reduction in disease parameters (AI) and in the reduction of serum levels of pro-inflammatory cytokines.

3

Administration of IL-18BP by Gene Therapy Reduces Inflammation in Rat AIA. Hubert Marotte[1], Jeffrey H. Ruth[1], Salahuddin Ahmed[2], Mohammad A. Amin[1], Phillip L. Campbell[1], Jean Dudler[3] and Alisa E. Koch[4], [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Toledo, Toledo, OH, [3]Service de Rhumatologie, Médecine Physique et Rééducation, Epalinges, Switzerland, [4]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Interleukin-18 (IL-18) is a proinflammatory cytokine that is of pivotal importance for the induction of production of T helper (Th)1 cells. Enhanced production of IL-18 has been linked to the pathogenesis of diseases such as rheumatoid arthritis (RA). The natural inhibitor of IL-18 is the IL-18 binding protein (IL-18BP), which appears to be a promising novel therapeutic strategy for RA. This study examined expression of rat IL-18 and IL-18BP at various time points in the rat adjuvant-induced arthritis (AIA) model. Then, the benefit of ankle intra-articular injection of adenovirus (Ad) producing murine (m) IL-18BP-IgG1 (which cross-reacts with rat IL-18) was explored in the rat AIA model, in which arthritis is maximal at days 14-18 post-adjuvant injection.

Methods: After induction of rat AIA, 3 rats were sacrificed at various time points (Day 0, 7, 11, 14, 18, 25, and 45). Ankle joints were homogenized and used for mRNA isolation. Rat IL-18 and IL-18BP expression at the mRNA level was assessed using qRT-PCR. In a preventative study, rats were divided into an AdmIL-18BP-IgG1 group (n=8) and an Ad green fluorescent protein (AdGFP) group (n=7). On day 8 after AIA induction, 1×10^8 plaque-forming units of the adenovirus (AdmIL-18BP-IgG1 or AdGFP) were injected into each ankle in a 10 µL volume. Clinical parameters (body weight, circumference, volume of both ankles, and articular score) were assessed on days 0, 2, 4, 7, 9, 11, 14, 16, 17, and 18 after adjuvant injection.

Results: IL-18 and IL-18BP were both expressed in joints during development of rat AIA. We found a time-dependent increase of both IL-18 and IL-18BP. Furthermore, we observed a decrease in the [IL-18BP/IL-18] expression (roughly 40%) from day 7 to day 45. Administration of AdmIL-18BP-IgG1 decreased articular index scores at days 15 and 17 compared to AdGFP therapy (mean ± SEM; 2.9 ± 0.3 vs. 3.7 ± 0.2; $p < 0.05$ at day 15 and 3.1 ± 0.3 vs. 3.9 ± 0.1; $p < 0.05$, respectively); and paw volume at day 18 (2.1 ml ± 0.1 vs. 2.6 ml ± 0.1; $p < 0.05$). We found a decrease in the change in ankle circumference (minus day 0) values at day 18 compared to day 0 in the AdmIL-18BP-IgG1 group versus the AdGFP group (19.4 mm ± 2.3 vs. 25.2 mm ± 1.8; $p < 0.05$).

Conclusion: In rat AIA, we observed a decrease in the [IL-18BP/IL-18] expression before and during arthritis development. Preventatively, AdmIL-18BP-IgG1 restored IL-18BP expression and reduced joint inflammation in rat AIA, suggesting a potential benefit of similar therapy in RA.

Active Immunization Against IL-23 p19 Improves Collagen-Induced-Arthritis. Emilie Duvallet[1], Rojo Ratsimandresey[2], Eric Assier[1], Laure Delavallée[1], N. Bessis[1], Jean-François Zagury[2] and Marie-Christophe Boissier[3], [1]EA 4222 Paris 13 University, Bobigny, France, [2]Paris, France, [3]AP-HP, Avicenne hospital, Bobigny, France

Purpose: IL-23 is a pro-inflammatory cytokine known to be essential for the differentiation of the Th17 lymphocytes, a subtype of T lymphocytes implied in autoimmunity. Its subunit, IL-23 p19, is specific of this cytokine. We had previously demonstrated for IL-1beta and TNF-alpha, that active immunization against these cytokines could be protective in animal models of arthritis. The aim of this study was to evaluate the effect of two vaccines targeting the IL-23 p19 subunit, IL23-K1 and IL23-K2, on collagen-induced-arthritis (CIA).

Method: Using bioinformatics, we defined two peptides in IL-23 p19. Each peptide was coupled with keyhole limpet hemocyanin (KLH). Anti-murine IL-23 immunization was performed by injecting intra-muscularly IL23-K1 or IL23-K2 formulated in incomplete Freund adjuvant (IFA), four times (D0, 7, 28, 49) in DBA/1 mice. Control groups received KLH or PBS at the same dates. CIA was induced by two subcutaneous injections of bovine type II collagen, the first at Day 40 in Complete Freund Adjuvant, the second at Day 61 in IFA. Anti-IL-23 and anti-KLH antibody levels were assessed by ELISA. Pro and anti-inflammatory cytokines were quantified by qRT-PCR on the spleen and the synovium.

Results: The clinical scores show that mice treated with either IL23-K1 or IL23-K2 develop less arthritis than the negative controls ($p<0.05$). Mice vaccinated by IL23-K1 produced more anti-IL23 antibodies than the one vaccinated by KLH ($p<0.001$). mRNA quantification showed that the IL23-K1 vaccination led to an increase of IL-10 in the spleen ($p<0.05$ vs KLH), without any effect on IL-17 level. Histology examination showed that IL23-K1 permitted a strong decrease of the joint destruction and inflammation ($p<0.01$ vs KLH and $p<0.001$ vs PBS).

Conclusion: These data show that targeting IL-23 p19 using a vaccination strategy may be efficient in CIA.

Disclosure: E. Duvallet, None; **R. Ratsimandresey**, None; **E. Assier**, None; **L. Delavallée**, None; **N. Bessis**, None; **J. F. Zagury**, None; **M. C. Boissier**, None.

IL-17 Upregulates Neutrophil Chemokines in Macrophages and RA Synovial Tissue Fibroblasts as Well as in Experimental Arthritis. Shiva Shahrara, Sarah R. Pickens, Chiang-Ching Huang and Richard M. Pope, Northwestern University Feinberg School of Medicine, Chicago, IL

Introduction: Previous studies have shown that IL-17 plays an important role in experimental arthritis, yet the mechanism by which it may contribute to the pathogenesis of rheumatoid arthritis (RA) is undefined.

Purpose: These studies were performed to identify downstream targets of IL-17 in cells present in RA synovium, namely macrophages and RA synovial tissue (ST) fibroblasts, as well as in an IL-17 experimental arthritis model.

Methods: RA ST fibroblast from 6 patients were treated with IL-17 (50 ng/ml) for 5h or left untreated. Thereafter, cells were harvested and microarray was performed using Illumina BeadArrays. The data were normalized by a quantile normalization procedure, the chip to chip variation was adjusted by the ComBat algorithm and IL-17 differentially expressed genes were identified by Student's t test. The biological function was then identified employing the PANTHER gene ontology analysis. Genes identified by microarray were confirmed by real-time RT-PCR. Macrophages In vitro differentiated from normal monocytes were also examined for IL-17-induced target genes that were identified in RA fibroblasts. Next, we examined whether local expression of IL-17 in the ankle joints modulated the expression of IL-17 downstream target genes identified in RA fibroblasts and macrophages using ELISA. Finally, ankles harvested from adenovirally expressed IL-17 (Ad-IL-17) or the control group (Ad-CMV) were stained with GR1.

Results: Employing microarray, we found that genes upregulated by IL-17 in RA ST fibroblasts included neutrophil chemokines which consisted of CXCL1, 2, 5 and 8 as well as leukemia inhibitory factor (LIF). Expression of CXCL1, 2 and 5 was confirmed in IL-17 activated RA fibroblasts employing real-time RT-PCR. Results from these studies demonstrated that while CXCL2 was activated as early as 2h ($p<0.05$), CXCL1 and 5 were significantly upregulated within 6-8h ($p<0.05$). Interestingly, RA ST fibroblasts activated with IL-17 and TNF-a demonstrated significantly greater levels ($p<0.01$) of CXCL1, 2 and 5, compared to cells activated with IL-17 or TNF-a alone. CXCL1 and CXCL5 were also upregulated ($p<0.05$) following IL-17 stimulation employing in vitro differentiated macrophages starting at 4 to 6h, respectively. Examination of murine ankles injected with Ad-IL-17 demonstrated increased levels of CXCL1 and CXCL5 on days 4 and 10 post injection, compared to the Ad-CMV control group. In contrast CXCL2 was not different between the two groups. Consistently, anti-GR1 staining was 5 to 10 fold higher in the Ad-IL-17 group on days 4 and 10, respectively, compared to that of controls.

Conclusion: Collectively, our results obtained from control macrophages and RA ST fibroblasts, as well as the data generated from IL-17 experimental arthritis model, suggest that IL-17 can induce the expression of neutrophil chemokines and thereby modulate migration of neutrophils into the arthritic joint. IL-17 and its activated downstream factors may be a therapeutic target in patients with RA.

IL-18 Receptor Null Mice Are Resistant to K/BxN Serum Transfer Arthritis Due in Part to Impaired Angiogenesis. Mohammad Amin[1], Jeffrey H. Ruth[1], Yong Hou[1], Phillip L. Campbell[1], Amrita Seehra[1] and Alisa E. Koch[2], [1]University of Michigan, Ann Arbor, MI, [2]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Interleukin-18 (IL-18) is a pleiotropic cytokine which plays a key role in the pathogenesis of chronic inflammatory diseases such as rheumatoid arthritis (RA). We have previously shown that IL-18 is a novel mediator of angiogenesis, a process essential for the development of the RA synovial tissue pannus and consequent ingress of inflammatory leukocytes. This study investigated the mechanisms of decreased arthritis and angiogenesis in IL-18 receptor null mice.

Methods: We performed the K/BxN serum transfer arthritis model in IL-18 receptor null and wild type (wt) mice to determine the role of the IL-18 receptor in arthritis and angiogenesis. In this model, mice develop arthritis starting from day 2-3, and arthritis lasts for 2-3 weeks. We scored front paws and measured ankle circumference. We measured hemoglobin (Hb%), which correlates with vascularity, in arthritic ankle homogenates. We performed immunohistochemistry using rabbit anti-human von Willebrand factor (vWF) to examine blood vessels in mouse joint sections. We used Matrigel plug angiogenesis assays with IL-18 receptor null and wt mice. We performed enzyme linked immunosorbent assays (ELISAs) using ankle homogenates of arthritic mice for cytokine determination.

Results: IL-18 receptor null mice were resistant to K/BxN arthritis, showing a significant decrease in articular index and ankle circumference compared to wt mice ($p<0.05$). Mouse ankles were harvested on day 7 and homogenized to determine Hb%. We found >4 fold significant decrease in Hb% levels in IL-18 receptor null mouse ankle homogenates compared to wt mouse ankle homogenates ($p<0.05$). There was a significant ~2 fold decrease in blood vessels in IL-18 receptor null mouse joint sections compared to wt mice, as determined by vWF, an endothelial cell marker. In the Matrigel plug angiogenesis assay, acidic fibroblast growth factor induced singnificantly more angiogenesis in wt than IL-18 receptor null mice. To determine the mechanism of impaired angiogenesis and defective arthritis in IL-18 receptor null mice, we performed ELISAs for angiogenic mouse basic fibroblast growth factor (bFGF) and KC/CXCL1, a functional homologue of human IL-8, using mouse ankle homogenates. We found more than a 3 fold significant decrease in bFGF and 5 fold significant decrease in KC/CXCL1 in IL-18 receptor null mouse ankle homogenates compared to wt mouse homogenates, suggesting that the IL-18 receptor is critical in the production of potent angiogenic factors, such as bFGF and KC/CXCL1. This also suggests that the IL-18 receptor plays an important role in both angiogenesis as well as in arthritis development.

Conclusion: These studies suggest that IL-18 receptor null mice have impaired angiogenesis and arthritis in part due to decreased bFGF and KC/CXCL1. These results provide strong evidence that the IL-18 receptor plays an essential role in angiogenesis and arthritis in rodent models of RA, and suggest a novel therapeutic avenue for RA.

7

Blockade of the IL-7 Receptor Inhibits Collagen-Induced Arthritis and Is Associated with Reduction of T-Cell Activity and Proinflammatory Mediators. Sarita A.Y. Hartgring[1], Cynthia R. Willis[2], Dina Alcorn[2], Laurel J. Nelson[2], Johannes W. J. Bijlsma[1], Floris P.J.G. Lafeber[1] and Joel A.G. van Roon[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Amgen Inc., Seattle, WA

Purpose: High levels of IL-7 are found in several arthritic conditions including rheumatoid arthritis (RA). IL-7 induces T cell-dependent activation of monocytes, B cells, and osteoclasts. IL-7 activity is critically dependent on signaling through the IL-7receptor α (IL-7Rα). Increased intraarticular IL-7Rα expression is present in the synovium of RA patients, and this receptor is expressed on highly proliferating synovial T cells but not on regulatory FoxP3+ T cells. Inhibition of IL-7/IL-7Rα signaling *in vitro* decreased IL-7-induced Th1 activity of

mononuclear cells from RA patients. Our purpose was to evaluate the effects of prophylactic and therapeutic IL-7Rα blockade in the collagen-induced arthritis (CIA) model. Additionally, we assessed the mechanisms by which IL-7Rα blockade regulates CIA.

Method: CIA was initiated by immunizing male DBA/1 mice with chicken type II collagen. Mice were treated with 100mg anti-IL-7Rα (on day 21, 24, 27, and 30). Clinical arthritis was determined by visual examination of swelling and redness of the paws. Radiographs of the ankles were taken on day 33, and joint destruction was scored. Cellularity of thymus and spleen and numbers of T-cell subsets, B cells, macrophages, and dendritic cells were assessed. T-cell cytokines, indicative of Th1, Th2, and Th17 activity and several proinflammatory mediators were assessed by multi-analyte profiling in paw protein lysates. In addition, T-cell associated cytokines were measured by intracellular cytokine staining and by ELISA in supernatants of collagen-restimulated lymph node cell cultures.

Results: Anti-IL-7Rα treatment significantly reduced arthritis severity, associated with reduced radiological joint damage (both $p<0.05$). Both thymic and splenic cellularity were reduced by 30% upon IL-7Ra treatment. IL-7Rα blockade reduced splenic numbers of total, naïve, and memory CD4 and CD8 T cells (all $p<0.05$). Significant reductions in T-cell associated cytokines (IFNγ, IL-5, and IL-17) were measured. In addition, IL-7Rα blockade significantly decreased (at least $p<0.05$) local levels of proinflammatory cytokines, chemokines, acute phase reactants, and factors associated with tissue destruction (incl. TNFα, IL-1β, CRP, RANKL). IL-7Rα blockade did not affect numbers of B cells, macrophages, DC subsets, or B-cell activity (indicated by serum anti-collagen IgG antibodies).

Conclusion: Blockade of the IL-7Rα potently inhibited joint inflammation and destruction, associated with reductions of T-cell numbers, T-cell cytokines and numerous mediators that induce inflammation and tissue destruction. This study demonstrates an important role of IL-7R-driven immunity in experimental arthritis and indicates the therapeutic potential of IL-7Rα blockade in human arthritic conditions.

8

In Vitro and In Vivo Properties of MEDI-571, a Human Anti IL-17A Antibody in Development for the Treatment of Patients with Rheumatoid Arthritis. Caroline Langham[1], Caroline Russell[2], Wendy Barker[1], Mark Abbott[1], Sarah Almond[1], Elizabeth Kelly[1], Sarah Dawson[1], Maurice Needham[1], Ian Anderson[2], Fraser Welsh[2] and Matthew A. Sleeman[2], [1]Astrazeneca, Loughboruough, United Kingdom, [2]MedImmune LLC, Cambridge, United Kingdom

Purpose: IL-17A has been proposed as a key cytokine involved in the pathogenesis of a number of inflammatory diseases such as rheumatoid arthritis (RA). Recently clinical trials have been initiated with antibodies to this cytokine to investigate the IL-17 axis in RA. Using a panel of *in vitro* assays and *in vivo* models of IL-17A activity we describe the activity of a novel anti-human IL-17A IgG1 (MEDI571) for the treatment of RA.

Method: The ability of MEDI571 to neutralise IL-17A activity was assessed in multiple *in-vitro* assays. HT1080 cells, RA synovial fibroblasts and chondrocytes were stimulated with IL-17A alone or in combination with TNFa and the levels of IL-6 and/or IL-8 quantified by ELISA. The *in vivo* activity of MEDI571 was investigated using a rodent airpouch model (Willoughby et al., 1986). A dose range of MEDI571 was delivered i.p. 24hrs prior to direct challenge of the airpouch with 0.3mg of IL-17A. Total white cell influx and IL-6 levels within the pouch were calculated. The role of native IL-17A in arthritis was investigated in a rat SCW induced arthritis model using an anti-mouse IL-17A antibody (MAB421).

Results: IL-17A dose dependently induced IL-6 and IL-8 production from HT-1080 cells and OA chondrocytes, and IL-8 from RA synovial fibroblasts. MEDI-571 inhibited the production of IL-6 by IL-17A induced HT1080 cells with an IC50 of 830pM. The IC50s of MEDI571 in the human chondrocyte assay were 1.44 and 1.3nM for IL-6 and IL-8 respectively. MEDI571 inhibited IL-17A and IL-17A/TNF synergised IL-8 induction from RA synovial fibroblasts with IC50s of 2.85 and 4.97 nM respectively. *In vivo* systemic administration of MEDI571 (i.p.) prior to the administration of human IL-17A (0.3 μg) directly to the airpouch completely inhibited the white blood cell and IL-6 responses with IC50s of 0.68 mg/kg and < 0.1mg/kg respectively. To strengthen rationale we also evaluated an anti mouse IL-17 antibody in a rat SCW arthritis model. In this system blocking IL-17A had a protective effect against arthritis at 1mg/kg as determined by ankle width and radiographic score.

Conclusion: Pre-clinical research has shown that IL-17A plays a significant role in RA. Our data supports this observation, demonstrating that IL-17A is instrumental in the induction of key mediators such as IL-6 and IL-8 from synovial fibroblasts and chondrocytes. In all cases,

MEDI-571 was able to inhibit these activities. Furthermore, in vivo we demonstrated that MEDI-571 could inhibit IL-17A induced inflammation. Moreover IL-17 blockade in the SCW arthritis model could protect against joint damage. These observations support the hypothesis that in RA, inhibiting the IL-17A network within key compartments of the inflamed joint may suppress proinflammatory cytokines and inflammatory cell trafficking, thus potentially provide clinical benefit.

ASC Deleted Mice Are Resistant to Collagen-Induced Arthritis. Hideshi Yamazaki[1], Michiko Takeoka[1], Takashi Ehara[2], Naoki Itano[1], Hiroyuki Kato[3] and Shun'ichiro Taniguchi[1], [1]Shinshu University Graduate School of Medicine, Matsumoto, Japan, [2]Shinshu Unversity School of Medicine, Matsumoto, Japan, [3]Shinshu University School of Medicine, Matsumoto, Japan

Purpose: Although the major pro-inflammatory cytokines tumor necrosis factor α (TNFα), IL-1β, and IL-6 are all considered to be key mediators in joint inflammation and cartilage and bone destruction in rheumatoid arthritis (RA), increased attention is also being given to the involvement of IL-18 in RA pathogenesis. IL-18 and IL-1β are generated via cleavage of their pro-forms in the presence of the apoptosis-associated speck-like protein containing a caspase recruit domain (ASC), a known adapter protein that activates upstream procaspase-1. As such, we investigated the involvement of ASC in the development and progression of autoimmune arthritis.

Method: In experiment 1, collagen-induced arthritis (CIA) was developed in highly susceptible DBA/1J mice and alterations in the expression of ASC, pro-inflammatory cytokines, and proteins were evaluated by immunohistochemistry and Western blot analysis. In experiment 2, CIA was developed in ASC-deleted ($ASC^{-/-}$) mice and wild-type ($ASC^{+/+}$: C57BL/6J) mice following four back-crosses to the DBA/1J background. Histological findings and expression of pro-inflammatory cytokines in knee joints were then compared between the two groups, and disease severity in joint sections was graded using a scoring system.

Results: Experiment 1 revealed that ASC, caspase-1, IL-1β, and IL-18 were expressed in the joints of CIA mice, whereas no such expression was observed in controls. In experiment 2, histological analysis and disease scores revealed significant suppression of joint destruction in the CIA-$ASC^{-/-}$ mice (n=5) compared with CIA-$ASC^{+/+}$ mice (n=6). Expression of IL-1β and IL-18 was also suppressed in the joints of CIA-$ASC^{-/-}$ mice compared with wild-type mice.

Conclusion: This study showed increased expression of ASC, caspase-1, IL-1β, and IL-18 in CIA mice and suppressed histological scores associated with diminished levels of IL-1β and IL-18 in the joints of CIA-$ASC^{-/-}$ mice. These data suggest that ASC signaling pathways that include caspase-1 activation might be involved in the exacerbation of RA. However, the expression of IL-1βand IL-18 witnessed in CIA-$ASC^{-/-}$ mice indicates that pathways other than ASC may be involved as well.

Overexpression of T-Bet in T Cells Attenuates the Development of Collagen Induced Arthritis. Yuya Kondo, Isao Matsumoto, Yao Zhaojin, Makoto Sugihara, Taichi Hayashi, Daisuke Goto, Satoshi Ito, Satoru Takahashi and Takayuki Sumida, University of Tsukuba, Tsukuba, Japan

Purpose: CD4+ T cells play an important role in the generation of rheumatoid arthritis, however it is unclear whether Th-1 or Th-17 cells are the pathogenic mediator of arthritis. To clarify the influence of overexpression of Th-1 specific master regulator T-bet on the pathogenesis of collagen induced arthritis (CIA).

Method: 1) Arthritis was induced with chicken type II collagen (CII) emulsified with complete Freud's adjuvant (CFA) in C57BL/6 mice (B6) and T-bet transgenic (T-bet Tg) mice under CD2 promoter, the incidence and severity of arthritis was assessed. 2) Cells in draining lymph nodes harvested 10 days after immunization of CII were analyzed for the proportion and number of T cell subsets by flow cytometry. 3) After these cells were cultured *in vitro* with CII for 72 h, the expression of T-bet in CD4+ cells was analyzed by intracellular staining. 4)

Cytokine production by CD4+ T cells was analyzed by intracellular cytokine staining, and cytokine levels in supernatants were measured by enzyme-linked immunosorbent assay (ELISA). 5) CII specific IgG in sera collected 56 days after immunization was measured by ELISA.

Results: 1) The incidence and severity of arthritis was significantly suppressed in T-bet Tg mice. 2) The number of total T cells, CD4+ T cells and CD8+ T cells were decreased in the draining lymph nodes harvested from T-bet Tg mice compared with B6 mice. 3) The proportion of T-bet expression in CD4+ T cells was elevated. 4) Flow cytometry analyses in CD4+ T cells restimulated with CII in vitro revealed that the proportion of IFNγ+ cell was not increased in T-bet Tg mice. Furthermore, not only IL-17 level but also IFNγ level in supernatants were significantly reduced in T-bet Tg mice. 5) CII specific IgG production was suppressed in T bet Tg mice.

Conclusion: In T-bet Tg mice, overexpression of T-bet in T cells attenuates CIA. The mechanism might be due to decreased number of T cells and low immunity response to CII, not the predominant Th-1 differentiation.

TGF-β-Induced CD4+Foxp3+ Cells but Not Natural CD4+CD25+ Cells Suppress Established Collagen-Induced Arthritis. Ning Kong[1], Xiao H. Zhou[2], Julie Wang[2], Huimin Fan[3], Zhongmin Liu[3], David Brand[4], Hejian Zou[5] and Song Guo Zheng[2], [1]University of Southern California, Los Angeles, CA ; Huashan Hospital, Fudan University, Shanghai, China, [2]University of Southern California, Los Angeles, CA, [3]East Hospital, Tongji University, Shanghai, China, [4]VA Medical Center, Memphis, Memphis, TN, [5]Huashan Hospital, Fudan University, Shanghai, China

Purpose: Diminished frequency and functional activity of $CD4^+CD25^+Foxp3^+$ regulatory T cells (nTregs) contribute to the development of rheumatoid arthritis (RA). Nonetheless, adoptive transfer of nTregs to established collagen-induced arthritis (CIA) failed to improve the manifestations of arthritis. Inability of nTregs in suppressing established CIA could be explained by the resistance of T effector to nTregs, abolishing effect of inflammatory cytokines on nTregs and the plasticity of nTregs in CIA. Our group recently reported that, unlike nTregs, TGF-β-induced $CD4^+CD25^+$ cells (iTregs) are more stable when stimulated with IL-6. This finding suggests that iTregs may be stable and functional following adoptive transfer of the established CIA.

Method: Naïve $CD4^+$ cells isolated from CII transgenic DBA/1 mice were stimulated with their cognate CII peptide and IL-2 with (iTregs) or without TGF-β(CD4con). nTregs were sorted from the thymus in similar mice. $5x10^6$ of these cells were i.v. injected into DBA/1J mice on the day 0 or day 28 after immunization with CII and CFA. The incidence and clinical severity of disease were measured. Arthritis severity was further evaluated by measuring specific anti-CII IgG subsets in serum and also by histological examination. To determine the fate of both nTregs and iTregs following adoptive transfer to established CIA, these cells were labeled with CFSE and intracellular IL-17, IFN-γ, IL-4 productions in donor and recipient cells were determined by flow cytometry.

Results: Adoptive transfer of iTregs and expanded nTregs but not CD4con cells to DBA/1 mice at day 0 when immunized with CII/CFA prevented the incidence and severity of arthritis. Interestingly, adoptive transfer of iTregs but not nTregs significantly ameliorated the manifestations of arthritis when these cells were adoptively transferred into DBA/1 mice at day 28 after immunization. Using CFSE-labeled donor cells, we were able to observe that relative to iTregs, nTregs were prone to apoptosis, and Th17 and Th2 conversion, and lost Foxp3 in draining lymph nodes at one week after transfer in CIA. Conversely, iTregs maintained Foxp3 expression and did not convert to T help cells in a similar inflammatory milieu. Numbers of Th17 cells in lymph nodes in CIA mice receiving nTregs were 10-fold greater than those seen in mice receiving iTregs. Conversely, the numbers of $CD4^+Foxp3^+$ cells and of $CD4^+IL\text{-}10^+$ cells in the lymph nodes were 8-fold less in mice receiving nTregs than in mice receiving iTregs.

Conclusion: iTregs, unlike nTregs, are stable and functional when adoptively transferred into established collagen-induced arthritis. They suppress Th17 cell differentiation and promote the development of $Foxp3^+$ regulatory T cells and $CD4^+IL\text{-}10^+$ cells. This study may provide a novel therapeutic approach for the treatment of Rheumatoid Arthritis.

The Effect of Synthetic Retinoid, Am80, On T Helper Cell Development and Antibody Production in Murine Collagen-Induced Arthritis. Toshihiro Nanki, Aya Sato, Kaori Watanabe, Kayoko Kaneko, Yousuke Murakami, Miwako Ishido and Nobuyuki Miyasaka, Tokyo Medical and Dental University, Tokyo, Japan

Purpose: Retinoids are the compounds that bind to the retinoic acid binding site of retinoic acid receptors and have biological activities of vitamin A. Recent studies indicate that retinoids promote differentiation into Th2 cells and regulatory T cells (Treg), and suppress Th1 and Th17 cell differentiation in vitro. Previously it was reported that synthetic retinoid, Am80, ameliorated murine collagen-induced arthritis (CIA). In this study, we examined the effects of Am80 on CIA more precisely, and also on T helper (Th) phenotype development and antibody production in vivo.

Method: We induced CIA in DBA1/J mice by immunization with bovine type II collagen (CII) at days 1 and 22. Am80 was orally administrated once a day from day 1 for 5 weeks or from day 15 for 3 weeks. Effects of Am80 were evaluated by clinical arthritis score, paw thickness, histologically inflammatory changes, and bone destruction by radiograph. IFN-γ and IL-17 production by CII-stimulated splenic T cells and serum anti-CII Ab levels were analyzed by ELISA. Foxp3 expression in splenic CD4 T cells was examined by FACS.

Results: Treatment with Am80 from day 1 significantly lowered clinical arthritis score and paw thickness. Cellular infiltration in the ankle joint and bone destruction of MTP joint were also suppressed by the Am80 treatment. Moreover, Am80 decreased IL-17 and increased IFN-γ production by CII-stimulated splenic T cells of the CIA mice. Proportion of Foxp3+ CD4 T cells in the spleen was decreased by the treatment. It is thus indicated that Am80 inhibited Th17 and Treg, and enhanced Th1 differentiation in vivo. Serum anti-CII Ab levels were also decreased. In contrast, treatment with Am80 from day 15 did not alter clinical arthritis score. IL-17 and IFN-γ production by CII-stimulated splenic T cells was not also significantly changed by the treatment from day 15. However, proportion of Foxp3+ CD4 T cells in the spleen and serum anti-CII Ab levels were decreased.

Conclusion: Am80 has an inhibitory effect on CIA and might regulate both Th development and antibody production in vivo. Decreased Th17 by the treatment with Am80 might be responsible for the attenuation of arthritis.

CTLA4-Ig Modifies Dendritic Cells From Mice with Collagen-Induced Arthritis to Increase the CD4+CD25+Foxp3+ Regulatory T Cell Population. Kyung-Su Park[1], Mi-La Cho[2], Chang-Hoon Lee[1], Ji-Min Kim[1], Ho-Sung Yoon[1], Kwi-Young Kang[1], Seung-Ki Kwok[1], Ji-Hyeon Ju[1], Hyeok-Jae Ko[3], Chong-Hyeon Yoon[4], Jun-Ki Min[5], Yeon-Sik Hong[6], Sang-Heon Lee[7], Sung-Hwan Park[8] and Ho-Youn Kim[1], [1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [2]Catholic Institute of Medical Sciences, The Catholic University of Korea, Seoul, South Korea, [3]Daejeon St. Mary's Hospital, Daejeon, South Korea, [4]Uijeongbu St. Mary's Hospital, Uijeongnbu, South Korea, [5]Holy Family Hospital, Bucheon, South Korea, [6]Incheon St. Mary's Hospital, Incheon, South Korea, [7]Konkuk University Hospital, Seoul, South Korea, [8]Kangnam St Mary's Hosp, Seoul, South Korea

Purpose: CTLA4-Ig is a therapeutic agent used in the treatment of rheumatoid arthritis. It binds to B7 molecule and induces dendritic cells (DCs) to express indoleamine 2,3-dioxygenase (IDO), which is known to be involved in the generation of $CD4^+CD25^+Foxp3^+$ regulatory T cells (Tregs). In this study, we investigated whether CTLA4-Ig increased $CD4^+CD25^+Foxp3^+$ Treg population in collagen-induced arthritis (CIA) mouse model.

Method: CTLA4-Ig or PBS was administered into CIA-induced mice and then arthritis index was measured and $CD4^+CD25^+Foxp3^+$ Treg and CD4+IL-17+T cell population were examined in the joint and the spleen. DCs and CD4+T cells from CIA mice were cultured with anti-CD3 in the presence of CTLA4-Ig or control-Ig and then $CD4^+CD25^+Foxp3^+$ Treg population were examined. Spleen DCs from CIA mice were pretreated with CTLA4-Ig and then adoptively transferred into CIA-induced mice. Arthritis index was measured and $CD4^+CD25^+Foxp3^+$ Treg and CD4+IL-17+T cell population were examined in the spleen of DC-transferred mice.

Results: CTLA4-Ig suppressed CIA and increased the $CD4^+CD25^+Foxp3^+$ Treg population, but decreased the $CD4^+IL\text{-}17^+$ T cell population. When DCs and $CD4^+$T cells from CIA mice were cultured with anti-CD3, CTLA4-Ig increased the $CD4^+CD25^+Foxp3^+$ Treg population in a

TGF-beta-dependent, IDO-independent manner, but control-Ig did not. When adoptively transferred, CTLA4-Ig-treated DCs suppressed CIA and increased the $CD4^+CD25^+Foxp3^+$ Treg population but untreated DCs did not.

Conclusion: CTLA4-Ig suppressed CIA by modifying DCs from CIA mice to increase CD4+CD25+Foxp3+Treg population.

Naive CD4+ T Cells From Arthritis Susceptible DBA/1 Mice Demonstrate a Dichotomous Response to TCR Activation in the Presence of TGF-β Enhanced RORγt and Increased Th17 Expression Yet Reduced Foxp3. Yoshiaki Morita[1], Cong-Qiu Chu[2], Doaa Ismail[1] and Keith B. Elkon[3], [1]University of Washington, Seattle, WA, [2]University of Washington; Oregon Health and Science Univ, Portland, OR, [3]Division of Rheumatology, University of Washington, Seattle, WA

Purpose: DBA/1 mice are unusual in their susceptibility to collagen-induced arthritis (CIA). We previously showed that one mechanism responsible for DBA/1 susceptibility is a relatively high Th17/Th1 cytokine response following immunization with type II collagen in complete Freund's adjuvant . The goal of this study was to identify the mechanisms responsible for the differential cytokine production by $CD4^+$ T cells in DBA/1 mice.

Method: Naïve $CD4^+$ T cells were purified using magnetic beads (CD4/CD62L) separation and stimulated with anti-CD3/CD28 under Th1, Th2, Th17 and Treg conditions *in vitro*. Cytokines were quantified by intracellular staining and flow cytometry or by ELISA. Transcription factor expression was determined by RT-PCR, immunoblotting or flow cytometry.

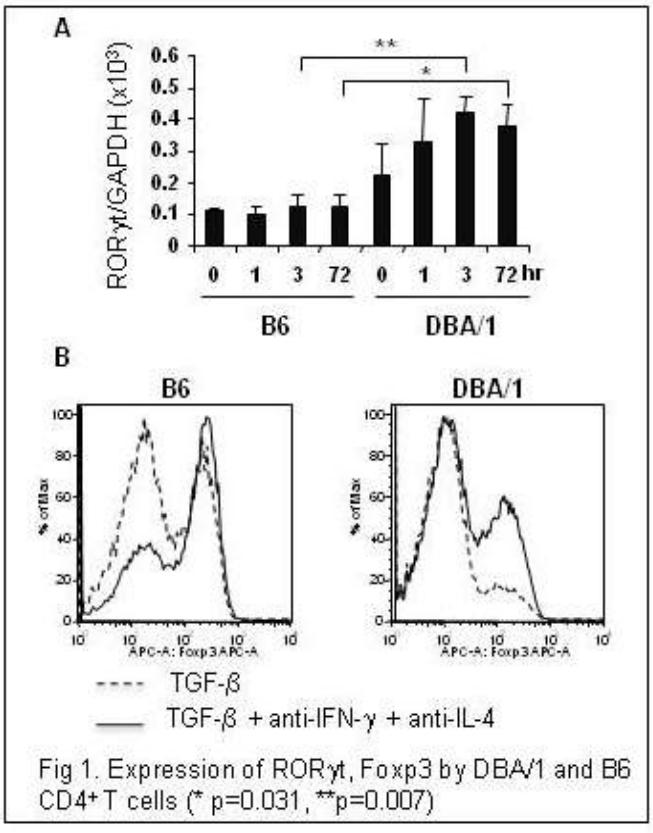

Fig 1. Expression of RORγt, Foxp3 by DBA/1 and B6 $CD4^+$ T cells (* p=0.031, **p=0.007)

Results: Purified naïve $CD4^+$ T cells from DBA/1 mice produced more IL-17 under Th17 conditions compared to B6, Balb/c or C3H mice. Consistent with this finding, naïve DBA/1 $CD4^+$ T cells also expressed increased levels of RORgt mRNA (Fig 1a). This abnormality was not, however, confined to Th17 as DBA/1 derived $CD4^+$ T cells polarized under the appropriate conditions also produced significantly higher levels of IFN-g and IL-4 compared to those from other strains. Detailed investigation revealed no differences in $CD4^+$ T cell survival, upstream TCR signaling or intracellular CD69 expression amongst strains. Since IL-17 is induced by exposure of $CD4^+$ T cells to IL-6 and TGF-b, we next examined expression of STAT3 and SOCS3. However, expression of these phosphoproteins was equivalent between strains thereby indicating a normal IL-6 pathway. DBA/1 $CD4^+$ T cell responses to TGF-b were examined under Th17 and Treg polarizing conditions (TGF-b, IL-2 and anti-IL-6). DBA/1 $CD4^+$ T showed a striking impairment of Foxp3 expression compared to controls. Although the magnitude of this difference was reduced in the presence of neutralizing IFN-g and IL-4 antibodies, Foxp3 expression remained lower in DBA/1 compared to B6 $CD4^+$ T cells following exposure to TGF-b (Fig 1b).

Conclusion: These results indicate that naïve DBA/1 $CD4^+$ T cells have a dichotomous response to TGF-b in that TGF-b promotes Th17 skewing yet fails to upregulate Foxp3, even when IFN-g and IL-4 are neutralized. This observation may help elucidate the branch point of TGF-b signal transduction and the enhanced RORgt and Th17 expression that likely contribute to greater susceptibility of DBA/1 mice to CIA.

15

GILZ Is a Novel Regulatory Protein in Collagen-Induced Arthritis. Devi Ngo[1], Elaine Beaulieu[1], Florence Apparailly[2], Gabriel Courties[2], Virginie Escriou[3], Daniel Scherman[4], Christian Jorgensen[2], Yuan Yang[1], Leilani Santos[1] and Eric F. Morand[1], [1]Monash University, Clayton, Australia, [2]Inserm U844, Montpellier, France, [3]Inserm U640, Paris, France, [4]Inserm U640, CNRS, UMR8151, University Paris Descartes, ENSCP, Paris, France

Purpose: Glucocorticoid-induced leucine zipper (GILZ) is a glucocorticoid (GC)-induced transcription factor that is reported to bind to NFκB and AP-1, inhibiting T cell and macrophage function. Its expression and function in animal models of RA have not previously been reported. We herein report GILZ expression in murine collagen-induced arthritis (CIA), and describe the function of endogenous GILZ for the first time in vivo.

Methods: GILZ was detected in mouse paw, synovium, spleen, and macrophages using immunohistochemistry, qPCR and immunoblotting. CIA was induced in DBA/1 mice and GILZ expression was silenced in vivo using cationic liposome-encapsulated (lipoplexed) GILZ siRNA.

Results: In murine CIA synovium, GILZ was detected in synovial lining and endothelial cells. The GC dexamethasone (0.25 mg/kg) significantly inhibited clinical expression of CIA, accompanied by significantly increased GILZ expression in synovium, peritoneal macrophages and spleen cells. Intravenous (IV) injection of red fluorescent siRNA lipoplexes resulted in lipofection of 20% of circulating monocytes within 4hrs. Compared to control (non-targeting) siRNA, IV administration of GILZ siRNA lipoplexes significantly inhibited GILZ protein expression in vivo. To determine the function of constitutive GILZ expression in the regulation of arthritis, GILZ was silenced in vivo in mice developing CIA. GILZ silencing resulted in marked and significant exacerbation of CIA clinical score compared to control (non-targeting) siRNA, associated with increased synovial expression of IL-1 and TNF but without affecting anti-type II collagen autoantibodies.

Conclusion: These findings demonstrate that GILZ acts as an endogenous inhibitor of inflammation and cytokine production in CIA. GILZ induction during GC inhibition of murine CIA suggests that GILZ may contribute to the therapeutic effects of GC in this model and in RA. This suggests that modulation of GILZ in human RA could be a promising therapeutic approach.

16

Comprehensive Insight of the Immunosuppressive Effect of Mesenchymal Stem Cells in Arthritis. Carine Bouffi[1], Claire Bony[1], Gabriel Courties[1], Christian Jorgensen[2] and Danièle Noël[1], [1]Inserm U844, Montpellier, France, [2]Inserm u844, Unite ImmunoRhumatologie Therapeutique, Montpellier, France

Purpose: Multipotent mesenchymal stromal cells (MSC) are adult stem cells characterized by their differentiation potential and their immunosuppressive properties. Among the proposed mediators of this immunomodulatory effect, IDO, iNOS, IL-6 and PGE2 were consistently reported to play a major role, at least *in vitro*. The aim of our study was to better understand the molecular mechanisms involved in the immunosuppressive effect of MSCs *in vivo* and relied on the murine experimental model of collagen-induced arthritis (CIA).

Method: MSCs were isolated from DBA1 mice and wild type (wt), inducible nitric oxid synthase $(iNOS)^{-/-}$ or IL-$6^{-/-}$ C57Bl6 mice. Cells were immunophenotyped by flow cytometry. Their capacity to differentiate into 3 lineages was induced by culture in specific conditions and immunosuppression was evaluated in concanavalin A-induced proliferative assay. In vivo, 10^6 MSC were intravenously injected at various times after collagen II (bCII) immunization of DBA1 mice. Arthritis was evaluated by the measure of paw swelling and immunological parameters (collagen II-specific immunoglobulins, inflammatory cytokines and proliferation of T lymphocytes).

Results: All primary MSC populations were characterized by their common phenotype, trilineage differentiation potential and immunosuppressive potential. Using a proliferative assay, $iNOS^{-/-}$ or IL-$6^{-/-}$ MSCs exhibited a highly reduced immunosuppressive effect compared to wt MSCs while IDO activity was totally absent in murine MSCs. These results were confirmed *in vivo* in the CIA model. When injected on day 18 and 24, syngeneic MSCs were able to significantly decrease the incidence and the clinical signs of arthritis. A similar beneficial effect was also observed when allogeneic wt C57Bl6 MSCs were injected. The immunological parameters (proliferative assay, bCII-specific IgG1/IgG2A, cytokine profile) confirmed a decreased inflammatory response when MSCs were administered. However, when $iNOS^{-/-}$ or IL-$6^{-/-}$ MSCs were injected, the therapeutic effects of MSCs were partially reversed. This suggests that NO, IL-6-induced PGE2 secretion or IL-6-dependent dendritic cell maturation play only minor roles as well as $CD4^+CD25^+Foxp3^+$ T reg cells that were only slightly increased.

Conclusion: Our study shows the efficacy of systemic injection of syngeneic or allogeneic MSCs in the treatment of experimental arthritis in a restricted window of application. The mechanism of immunosuppression is complex and relies on more than one molecular pathway.

A20 Gene Transfer Suppresses Inflammation and Bone Destruction through Inhibition of NF-Kappab Activation in Vitro and Vivo. Sang-IL Lee[1], Hyun-Ok Kim[2], Wan Hee Yoo[3], Eun-Gyeong Lee[3], Yun-Kyung Hong[3] and Sang-Hyon Kim[4], [1]College of Medicine, Gyeongsang National University, Jinju, South Korea, [2]Gyongsang University, Jinju, South Korea, [3]Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [4]Dongsan Medical Center, Keimyung University, Daegu, South Korea

Purpose: The nuclear factor-kappaB (NF-kB) activation plays a pivotal role to develop inflammation and bone destruction in rheumatoid arthritis (RA), and A20 downregulates NF-kB activation through the cooperative activity of its two de-ubiquitination and ubiquitin ligase domains. However, there has been no study addressing whether A20 show the therapeutic efficacy in RA. Thus, the current study was performed to determine whether A20 can block the action of fibroblast-like synoviocytes (FLS) and also suppress disease activity and joint destruction in mouse model of collagen-induced arthritis (CIA).

Method: The recombinant adenovirus carrying the gene that encodes A20 (Ad-A20) or beta-galactosidase (Ad-Bgal) were used. The inhibition of NF-kB activation and inflammatory chemokines/MMPs expression were assessed by EMSA and ELISA, respectively, after infection of Ad-A20 into FLS. The therapeutic effect was determined by clinical, histologic and immunostaining analyses after periarticular injection of Ad-A20 into the ankle joints of CIA mice. The inhibition of NF-kB activation was determined by EMSA and the levels of various cytokines in the joints and serum were measured by ELISA.

Results: Infection of FLS with Ad-A20 inhibited TNFα-induced nuclear translocation and DNA binding of NF-kB. Ad-A20 suppressed production of chemokines, such as ENA-78 and RANTES, and activation of MMP-1 and MMP-3 in FLS. Periarticular injection of Ad-A20 significantly reduced the intensity of clinical manifestations and effectively prevented joint destruction in CIA. These inhibitory effects were paralleled by diminished DNA binding of NF-kB. Furthermore, A20 treatment suppressed levels of RANKL, TNFα, and IL-6.

Conclusion: This study demonstrates that Ad-A20, most likely acts through inhibition of NF-kB activation, show therapeutic effects on inflammation and bone erosion in vitro and vivo. These results suggest that A20 can be used as a promising candidate in the field of treatment for RA.

Local Gene Therapy in Experiment Arthritis with Plasmid Encoding Soluble TNF Receptor Type I (sTNFRI). A. Denys, EA4222, Bobigny, France

Purpose: Gene therapy is an alternative for the continuous delivery of anti-inflammatory molecules such as TNF-alpha in rheumatoid arthritis (RA). We already demonstrated the interest of a non viral gene transfer strategy, namely electrotransfer (ET), to administrate sTNFRI by a systemic (im) way and to cure collagen-induced arthritis in mice (CIA). However, intra-articular (i.a) non viral gene therapy using electrotranfer is also of interest in joint-targeted diseases such as rheumatoid arthritis (RA). Our objectives were 1) to evaluate the therapeutic effect of mTNFR-Is gene intra-articular ET in CIA and 2) to investigate the mode of action by evaluating the effect on cytokine mRNA expression in the joints during arthritis development.

Methods: CIA was induced in DBA/1 mice with native collagen type II (CII) emulsified in complete Freund's adjuvant. A plasmid pVax1 mTNFR-Is/mIgG1 (encoding the fusion protein formed with murine sTNFRI and the heavy chain of IgG1) was synthetised. The plasmid was injected into both knees at time of clinical symptoms onset. After plasmid injection, an electric field was applied with electrodes placed apart on either side of the joint. mTNFR-Is joint secretion was evaluated in knee-conditioned media by ELISA. IL-10, IL-17 and TNF-α mRNA expression in the joints were measured by real time quantitative RT-PCR.

Results: After i.a. ET of various plasmid doses (10, 20 and 40 µg), a dose dependent expression of mTNFR-Is was observed in knee-conditioned media, and maximal secretion was observed after injection of 20 µg plasmid. Treatment of CIA with pVax mTNFR/mIgG1 electrotransfer have no systemic effect on clinical arthritis development. More interestingly the histological analysis revealed that 1) inflammation in ankles ($p<0.05$ versus NaCl and $p<0.001$ versus empty pVAX1) and in knees ($p<0.001$ versus NaCl and empty pVAX1) was lower in pVax1mTNFR-Is injected joints compared to controls, 2) destruction in ankles ($p<0.05$ versus NaCl and $p<0.001$ versus empty pVAX1) and in knees ($p<0.001$ versus empty pVAX1) was lower in pVax1mTNFR-Is injected joints compared to controls. In addition, increased IL-10, IL-17, TNF-*f*Ñ*f*nexpression were shown 15 days after ET in pVax1 mTNFR-Is/mIgG1 ET mice, as compared to NaCl ($p<0.01$).

Conclusion: These data demonstrate the feasibility and the effectiveness of local non viral gene therapy in arthritis and show that local mTNFR-Is gene delivery modulates some pro-and anti-inflammatory gene cytokine expression within the joints.

Targeted Adoptive Cellular Combination Gene Therapy of Inflammatory Arthritis Using Lentivirally Transduced Dendritic Cells. Ingo H. Tarner[1], Ulrich Purath[1], Remi J. Creusot[2], C. Garrison Fathman[2], Ulf Müller-Ladner[1] and Elena Neumann[3], [1]Justus-Liebig-University of Giessen, Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Stanford Univ Med Ctr, Stanford, CA, [3]Justus-Liebig-University of Giessen and Kerckhoff-Clinic, 61231 Bad Nauheim, Germany

Purpose: Systemic immunosuppressive treatment, e.g. by biologic cytokine inhibitors, of rheumatoid arthritis is limited by systemic adverse effects. Local delivery of cytokine inhibitors or anti-inflammatory molecules would therefore be advantageous. Immune cells such as lymphocytes have been shown to migrate into inflamed tissues, such as the joints in arthritis, and to deliver anti-inflammatory agents *in vivo*. Dendritic cells (DC) were chosen in this study for gene delivery because they are potent antigen-presenting cells that have been shown to modulate inflammatory responses when expressing anti-inflammatory molecules. In previous studies we have shown that gene transfer of single anti-inflammatory molecules prevents onset of arthritis in the model of collagen-induced arthritis but does not ameliorate established disease. Therefore, we hypothesized that the combined transfer of different anti-inflammatory molecules would be more effective.

Method: DC were isolated from murine bone marrow by magnetic bead-separation of T-cells, B-cells and granulocytes, cultured in presence of IL-4 and GM-CSF and transduced using three different lentiviral bicistronic constructs encoding the marker GFP and IL-12p40 (DCp40), an anti-TNF single chain variable fragment (DCTNF) or human galectin-1 (DCGal-1), respectively. Different dual (DCp40+DCGal-1, DCp40+DCTNF, DCGal-1+DCTNF) and triple (DCp40+DCGal-1+DCTNF) combinations of transduced cells were adoptively transferred into DBA/1 mice after the onset of clinical arthritis. Clinical disease severity, histological severity (pannus formation, cartilage degradation and bone erosion), systemic anti-collagen antibody levels and local cytokine gene expression were analyzed and DC migration was examined histologically.

Results: Transduced DC were found to migrate into the inflamed paws and to be localized near sites of bone erosion. The combination of DCp40 + DCGal-1 resulted in a significant reduction of pannus formation and bone erosion, whereas the other combinations did not. Clinically, there was a trend towards less disease severity in this treatment group which did not reach significance. Local expression of IL-10 in the paws was increased in the DCp40 + DCGal1 group whereas IFNg was reduced and TNF unaltered. Splenic expression of all three cytokines was reduced in this treatment group. Of note, triple gene therapy was not superior to the combination of DCp40 and DCGal-1.

Conclusion: Lentivirally transduced DC are able to migrate into inflamed joints in inflammatory arthritis. The combined transfer of the inhibitory IL-12p40 subunit and galectin-1 has anti-destructive effects and shifts the local cytokine expression towards a Th2 pattern, while clinical efficacy is limited. Routine application is impeded by the inherent complexity of the technique and the variability of gene transduction and expression.

RNAi-Mediated Gene Therapy of PBEF Reduces the Severity of Collagen-Induced Arthritis in Mice. Gabriel Courties[1], Diego Kyburz[2], Virginie Escriou[3], Daniel Scherman[4], Christian Jorgensen[5], Steffen Gay[6] and Florence Apparailly[7], [1]Inserm U844, Montpellier, France, [2]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [3]Inserm U640,CNRS, UMR8151, University Paris Descartes, ENSCP, Paris, France, [4]Inserm U640, CNRS, UMR8151, University Paris Descartes, ENSCP, Paris, France, [5]Inserm u844, Unite ImmunoRhumatologie Therapeutique, Montpellier, France, [6]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [7]Inserm u844, Montpellier, France

Purpose: PBEF (Pre-B cell colony-enhancing factor/visfatin) is a hormone released by adipose tissue described as a new marker of inflammation in rheumatoid arthritis (RA) with pro-inflammatory and matrix-degrading activities. We previously showed that in vitro PBEF lead to the expression of pro-inflammatory mediators (IL-6, TNF) and matrix degrading enzymes (MMPs) in synovial fibroblasts and/or monocytes. The purpose of this study was to examine the therapeutic effects of systemic delivery of anti-PBEF siRNA lipoplexes in mouse arthritis pre-clinical model.

Method: Collagen-induced arthritis (CIA) was induced in male DBA/1 mice, and 0,5 mg/Kg small interfering (si)RNA against mouse PBEF (siPBEF) or non targeting siRNA (siCT) sequences formulated with the cationic liposome RPR209120/DOPE were injected intravenously weekly during arthritis progression. Clinical and biological features of the disease were investigated.

Results: Systemic siPBEF delivery significantly decreased clinical disease activity scores of CIA as evidenced by paw swelling measures. Importantly, RNAi-mediated PBEF silencing significantly decreased IL-6 secretion in both sera and spleen, without altering serum anti-collagen (bCII) antibodies levels and bCII-specific T cell proliferation. Importantly, frequencies of the IFN-γ- and IL-17A-producing CD4+ cells were decreased within spleen and liver, while frequency of the IL-10-producing CD4+/CD25+/Foxp3 cells was increased. Histological scores of inflammation and cartilage damage, bone erosion, and mRNA levels of pro-inflammatory cytokines and MMPs in the joints will be investigated, as well as immunohistochemical staining of PBEF in the joints.

Conclusion: These results provide novel evidence that systemic PBEF inhibition efficiently reduces experimental arthritis and might be proposed as novel therapeutic target for RA.

RNA Interference Targeting the Cytosolic Phospholipase A2 ALPHA (CPLA2A) for Efficient ANTI-Inflammatory Therapy in Arthritis. Gabriel Courties[1], Michel Baron[2], Peter van Lent[3], Virginie Escriou[4], Daniel Scherman[5], Wim van den Berg[3], Alain Cantagrel[6], Christian Jorgensen[7], jean Luc Davignon[8] and Florence Apparailly[9], [1]Inserm U844, Montpellier, France, [2]Toulouse, France, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]Inserm U640,CNRS, UMR8151, University Paris Descartes, ENSCP, Paris, France, [5]Inserm U640, CNRS, UMR8151, University Paris Descartes, ENSCP, Paris, France, [6]JE 2510, Purpan University Hospital, Toulouse, France, [7]Inserm u844, Unite ImmunoRhumatologie Therapeutique, Montpellier, France, [8]JE2510, Toulouse, France, [9]Inserm u844, Montpellier, France

Purpose: The cytosolic phospholipase $A_2\alpha$ (cPLA2a) plays a critical role in the development and duration of inflammatory disorders. We aimed at better assessing the molecular mechanisms of the in vivo cPLA2a silencing using specific siRNA sequences and evaluating the therapeutic potential of RNAi-based anti-cPLA2a strategy.

Method: A cPLA2a siRNA sequence was validated in vitro on the NIH3T3 cell line, assessing the protein levels by western blotting and the mRNA by RT-qPCR after nucleofection. For in vivo administration, 10µg of siRNA were formulated as lipoplexes with the RPR209120/DOPE liposome and a carrier DNA, and weekly injected intravenously in DBA/1 mice before collagen-induced arthritis (CIA) onset. Clinical course of the disease was assessed by paw thickness over time, radiological and histological scores were obtained at euthanasia on day 56. The immunological balance was assessed using anti-type II collagen (bCII) assays, measuring the bCII-specific T cell proliferation, and quantifying cytokine levels in sera and knee-conditioned media by ELISA. The specific silencing of cPLA2a was assessed by RT-qPCR and functional assay using the fluorogenic phospholipase A2 substrate PED6 in organs targeted by siRNA lipoplexes.

Results: First, siRNA sequences targeting cPLA2a were shown in vitro to strongly reduce the expression of cPLA2a at both mRNA (70%) and protein (60-90%) levels. Weekly intravenous injections of anti-cPLA2a siRNA-lipoplexes significantly reduced incidence (38% versus 88%) and severity (1.97 ± 0.02 versus 2.19 ± 0.05 mm) of CIA, as compared with the irrelevant siRNA lipoplex-injected group. Histological scores of inflammation and cartilage damage or bone erosion were also lowered, as well as proteoglycan degradation and MMPs activity. The clinical effect was associated with decreased joint inflammation markers as assessed by a lower cPLA2a activity and local inhibition of IL-1β and TNF-α secretion in knee-conditioned media. Serum levels of anti-bCII IgG2a antibodies were also decreased in the cPLA2a siRNA-treated group compared with control animals, as was reduced the IFN-γ production by draining lymph nodes cells, reflecting altogether a decrease of the Th1-mediated autoimmune response.

Conclusion: Our data show that cPLA2a is a suitable target in CIA and that specific siRNAs may be used to control arthritis. Our observation opens new avenues for alternative treatment of RA.

Arthritic Joint-Targeting siRNA/Wrapsome® as a Treatment Strategy for Rheumatoid Arthritis. Yukiko Komano[1], Nobuhiro Yagi[2], Ikumi Onoue[1], Kayoko Kaneko[1], Nobuyuki Miyasaka[1] and Toshihiro Nanki[1], [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Kyowa Hakko Kirin Co., Ltd.

Purpose: To explore the therapeutic potential of systemically administered small interfering RNAs encapsulated with Wrapsome® (siRNA/WS) for rheumatoid arthritis (RA), which contains siRNA in a core that is fully enveloped by a neutral lipid bilayer.

Method: Tissue distributions of fluorescence (Cy5)-labeled siRNA/WS or naked Cy5-labeled siRNA injected intravenously into collagen-induced arthritis (CIA) mice were assessed by fluorescence stereoscopic microscope and flow cytometry. Efficacy of siRNA targeting TNF-α/WS for CIA was evaluated with arthritis scoring system, and levels of TNF-α mRNA in joints were measured using real-time RT-PCR assay.

Results: Observation with stereoscopic microscope showed that levels of Cy5 was more intense in arthritic joints than in non-arthritic sites in mice treated with Cy5-siRNA/WS, and remained highly intense up to 48 hrs post-injection. On the contrary, the levels of Cy5 in arthritic joints in mice treated with naked Cy5-siRNA rapidly diminished. Cells in the synovium showed the highest intensity of Cy5 in those tested

including spleen, peripheral blood, lung, and bone marrow. Most of the Cy5-positive cells in the synovium were monocytes/macrophages ($CD11b^+$ or $F4/80^+$), whereas, there were a few Cy5-positive lymphocytes. Mice treated with TNF-α siRNA/WS showed decreased severity of arthritis compared with control siRNA/WS. The Levels of TNF-α mRNA in the joints of mice treated with TNF-α siRNA/WS were significantly lower than those in controls.

Conclusion: Using the Wrapsome®, efficient and targeted delivery of siRNAs to arthritic joints was achieved. The siRNA/WS were incorporated into monocytes/macrophages in the inflamed synovium, indicating that it could be a therapeutic tool to silence expressions of inflammatory cytokines produced by those cells *in situ*.

IL-17 Is An Angiogenic Mediator in Rheumatoid Arthritis. Shiva Shahrara, Sarah R. Pickens and Richard M. Pope, Northwestern University Feinberg School of Medicine, Chicago, IL

Introduction: IL-17 has a profound effect in experimental arthritis, however its role in rheumatoid arthritis (RA) is less clear. We recently demonstrated that IL-17 and the percentage of TH-17 cells is increased in RA synovial fluids. Although IL-17 is capable in inducing selected chemokines from RA synovial fiblasts, its potential role in mediating angiogenesis of RA is undefined.

Purpose: Studies were performed to identify a novel role for IL-17 in mediating angiogenesis.

Methods: Various concentrations of IL-17 were employed to examine human microvascular endothelial (HMVEC) chemotaxis using a Boyden chamber. HMVEC chemotaxis was examined with heat inactivated IL-17, as well as neutralization of IL-17 by an anti-IL-17 antibody or IgG control. A series of checkerboard experiments were performed by placing increasing doses of IL-17 together with HMVECs in the lower chamber, in addition to placing different concentrations of IL-17 in upper chamber. Next we determined the role of IL-17 receptors in IL-17-mediated HMVEC chemotaxis. We also examined the signaling pathways associated with IL-17-induced HMVEC chemotaxis and tube formation.

Results: IL-17 was chemotactic for HMVECs at concentrations ranging from 0.01 ng/ml ($p<0.05$) to 100 ng/ml ($p<0.05$) ($n=5$). The mean concentration of IL-17 in the 30 RA synovial fluid analyzed was 233 ± 64 pg/ml, a concentration that was highly chemotactic for HMVECs. Consistently, heat inactivation of IL-17 or incubation of IL-17 (50 ng/ml) with IL-17-neutralizing antibody suppressed HMVEC migration. Checkerboard experiments demonstrated that IL-17 was chemotactic not chemokinetic. Next experiments were performed to determine which IL-17 receptor is involved in HMVEC chemotaxis. Although some reduction of HMVEC chemotaxis was noted with each antibody, a significant ($p<0.05$) reduction was noted only when both IL-17RA and IL-17RC were neutralized. Our results also demonstrate that IL-17 stimulates phosphorylation of ERK, JNK and AKT1 in HMVECs, while it had no effect on p38. To determine which signaling pathways mediate HMVEC migration, cells were pre-incubated with chemical inhibitors to ERK, JNK and PI3K prior to performing chemotaxis. Results from these studies demonstrate that while the inhibition of ERK and JNK was ineffective inhibition of PI3K markedly reduced ($p<0.05$) IL-17-mediated HMVEC chemotaxis. Consistently, inhibition of PI3K also reduced IL-17-mediated tube formation by 60% ($p<0.05$), whereas inhibitors to ERK and JNK were ineffective.

Conclusion: These results suggest that IL-17 may be a key initiator of angiogenesis in the RA joint, supporting IL-17 as a potential therapeutic target in RA.

Variant Angiopoietin-1 with 269Gly Insertion Contributes to the Pathogenesis of Pulmonary Hypertension: A Novel Mechanism for Stimulating Pulmonary Smooth Muscle Cell Growth. Aya Mashida[1], Akira Hashiramoto[2], Takako Kawazoe[2], Koichiro Komai[1] and Shunichi Shiozawa[3], [1]Department of Biophysics, Graduate School of Health Sciences, Kobe University, Kobe, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe, Japan, [3]Department of Biophysics Graduate School of Health Sciences, Kobe University/ The Center for Rheumatic Disease, Kobe University Hospital, Kobe, Japan

Purpose: Pulmonary hypertension (PH) is often a major fatal cause in rheumatic diseases such as Mixed Connective Tissue Disease (MCTD) and Systemic sclerosis (SSc). We previously identified two variants of *Ang-1* mRNA with or without having 3-bp GGT that encodes ^{269}Gly; we call them as Ang-1/ins and Ang-1/del, respectively. Notably, Ang-1/ins is genetically associated with the PH of patients with MCTD and SSc (Shiozawa K *et al*, Arthritis Rheum. 52: suppl (9). S283, 2005). We also reported that Tie2, a specific receptor for Ang-1, was highly expressed in Human Pulmonary Artery Endothelial Cells (HPAEC) as compared with Human Pulmonary Artery Smooth Muscle Cells (HPASMC), and Ang-1/ins strongly induced phosphorylation of ERK in HPAEC and in a co-culture of HPAEC and HPASMC (Kawazoe T *et al*, Arthritis Rheum. 58: suppl (9). S1321, 2008). The present study clarifies the mechanism that HPASMC is stimulated by HPAEC, where Ang-1/ins plays a role in over stimulating pulmonary smooth muscle growth.

Method: HPAEC was stimulated with Ang-1 variants, and phosphorylation of Tie2 was evaluated by immunofluorescent staining. HPAEC or HPASMC were cultured to 70, 100 and 120% confluence state, and the phosphorylated ERK (pERK) upon stimulation of Ang-1 variants was examined by westernblot. After stimulated with Ang-1 variants, culture supernatant of HPAEC was collected and further incubated with HPASMC to determine pERK by westernblot. Finally, the release of endothelin-1 (ET-1) from HPAEC was measured by ELISA upon stimulation with Ang-1 variants.

Results: In a culture of HPAEC, Ang-1/ins phosphorylated Tie2 to the levels far stronger than those with Ang-1/del under immunofluorescent staining. Under confluency, while the extent of phosphorylation of ERK by Ang-1/ins was comparable to the levels by Ang-1/del in HPASMC, the phosphorylation of ERK by Ang-1/ins was significantly higher than those by Ang-1/del in HPAEC. The culture supernatant of HPAEC stimulated with Ang-1/ins phosphorylated ERK of HPASMC more strongly than the supernatant stimulated by Ang-1/del. Similarly, the release of ET-1 from HPAEC was significantly higher when stimulated with Ang-1/ins as compared with those with Ang-1/del ($p<0.05$).

Conclusion: Ang-1/ins increases the phosphorylation of ERK directly in HPAEC and indirectly in HPASMC *via* mediators released from HPAEC. Enhanced production of ET-1 in HPAEC could be one of such mediators. Ang-1/ins, therefore, could contribute to the progression of vasoconstriction and smooth muscle cell hyperplasia in the pathogenesis of PH.

Engagement of Tie2 Signaling Is Enhanced in the Synovial Tissue of Patients with Rheumatoid Arthritis Compared to Psoriatic Arthritis and Is a Consequence of Angiopoietin 1 Activation of Macrophages. Sarah Krausz[1], Daphne de Launay[1], Paul P. Tak[2] and Kris A. Reedquist[1], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Angiogenesis makes critical contributions to inflammation and joint destruction in rheumatoid arthritis (RA)and psoriatic arthritis (PsA). Angiopoietins (Ang) 1 and 2, which mediate blood vessel remodeling, as well as their receptor Tie2, are expressed in RA and PsA synovial tissue. Although Tie2 expression has been reported on synovial endothelial cells, fibroblast-like synoviocytes (FLS) and macrophages, little is known about how Tie2 signaling contributes to pathology in RA. Here, we examined the expression of Ang1 and Ang2, and the cellular distribution of total and active, phosphorylated active Tie2 in RA and PsA synovial tissue.

Method: Quantitative analysis of Ang1, Ang2, Tie2 and active phospho (p)-Tie2 expression in the synovial tissue of patients with active RA (n=17) and PsA (n=14) was performed by immunohistochemical staining and quantitative digital analysis. Immunofluorescent double staining was performed on synovial tissue biopsy sections using anti- Tie2 and p-Tie2 antibodies in combination with antibodies recognizing cellular markers (CD3, CD22, CD31, CD55, C68, CD163, and vWF). Tie2 expression on human peripheral blood (PB) monocytes and PB-derived macrophages were examined for Tie2 expression by FACs analysis.

Results: Ang1 expression was significantly higher in RA synovial tissue compared to PsA ($p<0.005$). In contrast, Ang2 expression was higher in PsA synovial tissue than in RA ($p<0.01$). Comparing the relative expression of Ang1 and Ang2 in each patient, we found that the ratio of Ang1 expression to Ang2 was approximately 10-fold higher in RA synovial sublining tissue (4.04+/-0.80, mean+/-SEM, arbitrary units) than in PsA (0.48+/-0.09) ($p<0.001$). This was associated with increased relative activation of Tie2 in RA synovial tissue compared to PsA ($p<0.05$). Within the RA patient cohort, a signficant positive correlation was observed between Ang1 expression and Tie2 phosphorylation ($R = 0.412$, $p<0.05$) which was not observed in PsA. Instead, a strong negative correlation was observed between Ang2 expression and Tie2 phosphorylation in PsA ($R = -0.782$, $p<0.001$). Immunofluorescent staining of RA synovial tissue detected active Tie2 predominantly in synovial macrophages, and only infrequently in endothelial cells and FLS. FACS analysis confirmed that Tie2 was expressed on the surface of not only PB monocytes, but also PB-derived macrophages.

Conclusion: Ang1 expression relative to Ang2 is significantly increased in RA synovial tissue compared to PsA, associated with increased activation of Tie2. Macrophages are the primary targets of Ang/Tie2 signaling in RA and PsA synovial tissue, identifying a novel functional interaction between angiogenic factors and macrophages in RA and PsA.

Macrophage Polarization Conditions and Relative Availability of Ang-1 and Ang-2 Determine the Contributions of Tie2-Bearing Macrophages to Inflammation and Tissue Remodeling. Sarah Krausz[1], Carmen A. Ambarus[1], Dominique L. Baeten[2], Paul P. Tak[3] and Kris A. Reedquist[1], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: We have recently identified Tie2-expressing macrophages as the primary targets of angiopoietin (Ang) signaling in rheumatoid arthritis (RA) synovial tissue. Although Ang-1 and Ang-2 are thought to contribute to blood vessel generation and remodeling needed for the maintenance of inflammation and tissue remodeling in RA, the (patho)physiological consequences of macrophage Tie2 engagement are unknown. Here, we examined how polarizing stimuli might regulate Tie2 expression on human macrophages and the effect of Ang-1 and Ang-2 stimulation on macrophage production of cytokines, chemokines and factors regulating tissue remodeling.

Method: Tie2 expression on human peripheral blood (PB) monocytes and PB-derived macrophages differentiated in the absence or presence of GM-CSF, IFN-gamma, LPS, TNF-alpha, M-CSF, IL-4, IL-10, or IL-6 were examined for expression of Tie2 and other macrophage markers by FACs analysis. Effects of Ang-1 and Ang-2 stimulation, alone or in combination with TNF-alpha or LPS, on macrophage IL-6 and IL-8 production were assessed by ELISA. Proteomic approaches were used to identify soluble factors involved in angiogenesis and tissue remodeling in culture supernatants of macrophages stimulated with Ang-1 and Ang-2, and candidate secreted products were validated by ELISA.

Results: Tie2 was expressed monocytes, and most polarizing stimuli had no effect on Tie2 expression. Exceptions included IFN-gamma and IL-10, which upregulated Tie2 expression, and IL-4, which suppressed Tie2 expression. Compared to macrophages differentiated in medium alone, Tie2 expression was significantly enhanced in macrophages exposed to IL-10 ($p<0.05$). Tie2 expression was associated with expression of CD163, a marker of alternatively-activated macrophages. Ang-1 induced IL-6 production in GM-CSF-differentiated macrophages ($p<0.01$) and enhanced TNF and LPS-induced IL-6 production ($p<0.05$), while effects of Ang-2 were limited to suppression of LPS-induced IL-6 production. In IL-10-differentiated macrophages, Ang-2 enhanced LPS-dependent IL-6 production. No effects of Ang-1 or Ang-2 on IL-8 production were observed. Proteomic analyses identified CCL2, CCL3, MMP-9, TIMP-1, and uPA as secreted gene products regulated by macrophage Tie2 signaling.

Conclusion: Macrophage Tie2 expression is tightly regulated by the polarizing conditions macrophages are exposed to during differentiation at sites of inflammation. Macrophage Tie2 is functional and differentially contribute macrophage expression of inflammatory cytokines, chemokines, and tissue remodeling factors dependent upon polarization conditions, relative levels of Ang1 and Ang2, and presence of other inflammatory stimuli, such as TNF-alpha and LPS. Tie2-bearing macrophages may be important in coordinating angiogenic and inflammatory stimuli to determine the balance of tissue destruction and remodeling in the synovium of patients with inflammatory arthritis.

Aggressiveness of Rheumatoid Arthritis Synovial Fibroblasts Is Characterized by Fast Transendothelial Migratory, Invasive and Neoangiogenic Potential. Birgit Zimmermann[1], Stephanie Lefèvre[1], Silvia Fischer[2], Julia Gansler[2], Angela Lehr[3], Stefan Rehart[3], Henning Stürz[2], Jürgen Steinmeyer[2], Ulf Müller-Ladner[1] and Elena Neumann[1], [1]Justus-Liebig-University of Giessen, Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Justus-Liebig-University of Giessen, Giessen, Germany, [3]Markus-Hospital, Frankfurt, Germany

Purpose: In rheumatoid arthritis (RA), synovial fibroblasts (SF) are activated cells that participate in cartilage degradation and joint destruction. Recently, we demonstrated the long-distance migratory behavior of RASF and examined the early events in this process that may contribute to the spreading of the disease between joints.

Method: In vitro transmigration assays through human umbilical vein endothelial cells (HUVECs) cultured in monolayers on rat tail collagen in transwell-chambers were performed. RASF were placed on the endothelial monolayer and the number of migrating RASFs was counted at different time points (4-16 h). RASF migration in vivo was investigated using the SCID mouse model of RA: $1.5x10^5$ RASF were implanted together with healthy human cartilage in a carrier matrix at the ipsilateral site (I). Cartilage without RASF was implanted at the contralateral site (IL) of the SCID mice. Neoangiogenesis adjacent to the implated cartilage was determined (35 hours, 6, 12, 18, 24, 30 days). Implants and spleens were removed and cartilage invasion of RASF was analyzed histologically using an established scoring system. Implants and spleens were analyzed immunohistochemically with species-specific antibodies.

Results: RASF transmigration through endothelial monolayers and collagen coating was already detectable after 4 hours (21.8%±0.2%). In all settings, the number of migrating cells increased over time. At the ipsilateral implant, invasion started at day 18 (mean invasion score: 0.86), at the contralateral site after 24 days of implantation (mean invasion score: 0.43). The invasion increased continously over time. Interestingly, RASF could be detected in all spleens of the SCID mice at every timepoint. Neoangiogenesis and vessel formation into both implants could be observed already after 35 h, which was more prominent at the ispilateral site.

Conclusion: Neoangiogenesis appears to be a very early event in RASF migration in the SCID mouse model for RA, which facilitates not only the rapid transmigration of RASF into the circulation and the migration to the contralateral implant but adds also to the knowledge of the pathophysiologic puzzle of spreading of human RA.

28

Regulation of the Fusion of Mononuclear Osteoclasts Into Bone-Resorbing Osteoclasts by GM-CSF Via RAS/ERK Pathway. Eun Gyeong Lee[1], Hee Jin Yun[1], Yun Kyung Hong[1], Myung Soo Lee[2], Sang-IL Lee[3], Hyun-Ok Kim[4], Min Ho Hwang[5], Sung Il Kim[6] and Wan-Hee Yoo[1], [1]Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Wonkwang university hospital, Iksan, South Korea, [3]College of Medicine, Gyeongsang National University, Jinju, South Korea, [4]Gyongsang University, Jinju, South Korea, [5]Presbyterian medical center, Jeonju, South Korea, [6]Pusan National University Mediacal School, Busan, South Korea

Purpose: GM-CSF has been shown to suppress RANKL-mediated osteoclast differentiation by inhibiting c-Fos. However, GM-CSF plays a critical role in osteoclast-mediated bone destruction under certain pathologic conditions including rheumatoid arthritis. Thus, this study was performed to define the role of GM-CSF in fusion of mononuclear osteoclasts for osteoclast differentiation and bone resorption.

Methods: Prefusion osteoclasts (pOCs) were generated from bone marrow macrophages treated with M-CSF and RANKL. pOCs were cultured to investigate the effect of GM-CSF on multinuclear cell formation. Expression of c-Fos, NFATc1, and DC-STAMP were determined by RT-PCR and Immunoblotting. We used constitutively active (CA)-MEK adenovirus to examine the phosphorylation of ERK induced by GM-CSF.

Results: GM-CSF enhanced the fusion of pOCs for osteoclastogenesis. GM-CSF-stimulated pOCs had intact actin ring and could resorb bone. GM-CSF induced the expression of DC-STAMP, which was mediated by inducing NFATc1 via induction of c-Fos. The expression of c-Fos and NFATc1 was regulated by ERK pathway. In addition, pOCs infected with constitutively active (CA)-MEK adenovirus expressed

c-Fos and NFATc1. The ectopic expression of CA-MEK induced NFATc1 binding to the DC-STAMP promoter and promoted the expression of DC-STAMP. CA-MEK-infected pOCs undergo cell-cell fusion and resorb bone.

Conclusion: GM-CSF can induce the fusion of pOCs into multinucleated osteoclasts by inducing the expression of DC-STAMP and thus involve in osteoclast differentiation. GM-CSF-stimulated pOCs have a typical actin ring structure and can induce bone resorption.

Role of Endogenous Tachykinins in Methotrexate-Induced Hepatotoxicity. Jaroslaw Biernat, Ryszard Sendur, Rafal Obuchowicz, Tomasz Brzozowski and Wieslaw W. Pawlik, Jagiellonian University, Cracow, Poland

Purpose: Methotrexate (MTX), a folic acid antagonist, is widely used as a chemotherapeutic agent and as immunomodulator substance in rheumatoid and psoriatic arthtritis as well. However, the efficacy of this agent often is limited by severe side effects especially in in the liver, including progressive hepatic fibrosis and cirrhosis.

MTX is tranformed in the liver to its major extracellular metabolite, 7-hydroxymethotrexate whilst inside the cells, MTX is stored in a polyglutamated form. Long-term administration leads to MTX polyglutamates accumulation and thus decreases folate levels by inhibition of dihydrofolate reductase,

In our previous experiments upon hepatoprotective mechanisms of the liver we showed that vanilloid-sensitive neurons play an important role in the dilation of hepatic artery branches and that microcirculatory hepatic blood flow is crucial for maintaining antioxidative function of hepatocytes. Basing on these observations we decided to compare and contrast the effects of sensory denervation and CGRP receptor antagonist in the protective circulatory mechanisms of the liver subjected to single and repeteated doses of MTX. In addition, we used NK-1, NK-2 and NK-3 receptor antagonists to find the role of endogenous tachykinins in this model of liver injury.

Method: Experiments were performed on Wistar rats weighing 200-220g. under pentobarbital anesthesia. Mean arterial blood pressures (AP), portal blood flow (PBF) and microcirculatory hepatic blood flow (HBF) using laser-Doppler flowmetry were measured. At the end of each experiment, the venous blood samples were taken to establish the levels of hepatic tissue injury markers (ALT, AST). Experimental groups: control group (placebo pre-treated), MTX – single dose 10 mg/kg i.p., MTX – 5 consecutive doses 10mg/kg i.p. for 5 days, single dose of MTX + sensory denervation (capsaicin), 5 doses of MTX + sensory denervation (capsaicin), single dose of MTX + CGRP receptor antagonist (CGRP 8-37), 5 doses of MTX + CGRP receptor antagonist (CGRP 8-37), MTX + NK-1, NK-2 or NK-3 receptor antangonists..

Results: Single dose of MTX (10 mg/kg i.p.) failed to increase both hepatic tissue injury markers (ALT, AST) and hemodynamic parameters however when given repeatedly for 5 days in 30% of rats ALT and AST increased 2-3 times. In this group non-sigificant reduction of HBF and HABF was recorded.

Both sensory denervation and blockade of CGRP receptors (but not NK-2 or NK-3) significantly excerbated hepatic tissue injury induced by dosing of MTX (80 and 90% of animals resepectively). In both groups HBF was reduced by 25 and 31 % respectively.

Interestingly blockade of NK-1 receptors protected the liver against MTX without interfering with circulatory parameters.

Conclusion: Above results indicate that blockade of NK-1 receptors protects the liver against repeteated doses of MTX and this mechanism is independent of vasodilatatory mechanisms of hepatic artery branches. However both sensory denervation and the blockade of CGRP receptors exacerbate the course of liver injury subjected to repeteated doses of MTX .

Blocking ERK1/2 Reduces TNF-α-Induced-IL-18 Bioactivity in Rheumatoid Arthritis Synovial Fibroblasts by Induction of IL-18BP. Hubert Marotte[1], Salahuddin Ahmed[2], Jeffrey H. Ruth[1] and Alisa E. Koch[3], [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Toledo, Toledo, OH, [3]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Rheumatoid arthritis (RA) and osteoarthritis (OA) are two common chronic joint disorders whose etiology remains unknown. Interleukin-1 (IL-1) family members play a key part in the pathogenesis of both RA and OA. Among the IL-1 cytokine family members, IL-18 is a proinflammatory cytokine which modulates Th1 development. A defect of the natural inhibitor of IL-1 was previously described in RA and blockade of IL-18 bioactivity by the use of its natural inhibitor IL-18 binding protein (IL-18BP) appears to be a promising novel therapeutic strategy. We previously observed that TNF-α induced IL-18 and IL-18BP in a time dependent manner.

Methods: Levels of IL-18 and IL-18BP expression were determined by enzyme-linked immunosorbent assays (ELISA) in OA and RA synovial fluids, followed by free IL-18 calculation. IL-18 and IL-18BP synthesis in RA synovial fibroblasts treated with TNF-α were assessed by qRT-PCR and ELISA, respectively, followed by IL-18 bioactivity determination using human myelomonocytic KG-1 cells. Since caspase-1 is needed to cleave pro-IL-18 to bioactive IL-18, its expression and its activity were determined by a qRT-PCR and colorimetric assay, respectively. Chemical signaling inhibitors and antisense oligonucleotides were used for validation of the signal transduction pathways involved in IL-18BP/IL-18 regulation.

Results: IL-18BP was lower in RA synovial fluid than in OA synovial fluid ($p < 0.05$; n=8 donors) and free IL-18 was higher in RA synovial fluid than in OA synovial fluid. TNF-α induced RA synovial fibroblast IL-18, caspase-1, and IL-18BP at the mRNA level ($p < 0.05$; n=3); caspase-1 activity ($p < 0.05$; n=4); and IL-18 bioactivity. Evaluation of signaling pathways suggested that TNF-α-induced-IL-18 production through extracellular signal-regulated kinases (ERK)1/2, protein kinase C (PKC)δ, and Src pathways, whereas IL-18BP synthesis was mediated through nuclear factor kappa-light-chain-enhancer of activated B cells (NFκB), PKC, Src, and c-Jun N-terminal kinases (JNK) pathways. Furthermore, addition of exogenous IL-18BP-Fc reduced the RA synovial fibroblast phosphorylation of ERK1/2 induced by TNF-α.

Conclusion: These results suggest that IL-18BP reduces IL-18 bioactivity induced by TNF-α, by regulating the ERK1/2 pathway in RA synovial fibroblasts. Targeting IL-18 by induction or addition of exogenous IL-18BP may provide another therapeutic option in the management of RA.

TANK Binding Kinase (TBK1)-Dependent Gene Expression in Synoviocytes. Deepa Hammaker, David L. Boyle and Gary S. Firestein, UCSD School of Medicine, La Jolla, CA

Purpose: Innate immune responses in rheumatoid synovium are activated by toll-like receptors (TLRs) in response to endogenous and exogenous antigens. TLR3 is activated by viral RNA as well as dsRNA from necrotic cells in the rheumatoid synovium, leading to increased proinflammatory mediator production. TLR3 is a potent activator of two I kappa B kinase (IKK)-related kinases, IKKe and TANK-binding kinase 1 (TBK1). Recent studies demonstrate that K/BxN serum-induced arthritis is less severe in IKKe-/- mice and that IKKe regulates chemokine, protease and IFN gene expression. However, it is not clear whether the two IKK-related kinases are redundant or whether targeting one of them might have a more prominent effect on IFN signatures. Therefore, we determined which genes are regulated by IKKe or TBK1 in cultured synoviocytes.

Method: Mouse fibroblast-like synoviocytes (FLS) from wild type (WT) and IKKe-/- mice were cultured and transfected with either scrambled (sc) or TBK1 siRNA by nucleofection. The cells were then stimulated with 20ug/ml polyI:C (PIC) for 1, 2, 3, 6, and 24h. Gene expression was assayed by qPCR. Cytokine production in culture supernatants was assayed by ELISA or multiplex analysis after 24h. IP-10 and IFNb luciferase reporter constructs were used to assay promoter activity.

Results: To determine the effect of TBK1 deficiency in the presence or absence of IKKe, WT and IKKe-/- FLS were transfected with TBK1 siRNA and then stimulated with PIC. Four patterns of IKKe/TBK1-mediated gene regulation emerged. 1) Genes regulated by TBK1 but not IKKe: IFNb, IP-10 gene, and IRF7 expression were decreased significantly by TBK1 but not IKKe deficiency after PIC stimulation (see

Figure; 94±10%, 76±10%, and 67±5% inhibition, respectively; n=3/group, $p<0.05$). Combined deficiency was not additive indicating that TBK1 is the primary regulator. Luciferase promoter constructs for IFNb and IP-10 promoters showed that TBK1 deficiency decreased gene transcription. 2) Genes regulated by IKKe but not TBK1: G-CSF had the opposite profile because it required IKKe but not TBK1 (see Figure, n=3, *$p<0.02$). Combined deficiency was not additive, indicating that TBK1 does not participate. 3) Genes regulated by both IKKe and TBK1: RANTES, IL-6, and KC expression were decreased by either IKKe or TBK1 deficiency. 4) Genes not regulated by IKKe or TBK1: MIP-1a and MCP1 were unaffected by either TBK1 or IKKe deficiency.

Conclusion: IKKe and TBK1 independently regulate cytokine and IFN responses after TLR3 ligation, indicating that the two signaling pathways are not redundant. Of the two kinases, TBK1 is the critical regulator of PIC-induced IFNb, IP-10, and IRF7 expression in FLS. Because IRF7 can serve as a master control of type I IFN responses in autoimmunity, TBK1 might be a better therapeutic target than IKKe.

32

GILZ Is a Novel Regulatory Protein in RA. Elaine Beaulieu[1], Devi Ngo[1], Qiang Cheng[1], Leilani Santos[1], Malcolm Smith[2], Michelle Leech[1] and Eric F. Morand[1], [1]Monash University, Clayton, Australia, [2]Repatriation General Hospital, Adelaide, Australia

Purpose: Glucocorticoid-induced leucine zipper (GILZ) is a glucocorticoid (GC)-induced transcription factor with recently described inhibitory effects on T cell and macrophage function via binding to NFκB and AP-1. Its expression and function have not previously been reported in RA. We herein report GILZ expression in human RA, and novel regulatory functions in FLS and human endothelial cells.

Methods: GILZ was detected in synovial sections from normal and RA subjects, and in cultured RA FLS and umbilical vein endothelial cells (HUVEC), using immunohistochemistry, qPCR and immunoblotting. The effects of GILZ overexpression on RA FLS and HUVEC cytokines and chemokines were examined, and GILZ effects on whole blood leukocyte adhesion and rolling interactions with HUVEC were examined in a flow chamber.

Results: GILZ was detected in normal synovium in lining and sublining layers. Compared to normal synovium, synovial sublining and endothelial GILZ were significantly increased in active RA. In RA FLS, the GC dexamethasone (Dex) potently and highly significantly upregulated GILZ mRNA and protein, with up to a 150-fold increase in mRNA within 4 hours which was GC receptor-dependent. In contrast, TNF and LPS significantly inhibited both endogenous and Dex-induced RA FLS GILZ expression. RA FLS release of the pro-inflammatory cytokines IL-6 and IL-8 was inhibited by GILZ without affecting proliferation. Unexpectedly, GILZ was also expressed in synovial endothelial cells and cultured HUVEC. HUVEC GILZ was significantly increased by Dex and inhibited by TNF. TNF also induced leukocyte rolling and adhesion interactions with HUVEC, which were in turn inhibited by restoration of GILZ. This was not due to an effect of GILZ on HUVEC release of the chemokines IL-8, RANTES, IP-10 and MCP-1.

Conclusion: We report the first expression and functional data regarding GILZ in human RA and human endothelial cells. GILZ expression in RA FLS is exquisitely sensitive to induction by GC, and its expression inhibits FLS cytokines. GILZ is expressed in vascular endothelial cells, where it inhibits leukocyte–endothelial interactions. These findings identify GILZ as a novel regulatory protein in RA.

IL-6 Reduces Blood Lipid Levels Via up-Regulation of VLDL Receptor. Misato Hashizume, Hiroto Yoshida, Nobuo Koike, Miho Suzuki and Masahiko Mihara, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan

Purpose: It is reported that the treatment of rheumatoid arthritis (RA) patients by IL-6 or TNF-α blocker increased blood levels of total cholesterol (T-Chol), and triglyceride (TG), which were inversely related to the disease activity of RA. But it remains to be clear why blockades of IL-6 and TNF-α change lipid level. On the other hand, there are reports describing that T-Chol and TG levels are low in RA patients. Serum lipid level is controlled by the lipid synthesis in liver and the lipid uptake into tissues mediated by lipoprotein receptor. In the present study, we investigated the influence of IL-6 and TNF-α on lipid metabolisms.

Method: Vascular skeletal muscle cells (VSMC) were cultured in the presence of IL-6, IL-6 + soluble IL-6 receptor (sIL-6R) or TNF-α for 24 h. After culture, mRNA expression of very-low-density lipoprotein receptor (VLDL receptor), low-density lipoprotein receptor (LDL receptor) and low-density lipoprotein-related protein-1 (LRP-1) were measured by real-time PCR. Human IL-6 was injected into mice twice a day for 2 weeks and then VLDL receptor protein expression in liver, adipose tissue and heart and blood T-Chol and TG levels were investigated. Anti-IL-6R antibody was injected once at 2 weeks after first IL-6 injection. Two weeks after anti-IL-6R antibody injection blood was collected and then lipid levels and SAA level were measured.

Results: At first, we examined if IL-6 induced the expression of mRNA for VLDL receptor, LDL receptor and LRP-1 in VSMC. IL-6 + sIL-6R significantly induced expression of VLDL receptor mRNA in VSMC, but IL-6 or sIL-6R alone and TNF-α did not do so. None of these cytokines induced LDL receptor and LRP-1 mRNA expression. Therefore, we examined if IL-6 actually induced VLDL receptor expression and reduced blood lipid levels in vivo. Continuous injection of IL-6 into mice significantly increased the expression of VLDL receptor in heart, adipose tissue and liver and simultaneously decreased blood T-Chol and TG levels. Furthermore, the injection of anti-IL-6R antibody normalized the reduced levels of T-Chol and TG caused by IL-6 injection, whereas it never influenced blood levels of T-Chol and TG in normal mice.

Conclusion: We demonstrated here that IL-6 increased VLDL receptor expression in several tissues and decreased blood lipid levels. Taken together with the fact that IL-6 is overproduced in RA patients, we conclude that the elevation of lipid levels in anti-IL-6 therapy is due to the inhibition of IL-6 signaling which caused reduction in lipid levels. And the elevation of lipid levels in anti-TNF therapy is mediated the suppression of IL-6 production. The study to investigate the influence of IL-6 on lipid synthesis is now underway.

Ltα_1ß$_2$-Ltßr Signaling Is Crucial for the Tolerance Against Extractable Nuclear Antigens. Jens T. Van Praet[1], Inge Vanassche[1], Sigurd Delanghe[1], Michael Drennan[1], Nele Degryse[1], Julie Coudenys[1], Tine Decruy[1], Amélie Dendooven[2], Filip De Keyser[1], Carl F. Ware[3] and Dirk Elewaut[1], [1]Ghent University Hospital, Ghent, Belgium, [2]Utrecht University Medical Center, Utrecht, Netherlands, [3]La Jolla Institute for Allergy and Immunology, La Jolla, CA

Purpose: The lymphotoxin-β receptor (LTβR), a member of the immediate TNF family, controls the development of lymph nodes and Peyers' patches. In the adult, LTβR signaling is required for the maturation and maintenance of the microarchitecture of lymphoid tissue. The membrane-bound $LT\alpha_1\beta_2$ and LIGHT are its currently identified ligands. A soluble lymphotoxin-β receptor-immunoglobulin (LTβR-Ig) fusion protein antagonizes LTβR signaling and is currently being tested for treatment of autoimmune diseases. As the induction of antinucleair antibodies and anti-dsDNA antibodies during TNFα blockade is a well known phenomenon, we examined whether LTβR signaling is involved in tolerance against nuclear antigens.

Methods: Sera were collected from $LT\alpha^{-/-}$, $LT\beta^{-/-}$, $LT\beta R^{-/-}$, $LIGHT^{-/-}$, and wild-type controls, as well as from C57BL/6 mice treated with different regimens of LTβR-Ig or control IgG. $LT\beta R^{-/-}$ mice and wild-type controls were sacrificed at 24 weeks of age and kidneys were removed for pathological analysis. Sera from cell specific knockouts of LTβ by Cre mediated recombinase in CD4 T cells (CD4-$LT\beta^{-/-}$), B cells (MB1-$LT\beta^{-/-}$), or epithelial cells (K5-$LT\beta^{-/-}$) were analyzed. Anti-extractable nuclear antigen (anti-ENA) antibodies were detected by line immune assay (INNO-LIA ANA update), anti-dsDNA antibodies by ELISA (Alpha Diagnostic International).

Results: We observed at least one anti-ENA in 24 % of 3 months old and 27% of 6 months old $LT\beta R^{-/-}$ mice, in contrast to none of age-matched wild-type controls ($p<0.05$). At the age of 6 months, the most prevalent anti-ENA were anti-RNP (20%), anti-CENPB (20%) and

anti-Topo-I/Scl70 (20%). No anti-dsDNA antibodies could be detected. Similar patterns were found in $LT\alpha^{-/-}$ and $LT\beta^{-/-}$, but not $LIGHT^{-/-}$ mice. Intriguingly, preliminary data suggested T nor B cell specific deletion of LTβ results in anti-ENA at the age of 3 months, whereas epithelium specific deletion resulted in the occurrence of at least one anti-ENA in 1 out of 4 mice. When LTβR-Ig was administered during fetal ontogeny only, no anti-ENA induction in 3 months old offspring was observed. In contrast, prolonged postnatal administration until the age of six weeks induced anti-ENA at the age of 3 months (39% vs. 0% control Ig, $p<0.05$). Histopathological analysis did not reveal signs of lupus nefritis in $LT\beta R^{-/-}$ mice nor controls.

Conclusion: These studies provide a novel role for the $LT\alpha_1\beta_2$-LTβR pathway in maintaining tolerance against extractable nuclear antigens. The presence of anti-ENA was not dependent on the structural lymphoid defects caused by the embryological absence of LTβR signaling. Surprisingly, epithelial deletion of LTβ seems to be sufficient for developing anti-ENA. The uncoupling of detection of antinuclear antibodies and pathological damage parallels the observations seen in patients under TNFα blocking therapy.

IL-18 as An In Vivo Mediator of Monocyte Recruitment in Animal Models of Rheumatoid Arthritis. Jeffrey H. Ruth[1], Christy C. Park[2], M. Asif Amin[1], Charles A. Lesch[1], Shiva Shahrara[3] and Alisa E. Koch[4], [1]University of Michigan, Ann Arbor, MI, [2]Univ of Tennessee, Knoxville, TN, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Interleukin-18 (IL-18) is a type-1 cytokine associated with proinflammatory properties. IL-18 is present at increased levels in serum and the rheumatoid synovium, as well as in the bone marrow in many human rheumatologic conditions including rheumatoid arthritis (RA), juvenile RA, adult-onset Still's disease, and psoriatic arthritis. IL-18 function was investigated in pertinent animal models of rodent RA to determine its proinflammatory and monocyte recruitment properties. We have previously shown that IL-18 acts on endothelial cells to induce angiogenesis and cell adhesion, however little is known about the monocyte chemotactic activity of IL-18. We clarified the cellular and molecular mechanisms induced by IL-18 on monocyte activation and recruitment contributing to the joint pathology observed in various rodent RA models.

Methods: We utilized a modified Boyden chemotaxis system to examine monocyte recruitment to recombinant human (rhu) IL-18 *in vitro*. Monocyte recruitment to rhuIL-18 was then tested *in vivo* using an RA synovial tissue (ST) severe combined immunodeficient (SCID) mouse chimera. We defined monocyte specific signal transduction pathways induced by rhuIL-18 by Western blotting analysis, and linked this to *in vitro* monocyte chemotactic activity. Finally, the ability of IL-18 to induce a cytokine cascade during acute joint inflammatory responses was examined by inducing wild-type (Wt) and IL-18 gene knockout mice with zymosan induced arthritis (ZIA).

Results: We engrafted SCID mice with RA ST and examined rhuIL-18 mediated monocyte migration into human ST. We found that intragraft injected rhuIL-18 was a robust monocyte recruitment factor to both human ST and regional (inguinal) murine lymph node (LN) tissue. IL-18 gene knockout mice also showed pronounced reductions in joint inflammation during ZIA compared to Wt mice. Many proinflammatory cytokines were reduced in IL-18 gene knockout mouse joint homogenates during ZIA including macrophage inflammatory protein-3α (MIP-3α/CCL20), vascular endothelial cell growth factor (VEGF) and IL-17. Signal transduction experiments revealed that IL-18 signals through p38 and ERK½ in monocytes, and that IL-18 mediated in vitro monocyte chemotaxis can be significantly inhibited by disruption of this pathway.

Conclusion: Our data shows that IL-18 is chemotactic for monocytes *in vitro* and signals in monocytes through the p38 and ERK½ pathways. Using the RA ST SCID mouse chimera, we found that IL-18 stimulates monocyte recruitment to engrafted ST and murine inguinal LNs. We also found that IL-18 initiates a proinflammatory cytokine cascade in acute articular inflammatory responses during ZIA by promoting IL-17, MIP-3α/CCL20 and VEGF production. These findings support the notion that IL-18 serves a hierarchal position for initiating joint inflammation during arthritis development.

The Effects of Interleuikin-32 Alpha On Development of Inflammatory Synovitis and Cartilage Destruction in Mice. Masanori Nakayama and Yasuo Niki, Keio University, Tokyo, Japan

Purpose: Recently, interleukin-32 (IL-32) has been reported to participate in the inflammatory process of rheumatoid arthritis (RA) through production of TNF-alpha (TNFα). IL-32 expression in RA synovia correlates with serum inflammatory markers (i.e. CRP and ESR) and the levels of TNFα, IL-6 and IL-1. It is still known that IL-32 has six subtypes; alpha-sigma. In this study, arthritogenic role of IL-32 alpha (IL-32α) was investigated by genetic overexpression of IL-32α in mice and intra-articular injection of recombinant human IL-32 alpha (rhIL-32α).

Method: We generated IL-32 transgenic (Tg) mice, which overexpressed human IL-32α under a control of ubiquitous CAG promoter constructed by the first intron of the chicken beta-actin gene and a portion of the rabbit beta-globin gene. IL-32 Tg mice do not spontaneously exhibit arthritic phenotype despite high level of IL-32 expression in joints. Knees of Tg mice and normal C57BL/6 mice were injected once with LPS (100 ng) or Zymosan (100ng). Injection of PBS to the contralateral knee was served as a control. A week after injection, histopathological examination was performed, and TNFα mRNA expression was quantitatively measured using real time PCR.

Knees of two different background wild type mice (C57BL/6, Balb/C) were injected with rhIL-32α (100ng). A week after the injection, histopathological analysis and TNFαmRNA expression were measured as well.

Results: A single intra-articular injection of LPS resulted in development of severe synovitis with articular cartilage destruction in Tg mice but not in normal C57BL/6 mice. Less severe arthritic changes were observed in Tg mice receiving Zymosan injection. TNFα mRNA expression in synovia from Tg mice was prominent and significantly higher than that from normal C57BL/6 mice.

After intra-articular injection of rhIL-32, histopathological examination revealed that both C57BL/6 and Balb/c mice represented inflammatory synovitis and depletion of proteoglycan as assessed by safranin O staining. TNFα mRNA expression in synovia was equally upregulated in both Balb/c and C57BL/6 mice with statistically significance as compared to control mice injected with PBS.

Conclusion: The present study revealed that IL-32α contributes to development of inflammatory arthritis in mice. Given that single intra-articular injection of LPS induced inflammatory arthritis in IL-32α Tg mice, IL-32α may augment Toll-like receptor-4 (TLR-4) signaling pathway, which may result in production of variety of inflammatory cytokines including TNFα. Moreover, single injection of rhIL-32α was capable of inducing synovitis and cartilage degradation in wild type mice, indicating that IL-32 modulates inflammatory process in combination with natural ligand of TLR-4.

Up-Regulation of the Histone Methyltransferase EZH2 by TNF-α in Synovial Fibroblasts Is Mediated through NF-KB/JNK-Activity and Enhances Cell Migration. Michelle Trenkmann[1], Matthias Brock[2], Renate E. Gay[1], Christoph Kolling[3], Rudolf Speich[2], Beat A. Michel[1], Steffen Gay[1] and Lars C. Huber[2], [1]Center of Experimental Rheumatology, Zurich Center of Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland, [2]Department of Internal Medicine, University Hospital Zurich, Zurich, Switzerland, [3]Schulthess Clinic, Zurich, Switzerland

Purpose: Previously we reported that the histone methyltransferase Enhancer of Zeste homologue 2 (EZH2) is up-regulated in rheumatoid arthritis (RA) compared to osteoarthritis (OA) synovial fibroblasts (SF) and is further induced by TNF-α. Beside its function in epigenetic gene silencing, EZH2 has also been shown to play a role in actin polymerization and therefore might contribute to cell migration. Here we addressed the pathways by which TNF-α regulates EZH2 and investigated the impact of EZH2 on migration of SF.

Method: RASF and OASF were pre-treated with the IKK-2 inhibitor sc-514 (50 μM), JNK Inhibitor II (20 μM), ERK Inhibitor II (10 μM) or p38 inhibitor SB203580 (10 μM) for 1h and stimulated with TNF-α (10 ng/ml) (n=4 each). After 48h, expression of EZH2 mRNA was quantified by real-time PCR. The effects of the kinase inhibitors were calculated for each individual experiment as compared to TNF-α-stimulation alone. For a reportergene assay, RASF were transfected with a luciferase vector containing the EZH2 promoter or the EZH2 promoter with a mutated binding site for the transcription factor E2F. Luciferase activity was measured upon stimulation with TNF-α for 24h

(n=7). For migration analysis, RASF and OASF (n=5 each) were transfected with a vector containing the coding sequence of EZH2 and cell migration was measured using a modified fluorescence Boyden chamber assay.

Results: Stimulation with TNF-α induced the expression of EZH2 by 4±1.4-fold in RASF and 4.4±2-fold in OASF. The inhibitors for IKK-2 and JNK had both a strong effect on the expression of EZH2 by reducing the TNF-α-mediated up-regulation by 105±14% (IKK2) and 47±17% (JNK) in RASF and 86±17% and 81±4% in OASF ($p<0.05$ for each). The ERK inhibitor decreased the induction of EZH2 by 77±18% in OASF ($p<0.05$) while the result in RASF was not significant (26±64%). Inhibition of p38 did not affect the expression of EZH2.

To detect upstream regulators of EZH2, a reportergene assay was performed employing a mutated E2F binding site. TNF-α increased the activity of the EZH2 promoter in RASF by 1.54±0.7-fold whereas mutation of the E2F binding site abolished this effect (0.98±0.3-fold, $p<0.05$). Moreover, SF transfected with EZH2 revealed an increased migratory activity as compared to the mock control (RASF: 398±191 vs. 351±156 RFU, $p<0.09$; OASF: 420±95 vs. 286±68 RFU, $p<0.04$).

Conclusion: Our data emphasize that the TNF-α induced up-regulation of EZH2 in SF is mediated through the NF-κB and JNK pathways and that the EZH2 promoter activity is directly regulated by the transcription factor E2F. Enhancing their migratory activity through the induction and overexpression of EZH2 might contribute to the aggressive phenotype of RASF.

Disclosure: M. Trenkmann, None; **M. Brock**, None; **R. E. Gay**, None; **C. Kolling**, None; **R. Speich**, None; **B. A. Michel**, None; **S. Gay**, None; **L. C. Huber**, None.

Regulation of Pleitropic Effect of TRAIL On RAFLS by TRAIL-R1 and -R2. Rachel Audo[1], Angelique Bruyer[1], Bernard Combe[2], Michael Hahne[1] and Jacques Morel[2], [1]IGMM-CNRS UMR5535, Montpellier, France, [2]Department of Immuno-rheumatology, Montpellier, France

Purpose: A hallmark of rheumatoid arthritis (RA) is the pseudo-tumoral expansion of fibroblast-like synoviocytes (FLS), and RAFLS have been proposed as a therapeutic target. TNF-related apoptosis-inducing ligand (TRAIL) has been described as a pro-apoptotic factor on RAFLS and suggested as a potential drug. We have previously shown that exposure to TRAIL induces apoptosis only in a portion of RAFLS. In the surviving cells, TRAIL induced RAFLS proliferation. To evaluate possibilities to overcome TRAIL resistance in RAFLS, we compare FLS resistant (RAFLS-R) and RAFLS-sensible (RAFLS-S) to TRAIL-induced apoptosis including expression levels of the TRAIL receptors (TRAIL-R).

Method: Cell surface expression of the four membrane-bound TRAIL-R was measured by flow cytometry. To examine the implication of TRAIL-R in TRAIL apoptosis and proliferation, RAFLS were transfected with siRNA against TRAIL-R1 and TRAIL-R2. After 3 days, efficiency of silencing was assessed by western blot and FACS analysis. RAFLS were then cultured with TRAIL for 24 hours. Apoptosis was analyzed by flow cytometry, using annexin V-FITC binding and TOPRO-3 up-take. Proliferation was measured using incorporation of [3H] thymidine.

Results: Depending on the patient, we observed inter-individual variability in sensitivity of RAFLS to TRAIL-induced apoptosis. We therefore classified the cultures depending on their sensitivity (<10%; RAFLS-R and > at 30%, RAFLS-S). We observed that TRAIL-R4 and, surprisingly also TRAIL-R1 were significantly more expressed in RAFLS-R ($p=0.034$ and $p=0.0015$ respectivly). Silencing of TRAIL-R2 significantly reduced TRAIL induced apoptosis or proliferation (25.2±2.6 to 8.9±5.9; $p<0.01$, $n=7$). In contrast, silencing of TRAIL-R1 sensitized RAFLS for TRAIL-induced apoptosis (25.2±2.6 to 35.8±6.7; $p<0.05$; $n=7$) while it did not influence the TRAIL-induced cell death.

Conclusion: Using siRNA silencing, we confirmed the implication of TRAIL-R2 in apoptosis and proliferation induced by TRAIL. Using this approach, we also found that TRAIL-R1 may not be involved in RAFLS apoptosis or proliferation induced by TRAIL, but could be a survival factor protecting RAFLS against TRAIL-induced apoptosis. This is consistent with our observation that TRAIL-R1 is significantly more expressed in the cell surface of RAFLS-R.

Critical Role for Apoptosis Signal-Regulating Kinase in the Development of Inflammatory K/BxN Serum Induced Arthritis. Stephen J. Mnich[1] and Medora M. Hardy[2], [1]Pfizer Corp, St Louis, MO, [2]Pfizer Corp, St. Louis, MO

Purpose: Apoptosis signal-regulating kinase 1 (ASK1), is a member of the MAP3K family that activates both JNK and p38 MAPK in response to stress-related stimuli. ASK1 has been implicated in the pathogenesis of a variety of apoptosis- and stress-related diseases. Notably, activation of ASK1 has been reported to occur via the TNF receptor. In this report, we show that ASK1-/- mice were resistant to inflammation and the infiltration of inflammatory cells into the ankle joints induced in the K/BxN serum transfer model of RA.

Method: Arthritis was induced in this model by injection of serum from K/BxN mice into healthy, female ASK1-/- and wild type (wt) C57BL/6 mice. The p38a MAPK inhibitor, SD-0006 was administered to wt mice as a comparator. Inflammatory repsonses were assessed at various times through 12 days. Ankle edema, histopathological and immunohistological evaluation of inflammatory cell infiltration, and transcriptional profiling were evaluated.

Results: Both ASK1 deficiency and p38 inhibition resulted in marked attenuation of edema, cartilage damage, bone absorption, and inflammatory cell infiltration. Transcriptional profiling of mRNA prepared from pulverized paw tissue demonstrated that the production of many proinflammatory genes including IL-6, IL-1b, TIMP1, MMP-3 were maintained at basal levels by either ASK1 deficiency or prophylactic p38 MAPK inhibition in K/BxN mice. To understand the role of ASK1 in human RA, *in vitro* studies using human RA synovial fibroblasts (RASF) suggest that ASK1 plays a role in the proinflammatory responses to TNF-a. Synovial fibroblasts from RA patients produced elevated levels of IL-6 following stimulation with TNF- *a.* Consistent with a role for ASK1, both p38 and JNK were activated by this stimulation. IL-6 production was only blocked partially (~30%) by either a SD-0006 or SP600125, a JNK inhibitor. In contrast, dual inhibition with both p38/JNK inhibitors almost completely abolished TNF-a-induced IL-6 production from these cells. Finally, ablation of ASK1 expression in RASF using siRNA for ASK1, but not ASK2, inhibited ASK1 mRNA and protein, and resulted in an ~60% inhibition of TNF-a-induced IL-6 production.

Conclusion: This study is the first to suggest that ASK1 is critical for the development of RA and that ASK1 may be involved in the production of proinflammatory mediators in response to TNF-a stimulation in the RA joint.

Annexin-1 Regulates Inflammation and Glucocorticoid Sensitivity of Human RA Synovial Fibroblasts. Yuan Yang[1], Yuan Jia[1], Wuqi Song[1], Devi Ngo[1], Zhanguo Li[2] and Eric F. Morand[1], [1]Monash University, Clayton, Australia, [2]Peking University People's Hospital, Beijing, China

Purpose: Annexin-1 (Anxa1) is a mediator of the anti-inflammatory actions of glucocorticoids (GC). Anxa1 is expressed in RA synovium, and Anxa1-/- mice exhibit increased experimental arthritis. The mechanism of action of Anxa1 is not well understood. We explored inflammatory signal transduction events modulated by Anxa1 in rheumatiud arthritis (RA) synovial like fibroblasts (FLS) and normal human lung fibroblasts (NHLF).

Methods: Anxa1 siRNA, GC-induced leucine zipper (GILZ)- and mitogen-activated protein kinase (MAPK) phosphotase-1 (MKP-1)-luc plasmid were transfected using lipofectamine and Amaxa. Promoter activities were examined by luciferase assay. Transfected fibroblasts were treated with TNF and/or dexamethasone (DEX) or TNF and/or MAPK or NF-kB inhibitors. IL-6 was measured by ELISA and real-time PCR. MAPK activities were detected by Western Blot and ELISA kits. Proliferation was measured by H3-thymidine incorporation.

Results: Anxa1 mRNA and protein were successfully knocked down in RA FLS using Anxa1 siRNA. Anxa1 silencing in RA FLS significantly increased TNF-induced proliferation and impaired inhibitory effect of DEX on TNF-induced IL-6 production. ERK and serine-536 NF-kB –p65 phosphorylation were increased by Anxa1 silencing. Inhibition of ERK, JNK or NF-kB pathways significantly reduced TNF-induced proliferation of RA FLS. GC induction of FLS expression of the anti-inflammatory genes G ILZ and MKP-1 was significantly impaired in the absence of Anxa1, which paralleled the impaired inhibitory effect of DEX on TNF induced

IL-6. Similarly, silencing of Anxa1 in NHL fibroblasts significantly increased responsiveness to TNF, including increased IL-6, proliferation, and ERK activity, impaired inhibitory effects of DEX on TNF-induced IL-6 release, and impaired DEX-induced GILZ and MKP-1 mRNA. Cotransfection studies in NHL fibroblasts showed that Anxa1 silencing significantly reduced DEX-induced GILZ- and MKP-1 promoter activity in comparison to control siRNA transfected cells.

Conclusion: These data demonstrate that endogenous Anxa1 is a critical endogenous inhibitory regulator of cytokine expression, proliferation and MAPK activation, and mediates GC sensitivity via activation of GILZ and MKP-1.

Elevated Serum CX3CL1 Levels in Patients with Idiopathic Inflammatory Myopathy. Nobuyuki Yajima[1], Michihito Sato[2], Ryo Takahashi[2], Kuninobu Wakabayashi[2], Takeo Isozaki[2], Tuyoshi Odai[2], Yusuke Miwa[3] and Tsuyoshi Kasama[2], [1]Tokyo, Japan, [2]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [3]Showa University, School of Medicine, Shinagawa-ku Tokyo, Japan

Purpose: Given that the chemokine CX3CL1 plays an important role in the pathogenesis of a variety of inflammatory diseases, our aim in the present study was to determine the involvement of soluble CX3CL1 in idiopathic inflammatory myopathies such as dermatomyositis (DM) and polymyositis (PM), and its relationship to disease activity and systemic complications.

Method: Twenty-three patients presenting with an idiopathic inflammatory myopathy such as DM (n=15) or PM (n=8) participated in this study between March 2004 and February 2008. Serum samples were collected from all patients during both active (newly diagnosed, untreated) and inactive disease states (after clinical remission), and were also collected from 52 healthy individuals, who served as controls. Serum levels of CX3CL1 were measured using an enzyme-linked immunosorbent assay. The relationship between serum levels of CX3CL1 and those of creatine kinase (CK) was examined. Serum CK levels were determined as an index of the myositis disease activity. In addition, the correlations between serum CX3CL1 levels and systemic complications were examined.

Results: Serum CX3CL1 levels were significantly higher in all inflammatory myositis patients than in healthy individuals (6212.4±2353.9 pg/ml vs. 92.3±83.3 pg/ml). Within the myositis group, serum CX3CL1 levels were significantly higher in patients with DM (9058.1 ±3501.8 pg/ml) than in those with PM (1232.4±539.9 pg/ml), and were significantly higher in DM patients with interstitial pneumonitis than in those without the pulmonary complication. There was a significant correlation between serum CX3CL1 and CK levels, and serum CX3CL1 levels were significantly diminished after clinical remission.

Conclusion: Our findings suggest that CX3CL1 plays a crucial role in the pathogenesis of idiopathic inflammatory myopathies, especially DM, and that CX3CL1 in serum may serve as an additional serologic marker of inflammatory disease activity in DM patients.

Ablation of CCR2 Exaggerates Arthritis and Enhances Bone Destruction in IL-1ra-/- Mice. Fujii Hiroshi[1], Baba Tomohisa[2], Hamano Ryoko[1], Yamada Kazunori[1], Onoe Tamehito[1], Mitsuhiro Kawano[1], Yamagishi Masakazu[3] and Mukaida Naofumi[2], [1]Kanazawa University Graduate School of Medicine, Kanazawa, Japan, [2]Cancer Research Institute, Kanazawa University, Kanazawa, Japan, [3]Kanazawa University Graduate School of Medicine, Japan

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by the infiltration of macrophages and neutrophils into the joint space. Chemokine receptors, CCR2 and CX3CR1, are expressed on macrophages infiltrating into the synovium of RA patients. However, it still remains unclear on the roles of CCR2- or CX3CR1-mediated signals in RA. Hence, we investigated the roles of CCR2- or CX3CR1-mediated signals in arthritis developed spontaneously in IL-1ra-deficient mice, by ablating CCR2 or CX3CR1 gene in IL-1ra-deficient mice.

Method: IL1ra-deficient, IL1ra-CX3CR1-double deficient and IL1ra-CCR2-double deficient mice underwent clinical assessment of arthritis, histological examination, assessment of bone mineral density, determination of cytokine and protein levels and assessment of osteoclastogenesis.

Results: Consistent with the previous report, IL-1ra-deficient mice developed multiple arthritis until 12 weeks after birth. Ablation of CCR2 gene but not CX3CR1 gene exaggerated arthritis in IL-1ra-deficient mice, as evidenced by augmented arthritis clinical scores and histopathological scores characterized by an aberrant neutrophil accumulation. Moreover, IL-1ra-CCR2-double deficient mice exhibited lower bone mineral density on computer tomography and higher serum concentration of cartilage oligomeric matrix protein, than IL-1ra-deficient mice. Furthermore, tartrate-resistant acid phosphatase-positive osteoclasts were increased in the joints of IL-1ra-CCR2-double deficient mice, compared with IL-1ra-deficient mice. Immunohistochemical analysis revealed that neutrophils in the inflamed joint expressed RANKL and ADAM 8, factors crucially involved in osteoclast formation. **Conclusion:** Ablation of CCR2 could aggravate arthritis developed spontaneously in IL-1ra-deicient mice, with enhanced accumulation of neutrophils, which express RANKL and ADAM 8, thereby inducing bone destruction.

Correlation Between Serum Visfatin/PBEF and BAFF Levels After Rituximab Treatment in Patients with Active Rheumatoid Arthritis. Ladislav ŠEnolt[1], Hana Hulejová[1], Olga Krystufkova[1], Markéta Polanská[1], Maria Filková[1], Karel Pavelka[1] and Jiri Vencovsky[2], [1]Institute of Rheumatology, Department of Rheumatology of the First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [2]Institute of Rheumatology, Department of Rheumatology of the First Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic

Purpose: Visfatin, also known as pre-B cell colony-enhancing factor (PBEF), is an insulin mimetic adipokine that is up-regulated in a variety of inflammatory diseases including rheumatoid arthritis (RA). Increased levels of visfatin in the systemic circulation of patients with RA were demonstrated to correlate with the clinical disease activity. Visfatin mRNA has been shown previously up-regulated in B-cells by BAFF (B-cell activation factor of the TNF family), a crucial cytokine for B-cell maturation and survival. In addition, BAFF serum levels increase during B-cell depletion. The aim of this study was to characterize the effect of B-cell depleting treatment (rituximab) on the serum levels of visfatin and study whether visfatin correlates with the changes of disease activity, B-cell depletion or serum BAFF levels.

Method: Serum levels of visfatin (BioVision, USA) and BAFF (R&D Systems Inc.) were measured in 31 patients (26 female, 5 male) with active RA before and 16 weeks after the rituximab treatment (W16). Disease activity was assessed by DAS28. CD19+ B-cells were examined in fresh peripheral blood mononuclear cells by seven-color flow cytometry (CyAn ADP).

Results: Following rituximab treatment, a majority of patients experienced significant reduction of disease activity (DAS28: 6.77±0.93 vs. 4.98±1.38; $p<0.0001$) and B-cell depletion (0.17±0.12 vs. 0.004±0.01 G/l, $p<0.0001$). Serum levels of visfatin significantly decreased (1.92±1.65 vs. 0.94±0.7 ng/ml; $p<0.01$), while BAFF levels significantly increased (1.43±1.02 vs. 4.22±2.27 ng/ml; $p<0.0001$) following the treatment. Serum BAFF, but not visfatin levels, correlated negatively with the B-cell numbers only at baseline ($r= -0.45$, $p=0.01$). Visfatin did not correlate with BAFF at baseline, however it negatively correlated with BAFF at W16 ($r= -0.46$, $p=0.01$). Visfatin levels correlated neither with C-reactive protein nor DAS28 both at baseline or W16.

Conclusion: In this study we found, that therapeutic B-cell depletion in patients with active RA has a differential effect on serum levels of the two B-cell effecting proteins - visfatin and BAFF and induces their correlation. We suggest that the lack of B–cells and improvement of disease activity can be responsible for the visfatin decrease in the circulation. The several time-point follow-up longitudinal studies could elucidate the association of visfatin with the extent of B-cell depletion and further repopulation and return of disease activity.

This study was supported by MHCR Research Projects 00000023728 and IGA NS/10614-3.

The PEG Component of Certolizumab Pegol Inhibits Degranulation by Stimulated Mast Cells. Sabrina Lamour, Marguerite Bracher and Andrew Nesbitt, UCB, Slough, United Kingdom

Purpose: The administration of some conventional injectable TNF inhibitors is associated with severe injection-site pain (ISP), including stinging and burning. ISP may be linked to the inflammatory mediators released upon degranulation of mast cells, which are highly responsive skin cells that can rapidly secrete an array of inflammatory mediators. In contrast to conventional TNF inhibitors, the anti-TNF certolizumab pegol (CZP) lacks an Fc region and instead consists of a Fab' molecule site-specifically linked to a 40 kDa PEG moiety. A low incidence of ISP has been observed in patients receiving CZP in clinical trials in patients with rheumatoid arthritis.(1-3) The objective of our investigations was to determine if the PEG moiety of CZP inhibits the non-immune–stimulated degranulation of mast cells and may be responsible for the low incidence of ISP associated with CZP.

Methods: Mast cells were cultured in vitro from stem cells over an 8–12 week period using the method of Saito et al.(4) The development of stem cells into mast cells was confirmed by identification of mast cell markers, including CD117, CD203c and CD32, using flow cytometry. Mast cell degranulation, as measured by β hexosaminidase release, was stimulated by the addition of compound 48/80, a known non-immune activator of mast cells, which causes degranulation. Titrations of CZP, PEG, and a mixture of PEG and naked Fab' at a PEG concentration of 45mg/mL were incubated with the mast cells and a fixed amount of compound 48/80 to determine the effect on mast cell degranulation. Mast cell viability at the end of the experiment was assessed using the Promega Cell titer 96 Aqueous One Solution cell proliferation assay.

Results: Compound 48/80 stimulated mast cell degranulation as measured by β hexosaminidase release, although the absolute level varied between cell preparations. PEG (45 mg/mL) inhibited mast cell degranulation stimulated by 20μM and 200μM compound 48/80 by 66% (n=3) and 57.5% (n=4) respectively (P< 0.001). CZP (100 mg/mL), PEG alone (45mg/mL) and the mixture of PEG (19.8mg/mL) and naked Fab' (23.9 mg/mL) all inhibited the majority of mast cell degranulation. None of the reagents affected overall cell viability.

Conclusion: PEG inhibited compound 48/80–stimulated degranulation of mast cells. The concentrations at which an effect is observed are what might be expected at the injection site but not systemically. This beneficial effect of PEG on mast cells may explain the low level of ISP observed with CZP in clinical trials. However, the exact mechanism behind this activity is unclear and warrants further investigation.

Utilising Assay Systems Relevant to IL-6 Mechanisms in Rheumatoid Arthritis to Demonstrate Efficacy of a Novel Human Anti-IL-6 Antibody, CAT6001. Donna K. Finch[1], Elizabeth Rendall[2], Sylvia Salter[2], Monisha Sinha[1], Nicholas Cox[2], Caroline Grahames[2], Jamie Campbell[1], Steven Lane[1], David Lowe[1], Duncan Cochrane[1], Matthew Sleeman[1], S. Cruwys[2] and Philip R. Mallinder[2], [1]MedImmune Ltd, Cambridge, United Kingdom, [2]AstraZeneca R&D Charnwood, Loughborough, United Kingdom

Purpose: IL-6 was first identified as a B-cell differentiating factor. Recent clinical data with tocilizumab have shown IL-6 to have multiple effects in RA. Using a panel of *in vitro* and *in vivo* assays, each designed to reflect an aspect of RA pathology with IL-6 involvement, we describe the activity of a novel anti human IL-6 neutralizing antibody (CAT6001), engineered for very high affinity to IL-6.
Method: The IL-6-dependent proliferation of TF1 and B9 cells was measured using 3H-thymidine incorporation. IL-6-dependent IgM release from a B cell line (SKW6.4), was measured by ELISA. Primary fibroblast-like synoviocytes from RA patients were stimulated with IL-1β and IL-6Rα for 48hrs to produce IL-6 and VEGF, which were detected by ELISA. In a model of murine acute phase protein production, mice were treated with 12μg/kg huIL-6 i.p. daily for 7 days; CAT6001 (8 to 467 μg/kg s.c.) or isotype control was given in a single administration. Animals were sacrificed on day 7 and plasma haptaglobin levels measured.

Results: CAT6001 (<1 pM affinity for IL-6) potently blocked IL-6 driven cell proliferation of the haematopoietic cell line TF-1 (pIC50 1.61pM). IL-6-induced production of IgM from a B cell line (SKW6.4) and IL-6 induced proliferation of a B cell hybridoma cell line (B9), were potently inhibited by CAT6001 (pIC50 2.63pM and Kb 0.3pM respectively). Primary fibroblast-like synoviocytes from RA patients

dose dependently expressed IL-6 upon stimulation with IL-1β. The addition of exogenous soluble IL-6Rα resulted in the release of VEGF, a key angiogenic factor. CAT6001 blocked this IL-1β-stimulated VEGF release (IC50 340pM). Thus IL-6 plays a key role in mediating the effects of other pro-inflammatory cytokines on angiogenic factor release from activated RA synovial fibroblasts. In a murine *in vivo* model, recombinant human IL-6 induced an increase in serum levels of the acute phase protein haptoglobin. The production of this acute phase protein was inhibited in a dose dependent manner by administration of CAT6001.

Conclusion: These assay systems were used to exemplify the classical role of IL-6 in RA, such as IgM production from B cells, proliferative effects on multiple cell lineages, activation of synovial fibroblasts and production of angiogenic factors *ex vivo*, and systemic release of acute phase proteins *in vivo*. In all these models, CAT6001 potently inhibited these IL-6 driven mechanisms which supports the continued development of this molecule as a possible therapeutic agent for patients with RA.

Progesterone Receptor Is Not Required for Progesterone Suppression of TLR-Induced Cytokine Production by Dendritic Cells in Vitro. Grant C. Hughes, Chang Li, Alan Wong, Kevin E. Draves and Edward A. Clark, University of Washington, Seattle, WA

Purpose: Progesterone (Pg) is a steroid hormone that governs reproductive functions in mammals. In reproductive tissues, Pg acts through a ligand-activated transcription factor called Pg receptor (PR) and through putative membrane Pg receptors (mPRs). Pg also can regulate inflammation and immunity. Specifically, Pg treatment can directly suppress TLR-induced interferon-alpha (IFN-α) production by plasmacytoid dendritic cells (pDCs) and suppress Th1-related autoimmunity in mice. While pharmacologic experiments suggest PR may be important in mediating Pg's immunoregulatory effects, the exact receptors involved are not known. Therefore, we used mice deficient in PR (PRKO) to assess the role of PR in TLR-induced IFN-α production and Th-related immune responses.

Method: Spleens, bone marrow and sera were obtained from mice heterozygous (PR+/-) or homozygous (PR-/-) for deletion of PR. PRKO mice were provided by Dr. Bert O'Malley of Baylor College of Medicine, Houston, TX. Freshly isolated splenocytes were assessed for production of IFN-α and Th-related cytokines after stimulation with various TLR ligands. Bone marrow-derived dendritic cells (BMDCs) were similarly analyzed. Serum IgM and IgG subclass levels from non-immunized mice were assessed. Cytokine and Ig levels were compared with paired T-tests. Pg 50% maximum inhibitory concentrations (IC50) were estimated by non-linear regression analysis.

Results: pDC-restricted, CpG-induced IFN-α induction in splenocytes from PR+/- and PR-/- mice showed similar sensitivity to Pg (est. IC50 4.6 x 10-7 M vs. 1.0 x 10-6 M, respectively) or medroxyprogesterone acetate (MPA, est. IC50 1.1 x 10-7 M vs. 7.7 x 10 -8 M, respectively) suppression. A similar result was obtained with CpG-induced IL-12p40. BMDCs from PR+/- and PR-/- mice showed similar degrees of sensitivity to Pg suppression of CpG- and LPS-induced IL-12p40. However, the absolute amount of CpG-induced IFN-α produced by pDCs in PR-/- splenocytes was significantly higher than that produced by PR+/- pDCs, a difference that could not be accounted for by pDC numbers. TLR-induced IL-12p40 production, by either splenocytes or BMDCs, showed more variability and no statistically significant differences. Given the known effects of Pg and IFN-α on Th-related immune and autoimmune responses, we measured serum Ig levels. We observed no statistically significant differences in serum IgM, IgG, IgG1, IgG2a, or IgG3, though there was a trend toward decreased IgG1/IgG2a ratios in PR-/- mice.

Conclusion: PR does not appear to be required for the in vitro suppressive effects of Pg on TLR-induced cytokines, suggesting the involvement of other molecules such as mPRs or glucocorticoid receptors. However, PR signaling appears to regulate TLR-induced IFN-α induction in vivo, perhaps indirectly, via cells other than splenic or bone marrow leukocytes. The role of PR in TLR-induced immune responses is the subject of ongoing investigation.

Systemic Sclerosis Organ Involvement Is Associated with Increased Adipokine Expression. Elena Neumann[1], Klaus Frommer[1], Massimiliano Vasile[2], Tim Schmeiser[1], Oliver Distler[3], Steffen Gay[3], Valeria Riccieri[2], Andreas Günther[4], Elke Roeb[5] and Ulf Müller-Ladner[1], [1]Justus-Liebig-University of Giessen, Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Cattedra di Reumatologia, Dip Clinica e Terapia Medica, Sapienza Università di Roma, Roma, Italy, [3]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [4]Internal Medicine / Pneumology, University of Giessen, Gießen, Germany, [5]Internal Medicine / Gastroenterology, University of Giessen, Gießen, Germany

Purpose: Systemic sclerosis (SSc) is a connective tissue disorder characterized by progressive fibrosis of the skin and remodeling of the microvasculature. Increased extracellular matrix deposition also affects most internal organs including the gastrointestinal (GI) tract and lungs. Lung fibrosis represents the most common cause of death in SSc. We recently showed that severe fibrosis, increased expression of profibrotic cytokines and numbers of inflammatory cells are important hallmarks in the gastric wall (GW) of SSc patients. Adipokines such as adiponectin, visfatin/PBEF or resistin are immunomodulatory cytokine-like mediators. The present study analyzed whether adipokines are present in SSc-associated inflammation.

Method: Gastric biopsy samples obtained during esophagogastroscopy (corpus, esophagus, antrum) of 5 SSc patients and 2 healthy controls; lung tissues from patients with IPF, EAA/NSIP, controls as well as skin biopsy samples (2 SSc; 2 controls) were obtained. In bronchoalveolar lavages (BAL) of healthy controls (9), patients with SSc (22), IPF (6), and EAA/NSIP (4) adiopokines were measured (ELISA). Adiponectin, visfatin and resistin immunohistochemistry and double stainings with CD45 (LCA), CD3 (T cells), CD20 (mature B cells), CD68 (macrophages), vimentin (fibroblasts), CD31 (endothelial cells) were performed. Affymetrix analysis was performed using skin fibroblasts stimulated with adiponectin.

Results: Expression of adipokines in fibrotic skin, fibrotic lung tissue and the GI-tract of SSc was increased as compared to controls. In the GW, adipokines were localized at sites of inflammation in the mucosal layer without fibrosis in this area. Strongest expression showed adiponectin and visfatin. Adipokines were expressed by fibroblasts, inflammatory cells (CD45) and perivascular. In fibrotic lung tissue increased amounts of adipokines were detectable. Adipokine levels were increased in the BAL of fibrotic lungs when compared to controls (2.5fold) and to idopathic pulmonary fibrosis (1.7fold). Affymetrix array results showed a reduced expression of matrix components and an upregulation of matrix-degrading enzymes (MMPs).

Conclusion: The data show that in SSc patients adipokines are increased at sites of fibrosis in skin and lung. In contrast, adipokines are expressed in the GW at site of inflammation without fibrosis. Further analysis of the role of adipokines in fibrosis and inflammation may help to understand the pathophysiological mechanisms in SSc. Especially the role of adipokines with anti-fibrotic potential are of distinct interest for future investigations.

New Directions for Environmental Research: Results From the Genetic and Environmental Factors in Systemic Lupus Erythematosus (GenES) Study. Glinda S. Cooper[1], Joan E. Wither[2], Sasha R. Bernatsky[3], Jaime O. Claudio[4], Ann E. Clarke[3], John D. Rioux[5], Andrew Paterson[6], CaNIOS LuNNET Investigators and P. R. Fortin[7], [1]US EPA, Washington, DC, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]McGill University Health Center, Montreal, QC, [4]Toronto Western Hospital, Toronto, [5]Montreal Heart Institute, Montreal, QC, [6]The Hospital for Sick Children Research Institute, Toronto, ON, [7]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: The aim of this study was to examine the associations between occupational and non-occupational exposures to sunlight and other potential risk factors for systemic lupus erythematosus (SLE) in the GenES study, a case-control study conducted through the Canadian Network for Improved Outcomes in SLE (CaNIOS).

Methods: SLE cases (n=258) fulfilling ACR disease classification criteria were recruited through 11 rheumatology centers across Canada. Controls (n=263) were randomly selected using lists of working phone numbers and matched to cases by area of residence, sex, and age. Participants completed a structured telephone interview with sections on work history and leisure time activities, with a focus on specific exposures including sunlight, silica, and solvents. All exposures were limited to experiences that occurred before diagnosis age (patients) or corresponding reference age (controls). We used logistic regression to estimate odds ratios (OR) and 95% confidence intervals (CI), adjusting for age, sex, and area.

Results: An association was seen with outdoor work in the 12 months preceding diagnosis (OR 2.0, 95% CI (1.1, 3.8)), but there was no association with total number of years of outdoor work. The frequency of responses concerning most of the specific types of leisure time sun exposure during the 5 years preceding diagnosis was similar in patients and controls. The exception was beach or other sunny vacations, which was reported more often by patients than controls (OR 2.4, 95% CI (1.5, 3.7)). There was little difference between patients and controls in smoking history, personal use of permanent hair dyes, occupational exposure to hair dyes, permanents and relaxers, gasoline, or pesticides, work involving drawing blood or giving injections, or work in a dry cleaner. Relatively strong but imprecise associations were seen with several exposures not previously reported with respect to SLE: artist working with paints, dyes or developing film (OR 3.9, 95% CI (1.2, 12.1)), work that included applying nail polish or nail applications (a source of exposure to di-*n*-butyl phthalate, OR 10.5, 95% CI (1.3, 84.3)), and work involving sterilizing dental equipment (OR 3.9, (0.8, 20.0)); these estimates are based on small numbers of exposed individuals. Patients were more likely than controls to report participation in pottery or ceramics work as a leisure time activity, with an increased risk seen among individuals with a total frequency (i.e, product of number of years times the average number of days per year) of at least 26 days (OR 2.2, 95% CI (1.2, 3.8)).

Conclusion: In addition to silica dust, these data support the role of other specific environmental exposures in the development of SLE.

A Tobit Model for Predicting Health Utilities Index Mark 3 From Osteoarthritis Disease Duration: a Population-Based Study. Eric C. Sayre[1], Philippe Finès[2], William M. Flanagan[2], Jolanda Cibere[3], M. Mushfiqur Rahman[1], Jaafar Aghajanian[1], Weiqun Kang[1], Nick J. Bansback[4], Aslam H. Anis[5], Elizabeth M. Badley[6] and Jacek Kopec[3], [1]Arthritis Research Centre of Canada (ARC), Vancouver, BC, [2]Statistics Canada, Ottawa, ON, [3]University of British Columbia and ARC, Vancouver, BC, [4]University of British Columbia, Vancouver, [5]Univ of British Columbia, Vancouver, BC, [6]Toronto Western Res. Institute, Toronto, ON

Purpose: Osteoarthritis (OA) is usually a slowly progressive disease. With longer disease duration, health-related quality of life (HRQoL) declines, but this has not been well quantified. The purpose of this study is to understand the decline in HRQoL over time due to OA disease duration (OAD).

Method: We used biyearly longitudinal data (1994-2002) from the National Population Health Survey (n=10,920), weighted for the 2002 Canadian population. Self-reported arthritis/OA was extracted from each cycle to determine a discrete (interval) OAD variable, which was categorized into 4 levels: no OA; <4 years; 4-7.9 years; 8+ years. Latent HRQoL (LHRQoL; unbounded above) was measured by the observed Health Utilities Index Mark 3 (HUI3; bounded above at 1). LHRQoL in 2002 was predicted in a cross-sectional Tobit regression model from OAD as of 2002, adjusted for gender, age group (decades) and BMI (<25, 25-29.9, 30+). Interactions were tested between gender and OAD (dropped at alpha=0.05), and gender and BMI (retained). Variance estimates were bootstrap adjusted. Regression coefficients represent effects on LHRQoL; predicted LHRQoL can be truncated above at 1 to convert to HUI3 scale.

Results: Table 1 lists the regression coefficients with 95% confidence intervals (CIs). Compared to no OA, the effect (95% CI) on LHRQoL due to <4 years of OA is -0.078 (-0.101, -0.055), the effect of 4-7.9 years of OA is -0.143 (-0.198, -0.088), and the effect of 8+ years of OA is -0.162 (-0.203, -0.120). Other variables that were associated with lower HUI3 included female, older age (a nearly monotonic decline

decade to decade), and heavier BMI (in males, a reduced effect). Except on covariate combinations that predict LHRQoL above 1, coefficients may be interpreted as effects on HUI3.

Table 1. Tobit model for HUI3

Variable	Coefficient (95% CI)
OAD (reference=No OA)	*
<4 years	-0.078 (-0.101, -0.055)
4-7.9 years	-0.143 (-0.198, -0.088)
8+ years	-0.162 (-0.203, -0.120)
Gender (reference=Female)	*
Male	0.060 (0.028, 0.091)
Age group (reference=80+)	*
12-19	0.250 (0.206, 0.295)
20-29	0.246 (0.206, 0.286)
30-29	0.247 (0.206, 0.288)
40-49	0.215 (0.173, 0.257)
50-59	0.170 (0.130, 0.210)
60-69	0.167 (0.125, 0.209)
70-79	0.113 (0.070, 0.155)
BMI (reference=30+)	*
<25	0.070 (0.044, 0.097)
25-29.9	0.053 (0.024, 0.083)
Male & BMI <25	-0.065 (-0.100, -0.030)
Male & BMI 25-29.9	-0.022 (-0.060, 0.015)
[1]Scale	0.217 (0.208, 0.225)

[1]Scale estimates the standard deviation of the normal error term.

Conclusion: LHRQoL is affected in a monotonic, nonlinear way by OA disease duration. Adjusted for age, gender and BMI, the average drop in HUI3 between no OA and <4 years of OA is nearly matched by the subsequent drop between <4 years and 4-7.9 years of OA. However, the reduction from there to 8+ years of OA is only a quarter the size of the previous declines. Most of the negative effects of OA on LHRQoL appear to occur in the first 8 years. This may (in part) be due to disease adaptation, or treatments such as eventual surgery.

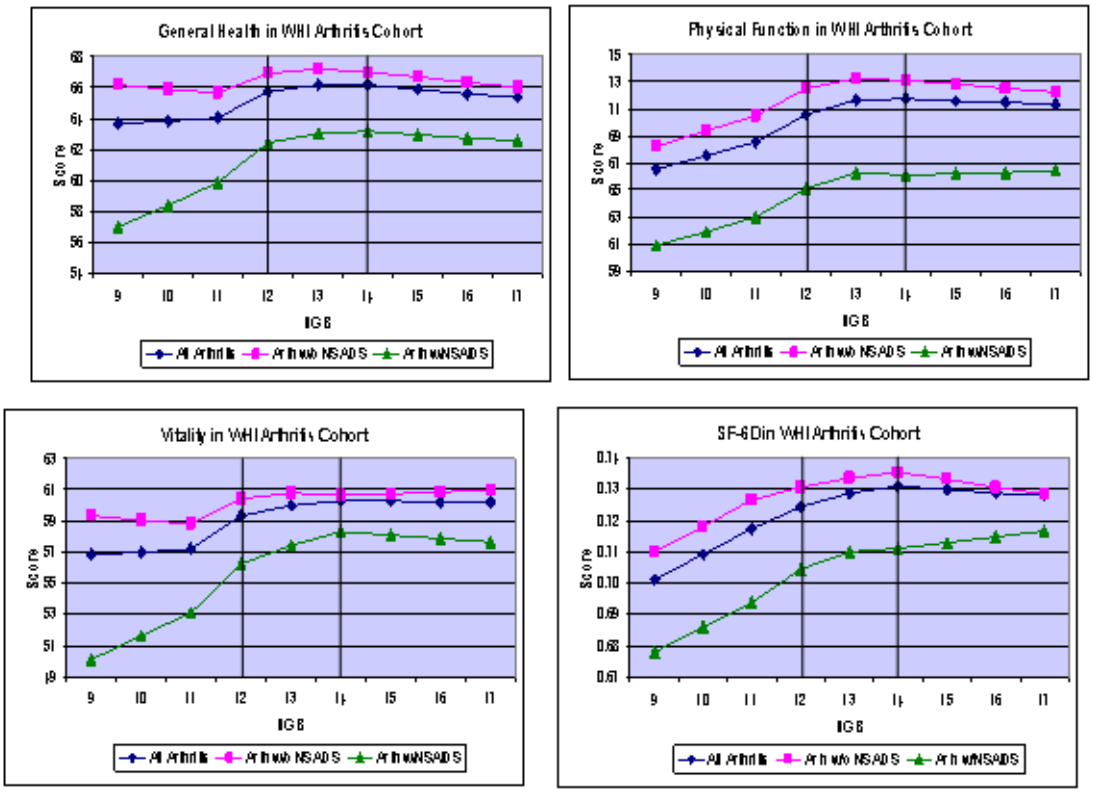
Relationship of Functional Outcomes to Hemoglobin Levels in Women with Self-Reported Arthritis: Results From the Women's Health Initiative. Charles B. Eaton[1], Marc C. Hochberg[2], Byron Cryer[3] and Annlouise R. Assaf[4], [1]Alpert Medical School of Brown University, Pawtucket, RI, [2]University of Maryland School of Medicine, Baltimore, MD, [3]University of Texas Southwestern, Dallas, TX, [4]Pfizer, Inc. and Alpert Medical School of Brown University, Providence, RI

Purpose: Gastrointestinal (GI) blood loss is a recognized complication of the use of non-steroidal anti-inflammatory drugs (NSAIDs) in patients with arthritis. We examined the relationship of patient reported outcomes of Overall Health, Vitality, Physical Function, and Quality of Life to hemoglobin levels in elderly women to determine whether hemoglobin levels as marker of chronic blood loss were associated with functional outcomes.

Method: Post-menopausal women (N=65,181) with self-reported arthritis at baseline in the WHI clinical trial (RCT) and observational cohorts, excluding participants with a self-reported diagnosis of sickle-cell anemia, chronic kidney disease, congestive heart failure, cancer, rheumatoid arthritis (RA), or those who reported being on erythropoietin, had hemoglobin levels measured and completed Short Form Health Survey (SF-36) subscales for patient centered outcomes of: overall health, vitality/fatigue, physical function and quality of life (SF-6D). Multiple linear regression analysis adjusted for age, race, education, RCT, Body Mass Index (BMI), depression, physical activity, disability, hospitalizations, lupus, diabetes, cardiovascular disease, and liver disease was performed. Multi-covariate adjusted least square (LS) means for each level of hemoglobin are plotted below.

Results:



Participants with arthritis had worse functional outcomes when hemoglobin levels were below 14 g/dL compared to ≥14 g/dL (P<.001). Participants with arthritis who were taking NSAIDs had worse outcomes than those not taking NSAIDs at all levels of hemoglobin (P<.05)

Conclusion: Differences in hemoglobin levels are related to differences in functional outcomes in post-menopausal women with self-reported arthritis excluding RA. This effect appears more profound in subjects taking NSAIDs.

51

How Valuable Is a Rheumatologist: An Analysis of Downstream Revenue. Gary S. Firestein, UCSD School of Medicine, La Jolla, CA

Purpose: As a cognitive specialty, rheumatology experiences many problems faced by primary care in terms of low compensation and high overhead. In a group practice, the downstream benefits of a rheumatologist to the enterprise are rarely considered when determining the value of the services. To address the this question, the downstream revenue that accrues to a medical system was evaluated to provide a more accurate assessment of the marginal benefit of adding a clinical rheumatologist to the practice.

Method: Retrospective reviews were performed to assess professional fees and hospital services (imaging and laboratory) for patients with osteoarthritis (OA; Dx 715.20) or rheumatoid arthritis (RA; Dx 714.0) at the UCSD Medical Center Hillcrest Arthritis Clinic. Infusion center and physical therapy was not evaluated because the charges for these activities could not be captured.

Results: Two separate analyses were performed. First, 100 consecutive patients with OA seen in consultation by rheumatology in 2004 were identified and their disposition over the ensuing 3 years was determined. Of these, 28% of patients were referred to orthopedics for consultation. 42% of these had a surgical procedure, most commonly total joint replacement. Because the average OA patient is seen about 3 times/yr by our rheumatology service, a practice with 3600 visits/yr and, therefore, 1200 unique patients would be expected to contribute 141 surgeries/yr after 3 years. Based on current reimbursement, this would generate $1,075,000 in additional professional fee charges for orthopedics. In the second analysis, RA patients in the the health care system that were followed primarily by rheumatology were evaluated for downstream revenue in a single year (2006). 724 separate visits were tracked at one of our clinic sites. In addition to professional fees for the rheumatologist, $1,400,000 in professional fee charges for these patients were generated through consultation and non-rheumatology services, including Anesthesia ($200,000), Cardiology ($116,000), Orthopedics ($557,000), Radiology ($452,000), and Pathology ($48,000). Outpatient hospital charges for imaging and laboratory services during the same period were $1,011,000. Combined, each RA patient generated an average of $3000 in downstream charges, not including infusion center charges or physical therapy.

Conclusion: A clinical rheumatologist has profound effects on utilization in an integrated health care system. Every professional fee dollar charged by a rheumatologist for an RA patient generates approximately 20-30 fold additional charges for the enterprise. Clinical activity for a rheumatologist can lead to a substantial numbers of orthopedic procedures for OA patients, with additional impact on Anesthesia and Radiology. Therefore, an integrated healthcare system seeking to optimize utilization and enhance revenue should provide support to increase and incentivize rheumatology clinical services.

Disappearing Act? Trends in the Extra-Articular Manifestations of Rheumatoid Arthritis (1995-2007). Elena Myasoedova[1], Cynthia S. Crowson[1], Carl Turesson[2], Sherine E. Gabriel[1] and Eric L. Matteson[1], [1]Mayo Clinic, Rochester, MN, [2]Malmö, Sweden

Purpose: To evaluate recent incidence trends in extra-articular manifestations of rheumatoid arthritis (ExRA).

Method: Information on ExRA manifestations was abstracted by medical record review of a population based incident cohort of patients with RA who first fulfilled 1987 ACR criteria for RA between 1/1/1995 and 1/1/2008. The patients were followed from 1/1/1995 until death, migration, or 1/1/2009. The date of ExRA incidence was recorded and ExRA were classified according to predefined criteria used in our previous studies (Ann Rheum Dis 62:722-727, 2003). ExRA events prior to the RA incidence date were excluded from each analysis. The cumulative incidence of ExRA adjusted for competing risk of death was estimated at 10 years follow-up. Incidence rates were compared to those reported for the previous decade (i.e. incident RA cases between 1/1 1985 and 12/31/1994 from the same population base, followed through 12/31/2000 (J Rheumatol 29:62-67, 2002).

Results: The study population included 463 RA patients with incident RA (mean (SD) age at incidence 55.6 (15.6) years). Of these, 320 (69%) were female; rheumatoid factor (RF) was present in 306 (66%) patients. The mean (median) follow-up was 6.3 (5.8) years (total of

2,956 person-years). ExRA developed in 159 patients, including 22 who developed severe disease manifestations of ExRA. The 10-year cumulative incidence for ExRA during the 1985-94 decade was similar to the 1995-2007 period (43.5% vs 46%), whereas there was a slight decrease in severe ExRA (8.4% vs. 6.5%, respectively). The most common ExRA in our cohort were subcutaneous nodules (n=110, 10-year cumulative incidence 30.9%) and keratoconjunctivitis sicca (n=39, 10-year cumulative incidence 9.9%). The 10-year cumulative incidence of vasculitis decreased significantly from the 1985-94 decade (3.6%) to 0.6% in 1995-2007 period, p=0.03).

Conclusion: During the 1995-2007 period, incident ExRA were common with a 10-year cumulative incidence of 46% of RA patients, which is similar to the previous decade. News of the demise of ExRA is premature, but there may be a decrease in the incidence of severe ExRA, in particular vasculitis.

Patients' Reactions to ACR Hotlines. Liana Fraenkel[1] and Ellen Peters[2], [1]Yale University, New Haven, CT, [2]Decision Research, Eugene, OR

Purpose: The ACR response to reports of extremely rare, but serious, adverse events (AEs) includes publishing a “hotline” recommending that physicians inform their patients of newly recognized risks. There are no data, however, describing how patients react to this information, and the consequences of disclosing dreaded, albeit rare AEs, on treatment planning are not known. The objective of this study was to examine how patients react to the disclosure of rare AEs associated with medications commonly used by rheumatologists.

Methods: Patients' risk perceptions are most often studied using written scenarios. In order to more closely represent how information is communicated in clinical practice, we developed a video in which a physician described the availability of a new medication associated with a rare AE (jaw osteonecrosis or progressive multifocal leukoencephalopathy). Consecutive patients attending outpatient clinics viewed the video and then rated their willingness to take the medication, as well as their worry and perceived chance of developing the rare AE on 11-point numeric rating scales. We examined the association of demographic variables with patients' reactions using logistic regression. Willingness, worry, perceived chance, and age were classified into two groups using the median. Race was classified as White vs non-White. Education was classified as college graduate or higher vs some college or less. Self-reported health status was included in the model as a covariate.

Results: 216 patients participated. The mean age (SD) was 59 (13), 39% were college graduates, 70% were White, 26% were Black, and 62% were female. The median (Q1-Q3) willingness to take the medication was 5 (0-8). The median level of worry was 8 (3-10), and the median perceived chance of developing the AE was 5 (3-10). Women were less willing to take the medication, were more worried about the AE and perceived a greater chance of developing the AE compared to men (Table 1). A similar pattern was seen for non-White vs White subjects. Lower education was also associated with increased worry and perceived chance (Table 1). Dummy variable regression demonstrated that black women were significantly less willing to take the medication [Adj OR (95%CI) = 0.37 (0.14 - 0.95)] and more worried about the risk of the AE [Adj OR (95%CI) = 3.05 (1.32 - 7.06)] than White women or men after adjusting for education, age and health status.

Conclusion: Demographic characteristics influence how patients react to risks of rare, but serious, AEs. More socially vulnerable individuals appear to be especially affected. The results are consistent with risk reactions in the environmental science literature and emphasize the need for further research to facilitate risk communication in clinical practice.

Table 1. Associations between Demographic Characteristics and Reactions to Risk Information

	Adjusted Odds Ratio (95% CI)		
Characteristic	Willingness	Worry	Perceived Chance
Female vs Male	0.47 (0.26 - 0.85)	2.46 (1.31 - 4.61)	3.62 (1.90 - 6.91)
Non-White vs White	0.47 (0.23 - 0.93)	2.30 (1.25 - 4.57)	2.09 (1.07 - 4.07)
Less vs More Education	0.84 (0.46 - 1.54)	1.92 (1.02 - 3.62)	2.79 (1.47 - 5.31)

Older vs Younger	0.54 (0.30 - 0.99)	0.91 (0.50 - 1.66)	1.62 (0.88 - 3.02)

Disclosure: L. Fraenkel, NIH, AF, 2 ; **E. Peters**, None.

WCWL Rheumatology Priority Referral Score Reliability and Validity Testing. Avril Fitzgerald[1], Barbara Conner Spady[1], Carolyn DeCoster[1], Ray Naden[2], Gillian A. Hawker[3], Thomas Noseworthy[1] and the WCWL Investigators[4], [1]University of Calgary, Calgary, AB, [2]New Zealand Ministry of Health, Auckland, New Zealand, [3]Women's College Hospital, Toronto, ON, [4]Calgary, AB

Purpose: Rheumatology consultation demand exceeds supply of rheumatologists in many countries. Western Canada Waiting List (WCWL) has developed a diagnosis independent, priority-referral score (PRS) for rating relative urgency for referral to rheumatologists by primary care providers (PCPs). This paper reports the reliability and validity of the PRS.

Method: To develop WCWL PRS, a clinical panel of 5 rheumatologists and 5 PCPs, using anonymous case scenarios, engaged in a deliberative process leading to development of criteria and levels. Relative weights were generated using discrete choice experiment software (1000 Minds ®). Reliability and validity of PRS were tested independently with another 14 rheumatologists and 10 PCPs. These physicians clinically ranked, and then PRS scored, 16 case scenarios representative of the range of case-mix and urgency of referrals from PCPs to rheumatologists. Participants also rated relative urgency using visual analogue scale (VAS) and maximum acceptable waiting time (MAWT) for each case. Retesting was performed 6-12 weeks later, using altered case identifiers.

Results: The inter- and intra-rater reliability coefficients (ICC) for PRS and clinical ranking are shown for rheumatologists, and inter-rater reliability coefficients for PCPs (retesting in progress).

Inter-rater Correlation Coefficients (ICC) for Urgency Scores

	Rheumatologists		PCPs
Method	Time 1	Time 2	Time 1
PRS	0.80	0.80	0.81
Clinical Rank	0.81	0.78	0.60
VAS	0.70	0.75	0.69
MAWT	0.46	0.43	0.38

Intra-rater Correlation Coefficients (ICC) for Urgency Scores

Method	Rheumatologists	
	Average	Range
PRS	0.83	0.57-0.97
Rank	0.94	0.74-

		0.97
VAS	0.82	0.74-0.95
MAWT	0.85	0.65-0.96

Three emergent cases were correctly identified by 14, 12 and 10 rheumatolgists initially, and 14, 13 and 13 on retesting. These emergent cases were correctly identified by 10, 8 and 7 of the 10 PCPs.

Conclusion: Average correlation between rheumatologists' clinical rankings and PRS-derived rankings is moderately strong at 0.71. Inter-rater and intra-rater ICCs for clinical ranking and PRS for rheumatologists are strong and consistent over six weeks. PCPs demonstrate higher inter-rater reliability with PRS than clinical ranking. Using PRS, PCPs have similarly high inter-rater reliability as rheumatologists. Emergent cases are identified by rheumatologists correctly, or score high on urgency. These results show acceptable performance of the PRS, albeit further testing of specific case mix groups is required. Implementation and pilot testing is in progress.

Validation of Administrative Data to Identify Rheumatoid Arthritis. Liron Caplan[1], Jay R. McDonald[2], Janis Kuhn[2], Angelique L. Zeringue[2], Prabha Ranganathan[3], Lisa A. Davis[1], Fran Cunningham[4] and Seth A. Eisen[5], [1]Univ of CO Denver School of Med, Aurora, CO, [2]St. Louis Veterans Affairs Medical Center, St. Louis, MO, [3]Washington University, St Louis, MO, [4]Hines, IL, [5]St. Louis Veterans Affairs Medical Center, Washington, DC

Purpose: Observational studies frequently rely on International Classification of Diseases (ICD)-9 codes and pharmacy data to identify subjects with rheumatoid arthritis (RA). Prior studies have examined the diagnostic parameters for ICD-9 codes and/or pharmacy data, however, these studies have drawn subjects only from rheumatology clinics (Arthritis Rheum 2004;51(6):952-957; Arthritis Rheum 2000;40(9):1594-1600) or limited the eligible population to total knee replacement recipients (J Clin Epi 2003;56:515-519), introducing the possibility of bias. The purpose of our study was to determine the diagnostic metrics of ICD-9 codes for RA from inpatient and outpatient administrative data.

Methods: This retrospective study utilized administrative data from inpatient and outpatient national VA databases based on clinical encounters from 10/1998 until 9/2006. We defined RA by the presence of an ICD-9 code compatible with RA and a disease modifying antirheumatic drug (DMARD), and matched these cases to controls (subjects without an RA ICD-9). The sensitivity, specificity, positive and negative likelihood ratios, positive and negative predictive values, and accuracy of the administrative data was then determined by applying two different gold standards, based upon the electronic medical record: 1) clinician documentation of RA; or 2) presence of at least 4 of 7 American College of Rheumatology Classification Criteria for RA.

Results: Diagnostic parameters listed in Table 1 were determined from a sample of 150 cases and 530 controls. Sensitivity was very high and specificity was modest, regardless of the chosen gold standard.

Conclusion: The combination of an ICD-9 compatible with RA and a DMARD is a highly sensitive method of identifying cases of rheumatoid arthritis from administrative data.

		Gold standard = Clinician documentation of RA			**Gold standard = At least 4 of 7 ACR criteria for RA**		
Parameter	**Definition**	Proportion	Confidence Interval		Proportion	Confidence Interval	
		Estimate	Lower	Upper	Estimate	Lower	Upper
Sensitivity	a/(a+c)	0.9933	0.9803	1.0064	1.0000	1.0000	1.0000

Specificity	d/(b+d)	0.7075	0.6688	0.7463	0.6104	0.5719	0.6489
Likelihood Ratio +	a/(a+c)/(b/b+d))	3.3966	2.9734	3.8800	2.5667	2.3251	2.8333
Likelihood Ratio -	c/(a+c)/(d/b+d))	0.0094	0.0013	0.0665	0.0000	#DIV/0!	#DIV/0!

Increased Risk of Lower Gastrointestinal Events (GI) in Rheumatoid Arthritis (RA). Elena Myasoedova, Nicholas J. Talley, Cynthia S. Crowson and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: There is strong evidence of increased risk of upper GI disorders in RA as compared to non-RA subjects. Lower GI complications in RA are much less studied. The purpose of this study was to estimate the risk of incident lower GI events in RA patients compared to non-RA subjects.

Method: We collected data on incident lower GI events from the medical records of a retrospectively identified population-based inception cohort of RA patients first diagnosed with RA (1987 ACR criteria) between 1/1/1980 and 1/1/1998. Data on incident lower GI events were obtained similarly for a comparison cohort of non-RA subjects from the same population matched for age, sex and calendar year to RA patients. Person-years methods were used to estimate the incidence of lower GI events within the RA and non-RA cohorts. Subjects with a history of upper and/or lower GI events prior to RA incidence date or the corresponding index date for non-RA subjects were excluded from the analysis of each individual GI event. Relative risks (RR) were estimated by dividing the rates of lower GI events in RA patients by the rates of those in non-RA subjects.

Results: The study population included 423 RA patients (mean age [SD] 56.5 [16.1], 68% female) and 422 non-RA subjects (56.3 [16.4], 68% female). Non-RA subjects had more diagnoses of lower GI events prior to the index date (p=0.03). Other baseline characteristics (number of upper GI diagnoses, number of surgeries and hospitalizations due to GI disorders prior to incidence/index date) were similar in both cohorts. RA patients were more likely than non-RA subjects to experience lower GI bleeding/perforation (RR 1.5; 95% confidence interval [CI] 1.01,2.1), diverticulitis (RR 2.6; 95% CI 1.3, 5.5), lower GI ulcers (RR 2.9; 95% CI 1.2, 9.1) and appendicitis (RR 4.7; 95% CI 1.1, 66.5). RA patients were more likely than non-RA subjects to undergo any lower GI surgery (RR 1.8; 95% CI 1.1, 3.0), particularly surgery due to bowel obstruction (RR 2.5; 95% CI 1.01, 8.0). RA patients had higher risk of hospitalization for any GI-related reason (RR 1.7; 95% CI 1.2, 2.3). In particular, RA patients were more likely to be hospitalized for diverticular disease (RR 3.5; 95% CI 1.7, 8.2), GI bleeding/perforation (RR 1.8; 95% CI 1.2, 2.7) and infectious colitis (RR 2.5; 95% CI 1.01, 8.0). No differences were found between RA and non-RA subjects regarding the risk of other lower GI events such as erosions and vasculitis.

Conclusion: RA patients are at increased risk of incident lower GI events as compared to non-RA subjects. RA patients have increased risk for surgical interventions and hospitalizations for lower GI events than subjects without RA. Further studies are underway to determine the reasons for the increased risk of lower GI events in RA.

Are Rheumatoid Arthritis Patients Experiencing Less Coronary Heart Disease in Recent Years? Cynthia S. Crowson, Elena Myasoedova, Veronique Roger, Eric L. Matteson, Hilal Maradit Kremers, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: Patients with rheumatoid arthritis (RA) suffer from an excess burden of coronary heart disease (CHD) and heart failure (HF). The purpose of our study was to examine whether the risk of CHD and HF in RA patients has changed in recent years.

Method: A population-based inception cohort of RA subjects who fulfilled 1987 ACR criteria for RA between 1-1-1980 and 1-1-2008 was assembled and followed until death, migration, or 7-1-2008. The presence of CHD (physician diagnosis of coronary artery disease, hospitalized or silent myocardial infarction [MI], revascularization, angina) and HF (Framingham diagnostic criteria) was ascertained by review of the medical record. Cox proportional hazards models with age as the time scale and adjusted for sex were used to assess the risk of CHD and HF according to calendar year of RA incidence (1980-84 vs. 1995-2007). Patients with CHD or HF prior to RA incidence were excluded from the analyses.

Results: The study included 741 RA patients (mean age [SD] 56 [15.8] years, 69% women). The patients were followed up for a mean of 9.6 years during which 89 patients developed CHD (excluding 83 patients with CHD prior to RA incidence] and 82 patients developed HF (excluding 20 patients with HF prior to RA incidence). The 5 year risk of CHD was 7.0% and 4.9% for patients with incident RA in 1980-94 and 1995-2007, respectively. The age and sex adjusted risk of CHD was significantly lower in 1995-2007 compared to 1980-94 (hazard ratio [HR]: 0.58; 95% confidence interval [CI]: 0.35, 0.95; p=0.03). The 5 year risk of HF was 6.0% and 5.5% for patients with incident RA in 1980-94 and 1995-2007, respectively). The age and sex adjusted risk of HF was similar in 1995-07 compared to 1980-94 (HR: 0.87; 95% CI: 0.54, 1.40; p=0.57).

Conclusion: The risk of CHD for patients with incident RA declined over time, but the risk of HF was unchanged. This suggests that efforts to reduce CHD risk in RA patients may have been effective in reducing the excess burden. However, the mechanism underlying HF in RA patients may differ from that of CHD. More research is needed to understand the reasons for these trends in the risk of CHD and HF in RA along with intensification of the efforts to prevent HF.

The Effect of Hydroxychloroquine and Methotrexate On Glycated Hemoglobin. Laura R. Rekedal, Elena Massarotti, Rajesh K. Garg, Radhika Bhatia, Bing Lu and Daniel H. Solomon, Brigham & Women's Hospital, Boston, MA

Purpose: Cardiovascular disease is a common comorbidity of many rheumatic diseases and inflammation appears to promote insulin resistance. Data suggest that hydroxychloroquine (HCQ) may improve insulin metabolism and lower glycated hemoglobin (HbA1c) in non-rheumatic patients. Additionally, epidemiologically it may reduce the risk of diabetes among those with RA. However, there is little information on HCQ's effect on rheumatic disease patients with diabetes mellitus (DM) or the effect of methotrexate (MTX) on HbA1c. We examined medical records of patients with DM to measure changes in HbA1c from before to after starting HCQ or MTX.

Method: We utilized a longitudinal medical record system to search for patients who meet all of the following criteria: a) initiated either HCQ or MTX, b) have a diagnosis of DM or HbA1c $\geq$ 7%, and c) have 2+ HbA1c measurements. The individuals meeting these criteria, with HbA1c readings both before and within 12 months after initiation of the drugs of interest, were reviewed using a structured data abstraction form examining rheumatologic diagnosis (RA, SLE, or other rheumatologic condition), use of oral corticosteroids in the twelve months post-HCQ or MTX initiation, body mass index (BMI), age, and gender. Adjusted linear regression models were examined to determine change in HbA1c from pre-drug values to lowest post-drug values within twelve months. **Results:** We identified 82 patients who met inclusion criteria: 45 HCQ users and 37 MTX users. The patients were similar in age (mean 61), gender (79% female) and mean pre-drug HbA1c levels (HCQ 7.71% and MTX 7.38%, p = 0.35). Mean BMI for HCQ users (35.4 kg/m^2) was slightly higher than MTX users (32.2 kg/m^2). Steroid use in the 12 months after DMARD initiation was more common in MTX (44%) than HCQ (33%). The mean reduction in HbA1c between pre and post HCQ was 0.66% (95% CI 0.26 – 1.05) versus 0.11% (95% CI -0.18- 0.40) for MTX. In fully adjusted analyses the drop in HbA1c among HCQ users was 0.54% greater than the drop among MTX users (p = 0.041).

Conclusion: HCQ initiation was associated with a significant reduction in HbA1c among rheumatic disease patients with DM or pre-treatment HbA1c ≥ 7%. MTX may be associated with a reduction in HbA1c but our sample size was small and there were several possible confounders. This work is an extension of previous randomized controlled trials of anti-malarials in non-rheumatic diabetic populations, in whom HCQ was associated with a significant reduction in HbA1c. Further prospective studies are warranted to determine the clinical relevance of HCQ's potential benefits on insulin resistance in rheumatic disease.

Different Utility Measurement Instruments May Not Discriminate Across Disease Severity: Results From a Cohort of Rheumatoid Arthritis Patients in Portugal. Elizabeth Benito-Garcia[1], Sofia Pedro[1], Joana Vasconcelos[1], Rita A. Marques[1], Andreia Rodrigues[1], Irina Chaves[1] and Pieter Drost[2], [1]Bioepi, Oeiras, Portugal, [2]Bristol-Myers Squibb International Corporation, Braine-l'Alleud, Belgium

Purpose: Decision-making in Rheumatoid arthritis (RA) is often based on non-specific disease outcome measures as improvement in Health-Related Quality of Life (HRQoL). It is therefore crucial that HRQoL discriminate across RA severity. Several utility measures have been validated, either direct (i.e. standard gamble) or indirect (i.e. EuroQol (EQ-5D), Brazier's Short Form-6D (SF-6D), VAS-QoL). These utility values are commonly mapped to the Health Assessment Questionnaire (HAQ) to discriminate HRQoL across different RA disease states. We evaluated whether the EQ-5D, SF-6D and the VAS would lead to similar utility values and if they would discriminate across disease severity among a cohort of RA patients in Portugal.

Method: A total of 713 patients from an ongoing biannual cohort of Portuguese RA patients since 2003 (NDB-Portugal), were included in this study. Utility measures were assigned to each level of HAQ defined from previously determined cut off points, using 0.50 intervals. Mean and standard deviation utility measures were calculated using the last observation per patient.

Results: Table 1 shows the results of the utility measures per level of HAQ (by 0.50 intervals).Overall, utilities decreased as HAQ scores worsened. However, the mean utility values of patients varied significantly depending on the utility measurement method. Mean utility measured using the EuroQOL-5D was 0.48 and mean HAQ was 1.4 (0-3, 3 corresponding to the worst disability). Utilities per HAQ intervals using SF-6D did not differentiate across the different levels of disease severity (HAQ 0-0.5 = 0.67 ; HAQ 2.5-3 = 0.55). The EQ-5D differentiated more across the severity groups (HAQ 0-0.5 = 0.83 ; HAQ 2.5-3 = 0.08). VAS-Qol only discriminated marginally (HAQ 0-0.5 = 0.74 ; HAQ 2.5-3 = 0.45).

Conclusion: In a cohort of Portuguese RA patients, different utility measurement instruments resulted in different utility scores. Furthermore, not all utility measures discriminated across disease severity. The results of this analysis show that the use of different HRQoL measurement instruments may lead to different utility values, and therefore, to different resource allocation decisions.

Table 1. Euro-Qol, SF-6D and VAS-QoL utility measures for RA patients stratified by level of HAQ using 0.50 intervals.

Mortality Trends Related to Dermatomyositis and Polymyositis, State of Sao Paulo, Brazil, 1985-2007: A Study Using Multiple-Cause-of-Death. Deborah C.C. Souza[1], Augusto H. Santo[2], José M.P. Souza[2], Celso Escobar Pinheiro[3] and Emilia I. Sato[1], [1]Escola Paulista de Medicina, Sao Paulo, Brazil, [2]Faculdade de Saude Publica/USP, Sao Paulo, Brazil, [3]Datasus, Ministério da Saúde, Rio de Janeiro, Brazil

Background: Dermatomyositis (DM) and polymyositis (PM) are rare systemic autoimmune rheumatic diseases with high fatality rates. Population-based mortality studies in DM/PM are few around the world and absent in Brazil.

Purpose: To study the mortality related to DM/PM in the State of Sao Paulo, Brazil, from 1985 to 2007.

Methods: The mortality data came from the annual multiple-cause-of-death files of the State Data Analysis System Foundation, the institution in charge of vital statistics in Sao Paulo. All deaths which listed DM or PM on any line of the medical form of the death certificate were selected. The variables sex, age and underlying, associated or total mentions of causes of death were studied. Statistical analyses were performed by chi-square and H Kruskal-Wallis tests, variance analysis and linear regression. A p value less than 0.05 was regarded as significant.

Results: In this period 318 deaths related to DM and 316 related to PM occurred. Among them 55.2% were selected as an underlying cause and 44.8% as an associated cause of death. Seventy-one percent of deaths occurred among women. The DM age-and sex-standardized mortality rates did not present significant trend variation, however a decrease of PM underlying and total mentions death rates was observed ($p<0,05$). Considering all DM and PM deaths for the entire period, the mean ages at death were 47.76±20.81 and 54.24± 17.94, respectively ($p=0.0003$) and the mean standardized mortality rates were 0.39 deaths per million inhabitants in both DM and PM. Among PM deaths in women an increasing mean age at death was observed over the 23 years period ($p=0.004$). For DM and PM as an underlying cause, the main associated causes of death were, respectively: pneumonias (43.8%; 33.5%), respiratory failure (34.4%; 32.3%), interstitial pulmonary diseases and others pulmonary conditions (28.9%; 17.6%) and septicemias (22.8%; 15.9%). Among DM and PM deaths as an associated cause, the main underlying causes of death were, respectively, respiratory disorders (28.3%; 26.0%), circulatory disorders (17.4%; 20.5%), neoplasms (16.7%; 13.7%), infectious and parasitic diseases (11.6%; 9.6%) and gastrointestinal disorders (8.0%; 4.8%). Among 318 deaths related to DM, 36 neoplasms, and among 316 related to PM, 20 neoplasms occurred concurrently ($p=0.03$).

Conclusion: The mortality related to DM occurs at an earlier age in relation to PM deaths. The increase of the mean age of female deaths observed in deaths related to PM might reflect an increase in life expectancy of the state population. The association between neoplasms and DM and in lower degree with PM deaths is consistent with latest researches. Practically half of deaths related to DM and PM have been underestimated in primary mortality statistics, where DM reaches 28,4% and PM 26,8% as an underlying cause of death. The comprehension of the natural history of DM/PM has been extended due to the consideration of all mentions of causes of death.

Race Is Associated with the Risk of Developing Hyperuricemia in Men: Findings From the Coronary Artery Risk Development in Young Adults (CARDIA) Cohort. Angelo L. Gaffo[1], David R. Jacobs Jr.[2], Cora E. Lewis[3], T. R. Mikuls[4] and Kenneth G. Saag[3], [1]Birmingham VA Medical Center, Birmingham, AL, [2]University of Minnesota, Minneapolis, MN, [3]University of Alabama at Birmingham, Birmingham, AL, [4]U Nebraska, Omaha, NE

Purpose: The association between race and serum urate (SU) concentrations has not been well defined. Some but not all studies suggest that being African-American has an independent association with higher concentrations of serum urate. We sought to determine if this was true in a bi-racial cohort of young African-Americans and Whites.

Methods: Data from 5115 participants at cohort baseline and follow-up of up to 20 years was utilized, with balanced proportions of Caucasians and African Americans. SU was measured at baseline and at years 10, 15, and 20 of follow-up. The relationships between SU, hyperuricemia (defined as a SU of 6.8 mg/dL or more), and race/ethnicity were determined in sex-specific multivariable adjusted cross-sectional and Cox-proportional hazard analyses. The latter analysis was performed only among those who did not have

hyperuricemia at baseline. Covariates included age at inception, body mass index, development of hypertension, serum creatinine, medication use, diet and alcohol intake, and menopausal symptoms in women.

Results: Referent to Whites, African-American men and women had significantly lower concentrations of SU at the beginning of follow-up. For African-American men the risk of developing hyperuricemia compared with Whites was significantly decreased by approximately 30% at year 20, after multivariable adjustment. African-American women had an approximate 43% greater risk of developing hyperuricemia when compared to Whites, but this increase was not significant after multivariable adjustment (Table). Renal function, presence of hypertension, and use of diuretics had stronger associations with higher concentrations of SU in women than in men.

Conclusion: Contrary to what has been previously reported and hypothesized given the association between race and hypertension, we found that African-American men had lower risks of developing hyperuricemia than Whites and African-American women had a non-significant increased risk. Differences in renal handling of SU, like higher rates of filtration with lower rates of excretion or reabsorption in African-American men could help explaining these findings.

Table. Sex-specific, multivariable-adjusted risk of developing hyperuricemia* by race (HR=Hazard ratio, CI=Confidence interval, AA= African-Americans, NA=not applicable).

	Men HR	**95% CI**	**Women HR**	**95% CI**
	AA vs. Whites (ref)		**AA vs. Whites (ref)**

Obesity, Weight Gain, and Risk of Prevalent Gout in Women in the Atherosclerosis Risk in Communities (ARIC) Study. Janet W. Maynard[1], Mara A. McAdams[2], Alan N. Baer[1], Anna Kottgen[2], Josef Coresh[2] and Allan C. Gelber[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins School of Public Health, Baltimore, MD

Purpose: Gout is a major form of inflammatory arthritis in women; yet, few studies have focused on the epidemiology of gout in women. In the Atherosclerosis Risk in Communities (ARIC) Study, we evaluated the relationship of obesity, and of weight change, with gout in women.

Methods: ARIC is a population-based cohort study of 15,792 individuals (55% women) recruited in 1987-1989. Our study population consisted of African-American and Caucasian women who were followed for up to 12 years. A woman was considered to have gout if one or more of the following criteria were met: [a] gout was self-reported, [b] surveillance of hospital discharge summaries revealed an ICD-9 code for gout (274.0, 274.1, 274.8, or 274.9), or [c] use of a medication taken exclusively to treat gout at any study visit. Anthropometric variables were obtained at cohort entry. We grouped body mass index (BMI) into 5 categories: <25, 25-30, 30-35, 35-40, and >40. Obesity was defined as BMI >30. High waist-to-hip ratio (WHR) was defined as >0.8. Weight change was calculated by subtracting the participant's weight at cohort entry from her self-reported weight at age 25. Weight change was categorized as: no weight change (weight loss or gain

<10 lbs), low weight gain (weight gain of >10 to <30lbs), and high weight gain (>30 lbs). Baseline characteristics included dietary habits, comorbidities, and medication use. Prevalence ratios rather than odds ratios were used as gout was not a rare outcome.

Results: 399 women (4.8%) have gout in the ARIC cohort. Higher BMI, weight gain, and weight at age 25 are strong risk factors for gout in women.

	Unadjusted		Adjusted^	
	PR	CI	PR	CI
BMI				
<25 (reference)	1.0		1.0	
25-30	2.22	1.61-3.04**	1.66	1.19-2.32**
30-35	3.56	2.59-4.91**	2.47	1.76-3.47**
35-40	6.10	4.37-8.51**	3.72	2.57-5.37**
>40	8.55	6.02-12.13**	5.39	3.64-7.99**
Obesity	3.18	2.62-3.86**	2.30	1.86-2.83**
High WHR	2.64	1.73-4.04**	1.78	1.14-2.78*
Weight change				
No change (reference)	1.0		1.0	
Low weight gain	1.65	1.12-2.42*	1.50	1.02-2.22*
High weight gain	2.99	2.11-4.24**	1.99	1.38-2.85**

^ Adjusted for baseline age, race, organ meat, protein, alcohol, and shellfish intake, diuretic and oral contraceptive pill use, menopausal status, hypertension, diabetes, and chronic renal insufficiency.

Key: PR=Prevalence ratio; CI=confidence interval; BMI=body mass index; WHR=waist-to-hip ratio

*=p<0.05 **=p<0.001

Conclusion: Obesity, elevated waist-to-hip ratio, and weight gain are strongly related to risk of prevalent gout in women. The magnitude of the association between both BMI and weight gain with gout became greater with increasing categories, indicative of dose-response relationships. To our knowledge, our study is the first to demonstrate an association between anthropometric measures and gout in women. The mechanisms by which obesity predisposes to gout are important to elucidate and may offer complementary management strategies.

Factors Associated with Prolonged Follow-up of Osteoarthritis in a Tertiary Level Rheumatology Service. Carol M. Sinnott, John Stack and Sinead Harney, Cork University Hospital, Cork, Ireland

Purpose: Osteoarthritis (OA) is the commonest cause of disability in the elderly and the second most common diagnosis made in older patients attending their general practitioner. 25% of people over 55 years have OA associated pain. The mainstay of healthcare provision in this group occurs in a primary care setting, with referral to tertiary rheumatological outpatients (ROP) only made in severe, complex or unclear cases. Given the high prevalence of the disease, ongoing follow-up of these patients at ROP has a considerable impact on services, where long waiting lists already exist. The aim of this study was to examine factors associated with prolonged follow-up of patients with OA at a tertiary level rheumatology department, in an effort to optimize the outpatient service provided.

Method: A retrospective review of eighty consecutive patients with a diagnosis of OA attending ROP was performed. All patients were referred by their general practitioner. OA was clinically and radiologically diagnosed. Exclusion criteria included a history of inflammatory arthritis, connective tissue disease, gout or other active medical conditions. Prolonged follow-up was defined as greater than the median number of consultations. Data was collected on sociodemiographic variables, disease characteristics, use of diagnostic tools and attendance at ROP. Statistical analysis was conducted using Minitab 15.

Results: 80 patients were included in the analysis. 81.25% (n=65) were female. The mean age was 62years (SD 11, IQ range 56 to 72). The median number of consultations per patient was 3 (IQ range, 2 to 5). 42.5% (n=34) patients had greater than 3 consultations. Table 1 demonstrates diagnostic tools and management options used.

Table 1. Investigations and Management Options Used

Investigations requested	**No of patients (%)**
Plain radiographs	78 (97.5%)
Magnetic resonance imaging	16 (20%)
Auto-antibodies	53 (66.25%)
Inflammatory markers	63 (78.75%)
Management options used	
Paracetamol	43 (53.75%)
Nonsteroidal anti-inflammatories	29 (36.25%)
Opiates	42 (52.5%)
Glucosamine	9 (11.25%)
Physiotherapy referral	56 (70%)
Orthopaedic referral	24 (30%)
Weight loss advice	7 (8.75%)

On univariate analysis, prolonged follow- up was associated with age greater than 70years ($p<0.05$), referral for magnetic resonance imaging ($p<0.05$), prescription of opiate analgesia ($p<0.05$) and referral to orthopaedic ($p<0.05$) or physiotherapy services ($p<0.05$). On multivariate regression analysis for number of consultations versus significant factors on univariate analysis, referral to orthopaedic services and older age were significantly associated with longer follow-up.

Conclusion: Patients who require prolonged follow up for OA in ROP are older and require orthopaedic referral. A potential explanation for this is the long wait list that exists for orthopaedic outpatient consultation, necessitating interval review at ROP. Strategies that increase the capacity of orthopaedic services or enhance appropriate referral from the primary care sector direct to orthopaedic services may help reduce the necessary number of patient visits to ROP, thereby optimizing use of and access to tertiary rheumatological services.

Work Productivity Measures as Treatment Goals Beyond Signs and Symptoms. V. Strand[1], O. Purcaru[2] and Arthur Kavanaugh[3], [1]Stanford University, Palo Alto, CA, [2]UCB, Brussels, Belgium, [3]UCSD, San Diego, CA

Purpose: Rheumatoid arthritis (RA) significantly impairs patients' ability to work outside the home and to perform household duties and participate in leisure, social and family activities. However, data from randomized, controlled trials (RCTs) on treatment impact on work and home productivity are limited. This analysis reviews the available productivity data from RCTs of anti-TNF agents in early- and late-stage RA.

Method: Published studies of anti-TNFs for the treatment of both early- and late-stage RA were examined for productivity measures. 6 studies were identified: 4 in early RA (ASPIRE, COMET, DE032 [PREMIER companion study], and PROWD), and 2 in late-stage RA (RAPID 1 and 2) (Table). ASPIRE, COMET, and PROWD assessed changes in employment or working time lost; DE032 and RAPID 1 and 2 assessed absenteeism (work days missed due to RA) and presenteeism (decreased productivity at work). DE032 and RAPID 1 and 2 also assessed home productivity.

Results: All 6 trials showed that anti-TNFs significantly decrease productivity losses at paid work, although all used different measures (Table). DE032 and RAPID 1 and 2 also demonstrated that anti-TNFs significantly decrease productivity losses at home. Results from RAPID 1 and 2 using the novel Work Productivity Survey demonstrated that certolizumab pegol significantly reduces household days lost, household days with productivity reduced ≥50%, and days of lost participation in family, social and leisure activities relative to PBO + MTX.

RCT	**Work Productivity**		**Home Productivity**	
ASPIRE (Change from BL to Wk 54)	PBO + MTX	INF + MTX		
Became unemployable	14%	8%*		
Became employable	36%	40%		
COMET (Wk 52)	PBO + MTX	ETN + MTX		
Stopped work since prior visit	24%	9%*		
PROWD (Wk 56)	PBO + MTX	ADA + MTX		
Working time lost	18.4%	8.6%*		
All cause or impending job loss	39.7%	18.7%*		
DE032 (Wk 52)‡	PBO + MTX	ADA + MTX	PBO + MTX	ADA + MTX
Days missed due to RA	24	11*	12	6*
Degree of work performance affected (0-100 VAS; change from BL)	-28.2	-35.8*	-26.8	-36.6*
RAPID 1 (Wk 52)	PBO + MTX	CZP† + MTX	PBO + MTX	CZP† + MTX
Days missed due to RA per month	4.5	1.0*	7.2	2.4*
Days with productivity reduced by ≥50% per month	4.4	2.1*	7.3	4.2*
Days missed social/family/leisure activities per month			3.7	1.6*
RAPID 2 (Wk 24)	PBO + MTX	CZP† + MTX	PBO + MTX	CZP† + MTX
Days missed due to RA per month	2.5	1.3	6.5	2.7*
Days with productivity reduced by ≥50% per month	9.3	3.1*	9.2	5.2*

Days missed social/family/leisure activities per month			3.8	1.4*

*P≤0.05 vs control group. †CZP 200 mg group. ‡Home productivity results based on homemakers only.

ADA=adalimumab; CZP=certolizumab pegol; ETN=etanercept; INF=infliximab; PBO=placebo.

Conclusion: Reductions in productivity loss may substantially improve the overall quality of life for patients with RA. Productivity measures, which assess both work and home productivity should be considered for inclusion into RCTs as well as registries for patients with RA.

Factors Associated with Fatigue in Early Arthritis: Results From the ESPOIR Cohort. AC Rat[1], J. Pouchot[2], B. Fautrel[3], P. Boumier[4], P. Goupille[5] and F. Guillemin[6], [1]Nancy-University CIC-EC CIE6, Nancy, France, [2]Paris University, Internal medicine, France, [3]Rheumatology, Paris VI University, France, [4]CHU Amiens, France, [5]Tours university, France, [6]Nancy-University EA 4003, France

Purpose: Fatigue has a major impact on patients in early arthritis (EA) and its measure is highly recommended. However, to interpret such a measure, factors associated with fatigue and its change should be known not only in established rheumatoid arthritis (RA) but also in EA. The aims of this study based on the data of the ESPOIR cohort, were: 1) to study determinant factors of fatigue in patients with early arthritis at baseline, 2) to analyse factors associated with fatigue changes during the first year following inclusion.

Method: The ESPOIR cohort is a multicenter national cohort of 813 patients followed for arthritis of less than 6 months duration. At baseline and at each visit (every 6 months) a set of clinical and biological variables are recorded: sociodemographic, disease characteristics, and patient reported outcome measures (fatigue visual analogue scale (f-VAS), SF36, AIMS2-SF). Determinant factors of fatigue were studied with various regression models using the f-VAS and the vitality dimension of the SF36 as dependant variables for fatigue assessment.

Results: A total of 813 patients with early arthritis (48 ± 13 years, 77% women, DAS28 11 ± 1, ACR criteria for RA 71%) were included. At baseline, only 22% of the patients reported having no fatigue (f-VAS ≤ 20 mm).The level of fatigue decreased at 6 months and then remained stable at 1 year. Results of the multivariate analysis of determinant factors of fatigue at baseline are reported in the table. Over time, factors independently associated with a higher fatigue level decrease were a larger improvement of physical function (p=0.03) and mental health (p<.0001) dimensions of the AIMS2-SF for the model with the vitality dimension of the SF36,and a larger improvement of the DAS28 (p=0.003), and of the mental health (p<.0001) dimension of the AIMS2-SF and the absence of a Sjogren syndrome (p=0.001), for the model with f-VAS.

Conclusion: Factors associated with fatigue are slightly different for the 2 studied measures of fatigue. Demographic, patient, and disease characteristics and QoL are independently associated with fatigue at baseline. The evolution of fatigue is mainly associated with the evolution of the different dimensions of QoL.

Table: determinant factors of fatigue at baseline: multivariate analysis

	Vitality (SF36) (R^2=0.44)		Fatigue (VAS) (R^2=0.24)	
	ß	p	ß	p
Age	0.1(0.0)	0.009	-0.2(0.1)	0.003
Sex (male/female)		NS	5.8(2.2)	0.007
Socio-economic level (low/interm/high)	1.8(0.6)	0.005	-4.0(1.1)	0.0003

Smoker (yes/no)		NS	-5.9(2.2)	0.008
Comorbidity (yes/no)	2.2(1.1)	0.05	4.1(1.9)	0.03
Wake up at night (yes/no)	-2.0(1.2)	0.09	4.6(2.1)	0.03
DAS28	-1.1(0.5)	0.03	2.3(0.8)	0.007
Sjrogren syndrom (yes/no)		NS	7.5(2.1)	0.0003
AIMS2-SF physical function	-2.1(0.4)	<.0001	1.7(0.7)	0.01
AIMS2-SF symptoms	-2.1(0.5)	<.0001	0.8(0.5)	NS
AIMS2-SF mental health	-6.3 (0.7)	<.0001	2.4(0.5)	<.0001

SF36 and AIMS2-SF scores range from 0 (worst QoL) to 100 (best QoL). Fatigue VAS range from 0 (no fatigue) to 100 (worse fatigue)

Relationship Between Radiographic Damage and Employment Over Time in Patients with Early Rheumatoid Arthritis (RA): Results From the PREMIER Health Economic Companion Study DE032. Ronald van Vollenhoven[1], Mary Cifaldi[2], Sanjoy Roy[2], Naijun Chen[2] and Martin J. Bergman[3], [1]Karolinska University Hospital and Karolinska Institute, Stockholm, Sweden, [2]Abbott Laboratories, Abbott Park, IL, [3]Taylor Hospital, Ridley Park, PA

Purpose: The relationship between joint damage and outcomes in early RA is poorly characterized. We evaluated the relationship between radiographic progression and employment status in the PREMIER health-economic companion study DE032.

Methods: PREMIER was a 2-year, multi-center, randomized, double-blind trial of adalimumab (ADA), methotrexate (MTX), and ADA+MTX in patients with early RA (<3 years). The DE032 companion study collected pharmacoeconomic data on a large subset of participating patients. A multivariate logistic regression model was used to evaluate the association between baseline radiographic scores (modified total Sharp score [mTSS]) and baseline self-reported employment status, with adjustments for age, sex, and baseline Health Assessment Questionnaire (HAQ). A receiver-operating characteristic (ROC) analysis determined the baseline mTSS cut-off value to differentiate between employed vs. unemployed patients with an optimum balance between sensitivity and specificity. Generalized estimating equation (GEE) models were used to estimate the relationship between mTSS and employment status over time, controlling for age, sex and HAQ. At the end of the study, whether patients gained or retained their employment was compared for patients who were radiographic progressors (ΔmTSS>0) vs. those who were non-progressors (ΔmTSS≤0) within treatment groups.

Results: At baseline, 55% of patients were employed, and patients with lesser mTSS scores were more likely to be employed. For each unit increase of the mTSS, patients had 1.2% decreased odds of being employed ($p< 0.05$) compared with those with a 1-point lesser score. An absolute mTSS of 14 was the cut-off value for being employed with the greatest sum of sensitivity (60%) and specificity (58%). Over 2 years, patients with greater mTSS progression were more likely to stay or become unemployed; a 1-point increase in mTSS was associated with 1.1% decreased odds of being employed ($p<0.01$). Further, patients with mTSS>14 were 40% more likely to be unemployed than patients with mTSS≤14. The ADA+MTX group was more likely to have unchanged or decreased mTSS (non-progressors) and retained or gained employment than the MTX group (29% vs. 11%, $p<0.0001$). Patients who were progressors and lost employment or stayed unemployed were less likely to be in the ADA+MTX group than the MTX group (19% vs. 29%; $p<0.001$).

Conclusion: Patients with early RA with lesser baseline mTSS were more likely to be employed than patients with greater mTSS. Over 2 years, the beneficial radiographic effect of combination therapy with ADA+MTX was associated with more favorable employment status.

Care for RA Has Not Improved Overtime: A Population Based Study. Diane V. Lacaille[1], M. Mushfiqur Rahman[2] and John Esdaile[3], [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada / University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Purpose: Treatment guidelines for rheumatoid arthritis (RA) have shifted to early, aggressive, and persistent use of disease-modifying anti-rheumatic drugs (DMARDs) and referral to a rheumatologist when possible. Previous quality of care studies in RA have consistently shown suboptimal care. The purpose of this study was to evaluate whether compliance with guidelines, and quality of care for RA, have improved over time.

Method: Using administrative billing data from the Ministry of Health, we have assembled a population-based cohort of all RA cases who received care by a physician for RA between 01/1996 and 03/2006. Previously published RA criteria included: at least 2 MD visits, at least 2 mos apart, where ICD-9 code for RA was used for reimbursement of MD visits. Cases were excluded if they had at least 2 subsequent visits for another type of inflammatory arthritis, if assessment by a rheumatologist did not confirm the diagnosis of RA made by another physician, or if no subsequent RA visits occurred over > 5 years. Administrative data on all health care services used were obtained, including all meds, MD visits, hospitalizations and procedures. To evaluate quality of care over time, we compared the cumulative incidence of first DMARD use and rheumatologist referral in 3 incident cohorts with first RA visits in 1997-99; 1999-01 and 2001-03, using Kaplan Meier analysis. We also compared prevalence of DMARD use and other quality of care indicators, over a 3 year period, in 3 prevalent cohorts followed over the years: 1997-99; 2000-02; 2003-05.

Results: Our population-based cohort includes 37,151 RA cases with 192,735 person-yr of follow-up, yielding an RA prevalence of 0.96%. The cumulative incidence of first DMARD use over 3 years of follow-up after diagnosis, was 25% after 1 yr, 28% after 2 yrs and 30% after 3 yrs, in the incident cohort diagnosed in 1997-99. DMARD use did not improve in incident cohorts diagnosed later, with incidence of DMARD use of 25% and 26% at 1 yr, and of 29% and 30% at 3 yrs, in the 1999-2001 and 2001-2003 incident cohorts, respectively. Cumulative incidence of rheumatologist referral at 3 yrs was 38%, 38% and 40% for the 1997-99, 1999-01, and 2001-03 incident cohorts, resp. Prevalence of DMARD use, rheumatologist referral and other quality of care indicators did not increase over time either, when assessed over 3 year periods in prevalent cohorts (Table 1).

	1997-1999 cohort N = 16,989	2000-2003 cohort N = 23,572	2003-2005 cohort N = 26,748
DMARD use	48.7%	45.2%	49.6%
Referral to rheumatologist	45.2%	42.5%	46.8%
Proportion of time on DMARDs once started	78%	79%	80%
Glucocorticosteroid use	38.8%	35.3%	36.9%
Traditional NSAID use	66.3%	56.3%	55.5%
Coxib use	17.9%	37.3%	30.2%
Orthopedic procedure	3%	1.9%	1.4%

Conclusion: Care for RA remains suboptimal despite current treatment guidelines and does not appear to have improved over time. Efforts to educate family physicians and consumers about the shift in RA treatment paradigms and to improve access to rheumatologists are needed.

Impact of Maintaining Physical Function On Employment Status Over Time. Chris Bojke[1], Mary Cifaldi[2], Saurabh Ray[2] and B. Van Hout[3], [1]Pharmerit International, York, United Kingdom, [2]Abbott Laboratories, Abbott Park, IL, [3]University Medical Centre Utrecht, Utrecht, Netherlands

Purpose: This study analyzed the impact of physical functioning (measured by the Health Assessment Questionnaire [HAQ]) on self-reported employment status over time using econometric methods that use all time-point observations over the course of a 2-year study. Data were from PREMIER, a prospective, multicenter, randomized, double-blind, active comparator-controlled, Phase III trial comparing treatment with adalimumab, methotrexate (MTX), and the combination of adalimumab plus MTX in patients with early RA.

Methods: The analysis included 664 patients who supplied self-reported responses over scheduled, unequally spaced time periods. Patients indicated whether they were employed (categorical response of employed, unemployed, or retired) and the extent to which RA had hindered work since the last observation on a continuous visual analog scale (VAS) response (0–100). Ordered, discrete categories were created by combining the discrete employment and continuous VAS responses into non-overlapping and exhaustive states (employed/VAS=0, employed/0<VAS≤25, employed/25<VAS≤50, employed/50<VAS≤100, unemployed, retired). HAQ status over time was coded as weeks spent in each HAQ category (0, 0.5, 1, 1.5, 2, 2.5, 3). An ordered logistic regression model using lagged employment status and HAQ by time interactions as explanatory variables was estimated to provide parameter/transition probability estimates to populate a Markov chain model of employment. The intuition underpinning the model is that the longer the time period, the greater the influence of HAQ state becomes relative to lagged employment state.

Results: The retired patients never switched employment categories and so were excluded from the analysis. A Somer's D of 0.81 and c value of 0.905 were indicative of a good fit and the null hypothesis that the regression coefficients were zero was rejected ($p<0.0001$). Lagged status was a significant predictor of current status ($p<0.0001$), with lagged unemployment particularly strongly associated with current unemployment. HAQ by time interactions were also statistically significant ($p<0.0001$), with weeks spent in states 0 and 0.5 leading to increased probabilities of better employment states (proportional odds ratios for 1 week in HAQ state 0 or 0.5 were 1.039 and 1.005, respectively). Time spent in HAQ state 1 or greater led to increasing probabilities of worse employment states (odds ratios=0.969, 0.944, 0.935, 0.872, and 0.658).

Conclusion: A regression model evaluating the effect of physical function on the combination of self-reported employment status and degree of work impairment demonstrated that although lagged employment state was a strong predictor of future states, HAQ status significantly changed the transition probabilities. Specifically, time spent in HAQ states ≤0.5 led to better employment states.

Changes in Health Care Utilization and Costs for Employed Patients with Rheumatoid Arthritis From 1997–2006. H. Birnbaum[1], C. Pike[1], R. Banerjee[1], T. Waldman[1] and Mary Cifaldi[2], [1]Analysis Group, Inc., Boston, MA, [2]Abbott Laboratories, Abbott Park, IL

Purpose: A retrospective analysis of claims data was used to assess changes in health care utilization and costs between 1997 and 2006 for employed patients with rheumatoid arthritis (RA).

Method: Using 2 separate administrative claims databases, 2 cohorts of employed patients with RA ("patients") and matched employed controls without RA ("controls") were identified: a 1997 cohort and a 2006 cohort. Patients in both cohorts were required to have at least 1 prior RA diagnosis, be age 18 to 64 years, have 12 months of continuous eligibility, and be employees with disability data in the index year. Patients in the 2006 cohort were matched to patients in the 1997 cohort on a 3:1 basis by age (±2 years), sex, and geographic region. Employed controls with no RA diagnosis in their claims history who had disability data and met the eligibility and age requirements were matched 1:1 to each patient cohort. Differences in comorbidities, resource utilization, health care costs, and work loss costs between patients and controls in each cohort were calculated; these relative changes were compared between the 1997 and 2006 cohorts using a difference-in-differences methodology. Costs were inflated to 2006 dollars. To assess statistical significance, paired *t*-tests were used for continuous outcomes and generalized estimating equations were used for binary and count outcomes.

Results: The 1997 and 2006 cohorts contained 279 and 837 patients, respectively, and a corresponding number of controls. There were no statistically significant differences between cohorts in the relative prevalence of non-RA comorbidities or the Charlson comorbidity index,

except for the relative prevalence of cardiovascular disease, which decreased by 11.1% from 1997 to 2006 ($p<0.05$). The relative percentages of patients seeking primary care and non-rheumatologist outpatient care decreased by 9.9% ($p<0.05$) and 16.3% ($p<0.01$), respectively. Relative number of emergency department (ED) visits decreased by 1.1 visits/patient ($p<0.01$) and days hospitalized decreased by 0.9 days/patient ($p<0.05$). Rheumatologist visits increased by 0.9 visits/patient ($p<0.01$) and other physician visits increased by 1.2 visits/patient ($p<0.01$). Relative direct costs were unchanged; drug costs rose $633/patient ($p<0.05$) but were offset by declines in medical costs/patient ($618 [p=0.68]). Relative RA-specific total costs increased by $1,432/patient ($p<0.01$) due to increases in both relative medical ($612 [$p<0.01$]) and drug ($820 [$p<0.01$]) costs/patient. Relative number of work days lost fell by 4.8 days/patient ($p=0.35$). Relative indirect costs declined by $423/patient ($p=0.32$).

Conclusion: Between 1997 and 2006, hospital days and ED visits decreased, but total health care costs were unchanged. Treatments introduced during this period may be associated with cost savings from changes in medical services utilization. Reduction in ED visits and hospital days also suggests improved quality of life.

Tolerability of Non-Selective NSAIDs and Celecoxib Among Patients with Gastroesophageal Reflux Disease and Osteoarthritis or Rheumatoid Arthritis. B. Cryer[1], X. Luo[2], AR. Assaf[2] and George Sands[3], [1]University of Texas Southwestern Medical School, Dallas, TX, [2]Pfizer Inc, New London, CT, [3]Pfizer Global Pharmaceuticals, New York, NY

Purpose: Gastrointestinal (GI) symptoms are common in patients taking nonselective nonsteroidal antiinflammatory drugs (nsNSAIDS) and are often a reason for therapy discontinuation. In osteoarthritis (OA) and rheumatoid arthritis (RA), selective COX-2 NSAID use is typically associated with less dyspepsia than with nsNSAIDS. In patients with gastroesophageal reflux disease (GERD), little is known about NSAID tolerance. Therefore, we studied nsNSAID and celecoxib prescription patterns, including discontinuations, in OA/ RA patients with concomitant GERD.

Methods: This is an observational study of GERD patients with a diagnosis OA/RA using two separate databases, the PharMetrics Patient-Centric and Medstat databases, each containing longitudinal records of medical and pharmacy claims for millions of unique patients. In each database, we performed parallel and separate analyses of adult patients with their first GERD diagnosis in 2006 and who were subsequently diagnosed with OA or RA, in the same year. We excluded patients with peptic ulcer, GI bleeding, Barretts Esophagus, esophageal cancer or eosinophilic esophagitis, rendering 22,831 patients (PharmMetrics) and 29,319 patients (Medstat) with GERD and OA/RA. From these groups we next identified GERD/OA or GERD/RA patients who were first prescribed a nsNSAID or celecoxib during the 90 days following their diagnosis of OA or RA (index prescription), excluding those taking a nsNSAID, celecoxib or gastroprotective agent [GPA (H_2-blocker or proton pump inhibitor)] during the 90 days preceding the index prescription date. NsNSAID utilization and discontinuations were evaluated and Kaplan-Meier survival curves were constructed. Reasons for discontinuations are not available in these databases.

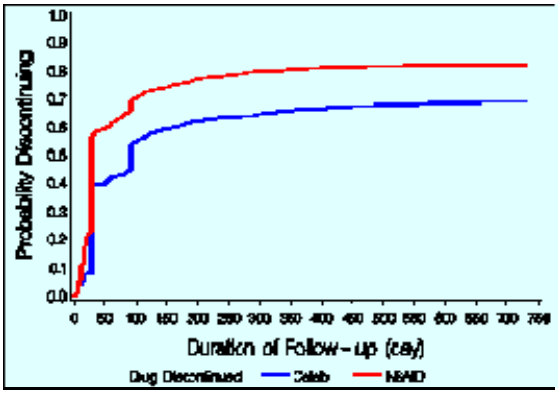
Results:

NSAID Naïve and GPA Naïve GERD/OA or GERD/RA Patients Initiating nsNSAID or Celecoxib in 2006				
	Discontinue Treatment within 60 days of Initiation			
	PharMetrics		MedStat	
	N	Probability Discontinuing	N	Probability Discontinuing
New nsNSAID Users	1680	61%	3204	56%
New Celecoxib Users	372	42%	880	33%

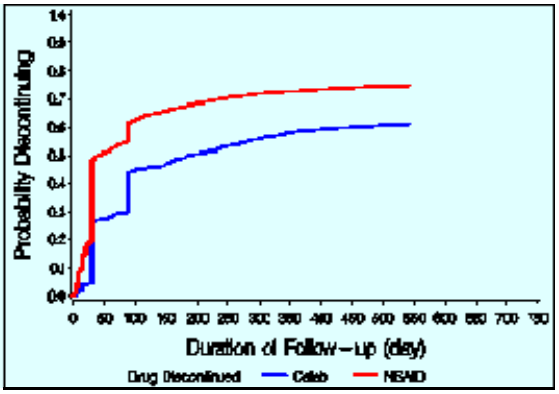
$p<0.001$ by log rank test of equality of the two survival curves in PharMetrics & MedStat

Kaplan-Meier Survival Curves: Time to Discontinuation of nsNSAIDS vs. Celecoxib.

Pharmetrics



Medstat



Most nsNSAID discontinuation occurred within 60 days of treatment initiation, but not with celecoxib. Patients who tolerated nsNSAID or celecoxib for 60 days without discontinuation were likely to continue treatment for the remainder of the evaluation period. Replication of these observations in two separate, large patient databases increases the confidence in this study's conclusion.

Conclusion: In patients with GERD/OA or GERD/RA who require antiinflammatory treatment, significantly fewer patients discontinue celecoxib when compared to those discontinuing nsNSAIDS.

The Effect of Diabetes Over the 6 Month Recovery After Total Knee Arthroplasty. C. Allyson Jones[1], Lauren A. Beaupre[1], G.S. Jhangri[1] and Marie E. Suarez-Almazor[2], [1]University of Alberta, Edmonton, AB, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX

Purpose: Although the medical effects of diabetes on surgical outcomes has been examined for total knee arthroplasty (TKA), the impact of diabetes on pain relief and functional recovery has not been clearly delineated. Diabetes is well known for associated musculoskeletal and peripheral neurologic problems which may interfere with recovery after joint arthroplasty. We looked at the pattern of recovery for pain and function in TKA to determine whether differences existed between diabetes (DM) and nonDM patients.

Method: Longitudinal prospective inception cohort of 405 patients receiving elective primary TKA were followed within a month prior to surgery, and 1, 3, 6 months after surgery. The outcome measures, knee pain and function were measured using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Diabetes status was extracted from the chart and reported by the patient. The Center for Epidemiologic Studies-Depression (CES-D) was used to screen for depression. Social support was evaluated using the Medical Outcomes Study Social Support Survey. Measurements were repeated at each of the follow-up interviews. Linear mixed models were developed for pain and functional recovery to evaluate changes over time and between group differences (DM and nonDM) while adjusting for covariates.

Results: Patients had a mean age 68 (SD10) yrs; 249(61.5%) were female; 60(14.8%) had DM. 7% of DM and 3% of nonDM patients had surgical complications (p=0.2). Pre-operative pain (p=0.9) and function (p=0.3) scores were similar regardless of DM. After controlling for age, sex, baseline pain or function and time, DM had a significant deleterious effect (-2.7, p=0.03) along with depression (-3.1, p=0.02), kidney disease (-4.9, p=0.04) and social support (-0.05, p=0.03). No interactions were found between diabetes and depression or kidney disease. DM was not a significant factor in functional recovery (p=0.14), neither was obesity or cardiovascular disease.

Conclusion: Because patients with DM who undergo TKA may have slower pain relief over a 6 month recovery, pain management should be monitored and treated more actively in this subgroup of patients. Knowing that pain relief may take longer in this subgroup can assist clinicians in setting realistic patient expectations for recovery time.

Population-Based Estimates of Uveitis Incidence in Patients with Ankylosing Spondylitis. SM Szabo[1], Katherine Gooch[2], K.M. Johnston[1], Walter P. Maksymowych[3], Diane V. Lacaille[4], Aileen Pangan[2] and AR Levy[1], [1]Oxford Outcomes, Vancouver, BC, [2]Abbott Laboratories, Abbott Park, IL, [3]University of Alberta, Edmonton, AB, [4]University of British Columbia, Vancouver, BC

Purpose: Noninfectious uveitis is the most common extra-articular manifestation of ankylosing spondylitis (AS), with a reported lifetime prevalence of up to 40% in patients with AS. However, those prevalence estimates were based on self-report, examination, or chart review and lacked standardized definitions of uveitis. Accurate, population-based estimates of the incidence of uveitis due to AS, would be valuable for 2 reasons: first, to allow calculation of the excess risk of uveitis due to AS; second, to facilitate a more thorough quantification of the burden of illness of AS, because the impact of uveitis is not frequently included in burden-of-illness models. We compared the incidence of uveitis in patients with AS with estimates of the incidence of uveitis in the general population.

Methods: We designed a retrospective cohort study using the Régie de l'Assurance Maladie du Québec (RAMQ) databases, which contain population-based, longitudinal, patient-level, physician billing data. These data include records of physician services delivered in outpatient clinics, offices, and hospitals and patient sociodemographic data. Entry into the AS cohort was defined at first physician diagnosis of AS (ICD-9 720.0) between 1998 and 2006 with no such diagnosis in the 2 preceding years. A comparison cohort was generated using a 1% random sample of individuals from Québec without AS (no diagnosis of 720.0 within the period). Incident cases of noninfectious uveitis were identified from either cohort using ICD-9 codes 363.2, 363.3, or 364.0. Cohort members were censored at RAMQ plan deregistration or at the end of the study period (December 31, 2006). A standardized incidence ratio (SIR) was calculated comparing the 10-year incidence rate of uveitis in persons with AS vs. without AS, adjusted for age and sex.

Results: The sample included 7,663 patients with AS (Québec 2006 population: 7,631,552) diagnosed between 1998 and 2006; 4,175 (54.5%) were male. The crude 10-year incidence rate of uveitis in the AS population was 374.0/10,000 persons compared with 21.1/10,000 persons in the non-AS population. The SIR for the development of uveitis during the study period was 22.7 for those with AS vs. those without AS.

Conclusion: We found that noninfectious uveitis is much more common in patients with AS than in the general population; patients with AS have a >20-fold increased risk of developing uveitis. This study provides robust, population-based estimates of uveitis incidence that could be incorporated into AS models. As uveitis imposes a cost, both because of the need for treatment and because of its substantial negative impact on health-related quality of life, failing to incorporate uveitis incidence in AS models may underestimate the true burden of illness with AS.

Comparisons Between Three Work-Related Patient-Reported Outcome Instruments in Patients with Ankylosing Spondylitis. Walter P. Maksymowych[1], Katherine Gooch[2], M. Lorimer[2], H. Khong[3] and A. Boonen[4], [1]University of Alberta, Edmonton, AB, [2]Abbott Laboratories, Abbott Park, IL, [3]Vcomtech, Edmonton, AB, [4]Maastricht University Medical Centre, Maastricht, Netherlands

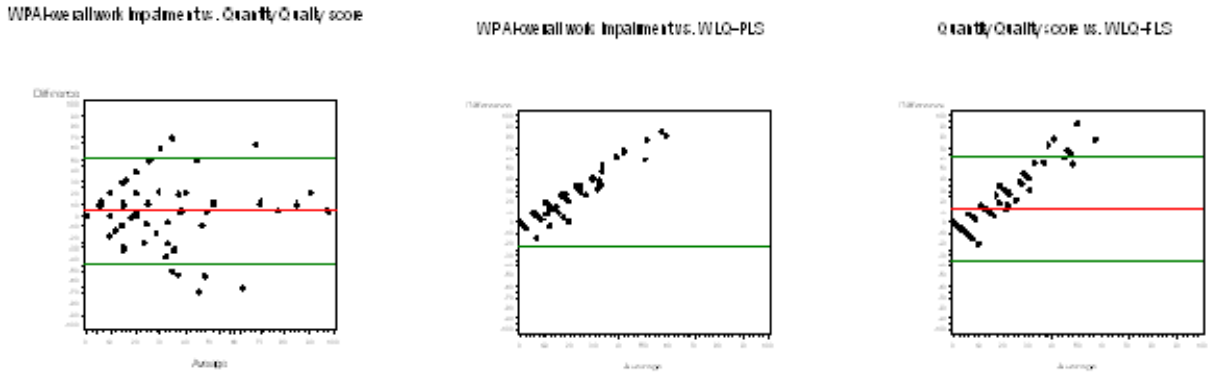
Purpose: Ankylosing spondylitis (AS) is a chronic, progressive, inflammatory disease that results in functional limitations and impairment of health-related quality of life, typically affecting patients during their working years. OMERACT has identified the need to determine which patient-reported outcome (PRO) instruments are best suited to measure work productivity. We evaluated the agreement between 3 PRO measures of presenteeism, defined as the impact of disease on a patient's ability to perform at work.

Methods: Data were obtained from the Patient-Reported Outcomes in Employment Study (PROSE), a longitudinal, observational study of AS and work productivity. Participants diagnosed with AS completed an online patient survey that included 3 measures of work productivity: 1) the Work Productivity and Activity Impairment Questionnaire (WPAI) presenteeism score, 2) the Work Limitations

Questionnaire (WLQ-25), and 3) the Quality Quantity Method (QQ). Scores were calculated and transformed to a 0–100 scale, with greater scores indicating greater work impairment. Descriptive statistics were used to describe the complete and employed-only cohorts. Agreement between the instruments was assessed by comparing score distributions, means, Pearson's correlation coefficients (r), and Bland-Altman (BA) plots. The comparative analysis included only employed patients and baseline surveys.

Results: Of 175 surveys obtained, 77% were completed by employed patients with AS. Mean (SD) age of the employed patients was 44.1 (10.9) years; 78% of patients were men. The means of work productivity scores at baseline were WPAI, 22.55; WLQ, 5.53; and QQ, 19.37. The WPAI and WLQ were highly correlated (r=0.63), the QQ and WLQ were moderately correlated (r=0.38), and the WPAI and QQ were moderately correlated (r=0.49). Results of BA plots (figure) show that, although the mean of the difference between WPAI and QQ scores was relatively small (2.64), the limits of agreement were large (–45.61, 50.89), so WPAI and QQ scores do not have substantial agreement. The large means of differences (WPAI and WLQ [16.62] and QQ and WOQ [13.21]), large limits of agreement, and increasing dispersion as average values increase suggest that the WLQ has poor agreement with the QQ and the WPAI.

Bland-Altman Plots of Agreement Between Work Productivity Measures



Conclusion: The use of different work productivity measures may yield different work productivity loss results. These analyses suggest that the 3 instruments evaluated are not interchangeable for assessing work productivity in AS.

The Georgia Lupus Registry: Exploring Early Lupus Subtypes. Rebecca A. Speckman[1], Cristina M. Drenkard[2] and S. Sam Lim[2], [1]Rollins School of Public Health, Emory University, Atlanta, GA, [2]Emory University, Atlanta, GA

Purpose: In SLE and other diseases with a wide variety in manifestations between patients, it has been suggested that identification of subtypes (i.e., subgroups with homogeneous manifestations) may help elucidate risk factors and pathophysiology of disease. Our objective was to use formal cluster analysis techniques to explore potential early lupus subtypes.

Method: The Georgia Lupus Registry is a population-based registry designed to assess the incidence (2002-2004) and prevalence (2002) of SLE in Atlanta. 234 patients met our case definition for "early lupus" with a date of diagnosis in 2002-2004 and ≥ 4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by the patient's rheumatologist. *K*-means is a cluster analysis method that partitions patients into mutually exclusive clusters based on their similarity to each other. *K*-means was performed using 26 clinical and 11 laboratory variables. A set of potential early lupus subtype clusters was chosen based on conservation of cluster membership.

Results: Clusters 2 and 3 appeared to be similar to the MCTD phenotype and were more likely to be Black with a lower mean age of onset. Cluster 3, with high probability of alopecia and anti-RNP and medium probability of Raynaud's syndrome, had relatively high probabilities of malar rash, discoid rash, and leukopenia. Cluster 4, characterized by high probability of proteinuria, thrombocytopenia, anti-DNA, and low complement, had an intermediate age of diagnosis and likelihood of being Black. Cluster 1 (the reference group) was characterized by arthritis and lower probability of other manifestations.

	Cluster 1	*Cluster 2*	*Cluster 3*	*Cluster 4*
Number of patients (row %)	37 (24.5)	47 (31.1)	32 (21.2)	35 (23.2)
Characteristic clinical features	arthritis	arthritis	arthritis, alopecia, Raynaud's, malar rash, mucosal ulcers, discoid rash, pleuritis	pleuritis
Characteristic laboratory features		anti-RNP, anti-DNA, (anti-Sm)	anti-RNP, anti-DNA, anti-Sm	proteinuria, lymphopenia, low complement, thrombocytopenia
Black n (column %) White OR (95% CI), for Black	22 (59.5) 15 (40.5) (ref)	40 (85.1) 7 (14.9) **3.9 (1.4, 11.0)***	27 (84.4) 5 (15.6) **3.7 (1.16, 11.7)***	28 (80.0) 7 (20.0) 2.7 (0.9, 7.8)
Mean age at diagnosis (SE)	47.0 (2.9) (ref)	**35.7 (2.3)***	**35.3 (2.9)***	40.3 (2.9)

* significant compared to Cluster 1 at $p < 0.05$

Conclusion: The characteristics of these clusters of SLE patients early in disease are putative early lupus subtypes. Our study signals the possibility of a group of Blacks with disease at a younger age that has a greater association with the MCTD-like phenotype. The exploration of risk factors for disease phenotypes suggested by cluster analysis may provide another degree of insight into SLE etiology and pathophysiology.

Quality of Life in Patients with Systemic Lupus Erythematosus (SLE) Compared to Related Controls within a Unique African American Cohort. April L. Barnado[1], L. Wheless[2], C. Demos[2], GS Gilkeson[3] and DL Kamen[4], [1]Duke Univ SOM, Durham, NC, [2]MUSC, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC, [4]MUSC PO Box 250637, Charleston, SC

Purpose: To characterize health-related quality of life (QOL) in African Americans with SLE and assess the impact of the caregiver role among their unaffected relatives. The cohort is an African American Gullah population with a proven homogeneous genetic and environmental background, a high prevalence of multi-patient families with SLE, and a distinct cultural identity.

Methods: We collected and compared demographic and socioeconomic data, past medical history, and Short-Form 36 (SF-36), a generic measure of QOL, in SLE cases and related controls. Categorical variables were examined by chi-square test and Fisher's exact test. Differences between the means of continuous variables were tested using Student's t-test. We assessed the relationship between SF-36 and demographic and socioeconomic data and past medical history using Pearson correlation coefficient and multiple linear regression. P-values < 0.05 were considered significant.

Results: Cases (n = 60) and related controls (n = 39) are compared in Table 1. Compared to related controls, cases had a lower Physical Component Scale (PCS, 43 vs 53, p<0.01), but not Mental Component Scale (MCS, 55 vs 56, p=NS). For cases, PCS correlated negatively with disability (r = -0.38, p<0.01) and positively with employment (r = 0.43, p<0.01). For related controls, PCS correlated negatively with age (r = -0.36, p=0.03). Following adjustment for socioeconomic factors and age, PCS was still significantly lower for cases (p < 0.05). For both cases and related controls, MCS did not correlate with demographic or socioeconomic data or past medical history.

Conclusion: As expected, SLE cases had significantly lower PCS compared to related controls. This difference remained after adjustment for socioeconomic and demographic factors. In contrast, cases had a MCS similar to related controls. We hypothesize that this lack of effect of SLE on MCS may be due to disease coping mechanisms interplaying with cultural and religious factors unique to the African American Gullah population. We did not find a negative impact of the cases' SLE on the related controls. Older age was associated with lower QOL scores in related controls but not cases, again suggesting coping mechanisms developing in the cases.

Table 1. Characteristics of African American SLE cases compared to related controls.

Characteristics	**SLE cases (n = 60)**	**Related controls (n = 39)**	**P value§**
Mean age (years)	40.4	43.1	0.43
Sex (% female)	93	85	0.16
Currently working (%)	28	69	<0.01

Utility-based Outcomes Made Easy: The Number Needed Per QALY Gained (NNQ)-Observational Study of TNF Blockade in Inflammatory Arthritis. A. Gülfe[1], L.E. Kristensen[1], Ingemar F. Petersson[1], Lennart TH Jacobsson[2], Tore Saxne[1] and P. Geborek[1], [1]Lund University, Lund, Sweden, [2]Lund University, Malmö, Sweden

Purpose and Background: Funding agencies or tax payers incur great costs due to new treatment modalities in arthritis care. The outcome measures used are not always intuitive for the clinician or easy to understand for the layman.

Objectives: 1. To develop a simple, utility based outcome measure, the NNQ (number needed to gain 1 quality adjusted life year, QALY) that can assist judging to what extent a therapeutic intervention may be worth while;

2. To apply it in a cohort of patients with established rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondarthritis (SpA) treated with TNF blockers in a "real life", clinical setting.

Method: Patients: 1st and 2nd anti-TNF treatment courses for RA, PsA and SpA patients having utility data at baseline and at least once more during 12 months were retrieved from the South Swedish Arthritis Treatment Group (SSATG) registry of patients receiving biologic drugs. Patients were enrolled 2002-2006.

NNQ: Utility is a measure of health related quality of life (0=death, 1=perfect health) often derived from preference based, generic instruments, e g EuroQoL-5-dimensions, EQ-5D. Economic models utilize quality adjusted life years (QALYs); a year spent in perfect health yields 1 QALY, a year in a state with utility 0.5 yields 0.5 QALY, etc. The number needed to gain 1 QALY, NNQ, is the number of patients one has to subject to an intervention to gain 1 QALY. We obtained mean QALY gain as the mean utility gain from baseline over 1 year. By inverting this value, one gets the NNQ.

Results: There were 1001 eligible 1st anti-TNF courses for RA, 241 for PsA and 255 for SpA. The NNQ for 1st and 2nd courses are given in Table 1. NNQ was calculated based on mean QALY gain for all courses assuming 1 year duration of therapy (not time corrected – LOCF approach) and on each course contributing QALYs only for the actual time on treatment (time corrected).

Not time corrected	**RA**	**PsA**	**SpA**
1st course	4.5 (4.1-5.0)	4.5 (3.8-5.6)	4.1 (3.6-4.9)
2nd course	6.4 (5.3-7.9)	4.2 (3.2-6.2)	4.3 (3.2-6.8)
Time corrected			
1st course	4.7 (4.3-5.2)	4.8 (4.0-5.9)	4.4 (3.8-5.3)
2nd course	6.7 (5.7-8.2)	4.7 (3.6-6.9)	4.5 (3.3-6.8)

Table 1. NNQ (mean[95% CI]) for anti-TNF treatment of RA, PsA and SpA.

Conclusion: NNQ was easy to calculate and relate to the "real world" clinical situation. Correcting for actual time on treatment increases NNQ somewhat, as expected, due to lower QALY gain for courses <1 year. EQ-5D was found to perform well across 3 different diagnoses. In our setting, NNQ in RA was found to be higher in 2nd than in 1st anti-TNF courses, maybe due to selection of treatment resistant patients. By contrast, NNQ was about the same in 1st and 2nd anti-TNF treatment of PsA and SpA. The latter finding must be interpreted cautiously because of limited cohort size.

Impact of Specialty Pharmacy Management On Medication Compliance, Medical Utilization and Costs for Patients with Rheumatoid Arthritis. Jane Barlow[1], Wenyi Wang[1], Richard Faris[2], Susan O'Connor[1], Susan Garavaglia[1] and Ronald Aubert[1], [1]Medco Health Solutions, Inc., Franklin Lakes, NJ, [2]Medco Health Solutions, Inc., Memphis, TN

Purpose: Specialty pharmacy serves the medication needs of patients with complex chronic conditions, such as rheumatoid arthritis (RA). In addition to prescription fulfillment and coordination of coverage and payment, specialty pharmacy provides comprehensive therapy management. This includes programs to promote patient adherence and help the patient improve his/her quality of life, clinical services to assist the patient under the supervision of his/her physician in implementing the prescribed course of treatment, and 24 hour telephonic access to specially trained pharmacists and registered nurses.This study evaluates the impact one specialty pharmacy's management of RA patients who use either adalimumab or etanercept.

Method: A retrospective cohort study using integrated pharmacy and medical claims to compare RA patients who had specialty pharmacy management from 2006 to 2008 to patients who filled claims only in retail pharmacy during the same period. The study sample includes a total 4,388 patients between age 18 and 62 with a documented RA diagnosis in 2005 or 2006. The study group consisted of 3,054 patients who filled at least one adalimumab or etanercept prescription through a specialty pharmacy in 2006 and refilled the prescription through the specialty pharmacy in 2007 or 2008. The Control group consisted of 1,334 patients who filled at least one prescription of these drugs through retail pharmacy in 2006 and refilled the prescription only through a retail pharmacy in 2007 or 2008. Compliance, medical services and cost

outcomes were compared between the study and control groups each year from 2006 to 2008 by controlling age, gender and comorbidities. Generalized linear regression models were used to estimate the adjusted compliance rates and costs. Logistic regression models were used to estimate the likelihood of patients having hospitalizations, outpatient visits, and ER visits.

Results: After 2 years follow-up, compared to the control group, patients who filled RA medications through a specialty pharmacy had 16.0% higher compliance rate ($p<0.0001$); per patient per year drug cost (AWP) was $4000 higher ($p<0.0001$) and overall medical expenses per patient per year was $1,534 lower ($P<0.01$). The study group had a lower percent of patients using medical services: office visits (82.5% vs. 88.4%, $p< 0.001$) and ER visits (13.4% vs. 15.7%, $p=0.0219$). The study group also had lower hospitalization rates and shorter length of hospital stay, but both were not statistically significant.

Conclusion: Patients who received their RA medication from a specialty pharmacy were more likely to be compliant than those who received their medication from a retail pharmacy. For overall medical and cost outcomes, these patients used less medical services and overall had lower medical expenses. Use of specialty pharmacy may be associated with higher compliance to RA treatment and lower utilization and costs of medical services.

Predictors of Quality of Life (QOL) in Rheumatoid Arthritis (RA) Patients. S. C. Bae[1], Soo-Kyung Cho[1], Yoon-Kyoung Sung[1], Hyeseon Lee[1], Kyounghee Jung[1] and Tae-Jong Kim[2], [1]Hanyang Univ Medical Center, Seoul, South Korea, [2]Chonnam National University Medical School, Gwangju, South Korea

Purpose: To identify the predictors for health-related quality of life (HR-QOL) in RA patients according to their disease activities.

Method: Two hundred twenty three RA patients diagnosed with the American College of Rheumatology criteria were recruited from the Hospital for Rheumatic Diseases in Hanyang University, Seoul, Korea (from Hanyang University Medical center Arthritis Network, HUMAN). Their health status was measured with European quality of life (EQ-5D). Multiple regression analysis was used to investigate associations between the dependent variable (HR-QOL) and independent variables (health assessment questionnaire [HAQ], DAS28 score, age, disease duration, VAS, co-morbidity, operation history, and demographic features). Then, RA patients were divided into three subgroups according to their disease activity: remission (DAS28 $\leq$2.6), low and moderate disease activity (2.6<DAS28$\leq$5.1), and high disease activity (DAS28>5.1). Predictors for HR-QOL in each group were also identified.

Results: HAQ ($p<0.001$), disease duration ($p=0.024$) and patient assessed pain-VAS ($p=0.001$) were significant predictors of EQ-5D utility in multiple stepwise regression models. In patients with remission (n=34), QOL was affected by pain-VAS ($p=0.011$) and age ($p=0.03$) ($R^2=0.868$). For patients with low and moderate disease activity (n=152), HAQ ($p<0.001$) and pain-VAS ($p=0.004$) were predictors for HR-QOL ($R^2=0.439$). Among high disease activity patients(n=37), co-morbidity ($p=0.006$), recent operation history ($p=0.002$) and disease duration ($p=0.004$) in addition to pain-VAS ($p=0.01$) affected QOL ($R^2=0.937$), while HAQ was not associated with QOL in this group($p=0.108$).

Conclusion: There were differences in predictors of QOL according to the disease activity of RA patients. Pain was a major predictor for QOL in RA patients and HAQ was important in patients with low and moderate disease activity. However, in patients with high disease activity, co-morbidity and operation history are more important predictors for QOL than HAQ. It might be important for physicians to notice that different factors are influencing the QOL in RA patients as their disease activities.

Converting MHAQ, MDHAQ and HAQII Scores Into HAQ Scores Using Models Developed with 59,281 RA Patients. Jaclyn K. Anderson[1], F. Wolfe[2] and Kaleb D. Michaud[1], [1]University of Nebraska Medical Center and NDB, Omaha, NE, [2]National Data Bank, Wichita, KS

Purpose: The Stanford Health Assessment Questionnaire Disability Index (HAQ) is the gold standard functional status questionnaire in rheumatology, but is lengthy with 41 questions. Three prominent and much shorter versions, multidimensional HAQ (MDHAQ), modified HAQ (MHAQ), and HAQII, are often used in outcomes research as HAQ substitutes without demonstrated equivalence. Due to differing psychometric properties of each measure, we seek to develop a method of conversion between these three versions and the original HAQ.

Method: Utilizing previously collected data from the National Data Bank for Rheumatic Disease (NDB) long-term outcomes study from 1998-2008, analysis was limited to comparison in rheumatoid arthritis (RA) patients at a random observation at which the HAQ was asked in conjunction with the MHAQ, MDHAQ, and HAQII. Univariate linear regression analyses were performed with 30 explanatory variables believed to be important indicators of the HAQ score with variables not contributing to the model excluded from further analysis. The developed models were limited to 80% of the data with the remaining 20% used to test the model fit. Predicted values were constrained to the 0 to 3 range of the HAQ. Graphical fits are presented in lowess curves.

Results: The number of unique RA patients completing the HAQ and alternatives were: 29,686 MHAQ, 13,666 MDHAQ, and 19,117 HAQII. Table 1 displays coefficients (standard error [SE]) for the final models. The square root of MHAQ was more closely correlated with HAQ than the untransformed variable (0.881 vs. 0.857), improved the R^2 modestly (ΔR^2=0.042), and was included in the final model. Addition of pain VAS, number of years smoked, and patient global severity improved R^2 by 0.013 but were not included in favor of parsimony. Transformed versions of the MDHAQ and HAQII did not significantly improve model fit. Including age and sex in the HAQII model produced a nonsignificant improvement (ΔR^2=0.002). For each measure both the 80% development sample and 20% validation sample closely approximated the fitted HAQ values and demonstrate nearly identical lines (Figure 1).

Conclusion: We have developed conversion formulas between the MDHAQ, MHAQ, and HAQII and HAQ in a large sample of RA patients. We feel the models we have developed are useful for conversion of the measures in the research setting with application to the individual patient inappropriate.

Table 1. Model Coefficients.

Model	Measure (SE)	AGE (SE)	SEX (SE)	Constant (SE)	√MHAQ (SE)	R^2 20% Validation Sample
MHAQ	0.380(0.012)	0.006(0.000)	-0.240(0.005)	-0.068(0.010)	1.085(0.015)	0.816
MDHAQ	1.113(0.005)	0.004(0.000)	-0.206(0.007)	0.053(0.014)	-	0.802
HAQII	0.993(0.004)	-	-	0.044(0.005)	-	0.838

HRQoL Domain Coverage of the Patient Generated Index in Patients with Systemic Sclerosis: An Application of the PROMIS Framework. S. de Achaval[1], M. Kallen[1], V. Cox[1], M. Mayes[2] and Marie E. Suarez-Almazor[1], [1]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [2]U.Texas Houston, Houston, TX

Purpose: Systemic sclerosis (SSc) is a multifaceted disease severely impacting patient health-related quality of life (HRQoL). Available instruments assessing SSc patient HRQoL inadequately capture the wide spectrum of symptoms and burden SSc patients experience. The Patient Generated Index (PGI) assesses HRQoL from the subjective view of factors deemed important per individual patient. We mapped the range of HRQoL issues reported by SSc patients on the PGI onto currently established PROMIS (Patient Reported Outcomes Measurement Information System) domains to investigate PGI domain coverage. PROMIS, an NIH initiative, currently proposes a framework to comprehensively measure patient-reported symptoms and outcomes.

Methods: A cross-sectional study was performed with 62 SSc participants. The PGI was completed in 4 stages: 1) patients identified the 5 most important life areas affected by SSc, 2) they scored each area using a 0 (bad as could be) to 6 (good as could be) scale, with “last month” as time reference, 3) with 10 points “to spend” they distributed points per life area to indicate most-to-least important areas, 4) they ranked their life areas. All identified life areas from PGI stage 1 were then categorized into one general and 2 specific PROMIS framework domains. Descriptive statistics were calculated for patient characteristics and the self-reported HRQoL life areas. Correlations between PGI score and standardized instruments used in SSc patient assessment (e.g., HAQ-DI, SF-36, Symptom Burden Index (SBI)) were obtained to assess validity of the PGI in this patient population.

Results: Patients were mostly female (87%), English-speaking (87%), white (69%), and had a mean age of 53 years. Mean disease duration was 8 years; 63% had diffuse disease. A total of 279 individual life area responses were recorded, 53% of which were in the general domain social health, particularly in the specific domains of social function and relationships. Another 20% were in the general domain physical

health, most in the specific domains of physical function, symptoms, sleep/wake function, and sexual function. Some 17% were categorized in the general domain mental health, with a majority in the specific domains of emotional distress and psychological function. Ten percent overlapped 2-3 domains. Patient responses were found to be distributed across 8 of 9 specific domains in the current PROMIS framework. Statistically significant correlations ranging in absolute value from 0.26-0.50 were observed between the PGI and HAQ-DI, both SF-36 component scores, 7 of 8 SF-36 subscales, and 7 of 9 SBI components.

Conclusion: The social health domain was reported as most affected by SSc. The PGI is an individualized, wide-spectrum HRQoL instrument for SSc patients. Implementation of this single instrument may allow for a more comprehensive coverage of the multiple HRQoL areas affected by SSc.

ACR Poster Session A

Fibromyalgia and Soft Tissue Disorders

Sunday, October 18, 2009, 9:00 AM - 6:00 PM

81

Validation of the Skin Extensibility Test in Joint Hypermobility. Adam Farmer[1], H. Douthwaite[1], Qasim Aziz[1] and Rodney Grahame[2], [1]Wingate Institute of Neurogastroenterology, London, United Kingdom, [2]Univ College Hospital, London, United Kingdom

Purpose: Generalised joint hypermobility (JHM) is common and is a feature of many of the hereditary disorders of connective tissue (HDCTs), including the benign joint hypermobility syndrome (BJHS) and Ehlers-Danlos syndrome (EDS). JHM can be evaluated using the Beighton score [1]. Skin hyperextensibility, too is a feature of HDCTs and forms part of the Revised 1998 Brighton diagnostic criteria for BJHS [2]. There is a paucity of data in the literature examining the use of paraclinical methods for determining skin extensibility as a function of connective tissue deficiency. We aimed to evaluate skin extensibility and skin thickness in a cohort of healthy volunteers.

Methods: 250 healthy volunteers, without BJHS, had their demographics and Beighton score recorded. Skin extensibility was measured by placing 2 dots (applied with a Pilot V5 Hi-Techpoint 0.5 ball-point pen) on the dorsum of the right hand overlying the space between the 2nd and 3rd metacarpals, approximately 10mm apart, and the distance between them was measured accurately (to +/-0.01mm) using an electronic caliper. A lateral stretching force was applied to the dots until the skin was taut and the increase in distance between the dots was noted and transformed into a percentage increment based on the initial measurement. Skin fold thickness was measured using a Harpenden caliper [3]. A corrected skin extensibility score (CSES) was calculated by multiplying the percentage increment by skin thickness (skin fold/2).

Results: 250 healthy volunteers (131 female) with a median age of 31 years (range 18 - 89 years) were studied. The prevalence of JHM of 17.6% as assessed by using the Beighton score = > 4/9. Skin thickness negatively correlated with age ($p<0.0001$ $r=-0.49$). Male gender and those who had JHM had thicker skin ($p=0.003$, $p=0.0002$ respectively). Asians were significantly more hypermobile than caucasians and afro-caribbeans ($p<0.05$). CSES was positively correlated with Beighton score, $r=0.48$, $p<0.0001$. The mean CSES was 23.84 (SEM +/- 0.84) in the hypermobile group vs. 13.55 (SEM +/- 0.34) in the normal mobility group, $p<0.0001$. Using a CSES>18 as the cut off for a positive test, sensitivity was 0.85, specificity 0.84, negative predicted value 0.96, positive predicted value 0.53. Using the receiver operator characteristics for the test, the area under the curve was 0.91, 95% confidence interval 0.87-0.96.

Conclusion: The CSES represents a useful adjunct in the clinician's armamentarium for the evaluation of tissue laxity in healthy subjects without BJHS. It provides an objective measure of skin extensibility corrected for skin thickness with excellent sensitivity and specificity. Further work is now warranted to validate this test in a cohort of patients with BJHS and EDS. References: 1.Beighton P et al. Ann Rheum Dis 1973;32:413-8. 2.Grahame R et al. GH-IGF1 Axis in Severe Fibromyalgia Patients: Screening Data From the CT27560 Trial. C. Alegre[1], G. Cuatrecasas[2], J. Cabrera[3] and Fernandez-Sola Joaquim Sr.[4], [1]Rheumatology, Barcelona, Spain, [2]Endocrinology, Barcelona, Spain, [3]Merck S.L., Madrid, Spain, [4]HOSPITAL CLINIC, Spain

Purpose: Fibromyalgia syndrome (FM), defined by tender points and weakness is becoming widespread. Some studies have shown disturbances in the GH axis in global FM (1), although not clear subgroup stratification according to GH secretion or resistance had been done. Two intervention studies have been published so far (2,3). CT27560 compares GH +triple therapy (2 antidepressive + opioid analgesia) vs triple therapy alone, in a low IGF-1 but normal ITT and GT responders, in a selective cohort of severe FM. We present screening data of the pre-selected patients for the trial.

Methods: All patients (n=164 women) had>16 tender points and FIQ scale>75. Mean age was 50± 9,4 years and mean BMI was 27,2±4,1 Kg/m2. They had 2 basal GH and IGF-1 determinations (IGF-1<150 uU/ml corresponded to-2SD and <250 uU/ml to-1 SD according to control population), insulin-tolerance test (ITT) or glucagon test for the GH secretion analysis,(cut-off 5 ng/ml) and a modified generation test (GT) for the insensitivity analysis (cut-off >50% IGF-1 response) . IGF1 was measured by chimioluminiscensce or RIA depending on the center.

Results: 19/164 (12,75%) had IGF-1>150 ug/l and 4/164 had IGF-1>250 ug/l (2,68%). 7/95p had an ITT<3ng/ml (7,36% of the total),15/95 had an ITT<5 ng/ml (15,7%), criteria for AGHD. 5 patients were retested, previous withdrawal of the antidepressant drug, 1 normalized its response (glucagon test). 9/95 had basal GH>5 ng/ml (9,4%), 8/95 had a GT<50% IGF-1 response (8,4%), criteria for GH insensitivity. No correlation was found between basal GH or IGF-1 and GT response. No statistical differences were seen between the centers when analyzing IGF-1, % of itt non-responders and % of GT non-responders (Student t test).

Conclusion: Severe fibromyalgic syndromes have a high prevalence of GH axis disfunction. Some patients show classic biochemical patterns of AGHD and might be candidates for substitution treatment. The majority stands with normal-low IGF-1 but correct secretion test, suggesting certain GH insensitivity in this disease. This seems to be confirmed by the % of non responders to the GT

Accuracy of Physical Examination in the Evaluation of Subacromial Impingement Syndrome. Lucía Silva, José-Luis Andreu, Pilar Muñoz, Teresa Otón, Alejandro Prada, José Campos, Mónica Fernández-Castro, Jesús Sanz, Carmen Barbadillo and Juan Mulero, Rheumatology Department. Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Purpose: Shoulder pain due to subacromial impingement syndrome (SIS) is a common presenting complaint in rheumatology units. Physical examination (PE) of the shoulder includes several manoeuvres that explore subacromial space (SAS). High resolution ultrasonography (HRUS) has been advocated as a precise tool in the diagnosis of painful shoulder since it can evaluate the dynamic signs of impingement. The objective of this study is to compare PE findings with HRUS changes of subacromial space in patients with painful shoulder.

Method: Consecutive patients with painful shoulder referred to our unit were included in the study. After obtaining a signed informed consent, in the same day, a pre-defined physical examination was done separately by two rheumatologists, and a HRUS examination (GE Logic-5 Pro) was carried out by a third rheumatologist, blinded for the clinical findings. Sensitivity, specificity, positive and negative predictive values, and precision of the different PE manoeuvres for the diagnosis SAS pathology were calculated.

Results: Fourteen men and sixteen women were included. Mean ± SD age was 54.87 ± 13.8 years and the median duration of symptoms was 97.5 days. Sensitivity for Neer's manoeuvre was 100% and precision was 41%. Hawkins' test achieved a sensitivity of 67% and a precision of 34%. For Yocum's manoeuvre, sensitivity was 67% and precision 31%. For impingement manoeuvre values were: sensitivity, 67% and precision, 24%. Jobe's manoeuvre obtained a sensitivity of 100% and a precision of 38%. For Patte's manoeuvre sensitivity was 100% and precision 59%; and for resisted abduction 33% and 31% respectively. No test obtained a high positive predictive value for the diagnosis of SIS, although Neer, Jobe and Patte manoeuvres had a negative predictive value of 100%.

Conclusion: Most of PE manoeuvres detect reasonably well subacromial impingement of the shoulder, although only Patte manoeuvre has an acceptable accuracy.

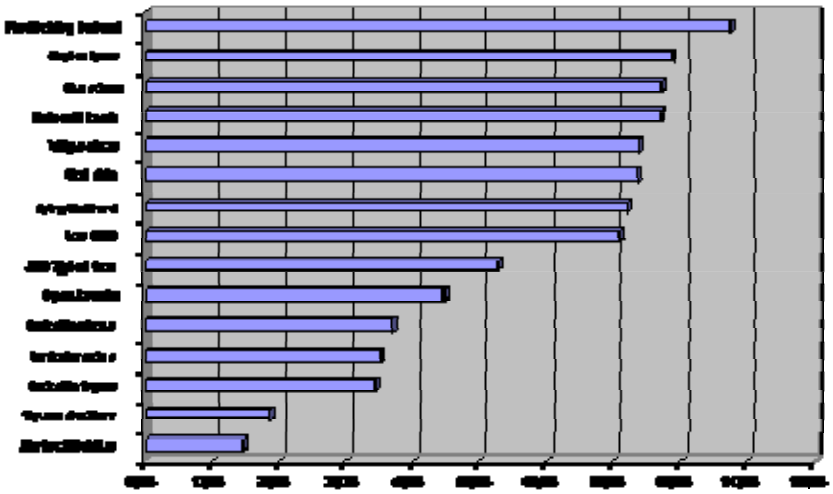
Signs and Symptoms of Joint Hypermobility Syndrome to Consider When Diagnosing This Condition. Jaime F. Bravo[1] and Carlos Wolff[2], [1]San Juan de Dios Hospital, Santiago, Chile, [2]University of Chile, Santiago, Chile

Purpose: To facilitate the diagnosis of Joint Hypermobility Syndrome (JHS), a frequent form of Ehlers-Danlos Syndrome (EDS) that for most authors is the same as EDS type III, which usually goes undiagnosed.

Methods: We have studied 1395 JHS patients during the last 8 years, in our adult Rheumatology Clinic, in Santiago, Chile. In this study, the Beighton score (BSc), the Brighton Criteria (BC) and a checklist for frequent signs and symptoms of JHS were used. Age range: 16 - 87 y/o. Average age: 45.9. Females 78.1%. Patients were grouped by ages. Group A (226 patients; 16.2%) less than 30 y/o, Group B, (571; 40.9%) and Group C. (598; 42.9%) 50 y/o or older. Chi square test was used for statistical analysis.

Results: In the total group we found: negative BSc 56.9%; Marfanoids 14.6%; Light blue sclera 77.2% (M 56.0%, F 83.1%); Dysautonomia (Dys) 44.6% (M 23.8%, F 50.5%). Frequency of Dys in M by groups: A 52.0%, B 27.7%, C 10.6%; In F: A 80.2%, B 61.8%, C 27.8%. Low BMD, Osteopenia and Osteoporosis (O), was present in 70.9% (M 79.3%, F 69.1%). Frequency of low BMD in M by groups: A 66.7%, B 74.4%, C 86.7%. In F: A 68.6%, B 63.2%, C 73.4%. Frequency of O: M 25.6%, F 23.1%. O: in M by groups: A 16.7% B 16.3%, C 35.0%, in F: A 17.6%, B 14.5%, C 30.2%. Frequency of other signs studied are noted as follows:



Conclusion: The following signs and symptoms were frequent enough (≥ 45%) to feel that they are important when considering the diagnosis of JHS: Hand holding the head; elephant paw; light blue sclera; horizontal thumb: valgus elbow; soft skin; flying bird hand; typical JHS face; low BMD and Dys. There was no significant difference between sexes regarding low BMD at all ages. Dys was significantly more noticeable in women than in men at all ages. All patients had a positive BC, since this is required by the JHS definition. As noted in our previous studies, the BSc was again negative, (56.9%). This is important since in some studies, many JHS patients are not included when applying only the BSc rather than the BC. We suggest preparing a checklist similar to the one used here to facilitate JHS diagnosis.

An in Vitro Model of Human Tenocytes to Investigate the Effectiveness of a Novel Formulation for the Prophylaxis and Treatment of Tendinopathies. Anna Torrent[1], Ramon Ruhí[1], Cristina Martínez[2], Mar Cid[2], Constanze Csaki[3] and Mehdi Shakibaei[3], [1]BIOIBERICA S.A., Palafolls (Barcelona), Spain, [2]BIOIBERICA S.A., Barcelona, Spain, [3]Ludwig-Maximillians-University, Munich,Germany

Purpose: Clinically, tendinopathies pose a major problem as they require lengthy treatment protocols and the tendon often heals unsatisfactorily. Tendons have a limited capacity for self-repair due to low cell density and little mitotic activity. Pro-inflammatory cytokines such as interleukin-1β (IL-1β) have been identified as the main initiators of tendinopathies, stimulating inflammation, apoptosis and extracellular matrix (ECM) degradation. The aim of this study was to evaluate the potential effectiveness of a novel formulation (BIS-033) including mucopolysaccharides, in an *in vitro* model of tendon inflammation.

Method: In monolayer cultures primary human tenocytes were either treated with BIS-033, non-stimulated or stimulated with IL-1β, stimulated with IL-1β and BIS-033 or pre-stimulated with BIS-033 followed by co-treatment with BIS-033 and IL-1β. Cell viability, adhesion, proliferation and production of ECM were analysed with light microscopy and transmission electron microscopy (TEM). Immunofluorescence was used to evaluate production of type I collagen, the main extracellular matrix protein produced by tenocytes. We also studied the expression of the signal transduction and adhesion molecule β1-integrin. Western blotting (WB) was performed to evaluate expression of apoptotic and inflammatory markers (MMP-1, Cox-2, Caspase-3).

Results: BIS-033 had a potent stimulatory effect on human tenocyte proliferation and ECM production. BIS-033 was able to suppress the catabolic, apoptotic and inflammatory effects induced by IL-1β in human tenocytes. This was demonstrated by the suppression of IL-1β-induced expression of MMP-1, Cox-2 and Caspase-3 and up-regulation of type I collagen and β1-integrin.

Conclusion: The methodology and results demonstrate that this *in vitro* model is useful for evaluating the potential effectiveness of new compounds and formulations on tendon disorders. The results presented also suggest that this formulation inhibits catabolic and inflammatory processes in an *in vitro* model of tendonitis. BIS-033 may therefore be used on prophylaxis and treatment of tendinopathies to stimulate tendon healing, regeneration and repair.

The Instability of Fibromyalgia Diagnosis: Associations with Measures of Severity. F. Wolfe[1], Daniel Clauw[2], MA Fitzcharles[3], Don L. Goldenberg[4], KA Harp[1], RS Katz[5], PJ Mease[6], KD Michaud[7], Anthony S. Russell[8], lJ Russell[9], JB Winfield[10] and MB Yunus[11], [1]National Data Bank, Wichita, KS, [2]University of Michigan, Ann Arbor, MI, [3]MGH, Montreal, QC, [4]Newton-Wellesley Hosp, Newton, MA, [5]Rheumatology Associates, Chicago, IL, [6]Seattle Rheumatology, Seattle, WA, [7]U Neb Med Cntr and NDB, Omaha, NE, [8]U Alberta, Edmonton, AB, [9]U TX Hlth Sci Ctr, San Antonio, TX, [10]UNC, Chapel Hill, NC, [11]U IL Coll of Med, Peoria, IL

Purpose: To determine the percent of patients diagnosed with Fibromyalgia (FM) who do not satisfy American College of Rheumatology (ACR) criteria; to determine the comparative characteristics of these patients, and to investigate the use of ACR criteria among rheumatologists.

Methods: As part of a two-phase multicenter study to develop simple clinical criteria for fibromyalgia, we evaluated 920 FM patients and pain controls. FM patients were consecutive FM patients seen during routine practice who carried a diagnosis of FM made previously by the examining rheumatologist. Patients underwent a detailed interview and examination, including TP examination and assessment of the extent of widespread pain using a widespread pain index (WPI). Physicians enrolled 258 valid patients in Phase I whose clinical diagnosis was fibromyalgia and 256 who were control subjects. We report here on the Phase I study because it also included patients' self-report data.

Results: 25.4% of patients being treated for FM did not satisfy ACR criteria. We called this group "prior fibromyalgia." In addition, rheumatologists had not used ACR criteria in 36.4% of fibromyalgia diagnoses. There was a clear difference in clinical findings and symptom severity among the groups, with prior fibromyalgia generally occupying the midpoint between current fibromyalgia and controls (Table 1). With respect to diagnostic variables, the TP count (15.9 vs. 7.9) and the WPI (11.4 vs. 7.2) were significantly less abnormal in prior FM than in ACR (+) patients. These differences also extended to non-criteria severity measures such as fatigue, unrefreshed sleep, somatic symptoms, cognition, function, and pain medications. No set of class variables could be found that could adequately separate prior FM from ACR (+) FM or control subjects.

Conclusion: ACR criteria do not adequately diagnose or describe the characteristics of all FM patients in clinical practice. ACR criteria are not used by a third of rheumatologists diagnosing fibromyalgia, and 25.5% of patients being treated for fibromyalgia by rheumatologists do not satisfy these criteria. Current FM criteria aggregate and confound diagnostic status and symptom severity, features that should be separated to enable more adequate FM evaluation and management.

Variable	Current FM	Prior FM	Control
	Mean (SD)	Mean (SD)	Mean (SD)
MD Widespread pain index (0-19)	11.4 (4.1)	7.2 (3.9)	3.3 (2.5)
Tender point count (0-18)	15.9 (2.3)	7.9 (4.1)	2.5 (3.0)
MD global severity, categorical (0-3)	2.1	1.5	1.1
MD Somatic symptoms (0-3)	2.3 (0.7)	1.9 (0.7)	1.2 (0.5)
Patient VAS unrefreshed sleep (0-10)	7.3 (2.7)	5.2 (3.4)	3.1 (3.0)
Patient VAS pain (0-10)	6.5 (2.3)	4.9 (2.7)	4.1 (2.8)
Patient VAS fatigue (0-10)	7.0 (2.4)	5.0 (3.1)	3.3 (2.9)
Patient cognition, categorical (0-3)	1.7	1.3	0.6
HAQ-II (0-3)	1.3 (0.6)	1.0 (0.7)	0.7 (0.6)
Number of pain medications	3.3 (2.3)	2.5 (1.4)	1.9 (1.9)

Comparison Between Pressure and Thermal Conditioning Stimuli in the Evaluation of Descending Noxious Inhibitory Control (DNIC) in Fibromyalgia Patients and Healthy Controls. Rachel K. Harrison[1], Craig Urwin[1], Rupal Bhavsar[1], Richard E. Harris[1], Daniel Clauw[2] and Steven E. Harte[1], [1]U. Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

Purpose: Endogenous pain modulation is commonly evaluated using DNIC testing paradigms. These procedures incorporate a conditioning stimulus (a noxious stimulus that evokes DNIC activation) and a test stimulus (a noxious stimulus used to evaluate the analgesic response to the conditioning stimulus). DNIC paradigms vary greatly in regards to experimental parameters, including the type of noxious stimuli employed. It is not clear, however, if certain parameters affect DNIC outcomes differently. Previous studies indicate that individuals with fibromyalgia (FM) have attenuated DNIC compared to pain-free controls. Therefore, we compared the effects of 2 different conditioning stimuli on DNIC activation in FM patients and healthy controls (HCs) to determine if different stimuli produce different DNIC effects.

Method: Right-handed females (FM = 18, HC = 15) underwent DNIC testing with pressure as the test stimulus, and either noxious pressure or cold water as the conditioning stimulus. Baseline intensity of the test stimulus was rated during 30-s of continuous pressure applied to the left thumbnail on a 0-100 rating scale. DNIC was induced 5-min later by applying 60-s of continuous pressure to the right thumbnail. Alternatively, subjects immersed their right hand into a 12 degree Celsius water bath for 60-s. Parallel to the last 30-s of pressure or cold water conditioning, the same test stimulus was reapplied to the left thumbnail and rated. DNIC was evaluated as the difference in pain rating of the test stimulus applied before and during the conditioning stimulus.

Results: Differences in DNIC between groups were assessed with separate repeated measures general linear models, one for pressure and one for cold water. Preliminary data indicate a significant GROUP X DNIC interaction when pressure was used as the conditioning

stimulus, p = 0.038. Ratings of the test stimulus taken before and during application of the pressure conditioning stimulus revealed DNIC-induced analgesia in HCs (Mean ± SD, 57.83 ± 18.07 vs. 40.17 ± 24.90). In contrast, FM patients exhibited hyperalgesia during concomitant pressure stimulation (57.70 ± 26.32 vs. 64.00 ± 24.90). When cold water was used as the conditioning stimulus, modest differences in DNIC were observed between HCs (58.17 ± 22.19 vs. 39.03 ± 21.81) and FM patients (60.10 ± 20.95 vs. 51.00 ± 27.09), however no significant GROUP X DNIC interaction was found, p > 0.30.

Conclusion: These data suggest that DNIC testing using pressure as both a conditioning and test stimulus identifies attenuated DNIC in FM. The cold water conditioning stimulus led to less robust differences between FM patients and HCs. In contrast to other DNIC paradigms that either use sophisticated and/or expensive test stimuli (e.g. thermal probes), or very noxious conditioning stimuli that individuals may be reluctant to undergo repeatedly, this paradigm can be performed longitudinally in nearly any setting.

Severity of Anger, and Not Clinical Pain, Correlated with Nociceptive Flexion Reflex Threshold in Fibromyalgia: An Exploratory Analysis. Dennis C. Ang[1], Rafael Chakr[1], Steven A. Mazzuca[1] and Christopher France[2], [1]Indiana University, Indianapolis, IN, [2]Ohio University, Athens, OH

Purpose: While the exact cause of fibromyalgia (FMS) is yet to be fully understood, the phenomenon of central sensitization (CS) is thought to play a major pathogenetic role. CS, associated with hyperexcitability of spinal cord dorsal horn neurons, is manifested by below-average endogenous pain-inhibitory capacity and above-average pain sensitivity. In addition, well-studied psychological features of FMS, such as catastrophizing and anger regulation, may exert their harmful effects by direct amplification of the central nervous system's processing of pain, as part of CS. As an objective CS assessment tool, the nociceptive flexion reflex (NFR), via elicitation of a spinal reflex of the lower extremity after stimulation of a sensory nerve, might overcome the self-report bias of other CS assessment tools. Therefore, our goal was to study the correlations between self-report clinical pain, anger, and catastrophizing with NFR.

Method: Cross-sectional analyses of women with FMS that completed survey questionnaires on pain, anger, depression and catastrophizing were performed. Using a previously validated protocol, NFR test was performed to all participants. The protocol-derived NFR threshold was the main outcome measure. The secondary outcome was the first reflex NFR threshold.

Results: The 36 female participants had a mean age of 47± 11 years and mean disease duration of 12 ± 6 years. The mean fibromyalgia impact questionnaire (FIQ) score was 62 ± 16, suggesting a moderate-to-severely ill patient population. On bivariate analyses (table), anger out expression consistently correlated with the two NFR measures (r= -0.39 to -0.37, p<0.05). There was a trend for current pain, for bodily pain inventory (BPI) pain intensity and catastrophizing to correlate with first reflex NFR threshold (r=-0.33, p=0.06; r=-0.30, p=0.08; and r=-0.32, p=0.06, respectively). In multiple regression analyses, only anger out correlated with protocol-derived NFR threshold (r=-1.4, p=0.02).

Conclusion: Our study showed a consistent association between anger out expression and NFR threshold, an objective measure of nociception. Self-report clinical pain and catastrophizing did not correlate with NFR threshold. The exploratory nature of our study warrants confirmation in larger studies to better understand the potential link between the psychological and biological mechanisms of fibromyalgia.

Table: Pearson's correlation coefficients between objective and self-report variables

	Protocol-derived NFR threshold	First reflex NFR threshold
BPI pain intensity	-0.26	-0.30†
Current pain	-0.23	-0.33†
Pain catastrophizing	-0.24	-0.32†
Anger out	-0.37*	-0.39*

NFR: nociceptive flexion reflex; BPI: Brief Pain Inventory
*p<0.05

†p<0.10

Neuroimaging of Evoked Pain in Individuals with Fibromyalgia and Healthy Controls. Eric Ichesco[1], Rupal Bhavsar[1], Richard Harris[1], Daniel Clauw[2], Richard Gracely[3] and David A. Williams[1], [1]U. Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]U. North Carolina, Chapel Hill, NC

Purpose: Prior neuroimaging studies in fibromyalgia (FM) have identified augmented neuronal activity in response to evoked pain when compared to healthy controls (HC). Affected regions are largely contained within the pain matrix (e.g., insula, thalamus, primary and secondary somatosensory cortex, anterior cingulate and the inferior parietal lobe). To date, the majority of the functional magnetic resonance imaging (fMRI) studies in FM have been on a relatively small scale. Heterogeneity within FM as a disease state however suggests the need to replicate earlier findings in a larger sample.

Methods: 57 individuals (mean age 45) satisfying American College of Rheumatology criteria for FM and 20 HC (mean age 42) were studied. During a 10 min fMRI scan, 2 Kg. of pressure (mild pressure) was applied three times to the left thumbnail in random sequence for 25s. A 3-Tesla GE Sigma Scanner with neuro-optimized gradients (FOV = 22cm, T2* weighted, single shot, reverse spinal acquisition, GRE, TR = 2500, TE = 30, FA = 90, 64 x 64) was used to acquire fMRI data. Pre-processing and analysis of BOLD signal was performed using SPM2. Group level T statistical images were generated and uncorrected voxel level threshold of $p<0.002$ was used to identify significant activations.

Results: In FM, 2 Kg. of pressure resulted in significant neural activity in insula (Z = 3.21). bilateral inferior parietal lobes (BA 40, Z = 4.48-4.81), primary somatosensory cortex (Z = 4.03) and secondary somatosensory cortex (Z = 4.69), putamen (Z = 3.27) and caudate (Z = 3.24). Additional activations were observed in the cerebellum (Z = 4.95) and the middle frontal gyrus (Z = 4.37). HC's only had significant activation in the contralateral inferior parietal lobe (BA 40, Z = 3.18) using the same stimulus intensity.

Conclusion: In contrast to HC, mild pressure stimuli resulted in more extensive activation of pain matrix regions in individuals with FM. This study reconfirms an augmented involvement of the "pain matrix" in the processing of evoked pain in FM and supports the role of central mechanisms being responsible for the pain of FM.

Best Websites for Fibromyalgia. Robert S. Katz[1], Lauren Kwan[2] and Jessica L. Polyak[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL

Purpose: Patients with fibromyalgia usually turn to the Internet to gain a better understanding of their illness and for recommended treatment. Finding accurate, reliable information on the Internet can be difficult for patients trying to learn more about their illness. We created a rating system for health care professionals to assess the quality of these websites. We reviewed 20 Internet sites to determine which appear to be the best regarding accurate and comprehensive patient information.

Method: We assessed the top 20 sites using the Google search engine under the term fibromyalgia. We rated each site using the following criteria to assess: accuracy, no promotion, graphics, ease of use, links, and comprehensive information. We assigned numbers from zero to 10 and then added them to determine the total sum for the six categories.

Results: The top four websites were webmd (55 of possible 60 points); medlineplus (53 points); mayoclinic (52 points); and fmaware.org (52 points). Each of these sites provided pt with accurate, user-friendly, comprehensive information, which was reviewed and rated by health care professionals specializing in Rheumatology. By determining which sites are the best resources we can better help our patients to understand Fibromyalgia and provide them with additional learning tools.

Conclusion: Finding reliable information on the Internet can be difficult for patients who seek additional learning tools and resources about their illness. By assessing the top 20 websites we are able to provide useful, informative information to our patients. Internet based research is another method to provide patient education outside of the healthcare setting.

A Tale of Two Cities – The Effect of Low Intensity Conflict On Prevalence and Characteristics of Musculoskeletal Pain Associated with Chronic Stress. Jacob Ablin[1], Hagit Cohen[2], Daniel Clauw[3], Ronit Shalev[4], Eti Ablin[4], Lily Neumann[5] and Dan Buskila[6], [1]Rheumatology institute, Tel Aviv, Tel Aviv, Israel, [2]Ben-Gurion University, Beer Sheva, Israel;, Beer Sheva, Israel, [3]University of Michigan, Ann Arbor, MI, [4]Haifa University, Haifa, Israel, [5]Ben-Gurion University, Israel, [6]Soroka Medical Center, Beer Sheva, Israel

Purpose: Although both acute and chronic stress lead to pain, the precise characteristics of this association have not been defined. Sderot is an Israeli town exposed to repeated missile attacks. Ofakim, a town of similar demographic and socioeconomic characteristics, had not been targeted, as of the period of our study. We examined the occurrence and characteristics of pain and related symptoms in Sderot and Ofakim.

Method: The study was conducted as a population survey. 1750 households were contacted by telephone in Sderot and 1939 in Ofakim, with a 59% and 52% participation respectively. A total of 2,030 interviews were conducted.

1024 individuals in Sderot and 1006 in Ofakim were interviewed regarding pain, somatic symptoms, mood, trauma - exposure, and general health status.

Results: Significantly higher levels of trauma-related symptoms and somatic symptoms were noted in Sderot compared with Ofakim ($p<0.001$). Chronic widespread pain (CWP) was more common in Sderot (11.1%) than Ofakim (8.3 %; OR 1.37, $p=0.038$). Women were more likely (13.9% vs. 9.3%; OR 1.45, $p=0.06$) than men (8.9% vs.7.3%, OR 1.24, $p=0.37$) to experience CWP in Sderot vs. Ofakim. Amongst males, Chronic Regional Pain was more common in Sderot (19.2%) than in Ofakim (14.2%; $p=0.036$). Pain Severity in Sderot was significantly higher than in Ofakim ($p<0.001$).

Conclusion: In the current study we have demonstrated the effect of ongoing missile attacks on the civilian population of the Israeli town of Sderot, compared with the town of Ofakim. Significantly increased rates of somatic complaints, including pain, fatigue and IBS-like symptoms, were reported by individuals in Sderot, as well as significantly higher rates of trauma-related symptoms. Widespread pain was reported significantly more frequently by inhabitants of Sderot compared with Ofakim but was not independent of increased self-reported depression. These results strengthen the relationship between low - intensity military conflict and the development of "unexplained" somatic complaints and draw attention to the need for medical resource - allocation to such areas, in order to meet these needs. The results highlight the contribution of external "environmental" factors such as stress to the occurrence of chronic pain as part of a spectrum of related somatic and affective symptoms. It remains to be investigated to what extent these external factors may interplay with a genetic predisposition in the pathogenesis of this symptom array.

Serum Hydrogen Peroxide Levels Are Elevated in Fibromyalgia Syndrome. I. Jon Russell, Yangming Xiao, Wanda L. Haynes and Joel E. Michalek, The University of Texas Health Science Center at San Antonio, San Antonio, TX

Purpose: The fibromyalgia syndrome [FMS] is perceived as a disorder of central sensitization. Proposed initiating factors include genetic predisposition, physical trauma, and infection, but free radical-mediated oxidative stress, and inflammatory cytokines may also play important roles in its pathogenesis. Previous studies have reported oxidative stress in the patients with FMS, but the results were inconsistent. The present study was designed to measure serum hydrogen peroxide [H2O2] and total antioxidant capacity in patients with FMS and whether they correlated with FMS symptom severity.

Method: Primary FMS patients [1990 ACR Criteria] and healthy normal controls [HNC] were demographically matched 1:1. Clinical measures were assessed at the time of phlebotomy using validated methods. Total H2O2 [µmol] was measured by the colorimetric method of Alindag using aliquots of frozen [-70°C] serum. Serum total antioxidant capacity [mmol Trolox equil] was measured as directed [Sigma, Cat# CS0790]. The oxidative stress index [OSI] was calculated as [total H2O /total antioxidant capacity level] x100.

Results: Twenty three FMS and 1:1 matched HNC were studied. FMS serum exhibited significantly higher levels of serum total H2O2 and higher oxidative stress index than HNC. However, serum total antioxidant capacity of FMS patients did not differ from HNC. There was no significant correlation between H2O2 or oxidative stress parameters and clinical measures.

Variables	FMS	HNC	P-value

	[mean ± SD]	[mean ± SD]	
Number	23	23	
Age [years]	48.6 ± 8.0	48.1 ± 10.8	>0.05
Gender [%F]	96	96	>0.05
Ethnicity [%C]	70	70	>0.05
APT	3.3 ± 0.8	5.1 ± 0.6	<0.001
TPI	39 ± 7.7	2.9 ± 8.4	<0.001
CESD	44.2 ± 20.6	34.1 ± 11.6	<0.001
Zung-A	44.2 ± 7.6	34.1 ± 5.2	<0.001
Total hydrogen peroxide [μM]	14.60 ± 5.67	11.10 ± 3.56	0.016
OSI	1.34 ± 0.57	1.06 ± 0.34	0.043
Total antioxidant capacity [mM]	1.10 ± 0.13	1.07 ± 0.17	0.25

APT=Average Pain Threshold, TPI=Tender Point Index, CESD = center for epidemiologic studies depression scale, Zung-A=Zung Anxiety Scale Score, and OSI = oxidative stress index.

Conclusion: These findings support the hypothesis that FMS is subject to increased oxidative stress. We hypothesized that an imbalance of pro-oxidant and antioxidant systems could generate an excess of reactive oxygen species capable of reacting with cellular lipids, proteins, and DNA to cause neuronal cell injury. If this mechanism contributes importantly to the pathogenesis of FMS, it may herald the first preventive therapy for this condition.

The Effect of Somnolence On Pain, Function, and Sleep Responses to Pregabalin in Patients with Fibromyalgia. Lynne Pauer[1], Gary Atkinson[2], Danielle Lauren Petersel[3], Bernhardt G. Zeiher[4] and Alison Gagnon[5], [1]Pfizer Inc, New London, CT, [2]Pfizer Global Research and Development, Sandwich, United Kingdom, [3]Pfizer Global Research and Development, New York, NY, [4]Pfizer Inc., New London, CT, [5]UBC Scientific Solutions, Southport, CT

Purpose: Somnolence is one of the more common adverse events (AEs) associated with pregabalin therapy. In fibromyalgia studies, somnolence was reported in 19.2% of pregabalin patients and 4.6% of placebo patients. The objective of this report was to evaluate whether somnolence influenced the treatment response to pregabalin in fibromyalgia patients by comparing pain, function, and sleep outcomes between patients reporting somnolence on study and those not reporting somnolence.

Methods: Data from 3 similarly designed randomized, double-blind, placebo-controlled studies of pregabalin in fibromyalgia were pooled for this analysis. Patients meeting ACR criteria for fibromyalgia for ≥3 months with pain visual analog scale score ≥40 mm were treated for 13–14 weeks with pregabalin at doses of 300 (n=551), 450 (n=555), and 600 (n=564) mg/day or placebo (n=558). Efficacy outcomes of endpoint mean pain score, endpoint mean Fibromyalgia Impact Questionnaire (FIQ) total score, Medical Outcomes Survey-Sleep Scale (MOS-SS) sleep disturbance and sleep problems index scores, and sleep quality diary mean score were analyzed using least square means and analysis of covariance with effects for treatment, somnolence, and treatment by somnolence interaction. The mean changes from

baseline were compared between patients who reported AEs of somnolence at any time (n=366) during the study and those who did not (n=1861). The covariate of baseline quantity of sleep was used for analysis of pain and sleep outcomes and baseline FIQ total score for analysis of function.

Results: The changes from baseline with pregabalin treatment for each of these endpoints were similar regardless of whether somnolence was reported (pain: no somnolence, –1.55 to –1.76 vs somnolence reported, –1.79 to –2.05; FIQ: –11.57 to –14.07 vs –12.04 to –14.71; sleep disturbance: –18.23 to –23.84 vs –22.41 to –25.49). No significant treatment by somnolence interaction was observed for endpoint mean pain score (*P*=0.785), FIQ (*P*=0.497), sleep disturbance (*P*=0.308), sleep problems index (*P*=0.190), or mean sleep score (*P*=0.891). The placebo-corrected differences in response (pregabalin − placebo) for each endpoint showed that patients without somnolence had a somewhat greater improvement with pregabalin treatment (pain: no somnolence, –0.46 to –0.59 vs somnolence reported, –0.17 to –0.43; FIQ: –1.89 to –4.39 vs 0.04 to 2.72; sleep disturbance: –7.48 to –13.09 vs –4.00 to –7.07).

Conclusion: The magnitude of pregabalin treatment response on pain, function, and sleep outcomes was comparable between fibromyalgia patients reporting somnolence and not reporting somnolence. No statistically significant interaction of treatment by somnolence was observed. Therefore, the benefits observed with pregabalin treatment cannot be attributed to the occurrence of somnolence.

Test-Retest Reliability of the Mental Clutter Scale in Individuals with Fibromyalgia. Robert S. Katz and Frank Leavitt, Rush University Medical Center, Chicago, IL

Purpose: Defining and measuring fibrofog is central to an understanding of cognitive disability in fibromyalgia (FMS). Factor analysis of a new 16-item measure of fibrofog known as the Mental Clutter Scale (MCS), revealed a two dimension construct of cognition and mental clarity. This study aimed to evaluate the test-retest reliability of the MCS and its two subscales in patients with FMS.

Method: A total of 32 patients with fibromyalgia filled out the Mental Clutter Scale on two separate test sessions. The first Mental Clutter Scale was completed at a medical office visit according to a standard protocol. The second MCS was completed by mail. The interval between test sessions ranged from 4 days to 2 weeks. The median interval was 5 days.

Results: FMS patients were predominantly female (84.4%) with a mean age of 48.7±12.7 years and a mean level of education of 14.9±2.2 years. The MCS quantifies cognitive status along the dimensions of cognition and mental clarity. The eight items representing Cognition are displayed in Table 1. The eight items representing the Mental Clarity domain are displayed in column 2. Test-retest correlations (Pearson r) for the Full Scale as well as the two subscales were 0.93, 0.88 and 0.92 respectively. Differences were not significant at the $p<0.05$ level. Variations in mean measurement due to chance fluctuations from Test 1 to Test 2 were minimal as displayed in Table 2.

Table 1. Two Subscales of the Mental Clutter Scale.

Cognition Scale	**Mental Clarity Scale**
Concentration	Spaciness
Memory	Haziness
Staying Focused	Confusion
Multitasking	Cluttered Thinking
Expressing Self	Fogginess
Thinking Clearly	Rushing Thoughts
Perceptual Clarity	Fuzzy Headedness

Mental Speed	Information Overload

Table 2. Comparison of Immediate and Retest Reliability Scores.

	TEST (mean)	(sd)	RETEST (mean)	(sd)
Full Scale	4.36	2.22	4.39	2.26
Cognition Scale	4.71	2.27	4.49	2.21
Mental Clarity Scale	4.09	2.40	4.29	2.41

Conclusion: The MCS and its two subscales (Cognition and Mental Clarity) have excellent test-retest reliability for time intervals ranging from 4 days to 2 weeks. With respect to reproducibility, the MCS is an acceptable measure for use in individuals with fibromyalgia. High reliability allows changes in the fibrofog condition to be tracked with a fair degree of precision.

Hyperalgesia of Fibromyalgia Patients Is Maintained by Muscle Afferent Input: A Randomized, Double-Blind, Placebo Controlled Study. Roland Staud, Susann Nagel, Michael E. Robinson and Donald D. Price, Univ of Florida, Gainesville, FL

Purpose: Fibromyalgia syndrome (FM) is characterized by pain and widespread hyperalgesia to mechanical, thermal, and electrical stimuli. Despite convincing evidence for central sensitization of nociceptive pain pathways, the role of peripheral tissue impulse input in the initiation and maintenance of FM is unclear. In contrast, peripheral impulse input has been found to contribute to pain in irritable bowel syndrome (IBS) and complex regional pain syndrome (CRPS). Because of the considerable overlap between FM and IBS, similar pain mechanisms may be operant in both chronic pain syndromes.

Method: This randomized, double-blind, placebo-controlled trial of 22 normal female controls (NC) and 28 female FM subjects tested the effects of trapezius muscle (TrapM) tender point injections with 1% lidocaine (50 mg) on local pain thresholds as well as on remote heat hyperalgesia at the forearm. Prior to muscle injections shoulder pain was standardized by tonic mechanical muscle stimulation, resulting in local pain ratings of 4.0 ± 0.5 VAS units. Tonic muscle stimulation was interrupted for the TrapM injections but continued afterwards at the same level. Mechanical pain thresholds were tested at the shoulders using an electronic algometer. Heat hyperalgesia at the forearm was determined using 10 sec sensitivity adjusted stimuli between 45 and 49 ^{0}C.

Results: NC as well as FM subjects experienced significant increases of TrapM pressure pain-thresholds from lidocaine but not placebo injections ($p < .001$). Additionally, heat-hyperalgesia of FM participants was significantly reduced at areas remote from the injection site (forearm) by lidocaine but not placebo ($p = .02$). Neither lidocaine nor saline injections significantly affected clinical FM pain ratings, a result most likely due to the very low dose of lidocaine (50 mg) used in this trial. The subjects were unable to estimate which study drug they received, thus maintaining allocation concealment.

Conclusion: Lidocaine injections increased local pain-thresholds and decreased remote secondary heat hyperalgesia in FM patients, emphasizing the important role of peripheral impulse input in maintaining central sensitization in this chronic pain syndrome; similar to other persistent pain conditions like IBS and CRPS.

Determinants of the Quality of Life in Patients with Fibromyalgia: a Structural Equation Modeling Approach. Shin-Seok Lee[1], Seong Ho Kim[2], Seong-Su Nah[3], Ji Hyun Lee[4], Seong-Kyu Kim[5], Yeon-Ah Lee[6], Seung-Jae Hong[6], Hyun-Sook Kim[7], Hye-Soon Lee[8], Hyoun-Ah Kim[9] and Chung-Il Joung[10], [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Dongguk University College of Medicine, Gyeongju, South Korea, [3]Soonchunhyang University College of Medicine, Cheonan, South Korea, [4]Maryknoll Medical Center, Busan, South Korea, [5]Catholic University of Daegu School of Medicine, Daegu, South Korea, [6]School of Medicine, Kyung Hee University, Seoul, South Korea, [7]College of Medicine, Chosun University, Gwangju, South Korea, [8]Hanyang Univ Medical Center, Seoul, South Korea, [9]Ajou University School of Med, Suwon, South Korea, [10]Konyang University Medical School, Daejeon, South Korea

Purpose: Health-related quality of life (HRQOL) in patients with fibromyalgia (FM) is lower than in patients with other chronic diseases and the general population. Although various factors affect HRQOL, including socioeconomic status, no studies have examined a casual model of HRQOL as an outcome variable in FM patients. We examined the relationships between sociodemograhpic status, physical function, social and psychological factors, and HRQOL, and the effects of physical, psychological, and social influences on HRQOL were assessed in a hypothesized causal model using a structural equation modeling (SEM) approach.

Method: HRQOL was measured using the SF-36, and a Korean version of the Fibromyalgia Impact Questionnaire (FIQ) was used to assess the physical dysfunction. Social and psychological status were assessed using the Beck Depression Inventory (BDI), the State-Trait Anxiety Inventory (STAI), the Self-Efficacy Scale, and the Social Support Scale. SEM analysis was used to test the structural relationships of the model using AMOS software, with the maximum likelihood ratio as the method of estimation.

Results: Of the 336 patients, 301 (89.6%) were women with an average age of 47.9±10.9 years (mean±SD). The mean scores of the physical (PCS) and mental (MCS) component summary of the SF-36 were 35.9±7.5 and 33.7±11.8, respectively. The SEM results supported the hypothesized structural model ($\chi^2 = 2.336$, df = 3, p = 0.506). The final model showed that PCS was directly related to self-efficacy and inversely related to FIQ, and MCS was directly related to social support and inversely related to FIQ, BDI, and STAI.

Conclusion: In our causal model of FM patients, HRQOL was affected by physical, social, and psychological variables. In these patients, higher levels of physical function and self-efficacy can improve the physical component of HRQOL, while physical function, depression, anxiety, and social support affect the mental component of HRQOL.

Measures of Tenderness as Predictors of Clinical Pain in Patients with Fibromyalgia. Roland Staud, Jamie Goldman, Susann Nagel, Michael E. Robinson and Donald D. Price, Univ of Florida, Gainesville, FL

Purpose: Fibromyalgia (FM) patients complain of widespread pain, tenderness, and distress. Although tender points (TP) are part of the 1990 ACR Criteria for FM, they represent better predictors of distress than tenderness in this pain population. Since tenderness not only represents a risk factor for chronic pain, but correlates with clinical and experimental pain intensity, other methods than TP are needed to characterize FM. Therefore we used painful heat stimuli at TP areas to characterize the widespread hyperalgesia of FM patients. Mechanical pain threshold testing at TP sites was used for comparisons.

Method: 32 normal controls (NC) and 30 FM patients received 5sec heat-stimuli of 45 and 47^{0}C to 16 body areas corresponding to TP-locations. The participants rated experimental and clinical pain using a visual analogue scale (VAS). In addition mechanical pain-thresholds (MPT) were obtained at the same TP areas using an electronic algometer..

Results: NC and FM patients had 4.5 and 16.3 TP, respectively. FM patients' clinical pain ratings were 4.3 VAS units. Average pain ratings at all TP sites for MPT, 45 and 47^{0}C heat stimuli, were 522.2kPa, 2.2VAS, and 3.5VAS units for NC and 227.8kPa, 4.1VAS and 5.8VAS units for NC and FM subjects, respectively. These group differences were all highly significant (p<.001). A Pearson's product moment correlation between TP, MPT, and suprathreshold heat pain ratings was significant for TP count and MPT (r=-0.7; p<.001) as well as TP count and 45^{0}C heat pain ratings (r=0.05; p=.008) in FM patients. Although NCs' correlations of TP count with MPTs were significant (r=-0.63; p <.001), correlations between TP and heat pain ratings were not (p > .05). Correlations of clinical FM pain with MPT and heat pain ratings ranged between r=-0.5 (p< .02) and r=0.4 (p=.04), respectively.

Conclusion: These results show not only that mechanical and heat-pain tenderness are significantly different between FM and NC but also that these measures can be used to characterize the abnormally widespread tenderness of FM patients. As hypothesized MPT and suprathreshold heat pain ratings may also be useful for prediction of clinical FM pain.

Treatment of Fibromyalgia with Pindolol: A 12-Week, Open-Label, Fixed Dose Escalation, Observational Study. Patrick B. Wood[1] and Andrew J. Holman[2], [1]LSUHSC-Shreveport, Shreveport, LA, [2]Pacific Rheumatology Assoc, Renton, WA

Purpose: Fibromyalgia(FM) is an enigmatic, musculoskeletal disorder associated with varied symptom domains often inadequately responsive to current pharmacotherapeutic options. Objective abnormalities associated with the disorder include dysautonomia and increased responsiveness of cortical neurons to painful stimulation. As a novel choice, pindolol, a lipophilic mixed beta1/beta2 receptor antagonist with intrinsic sympathetic activity, was evaluated in a pilot study. Its potential therapeutic benefit in FM may relate either to reduction of a beta-adrenergic dependent sensitization of peripheral nociceptors or attenuation of stress-induced cortical hyper-excitability.

Method: In a tertiary, FM referral clinic, pindolol response was evaluated in an open-label, fixed dose escalation trial design in subjects meeting 1990 ACR criteria for FM. Subjects continuing concomitant medications were evaluated at baseline (visit 1) and began pindolol at 2.5 mg po qhs continued for 7 days after which they increased the dose to 5 mg po qhs. Two follow up visits were conducted at 4 weeks (Visit 2) and 12 weeks (Visit 3). The primary outcome measure was reduction in total score on the Fibromyalgia Impact Questionnaire (FIQ). Secondary outcomes included total score on the Fibromyalgia Symptom Inventory (FSI), tender point count (TPC) and tender point score (TPS) calculated as the sum of 18 tender points scored as 0 for painless, as 1 for classic 4 kg tenderness, as 2 for tenderness with grimace and as 3 for pain with withdrawal. Response to treatment was operationally defined as $\geq$ 30% reduction in total FIQ score. A repeated measures ANOVA was used to evaluate outcomes.

Results: Over a five month period, 22 female patients (mean age 51.1 [range 26-74], mean BMI 31.7) began pindolol as described and continued therapy for a mean pindolol exposure of 105.2 ± 18.0 days. Overall, FIQ decreased from a baseline of 50.3 ± 12.4 to 42.6 ± 19.1 ($p = 0.008$). Similar statistically significant outcomes were found for change in FSI ($p=0.001$), TPC ($p=0.009$) and TPS ($p=0.016$). Seven of 22 patients (31.7%) were defined as responders by FIQ. Among responders, FIQ decreased from a baseline of 47.7 ± 14.4 to 21.4 ± 11.5 (-55%; $p=0.002$), FSI decreased from 47.9 ± 12.0 to 30.4 ± 9.8 (-36%; $p=0.007$), TPC decreased from 15.1 ± 1.8 to 10.9 ± 4.6 (-28%; $p=0.028$) and TPS decreased from 25.9 ± 6.7 to 15.9 ± 8.0 (-38%; $p=0.006$). Responders and non-responders did not differ at baseline in terms of clinical parameters. Regression analysis demonstrated correlation between patient age and improvements on both FIQ total score and TPS (FIQ: $r2= 0.268$, $p=.014$; TPS: $r2=0.289$, $p<.01$). Side effects were mild and consisted of increased diaphoresis (n=9) and increased frequency/intensity of dreams (n=5), which are in accordance with product labeling.

Conclusion: This pilot study suggests that pindolol, a generic, inexpensive and familiar medication, is safe and efficacious in a subset of patients with FM. Further studies are indicated to confirm these results and elucidate pindolol's mechanism of action in patients with FM.

Sustained Depletion of Biogenic Amines Causes Chronic Muscular Pain and Tactile Allodynia Accompanied by Depression: A Putative Animal Model of Fibromyalgia. Tomoya Oe, Yukinori Nagakura, Toshiaki Aoki and Nobuya Matsuoka, Astellas Pharma Inc., Tsukuba, Japan

Purpose: Fibromyalgia (FM) is a musculoskeletal syndrome characterized by chronic widespread pain, tenderness to palpation, and various concomitant symptoms, including depression. Although exact pathogenesis of FM remains to be elucidated, dysfunction of biogenic amine-mediated central nervous system (CNS) pain control may underlie the pathophysiology of FM. To establish new treatments for pain-centered FM symptoms, the development of animal models which mimic the features of human FM patients is an urgent issue. In the present study, we developed an FM animal model by using reserpine (long-acting depletor) or tetrabenazine (short-acting depletor) to deplete biogenic amines in the CNS.

Method: Male and female SD rats were used in the present study. Reserpine (1 mg/kg) was subcutaneously administered to animals once daily for 3 consecutive days, while tetrabenazine (20 mg/kg) was given as a single intraperitoneal dose. Muscle pressure threshold (to the gastrocnemius muscle) and tactile response threshold were determined using the Randall-Selitto apparatus and von Frey filaments, respectively. Biogenic amine (dopamine, norepinephrine, and 5-hydroxytriptamine) content in the brain and spinal cord was measured using HPLC. Immobility time in the forced swim test (index of depression) was assessed using an automated swimming behavior analysis system. The effect of drug administration (pregabalin, duloxetine, pramipexole, and diclofenac) on pain thresholds was evaluated 5 days after the last injection of reserpine.

Results: Reserpine significantly reduced muscle pressure and tactile response thresholds, and these effects were sustained for 1 week or more in both male and female rats. In contrast, tetrabenazine did not produce significant decreases in these thresholds. Reserpine administration decreased the content of dopamine, norepinephrine, and 5-hydroxytriptamine in the spinal cord, thalamus, and prefrontal cortex for over a week. Further, reserpine significantly increased immobility time in the forced swim test. Pregabalin (10, 30 mg/kg, p.o.), duloxetine (30 mg/kg, p.o.), and pramipexole (0.3, 1 mg/kg, s.c.), but not diclofenac (1 - 10 mg/kg, p.o.), significantly attenuated the reserpine-induced decrease in muscle pressure threshold.

Conclusion: Sustained depletion of biogenic amines caused FM-like pain symptoms accompanied by depression in rats. The validity of the use of this reserpinized animal as an FM model is demonstrated from three different aspects: face validity (manifestation of chronic pain and comorbid symptoms), construct validity (involves dysfunction of biogenic amine-mediated CNS pain control), and predictive validity (similar responses to treatments used in FM patients). This animal model will contribute to the better understanding of FM pathophysiology and evaluation of anti-FM drugs.

Hand Joints and Tendons Involvement in Antiaromatase Users: a Follow-up Clinical and Ultrasonographic Study (D5392L00013). K. Briot[1], B. Lecoq[2], A. Fontana[3], F. Debiais[4], T. Schaeverbeke[5], M. Licour[6] and C. Roux[1], [1]Cochin hospital, Paris, France, [2]CHU Caen, Caen, France, [3]Hopital Edouard Herriot, Lyon, France, [4]CHU Poitiers, Poitiers, France, [5]CHU Bordeaux, Bordeaux, France, [6]Astra Zeneca, Rueil Malmaison, France

Purpose: Aromatase inhibitors (AIs) are standard adjuvant endocrine-therapy in postmenopausal women with hormone-sensitive breast cancer, but can cause musculoskeletal symptoms. The pathogenic and anatomic features of AI-induced pain have not been clearly delineated. Previous studies showed that hand is the most common site of these symptoms.

The objective of the study was to describe the 6-month changes in clinical rheumatologic and ultrasonographic (US) examination of hands in anastrozole users.

Method: 106 postmenopausal women (mean age 62.9 ±6.9 years) were included in a 6-month prospective open study. All of them were naïve of AI and tamoxifen treatment and began anastrozole. Rheumatologic and US examination (mode B and power Doppler) of hands (wrists and fingers) were assessed at baseline and 6 months. Synovitis was graded on a scale of 0–3 according to a semiquantitative scale and Power Doppler was graded as positive (PD+) or negative (PD-).

Results: At baseline, 27 (25.5%) patients described hands pain which are associated with one tenosynovitis but no clinical synovitis whereas US evaluation showed synovitis in 15 patients (55.6%), with PD+ in 7 patients (25.9%) and tenosynovitis in 3 patients (11.1%) with PD+ in 2 patients (7.4%). After 6 months of treatment, 24 patients had still pain associated with one clinical synovitis and no tenosynovitis.

Among the 79 women (74.5 %) without baseline hands pain, physical evaluation found no synovitis and one tenosynovitis. US exam revealed synovitis in 39 patients (49.4%) with PD+ in 15 patients (19%) and tenosynovitis in 13 patients (16.5%) with PD+ in 4 patients (5.1%). At 6 months, 25 patients (31.6%) reported hands pain with clinical synovitis (n=2, 2.5%) and tenosynovitis (n=2, 2.5 %).

The results of US examination at 6 months are reported in the table

	Patients with hand pain at baseline (n=27)	Patients without hand pain at baseline (n=79)

	N (%)	N (%)
Synovitis at baseline	15 (55.6)	39 (49.4)
PD+	7 (25.9)	15 (19.0)
Synovitis at M6	15 (55.6)	38 (48.1)
Yes	14 (51.9)	34 (43.0)
Grade 1	8 (29.6)	21 (26.6)
Grade 2	2 (7.4)	6 (7.6)
Grade 3	7 (25.9)	17 (21.8)
PD+		
Tenosynovitis at baseline	3 (11.1)	13 (16.5)
PD+	2 (7.4)	4 (5.1)
Tenosynovitis at M6	5 (18.5)	13 (16.5)
PD+	3 (11.1)	9 (11.5)

Among patients without pain before initiation of anastrozole, who experienced hands pain (n=25), US examination showed 16 synovitis (64%) with PD+ in 9 (36%) and 8 tenosynovitis (32%) with PD+ in 6(24%).

Conclusion: This prospective study suggests that 30% of women without hands pain before beginning anastrozole experienced hands pain which are not associated with a significant increase in US synovitis, and that structural changes in joints of the hand are frequent in postmenopausal women with symptoms or not.

Is Sleep Quality a Bookmark of Clinical Severity in Fibromyalgia? Casanueva Fernández B[1], Belenguer Prieto R[2,] Peña Sagredo JL[3], González-Gay MA[4],1- Rheumatologist. Rheumatology Services at the Specialist Clinic of Cantabria. Santander. Cantabria, Spain, 2- 9 d'Octubre Hospital, Valencia, Spain, 3- Rheumatology Services at Valdecilla Hospital, Santander, Cantabria, Spain, 4- Rheumatologist, Rheumatology Services at Xeral Hospital, Lugo, Spain.

Purpose & Background: The aim of the present study is to analyze if the quality of sleep, assessed with the Pittsburgh Sleep Quality Index (PSQI), has influence over pain symptoms, fatigue, anxiety, depression, psychological pattern, coping, impact of the illness, stress, quality of life and invalidity, in patients with fibromyalgia (FM).

Methods: A total of 510 patients (480 women and 30 men) with a diagnosis of FM (ACR criteria) were included. The delay in diagnosis, work activity, granting of disability, questionnaire about 75 symptoms, analysis of pain, catastrophic thinking, fatigue, anxiety, depression, psychological pattern, coping, impact of fibromyalgia, state of health, stress, quality of life, handicap, and sleep analysis were reviewed for all patients. After applying the PSQI the patients were classified into four groups. The first group contained 15 patients whose total score in the PSQI was ≤ 5; they were considered good sleepers (GS). A second group consisted of 41 patients whose score in the PSQI was between 6 and 8; this group was termed slightly bad sleepers (SBS). A third group was made up of 105 patients, with a score oscillating between 9 and 11, and who were considered moderately bad sleepers (MBS). Finally, there was a fourth group, made up of 349 patients who scored ≥ 12, and considered to be very bad sleepers (VBS). The SPSS 15 statistical package for Windows was used for the statistical analysis of the data.

Results: In our sample, 68% of the patients show severe sleep alterations and only 3% could consider themselves good sleepers. The VBS patients showed statistically significant differences with respect to GS, SBS and MBS in the number of symptoms, pain, fatigue, depression, anxiety, quality of life, impact of FM, state of health and stress level. The SBS showed statistically significant differences with respect to the MBS in pain levels, fatigue, impact of FM, catastrophic thinking, physical function, and self perception of general health and vitality.

Conclusion: The degree of sleep change, evaluated with the PSQI, permits the differentiation of four groups of patients who present not only significant statistical differences regarding quality of sleep but also relating to severity of pain, fatigue, depression, anxiety , impact of FM and quality of life. Thus, beyond merely evaluating the quality of sleep, the PSQI does serve as a bookmark of global clinical severity in patients with FM.

Medical Resource Utilization and Workdays Lost in a European Survey of Patients with Fibromyalgia. Joris Kleintjens[1], Pascale Peeters[2], Anke van Engen[1], Gavin Taylor-Stokes[3], Katell le Lay[4] and Charles Taieb[5], [1]Quintiles Consulting, WT Hoofddorp, Netherlands, [2]Quintiles Consulting, Levallois-Perret, France, [3]Adelphi Group, Macclesfield, Cheshire, United Kingdom, [4]Pierre Fabre, Boulogne-billancourt, France, [5]PFSA, Boulogne, France

Purpose: Fibromyalgia or fibromyalgia syndrome (FMS) is characterized by chronic widespread muscular pain and generalized tender points, often accompanied often accompanied by a number of associated symptoms such as fatigue, sleep disturbance, psychological distress. The objective of this study was to assess the medical resource utilization (MRU) and workdays lost (WDL) of FMS patients according to their health status defined by level of pain and fatigue.

Method: The Adelphi Fibromyalgia Disease Specific Programme is a cross-sectional survey among 2,159 FMS patients in France, Germany, Italy, Spain and the UK. The survey included one questionnaire filled in by the patient and one by the physician. Patient health states were defined on the basis of items 15 and 16 (100mm VAS scales) of FIQ (Fibromyalgia Impact Questionnaire).

Results: From the pool of 2159 FMS patients, 802 patients (<40mm; 37.1%) presented with mild pain, 729 with moderate pain (40-70mm; 33.8%), and 628 with severe pain (>70mm; 29.1%). Most patients with moderate (80.5%) or severe pain (95.5%) also suffered from fatigue. A total of 1341 patients had significant fatigue (cut off: 50mm), associated with mild (N=154), moderate (N=587) or severe (N=600) pain. In these patients, the annual number of physician visits per patient (5.71, 6.14 and 7.47 respectively), co-medication costs per 4 weeks (£3.66, £5.48 and £8.11), as well as the annual hospitalisation rate (2.6%, 5.6% and 7.5%) and length of stay per patient per year (0.42, 1.69 and 1.95 days, respectively) increased following the level of pain. Similarly, the percentage of patients on sick leave and its duration were larger in patients with fatigue and moderate (11.9% and 40 weeks) or severe (20.0% and 44 weeks) pain, compared to patients with mild pain (8.4% and 33 weeks).

Conclusion: In FMS patients who present with significant fatigue, medical resource utilization and workdays lost increase with respect to the level of pain.

SELDI-TOF Proteomic Whole Saliva Profiling in Fibromyalgic Patient. Camillo Giacomelli, Laura Bazzichi, Federica Ciregia, Chiara Baldini, Francesca Sernissi, Laura Giusti, Arianna Consensi, Claudia Ferrari, Antonio Lucacchini and Stefano Bombardieri, University of Pisa, Pisa, Italy

Purpose: Fibromyalgia (FM) is a chronic non inflammatory musculoskeletal disorder characterised by widespread pain and by the presence of at least 11 out of 18 specific tender points on physical examination. Currently no validated laboratory biomarkers are available for FM and the diagnosis of the disease remains exclusively clinical. The aim of the present study was to perform a proteomic analysis of FM patients' saliva with surface-enhanced laser desorption/ionization time-of-flight/mass spectrometry (SELDI-TOF/MS).

Method: In the first step we enrolled 40 females (mean age 43.60±11.30 yrs, M±SD) all fulfilling the ACR criteria for FM and 35 healthy controls with similar demographic characteristics. In order to confirm these preliminary results, in the second step, we performed other independent experiments on a validation set composed by 26 FM subjects and 16 healthy controls. Whole saliva samples are centrifuged to remove undissolved material. Aliquots of resulting supernatants are analysed by SELDI-TOF/MS. Saliva is applied to the spots of Protein Chip Arrays (CM10, Q10, H50). After an incubation period (1h), unbound proteins and other contaminants are washed off the spots using buffers as required by the array chemistry; only proteins interacting with the chemistry of the array surface are retained for analysis. Finally matrix (sinapinic acid-SPA) is applied to each spot to facilitate laser desorption and ionization. The statistical analysis was performed using cluster analysis, and the difference between two groups was underlined using t-student test.

Results: The analysis of the obtained spectra on three chips, after validation, allowed us to observe 14 peaks (ranging from 3374 and 24087 *m/z*) differently expressed in FM patients ($p<0.05$) with respect to the controls. The preliminary results obtained by SELDI-TOF analysis were compared with those obtained in an our previous work (work submitted) performed in whole saliva of FM patients by using two-dimensional electrophoresis (2DE) and matrix-assisted laser/desorption ionisation time-of-flight (MALDI-TOF-MS). The m/z of two peaks increased in FM patients (11040, 22961) well overlap with the molecular weight of calgranulin A and C (11 kDa) and Rho GDP-dissociation inhibitor 2 (23 KDa), found up-regulated in FM patients with 2DE. Further studies could be useful to confirm these data and identify other significant peaks detected.

Conclusion: These preliminary results showed the possibility to identify a salivary biomarker through salivary proteomic analysis with SELDI-TOF in FM patients. This study demonstrated that 2DE-MALDI-TOF-MS and SELDI-TOF-MS might be valid complementary techniques able to identify the potential novel diagnostic biomarkers for FM.

104

What Is the True Cost of Fibromyalgia to Our Society: Results From a Cross-Sectional Survey in the United States. Don L. Goldenberg[1], Caroline Schaefer[2], Kellie Ryan[2], Arthi Chandran[3] and Gergana Zlateva[3], [1]Newton-Wellesley Hosp, Newton, MA, [2]Covance Market Access Services, Gaithersburg, MD, [3]Pfizer Inc, New York, NY

Purpose: Patients with fibromyalgia (FM) report persistent, widespread pain, fatigue, and significant functional limitations. While several retrospective studies have documented that FM is associated with substantial direct and indirect health care costs[1], patient-level research has not been reported in the US. The objective of this study is to assess direct and indirect costs associated with FM in routine clinical practice in the US.

Method: This cross-sectional, observational study recruited 203 FM subjects from 20 community-based physician offices. Subjects completed questions about pain, health-related quality-of-life, productivity, and out-of-pocket expenses related to FM; site staff recorded subjects' treatment and medical resource use based on a review of medical records. Annual costs from a societal perspective were calculated in 2009 US dollars.

Results: Subjects had a mean (SD) of 6.1 (8.2) FM-related office visits over the past 3 months with a mean (SD) of 4.2 (4.5) visits to physicians, corresponding to 24.4 office visits and 16.8 physician office visits per year. Most subjects (92%) were taking at least one, and over half (54%) were taking 3 or more prescription FM medications. The highest proportions of subjects were prescribed anti-depressants (56%), analgesics other than anti-inflammatories (52%) and anti-epileptics (38%). Subjects employed full- or part-time (40% of sample) reported missing a mean (SD) of 1.8 (3.9) days of work to FM over the last 4 weeks, corresponding to 23.4 days of work missed due to FM per year. Among subjects not employed, 38% reported being disabled due to FM and 34% reported being unemployed or retired early due to FM. The mean (SD) annual direct costs per subject for FM were $7,973 ($7,341), including physician office visits $1,528 ($1,953), diagnostic tests $435 ($1,859), prescription medications $3,419 ($3,667), emergency room visits $43 ($323), and out-of-pocket costs incurred by subjects for FM treatments $1,798 ($3,056) and home healthcare services $750 ($1,756). The mean (SD) annual indirect costs per subject for FM were $10,697 ($20,463), including $1,228 ($4,904) related to absenteeism and $9,470 ($20,446) related to disability due to FM, including both disability payments and the opportunity cost of not working. These figures do not include additional substantial indirect costs related to FM, including reductions in work schedule or early retirement for patients, and lost productivity for caregivers due to FM.

Conclusion: FM imposes a significant economic burden on society. Consistent with other studies, there are substantial direct and indirect costs associated with FM, with indirect costs due to lost productivity accounting for the largest proportion of costs.

Telephone-Delivered Cognitive Behavioral Therapy (CBT) On Clinical Symptoms and Nociceptive Responding in Fibromyalgia (FM) – A Pilot Study. Dennis C. Ang[1], Rafael Chakr[1], Steven A. Mazzuca[2] and Christopher France[3], [1]Indiana University, Indianapolis, IN, [2]Indiana Univ Sch of Med, Indianapolis, IN, [3]Ohio University, Athens, OH

Purpose: Traditional CBT (face-to-face) has been shown to improve the clinical symptoms of FM. However, due to cost and scarcity of skilled therapist, practical application of CBT is limited. More importantly, although various psychological models have been theorized to explain CBT's beneficial effects, the biological mechanisms of CBT have been unexplored. Thus, we sought to determine the effects of telephone-delivered CBT on self-reported pain, physical function and nociceptive responsivity (i.e., nociceptive flexion reflex/NFR). NFR is a neurophysiological tool that measures responsivity to noxious stimulation via elicitation of a spinal withdrawal reflex upon stimulation of a sensory nerve.

Method: FM patients with Fibromyalgia Impact Questionnaire (FIQ)-pain score ≥ 4 and FIQ-physical impairment (FIQ-PI) score ≥ 2 were randomized to 6 sessions of telephone-delivered CBT or usual care (UC). CBT was delivered from week 0 to 6. Assessments were done at baseline, week 6 and 12. Study endpoint was the change from baseline in NFR threshold (milliamperes/mA). Clinical endpoints were the changes from baseline in the FIQ-PI, FIQ-pain; and the proportion of subjects achieving a clinically meaningful reduction (i.e. 14%) in the total FIQ.

Results: The 28 female participants had a mean age of 47 ± 11 years, mean disease duration of 12 ± 6 years, and were 80% white, and 83% with > high school education. At study entry, 15 (53%) were on narcotics and 19 (68%) were on antidepressant other than tricyclics. There were no differences in the demographics, depression severity, and medication usage between the treated and the usual care groups.

Baseline Characteristics

	CBT (n=15)	**UC** (n=13)
Nociceptive Responsivity		
NFR threshold (mA†)	32.5 ±15	37.6 ± 10
Clinical Outcomes		
FIQ-PI (0-10*)	5.6 ± 1.8	5.4 ± 1.7
FIQ-pain (0-10*)	7.6 ± 1.8	7.8 ± 1.4
Total FIQ (0-100*)	62.2 ± 15	67.8 ± 12

†Lower values reflect higher responsivity to electrical stimulation.

***Higher scores reflect more severe symptoms.**

Mean Changes from Baseline to Week 12

	CBT (n=15)	UC (n=13)	Mean Difference	P value
Nociceptive Responsivity				
NFR threshold	7.3 ± 9.2	-5.4 ± 13.5	-12.7 ± 11.4	0.006
Clinical Outcomes	-0.6 ± 2.3	0.5 ± 1.2	1.1 ± 1.9	0.13
FIQ–PI				
FIQ-pain	-0.6 ± 1.6	-0.3 ± 1.7	0.3 ± 1.7	0.6

Compared to usual care, CBT resulted in marginal improvements in clinical outcomes (table) and in the percent of patients with clinically meaningful improvements in total FIQ score (33% vs. 15%, p=0.3). However, CBT also resulted in a significant lowering of nociceptive responding, as evidenced by an increase in the NFR threshold, relative to controls.

Conclusion: This small pilot study was powered primarily to detect an effect of CBT on the NFR threshold. These data indicate the need for a larger study to confirm that changes in central sensitization, as reflected in the NFR, may underlie the benefits of CBT in FM patients.

OAZ Interfere with the Production of Antinuclear Antibody in Patients with Systemic Lupus Erythematosus. Xuebing Feng[1], Ronliang Li[2], Jing Huang[2], Betty P. Tsao[3] and Lingyun Sun[1], [1]the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [3]Division of Rheumatology, UCLA, Los Angeles, CA

Purpose: To study whether gene expression levels of OAZ (Olf1/EBF associated zinc finger protein, a transcription factor encoded by a positional SLE candidate gene) and its possible downstream gene, ID3 (inhibitor of differentiation 3), play a functional role in the pathogenesis in SLE.

Method: Gene expression levels in peripheral blood cells (PBLs) measured using quantitative real-time quantitative PCR (qPCR) were assessed for association with disease activity and the presence of specific autoantibodies. Peripheral blood mononuclear cells (PBMCs) from 5 SLE patients were incubated with specific siRNAs for 3 days, then cells were harvested for measuring mRNA levels using qPCR, and supernatants for levels of secreted cytokines, chemokine, and antinuclear antibodies (ANA) using ELISA. Indirect immunofluorescence was also applied for ANA detection.

Results: OAZ and ID3 gene expressions in PBLs from 30 SLE patients were significantly increased than PBLs from 20 normal controls ($p < 0.01$). In SLE patients, OAZ and ID3 transcripts were positively correlated with SLEDAI score ($r = 0.74$ and 0.69, $p < 0.0001$) and OAZ expressions were higher in those positive for IgG antibodies to dsDNA or RNA-containing proteins ($p < 0.05$). Co-culturing with OAZ siRNAs reduced mRNA levels of OAZ and ID1-3 by 73.5%, 68.7%, 70.2% and 67.7% respectively as compared to those co-cultured with non-targeting siRNA. Compared to negative control groups, OAZ silencing resulted in reduced ANA (shown in Figure 1), IFN-gamma, IL-10, IL-12 and IL-21, and elevated CCL2 levels in culture supernatants ($p < 0.05$). The declined ANA levels correlated with the ratio of OAZ inhibition ($r = 0.88$, $p = 0.05$), reduced IL-21 levels ($r = 0.99$, $p < 0.01$), and elevated CCL2 levels ($r = -0.98$, $p < 0.01$).

Conclusion: OAZ, a new lupus candidate gene, is highly expressed in SLE PBLs, which may act through the regulation of ID genes as well as cytokines and chemokines to increase the ANA secretion. Our data show a role of OAZ-ID pathway in the pathogenesis of SLE.

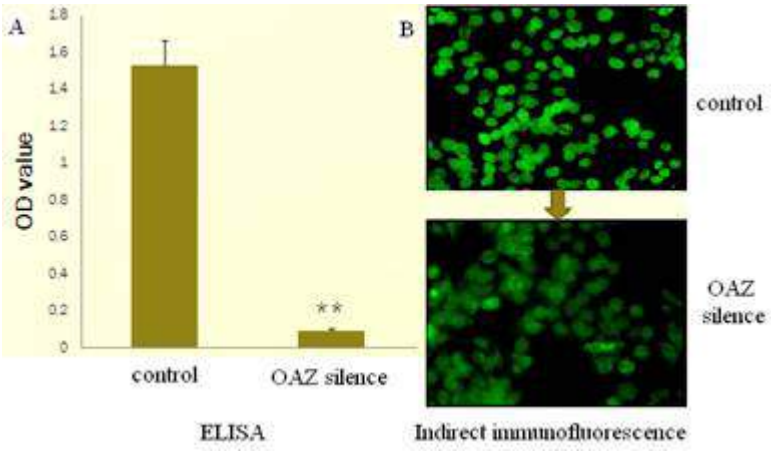

Figure 1 Decreased ANA production after OAZ silence as detected by ELISA and indirect immunofluorescence.

The Epigenome of SLE. Kathleen E. Sullivan[1], Zhe Zhang[2] and Michelle Petri[3], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Bioinformatics, Philadelphia, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Systemic lupus erythematosus is a polygenic disorder where recent data have implicated interferons in the pathogenesis of the disease. The expression of many genes downstream of interferons are regulated at the level of histone modifications. We examined whether the disease process could significantly alter histone modifications at multiple gene loci and in turn alter the competence for expression of genes relevant to the SLE disease process.

Method: We examined H4 acetylation and gene expression in monocytes from patients with systemic lupus erythematosus to define alterations to the epigenome. Monocytes from 14 controls and 24 SLE patients were used for analysis by chromatin immunoprecipitation for H4 acetylation and gene expression arrays. Primary monocytes treated with a-interferon were used as a comparator. Data were analyzed for concordance of H4 acetylation and gene expression. Network analyses and transcription factor analyses were performed to identify potential pathways.

Results: H4 acetylation was significantly altered in monocytes from patients with systemic lupus erythematosus. Sixty three percent of genes with increased H4 acetylation had the potential for regulation by IRF1. IRF1 binding sites were also upstream of nearly all genes with both increased H4 acetylation and gene expression. a-interferon was a significant contributor to both expression and H4 acetylation patterns but the greatest concordance was seen in the enrichment of certain transcription factor binding sites upstream of genes with increased H4 acetylation in SLE and genes with increased H4 acetylation after a-interferon treatment.

Conclusion: Monocytes have been significantly altered as a consequence of the disease process. Alterations to the epigenome can be long lived and can contribute to sustained pathologic cell behavior.

RFX1 Regulates the Expression of CD11a and CD70 in CD4+ T Cells of Patients with Systemic Lupus Erythematosus. Ming Zhao[1], Fei Gao[1], Xiaoyan Wu[1], Jinling Tang[1], Yongqi Luo[1], Yimin Sun[2], Bruce C. Richardson[3] and Qianjin Lu[1], [1]The Second Xiangya Hospital, Central South University, Changsha, China, [2]Tsinghua University School of Medicine, Beijin, China, [3]University of Michigan, Ann Arbor, MI

Purpose: Abnormal T lymphocyte activation plays an important role in the pathogenesis of systemic lupus erythematosus (SLE). CD11a and CD70 are overexpressed in $CD4^+$ T cells of patients with SLE, contributing to T cell autoreactivity and autoantibody production, respectively. To understand why these genes are overexpressed, we sought to identify key transcription factors involved in CD11a and CD70 regulation.

Method: Peripheral blood mononuclear cells from 35 patients with SLE and 30 healthy controls were isolated by Ficoll-Hypaque density gradient centrifugation, and the CD4+ subpopulation was extracted using Miltenyi beads. Transcription factor activity and expression levels were assessed using oligonucleotide array-based assays, real-time RT-PCR and Western blot. RFX1-expressing and RFX1 siRNA constructs were transfected into $CD4^+$ T cells using Human T cell Nucleofector kits. CD11a and CD70 transcription levels were measured by RT-PCR, and IgG levels were measured by ELISA. The promoter region of CD11a and CD70 were cloned into pGL3 vectors. The binding and regulatory activity of RFX1 was determined by ChIP and luciferase assays. Protein interactions with RFX1 were examined by immunoprecipitation.

Results: Compared to healthy controls, the activity of several transcription factors, including RFX1, MIF1 and SRF was downregulated in $CD4^+$ T cells from SLE patients . The reduction in RFX1 expression was confirmed by quantitative RT-PCR ($p<0.01$) and Western blot ($p<0.05$). Transfecting lupus CD4+ T cells with RFX1 led to significant decreases in CD11a and CD70 expression and B cell stimulation. In contrast, knocking down RFX1 expression with RNAi induced CD11a and CD70 overexpression in normal CD4+ T cells, and significantly increased IgG production by autologous B cells. Moreover, we found that RFX1 could directly regulate the expression of CD11a and CD70 by binding to their promoter regions, as shown by ChIP and luciferase reporter assays. In addition, IP revealed that the regulatory activity of RFX1 in $CD4^+$ T cells was dependent on the recruitment of co-repressors, such as the acetylation factor HDAC1 and the methylation factor DNMT1.

Conclusion: Our data suggest that overexpression of CD11a and CD70 in $CD4^+$ T cells of SLE patients is caused at least in part by the downregulation of RFX1. Reduced RFX1 may decrease the recruitment of HDAC1 and DNMT1 to the promoter regions of CD11a and CD70, facilitating their expression and promoting autoimmune responses.

109

Analysis of SLAM Family Receptors in SLE. Jong R. Kim[1], Rahul K. Patel[1], Stephen O. Mathew[1], Raymond M. Pertusi[2] and Porunelloor Mathew[1], [1]University of North Texas Health Science Center, Fort Worth, TX, [2]Harvard Vanguard Medical Associates, Boston, MA

Purpose: The SLAM family receptors play a critical role in activation and regulation of immune function.SLAM family receptor genes are also located on chromosome region 1q23, a region linked in genetic studies of systemic lupus erythematosus. Here, we investigated the expression and alternative splicing of 2 SLAM family receptors, 2B4 and CS1, in patients with systemic lupus erythematosus.

Methods: 45 patients with SLE and 30 healthy controls were studied. SLEDAI scores of SLE patients were calculated at the time of enrollment. Peripheral blood mononuclear cells (PBMC) were isolated and studied for 2B4 and CS1 expression on T, B, NK, and monocytes by flow cytometry. Total RNA was isolated from PBMC and reverse transcriptase PCR (RT-PCR) was performed for 2B4, CS1. Single-stranded conformational polymorphism (SSCP)-heteroduplex mobility shift assay (HMA) was conducted for analysis of 2B4 and CS1 polymorphisms.

Results: Overall proportions of 2B4+ and CS1+ PBMCs were comparable in SLE and control subjects. However, frequency of 2B4+ cells was significantly decreased in CD56+ NK cells and CD14+ monocytes from patients with SLE compared to healthy controls ($p<0.05$). Also, increased CS1+ expression was noted in B cells of SLE patients vs. healthy controls. This increased CS1+ expression was associated with increased percentage of CD19 low B cells. The proportion of CS1 expressing cells in T cells, NK cells and monocytes was not

significantly different between healthy controls and SLE patients. Two patients with SLE showed increased expression of h2B4-B splice variant over h2B4-A isoform, while 2 other SLE patients showed more predominance of h2B4-A over 2B4-B than healthy controls. However, there was no direct correlation between differential expression ratio of h2B4-A over h2B4-B and SLEDAI. Healthy individuals as well as most of SLE patients expressed similar or higher level of CS1-L isoform over CS1-S. However, the CS1-S isoform was overexpressed in 2 SLE patients.

Conclusion: These findings suggest a role for the differential expression of SLAM family receptors 2B4 and CS1 in systemic lupus erythematosus. In particular, we found decreased 2B4+ expression in NK cells and monocytes and increased CS1+ expression in B cells of SLE patients versus controls, as well as differential isoform expression in some SLE patients. Further functional studies and downstream signaling studies may be warranted to help confirm these findings and characterize their contribution to immune dysregulation in SLE.

Association Study of a Polymorphism of the CD244 Gene with Susceptibility to Systemic Lupus Erythematosus and with Clinical Features. Yuko Ota, Yasushi Kawaguchi, Manabu Kawamoto, Katsunori Ikari, Yasuhiro Katsumata, Takahisa Gono, Kae Takagi, Masako Hara and Hisashi Yamanaka, Tokyo Women's Medical University, Tokyo, Japan

Purpose: CD244 belongs to a signaling lymphocyte activation molecule (SLAM) family and is expressed on all NK, γ α, and memory CD8+ (αβ) T cells. Recent findings on the molecular mechanisms of CD244 have indicated their important roles in the immune system in NK cells and T cells. It is possible that SLAM family proteins contribute to the development in autoimmune disorders, because a causal variant of a murine lupus model was identified in Ly108 gene, another member of the SLAM family. In human, a family-based association study of UK and Canadian families with systemic lupus erythematosus (SLE) revealed variants in the promoter and coding region of SLAMF7 and LY9, which were situated adjacent to CD244. The strongest association was detected in exon 8 of LY9. Those evidences suggest that CD244, one of the SLAM family, may be involved in disease susceptibility to SLE. Recently, it was reported that a single nucleotide polymorphisms (SNPs) in CD244 gene was significantly associated with susceptibility to RA. They did not replicate association of the LY9 gene with susceptibility to SLE in a Japanese population and very recent report did not replicate the association in 16 collections from 9 European countries, either. In the present study we explored the association of a single nucleotide polymorphism (SNP) of the CD244 gene with susceptibility to systemic lupus erythematosus (SLE) and with clinical manifestations of SLE in the Japanese population.

Method: Two hundred forty-three patients with SLE and 756 healthy controls (HC) were enrolled in this study. Two SNPs (rs6682654 and rs3766379) in the CD244 gene were determined by allelic discrimination with the use of a specific TaqMan probe.

Results: Only a SNP at rs3766379 of the CD244 gene was significantly associated with susceptibility to SLE (P = 0.023, odds ratio 1.3 [95% confidence interval 1.0-1.6]). The association was preferentially observed in subsets of SLE patients with nephritis and neuropsychiatric (NP)-lupus. The frequency of allele at rs6682654 was strongly associated with nephritis (P = 0.00065, odds ratio 2.0 [95% confidence interval 1.3-3.0]) and NP-lupus (P = 0.00000016, odds ratio 3.5 [95% confidence interval 2.1-5.7]), and the frequency of allele at rs3766379 was strongly associated with nephritis (P = 0.0014, odds ratio 1.9 [95% confidence interval 1.3-2.7]) and NP-lupus (P = 0.00000026, odds ratio 3.2 [95% confidence interval 2.0-5.0]).

Conclusion: In this study, the CD244 gene was one of susceptibility-genes in patients with SLE. Especially, there was a strong association in SLE patients with nephritis and NP-lupus, suggesting that this genetic marker could predict the involvement of those severe complications.

111

Differential MicroRNA Expression and the Contribution of MiR-126 to CD4+ T Cell DNA Hypomethylation in Systemic Lupus Erythematosus. Sha Zhao, Yu Wang, Yusheng Liang, Hai Long, Shu Ding, Ming Zhao, Heng Yin and Qianjin Lu, The Second Xiangya Hospital, Central South University, Changsha, China

Purpose: Epigenetic alterations, particularly DNA hypomethylation, play essential roles in the pathogenesis of systemic lupus erythematosus (SLE). MicroRNA (miRNA) genes are also implicated in autoimmune disorders, and are known to be differentially expressed in SLE patients. Here we investigated the expression of miRNAs in $CD4^+$ T cells from patients with SLE, as well as the effect of miRNA-126 upregulation on T cell DNA hypomethylation.

Method: Total RNA was extracted from $CD4^+$ T cells of 12 patients with SLE and 10 age- and gender-matched controls, and analyzed by miRNA microarray. Expression levels of miR-126 and miR-142-3p were further confirmed by stem-loop qPCR for 30 SLE patients and 20 healthy controls. DNMT1 expression was determined by Western blotting in 8 SLE and 7 normal $CD4^+$ T cell samples. Control CD4+ T cells were transfected with a plasmid encoding miR-126 and a negative control plasmid. 48h after transfection, miR-126 and DNMT1 expression were detected by stem-loop qPCR and Western blotting, respectively. Phosphorylated and total PKC-δ and ERK1/2 were quantified by Western blotting. The methylation status of CpG pairs within CD11a and CD70 promoter regulatory elements was detected by sodium bisulfite sequencing, and the expression of CD11a and CD70 was determined by flow cytometry.

Results: Of the 900 miRNAs analyzed by microarray, 11 were significantly upregulated or downregulated in SLE CD4+ T cells relative to controls, four of which, miR-126, miR-142-3p, miR-142-5p and miR-638, putatively target epigenetic regulation-associated genes. The upregulation of miR-126 and downregulation of miR-142-3p were confirmed by stem-loop qPCR ($p<0.001$, $p<0.05$, respectively). DNMT1 expression was decreased in SLE $CD4^+$ T cells, compared to normal controls ($p<0.05$), and negatively correlated with miR-126 expression ($r=-0.628$, $p=0.012$). 48h after transfecting $CD4^+$ T cells with a miR-126-encoding plasmid, DNMT1 expression and the phosphorylation of PKC-δ and ERK1/2 were decreased ($p=0.014$, $p= 0.048$, $p=0.003$, respectively). Additionally, methylation levels of the CD11a and CD70 promoter regions were significantly decreased (p=0.008, p=0.025, respectively), whereas both CD11a and CD70 expression levels were increased (p=0.002 and 0.007, respectively) compared to negative controls.

Conclusion: Our data suggest that differential expression of a set miRNAs in $CD4^+$ T cells contribute to the pathogenesis of SLE. Specifically, by inhibiting DNMT1 expression as well as PKC-δ and ERK1/2 phosphorylation, miR-126 may trigger DNA demethylation in $CD4^+$ T cells of patients with SLE.

112

Increased Proximal B Cell Receptor Signaling in the Naive B Cell Population of SLE Patients. Nan-Hua Chang[1], Julie Kim[2], Elaheh Aghdassi[1], Dafna Gladman[3], Murray Urowitz[3], Paul R. Fortin[3] and Joan E. Wither[3], [1]University Health Network, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: SLE patients have an increased proportion of activated B cells in their peripheral blood. This may be due to B cell hyper-responsiveness, as supported by studies demonstrating increased calcium flux and tyrosine phosphorylation following IgM crosslinking of the B cells. However, in many of these studies, the precise B cell subsets that mediate this altered response have not been identified. In this study, PhosFlow was used to address this question.

Method: Patients (N=26) satisfying at least 4 ACR criteria, taking ≤ 20 mg of prednisone, and between the ages of 18-44 yrs were recruited from the University of Toronto Lupus Clinic. Healthy controls (N=16) without a family history of systemic autoimmune disease were also recruited. PBMCs were isolated over a Ficoll gradient, rested for 1 hr at 37°C, and stimulated with goat anti-human IgM $F(ab')_2$ Ab for 2 or 10 min. The cells were then fixed and frozen at -80°C. Upon thawing the cells were stained with various combinations of labeled mAb to identify specific B cell subsets, permeabilized with methanol, and then stained with Ab directed against phospho (p)-SYK, p-PLCγ2, and p-ERK.

Results: SLE patients have increased basal levels p-SYK and p-ERK in the $CD20^+IgD^+CD27^-$ naïve B cell subset as compared to controls. Basal levels of p-SYK, but not p-ERK, significantly correlated with the proportion of activated $CD86^+$ cells in this subset, but not with disease activity, as measured by the SLEDAI-2K. The naïve B cell subset of SLE patients also demonstrated increased levels of p-SYK following IgM crosslinking at 2 and 10 min as compared with controls (mean ± SD increased % above background; 2 min , controls = 9.75 ± 7.69, patients = 17.64 ± 13.71, p=0.022; 10 min, controls = 5.48 ± 4.09, patients = 11.49 ± 9.54, p= 0.0088). Similar trends to increased

proportions of p-PLCγ2^{+} and p-ERK^{+} cells were also seen but did not achieve statistical significance. There was a significant correlation between the proportions of p-SYK^{+} and p-PLCγ2^{+}, but not p-ERK^{+}, cells in SLE patients. There was no correlation between the levels of these signaling molecules following activation and their basal levels, disease activity, or treatment. In the transitional B cell subset, CD38^{++}IgM^{high} subset of the naïve B cell population, basal levels of p-SYK or p-ERK were not elevated; yet, there was an increase in the levels of p-SYK following IgM crosslinking (mean ± SD increased % above background; 2 min, controls = 33.04 ± 9.86, patients = 60.32 ± 16.34, p<0.0001; 10 min, controls = 18.37 ± 11.98, patients = 33.18 ± 17.28, p= 0.0029).

Conclusion: The naïve B cell compartment of SLE patients is hyper-responsive to IgM crosslinking and can be seen earlier in transitional B cells. The altered expression of p-SYK suggests that this results from differences in proximal signaling events.

Elevated Levels of Cytokines and Chemokines in Patients with SLE in a Multi-Center, Multi-Ethnic, US Multi-Institutional Cohort.

Alan M. Seif[1], Gerald Mc Gwin II[2], Renan Aguilar-Valenzuela[1], Laura Aline Martinez-Martinez[1], Elizabeth Papalardo[1], Jigna Liu[2], John D. Reveille[3], Luis M. Vila[4], Neha Dang[1], Ellis Doan[1], Graciela S. Alarcon[2] and Silvia S. Pierangeli[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Texas Health Science Center Houston, Houston, TX, [4]Univ of PuertoRico Schl of Med, San Juan, PR

Purpose: Studies have proposed that certain cytokines, chemokines and cellular adhesion molecules, are associated with SLE but whether these biomarkers are elevated in plasma of SLE patients and their association with disease activity is not clearly known. Objectives: a) To examine whether the levels of cytokines/chemokines are elevated in SLE patients and whether they correlate with disease activity (SLAM-R) and with damage accrual (SLICC-ACR Damage Index, SDI).

Method: Sera/plasma from 56 SLE patients (ACR criteria) from a multi-ethnic, multi-center cohort were assessed. Patients that were on more than 10 mg prednisone/day or on other immunosuppressive therapy were excluded; likewise patients that were on either statins or hydroxycholoroquine. In the SLE group (n=56, age range 16-67), 87% were females. In the control group (n=32 with no evidence of autoimmune or inflammatory diseases; age range: 18-65), 85% were females. Levels of IL1b, IL-6, IL-8, IFN- α, IP-10, MCP-1. VEGF, TNF- α, VEGF were measured in serum using a Millipore Millliplex™ Multiplex Assay, anticardiolipin antibodies (aCL), sE-sel, sVCAM-1 and sTF were detected by ELISA, and hsCRP by nephelometry.

Results: aCL IgG, aCL IgM and hsCRP were elevated in 64%, 13% and 50%of the SLE subjects, respectively. Other results in table below.

Biomarker	# of SLE samples elevated/(%)	p values SLE vs. controls
IL1b	18/56 (32)	0.1067
IL-6	32/56 (57)	<0.0001
IL-8	19/56 (32)	0.5552
TNF-α	31/56 (55)	<0.0001
VEGF	43/56 (77)	0.0002
IFN-α	43/56 (77)	<0.0001
MCP-1	17/56 (30)	0.0919
IP-10	53/56 (94)	<0.0001

sCD40L	51/56 (91)	<0.0001
sTF	12/14 (86)	<0.0001
sE-sel	10/21(48)	<0.0001

The levels of IFN-α correlated with SLAM-R scores but statistical significance was not reached (p=0.0546); the levels of IL1-b and sVCAM-1 correlated with SDI scores (p=0.0476 and 0.0009, respectively).

Conclusion: Significant number of SLE patients' samples had elevated levels of IgG aCL, hsCRP, IL-6, TNF-α, VEGF, IFN-α, IP-10, sTF, E-sel, sCD40L and their titers were significantly different from controls. IFN- α levels correlated with disease activity (SLAM-R scores) and IL-1b and sVCAM-1 levels correlated with SDI scores. This study underscores the importance of identifying biomarkers of disease that may help predict disease activity and/or damage and possibly improve the treatment strategies of patients with SLE.

IL-21R Expression and IL-21/IL-21R Interaction On B and T Cell Subsets From Lupus Patients and Controls. Vinh Nguyen[1], Christelle Samen[2] and Violeta Rus[1], [1]University of Maryland Sch of Medicine, Baltimore, MD, [2]University of Maryland at Baltimore County, Baltimore

Purpose: IL-21 plays an important role in the development of autoimmunity in murine models of lupus. Recent studies have revealed a strong association between genetic polymorphisms in IL-21 and IL-21R and SLE. Our group and others have reported increased expression of IL-21 in CD4 cells and serum of patients with active SLE. While these data suggest that IL-21 blockade may be an attractive therapeutic target, limited data currently available have shown that IL-21R expression and IL-21 induced proliferative responses are decreased in B cells from SLE patients, suggesting that IL-21 blockade might not be suitable in SLE patients. To address this question we set to characterize the expression of IL-21R and the effect of IL-21/IL-21R interaction on subsets of T and B cells from SLE patients and controls.

Methods: PBMC were obtained from 20 patients with SLE and 18 controls. IL-21R expression was determined by RT-PCR from purified CD4 and CD19 cells and by flow cytometry of unstimulated and stimulated naïve and memory CD4 T cells and B cells. The proliferative response of stimulated CD4 and CD19 cells to IL-21 was determined by [^{3}H] -Thymidine incorporation. IL-21 induced plasma cell (PC) differentiation, STAT3 activation, IgG and IL-10 production was determined by immunostaining and ELISA.

Results: IL-21R mRNA expression did not differ in CD4 and CD19 cells from SLE patients and controls. Surface expression of IL-21R was detected at low levels on unstimulated CD4 cells from SLE patients and controls (MCF 16.7±7 and 15.9±7, respectively) and was upregulated to a similar extent with anti-CD3/CD28 stimulation in both groups (MCF 19.8±7 and 19.4±7, respectively). IL-21R expression was higher on unstimulated and stimulated memory CD4 compared to naïve CD4 cells. CD4 cells from both patients and controls proliferated in a dose dependent fashion in response to IL-21. The stimulation index was significantly decreased in lupus patients compared to controls at lower but not higher IL-21 doses. IL-21R expression on lupus B cells displayed a trend toward upregulation at baseline (MCF:51± 20 for patients vs. 43±18 for controls) which was further upregulated with anti-CD40 stimulation (MCF: 58±15 for patients vs. 48±12 for controls). Furthermore, IL-21 enhancement of anti-CD40 induced B cell proliferation displayed a trend for higher responsiveness in lupus patients at the highest dose of IL-21. PC differentiation was enhanced to a similar extent by IL-21 in both patients (from 7%±3% to 19%±10%) and controls (from 5%±3% to 16%± 6%). Similarly, levels of IL-21 induced STAT3 activation, IgG and IL-10 production were comparable in B cells from patients and controls.

Conclusion: IL-21R expression and the responsiveness of B cells to IL-21 are comparable in lupus patients and controls. Increased IL-21 production by CD4 T cells may promote the generation of T cell dependent B cell responses in human SLE. Therapeutic targeting of IL-21 could be beneficial in patients with SLE.

Autoantibodies to Angiotensin Converting Enzyme 2 in Patients with Rheumatic Diseases. Yuko Takahashi, Shiori Haga, Hiroyuki Yamashita, Yukihito Ishizaka and Akio Mimori, International Medical Center of Japan, Tokyo, Japan

Purpose: Angiotensin-converting enzyme 2 (ACE2), a homologue of ACE, degrades angiotensin (Ang) II to Ang-(1-7). Recent studies have indicated that ACE2 plays a vasoprotective role in cardiovascular pathophysiology. We explored the hypothesis that serum autoantibodies to ACE2 predispose patients with rheumatic diseases to vasculopathies.

Methods: Serum samples were obtained from 30 patients with systemic lupus erythematosus (SLE), scleroderma, or mixed connective tissue disease, and 30 normal control subjects. Of these, 9 patients had vasculopathies including pulmonary arterial hypertension (PAH) (n=4), progressive digital ischemia (n=2), or cutaneous vasculitis (n=3). The sera were assessed for anti-ACE2 antibodies by enzyme-linked immunosorbent assay (ELISA) using purified recombinant human ACE2.

Results: Serum anti-ACE2 antibodies were detected in all of the 9 patients with vasculopathies and were negative in the remaining patients and healthy subjects. A patient with active SLE and ischemic digital gangrene (case 1) and a scleroderma patient with lethal PAH of rapid progression (case 2) showed extremely high serum levels of anti-ACE2 antibodies. The sera of case 1 and case 2 showed a deficient peptidase activity of ACE2. Digital ischemia in case 1 resolved after combination therapy with a steroid, vasodilating drugs, and plasmapheresis. The serum tests in case 1 after therapy showed that the ELISA score of anti-ACE2 antibodies was markedly reduced ($p<0.05$) and ACE2 activity had recovered significantly ($p<0.05$) compared to those before therapy. The serum ACE2 protein levels assessed by immunoblotting were similar between before and after therapy for case 1. These results suggested that anti-ACE2 antibodies inhibited enzymatic activity of ACE2.

Conclusion: Serum autoantibodies to ACE2 may be associated with vasculopathies in patients with rheumatic diseases.

Proteomic Analysis of Autoantigens in SLE Patients with CNS Involvement. Nobuko Iizuka[1], Kazuki Okamoto[2], Reiko Matsushita[1], Mitsumi Arito[2], Kouhei Nagai[2], Manae S. Kurokawa[2], Naoya Suematsu[2], Kayo Masuko[2], Shunsei Hirohata[1] and Tomohiro Kato[2], [1]Kitasato University School of Medicine, Kanagawa, Japan, [2]St.Marianna University Graduate School of Medicine, Kawasaki, Japan

Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that affects multiple organs. Involvement of central nervous system (CNS) in SLE (CNS Lupus) indicates poor prognosis. The molecular mechanism of CNS Lupus has not been clarified yet. Several reports suggest that patients with CNS Lupus have anti-neuronal cell antibodies in cerebrospinal fluid (CSF) which possibly cause CNS manifestations. Further, the anti-neuronal cell antibodies can be a diagnostic marker for CNS Lupus when their target antigens are identified. Thereby, using proteomics analysis, we tried to identify candidate autoantigens for the anti-neuronal cell antibodies.

Method: Serum samples were prepared from 30 patients with CNS Lupus (CNS Lupus group) and 30 patients with SLE but not CNS involvement (non CNS-SLE group). Proteins, extracted from cultured human neuroblastoma (SK-N-MC) cells, were separated both by SDS-PAGE (1-DE) and two-dimensional electrophoresis (2-DE). The separated proteins were transferred to PVDF membranes and autoantigenic proteins were detected by western blot using the serum samples. Then, the detected autoantigenic proteins were identified using matrix-assisted laser desorption/ionization-time-of-flight (MALDI-TOF) mass spectrometry and the subsequent protein date base searching.

Results: On the 1-DE western blot analysis, 4 protein bands (B1-B4) were positively reacted more frequently (p-value <0.02) in the CNS Lupus group than in the non CNS-SLE group. In the 2-DE, we detected 3 spots which corresponded to the B1 band, one spot for the B2 band and 2 spots for the B3 band. We could not detect the spots which corresponded to the B4 band. We identified 3 proteins for the B1 band which were NADH dehydrogenase ubiquinone iron-sulfur protein 3 (NDUFS3), heat shock protein beta-1 (HSPB1) and peroxiredoxin-4 (PRDX4). To identify the antigenicities of these 3 proteins, we prepared PRDX4 recombinant protein and commercially obtained NDUFS3, HSPB1 recombinant proteins as antigens for western blot. All of the 5 serum samples which reacted to the B1 band reacted to only PRDX4 but not NDUFS3 nor HSPB1. We also identified ubiquitin carboxyl-terminal hydrolase isozyme L1 (UCH-L1) from one spot in the B2 band and histon H2A type1 were identified from both of 2 spots for the B3 band.

Conclusion: We identified 3 candidate autoantigens for anti-neuronal cell antibodies which can be a useful marker specific for CNS Lupus.

Expression Profiling of the Vascular Endothelium in Patients with SLE Using a Novel Methodology: Human Endothelial Sampling Coupled with Microarray Analysis. Diana Goldenberg[1], Mikhail Olferiev[1], Duygu Onat[2], Mary K. Crow[1], Paolo Colombo[2] and Jane E. Salmon[1], [1]Hospital for Special Surgery, New York, NY, [2]Columbia University College of Physicians and Surgeons, New York, NY

Purpose: Systemic inflammation is considered causative of endothelial dysfunction and thereby accelerates atherosclerosis in Systemic Lupus Erythematosus (SLE). In humans, determination of endothelial function relies on measurement of endothelium-dependent vasodilation and circulating endothelial progenitor cells (EPCs). Both techniques have disclosed fundamental abnormalities in SLE; however, neither can identify the molecular events underlying these abnormalities. Herein, we introduce endothelial cell (EC) sampling coupled with gene expression profiling as a new method to characterize the pathophysiology of endothelial dysfunction in SLE.

Methods: Seven ambulatory adult patients meeting American College of Rheumatology criteria for SLE (4 males, 3 females) were studied (29.7 ± 8.2 yrs, mean SLEDAI score 9.3) and 6 age-matched healthy subjects were studied. ECs were collected from arm veins using endovascular wires. ECs were purified; amplified RNA was hybridized with Affymetrix HG-U133 2.0. Data was analyzed using GeneSpring GX 10.0 software. Samples were normalized to the baseline median level according to the MAS5 algorithm. Student T test analysis for multiple samples was performed. Differentially expressed genes with >2.0 fold expression and $p<0.05$ were selected.

Results: No adverse events were observed. A total of 2108 genes were differentially expressed between the SLE patients and controls. Functional analysis identified genes linked to apoptosis (TRAF2, AIFM3 and CASP12), cellular adhesion (EED), stress and immune response (SOCS2), inflammation (CES1), interferon (IFIT2, IFNAR1, OAS2, PRKRA and STAT6) and the insulin-like growth factor (IGF) pathways (PAPP-A, IGF-1, IGF-1 receptor, IGFBP3 and IGFBP4).

Conclusion: We documented feasibility, safety, and potential clinical relevance of endothelial expression profiling in SLE. This novel approach may identify processes relevant to the pathophysiology of endothelial dysfunction in SLE, disclose yet unrecognized biologic pathways, and generate novel hypotheses to be tested further.

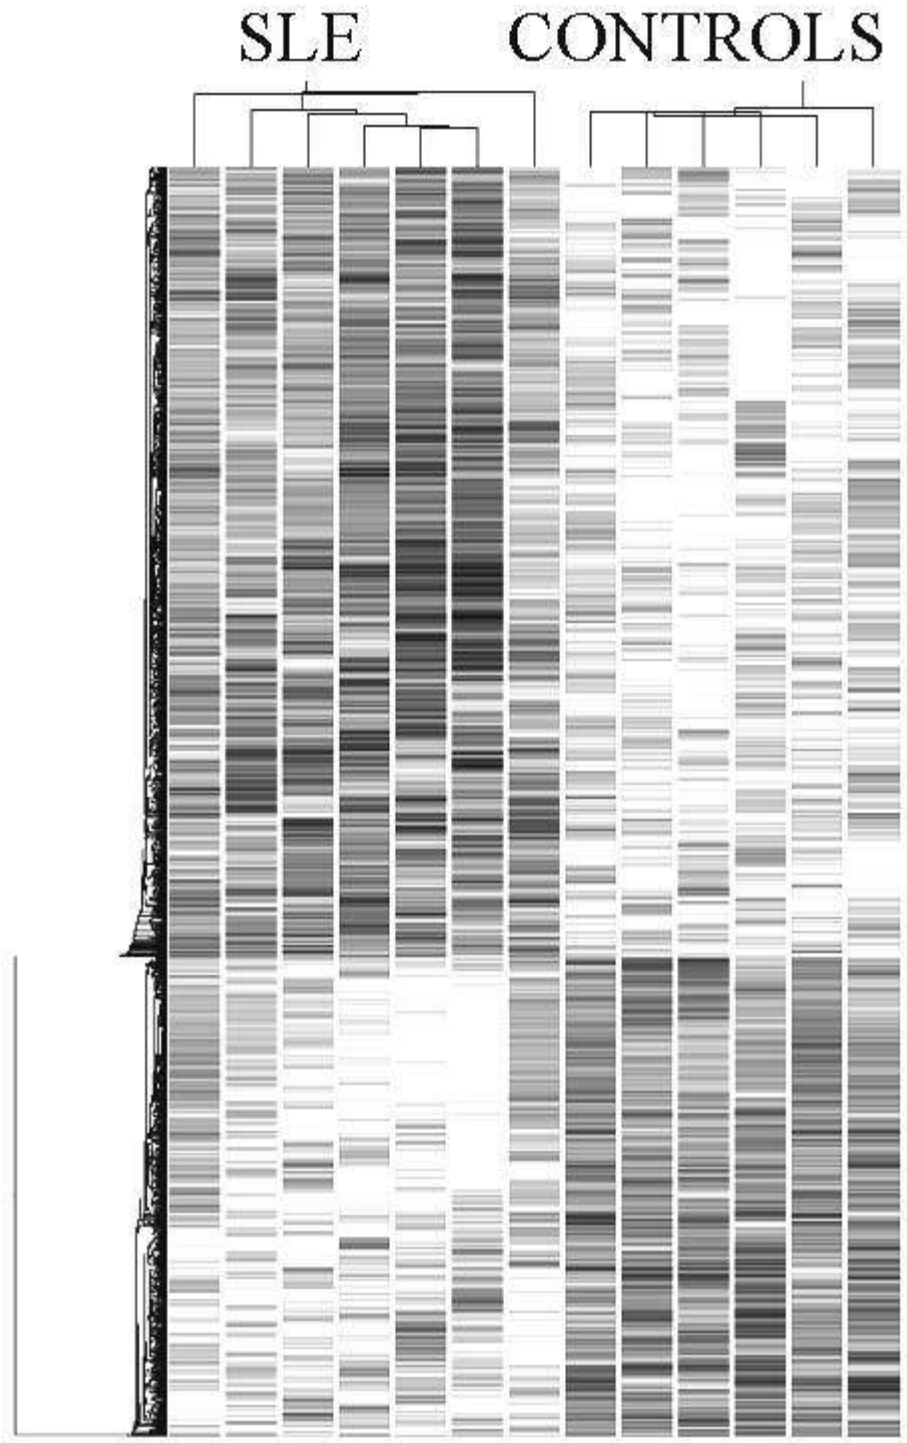

Figure 1. Hierarchical cluster of endothelial gene expression. Black represents upregulation in SLE compared with controls and white represents downregulation in SLE compared with controls.

Cyclophilin A Is High Expressed in Active SLE and Induced Increased CD147 and Interferon Gamma Production in Jurkat T Cells.
Yile Ren, Wenfeng Tan, Xiaohua Liu and Miaojia Zhang, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Purpose: It has been reported that high expression of CD147 and interferon gamma (IFN-γ) in activated T lymphocytes may contribute to development of SLE , but the exact mechanism remains unclear. Recently, the accumulated evidence shown that Cyclophilin A(CyPA) might act as a bridge between T lymphocytes and SLE and play an important role in SLE pathogenesis, which prompted us to test the relationship between CyPA, CD147 and IFN-γ.

Method: Sera were collected from 37 active SLE, 20 inactive SLE and 30 normal controls and CyPA levels were detected by ELISA. After Jurkat T cells were treated with CyPA(0.2 μg/ml)for 24 h, the expression of CD147 was measured by flow cytometry. Jurkat T cells were also treated with CyPA(2 μg/ml), PHA(5 μg/ml)and CyPA(2 μg/ml)plus PHA(5 μg/ml)for 6h or 24h, respectively, and the expression of IFN-γ mRNA and protein in supernatant were detected by RT-PCR and ELISA.

Results: The mean serum CyPA level was significantly higher in active SLE patients (2.72ng/ml) compared to in inactive SLE patients (0.81ng/ml) or in normal controls (0.34ng/ml)($p < 0.05$). After stimulated with CyPA for 24h, the positive rate of CD147 in Jurkat T cells significantly increased (Stimulated group vs non-stimulated: 52.01% vs. 40.67%, $p<0.05$). The higher expression of IFN-γ mRNA only be detected in Jurkat T cells after treated with CyPA plus PHA for 6h. IFN-γ protein level also shown a significant increase in supernatant of Jurkat T cells after treated with CyPA plus PHA compared to with CyPA or PHA alone. (CyPA plus PHA vs CyPA vs PHA: 16.51pg/ml vs 2.04pg/ml vs 2.74 pg/ml, $p<0.05$).

Conclusion: Cyclophilin A was high expressed in active SLE and induced a increased CD147 and IFN-γ production in Jurkat T cells, which suggested that CyPA might contribute to SLE disease activity by triggering T lymphocytes activation.

Dual Effect of *MIF* Gene Polymorphisms On the Development and the Severity of SLE.
A G. Sreih[1], R. Ezzeddine[2], L. Leng[1], A. LaChance[1], G. Yu[1], Elisabet Svenungsson[3], Iva Gunnarsson[3], Y. Mizue[4], J. Cavett[5], S. Glenn[5], B. Pons-Estel[6], A. Perl[7], J. Salmon[8], Marta E. Alarcon-Riquelme[9], J.B. Harley[5] and R. Bucala[1], [1]Yale Univ Schl of Medicine, New Haven, CT, [2]BMS, Wallingford, CT, [3]Karolinska Institutet, Stockholm, Sweden, [4]Sapporo Immunodiagnostics, Tokyo, Japan, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]Sanatorio Parque, Rosario, Argentina, [7]Upstate Medical Univ, Syracuse, NY, [8]Hospital for Special Surgery, New York, NY, [9]Uppsala University, Uppsala, Sweden

Purpose: SLE is a complex autoimmune disease and its etiology remains unknown. Functional polymorphisms in the gene for Macrophage Migration Inhibitory Factor (MIF) have been associated with several autoimmune disorders, and we hypothesized that *MIF* expression may influence the development or the clinical severity of SLE. There are two polymorphic sites in the *MIF* promoter that correlate with MIF production in vivo: a -173 G/C SNP and a -794 $CATT_{5-8}$ repeat. In the latter case, increasing repeat number leads to higher *MIF* expression. We studied the association of *MIF* gene polymorphisms and MIF plasma levels with SLE susceptibility and severity.

Method: The study consisted of 1369 patients and 1826 controls from the US, Sweden, and Argentina, and focused on 2 ethnic groups: Caucasians and African-Americans. The frequencies of high expression *MIF* genotypes (-173*C or -794 $CATT_7$) and high expression haplotypes (-173*C/-794 $CATT_7$) were compared between patients and controls, and in the same SLE cohort, between patients with severe end-organ involvement and those without. We also compared the frequency of low expression -794 $CATT_5$-containing genotypes between those groups. Plasma MIF was measured in 200 patients and controls and analyzed in relation to *MIF* polymorphisms.

Results: The frequency of high expression -173*C-containing genotypes was lower in the African-American patients than controls (49.7% vs 64.2%, p=0.007), whereas the frequency of high expression -794 $CATT_7$-containing genotypes was lower in the Caucasian patients as compared to controls (21% vs 24%, p=0.05). Both Caucasians and African-Americans with -173*C/-794 $CATT_7$ haplotypes had lower SLE

incidence (OR 0.63 [0.53, 0.89], p=0.001 in Caucasians, and OR 0.46 [0.23, 0.95], p=0.012 in African-Americans). MIF levels were lower in patients than in controls and reflected the low frequency of high expression *MIF* polymorphisms in the patient group. In contrast, Caucasian patients with nephritis, serositis, and males with cerebritis had reduced frequencies of low expression genotypes (-794 $CATT_5$) compared to patients without organ involvement (36% vs 64%, p=0.023 for nephritis, 42% vs 58% p=0.005 for serositis, and 11% vs 89%, p=0.04 for cerebritis).

Conclusion: MIF plays a dual role in the pathogenesis of SLE. High expression *MIF* genotypes lower the susceptibility to SLE, however once SLE develops, low expression *MIF* genotypes confer protection from end-organ damage. These data highlight the complex relationship between immune cytokine activation and SLE. Since MIF is expressed upstream of cytokines such as TNF, these results support long-standing observations suggesting that TNF is protective with respect to SLE initiation.

Dysregulated Balance of Th17 and Th1 Cells in Systemic Lupus Erythematosus. Kamini M. Shah, Won-Woo Lee, Seong Wook Kang, Sang-Hyun Kim, Seung-Hyun Lee, Joe Craft and Insoo Kang, Yale University School of Medicine, New Haven, CT

Purpose: To analyze the balance of T helper (Th)17 and Th1 cell responses in peripheral blood from patients with systemic lupus erythematosus (SLE) and healthy subjects.

Method: Peripheral blood mononuclear cells from 25 adult patients with SLE and 26 healthy subjects were stimulated for 4 hours *ex vivo* with phorbol myristate acetate and ionomycin. The frequency of CD4+ T cells producing IL-17 and/or IFN-γ was measured using flow cytometry. The expression of Th17 cell-associated chemokine receptors CCR4 and CCR6 on CD4+ T cells as well as plasma levels of Th17-polarizing cytokines were assessed.

Results: Patients with SLE had an increased frequency of IL-17+CD4+ T cells (mean ± SD, 1.8 ± 1.26% vs. 0.6 ± 0.27%, $P < 0.001$) and CCR4+CCR6+CD4+ T cells (7.32 ± 7.27% vs. 2.18 ± 2.16%, $P = 0.021$) compared to healthy subjects. However, the frequency of IFN-γ+CD4+ T cells was similar between the two groups, indicating the altered balance of Th17 and Th1 cell responses in SLE. The frequency of IL-17+CD4+ T cells and CCR4+CCR6+CD4+ T cells correlated with disease activity ($r = 0.576$, $P = 0.003$ and $r = 0.645$, $P = 0.013$, respectively). Plasma levels of Th17-polarizing cytokine IL-6 was higher in patients with SLE than in healthy subjects (4421.95 ± 3608.13 pg/ml vs. 2803.08 ± 955.82 pg/ml, $P = 0.029$).

Conclusion: We demonstrate an enhanced Th17 cell response that correlates with disease activity in patients with SLE, proposing a potential role for IL-17 in the pathogenesis of lupus. Our data suggest that the mechanism involved in balancing Th17 and Th1 cell responses as well as in producing IL-6 are dysregulated in SLE, leading to the increased Th17 cell response. The utilization of CCR4 and CCR6 as markers for disease activity as well as therapy blocking IL-17 may be considered in SLE.

Mutations in Complement Regulatory Proteins Predispose to Preeclampsia in Patients with Lupus or Antiphospholipid Antibodies. Jane E. Salmon[1], Veronique Fremeaux-Bacchi[2], M. Kathryn Liszewski[3], Michael Triebwasser[3], Celia Fang[4], Marta Guerra[1], Lubka Roumenina[2], Michael D. Lockshin[1], Michelle Petri[5], D. Ware Branch[6], Carl A. Laskin[7], Joan T. Merrill[8], David Kavanagh[9], Jill P. Buyon[10] and John P. Atkinson[3], [1]Hospital for Special Surgery, New York, NY, [2]Hôpital Européen Georges Pompidou, Paris, France, [3]Wash Univ, St. Louis, MO, [4]S F VA Med Center, San Francisco, CA, [5]Johns Hopkins Univ, Baltimore, MD, [6]Univ of Utah, Salt Lake City, UT, [7]Mt. Sinai Hosp, Toronto, ON, [8]Okla Med Res Found, Oklahoma City, OK, [9]Univ Newcastle, Newcastle, United Kingdom, [10]NYU School of Medicine, New York, NY

Purpose: Pregnancy in women with SLE or antiphospholipid antibodies (APL) is associated with an increased risk for preeclampsia (PE). Our studies in pregnant mice indicate that complement activation targeted to placenta drives angiogenic imbalance, placental insufficiency

and endothelial injury. In normal pregnancies, excessive complement activation is prevented by complement regulatory proteins that are highly expressed on trophoblasts [including membrane cofactor protein (MCP), DAF, and CD59], as well as circulating complement regulatory proteins [complement factor H (CFH) and complement factor I (CFI)]. Loss-of-function mutations occur in CFH, MCP and CFI leading to undesirable complement activation in patients with atypical hemolytic uremic syndrome (aHUS), a thrombotic microangiopathy not unlike that seen in PE, APS and SLE. Here we use the PROMISSE Study (**P**redictors of p**R**egnancy **O**utcome: bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic lupus **E**rythematosus), a prospective study of 250 pregnant patients with SLE and/or APL, to test the hypothesis that impaired capacity to limit complement activation predisposes to PE.

Method: Genes for MCP, CFH, and CFI were sequenced in the 40 patients enrolled in PROMISSE who developed PE or had PE in a previous pregnancy. PE was defined as hypertension (>140 syst or >90 diast) and proteinuria (≥1+). PE patients were matched by age and ethnicity to 34 patients without PE [SLE and/or APL (disease controls, DC) and healthy controls (HC)] and MCP, CFH and CFI were sequenced.

Results: We discovered heterozygous mutations in 7 of 40 patients (18%) with PE: 4 in MCP, 2 in CFI and 1 in CFH. Five of these patients had complications in previous pregnancies. We did not find mutations in patients without PE (19 HC, 15 DC) (7/40 vs 0/34, $p<0.02$). Five of these 7 mutations were previously identified in aHUS: 3 with MCP A304V (associated with deficient control of alternative pathway activation) and 2 with CFI IVS12+5 G>T. Two patients had novel mutations: MCP K32N which is the first MCP mutation that exclusively causes impaired ability to bind and regulate C4b, and CFH S40A which enhances C3b binding.

Conclusion: The first genetic variants associated with PE in SLE and/or APL patients are in complement regulatory proteins. That mutations in complement regulatory proteins were present in 18% of PROMISSE patients with PE underscores the importance of complement in PE, defines likely mechanisms for increased risk in patients with SLE and/or APL, and suggests new targets for treatment.

Tuning of Adenosine-to-Inosine Editing in UCTH Gene Transcripts of Systemic Lupus Erythematosus (SLE) T Lymphocytes. Dama Laxminarayana[1], Kenneth O'Rourke[2] and Irene Olorenshaw[2], [1]Wake Forest Univiversity School of Medicine, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC

Purpose: Adenosine deaminases that act on RNA (ADARs) edit gene transcripts by the site specific conversion of adenosine to inosine by hydrolytic deamination at C6 of the Adenosine (A). The translation machinery reads inosine (I) as guanosine (G), leading post transcriptional A to G changes in the gene transcripts. Such alterations in the primary sequences of RNA molecules lead to increasing the flexibility of eukaryotic gene expression and alter the function of the affected RNAs. We and other investigators demonstrated the up-regulation of type I IFN inducible transcript editing gene, 150-kDa (ADAR), in SLE T lymphocytes. Such up-regulation of the 150-kDa ADAR1 alters the ratio of ADAR1 versus ADAR2 expression in SLE T cells. *Ubiquitin Carboxyl-Terminal Hydrolase (UCTH)* is a deubiquitinating enzyme and plays an important role in cellular functions. Therefore, the goal of these experiments is to identify and compare A to I editing in novel *UCTH* gene transcripts of healthy controls and SLE patients.

Methods: The *UCTH* gene transcripts are edited by ADAR enzymes. Therefore, we assessed the role of altered ADAR enzymes expression in editing of *UCTH* gene transcripts of SLE T cells. The base position numbers of *UCTH* gene transcripts reported here are used from the accession number AF056490. The UCTH gene transcripts from normal and SLE T cell samples were amplified and cloned into pCR2.1-TOPO vectors and analyzed for transcript editing. A total of 159 clones from eight control T cell samples and 200 clones from ten SLE patients were sequenced using T7 and M13 primers and an automated ABI-377 sequencer.

Results: Two hot spots for A to I editing were observed in the *UCTH* gene transcripts of SLE T cells and termed as site1 and 2. The site 1 consists of known edited bases and well documented as a substrate for ADARs. Seventy two percent of A to G discrepancies observed in *UCTH* gene transcripts of control samples are clustered in site 1. The frequency of such editing in this site of SLE samples is 43.3%, which indicates substantial reduction of editing at this site of SLE patients ($p<0.001$). The second hot spot consists of novel edited bases between nucleotides 39707 to 39718, and the frequency of editing in this site in SLE samples is 30% and 2.3% in control samples. About 13 folds increase in editing frequency has been observed at this site in SLE patients compared to controls ($p<0.001$). The other important

finding of this study is the compensatory alteration of A to I editing frequencies at hot spots in *UTCH* gene transcripts of SLE. In general these results demonstrate altered and site selective editing in UCTH gene transcripts of SLE patients.

Conclusion: Based on these results, it is proposed that altered transcript editing contributes to the modulation of gene expression and immune functions in SLE patients and play an important role in the initiation and propagation of SLE pathogenesis. .

Genetic Risk Factors for Thrombosis in An Ethnically Diverse Systemic Lupus Erythematosus (SLE) Population. R. Kaiser[1], Y. Li[2], M. Chang[2], J. Catanese[2], A.B. Begovich[3] and L.A. Criswell[1], [1]UCSF, San Francisco, CA, [2]Celera, Alameda, CA, [3]Roche Diagnostics, Pleasanton, CA

Purpose: Thrombosis is a devastating SLE complication. Established risk factors such as antiphospholipid antibodies (aPL) do not completely explain this increased thrombosis risk. We investigated whether previously described and novel single nucleotide polymorphisms (SNPs) recently associated with risk for thrombosis in the general (non-SLE) Caucasian population help explain the increased risk of thrombosis in an ethnically diverse SLE population.

Methods: Subjects were enrolled in a large SLE cohort through diverse recruitment sources, completed an extensive questionnaire, and had thrombosis phenotypes well-characterized. We genotyped 1513 SLE subjects for established and novel SNPs recently suggested to be associated with deep venous thrombosis in the general Caucasian population. Each SNP was tested for association with thrombosis in bivariate analysis. Statistically significant results from bivariate analyses ($p \leq 0.05$) were evaluated in a logistic regression model that included aPL, disease duration, ever history of smoking, and medication treatment history as covariates. In sensitivity analyses, thrombosis subgroups were analyzed as distinct outcomes because certain SNPs have been shown to be risk factors specifically for arterial or venous thrombosis.

Results: 1380 SLE patients (91%) were female, 874 (58%) Caucasian, 232 (15%) Hispanic, 190 (13%) African American and 217 (14%) Asian American. Average age at SLE diagnosis was 33.3 ± 13.4 years and average disease duration was 8.96 ± 8.2 years. 587 subjects (40%) were ever-smokers, and 841 (53%) had a history of immunomodulator therapy (cytoxan, methotrexate, etc.). 357 (25%) subjects had a total of 499 thrombotic events. 444 (31%) subjects were positive for either anticardiolipin antibodies or the lupus anticoagulant. No SNPs deviated from Hardy Weinberg Equilibrium. Table 1 summarizes multivariate genetic association results for the outcomes of arterial and venous thromboses. No SNPs were significantly associated with the combined outcome of venous and/or arterial thrombosis.

Conclusion: This is the first study to assess these genetic risk factors for thrombosis in a large, ethnically diverse SLE population and may help to identify SLE subjects at higher risk for thrombosis. Although confirmation of these findings in independent study populations is needed, the magnitude of some of these associations implies the potential for substantial clinical significance.

124

Novel Single Nucleotide Polymorphisms (SNP) Associated with Systemic Lupus Erythematosus (SLE). R. Kaiser[1], Y. Li[2], M. Chang[2], J. Catanese[2], Jeffrey C. Edberg[3], G. S. Alarcon[4], A.B. Begovich[5] and L.A. Criswell[1], [1]UCSF, San Francisco, CA, [2]Celera, Alameda, CA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]for the PROFILE study group, [5]Roche Diagnostics, Pleasanton, CA

Purpose: Prior work suggests that polymorphisms implicated in thrombosis risk [Mannose Binding Lectin (MBL) D allele] may also confer risk of developing SLE, a systemic autoimmune disease with a higher incidence of thrombosis that occurs at younger ages than in the general population. In a case-control analysis, we aimed to determine whether established and novel single nucleotide polymorphisms (SNP) recently suggested to be associated with deep venous thrombosis in the general population were risk factors for the development of SLE.

Methods: Subjects were enrolled in one of two North American SLE cohorts. SLE cases met American College of Rheumatology criteria. We genotyped 6909 subjects (2954 cases and 3955 controls) for 33 SNPs – some putative risk factors and many recently suggested to be associated with thrombosis in the general population. In bivariate analysis, we compared SLE subjects with thrombosis (myocardial infarction, stroke, pulmonary embolism, deep venous thrombosis, retinal vein thrombosis, recurrent miscarriages) to SLE subjects without thrombosis among the cohort for which thrombosis phenotypes were well-characterized (1452 cases and 1672 controls) as well as all SLE subjects versus healthy controls (controlling for cohort).

Results: In the overall study population, 2641 (91%) of SLE cases were female, 1500 (52%) Caucasian, 453 (16%) Hispanic, 716 (25%) African American and 217 (7%) Asian American. In the subgroup for which thrombosis phenotypes were well characterized, 360 (23%) subjects experienced at least one thrombotic event. Genetic association results are summarized in the table below, and support association of some of these genetic variants with risk of SLE. Some of these SNPs are located in genes involved in the coagulation cascade (FV and FIX) while other are involved in platelet aggregation (GP6) or in antiphospholipid antibody production (APOH). Many of these SNPs were protective for SLE in Asian-Americans. For some SNPs (FIX, GP6), odds ratios were in different directions for different ethnicities.

Conclusion: Many of the SNPs we recently demonstrated to be risk factors for thrombosis in SLE (APOH, MTHFR, FV, VKORC1) appear to be equally or more strongly associated with SLE itself. This suggests a common genetic predisposition for the development of SLE and the complication of thrombosis and may help to explain ethnic differences in SLE outcomes.

Association Analysis of *EGR2* Gene with SLE Susceptibility. Keiko Myouzen[1], Yuta Kochi[1], Kenichi Shimane[1], Akari Suzuki[1], Keishi Fujio[2], Tomohisa Okamura[2], Ryo Yamada[3], Yusuke Nakamura[4] and Kazuhiko Yamamoto[1], [1]Laboratory for Autoimmune diseases, Center for Genomic Medicine,The Institute of Physical and Chemical Research (RIKEN), Tokyo, Japan, [2]Department of Allergy and Rheumatology,Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Laboratory of Functional Genomics, Human Genome Center,The Institute of Medical science, The University of Tokyo, Toyko, Japan, [4]Laboratory of Molecular Medicine, Human Genome Center,The Institute of Medical science, The University of Tokyo, Tokyo, Japan

Purpose: Early growth response 2 (*EGR2*) gene is a zinc-finger transcription factor, whose knockout in mice has been shown to develop a lupus-like autoimmune disease. We performed case-control association study to analyze the association of *EGR2* with SLE susceptibility in Japanese population.

Method: We selected 20 tag SNPs from 80 kb region including *EGR2* and genotyped them using TaqMan assays. We compared the allele frequency of SNPs between two sets of case-control subjects in Japanese population (1st set, 376 SLE patients and 940 controls; 2nd set, 243 SLE patients and 881 controls). We analyzed the correlation between *EGR2* expression and SNP genotypes in EBV-transformed lymphoblastoid cell lines from HapMap individuals. We also performed luciferase assays to assess the transcriptional enhancer and repressor activity of DNA sequences surrounding the disease-associated SNPs.

Results: We identified a significant association of rs10761670 (A/T; T allele was susceptible allele) in the 5' flank region of *EGR2* with SLE susceptibility (1st set: p=0.049, OR=1.19 [95%CI 1.00-1.41]; 2nd set: p=0.029, OR=1.22 [95%CI 1.02-1.53] and pooled: p=0.0036, OR=1.22 [95%CI 1.07-1.39]). We also found a significant positive correlation between the number of susceptible alleles of rs10761670 and the transcriptional level of *EGR2* (R=0.23, p=0.0007). Among the SNPs in complete disequilibrium with rs10761670 (r^2=1.0), two SNPs (rs1412554 and rs1509957) affected transcriptional activity in luciferase assays, and thus they could be candidates for causal variants in this region.

Conclusion: *EGR2* is a genetic risk factor for SLE, in which increased gene expression may contribute to SLE pathogenesis.

Genetic Ancestry, Socioeconomic Status, and Disease Characteristics Among Hispanics with Systemic Lupus Erythematosus. I. B. Richman[1], J. Barton[1], L. Trupin[1], M. A. Petri[2], E. H. Yelin[1], M.F. Seldin[3] and L. A. Criswell[4], [1]UCSF, San Francisco, CA, [2]JHU, Baltimore, MD, [3]Univ. of California, Davis, [4]Univ. of California, San Francisco, CA

Purpose: Systemic lupus erythematosus (SLE) is more severe among Hispanics than among Caucasians in the U.S. The extent to which genetic and environmental factors contribute to these disparities is incompletely understood. The objective of this study was to determine whether genetic ancestry and socioeconomic status (SES) are associated with disease characteristics including renal involvement, age at diagnosis, and disease activity among Hispanic adults with SLE.

Method: This was a cross-sectional study of Hispanic adults with SLE enrolled in an ongoing study of the genetics of SLE. We confirmed SLE diagnosis and clinical characteristics by chart review. A subset of participants was enrolled in a prospective cohort study of SLE through which SES data and the Systemic Lupus Activity Questionnaire (SLAQ), a measure of disease activity, were collected. All participants were genotyped for a set of 112 single nucleotide polymorphisms informative for continental ancestry. Continental ancestry was estimated for each participant using the program STRUCTURE. We assessed the relationship between SLE characteristics and genetic ancestry using linear and logistic regression models adjusted for sex, disease duration, educational attainment, language, insurance status and type, and access to a rheumatologist.

Results: Genetic ancestry estimation for 222 Hispanic SLE cases demonstrated that participants had on average 48% European ancestry, 39% Amerindian ancestry, 8% east Asian ancestry and 5% African ancestry. Forty percent of participants (n=89) had a history of renal involvement. The mean age at diagnosis was 31 (SD 12) and the mean SLAQ score was 13 (SD 8). In multivariable analysis, participants with a larger European ancestry contribution had a lower odds of renal involvement than those with a smaller European ancestry contribution. A 25% increase in European ancestry contribution was associated with a 65% reduction in the odds of having renal disease (OR 0.35, 95% CI 0.17-0.72, p=0.004) after adjustment for covariates. European ancestry was also associated with age at diagnosis. A 25% increase in European ancestry contribution was associated with a 4.8 year increase in age at diagnosis (95% CI 1.2-8.5, p=0.009) in multivariable analysis. European ancestry was not associated with SLAQ score, but health insurance type was. Compared to those with private health insurance, those with public insurance had on average a 4.4 point (95% CI 1.0-7.8, p=0.011) higher SLAQ score after adjusting for covariates.

Conclusion: Both genetic ancestry and SES are associated with disease characteristics among Hispanic adults with SLE. Different facets of SLE may be differentially affected by genetic and environmental influences. Understanding the factors that contribute to SLE disease characteristics can help identify at-risk individuals and aid in devising targeted interventions to reduce health disparities in SLE.

Ro60 Associated ssRNA Links Inflammation with Fetal Cardiac Fibrosis Via Ligation of Toll Like Receptors: A Potential Pathway to Heart Block. David Alvarez[1], Elena V. Komissarova[1], Jordan Swartz[1], Franck Barrat[2], Tania L. Rivera[1], Robert M. Clancy[3] and Jill P. Buyon[3], [1]NYU SOM, New York, NY, [2]Dynavax Technologies, Berkeley, CA, [3]NYU School of Medicine, New York, NY

Purpose: Exploration of pathogenic mechanisms coupling anti-Ro/La antibodies to fetal cardiac injury has focused on the protein target of the maternal immune response. The relevance of Interferon Type I and Toll like receptor (TLR) signaling in SLE supports the potential importance of Ro associated ssRNAs in the cascade to congenital heart block (CHB). Objective: To address the hypothesis that ssRNA induces macrophage activation via TLR ligation following uptake of a complex of Ro60, hY3 or mutant pre 5S (m-pre5S) RNA and anti-Ro with release of proinflammatory and profibrotic factors which result in scarring of the conduction system and endocardial fibroelastosis.

Method: In vitro conditions included evaluation of human macrophages for secretion of TNFa (inflammatory component) and transdifferentiation of human fetal cardiac fibroblasts and collagen production (fibrosing component) as well as staining of human fetal hearts.

Results: The TLR component was evaluated by transfection of ssRNA. Treatment of IFNg-primed macrophages with hY3 or m-pre5S RNA (2.5mg each) significantly stimulated TNFa release (1,121±373pg/mL p=0.02, N=14, and 1,072±338pg/mL respectively vs resting macrophages 92±40 pg/mL, p=0.01, N=14), an effect not observed with transfected ssRNA41 (control RNA) or modified hY3 RNA (base substitution of hY3, A/U). Both theTLR7/8 antagonist IRS661(32ng/mL) and chloroquine (10mM) significantly decreased TNFa release induced by either hY3 or m-pre5S RNA (IRS661: 159±77pg/mL p=0.03, N=9 for hY3, and 71±29pg/mL p=0.03, N=9 for pre-5S; chloroquine: 267±89pg/mL p=0.03, N=9 for hY3, and 180±70pg/mL p=0.03, N=9 for pre-5S). Immune complexes generated by incubation of an IgG fraction from a CHB mother with native Ro60-hY3 (CHB IgG Ro60-hY3) significantly increased TNFa secretion compared to CHB IgG Ro60-ssRNA41 or normal IgG (healthy donor absent anti-Ro) incubated with Ro60-hY3 (687±248pg/mL vs 246±103pg/mL p=0.05, N=3 vs 18±11pg/mL p<0.001, N=3). Fibrosis was evaluated using the identical supernatants (sups). Transdifferentiation of fibroblasts (SMAc staining, N=5) was markedly increased by incubation with sups generated from macrophages + hY3 or m-pre5s RNA, CHB IgG Ro60-hY3, not control ssRNAs or normal IgG Ro60-hY3. IRS661 and chloroquine each abrogated induced SMAc. Collagen secretion was stimulated by sups of macs + hY3 (766±82ng/mL, p=0.003 vs macs) compared to ssRNA41 (150±30ng/mL, p=NS vs macs) or hY3-A/U (197±27ng/mL, p=NS vs macs), and macs + CHB IgG Ro60-hY3 (650ng/mL) compared to normal IgG Ro60-hY3 (200ng/mL). TLR7 expressing mononuclear cells were observed in a CHB heart, not normal heart, and localized near the AV groove at a site enriched in fibrosis.

Conclusion: These data support a novel injury model in CHB whereby endogenous ligand, Ro60 associated ssRNA, forges a nexus between TLR ligation and fibrosis instigated by binding of anti-Ro to the target protein accessible via apoptosis.

Chronic Exposure to Type I Interferon Modulates CD4 T-Cell Function in Systemic Lupus Erythematosus (SLE). Wan-Sik Uhm, Jakub K. Loster, S. Sam Lim, Jorg J. Goronzy and Cornelia M. Weyand, Lowance Center for Human Immunology and Rheumatology, Atlanta, GA

Purpose: In patients with SLE, circulating IFNα levels and transcripts of IFN-induced genes are increased and correlate with disease activity and severity. Type I IFN, now considered a central pathogenic factor in SLE, regulates multiple immune pathways and critically determines T-cell development and effector functions. TNF-related apoptosis-inducing ligand (TRAIL), a member of the TNF superfamily, is a quintessential IFN-induced gene. Expressed on the surface of CD4 T cells, TRAIL mediates proinflammatory and cytotoxic effector functions. Here, we have studied how chronic IFNα exposure affects TRAIL-expressing T cells in SLE.

Method: Patients with active SLE (n=77) and age-, sex-, and ethnicity-matched controls (n=77) were recruited through the SLE clinic. Spontaneous and IFNα-induced expressions of TRAIL on the surface and in the cytoplasm of CD4 T cells were examined by flow cytometry. IFNα-induced intracellular signaling events (pSTAT1, 3, 4, and 5) were quantified by phosphoflow studies. Transcripts of the IFNα-induced genes TRAIL and IFN-induced protein with tetratricopeptide repeats 1 (IFIT1) were determined by RT-PCR. TRAIL expression on CD4 T cells was studied after withdrawal from IFNα or after exposing them chronically to exogenous IFNα.

Results: Freshly isolated CD4 T cells from SLE patients expressed TRAIL at higher density (p=0.02). However, stimulation with exogenous IFNα revealed a defect in the inducibility of TRAIL on SLE T cells, both on protein (p<0.001) and transcription levels (p<0.001). Diminished responsiveness to IFN stimulation also involved IFIT2 (p<0.01), another IFN-inducible gene. This defect in IFN responsiveness could not be attributed to attenuated IFN signaling. The levels of pSTAT1 in SLE T cells after 15, 30, and 45 minutes of IFNα stimulation were even higher than in controls (p<0.05). Upregulation of pSTAT4 was indistinguishable in SLE and control T cells. Culturing of SLE T cells in IFNα-free medium restored responsiveness to an IFNα challenge. Conversely, exposure of healthy CD4 T cells to exogenous IFNα diminished TRAIL induction, resembling SLE T cells.

Conclusion: CD4 T cells from SLE patients fail to respond adequately to an IFNα challenge and express significantly lower surface levels of the effector molecule TRAIL. IFNα-low responsiveness can be induced in healthy T cells by chronic exposure to the cytokine and reverted

in SLE T cells by withdrawal of the cytokine. The adaption of SLE T cells to continuous IFNα stimulation involves a mechanism distal from STAT1 signaling and proximal from the TRAIL promoter. The inability of SLE T cells to appropriately respond to type 1 IFN may deprive SLE patients of prompt and effective anti-pathogen immunity and render them infection susceptible.

Prevalence and Characteristics of Articular Manifestations in Human Imunodeficiency Virus Infection. Paul Etau Ekwom, Kenyatta National Hospital, Nairobi, Kenya

Purpose: Articular manifestations have been reported in HIV infection with a prevalence of 2.5 to 68%. The study´s objective was to determine the prevalence, types and characteristics of articular manifestations in the HIV infected patients.

Method: This was a cross sectional descriptive study at the Comprehensive care clinic (HIV outpatient clinic) at the Kenyatta National Hospital from October 2007 to March 2008. A sample of 214 patients with HIV infection was consecutively interviewed. 21 patients were excluded due to presence of other articular/rheumatologic diseases, trauma or failure to carry out the laboratory/radiologic tests 193 patients were recruited, interviewed and examined as per the gait, arms, spine, and legs (GALS) locomotor screen. Their World Health organization (WHO) clinical stage of HIV infection was also determined.Those with abnormal GALS screen were further interviewed and examined as per the American College of Rheumatology Ad hoc committee on clinical guidelines for the initial evaluation of adults with acute musculoskeletal symptoms, their global functional status was assessed and pain was assessed by use of a four point likert scale. Blood was drawn for total blood count, erythrocyte sedimentation rate and Cluster of differentiation 4 (CD4) cell count determination. Additional uric acid, rheumatoid factor and antinuclear antibody tests were carried out for patients with arthritis. Patients with hip and alternating buttock pains had plain radiographs of the hip and sacroiliac joints done which were evaluated for features of avascular necrosis and sacroillitis respectively.

Results: Thirty three of the 193 study patients were diagnosed to have articular disease with a prevalence of articular manifestations in HIV infection of 17.1%, 95% Confidence interval of 12.1-22.1%. The type prevalence was; HIV associated arthritis; 0.5%, undifferentiated spondyloarthropathy; 1% and HIV associated arthralgia 15.6%

Characteristics of patients with articular disease:
The mean age was 36 ± 9.0 years (range 23-63 years) with 23 (69.7%) females and 10 (30.3%) males with a ratio of 1:2.3.
Majority, (65.2%), were in WHO clinical stage **III** and stage **II** of HIV infection.
Majority, (51.5%), had oligoarticular presentation with a mean duration of joint pains of 53.3 ± 75.3 days (range 2-365 days).
Majority (57.6%) of the patients, using the four point Likert pain scale, reported mild joint pains.
The mean CD4 cell count cell count was 330.4 ± 220.2 cells/mm^3. compared to 362.1 ± 223.9 cells/mm^3in those with no articular disease there being no statistically significant difference with at a p value of 0.459.
Majority (51.5%) had no impairment in their vocational activities, avocational activities or activities of daily living but six (18.2%) of the 33 patients with articular disease had missed work or school. The total hours missed from work or school was 700 hours. (Range: 2-240 hours)

Conclusion: Articular disease in HIV infection is common and is a cause of morbidity. The study did no show any correlation between CD4 cell count and articular manifestations.

Rheumatologist's Knowledge, Attitudes and Concerns Regarding Progressive Multifocal Leukoencephalopathy(PML). Leonard H. Calabrese[1], Eamonn S. Molloy[2] and Alan j. Taege[3], [1]Rheumatic & Immunologic Disease and Infectious Disease, Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland Ohio

Purpose: PML is a highly fatal opportunistic infection classically associated with profound immunosuppression in the settings of HIV, cancer and transplantation. PML is increasingly reported with several biologic agents frequently used by rheumatologists. Though genuinely rare, biologic-associated PML has led to an aggressive risk-mitigation program for one agent (natalizumab), the voluntary withdrawal from the market of another (efalizumab) and several 'dear health care provider' letters regarding rituximab and mycophenolate. The risk of PML has added to the complexity of both physicians' and patients' shared decision making in drug selection; thus it is important to know what the level of physician knowledge is regarding this infection as well as prevailing attitudes and concerns in order to identify possible gaps in learning.

Method: A brief 10 question multiple choice survey was crafted to asses the domains of knowledge, attitudes and needs/concerns regarding PML. The survey was distributed via e-mail to a subset of clinical rheumatologists identifying themselves as members of the ACR. An open-ended question provided an opportunity to identify areas of educational need.

Results: 176 responses were analyzed representing a calculated 15% response rate. 53% of physicians identified themselves as moderately or extremely aggressive in their use of immunosuppressive and/or biologic therapies. 32% rated themselves as moderate to high in their knowledge of PML while 24% believed they were moderate to extreme in their deficiency of knowledge. When quizzed, only 16.5% could identify the correct answer on the prevalence of JC virus infection in the general population; 41% could not identify the diagnostic test of choice for PML (CSF PCR for JC). Regarding RA/SLE/CTD patients, 43% of respondents were somewhat to extremely concerned about PML as a complication for patients on TNF inhibitors, while 73% were similarly concerned when using rituximab. Only 24% and 31% of respondents felt that PML was somewhat to extremely likely to affect their use of TNF inhibitors or abatacept while 64% were similarly affected in terms of rituximab. Rheumatologists believed that 62% of their patients had somewhat to extreme concern about PML as a complication of their therapy. Finally, only 7% of rheumatologist responded that they have little or no educational needs regarding PML while over 80% felt moderate to extreme needs for education. In the open-ended question regarding specific needs, 93 of 176 responded; the majority identified needs including basic biology and mechanisms, appropriate diagnostic assessment and further understanding of risk-benefit analysis.

Conclusion: 1. Rheumatologists have important real and perceived learning gaps regarding PML. 2. Concerns regarding PML appear to affect both physician and patient decisions regarding the use of biologic agents. 3. The vast majority of rheumatologists surveyed describe strong educational needs regarding PML as a complication of anti-rheumatic therapy.

Investigation of Possible Etiological Link Between Parainfluenza-1 and Giant Cell Arteritis. Trevor E. Davis[1], Gino Battaglioli[2], Joaquim Pinheiro[1], J. Andrew Carlson[3], Daryl M. Lamson[2] and Kirsten St. George[2], [1]Albany Medical Center, Albany, NY, [2]New York State Dept of Health, Slingerlands, NY, [3]Albany Medical Colleg, Albany, NY

Purpose: An infectious etiological trigger of Giant Cell Arteritis (GCA) is suggested by initial symptoms resembling a viral prodrome and by epidemiology which reveals both temporal and geographical clusters of GCA. The histologic hallmark of GCA is multinucleated giant cells found in temporal artery biopsies. Only a small number of human viruses are known to induce multinucleated giant cells, including respiratory syncytial virus (RSV), human parainfluenza virus (HPIV), measles virus, Epstein Barr Virus, and herpes simplex virus. Serological testing for HPIV-1 antibodies, revealed a correlation between recent infection and GCA, but this has not yet been clearly confirmed or refuted by biopsy studies. We hypothesized HPIV-1 would be detected more frequently in GCA-positive temporal artery biopsies than in GCA-negative biopsies. Furthermore there would be no difference in frequency of detection for other common respiratory viruses including influenza A and B, RSV (1, 2, and 3), HPIV (2, 3, and 4), human metapneumovirus, enterovirus, and rhinovirus.

Method: After IRB approval, we obtained archived temporal artery biopsy samples from 80 consecutive symptomatic patients referred to Albany Medical Center for pathological examination in 2003-2007. An *a priori* power analysis indicated that the specimens available were sufficient to detect an increase in the proportion of HPIV-1 by 30% in GCA-positive biopsies, compared with negative biopsies, with a

power of 80%, and alpha of 0.05. Pathologic examination was accomplished previously by established techniques. Samples were formalin fixed and paraffin embedded. For molecular analysis, paraffin was removed using xylene and sample nucleic acid was extracted using a WaxFree extraction kit in accordance with the manufacturer's protocol. The samples were then prepared for reverse transcription polymerase chain reaction using the ResPlex II and run per protocol developed at the Wadsworth Center in collaboration with Genaco.

Results: In the 68 temporal artery biopsy samples adequate for PCR studies, 12 were previously classified, by a pathologist, as positive for GCA, and 56 were negative. No viral nucleic acid (including HPIV-1) was detected in any of the specimens, including the 12 GCA positives (proportion = 0.00, 1 sided 95% CI, 0.00-0.28). The observed number of HPIV-1 positives, 0 in 12 GCA (+) temporal artery biopsies, is significantly less ($p<0.05$ by 1-sided Fisher's exact test) than the minimum we expected *a priori*, if HPIV-1 were etiologically related to GCA.

Conclusion: Our findings do not support the role of HPIV-1 as an etiologic agent for GCA. However, it is possible that the current methodology is insufficient to confirm this relationship. For instance, if the virus is not infecting the temporal arteries directly but rather causing the pathologic changes of GCA indirectly such as through immune complex deposition or if the virus infected the tissue but is no longer present. Further investigation into a possible causative agent of GCA is necessary.

Usefulness of Procalcitonin Measurement in Differentiating Between Activity of Systemic Autoimmune Disease and Bacterial Infection. Olga Sleglova[1], Helena Dejmkova[1] and Jana Uhrova[2], [1]Institute of Rheumatology, Prague 2, Czech Republic, [2]Institute of clinical biochemistry, Prague 2, Czech Republic

Purpose: To investigate whether the determination of serum procalcitonin (PCT) in systemic autoimmune disease will help to discriminate disease flares from bacterial infection. PTC, the precursor of the calcitonin, is synthesized in the parafollicular C- cells of the thyroid. PCT in serum increases in severe bacterial and fungal infections. The first published study reported the usefulness of PTC as a screening biological tool in emergency medicine. But more than eleven years after the first publication assessing the usefulness of serum PCT dosage, its exact place in the diagnostic process remained to be defined.

Method: Patient with systemic autoimmune disease (systemic lupus erythematosus, systemic sclerosis, rheumatoid arthritis, antiphospholipid syndrome and other) who were admitted to our hospital due to either a suspected deterioration of there primary diseases or an infectious disease were enrolled. Serum PCT level were measured in 113 serum samples. 76 samples were obtained from patients with disease deterioration without a detectable infection. 37 samples were obtained from patients with bacterial infections. 22 patients have systemic infections, 15 have local infections. Control group contained 80 patients without disease deterioration and without detectable infection, who came to outpatient department to routine control.

Results: 80 patients (49 female, 31 male), mean age 42 ± 19,7 in the control group and 113 patients (32 female, 26 male) mean age 46± 18,9 in the active group were enrolled. 79 of the 80 serum from the patients of control group serum PTC level were within the normal range.In 75 samples obtained from patients with disease deterioration without a detectable infection were serum PTC within the normal range in 67 samples. In the group with bacterial infection PCT level were elevated in 26 patients (19 patients with systemic and 7 with local infections). The PCT sensitivity was 84,0 % for identifying bacterial infection. Specificity was 81,4 %.

Conclusion: Serum PTC level is not elevated in patients with systemic autoimmune disease (with flare or without flare). PCT concentration offer good sensitivity for the early diagnosis of systemic bacterial infection. It can serve as a useful marker for the detection of systemic bacterial infection in patients with systemic autoimmune disease. PTC is not sufficient for ruling out localised bacterial infection.

Norovirus and Influenza B Virus as Underappreciated Causes of Postinfectious Arthritis. Gita Gemulla, Normi Bruck, Manfred Gahr and Frank Pessler, Technical University Dresden Children's Hospital, 01307 Dresden, Germany

Purpose: Viruses are well-known causes of postinfectious arthritis. However, arthritis associated with noroviruses or influenza viruses has, to our knowledge, not been described in the literature. Here, we report 3 pediatric patients who developed a transient oligoarthritis of a lower extremity following infection with norovirus (n=2) and influenza B virus (n=1).

Method: Case series. Inclusion criteria: new onset synovitis in patients <16 years during or within 3 weeks of infection with a virus previously not associated with post-infectious arthritis.

Results: The patients were seen in 2008 and 2009.

Patient 1 was a 15-month-old Caucasian girl who presented to the hospital with high fever, upper respiratory symptoms, abdominal pain, vomiting, refusal to bear weight on the left lower extremity, and a swollen, warm (but not hot) left ankle joint. Ultrasound revealed an effusion in the talocrural joint. Osteomyelitis was ruled out by MRI. Cloudy synovial fluid was aspirated. The day after admission, the patient developed profuse diarrhea. Arthritis resolved with supportive treatment over several weeks. At 5 months follow up the patient has mild intermittent ankle pain and low-grade soft tissue swelling, but no joint effusion.

Patient 2 was an 11-year-old Caucasian girl who presented to the emergency room with acute painful swelling of the left knee. The week prior she had gastroenteritis with high fevers. The knee joint was swollen, warm, and painful with active and passive motion. A large joint effusion and mildly thickened synovium were seen sonographically. Joint aspiration revealed cloudy synovial fluid (cell count, 4900 cell/mm^3). In both patients, synovial fluid and blood cultures were sterile, and stool cultures for enteric bacterial pathogens and stool PCR for rotavirus were negative. However, norovirus was detected by stool PCR in both patients.

Patient 3 was a 12-year-old Caucasian girl who was seen in the pediatric rheumatology clinic because of erythema and painful swelling in the 3rd PIP and 1st MTP joint of the left foot. Two weeks prior she had the flu with high fevers, malaise, headaches, photophobia, myalgia and arthralgias. A nasopharyngial swab was positive for influenza B virus by culture and PCR, whereas extensive serological investigations for other viral or bacterial pathogens were negative. After initial improvement on treatment with ibuprofen and physical therapy, the patient returned 6 weeks later with recurrent swelling and pain in the same joints. Treatment with ibuprofen and intra-articular injection of triamcinolone hexacetonide led to resolution of symptoms in patients 2 and 3. They remain in remission at 3 months (patient 2) and 12 months (patient 3) follow up.

Conclusion: Although it is impossible to demonstrate causality in this small series, noro- and influenza viruses may constitute hitherto underappreciated causes of a transient postinfectious synovitis.

Septic Arthritis: A 20-Year Review of Cases in Two Teaching Hospitals. Alejandra C. Rodriguez-Paez[1], Sherrilyn Tittermary[1], Charles H. Pritchard[2] and Lawrence H. Brent[1], [1]Albert Einstein Medical Center, Philadelphia, PA, [2]Abington Memorial Hospital, Willow Grove, PA

Purpose: Septic arthritis is a cause of considerable morbidity and mortality. Gram-positive bacteria remain the most common causative agents. The epidemiology of septic arthritis may be changing including an increase in methicillin-resistant *Staphylococcus aureus* (MRSA) and a decrease in gonococcal septic arthritis. The purpose of this study was to analyze changes in clinical features of patients with septic arthritis over time including causative microorganisms, associated co-morbidities, and outcomes of patients evaluated in two teaching institutions.

Method: Retrospective review of medical records of patients admitted to Albert Einstein Medical Center and Abington Memorial Hospital from 1988 to 2008 was performed on patients with septic arthritis. Data collected included patient demographics, clinical and laboratory features, associated co-morbidities, and disposition. The diagnosis of septic arthritis was defined as definite (inflamed joint and positive synovial fluid culture), probable (inflamed joint and negative synovial fluid culture but positive culture from another source), or possible (inflamed joint with negative cultures). Data was analyzed using SPSS 11.0 for descriptive statistics, and Chi-squared test to compare variables in the time periods 1, 2, 3 (1988-1994, 1995-2001, 2002-2008, respectively).

Results: A total of 466 patients were identified. The relative incidence of septic arthritis was stable over all time periods. Patients were younger in the time period 1 (49.3 yr) compared to time period 2 (57.4 yr, p=0.006), and 3 (55.6 yr, p=0.016). There was no difference in

gender through the different time periods. The most common etiology was methicillin-sensitive *Staphylococcus aureus* (MSSA) (27.9%), followed by MRSA (15.5%), the incidence of which did not change over time. The incidence of gonococcal septic arthritis decreased from time period 1 to period 2 and 3 (20.5% vs. 0.9% and 0.6%, p<0.001). An increased incidence over time was noted only for *Staphylococcus epidermidis* (p=0.007) and *Proteus mirabilis* (p=0.02). Comorbidities including coronary artery disease (p=0.017), cancer (p=0.04), congestive heart failure (p=0.021), diabetes mellitus (p=0.027), and liver disease (p=0.011), increased in prevalence and were significantly different among the time periods. Most patients were likely to be discharged home independently among the time periods, but the percentage decreased significantly over time (53% vs. 32.7% vs. 29.1%, p=<0.001). The mortality rate decreased overtime (7.2% vs. 5.7% vs. 4.1%, p=<0.01).

Conclusion: The microbial etiology of septic arthritis has changed over the past 20 years. While staphylococcal infections remained stable over time, gonococcal infections drastically decreased. Comorbid medical conditions increased in association with septic arthritis over time. Patients were less likely to be discharged home independently over time.

NEW PPD-POSITIVE Test DURING Infliximab Treatment. María Montoro[1], C. Gonzalez[2], Francisco J. López-Longo[1], Enrique Calvo[1], E. Becerra[1], Carmen Martinez[1], D. Gerona[1], F. Aramburu[1], Carolina Marín[1], I. Monteagudo[1] and L. Carreño[3], [1]HGU Gregorio Marañón, Madrid, Spain, [2]H Gregorio Marañón, Madrid, Spain, [3]Hospital Gregorio Marañon, Madrid, Spain

Purpose: Background: Latent tuberculosis (TB) treatment is mandatory when anti-TNF treatment is indicated. However, primary TB infection may occur after anti-TNF therapy has started. **Objectives:** To evaluate PPD test conversion during infliximab treatment in patients with negative PPD and booster tests before infliximab therapy was started.

Method: All patients treated with infliximab in our Infusion Center during 5 months were included in the study. PPD test: five PPD-S units in one ml were injected intracutaneously into the volar forearm. Reaction was read measuring the transverse diameter of induration 48 hours later. Reactions ≥ 10 mm were considered positive. When tuberculine test is negative, it is repeated one week after (booster). Patients with positive PPD or booster test are considered to have latent TB and treated accordingly.

Results: 185 patients being treated with infliximab were included in the study: 60/185 rheumatoid arthritis, 81/185 ankylosing spondylitis, 33/185 other spondyloarthritis, 11/185 other connective tissue diseases. 120/180 (64.9%) had negative PPD/booster test before infliximab therapy started and a new tuberculin/booster test was performed during infliximab treatment. In 96/120 (80%) patients PPD/booster remained negative, 4/120 (3.3%) had a positive PPD test and 10/120 (8.3%) a positive booster. Nine patients were not available to perform the test. One patient developed miliary TB (previous PPD/booster test negative), typically associated with primary infection, before the second tuberculin/booster test was performed.

Conclusion: 14/120 (11.7%) patients previously negative showed positive PPD/booster test after infliximab treatment started. Positive booster was more frequent than PPD positive test. New primary TB infection may happen in patients treated with infliximab and may cause clinical disease. PPD/booster tests should be routinely included in the follow-up of patients treated with anti-TNF and prophylactic treatment started when appropriated.

Ocular Syphilis (Os): An Increasing and Confusing Cause of Uveitis. Mario Agudo Sr.[1], David de la Hera Sr.[1], Ricardo Blanco Sr.[1], Joaquin Cañal[1], Juan Ventosa[1], Fernando Martinez-Sanz Sr.[1], Victor M. Martinez-Taboada Sr.[1], Marien Peiro[1], Jose Luis Peña Sr.[1], Ignacio Villa Sr.[2], Lorena Alvarez-Rodriguez[1], Manuel Gutierrez-Cuadra[1], Maria del Carmen Fariñas[1] and Cristina Martinez-Dubois[1], [1]Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Hospital de Sierrallana, Torrelavega, Spain

Purpose: The ocular involvement may be the first manifestation of syphilis presenting as uveitis, indistinguishable morphologically from inflammatory uveitis.

Method: We describe 6 patients that presented with OS, diagnosed at the Multidisciplinary Uveitis Unit of our Hospital. The diagnosis of syphilis was performed by the following tests: RPR, TPHA, Western Blot and detection of specific anti-*Treponema pallidum* antibodies (QL). The ophthalmological exploration besides the routine tests included: slit lamp examination, retinography and ocular coherence tomography. For neurosyphilis a study of the cerebrospinal fluid (VDRL, cells and proteins) was performed.

Results: Six patients (3 women and 3 men, median age 47 years, range 20 to 70 years) were diagnosed with OS as the first manifestation of syphilis. Five patients had panuveitis with more severe involvement of the posterior pole; the remaining case had isolated posterior uveitis. In 4 cases the OS was bilateral. The median diagnostic delay was 1.5 months (range 0-15). Prior to their diagnosis 3 patients were treated as non-infectious uveitis with high doses of prednisone, combined with methotrexate in 1 of them.Once the diagnosis of OS was made, five patients received penicillin G 2 million Units /4h i.v. for 2 weeks with marked improvement and no relapses. The only patient treated with penicillin G benzathine 2.4 million Units weekly during 3 weeks had a relapse; she was then treated with penicillin G 2million Units /4h i.v. for 2 weeks, but the inflammation persisted, suffering a detachment of the retina; he required laser therapy and ceftriaxone. In the whole group the median visual acuity at diagnosis was 0.1 (range 0.05-0.8) improving after treatment to 0.7 (range 0.05-1). One patient had positive serology for HIV infection and another had neurosyphilis.

Conclusion: We conclude that in order to avoid diagnostic delays and potentially harmful treatments with prednisone and immunosuppressive agents, OS should be considered early in the differential diagnosis of panuveitis or isolated posterior uveitis. The best therapeutic results were obtained with high dosages of i.v. penicillin.

137

Reliability of Tuberculosis Screening Tests in Patients Receiving Tumor Necrosis Factor Antagonist Therapy in a United States Rheumatology Clinic. Himabindu Borra[1], Michelle Sit[2], Michael J. Morris[1], Kirk H. Waibel[1], Ramon A. Arroyo[1], Gerald A. Merrill[1] and Daniel F. Battafarano[1], [1]San Antonio Military Medical Center (SAMMC), San Antonio, TX, [2]David Grant Medical Ctr, Travis AFB, CA

Purpose: To assess the reliability of latent tuberculosis infection (LTBI) screening in patients treated with tumor necrosis factor (TNF) antagonist therapy in an outpatient rheumatology clinic.

Methods: Rheumatology clinic patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA) being treated with TNF antagonist therapy were recruited in an ongoing IRB approved study. Patients with prior Bacillus calmette-Guerin (BCG) vaccination, previous positive tuberculin skin test (TST) or no documentation of TST prior to anti-TNF initiation were excluded. Enrolled patients consented to yearly TST, anergy screening, and chest x-ray (CXR). Quantiferon-TB Gold (QTB-G) blood testing became available 18 months after study initiation and was performed yearly thereafter. CXRs were interpreted by a pulmonologist. PPD induration of ≥ 5 mm at 48-72 hours was considered positive and anergy testing was correlated. Seroconverted patients and those with CXR findings concerning for LTBI were referred to Infectious Disease for evaluation.

Results: One-hundred and twenty-six patients were screened and 104 met inclusion criteria and consented to participate. Of these, 66 (63%) were female and 65 (63%) were Caucasians with a mean age of 54 (range 19-79). Seventy-five patients had RA, 17 had PsA, and 12 had AS. Forty- eight (46%) were on other immunosuppressive agents including prednisone (<10mg), methotrexate, leflunomide, sulfasalazine, and hydroxychloroquine. Duration of TNF antagonist therapy ranged from 2 weeks to over 10 years. Number of patients enrolled and their results to date are as follows:

Year	Participant number	Abnormal CXRs/total* (%)	+TSTs/total (%)	Anergic pts/Total (%)	+QTB-G/total (%)
0	104	12/98 (12)	1/104 (1)	37/68 (54)	0/12 (0)
1	47	13/43 (30)	1/47 (2)	28/39 (72)	0/32 (0)

2	4	0/4 (0)	0/4 (0)	0/4 (0)	0/4 (0)

*Abnormal CXR findings were not consistent with TB

The 2 patients with positive TSTs had indurations measuring 11 mm and 15 mm.

Conclusion: In this ongoing study of TNF antagonist treated patients in a typical US rheumatology clinic, 2 patients had TST seroconversion with negative QTB-G. In addition, 61% of our patients were anergic and at risk for LTBI. The implications of the current results are uncertain during this limited observation period. Further data collection from our patient population will better clarify the incidence of LTBI versus false positive or false negative TSTs. We recommend continued vigilance and screening for pulmonary and extra-pulmonary TB in patients treated with TNF antagonist therapy.

The "Alarmin" S100A8 Causes Severe Cartilage Damage in Antigen-Induced Arthritis through TLR4 Activation and Upregulation of FcgRI and FcgRIV. Peter van Lent[1], Arjen Blom[1], Annet Sloetjes[1], Thomas Vogl[2], Johannes Roth[2] and Wim B. van den Berg[1], [1]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [2]University of Muenster, Muenster, Germany

Purpose: The "alarmins" S100 A8 and A9 have been described not only as markers for inflammation but may also be involved in induction of erosive cartilage destruction (1). S100A8 represents the active form whereas S100A9 binds to S100A8 protecting the protein from degradation. The aim of the study is to identify the mechanisms of S100 involvement in severe cartilage destruction during antigen-induced arthritis.

Methods: Antigen-induced arthritis (AIA) was induced in knee joints of S100A8/A9-/- mice (myeloid cells also lack S100A8) and their WT controls and severe cartilage destruction was measured using immunolocalisation of VDIPEN neoepitopes and chondrocyte death. rS100A8 was injected into mouse knee joints, synovium was isolated and mRNA levels were measured using RT-PCR. M-CSF stimulated bone marrow macrophages were stimulated by rS100A8 ,rS100A9 and S100A8/S100A9 complexes and mRNA and protein levels of FcγR were measured using RT-PCR and FACS analysis.

Results: AIA was induced in control and S100A9 deficient mice. Cartilage proteoglycan loss at day 2 was not different in the knockouts, but VDIPEN expression and severe surface erosion was markedly suppressed at day 7. To identify the mechanism of S100 involvement, we injected rS100A8 (5 µg) into the knee joint of normal mice. This caused only mild joint inflammation, but pronounced upregulation of activating FcγRI and IV (mRNA levels 64 and 256 fold respectively). We know from earlier studies that FcγRI and IV are crucial factors in immune complex mediated cartilage damage in this model. In vitro analysis with bone marrow derived macrophages confirmed this upregulation by S100A8 and showed profound increases of type I and IV protein expression with FACS analysis. S100A9 or S100A8/S100A9 complex were less potent in stimulating activating FcγRI and FcγRIV. Similar studies with a granulocyte cell line did not show any upregulation of Fc receptors, underlining the specificity for macrophages. Of great interest when bone marrow cells were taken from TLR4-/- mice, S100A8 mediated upregulation of FcγRI and IV was virtually absent, identifying that S100A8 caused this effect through TLR4. TLR4 and activating FcγR were highly expressed in inflamed synovium taken at day 7 AIA whereas in S100A9-/- knockout activating FcγR were strongly diminished underlining that S100A8/S100A9 regulates FcγR expression during AIA.

Conclusion: S100A8 is a strong inducer of activating FcγRI and IV through activation of TLR4 and drives FcγR expression and severe cartilage destruction in antigen-induced arthritis.

Vitamin D Limits TLR9/IFN-Alpha Induced Antigen Presenting Cell Maturation. Melissa A. Lerman, Homaira Rahimi, Edward M. Behrens and Jon M. Burnham, Children's Hospital of Philadelphia, Philadelphia, PA

Purpose: Overactivation of antigen presenting cells (APC) plays an integral role in systemic lupus erythematosus (SLE) pathogenesis. Increased expression of interferon-a (IFNa) results in clinical and laboratory features of SLE, and IFNa drives *in vitro* monocyte maturation in SLE sera. Stimulation through toll-like receptor-9 (TLR9) has also been shown to be important in APC activation in SLE via IFNa dependent and independent mechanisms. 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D$) can limit IFN-induced maturation of monocytes. The ability of $1,25(OH)_2D$ to limit monocyte maturation in SLE has not been examined. We explored whether $1,25(OH)_2D$ treatment could affect APC maturation via TLR9 and IFNa mediated pathways in mice and humans, respectively.

Methods: C57/BL6 bone marrow-derived murine cells were harvested and matured in culture for one week with cytokines to differentiate distinct APC populations. Cells were stimulated through TLR9 via CpG-DNA in the presence or absence of $1,25(OH)_2D$. CD11c+ dendritic cells and CD11b+ macrophages were analyzed for surface activation markers. Human monocytes were elutriated from whole human blood and incubated with sera from 15 patients with SLE and 5 control patients in the presence or absence of $1,25(OH)_2D$. These cells were also stimulated with IFNa +/- 1,25(OH)2D and cell surface activation markers were assessed using flow cytometry.

Results: In murine dendritic cells, incubation with $1,25(OH)_2D$ inhibited direct TLR9-induced activation, as evidenced by lower levels of MHC Class II, CD40, and CD86. We next explored whether $1,25(OH)_2D$ would maintain its inhibitory potential on human monocytes grown in the TLR9 induced, interferongenic environment of SLE sera. In human monocytes, stimulation with exogenous IFNa increased expression of MHC Class II, CD40, and CD86. However, when $1,25(OH)_2D$ was added to human monocytes cultured in the 5 control or 15 SLE sera, expression as measured by median florescence intensity (MdFI) of MHC Class II (median MdFI of 6587 vs 3631), CD40 (1010 vs 733), and CD86 (2481 vs 1961) was significantly reduced (all $P < 0.05$, Mann-Whitney test).

Conclusion: We demonstrated that $1,25(OH)_2D$ limits APC activation via direct TLR9 activation in murine bone marrow-derived APCs, and via IFNa-induced activation of human APCs. We also show that 1,25(OH)2D inhibits APC activation by SLE sera, suggesting that it may be possible for 1,25(OH)2D to reduce the immunostimulatory effects of the SLE cytokine milieu. Together, these results suggest that 1,25(OH)2D could inhibit APC activation in SLE by preventing both direct TLR9 activation via the putative TLR9 ligands present in SLE patients as well as by the soluble cytokine mediators in the sera of SLE patients. Further clinical trials are warranted to test this hypothesis.

Role of Interferon Regulatory Factors in the Synoviocyte Type I IFN Response. Susan E. Sweeney, Trevor B. Kimbler and Gary S. Firestein, UCSD School of Medicine, La Jolla, CA

Purpose: Activation of innate sensors likely contributes to synovial inflammation in rheumatoid arthritis (RA). Of the receptors implicated in RA, TLR3 expressed by synoviocytes binds to ligands such as dsRNA and necrotic debris in the joint. TLR3 ligation activates NF-κB, MAP kinases, as well as interferon regulatory factors 3 and 7 (IRF), resulting in production of type I IFNs (IFNα and β), RANTES, IP-10, MCP-1 and other viral-stress inducible genes. Previous studies indicate that IRF3, rather than IRF7, plays a key role in production of the type I IFN response in primary human synoviocytes. The present study was designed to investigate the mechanism of this regulation in cultured synoviocytes and to determine the role of IRF3 and IRF7 in the expression of other cytokines, chemokines, and degradative enzymes implicated in RA.

Method: Fibroblast-like synoviocytes (FLS) were stimulated with poly (I-C) and transfected with IRF3 or IRF7 siRNA or control scrambled siRNA to knockdown transcription factor expression. Western blots, luciferase assay after transfection with an IFN-stimulated response

element (ISRE) reporter construct, AP-1 DNA binding assays, and Q-PCR were performed to evaluate the role of IRF3 and IRF7 in poly (I-C)-induced gene expression.

Results: IRF3 siRNA markedly decreased poly (I-C)-induced IFNβ, IRF5, IRF7, RANTES, IP-10, MCP-1, and MIP1α gene expression (90-100% inhibition; $p<0.01$). IRF3 deficiency also decreased ISRE promoter activity by 57%, suggesting that this transcription factor acts by modulating IFN-responsive gene transcription (n=3, $p<0.03$). IRF7 knockdown had minimal effect on most genes but did decrease MIP1α by 70%. ISRE activity was not significantly decreased by IRF7 deficiency (21% inhibition, n=3, $p>0.1$). Surprisingly, IRF3 knockdown almost completely blocked expression of other genes involved in RA, such as MMP3, MMP9, IL-6 and IL-8. IRF7 siRNA had little or no effect on these genes. We then investigated a possible role for IRF3 in AP-1 activation because this promoter is present in all four of these genes and is the dominant promoter element in MMP gene expression. IRF3 deficiency decreased AP-1 binding by 52% compared with control (n=3, $p <002$).

Conclusion: In contrast to immune cells, IRF3 rather than IRF7 is the dominant IRF transcription factor that regulates TLR3-mediated type I IFN responses in human synoviocytes. IRF3 activates synoviocyte IFN-response gene expression by increasing ISRE promoter activity. In addition, IRF3 can regulate other cytokines, chemokines, and MMPs through a novel mechanism that involves the AP-1 promoter site. Because the signaling pathway modulated by IRF3 plays a crucial role in synoviocytes, targeting IRF3 represents a potential approach to suppress diverse mediators while limiting suppression of IRF7-mediated adaptive immune responses.

Modulation of TLR7 and TLR8 Activation in Human Macrophages. Elena V. Komissarova[1], Ekambar R. Kandimalla[2], Sudhir Agrawal[3], Robert M. Clancy[4] and Jill P. Buyon[1], [1]NYU School of Medicine, New York, NY, [2]Idera Pharmaceuticals, Cambridge, MA, [3]D. Phil, CEO, CSO, and President, Idera Pharmaceuticals, Cambridge, MA, [4]Tisch Hospital 4-407, New York, NY

Purpose: Two percent of neonates born to mothers with SSA/Ro autoantibodies have congenital heart block (CHB). It has been hypothesized that macrophage engagement of Toll-like receptors (TLR) via binding to the ssRNA moiety of the target autoantigen exposed on the surface of the fetal cardiocytes is involved in the pathogenesis. Using a RNA-based TLR agonist and an antagonist of TLR7 and TLR9, activation of TLR was studied by TNFα release.

Method: Macrophages were derived from CD14+ monocytes of healthy donors cultured in suspension with growth medium RPMI1640/10% FBS and 10ng/ml GM-CSF for at least 7 days. Cells were plated at $4x10^5$ per well into 12-well plates and adhered macrophages were treated with TLR7 or TLR8 agonists in the absence or presence of antagonist for 24 hours. The levels of TNFα in culture supernatants were measured by ELISA. Cytotoxicity of compounds for macrophages was assessed in MTS assay. Expression of TLR7 and TLR8 mRNA was determined in RT-PCR.

Results: Macrophages from different donors showed variability in the levels of TLR7 and TLR8 mRNA expression and corresponding variability in response to TLR agonists.TLR7 agonist R837 (imiquimod, InvivoGen) at 5μg/ml induced statistically significant TNFα release from 31.6 to 457.7±85.9pg/ml ($p=0.0033$, N=7). RNA-based TLR8 agonist at 20μg/ml induced statistically significant TNFα release from 31.6 to 621± 124.6pg/ml ($p=0.0029$, N=7). The novel TLR antagonist at 80μg/ml (nontoxic for macrophages) reduced the induced TNFα release by TLR8 agonist (20μg/ml) from 621±124.6 to 11.4±5.9pg/ml (N=3). Endosomal acidification neutralizing agent, chloroquine at a nontoxic concentration of 5μg/ml inhibited the induced TNFα secretion by R837 (5μg/ml) from 457.7±85.9 to 184.6±31.07 ($p=0.0086$, N=6) and by TLR8 agonist (20μg/ml) from 621±124.6 to 4.4 pg/ml (N=2). No toxicity was seen in macrophages exposed for 24 hours to TLR antagonist at concentrations up to 100 μg/ml (MTS assay). In contrast, after a 24-hour exposure to 21μg/ml chloroquine only 75% of the macrophages were viable in MTS assay. The LC_{50} value for chloroquine was 40μg/ml.

Conclusion: Variability of TLR7 and TLR8 expression in isolated human macrophages from different donors may be relevant to the inflammatory cascade to CHB and discordant disease in fetuses exposed to anti-Ro antibodies. Given the profound TLR inhibition, antimalarial compounds, already in use during human pregnancy, and TLR antagonist studied herein may be relevant candidates for study in the prevention of disease.

Functional Role of the Intracellular Pattern-Recognition Receptor Nucleotide-Binding Oligomerization Domain 1 (NOD1) in Rheumatoid Arthritis Synovial Fibroblasts. Kazuhiro Yokota[1], Astrid Jungel[1], Christoph Kolling[2], Toshihide Mimura[3], Renate E. Gay[1], Beat A. Michel[1], Steffen Gay[1] and Caroline Ospelt[1], [1]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland, [3]Dept. Rheum. & Appl. Immunol. Fac. Med. SMU, Saitama, Japan

Purpose: Previously, we have reported that synovial fibroblasts (SF) express functional pattern-recognition receptors (PRRs), such as Toll-like receptors (TLRs) and nucleotide-binding oligomerization domain 2 (NOD2). Activation of these innate immune receptors on SF plays a key role in the pathogenesis of rheumatoid arthritis (RA) by induction of proinflammatory cytokines, chemokines, and matrix degrading enzymes. Since cytoplasmic PRR NOD1 was shown to have proinflammatory functions in different cell types, we analyzed here the function and expression of this receptor in RASF and a possible crosstalk with TLR pathways.

Method: RASF were stimulated with the NOD1 ligand L-Ala-γ-D-Glu-mDAP (Tri-DAP), the TLR2 ligand bLP, the TLR3 ligand poly I:C, the TLR4 ligand LPS or with TNF-α or IL-1β. Real-time PCR was employed to quantitate the levels of mRNA for IL-6, CCL5/RANTES, matrix metalloproteinases (MMPs), and TLRs. ELISA was used to quantitate protein levels of IL-6.

Results: Stimulation of RASF (n=6) with Tri-DAP for 24 h significantly up-regulated the expression of the proinflammatory cytokine IL-6 (3.7±1.6-fold, $p<0.05$), and the chemokine CCL5 (86.2±47.0-fold, $p<0.05$). Also the matrix degrading enzymes MMP-1 (25.0±11.6-fold, $p<0.05$), MMP-3 (6.6±1.9-fold, $p<0.05$), MMP-9 (3.8±1.2-fold, $p<0.05$), and MMP-13 (2.3±0.6-fold, $p<0.05$) were significantly up-regulated by stimulation of NOD1. Whereas the expression of TLR4 was not changed by Tri-DAP, mRNA levels of TLR2 and TLR3 increased 3.6±0.7-fold ($p<0.05$) and 2.5±0.8-fold ($p<0.05$) respectively. To elucidate a possible crosstalk between NOD1 and TLR pathways, RASF were cultured with Tri-DAP in the presence or absence of TLR ligands (bLP, poly I:C, LPS) (n=6). NOD1 as well as TLR stimulation significantly increased the levels of IL-6. However, there was no synergistic or antagonistic effect by simultaneous stimulation of the two types of receptors. To gain further knowledge about how the expression of NOD1 is regulated in RASF, we stimulated RASF with Tri-DAP, TLR ligands, TNF-α or IL-1β. RASF expressed high levels of NOD1 mRNA which was up-regulated by poly I:C after 8 h (n=3, 2.5±0.3-fold, $p<0.05$) and after 24 h (n=5, 2.9±0.3-fold, $p<0.05$), and by LPS after 8 h (n=3, 2.2±0.3-fold, $p<0.01$). In contrast, the expression of NOD1 was not changed by Tri-DAP, bLP, TNF-α or IL-1β at any time-point.

Conclusion: NOD1 is a newly described innate immune receptor expressed on SF and induces the expression of proinflammatory and matrix degrading molecules.

Adrenomedullin Induces Semi-Matured Tolerogenic Dendritic Cells: Implication of a Neuropeptide in Peripheral Tolerance. Sandrine Rullé[1], Marie-Dominique Ah Kioon[2], Carine Asensio[2], Hang-Korng Ea[2], Marie-Christophe Boissier[1], Frederic Lioté[2] and Geraldine Falgarone[1], [1]Paris 13 University; AP-HP, Bobigny, France, [2]Rheumatology Department; Inserm UMR-S606; Paris-Diderot University, hôpital Lariboisiere, Paris, France

Purpose: Dendritic cells (DC) are antigen presenting cells and are also important for tolerance. They can stimulate or expand regulatory T cells (Treg) to favor the immune response control. Among molecules expressed by tolerogenic DC, indoleamine dioxygenase (IDO) can promote Treg development and suppress T cell activation (1). Adrenomedullin (AM) is a neuropeptide with anti-apoptotic and anti-inflammatory effects and can reduce arthritis in collagen-induced arthritis. AM could decrease TH1 effector cells and favor Treg expansion (2). AM and its receptors are expressed by several immune cells but its role in immune homeostasis is unknown. The aim of this study is to evaluate AM effects on DC maturation and functions.

Methods: Bone marrow-derived DC were cultured in Gm-CSF during 6 days, stimulated or not with CpG motifs, lipopolysaccharide (LPS), AM alone or in combination during 24 hours. DC maturation was evaluated by flow cytometry, cytokine titration, allogeneic T cell

proliferation and endocytosis analysis. The expression of IDO, AM, AM receptors CLR/RAMP (Calcitonin receptor Like Receptor/ Receptor Activating Modifying Protein) and orphan receptors RDC-1 and L1 were studied by q-RT-PCR and western blot.

Results: In comparison with LPS- or CpG-stimulated DC, AM-stimulated DC expressed lower MHC class II, CD40, CD80 and CD86 molecules, and secreted less pro-inflammatory cytokines (IL-12p70, IL-1α, IL-1β) than mature DC; surprisingly, AM seemed to reduce LPS induced-TNF secretion and induces high levels of IFN gamma but not of IL-10.

However, allogeneic and endocytosis capacities were comparable to that of semi-mature and mature DC. Moreover, although DC expressed at basal level the AM receptor CLR, the co-factor RAMP-2, and RDC-1, DC maturation was accompanied with an increase of all these molecules. DC expressed also low level of secreted AM and exogenous AM increases this level. Finally IDO mRNA was expressed after AM stimulation.

Conclusion: For the first time, we have demonstrated that AM and its receptors are expressed in DC and that exogenous AM is able to modify DC phenotype and functions. AM-stimulated DC are characterized by a semi-mature phenotype with reduced endocytic capacities. This action seems to be specific of its receptors CLR and RAMP. Through IDO expression and others yet unknown mechanisms, this effect could be involve in peripheral tolerance and could be a promising strategy to favor Treg expansion.

144

Expression of Sirtuins in Rheumatoid Arthritis Synovial Fibroblasts. Fabienne Niederer[1], Fabia Brentano[1], Caroline Ospelt[1], Beat A. Michel[1], Christoph Kolling[2], Renate E. Gay[1], Steffen Gay[1] and Diego Kyburz[1], [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland

Purpose: Sirtuins are a conserved family of NAD+ dependent histone deacetylases (HDAC) and mono-ADP-ribosyltransferases. The seven human sirtuins, SIRT1-7, are critical regulators of many cellular processes, including cell survival. Sirtuins are also mediators of inflammation in a variety of diseases. Since it is not known whether sirtuins contribute to the development of rheumatoid arthritis (RA), we analyzed the expression and regulation of SIRTs in synovial fibroblasts (SF) of RA and osteoarthritis (OA) patients.

Methods: RASF and OASF were obtained from patients undergoing joint replacement surgery. Cells were lysed and RNA was extracted using the RNeasy Mini Kit. Expression of SIRT1-4, 6 and 7 mRNA in RASF (n=8) and OASF (n=4) was measured with SYBR green Real-time PCR. RASF (n=4,8) were stimulated with the TLR2 ligand Pam3 (300 ng/ml), the TLR3 ligand poly(I-C) (10 µg/ml) and the TLR4 ligand LPS (10 ng/ml) for 24 hours.

Results: We show that both RASF and OASF express all analyzed SIRTs. However, basal mRNA levels of SIRT1 and SIRT4 were 3.9 fold (ΔCT RASF 8.6 ± 1.4; OASF 10.6 ± 0.9; p=0.03) and 3.8 fold (ΔCT RASF 14.4 ± 1.2; OASF 16.3 ± 0.9; p=0.02) higher in RASF as compared to OASF. Stimulation with the TLR2 ligand Pam3 reduced the expression of SIRT2 (p=0.04), SIRT3 (p<0.01) and SIRT7 mRNA (p<0.01) by 30 % each. Poly(I-C) significantly lowered the expression levels of SIRT1 mRNA by 40 % (p<0.01), SIRT2 mRNA by 70 % (p<0.01) and SIRT3 mRNA by 50 % (p<0.05), whereas stimulation with LPS decreased the levels of SIRT2 (p<0.01) and SIRT7 (p<0.01) mRNA in RASF by 50 and 25 %, respectively.

Conclusion: Based on the fact that the expression of TLRs has been observed already in early arthritis, our findings suggest that stimulation of TLR effector pathways may result in a decreased expression of sirtuins in RASF and thereby contributes to the activation of RASF by inhibiting the cell protective effects of specific sirtuins.

Anti-TNF Therapy Leads to Decreased TNF Expression and NF-Kappa-B Signalling in RA Neutrophils. Helen L. Wright[1], Batsi Chikura[2], Roger C. Bucknall[2], Robert J. Moots[1] and Steven W. Edwards[1], [1]University of Liverpool, Liverpool, United Kingdom, [2]Royal Liverpool Hospital, Liverpool, United Kingdom

Purpose: Neutrophils are the major cell infiltrate in RA synovial fluid and are a source of TNFα, expressing the membrane-bound TNFα precursor protein (mTNF) that becomes active extracellularly upon cleavage. mTNF may also induce signalling via cell-cell contact with TNF receptors on neighbouring cells, and may also reverse-signal via engagement of soluble- or cell-expressed TNF receptors, or anti-TNF drugs. The purpose of this investigation was to investigate the effect of anti-TNF therapy on neutrophils from RA patients.

Method: 20 patients with RA were prescribed Etanercept, Adalimumab or Infliximab. Blood was collected before commencement of anti-TNF therapy, and at 4 and 12 weeks after first infusion. Neutrophils were isolated by one-step centrifugation through Polymorphprep, and expression of mTNF was measured by flow cytometry. Protein levels were analysed by Western blot, and mRNA was quantified by real-time PCR. Neutrophils from age-matched controls were also analysed.

Results: 80% (16/20) of patients achieved a response to therapy in accordance with EULAR guidelines. Baseline mTNF was significantly higher in RA patients compared to controls, and decreased significantly after 12 weeks therapy ($p<0.05$). mTNF levels at 4 weeks significantly correlated with 12-week DAS28 ($p<0.05$, $r_s=.560$). PCR analysis of TNFα mRNA levels showed a significant correlation between the decrease in TNFα mRNA and the decrease in disease activity (DAS28) from baseline to 12 weeks ($p<0.05$, $r_s=0.582$). Patients achieving low disease activity (DAS28 $\leq$3.2) after 12 weeks showed a significantly greater decrease in TNFα mRNA levels compared to other patients ($p<0.05$). Patient neutrophils showed significantly increased phosphorylation of NFκB (p65), elevated levels of the anti-apoptotic protein Mcl-1 and lower activation of caspase-9 compared to controls. Expression of caspases-8 and -3 was unchanged by anti-TNF therapy. Neutrophils from patients who achieved low disease activity after 12-weeks showed a significant decrease in NFκB phosphorylation compared to other patients ($p<0.05$).

Conclusion: Neutrophils from RA patients had an activated phenotype characterised by enhanced NFκB signalling, and levels of proteins which may induce slower rates of constitutive apoptosis. RA neutrophils expressed significantly higher membrane TNFα levels than controls, and mTNF expression following 4-weeks anti-TNF therapy was indicative of 12-week DAS28. Intracellular signalling via NFκB was reduced by anti-TNF therapy in those patients who went on to achieve low disease activity, and these patients also showed a significant decrease in TNFα mRNA production.

Active Involvement of "Alarmins"S100A8 and S100A9 in Synovial Activation and Joint Destruction During Osteoarthritis. Peter van Lent[1], Arjen Blom[1], Johannes Roth[2] and Wim B. van den Berg[1], [1]Radboud University Medical Center, Nijmegen, Netherlands, [2]University of Muenster, Muenster, Germany

Purpose: Prominent proteins released by activated macrophages are the "alarmins" S100 A8 and A9. Both proteins accumulate in inflammatory synovial fluids and have been postulated to be involved in the pathogenesis of RA. S100A8 is assumed to be the active component whereas S100A9 functions as the regulatory subunit preventing S100A8 from degradation. The aim is to study the active involvement of S100A8/A9 in synovial activation and cartilage destruction in osteoarthritis.

Methods: Experimental OA was either induced by transection of the medial anterior meniscotibial ligament which leads to destabilisation of the medial meniscus (DMM) or by injection of collagenase into murine knee joints, which causes local instability. OA phenotypes were studied within 8 weeks after induction. Collagenase-induced-osteoarthritis involves chronic synovial activation in contrast to DMM. Synovial expression of S100A8 and S100A9 during the course of osteoarthritis was measured using immunolocalisation. Both models were induced in $S100A9^{-/-}$ deficient mice (myeloid cells also lack S100A8 at the protein level). Synovial activation and cartilage destruction was measured by histology. MMP-mediated cartilage destruction was measured with immunolocalisation using anti-VDIPEN antibodies.

Results: Kinetic studies show that in the surgically induced DMM model, S100A8 and A9 was marginally expressed within the synovium, only evident at day 7 after induction and consistent with limited synovial thickening. In addition, cartilage destruction was measured in various cartilage surfaces (medial and lateral tibia and femur) of the knee joint. No differences in cartilage destruction were observed in S100A9$^{-/-}$ and WT mice at day 42 after induction of DMM.

In contrast, during the course of collagenase-induced osteoarthritis, S100A8 and S100A9 was strongly upregulated in synovium at day 7 and remained high at day 14 ,28 and 42. Expression of these proteins nicely correlated with thickening of the synovial lining layer comprising activated macrophages. When collagenase-induced-osteoarthritis was elicited in S100A9$^{-/-}$ mice, significantly lower synovial activation was observed when compared to WT mice. Synovial activation was 62% lower at day 42. Cartilage destruction was strongly and significantly lower in all surfaces and ranged from a 45% reduction in the lateral tibia to 73% reduction in the medial femur. In line with this, MMP-mediated cartilage destruction (VDIPEN) was clearly present in cartilage of osteoarthritic controls but markedly decreased in medial cartilage layers of day 42 osteoarthritic S100A9$^{-/-}$ mice, suggesting that S100A8/A9 are involved in activating MMPs.

Conclusion: Alarmins S100A8/A9 play a crucial role in synovial activation and cartilage destruction in an osteoarthritis model that shows clear synovial involvement. S100A8/A9 expression in the synovium causes pathology probably by stimulating MMP-mediated damage in the cartilage matrix.

Inhibition of Jak3-Stat6 Pathway Leading to An Anti-Inflammatory Process in Rheumatoid Arthritis. Kunihiro Yamaoka, Keisuke Maeshima, Koichi Oshita, Kazuyoshi Saito and Yoshiya Tanaka, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Purpose: Janus kinase 3 (Jak3) is a tyrosine kinase necessary for lymphocyte differentiation and proliferation, causing severe combined immunodeficiency. Because of its necessity for lymphocyte function, it is also known to be expressed at the inflammation site such as synovium from rheumatoid arthritis (RA) patients. Recently, a transcription factor Stat6, which is activated by Jak3 was reported to be specifically expressed on dendritic cells in the synovium from RA patient. Recent clinical trials of a Jak inhibitor CP-690,550 for RA has been conducted showing dramatic effects. Herein we have analyzed the function of dendritic cells (DCs) from Jak3 and Stat6 deficient mice to elucidate the involvement of Jak3-Stat6 in inflammatory process.

Objective: To elucidate the role of Jak3-Stat6 in dendritic cell function and inflammatory process.

Method: Jak3 and Stat6 deficient mouse was used to obtain splenic DCs or bone marrow derived DCs. Mouse bone marrow and purified human monocyte was cultured with GM-CSF and IL-4 or GM-CSF only to derive DC in vitro. Human monocyte and bone marrow derived DCs was positively purified with CD14 or CD11c microbeads respectively. Jak3 and Stat6 expression was analyzed by western blotting and cytokine concentration was measured by enzyme-linked immunosorbent assay (ELISA) or cytokine beads array.

Results: Jak3 and Stat6 deficient mice showed normal DC development in vivo and in vitro. Further evaluation with DC cell surface marker and antigen uptake was comparable with wild-type mice. Surprisingly, both Jak3 and Stat6 deficient DCs showed increased IL-10 production in response to toll-like receptor ligand stimulation while other inflammatory cytokine (TNF-a, IL-6) was at comparable level with wild type DCs. We further evaluated the cytokine profile with different genetic background and found that overproduction of IL-10 by Stat6-/- DCs was a consistent phenomenon.

Conclusion: We have evaluated DCs from Jak3 deficient and Stat6 deficient mice and found normal development with high production of IL-10 which was not affected by genetic background of the mice. Recently, a Jak inhibitor possessing high potency to Jak3 has been shown to have anti-rheumatic activity. It has shown potent anti-inflammatory effect with minimum side effect on haematopoietic cells leading to a question on its mechanism of action. Our results suggests that Jak3-Stat6 not only plays an important role in lymphocyte function but also has essential roles in regulating DC function and its inhibition leads to suppression of RA by enhancing IL-10 production by DC.

BAFF Induction by Viral Infection Is a General Phenomenon but Types of Viruses as Well as Mechanisms Involved in This Process Are Cell Type-Dependent. Marc Ittah[1], Corinne Miceli-Richard[2], Nicolas Gestermann[1] and Xavier Mariette[3], [1]Bicêtre hospital, INSERM U802, Le Kremlin Bicêtre, France, [2]Bicêtre hospital, INSERM U 802, Le Kremlin Bicêtre, France, [3]Bicetre Hospital, Paris-Sud University, Le Kremlin Bicetre, France

Purpose: B-cell activating factor (BAFF) plays a key role for promoting B-lymphocyte activation and survival. In primary Sjögren's syndrome (pSS), we have previously shown that salivary gland epithelial cells (SGECs), the resident targeted cells of autoimmunity in this disease, are able to produce BAFF after infection with a double stranded RNA virus through a Protein Kinase RNA-dependent (PKR) mechanism. In this study, we wanted to assess the effect of different viruses or agonists on different cell types, SGECS but also dendritic cells (DCs) and monocytes,on BAFF induction.

Method: Peripheral blood mononuclear cells (PBMCs) were isolated from peripheral blood by Ficoll-density gradient centrifugation. Monocytes were separated from PBMCs by immunomagnetic anti-CD14-beads. DCs were differentiated from monocytes with GM-CSF and IL-4 during 7 days. Cultures of SGECs were established from minor salivary glands. Cells were stimulated with poly (I:C), reovirus-1 (a double-stranded RNA virus), or Sendaï virus (a single-stranded RNA virus). To prevent PKR activation or type 1 IFN pathway induction, 2-Aminopuirine or anti-IFNAR1 was used, respectively before in vitro treatment. Expression of BAFF mRNA was investigated by Q-PCR and BAFF protein was assessed in the supernatant by ELISA.

Results: Poly(I :C) increased BAFF expression by DC but 2-Aminopurine failed to reduce this expression. Poly(I:C) and reovirus-1 had no effect on BAFF expression by monocytes. However Sendaï virus induced BAFF expression both by SEGCs and monocytes. The 2-aminopurine also failed to reduce BAFF expression on Sendaï infected monocytes. However, blocking type 1 IFN receptor by the anti-IFNAR1 antibody, on Sendaï infected monocytes, induced a strong inhibition of BAFF expression (Figure 1-A, -B).

Conclusion: Double stranded RNA viruses may induce BAFF in SGECs and DC but through a PKR-dependant mechanism only in the latter. Single stranded RNA viruses may induce BAFF in SGECs and in monocytes through a PKR-independent and a Type 1 IFN-dependant mechanism. Thus, BAFF induction by viral infection is a general phenomenon but types of viruses as well as mechanisms involved in this process are cell type-dependent.

Figure 1: Induction of BAFF mRNA and protein in blood monocytes stimulated with type 1 IFN or infected with sendai virus. *: $p<0.05$

Double Role of Mannose-Binding Lectin in Relation to Carotid Intima-Media Thickness in Patients with Rheumatoid Arthritis. Lone N. Troelsen[1], Peter Garred[2], Buris Christiansen[3], Chr. Torp-Pedersen[3], Ib J. Christensen[4], Eva Narvestad[5] and Soren Jacobsen[6], [1]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Denmark, 2100-DK Copenhagen, Denmark, [2]2Laboratory of Molecular Medicine, Department of Clinical Immunology, Rigshospitalet, Copenhagen University Hospital, Denmark, 2100-DK Copenhagen, Denmark, [3]3Department of Cardiology, Gentofte University Hospital, Hellerup, Denmark, 2900-DK Hellerup, Denmark, [4]4Finsen Laboratory, Copenhagen Biocenter, Copenhagen, Denmark, 2200-DK Copenhagen, Denmark, [5]5Department of Radiology, Rigshospitalet, Copenhagen University Hospital, Denmark, Denmark, [6]Copenhagen University Hospital, Copenhagen, Denmark

Purpose: Patients with rheumatoid arthritis (RA) have increased risk of atherosclerosis and cardiovascular disease (CVD) that cannot be explained by excess of traditional risk factors. Several studies indicate that mannose-binding lectin (MBL) may modify development of atherosclerosis; both high and low serum levels of MBL are reported to be associated with CVD. In a recent follow-up study we experienced that genetically determined high serum levels of MBL increased the risk of myocardial infarction and ischemic heart disease in patients with RA. Intima-media thickness of the common carotid artery (ccIMT) is a validated non-invasive anatomic measure of subclinical CVD. We examined the relation between ccIMT and MBL in 114 RA patients.

Methods: In a cross-sectional study *MBL2* extended genotypes (YA/YA, YA/XA, XA/XA, YA/YO, XA/YO and YO/YO) and serum concentrations of MBL were assessed. ccIMT was determined by means of ultrasonography. The following traditional and RA related cardiovascular risk modifiers were assessed: male sex, age, blood pressure, smoking, body mass index, story of diabetes, lipid profile, insulin resistance, duration of RA, joint destruction calculated by Total Sharp Score, functional disability assessed by the Health Assessment Questionnaire score, serum anti-cyclic citrullinated peptide antibodies, C-reactive protein, serum IL-6, serum TNF-a, serum non-galactosylated IgG and present treatment with antirheumatic drugs.

Results: The median ccIMT was 0.67 mm (range: 0.37-1.1 mm). In one-way analysis of variance we found no significant difference in ccIMT and the investigated *MBL2* genotypes (P-value = 0.625). Using a general linear model, ccIMT was not linearly associated with serum MBL (P-value = 0.284) but was highly associated with the quadratic term of serum MBL (MBL^2) (P=0.002) reflecting a U-shaped relation. MBL^2 was also significantly associated with ccIMT in a multivariate analysis adjusting for traditional and RA related risk factors for CVD (p=0.025).

Conclusion: In RA patients, a quadratic U-shaped relation between serum MBL and ccIMT was observed independent of the effects of traditional and RA related risk factors for CVD. These results provide further support to the notion that both high and low levels of MBL may be associated with CVD. Future studies should focus on the differentiated mechanisms by which MBL may influence development of atherosclerosis in RA and if our findings may be applicable beyond RA.

Accelerated Glomerular Injury in Mer Deficient Mice with Anti-GBM Nephritis. Wen-Hai Shao[1], Yuxuan Zhen[1], Joshua Rosenbaum[2], Robert A. Eisenberg[3], Tracy L. McGaha[4], Mark Birkenbach[1] and Philip L. Cohen[1], [1]Temple University, Philadelphia, PA, [2]University of Miami, Miami, FL, [3]University of Pennsylvania, Philadelphia, PA, [4]Medical College of Georgia, Augusta, GA

Purpose: The Mer receptor tyrosine kinase plays an important role in clearance of apoptotic cells and in modulation of both innate and adaptive immunity. Mice with the Mer kinase domain deletion (Mer-KO) develop progressive lupus-like autoimmunity. In kidney, Mer expression was shown in the glomeruli with immunofluorescence staining. We thus compared the susceptibility of WT and Mer-KO mice to nephrotoxic anti-glomerular basement membrane-induced murine nephritis.

Method: We induced nephritis in our experimental mice by iv injection of 7.5 ml of nephrotoxic serum per kg mouse body weight. The nephrotoxic serum was raised in sheep against mouse glomerular basement membrane.

Results: Mer-KO but not WT B6 recipients showed increased proteinuria by day 3. Glomeruli from Mer-KO mice were hyperplastic and later became necrotic. PAS-positive staining was evident in Mer-KO capillary spaces as well within tubules, consistent with massive protein leakage. Apoptotic bodies were detectable in the Mer-KO kidney. This early pathological change was associated with a lower survival rate in Mer-KO mice compared to WT. We observed early deposition of mouse anti-sheep IgM antibody on glomeruli from Mer-KO mice but not WT mice. Cytokine profile changes are undergoing investigation.

Conclusion: We discovered a novel protective role of Mer in the development of anti-GBM nephritis. Our data suggest that Mer acts to preserve the kidney from immune-related inflammation.

The C-Terminus of the Cyclin Dependent Kinase Inhibitor p21$^{(WAF1/CIP1)}$ Suppresses Cytokine Production and Inflammatory Arthritis. Melissa Mavers[1], Hemant Agrawal[2], Dimitrios Balomenos[3] and Harris R. Perlman[4], [1]Saint Louis University School of Medicine, St. Louis, MO, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Centro Nacional de Biotecnología, Madrid, Spain, [4]Northwestern University, Chicago, IL

Purpose: Rheumatoid arthritis (RA) is a destructive autoimmune disease of unknown etiology. Previous studies demonstrated reduced expression of cyclin dependent kinase (CDK) inhibitors, which suppress cell cycle progression, in RA joints. We have shown that the CDK inhibitor p21 also suppresses inflammatory cytokine production by macrophages (MΦ), including IL-1β, IL-6, and TNFα. Furthermore, deficiency for p21 results in increased severity of lipopolysaccharide (LPS)-induced endotoxic shock. Herein, we further elucidate the role of p21 in suppression of inflammatory disease and determine the domain of p21 important for this function.

Methods: Wild-type (Wt) or p21-/- mice (C57BL/6) were injected intraperitoneally (i.p.) with 300 μL K/BxN serum and ankle circumference was measured over 7-25 days. Ankles were then harvested and embedded in paraffin for sections, which were stained for histochemical or immunohistochemical analysis and scored by a pathologist blinded to the study. For peptide studies, a polycationic peptide derived from HIV-1 Tat was fused to p21-mimetic peptides. Thioglycollate-elicited peritoneal MΦ were incubated with peptide (10 μM) for 2 hr, followed by 6 hr of 10 ng/ml LPS stimulation (in the presence of peptide). Supernatants were then collected and analyzed for various cytokines by multiplexed bead array. For *in vivo* studies, Wt B6;129 mice were injected i.p. with 10 mg/kg peptide 30 minutes prior to K/BxN serum and daily throughout.

Results: Mice deficient for p21 developed more severe arthritis, with enhanced ankle swelling, joint destruction, and inflammatory infiltrate, as compared to Wt mice. Furthermore, the disease failed to fully resolve in p21-/- mice. To determine the domain of p21 important in suppression of cytokine production, MΦ were treated with Tat-conjugated peptides corresponding to several domains of p21 prior to, and during, incubation with LPS. Peptides corresponding to amino acids (aa) 46-65 and aa 141-160 reduced the production of inflammatory cytokines as compared to a control peptide. *In vivo* treatment with these peptides demonstrated that the aa 141-160 peptide was superior in suppressing inflammatory arthritis, with 36.1-, 6.4-, and 3.6-fold reductions in ankle swelling at days 2, 4, and 7 post-K/BxN serum injection, respectively, as compared to control peptide.

Conclusion: These data demonstrate a pivotal role for the CDK inhibitor p21 in the suppression of inflammation. A peptide corresponding to aa 141-160, which significantly reduces cytokine production and the severity of inflammatory arthritis, contains the proliferating cell nuclear antigen binding domain and a putative cyclin-binding domain. Therefore, therapies using mimics to this p21 domain may have potential in the treatment of inflammatory disease.

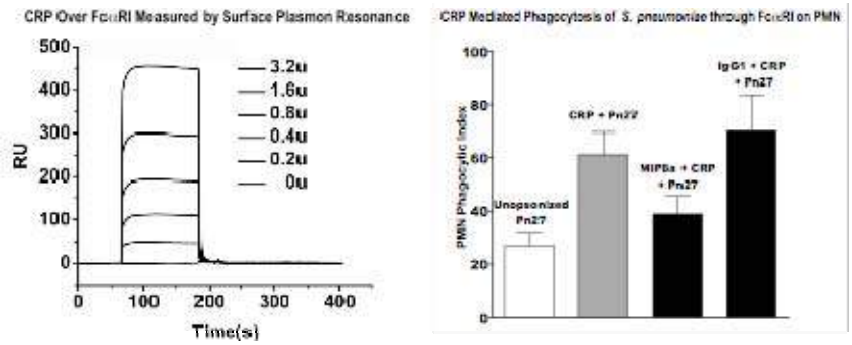
C-Reactive Protein Binds and Induces Phagocytosis through FcαRI. Kristopher D. Marjon[1], Jinghua Lu[2], Lorraine L. Marnell[1], Kye S. Park[1], Carolyn Mold[1], Peter D. Sun[2] and Terry W. Du Clos[3], [1]University of New Mexico, Albuquerque, NM, [2]National Institute of Allergy and Infectious Disease, Rockville, MD, [3]VA Medical Center, Albuquerque, NM

Purpose: C-reactive protein (CRP) is an acute phase serum pentraxin and its serum concentration can increase up to a thousand fold due to inflammatory stimuli. Pentraxins such as serum amyloid P component (SAP) and CRP have been shown to interact with the FcγR family. FcαRI is a receptor for IgA that is functionally related to FcgR, but has a higher sequence homology and structural similarity to members of the leukocyte receptor complex. FcαRI plays a role in IgA-mediated host defense and immunoregulation. FcαRI is expressed on neutrophils, eosinophils, monocytes, and dendritic cells. The purpose of this study was to determine if CRP functionally interacts with an additional immunoglobulin receptor such as FcαRI.

Methods: CRP or IgA binding affinity to FcαRI was quantitatively measured by surface plasmon resonance (SPR). CRP and IgA binding to rat basophilic leukemia (RBL) cells and FcαRI-transfected RBL (G248) cells was measured by flow cytometry. FcαRI mediated degranulation of RBL and G248 cells was measured using a colorimetric assay for β-hexosaminidase release. CRP-mediated phagocytosis was measured using human neutrophils and CRP-opsonized FITC labeled *Streptococcus pneumoniae* type 27 (*Pn*27). Phagocytosis was measured by flow cytometry using intracellular fluorescence of neutrophils after quenching

extracellular bacterial fluorescence with trypan blue. Specificity of CRP mediated phagocytosis though FcaRI was established by inhibition with anti-FcαRI mAb MIP8a.



Results: We report that CRP interacts with FcαRI with micromolar affinity and induces cellular responses. CRP bound to G248 cells and was inhibited by MIP8a, a well characterized mAb that blocks IgA binding to FcαRI, to the level of background binding to untransfected RBL cells. CRP also induced degranulation in G248 cells comparable to IgA induced degranulation. SPR studies confirmed the binding interaction between CRP and FcαRI and also demonstrated that C1q inhibited CRP binding to both FcαRI and FcγRIIa. IgA and CRP do not compete for FcαRI but are both inhibited by MIP8a. To investigate the role of this interaction further we used human neutrophils to determine if CRP could induce phagocytosis of heat-killed *S. pneumoniae* type 27. We found that CRP increased the phagocytic index above background and that CRP-mediated phagocytosis was inhibited by MIP8a.

Conclusion: These findings shed light on a novel interaction for CRP and FcαRI and give insight into a functional role between the two. This study broadens the functional role for CRP in innate immunity and identifies FcαRI as an additional CRP receptor on neutrophils.

Suppressor of Cytokine Signaling 3 Dampens Invariant NKT Cell Responses by Inhibiting the Immunostimulatory Function of Antigen-Presenting Cells. Sharon Veenbergen[1], Miranda B. Bennink[1], Jerome Biton[2], Natacha Bessis[2], Onno J. Arntz[1], Wim B. van den Berg[1] and Fons A. van de Loo[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]EA 4222 Paris 13 University, Bobigny, France

Purpose: Invariant NKT (iNKT) cells are a remarkably plastic population that orchestrate innate and adaptive immune responses, but their exact role in rheumatoid arthritis remains to be elucidated. Invariant NKT cells are activated by costimulatory cytokines such as IL-12 and IL-18 as well as glycolipids presented by antigen-presenting cells (APCs) in a CD1d-dependent manner. Recent studies have shown that APCs with enhanced suppressor of cytokine signaling (SOCS)3 expression exhibit a tolerogenic phenotype and are able to steer the outcome of T helper immunity. The aim of the present study was to determine the effect of enhanced SOCS3 expression in APCs on iNKT cell immune responses under normal and arthritic conditions.

Methods and Results: We injected 3x10e8 infectious particles of adenovirus encoding SOCS3 intravenously in DBA1/J mice which resulted in enhanced SOCS3 transgene expression in especially macrophage-like cells of both liver and spleen. These splenic APCs isolated from SOCS3-treated and control mice showed no differences in surface expression of CD1d. Interestingly, enhanced SOCS3 expression in splenic APCs led to decreased production of IL-18 and IL-12 by these cells upon TLR2 and 4 stimulation. A co-culture of SOCS3-transduced APCs with the iNKT cell hybridoma DN32.D3 led to a significant inhibition of IL-2 and IFNgamma production by the iNKT cell clone upon stimulation with alpha-galactosylceramide (aGC). A combination of aGC and TLR agonists led to a more pronounced IL-2 and IFNgamma production by the iNKT cells in the presence of APCs from control mice, however, this cytokine production was completely inhibited using APCs from SOCS3-treated mice. This suggests that the cytokine-dependent activation of iNKT cells induced by TLR

engagement on APCs can be modulated by SOCS3. Next, we injected adenoviruses encoding SOCS3 intravenously just before clinical manifestation of collagen-induced arthritis (CIA). As described previously by us, applying this strategy leads to a clear protection against arthritis development. Here, we show that the induction of CIA caused an increase in liver and spleen iNKT cell percentages in control mice, which was markedly reduced in SOCS3-treated mice. In addition, SOCS3 gene transfer reduced the expression of the CD69 early activation marker on the iNKT cell population from both the liver and spleen. Furthermore, primary liver iNKT cells from SOCS3-treated mice also produced less IFNgamma and IL-4 upon aGC stimulation.

Conclusion: This study clearly showed that ectopic expression of SOCS3 in APCs dampens the iNKT cell immune response. This result suggests that modulation of APC function could be a feasible approach to fine-tune the iNKT cell immune response in autoimmune diseases e.g. rheumatoid arthritis.

Over-IFNg-Production by NK Cells During SLE Flares. Baptiste Hervier[1], Vivien Beziat[2], Julien Haroche[3], Pierre Lebon[4], Pascale Ghillani[5], Patrice Debré[6], Vincent Vieillard[2] and Zahir Amoura[3], [1]Hôpital Pitié-Salpétrière, Paris, France, [2]INSERM 543, Paris, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [4]Department of Virology, Saint-Vincent de Paul Hospital, Paris, France, [5]Hôpital Pitié-Salpetrière, Paris, France, [6]INSERM U543, Paris, France

Purpose: To determine the phenotype and the functionality of natural killer cells (NK) in systemic lupus erythematosus (SLE).

Method: Sixty-three patients with SLE were included (61 females, 2 males, median age 33 years) and compared to 20 healthy controls. SLE flares were defined by a SLEDAI ≥ 4.

All the immunologic tests were done on freshly isolated PBMCs. NK cell phenotype was determined by flow cytometry. NK cell natural cytotoxicity and antibody mediated cytotoxicity (ADCC) were determined both by 51Cr release assay and CD107a mobilization assay. IFNg production by NK cells was evaluated by flow cytometry after an overnight in vitro stimulation by IL12 and IL18. IFNa levels in SLE patient sera were calculated using an antiviral cytopathic bioassay.

Results: During SLE flares, lymphocyte count was decreased but percentage of CD3- CD56+ NK cells and CD3- CD56dim NK cells were not modified. The NK cell phenotype during SLE flares was significantly altered: expressions of CD69 & NKG2A were increased, whereas expressions of CD16, CD8 and KIR 2DL1 were decreased. The natural cytotoxicity and ADCC of NK cells were not modified in SLE patients. The in vitro production of IFNg by NK cells during SLE flares was dramatically increased, as attested by a higher percentage of IFNg positive NK cells (50.2% for active patients vs 31.7% for inactive patients, $p<0,007$). Whereas serum levels of IL12 and IL18 were equivalent in active compared to inactive SLE patients, IFNa serum levels were positively correlated with the disease activity score. Moreover, these levels were positively correlated with the percentage of IFNg positive NK cells ($p<0,04$).

Conclusion: During SLE flares, NK cells disclose a phenotype in agreement with an impaired maturation. In vitro, these particular NK cells are able to produce larger amount of IFNg in response to IL12 and IL18. This over-production of IFNg is correlated with IFNa serum levels, suggesting that the link between innate and adaptative immunity in SLE is assumed by NK cells through these cytokines.

Regulatory Natural Antibodies to Apoptotic Cell Membrane Determinants Inhibit TLR Mediated Activating MAPK Signal Transduction in Dendritic Cells. Gregg J. Silverman and Yifang Chen, UC San Diego, La Jolla, CA

Purpose: Naturally arising antibodies (NAbs) to apoptotic cell membrane (ACM) determinants, such as phosphorylcholine (PC), can distinguish cells undergoing cell death from healthy cells, and form complexes that have potent properties to downregulate inflammatory responses. By recruitment of early complement factors, C1q and MBL, these NAbs amplify the immunomodulatory properties of ACMs and can inhibit MyD88- and TRIF-dependent TLR signaling in macrophages and dendritic cells (DCs), as well as prevent collagen-induced arthritis. To better understand the signal transduction pathways responsible for these immunosuppressive properties, we have investigated for effects on the Mitogen Activated Protein Kinase (MAPK) system that plays central roles in TLR responses.

Method: Cytokine production and MAPK signaling responses were studied in LPS stimulated murine bone-marrow derived conventional DCs, using standard approaches that include ELISA, Luminex assays, immunoblotting, intracellular flow cytometry and quantitative PCR of transcripts.

Result: We found that a monoclonal IgM anti-PC Mab, but not isotype control, only when co-incubated in serum-free media with purified early complement factors, MBL and C1q, significantly inhibited LPS-induced DC secretion of IL-6, TNFa, IL-12p70, IL-10, IP-10, MCP-1, while there was no induction of TGFb. This anti-ACM NAb also significantly inhibited LPS-mediated phosphorylation of cytoplasmic P38 MAPK, while there was no effect on JNK or ERK1/2. The regulatory NAb also inhibited LPS-mediated phosphorylation of the downstream nuclear transcription factor, ELK. The inhibitory activity of the regulatory NAb on P38 MAPK was comparable to that of dexamethasone, a potent glucocorticoid, which acts in part via transactivation of the dual specificity phosphatase, MKP-1 (also known as DUSP-1 and CL100). Moreover, co-incubation of the anti-ACM NAb with LPS, but not LPS alone, anti-ACM NAb alone, or LPS with isotype control, induced the early (i.e., 10 minute) induction of MKP-1 at a protein and transcript level, while the related MKP-5 was not induced. Intracellular flow cytometric studies confirmed that the NAb, when added to LPS-stimulated DC cultures, rapidly induced MKP-1 levels and suppressed P38 kinase phosphorylation. Studies in MKP-1 deficient cells are currently in progress.

Conclusion: Our studies demonstrate that an IgM regulatory NAb, which forms complexes with ACM and early complement factors to inhibit a broad range of pro-inflammatory TLR responses, can suppress activating P38 MAP kinase responses known to play central roles in inflammatory signal transduction pathways. These studies also provide the first evidence of potentially overlapping pathways responsible for the anti-inflammatory properties of glucocorticoids and regulatory NAbs.

Mannose Binding Lectin Gene-2 Haplotype Analysis in Korean Patients with Ankylosing Spondylitis. Churl Hyun Im[1], Eun Ha Kang[2], Joonwan Kim[1], Ran Song[1], Jin Hyun Kim[1], Yun Jong Lee[2], Kyung Sook Park[3], Eun Young Lee[1], Eun Bong Lee[1] and Yeong Wook Song[1], [1]Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seongnam, South Korea, [3]Sungshin Women's University, Seoul, South Korea

Purpose: Mannose binding lectin (MBL) is a component of innate immune system, and it's serum levels or genetic polymorphisms are associated with autoimmune diseases such as systemic lupus erythematosus or rheumatoid arthritis. It was reported that MBL deficiency showed more severe radiographic progression in ankylosing spondylitis (AS) patients. We investigated MBL2 genetic polymorphisms and haplotype analysis in AS patients and healthy controls.

Methods: 95 AS patients, diagnosed by modified New York classification criteria, and 252 healthy controls were enrolled and their clinical data were evaluated. MBL2 gene promoter polymorphisms at -550 (H/L), -221 (Y/X), +4 UTR (P/Q) and exon polymorphisms at codon 52 (Arg/Cys), 54 (Gly/Asp, or A/B), 57 (Gly/Glu) were investigated using polymerase chain reaction and restriction fragment length polymorphism. Genetic polymorphisms and their associations were analyzed by SPSS program (ver 12.0). Haplotype associations were analyzed by Unphased program (ver 3.1.2).

Results: MBL 52 and MBL 57 genetic polymorphisms were not found in this population. Other MBL2 genetic polymorphisms were not significantly different between AS patients and healthy controls. In haplotype analysis, haplotype frequency of HYPB (4.40 % vs 0.52 %, OR 9.14, 95 % CI: 1.80 - 46.49, p value=0.0040), LYPA (16.78 % vs 8.95 %, OR 2.02, 95 % CI: 1.17 - 3.47, p value = 0.015) were significantly increased in AS patients than healthy controls. In contrary, LYPB haplotype frequency was significantly decreased in AS patients than healthy controls (9.26 % vs 21.64 %, OR 0.46, 95 % CI 0.25 - 0.85, p value = 0.0009). Clinical characteristics including family history for AS, HLA-B27 positivity, uveitis, or peripheral joint involvements were not associated with any MBL2 genetic polymorphisms or haplotypes.

Conclusion: Haplotypes of MBL2 genetic polymorphisms are associated with AS patients, suggesting that MBL2 genetic polymorphisms may have a role in development of AS.

SLP-76 Is Required for Optimal NK Cell Activation and Shaping of the Ly49 Receptor Repertoire. Rebecca May and Taku Kambayashi, University of Pennsylvania, Philadelphia,, PA

Purpose: Natural killer (NK) cells are innate immune cells that provide a critical line of defense against intracellular pathogens and tumors by displaying cytotoxicity and producing immune-activating cytokines. The activation of NK cells is regulated by the expression of activating receptors that are finely counterbalanced by inhibitory receptors. Although mechanisms by which activating signals are blocked by inhibitory receptors are well defined, the proximal signaling pathways that lead to NK effector function are incompletely understood. The adaptor molecule SLP-76 is important in mediating signals downstream of ITAM-containing activating receptors in a variety of hematopoietic cell types. Thus, we examined whether SLP-76 is important also in NK cell signaling downstream of the Ly49D activating receptor.

Methods: To investigate the involvement of SLP-76 in Ly49D signal transduction, SLP-76 phosphorylation and clustering at the plasma membrane was examined in Ly49D-activated NK cells. Furthermore, the role of SLP-76 in NK cell signal transduction, activation, and development was assessed in SLP-76-deficient compared to wildtype (WT) NK cells.

Results: SLP-76 was phosphorylated and clustered at the plasma membrane following Ly49D stimulation, suggesting that SLP-76 is activated downstream of the Ly49D receptor. SLP-76 was required for optimal signal transduction through Ly49D as NK cells from SLP-76-deficient mice exhibited diminished ERK and Akt phosphorylation compared to WT mice. This correlated with decreased IFNγ production and cytotoxicity by SLP-76-deficient NK cells. NK cells from SLP-76-deficient mice appeared developmentally mature as expression of late maturation markers DX5 and CD11b were expressed normally. However, Ly49 family member inhibitory and activating receptors were expressed on a significantly lower proportion of NK cells from SLP-76-deficient compared to WT mice. Moreover, this selective developmental defect was NK cell-autonomous as WT/SLP-76 mixed bone marrow chimeras failed to correct the defect. However, this defect was not observed when SLP-76 was inducibly deleted in NK cells after full maturation. Despite normal development, these SLP-76-deficient NK cells still displayed defective IFNγ production and cytotoxicity.

Conclusion: SLP-76 is vital for Ly49D-mediated NK cell signaling and in shaping of the NK cell Ly49 repertoire during development. These results demonstrate a critical role of SLP-76 in NK cell tolerance and activation.

Mutation of Y145 of SLP-76 Reduces FcγR- and Integrin-Dependent Neutrophil Functions and Protects Mice From Dermal Inflammation and Serum-Induced Arthritis. Laurie E. Lenox[1], Christopher Prieto[1], Martha S. Jordan[2], Ralph M. Bunte[3], Karsten Sauer[4], Gary A. Koretzky[5] and Kim E. Nichols[6], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Abramson Family Cancer Research Institute, Univeristy School of Medicine, Philadelphia, PA, [3]University Laboratory Animal Resources, Philadlephia, PA, [4]The Scripps Research Institute, La Jolla, CA, [5]Univ Pennsylvania 415 BRB 2/3, Philadelphia, PA, [6]Children's Hospital of Philadelphia, Philadelphia

Purpose: SLP-76 is an essential adaptor molecule in neutrophils, where it is required for FcγR- and integrin-induced functions. SLP-76 contains three N-terminal tyrosines at residues 112, 128 and 145 that together are critical for its function. We sought to explore the relative importance of these tyrosines during neutrophil activation.

Methods: We examined in vitro functions using bone marrow isolated neutrophils isolated from knock-in mice harboring phenylalanine substitution mutations at tyrosines 112 and 128 (Y112/128F) or 145 (Y145F). We also examined the effects of these mutations on in vivo neutrophil activation using models of dermal inflammation and serum-induced arthritis.

Results: Mutations at Y112/Y128 and Y145 both interfered with SLP-76 activity; however, the Y145F mutation had a greater impact than Y112/128F on many in vitro FcγR-induced functions such as calcium mobilization and reactive oxygen intermediates (ROI) production. These tyrosine units (Y112/128 and Y145) are both key motif within SLP-76 that are similarly required for integrin-dependent functions such as spreading, degranulation and ROI production. In vitro functional defects were recapitulated in vivo, where mice expressing the Y→F mutations exhibited greater attenuation of neutrophil-mediated inflammatory responses. Most notably, the Y145F mutation protected against the development of joint inflammation in the neutrophil-dependent K/BxN model of serum-induced arthritis.

Conclusion: These data indicate Y145 is the most critical tyrosine supporting SLP-76 function in neutrophils. Future efforts to dissect how Y145 mediates SLP-76-dependent signaling in neutrophils will increase our understanding of this lineage and provide insights into the treatment of inflammatory conditions.

The NF-Kb Essential Modulator Zinc Finger Domain Regulates NF-Kb Activation by Innate Immune Receptors in T Cells and Links to Inflammatory Disease. Eric P. Hanson[1], Linda Shawver[1], Lisa A. Madge[2], Michael J. May[2] and Jordan S. Orange[1], [1]Joseph Stokes Jr Research Institute, Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA

Purpose: NEMO-ID is a rare X-linked congenital immunodeficiency which results from mutations in IKBKG, the gene coding for the NF-κB essential modulator, a transcription factor with an important role in immunity, development and programmed cell death. A recently published database of naturally occurring NEMO hypomorphic mutations has revealed novel genotype-phenotype correlations that link protein regions to defects in innate and adaptive immunity, in addition to unexpected links to inflammatory disease. Eight of 32 (25%) of the mutations described in this database are associated with inflammatory or autoimmune disease. These mutations cluster in the 1st coiled coil/alpha helix domain or result in partial or complete truncation of the C-terminal zinc finger domain. Individuals with NEMO-ID, due to the E391X mutation that results in loss of the C-terminal Zinc finger domain, have recently been described; these patients exhibit prolonged systemic inflammation following infection and inflammatory colitis.

Method: A NEMO-deficient T cell line was stably reconstituted with E391X or with the naturally occurring Q403X partial zinc finger truncation mutation and the effects of TNF Receptor, Toll-like receptor and T Cell receptor activation were measured by standard biochemical assays and microscopy.

Results: Activation of E391X-reconstituted cells with the TLR5 ligand, flagellin, or with TNF-α led to increased and sustained IKK complex activation. This was accompanied by increased IkBα degradation, and nuclear translocation and DNA binding of the p65 subunit of NF-κB. However, the nuclear translocation of zinc finger truncated NEMO was impaired.

Conclusion: These results indicate that the zinc finger has an important role in regulating IKK complex kinase activity and nuclear translocation of NEMO following TNF-α activation. In conclusion, these results provide insight into the phenotype of inflammatory disease in individuals with NEMO-ID, suggest broader implications for understanding the regulatory role of NEMO in NF-κB activation, and may help direct the rational development of immunomodulatory therapy.

Incidence of Herpes Zoster in Patients with Giant Cell Arteritis: A Population-Based Cohort Study. Valentin S. Schäfer, Tanaz A. Kermani, Cynthia S. Crowson, Gene G. Hunder, Sherine E. Gabriel, Eric L. Matteson and Kenneth J. Warrington, Mayo Clinic, Rochester, MN

Purpose: The incidence of herpes zoster (HZ) in patients with giant cell arteritis (GCA) is unknown. The aim of this study was to determine whether GCA is associated with an increased risk of HZ.

Methods: All incident cases of GCA diagnosed between January 1, 1950 and December 31, 2004 were identified for this population-based study. For each GCA patient, 2 subjects without GCA of the same sex and similar age and length of medical history were selected from the same population. Each non-GCA subject was assigned an index date corresponding to the date of diagnosis of GCA of the corresponding GCA patient. Cases of HZ were identified in both groups using diagnostic codes. Medical records of all patients with a code of HZ were reviewed to confirm the diagnosis. Patients in both cohorts were followed until death, last contact, or December 31, 2006. The proportions of patients with a history of HZ in the GCA and non-GCA cohorts were compared by Chi-square test. The cumulative incidence of HZ during follow-up was estimated using Kaplan-Meier methods. Cox proportional hazard models were used to examine the influence of GCA on the development of HZ after adjusting for age, sex and calendar year of GCA diagnosis index date.

Results: The study population consisted of 204 GCA patients and 407 non-GCA subjects. The GCA cohort consisted of 163 (79%) women and 41 (21%) men, mean age 76.0 (± 8.2) years with median follow-up 7.7 years (total 1856 person-years). The non-GCA cohort consisted of 325 (80%) women and 82 (20%) men, mean age 75.6 (± 8.4) years with median follow-up 8.1 years (total 3890 person-years). At index date, 26 (13%) GCA patients and 48 (12%) non-GCA patients had a history of HZ (p=0.73). During follow-up, 21 GCA patients and 38 non-GCA subjects developed HZ. The 2, 10 and 20 year cumulative incidences (± standard error) of HZ were 2.5% (± 1.2%), 14.5% (± 3.5%) and 26.7% (± 7.0%) among GCA patients and 2.0% (± 0.8%) 12.4% (± 2.3%) and 22.2% (± 4.2%) among non-GCA patients. There was no difference in the development of HZ in GCA patients compared to non-GCA patients (HR: 1.22; 95% CI: 0.71, 2.08; adjusted for age, sex and calendar year). There were no differences in the short-term occurrence of HZ following index date. No GCA patients and 1 non-GCA subject developed HZ within 6 months of index date. One GCA patient and 5 non-GCA subjects developed HZ within 1 year of index date. Four (19%) GCA and 9 (24%) non-GCA subjects were diagnosed with post-herpetic neuralgia (PHN) (p=0.64). The median duration of pain from PHN was similar; 4 months in GCA patients (range 2-36 months) and 2 months in non-GCA subjects (range 1-16 months, rank-sum p=0.50).

Conclusion: Patients with GCA do not appear to be at increased risk of HZ compared to age and gender-matched referent subjects, even during the first six months of therapy when glucocorticoid doses are usually highest. The occurrence of postherpetic neuralgia was similar in patients with, and without GCA.

Evaluation of 18F-FDG PET as a Diagnostic Procedure in Giant Cell and Takayasu Arteriitis by Investigator Dependant Assessment and Standard Uptake Value. Petra Lehmann[1], Sarah Buchtala[2], Nelli Achajew[1], Peter Haerle[1], Boris Ehrenstein[1], Hamid Lighvani[1], Martin Fleck[1] and Joerg Marienhagen[1], [1]University Hospital Regensburg, Regensburg, Germany, [2]University Hospital Regensburg, Germany

Purpose: Large vessel vasculitis can be visualized by positron emission tomography (PET) due to an enhanced uptake of radioactive labeled fluoro-18-deoxyglucose (18F-FDG). Previous studies have demonstrated a high sensitivity of this method compared to MRI or conventional angiography. However, the significance and diagnostic value of FDG-PET is yet undetermined. We therefore performed a study to evaluate the reliabilitiy and validity of FDG-PET for the diagnosis of giant cell arteriitis (GCA) and Takaysu arteriitis (TA) and calculated a cut-off value for the maximum standardized uptake value (SUVmax).

Method: We selected patients with established diagnosis of GCA or TA (according to ACR criteria or positive arterial biopsy) and a pathologic ^{18}F-FDG PET in clinical routine. These PET scans and PET scans obtained from age- and sex-matched oncologic control patients were independently re-evaluated by two experienced nuclear specialists. As an observer independent approach, SUVmax was separately assessed for vessels of the upper (carotid/axillar region) and lower (iliacal region) extremities and a ROC analysis performed to establish a cut-off value for vasculitis.

Results: PET scans of 20 patients and 24 controls were evaluated. In 86% of the examinations, both observers agreed on the diagnosis or exclusion of vasculitis. The inter-rater agreement measured by Cohens kappa was 0.72($CI_{95\%}$: 0,52- 0,93). Specificity was calculated with 79% ($CI_{95\%}$: 58%- 93%) Sensitivity with 65 % ($CI_{95\%}$:41% – 85%), yielding an overall diagnostic accuracy of 73 % ($CI_{95\%}$: 57%- 85 %). The mean SUVmax of the carotid and subclavian region was significantly higher in vasculitis than in control patients (2.78 ± 1.02 vs. 2.04 ± 0.62; difference 0.7375; $CI_{95\%}$: 0.2023-1.2727, p=0.0085). SUVmax of the iliacal regions did not differ significantly between vasculitis and control patients. ROC analysis revealed the highest sensitivity of 60% and specifity of 75% for a SUVmax cut-off point of 2.24 (AUC 0.72).

Conclusion: 18F-FDG PET findings are reproducible and independent of the investigator. Calculation of SUV of the upper extremities has the potential to improve the clinical utility of this method. However, the low sensitivity and specifity indicate that enhanced vascular uptake might be overrated if clinical details are suggestive for vasculitis. Therefore, the diagnosis of large vessel vasculitis should not be based on PET only.

162

Malignancy Risk in Giant Cell Arteritis: A Population-Based Cohort Study. Tanaz A. Kermani, Valentin S. Schäfer, Cynthia S. Crowson, Gene G. Hunder, Sherine E. Gabriel, S.R. Ytterberg, Eric L. Matteson and Kenneth J. Warrington, Mayo Clinic, Rochester, MN

Purpose: To determine the incidence of malignancy in a population-based cohort of patients with giant cell arteritis (GCA).

Methods: All incident cases of GCA diagnosed between January 1, 1950 and December 31, 2004 were identified for this population-based study. For each GCA patient, 2 subjects without GCA of the same sex and similar age and length of medical history were selected from the same population. Each non-GCA subject was assigned an index date corresponding to the date of diagnosis of GCA of the corresponding GCA patient. Diagnostic codes for malignancy were used for case ascertainment in both groups. Medical records of all subjects with a malignancy code were reviewed, and the diagnosis confirmed based on histopathology. Patients in both cohorts were followed until death, last contact, or December 31, 2006. The cumulative incidence of malignancy during follow-up was estimated using Kaplan-Meier methods. Cox proportional hazard models were used to examine the influence of GCA on the development of cancer.

Results: Our study included 204 GCA patients and 407 non-GCA subjects. The GCA cohort consisted of 163 (79%) women and 41 (21%) men, mean age 76.0 years (± 8.2 years) with median follow-up 7.7 years (total 1856 person-years). The non-GCA cohort consisted of 325 (80%) women and 82 (20%) men, mean age 75.6 years (± 8.4 years) with median follow-up 8.1 years (total 3890 person-years). Eighty-four (41%) GCA patients and 154 (38%) non-GCA subjects were ever-smokers (p=0.32). During follow-up, 52 GCA patients and 107 non-GCA subjects developed malignancy (HR: 1.07; 95% CI: 0.77, 1.50). Excluding patients with prevalent cancer at index date, 46 GCA patients and 76 non-GCA subjects developed a cancer during follow-up (HR: 1.26; 95% CI: 0.87, 1.83). Adjustment for smoking did not alter the results. The 1, 10 and 20 year cumulative incidences (± standard errors) of any malignancy (excluding patients with prevalent cancer) were 5.9%, 33.6% and 50.0% among GCA patients and 2.6%, 27.0% and 47.0% among non-GCA patients. GCA patients appeared more likely to be diagnosed with malignancy in the first year following index date (HR: 2.35; 95% CI: 0.87, 6.31; p=0.09), but this finding was statistically non-significant. There were no differences between the two groups with respect to frequency of hematologic (p=0.27) or solid (p=0.88) malignancies. Non-melanoma skin cancers were the most commonly observed cancers in both cohorts. While similar types of cancers were noted in both groups, colon cancer appeared more commonly in the GCA group (HR: 2.71; 95% CI: 0.94, 7.83; p=0.07). There was no difference in mortality between GCA and non-GCA patients following any incident malignancy (HR: 0.80; 95% CI: 0.52, 1.24; p=0.32).

Conclusion: GCA patients are not at increased risk of first cancer after diagnosis. The occurrence of colon cancer may be higher in GCA patients. Mortality following cancer is similar in GCA and non-GCA subjects.

Cancer Preceding Giant Cell Arteritis: A Case-Control Study. Tanaz A. Kermani, Valentin S. Schäfer, Cynthia S. Crowson, Gene G. Hunder, S.R. Ytterberg, Eric L. Matteson, Sherine E. Gabriel and Kenneth J. Warrington, Mayo Clinic, Rochester, MN

Purpose: To study the association between previous cancer and giant cell arteritis (GCA).

Methods: All incident cases of GCA diagnosed between January 1, 1950 and December 31, 2004 were identified for this population-based study. For each GCA patient, 2 subjects without GCA of the same gender, similar age and length of medical history were selected from the same population. Each non-GCA subject was assigned an index date corresponding to the date of diagnosis of GCA of the corresponding GCA patient. Diagnostic codes for malignancy were used for case ascertainment in both groups. Medical records of all subjects with a malignancy code were reviewed, and the diagnosis confirmed based on histopathology. Both groups were followed until diagnosis of GCA/index date. Logistic regression models were used to examine the association between previous malignancy and GCA status.

Results: Our study included 204 GCA patients and 407 non-GCA subjects. The GCA group consisted of 163 (79%) women and 41 (21%) men, mean age 76.0 years (± 8.2 years). The non-GCA group consisted of 325 (80%) women and 82 (20%) men, mean age 75.6 years (± 8.4 years). Median length of medical history prior to index date was 44.5 years (total 9288 person-years) in the GCA group and 45.8 years (total 16,965 person-years) in the control group. Eighty-four (41%) GCA patients and 154 (38%) non-GCA subjects were ever-smokers (p=0.32).

At index date, 45 (22%) GCA patients and 125 (31%) non-GCA patients had a previous cancer (age, sex and calendar year adjusted OR: 0.63; 95% CI: 0.42, 0.94; p=0.022). Further adjustment for smoking did not alter these results. Mean age at diagnosis of first cancer before index date was similar in cases (67.5 ±11.9 years) and controls (64.9 ±13.2 years), p =0.32. Mean duration from first cancer to index date was 9.8 years (±9.9) in GCA patients and 11.7 years (±10.8) for non-GCA patients (p=0.31). In the year prior to index date, 7 (3.4%) GCA patients and 11 (2.7%) controls had a malignancy (age, sex and calendar year adjusted OR: 1.25; 95% CI: 0.47, 3.30; p=0.65). Excluding non-melanoma skin cancers, fewer women with GCA had cancer before index date than women controls (10% vs. 22%, p=0.003) while similar number of GCA and non-GCA men experienced malignancy before index date (15% vs. 18%, p=0.59). This apparent gender difference did not reach statistical significance (p=0.34). GCA patients had fewer solid tumors compared to controls (22% vs. 29%, p=0.038). Cancer types were similar in both groups but fewer gynecological malignancies were noted in GCA patients (OR: 0.39; 95% CI 0.13, 1.15; p=0.09). Colon cancer also appeared less commonly in cases compared to controls (OR: 0.22; 95% CI 0.03, 1.74; p=0.15).

Conclusion: In this population-based case-control study, GCA patients had significantly fewer malignancies prior to index date compared to age-and gender-matched population controls. While we adjusted for smoking, the effect of other confounders cannot be eliminated. Alternatively, immunologic phenotypes that predispose GCA in some people may have a protective role in the development of cancer.

Clinical Impact and Management of the Pathologic Diagnosis of "Healed Arteritis". Yvonne C. Lee, Erika H. Noss, Anne H. Fossel, Robert F. Padera, Don C. Bienfang, Matthew H. Liang and William P. Docken, Brigham and Women's Hospital, Boston, MA

Purpose: Healed arteritis is a pathologic diagnosis associated with clinical uncertainty. Although histologic characteristics of healed arteritis have been described, no standardized diagnostic criteria are available. Some have questioned whether healed arteritis exists or whether it simply reflects changes due to aging and atherosclerosis. We describe the clinical implications and management of a pathologic diagnosis of healed arteritis.

Method: Pathology reports with the diagnosis of “healed arteritis” were identified from 418 temporal artery biopsies performed between 1994 and 2003 at an academic medical institution. Two rheumatologists reviewed the medical record for clinical symptoms (unexplained headache, visual changes, jaw claudication, fever) preceding biopsy, corticosteroid treatment at the time of biopsy, corticosteroid treatment following the diagnosis of healed arteritis, and long-term outcomes. Corticosteroid dosing at the time of biopsy was categorized as: 1) no corticosteroids, 2) low/moderate dose steroids (< prednisone 40 mg daily) and 3) high dose steroids (≥ prednisone 40 mg daily). Corticosteroid dosing post-biopsy was categorized as: 1) no corticosteroids, 2) low/moderate dose steroids (< prednisone 40 mg daily for a month) and 3) high dose steroids (≥ prednisone 40 mg daily for a month).

Results: 43 (10.5%) patients with healed arteritis were identified. Thirty-six (83.7%) were women. Mean age was 73.2 years, and mean erythrocyte sedimentation rate was 76.7 mm/hr. Twelve (27.9%) had a documented history of polymyalgia rheumatica/giant cell arteritis

(GCA) in the medical record. The most common reason for biopsy was unexplained headache (60.5%). Data on corticosteroid dosing was available for 38 out of 43 patients at the time of biopsy and 36 out of 43 patients post-biopsy. At the time of biopsy, 17 (44.7%) were not treated with corticosteroids, 7 (18.4%) were treated with low/moderate dose corticosteroids, and 14 (36.8%) were treated with high dose corticosteroids. Among those on corticosteroids, median dose was prednisone 40 mg daily. Median treatment duration was 7 days. After a pathologic diagnosis of healed arteritis was reported, 11 (30.6%) received no additional corticosteroid treatment, 15 (41.7%) were treated with a low/moderate corticosteroid regimen, and 10 (27.8%) received high dose corticosteroids for at least a month, consistent with treatment for active GCA. Among the 43 patients with healed arteritis, 1 developed visual loss, and 1 developed aortic/large vessel disease, unexplained by another diagnosis.

Conclusion: In this cohort, over 10% of temporal artery biopsies received a pathologic diagnosis of "healed arteritis." Given a pathology report indicating healed arteritis, clinicians frequently changed treatment, favoring low/moderate corticosteroid regimens over no corticosteroids or high dose regimens. On follow-up, only 1 case of visual loss and 1 case of aortic/large vessel disease were noted.

Correlation of Clinical Features and Outcomes of Temporal Artery Biopsy in Giant Cell Arteritis. Anisha Sodha[1] and Antoni Chan[2], [1]Royal Berkshire Hospital, NHS Foundation Trust, Reading, England, [2]Royal Berkshire Hospital, NHS Foundation Trust, Reading RG1 5AN, United Kingdom

Purpose: Giant cell arteritis (GCA) is the commonest form of primary vasculitis in adults. Features at presentation can be variable making diagnosis difficult. Despite the advent of new investigations such as ultrasound, temporal artery (TA) biopsy remains the gold standard for diagnosis. The aims of this study were threefold; to investigate correlation of clinical features at presentation and outcome of biopsy; to analyse histological specimens; and to determine if biopsy results affect management of patients with suspected GCA.

Method: Our retrospective study identified all patients referred for TA biopsy in our hospital between the years 2003 to 2008. Of these 113 patients, 106 sets of notes were analysed, giving us a 99% confidence interval. Specifically designed proformas identified presenting clinical features, ESR and CRP, treatment commenced, temporal artery biopsy specimen length and result. We compared positive and negative biopsy patients, and obtained final diagnoses from medical records.

Results: Of the presenting features, 78.3% of all patients had temporal headaches, 51.8% had visual symptoms and 28.3% had jaw claudication. 30.2% of all biopsies were positive. Jaw claudication was the most predictive clinical feature of a positive biopsy, being present in 50% with a positive biopsy compared to 18% with a negative biopsy ($p=0.001$). An abnormal artery on clinical examination also had predictive value (59.4% compared to 39.4% in positive and negative biopsy groups respectively). Mean CRP and ESR were higher (101.6 mg/L and 77.9 mm/hr respectively), in biopsy positive compared to (61.06 mg/L and 62.1 mm/hr respectively) in biopsy negative patients. Patients with positive biopsies also had more systemic features (fever and weight loss). The mean specimen length was 8.43mm. Biopsies of length greater than 10mm yielded significantly more positive results. Considering the ACR classification for GCA, 86.7% with a positive biopsy had at least 3 criteria before biopsy compared to 59% with a negative biopsy. Management plans were altered for 79.5% after biopsy results. In biopsy negative patients, 62% had steroids reduced, while 69% had diagnosis changed.

Conclusion: The four most predictive features were jaw claudication, abnormal temporal artery on examination, elevated CRP/ESR, and the presence of systemic features. Specimens longer than 10mm allowed for better histological analysis and had a higher positive yield rate. Biopsy results affected management in a large proportion (80%) of patients. A negative biopsy, along with observing a poor response to steroids, may be useful as it prompts clinicians to look for other diagnoses. We conclude that temporal artery biopsy should remain gold standard for diagnosis of GCA until other investigative modalities are validated and committing patients to long term corticosteroids is justified with histology.

Long-Term Prognosis and Causes of Death in PMR: The Prospective, Double-Cohort GRACG Study. Jean Schmidt[1], Pierre Duhaut[1], Valery Salle[1], Amar Smail[1], Denis Chatelain[1], Sylvie Bosshard[2], Jean -Charles Piette[3], Hélène Pellet[2] and Jean-Pierre Ducroix[1], [1]Amiens University Hospital, Amiens, France, [2]Claude Bernard University, Lyon, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France

Purpose: Survival in Giant Cell Arteritis has been shown to be similar as in the general population, with a slight increase of cardiovascular mortality at least during the first two years of the disease. However, data on survival and causes of death in pure polymyalgia rheumatica (PMR) not associated with GCA are scarce. Our goals were 1- to assess survival on a large, prospective cohort of PMR patients, and 2- to assess the causes of death.

Method: Patients with pure PMR were included in a multicenter study at the onset of the disease, before any steroid therapy or at the latest within 48 hours after steroid onset. Patients with signs or symptoms of temporal arteritis, or with a positive temporal artery biopsy, are excluded from this analysis. All patients fulfilled the Hunder criteria. Inclusion was performed on a pre-formatted questionnaire collecting initial clinical and biological data, and final inclusion was declared after an independent, centralized review of the questionnaire. Age- and sex-matched, population based, randomly selected controls were included at the time of inclusion of the cases. Current (diagnosed within the year before inclusion) or active cancers were exclusion criteria for both cases and controls. Patients and controls were then followed up with a pre-established questionnaire every 6 months during a five-year period. Survival was estimated by Kaplan-Meir methods, log-rank tests were performed for univariate analysis, and lifetest procedure (SAS) for multivariate analysis.

Results: One hundred and ninety five cases (117 females, 78 males, mean age 74 ± 8 years) were included from 1991 to 2007 and compared to 724 controls. Loss of follow-up was less than 2 % in cases and controls. Mains causes of death (% of total death in each group) are given in the table below:

	Cerebral Infarction	Cancers	Septic shock	Dementia	Myocardial Infarction	Cardiac failure	Respiratory Failure
Patients	13.6	25	11.4	0	0	6.8	0
Controls	5.3	12.6	4.5	2.7	7.2	15.3	3.6

Unknown causes accounted for 40.9% of total deaths in cases, and 38.7 in controls (NS). Pulmonary embolism, mesenteric infarction, occlusion, sigmoiditis, post-operative complications accounted for less than 2 death causes each. Survival was superior in controls than in cases ($p = 0.005$, log rank test). Over the whole period of follow-up, infection-related or cerebral infarction-related death rates were not statistically different between cases and controls ($p = 0.11$ and 0.44, respectively), whereas cancer-related death causes were more frequent in cases ($p = 0.05$), and cardiac-related causes more frequent in controls ($p = 0.022$).

Conclusion: Unlike in GCA, overall mortality seems higher in PMR patients than in population based, age- and sex-matched controls, and the mortality increase is associated with cancers undiagnosed, unknown, or non-existent at the time of PMR diagnosis.

Elevations in Central Pulse Pressure Are Associated with An Increased Risk of Critical Ischemia Requiring Revascularization in Takayasu Arteritis. Stuart M. Levine and Allan C. Gelber, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Takayasu arteritis (TA) is a large vessel vasculitis which can lead to critical ischemia and significant morbidity. Recent data suggest that an elevated central pulse pressure (PP) is a valid and important predictor of major cardiovascular morbidity in the general population. The predictive value of central PP monitoring has not been previously examined in TA. Given both the frequent difficulty and

limitation in measuring peripheral blood pressures in patients with TA, we examined whether central PP measurement can identify those patients at greatest risk for major vascular compromise.

Method: Invasive arteriography with central hemodynamic monitoring was performed on consecutive patients with TA. Pulse pressure was defined as the difference between systolic and diastolic BPs. Peripheral PP was obtained at the time of angiography at a site where a BP was measurable; central PP was determined centrally during angiography, and the aortic site with the highest BP reading was selected for analysis. All revascularization procedures (angioplasty/stenting or surgical bypass grafting) were ascertained by history during routine clinical follow-up. Student's t-test was used to compare mean PP values between those patients with TA who did, versus those who did not, undergo a revascularization procedure; Fisher's exact test was used to compare categorical variables between these two groups.

Results: A total of 27 patients meeting ACR classification criteria for TA were evaluated. Mean age was 39 +/-13 years; all but 1 was female. In total, 49 arteriograms were performed, with an average of 1.7 arteriograms per patient (range 1-4). Overall, 11 of the 27 (41%) patients underwent a revascularization procedure. Importantly, elevations in central PP were significantly associated with undergoing a revascularization procedure. As such, mean central PP was greater in those requiring revascularization compared to those who did not (97 +/- 20 mmHg vs.75 +/-24; p=0.02), whereas peripheral PP did not differ between the two groups (68 +/- 36mmHg vs. 60 +/-39, p=0.57). In addition, the median central PP in the cohort as a whole was 93 mmHg. It is noteworthy that 73% of those undergoing revascularization, and only 31% of those who did not, had a central PP value above this level (p=0.05). In contrast, no significant difference between the two groups was observed in the proportion of patients exceeding the median peripheral PP value of 65mmHg, accordingly to their vascular procedure status (55 vs. 44%, p=0.7).

Conclusion: Central pulse pressure determination may offer a predictive benefit in terms of identifying which patients with TA are at greatest risk for requiring revascularization. This might be particularly important in patients with non-detectable peripheral BPs, in whom accurate pulse pressure determination is not possible.

Metabolic Steroid Side Effects in GCA and PMR: The GRACG, Prospective Double Cohort Study. Jean Schmidt[1], Pierre Duhaut[1], Amar Smail[1], Valery Salle[1], Denis Chatelain[1], Sylvie Bosshard[2], Jean -Charles Piette[3], Hélène Pellet[2], Jean-Pierre Ducroix[1] and GRACG study members[4], [1]Amiens University Hospital, Amiens, France, [2]Claude Bernard University, Lyon, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [4]France

Purpose: Steroids remain the only validated treatment of Giant Cell arteritis (GCA) and Polymyalgia Rheumatica (PMR). Incentives to test biotherapies or DMARTS are high, based on the notion that steroid side effects impose a heavy burden in the elderly. However, data on side effects incidence are scarce, and relative risks as compared to the general population of same age range, unknown. Our goal was to assess the relative risks of metabolic complications, i.e. incident diabetes, bone or vertebra fractures, and osteonecrosis of the hip in GCA and PMR patients.

Method: We designed a prospective, multicentric, double cohort study. Patients with GCA and/or PMR were included at the onset of the disease, before any steroid therapy or at the latest within 48 hours after steroid onset. All GCA patients fulfilled the ACR criteria, and all PMR patients, the Hunder criteria. Inclusion was performed on a pre-formatted questionnaire collecting initial clinical and biological data, and final inclusion was declared after an independent, centralized review of the questionnaire. Age- and sex-matched, population based, randomly selected controls were included at the time of inclusion of the cases. Patients and controls were then followed up with a pre-established questionnaire every 6 months during a five-year period. Semestrial density incidences for metabolic side effects, and 5-year cumulative incidences, were computed.

Results: Seven hundred and forty four cases (517 females, 227 males, mean age 74 ± 8 years; 606 GCA, 138 PMR) were included from 1991 to 2007 and compared to 711 controls. Results are given in the table below.

	5-year cumulative incidence (%)				
	Cases	Controls	RR	95% CI	p
Diabetes	7.11	2.21	3.22	1.86-5.58	6.10^{-6}

Bone fractures	9.40	4.97	1.89	1.28-2.79	0.001
Vertebral fractures	11.28	4.00	2.82	1.87-4.24	1.10^{-7}
Hip Osteonecrosis	2.01	0	NA	NA	5.10^{-5}

Diabetes was present at diagnosis in 10.50 % of cases and 14.1 of controls (p = 0.037). Incident diabetes mainly occurred during the first year of treatment, without further increased incidence afterwards. Bone fracture incidence was similar in cases and in controls during the first two years, and increased afterwards. Vertebra fractures were constantly more frequent in cases than in controls over time, with a proportion of attributable risk to steroid assessed at 64%.

Conclusion: Steroid-attributable cumulative incidence of metabolic side effects did not exceed 7.3 % of patients (for vertebral fractures) and was lower for diabetes, bone fractures or osteonecrosis. These incidences should be taken into account when designing trials on steroid-sparing agents and measuring their potential benefits or risks in GCA and/or PMR patients.

Quality of Life in GCA/PMR Patients Under Steroid Therapy: The GRACG Study. Pierre Duhaut[1], Jean Schmidt[1], Laurence Le Page[1], Julien Desblache[1], Sylvie Bosshard[2], Jean -Charles Piette[3], Hélène Pellet[2], Jean-Pierre Ducroix[1] and GRACG study members[4], [1]Amiens University Hospital, Amiens, France, [2]Claude Bernard University, Lyon, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [4]Amiens, France

Purpose: Corticosteroids remain the only validated treatment of GCA and PMR, with remarquable efficacy on disease symptoms at the expense of long term side effects. Recent trials on biotherapies or DMARTs have failed to show any sparing effect on steroid dose or duration. Side effects are supposed to be a burden in the elderly. However, treatment duration of GCA or PMR is shorter than in most other inflammatory diseases, and personal tolerance may be different in the elderly than in younger, more active patients. Our goal was to assess the feelings and perceptions about steroid treatment –efficacy, inconveniences, daily burden- in GCA and PMR patients, independently of physicians perceptions.

Method: Living patients included in the prospective, multicentric GRACG study constituted the target population. First, a letter was sent to sample of 100 patients randomly selected from the database, and they were asked to write freely on a blank sheet all their feelings about the action, whether positive or negative, of steroids, and the course of the disease in relation with treatment. From the answers, a pre-formatted questionnaire including all remarks classified by topics was build, and send to all living patients of the cohort. Main topics defined by the patients covered weight and appetite, diet, quality of sleep and mood, physical signs or symptoms, associated treatments, duration of treatment, pain and fatigue.

Results: Three hundred and thirty patients answered to the preformatted questionnaire (224 women and 106 men, mean age 72 ± 7 years), including 115 with pure GCA, 91 with pure PMR, and 124 with GCA-PMR. Perception on duration of treatment did not differ between the 3 groups, and was considered as no or little constraining by 61%, 76% and 65 % of patients, respectively. 73 % were ‘less tired’ than before the disease, and only 1% declared being ‘more tired’. Pain completely disappeared in 73 % of patients, whereas 7% considered having more pain than before. 84 % were globally satisfied or very satisfied by the treatment, 1% were not satisfied at all, 2 % ‘little satisfied’. 86 % gained no weight or ‘a little’, 63 % declared that food preparation under diet rules was ‘easy or very easy’, and half of them that diet did not affect their social relations. For all items analyzed, there was no significant difference between the 3 subgroups or between men or women.

Conclusion: Overall, steroid treatment and its constraints (mainly sugar and salt-poor diet) was better tolerated in GCA/PMR patients than usually estimated. The majority of patients emphasized their well-being by comparison to the pain of the disease. In this age range, some constraints may be better accepted than in young patients, more particularly when diet and food preparation is concerned: avoiding visible side effects such as cushingoid face or weight gain may have contributed to the good acceptance of treatment.

Experience of Performing Temporal Artery Ultrasound Scanning in the Diagnosis of Temporal Arteritis in a Large Teaching Hospital. Alice Lorenzi[1], Ismael Atchia[2] and Philip Platt[1], [1]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [2]Northumbria-Healthcare NHS Foundation Trust, Northumbria, United Kingdom

Purpose: Accurate diagnosis of temporal arteritis (TA) is vital. A missed diagnosis may result in blindness and other vascular complications. However, a false positive diagnosis results in significant associated morbidity as a consequence of prolonged exposure to high dose corticosteroid (CS) – including steroid induced diabetes, weight gain, osteoporosis and increased risk of infection. We have introduced temporal artery ultrasound scanning (as described by Schmidt et al 1997 – New Eng. Journal Med.) to our diagnostic TA work up. We report the results of our first 100 scans and correlate these with biopsy results.

Method: 94 patients with suspected TA consecutively referred patients from primary and secondary care were scanned. All patients were assessed according to our normal clinical assessment procedure. In addition, all patients were scanned using a Toshiba Aplio scanner with power Doppler and 6 patients were subsequently re-scanned on symptomatic recurrence. Of these, 34 met routine clinical criteria for TA biopsy, did not have contraindications, consented to the procedure and were biopsied.

Results: In 3 of 34 patients biopsy failed to provide an arterial sample (all had positive scans). In 31 successfully biopsied patients, 27 had scan and biopsy results that were concurrent (14 positive, 13 negative). The 4 cases in which a negative scan was associated with a positive biopsy were in patients in whom steroids had been prescribed for more than 2 weeks at a therapeutic dose (>60mg oral prednisolone). The scan was quick to perform and well tolerated by patients. Four patients with negative scans and no biopsy have been treated for TA on clinical suspicion alone. In 1 patient with a movement disorder we failed to get an adequate scan because of movement artefact.

Conclusion: Doppler USS scanning is a useful adjunct to the diagnostic work up of patients with suspected TA. It is acceptable to patients, quick to perform and provides reassurance to those in whom clinical suspicion is low.

Further validation is required before this technique can be considered diagnostic. However, in our hands TA USS is currently very useful as a test with high negative predictive value – allowing us to prevent unnecessary CS exposure. Scans are only useful if performed less than two weeks after starting high dose CS.

Consistency of DEI.Tak and Kerr Criteria for Disease Activity Assessment in Takayasu's Arteritis. Sibel Zehra Aydin, Neslihan Yilmaz, Servet Akar, Kenan Aksu, Sevil Kamali, Omer Karadag, Muge Bicakcigil, Huseyin T. Ozer, Sedat Kiraz, Fatos Onen, Murat Inanc, Gokhan Keser, Nurullah Akkoc and Haner Direskeneli, Turkish Takayasu's Arteritis Study Group, Istanbul, Turkey

Purpose: DEI.Tak (Disease Extent Index-Takayasu)(Sivakumar MR, Misra R and Bacon PA, 2005) is a new index developed for the follow-up of Takayasu's Arteritis (TA), assessing only clinical findings without the requirement of imaging techniques. We aimed to compare the effectiveness of DEI.Tak with active disease definition defined by Kerr et al. which includes imaging methods in a large cohort of TA patients in Turkey.

Method: The initial DEI.Tak forms were filled cross-sectionally for 105 TA patients in 7 centers to detect the baseline damage. Follow-up was performed in 144 visits only by including the new or worsening symptoms within the last 6 months, reflecting current activity. Scores were compared with physician's global opinion (PGO) (inactive, persistent and active disease), activity according to Kerr criteria and treatment changes.

Results: TA patients were mostly female (90%) with a mean (SD) age of 39.5 (12.1) years. Mean (SD) disease duration was 11.2 (8.9) years. The mean time period between the first and final evaluation was 27.8±29.5 months. At follow-up, most of the evaluations (69.4%, 100/144) showed no difference according to DEI.Tak (score=0). However, 14% of these patients (n=14) were accepted to be active and 17% (n=17) persistent disease according to PGO. Eighteen percent of patients (8/44) with a DEI.Tak ≥ 1 were inactive according to PGO. According to

Kerr criteria, 44 of 112 patients were active (39.3%). The total agreement between DEI.Tak and Kerr criteria was 93% (kappa value: 0.78). Compared to PGO, Kerr criteria had a total agreement of 76% (85/112) and DEI.Tak 68% (97/144). Patients requiring an increase in drug doses or new therapies had higher DEI.Tak scores compared to patients without modification (1.3±1.9, 1±1.3 vs 0.2±0.6 respectively, p<0.001).

Conclusion: In over 2 years of follow-up, most patients with TA of long disease duration showed no clinical activity with DEI-Tak. The agreement between Kerr criteria and DEI.Tak is excellent. However using Kerr criteria instead of DEI.Tak increased the consistency with PGO, which can be explained by the influence of imaging methods or acute phase-reactants to physician's decisions.

Side Effects of Long-Term Use of Glucocorticoids in Giant Cell Arteritis. Rosaria Talarico, Chiara Stagnaro, Anna d'Ascanio and Stefano Bombardieri, University of Pisa, Pisa, Italy

Purpose: Giant cell arteritis (GCA) represents the most common vasculitis in the elderly, and it usually involves large and medium sized arteries. Glucocorticoids (GC) are commonly used for the treatment or GCA, although their long-term use is limited by concomitant appearance of side effects. The aim of this study was to retrospectively evaluate the prevalence GC-related long-term side effects in a cohort of patients with GCA, followed in the last twenty years in a single centre.

Method: Two hundred and ten GCA patients (176 females, mean ± SD age 77±8 years) were retrospectively studied. The diagnosis was made according to the ACR criteria in 196 patients and on the basis of the clinical decision in the others. The main GC related side effects evaluated were: diabetes arterial hypertension, cataract, gastropathy, osteoporosis (T score £ 2.5 SD), morphometric vertebral fractures, arisen after starting GC therapy. In those cases in which diabetes and arterial hypertension were pre-existing, any further worsening that required higher doses of antidiabetic or anti-hypertensive therapy were evaluated as side effects. Bone mineral density was examined by dual-energy X-ray absorptiometry (DXA). On the basis of the GC treatment duration (months), we have conventionally subdivided our cohort into 4 groups: I) from 6 to 12, II) from 12 to 24, III) from 24 to 60, IV) >60; moreover, on the basis of the total GC doses (grams), we have further subdivided the patients into 3 groups: A) <3, B) between 3 and 6, C) >6 g.

Results: GC alone were administered to 45% of patients, while 55% received GC plus immunosuppressant agents (methotrexate 91 patients, cyclophosphamide 13, azathioprine 7 and infliximab 4); 51% received calcium/vitamin D supplements and bisphosphonates, 30% calcium/vitamin D alone, while 19 % of patients, mainly due to a poor compliance, did not assume any osteoporosis treatment. Prevalence of diabetes was 5% (9/196), of which 2 new onsets and 7 worsened; arterial hypertension was reported in53% (103/196), all of which worsened. Prevalence of the other side effects was: cataract 42% (82/196), osteoporosis 37% (72/196), gastropathy 17% (34/196), vertebral fractures 10% (19/196). No significant differences in the prevalence of side effects was noted among sub-groups of GC duration and total dose, with the exception of vertebral fractures, that were reported as follows: I) 2%, II) 6%, III) 22%, IV) 38% (*p* 0,0002) and A) 2%, B) 15%,C) 21% (*p* 0,0033). Additionally, significant differences were observed in the prevalence of arterial hypertension (64% vs 46%, *p* 0,003) and osteoporosis (64% vs 31% p 0,04) between the groups of patients who received only GC and GC plus immunosuppressant therapy, respectively.

Conclusion: The most frequent side effect reported was arterial hypertension, which was pre-existing in all cases. Vertebral fractures correlated with duration and total doses of GC; the use of immunosuppressant agents seems to be useful to reduce the side effects of GC in GCA, sparing steroid doses.

Clinical Profile and Long-Term Outcome in a Monocentric Cohort of 210 Patients with Giant Cell Arteritis. Rosaria Talarico, Chiara Stagnaro, Anna d'Ascanio and Stefano Bombardieri, University of Pisa, Pisa, Italy

Purpose: Glucocorticoids (GC) are commonly used for the treatment or GCA; however, tapering or withdrawing GC therapy can be associated with disease flares. The aims of this study were to retrospectively evaluate the prevalence of clinical findings and the long-term outcome in a cohort of patients with GCA, followed in the last twenty years in a single centre.

Method: Two hundred and ten GCA patients (176 females, mean ± SD age 77±8 years) were retrospectively studied. The diagnosis was made according to ACR criteria in 196 patients and on the basis of the clinical decision in the others. Clinical features at the onset, therapeutic approach in all cases and long-term outcomes in patients with a minimum follow-up of 5 years were retrospectively analysed. We have defined as disease flare any further clinical manifestations compatible with the clinical spectrum of GCA and/or an increase of ESR ≥ 40 mm/hour, not otherwise justifiable, that required higher doses or new introduction of GC therapy.

Results: The most frequent clinical manifestations included: new onset headache and/or scalp pain 77%, constitutional symptoms 46%, jaw claudicatio 36%, vision loss 34%, abnormal temporal artery on examination 32%, dizziness 29%, neuropsychiatric symptoms 29%, cough 10%, cerebrovascular accidents 6% and hearing loss 5%. Irreversible blindness was reported in 7% of patients, mainly due to a latency period between onset and treatment of ≥ 2 months. Temporal artery biopsy was performed in 160/210 of patients, resulting positive in 58%. High-medium doses of pulse intravenous GC were administered at the onset (250-500mg for 3 consecutive days in those cases characterized by severe visual or neurological involvement and 40 mg in the others), followed by a rapid tapering scheme to low GC oral regimen; specifically, all our patients received a single morning mean dose of 4 mg of methyl-prednisolone. GC alone were administered to 45% of patients, while 55% received GC plus immunosuppressant agents, which in the majority of cases (91) consisted of methotrexate (MTX) at a mean dose of 10 mg/week; 13 patients were treated with cyclophosphamide, 7 patients with azathioprine, and 4 with infliximab. A total of 137 patients were followed for a minimum period of 5 years. At least one disease flare was observed in 13% of patients treated with GC plus immunosuppressant agents and in 35% of cases treated with only GC ($p < 0.0005$). Additionally, 53% and 36% stopped GC within 2 years from the onset in the group of GC plus immunosuppressant agents and in the group who received GC alone respectively ($p < 0.02$)

Conclusion: According to the literature data, new onset headache represents the most frequent clinical finding in GCA. GC still remain the therapy of choice, being essential in inducing remission and improving the visual prognosis in GCA; nevertheless the use of steroid sparing drugs seems to be useful in order to reduce the frequency of disease flares.

Definition of Remission and Relapse in Polymyalgia Rheumatica – Data From a Literature Search and a Delphi Based Expert Consensus. Christian Dejaco[1], Christina Duftner[1], Marco A. Cimmino[2], Bhaskar Dasgupta[3], Carlo Salvarani[4], Cynthia S. Crowson[5], Hildal Maradit-Kremers[5], Andrew Hutchings[6], Eric L. Matteson[5], Michael Schirmer[7] and ACR group for Development of Classification Criteria for PMR, [1]General Hospital of the Elisabethinen, Klagenfurt, Austria, [2]University, Genova, Italy, [3]Southend University Hospital, Essex, United Kingdom, [4]Arcispedale S. Maria Nuova, Reggio Emilia, Italy, [5]Mayo Clinic, Rochester, MN, [6]London School of Hygiene and Tropical, London, United Kingdom, [7]Medical University, Innsbruck, Austria

Purpose: To compare definitions of remission (REM) and relapse (REL) in PMR in current studies, and definitions based on an expert consensus using a Delphi survey.

Methods: A literature search was conducted in PubMed, key items “polymyalgia rheumatica”, “remission” and “relapse”. Relevant studies published through 11/03 (update 06/09) were screened for definitions on REM and REL and parameters relevant for monitoring PMR disease activity. For the Delphi survey 25 rheumatologists (R) and 25 general practitioners (GP) were invited. The questionnaire included clinical (n=33), laboratory (n=54) and imaging (n=7) parameters from literature research. The importance (“essential”, “less important”, “not important”) and availability (“routinely available”, “not always available”, “not available”) were assessed. A consensus was defined by agreement of >80%. Parameters considered “not important” or “not available” by >50% were excluded.

Results: Of the 6025 articles screened, definitions on REM and REL were available in 22 and 26 studies, respectively. Definitions on REM included improvement of pain (n=6), morning stiffness (MS, n=5), absence of PMR clinical symptoms (PCS, n=16), normal ESR (n=19), CRP (n=9), blood count (n=2) and fibrinogen (n=1) and low/no therapy (n=5). REL was defined by a flare of PCS (n=26), elevation of ESR (n=18), CRP (n=10) and response to corticosteroids (n=14).

In Delphi exercise 34/50 responded to the 1st and 22/34 experts to the 2nd questionnaire rounds. In the 1st round 63/94 items were excluded. After the 2nd round a consensus was obtained on the following parameters to be essential for the definition of REM and REL (limits of metric parameters with highest agreement rate in parentheses):

REM: MS (a limit of <15min had a 94.7% agreement), patients`assessment of pain [<10mm on a VAS (range 0-100mm), 58.8%], limitation of upper limb elevation (LULE, qualitative item), shoulder-pain worsened by mobilization (qualitative), clinical sign of coxo-femoral synovitis (qualitative), ESR (<20mm/1sth, 57.9%), CRP (<0.8mg/dL, 68.4%).

REL: MS (>30min, 94.7%), patients assessment of pain (>20mm, 93.8%), corticosteroid dose required to control symptoms (any dose increment, 62.4%), LULE, shoulder-pain worsened by mobilization, clinical sign of coxo-femoral synovitis, ESR (>40mm/1sth, 57.9%), CRP (>1.0mg/dL, 52.6%).

Conclusion: In a literature search and a consensus based Delphi survey the absence of typical clinical symptoms, normal ESR- and CRP-levels were considered to be important for the definition of REM and REL in PMR.

Increased Interferon Gamma Response to M. Tuberculosis Is Present in Patients with Active Takayasu's Arteritis. Omer Karadag[1], Kenan Aksu[2], Abdurrahman Sahin[1], Figen yargucu Zihni[2], Burcin Sener[1], Nevsun Inanc[3], Umut Kalyoncu[1], Sibel Zehra Aydin[3], Sibel Ascioglu[1], Pinar Talu Ocakci[2], Sule Apras Bilgen[1], Vedat Inal[2], Haner Direskeneli[3], Meral Calguneri[1], Ihsan Ertenli[1] and Sedat Kiraz[1], [1]Hacettepe University, Ankara, Turkey, [2]Ege University, Izmir, Turkey, [3]Marmara University, Istanbul, Turkey

Purpose: A possible relationship between Takayasu arteritis (TA) and Tuberculosis (TB) has been suggested. An increased frequency of tuberculin skin test (TST) was observed in TA patients. Quantiferon-TB Gold (QFT-G) is a new in vitro assay measuring interferon-gamma responses of PBMNc after stimulation by M. tuberculosis antigens and helpful in diagnosing latent TB infection. The aim of this study was to evaluate the frequency of latent TB infection among TA patients using both TST and QFT-G test and investigate its relationship with disease activity

Method: Ninety four (male/female:7/87) TA patients fullfilling ACR 1990 TA criterias from three different University Hospitals in Turkey and 97 control subjects without inflammatory diseases were included in the study. Data about medical history, TB exposure (previous TB infection or family history of TB), socioeconomic indicators (education status, income and job), smoking and demographics were collected for both TA and control groups. TST and QFT-G test (ELISA) were performed in both groups. Disease activity previous and current treatments were recorded. TST values ≥5 mm for TA patients and ≥15 mm for controls was accepted as TST positivity.

Results: Eventhough TA group was older (40 ±12 vs. 32± 8, p<0.001) there was no difference between TA patients and controls regarding smoking, socioeconomic indicators and medical history except previous TB infection. 6 TA patients and one control had a history of TB infection (p=0.05). Although TST positivity was higher in TA group [55 patients (62.5%) vs 24 controls (41.4%), p=0.008] , QFT positivity was similar between two groups [21 patients (22.3%) vs 24 controls (22.4%), p>0.05] . Thirty-four (36.1%) TST(+) TA patients were QFT(-), 2 of QFT(+) TA patients were TST(-). Thirty five (40%) TA patients had active disease whereas 53 (60%) were in remission. Active and remission groups were similar in previous TB infection history, TB exposure and TST(+), but active TA patients had higher QFT positivity than patients in remission [13 (37.1%) vs. 8 (15.1%), p=0.018]. No significiant difference was found between active and remission groups regarding previous/current treatments except for cyclophosphamide Twenty two (42.9 %) patients on cyclophosphamide treatment had QFT positive, but 9 of other TA patients had QFT positive (p=0.003).]

Conclusion: Despite similarity of QFT positivity between TA and control group, active TA patients had higher latent TB infection demonstrated by QFT. This result may suggest that In TA patients with latent TB infection, an infection-induced autoimmunity possibly induced by chronic antigenic stimulus, molecular mimicry and/or other tissue specific antigens may increase disease activity in TA.

Study of Vascular Endothelial Growth Factor (VEGF) and Hypoxia Inducible Factor 1 Alpha (HIF-1α) Gene Polymorphisms in Patients with Polymyalgia Rheumatica. Esther F. Vicente[1], María E. Fernández-Contreras[2], Santos Castañeda[1], Ana M. Ortiz[1], Amparo Casado[1] and Carlos Gamallo[3], [1]Rheumatology. Hospital de la Princesa, Madrid, Spain, [2]CIBERED. Hospital Universitario de la Princesa, Madrid, Spain, [3]CIBERED. Pathology Department. Hospital Universitario de la Princesa, Madrid, Spain

Purpose: The role that angiogenesis might play in the pathogenesis of polymyalgia rheumatica (PMR) is controversial. The purpose of our study was to determine the genotype frequencies of some vascular endothelial growth factor (VEGF) and hypoxia inducible factor (HIF)-1α single nucleotide polymorphisms (SNPs) in PMR patients, and to evaluate their possible divergence from a group of healthy volunteers. A secondary objective was to analyze the association of VEGF and/or HIF-1α genotype with some of the most frequent clinical manifestations of PMR, as well as with concurrent risk factors for cardiovascular disease (CVDRF).

Method: A cross-sectional study including 80 patients with clinical diagnosis of isolated PMR (67.5% females) and a group of 154 healthy volunteers (60% females) was performed. Samples consisted of genomic DNA extracted from whole peripheral blood mononuclear cells. Identification of -G634C VEGF and HIF-1α (C1772T and G1790A) SNPs was performed by polymerase chain reaction (PCR) and subsequent RFLP using Bsc4I, Aci I and BsmFI endonucleases. Mutation refractory PCR was used to determine -A2578A and -G1154A VEGF SNPs. Demographic, clinical and analytical variables, as well as the typical CVDRF (smoking, hypercholesterolemia, diabetes mellitus and hypertension) were collected. Immunossupressive treatments and glucocorticoid dose were compiled. Anemia (Hb<11g/dl), increased erythrocyte sedimentation rate (>40 mm/h) and biochemistry were also analyzed. Genotype differences between patients and healthy volunteers and associations of HIF-1α and VEGF genotype with the variables included, were estimated using the Fischer exact test or the Pearson's χ^2 test. Statistical significance was assumed for $p<0.05$ two-tail tests (SPSS software, v 15.0).

Results: Comparisons of genotype frequencies between patients and healthy volunteers yielded the following **results:** The frequencies of carriers of the variant VEGF -1154A and -2578C alleles in PMR patients were 91.3% and 97.8% ($p<0.0001$ and $p=0.03$, respectively). The genotype distribution of -G634C SNP did not differed from that of healthy donors. Variant HIF-1α 1772TT homozygous were predominant within the PMR group (23.9 vs. 5.4%; $p=0.001$). None of the studied polymorphisms showed any relationship with the clinical manifestations studied nor with the classical CVDRF.

Conclusion: The genotype distributions of -G1154A, -A2578C (VEGF) and C1772T (HIF-1α) genotypes observed in PMR patients strikingly diverged from those of healthy volunteers, the variant alleles being more frequent among the former. However, the studied polymorphisms do not seem to be related with the PMR clinical manifestations, or with the analyzed CVDRF.

Giant Cell Arteritis: A Negative Association with Cancer? Eamonn S. Molloy, Gary S. Hoffman and Carol A. Langford, Cleveland Clinic, Cleveland, OH

Purpose: To ascertain the odds of cancer associated with giant cell arteritis (GCA) as compared with non-GCA controls.

Methods: Data was obtained from the 2004 US Nationwide Inpatient Sample, a national hospital discharge database. Diagnoses were identified by ICD9 coding. Records coded for GCA (n=4,566) were matched with 18,264 controls (1:4); matching variables were age, sex, race and admission status (elective/non-elective). Conditional logistic regression was used to calculate odds ratios (OR) for GCA compared to controls, for cancer outcomes (all cancers, hematologic cancer, non-hematologic cancer, metastatic cancer) and non-malignant neoplasms. Demographic and clinical covariates were considered for inclusion in multivariate models, including age, sex, race, income, insurance payer, length of stay, AHRQ comorbidity measures.

Results: Based on both upon univariate (table 1) and multivariate analyses (table 2), GCA was associated with significantly reduced odds for all cancers compared to controls but.the odds of non-malignant neoplasms did not differ between GCA and controls.

Conclusion: GCA was associated with reduced odds of all measured cancer outcomes compared with non-GCA controls. There was however, no difference in the odds of non-malignant neoplasms between GCA and non-GCA controls, suggesting that the observed reduced

odds of cancer associated with GCA was not related to under coding of GCA where that was not the primary diagnosis. Potential, but not evaluable, explanations for these observations include [1] detection and management of pre-cancerous lesions may have occurred during initial evaluation for GCA, [2] more frequent physician visits and thus adherence to malignancy screening guidelines may have occurred in the GCA group [3] an effect of medications for GCA such as prednisone, aspirin and non-steroidal anti-inflammatory drugs could have influenced malignancy outcomes and [4] patients with a predisposition to GCA may be inherently less vulnerable to cancer. Further study will be required to explore these hypotheses.

Outcome	Odds Ratio	95% Confidence Interval	P Value
All cancer	0.47	0.41 – 0.54	<0.0001
Hematologic cancer	0.54	0.39 – 0.75	0.0002
Non-hematologic cancer	0.50	0.42 – 0.59	<0.0001
Metastatic cancer	0.39	0.30 – 0.50	<0.0001
Non-malignant neoplasms	0.97	0.79 – 1.21	0.81

Table 1. Results of univariate analyses for GCA versus controls.

Outcome	Odds Ratio	95% Confidence Interval	P Value
All cancer	0.48	0.41 – 0.56	<0.0001
Hematologic cancer	0.49	0.35 – 0.68	<0.0001
Non-hematologic cancer	0.53	0.45 - 0.64	<0.0001
Metastatic cancer	0.38	0.29 – 0.50	<0.0001
Non-malignant neoplasms	0.86	0.69 – 1.06	0.15

Toll-Like Receptor 2 Is a Receptor for beta2-Glycoprotein I On Endothelial Cells. Christophe Jamin[1], Jean-Eric Alard[1], Capucine Daridon[2] and Pierre Youinou[1], [1]Brest University Medical School Hospital, Brest, France, [2]Charite - Universitätsmedizin Berlin, , and Deutsches Rheumaforschungszentrum Berlin, 10117 Berlin, Germany, Berlin, Germany

Purpose: Toll-like receptors (TLRs) have long been suspected to bind to β2 glycoprotein I (β2GPI) on endothelial cells (ECs), yet interactions between TLRs and β2GPI have never been unequivocally proven. We elaborated the present study to identify the TLR directly involved in the binding of β2GPI on EC surface.

Method: ECs from human umbilical vein and EAhy926 cell line were cultured in vitro. Human and bovine β2GPI-specific antibodies were used to determine endogenous and exogenous expression of β2GPI in ECs. β2GPI-linked affinity column, confocal microscopy and western blotting analyses of purified lipid rafts were used to identify and localize the TLRs potentially associated with β2GPI. Co-immunoprecipitation with anti-β2GPI followed by mass-spectrometry identification of peptides were performed to identify which of the TLR2 or TLR4 interacted with β2GPI. Plasmon resonance-based approach was carried out to demonstrate the specific interaction. ECs deficient in TLR2 expression were obtained using short hairpin RNA interferences. Phosporylation status of IRAK following β2GPI stimulation of TLR2-deficient ECs was then evaluated.

Results: β2GPI is not synthesized and secreted by ECs in vitro, but rather taken up by ECs from fetal calf serum. β2GPI was localized within lipid rafts fraction of EC membrane together with TLR2 and TLR4. Mass-spectrometry analyses of anti-β2GPI co-immunoprecipitated protein indicated that TLR2, and not TLR4, interacted with β2GPI. Plasmon resonance experiments further confirmed that only TLR2 could bind β2GPI. Short hairpin RNA interferences generated TLR2-deficient ECs which loose their ability to bind biotinylated β2GPI and to trigger downstream phosphorylation of IRAK.

Conclusion: Though TLR4 may up-regulates TLR2 expression, thereby contributing to β2GPI uptake, our data demonstrate that direct binding of β2GPI on EC surface occurs through direct interaction with TLR2. Furthermore, signalling for anti-β2GPI may be envisioned as a multiprotein complex concentrated in lipid rafts on the EC membrane.

CC Chemokine Receptor 5 Ppolymorphism in Chronic Periaortitis. Luigi Boiardi[1], Augusto Vaglio[2], Carlo Buzio[2], Davide Nicoli[3], Enrico Farnetti[3], Bruno Casali[3], Nicolò Pipitone[1], Luca Magnani[4] and Carlo Salvarani[1], [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]Università di Parma, Parma, Italy, [3]Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, [4]Arcispedale S.Maria Nuova, Reggio Emilia, Italy

Purpose: Chronic periaortitis (CP) is a rare condition, characterized by a fibroinflammatory tissue surrounding the abdominal aorta and the common iliac arteries. Three main entities are included: idiopathic retroperitoneal fibrosis (IRF), inflammatory abdominal aortic aneurysms (IAAAs), and perianeurysmal retroperitoneal fibrosis (PRF). A systemic inflammatory nature of this condition is suspected by the presence of elevated acute phase reactants, constitutional symptoms and prominent adventitial inflammation. Chemokines may contribute to the inflammatory CP process through their binding to CC chemokine receptor 5 (CCR5). The aim of this study was to examine if the 32 base pair deletion allele in CCR5 (CCR5 delta 32 allele) might be associated with CP susceptibility.

Method: We enrolled 100 consecutive Italian patients with CP. As a control group we used 180 healthy blood donors from the same geographic areas. The CCR5 genotype of all CP patients and controls was studied by polymerase chain reaction amplification of the region which includes the 32 deletion (CCR5 delta 32).

Results: Homozygosity for CCR5 delta 32 allele was not detected in CP patients and controls. Carriers of the CCR5 delta 32 allele were significantly more frequent among the CP patients than among the controls (15% versus 5.6%; P corr = 0.018; odds ratio [OR] 3.0 [95% confidence interval (95% CI) 1.3-7.0]). No significant associations were found for comparisons of CP patients with and those without specific manifestations.

Conclusion: The presence of CCR5 delta 32 significantly influences disease susceptibility of CP in an Italian study population. Further studies are required to replicate our findings in other populations.

Disease Activity, Adverse Events and Quality of Life in the Second Year of Polymyalgia Rheumatica. Bhaskar Dasgupta[1], Andrew Hutchings[2] and UK PMR Study Group, [1]Southend University Hospital, Essex, United Kingdom, [2]London School of Hygiene and Tropical, London, United Kingdom

Purpose: PMR is a chronic inflammatory rheumatic disease of the elderly which can run a prolonged relapsing course of 2-3 years with adverse effects associated with long term steroid therapy. We have previously reported on the first year of an inception cohort study of 129 patients on the initial steroid response, quality of life, disability, course, adverse events and diagnostic uncertainty. The study showed severe impact on QOL, disability, frequent relapses and adverse events. We now report the 24 month follow up for this cohort study.

Method: A cohort of newly diagnosed PMR patients were studied from 8 centres meeting a modified version of the Jones & Hazleman criteria. 129 participants were recruited. Participants followed a tapered steroid schedule starting at 15mg daily oral prednisolone. Data on

disease activity, adverse events, and quality of life at 8 assessments were collected over 2 years. The impact of disease activity and adverse events on quality of life (physical and mental component of SF-36) on follow up was measured using general estimating equations and multivariable analysis adjusted for baseline covariates, comorbidity and socio-demographic variables.

Results: Relapse-free survival in the cohort at one and two years was 68.8% (95% CI 58..8 - 75.3) and 42.4% (95% CI 33.1 -51.4) respectively. The median (inter-quartile range) of mean daily steroid dosage and cumulative steroid dose at 24 months was 0.5 mg (0- 2.8) and 3310 mg (3300 – 3800) respectively. Adverse events over 24 months are as in the table.

	W3	W6	M3	M6	M12	M18	M24	Overall
% weight gain from baseline (mean)	0.1	1.0	2.5	3.6	4.4	2.6	2.0	-
Bruising (%)	2.3	3.9	8.7	9.8	13.1	12.8	6.7	22.5
Moonface (%)	0.8	6.3	15.9	17.9	12.3	6.4	1.0	28.7
Ankle oedema (%)	3.9	9.4	11.9	10.6	11.5	14.7	10.6	26.4
Poor diabetic control (%)	8.5	8.7	9.5	9.8	12.3	11.0	10.6	14.0
Fractures (%)	0.0	0.8	1.6	0.8	2.5	0.0	0.0	4.7

Improvement in QOL and HAQ at 12 months was maintained in the second year. In terms of disease activity both ESR ($p< 0.01$) and shoulder pain ($p< 0.01$) had significant impact on physical and mental component of scores of the SF-36. Among adverse events only bruising had an impact on physical QOL ($p= 0.02$).

Conclusion: Our study suggests that there is good control of disease activity in the second year in PMR although relapses continue to be reported. Chronic complications such as diabetes and hypertension were seen although we recorded few fractures – perhaps reflecting correct disease assessment and use of steroids in minimum effective doses. This also explains the reduction in weight gain, bruising and moonface in the second year.

QOL improves with steroid therapy in the first year and there does not appear to be a long term impact of PMR. Disease activity rather than adverse events were associated with changes in physical and mental quality of life

Interleukin 10 Promoter Polymorphisms in Patients with Elderly Onset Inflammatory Conditions. Lorena Alvarez-Rodriguez[1], Eugenio Carrasco-Marin[2], Marcos Lopez-Hoyos Sr.[2], Cristina Mata[3], Maria Jose Marin[2], Jaime Calvo Sr.[3], Ricardo Blanco Sr.[1], Lorena Fernandez-Prieto[2], Ignacio Villa Sr.[4], Cristina Martinez-Dubois[2], Vicente Rodriguez-Valverde[2] and Victor M. Martinez-Taboada Sr.[1], [1]Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Hospital Universitario Marques de Valdecilla-IFIMAV, Santander, Spain, [3]Hospital Sierrallana, Torrelavega, Spain, [4]Hospital de Sierrallana, Torrelavega, Spain

Purpose: Cytokines driving the inflammatory response seem to be disturbed in elderly-associated inflammatory conditions, such as polymyalgia rheumatica (PMR), giant cell arteritis (GCA) and elderly-onset rheumatoid arthritis (EORA). IL-10 is considered a suppressor cytokine that can counteract the effect of inflammatory cytokines. Genetic differences in the promoter of IL-10 have been studied in GCA with non-conclusive results. The aim of the present study was to assess the frequencies of two SNPs in the promoter region of the IL-10 gene in PMR, GCA and EORA patients and to investigate their association with clinical features and IL-10 production.

Method: Two SNPs (-1082 G/A and -592 C/A) in the IL-10 gene promoter were genotyped in 171 patients with PMR, 78 patients with GCA, 94 patients with EORA, 79 patients with young-onset rheumatoid arthritis (YORA) and 190 unrelated age-matched controls (HC). The genotype was determined using allele-specific PCR and restriction fragment length polymorphism analysis. Levels of serum IL-10 were measured by the cytometric beads array (CBA).

Results: Carriers of the A-1082 allele (A/A or A/G) were significantly more frequent in PMR (OR 3.0, 95% CI: 1.5-6.1, p=0.001), in GCA (OR 3.8, 95% CI: 1.7-8.5, p=0.001) and EORA (OR 3.0, 95% CI: 1.4-6.7, p=0.004) than in HC. Distribution of A-1082 allele in EORA was more similar to the other age-associated inflammatory conditions and differed from YORA where it was less frequent (OR 0.3, 95% CI: 0.1-0.9, p=0.03). The frequency of the A-592 allele (A/A or A/C) was similar between age-associated disorders and HC. Again, YORA and EORA patients differed marginally in the carriage rate for this allele (OR 0.5, 95% CI: 0.3-0.99, p=0.045). Haplotype analysis showed a similar frequency of haplotypes between PMR and EORA and diminished frequency of the ACC haplotype in GCA patients as compared with HC (; OR: 1.9, 95% CI: 1.3-2.8, p = 0.002). The ATA haplotype was more frequent in YORA than in EORA (OR 1.7, 95% CI: 1.1-2.8, p= 0.029) or HC (OR 1.87, 95% CI: 1.25-2.8, p= 0.005). In our study we did not find an association between any of the haplotypes and IL-10 serum levels or in vitro production of IL-10.

Conclusion: Our results suggest that the IL-10 A-1082 allele confers genetic susceptibility to elderly onset inflammatory conditions. YORA differs from EORA and the other age-related inflammatory conditions, and is associated with a lower IL-10 producing phenotype.

IgG4-Related Systemic Disease Accounts for a Significant Proportion of Thoracic Lymphoplasmacytic Aortitis Cases. John H. Stone[1], Arezou Khosroshahi[1], Vikram Deshpande[2] and James R. Stone[2], [1]Massachusetts General Hospital, Boston, MA, [2]Boston, MA

Purpose: IgG4-related systemic disease, a disorder recognized only recently, can cause lymphoplasmacytic inflammation in the thoracic aorta. The percentage of aortitis cases caused by IgG4-related systemic disease is not known. We hypothesized that IgG4-related systemic disease accounts for a subset of cases of thoracic aortitis and for a significant fraction lymphoplasmacytic thoracic aortitis cases. To test this hypothesis, we reviewed the experience at our institution with thoracic aortitis over a five-year period and evaluated the existing literature in light of this experience. We also sought to establish pathologic criteria for identifying involvement of the thoracic aorta by this disorder.

Methods: We searched our Pathology Service database to identify all patients with non-infectious thoracic aortitis who underwent resection over a 5-year time span. The essential inclusion criterion for the designation of non-infectious aortitis was the presence of chronic inflammation that was not characteristic of either atherosclerosis or aortic dissection. The exclusion criteria were a history of previous aortic surgery or evidence of an infectious aortitis. We subclassified the non-infectious aortitis cases into two categories based on the nature of the inflammatory component. Those cases with granulomatous inflammation with or without a significant plasma cell component were classified broadly as "granulomatous". Granulomatous inflammation was defined as an inflammatory infiltrate that was rich in activated (epithelioid) macrophages, with or without giant cells. In contrast, cases with lymphoplasmacytic infiltrates in which granulomatous inflammation was absent were classified as lymphoplasmacytic aortitis. All cases of lymphoplasmacytic aortitis along with representative cases of giant cell aortitis and atherosclerosis were stained by immunohistochemistry for IgG4 and for CD138, a plasma cell marker CD138. We thereby determined the fraction of plasma cells that stained for IgG4.

Results: Of 638 resected thoracic aortas, 33 (5.2%) contained non-infectious aortitis. Four of these cases (12% of all patients with non-infectious aortitis) had histologic features of lymphoplasmacytic aortitis. Three of those four cases (9% of non-infectious aortitis cases) demonstrated pathologic involvement by IgG4-related systemic disease. Among those three cases, an elevated proportion of plasma cells (0.82±0.08) stained for IgG4, compared with cases of giant cell aortitis (0.18±0.13) and atherosclerosis (0.19±0.08)($P < 0.00001$).

Conclusion: IgG4-related systemic disease accounted for 75% of lymphoplasmacytic aortitis cases and approximately 9% of all cases of non-infectious thoracic aortitis in our institution during a five-year period. Immunohistochemical assessment of the percentage of plasma cells that stain for IgG4 in resected aortas is helpful in identifying patients who have IgG4-related systemic disease. The knowledge that IgG4-related systemic disease can be associated with thoracic aortitis signals the need for a re-classification of non-infectious aortitis.

Changes in Gene Expression Induced by Blocking Interferon Gamma (IFNg) IN EX-Vivo Cultured Arteries from Patients with Giant-CELL Arteritis (GCA). Marc Corbera-Bellalta, Ester Lozano, Ana García-Martínez, Georgina Espígol-Frigolé, Sergio Prieto, Montserrat Butjosa, Ester Planas-Rigol, José Hernández-Rodríguez and Maria C. Cid, Hospital Clínic. IDIBAPS. University of Barcelona, Barcelona, Spain

Background: IFNg is barely detectable in normal arteries but strongly expressed in GCA lesions. Based on its crucial role in macrophage activation and granuloma formation, IFNg has been considered a potential therapeutic target in GCA. However blocking IFNg has not consistently demonstrated efficacy in animal models of other chronic inflammatory diseases, indicating the need for a better understanding of the role of IFNg in GCA.

Purpose: To investigate changes in gene expression induced by a neutralizing monoclonal antibody against IFNg as compared to glucocorticoids in *ex-vivo* cultured temporal artery biopsies from patients with GCA

Methods: Temporal artery sections from 2 patients with biopsy-proven GCA and 2 controls with normal temporal artery biopsies were cultured *ex-vivo*, on the reconstituted basement membrane Matrigel^{TM}. Sections were treated with medium, an anti-human monoclonal antibody (A6) (kindly provided by W Ferlin and MH Kosko-Vilbois, Novimmune SA) generated with high potency to block IFNg-induced responses *in vitro* (10 mg/ml), control IgG1 (same concentration), or dexamethasone (0,5mg/ml). After 5-day incubation, RNA was extracted, reverse- transcribed and a screening of gene expression (90 genes) was performed using real-time PCR-based micro fluidic expression cards (Taqman^{R} Human Immune Array) from Applied Biosystems. Data was analyzed with the SDS 2.3 software.

Results: GCA arteries had increased expression of macrophage (CD68), T cell (CD3, CD4, CD8) and B cell (CD19) markers, co-stimulatory molecules (CD28, CD40, ICAM-1), proinflammatory cytokines (IL-2, IL-1b, TNFa, IL-6), chemokines (CCL3, CCL19, CCL2, CCL5, CXC10, CXCL11), chemokine receptors (CCR2, CCR5, CCR7, CXCR3), and colony –stimulating factors (particularly CSF 3) compared to control arteries. Conversely, Th2 cytokines (IL-4, IL-10 and IL-13) were decreased. Treatment of GCA arteries with dexamethasone or A6 led to a dramatic decrease in all the above cell markers, co-stimulatory molecules, proinflamatory cytokines, chemokines and receptors and CSF3. Th2 cytokines slightly increased. Overall, the effect was more prominent for dexamethasone than for IFNg inhibition. Quantitative assessment of these markers by real-time PCR in a larger series of cultured arteries is ongoing with the aim of better discriminating potential relevant differences between dexamethasone effect and IFNg neutralization on cultured GCA arteries.

Conclusion: With the limitation of the reduced number of cases studied, these preliminary results indicate that IFNg neutralization, down-regulates a number of inflammatory markers which are thought to contribute to disease pathogenesis in GCA. SAF 05/06250 and MTV3 06/0710.

Utility of FDG-PET CT Scanning in a Rheumatology Service: Indications, Results and Influence On Management Decisions. Imran Riaz[1], Parasar Ghosh[1], Frances Borg[1] and Bhaskar Dasgupta[2], [1]Southend University Hospital NHS Foundation Trust, Westcliff on Sea, United Kingdom, [2]Southend University Hospital, Essex, United Kingdom

Purpose: ^{18}F-fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) with Computed Tomography (CT) is mainly used in the evaluation of malignancy, but is known to identify inflammatory conditions, including large vessel vasculitis and infiltrative diseases.The current data on utility of FDG-PET in rheumatology are sparse and the reiumbursement of such scans for non-oncology use is difficult. There are no existing rheumatology guidelines regarding its utility or indications**.**

Method: We report a retrospective case series of 31 rheumatology patients who had PET-CT from 2004-2008. Case notes were reviewed for the underlying diagnosis, indication for the scan and its effect on therapy decisions. The PET scans were reviewed, and FDG uptake was graded on a 4-point scale: none (grade 0), lower than liver uptake (grade 1), similar to liver (grade 2) and higher than liver (grade 3). Grade 2 or more was accepted as PET positivity.

Results: 31 patients were identified (16 male, median age 62, range 10-82, all caucasian).

PMR and GCA

11 patients had PMR and 7 had cranial GCA. All had systemic features and poor response to treatment. 5 patients had positive scans. In 4 of these, strong FDG uptake was seen in subclavian, aortic, and axillary arteries, suggesting the development of associated large vessel arteritis. All these patients had subsequent successful response to treatment with methotrexate or leflunomide. The remaining patient proved to have Erdheim Chester histiocytosis and was treated with infliximab. However, PET-CT was negative in all 7 patients with cranial GCA.

Large vessel ischaemia

Of 6 younger patients with symptoms of aortic, large vessel or peripheral ischaemia with inflammatory response, 2 were found to have inflammatory aortitis on PET-CT. Both had excellent response to therapy with methotrexate and high dose steroids.

Miscellaneous

Three patients with multisystem sarcoidosis and one with granulomatous mastitis underwent PET-CT to establish the burden of active disease, and guide the choice of therapy. PET was positive in all 4 patients. One was treated with steroids, two with infliximab and one with methotrexate and steroids.

In 3 patients with connective tissue disease and severe constitutional symptoms (1 Sjogrens, 1 RA and 1 post-thymectomy SLE) ; FDG-PET study was negative.

Conclusion: Our results suggest that PET-CT may be useful in ruling in or out large vessel arteritis in PMR and GCA patients with persistent systemic features; unresponsive to corticosteroid therapy and where other investigations (e.g. CT, MRI) have been non-contributory. It can also distinguish between inflammatory and atherosclerotic peripheral vascular disease. It may have a role in assessing active disease burden and planning immunosuppression in infiltrative diseases like sarcoidosis and histiocytosis.

We suggest the development of international guidelines for the indications for FDG-PET scanning in rheumatology.

Study of Vascular Endothelial Growth Factor (VEGF) and Hypoxia Inducible Factor 1 Alpha (HIF-1α) DNA Polymorphisms in Patients of with Giant Cell Arteritis. Santos Castañeda[1], María E. Fernández-Contreras[2], Esther F. Vicente[1], Isidoro González-Álvaro[1], Inmaculada Carvajal[1], Txaro García-Vicuña[1] and Carlos Gamallo[3], [1]Rheumatology Department. Hospital de la Princesa, Madrid, Spain, [2]CIBERED. Hospital de la Princesa, Madrid, Spain, [3]CIBERED. Pathology Department. Hospital Universitario de la Princesa, Madrid, Spain

Purpose: To determine the genotype distribution of 3 single nucleotide polymorphisms (SNPs) within vascular endothelial growth factor (VEGF) gene and two within hypoxia inducible factor (HIF)-1α in a group of giant cell arteritis (GCA) patients and to analyse the association of these VEGF and/or HIF-1α genotypic variants with the occurrence of the most representative clinical manifestations of GCA.

Method: A cross-sectional study including 60 patients (51 females) with biopsy-proven GCA and 154 healthy volunteers (60% females). Genomic DNA was extracted from whole peripheral blood mononuclear cells. Determination of C1772T and G1790A HIF-1α and -G634C VEGF SNPs was performed by PCR-RFLP using specific restriction endonucleases. A specific PCR was used for -A2578C and -G1154A VEGF identification. Demographic, clinical, analytical (haemoglobin, ESR and RF), arterial ischaemic manifestations (jaw claudication, visual impairment, stroke, ischaemic heart disease and peripheral arteriopathy), and classical risk factors for cardiovascular disease (CVDRF) as smoking, hypercholesterolemia, diabetes and hypertension were collected. Genotype differences between patients and controls, and the association of SNPs with demographic, analytical, and clinical variables were estimated using the Fischer exact test or the Pearson's $\chi 2$ test. Statistical significance was assumed for $p< 0.05$ two-tail tests (SPSS software, v 15.0).

Results: Comparisons of both overall and sex adjusted genotype frequencies showed: VEGF: The variant -634CC was infrequent in GCA patients, compared to healthy donors (5.4% vs. 33.7%; $p<0.001$), -634GG homozygous wild type prevailing (51.4% vs. 20.7%; $p<0.001$). The vast majority of GCA patients (86.8%) were carriers of the variant -1154A allele ($p< 0.0001$). HIF-1α: The variant homozygous 1772TT genotype was more frequent within the GCA group (12.8% vs. 4.4%; $p=0.03$). VEGF -2578CC genotype was related to the occurrence of severe ischaemic manifestations (22.2% vs. 0% in patients without ischaemia; $p=0.02$); meanwhile, the -2578A wild type allele was

associated to hypertension (p=0.007). Wild type homozygous 1772CC (HIF-1α) prevailing among patients with hypercholesterolemia (95% vs. 66.7% of patients with normal cholesterol; p=0.04).

Conclusion: The present study reveals differences in the genotype distribution of a number of VEGF and HIF-1α SNPs between GCA patients and healthy volunteers. Concerning clinico-pathological variables, VEGF -2578CC resulted to be associated to the occurrence of severe ischaemic manifestations of the disease, but none of the studied genotypes was related to the analysed CVDRF.

186

Identification of Target Antigens of Anti-Endothelial-Cell and Anti-Vascular-Smooth-Muscle-Cell Antibodies in Patients with Giant Cell Arteritis : a Proteomic Approach. Alexis Régent[1], Hanadi Dib[1], Christian Agard[2], Luc Camoin[3], Babette Weksler[4], Cedric Broussard[3], Loïc Guillevin[5] and Luc Mouthon[6], [1]Paris Descartes University, UPRES-EA 4058, Paris, France, [2]Internal medicine, Hotel Dieu hospital, Nantes, France, [3]Inserm U 567, CNRS UMR 8104, Cochin Institute, Paris, France, [4]Cochin Institute, Paris, France, [5]Hospital Cochin, Paris, France, [6]Paris Descartes University, UPRES-EA 4058, Department of Internal Medicine, Cochin Hospital, Paris, France

Purpose: In giant cell arteritis (GCA), immunological studies suggest the existence of a triggering antigen of unknown nature activating T-cell in the arterial wall. In experiments performed in animal models, a proliferation of T-cells from the xenotransplant suggests a possible recognition of a locally expressed antigen. We thus decided to use a proteomic approach in order to identify the target antigens of auto-antibodies directed against endothelial cells (EC) and vascular smooth muscle cells (VSMC).

Method: Sera from 15 GCA patients were tested in pools of 3 sera and compared to a sera pool from 12 healthy controls (HC). Serum IgG reactivity was analyzed by use of a 2-D electrophoresis and immunoblotting technique with antigens from normal human umbilical vein endothelial cells (HUVEC) and mammary-artery-VSMC. Targets antigens were identified by mass spectrometry (MALDI-TOF-TOF).

Results: Serum IgG recognized 162±3 and 158±61 protein spots from HUVEC and VSMC respectively, whereas serum IgG antibodies from HC recognized 79 and 228 protein spots respectively. Twenty-eight spots from HUVEC were recognized by at least 2/3 pools and not by HC. Twelve spots from VSMC were recognized by at least 3/5 pools and not by HC. Among identified proteins we found lamin A/C, voltage dependent anion selective channel protein 2, annexin V and other protein involved in cell energy metabolism and key cellular pathways.

Conclusion: IgG anti-EC antibodies and anti-VSMC antibodies are present in the serum of patients with GCA. These antibodies recognize cellular targets playing key roles in cell biology and maintenance of homeostasis. The function of these antibodies and their possible role in pathology have to be further explored.

ACR Poster Session A

Osteoarthritis Epidemiology & Imaging

Sunday, October 18, 2009, 9:00 AM - 6:00 PM

187

Clinical Burden of Erosive Hand Osteoarthritis. J. Bijsterbosch, I. Watt, I. Meulenbelt, FR Rosendaal, Twj Huizinga and M. Kloppenburg, LUMC, Leiden, Netherlands

Purpose: To investigate the clinical burden of erosive hand osteoarthritis (EHOA) in terms of pain, functioning, and quality of life.

Method: In this analysis 42 patients with EHOA and 194 patients with non-EHOA, participating in the Genetics ARthrosis and Progression (GARP) study, were included (83% women, mean age 65 yrs). EHOA was defined as the presence of erosive radiographic features in at least

2 interphalangeal joints. Self-reported pain was measured with the Australian/Canadian Osteoarthritis Hand Index (AUSCAN). The number of self-reported painful joints and pain intensity upon joint palpation were assessed. Functioning was evaluated with the AUSCAN, the Michigan Hand Outcome Questionnaire (MHQ), grip strength, pinch grip, finger-palm distance upon finger flexion, and the Hand Mobility in Scleroderma test (HAMIS). The HAMIS assesses all movements in the range of motion of the hand, higher scores reflecting worse mobility. Quality of life was assessed with the physical and mental component scales (PCS and MCS) of the Short Form-36 (SF-36). Additionally, patient satisfaction with hand function and aesthetics were evaluated. Measures were compared between patient groups using t-test and Mann-Whitney U test. To determine whether differences can be attributed to erosive disease or disease severity in general, corrections were made for the number of nodes using linear regression.

Results: Demographic characteristics did not differ between the groups. Patients with EHOA experienced more pain and reported more functional limitations, less satisfaction with hand function, and more aesthetic complaints than patients with non-EHOA (table). Grip strength and pinch grip did not differ. Finger mobility was worse in EHOA, while thumb mobility was comparable. The SF-36 was similar for the groups. After correction for the number of nodes, being higher in EHOA, only finger mobility, satisfaction with hand function and aesthetics remained significantly different between the groups.

	EHOA *n=42*	*Non-EHOA* *n=194*	*P-value*
Pain			
AUSCAN pain (0-20)	9.0 (5.0)	7.1 (4.8)	0.02
Number of painful joints (0-30)*	10 (6-17)	6 (2-12)	<0.01
Pain intensity (0-90)*	6.5 (3-13)	4 (1-10)	0.03
Function			
AUSCAN function (0-36)	17.3 (8.7)	13.3 (8.6)	<0.01
MHQ ADL (0-100)*	77 (64-88)	83 (70-94)	0.03
Grip strength, kg	19.7 (8.4)	21.2 (10.1)	0.37
Pinch grip, kg	3.2 (1.8)	3.1 (1.5)	0.79
HAMIS thumb (0-3)	1.5 (1.0)	1.3 (0.9)	0.19
HAMIS fingers (0-9)	1.8 (1.6)	0.6 (1.0)	<0.01
Finger-palm distance, mm*	45 (9-83)	0 (0-16)	<0.01
Quality of life			
SF-36 PCS	44.1 (9.0)	45.0 (9.1)	0.53
SF-36 MCS	50.2 (9.4)	50.6 (10.2)	0.82
MHQ function satisfaction (0-100)*	48 (29-59)	63 (40-83)	<0.01
MHQ aesthetic satisfaction (0-100)*	81 (63-83)	89 (75-100)	<0.01
Number of nodes (0-30)	***17.0 (3.5)***	***12.3 (5.4)***	***<0.01***

Values are means (SD) unless stated otherwise

*Median (interquartile range)

Conclusion: Patients with EHOA experience more pain, more functional limitations of especially the fingers, and less satisfaction with hand function and aesthetics than patients with non-EHOA. Quality of life was similar. Because of the higher number of nodes in EHOA, and the association between the number of nodes and outcome measures, it is unclear whether the differences can be attributed to erosive disease in itself or disease severity in general.

188

Long-Term Clinical and Radiographic Progression of Hand Osteoarthritis and Its Determinants. J. Bijsterbosch, I. Watt, I. Meulenbelt, F.R. Rosendaal, T.W.J. Huizinga and M. Kloppenburg, LUMC, Leiden, Netherlands

Purpose: Because of limited knowledge on the natural history of hand osteoarthritis (HOA), clinical and radiographic progression of HOA and their determinants were investigated over a 6-year period.

Method: Data of 242 HOA patients (mean age 60 yrs, 83% women) participating in the Genetics, ARthrosis and Progression (GARP) study were used. HOA was defined by the ACR criteria for clinical HOA or the presence of structural abnormalities in the hands (nodes/radiographic OA). Self-reported hand pain and function were assessed with the Australian/Canadian Osteoarthritis Hand Index (AUSCAN). The number of self-reported painful joints, number of nodes and pain intensity upon joint palpation were assessed. On standardized hand radiographs osteophytes (OP), joint space narrowing (JSN) and subchondral erosions were scored using the OARSI atlas. Baseline determinants of clinical progression, reflected by AUSCAN change, were evaluated using linear regression. Logistic regression was used to assess baseline determinants of radiographic progression, which was defined as a change in OP and/or JSN above the smallest detectable change. Adjustments were made for age, sex and BMI.

Results: There was a significant increase in OP and JSN with a mean change ± SD of 1.8 ± 2.3 and 1.1 ± 2.0, respectively. Radiographic progression was present in 53% of patients. A small but significant worsening in AUSCAN pain, AUSCAN function, and pain intensity was seen with mean changes ± SD of 0.5 ± 4.1, 2.0 ± 6.8, and 2.7 ± 7.0, respectively. The number of painful joints at baseline was positively associated with change on AUSCAN pain. No other determinants of clinical progression were found. Determinants of radiographic progression are shown in the table. Radiographic progression was not associated with AUSCAN change.

Table: Risk of radiographic progression related to tertiles of baseline features and HOA subtypes

	Tertiles	*Risk ratio (95% CI)*
Baseline features		
AUSCAN pain (0-20)	<4	1.0
	4-8	1.3 (0.8-1.7)
	>8	1.6 (1.2-2.0)
AUSCAN function (0-36)	<6	1.0
	6-15	1.2 (0.8-1.6)
	>15	1.4 (1.0-1.7)
Number of painful joints (0-30)	<4	1.0
	4-8	1.6 (1.2-2.0)
	>8	1.4 (1.0-1.8)
Pain intensity (0-90)	<1	1.0
	1-3	1.8 (1.3-2.2)

	>3	1.9 (1.4-2.3)
Number of nodes (0-30)	<6	1.0
	6-12	2.3 (1.7-2.8)
	>12	2.7 (2.1-3.1)
OP (0-90)	<6	1.0
	6-12	1.2 (0.8-1.7)
	>12	1.8 (1.4-2.2)
JSN (0-90)	<14	1.0
	14-21	0.7 (0.5-1.1)
	>21	1.4 (1.1-1.6)
HOA subtypes		
Erosive HOA[1]	-	1.8 (1.5 – 2.0)
Nodal HOA[2]	-	2.4 (1.8 – 2.9)
Thumb base involvement	-	1.6 (1.3 – 1.9)

[1]Presence of subchondral erosions in ≥ 2 interphalangeal joints

[2]Presence of nodes in ≥ 2 rays of either hand

Conclusion: Radiographic progression of HOA over 6 years was considerable and associated with higher baseline levels of pain and structural abnormalities. Erosive HOA, nodal HOA, and thumb base involvement were associated with a higher risk for radiographic progression. This suggests that it is severity rather than HOA subtype that determines the risk for progression. In contrast, clinical deterioration was small and difficult to predict. Radiographic and clinical progression were not associated. This has implications for the appreciation of clinical outcomes in OA research, including possible need for improvement of outcome measures.

Evaluation of the AUSCAN Index in Hand Osteoarthritis (HOA) Using Rasch Analysis. Ida K. Haugen[1], B. Slatkowsky-Christensen[1], Désirée M.F.M. van der Heijde[2] and T.K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands

Purpose: Previous studies of the Australian/Canadian (AUSCAN) index have shown satisfactory performance with regard to validity, reliability, and responsiveness. Our aim was to examine whether AUSCAN fits the Rasch model in a HOA cohort.

Method: AUSCAN index was completed by 209 HOA patients (190 women, 19 men) aged 50-70 at baseline and by 126 patients (115 women, 11 men) at 5-year follow-up. AUSCAN is a patient-reported questionnaire with three subscales: pain (5 items), stiffness (1 item) and physical function (9 items) on a 0-4 Likert scale. The Rasch Rating Scale Model (Winsteps software) was used for evaluation of item difficulty and person ability estimates, unidimensionality (fit statistics) and reliability. The Rasch model places both item and person ability estimates on the same logit scale. Items at the lower end (negative values) are "easier" items (most likely to be endorsed), while items at the other end (positive values) are considered as "difficult" (only endorsed when higher disability/pain). Mean person estimate should be close to mean item estimate (arbitrarily set to 0.0) for the scale to be well-targeted. High fit statistics (mean square (MNSQ) INFIT) > 1.2 indicate

measurement of another construct, while low fit statistics (< 0.8) indicate overlapping items. The analyses were first done for each subscale separately, and then for all 15 items together at both time points.

Results: Adequate range of item difficulty (2.52, 3.62 logits), and well-ordered category thresholds were found for the AUSCAN pain scale. Negative mean person estimates (-1.93 and -2.11) indicated that most items were too "difficult" in this sample. The most "difficult" item, "pain at rest", showed high fit statistics (1.49, 1.32), indicating measurement of an alternative construct. "Pain when gripping" showed low fit statistics (0.64, 0.56), indicating redundancy. Person and item reliability was excellent (> 0.91).

The AUSCAN physical scale showed large range of item difficulty (3.85, 3.75) and well-ordered category thresholds. Mean person estimates were closer to zero (-0.87, -0.65) than the pain subscale, showing better targeting of the scale. No items showed misfit to the model, and the reliability was excellent (> 0.93).

The only item in the stiffness scale showed high fit statistics (1.42, 1.43) when analysing all items together, indicating that this domain represents another construct different from pain and function. The hypothesis that pain and function are closely related was further emphasized since 4 of 5 pain items (except "pain at rest") showed low fit statistics, indicating redundant items.

Conclusion: Our findings, applying the Rasch model, confirmed unidimensionality of the the AUSCAN pain and physical function subscales. Pain and function seemed to capture the same construct, with possible redundant items, while morning stiffness was measuring a different construct. However, these findings need to be further analysed by residual component analyses.

190

Comparison of the Performance of AUSCAN Physical Function Subscale, AIMS2 and FIHOA in Hand Osteoarthritis (HOA) by Rasch Analysis. Ida K. Haugen[1], B. Slatkowsky-Christensen[1], Désirée M.F.M. van der Heijde[2], N. Bellamy[3] and T.K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Mayne Medical School, Herston, Australia

Purpose: Several indices exist for assessment of physical function in HOA. Our aim was to compare the performance of Australian/Canadian (AUSCAN) physical function scale, Arthritis Impact Measurement Scale 2 (AIMS2) hand/finger scale and Functional Index for Hand Osteoarthritis (FIHOA) using the Rasch model in a HOA cohort.

Method: 126 patients (115 women, 11 men) aged 55-75 years were examined using three self-reported questionnaires; AUSCAN, AIMS2 and FIHOA. AUSCAN and FIHOA are disease-specific indices with 9 and 10 items measuring physical function on a 0-4 and 0-3 Likert scale, respectively. AIMS2 hand/finger subscale consists of 5 items on a 0-4 Likert scale. Rasch Rating Scale Model (Winsteps software) was used for evaluation of item difficulty and person ability estimates, unidimensionality (fit statistics) and reliability. Fitting data to the Rasch model places both item and person ability estimates on the same logit scale. Items at the lower end (negative values) are "easier" items (most likely to be endorsed), while items at the other end (positive values) are considered as "difficult" (only endorsed when higher disability). Mean person estimate should be close to mean item estimate (arbitrarily set to 0.0) for the scale to be well-targeted. High item fit statistics (mean square (MNSQ) INFIT) > 1.2 indicate measurement of another construct, while low fit statistics (< 0.8) indicate overlapping items.

Results:

	AUSCAN	**AIMS2 hand**	**FIHOA**
Range of item difficulty (logits)	3.75	2.93	2.32
Mean (SD) item estimate	0.00 (1.10)	0.00 (1.04)	0.00 (0.65)
Mean (SD) person estimate	-0.65 (2.39)	-0.79 (1.32)	-1.16 (1.63)
Item reliability	0.98	0.99	0.93
Person reliability	0.93	0.70	0.85

High fit statistics **(MNSQ INFIT value)**		"Open a jar" (1.33)	"Accept handshake" (1.47) "Clench fist" (1.99)
Low fit statistics **(MNSQ INFIT value)**			"Cut meat" (0.67) "Fasten buttons" (0.67) "Sew/screwdriver" (0.69)
Well-ordered category thresholds	Yes	No	Yes

The comparison of the three questionnaires showed that AUSCAN had adequate range of item difficulty, best targeting of the scale (mean person estimate close to mean item estimate), and high person and item reliability. Negative person estimates indicate that the persons have less average disability than average of the scale, and few items were at the lower end of the scale for both AIMS2 and FIHOA. The FIHOA items also showed clustering with small spread of items along the disability scale (SD < 1). AUSCAN had no misfitting items, while the FIHOA had two items with high fit statistics (indicating measurement of another construct) and three items with low fit statistics (indicating redundancy). For AIMS2 we found disordered thresholds, and collapsing categories may be considered.

Conclusion: Our study confirmed that the AUSCAN physical function subscale is a unidimensional, well-targeted scale with high person and item reliability and well-ordered thresholds, and performs better compared to AIMS2 and FIHOA.

191

The Association Between Ultrasound (US), Joint Counts and Symptoms in Hand Osteoarthritis (HOA). Ida K. Haugen, B. Slatkowsky-Christensen, A. Mathiessen, T.K. Kvien and H.B. Hammer, Diakonhjemmet Hospital, Oslo, Norway

Purpose: To evaluate the relationship between US, joint counts and symptoms in a HOA cohort.

Method: 126 patients (115 women, 11 men) with mean age 68.5 years completed self-reported questionnaires, joint examination and US. Australian/Canadian (AUSCAN) hand index is a self-reported questionnaire measuring pain (5 items), stiffness (1 item) and physical function (9 items) on a 0-4 Likert scale. The subscales were normalized to a 0-10 scale, while Visual Analogue Scale (VAS) pain and global was measured on a 0-100 mm scale. Joint examination and US were done by two different rheumatologists at the same day blinded for the results from the questionnaire and the colleague's examination. Clinical assessment included counts (absent/present) of joints (DIP, PIP, MCP, CMC bilateral) with soft tissue swelling (SJC), bony swelling (BSJC), tenderness (TJC) and limited motion (LMJC). Same joints were examined by US (dorsal view) with scoring of osteophytes (OP), synovitis and vascularisation (Power Doppler, PD) on a 0-3 scale. Sum scores of OP, synovitis and PD were computed, and the number of affected joints were analysed after dichotomisation (0=absent, 1-3=present). The number of joints with OP vs. BSJC and synovitis vs. SJC were compared with students t test. Associations between US findings and joint counts vs. symptoms were assessed by Spearman rank correlation.

Results: US detected more OP than BSJC, with mean (SD) 15.9 (5.5) and 11.2 (5.0), respectively ($p<0.001$). However, clinical examination detected more swollen joints compared to the number of joints with synovitis, with mean (SD) 7.7 (4.5) and 4.7 (3.3), respectively ($p< 0.001$). Table 1 shows the correlations between US findings (sum score) and joint counts vs. symptoms. Similar correlations were found between US findings (number of affected joints) and symptoms.

US vs. symptoms	**AUSCAN pain**	**AUSCAN physical**	**AUSCAN stiffness**	**VAS pain**	**VAS global**
OP (score)	0.16 (0.11)	0.22 (0.04)	0.01 (0.91)	0.07 (0.49)	0.12 (0.25=

Synovitis (score)	0.26 (0.01)	0.32 (0.003)	0.22 (0.03)	0.24 (0.02)	0.25 (0.01)
PD (score)	0.20 (0.04)	0.22 (0.02)	0.19 (0.04)	0.09 (0.33)	-0.01 (0.95)
Joint count vs symptoms					
BSJC	0.12 (0.25)	0.15 (0.13)	0.08 (0.40)	-0.02 (0.80)	0.10 (0.30)
SJC	0.09 (0.36)	0.17 (0.10)	0.03 (0.76)	-0.07 (0.47)	0.00 (1.00)
TJC	0.45 (< 0.001)	0.44 (< 0.001)	0.34 (< 0.001)	0.25 (0.01)	0.40 (< 0.001)
LMJC	0.06 (0.54)	0.06 (0.53)	0.11 (0.22)	-0.07 (0.43)	-0.05 (0.57)

Conclusion: US is more sensitive than clinical examination in detection of OP, while SJC was more frequent than US detected synovitis. However, distinction between bony and soft tissue swelling may be difficult to assess clinically. US synovitis and vascularisation were correlated with all symptom scales and AUSCAN scales, respectively. Among joint counts, TJC was the only joint feature with significant correlations with patient-reported symptoms. .

192

Improvement of the Reproducibility of the Radiographic Kellgren-Lawrence (KL) Scoring System in Hand Osteoarthritis (HOA) Using A New KL Scoring System Aid. E. Maheu[1], P. Ravaud[2], G. Baron[2], F. Berenbaum[3], X. Chevalier[4], L. Gossec[5], D. Loeuille[6], J F. Maillefert[7], B. Mazières[8], F. Rannou[9], P. Richette[10] and C. Cadet[11], [1]St-Antoine Hospital, Paris, France, [2]Bichat Hospital, Paris, France, [3]St-Antoine hospital - APHP, Paris, France, [4]Hopital Henri Mondor, Créteil, France, [5]Cochin Hospital, Paris, France, [6]CHU de Nancy, Vandoeuvre les Nancy, France, [7]Chu Dijon Hopital General, Dijon, [8]CHU Larrey, Toulouse, France, [9]Cochin Hospital, AP-HP; INSERM (IFR 25), Paris, France, [10]Hopital Lariboisière, Paris, France, [11]Rheumatology, Paris, France

Purpose: KL radiographic scale is the most widely used tool altogether to define HOA, assess HOA severity and follow-up the radiographic progression, but its interobserver reliability is usually low.

Objective: To study the impact of a new KL Scoring System Aid (KLSSA) on the reliability of KL scoring.

Method: 20 posteroanterior radiographs of both hands of HOA patients (covering HOA radiographic spectrum) obtained from a trial were initially scored twice by 10 experienced readers, instructed to score the KL (0-4), using the score as detailed by Kallman [AR 1989;32:1585-91] and their view of the definition of KL grades at a 15-days interval. No preliminary training session. During the 1st session they also scored joint space narrowing (JSN) and osteophytes (0st) (0-4*).* The distal (DIP), proximal interphalangeal (PIP), metacarpophalangeal (MCP), scaphotrapezial and trapeziometacarpal joints (16 joints) of one hand selected at random (right/left) were scored. 8 readers (CC-EM designers of the KLSSA excluded) were then randomized to score again twice the 20 radiographs using or not the KLSSA. The KLSSA combines various levels of JSN (0-4) and Ost (0-4) for defining KL grades, presented in a table, accompanied by hand images to illustrate the grading. Radiographs were numbered at random from 1 to 20 for each session. *Statistics:* Intra-class correlation coefficient [95% confidence interval (CI)] for inter- and intraobserver precision; Bland-Altman graphical method for intraobserver precision.

Results: For interobserver reproducibility appear in the table.

	4 readers randomized without the KLSSA	***4 readers randomized to use the KLSSA***
	ICC [CI 95%]	***ICC [CI 95%]***

Interobserver reproducibility (1st reading) 1st turn before KLSSA		
Ost score (0-64)	0.66 [0.41-0.84]	0.50 [0.25-0.68]
JSN score (0-64)	0.47 [0.27-0.68]	0.58 [0.34-0.78]
KL score (0-64)	0.51 [0.26-0.72]	0.41 [0.20-0.64]
Interobserver reproducibility (3rd reading) 2nd turn with/without the KLSSA		
KL score (0-64)	0.48 [0.25-0.68]	0.79 [0.59-0.89]

Interobserver reproducibility improved only in the group using the KLSSA. Intra-observer reproducibility improved for the 4 readers without the KLSSA (0.87 to 0.95) and almost all those having used the system (0.57 to 0.89). One reader's precision decreased, probably due to the modifications induced by the use of the system on his own personal points of reference.

Conclusion: Interobserver reproducibility of KL grading in HOA significantly improved using the KLSSA. This system could help for case definition or radiographic progression assessment in future trials/epidemiological studies. Further work is needed to assess the longitudinal reproducibility with this system.

193

Is Matrix Gla Protein Level or Polymorphism Associated with Hand Osteoarthritis? D. Misra[1], S. Booth[2], M. McRosier[2], David T. Felson[3] and T. Neogi[1], [1]BUSM, Boston, MA, [2]USDA HNRCA, Tufts University, Boston, MA, [3]Boston University School of Medicine, Boston, MA

Purpose: Matrix Gla protein (MGP), which is present in cartilage and blood vessels, is a key regulator of vascular calcification. MGP's functionality is dependent upon vitamin K, low levels of which have been associated with increased prevalence of radiographic hand osteoarthritis (ROA). The mechanism by which vitamin K may exert its effects is not known, and may possibly be through MGP. Recently, MGP polymorphisms have been associated with coronary calcification (CAC) and kidney stones. We evaluated the relation of MGP serum concentrations and polymorphisms with hand ROA.

Method: 376 community dwelling elderly men and women (aged 60-80) who had hand x-rays, serum MGP levels and DNA evaluated for three MGP SNPs in a parent study assessing the effect of vitamin K supplementation on BMD and CAC were evaluated. Presence of hand ROA was defined on a per-joint basis as Kellgren and Lawrence grade ≥2. We evaluated the relation of serum MGP concentrations categorized into quartiles with the presence of hand ROA using logistic regression with GEE to account for correlated data, adjusting for potential confounders including age, sex, BMI, education, smoking, physical activity, baseline 25(OH)D, and phylloquinone (vitamin K). We also evaluated the relation of three MGP SNPs (rs2800802 (T-138C) [MGP802], rs1800801 (G-7A) [MGP801], rs4236 (A-102T) [MGP4236]) with hand ROA, adjusting for the same potential confounders, using the dominant, recessive, and additive modes of inheritance.

Results: Of the 376 participants, 59% were female, with mean age 70.6±5.5 and mean BMI 28.1±5.1. 70.5% had at least one hand joint with ROA. There was no significant association between serum MGP and presence of hand ROA (adjusted OR 1.34, 1.18, and 1.19 for quartiles 2-4, respectively, compared with the lowest quartile). See Table for the adjusted mean serum MGP concentrations for the 3 SNPs. The prevalence of hand ROA was 0.54 times lower in homozygous carriers of the minor allele of MGP802 (95% CI 0.30-0.96), and not significantly associated with the minor allele of MGP801 (adj OR 1.24) or MGP4236 (adj OR 1.22) compared with the respective major alleles, using the dominant mode of inheritance. Analyzed separately, the effect estimates were similar in men and women.

Conclusion: Our findings suggest that there may be an association between hand ROA and MGP polymorphism that is not reflected in concurrent MGP serum concentrations**.** The finding of an association with the minor allele of MGP802 is consistent with findings from other

studies for lower risk of kidney stones and CAC. Further studies are warranted to replicate and elucidate potential mechanisms underlying these observed associations as well as the role of vitamin K.

MGP SNP	Allele	Serum MGP (nM) (adjusted mean)	Hand ROA (adjusted OR (95% CI))
rs1800802 (MGP802)	AA	196.5	1.0 (ref)
	AG	204.0

The Ghent University Scoring System (GUSS™), An Optimised Scoring System to Monitor Disease Progression in Erosive Osteoarthritis of the Interphalangeal Finger Joints. Gust Verbruggen, Ruth Wittoek, Bert Vander Cruyssen and Dirk Elewaut, University Hospital Ghent, UGent, Ghent, Belgium

Purpose: To develop a quantitative radiographic scoring system, the Ghent University scoring system, GUSS™, to detect progression over shorter periods of time than an existing categorical anatomic phase scoring system (1) in erosive OA of the IP finger joints and to prove its reliability, responsiveness and sensitivity to change.

Method: Plain radiographs were obtained from 18 patients recruited into a randomized placebo-controlled trial of anti-tumour necrosis factor α therapy, at baseline, 6 and 12 months. Erosive progression and signs of repair or remodelling of the IP joints were scored by indicating the proportion of normal subchondral bone, subchondral plate and joint space on a 10-point incremental Likert scale from 0 to 100. Thirty joints showing tissue destruction typical of erosive OA were selected. All 90 radiographs were read twice in single order (i.e. blinded for patient and time) by two experienced readers. Cross sectional analysis was performed on all 90 radiographs and a longitudinal analysis on the change observed over time was done after unblinding for patient and time sequence. Inter- and intra-reader reproducibilities were studied using intraclass coefficients of correlation (ICC). Based on the within-variance of the two readers, the smallest detectable change (SDC) was calculated and allowed identifying joints as ‘progressors’ or remaining stable over time. Sensitivity to change was studied by calculating the standardised response means.

Results: Cross-sectional intra-observer reproducibilities ICC ranged from 0.73 to 0.99. Good inter-observer reproducibility was proven for the three variables and the total score (ICC 0.71 – 0.89). In order to identify ‘real’ change over background noise, a change of at least 40

units on the total score (range: 0-300) over 12 months (SDC 0-12: 36.0), and at least 50 units over 6 months (SDC 0-6: 47.6) had to be present. This allowed identifying 60% of all 30 joints as 'progressors' over 6 months compared to 33.3% with the classical anatomical scoring system, and 70% vs. 56.6% over 12 months. Standardised response means ranged from 0.19 to 0.32 for reader 1, and 0.19 to 0.47 for reader 2.

Conclusion: The new radiographic scoring system, GUSS™, is a reliable method to score radiographic change over time in erosive OA of the IP finger joints and detects more progression over a shorter period of time than the classical categorical anatomic phase scoring system.

Ultrasound Detection of Bone Erosions in Erosive and Non-Erosive Osteoarthritis of the Interphalangeal Joints: A Comparison to Routine Radiographs. Ruth Wittoek, Philippe Carron and Gust Verbruggen, University Hospital Ghent, UGent, Ghent, Belgium

Purpose: To determine if ultrasound (US) of the interphalangeal (IP) joints can detect more erosions than radiography and establish the presence of erosive disease in patients with erosive osteoarthritis (OA) of the IP joints earlier than conventional radiography (CR).

Method: The total number of IP joints examined was 684: 558 IP joints of 31 patients with erosive OA and 126 IP joints of 7 patients with non erosive OA. US exams and CR were independently graded for the presence of erosions by RW and GV, respectively. CR were scored by a well-described anatomic phase scoring system [1] in which the "E" (erosive) phase corresponds to the phase in which erosions are present. All US scans were performed using a MyLab 25 (Esaote, Italy) machine with a 10-18 MHz linear array transducer. US exams were scored for the presence or absence of erosions. Percentage of absolute agreement between both examinations was calculated. Ten images were read by a second US reader (PC) allowing calculation of the inter-observer reliability by Kappa (κ) statistics.

Results: Seventy-two of 558 joints of erosive OA patients were in the 'E' phase according to the radiographic scoring system (12.9%), 192/558 normal (N) and 168/558 stationary (S) joints were identified (34.4% and 30.1%). Partial or complete loss of the joint space (J) was seen in 55/558 joints (9.9%) and 66/558 joints were in the remodeled phase (R) (11.8%). No 'E' phase was identified in the non-erosive patients, 62/126 (49.2%) and 63/126 (50.0%), respectively were in the normal phase (N) and stationary (S) (showing degenerative features as osteophytes, ossicles, or joint space narrowing) phase. Only one joint (0.8%) showed loss of joint space ('J' phase). US detected erosions in 113/558 joints (20.3%), which are 41 more joints than radiography. US detected 94.4% of the radiographic erosive joints (68/72). Moreover, 45 erosions were identified in non-'E' phases: 30 in early disease (11 in 'N' (5.7%), 15 in 'S' (8.9%), 4 in 'J' (7.3%), and 15 in 'R' (22.7%) phases. US missed erosions in 4 joints in 'E' phase. Also six erosive joints were identified by US in the non-erosive patients (4.8%). A statistically different percentage of erosions in joints was seen in the radiographic normal joints in erosive vs. non-erosive OA (5.7% vs. 3.2%, $p < 0.05$), but not in the joints in 'S' phase. A very good percentage of absolute agreement between radiography and US was found for the detection of erosions (91.8%). Compared to CR as reference method to identify erosions, sensitivity of US was found 94.4% and specificity 90.7%. Accuracy of US in the detection of erosions in erosive OA is 91.2%. Inter-observer reliability for assessing the presence of erosions by US was very good ($\kappa = 0.91$).

Conclusion: US of the IP joints in erosive OA can detect erosions not seen with CR and may be supplementary to radiography in establishing erosive features in early disease.

Erosive Osteoarthritis Is a Progressive Disease That Commonly Affects the Feet. Allen P. Anandarajah[1], Ralf G. Thiele[2] and Johnny Monu[3], [1]Univ of Rochester Med Ctr, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester Medical Center, Rochester, NY

Background: Erosive osteoarthritis (EOA) is considered to be an aggressive subset of generalized osteoarthritis, characterized by the appearance of symmetrical erosions, mainly in the distal (DIP) interphalangeal and proximal interphalangeal (PIP) joints. Patients with EOA often experience pain, swelling and joint deformities. Previous studies indicate that hand deformities often contribute to a functional decline but few studies have systematically examined disease progression or the prevalence and severity of foot involvement.

Purpose: To follow disease progression over time and to determine extent of foot erosions in EOA.

Method: All patients with EOA were identified from the Rheumatology Clinic at the University of Rochester Medical Center over a period of 5 years. Patients with EOA were evaluated based on predetermined criteria for diagnosis of EOA. EOA was defined as the presence of erosions (≥ 2) in DIP joints on plain radiographs of hands, normal acute phase reactants (ESR and/or CRP), a negative rheumatoid factor and/or anti-CCP antibody, absence of psoriasis and a family history negative for psoriatic arthritis. The frequency of radiographs and treatment was based on individual physician preference. Radiographs were read by experienced musculoskeletal radiologists.

Results: A total of 51 patients fulfilled criteria for the diagnosis of EOA. To date results have been analyzed for 43 subjects that consisted of 36 females (F) and 7 males (M) with a mean age of 66.2 years. 20 patients (16F and 4M) had repeat x-rays of hands, of which 13 (10F and 3M) patients (65%) had an increase in extent and/or number of erosions while 7 (6 F and 1M) patients had no evidence for progression of erosive disease. The mean duration between repeat x-rays was 20.1 months. 7 of the 13 patients with radiographic progression were on the following medications: 4 hydroxychloroquine, 1 methotrexate, 1 sulfasalazine and 1 on glucosamine chondroitin sulfate (GCS) and 6 were not on anti-inflammatory agents. Among the patients with no change in erosions, 4 were on no therapy, 1 on hydroxychloroquine, 1 on methotrexate and 1 on GCS. Foot X-rays were available for 24 subjects. Of these, 10 (41.7%) had erosions in the MTP joints while 14 were without erosions. Repeat x-rays of feet were available in 6 patients with a mean time duration between x-rays of 13.1 months. Increase in extent of erosions was seen in one while 5 showed no evidence for radiographic progression.

Conclusion: EOA is characterized by a progression of erosive disease in the majority of patients. Foot involvement was observed in over a third of the patients who had x-rays but radiographic progression was more likely to occur in the hands. Although, often asymptomatic, erosions are a common finding in the feet of patients with EOA. Further studies are needed to assess the long-term impact of this disorder on quality of life and function.

Grey-Scale and Power Doppler Sonographic Findings in Patients with Erosive Osteoarthritis of the Interphalangeal Joints as Compared with Patients with Non-Erosive Osteoarthritis. Ruth Wittoek[1], Philippe Carron[1] and Gust Verbruggen[2], [1]University Hospital Ghent, University Ghent, Ghent, Belgium, [2]University Hospital Ghent, UGent, Ghent, Belgium

Purpose: To compare sonographic findings in patients with erosive osteoarthritis (OA) of the Interphalangeal (IP) finger joints and non-erosive OA of the IP joints, in order to evaluate the diagnostic value of ultrasound in distinguishing between erosive and non-erosive OA of the IP joints.

Method: A total of 310 proximal IP (PIP) and 248 distal IP (DIP) joints of 31 patients with radiographic erosive OA of the IP joints and 70 PIP and 56 DIP joints of 7 patients with non-erosive IP OA were examined by ultrasound using dorsal longitudinal and transverse scanning. One experienced examiner (RW) performed the scans using a MyLab 25 (Esaote, Italy) machine with a 10-18 MHz linear array transducer. Both Grey-scale and power Doppler (PD) sonography were performed. Representative images were digitally scored and were read under blinded conditions. Presence of effusion, synovitis, osteophytes, cartilage and PD signals intracapsular were scored in a dichotomous way (absent/present).The images of ten patients were reread by another investigator (PC), blinded for all clinical data, allowing to calculate the interobserver reliability by Kappa statistics (κ).

Results: Bone erosions, identified by a bone cortex discontinuation in the area adjacent to the joints, visualized in two perpendicular planes, were observed in 20.3% of joints of patients with erosive OA compared to 4.8% of joints of patients with non-erosive OA ($p < 0.01$). Remarkably more erosions were identified in the DIP than in the PIP joints (26.2% vs. 15.5%, $p < 0.05$) in the erosive OA group. Bone proliferations or osteophytes were seen in 55.9% and 58.7% of joints respectively, in patients with erosive and non-erosive OA. Effusion, represented by an anechoic signal in the joint space, different from cartilage, was found in 45.3 % of the erosive and 48.4% of the joints of patients with non-erosive OA. Grey-scale synovitis, represented by an anechoic or hypoechoic signal in the intracapsular area, was present in

respectively 16.3% and 12.7% of the joints in patients with erosive and non-erosive OA. No difference in PD signals were localized in the intracapsular area of the joints of patients with erosive and non-erosive OA (2.2% and 0.7% of joints, respectively).

Interobserver reliability was very good for all parameters ($\kappa = 0.91$ for erosions, $\kappa = 98$ for osteophytes, $\kappa = 0.98$ for hydrops, $\kappa = 0.99$ for synovitis, and $\kappa = 0.94$ for PD signal).

Conclusion: Ultrasound seems to be able to differentiate between erosive and non-erosive OA of the IP joints by identifying more erosions in the erosive form. Presence of osteophytes, effusion, synovitis and PD signals are comparable in both diseases.

ICAM-1 and VCAM-1 Concentrations in Synovial Fluid Correlate to the Degree of Synovitis Measured by MRI in Moderate to Severe Osteoarthritis of the Knee. Signe E.B. Andersen[1], Annette Jørgensen[1], Torkell Ellingsen[1], Niels Egund[2] and Kristian Stengaard-Pedersen[1], [1]Rheumatology Universityhospital, Aarhus, Denmark, [2]Radiology Aarhus Universityhospital, Denmark

Purpose: To quantify intercellular adhesion molecule-1 (ICAM-1) and vascular adhesion molecule-1 (VCAM-1) in plasma and synovial fluid (SF) from patients with moderate to severe osteoarthritis (OA) of the knee with and without joint effusion and to relate these findings to both the morphological changes measured by magnetic resonance imaging (MRI) and to parameters for pain and function.

Methods: The 24 OA patients fulfilled the ACR Criteria for primary OA of the knee joint and had a Lequesne Functional Index (LFI) score of 10 or more and a normal C-reactive protein (CRP). Exclusion criteria were secondary OA, inflammatory joint disease, significant OA symptoms of the other knee or co-morbidity. ICAM-1 and VCAM-1 concentrations in plasma and SF were quantified by validated ELISA kits. Synovitis, bone marrow lesions (BML) and effusion were estimated by MRI. The Western Ontario and McMaster Universities (WOMAC) index and LFI were performed, pain was estimated by visual analogue scale (VAS) and effusion was clinically assessed by presence or absence of ballottable patella sign (BPS).

Results: Levels of plasma ICAM-1 (median 234.47 ng/mL, range 143.92-338.82) and SF ICAM-1 (median 99.78 ng/mL, range 35.06-282.16) were positively correlated ($p < 0.0001$), ($r = 0.73$). Levels of ICAM-1 in SF differed between patients with and without PBS ($p = 0.012$). SF ICAM-1 correlated positively to MRI effusion ($p = 0.009$, $r = 0.54$), MRI synovitis (max) ($p = 0.004$, $r = 0.59$) and MRI synovitis (sum) ($p = 0.003$, $r = 0.61$). Plasma VCAM-1 (median 913.67ng/mL, range 509.81-1655.76) and SF VCAM (median 852.48 ng/mL, range 273.1-1710.01) did not correlate. SF VCAM-1 correlated positively to MRI effusion ($p = 0.041$, $r = 0.44$), MRI synovitis (max) ($p = 0.041$, $r = 0.43$) and MRI synovitis (sum) ($p = 0.025$, $r = 0.48$). SF VCAM-1 did not correlate to other parameters.

Conclusion: Our main finding in moderate to severe OA of the knee was that SF ICAM-1 and VCAM-1 correlated to the degree of synovitis measured by MRI. The plasma levels of ICAM-1 and VCAM-1 differed significantly between controls, OA patients without joint effusion and OA patients with joint effusion. Patients with joint effusions had the highest plasma concentration of ICAM-1 and VCAM-1.

In patients with moderate to severe knee OA and joint effusion; the concentrations of ICAM-1 and VCAM-1 in SF correlates to the degree of synovitis and effusion measured by MRI, which suggests a possible pathogenetic role for ICAM-1 and VCAM-1.

Baseline Effusion but Not Synovitis Predicts Cartilage Loss Over 30 Months in Subjects without Tibiofemoral Osteoarthritis - Results From the Multicenter Osteoarthritis (MOST) Study. Frank W. Roemer[1], Ali Guermazi[1], David T. Felson[1], Jingbo Niu[1], Michael C. Nevitt[2], Michel D. Crema[3], John A. Lynch[4], C. Lewis[5], James Torner[6] and Yuqing Zhang[1], [1]Boston University School of Medicine, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]BUSM, Boston, MA, [4]UCSF, San Francisco, CA, [5]UAB, Birmingham, AL, [6]UIowa, Iowa City, IA

Purpose: Synovitis and effusion are frequently present in knee osteoarthritis (OA) and correlate with pain and other clinical outcomes. If synovitis or effusion in OA appears to predispose to further structural progression has been questioned. Synovitis present in OA is thought to be triggered by cartilage detritus, and thus seems to be a secondary phenomenon. However, the clinical data supporting this theory is

limited. Synovial inflammation is regularly observed in early OA, but as to whether it occurs prior to damage of other tissues remains unclear. Aim of the study was to assess if presence of baseline synovitis and effusion in knees without OA, predicts future cartilage loss.

Method: The Multicenter Osteoarthritis (MOST) Study is a longitudinal observational study of subjects with OA or at risk of developing OA. The MRI protocol included axial and sagittal proton-density weighted fat-suppressed fast spin echo and coronal STIR sequences. MRI was performed at a 1.0 T extremity system. MRIs were assessed semiquantitatively according to the WORMS scoring system. Only knees without radiographic OA and no baseline tibio-femoral cartilage damage were included. A synovitis-surrogate of signal changes in the infrapatellar and intercondylar areas of Hoffa's fat pad, and effusion were both scored from 0-3. Presence of definite synovitis and effusion was defined as any grade ≥ 2. Knees with scores of either 0 or 1 were the reference. Logistic regression was used to estimate the risk of cartilage loss at follow-up. Cartilage loss was defined as an increase of at least 0.5 grade (subtle within-grade progression, that did not fulfill the criteria of a full-grade change) in any subregion. Adjustment was performed for possible confounders of future tibio-femoral cartilage damage, i.e. baseline effusion for synovitis model, synovitis for effusion model, patellofemoral cartilage damage, meniscus damage, meniscal extrusion, body mass index, age, gender, malalignment, bone marrow lesions.

Results: 514 knees were included (55.6% women, mean age 60.1 ± 7.2, mean BMI 29.1 ± 4.5). 43 (8.4%) knees showed synovitis, and 53 (10.3%) presented with joint effusion at baseline. 137 (26.7%) knees showed cartilage loss at follow-up. After adjustment, baseline synovitis was not associated with an increased risk of cartilage loss at follow-up (adjusted odds ratio 1.0 [95% confidence intervals 0.5-2.1, p=0.89]). Knees with baseline effusion had an increased risk for cartilage loss (adjusted odds ratio 2.7 [95% confidence intervals 1.4-5.1, p=0.002]).

Conclusion: Baseline synovitis does not predict cartilage loss, but joint effusion. However, contrast-enhanced MRI, which is able to directly depict the inflamed synovium, might yield different results. Baseline effusion as a reflection of synovial activation seems to play a role in predicting structural progression in early or pre-OA.

200

Anatomical Distribution of Synovitis in Knee Osteoarthritis and Its Association with Joint Effusion Assessed On Contrast-Enhanced MRI. Frank W. Roemer[1], M. Kassim Javaid[2], Ali Guermazi[1], Matthew Thomas[3], Amit Kiran[4], Leonard King[5], Richard Keen[6] and Nigel K. Arden[4], [1]Boston University School of Medicine, Boston, MA, [2]University of Oxford, Oxford, United Kingdom, [3]University of Southampton, Southampton, United Kingdom, [4]Oxford University, United Kingdom, [5]University of Southampton, United Kingdom, [6]University College London, United Kingdom

Purpose: Degenerative joints commonly demonstrate signs of synovitis, even in the early phase of disease, which is thought to be a secondary phenomenon due to damaged intraarticular tissues. Only assessment of synovitis on contrast-enhanced T1-weighted images correlates with microscopically proven synovitis, which is the rationale for using contrast-enhanced MRI. Aim of our study was to describe the distribution of synovial enhancement patterns and presence of joint effusion in patients with radiographic knee osteoarthritis (OA) using a novel comprehensive semiquantitative (SQ) scoring system.

Method: We used the baseline MRI from participants of a randomized treatment trial in knee OA including axial proton density (PD)-weighted (w) fat suppressed (FS), axial T1w FS contrast enhanced (CE) and sagittal T1w FS CE sequences. Synovial enhancement was scored semi-quantitatively from 0-3: 0 = no synovial thickening, 1 = <2 mm (equivocal synovial thickness), 2 = 2-4 mm (moderate synovitis) and 3 ≥4mm (severe synovitis). The following 11 subregions were assessed: suprapatellar, infrapatellar, medial parapatellar, lateral parapatellar, intercondylar, around the anterior cruciate ligament (ACL), posterior to the posterior cruciate ligament (PCL), medial perimeniscal, lateral perimeniscal, Baker's cysts and around loose bodies. Maximum synovial enhancement was grouped as absent (grade 0), equivocal (grade 1) and definite (grades 2 and 3). Effusion was scored from 0-3 on PD fs and T1w FS CE sequences according to the amount of capsular distension. We described the distribution of synovitis in the whole cohort and also by effusion status.

Results: 111 subjects were included (mean age 64.4 [range 51-81], 64% women, mean body mass index 29.3 [range 21-43]). All knees exhibited at least one subregion with equivocal synovial thickness, 89% of knees had at least one subregion with at least grade 2 and 40% had a maximum grade 3. The commonest sites for definite synovitis were posterior to the PCL in 71% and the suprapatellar region in 60% of all knees. The median number of affected sites with definite synovitis was 3. Overall percent agreement of effusion scored on PD fs and T1w

FS CE sequences was 65%, with a weighted kappa of 0.69. On T1w FS CE 73% of knees showed effusion, with 38% of knees exhibiting a grade 2/3 size effusion. Definite synovitis in at least one location was present in 78/81 (96.3%) knees with an effusion and in 21/30 knees (70%) without an effusion.

Conclusion: Disagreement of effusion assessment is due to overestimation of effusion on the PD fs sequence. Definite synovitis was present in the majority of knees without a measurable effusion. Synovitis in OA is common with the commonest site being the region posterior to the PCL. The clinical consequences of synovial enhancement at the different sites need to be explored.

201

Association of Contrast Enhanced MRI Demonstrated Synovitis in Knee Osteoarthritis with Clinical Signs. Matthew Thomas[1], Amit Kiran[2], Frank W. Roemer[3], Ali Guermazi[3], M. Kassim Javaid[2], Leonard King[1], Madeleine Sampson[4], Richard Keen[5], John A. Lynch[6] and Nigel K. Arden[2], [1]Southampton University, Southampton, United Kingdom, [2]Oxford University, Oxford, United Kingdom, [3]BUSM, Boston, MA, [4]Southampton University Hospital, Southampton, United Kingdom, [5]University College London, United Kingdom, [6]UCSF, San Francisco, CA

Purpose: Osteoarthritis (OA) is the most prevalent form of arthritis, a major cause of morbidity worldwide. Synovitis is common in OA and thought to be a secondary phenomenon related to structural changes. Its presence has been documented in early phases of OA. Only contrast (C) enhanced (E) T1 weighted images are proven to correlate with histologically proven synovitis. Few studies have been performed assessing the link between active synovitus and clinical signs of inflammation. The aim of our study was to describe the link between synovitus measured by contrast enhanced MRI and these signs of inflammation.

Method: Participants of the VIDEO study of knee OA were included. MRI was performed at baseline using axial proton density (PD) weighted fat suppressed (FS), axial T1 weighted FSCE and sagittal T1 weighted FSCE sequences. Synovitis enhanced was scored semi-quantitively from 0-3: 0= no synovial thickening, 1 = <2mm (equivocal synovial thickening), 2 = 2-4 mm (moderate synovitis) and 3 = ≥ 4mm (severe synovitis). 11 regions were assessed in this fashion (suprapatellar, infrapatellar, medial parapatellar, lateral parapatellar, intercondylar, ACL, posterior to PCL, medial perimeniscal, lateral perimeniscal, Baker's cyst and around loose bodies). A cumulative grade was obtained from summation of these individual scores to provide an estimate of the volume of synovitis, subsequently divided into quartiles for secondary analysis. Effusion was scored from 0-3 on PD FS and T1 FS CE sequences according to the amount of capsular distension. All participants were examined by a trained research nurse for effusion, joint line tenderness (JLT) and warmth. We describe the association of vol of synovitis with joint effusion, warmth and JLT. We also explored the association of perimeniscal and peripatellar synovitis with JLT. Correlation of clinical versus radiological grading of effusion is determined.

Results: 111 subjects were included. Age: mean=64.4, median(IQR) = 64 (58,70), range =51,81. Gender: m = 36.04% (40/111), f= 63.96% (71/111). BMI: mean = 29.3, median(IQR) = 28.2 (26.0,32.0), range =21.3,42.7. cumulative synovitis mean=8, median(IQR)=9(7,10), range=2,11

Table 1: association of clinical variable with cumulative synovitis MRI score.

Explanatory Variable	Outcome Variable	OR (CI)
cumulative synovitis score	Any clinical effusion	1.66 (1.32,2.09)
cumulative synovitis score	Severe clinical effusion	1.65 (1.24, 2.18)

There was no significant association of synovitis with warmth or JLT. There was no significant association of radiological effusion and clinical effusion.

Conclusion: We have demonstrated a strong association of cumulative synovitis score with radiological effusion but surprisingly no association with warmth or of JLT.

202

Association of Plasma n-3 and n-6 Fatty Acids with Synovitis in the Knee: The MOST Study. K. Baker[1], N. R. Matthan[2], A. H. Lichtenstein[2], A. Grainger[3], J. Niu[4], M. Clancy[4], C. Lewis[5], J. Buckwalter[6], M. Nevitt[7] and David T. Felson[8], [1]BUMC, Boston, MA, [2]Tufts University, Boston, MA, [3]U Leeds, Leeds, United Kingdom, [4]BUSM, Boston, MA, [5]UAB, Birmingham, AL, [6]U Iowa, Iowa City, IA, [7]UCSF, SF, CA, [8]Boston University School of Medicine, Boston, MA

Purpose: Studies have shown that fatty acids modulate the inflammatory response by multiple mechanisms. Specifically the n-6 fatty acid arachidonic acid (AA) and the n-3 fatty acids eicospentaenoic (EPA) and docosahexaenoic (DHA) can serve as precursors for the synthesis of bioactive lipid mediators including eicosanoids. Eicosanoids produced from AA induce eicosanoind-mediated inflammation while those produced from EPA and DHA inhibit inflammation. Synovitis represents an inflammatory process in the knee and has been shown to be a common feature in those with or at high risk of knee OA. We assessed the relationship of plasma n-6 and n-3 fatty acids with knee synovitis.

Methods: The MOST study is a NIH-funded longitudinal study of risk factors for knee OA in persons age 50-79 with or at high risk of knee OA. Participants were those who volunteered to obtain a 1.5 contrast enhanced MRI of one knee and had fasting blood drawn at the 30-month clinic visit. Synovitis was scored 0-3 in 4 compartments (suprapatellar pouch, medial and lateral parapatellar recesses and infrapatellar fat pad) and 0-1 in 2 compartments (medial and lateral posterior condylar) (Rheumatol 44:1569 2005). Synovitis in the whole knee was categorized as "extensive" ($\geq$ 1 compartment scored 3), "a lot" ($\geq$ 2 compartments scored 2 but no 3s), "some" ($\geq$ 4 compartments scored 1 or 1 scored 2), "none/questionable" ($<$ 4 compartments scored as 1). Inter-reader kappa was 0.9 ($p<.001$). Plasma samples stored at -80^{o}C were measured for fatty acid concentrations using gas chromotagraphy. We analyzed the concentration of 3 fatty acids, AA, EPA, and DHA in quartiles, with synovitis using a logistic regression model adjusting for age, sex, BMI, MRI bone marrow lesions.

Results: Of 500 subjects with a fatty acid measure, 28 were excluded, 11 were missing synovitis variables and 17 were taking fatty acid supplements. Mean age was 59.9 ± 7.3 years, mean BMI 29.5 ± 4.8 kg/m^2, and 50% were women. 49% had "some" synovitis and 16% "a lot/extensive". The odds of having "a lot/extensive" synovits was 3.4 times more (95% CI 1.4, 10.5) in the highest quartile of AA versus the lowest. Levels of EPA and DHA were not associated with synovitis.

Conclusion: These data suggest that higher tissue levels of AA may be associated with synovitis in the knee. The lack of a relationship of synovitis with EPA and DHA may be due to relatively low dietary intakes relative to those achieved with supplementation, which has resulted in decreased inflammatory mediators. Our findings indicate the potential for dietary manipulation as a therapy for synovitis.

	Arachidonic Acid

Relationship Between Active Appearance Modelling Score of DXA Images and Whole Organ Magnetic Resonance Imaging Score (WORMS) in Knee Osteoarthritis. Kanako Yoshida[1], Jennifer S. Gregory[1], Rebecca J. Barr[1], Sandro Galea-Soler[2], Salvatore Alesci[3], Fiona Gilbert[2], David M. Reid[2] and Richard M. Aspden[1], [1]Univeristy of Aberdeen, Aberdeen, United Kingdom, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]Wyeth Research, Collegeville, PA

Purpose: The use of plain radiographs for the assessment of Osteoarthritis (OA) is well established. More recently, Magnetic Resonance Imaging (MRI) has been used. We have shown that Active Shape Modelling (ASM) of hip radiographs can quantify OA severity and predict the risk of rapid progression. Active Appearance Modelling (AAM), an extension of ASM, allows assessment of simultaneous changes in both joint shape and intensity (i.e., bone mineral density (BMD) distribution), expressed in terms of "modes of variation", using dual energy X-ray absorptiometry (DXA) images.

The aim of this study was to examine the relationship between AAM score derived from DXA images, and Whole Organ Magnetic Resonance Imaging Score (WORMS) derived from MRI images, in patients with knee OA.

Methods: Thirty five subjects, with Kellgren-Lawrence grades (KLG) based on radiographs taken in the previous year were invited to undergo bilateral knee DXA scans (iDXA scanner, GE Medical Systems) and an MRI scan (3-T Achieva, Philips) of the knee with a higher KLG. An 85-point model template, developed using the AAM toolkit (Manchester University, Manchester, UK), was applied to DXA images. The model included the femur, tibia, osteophytes, tibial plateau, femoral condyles and intercondylar notch. WORMS was derived from the MRI images. Pearson's correlation was used for analysis.

Results: Appearance Modes (AppM) 1-7 were all significantly correlated with KLG, and AppM2 and 4 were also significantly correlated with total WORMS. A low AppM2 score was associated with higher KL grade (r=-0.68, $P<0.001$) and captured joint space narrowing, uneven distribution of BMD, bilateral osteophytes on femur and tibia, a wider medial femoral condyle, and a shallower intercondylar notch, all features typical of OA (Fig. 1). This mode had the strongest correlation with total WORMS and the constituents examined (marrow abnormality r=-0.68; cartilage r=-0.82; cyst r=-0.61; osteophytes r=-0.81; total WORMS r=-0.82; P<0.001). Marrow abnormality was observed in 11/18 knees (61%) classified as having doubtful OA.

Conclusion: This is the first report to examine relationships between the appearance of the knee joint, captured from DXA, and MRI signs of knee OA. Some appearance modes (2 and 4) are strongly linked with bone features, such as oedema and cysts, which suggest a link between the two. Use of AAM on DXA images, which are more economical and accessible than MRI, hold promise as a potential biomarker for knee OA.

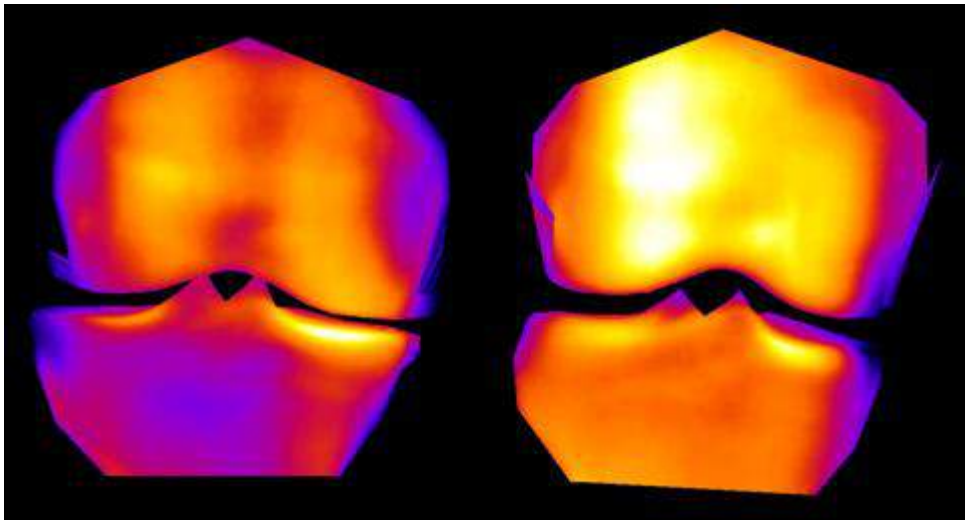

Fig 1

False-colour images of mode 2 (±2 SD) from AAM of the knee built from DXA images (medial compartment on the right). Low AppM2 scores (left image) show concurrent changes in joint space width, osteophytes, joint geometry and BMD distribution

Serum Transforming Growth Factor-Beta 1 as a Biomarker of Incident and Progressive Radiographic Hip and Knee Osteoarthritis: The Johnston County Osteoarthritis Project. A.E. Nelson[1], Y.M. Golightly[1], T. Stabler[2], V.B. Kraus[2], Jordan B. Renner[3] and J.M. Jordan[4], [1]Thurston Arthritis Research Center, Chapel Hill, NC, [2]Duke University Medical Center, Durham, [3]The University of North Carolina, Chapel Hill, NC, [4]UNC, Chapel Hill, NC

Purpose: To test whether serum transforming growth factor-beta 1 (sTGF-β1) predicts incident and progressive radiographic OA (rOA) in African Americans (AAs) and Caucasians.

Method: Serum TGF-β1 (sTGF-β1) was measured for 330 participants in the Johnston County OA Project, using a sandwich ELISA kit from Biosource International (Camarillo, CA). Among participants with sTGF-β1 data, paired longitudinal films were available for 658 hips and 618 knees. Incident rOA was defined as 1) development of K-L grade ≥2 from a baseline K-L grade <2, or 2) development of K-L grade ≥1 from a baseline K-L grade=0. Progression of rOA was defined as 1) an increase of ≥1 K-L grade from a baseline K-L grade ≥2, or 2) an increase by ≥1 K-L grade from a baseline K-L grade ≥1. Incident osteophytes (OST) and joint space narrowing (JSN) were identified in joints with grade=0 at baseline and ≥1 at follow-up; progression was defined as an increase of ≥1 grade from a baseline grade ≥1. Natural logarithm transformation was used to produce near-normal distributions for continuous sTGF-β1 (lnTGF-β1). Separate multivariable Weibull regression models were used to provide hazard ratios (HR) for a 1-unit increase lnTGF-β1 with each rOA outcome, accounting for variable follow-up times and clustering by individual, adjusted for age, race, gender, and body mass index (BMI). Interaction terms were considered statistically significant at $p < 0.1$.

Results: The mean (±SD) age of the sample was 62 ± 10 years, the mean BMI was 30 ± 7 kg/m2, with 61% women and 42% AA. The mean (± SD) sTGF-β1 was 17.8 ± 6.1 ng/ml (range 6.1-40.9 ng/ml); mean (± SD) follow up time was 6.1 ± 1.3 years. There were no significant interactions by race or gender. The HRs (Table) showed no significant relationship between higher lnTGF-β1 and incident rOA, OST, or JSN, before or after adjustment. There were no significant associations between lnTGF-β1 levels and progressive hip rOA; very few hips progressed from a baseline K-L ≥2, or had progressive JSN. The odds of progressive knee rOA by either K-L definition were 40-50% higher in association with higher lnTGF-β1 levels, but this was not statistically significant.

Conclusion: Levels of sTGF-β1 do not predict development of incident rOA, OST, or JSN at the hip or knee in this longitudinal, population-based study including AAs and Caucasians. That our findings failed to reach statistical significance, even in this largest study to date of this biomarker, make it unlikely that sTGF-β1 will be a robust, stand-alone biomarker for future studies.

Table. Adjusted* hazard ratios for lnTGF-β1 and rOA outcomes

Definitions of rOA Outcomes	n (hips with outcome)	Adjusted HR* for Hip rOA (95% CI)	n (knees with outcome)	Adjusted HR* for Knee rOA (95% CI)
Incident rOA (from baseline K-L<2 to K-L = 2)	**45**	**0.61 (0.25-1.47)**	**103**	**1.10 (0.46-2.63)**
Incident rOA (from baseline K-L<1 to K-L = 1)	54	1.05 (0.31-3.51)	94	1.04 (0.41-2.65)
Incident OST (from grade 0 to grade = 1)	**49**	**1.41 (0.38-5.25)**	**94**	**1.41 (0.56-3.56)**
Incident JSN (from grade 0 to grade = 1)	29	0.65 (0.20-2.09)	99	1.39 (0.50-3.88)
Progressive rOA (increasing = 1 grade from baseline K-L =2)	**10**	**2.74 (0.31-24.30)**	**86**	**1.36 (0.63-2.91)**
Progressive rOA (increasing = 1 grade from baseline K-L =1)	47	1.02 (0.46-2.28)	160	1.51 (0.82-2.79)
Progressive OST (increasing = 1 grade from baseline OST =1)	**19**	**0.55 (0.12-2.59)**	**76**	**0.55 (0.24-1.26)**
Progressive JSN (increasing = 1 grade from baseline JSN =1)	7	4.14 (0.62-27.7)	84	1.40 (0.64-3.03)

Longitudinal Rate and Sensitivity to Change in Knee Cartilage Morphology in Osteoarthritis as a Function of Radiographic Disease Grades (KLG 0 to 4) – Results From 716 Participants From the Osteoarthritis Initiative (OAI). Felix Eckstein[1], Marie-Pierre Hellio Le Graverand[2], Olivier D. Benichou[3], Donatus Dreher[4], Richard Y. Davies[5], Michael Nevitt[6], Jennifer Lee[7], Fred Baribaud[8], Alberto Gimona[9], Martin I. Hudelmaier[1], Wolfgang Wirth[1] and OAI investigators, [1]Paracelsus Medical Unversity & Chondrometrics Gmbh, Salzburg, Austria, [2]Pfizer Inc., New London, CT, [3]Lilly, Indianapolis, IN, [4]Merck Serono, Geneva, Switzerland, [5]Glaxo Smith Kline, Collegeville, PA, [6]UCSF, San Francisco, CA, [7]Wyeth Research, Collegeville, PA, [8]Centocor, PA, [9]Novartis, Basel, Switzerland

Purpose: The Osteoarthritis Initiative (OAI) is a large public study designed for identifying sensitive (imaging) biomarkers and risk factors of knee OA. To select suitable participants and adequately power clinical trials, reliable information on the rate and sensitivity to change in structural outcomes is required. Here we describe the rate of cartilage loss in 716 OAI participants across all radiographic grades.

Methods: One knee of 716 participants from the OAI was studied (public releases 0/1E1 and 0/1F1). Kellgren Lawrence grades were calculated (cKLG) from osteophyte and joint space narrowing scores from baseline fixed flexion radiographs: 65 knees were cKLG 0, 36 cKLG 1, 272 cKLG 2, 274 cKLG 3, and 69 cKLG 4. Cartilage segmentation was performed on baseline and year 1 follow up coronal FLASHwe MR images by 7 experienced readers, blinded to time point and cKLG. Changes in cartilage thickness (ThCtAB) were computed in femorotibial cartilage plates and in 16 subregions, 5 in the medial (MT) and lateral tibia (LT), and 3 in the weight-bearing femoral

condyles (cMF and cLF), respectively. The standardized response mean (SRM) was used to express the sensitivity to change. The changes for the subregions in each knee (in µm) were sorted in ascending order (Ranks 1-16), starting with the region showing the greatest thinning (Rank1). One way ANOVA with Bonferroni Dunn correction was used to compare rates of change (in µm) in the medial femorotibial compartment (MFTC=MT+cMF) and in Rank 1 between KL grades.

Results: The annual rate of change in MFTC cartilage thickness (MT+cMF) differed significantly with KLG (overall p=0.012); it was -8µm (-0.2%; SRM -0.12) in KLG 0, -71 µm (-2.1%; SRM -0.27) in KLG 1, –17 µm (-0.5%; SRM -0.17) in KLG 2, -45 µm (-1.3%; SRM -0.35) in KLG 3, and -42 µm (-1.5%; SRM -0.28) in KLG 4 knees. None of the between-KLG differences were, however, significant after Bonferroni-Dunn correction for multiple testing. Changes in rank1 (subregion with greatest reduction in each knee) showed a strong relationship with KLG (overall p<0.001). Rank 1 reductions were significantly greater in KLG 1,3 and 4 compared with KLG 0 or with KLG 2 knees.

Conclusion: Changes in cartilage thickness, measured quantitatively with MRI over 1 year, were relatively modest across all KL grades. A ranking system of subregional cartilage changes was more sensitive in detecting differences in rates of change between KL grades than analysis of cartilage plates. The rates of change in KLG 1, 3 and 4 knees were greater than those in KLG 0 knees. Surprisingly, the rates of cartilage thinning in KLG 1, 3 and 4 were also greater than those in KLG 2 knees, a subcohort commonly studied in drug trials.

The Relation of Reversible Knee MRI Features to Knee OA Symptom Fluctuation. David J. Hunter[1], Michel D. Crema[2], Ali Guermazi[3], Frank W. Roemer[3], Monica D. Marra[3], Marie-Pierre Hellio Le Graverand[4], Ling Li[1], Bradley T. Wyman[4] and Yuqing Zhang[3], [1]New England Baptist Hospital, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]BUSM, Boston, MA, [4]Pfizer Inc., New London, CT

Purpose: The osteoarthritis (OA) symptoms of pain and functional limitation are characterized by marked fluctuation. To date the time-varying risk factors for these dynamic fluctuations remain unknown. The objective of this analysis was to investigate the relation of change in specific structural features to the risk of knee pain and functional limitation fluctuation.

Method: 62 obese women with radiographic knee OA and 99 non-obese female controls (mean age 56.6 yrs) were imaged using 3T MRI during a longitudinal 24-month observational study (A9001140 study). Knee pain and functional limitation were defined using WOMAC questionnaire. Fluctuation in pain/ functional limitation was defined as a change ≥20% and absolute change of ≥10 (on 100mm scale). We identified knees that have experienced pain/ functional fluctuation at least at one but not at all visits. Each MRI was scored for subchondral bone marrow lesions (BMLs), synovitis, and effusion using the BLOKS instrument at baseline, 6, 12 and 24 months. Synovitis was scored 0-3 in Hoffa's fat pad, effusion was scored 0-3 for each knee, and BMLs were scored 0-3 in each of 5 sub-regions in the medial and lateral tibiofemoral compartments and 4 subregions in the patellofemoral compartment. Given the small number of observations with Grade 3 synovitis or effusion these were collapsed into Grade 2. We summarized BMLs within each knee to use data across sub-regions. We performed a self-matched case-control study, using each knee as its own control, to evaluate the relation of BMLs, synovitis, and effusion to the risk of pain/ functional fluctuation using a conditional logistic regression model.

Results: 77 participants experienced fluctuation in pain in at least one, but not all 4 visits for a total of 305 observations. 69 participants experienced fluctuation in function in at least one, but not all 4 visits for a total of 274 observations. The table below displays the results of the relation between MRI feature and symptom fluctuation. A 1 unit difference in effusion was associated with an increased risk of function fluctuation (OR 2.54 (95%CI 1.02-6.29). There were also strong trends to increased risk of pain fluctuation with effusion.

Predictor		Pain fluctuation OR (95% CI)	Function fluctuation OR (95% CI)
Synovitis	1	1.18 (0.43 -3.26)	0.64 (0.22 -1.90)
(0 as Ref.)	2	1.07 (0.23 – 4.97)	0.56 (0.11 – 2.74)

Effusion (0 as Ref.)	1	1.94 (0.85 – 4.40)	**2.54 (1.02 – 6.29)**
	2	3.01 (0.80- 11.39)	3.30 (0.86 – 12.67)
BML (0 as Ref.)	1	0.88 (0.31 – 2.46)	2.02 (0.61 – 6.70)
	2	2.08 (0.64 – 6.71)	1.84 (0.49 – 6.87)
	3	1.39 (0.42 – 4.58)	0.89 (0.24 – 3.38)

Conclusion: Change of MRI-detected effusion appears to be the most potent reason for fluctuation in functional limitation in persons with knee OA. The potential for clinical interventions to decrease effusion volume and by so doing reduce short term fluctuation in symptom severity warrant further investigation.

Stage of Knee OA and Odds of Cartilage Thickness Loss or Gain Over Two Years. L. Sharma[1], J. S. Chmiel[1], O. Almagor[1], W. Wirth[2], S. Cahue[1], M. Marshall[1] and F. Eckstein[2], [1]Northwestern Univ, Chicago, IL, [2]Paracelsus Med Univ, Chondrometrics Gmbh, Salzburg, Austria

Purpose: Small average annual loss of cartilage (C) in OA knees by quantitative MRI may be due to heterogeneous sampling of knees with C thinning and thickening (from swelling or hypertrophy). An understanding of the stage at which thickening and thinning reach peak prevalence aids conceptualization of knee OA natural history and trial design. C thickness should increase in more knees at early OA stages when swelling or anabolic processes may dominate. We determined %knees with subregional C thinning and thickening and tested if knees with moderate-severe OA were more likely to experience C loss and less likely to experience C thickening over 2 years than mildly diseased knees.

Method: Participants had knee OA, and underwent MRI including double oblique coronal FLASHwe, at baseline and two years. C thickness was determined in the medial tibia and weightbearing femur and in 8 subregions using custom software. We used logistic regression with GEE to analyze the relationship between baseline medial OA disease severity and the odds of baseline-to-2 year C thickness loss or gain (defined as ≥ 5%).

Results: We studied 244 knees (150 persons, 66 yrs, BMI 30, 74% women). At most subregions, %knees with C thickness loss (Table 1) was higher and %knees with thickness gain (Table 2) was lower in knees with worse OA at baseline than knees with less severe OA. Baseline medial joint space grade (mjsg) 2-3 (vs. 0-1 reference) was significantly associated with greater odds of thickness loss (right column Table 1), and with reduced odds of thickness gain in almost all subregions, although these did not reach significance (Table 2).

Conclusion: C thickness increase occurred in a subset of knees within each subregion. In most medial surfaces and subregions, worse baseline medial OA disease severity was associated with significantly greater odds of C thickness loss and a consistent although not statistically significant reduction in odds of C thickness gain.

Clinical Examination Findings of the Painful OA Knee and Correlation with MRI Abnormalities. C.Y. Wenham[1], A. Grainger[2], E.M Hensor[1], R.A. Maciewicz[3], J.C. Waterton[3] and P. Conaghan[4], [1]LIMM, University of Leeds, Leeds, United Kingdom, [2]U Leeds, Leeds, United Kingdom, [3]AstraZeneca, Macclesfield, United Kingdom, [4]U of Leeds, Leeds, United Kingdom

Purpose: Multiple clinical examination findings are common when examining the painful OA knee yet there is little literature on correlation with MR imaging. This study examined the relationship between compartment specific clinical findings and associated MR abnormalities.

Method: This was a cross-sectional study of people with painful, ACR OA knee. Detailed examination of the most painful knee was recorded within 48 hrs of 1.5 T contrast enhanced MR imaging of the knee. Logistic regression controlling for BMI, disease duration and gender was used to assess any association.

Results: 123 subjects were included. 64 (52%) women, mean age 63.4, mean pain VAS 61.3 mm. Crepitus was present in the patellofemoral (PF) compartment in 85 subjects (69%), lateral compartment in 39 (32%) and medial compartment in 44 (35%). 71 subjects (58%) had tenderness on PF compression, 101 (82%) medial joint line tenderness and 64 (52%) lateral joint line tenderness. 23 (19%) had medial knee pain on knee flexion and 50 (41%) medial pain with the joint held in maximal flexion.

At least one site with complete cartilage loss in the medial compartment was associated with medial crepitus (OR 2.15 (0.98-4.73) p=0.056). Lateral compartment crepitus was significantly associated with moderate-severe osteophytosis (OR 4.4 (1.68-9.69) p=0.02). Lateral compartment cartilage damage was uncommon but was associated with increased odds of lateral crepitus. Medial joint line tenderness was more common in those with a higher medial synovitis score (OR 2.12 (0.74-6.03) p=0.16). There was no association between lateral joint line tenderness and lateral synovitis scores (1.03 (0.46-2.28) p= 0.95) or between tenderness on PF compression and infrapatellar synovitis (0.74 (0.33-1.68) p=0.48). Greater area/thickness of cartilage loss and >1 site of complete cartilage loss were associated with greater odds of medial or lateral joint line tenderness or tenderness on PF compression (not statistically significant). Medial knee pain on knee flexion was significantly associated with medial synovitis (OR 3.23 (1.17-8.89) p=0.023). Medial knee pain with the joint held in maximal flexion was associated with medial MR findings of >75% area cartilage loss (2.61 (1.16-5.89) p=0.021), full thickness cartilage loss (3.07 (1.33-7.0) p=0.009) and medial meniscal maceration (2.80 (1.2-6.52) p=0.017).

Conclusion: This was a hypothesis generating dataset. Most examination findings did not correlate with specific pathologies. Crepitus was significantly associated with moderate-severe osteophytosis and was more common in those with complete cartilage loss. Compartment-specific tenderness was also associated with cartilage loss, but not significantly with synovitis. Medial compartment synovitis was significantly associated with medial pain both on knee flexion and with the knee held in maximal flexion.

209

Body Mass Index and Baseline Walking Speed as a Predictor for Longitudinal Cartilage Loss in Knee Osteoarthritis (KOA). Ji Yeon Lee, Grace H. Lo, Lori Lyn Price and Timothy McAlindon, Tufts Medical Center, Boston, MA

Purpose: Although BMI is a major risk factor for KOA its influence on progression of cartilage loss is less certain. Studies that examined the relationship between BMI and change in cartilage volume have generated inconsistent results. In this study, we sought to further explore this relationship controlling for covariates including walk speed.

Method: We studied participants in a double-blinded randomized controlled trial of vitamin D for KOA (Kellgren Lawrence grade 2-4). At present, treatment allocation remains blinded. 1.5 Tesla knee MRIs were obtained at baseline, 1 and 2 year follow-up visits. At baseline, we measured height, weight, and a timed 20m walk at a self-selected speed. A single reader used ANALYZE© software to register baseline and follow-up knee MRIs for each participant, and segmented the medial femoral (MFC) and medial tibial cartilage (MTC) volumes (intra-reader root mean square CV% was 1.2-2.5%). For participants without a 2-year MRI, 2-year cartilage loss was assumed to be double the 1-year change. We expressed cartilage loss as continuous (% change) and dichotomous outcomes (>3% loss). We used stepwise linear regression to evaluate baseline BMI as a predictor of change in cartilage volume, adjusting for age, sex, change in BMI and habitual walking speed. We used logistic regression to compute odds ratios for exposures classified in quantiles.

Results: Among 146 trial enrollees, analyzable data were available from 119 (complete 2-year data for 109 MTC and 104 MFC; 1-year data from 15). Their mean age was 63.0 ± 8.5yrs, 58% were female, mean baseline BMI was 30.0 ± 5.4 and 2-yr BMI change was 0.14 ± 1.9 kg/m². The mean 2-yr change for MFC was -4.22 ± 2.7% and for MTC was -4.14 ± 3.6%. Of the covariates, baseline BMI was the most consistent predictor of cartilage loss in the stepwise linear models (beta= 0.12, p=0.02 for MFC change, and 0.12, p= 0.05 for MTC). In the

logistic analyses, significant effects on MFC were also evident from age and walking speed (see Table). Other tested covariates had no substantial effects in these models.

Conclusion: In KOA, baseline BMI independently predicts medial compartment cartilage loss, although the magnitude of this effect is small. We did not observe an influence of BMI change, but the study may have been underpowered to evaluate this relationship as BMI change was minimal in this sample. Notably, slower habitual walking speed appeared protective for femoral cartilage loss. This could be mediated by biomechanical mechanisms such as lower adduction moment.

Table. Odds Ratio for >3% 2-yr Medial Femoral Cartilage Loss

BMI (kg/m²)		**p trend**
≤ 26	referent

Biochemical Markers of Wnt–Frizzled–b-Catenin Pathway and VEGF and Their Association with MRI Markers of Knee Osteoarthritis Progression. M. Corr[1], J. Niu[2], D.J. Hunter[3], A. Guermazi[4], N.E. Lane[5] and David T. Felson[4], [1]University California School o, La Jolla, CA, [2]BUSM, Boston, MA, [3]NEBH, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]UCDMC, Sacramento, CA

Purpose: The objective of this analysis was to assess the potential relationship between novel markers for bone and cartilage homeostasis (sFRP3 and DKK-1), and an angiogenic factor (VEGF) and 1) the progression of knee OA and 2) the presence of bone marrow lesions (BMLs).

Method: We conducted an analysis of data from the Boston Osteoarthritis of the Knee Study (BOKS).) All subjects in the study met ACR criteria for knee OA. Knee Magnetic resonance images (MRI) were scored for BMLs, attrition, osteophytes, synovitis and cartilage using the WORMS semi-quantitative grading scheme at baseline and at 30 months. Serum VEGF, sFRP3 and DKK-1 levels were assayed by ELISA on archived sera that was stored at -70 C. Because of nonparametric distribution of the data the natural log of each biomarker was used. To facilitate comparison between the biomarkers we used the standardized distribution of each biomarker as the predictor. We assessed whether increased levels of each biomarker was predictive of subsequent cartilage loss on knee MRI as defined by an increase in cartilage score in any of the plates from baseline to 30 month visit. We classified each subject according to maximum score of BML>0. Logistic regression

models were fit using BML as the outcome and biomarkers, age, sex and BMI as predictors. A Receiver Operating Characteristic (ROC) curve was generated for each model and the area under the curve was assessed. We also performed exploratory analyses to assess if the biomarkers were associated with attrition, osteophyte size, synovitis using the same methods.

Results: 124 subjects with knee OA were assessed. The mean (SD) age was 65 (9) years and 56% were male. At baseline 74% of participants had a maximum BML score > 0, 53% a maximum attrition score > 0, 78% a maximum osteophyte score > 2, and 64% had a maximum synovitis score > 0.

We found no relation between sFRP3, DKK-1 and VEGF with either presence of BML or OA progression defined as MRI cartilage loss (see table). Similarly we found no relation between these markers and attrition, osteophyte size, or synovitis.

	Prevalence of BML			**Cartilage loss**		
	OR (95% CI)	p-value	c-statistic	OR (95% CI)	p-value	c-statistic
Standardized Log VEGF	1.2 (0.8, 1.8)	0.44	0.66	1.1 (0.8, 1.6)	0.45	0.58
Standardized Log DKK	1.5 (0.9, 2.4)	0.08	0.66	1.3 (0.9, 1.7)	0.13	0.61
Standardized Log SFRP	1.2 (0.8, 1.9)	0.44	0.65	1.1 (0.8, 1.6)	0.44	0.59

Conclusion: We found no associations between sFRP3, DKK-1 and VEGF with either presence of BML or progression of cartilage loss. We would not advocate their use as markers for these structural changes in persons with knee OA.

Varus Thrust Is Associated with Cartilage Loss in Knee Osteoarthritis. William F. Harvey, J.Y. Lee, K.A. Carr, Melanie A. Ripley, Melynn Nuite, T. E. McAlindon and G.H. Lo, Tufts Medical Center, Boston, MA

Purpose: Varus thrust (VT), rapid lateral knee bowing during ambulation, can be recognized in the clinical setting without expensive gait lab equipment. VT has been shown to be predictive of longitudinal joint space narrowing (JSN) in knee osteoarthritis (KOA). JSN on radiograph is due to loss of cartilage, meniscal malposition or both. We sought to further characterize this by examining the relationship between VT and change in cartilage volume over 2 years.

Methods: We studied subjects enrolled in a double blind, placebo controlled study of Vitamin D to slow the progression of KOA over 2 years. The parent study is still blinded to treatment allocation. The primary outcome was cartilage volume based on MRIs of the study knee obtained at baseline and 2 years. The MRIs from each subject were registered using ANALYZE software for accurate comparison. Medial femoral and tibial cartilage were segmented manually using ANALYZE by one reader to generate volume. The percent change from baseline to year 2 was calculated. A convenience sample of consecutive subjects were videotaped at the 2 year visit walking on a flat surface at a self selected speed with a standard digital video camera (60 Hz) in the frontal plane. The videos were viewed on separate occasions by two rheumatologists trained to evaluate VT. Videos were scored as definite VT, possible VT and no VT. Both evaluators read all videos and disagreements were adjudicated by consensus of both. Stratifying by VT score, ANOVA and chi-square were used to compare the baseline subject characteristics. ANCOVA with Tukey's procedure was used to compare the mean percent change in cartilage volume (baseline – 2 years), controlling for age, sex, weight, height, 20 meter walk time and WOMAC pain.

Results: Of the 146 subjects enrolled in the trial, 78 had cartilage volumes at both time points and video recordings. Baseline characteristics are shown in the table. The prevalence of definite VT was 28%. Definite VT was associated with greater cartilage loss in the tibia compared to no VT and trended towards significance in the femur.

Conclusion: Definite VT was highly prevalent in a clinical trial of knee OA. Measurement of VT in the research setting may be of use in determining which subjects are more likely to develop cartilage loss, increasing the power of a study for detecting a difference. The videos were recorded at 2 years rather than baseline, a limitation to the study, precluding our ability to assign causality.

Table. Subject characteristics and results of ANCOVA for change in cartilage volume

	No VT N=41	Possible VT N=15	Definite VT N=22	p-value
Age (yrs - mean (SD))	63.0 (8.4)	63.1 (9.6)	63.6 (8.8)	*p=0.96

Risk of Subregional Cartilage Thickness Loss Associated with Malalignment in Knee OA. K. Moisio[1], F. Eckstein[2], A. Chang[1], J. S. Chmiel[1], O. Almagor[1], P. Prasad[1], W. Wirth[2], S. Cahue[1], M. Marshall[1] and L. Sharma[1], [1]Northwestern Univ, Chicago, IL, [2]Paracelsus Med Univ, Chondrometrics Gmbh, Salzburg, Austria

Purpose: Varus (VAR) and valgus (VAL) malalignment stress the medial and lateral tibiofemoral compartments, respectively. Recent studies suggest that cartilage loss is more pronounced in certain subregions, depending in part upon alignment (Eckstein 2008). We tested whether baseline VAR is associated with baseline-to-2-year cartilage thickness loss at the central and external (medial-most) medial tibial (T) and weightbearing femoral (F) subregions, and that VAL is associated with loss at the central and external (lateral-most) lateral T and F subregions.

Method: All participants had knee OA (K/L ≥2) and underwent full-limb x-ray for alignment at baseline and MRI at baseline and 2 years using double oblique coronal FLASHwe sequences. Cartilage thickness was determined in 5 subregions of each medial and lateral T surface and 3 subregions of each weightbearing F surface using custom software. Logistic regression with GEE was used to analyze the relationship of VAR (≥2° in VAR direction vs. non-VAR) and VAL (≥2° in VAL vs. non-VAL) with baseline-to-2-year cartilage thickness loss of ≥5% at each subregion, adjusting for age, gender, BMI, and baseline K/L grade.

Results: The sample included 261 knees (159 persons, 66 yrs, BMI 30, 75% women). 38% of knees were VAR and 31% were VAL. VAR at baseline was associated with a significant increase in the adjusted OR for cartilage thickness loss in the central and external subregions of the medial T and F surfaces (Table 1). Baseline VAL was associated with cartilage thickness loss in the central and external subregions of the lateral T and F surfaces and in the posterior and interior subregions of the lateral T surface (Table 2). VAR and VAL were each associated with reduced odds of thickness loss, significant in some subregions, in the unloaded compartment (Tables 1 and 2).

Conclusion: VAR at baseline was associated with baseline-to-2 year cartilage thickness loss in the central and external subregions of the medial T and weightbearing F surfaces. Similarly, baseline VAL was associated with cartilage thickness loss in the central and external subregions of the lateral T and F surfaces and the lateral T posterior and interior subregions.

Serum Levels of Inflammatory Markers, Knee Radiographic Osteoarthritis, and Knee Cartilage Loss in Older Adults. Changhai Ding[1], Flavia Cicuttini[2] and Graeme Jones[1], [1]University of Tasmania, Hobart, Australia, [2]Monash University, Melbourne, Australia

Purpose: The role of inflammation in osteoarthritis (OA) is unclear and the associations between serum levels of inflammatory markers and knee cartilage loss have not been reported.

Methods: A total of 172 randomly selected subjects (mean 63 years, range 52-78, 47% female) were studied at baseline and 2.9 years later. Serum high-sensitivity C-reactive protein (hs-CRP), interleukin 6 (IL-6) and tumor necrosis factor α (TNF-α) were assessed by

radioimmunoassay. T1-weighted fat-suppressed MRI of the right knee was performed to determine knee cartilage volume. Knee radiographic osteoarthritis (ROA) was also assessed.

Results: At baseline, quartiles of IL-6 and TNF- α were associated with increased prevalence of medial tibiofemoral joint space narrowing (grade ≥1) in multivariate analyses (OR: 1.42 and 1.47 per quartile, respectively, both P<0.05). Longitudinally, baseline IL-6 (but not TNF- α) predicted loss of both medial and lateral tibial cartilage volume (β: -0.89% and -1.02% per annum per quartile, P<0.05 and P<0.01, respectively), which was independent on TNF- α. Change in IL-6 was associated with increased loss of medial and lateral tibial cartilage volume (β: -0.95% and -0.79% per annum per quartile, both P<0.05) and change in TNF- α was also negatively associated with change in medial and lateral tibial cartilage volume (β: -0.81% and -0.82% per annum per quartile, both P<0.05). Serum hs-CRP was not associated with ROA and cartilage loss.

Conclusion: Serum levels of IL-6 and, to a lesser extent, TNF- α are associated with knee cartilage loss in older people suggesting low level inflammation plays a role in the pathogenesis of knee OA.

The Effect of Tears in Specific Meniscal Segments On Subregional Tibiofemoral Cartilage Thickness Loss in Knee OA. A. Chang[1], F. Eckstein[2], A. Guermazi[3], K. Moisio[1], J. S. Chmiel[1], O. Almagor[1], W. Wirth[2], P. Prasad[1], M. Marshall[1], S. Cahue[1] and L. Sharma[1], [1]Northwestern Univ, Chicago, IL, [2]Paracelsus Med Univ, Chondrometrics Gmbh, Salzburg, Austria, [3]Boston Univ, Boston, MA

Purpose: Meniscal (M) tears have been linked to knee OA progression, presumably via impaired load attenuation. How M tears influence OA pathogenesis is unclear; subregional examination may elucidate whether any impact is local. We tested if baseline medial M tear in a specific segment is associated with baseline-to-2 year cartilage thickness loss in subregions that the damaged segment overlies.

Method: Persons with knee OA by K/L ≥ 2 and symptoms had 1.5T MRI at baseline and 2 years later using double oblique coronal FLASH sequences, coronal T1-weighted spin-echo (SE), and sagittal fat-suppressed dual-echo turbo SE. M tears were graded separately (0-4, WORMS) for each segment [posterior horn (PH), body, anterior horn (AH)]. Mean cartilage thickness of 5 tibial (T) and 3 weightbearing femoral (F) subregions was determined using proprietary software. We used logistic regression with GEE to analyze the relationship between baseline tear (score ≥2) in each M segment and baseline-to-2 year cartilage thickness loss (of ≥5%), adjusting for age, gender, BMI, and M tear in the other two segments.

Results: Our sample consisted of 261 knees from 159 persons (66 yrs, BMI 30, 75% women). Table 1 shows the % of knees with M tears in each segment. The % knees losing cartilage in the medial T subregions was 33% (central), 36% (external), 20% (internal), 33% (anterior), and 28% (posterior), and in the F subregions was 36% (central), 33% (external), and 31% (internal). As in Table 2, baseline PH tear was significantly associated with T posterior subregion cartilage loss. Body tear was significantly associated with cartilage loss in the T central, external, and anterior subregions as well as F external subregion. There was no significant association between AH tear and cartilage thickness loss in any subregion.

Conclusion: Knees with medial M body tear had substantially increased odds of subsequent cartilage thickness loss in the subregions that the M body overlies, T external and F external, as well as in T central and anterior. PH tears were associated with T posterior region thickness loss. The lack of findings for AH tears may relate to the small numbers with tears in this segment. These findings suggest that at least some of the M tear effect is experienced locally.

Table 1. Medial Meniscal Tear Location (261 knees)

	PH	Body	AH	PH & body	AH & body	AH & PH	All segments	No tear
# (%) of knees	29 (11%)	10 (4%)	1 (0.4%)	40 (15%)	4 (2%)	0 (0%)	8 (3%)	169 (65%)

Table 2. Medial Meniscal Segment Tear Associated OR (95% CI) for Cartilage Thickness Loss in Medial Subregions (adjusted for age, gender, BMI, and tears in other meniscal segments)

Independent variable	T, central	T, external	T, internal	T, anterior	T, posterior	F, central	F, external	F, internal
PH tear	1.02 (0.50, 2.08)	0.97 (0.44, 2.13)	1.11 (0.47, 2.59)	0.57 (0.26, 1.27)	**2.63 (1.23, 5.62)**	1.58 (0.82, 3.04)	1.30 (0.63, 2.69)	0.54 (0.26, 1.16)

Active Appearance Modelling of DXA Images to Assess Severity of Osteoarthritis of the Hip. Rebecca J. Barr[1], Jennifer S. Gregory[1], Kanako Yoshida[1], Salvatore Alesci[2], Richard M. Aspden[1] and David M. Reid[1], [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Wyeth Research, Collegeville, PA

Purpose: The use of plain radiographs for the assessment of Osteoarthritis (OA) is well established. Our recent studies have found that new generation Dual Energy X-ray Absorptiometry (DXA) scanners, normally used for measuring Bone Mineral Density (BMD), produce images of sufficient quality to allow grading of OA severity using the Kellgren Lawrence (KLG) scoring system. We have also shown that Active Shape Modelling (ASM), a method for quantifying variations in the shape of the femur, can identify early onset and progression of hip OA from radiographs. The aim of this study was to develop this further by using Active Appearance Modelling (AAM) and DXA images to model not only the shape, but also the variation in image intensity (BMD distribution) within the femur.

Method: Sixty two subjects with hip OA were identified as having had a pelvic radiograph in the last 12 months using the local Radiology Information System, and invited to undergo a dual femur DXA scan using an iDXA scanner (GE Medical Systems). DXA images of each hip were graded using the KL system. An 85 point AAM template, that included the proximal femur, osteophytes, and parts of the pelvis, was applied to each image to provide a comprehensive model of the hip joint. Outputs from the AAM are independent “modes of variation” that describe changes in the shape of the hip and BMD distribution occurring together in the dataset. Correlations between the first 10 modes and KLG were assessed to identify modes likely to be of interest for assessing OA progression. These were then analysed using one-way ANOVA.

Results: Significant correlations were found between KLG and modes 2, 4 and 7 ($P < 0.001$, $r = 0.22 – 0.49$, Fig 1A). These modes reflected changes in BMD distribution, identifying common areas of sclerosis as well as changes in the shape of the femur, the pelvis and joint space narrowing (Fig 1B).Results were confirmed by one-way ANOVAs ($P < 0.001$).

Conclusion: Active Appearance Modelling can be used with DXA images to extend the ASM of the hip to collect information on BMD distribution. This additional information may further improve our ability to assess the early onset, severity and progression of hip OA.

Is Severe Osteoarthritis of the Knee Heritable: A Population Based Study. Allen D. Sawitzke[1], Josep Vergés[2], Eulàlia Montell[2], Marta Herrero[2] and Daniel O. Clegg[3], [1]Univ of Utah, Salt Lake City, UT, [2]Bioibérica S.A., Barcelona, Spain, [3]University of Utah Medical Ctr, Salt Lake City, UT

Purpose: Osteoarthritis (OA) is the most common rheumatologic diagnosis and is increasing in frequency with the aging of the populace. OA of the knee arguably accounts for the largest clinical costs as knee replacement is common and effective medical therapies to slow progression have not been described. While genetic predispositions to OA, are described, different genetic underpinnings may predispose to specific disease presentations. Clinical trial design of agents for OA structural modification would benefit from identifying and recruiting individuals at highest risk of progression at a time when their disease is potentially modifiable. The first step in defining patients at high risk for disease progression is to better understand the heritability of OA and if it is strongly heritable, genetic biomarkers can be identified. Ideally, the approach to identifying patients at risk for rapidly progressive OA would concurrently provide insight into selection of persons for development of specific biomarkers and for enrollment into studies.

Method: A unique resource, the Utah Population Data Base (UPDB) was used to test the heritability of severe OA of the knee. The UPDB is a genealogic resource with records on more than 7.1 million individuals that are used to define patterns of genetic inheritance. For this study, severe OA of the knee cases were defined as persons who underwent total knee arthroplasty (TKA) for OA in Utah over the years of study as found by search of the statewide hospital discharge data (1996-2007) using billing coding. Whenever possible, the cases were mapped to UPDB pedigrees for further analysis. Measures of risk to relatives of 1, 2 and 3 degree to cases was calculated. Control families were randomly selected from the UPDB as well to allow the calculation of risk accounted for by genetic factors.

Results: Over 18,000 OA patients who underwent TKA in Utah hospitals were linked to the UPDB and analysis performed. 683 Founder families were identified who had at least 5 affected cases for analysis as multiplex families. Members of these families had 1.1 to 60.8 times the likelihood of having OA complicated by a TKA as did members of control families. The population attributable risk was 21%. Siblings of affected cases were most likely to be affected with a relative risk of 2.07, followed by parents (1.79), children (1.74) and more distant relatives. All relations closer than second cousins were statistically at increased risk. Interestingly, spouses were also statistically at increased risk (RR 1.33).

Conclusion: Severe OA of the knee pedigrees can be identified and the risk for TKA due to OA of the knee in these families shows a graded heritable effect for 1, 2 and 3 degree relatives of the cases. Carefull selection of and analysis of these families at highest risk may help to outline a unique strategy for a biomarker development and ultimately to define selection criteria for studies of structural modification in OA of the knee.

Measures of Alignment in Knee OA: How Valid Are Clinical Methods?- Data From the Osteoarthritis Initiative. KD Gross[1], J. Niu[2], JP Goggins[2], TDV Cooke[3], MC Nevitt[4] and David T. Felson[5], [1]MGH Inst Health Prof, Boston, MA, [2]BUSM, Boston, MA, [3]Queens Univ, Kingston, ON, [4]UCSF, SF, CA, [5]Boston University School of Medicine, Boston, MA

Purpose: Standing long limb (LL) x-ray measures of Hip-Knee-Ankle (HKA) alignment provide valid information about load distribution and the likelihood of knee OA progression. In many clinics however, LL x-rays are unavailable and decisions about intervention to improve alignment are based on clinical measures whose validity is unknown. We determined the concurrent validity of clinical measures of standing knee alignment by comparing them to measures from LL x-rays.

Method: The Osteoarthritis Initiative (OAI) is a multi-center study that includes a progression subcohort of individuals with symptomatic knee OA. From this subcohort, bilateral fully extended LL x-rays were obtained as part of a 12-month follow-up exam. To these, we applied reference standard methods to measure HKA alignment in each knee (inter-rater ICC=0.98). At the same exam, clinical examiners used long-arm goniometers to obtain bilateral measures of standing tibiofemoral (TF) alignment (data from OAI public use data set). Varus angles were assigned negative values. We used Bland-Altman analysis to determine the limits of agreement between the two measures. Weighted kappa coefficients were calculated to assess agreement between categories of varus, neutral, and valgus alignment. While categories of varus, neutral, and valgus HKA alignment were defined according to traditional ≤-2º, -2º to 2º, and ≥2º cutpoints, a range of gender-neutral and gender-specific offset values were used to adjust TF measures before determining categorical agreement.

Results: 1175 subjects (55% female), mean age 62.0 +/- 9.2 yrs and mean BMI 29.6 +/- 4.7, contributed 2309 knees. Mean x-ray HKA alignment was -1.3º +/- 3.9º (range -16.0º, 17.9º). Mean clinical TF alignment was -0.2º +/- 4.1º (range -15.0º, 14.0º). On average, clinical alignment was 1.1º more valgus than x-ray alignment with 95% limits of agreement ranging from 6.3º more varus to 8.5º more valgus. At the highest level of categorical agreement (when clinically measured neutral alignment was defined as 1º to 3º in both genders), weighted kappa was only 0.36 (95% CI: 0.33, 0.39). When using a different offset for women and men, agreement did not rise substantially (weighted kappa=0.37, 95% CI: 0.34, 0.40). In 7.1% of knees, there was extreme disagreement between clinical and x-ray measures, such that one measure indicated varus while the other indicated valgus alignment (see table).

Table: Clinical vs. X-ray Alignment

X-ray HKA Alignment	**Clinical TF Alignment**			
# knees % knees	**Varus** (≤0º)	**Neutral** (1 to 3º)	**Valgus** (≥4º)	**Total**
Varus (≤-2º)	814 35.3	125 5.4	60 2.6	999 43.3
Neutral (-2º to 2º)	483 20.9	230 10.0	183 7.9	896 38.8
Valgus (≥2º)	103 4.5	90 3.9	221 9.6	414 17.9
Total	1400 60.6	445 19.3	464 20.1	2309 100.0

Conclusion: The 95% limits of agreement between clinical and x-ray alignment include important discrepancies of up to 8.5º. Despite adjusting clinical measures to maximize agreement in the categorization of varus, neutral, and valgus knees, the two methods agree only modestly.

Patella Alta Is Associated with Patellofemoral Malalignment: The MOST Study. J.J. Stefanik[1], Y. Zhu[1], A.C. Zumwalt[1], K.D. Gross[2], M. Clancy[1], J.A. Lynch[3], L.A. Frey Law[4], C.E. Lewis[5], A. Guermazi[6], C.M. Powers[7] and David T. Felson[6], [1]BUSM, Boston, MA, [2]MGH Inst Health Prof, Boston, MA, [3]UCSF, San Francisco, CA, [4]UIowa, Iowa City, IA, [5]UAB, Birmingham, AL, [6]Boston University School of Medicine, Boston, MA, [7]USC, Los Angeles, CA

Purpose: Research on risk factors for patellofemoral joint (PFJ) osteoarthritis (OA) has focused on patellar malalignment (patellar tilt angle and lateral displacement or bisect offset) and trochlear morphology (sulcus angle). Patella alta (PA), a high riding patella, has received much less attention despite being a known risk factor for patellar subluxation and dislocation in young persons. Patella alta is measured on a lateral knee radiograph by the Insall-Salvati ratio (ISR), a ratio between the length of the patellar tendon and length of the patella. Subjects with higher ISRs are hypothesized to have increased patellar malalignment due to the lack of osseous stability when the patella articulates superior to the femoral trochlea. The purpose of this study was to determine the association between the ISR and measures of PFJ malalignment, specifically patellar tilt angle (PTA) and bisect offset (BO).

Methods: The MOST study is an NIH funded cohort study of persons aged 50-79 years with or at risk for knee OA. We measured the ISR on weight bearing and flexed lateral knee radiographs and PTA and BO on baseline knee MRIs in 486 knees, one knee per subject. PTA was defined as the angle between a line connecting the posterior femoral condyles and a line defining the maximal patellar width. BO is a measure of the percent of the patellar lateral to the midline of the trochlea. ANOVA was used to determine the association between quartiles of the ISR and BO and PTA in two separate analyses.

Results: The mean ISR was 1.10, mean BO 59.79%, and mean PTA 8.81 degrees. The mean age of the sample was 62, mean BMI 30, and 60% of subjects were female. The means for BO and PTA were 9.82 and 3.56 greater in the highest ISR quartile compared to those in the lowest ISR quartile (see table). Similar results were seen when adjusting for isokinetic knee extensor strength, age, sex, and BMI.

Conclusion: Our results support the hypothesis that high ISRs, indicative of patella alta, are associated with increased PFJ malalignment. Since the ISR is unlikely to change over time, patella alta may be an important risk factor for PFJ OA, as it may cause patellofemoral malalignment.Longitudinal studies are needed to determine if higher ISRs increase the risk for PFJ malaignment.

Insall-Salvati Ratio (ISR)

	Quartile 1	Quartile2	Quartile 3	Quartile 4	P for trend
	0.64-0.99	1.00-1.08	1.09-1.20	1.21-1.58	(continuous ISR)

Persons with Patellofemoral Osteoarthritis Exhibit Increased Hip and Knee Moments During A Sit-to-Stand Task. Lisa T. Hoglund[1], Mary F. Barbe[2], Ann E. Barr[3], Howard J. Hillstrom[4], Margery A. Lockard[5], Jinsup Song[2], William R. Reinus[2] and Benjamin P. Heilman[6], [1]University of the Sciences in Philadelphia, Philadelphia, PA, [2]Temple University, Philadelphia, PA, [3]Thomas Jefferson University, Philadelphia, PA, [4]Hospital Special Surgery (HSS), New York, NY, [5]Drexel University, Philadelphia, PA, [6]Biomet Manufacturing Corporation, Warsaw, IN

Purpose: Patellofemoral (PF) osteoarthritis (OA) is common in middle-aged and older adults. Isolated radiographic PFOA has been reported in 24% of females and 15.4% of males ≥ 55 years. Increased joint stress is one factor in the development and progression of PFOA. Forceful quadriceps contraction with the knee in extreme flexion, e.g., during sit-to-stand (STS), produces high PF joint reaction force (JRF) and PF stress. Increased tibial abduction during STS was recently reported in persons with PFOA, a position reported to increase PF stress. The purpose of this study was to quantitatively examine the triplanar hip and knee kinetics during STS in persons with patellofemoral osteoarthritis.

Method: A cross-sectional study with 2 groups was conducted: subjects with bilateral, symptomatic, radiographic PFOA (PFOA) compared to asymptomatic subjects free from radiographic PFOA (control). Thirty-two adults (40-65 years) participated; 15 subjects remained after radiographic exclusions (30 lower extremities [LE]) with 8 in the PFOA group and 7 in the control group. Anthropomorphic and LE strength data were collected. Subjects performed STS from a stool at 110% knee height without hand use. Biomechanical data were collected in 3 anatomical planes with a Vicon 460™ system (5 cameras) and 2 Kistler™ force plates (one per foot). Hip and knee joint moments were normalized by body mass and examined at 4 events: Maximum (MAX), Minimum (MIN), Seat-Off (SO), and End of STS. The Temple University Institutional Review Board approved the protocol. A mixed model 2 factor ANOVA was used (group, limb); $\alpha = 0.01$.

Results: Increased hip and knee internal moments during STS were present in the PFOA group versus the control group. Hip extension (EXT), abduction (ABD), and external rotation (ER) moments were increased at the events of MAX, SO, and End of STS. Knee EXT and adduction (ADD) moments were increased at SO. Significant between-limb differences were present at the hip; the dominant (stronger) LE had increased ABD and ER hip moments at MAX and End. Significant group x limb interactions were found at the knee at MAX and End.

Conclusion: Increased knee EXT and ADD moments indicate that increased knee JRF are present during STS in persons with PFOA. The PF joint stress is likely to be increased and may be a factor in the progression or development of PFOA. Increased hip ABD and ER moments in the PFOA group may be a compensation to prevent "medial collapse" of the LE, reported in persons with PF pain syndrome and PFOA. This is the first study to report kinetics during STS in persons with PFOA. It indicates that increased hip and knee joint moments are associated with PFOA. Future research should examine interventions to decrease joint moments as a method of joint protection.

220

Minimum Joint Space Width (minJSW) and Mean JSW at a Constant Location in Evaluating Joint Space Narrowing (JSN) in Medial Tibiofemoral Osteoarthritis (OA)-Data From the Osteoarthritis Initiative. Thierry Conrozier[1], Muriel Piperno[1], Kenneth D. Brandt[2], Marie-Pierre Hellio Le Graverand[3], D.J. Hunter[4] and Eric Vignon[5], [1]Lyon Sud University Hospital, Pierre Bénite, France, [2]Kansas Univ Medical Center, Fairway, KS, [3]Pfizer Inc., New London, CT, [4]NEBH, Boston, MA, [5]Claude Bernard University, Lyon, France

Purpose: Measurement of a change in the minimum JSW (minJSW) is widely used to evaluate JSN in knee OA. Measurement of mean JSW at a constant location has recently been suggested as an alternative. The purpose of this study was to compare both methods of measurement in terms of their reproducibility and sensitivity to change.

Method: Knee radiographs from a subset of subjects in the OA Initiative (OAI) (Clinical Datasets 0.1.1 and 1.2.1 and Image Release 0.C.1 and 1.C.1) were used in this analysis. MinJSW and mean JSW in each of 16 consecutive slices of the medial tibiofemoral compartment in films of the left knee of a subset of subjects from the OAI Progression Cohort were measured at baseline and 1-year, using HOLY's software (Lyon, France). The 16 slices comprised 70% of the distance between the tibial axis and inner non-osteophytic limit of the medial compartment. Slices were numbered 1–16, with Slice 1 the most medial. The slice that contained minJSW was determined in each film.

Results: ***JSW:*** In baseline films, radiograph quality limited the measurement of JSW in all 16 slices to 71.1% of knees. Notably, JSW measurement in Slices 1, 2 and 3 was possible in only 69.1, 76.1 and 87.0% of knees Reproducibility of minJSW measurement was much

greater than that for slice JSW: SD of test-retest difference was only 0.02 mm for minJSW, but 0.09 - 0.14 mm for Slices 3- 11 and 0.17 - 0.49 mm for innermost and outermost slices. The magnitude of the mean difference in JSW between KL0 (n= 21) and KL4 (n=24) decreased progressively from Slice 1 to 16. In Slices 1, 2 and 3 the difference in JSW between KL 0 and KL 4 was greater than the difference between KL 0 and 4 in minJSW (4.13, 3.59, 3.34 mm vs. 3.28 mm). The mean location of minJSW shifted from Slice 5 in KL 0 knees to Slice 3 in KL 4 knees (p=0.021).

***JSN*:** 1-year JSN was evaluated in 123 knee pairs. JSN was significant only in Slices 3, 4 and 5 of KL3 knees ($p<0.02$) and in Slices 5- 9 of KL4 knees ($p<0.005$). JSN was 0.15 ± 0.36 mm ($p=0.009$, SRM = 0.41) and 0.15 ± 0.41 mm ($p=0.016$; SRM = 0.39), respectively, for minJSW and for the best-performing slice (Slice 3). The location of minJSW did not vary significantly over the 1-year interval.

Conclusion: Comparison of KL0 and KL4 knees suggests that the largest decrease in JSW occurs in the innermost portion of the medial compartment. However, measurement of JSW at a constant location in this region was often not technically possible. MinJSW and Slice 3 JSW offered similar sensitivity to change over 1 year but Slice 3 JSW was less reproducible and frequently could not be measured accurately. Thus, minJSW appears to be preferable to Slice JSN for evaluation of JSN in a series of radiographs .

Reduced Peripheral Nerve Function as a Risk Factor for Radiographic Knee Osteoarthritis. Sunil Abraham[1], C. Kent Kwoh[2], Robert M. Boudreau[1], Michael J. Hannon[1], Michael C. Nevitt[3], Anne B. Newman[1], Annemarie Koster[4], Suzanne Satterfield[5], Tuhina Neogi[6] and Elsa S. Strotmeyer[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh, VA Pittsburgh Healthcare System, Pittsburgh, PA, [3]University of California, San Francisco, San Francisco, CA, [4]National Institute on Aging, Bethesda, MD, [5]University of Tennessee, Memphis, TN, [6]Boston Univ Schl of Med, Boston, MA

Purpose: Neural deficits are postulated to play a role in the etiology of knee osteoarthritis (KOA), but few studies have examined this. One study with a small sample size has suggested an association between decreased vibratory perception threshold in the lower extremities and KOA.

We hypothesized that reduced peripheral nerve function would be associated with radiographic KOA (RKOA) in community dwelling older adults in a nested case control substudy of the Health Aging and Body Composition (Health ABC) cohort.

Method: The Health ABC Study is a longitudinal cohort of 3075 ambulatory, community-dwelling elderly aged 70-79 years at 1997-98 entry. The KOA substudy within Health ABC obtained fixed-flexion knee x-rays on participants who reported knee pain (most days of a month in the past year or moderate or worse WOMAC pain with any activity in past 30 days) at the Year 2 visit as well as a sample of controls without pain by this definition. Peripheral nerve function was assessed on the index (right if possible) leg at the Year 4 visit using peroneal motor nerve conduction studies (amplitude and velocity), 1.4-g and 10-g monofilament testing at the great toe, and average vibration threshold (quantitative sensory method) at the great toe in the index leg. RKOA was defined as a Kellgren-Lawrence grade ≥ 2 on fixed-flexion knee x-rays.

Multivariable logistic regression was used to determine the association of nerve function measures with knee OA with, while adjusting for height, weight, depression, age, race, gender, and diabetes.

Results: The sample of Health ABC participants with any peripheral nerve function testing and a knee x-ray (n = 978) was 60% women, 55% white, and 74+SD years of age; with a mean weight of 76+SD kg and a mean height of 1.65+SD m. The bivariate results comparing differences in peripheral nerve function in participants with RKOA vs. those without RKOA is summarized in Table 1.

Table 1	+ROA		-ROA		p-values
	Mean	(SD)	Mean	(SD)	
Peroneal motor nerve conduction velocity					
Amplitude (mV)	3.6	(1.9)	3.7	(1.7)	0.28
Nerve conduction velocity (m/s)	43.9	(5.5)	43.6	(5.5)	0.40

Average Vibration threshold (microns)	55.8	(37.9)	49.6	(34.9)	0.01
Monofilament testing	N	(%)	N	(%)	
Neither	30	(9.68)	54	(8.36)	0.75
10g	125	(40.32)	257	(39.78)	
1.4g	155	(50.00)	335	(51.86)	

Only reduced vibratory sense was significantly associated with an increased odds of RKOA in MV models. Adjusted OR=1.20 (95%CI: 0.84-1.3) per SD increase of vibration threshold.

Conclusion: In an elderly community-dwelling cohort, higher vibration thresholds, but not other measures of nerve function, were associated with greater odds of RKOA, supporting a possible role for large afferent nerve fiber dysfunction in the etiopathogenesis of knee OA. Further studies are needed to elucidate this relationship.

222

Relationship Between Self- Reported Comorbidity and Health Status in Early OA: The CHECK Study. Janet Wesseling[1], Sita MA Bierma- Zeinstra[2], Joost Dekker[3], Johannes WJ Bijlsma[4] and on behalf of CHECK study group, [1]University Medical Center, Utrecht, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]VU University Medical Center, Amsterdam, Netherlands, [4]University Medical Center, Utrecht

Purpose: Osteoarthritis (OA) is the most common diagnosis made in older patients with knee or hip pain in primary care. The prevalence of many other disabling conditions rises with age, and some chronic conditions can be found together with OA. An important question is to whether comorbidity and the presence of specific diseases impairs the clinical status of patients with early OA. The objective is to describe the relationship between comorbidity and the health status of participants with early osteoarthritis.

Method: In the Netherlands a prospective 10-year follow-up study was initiated by the Dutch Arthritis Association with participants with early OA related complaints of hip and/or knee: CHECK. Inclusion criteria were pain and/or stiffness of knee and/or hip, age 45- 65 years, and had never or not longer than 6 months ago visited the general practitioner for these symptoms for the first time. The WOMAC was utilized to measure pain, stiffness, and limitations in activities. Physical functioning and mental functioning were measured by SF-36, a generic measure of self-reported health related quality of life (HRQL). The presence of chronic disease was assessed with a standard consensus based list (self- reported health module of Statistics Netherlands), which consists of 24 diseases and disorders. It was investigated if the number of comorbidities influenced outcome and if specific conditions from this score had an effect beyond the comorbidity score.

Results: In CHECK 1002 participants were included, a mean age of 56 years, mean BMI of 26 kg/m^2 and 79% female. Over 64% of the included participants had comorbidity: severe disorders of neck, shoulder, elbow, wrist or hand (23%), hypertension (20%) and severe or persistent back disorder (18%) being most prevalent. After controlling for age, gender, and BMI, participants with more comorbidities had more pain (beta 0,5; $p \leq 0{,}001$), limitation in activities (beta 2,2 ; $p \leq 0{,}001$) and a worse health related quality of life (HRQL) (beta -2,2; $p \leq 0{,}001$). Beyond the score, results (controlling for age, sex, BMI) show that back disorder has the most negative effect on pain and function. Disorders of elbow, shoulder, wrist, or hand have the most negative effects on HRQL (Physical function subscale). On the contrary, participants with hypertension reported less pain and disability when controlling for the number of diseases.

Conclusion: The number of comorbidities deteriorates the health status of participants with complaints of early OA. Next to this, specific disease, like severe back disorder, further increases pain and impairs function. Also disorders of neck, elbow, shoulder, wrist or hand decrease the physical function in HRQL.

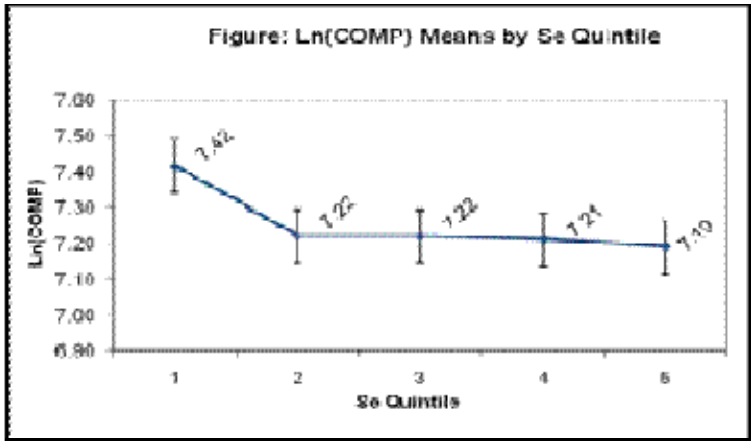
Selenium and Biomarkers of Joint Tissue Metabolism in a Community-Based Cohort: The Johnston County Osteoarthritis Project.

S. Addison[1], X. Shi[2], Todd A. Schwartz[3], V.B. Kraus[4], T. Stabler[5], C.G. Helmick[6] and J.M. Jordan[7], [1]University of North Carolina, Chapel Hill, NC, [2]Thurston Arthritis Research Center, Chapel Hill, NC, [3]The University of North Carolina, Chapel Hill, NC, [4]Duke University Medical Center, Durham, NC, [5]Duke University Medical Center, Durham, [6]Centers for Disease Control and Prevention, Atlanta, GA, [7]UNC, Chapel Hill, NC

Purpose: Selenium (Se) is an essential trace element required for the reduction of antioxidant enzymes that may be important in osteoarthritis (OA). We have observed that low Se levels are associated with radiographic osteoarthritis (rOA). The objective of this analysis was to examine associations between toenail Se levels and various putative OA biomarkers reflecting specific metabolic processes that may be influenced by Se level.

Method: A cross-sectional analysis was performed on 678 participants (36.6% African American; 48.8% male; mean age 63.7 (10.2) years) from the Johnson County Osteoarthritis Project to determine the association of Se with 6 biomarkers: cartilage oligomeric matrix protein (COMP), hyaluronic acid (HA), two markers of collagen turnover (C2C and CPII), and two markers of bone degradation (CTX-II and NTX-I). Toenail Se was measured by Instrumental Neutron Activation Analysis and mass spectroscopy. Biomarkers were measured by enzyme-linked immunosorbent assays. Spearman correlation coefficients were calculated between Se and the natural logarithm of each biomarker, as well as ln C2C/CPII, a ratio that reflects net collagen degradation or synthesis. Separate linear regression models were used to explore these associations, adjusting for age, gender, race, body mass index, and current smoking status. In addition, mean biomarker levels were calculated for each Se quintile and plotted with 95% confidence intervals.

Results: Mean Se levels were 0.80 ppm (range 0.31-2.10). In linear regression models, Se was correlated with ln COMP ($r = -0.15$, $p = <0.0001$). There was a borderline association between Se and ln NTX-I ($r = 0.07$, $p = 0.076$), but no significant association with ln HA, ln CTX-II, ln C2C, ln CPII, or ln C2C/CPII. Mean ln COMP was significantly higher in those in the first Se quintile (7.42 ppm) when compared to the other four Se quintiles (7.19-7.22 ppm) (Figure). Compared to the highest quintile of Se (quintile 5), the p-values for the effect of the other Se quintiles (quintiles 1-4) on ln(COMP) are 0.001, 0.763, 0.663, and 0.765.



Conclusion: Se levels were inversely associated with ln COMP, suggesting that cartilage and/or bone turnover may be the specific metabolic process linking low Se to rOA. The effect of Se appears limited to those in the lowest quintile, mirroring our prior findings in rOA. This suggests that Se deficiency may be important in OA, but that increases in Se levels above repletion may not have a significant impact.

Morphological Variations in Hip Shape: Validation of New Hip Measurement Software and Provisional Association with Total Hip Replacement-The Chingford Study. Alexander S. Nicholls[1], Harinderjit Gill[2], Tom Pollard[3], Debbie Hart[4], David W. Murray[5], Andrew Carr[6], TD. Spector[4], Amit Kiran[7] and Nigel K. Arden[8], [1]University of Oxford, Oxford, OX2 6HG, United Kingdom, [2]University of Oxford, [3]University of Oxford, Oxford, United Kingdom, [4]St Thomas Hospital, London, United Kingdom, [5]Univeristy of Oxford and Nuffield Orthopaedic Centre, WIndmill Rd, OX3 7LD, United Kingdom, [6]Oxford University, Oxford, OX3 7LD, United Kingdom, [7]Oxford University, United Kingdom, [8]Oxford University, Oxford, United Kingdom

Purpose: Over the past decade measures of hip morphology, including femoroacetabular impingment (FAI), have been recognised as a biomechanical risk factors for individuals who develop osteoarthritis (OA) in the hip. Few studies have examined this in combination with pelvic morphology in a cohort of healthy volunteers with prolonged follow-up. The present study validates a new software process that quantifies morphologoical parameters of the hip and pelvis.

Method: We developed a software program that measures 24 morphological parameters in the pelvis, acetabulum and proximal femur. We tested inter-user reproducibility by 4 trainee orthopedic surgeons (OS) measuring the same 10 blinded radiographs. Intra-user reproducibility was measured by one trainee OS measuring 10 blinded radiographs on three separate occasions.

We performed a nested case-control study using women from a well-described cohort of 1003 women who were recruited in 1989 and followed up for 20 years. A group of 45 age-matched individuals (aged 50-59 years at baseline; 15 total hip replacements & 30 controls) were randomly selected. Pelvis radiographs taken at study-year 2 were analyzed for variations in hip morphology using the new software. These measurements were correlated with current total hip replacement (THR) records, which were used as a clinical end-point for end-stage OA.

Result: Most morphological measures were reproducible, with the exception of horizontal toit externe (HTE). The alpha-angle was significantly greater in the cases than the controls (67.9 vs 49.4; $p = 0.002$). The Gosvig triangular index was positive in 50% of the caes and 0% of the controls ($p < 0.001$). In all other measurements, there were no significant differences between cases and controls.

	Inter-User Variability (Coefficient of Variation, %)	Intra-User Variability (Coefficient of Variation, %)
Alpha-angle	6	4
Femoral neck length	2	7
Femoral neck width	3	1
Femoral neck-shaft angle	1	1
Lateral centre edge angle (Wiberg Angle)	6	4
Extrusion Index	6	4
Horizontal Toit Externe	106	15

Conclusion: This software reproducibly measures a wide variety of hip morphological parameters. In this provisional nested case-control study, the alpha angle and Gosvig triangular index are strongly associated with future need for THR. This software allows us to look for interactions between these morphological parameters and subsequent formation of additive OA risk pathways.

Prevalence of Femoral Neck Protuberance On Hip MRI in a Swiss Male Population: A Cross-Sectional Study. Stephan Reichenbach[1], Peter Jüni[1], Stefan Werlen[2], Eveline Nüesch[1], Christian W. Pfirrmann[3], Sven Trelle[1], Reinhold Ganz[1] and Michael Leunig[4], [1]University of Bern, Bern, Switzerland, [2]Hospital Sonnenhof, Bern, Switzerland, [3]University Hospital Balgrist, Zurich, Switzerland, [4]Schulthess Clinic, Zurich, Switzerland

Purpose: Based on experimental and clinical studies, femoro-acetabular impingement was proposed to cause early osteoarthritis (OA) in the non-dysplastic hip. Femoro-acetabular impingement usually occurs as one of two different types, either 'cam' or 'pincer'. Cam impingement is predominantly seen in males, and is caused by the presence of a femoral neck protuberance (FNP) with a non-spherical femoral head and/or a decreased anterior head-neck offset. The increased radius of the femur entering the acetabulum results in decreased joint clearance with repeated shearing forces occurring between the femoral neck and the acetabular rim during flexion and internal rotation. The aim of this study was to determine the prevalence of FNP as a potential risk factor for hip OA in a population-based inception cohort study of young males.

Method: Study subjects were consecutively recruited young males undergoing conscription for the Swiss army, which is required for all citizens regardless of their health status. Participants completed a set of questionnaires pertaining to pain, stiffness, and physical function, and internal rotation was measured reliably using a newly developed examination chair. A random sample of the examined participants was subsequently invited to obtain magnetic resonance images (MRI) of the hip. FNP was assessed semiquantitatively using scores from grade 0 to grade 3: 0=normal, 1=mild, 2=moderate, 3= severe FNP. Overall prevalence estimates with 95% confidence intervals (95% CI) accounted for the oversampling of participants with decreased (<30°) and increased (≥40°) internal rotation using posts-stratification weights. Prevalence of different grades of FNP was calculated separately for participants with decreased, normal (≥30° and <40°) and increased internal rotation.

Results: Subjects who underwent imaging included 244 asymptomatic participants with a mean age of 19.9 years and a mean body mass index of 23.1 kg/m^2. Grade 1 FNP was found in 112 MRIs, grade 2 in 54 MRIs, and grade 3 in 13 MRIs. The prevalence of definite FNP (grade ≥ 2) was 0.24 (95% CI 0.19 to 0.30). FNP was more prevalent in participants with decreased internal rotation compared to normal or increased internal rotation (table 1, p-value for trend < 0.001).

Conclusion: Definite femoral neck protuberance on MRI can be found in every fourth young asymptomatic male individual, and in every second participant with decreased internal rotation. Table1: Prevalence of femoral neck protuberance in the general male population

	No. of MRI examined	**MRI with femoral neck protuberance grade≥2**	**Prevalence (95% CI)**
Overall	**244**	**67**	**0.24 (0.19 to 0.30)**
IR < 30°	83	40	0.48 (0.37 to 0.59)
30° ≤ IR < 40°	81	17	0.21 (0.13 to 0.31)
40° ≤ IR	80	10	0.13 (0.06 to 0.22)

IR: internal rotation

Interim Safety Data of Gardasil® in a Trial in Females with JIA and Seronegative Arthritis. Nora G. Singer[1], Michelle Wallette[2], Ingrid Tomanova-Soltys[3] and Gina Montealegre-Sanchez[3], [1]University Hospitals/Case Medical Center and Rainbow Babies & Childrens Hospital, Cleveland, OH, [2]University Hospitals/Case Medical Center, Cleveland, OH, [3]University Hospitals/Case Medical Center and Rainbow Babies and Children's Hospital, Cleveland, OH

Purpose: The purpose of the study is to assess the efficacy and safety of Human Papillomavirus Quadrivalent (Types 6, 11, 16, and 18) Vaccine Recombinant (qHPV vaccine) in females age 9-26 who have been diagnosed with juvenile idiopathic arthritis or seronegative inflammatory arthritis including SEA syndrome, psoriatic arthritis, anyklosing spondylitis and inflammatory bowel disease related arthritis are eligible for an open-label, Phase IV clinical trial. We hypothesized 9-26 y.o. females with inflammatory arthritis will have protective responses following qHPV vaccine. Measurement of serum mean geometric titers is planned. The purpose of this abstract is to report the safety profile of qHPV vaccine the 22 patients enrolled to date. We further hypothesized that qHPV vaccine would have an acceptable safety profile in this population despite concerns that the vaccine could trigger arthritis flare.

Method: This trial is actively enrolling. Data are descriptive and are taken from adverse event reporting during the conduct of the study.

Results: 22 adverse events (AE) in 13 patients were reported. No serious adverse events were reported. One AE, a vasovagal reaction was considered to be study related. AEs that were possibly related included: achiness (1), fever (1), fatigue (1), headache (1), dizziness (2) light-headed (2), arthralgia (1), exacerbation patellar enthesitis (1), arm stiffness (1). AEs considered not to be study related included: common cold (4), thrush (1), varicella zoster infection (1), flu symptoms (1), rash (1), sinusitis (1), whiplash (1).

Conclusion: Vaccination with qHPV vaccine in the first 22 subjects has been associated with AEs but not SAEs. Among AEs associated with vaccination, vasovagal reaction was considered study related. AEs that were possibly associated included stiffness in the extremity where vaccine was administered, mild exacerbation of underlying enthesitis and limited constitutional symptoms. Practices regarding the recommendation and use of qHPV vaccine in females with inflammatory arthritis vary within the rheumatology community. Our data indicate an acceptable safety profile for subjects participating in an open label Phase IV clinical trial of qHPV vaccine. Information regarding the efficacy of this vaccine is likely to impact medical decision-making of practitioners who counsel patients regarding vaccination and patients and their parents who will decide whether or not to undergo vaccination.

Immunologic Responsiveness in Patients with JIA On Methotrexate and Etanercept: Candida Skin Test and Tetanus Vaccination. Ankur Kamdar[1], Patricia C. Giclas[2] and Barry L. Myones[1], [1]Baylor College of Medicine, Houston, TX, [2]National Jewish Health, Denver, CO

Background: There is a paucity of data regarding response to vaccinations in patients with JIA treated with methotrexate (MTX). It is also unclear whether newer biologic agents affect vaccination response.

Purpose: To investigate delayed hypersensitivity response and vaccination response to protein (secondary) and polysaccharide (primary) in these patients.

Method: Patients with a diagnosis of polyarticular JIA on stable doses of NSAIDS and/or MTX were enrolled into this prospective study. All patients received 0.5cc Td vaccine IM, 0.5cc Pneumovax (23-valent) subcutaneously, and 0.1cc Candida antigen (1:100) intradermal skin test. Serum samples were obtained at time of vaccination and after 4-6 weeks. Tetanus toxoid (TT) titers were measured by standard EIA. Positive response was considered a 2-fold increase in titer (4-fold responses also reported), 0.10 IU/ml was considered a clinically protective titer by the clinical laboratory. Patients were educated on how to measure a Candida skin test response, and were asked to mail in the results. 10mm diameter erythema and/or induration reaction was considered positive. Serum samples were subjected to C4 allotyping, complement and Ig levels to examine alternative causes for non-response.

Results: 50 patients were included for primary analysis in this study. 3 additional patients were excluded because of reaction to vaccination requiring steroid treatment. Patients were subdivided into MTX and non-MTX groups for analysis. 38 patients were on MTX (including 16

on MTX + etanercept), and 12 patients were on NSAIDS (n=9) or no medications (n=3). For the Candida skin test, results for 38 patients were available for analysis. 92% (n=35) had a positive skin test. All 3 non-responders were in the MTX group with 1 on MTX and etanercept. The serologic response rate (2-fold increase) for Tetanus vaccination was 82% and 75% and was similar to vaccine failure in normals. The post geometric mean titers (GMT) were significantly different at 8.82 IU/ml (95% CI 6.41, 12.1) and 12.34 IU/ml (95% CI 7.61, 20) for the MTX and non-MTX group respectively ($p<0.001$). Additional analysis revealed significantly higher pre-vaccination TT titers in those that did not respond to the vaccination ($p=<0.0001$). Of 16 patients on both MTX and etanercept, 93% responded to Candida skin test and 87% responded to tetanus vaccination. If a positive response is defined as a 4 fold increase, the serologic response rate for Tetanus vaccination was 66% and 66% for both groups (69% for the MTX + etanercept group).

Conclusion: Tetanus vaccination appears safe and effective in patients with JIA on background of both methotrexate and etanercept. Methotrexate use in patients with JIA does not appear to impair delayed hypersensitivity response or secondary response to protein vaccination although post GMT differences suggest a slightly decreased level of response with patients on methotrexate. Continued investigation is ongoing to evaluate polysaccharide response in this cohort.

Analysis of Intracellular Methotrexate Polyglutamates in Juvenile Idiopathic Arthritis. M. L. Becker[1], L. van Haandel[2], A. S. Lasky[1], M. F. Hoeltzel[1], J. E. Neal[1], C. N. Palmer[1], J. F. Stobaugh[2] and J. S. Leeder[1], [1]Children's Mercy Hospitals and Clinics, Kansas City, MO, [2]University of Kansas, Lawrence, KS

Purpose: Recently, intracellular MTX polyglutamates ($MTXglu_n$) have been shown to be potentially useful biomarkers of response in adult RA patients. We aimed to measure total intracellular MTX glu_{TOT} concentrations in a cohort of JIA patients and determine predictors of $MTXglu_{TOT}$ variability and association with outcome.

Methods: After obtaining informed consent, 5 ml of blood was obtained from JIA patients maintained on a stable dose of MTX for 3 months or longer. Demographic characteristics, efficacy and toxicity outcomes were collected by chart review. $MTXPG_{1-7}$ in RBC lysates were quantitated using an innovative ion-pairing chromatographic procedure with mass spectrometric detection with improved sensitivity and specificity over existing HPLC separation followed by photochemical/fluorescence detection methods.

Results: Patients (n=85; 61 female) from a single center aged 10.1 ± 4.5 years (mean ± SD; range 1.5 to 19.5 yr) were included in the analysis. Mean MTX dose was 0.51 ± 0.25 mg/kg/dose (range 0.11 to 1.05 mg/kg/dose) for a median of 19 months (range 3 to 156 months). MTX was given SC in 54 (64%) subjects; 50 (59%) subjects had active arthritis.

Total intracellular $MTXglu_n$ ($MTXglu_{TOT}$) concentrations varied 40-fold, from 4.80nmol/L to 210.3nmol/L (median 75.5nmol/L), in our cohort. Concentrations of $MTXglu_{1-7}$ were measured individually and as a percentage of each patient's $MTXglu_{TOT}$. $MTXglu_6$ and $MTXglu_7$ concentrations were detected in 68 and 15 patients, respectively. $MTXglu_3$ was the most prominent subtype identified, comprising 41±10.3% of $MTXglu_{TOT,}$ and was most highly correlated with $MTXglu_{TOT}$ (r =0.96). Principal components and cluster analyses revealed that $MTXglu_{1+2}$ and $MTXglu_{3-6}$ formed two internally correlated subgroups, and $MTXglu_{3-6}$ correlated highly with $MTXglu_{TOT}$ (r=0.94). $MTXglu_{1+2}$ constituted 38.1 ± 19.5% of $MTXglu_{TOT}$ (range 5.2 to 92.9%).

Bi-variable analyses revealed the following were associated with $MTXglu_{TOT}$: age, weight, mg/kg dose, months on MTX, NSAID use and MTX route. Multivariable analyses with inclusion of these variables in the model resulted in only mg/kg dose ($p=0.03$), route ($p=0.01$), and months of MTX ($p=0.03$) remaining significant predictors of $MTXglu_{TOT}$ variability. Months on MTX had a negative association. Response to MTX (no active arthritis) was not associated with $MTXglu_{TOT}$ or any individual absolute $MTXglu_n$ concentration, however, responders tended to have higher proportions of $MTXglu_1$ ($p=0.04$) and lower proportions of $MTXglu_4$ ($p=0.04$).

Conclusion: In our cohort of JIA patients, $MTXglu_{TOT}$ varied 40-fold, but only 32% of this variability was attributed to dose, route and duration of treatment. Longer use of MTX was associated with lower intracellular $MTXglu_n$ levels. Up to $MTXglu_7$ was detected by our analysis, not previously reported. Unlike adults, long chain $MTXglu_n$ absolute concentrations were not associated with response to MTX, however, the proportion of glutamate substrates differ between responders and non responders and may be worthy of further investigation.

Effect of Route of Administration On Intracellular Methotrexate Polyglutamate Patterns in Juvenile Idiopathic Arthritis. M. L. Becker[1], R. Gaedigk[1], L. van Haandel[2], A. S. Lasky[1], M. F. Hoeltzel[1], J. E. Neal[1], C. N. Palmer[1], J. F. Stobaugh[2] and J. S. Leeder[1], [1]Children's Mercy Hospitals and Clinics, Kansas City, MO, [2]University of Kansas, Lawrence, KS

Purpose: The effects of methotrexate (MTX) in adults and children are unpredictably variable. The addition of glutamates to intracellular methotrexate ($MTXglu_n$) has been shown to enhance intracellular drug retention and folate pathway enzyme inhibition and may be a promising predictor of drug response. In JIA, the proportions of $MTXglu_{1-7}$ may be more important than absolute concentrations in association with drug response. We evaluated differences in demographics, genotype, and outcomes in 2 subgroups of JIA patients exhibiting specific patterns of MTX polyglutamation.

Methods: After obtaining informed consent, 5 ml of blood was obtained from JIA patients on a stable dose of MTX for 3 months. Demographic characteristics, efficacy and toxicity outcomes were collected by chart review. Genomic DNA was extracted from 200µl of whole blood and amplified in gene specific PCR reactions. An innovative ion-pairing chromatographic procedure with mass spectrometric detection was developed for the detection of $MTXPG_{1-7}$ in patient RBCs.

Results: JIA patients (n=85) from a single center were included in the analysis. Hierarchical clustering of the proportions of $MTXglu_{1-5}$ was performed. $MTXglu_{6-7}$ were excluded due to their relative minimal concentrations. Two distinct clusters were identified: group 1 (n=50) had low proportions of $MTXglu_{1+2}$ and high proportions of $MTXglu_{3-5}$ and group 2 (n=35) had high proportions of $MTXglu_{1+2}$ and low proportions of $MTXglu_{3-5}$. Bi-variable analyses revealed group 1 had a higher mean MTX dose (0.56mg/kg/dose vs. 0.44mg/kg/dose, p=0.02), had higher mean $MTXglu_{TOT}$ (92 nMol/L vs. 66.1, p=0.01) and were more likely to be dosed via the SC route (90% vs 26%, p<0.0001). Notably, of the patients on SC dosing, 83% were in group 1; and of the patients on oral dosing, 84% were in group 2. When all significant variables were entered into a multivariable regression model, only route remained significantly associated with subgroup (p<0.0001, 95% CI -2.22, -0.96). No differences were noted in demographics, outcome or genotype between the groups. Within each group, there were responders and nonresponders defined by the presence of active arthritis. There were no statistically significant differences between responders and nonresponders within groups, except for a higher liklihood of receiving an anti-TNF medication in the patients with active arthritris within group 2 (p=0.01).

Conclusion: Different routes of MTX administration were associated with opposite proportions of intracellular $MTXglu_n$, with higher proportions of long chain MTX polyglutamates ($MTXglu_{3-5}$) seen in patients using the subcutaneous route, and higher proportions of shorter chain polyglutamates ($MTXglu_{1+2}$) seen in patients using the oral route. There are likely additional factors contributing to therapeutic response beyond intracellular $MTXglu_n$ patterns. This observation may be better explained with additional measurements of intracellular folate polyglutamate concentrations and SNP combinations to determine other potential factors which may drive glutamation patterns intracellularly.

High Prevalence of Methotrexate-Related Gastrointestinal Side Effects in Children with Juvenile Idiopathic Arthritis. Maja Bulatovic[1], Marloes Heijstek[1], Marleen Verkaaik[1], Pieter Van Dijkhuizen[1], Wineke Armbrust[2], Esther Hoppenreijs[3], Sylvia Kamphuis[4], Carin Rademaker[1], Toine Egberts[1], Gerben Sinnema[1], Wietse Kuis[1] and Nico Wulffraat[1], [1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]University Medical Centre Groningen, Netherlands, [3]University Medical Centre st. Radboud Nijmegen, Netherlands, [4]Erasmus Medical Centre Rotterdam, Netherlands

Purpose: Methotrexate (MTX) is the most commonly used disease-modifying anti-rheumatic drug in children with juvenile idiopathic arthritis (JIA). A major drawback of MTX is the induction of gastrointestinal side effects in many JIA patients. Gastrointestinal complaints,

termed MTX intolerance, occur upon intake as well as prior to and when thinking of MTX. The latter two aspects are probably the result of a classical conditioning reaction. Intolerance to MTX could lead to refusal and premature discontinuation of an otherwise very efficacious drug. The aim of this study was to determine the prevalence of MTX intolerance in a large cohort of JIA patients.

Method: We performed a cross-sectional study in 283 JIA patients between 4 and 18 years of age from four University Medical Centres in the Netherlands. In order to establish MTX intolerance, all patients filled in a previously validated questionnaire consisting of five domains: abdominal pain, nausea, vomiting, oral pain and behavioural problems. Each domain contained three questions, pertaining to a respective complaint upon intake, prior to (anticipation) and when thinking (association) of MTX. Behavioural problems consisted of restlessness, crying, irritability and refusal of MTX. A patient could score 0 (no complaints), 1 (mild), 2 (moderate) or 3 (severe) points on each question. A patient with a total score of ≥5 with ≥1 point on anticipatory and/or associative complaints or ≥1 point on behavioural problems was considered intolerant to MTX. Analysis was performed with the SPSS statistical package.

Results: We evaluated 283 questionnaires. Hundred and fifty-five patients (54.8%) exhibited MTX intolerance independently of the route of administration. Out of 206 patients on oral MTX, 49.5% experienced intolerance, whereas a significantly higher percentage was intolerant to the drug if on subcutaneous (s.c) MTX, namely 68.8% out of 77 patients (p=0.006). Further analysis of patients intolerant to MTX in each domain separately revealed that significantly more patients showed behavioural problems and had vomiting complaints if on s.c. MTX.

Conclusion: The prevalence of MTX intolerance is high. Although it is present in patients on both oral and s.c. MTX, it is significantly higher in patients on s.c. MTX. This striking finding suggests a strong classical conditioning component in the development of MTX intolerance. Cognitive-behavioural therapy could be effective in reducing MTX intolerance. Currently we are performing a randomised multicentre trial comparing the effect of cognitive-behavioural therapy on MTX intolerance with either a switch to s.c. MTX or continuation of oral MTX.

Predictors of Hip Disease in Systemic Juvenile Idiopathic Arthritis (S-JIA). Michelle Batthish, Pascal N. Tyrrell, Rayfel Schneider and Brian Feldman, The Hospital for Sick Children, Toronto, ON

Purpose: Hip involvement occurs in 20-40% of all JIA cases. Patients with S-JIA are affected most frequently. The aim of this study is to investigate the predictors of clinical hip disease and radiographic hip damage in S-JIA.

Method: The medical records of all children (n = 101) with S-JIA – seen at The Hospital for Sick Children – from 1997 to 2007 were reviewed. 59 patients met the inclusion criteria and were further examined: (1) satisfied the ILAR classification criteria for S-JIA; (2) were first seen within 3 months of symptom onset; and (3) were followed for at least 6 months. Potential clinical and laboratory predictors were examined at presentation, and at 3 and 6 months. Clinical data included: fever, S-JIA rash, hepatomegaly or splenomegaly, lymphadenopathy, and arthritis. Laboratory data comprised: hemoglobin, leukocyte count, platelet count, ESR, serum albumin concentration, and quantitative immunoglobulin concentrations. To account for censored observations, we used survival analysis.

Results: During the study period, 59 children (32 girls) met our inclusion criteria. The mean age at diagnosis was 7.8 years and the mean duration of follow up was 4.3 years. 30 (51%) developed clinical hip disease; with 9 (15%) developing radiographic evidence of hip damage. The median time to develop clinical hip disease was 24 months. Gender and age at diagnosis did not predict time to develop hip disease. At presentation, patients in whom clinical hip disease later developed had large joint involvement (HR=1.22, p=0.0001), elevated IgG (HR=1.12, p=0.01) and IgM (HR=2.71, p=0.02) levels and higher CHAQ scores (HR=1.65, p=0.02). 3 months after disease onset, the 3 factors that were most predictive of hip disease were leukocytosis (HR=1.19, p=0.0009), an elevated IgG (HR=1.14, p=0.04) and the CHAQ score (HR=2.24, p=0.005). At 6 months, large joint involvement was most predictive for hip disease (HR=1.15, p=0.004). Given the small number of patients who developed radiographic evidence of hip damage, no significant predictors were found.

Conclusion: About half of S-JIA patients will develop hip disease within 2 years of diagnosis. Early presentation with large joint involvement, higher inflammatory markers and more marked disability predict an earlier development of hip disease. The early identification of an increased risk of hip disease in patients with S-JIA might suggest earlier, more aggressive interventions to prevent joint destruction.

Distinction of a Psoriatic Subset Within a SoJIA Clinic Population. Brandt P. Groh, Jennifer Lindenmuth, Barbara E. Ostrov, Catherine A. Bingham and Lisabeth V. Scalzi, Hershey Medical Center, Hershey, PA

Purpose: SoJIA is a somewhat heterogeneous disease process in terms of initial presentation and disease course over time. In our clinic population, 12 SoJIA patients have also been diagnosed with psoriatic rash, raising the question as to whether these patients might be more correctly classified as psoriatic arthritis with systemic onset.

Methods: All patients diagnosed with SoJIA onset between July 1991 and May 2009 were included. All patients met the ILAR SoJIA diagnostic criteria. There were 53 patients total: 12 in the "psoriatic" group, and 41 in the "classic" group. Clinical exam findings, lab findings and course details of interest were tabulated for comparison between the two groups. Intergroup differences were tested for significance by nonparametric statistical methods.

Results: Patients in the psoriatic group presented initially in a manner indistinguishable from the classic group. Both groups were comparable in age, sex and race distribution. The only significant differences in the disease course between the groups were the frequent development of enthesitis ($p < 0.0001$) and non-cervical spine axial involvement ($p < 0.0001$) in the psoriatic group. These disease features were not present near onset, and only became apparent later in the disease course of the psoriatic patients. There were no significant differences comparing presence of rash near onset, development of macrophage activation syndrome (MAS), family history of psoriasis in 1st or 2nd degree relatives, duration of the systemic phase, or duration of active arthritis between the two groups. Lab studies throughout indicated a comparable inflammatory response in both groups. Only peak ferritin values were significantly different ($p = 0.0018$), the psoriatic group mean of 5,810 mg/dL (CI 3231, 8389) being higher than the classic group mean of 1,995 mg/dL (CI 1255, 2735). There we no significant differences in ESR, CRP, ASO, ANA, PTT, fibrinogen, platelets, WBC and hemoglobin values at disease onset.

Conclusion: We describe a subset of soJIA patients who developed psoriasis. By clinical course, the psoriatic group was distinct from the other soJIA patients in the development of enthesitis and non-cervical spine axial involvement. Higher mean ferritin values in the psoriatic group did not translate into any increased incidence of MAS, but perhaps a larger population of similar patients would be disproportionately affected by this complication. Based on cytokine profiles and disease course, SoJIA is perhaps best classified as an autoinflammatory disorder. Psoriatic arthritis might also be autoinflammatory in some cases, based on the demonstration of substantial genetic overlap with autoinflammatory disorders (Arthritis & Rheum, 2006;58:2142-6). Although now clinically defined as a unique disorder, SoJIA may prove to be the final common pathway for at least two autoinflammatory disorders.

FSTL-1 Is Elevated in the Serum and Synovial Fluid of Patients with Systemic Juvenile Idiopathic Arthritis. David C. Wilson, Anthony D. Marinov, Yury Chaly and Raphael Hirsch, Childrens Hospital of Pittsburgh, Pittsburgh, PA

Purpose: Follistatin-like protein 1 (FSTL-1) is a secreted glycoprotein that is over-expressed in rheumatoid arthritis (RA) synovium. We have previously demonstrated a pro-inflammatory role for FSTL-1 in arthritis by showing that over-expression of FSTL-1 exacerbated murine collagen-induced arthritis (CIA) while its neutralization suppressed CIA. We also demonstrated that FSTL-1 over-expressed in the joint of mice with CIA and humans with rheumatoid arthritis. The current study was designed to determine whether FSTL-1 might represent a novel biomarker in juvenile idiopathic arthritis (JIA).

Methods: A sandwich type immunoassay was developed for detection of FSTL-1 protein using the Meso Scale Discovery (MSD) assay platform. Sera from patients with oligoarticular (n=27), polyarticular (n=10), and systemic (n=9) JIA were assayed and compared to sera from normal children (n=13). We also assayed FSTL-1 in synovial fluids from patients with oligoarticular (n=41), polyarticular (n=18), and systemic (n=12) JIA. These were assayed and compared to synovial fluid from normal arthritic children (n=4).

Results: The mean FSTL-1 serum titer in systemic JIA patients was increased 20% over that of controls ($p=0.004$ by Student's T-test). Synovial fluids had a mean FSTL-1 serum titer 5-fold higher than that of serum. FSTL-1 synovial fluid titer in polyarticular and systemic JIA was increased 2 fold over that of non-arthritic synovial fluid ($p=0.04$ and $p=0.005$, respectively, by Student's T-test).

Conclusion: The high levels of FSTL-1 in the synovial fluid, compared to the blood, suggests that it plays a role in the local inflammatory response in the joint and may be a novel biomarker of disease severity and course. Studies to address this possibility are currently underway.

Rapid and Sustained Remission of Macrophage Activation Syndrome (MAS) Associated with Systemic-Onset Juvenile Idiopathic Arthritis (SoJIA) by Treatment with Anakinra but without Cyclosporine. Normi Bruck, Juliane Hamel, Meinolf Suttorp, Manfred Gahr and Frank Pessler, Technical University Dresden Children's Hospital, 01307 Dresden, Germany

Purpose: To describe the dramatic response of two patients with MAS associated with SoJIA to treatment with Anakinra and a corticosteroid, but without cyclosporine.

Methods: We established a protocol for the treatment of MAS associated with SoJIA, allowing for a two week trial of Anakinra and a corticosteroid as initial treatment. Inclusion criteria: SoJIA as defined by the International League of Associations for Rheumatology classification of juvenile idiopathic arthritis (1) and MAS as defined by Ravelli et al. (2).

Results: Between September 2008 and March 2009, two patients met entry criteria.

Patient 1 was an 8-year-old Caucasian boy. At initial diagnosis of SoJIA, treatment with prednisolone and indomethacin led to almost complete resolution of clinical symptoms and normalization of laboratory abnormalities. However, during the prednisolone taper he suddenly developed thrombocytopenia and a dramatic rise in liver transaminases, ferritin, and D-dimers, accompanied by a paradoxically mild elevation of ESR and CRP. A bone marrow aspirate (performed after a 3 day methylprednisolone pulse) showed reduced cellularity and dysfunctional maturation in myelopoiesis, but no hemophagocytosis, but the patient nonetheless satisfied criteria for SoJIA-associated MAS (2). Treatment with oral prednisolone (2 mg/kg/day) and Anakinra (2 mg/kg/d s.c.) led to resolution of fevers and restoration of the patient's sense of well being within 3 days. All lab values normalized within 20 days. At 6 months follow-up, the patient remains in complete remission on monotherapy with Anakinra (2 mg/kg/d s.c.).

Patient 2 was a 12-year-old Caucasian girl. SoJIA-associated symptoms and laboratory abnormalities improved initially under treatment with prednisolone and ibuprofen. At the beginning of the prednisolone taper, the patient developed recurrent fevers, hepatosplenomegaly, general lymphadenopathy, pancytopenia with complete agranulocytosis, and highly elevated ferritin, D-dimer, LDH, ASAT, ALAT, and GGT levels. The bone marrow aspirate showed hemophagocytosis and complete absence of granulopoiesis. Treatment with dexamethasone (10 $mg/m^2/d$) led to a decrease in serum ferritin and liver transaminases, but did not affect fever or agranulocytosis. The patient defervesced within 48 h of starting Anakinra (2 mg/kg/d s.c.), and the granulocyte count normalized within 7 days. All other laboratory indices normalized within 14 days despite a dexamethasone taper. 14 weeks later, complete remission has been sustained on Anakinra monotherapy at a stable dose of 2 mg/kg/d.

Conclusion: Early initiation of IL-1 directed therapy may be effective for the treatment of MAS and could reduce the necessity for potentially toxic long-term treatment with corticosteroids, cyclosporine and/or etoposide.

Patterns of Non-Steroidal Anti-Inflammatory Drug Use for Juvenile Idiopathic Arthritis in the Era of Modern Aggressive Treatment. Rabina Kochar[1], Steven J. Spalding[2], Anil Jain[2], Kyle M. Walsh[3] and Philip J. Hashkes[2], [1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Yale University School of Public Health, New Haven, CT

Purpose: To describe trends in NSAID use for JIA and explore factors associated with anti-inflammatory use of NSAIDs by conducting a retrospective cohort study of treatment of patients with JIA.

Method: Through our electronic health record (EHR) system, we identified all individuals seen in pediatric rheumatology from 1/2003 to 6/2008 with a diagnosis of JIA. Subjects were excluded if they did not meet criteria for JIA or were seen only for a second opinion. Of 377 eligible patients, 100 were randomly selected for detailed analysis (EHR measureable characteristics not significantly different than the entire cohort, including medication use). Longitudinal data was extracted through a combination of manual review and automated extraction from the EHR. Background demographics and disease type data were collected, and data for disease activity status (number of active joints, joints with LOM, CHAQ score, pain score, physician assessment, inflammatory labs), medication use (NSAIDs, and other JIA medications) and adverse events were collected for each outpatient encounter. Longitudinal data were analyzed for factors predictive of NSAID use at an anti-inflammatory dose using Nonlinear Mixed Effects Regression analysis accounting for intra-subject correlation.

Results:

	N=100	
	N	**n**
DEMOGRAPHICS		
Sex (Female)	66	--
Ethnicity (Caucasian)	87	--
Oligoarticular	49	--
Systemic	5	--
Polyarticular RF-	25	--
Polyarticular RF+	2	--
Enthesitis-related	6	--
Psoriatic	6	--
Other	7	--
MEDICATIONS	Ever used	Used at last visit
NSAID any dose	90	40
NSAID anti-inflammatory	40	19
Methotrexate	58	42
Other DMARD	14	4
Biologic	17	17
Intra-articular Injection	45	--
Oral Corticosteroids	11	3

56% of patients were in a state of inactive disease and 20% had one active joint at last visit. NSAID use decreased by >50% over the study period. Less than 50% of NSAID users used at an anti-inflammatory dose. Factors associated with anti-inflammatory use included year of visit (OR = 0.605 for each subsequent year since 2003; p = 0.0076), number of joints with active arthritis (OR = 1.26 per joint; p = 0.0047), number of joints with limitation of motion (OR = 1.12 per joint; p = 0.0189), uveitis (OR = 0.013; p = 0.0078), and use of MTX (OR = 0.053; p = 0.023). The number of patients on biologics was not sufficient to analyze their effect on NSAID use.

Conclusion: While NSAIDs were used at some point by nearly all patients, only a minority ever used NSAIDs at an anti-inflammatory dose. This proportion of all types of NSAID use significantly decreased over time. Reduced anti-inflammatory use was associated with decreased disease activity, use of MTX, and treatment of isolated uveitis. The role of NSAIDs in treating JIA has changed markedly since past literature reports from the 1990s.

Performance of the RA Disease Activity Measures and JADAS in Polyarticular-Course Juvenile Idiopathic Arthritis. Sarah Ringold[1], Rachel Bittner[1], Tuhina Neogi[2], Carol A. Wallace[1] and Nora G. Singer[3], [1]Seattle Children's Hospital, Seattle, WA, [2]BUSM, Boston, MA, [3]University Hospitals/Case Medical Center/Rainbow Babies and Children's Hospital, Cleveland, OH

Purpose: To measure the abilities of the continuous measures of disease activity used in rheumatoid arthritis (RA) and the 3 Juvenile Arthritis Disease Activity Scores (JADAS-10, JADAS-27, JADAS-71) to classify the Pediatric ACR measures of response, flare, and inactive disease (ID) in polyarticular-course JIA (poly JIA).

Method: Secondary analysis of a randomized, controlled trial of infliximab in poly JIA (n=97). Disease activity was calculated at baseline and weeks 14, 28, and 52 using the DAS (Disease Activity Score), DAS28, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), and JADAS. Pediatric ACR response, flare, and ID were assessed contemporaneously. The ability of each continuous disease activity measure to classify each pediatric outcome was determined by area under receiver operating characteristic curves (AUC). The AUC of each of the scores for each of the outcomes were compared using empirical estimation methods. Positive predictive values (PPV) for ID were calculated by determining the maximum PPV value for which both the sensitivity and specificity were >= 0.5.

Results: The mean DAS, DAS28, CDAI, and SDAI at study entry were 3.46, 4.41, 27.22, and 29.55, corresponding to moderate (DAS/DAS28) and high (CDAI/SDAI) disease activity. At 52 weeks, mean values for each score corresponded to low/minimal disease activity. The AUCs for each pediatric outcome ranged from 0.73-0.94. The PPV of these scores for ID were 0.56-0.65. The mean JADAS-10, -27, and -71 at study entry were 20.6, 24.3, and 30.5. At 52 weeks, mean values for each score were 8.1, 8.6, and 9.7. The AUCs for each pediatric outcome ranged from 0.75-0.97. The PPV of these scores for ID were 0.83-0.86. The JADAS-10 had statistically significantly higher AUCs for the Pediatric ACR50, 70, and 90 measures than the SDAI, CDAI, JADAS-27, and JADAS-71 (95% CI: 0.01-0.20). The 3 JADAS also had statistically significantly higher AUCs for ID than the SDAI and CDAI (95% CI: 0.01-0.06). The AUC for the JADAS-27 and -71 for flare were statistically significantly higher than those of the DAS28 (95% CI: 0-0.13).

Conclusion: Each of the RA measures and JADAS versions showed good ability to classify participants based on the Pediatric ACR measures, flare, and ID in this specific cohort. There were some statistically significant differences between the scores AUC for the Pediatric ACR measures, flare, and ID, and the clinical significance of each of these comparisons requires additional exploration. Misclassification of active versus inactive disease by the RA scores and JADAS versions was not uncommon. Modification of these scores will be required if they are to be used to detect accurately both change in disease activity and ID.

Pilot Study of the Illness Perception Questionnaire-Revised (IPQ-R) in Children with Juvenile Idiopathic Arthritis (JIA). Alexandra I. Barsdorf[1], Kathleen M. Schiaffino[2], Lisa F. Imundo[3] and Deborah M. Levy[4], [1]Morgan Stanley Children's Hospital of New York-Presbyterian, Columbia University Medical Center, New Yok, NY, [2]Fordham University Graduate School of Arts & Sciences, Bronx, NY, [3]Morgan Stanley Children's Hospital of NY-Presbyterian, New York, NY, [4]Columbia University, New York, NY

Purpose: The way in which a child or adolescent comes to understand and form beliefs about his/her illness is called illness representation. Little research exists on how children and adolescents with a chronic disease, such as juvenile idiopathic arthritis (JIA), cognitively represent their illness. The goal of this pilot was to determine if the Illness Perception Questionnaire –Revised (IPQ-R) could be used to assess illness representations in children and adolescents with JIA who are 10 – 20 years old. The IPQ-R has been adapted for use in several chronic adult diseases, including asthma, chronic pain, diabetes, HIV, hypertension, and rheumatoid arthritis, but has not been tested for use with children or adolescents with JIA.

Methods: The IPQ-R was administered to 15 children recruited from a pediatric rheumatology clinic. The questionnaire was revised by substituting the term “JIA” in place of the term “my illness”. In addition, symptoms specific to JIA were added to the Identity list, and causes specific to JIA were added to the Causal subscale. Feedback was elicited using a semi-structured interview. Children were asked

"Tell me what you think about this questionnaire. Do you think it was easy or hard to answer?" and "What words did you find difficult to understand?"

Results: Internal consistency coefficients greater than .60 were found to be acceptable for IPQ-R subscales and were retained in the questionnaire. Chronbach alphas obtained included .63 for Personal Control, .81 for Timeline Acute/Chronic, .81 for Illness Coherence, .84 for Consequences, and .88 for Emotional Representations. . The domain "Treatment Control", demonstrated and alpha of .56 and .67 when item #19 ("There is very little that can be done to improve my arthritis") was deleted. Timeline Cyclical had an unacceptable reliability of .34. Reliability was not calculated for Causal items because of the small sample size.

Qualitative feedback demonstrated that children had minimal or no difficulty understanding questions on the IPQ-R. Average time to complete the questionnaire was approximately 13 minutes. Younger subjects (aged 10-12 years) required further explanation of the words "permanent, temporary, consequences, depressed, hereditary, germ, virus, financial consequences, immune system, and mental attitude".

Conclusion: The IPQ-R, with minor changes, is easily understood and completed by children and adolescents with JIA, and it can be used to accurately assess perceptions of illness. Results demonstrate that children and adolescents with JIA form illness representations along the same illness dimensions as adults with a chronic disease. Modifications to the IPQ-R for use in this population should include deletion of the Timeline Cyclical domain and item #19.

Feasibility Testing of An Online Self-Management Program for Adolescents with Juvenile Idiopathic Arthritis (JIA): A Pilot Randomized Controlled Trial. Jennifer N. Stinson[1], Patrick J. McGrath[2], Ellen E. Hodnett[3], Brian Feldman[1], Ciaran M. Duffy[4], Adam Huber[2], Lori B. Tucker[5], Ross Hetherington[1], Shirley ML. Tse[1], Lynn R. Spiegel[1], Sarah SC. Campillo[4], Navreet K. Gill[1] and Meghan White[1], [1]The Hospital for Sick Children, Toronto, ON, [2]IWK Health Centre, Halifax, NS, [3]University of Toronto, Toronto, ON, [4]Montreal Children's Hospital, Montreal, QC, [5]BC Childrens Hospital, Vancouver, BC

Purpose: To determine the feasibility of a 12-week internet-based self-management program of disease specific information, self-management strategies and social support with telephone support for youth with JIA and their parents aimed at improving their quality of life.

Method: A single-blinded pilot RCT was conducted to test the feasibility of the "Teens Taking Charge: Managing Arthritis Online" internet intervention across 4 tertiary level centres in Canada. Accrual rates were high ranging from 45% to 68% of eligible subjects at each site. Participants comprised 48 adolescents with JIA ages 12 to 18 years and one of their parents who were randomized to the attention control arm (n=24) or the internet intervention (n=24).

Results: There were no significant differences between groups on age (Mean=14.5 years ± 1.48), gender (86.7 % female), disease severity (Mean = 2.2 ± 2.3 rated on 10 cm VAS), onset subtype, or disease duration (Mean = 6.6 years ± 4.6) at baseline. Attrition rates were 4.2% (n=1, went into remission) and 16.7% (n=2 after randomization and n=2 during Week 1 due to problems accessing website) respectively from the control and intervention groups. 83.3% of participants randomized to experimental group completed all 12 online modules and weekly phone calls with coach in an average of 14.7 weeks (SD=2.08). Control group completed 90% of weekly attention control phone calls. Participants received a mean of 1.4 phone calls to maintain attention control contact and the experimental group received an average of 1.6 phone calls per week. Intervention group participants felt the website content, videos and weekly calls with coaches were very helpful. Two-thirds of participants found the email system helpful; while only half found the discussion board helpful. 94.1% of participants rated the website as easy to use and would recommend the website to other families. Overall participants liked the website finding it "very helpful", "straightforward" and "easy to navigate".

Conclusion: This pilot RCT was the crucial first step in ensuring the feasibility of an internet-based self-management treatment for adolescents with JIA. Findings from this study will be used to lay the ground work for a large scale multi-centered RCT to determine the effectiveness of the online self-management intervention in improving health-related quality of life and symptoms (physical and emotional) in youth with JIA.

Are Children with Juvenile Idiopathic Arthritis and Their Parents Reliable Reporters of Joint Involvement? Giovanni Filocamo, Angela Pistorio, Marta Bertamino, Alessandro Consolaro, Cristina Ferrari, Stefano Lanni, Bianca Lattanzi, Alessandro Parodi, Nicolino Ruperto, Alberto Martini and Angelo Ravelli, Pediatria-II, IRCCS G. Gaslini and University of Genova, Genova, Italy

Background: Quantitative joint counts are key outcome measures in children with juvenile idiopathic arthritis (JIA). However, assessment of the whole joints in all patients is time consuming and may be difficult in a busy clinical setting. Self or proxy-report of joint involvement, may help the physician to obtain information on the severity and distribution of arthritis.

Purpose: To investigate the reliability of self or proxy-report of joint involvement by children with JIA and their parents.

Methods: 220 children with JIA and 465 parents of children with JIA were asked to score the swelling or pain in 9 joints or joint groups. Afterward, a paediatric rheumatologist performed a formal joint assessment. Agreement between physician, parent, and child was assessed with Cohen's kappa.

Results: Table shows the k values for agreement in joint assessment between physicians, parents and children.

Joint	**k MD-parent**	**k MD-child**
Shoulder	0.15	0.15
Elbow	0.51	0.38
Wrist	0.41	0.47
Hand joints	0.52	0.52
Hip	0.28	0.33
Knee	0.54	0.59
Ankle	0.57	0.56
Foot joints	0.56	0.34
Cervical spine	0.35	0.69

Conclusion: Agreement between physicians and children and between physicians and parents was similar. Agreement was in the moderate range for all joints, except for the shoulder and hip, for which concordance was poor. Children agreed with physicians better than their parents in rating involvement of cervical spine. Overall, our results highlight the importance of obtaining children's' and parent's rating of joint disease but do not indicate that children's' and parent's assessment is a good surrogate for physicians' assessment.

The Impact of Time From Symptom Onset to First Pediatric Rheumatology Visit On Quality of Life and Functional Status in Canadian Children with Juvenile Idiopathic Arthritis (JIA). NJ Shiff[1], LB Tucker[1], J. Guzman[1], KG Oen[2], R. SM Yeung[3], CM Duffy[4] and ReACCh-Out Investigators, [1]BC Children's Hospital, Vancouver, BC, [2]University of Manitoba, Winnipeg, MB, [3]Hospital for Sick Children, Toronto, [4]Montreal Children's Hospital, Montreal, QC

Purpose: The impact of time from JIA symptom onset to a child's first pediatric rheumatology (PR) visit on functional status and health related quality of life were explored in a multicentre inception cohort of patients with newly diagnosed JIA, the Research on Arthritis in Canadian Children Emphasizing Outcomes (ReACCH-Out).

Method: ReACCH-Out patients enrolled within 2 weeks of presentation to PR were included if dates of symptom onset, first PR visit, and 6 mo follow up (FU) were recorded. Parents completed the Childhood Health Assessment Questionnaire (CHAQ), and the Juvenile Arthritis Quality of Life Questionnaire (JAQQ) at enrolment and 6 mo FU. The area under the curve (AUC) from onset to 6 month FU was calculated. Independent variables associated with CHAQ and JAQQ over time (identified in multivariable linear regression analyses) and previously identified potential confounders were entered as covariates into 2 final models in which time from symptom onset to first PR visit was the primary independent variable and AUC was the dependent variable.

Results: Eighty-two patients from the current cohort were included. Exploratory analyses, which excluded time to first PR visit, showed that the number of active joints at enrolment and enthesitis had the strongest association with AUC for both CHAQ and JAQQ. Table 1 shows the results for the final regression models with time to first PR as an independent variable and other associated factors as covariates.

Conclusion: Longer time from symptom onset to first PR visit is associated with reduced functional status and health related quality of life in children with JIA as measured by the CHAQ and JAQQ, even after adjusting for other associated factors, including the number of active joints at enrolment and the presence of enthesitis.

	CHAQ (n=82, R^2=0.37)			JAQQ (n=78, R^2=0.43)		
	Coefficient	95% CI	P value	Coefficient	95% CI	P value
Onset to 1st PR*	10.09	(5.26, 14.91)	<0.001	17.72	(9.90, 25.54)	<0.001
Active joints*	8.27	(4.05, 12.49)	<0.001	12.05	(5.42, 18.67)	0.001
History of fever	6.32	(-10.56, 23.20)	0.46	14.11	(-13.04, 41.28)	0.30
History of limp	1.79	(-8.16, 11.74)	0.72	12.58	(-3.16, 28.32)	0.12
Enthesitis	9.77	(-6.32, 25.45)	0.23	19.08	(-3.52, 41.67)	0.10
South Asian	-0.94	(-17.07, 15.18)	0.91	8.43	(-19.00, 35.86)	0.54
Parental University or Postgrad	0.61	(-9.29, 10.51)	0.90	-3.64	(-19.09, 11.82)	0.64

241

Predictors of Poor Growth in Early JIA: Results From the Childhood Arthritis Prospective Study (CAPS). MH Obeysekera[1], S.D. Lal[2], M. Lunt[1], E. Baildam[3], L. Wedderburn[4], A. Chieng[5], J. Gardner-Medwin[6], M. Friswell[7], Helen Foster[8], J. Davidson[6], W. Thomson[9] and K. Hyrich[9], [1]arc Epidemiology Unit, Manchester, United Kingdom, [2]ARC Epidemiology Unit, Manchester, United Kingdom, [3]Royal Liverpool Children's Hospital, Liverpool, United Kingdom, [4]UCL, London, United Kingdom, [5]Royal Manchester Children's Hospital, Manchester, United Kingdom, [6]Royal Hospital for Sick Children, Glasgow, United Kingdom, [7]University of Newcastle, Newcastle, United Kingdom, [8]Newcastle University, Newcastle upon Tyne, United Kingdom, [9]University of Manchester, Manchester, United Kingdom

Purpose: Juvenile Idiopathic Arthritis (JIA) has been associated with poor growth, particularly in children with severe disease, although these data have been based primarily in retrospective studies. The aim of this analysis was to study the height, change in height and factors associated with poor growth in an inception cohort of children with JIA over the first 2 years of disease.

Method: The analysis included children with JIA participating in the CAPS study, which recruits and follows children <16 years with new onset arthritis from five UK tertiary referral centres. Heights at presentation and at 2 years were standardised using normative data from the World Health Organisation and presented as z-scores. Height velocity was calculated using change in height over the first 2 years of follow-up. Factors associated with height at baseline (BL), year 2 (Y2) and growth over the 2 years were modelled using linear regression models. Covariates included age, gender, disease duration, subtype, JIA core outcome variables, and treatment.

Results: 304 children were included (median age 7.9 years (IQR 4.0-11.3) at first presentation, 68% female, 5% systemic, 54% oligoarthritis, 18% rheumatoid factor negative polyarthritis). 89% had normal height (height z-score greater than -2 standard deviations) at BL and at Y2 although median height was slightly below the population mean (median z-score BL -0.30 (IQR -0.92, 0.48), Y2.-0.36 (IQR -1.11, 0.35)); 4% developed new short stature at 2 years. At BL and at Y2, lower height z-scores were strongly associated with younger age (βcoeff 0.065 (95% CI 0.034, 0.096) per year increase) and higher Childhood Health Assessment Questionnaire (CHAQ) scores (βcoeff -0.304 (95% CI -0.499, -0.109) per unit increase CHAQ) at first presentation. There was an inverse relationship between younger age at onset and height velocity ($p< 0.001$). Patients with lower height velocity were also found to have a higher active ($p=0.018$) and limited ($p=0.005$) joint count at the end of the 2 year period. Children who required treatment with methotrexate or biologics were more likely to have short stature, although this effect disappeared after allowing for differences in disease severity.

Conclusion: This study demonstrates that the majority of children presenting with JIA in the modern era have normal height over the first 2 years of disease. However, younger age at onset and higher disease activity were associated with poor growth, even within the first 2 years of disease. Continued follow-up of these children will indicate if modern therapies can maintain height in children with JIA.

242

Balance in Juvenile Idiopathic Arthritis. KM Houghton[1] and M. MacLeod[2], [1]British Columbia Childrens Hos, Vancouver, BC, [2]BC Children's Hospital, Vancouver, BC

Purpose: Clinical observation suggests children with lower extremity arthritis have poor proprioception, demonstrated by difficulty balancing on one leg or single leg hopping. This is corroborated by studies in adults showing decreased proprioception in inflammatory and degenerative arthritis. To date there are no studies looking at balance in children with juvenile idiopathic arthritis (JIA). The objective of this study was to evaluate and describe dynamic postural balance using the Biodex Balance System® (BBS) in a cohort of children with JIA.

Methods: 25 patients (14 boys) with JIA aged 8.7 to 18.2 years (median 13.8) were tested using the BBS. The BBS is a multiaxial tilting platform that allows objective measurement of the ability of a subject to maintain dynamic single and double limb postural stance on an unstable platform. The stabilometric technique allows assessment of overall (OA), anterior/posterior (AP) and medial/lateral (ML) stability. All children had active lower extremity arthritis within one year prior to testing. Data was collected for age, gender, leg dominance, JIA subtype and current medications. Isometric strength of both legs was tested by manual muscle testing (hip abductor, flexor, extensor; knee extensor, flexor; foot dorsiflexor, plantarflexor). Single leg static balance (BBS level 12) and bilateral static and dynamic balance [BBS level 2 (very unstable) and level 7 (moderately unstable)] were measured as AP, ML and OA stability scores. Correlation analyses were performed between stability indices (AP, ML, OA), lower extremity strength, disease activity [articular severity index, ASI], function (Child Health Assessment Questionnaire, CHAQ) and pain (Visual Analog Scale, VAS). Correlation coefficients of 0.3-0.5, 0.5-0.7, and 0.7-1.0 indicated low, moderate, and high correlations, respectively.

Results: Twenty patients had knee arthritis, 15 ankle, 11 foot, and 7 hip arthritis. All but 1 patient had multiple joints involved. Mean ASI on the day of testing was 4.4 (5.7). Mean CHAQ score was 0.13 (0.31) and mean VAS pain 10.2 (17.2). Balance summary measures are shown in Figure 1. Single leg balance was impaired in 12 patients (48%; 1 right leg, 8 left leg, 3 both); 23 patients (92%) were right side dominant. Bilateral static balance (OA) was significantly better than dynamic balance (level 7 $p=0.0251$; level 2 $p=0.0001$). Ankle involvement significantly impaired dynamic balance (level 7 AP $p=.029$; level 2 OA $p=.011$; level 2 AP $p=.0003$). Hip abduction and hip flexion strength had low correlation with single leg balance; hip abduction, hip flexion, knee flexion and ankle plantarflexion strength had

low correlation with bilateral static and dynamic balance. Pain, but not disease activity or function, had a low negative correlation with static balance.

Conclusion: These preliminary results suggest children with leg arthritis and ankle disease in particular, have impaired dynamic balance. As strength and balance are shown here to be positively related, proprioceptive exercises are likely to emerge as an important therapy in the treatment of children with JIA and lower extremity arthritis.

Efficacy of Intra-Articular Steroid Injection Into the Temporomandibular Joint in Children with Juvenile Idiopathic Arthritis.

Rotraud K. Saurenmann[1], Lukas Muller[2], Silke Schroeder[1], Timo Peltomaki[2], Elvira Cannizzaro[1] and Christian Kellenberger[3], [1]University Children's Hospital, Zurich, Switzerland, [2]Orthodontics and pediatric dentistry, University of Zurich, Zurich, Switzerland, [3]Zurich University Children's Hospital, Switzerland

Background: Intra-articular steroid injection is a common treatment modality in juvenile idiopathic arthritis (JIA). Little is known about the optimal technique for the injection of the temporomandibular joint (TMJ) and about the efficacy and side effects of this method.

Purpose: To study the efficacy of TMJ steroid injections on inflammation on magnetic resonance imaging (MRI) in children with JIA.

Methods: 33 consecutive JIA patients with MRI confirmed diagnosis of TMJ arthritis received an intra-articular injection of triamcinolone hexacetonide into 57 affected joints. Immediately after injection the location of the injected medication was controlled by MRI. Follow-up MRI was performed 1-3 months later and the change of inflammatory signs on MRI was compared to the grade of successful intra-articular placement of the medication.

Results: The injection resulted in intra-articular fluid collection in 37/57 joints (65%). The amount of intra-articular fluid was a trace in 13 (23%), small in 8 (14%) and moderate/large in 16 (28%). Improvement of inflammation on follow-up MRI was found in 15% with extra-articular injection and 73% with intra-articular injection. 12/21 joints (57%) with trace/small amount of fluid after injection but 15/16 joints (94%) with moderate/large amount of fluid after injection had improvement of inflammation on follow-up MRI. No significant deterioration of deformity of the condylar head was observed following intra-articular injection.

Conclusion: The efficacy of intra-articular steroid injection into the TMJ is strongly related to the grade of successful intra-articular placement of the medication. We did not observe any negative effects on the condylar head following steroid injection, but the observation period may have been too short.

Delayed Clinical Response in Great Part of Patients with Juvenile Idiopathic Arthritis Initially Not Responding to Etanercept. M.H. Otten[1], F.H.M. Prince[1], M. Twilt[1], M.A.J. van Rossum[2], W. Armbrust[3], E.P.A.H. Hoppenreijs[4], S.S.M. Kamphuis[1], Y. Koopman-Keemink[5], N.M Wulffraat[6], S.L. Gorter[7], R. ten Cate[8] and L.W.A. van Suijlekom-Smit[1], [1]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands, [3]University Medical Center Groningen, Groningen, Netherlands, [4]Radboud University Medical Center, Nijmegen, Netherlands, [5]Juliana Children's Hospital, The Hague, Netherlands, [6]University Medical Center Utrecht, Utrecht, Netherlands, [7]Academic Hospital Maastricht, Maastricht, Netherlands, [8]Leiden University Medical Center, Leiden, Netherlands

Purpose: To evaluate clinical response in Juvenile Idiopathic Arthritis (JIA) patients who initially failed to meet response criteria at 3 months of etanercept therapy.

Methods: This study is embedded in the Arthritis and Biologicals in Children (ABC) project, a prospective ongoing multicentre, observational study of all Dutch JIA patients using etanercept.[1] Response was assessed in all patients using the American College of Rheumatology (ACR) Pediatric 30 criteria at start, 3 and 15 months of therapy.

Results: In total 179 patients in the register had a minimum follow-up of 15 months (70% female, median age onset 5.8 years). Thirty-four patients did not respond after 3 months, of which 21 continued etanercept and 12 (57%) achieved an ACR 30 response thereafter. Overall, 7% of the 179 patients were delayed responders after 3 months of treatment and this was most likely in those with the oligoarticular, arthritis psoriatica and enthesitis related arthritis subtypes.

Conclusion: In JIA patients 57% of non-responders at 3 months who continue etanercept eventually respond. Therefore, we suggest extending the use of etanercept in non-responding patients beyond the commonly recommended 3 months therapy window to achieve higher response rates in JIA patients.

Growth in a UK Cohort of Juvenile Idiopathic Arthritis (JIA) Patients Treated with Etanercept and/or Methotrexate. Taunton R. Southwood[1], Carole Cummins[1], Kate Cotter[1] and British Society of Paediatric and Adolescent Rheumatology[2], [1]University of Birmingham and Birmingham Childrens Hospital, Birmingham, United Kingdom, [2]Liverpool, United Kingdom

Purpose: Since 2004, the British Society for Paediatric and Adolescent Rheumatology (BSPAR) Biologics and New Drug Register has enrolled and monitored JIA patients treated with etanercept and/or methotrexate. Here we report change in height standard deviation scores (SDS) after monitoring for 2 years.

Method: After informed consent, JIA patients treated with etanercept and/or methotrexate were enrolled and disease subtype/activity, growth parameters, co-morbidity, treatment efficacy and safety data were recorded at baseline, 3 and 6 months and annually thereafter. Height and weight SDS, BMI and International Obesity Taskforce cut-offs were calculated from British 1990 growth charts and Excel add-on program LMS Growth 2.64 (H Pan & T Cole). Patients with missing/erroneous measurements were excluded.

Results: 702 JIA patients were enrolled from 29 UK centres (67% female, 13% systemic arthritis). Height SDS for the cohort and treatment groups at baseline (table 1) were left skewed; there was a moderate correlation with disease duration ($r = -0.255$, $p<0.01$). 21% of the cohort were thin (23% of systemic arthritis patients had grade 3 thinness), 18% were overweight or obese.

Table 1 Height SDS at baseline

Treatment group at baseline	n	Age at baseline	Height SDS (mean ± SD)
Etanercept alone	221	11.0 ± 3.5	– 0.74 ± 1.35
Etanercept and Methotrexate	315	11.2 ± 4.37	– 0.86 ± 1.43
Methotrexate alone	166	8.0 ± 4.75	– 0.13 ± 1.38 (P<0.001)

Girls (– 0.83 ± 1.26) had a lower height SDS than boys (– 0.39 ± 1.55) ($p<0.001$). Patients with systemic arthritis were shorter than other forms of JIA (mean SDS -1.42 ± 1.47) and were more likely than others to be treated with both etanercept and methotrexate, $p<0.001$). Height monitoring data at 1 year follow up was available in 338 patients (table 2). The mean difference in height SDSs between baseline and 2 years for all patients with both measurements (n=201) was 0.278 (paired t test $p<0.001$).

Table 2 Change in Height SDS after monitoring for 1 and 2 years

Treatment group at baseline	1 year after baseline (n=338)		2 years after baseline (n=201)	
	n	mean ± SD	n	mean ± SD
Etanercept alone	107	0.54 ± 0.86	68	0.31 ± 0.94
Etanercept and Methotrexate	148	0.45 ± 0.71	96	0.35 ± 0.86
Methotrexate alone	83	0.12 ± 0.79	37	0.02 ± 1.43
		P = 0.001		NS

Conclusion: Children with JIA starting etanercept and/or methotrexate were shorter than expected and significant proportions were either thin or overweight/obese. After two years, there was an improvement in height SDS for the whole cohort. A statistically significant increase in height gain was seen in etanercept and combined etanercept / methotrexate treated patients compared with patients treated with methotrexate alone at one year but not at 2 years, possibly due to lower patient numbers. There is potential for confounding by pubertal

stage and associated growth spurts as final adult height has not yet been measured and children treated with methotrexate alone were younger than those on etanercept.

Risk of Relapse After Discontinuation of Medications in Patients with Polyarticular Course Juvenile Idiopathic Arthritis. Diana Milojevic[1], Megan L. Curran[1] and Beth S. Gottlieb[2], [1]UCSF, San Francisco, CA, [2]Schneider Childrens Hospital, New Hyde Park, NY

Purpose: Two goals of medical treatment in juvenile idiopathic arthritis (JIA) are to achieve remission of the disease and minimize medication toxicity. Discontinuation of medications during disease quiescence decreases cumulative toxicity. It is not known if the type of treatment used to achieve clinical remission on medications (CRM) affects the subsequent duration of inactive disease off medications in polyarticular JIA. In this study, we compare the risk of relapse during inactive disease off medications in polyarticular course JIA patients who achieved CRM with methotrexate versus methotrexate and etanercept.

Methods: This is a retrospective study of 64 JIA patients who achieved CRM and were subsequently taken off all medications. They belonged to one of the following four sub-types of JIA as defined by ILAR criteria: extended oligoarticular, psoriatic, polyarticular rheumatoid factor (RF) negative and polyarticular RF positive. Group 1 consisted of 26 patients treated with methotrexate and followed from 1995 to 2000, prior to the introduction of etanercept into clinical practice. Groups 2 and 3 were patients followed from 2003 to 2008, treated with methotrexate alone (22 patients, group 2) or with methotrexate and etanercept (16 patients, group 3). The Wallace Criteria were used to define CRM. All patients achieved CRM and were taken off all medications after one year of inactive disease. Relapse was defined as persistent arthritis in at least one joint for at least 6 weeks.

Results: Patients treated with the combination of methotrexate and etanercept (group 3) had significantly more active joints ($p < 0.001$) and significantly higher weekly and cumulative methotrexate dosages ($p = 0.02$ and $p = 0.009$, respectively). On average, prior to achieving CRM, patients in group 3 were treated with methotrexate for 23 months and etanercept for 6.2 months, while group 1 patients were treated with methotrexate for 8.7 months and group 2 patients for 16 months. Type of treatment did not significantly affect the risk of relapse in the three groups ($p = 0.56$), although compared to group 1, the risk in group 2 was 4% lower (HR 0.96, 95% CI 0.45, 2.04) and in group 3 was 49% higher (HR 1.49, 95% CI 0.66, 3.35). The risk of relapse did not significantly change after adjusting for age, gender, sub-type of JIA, number of affected joints, weekly and cumulative dosages of methotrexate, time from diagnosis to treatment and duration of methotrexate treatment.

Conclusion: Our results indicate that treatment with methotrexate and etanercept compared to treatment with methotrexate alone does not significantly affect the risk of relapse in patients with polyarticular course JIA who achieved CRM and were off all medications. However, patients treated with methotrexate and etanercept had more severe disease, indicated by more active joints and longer duration of methotrexate treatment prior to achieving remission.

The Peripheral Blood Genes That Account for Predictability of Clinical Response to Tocilizumab (TCZ) Treatment, Corticosteroid Dose Reduction, and Serum IL-6 Normalization at Week 48 On Systemic Onset Juvenile Idiopathic Arthritis (sJIA) Patients. Norihiro Nishimoto[1], Yuichi Kawata[2], Hooi-Ming Lee[3], Chieko Aoki[1], Yasuo Adachi[1], Hidehiko Sugino[3], Tomoyuki Imagawa[4], Masaaki Mori[4], Minako Tomiita[5], Naomi Iwata[6], Takuji Murata[7], Mari Miyoshi[8], Syuji Takei[9], Yukoh Aihara[10], Takahiro Ochi[11] and Shumpei Yokota[4], [1]Wakayama Medical University, Osaka, Japan, [2]Chugai Pharmaceutical Co.,Ltd., Tokyo, Japan, [3]Osaka University, Osaka, Japan, [4]Yokohama City University, Yokohama, Japan, [5]Chiba University, Chiba, Japan, [6]Aichi Children's Health and Medical Center, Daifu, Japan, [7]Osaka Medical College, Takatsuki, Japan, [8]Kobe Children's hospital, Kobe, Japan, [9]Kagoshima University, Kagoshima City, [10]Yokohama City University Medical Center, Yokohama, Japan, [11]Osaka Police Hospital, Osaka, Japan

Purpose: TCZ, an anti-interleukin-6 receptor (IL-6R) antibody, has been demonstrated to improve the signs and symptoms of sJIA. In the phase 3 trial, 86% of the children achieved JIA70 (70% or more improvement of signs and symptoms of JIA) at week 48. Consequently, corticosteroid doses could be reduced to 5mg/day or less in 44% of the patients at week 48. Furthermore, serum IL-6 levels decreased to normal range (<35pg/ml) in 51% of the patients at the same time, suggesting that such patients can extend the treatment interval or discontinue TCZ treatment without acute flare. To identify the genes expressed in peripheral blood that account for predictability of the response to TCZ treatment, capability of corticosteroid dose reduction, and serum IL-6 normalization, at week 48 on sJIA patients.

Method: We have analysed peripheral blood mRNA expression of 29640 genes using DNAchip (AceGene Human 30K; DNA Chip Research Inc., Yokohama, Japan) in patients with sJIA treated with TCZ and selected the genes that could be used to distinguish (1) JIA70 achieved and not-achieved groups, (2) patients who could be reduced prednisolone dose to 5mg/day or less and those who could not be, and (3) attained and unattained groups of serum IL-6 normalisation (< 35pg/ml). Cross validation was performed by leave one out method.

Results: To distinguish JIA70 achievement, corticosteroid reduction, and IL-6 normalisation, 143 genes ($p<0.01$), 40 genes ($p<0.01$), and 86 genes ($p<0.05$) were selected, respectively. Cross validation revealed that the gene sets distinguished the patients with JIA70 response, corticosteroid reduction, and IL-6 normalisation at accuracy of 84, 84, and 72%. Specifically, the gene sets well predicted the corticosteroid dose reduction with sensitivity 79%, specificity 88%, positive predictive value 83%, and negative predictive value 84%. **Conclusion:** Gene expression profile in peripheral blood cells at baseline may be useful to predict the clinical response, corticosteroid dose reduction, and serum IL-6 normalization by TCZ therapy at week 48.

Gene Expression Signatures in Polyarticular Juvenile Idiopathic Arthritis Predict Likelihood of Achieving Inactive Disease within Two Years of Treatment. Rachel Mason[1], Michael Barnes[2], Robert A. Colbert[3], Susan D. Thompson[2], David N. Glass[2] and Thomas A. Griffin[2], [1]Xavier University, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]NIAMS/NIH, Bethesda, MD

Purpose: We tested the ability of recently identified gene expression signatures in polyarticular juvenile idiopathic arthritis (JIA) (Griffin, *et al.*, *Arthritis Rheum*, 2009) to predict disease outcomes within two years of starting treatment with methotrexate and/or anti-tumor necrosis factor (TNF) medications. Signature I (S-I) contains monocyte-associated genes and correlates with more severe arthritis at baseline, while Signature III (S-III) is associated with reduced numbers of circulating T lymphocytes and is linked to milder arthritis at baseline.

Method: S-I and S-III were quantified in peripheral blood mononuclear cells (PBMC) from a cohort of 59 subjects with recent-onset polyarticular JIA prior to treatment with methotrexate and/or anti-TNF medications. Clinical data from this observational study were reviewed at baseline through 24 months to identify subjects achieving inactive disease (ID) and those treated with anti-TNF medications. ID was defined as no joints with active arthritis, erythrocyte sedimentation rate levels within normal limits, and physician's global assessment of disease activity score of zero. Outcomes were compared between subject groups defined by S-I and S-III. Statistically significant differences were determined by chi-square analysis.

Results: Fourteen subjects expressed only S-I, 12 subjects expressed only S-III, 12 subjects expressed both signatures, and 21 subjects expressed neither signature. ID was achieved at comparable rates for subjects with or without S-I (46% vs. 45 %). This contrasts with 58% of S-I subjects being treated with anti-TNF medications compared to only 30% of the other subjects ($p=0.03$). Conversely, ID was achieved by only 33% of S-III subjects compared to 54% of subjects lacking S-III ($p=0.11$), despite comparable rates of treatment with anti-TNF medications (46% vs. 40%). Notably, this difference in rate of achieving ID was quite pronounced when subjects expressing only S-III were compared to all other subjects (17% vs. 53% ($p=0.02$)).

Conclusion: Subjects expressing S-I, who clinically had more severe arthritis at baseline, were treated more often with anti-TNF medications, but achieved a similar rate of ID compared to other subjects. Conversely, subjects expressing S-III were treated with anti-TNF medications at comparable rates, but achieved a lower rate of ID. We speculate that S-III identifies a subset of polyarticular JIA patients with milder arthritis at baseline that is more difficult to control over time, warranting more aggressive early therapy than in current clinical practice. Thus, PBMC gene expression signatures may be useful tools for guiding therapy in polyarticular JIA.

Enhanced Drug Safety Surveillance (EDSS) Pilot Project. Carol A. Wallace[1], Audrey F. Hendrickson[1] and Rachel E. Sobel[2], [1]Seattle Children's Hospital, Seattle, WA, [2]Pfizer, Inc., New York, NY

Purpose: Medication safety is of utmost importance for pediatric rheumatologists (PR), yet there is little to no information available regarding long-term safety in children or the occurrence of rare adverse events for most of the medications used to treat JRA/JIA (Juvenile Rheumatoid Arthritis/Juvenile Idiopathic Arthritis), including nonsteroidal anti-inflammatory drugs. Additionally, there is currently no effective method to monitor potential long-term effects of the many medications used for the treatment of JRA/JIA. The FDA has a voluntary MedWatch reporting system in place (passive surveillance), however only a small proportion of physicians fill out these reports, even though their patients may experience significant events that might be related to medications. A long-term registry of all children with JRA/JIA in North America would foster the collection of this critical information. The objective of this project is to partner with Pfizer, Inc. to implement a pilot process that would facilitate capture of significant safety and medical events in children with JRA/JIA utilizing the CARRA (Childhood Arthritis and Rheumatology Research Alliance) physician network.

Method: The EDSS Pilot Project facilitates significant safety and medical event collection by monthly survey of treating PR for two years. The survey asks if any of their JRA/JIA patients had an SAE (Serious Adverse Event) or IME (Important Medical Event) during the preceding month. When an SAE or IME is identified, the CARRA coordinating center assists the CARRA physician in completing a MedWatch form, which is then submitted to Pfizer, the FDA, and other pharmaceutical companies as appropriate. Collection of the unduplicated number of JRA/JIA patients seen at each site every 6 months for 2 years gives a denominator for the SAE/IME events. If site databases allow, PR also provide denominator information on JRA/JIA by subtype as well as medications prescribed.

Results: As of 4/30/09, there were 73 PR responses to the initial survey from 30 CARRA sites. 68.1% of respondents indicated that they have never filed a MedWatch Report (or filed >5 yrs ago). 74 PR at 27 sites completed follow-up monthly surveys, with 328/439 surveys completed, a 74.7% response rate. Aggregate six-month site data reveals 4,372 patients seen at 19 sites by 57 PR with 56 SAEs/IMEs reported during these six-month time periods, or 2.14 SAE/IMEs per 100 patient-years of observation. Infection was the most common SAE/IME followed by flare of JIA, neurological adverse events, and elevated liver function tests.

Conclusion: More than two-thirds of participating PRs have never previously filed a MedWatch form. The EDSS is a simple and effective tool that is increasing SAE/IME reporting and has generated rates consistent with the Amgen Etanercept/Methotrexate JIA Registry.

Malignancy in Juvenile Idiopathic Arthritis. S. Bernatsky[1], A. Rosenberg[2], Kiem G. Oen[3], Rosalind Ramsey-Goldman[4], Y. St. Pierre[1], E. Turnbull[1] and A. E. Clarke[1], [1]MUHC, Montreal, QC, [2]Royal Univ Hosp, Saskatoon, [3]University of Manitoba, Winnipeg, MB, [4]Northwestern University, Chicago, IL

Purpose: There is considerable interest in the increased risk of malignancy in adult rheumatoid arthritis, particularly for lymphoma and lung cancer. However, to date there have been no assessments specifically in JIA Our objectives thus were to assess the observed malignancy incidence in JIA, and compare this to the expected incidence, based on general population cancer data.

Methods: We examined cancer occurrence within the JIA clinic registries maintained at two North American pediatric rheumatology centers. The subjects in the clinic registries were linked to regional tumor registries to determine the occurrence of cancers over the observational interval, which spanned the calendar years 1974-2006. In-situ cancers were excluded. The person-years of follow-up for each subject were calculated from the date first seen at the rheumatology clinic, and the first of three possible events: death, cancer, or the end of the study interval (December 31, 2006). Pooling the data, we determined the total number of observed cancers occurring over the total person-years of observation. The total number of cancers expected to occur over the observation interval was determined by multiplying the

person-years in the cohort by the geographically matched age, sex, and calendar year-specific cancer rates, and summing over all person-years.

Results: The study sample was comprised of 1,168 patients. The proportion of females in the cohort was 67.3%, and the average age at cohort entry was 8.9 years (SD=5.1). The vast majority of cohort members were Caucasian (80.5%), with the second largest racial/ethnicity group being individuals of First Nations/Inuit origin (16.9%). Subjects were observed for a total of 16,396 patient-years, with an average follow-up of 14.0 years (SD=8.1). Within this observation interval, based on regional age- and sex-appropriate cancer rates, **six** invasive cancers would have been expected, however, **no** invasive cancers occurred in our subjects.

Conclusion: No invasive cancers were demonstrated in this large sample of individuals with JIA, observed for an average of 14 years each. These data suggest that, at least in the initial years following JIA diagnosis, the risk of invasive cancers is not markedly increased. A potential limitation is the small number of specific minorities (e.g. blacks, Asians, Hispanics, etc.). Hence, study of longer-term cancer outcomes, ideally in a multi-center, multi-ethnic cohort, is of further interest.

Antibody against Mutated Citrullinated Vimentin (anti-MCV) as a Serological Marker for Juvenile Idiopathic Arthritis. Priscila Lora[1], Sandra Machado[2] and Ricardo M. Xavier[3], [1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil, [3]Porto Alegre, Brazil

Background: RF, ANA and anti-CCP are some biomarkers that have been used in the diagnostic of JIA. Nevertheless none of them have demonstrated great predictive value for this use. It has been suggested that anti-MCV antibodies are more sensitive than anti-CCP antibodies to diagnose RA and also that it correlates with RA activity (DAS 28).

Purpose: To study the presence of anti-MCV antibodies in a group of patients with AIJ.

Methods: Anti-MCV antibodies were tested in serum from 33 patients with JIA and 7 control individuals without symptoms or signs of rheumatic diseases using an ELISA test (Orgentec, Grm). Anti-CCP antibodies were tested by ELISA test, second generation (DIASTAT, Scotland). The procedures were conducted according to the manufacturer's instructions. All measurements were performed by experienced operators who were blinded to clinical conditions. The study was approved by local ethics committee.

Results: Anti-MCV was observed in 30.3% of JIA patients (10/33), being absent in all controls (specificity= 100%). Besides, none of JIA patients presented anti-CCP antibodies. In clinical aspects, there was no difference in the age of onset ($p = 0.12$) and duration of the disease ($p = 0.37$) between those who were anti-MCV positive or negative. Polyarthritis was the most frequent subtype (39% 13/33) and showed the highest prevalence of anti-MCV (15.5%, 5/33). (table I).

Conclusion: In our cohort of patients with JIA, anti-MCV was highly specific when JIA patients were compared to a small group of controls, and the sensitivity of anti-MCV was superior to anti-CCP, since none of these patients presented anti-CCP antibodies. Further studies with larger sample sizes and including patients with others inflammatory diseases could help to better identify the clinical performance of anti-MCV in JIA.

Table I: JIA patients' demographic data and biomarkers frequency.

JIA subtype	Polyarthrits	Oligoarthritis	Systemic	Psoriatics
	(n=13)	(n =12)	(n = 5)	(n = 3)

What Should Medical Students Know about Pediatric Musculoskeletal (pMSK) Medicine? Sharmila Jandial[1], Jane Stewart[1], Lesley Kay[2] and Helen Foster[1], [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Newcastle Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom

Purpose: Children and adolescents with musculoskeletal (MSK) complaints commonly present to doctors working in primary and secondary care, rather than direct to sub-specialists. Appropriate triage relies on competent clinical skills and knowledge, yet many doctors report low confidence in their pMSK clinical assessment [Jandial 2008]; this may contribute to reported delay in access to care for children with chronic arthritis [Foster 2007]. pMSK medicine is not currently included in most medical schools in the UK [Jandial 2009] and North America [Oswald 2008]. Our aim was to derive consensus based pMSK learning outcomes, including rheumatology and orthopaedics, relevant to the graduating doctor and provide the basis for a pMSK curriculum.

Method: Participants were recruited from national professional bodies, including paediatric rheumatology and orthopaedics, general and sub-specialist paediatrics, family practice, allied health professionals and medical students with UK wide representation. Qualitative and quantitative methods and analysis were used; initially systematic review followed by focus groups and interviews to derive relevant pMSK themes, followed by a modified Delphi process to derive consensus with refinement by group nominal technique. The project had full ethical approval.

Results: The project resulted in 47 pMSK learning outcomes with broad themes of establishing interaction (with child/parent) [n=4], history taking and physical examination including assessment of pain [n=26], initial investigations and management [n=17]. Relevance to the graduating doctor, rather than subspecialist was deemed paramount; the inclusion of "core" presentations [n=8] and "core" conditions [n=14] were added to give context and covered knowledge of normal pMSK developments, "red flags" to suggest life threatening problems, common conditions encountered in family practice, medically significant (albeit less common) conditions, initial investigations and referral pathways to facilitate access to appropriate care. Core presentations included swollen joint(s), arthralgia and polyarthralgia, limping child, fracture, back pain, unexplained fever, loss of limb function and core conditions included juvenile idiopathic arthritis, bone and joint sepsis, Perthes disease, talipes, slipped capital femoral epiphysis, malignancy, scoliosis, common fractures, non-accidental injury, rickets, growing pains and normal variants.

Conclusion: This set of pMSK learning outcomes is relevant to all medical students to be acquired by the time of graduation from medical school and are consensus derived involving the breadth of stakeholders within pMSK medicine. They are useful to establish curricula, produce teaching resources and be incorporated into assessments.

An Evidence and Practice Based Regional Musculoskeletal Examination for School Aged Children – pREMS. Helen Foster[1], Tim Rapley[1], Ben Heaven[1], Lesley Kay[2] and Carl May[1], [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Newcastle Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom

Purpose: Competent examination of the paediatric musculoskeletal (pMSK) system is essential in the process of making a diagnosis in children presenting with MSK complaints. The aim of this project was to develop a regional examination for school-aged children that is evidence based, age appropriate and brings together primary research on clinical technique, systematic review, and expert consensus in a similar format to REMS [Coady 2004].

Method: Video observations of 89 MSK examinations by staff (doctors n=11; therapists n=8) of school-aged children attending outpatient clinics in 7 UK paediatric rheumatology centres, and 14 semi-structured review interviews with clinicians. Qualitative and quantitative analyses revealed descriptions, frequencies and variations in technique for joint regions in various clinical scenarios. Systematic literature review and data from clinical observation were combined to derive a proposed regional MSK examination with feedback from a further group of 37 pMSK experts through a web-based survey. All results were collated and discussed by consensus development groups to derive pREMS (paediatric Regional Examination of the MSK system).

Results: Systematic review revealed little evidence about pMSK examination. Video observation showed variation in examination techniques used between therapists and doctors between orthopaedics and rheumatology, especially at the hip and the knee in the context of mechanical and inflammatory clinical scenarios and with differences from those techniques used in adult REMS. pREMS is based on "look, feel, move" similar to adult REMS but with the addition of a "measure" option (e.g muscle strength) with reference given to age specific range of joint movement. Further manoeuvres were added based on the clinical scenario (such as suspected hypermobility, mechanical knee pain) and including specific tests as appropriate (e.g patella apprehension test). Where there was variation in technique the consensus group proposed a test based on the study results and, where available, the literature. The consensus group decided that pREMS in entirety was aimed at trainees in paediatric rheumatology although some components of pREMS (e.g hip abduction and adduction) are essential for medical students and others were aimed at paediatric orthopaedics (e.g foot and thigh angle).

Conclusion: pREMS is the first evidence and consensus based regional examination for school aged children based on clinical practice, and gives a series of clinical manoeuvres that are relevant to clinical scenarios. A structured approach with guidance on the level of skills required for undergraduate and postgraduate medicine is an important step towards improved pMSK clinical skills relevant to clinical training.

Assessment of Joint Cartilage Thickness by Ultrasound in Healthy Children: Age and Sex-Related Standard Reference Values. Anne Helene Spannow[1], Mogens Pfeiffer-Jensen[2], Niels Trolle Andersen[3], Elisabeth Stenbøg[1] and Troels Herlin[1], [1]Aarhus University Hospital Skejby, Aarhus N, Denmark, [2]Aarhus University Hospital Aarhus Sygehus, Aarhus C, Denmark, [3]Aarhus University, Aarhus C, Denmark

Purpose: Loss of joint cartilage may be an early feature of destructive disease in juvenile idiopathic arthritis (JIA). When using conventional radiography early inflammatory changes are generally not detected and only late changes such as joint space narrowing and bone erosions are visualized. Joint cartilage is easily visualized with high frequency ultrasonography (US) but before US measurements of cartilage thickness is implemented there is a need for age- and sex-related normal standard reference values. The aim of the study was to establish age- and sex-related normal standard reference values for cartilage thickness US measurements in JIA target joints

Methods: In 394 healthy Danish Caucasian children (215 boys/179 girls) we performed a cross-sectional study of bilateral greyscale US cartilage thickness measurements of the knee, ankle, wrist, and 2nd metacarpophalangeal (MCP) and 2nd proximal interphalangeal (PIP) joints making a total of 3940 joints investigated. Ultrasonographic settings: B-mode obtained on a real-time Hitachi EUB-6500 CFM scanner, equipped with a linear 6-13 MHz transducer (d-THI, frequency 14MHz, dynamic range 65), all measurements were obtained blinded and US images and cartilage thickness measurements for each child were stored on DVD. All statistics were performed with the STATA version 10 statistical package.

Results: There was a significant difference in cartilage thickness measurements between sexes, ($p<0.001$ for all joints), boys having thicker cartilage compared to girls. Our results showed a clear decrease in cartilage thickness with increasing age for both sexes. A formula for

calculating cartilage thickness for different ages and sexes in childhood was suggested. Given the estimate of the thickness y_8 for a 8-years old child, the slope β and the standard deviation of the residual sd_{line} an estimate of the thickness y_x for a x-years old child can be calculated by $y_x = y_8 + \beta*(x-8)$ and a 95% PI by $y_8 + \beta*(x-8)$ +/- 1.96 * $sd_{line.}$ No difference between the right and left side of the investigated joints was observed.

Difference in cartilage thickness between boys and girls age 7-16 years		
	Difference boys – girls (mm)	**95% CI**
Knee	0.471	0.383–0.559
Ankle	0.120	0.083–0.157
Wrist	0.257	0.185–0.328
MCP	0.256	0.221–0.291
PIP	0.124	0.098–0.149

Conclusion: We have been able to establish age- and sex-related normal reference intervals for cartilage thickness measurements in the knee, ankle, wrist, and MCP and PIP joints with US for children with the age between 7 – 16 years and established a formula for calculation of hyaline cartilage thickness measurements in all age-groups throughout childhood.

Knee Joint in JIA: A Prospective Study-Ultrasound Is More Sensitive Than Both Clinical Examination and MRI in Detecting Disease Activity. Laura Pascoli[1], Noel Napier[1], Maria Wray[2], Maura McCarron[2], Catherine McAllister[1] and Madeleine E. Rooney[3], [1]Belfast Trust, Belfast, Northern Ireland, [2]Belfast trust, Belfast, Northern Ireland, [3]Queen's University Belfast, Belfast, Northern Ireland

Purpose: Since 2004 we have undertaken a prospective study of children with newly diagnosed JIA with knee involvement. At outset and at regular intervals for 2 years, clinical, ultrasound (US) and MRI scans of the knees were obtained. We noted that, not infrequently, knees deemed clinically normal had appreciable effusions on US. We therefore wished to assess the accuracy of clinical, US and MRI assessments of the knee joints in children with JIA.

Method: Clinical assessments and US images from children who were recruited to our prospective study were obtained on the same day and analysed in a blinded fashion. A subgroup of these children had MRI scans of the knee obtained within 0 to 14 days from clinical and US examinations. Clinical and US assessment of the knee were scored from 0-3, where 0 = normal; 1 = mild; 2 = moderate; 3 = marked. Effusion and SH, were scored according to our modified scoring system created utilizing the assessment of knee involvement in adults[1-3]. The scans were scored independently by a musculoskeletal radiologist (NN): E (0-3), SH (0-3). Ordinal regression analysis to compare clinical, US and MRI assessment was undertaken (SPSS version 15).

Results: One hundred an ninety four clinical assessments and matching US scans were analysed from 40 children over a two year period. Of these 40 had matching MRI scans. To date we have scored the first 19. Of the 194 clinical versus US assessments, 134 had clinically normal knees, however only 62 of these had normal US (46 had mild E on US, 21 moderate, and 5 marked E). Sixty had abnormal clinical examinations, and 59 matched US were abnormal. Thirty-two were deemed to have a mild E clinically, however only 4 US demonstrated mild E (23 moderate E, 4 marked E, and 1 no E). Finally, 11 knees had marked E on examination, and 10 US scans showed marked E (1 scan a mild E). Ordinal regression analysis confirmed that there was 7.7 units of difference between Clinical scores and US score ($p< 0.001$), confirming greater sensitivity with US. With 6 units = 1 point on the scoring system. Thus, US on average scored 1.3 point higher on the scoring system when compared to clinical examination. US and MRI scans were compared for E and SH scores. US gave a higher grading than MRI with 4.1 units of difference ($p<0.001$). Thus, US on average scored 0.7 point higher on the scoring system compared to MRI.

Conclusion: A significant number of knee joint effusions are missed on clinical examination. US was much more sensitive at identifying joint effusions and synovial hypertrophy when compared to clinical assessment and MRI. The finding that US, in this study, was more sensitive than MRI at detecting joint effusions, was may be due to: 1) the time delay between US and MRI; 2) lower sensitivity of MRI as T2 weighted images rather than contrast with gadolinium was used. There was good correlation between US and MRI in detecting pathology.

US of the knee is a simple, cheap, and effective method of detecting joint effusions and synovial hypertrophy in JIA and should be used as an adjunct to clinical examination, especially when joint injections are being considered.

Ultrasound Abnormalities of Enthesitis in Juvenile Idiopathic Arthritis and Correlation with Clinical Examination. Sandrine Jousse-Joulin[1], Sylvain Breton[2], Claire Cangemi[2], Elisabeth Finel[3], Loic De Parscau[3], Alain Saraux[1] and Valerie Devauchelle-Pensec[1], [1]Rheumatology, Brest, France, [2]Radiology, Brest, France, [3]Paediatric, Brest, France

Purpose: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous condition including a subtype with enthesitis. The clinical assessment and quantification of peripheral enthesitis is quite difficult and lack of sensitivity. Ultrasonography is an attractive imaging technique that could permit the detection of enthesitis under clinical investigation. However, US aspect of enthesitis in children with JIA has never been described.

The aim of our study was to describe ultrasonography (US) in B mode with power Doppler abnormalities in peripheral enthesitis in JIA and to compare US findings with clinical examination.

Method: Patients with recent JIA in according to Durban criteria were included. US examination was performed by a rheumatologist experienced in musculoskeletal US (SJJ), and blinded to the diagnosis. Ultrasound in B mode and power Doppler was performed with an HDI 5000 ultrasonography system (IU-22 Philipps) using a 12, 5-MHz linear array. Five peripheral entheseal insertion sites were examined bilaterally: patella (two sites of insertions of the patellar tendons), quadricipital femoral tendon insertion, Achilles tendon and plantar fascia insertions on the calcaneus. Physical examination was performed by an experimented practitioner (VDP) who considered pain, tenderness and swelling. In absence of consensus, US enthesitis (USE) was considered as detection of vascularization at the site of the enthese and graded from 0 to 3.In absence of consensus, particular attention was given to the detection of vascularization at cortical bone insertion of entheses and junction with the cartilage; the thickness of body of tendon, and bursa

Results: Eighteen patients with JIA were included (10 females, median age 12.1 ± 3 years, range 3.6 to 16.9 years). 38.9% (7/18) had arthritis and enthesitis, 16.7% (3/18) had polyarthritis with rheumatoid factors and 33.3% (6/18) had oligoarthritis. 173 entheseal insertion sites were evaluated and 8.1% (14/173) had USE, among them 42.9% (6/14) were not diagnosed by clinical examination. Overall, USE and physical examination were significantly associated ($p<0.0001$) for pain only. However, inter-observer agreement between USE and clinical evaluation was moderate (kappa 0.43). It was also strongly associated with the diagnosis of arthritis/enthesitis ($p< 0.0001$) and the HLA-B27 status ($p= 0.002$). USE were preferentially located at proximal insertion of the patellar tendon.85.7% (12/14) of USE were graded 3. Thickness of the enthesitis was not associated to USE or clinical findings as bursitis. The cartilage vascularization rarely found (4%, 7/173) was not associated with USE or clinical findings and was also found in a cohort of healthy children.

Conclusion: USE was associated with clinical examination, however, enthesitis were frequently undiagnosed by clinical examination. USE can be defined by Doppler vascularization at cortical bone insertion of entheses. Tendon thickness is probably not a good diagnosis criteria for USE and the cartilage vascularization should be a normal aspect.

Proposal for Outcome Measures for Juvenile Idiopathic Arthritis (JIA)–Associated Uveitis From the JIA-Uveitis Outcomes Working Group. Ivan Foeldvari[1], J. Anton[2], J. Deboer[3], C. Edelsten[4], E. Graham[5], K. Kotaniemi[6], F. Mackensen[7], S. Nielsen[8], C. E. Rabinovich[9], A. V. Ramanan[10], K. Minden[11], R. K. Saurenmann[12], Justine A. Smith[13] and A. Heiligenhaus[14], [1]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg, Germany, [2]Childrens Hosp, Barcelona, Spain, [3]Children Hosp, Utrecht, Netherlands, [4]GOS, London, United Kingdom, [5]St T. Hosp, London, United Kingdom, [6]Rheum Found Hosp, Heinola, Finland, [7]Uni. Heidelberg, Heidelberg, Germany, [8]Uni Child Hosp, Copenhagen, Denmark, [9]Duke Univ Med Ctr, Durham, NC, [10]Hosp Childr, Bristol, United Kingdom, [11]DRFG, Berlin, Germany, [12]Uni Child Hosp, Zurich, [13]Oregon Health & Science Univ, Portland, OR, [14]Ophth., Muenster, Germany

Purpose: Uveitis associated with JIA is a leading cause of vision loss in children in the Western world. To date no standardized criteria exist to evaluate the efficacy of treatment approaches. Our multidisciplinary group is focusing on the development of outcome measures.

Aim: To develop outcome measures for JIA-associated uveitis to facilitate the evaluation of the efficacy of a given treatment on the activity and complications of uveitis.

Methods: An expert group of paediatric rheumatologists and ophthalmologists specializing in uveitis was established. Three face-to-face meetings were conducted, using the Delphi process, in order to develop outcome measures.

Results: Proposed JIA-associated uveitis outcome measures

Domain	Item
Grade of flare /visit (SUN grading system)	□ Slit lamp examination □ (optional tool – flare meter)
Grade of uveitis activity (cells)/ visit (adapted from SUN grading system)	□ Slit lamp examination (record number of cells)
Number of visits with active uveitis	□ Records of the treating physician (require at least 4 visits/year)
Duration of activity (at least 3 monthly visits)	□ Slit lamp examination □ (optional tool- flare meter)
Visual acuity (as defined by WHO criteria, adapted for use in children)	□ Snellen visual acuity
Development of a new complication (SUN criteria except blindness)	□ Posterior synechiae – in quadrants – yes/no □ Glaucoma - yes /no □ Ocular hypertension > 24 mmHg) - yes /no □ Cataract (LOCS III criteria) □ Band keratopathy - yes/no □ Macular edema – assessed preferably by OCT – yes /no
Quality of life	□ Global assessment by parents - VAS score □ Global assessment by child – VAS score □ CHAQ □ CHQ □ (Pediatric uveitis specific quality of life instrument – does not yet exist - research tool)

	□ Number of missed school days
Global disease activity	□ assessment by parents - VAS score □ assessment by children – VAS score □ Uveitis activity /severity and overall uveitis related concerns by treating ophthalmologist □ Overall disease activity and uveitis activity assessment by treating paediatric rheumatologist □ CHAQ □ Pediatric ACR
Biomarkers	□ (Disease specific biomarkers – research tool)
Need for surgery	□ Yes /no according to patient's records

Conclusion: In the next step this proposed domains and items will be validated prospectively on consecutive patients, at the time that a change in treatment is made. The aim is to develop validated outcome measures in compliance with the OMERACT procedure.

Determination of Response to Treatment of Anterior Uveitis with Juvenile Idiopathic Arthritis and Isolated Chronic Idiopathic Uveitis. S. Charuvanij[1], J. Guzman[1], C. Lyons[2] and R. Petty[1], [1]Division of Rheumatology, BC Children's Hospital, Vancouver, BC, [2]Department of Ophthalmology, BC Children's Hospital, Vancouver, BC

Purpose: Chronic Idiopathic Uveitis (CIU) and chronic anterior uveitis with Juvenile Idiopathic Arthritis (JIA+U) pose difficult therapeutic challenges. Topical corticosteroids are usual initial therapy. Non-responders are usually treated with oral or subcutaneous methotrexate (MTX). Non-response to the combination of MTX and topical corticosteroids therapy usually prompts addition of an anti -TNF agent, cyclosporine (CyA) or mycophenolate mofetil (MMF). This study evaluates treatment requirements in 71 children with chronic anterior uveitis.

Method: A retrospective chart review of children with JIA+U and CIU seen between January 1999 and June 2009 at British Columbia's Children's Hospital, Vancouver, Canada. Remission of uveitis was defined as ≤ 1 cell in the anterior chamber at the last slit-lamp examination.

Results: Of 71 patients with chronic uveitis 43 had JIA and 28 had isolated CIU. Of those with JIA, 25 had persistent oligoarticular JIA, 10 had extended oligoarticular JIA, 4 had enthesitis-related arthritis, 3 had rheumatoid factor negative polyarticular JIA and 1 had psoriatic arthritis. Mean age at diagnosis of JIA was 4.6 yrs. The mean of diagnosis uveitis in the JIA group was 6 yrs and in the CIU group was 8.7 yrs. Females and Caucasians were predominant in both groups. ANA was present in 21 JIA patients (48.8%) Bilateral uveitis was present in 20 (51%) JIA and 24 (85%) CIU patients. The most common complications were cataract, posterior synechiae and glaucoma. The mean follow up of JIA+U was 5.7 yrs and of CIU 3.9 yrs. All children received topical corticosteroids as initial therapy, which adequately controlled uveitis in 7 patients with JIA (16.2 %) and 8 (28.5%) with CIU. Twenty-one (48.8%) of those with JIA and 15 (53.6%) of those with CIU additionally required oral or subcutaneous MTX. Fourteen patients (9 with JIA and 5 with CIU) received infliximab, (4 – 10 mg/kg every 4 – 8 weeks), leading to remission in 8 patients, but failing to control uveitis in 6 after 38 to 945 days (median 624 days, IQR 178.8 - 795.7) of therapy. Three of these patients received CyA, and 1 received MMF. Age of the time diagnosis of uveitis, sex, ethnicity, JIA, JIA subtype, ANA, RF and HLA-B27 were not associated with the response to treatment.

Conclusion: Control of uveitis with topical corticosteroids was achieved in < 20% of children with JIA and < 30% of those with CIU. A combination of topical corticosteroids and MTX was effective in 48.8% of patients with JIA and 53.6 % of those with CIU. Initial treatment of uveitis with topical corticosteroids and MTX may minimize the toxicity of corticosteroids and should be prospectively evaluated. The failure of infliximab to promptly control disease in 42.8% of MTX-resistant patients, suggests that alternative therapy should be considered.

Disclosure: S. Charuvanij, None; **J. Guzman**, None; **C. Lyons**, None; **R. Petty**, None.

Comparison Between Infliximab and Adalimumab for the Treatment of Refractory Chronic Uveitis in Childhood. Gabriele Simonini[1], Cecilia Bresci[1], Monica Lo Russo[1], Ilaria Pagnini[1], Cinzia De Libero[2], Roberto Caputo[2] and Rolando Cimaz[1], [1]University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy, [2]Ophtalmology Unit, Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy

Purpose: we wanted to compare the efficacy of Infliximab (I) *vs* Adalimubab (A) in the treatment of childhood chronic uveitis during the first year of treatment.

Methods: Eighteen patients (median age 11 yrs, range 5–21) with chronic uveitis were enrolled. Before anti-TNF treatment, children had presented active uveitis despite Metothrexate and/or Cyclosporine A. All were also receiving oral prednisone (1–2 mg/kg/day) for at least 1 month. Nine children (5F 4M; diagnoses: JIA 4 pts, idiopathic uveitis 3, early-onset sarcoidosis 1, Behçet's 1) received I (6 mg/kg), administered at weeks 0, 2, 6, then every 6–8 weeks. Nine children (6F, 3M; JIA 7 pts, idiopathic uveitis 2) received A **(**24 mg/sq.mt., every 2 weeks). Absence or recurrence rate of uveitis up to the last visit, visual acuity pre- and post-biologics, and tapering of oral corticosteroids were recorded.

Results: In the Infliximab group, median follow-up time of treatment was 30 months (range 16–38 months) with a median number of infusions of 22 (range 11–30); in the Adalimumab group, median follow-up was 8 months (range 5-12) with a median number of administrations of 16 (range 9-24). The two groups did not differ as for age, gender, previous cumulative corticosteroid dose, previous treatments duration, active uveitis duration, number of previous flares.

During the first year of treatment after starting anti-TNF therapy, all children achieved a complete remission, on **I** over a median period of 10 weeks (range 6–16 weeks), on **A** over a median period of 8 weeks (range 8-14). Steroid administration was always discontinued during the first months (on **I** range 2–5 mo., on **A** range 3-5, p= NS). Survival Cox-regression analysis, limited to the first year of treatment and at mean of covariates (gender, age at uveitis onset, disease duration, underlying diagnosis, and concomitant medication), did not show statistical significant differences between the two treatment with regard to time to remission, time to steroid discontinuation, and remission duration (Figure).

Conclusion: Even if limited to a small group and in a short-term analysis, this comparative cohort-study suggests that Adalimubab is as efficacious as Infliximab in the treatment of sight-threatening childhood uveitis.

Safety and Efficacy of Anti-TNF Agents in Refractory Uveitis in Juvenile Idiopathic Arthritis: The Italian REGISTRY. Maria Elisabetta Zannin[1], Giorgia Martini[2], Irene Pontikaki[3], Rolando Cimaz[4], Loredana Lepore[5], Claudia Bracaglia[6] and Francesco Zulian[7], [1]University of Padua, Padua, Italy, [2]Dpt of Pediatrics, University of Padua, Padua, Italy, [3]Gaetano Pini Institute, Milan, Italy, [4]University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy, [5]IRCCS Burlo Garofalo, Trieste, Italy, [6]Division of Rheumatology, Rome, Italy, [7]Dpt of Pediatrics, Rheumatology Unit, University of Padua, Padua, Italy

Purpose: Recently, tumour necrosis factor-alpha (TNF-α) blocking agents have been used to treat chronic and refractory uveitis, in adults as well as in children. Since 2007 an national registry, reporting all patients with Juvenile Idiopathic Arthritis (JIA)-related uveitis treated with anti-TNFα agents, have been established in Italy.

We report the results of two-year follow-up on safety and efficacy of anti-TNFα treatment in refractory uveitis, associated to JIA.

Methods: A cohort of children treated with anti-TNFα agents for refractory JIA-related uveitis between January 2007 and December 2008 were followed by a standardized protocol. Uveitis course, ocular complications, type and dosage of anti-TNF agents used, and side effects have been analysed.

Results: Fifty-three patients (45 female, 8 male) have been included in the registry, mean age 10.7 years and mean follow-up 10.4 months. All patients failed previous traditional immunosuppressive treatments (MTX, CyA, MMF). Twenty-eight patients were initially treated with adalimumab (ADM), 25 with infliximab (IFX). Five patients (9,4%) shifted from IFX to ADM due to infusion reactions (3) or inefficacy (2). The mean IFX dosage was 4.9 mg/kg (range 3.0-6.0), the mean ADM dosage was 0.9 mg/kg (range 0.5 -1.3 mg/kg). Side effects have been reported in 8/46 (17.4%) including, during IFX treatment, headache (3), infusion reactions (3), irritability (1), recurrent upper respiratory tract infections (1), and, during ADM treatment, urticarial rash (1), hypertransaminasemia (1) and menomethrorragia (1).

In 28/53 subjects with at least one year F/U, cataract was present at treatment start in 12 subjects (42.9%), vitreitis in 3 (10.7%), cystoid macular edema (CME) in 2 (7.1%) and ocular hypertension in one. After one year of treatment, no new ocular complications appeared and the pre-existing remained stable. All 15 patients with no ocular complications at the treatment start did not develop complications at the end of the one-year F/U.

Conclusion: Anti-TNF agents, IFX and ADM, appear to be effective and safe for the treatment of refractory JIA-related uveitis. The national registry represents an innovative instrument to improve the quality of the clinical research and to address the safety issues for the health regulatory agencies.

Health-Related Quality of Life of Children with Cryopyrin-Associated Periodic Syndromes (CAPS) Before and After IL-1 Blockade.

Roberta Caorsi[1], Giulia Paloni[2], Maria Alessio[3], Francesco Zulian[4], Marco Cattalini[5], Donato Rigante[6], Nicola Ruperto[7], Alberto Martini[1], Loredana Lepore[2] and Marco Gattorno[1], [1]Istituto Giannina Gaslini, Genoa, Italy, [2]IRCCS Burlo Garofalo, Trieste, Italy, [3]Dpt of Pediatrics, Rheumatology Unit, University of Naples Federico II, Naples, Italy, [4]Dpt of Pediatrics, Rheumatology Unit, University of Padua, Padua, Italy, [5]Dept of Pediatrics, Spedali Civili e University of Brescia, Brescia, Italy, [6]Univ Cattolica Sacro Cuore, Rome, Italy, [7]IRCCS Istituto G. Gaslini, Universita' di Genova, Genova, Italy

Purpose: to evaluate the health quality of life in patients affected by cryopyrin-associated syndromes and its change after treatment with IL-1 beta receptor antagonist (Anakinra).

Method: 19 patients (F:M = 10:9, median age 12.4 years, range1.59-32) with a clinical diagnosis of Muckle-Wells syndrome (4 pts) or CINCA/NOMID (15 pts) were enrolled. 70% of them carried mutations of NALP3 gene. Patients were asked to evaluate their quality of life before treatment with Anakinra and at follow-up. The Child Health Questionaire (CHQ-PF 50) was used to access the health related quality of life; the results were compared with the ones obtained from an healty patients control group of 315 healthy children (52.2% female), with a mean (SD) age of 11.2 (3.8) years.

Results: At baseline the patients showed a poorer health-related quality of life than healthy children, with a major impact on physical concepts (PhS, mean 38.2, SD 3.9; controls 54.5, SD 3.1, $p < 0.001$) in respect to psychosocial concepts (PsS, mean 41.2, SD 8.9, controls 51.2 SD 7.4, $p < 0.01$) with a clear difference in the impact of the disease activity on HRQOL between CINCA/NOMID and MWS patients.

14 out of 19 patients were treated with IL-1 blockers (Anakinra) at the minimal dosage able to determine the complete control of the clinical and laboratory features (from 1 to 3.5 mg/kg/day). The mean duration of treatment 37.5 months (range 12-54 months). Independently from treatment duration, all treated patients displayed a significant improvement in all health concepts (PhS mean 52.2, SD 4.5; $p < 0.001$ Wilcoxon Pairs Test; PsS mean 47.8 SD 8.4; $p < 0.01$) at follow-up. Both CINCA and MWS patients showed significantly lower values than healthy controls in most of the CHQ health concepts, particularly those related to physical domains. The most impaired CHQ health concepts were global health (GGH), physical functioning (PF), role/social limitations–emotional/behavioural (REB), bodily pain/discomfort (BP), general health perception (GH) and parental impact emotional (PE).

Conclusion: Patients with CAPS present a severe limitation of health related quality of life. Long term IL-1 blockade produces a significant and persistent improvement not only in the clinical manifestations associated with the disease, but also on the overall quality of life.

Mevalonate Kinase Deficiency: A French Multicenter Retrospective Study. B. Bader-Meunier[1], Benoit Florkin[2], L. Cuisset[3], D. Rabier[2], Mo Rolland[4], B. Neven[2], Anne Marie F. Prieur[5] and P. Quartier[1], [1]Hopital Necker-Enfants Malades, Paris, France, [2]Hôpital Necker, Paris, France, [3]Hôpital Cochin, Paris, France, [4]Hôpital de Lyon, Lyon, France, [5]Hopital Enfants-Malades, Paris

Purpose: To describe the wide spectrum of clinical and genetic manifestations of mevalonate kinase (MK) deficiency (MKD)

Method: A retrospective French study included patients who had clinically suspected MKD confirmed by at least one of the following criteria: i) mutated MVK gene, ii) decreased MK activity in lymphocytes or fibroblast, iii) elevated mevalonic acid in urine. Medical charts were reviewed or questionnaires were filled in by treating physician

Results: 40 patients (23 women and 17 men) belonging to 34 families were included. The median age at the onset of symptoms was 6 months. The median duration of the follow-up was 31 years. First symptoms occurred before age 2 years in 90% of patients Attacks of fever lasted from one to ten days. During the attacks, all the patients presented with at least two of the following features: arthralgia/arthritis (68%), lymphadenopathy (63%), abdominal pain (63%), diarrhea (63%), skin lesions (60%). Digestive symptoms were associated with rectitis and ulcerative colitis (1 patient each), anal ulcer and fistula (1 patient each), abdominal adhesions (3 patients). Less frequently, aphtous ulcers (38%), vomiting (32%), febrile seizures (7%), pericarditis (2%), hepatitis (2%), thrombocytopenia (7 %) and macrophage activation syndrome (7%) occurred. Additionally, 14 patients presented with severe lasting neurological, renal (including two patients with renal angiomyolipoma), pulmonary, ocular and/or endocrine involvements. During attacks, all patients had an increased C-reactive protein (median, 152 mg/L; range, 59-440), and leucocyte count (median, 20.8.109/L; range,7.5-59). Serum immunoglobulin (Ig) D concentration was > 100 IU/L in 20/24 patients, and median serum Ig A values 4 g/L (range, 1.1-20.9**).** Mevalonic aciduria tested during attacks was increased in the 20/20 tested patients. MK activity was decreased in comparison with controls in 33/33 tested patients. V377I mutation was the most prevalent mutation (21/34 families). MKD related-death occurred in two patients from staphylococcal sepsis associated with a macrophage activation syndrome, and from multiorgan failure secondary to the severe inflammatory response syndrome respectively. Non-steroid anti-inflammatory drugs, steroids, statin, colchicine, anti-tumor necrosis factor alpha, anti-interleukin-1 were tested to treat and prevent attacks, with variable success. One patient successfully received allogenic stem cell transplantation.

Conclusion: The present study emphasizes the clinical heterogeneity of MKD and underlines its severity in a subset of patients

ACR Poster Session A

Systemic Lupus Erythematosus Treatment, Demographic and Environmental Effects, and Other Outcomes
Sunday, October 18, 2009, 9:00 AM - 6:00 PM

263

Association of Adiponectin and Soluble Endothelial Protein C Receptor (sEPCR) with Longitudinal Assessments in the Induction Phase of a Randomized Multicenter Trial Comparing Mycophenalate Mofetil and Intravenous Cyclophosphamide. Robert M. Clancy[1], Ellen M. Ginzler[2], MMF/IVC Lupus Nephritis Induction Trial[3] and Mimi Kim[4], [1]NYU School of Medicine, New York, NY, [2]SUNY-Downstate Medical Center, Brooklyn, NY, [3]New York, NY, [4]Albert Einstein Coll Med, Bronx, NY

Purpose: A major barrier to understanding and treating lupus nephritis (LN) is the paucity of sensitive and validated biomarkers. Recent evidence has suggested that two markers found on the endothelium of LN biopsies merit focus. Adiponectin is expressed on the endothelium of all vessels in biopsies from patients with LN but decreased in areas of fibrosis and/or inflammation. Adiponectin knockout mice suggest that adiponectin may be a key regulator of proteinuria. Increased expression of membrane EPCR in LN biopsies predicts a poor response to therapy. Based on these vascular clues, this study leveraged the LN induction trial comparing intravenous cyclophosphamide (IVC) and mycophenolate mofetil (MMF) to evaluate the relationship between clinical response of LN and levels of adiponectin and sEPCR as a proxy for vascular “protective” molecules.

Methods: The endothelial markers, adiponectin, sEPCR, e-selectin, and nitric oxide were measured in 109 plasma from 48 patients enrolled in the LN induction trial. Response was evaluated based on reaching a primary endpoint with a prespecified decrease in urine protein/creatinine ratio and stabilization or improvement in serum creatinine. The span of the induction period was 24 weeks. Sample collection included visits 4 (4wks), 7 (15 wks) and 9 (24 wks).

Results: There was a consistent trend toward increased levels of plasma adiponectin in responders vs nonresponders (19.2 ± 6.8 vs 16.4 ± 9.1 at visit 4; 13.0 ± 5.2 vs 11.7 ± 6.5 at visit 7; 13.7 ± 7.8 vs 10.9 ± 4.9 at visit 9). In patients with subnephrotic proteinuria (<3g/day urine protein; 63% of the total), plasma adiponectin was similarly increased in responders vs nonresponders at all visits. Moreover, when combining data across all visits nonreponders had significantly lower adiponectin (p=0.0032). There was a tendency of sEPCR to decrease in responders vs nonresponders (243 ± 164 vs 284 ± 167 at visit 4; 338± 271 vs 341 ± 197 at visit 7; 260 ± 104 vs 368 ± 216 at visit 9). In comparing MMF vs IVC, sEPCR, levels were significantly higher in the IVC group when data was combined over all visits (p=0.005). Consistent with evidence that therapy in the responder arm mobilizes vascular protective molecules, levels of nitric oxide changed in the predicted direction (62 ± 47 vs 68 ± 66 at visit 4; 39 ± 46 vs 52 ± 65 at visit 7; 27 ± 33 vs 92 ± 55 at visit 9; p=0.02). Combining data across all visits, nonresponders had significantly higher NO levels than responders (p=0.046). The differences in plasma NO were not accounted for by clearance as fractional excretion of NO did not differ between responders and nonresponders. Levels of sE selectin did not track with response.

Conclusion: These results demonstrate longitudinal associations between increased adiponectin and decreased sEPCR levels as a combined biomarker of renal response. Accordingly, vascular protection tracks with favorable outcomes.

Mycophenolate Mofetil (MMF) Is Effective for Systemic Lupus (SLE) Arthritis, Final Results of An Organ-Specific, Double-Blind, Placebo-Controlled Trial. Joan T. Merrill[1], Molina Mhatre[2], Fredonna Carthen[3], Sandra K. Wilson[4], Stan Kamp[2], Joy G. Hutcheson[1], Joseph Rawdon[2], Eric Finley[2], Ewa Olech[2], Robert M. Clancy[5] and Jill Buyon[5], [1]OMRF, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma City, OK, [4]OK Med Resch Foundation, Oklahoma City, OK, [5]NYU School of Medicine, New York, NY

Purpose: Design of clinical trials for SLE is challenging, possibly due to the clinical and biologic heterogeneity of the disease, compounded by variable background treatments. This focused, proof of concept study of MMF combined an arthritis-specific primary outcome with simplification of background medications and a biomarker-linked responder analysis. We previously reported 3 month results (ACR 2008), and now submit final, six month data after crossover of placebo patients to MMF.

Methods: MMF or placebo (PBO) was dispensed in ascending dose with clinic visits and blood draws at 2, 4, 8, 12, 16, 20 and 24 weeks. 160 mg Depomedrol was given at baseline. Prednisone </= 10 mg/d and hydroxychloroquine were continued, but background immune suppressants were withdrawn.

Results: There was no difference in PBO (n=14) vs MMF (n=13) groups at baseline in age, gender, ethnicity, or # ACR criteria. Mean BILAG scores were 9.5 vs 9.0 at entry, with no difference in swollen or tender joint counts (jts). The pre-specified primary outcome (complete response: BILAG “C” arthritis at wk 12 with </= 25% baseline jts) was met in 0/14 placebo pts vs 4/13 MMF-treated, p=0.041. Major response (MR): BILAG C with </= 50% baseline jts, was met in 0 PBO vs 5 MMF, p=0.016. 4 PBO vs 9 MMF, p=NS, met partial response (PR) at 12 weeks (A to B or B to C in BILAG arthritis or </= 50% baseline jts). MMF, but not PBO, improved composite BILAG scores from mean 9.6 to 5.3 in 12 weeks (p=0.007) From week 12-24 all pts received MMF. 11 PBO-MMF pts completed 8-12 weeks of MMF with 3 MR and 5 PR (p=0.07 for MR and MR+PR vs PBO period). Combining all pts with at least 8 wks MMF, there were 9/24 MR (p=0.014 vs PBO), 19/24 MR+PR (p<0.001) and improved BILAG from median 9 to 2 (Day 0 vs wk 24 scores, p<0.001). Adverse events were minor, primarily URI or GI. Exploratory studies aimed to distinguish the baseline biology or MMR effects on responders vs non-responders. MMF decreased neutrophil CR3 at week 12 vs placebo (p =0.031) and dramatically decreased CR3 of those pts high at entry (>1,000 MFU). These pts had greater decrease in BILAG (p=0.063) and SLEDAI (p=0.015) vs pts with low baseline CR3 (<300 MFU). Other results included:

Baseline Marker	MR n=9	NR n=5	p value
GMCSF pg/ml	4.000	33.22	0.016
IL10 pg/ml	1.89	3.313	ns
IL4 pg/ml	0.132	1.652	0.032
IL1RA pg/ml	71.335	263.59	0.046
IP10 pg/ml	28.7	69.1	ns
Marker after Rx	MR	NR	p value
GMCSF pg/ml	2.584	41.611	0.016
IL10 pg/ml	1.37	2.84	0.045
IL2 pg/ml	0	1.546	ns
IL1RA pg/ml	127.99	223.95	ns
IP10 pg/ml	50.3	68.4	ns
Adiponectin ug/ml	19.8	27.6	ns
NO	11.0	15.9	ns
sE Selectin ng/ml	25.24	35.76	ns

Conclusion: MMF is effective in the treatment of arthritis in patients with SLE. A potential benefit on the vasculature and the possibility that vascular markers could predict or guide optimal treatment is also suggested.

Long-Term Outcomes-Mycophenolate Mofetil Treatment for Lupus Nephritis with Addition of Tacrolimus for Resistant Cases. J. Cortés-Hernández[1], M. Torres-Salido[1], A. Segarra-Medrano[2], M. Vilardell-Tarres[1] and Josep Ordi-Ros[3], [1]Systemic Autoimmune disease Research Unit. Hospital Vall d'Hebron., Barcelona, Spain, [2]Vall d'Hebron Hospital, Barcelona, Spain, [3]Hospital Vall d'Hebron, Barcelona, Spain

Purpose: Although mycophenolate mofetil (MMF) is increasingly used to manage lupus nephritis (LN), little is known about its long-term benefits and the role of anti-calcineurin agents for MMF-resistant nephritis. The aim is to report our long-term experience with MMF therapy as continuous induction-maintenance treatment in a cohort of 70 patients with LN followed during 5 years. We also report the efficacy of adding tacrolimus as a rescue therapy for resistant cases

Method: Seventy patients with LN were included (84% with type III/IV GMN and 40% with relapsing disease) and followed up to a mean of 60±23 months. Patients received 3 pulses methylprednisolone and MMF (2g/d) for induction and tapering doses of MMF for maintenance therapy. Tacrolimus (0.075 mg/kg/day into divided doses) was added for resistant cases. Primary end-point was the achivement of complete remission (presence of an inactive sediment, proteinuria <0.3 g/day and estable renal function) at 6, 24 and 60 months. Secondary end-points included partial remission, treatment failure, relapse and side effects.

Results: Forty-eight patients (69%) already met criteria for an early response at 12 weeks. See Table 1 for treatment outcomes. Long-term complete response was higher in patients with newly diagnosed glomerulonephritis than those with relapsed nephritis (64% vs. 32%, p=0.014). Renal function was permanently impaired at last follow-up in fourteen patients (20%), six of them had their creatinine level

doubled (9%) and two of them reached ESRD. Time to treatment failure was associated with persistent hypoalbuminemia and higher proteinuria (HR=0.87; 95%CI 0.81-0.95, p=0.001, and HR=1.29; 95%CI 1.03-1.62, p=0,030, respectively) and fewer early responses (HR 0.28, 95%CI 0.10-0.77, p=0.014). Twenty-six (37%) patients suffered a renal relapse. Time to flare was associated to persistent anti-dsDNA titres and younger age at renal flare (HR=1.001; 95%CI 1.001-1.003, p=0.005, and HR=0.36; 95%CI 0.14-0.90, p=0.29, respectively). Tacrolimus was added to MMF in seventeen (24%) patients. After a mean follow-up period of 23±3 months, twelve (70%) patients achieved response (6 CR and 6 PR). Proteinuria levels were significantly reduced by 3 months (p=0.0018). GI side effects (23%) were the most common reported. Three patients developed herpes Zoster and one developed pulmonary tuberculosis in the tacrolimus-combined therapy.

Table 1.

	6m	24m	60m
	N % (95%CI)	N % (95%CI)	N % (95%CI)
Response to therapy	13 19% (0-30%)	32 46% (34-58%)	36 51% (39-64%)
Complete response	48 69% (56-79%)	19 27% (17-39%)	12 17% (9-28%)
Partial Response	61 87% (77-94%)9 13% (6-23%)	51 73% (61-83%) 19 27% (17-39%)	48 69% (56-79%)
CombinedResponse Treatment Failure			22 31% (21-44%)
Relapse	6 (9)%	17 (24%)	26 (37%)
Initiation of Tacrolimus	5 (7)%	13 (19%)	17 (24%)
Death	0	0	1

Conclusion: MMF is an effective treatment for induction-maintenance of remission for LN. Combination therapy with tacrolimus is an effective and safe alternative for MMF-resistant patients.

Clinical Audit of the Therapeutic Efficacy of Mycophenolate Mofetil for the Treatment of Systemic Lupus Erythematosus (SLE).

Richard A. Hickman[1], B.H. Chaudhry[1], C.-S. Yee[1], S. Ghazali[1], V. Toescu[1], C.J. Day[2], C. Osafo[2], D. Adu[2] and C. Gordon[1], [1]University of Birmingham, Birmingham, United Kingdom, [2]University Hospital Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Purpose: Mycophenolate mofetil (MMF) is a novel, steroid-sparing agent that can induce remission in lupus nephritis but is not licensed for use in SLE and there have been no clinical trials in non-renal SLE. We performed an audit to determine whether 70% or more patients who were prescribed MMF, achieved improvement in their disease activity within one year of starting MMF and what proportion of patients had a reduction in their daily steroid dose.

Method: SLE patients attending specialised SLE clinics who were prescribed MMF for ≥ 1 year were studied (n=70). Five patients were not analysed because they were being managed by another centre or MMF was stopped because of increased disease activity before the target dose was achieved. There were 29 (45%) patients of Caucasian origin, 21 (32%) Afro-Caribbeans, 12 (18%) South Asians, 1 (2%) Chinese and 2 (3%) were of other origin. The mean ± sd age at diagnosis of SLE was 31 ± 12.5 years. The mean ± sd age for starting MMF was 31 ± 13.7 years. Disease activity on the date that MMF started and one year later was assessed by the BILAG index score (BIS). A standard was set such that 70% of patients should i) reduce their BIS by >1 category (eg. A to B, B to C etc.), ii) reduce their steroid dose to ≤10 mg, and iii) improve disease activity markers as determined by complement 3 (C3) and complement 4 (C4) levels.

Results: Of 49 (75%) patients that could improve their non-renal BIS (as they had BILAG A or B scores at baseline), 84% (n=41) demonstrated overall improvement in their non-renal BIS. Of 25 (38%) patients that could improve their renal BIS (n=25), 19 (76%) showed improvement in their renal BIS. 72% of patients (n=47) reduced their prednisolone dose. Overall, there was a non-significant reduction (p=0.24) in mean + steroid dose after one year of MMF therapy (mean steroid dose at baseline 20 ± 12.3 mg; mean steroid dose one year

later = 13.1 ± 6.0 mg). Of patients with prednisolone doses >10mg/day at MMF start (n=50), 19 (38%) had a reduction of their steroid dose by ≥10mg/day, whilst another 25 (50%) had a reduction of <10 mg/day; 24 (48%) of these patients with prednisolone doses >10mg/day had a steroid dose after one year of ≤10 mg/day. C3 and C4 significantly improved in those patients who initially had low values for C3 (n= 18) and for C4 (n=22): mean ± sd C3 at start= 0.58 ± 0.13 g/l, mean ± sd C3 after 1 year= 0.76 ± 0.26 g/l, p=0.03; mean ± sd C4 at start= 0.08 ± 0.024 g/l, mean ± sd C4 after 1 year= 0.14 ± 0.098 g/l, p=0.007. C3 values were normalized in 11 of 18 (61%) patients; C4 values were normalized in 8 of 22 (36%) patients.

Conclusion: MMF in conjunction with prednisolone appears beneficial in reducing disease activity in renal and non-renal disease in SLE. A randomised controlled trial assessing non-renal efficacy of MMF is needed.

267

Tolerability and Efficacy of Mycophenolate Mofetil in An Ethnically Diverse, University Based Cohort. Samantha Bell and Maria Dall'Era, UCSF, San Francisco, CA

Purpose: Mycophenolate Mofetil (MMF), an inhibitor of de novo purine biosynthesis, is increasingly used to treat a variety of manifestations of systemic lupus erythematosus (SLE). Data from several controlled clinical trials in lupus nephritis and from small case series in non-renal SLE have suggested that MMF is efficacious and well tolerated. Our aim was to assess the tolerability and efficacy of MMF in an unselected, "real world" cohort of ethnically diverse SLE patients who were prescribed MMF for renal and non-renal indications.

Methods: We retrospectively studied 100 SLE patients treated with MMF while being followed in the UCSF Lupus Clinic from October 1997 to June 2008. The mean disease duration for all patients was 11.18 years. All patients were included in the tolerability analysis. The efficacy analysis included those 28 patients (15 with lupus nephritis, 13 with non-renal lupus) who initiated MMF while in the UCSF Lupus Clinic and who were on MMF for at least two months. As part of the efficacy analysis, patients were further designated as switchers or controls. Switchers were patients who switched from another immunosuppressive agent to MMF, and controls were patients who started MMF as their first immunosuppressive agent. Efficacy was assessed by changes in prednisone dose, SLEDAI, complement C3, and anti-dsDNA. In renal patients, serum creatinine, proteinuria, and hematuria were also measured.

Results: 100 patients were included in the tolerability analysis: 16% African American, 28% Caucasian, 33% Asian/Pacific Islander, 16% Hispanic. 28 patients were included in the efficacy analysis. Indication for treatment with MMF varied: 74 patients for nephritis, 8 patients arthritis, 9 patients skin disease, 8 patients hematological, 1 hearing loss, 4 serositis, 2 vasculitis, 1 transverse myelitis, and 3 neuropathy. In the overall population, MMF was well tolerated. Kaplan-Meier analysis indicated 60% of patients continued MMF for > 4 years (75% of lupus nephritis patients, 25% non-renal patients). Fourteen patients discontinued MMF due to an adverse event: epigastric discomfort/nausea in 6 patients, diarrhea in 3 patients, herpes zoster in 1 patient, pruritis in 2 patients, serositis in 1 patient, and self-discontinuation in 1 patient. No patient discontinued MMF because of leukopenia.

In both lupus nephritis and non-renal lupus patients, we found a statistically significant reduction in prednisone dose and SLEDAI over the course of follow-up. Within the lupus nephritis group, we observed that serum creatinine, protein to creatinine ratio, anti-dsDNA, and urine red blood cells increased in the switcher group but decreased in the control group.

Conclusion: Our study demonstrates that MMF is well tolerated in a "real world" SLE population. Discontinuation due to an adverse event occurred in only 15% of patients treated with MMF, most commonly due to epigastric discomfort or diarrhea. Our data also suggest that MMF is efficacious for the treatment of lupus nephritis and non-renal lupus.

Mycophenolate Mofetil Dosing and Renal Relapse or Renal Endpoint in Lupus Nephritis. Mary Katherine Farmer-Boatwright, Keisha L. Gibson, Susan L. Hogan, Yichun Hu, Caroline E. Jennette and Mary Anne Dooley, Univ of NC at Chapel Hill, Chapel Hill, NC

Purpose: To examine the relationship between mycophenolate mofetil (MMF) dosing and renal endpoints in a SE US renal-biopsy based cohort. Endpoints included renal relapse, sustained doubling of creatinine, end-stage renal disease (ESRD) and death.

Methods: We performed a retrospective chart review of consented patients with proliferative or membranous nephritis from this registry. Data were examined using descriptive statistics and Wilcoxon two-sample test.

Results: Sixty-two subjects with a median age of 28.5 years (range 8.4-60.7) were included. Baseline estimated GFR (eGFR) and eGFR at last follow up were similar (84.3+/- 40.4 cc/min; 83.7 (+/- 47.9) cc/min). Median follow up was 36 months (range 6-114 months). The median maximum daily dose of MMF was 2000 mg (range 750-3000 mg). Seven patients (11%) reached a renal endpoint. They had an average daily maximum dose of 1607 mg MMF (+/- 453 mg), compared to those with no renal endpoint (2273 +/- 632 mg [$p = 0.013$]). We characterized 33 relapses in 25 patients at an average of 20.3 months (+/- 10.9) into treatment. The average maximum daily dose of MMF among relapsers was 2096 mg (+/- 637 mg) compared to 2400 mg (+/- 548 mg) in non-relapsers ($p = 0.069$). The average MMF dose at the time of first relapse was 1481 mg (+/- 790 mg), versus non-relapsers at 2400 mg (+/- 548 mg; $p<0.0001$). Two deaths occurred, both in patients who were non-relapsers: one due to CNS lymphoma, and the other to non-accidental trauma.

Conclusion: Our results suggest that lower doses of MMF are associated with renal relapse, doubling of serum creatinine, ESRD or death. Further studies are necessary to define the interaction between patient factors and dosing.

Systematic Review and Meta-Analysis of Randomized Trials of Mycophenolic Acid/ Mycophenolate Mofetil for Induction Treatment of Lupus Nephritis. Zahi Touma, M.B. Urowitz and Dafna Gladman, University of Toronto, Toronto Western Hospital, Toronto, ON

Background: Mycophenolic Acid (MPA, Myfortic) and Mycophenolate Mofetil (MMF, Cellcept) have emerged as a treatment modality for induction treatment of Lupus nephritis (LN) while the use of Cyclophosphamide has been accepted as the standard of care for many years.

Purpose: We conducted a systematic review and meta-analysis to assess the effectiveness and safety of MMF and MPA in the induction treatment of LN.

Methods: We searched MEDLINE, EMBASE, and the Cochrane Library for relevant articles without language restriction up to June 25, 2009. We also searched the bibliographies of selected articles. The primary outcome was renal remission (complete, partial and overall); secondary outcomes were adverse events (infections, leucopenia, gastrointestinal symptoms, herpes zoster, amenorrhea and alopecia) at end of original study, death and end stage renal disease (ESRD) using reported extended follow-up data. For binary outcome variables (renal remission and adverse events), we calculated the relative risks (RRs), as well as respective 95% confidence intervals (CIs).The Mantel-Haenszel fixed-effects model was used to determine the pooled RR along with its 95% CI for renal remission and adverse events for MMF versus Cyclophosphamide using data from all eligible randomized clinical trials (RCTs). We assessed statistical heterogeneity among RCTs using Cochran Q test and by calculating I2 values. We incorporated the random-effects model to deal with heterogeneity among studies. The Cochrane collaboration's software program, RevMan 5 was used to prepare and complete this review.

Results: The literature search resulted in 1551 citations. Abstracts of potentially relevant citations were reviewed. 76 citations were retrieved for detailed evaluation. We included RCTs comparing MMF/MPA versus Cyclophosphamide for induction therapy in patients with biopsy-proven LN with no restriction to age. We identified 4 RCTs with 618 patients for inclusions in the meta-analysis comparing MMF versus Cyclophosphamide. In 4 RCTs MMF (maximum dose used ranged from 2 to 3 g/d given for 6 months) was compared to intravenous Cyclophosphamide (according to the National Institutes of Health protocol 0.75-1g/m2 monthly for 6 months but in one study where it was administered orally as 2.5mg/day for 6 months). In all 4 RCTs patients were treated simultaneously with prednisone at 1mg/kg and tapered thereafter. We observed no significant difference for renal remission (partial, complete, and overall) comparing MMF with Cyclophosphamide. There was no significant difference for infections, leucopenia, gastrointestinal symptoms, herpes zoster and amenorrhea. There was a significant reduction in alopecia (relative risk [RR] 0.27, 95% CI 0.17-0.43) when MMF was compared with Cyclophosphamide.

The analysis of the extended follow-up data showed no significant reduction in ESRD and death when MMF was compared to Cyclophosphamide.

Conclusion: There was no significant difference for the induction treatment of LN when comparing MMF to Cyclophosphamide. Patients treated with MMF showed reduced risk for alopecia.

Identification of Factors Influencing Mycophenolic Acid Area Under the Curve in Systemic Lupus Erythematosus. Laurent Arnaud[1], Noël Zahr[2], Julien Haroche[1], Jean-Sébastien Hulot[2], Pierre Marquet[3], Christian Funck-Brentano[2], Jean-Charles Piette[1] and Zahir Amoura[1], [1]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [2]Department of Pharmacology, Pitié-Salpêtrière Hospital, Paris, France, [3]INSERM U850, Limoges, France

Purpose: Mycophenolate Mofetil (MMF) is widely used for the treatment of Systemic Lupus Erythematosus (SLE). Mycophenolic Acid (MPA) is the active metabolite of MMF. We have shown that MPA Area Under the plasma Concentration-time Curve from 0 to 12 hours (MPA $AUC_{0\text{-}12}$) > 35µg.ml/h is strongly associated with lower SLE disease activity. In this study, we sought to identify factors significantly influencing MPA $AUC_{0\text{-}12}$.

Method: MPA $AUC_{0\text{-}12}$ was determined in 71 consecutive SLE patients (61 women and 10 men, mean (± SD) age at sampling 34 ± 10 years) with stable MMF dose, using a Bayesian estimator developed for SLE. We performed a multiple linear regression built by the *Least Squares method* to identify factors significantly influencing the MPA $AUC_{0\text{-}12}$.

Results: Multivariate analysis including the following parameters: sex, age at sampling, ethnicity, Body Mass Index, daily doses of MMF, daily doses of steroids, hydroxychloroquine blood levels, creatinine clearance (MDRD), and albumin plasma level revealed that daily doses of MMF (p=0.03), albumin plasma level (p=0.04), and MDRD creatinine clearance (p=0.03) were the only 3 independent parameters associated with MPA $AUC_{0\text{-}12}$.

Conclusion: Not only daily doses of MMF but also albumin plasma level and MDRD creatinine clearance are significant parameters influencing MPA $AUC_{0\text{-}12}$. These findings argues strongly for individualized dosing regimen of MMF. Lupus nephritis patients with low albumin plasma level should receive a higher daily dose of MMF to ensure proper exposure to MMF.

Effect of Rituximab (RTX) On Anti-dsDNA and C3 Levels and Relationship to Response: Results From the LUNAR Trial. R. Furie[1], B. Rovin[2], G. Appel[3], D.L. Kamen[4], F.C. Fervenza[5], A. Spindler[6], R. Maciuca[7] and J. Garg[7], [1]NSLIJHS, Lake Success, NM, [2]Ohio State University Medical Center, Columbus, OH, [3]Columbia, New York, NY, [4]MUSC PO Box 250637, Charleston, SC, [5]Mayo Clinic, Rochester, MN, [6]Universidad Nacional Tucumán, Tucuman, Argentina, [7]Genentech, Inc., South San Francisco, CA

Purpose: Previous studies have suggested that improvements in anti-dsDNA titers and complement C3 levels are associated with remissions in lupus nephritis (LN). Changes in these serologic markers and relationship to renal response were assessed in the LUNAR trial.

Method: Pts with a diagnosis of active class III/IV LN and urine protein to creatinine ratio > 1 were randomized 1:1 to receive RTX (1000mg) or placebo (PLA) on days 1, 15, 168, and 182. Changes in anti-dsDNA titers and complement C3 levels were assessed at Week 52 and correlated to renal responses.

Results: 144 randomized pts (72 to each arm) comprised the intent-to-treat population. Mean daily MMF dose was 2.4±0.63g in PLA and 2.7±0.41g in RTX. Overall, there was no signficant difference in achieving a renal response between the PLA and RTX groups (p=0.55). Baseline median anti-dsDNA and mean C3 were 168.5 IU/mL and 74.1 mg/dL in the placebo group, respectively, and 122.5 IU/mL and 73.6 mg/dL in the RTX group. At Wk 52, there was a greater decrease in anti-dsDNA (p=.007) and greater increase in C3 (p=.025) in the RTX group compared to PLA. Changes by response status are presented in the table. Spearman's correlation coefficient between improvement in C3 and renal response was 0.55 (p<0.001) in PLA and 0.03 (p=0.8) in RTX. Correlation of change in anti-dsDNA to response was not statistically signfificant in either PLA or RTX.

Conclusion: RTX statistically significantly lowered anti-dsDNA titers and increased C3 levels compared to PLA. However, these changes did not translate into a significant clinical benefit for achievement of renal responses. There was a similar level of improvement in anti-dsDNA titers and absolute C3 levels in both RTX responders and RTX non-responders, suggesting that changes in these serologic markers at one year do not correlate with renal response in RTX-treated pts.

Tolerance and Efficacy of Rituximab (RTX) in Systemic Lupus Erythematosus (SLE): Data of 104 Patients From the AIR (« Auto-immunity and Rituximab ») Registry. Benjamin Terrier[1], Eric Hachulla[2], Béatrice Pallot-Prades[3], Jean Léone[4], Pierre Quartier[5], Olivier Fain[6], Jean Sibilia[7], Bernard Combe[8], Philippe Gaudin[9], Olivier Meyer[10], Arnaud Hot[11], Bertrand Godeau[12], Eric Vignon[13], Patrice Cacoub[14], Christine Bonnet[15], Claire Larroche[16], Xavier Mariette[1] and J.-E. Gottenberg[7], [1]Bicêtre, Kremlin Bicêtre, France, [2]Claude Hurier, Lille, France, [3]CHU Bellevue, Saint-Etienne, France, [4]CHU, Reims, France, [5]Necker-Enfants Malades, Paris, France, [6]Jean Verdier, Bondy, France, [7]Hautepierre, Strasbourg, France, [8]Lapeyronie, Montpellier, France, [9]CHU, Grenoble, [10]Bichat, Paris, France, [11]Edouard Herriot, Lyon, France, [12]Henri Mondor, Créteil, France, [13]Claude Bernard, Lyon, France, [14]Pitié-Salpétrière, Paris, France, [15]CHU, Limoges, France, [16]Avicenne, Bobigny, France

Purpose: To study safety and efficacy of RTX in 104 SLE patients included in the AIR registry.

Method: The French Society of Rheumatology and the Club Rhumatismes et Inflammation set up the AIR registry which includes patients treated with RTX for rheumatoid arthritis (RA) and other refractory autoimmune diseases.

Results: Epidemiological features: Among the 2235 patients in the registry, 104 SLE patients were included. 86 patients, who had at least 1 follow-up visit, were analyzed (women 80%, mean age 39±16 years, mean disease duration 8±7 years). Mean number of previous immunosuppressants (IS) was 2.4±1.4. 37% and 22% of patients had previously received mycophenolate mofetil (MMF) and cyclophosphamide (CYC), respectively. Indication of RTX: cutaneous and/or articular involvement in 43 patients (41%), renal involvement in 31 (30%, histological class IV: 19, III: 7, V: 4, and II:2 patients), autoimmune cytopenia in 24 (23%), other indications in 6 (6%). Disease activity before RTX: mean SLEDAI 10.5±9.5, mean BILAG 15.1±7.8 (all patients had BILAG A in >/= 1 organ domain), prednisone in 95 (91%) patients (mean: 28.2±20.5 mg/day). RTX administration: monotherapy in 26 patients (25%) and concomitant IS in 78 (75%) [hydroxychloroquine (n=49), MMF (n=19), CYC (n=10)]. Follow-up: Mean follow-up: 15.3±11.7 months = 96.4 patients-years (py). Tolerance: 1 severe infusion reaction, 5 delayed serum sickness-like reactions and 10 severe infections (8.9/100 py) were observed. 1 patient died due to infectious endocarditis. Outcome: Overall efficacy according to the clinician was observed in 63/86 patients (73%). Improvement of cutaneous and/or articular involvement was observed in 38/54 patients (70%), of renal involvement in 15/24 (63%), and of autoimmune

cytopenia in 14/19 (74%). In the 86 patients, mean SLEDAI, mean BILAG and mean prednisone dosage decreased from 10.7±9.4 to 3.3±4.7 ($p<0.0001$), 15.0±8.1 to 4.4±6.1 ($p<0.0001$) and from 26.2±17.5 to 12.6±9.7 mg/d ($p<0.0001$), respectively. RTX was effective in re-treated patients.

Conclusion: In patients with SLE, data from the AIR registry show short-term efficacy as well as a corticosteroid sparing effect of RTX. Tolerance was rather good but the rate of serious infections was higher than in RA (4.9/100 py) in the same AIR registry.

Combined Rituximab and Cyclophosphamide Therapy in Systemic Lupus Erythematosus. Anusha Ramanathan, Risa Alperin, Emma J. MacDermott, Alexa B. Adams and Thomas J. A. Lehman, Hospital for Special Surgery, New York, NY

Purpose: Although cyclophosphamide and mycophenolate mofetil have been used extensively as steroid sparing agents in systemic lupus erythematosus, their prolonged use caries increased risks of infection, infertility and future malignancy. Newer regimens are needed which minimize the duration of cytotoxic therapy while providing better disease control. In this study, we propose that a systematic regimen of cyclophosphamide plus rituximab achieves this goal.

Method: Fourteen patients (11 female, 3 male) with SLE who received combined rituximab and cyclophosphamide infusions at our institution between 2004 and 2008 were evaluated for clinical and laboratory parameters by prospective data collection. 10 patients had renal biopsy proven nephritis and 4 were treated for non-renal manifestations of SLE. Rituximab was administered at 750mg/m^2 on day 0 followed by cyclophosphamide at 750mg/m^2 on day 1, and this was repeated at days 14 and 15 for each course of therapy. Courses of therapy were separated by an interval of 6 months between the first and second course, and by 1 year between the second and third course. Mean number of treatments with rituximab and cyclophosphamide was 5.9 (SD 2.5) and 8 patients received at least 3 courses of therapy.

Results: From baseline to 1 year follow-up (6 months from last treatment), there was significant improvement in mean prednisone dose from 33.3 ± 19.7 to 11.9 ± 4.7 mg/day ($p = 0.0002$), and improvement in complement level (C3) from 70.3 ± 26.6 to 118.1 ± 30.3 mg/dl ($p = 0.0023$) with a decrease in ESR from 26.4 ± 15.2 to 14.8 ± 12.8 mm/hr ($p = 0.0134$) and decrease in SLEDAI score from 9.79 ± 5.99 to 1.43 ± 1.83 ($p = 0.0009$). Among 7 patients with proteinuria prior to treatment, mean 24 hour urine protein decreased from 1204 ± 833 to 147 ± 255 mg/day ($p=0.0156$). Two patients had hematuria prior to treatment which resolved. Hemoglobin (11.9 ± 2 vs 12.6 ± 1 gm/dl, $p=0.3575$) and WBC (7.9 ± 3 vs 8.2 ± 4/nl, $p=0.8077$) remained stable and there was no significant change in serum creatinine (0.7 ± 0.22 vs 0.69 ± 0.12 mg/dl, $p=0.8438$). Immunoglobulin levels were significantly lower at 1 year follow-up, with IgG going from 1191 ± 326 to 910 ± 289 mg/dl ($p=0.0039$) and IgM falling from 98 ± 54 to 41 ± 16 mg/dl ($p=0.0059$). There were no serious adverse events during the follow-up time, and minor infections occurred in four patients, all of whom responded promptly to antibiotic or antiviral treatment.

Conclusion: Combined therapy with Rituximab and Cyclophosphamide administered in a systemic manner is both well tolerated and effective as an alternative in the management of systemic lupus erythematosus. Long term, prospective studies are needed to determine optimal treatment protocol and late side effects.

Rituximab Therapy Induces Durable Remissions in Hispanic and African American Patients with Refractory Systemic Lupus Erythematosus (SLE). George A. Karpouzas[1], Maneesh Gogia[1], Rosalinda C. Moran[1] and Bevra H. Hahn[2], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Autoreactive B cells produce pathogenic autoantibodies (Ab) that deposit in tissues and cause injury in patients (pts) with SLE. While combinations of antimalarials, corticosteroids and immunosuppressives may control disease activity in most pts, about 10% suffer recalcitrant disease. Rituximab is a chimeric monoclonal Ab that eliminates B cells through binding of CD20 surface antigen. We evaluated the ability of Rituximab (RTX) to induce sustained remission in minority pts with refractory SLE.

Methods: We studied 35 pts with refractory SLE between 1/1/06 and 6/30/08. Subjects were given 4 weekly infusions of RTX monotherapy at 375mg/m^2. All had regular follow-up in a single academic center. Disease activity was measured with SLEDAI-2k every 3 months. Responses were reported in quarterly intervals and analyzed with paired t-tests.

Results: Thirty five pts received 1 cycle and 7 received a 2nd cycle within 9±2.4 months (mo) after the 1st infusion. Depletion of $CD19^+$ cells was observed in all ($p<0.001$-table). Baseline SLEDAI-2k was 8.5±0.8, significantly decreased in the 1st quarter (4.4±0.5, $p<0.0001$), and remained so to the end of the observation period. This was associated with a significant increase in serum complements. Sixteen pts with arthritis were followed over 15.2±5.1 mo: 75% had initial complete resolution, and 56% had sustained response (SR≥6 mo). Time to SR was 3.6±1.9 mo and SR lasted 13.2±1.3 mo. Primary and 2dary efficacy failures were seen in 19% and 25% of pts respectively. All (100%) achieved 2dary SR within 3.6± 1.3 mo of rechallenge. Among 13 pts with nephritis and baseline proteinuria of 4.5±1.5 g/24h followed over 11.5±5.7 mo, 92.3% had >50% improvement within 5±3.7 mo, and 53.8% achieved SR with proteinuria <500 mg/24 h within 6.8±3.7 mo.

Conclusion: In this open study, RTX therapy induced global durable responses in the majority of our cohort of Hispanic and AA pts with refractory SLE, and should, therefore, be considered as a therapeutic alternative in that context.

Rituximab in Cutaneous Lupus: Responsiveness Depends On Pattern of Skin Involvement. Edward M. Vital[1], Shouvik Dass[1], Maya H. Buch[1], Colin T. Pease[2], Michael F. Martin[2], Andrew C. Rawstron[2], Mark Goodfield[2] and Paul Emery[1], [1]University of Leeds, Leeds, United Kingdom, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Purpose: Rituximab in SLE has been described in >200 published cases; positive responses were seen in all systems. However, cutaneous pathology in lupus is heterogeneous, including some lesions that occur in patients without autoantibodies. Responses to targeted B cell therapies therefore warrant more detailed assessment.

Method: 35 SLE patients were treated with 2 x rituximab 1000mg + methylprednisolone 100mg. Patients with skin involvement were reviewed in a combined rheumatology/dermatology clinic. B cells were monitored using highly sensitive flow cytometry.

Results: 14 patients had significant cutaneous disease. Antimalarials (5/14) or other immunosuppressants (7/14) were continued. The skin was the primary indication for treatment in 3 patients.

Non-cutaneous disease: 12 had significant (BILAG A/B) non-cutaneous disease including renal(2), cerebral(3), haematological(3) and arthritis(3). Responses were good with reduction of BILAG A/B to C/D in 11/12.

Discoid LE: 4 patients had discoid disease. None showed significant change after treatment.
Cutaneous vasculitis: 2 patients had cutaneous vasculitis with purpura; both responded completely.

Changing pattern of lupoid cutaneous disease: 1 patient with papulosquamous subacute LE responded well for 11 months then relapsed with the same rash. In 3 other patients, acute photoaggravated LE responded, but they then developed disseminated discoid LE. In these patients B cell depletion was incomplete, transient improvement occurred during depletion, and change in pattern of skin disease occurred during repopulation.

Developing non-lupoid cutaneous disease: 3 patients developed non lupoid rashes. 2 patients were treated for arthritis with initial good response. Following a second cycle of rituximab 1 developed Sweet's syndrome and 1 pemphigus erythematosus. 1 patient was treated for thrombocytopenia and cerebral vasculitis but developed psoriasis. These rashes occurred while B cell depleted. All were biopsy-proven.

Conclusion: Responsiveness of cutaneous lupus to rituximab is complex. Discoid lesions did not respond. Acute non-discoid LE and vasculitis in patients with active systemic disease initially improved along with other manifestations. However, some patients switched to a disseminated discoid pattern following B cell repopulation. This may be explained by expansion of a T cell population during B cell depletion that becomes activated during repopulation. Alternatively transient and incomplete B cell depletion may alter the pathological B cell repertoire. Some patients develop other cutaneous diseases, but the mechanism for this is unclear. The role of B cells may vary between different patterns of skin disease in SLE and rituximab may not be the most appropriate therapy for all patients. Careful monitoring of the skin is needed when using rituximab in SLE. These results may have implications for the design and interpretation of clinical trials of B cell therapies in SLE.

Prolonged Immunoadsorption (IAS) Leads to Sustained Stabilization of Disease Activity in Lupus Nephritis. Georg H. Stummvoll[1], Peter Biesenbach[2], Sabine Schmaldienst[1], Josef S. Smolen[1] and Kurt Derfler[2], [1]Medical University of Vienna, Vienna, Austria, [2]Medical Uiversity of Vienna, Vienna, Austria

Purpose: SLE is characterized by pathogenic autoantibodies and immune complexes, which can effectively be removed by extracorporeal procedures such as IAS. After up to one year of IAS, we had previously observed a reduction of proteinuria, disease activity and autoantibody levels in highly active SLE with renal involvement with contraindication or refractoriness to cyclophosphamide (Cx). Antibody removal, however, does not block the formation of autoantibodies; thus, a large proportion of these patients underwent prolonged IAS (>1 yr for up to 10yrs) and are the focus of this report.

We evaluated patients under prolonged IAS for sustainability or further improvement of the primary response to IAS (proteinuria, disease activity, anti-dsDNA-Abs) and for the number of flares, infections, adverse events and tumors.

Methods: Highly active SLE patients with lupus nephritis (proteinuria 7.1±4.8 g/day, SLEDAI 20±8, anti-dsDNA 394±712 IU/ml) underwent IAS therapy if i.v. Cx was contraindicated or not effective enough to control disease activity. 13 patients responding to initial IAS therapy were included into the prolonged program, showing moderate disease activity at the start of the extension period (proteinuria 2.0±2.4, SLEDAI 3±2, anti-dsDNA 47±36 IU/ml). We defined the end of observation (EoO) upon either completion of 10 yrs of IAS therapy or the end of 2008. During IAS, oral immunosuppression and ACE/ATII-inhibitors were kept constant, steroids were tapered as clinically feasible. IAS was performed with high affinity columns using either sheep-IgG or Protein A as ligand. The effective removal of serum Ig was monitored. Severe infections were defined as requiring i.v. therapy or hospitalization, flares according to the SELENA protocol.

Results: Under prolonged IAS (mean observation period of 6.7±3.5 years), proteinuria further decreased from 2.0±2.4 g/d to 0.9±1.7g/d, $p<0.05$. Complete remission (proteinuria<0.5g/d) was achieved in 9 (69%) patients. One patient flared and was discontinued. Nine (69%) patients are still under IAS therapy at the EoO. In 4 patients IAS was stopped because of a sustained response. Disease activity and anti-dsDNA levels could be stabilized at low levels (SLEDAI 3±4, anti-dsDNA 26±24 IU/ml at EoO).

Severe infections (0.1±0.3 per patient year) and severe flares (0.1±0.2 per patient year) were uncommon. Tumors, anaphylactic or orthostatic adverse events were not observed.

Conclusion: Prolonged IAS can lead to sustained stabilization of disease activity in moderately active SLE patients and has an acceptable safety profile.

The Efficacy of Intravenous Immunoglobulin Therapy for Immune Thrombocytopenia Associated with Systemic Lupus Erythematosus. Eun Joo Song[1], Ji Hun Kim, Jin Young Kang[1], Kyung Hoon Kim[1], Jae Seok Seo[1], Eon Jeong Nam[2] and Young Mo Kang[1], [1]Kyungpook National University School of Medicine, Daegu, South Korea, [2]Kyungpook National Univ Hosp, Daegu, South Korea

Purpose: Severe immune thrombocytopenia (IT) usually occurs in the context of active systemic lupus erythematosus (SLE) and is conventionally treated by high-dose corticosteroid (HDCS) as the first-line therapy. In IT associated with SLE, intravenous immunoglobulin (IVIG) has been empirically used in cases refractory to or dependent on HDCS. However, the clinical efficacy of IVIG for treatment of IT associated with SLE remains undetermined. We sought to investigate the clinical efficacy of IVIG therapy for IT associated with SLE.

Method: We reviewed medical records of 350 admitted patients with SLE according to the American College of Rheumatology 1997 revised criteria, among whom 126 patients were identified to have IT. A retrospective analysis was made for 35 patients, who had platelet count $< 50 \times 10^9$/L and had been regularly followed for clinical examinations. Of these patients, 20 patients received IVIG (2 g/kg for 5 days) combined with HDCS (the combination therapy group), and 15 patients were treated with HDCS alone (the monotherapy group). Efficacy was evaluated on the basis of platelet count change by therapeutic regimens, cumulative doses of corticosteroid and numbers of days, which were required until the platelet count exceeded 50×10^9/L or 100×10^9/L, and the amount of transfusion which was needed for the prevention of bleeding in case of severe IT.

Results: At the baseline, there was no significant difference in clinical and demographic features between the combination therapy and monotherapy groups, although the mean platelet count was lower in the combination therapy group. The platelet counts on day 5 and day 14

after treatment were significantly higher in the combination therapy group than in the monotherapy group (96.9 ± 9.9 vs. 56.1 ± 8.8 $\times 10^9$/L at day 5, p=0.001; 162.8 ± 16.3 vs. 95.2 ± 15.3 $\times$ 10^9/L at day 14, p=0.003). The cumulative dose of corticosteroid and number of days, which were required until the platelet count exceeded 100 $\times$ 10^9/L, were statistically lower in the combination therapy group than in the monotherapy group respectively (482.8 ± 158.5 vs. 1033.3 ± 266.0 mg, p<0.001; 6.8 ± 0.7 vs. 12.3 ± 1.7 days, p=0.001). The amount of transfusion in each group was not significantly different.

Conclusion: Our results suggest that IVIG therapy has the advantage of faster restoration of normal platelet count with a lower cumulative dose of steroid, thus being warranted as an effective first-line treatment for severe IT associated with SLE.

Efficacy and Safety of Long-Term Use of Thalidomide for Refractory Cutaneous Lupus. J. Cortés-Hernández, M. Torres-Salido, S. Buján, M. Vilardell-Tarres and J. Ordi-Ros, Systemic Autoimmune disease Research Unit. Hospital Vall d'Hebron., Barcelona, Spain

Purpose: Cutaneous manifestations of lupus erythematosus are characterized by a great heterogeneity of clinical manifestations that usually have a chronic and relapsing course. Although is not a life-threatening condition, the lack of a rapid improvement can lead to a significant permanent scarring and disfigurating lesions. Thalidomide is increasingly being shown to be effective for the treatment cutaneous disease refractory to conventional management. The aim is to prospectively evaluate the clinical efficacy and safety of long-term treatment with low-dose of thalidomide in a cohort of 50 patients with refractory cutaneous lupus disease.

Methods: From 1992 to 2009, fifty consecutive patients with refractory disease (23 with discoid lupus erythematosus (DLE), 12 with subacute cutaneous lupus (SCLE), 4 with profundus lupus, 7 with acute cutaneous lupus, 1 with lupus tumidus, and 3 with a non-specific rash) were treated with thalidomide. Initial treatment was started at 100 mg daily. If the cutaneous lesions vanished, the dose was lowered to 50-25 mg daily as maintenance therapy. Patients were follow-up for a mean of 82±63 months (12-204). Complete response was defined as a total resolution of the cutaneous lesions. Partial response was considered when at least >50% of the improvement was achieved. Patients were followed up periodically and were assessed for the development of neuropathy and other adverse effects. Contraception was initiated in women of childbearing age.

Results: Forty-seven patients (94%) achieved complete or partial response with thalidomide therapy. Complete response occurred in forty-one patients (82%). Time to remission was as quick as to 10.7±5.30 weeks (4-28). There was an elevated rate of relapses (65.8%), usually 8-16 weeks after thalidomide's withdrawal or reduction. All patients achieved complete response after the drug was reintroduced. No response occurred in 3 patients (6%). The duration of thalidomide therapy was of 21±19.74 months (2-76). The most common adverse effects were sedation, constipation and weight gain. Five women developed amenorrhea during the treatment, but menses returned after its withdrawal. Seven patients (14%) reported symptoms of paresthesia, but only in three of them polyneuropathy was confirmed by EMG. One patient, heavy smoker and without antiphospholipid antibodies, had a stroke. None of the three patients with antiphospholipid antibodies developed a thrombotic event. Thalidomide did not improve the systemic disease or the scarring alopecia.

Conclusion: Low dose thalidomide is a safe and an effective treatment for the different manifestations of cutaneous lupus refractory to conventional therapy. In view of the high rate of relapses after treatment discontinuation, a long-term maintenance dose might be required. The rapid response achieved and the safe profile support that thalidomide, alone or in combination, might be used as initial therapy to avoid sequelae.

The Effects of Hydroxychloroquine On Antiphospholipid Antibodies in SLE Patients. Anna Broder and Chaim Putterman, Division of Rheumatology, Albert Einstein College of Med, Bronx, NY

Purpose: Treatment with hydroxychloroquine (HCQ) is associated with a decreased risk of thrombosis in antiphospholipid (APL) syndrome. In vitro, HCQ decreases the binding of APL-beta2 glycoprotein complexes to phospholipid bilayers and reduces clinical APL assays. The time-dependent effects of HCQ on APL antibodies in SLE patients have not been studied extensively. We investigated a potential association between changes in APL antibody (Ab) titers over time and HCQ therapy.

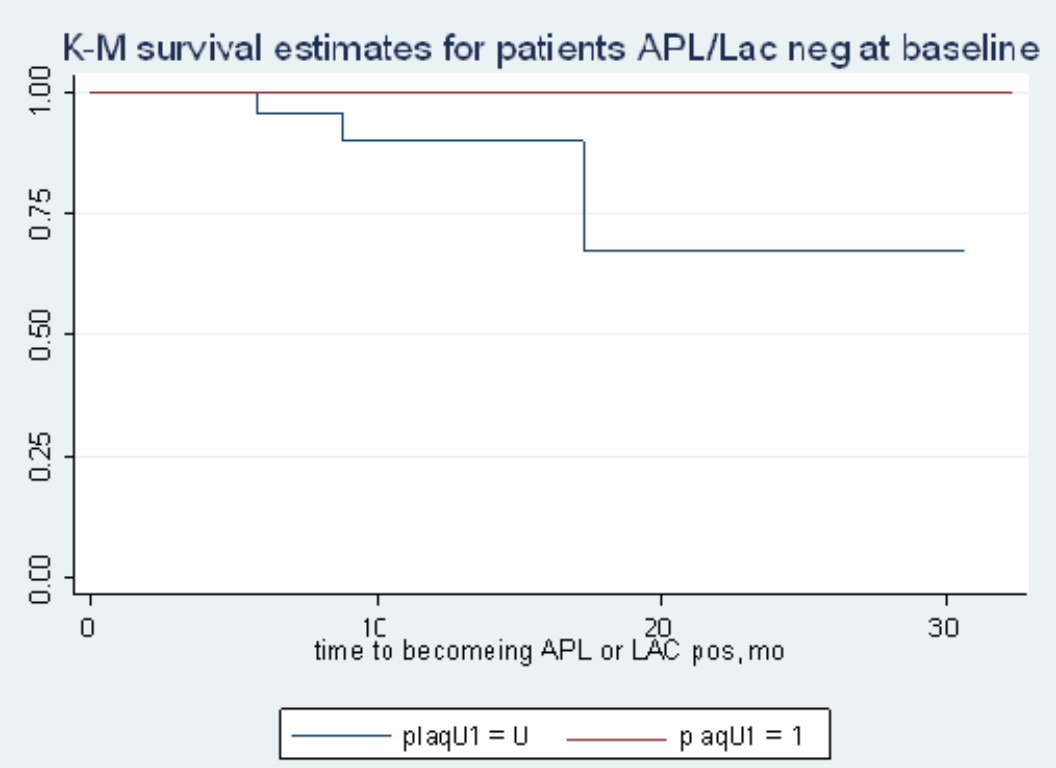
Method: We identified all SLE patients followed at a tertiary care center who had APL Abs or lupus anticoagulant (Lac) checked at least twice between 2002 and 2009. At baseline, patients were defined as APL/Lac- if all APL Abs and Lac were negative. Similarly, patients were defined as APL/Lac+ if at least one APL Ab or Lac was positive at baseline. We used the standard laboratory cut-offs for the above definitions. In the APL/Lac+ group an "event" was defined as APL Ab and/or Lac conversion from positive to negative. In the APL/Lac- group an "event" was defined as APL or Lac conversion from negative to positive. "Time to event" was defined as the number of months to censoring or conversion. Patients were defined as HCQ+ if they were on HCQ at the event time, and HCQ- if they were not on HCQ at the event time.

Kaplan-Meier graphs were generated separately for the APL/Lac+ and APL/Lac- groups.

Results: Eighty four patients met the above inclusion criteria. The median age was 31.5, IQR (21, 40.8) years. Seventy eight (93%) were women; 63 (75%) were African-American or Hispanic. HCQ data was available for 58 (69%) patients: 31 (64%) were HCQ-, 27 (46%) were HCQ+. At the event time the HCQ+ and HCQ- groups were similar in age (median 26, IQR (20,30) years), race (76% Hispanic or African American), gender (91% women), and had similar duration of follow-up (median 10.6, IQR (3.5, 17.2) months), platelet counts (median 237, IQR (183, 299) 10^9/l), serum creatinine levels (median 0.8, IQR (0.6-1.0) mg/dl), and complement levels. The frequency of elevated anti-DsDNA titers (≥99 IU/ml) was 39% (n=9) HCQ+ vs. 23% (n=5) HCQ-, p=0.3. HCQ+ patients had a lower frequency of Warfarin therapy, 33% (n=9) in HCQ+ vs. 64% (n=20) in HCQ- group, p=0.02. HCQ+ patients more likely to use Prednisone: 100% (n=27) HCQ+ vs. 74% (n=24), p=0.004. HCQ+ patients were more likely to use disease modifying drugs such as Azathioprine, Mycophenolate Mofetil, or Cyclophosphamide: 81% (n=22) HCQ+ vs. 52% (n=16) HCQ-, p=0.02.

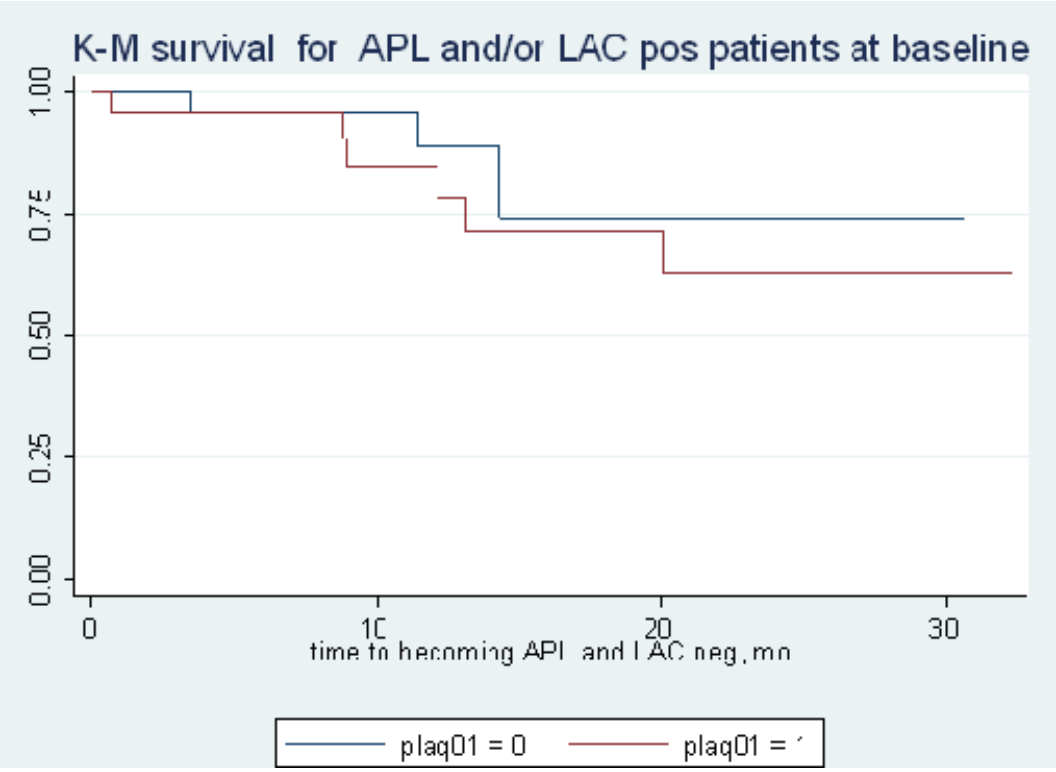
Thirty two patients, 16 (50%) HCQ+ and 16 (50%) HCQ-, were APL/Lac- at baseline. Three (9%) patients became APL/Lac+. All 3 were in the HCQ- group.

The differences were statistically significant by the log-rank test (p=0.0026)



Twenty six patients, 11 (42%) HCQ+ and 15 (58%) HCQ-, had at least one APL/Lac+ at baseline. Six(55%) were on HCQ and 3(20%) were not on HCQ at the time of conversion to all APL/Lac-.

The differences were statistically significant by the log-rank test (p=0.0009)



Conclusion: In our study cohort HCQ therapy in APL Abs/Lac+ patients is associated with an increased rate of conversion to APL Abs/Lac-HCQ may play a role in decreasing APL antibody levels in APL-positive patients and maintaining low APL levels in APL-negative patients.

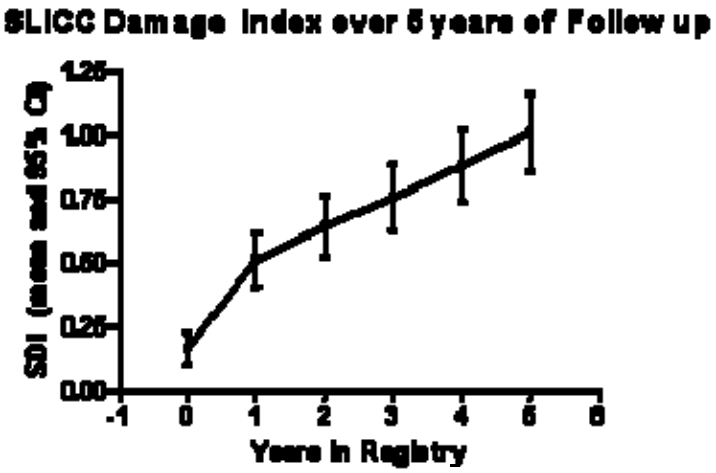
Damage Due to Glucocorticoids in a Multicentre SLE Inception Cohort. Murray Urowitz[1], Dafna Gladman[1], Dominique Ibañez[1] and Systemic Lupus International Collaborating Clinic (SLICC), [1]University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: As survival has increased in patients with SLE, organ damage has been shown to accumulate over time as a result of both the disease and its treatment especially corticosteroids. We determined the contribution of corticosteroids to the pattern of damage accumulation in a multicentre, inception cohort of SLE patients followed for 5 years.

Method: An international consortium comprising 27 centres from 11 countries has established an inception cohort followed yearly according to a standardized protocol between 2000 and 2009. Of these, 298 patients have been followed for a minimum of 5 years and constitute the study population. Accrued damage was measured using the SLICC/ACR Damage Index (SDI). Organ damage was categorized into the following groups: definitely related to steroids (cataracts, osteonecrosis, osteoporosis); possibly related (cardiovascular, peripheral vascular, neuropsychiatric, diabetes); independent of steroids (renal, pulmonary, gastrointestinal, skin, gonadal failure and malignancy). Descriptive statistics were used.

Results: Of the 298 patients followed for at least 5 years, 86.6% were female, 55.4% % were Caucasian, 12.1% were Black, 14.4% were Asian, 16.1% Hispanic and 2.0% Other. 41.9% were married and 60.4% had at least College education. Their age at enrolment was 35.3 yrs and SLEDAI-2K at enrolment was 5.9. The duration from diagnosis to enrolment was 5.5 months. Glucocorticoids were taken by 66.1% of the patients at enrolment, 72.8% at year 1 and persistently in 76% of the patients thereafter. The mean SDI increased from 0.16 to 1.01 over 5 years.



Damage definitely due to glucocorticoids increased over 5 years whereas damage independent of glucocorticoids remained stable over 5 years (table)

Year	Definitely glucocorticoid (%)	Possibly glucocorticoid (%)	Independent of glucocorticoids
0	11.3	43.4	45.3
1	12.9	42.6	44.5
2	15.6	40.2	44.3
3	18.3	37.6	44.1
4	21.8	36.7	41.6
5	25.5	32.1	42.1

Conclusion: With improving survival patients with SLE accrue organ damage a significant portion of which is glucocorticoids related. In this study 25.5% of accrued damage in the first 5 years of disease is definitely related to glucocorticoids therapy.

BILAG Versus SELENA-SLEDAI Scoring in Systemic Lupus Erythematosus (SLE) Patients in EXPLORER. C. Gordon[1], Joan T. Merrill[2], D.J. Wallace[3], H. Hsieh[4] and P. Brunetta[4], [1]University of Birmingham, Birmingham, United Kingdom, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Cedars-Sinai Medical Center/UCLA, West Hollywood, CA, [4]Genentech, Inc., South San Francisco, CA

Purpose: SLE is a heterogenous autoimmune disease affecting multiple organ systems. B cells may play a central role in SLE, but measurement of efficacy is complex due to heterogenous manifestations of disease activity. Rituximab (RTX) induces peripheral CD20+ B

cell depletion. The EXPLORER trial assessed the efficacy and safety of RTX vs placebo (PLA) over 52 weeks in moderate to severely active extrarenal SLE. Our objectives were to report and assess the correlation of BILAG index vs SELENA-SLEDAI (S-S) scoring of disease activity in SLE in the EXPLORER trial.

Methods: The BILAG and the S-S indices measure disease activity either in the previous month, or within the prior 10 days, respectively. S-S is a global composite index that includes 24 clinical and laboratory variables weighted by the type of manifestation but not by severity. The BILAG is an index measuring 8 organ systems weighted by severity. It was devised to provide separate letter scores (ordered from A-E with A indicating the most severe disease) for each domain. Two systems of global scores were applied. System 1 was derived by summing 8 domains scores and assigning 9, 3, 1, 0, 0, to letter scores A, B, C, D, and E, respectively. System 2 summed 8 domains scores and assigned 12, 5, 1, 0, and 0, to A, B, C, D, and E, respectively. In EXPLORER pts, BILAG was assessed monthly and S-S was assessed on alternate months from baseline through 12 months. The correlations of S-S and BILAG were assessed by the global scores, and specifically in the musculoskeletal (MUS) and mucocutaneous (MUC) domains, the most prevalent systems involved in EXPLORER pts.

Results: The intent to treat (ITT) population included 88 and 169 patients in the PLA and RTX groups. A total of 1877 patient visits were assessed by both S-S and BILAG. S-S is positively correlated with BILAG in global scores with a Pearson correlation coefficient of 0.57 and 0.58 using BILAG scoring system 1 and 2, respectively. There were 383 and 645 patient-visits indicated as severe disease by S-S ($\geq$ 11) and BILAG ($\geq$ 1A or $\geq$ 3B), respectively. There were 689 and 1005 patient-visits indicated as mild disease by S-S (1-5) and BILAG ($\leq$ 1B). In the MUC domain, the concordance rate of presenting or not presenting activities by both S-S and BILAG was 88.55% (Kappa=0.73), In the MUS domain, the concordance rate was 68.83% (Kappa=0.4). Most of the discordance (8.84%) in the MUS domain resulted from a C score being present in BILAG without concomitant presence in the S-S.

Conclusion: Disease activity assessed by either the BILAG index or the S-S correlated well in describing disease status in a cross-sectional analysis. Overall, the BILAG index discriminated severe and mild disease activity more than the S-S did in this cohort. Implementing an alternative scoring system for the BILAG didn't alter the correlation with S-S activity when evaluating global scores in this study population.

Immunosuppressive Drugs in SLE Differ in Their Hematologic Side-Effects. Waleed Bolad[1], Laurence Magder[2] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]University of MD, Baltimore, MD, [3]Johns Hopkins Univ, Baltimore, MD

Purpose: The adverse reactions of mycophenolate mofetil (MMF) have been long studied in the renal transplant patient population. Bone marrow suppression leading to cytopenias is a major potential concern, and requires regular monitoring. The reported incidence of leukopenia in these trials ranges from 23% to 46%, hypochromic anemia 26% to 43%, and thrombocytopenia 24% to 36%. The safety of MMF in patients with severe renal impairment and in SLE has yet to be established. Azathioprine (AZA) and methotrexate (MTX) are both known to have dose related bone marrow suppression, particularly in the renally impaired, that results in leukopenia in up to 27% of patients and thrombocytopenia in up to 5%. **Method:** 456 SLE patients in a prospective cohort were included: 245 on mycophenolate (MMF), 199 on azathioprine (AZA), 102 on methotrexate (MTX), and 85 on one or more. We compared the times that the patients were on immunosuppressants with the times they were not on immunosuppressants with respect to platelet, hematocrit and white blood cell counts. Mixed effects models were used to control for sex, ethnicity, age and account for repeated measures in the same patient.

Results: The median number of quarterly visits on medication was 16 (MMF), 19 (AZA) and 16 (MTX). The patients were 89% female (MMF), 91% (AZA) and 94% (MTX). The ethnicity was African-American in 49% (MMF), 53% (AZA), 44% (MTX) and Caucasian in 42% (MMF), 40% (AZA) and 49% (MTX). The average age was 38.6 (MMF), 39.0 (AZA) and 44.9 (MTX). Comparison was made of off the immunosuppressive versus on the immunosuppressive, controlling for sex, ethnicity, age and accounting for repeated measures in the same patient.

	PLT		WBC		HCT	
	Estimated Effect (95% CI)[2]	P-value[1]	Estimated Effect (95% CI)[3]	P-value[1]	Estimated Effect (95% CI)[4]	P-value[1]

MMF	16.1 (12.9, 19.2)	<.0001	0.85 (0.67, 1.03)	<.0001	0.29 (0.17, 0.42)	<.0001
AZA	9.6 (6.5, 12.6)	<.0001	-0.41 (-0.58, -0.23)	<.0001	-0.61 (-0.74, -0.49)	<.0001
MTX	0.3 (-4.2, 4.8)	.90	-0.38 (-0.64, -0.12)	.0037	-0.06 (-0.23, 0.12)	.53

Conclusion: MMF is the safest immunosuppressive in SLE for the hematologic system and actually significantly increases all blood counts. AZA is safer than MTX in terms of platelets but MTX is safer than AZA in terms of hematocrit. These results have important clinical ramifications in terms of choosing an immunosuppressive, especially in SLE patients with baseline cytopenias. Furthermore, these data suggest that cytopenias on MMF should not be ascribed to MMF, but to lupus or other processes.

Comorbidity in SLE Compared with Rheumatoid Arthritis and Non-Inflammatory Rheumatic Disorders. Frederick Wolfe[1], KD Michaud[2], Tracy Li[3] and RS Katz[4], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]U Neb Med Cntr and NDB, Omaha, NE, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Rheumatology Associates, Chicago, IL

Purpose: Although comorbidity is well described in SLE, there have been no head-to-head comparisons of comorbidity prevalence in SLE and other rheumatic conditions. We used self-report comorbidity from patients participating in a longitudinal study of rheumatic disease outcomes to evaluate comparative comorbidity and the potential contribution of fibromyalgia; to describe the prevalence of comorbid condition in SLE,; to determine the relative risk (RR) of comorbidity in SLE compared with other rheumatic conditions; and to evaluate the effect of FM.

Methods: We evaluated 1,316 community SLE patients, 14,252 with rheumatoid arthritis (RA), and 3,768 with non-inflammatory rheumatic disorders (NIRD), excluding FM, and a comorbidity index was calculated (Michaud 2007). The presence of FM was determined using survey FM criteria (Katz 2006). We determined damage by the newly developed Lupus Damage Index Questionnaire (LDIQ), a self-report version of the ACR/Systemic Lupus International Collaborating Clinics (SLICC) Damage Index (SDI).

Results: The comorbidity index score was significantly increased in SLE 2.6 (95% CI 2.5, 2.7) compared with RA 1.7 (1.7, 1.7) and NIRD 1.9 (1.8, 1.9), and this increase was observed at all age levels and remained significant after non-linear adjustment for age and sex. To test the potential effect of simultaneous fibromyalgia, we examined differences between the comorbidity index before and after adjusting for the presence of FM using survey FM criteria. The presence of FM was associated with a 1-unit increase in the comorbidity index, but did not change the comorbidity scores in the 3 disorders. Survey FM was present in 24.4% with SLE, 17.0% with RA and 14.4% with NIRD.

Hypertension (37.4%) and depression (33.8%) were the most common current comorbid conditions among those with SLE. SLE patients differed most from those with RA in RR of current comorbid renal disease (RR 5.7), neurologic disorder (3.7), myocardial infarction (RR 2.8), pulmonary disease (RR 2.3), and stroke (RR 2.0). Patterns were very similar when SLE was compared with NIRD, and in comparisons utilizing lifetime rather than current comorbidity.

Comorbidities in SLE, as measured by the comorbidity index, were most strongly associated with the LDIQ damage score (r=.502) and with SF-36 PCS (r=.383), SF-36 pain (r=.359), and with the Symptom Intensity Scale (FM scale) (r=.331). Associations with correlation coefficients <0.300 included fatigue, patient global, SF-36 mental health, and HAQ disability.

Conclusion: Comorbidity is increased generally in SLE compared with RA and NIRD, including expected cardiovascular and renal conditions. Although more patients with SLE satisfied survey FM criteria, the presence of FM did not alter the increase in comorbidity in SLE. Increase in comorbid conditions is consistent with known increased mortality in SLE.

284

Multiorgan Dysfunction, High SLEDAI Scores, and Markedly Elevated Ferritin Levels Correlate with Macrophage Activation Syndrome in Adult Patients with SLE. B. Shakoory[1], R. D. Sanders[2], Vishnu Reddy[2], G. S. Alarcon[1], R. Q. Cron[3] and W. W. Chatham[1], [1]UAB Rheumatology, Birmingham, AL, [2]UAB Pathology, Birmingham, [3]UAB Pediatric Rheumatology, Birmingham, AL

Purpose and Background: SLE is the 2nd autoimmune disease recognized to be complicated by MAS. However, clinical similarities between underlying disease activity, sepsis syndromes and malignancies and MAS can delay its diagnosis resulting in increased mortality. Aggressive immunosuppression of MAS requires its accurate and timely diagnosis. We demonstrate the clinical correlates of MAS in SLE patients and compare the accuracy of the clinical assessment with other diagnostic tools in correctly identifying MAS.

Methods: Patients with SLE (≥ 4 ACR criteria) between 2006 and 2008 with available bone marrow specimens were identified. The specimens were examined by hemopathologists and graded from 0-4 based on presence of CD-163+ histiocytes. Abstraction of clinical, laboratory and radiographic features within 30 days of bone marrow biopsies took place independently and blinded from the pathology data. The likelihood of MAS was determined by a rheumatologist based on clinical parameters including organ systems involved, and changes in the blood cell counts, blood levels of LDH, ALT, AST, D-dimer, ferritin, and CRP. The "Clinical" decision was denoted as a weighted score of 1= low, 2= maybe, 3= probable, 4= highly likely. The suggested 2004 criteria for MAS in systemic juvenile idiopathic arthritis (MAS-04) and the weighted clinical parameters were compared with the validated 2004 diagnostic criteria for hemophagocytic lymphohistiocytosis (HLH-04) to determine the respective sensitivity, specificity and positive (P) and negative (N) predictive values (PV) and overall accuracy. Clinical features, severity and length of hospital stay of SLE patients with and without HLH-04 defined MAS were compared using Student's t test (SAS 9.1).

Results: The group consisted of 18 adults with SLE with mean age of 45.3; 88.9% were women and 66.7% were African American. Four patients (22%) had MAS per HLH-04 criteria. Both "Clinical" and MAS-04 scores were highly correlated with the HLH-04 score (Clinical: $r=0.88$, $p<0.0001$ and MAS-2004 $r=0.74$, $p<0.0005$). For diagnosis of MAS by HLH-04, the Clinical score had a sensitivity= 100%, specificity=92%, PPV= 80%, NPV=100% and accuracy= 94%) as compared to 100%, 0%, 22%, 0% and 94% for the MAS-04 criteria. MAS patients experienced longer hospital stay (27.5 vs.11.2 days; $p<0.0001$), longer intubation (17.2 vs. 0.07 days; $p<0.05$), higher SLE disease activity by SLEDAI (18.0 vs. 5.4; $p<0.05$) and higher ferritin levels (20659, vs. 1083; $P<0.0005$).

Conclusion: and clinical implications: The clinical diagnosis of MAS has adequate metric properties when compared with the HLH-04 criteria. Readily available clinical data may allow the diagnosis and prompt treatment of MAS in SLE patients with high levels of disease activity (SLEDAI) even in the absence of bone marrow histopathologic data. This will result in its earlier diagnosis and prevent undue morbidity and mortality. Moreover, the MAS-04 score is not appropriate in the setting of SLE.

Pancreatitis in Systemic Lupus Erythematosus. Ashima Makol[1] and Michelle A. Petri[2], [1]Michigan State University, East Lansing, MI, [2]Johns Hopkins University, Baltimore, MD

Purpose: Pancreatitis is a rare but potentially life threatening complication of systemic lupus erythematosus (SLE). Its incidence and etio-pathogenesis in lupus is unclear, but vasculitis of the gastrointestinal tract is the most commonly proposed mechanism. We determined the frequency and associated factors of SLE-related pancreatitis.

Method: A large prospective cohort was reviewed to identify patients who developed episodes of acute pancreatitis since the diagnosis of SLE. Clinical and laboratory parameters of SLE patients who developed pancreatitis were compared to SLE patients who did not develop pancreatitis. Statistical analysis was done using chi-square test or Fischer's exact test for dichotomous variables and Student's t-test for continuous variables. For demographic, physical and laboratory variables that were found to be different between patients with and without pancreatitis, multiple logistic regression analysis was used to identify the variables that independently predicted pancreatitis. A two tailed P value of <0.05 was considered statistically significant in all comparisons in the study.

Results: 76 of 1811 patients developed one or more episodes of pancreatitis. Five patients were excluded due to non availability of records or based on exclusion criteria. 71 remaining SLE patients developed 152 episodes of pancreatitis, with a mean of 2.1 episodes/person and an

average frequency of 0.10 episodes/person/year. The etiology was found to be related to SLE, in 63 patients (Prevalence 3.5%). 12 (19%) patients had elevated triglycerides, 29 (46%) had antiphospholipid antibodies (aPL) and 11 (17%) were on an immunosuppressive drug during their episode of pancreatitis. 73% patients showed complete resolution of pancreatitis, 14% developed chronicity and 3% died. Pancreatitis attributed to SLE was associated with lower household income, less private insurance, more disability and smoking. Associated clinical conditions included fever, vasculitis, pleurisy, psychosis, organic brain syndrome, cognitive impairment, anemia, Sjogren's syndrome, anti-La, hypertension, diabetes mellitus, venous thrombosis, stroke and myocardial infarction. SLE patients with pancreatitis accrued more permanent organ damage, including pancreatic insufficiency, renal and neuropsychiatric damage. No association was found with any aPL, immunosuppressant medication or steroids.

Conclusion: Our series found that SLE-attributable pancreatitis, although rare, identified a subset of SLE patients with much higher organ damage and mortality. Antiphospholipid antibodies were not associated, but a history of thrombosis, cutaneous vasculitis, secondary Sjogren's and triglyceridemia were all suggested as potential mechanisms. Only triglyceridemia remained in the multiple regression model in terms of a causative variable.

Comparison of Quantiferon-TB Gold Test and Tuberculin Skin Test for Identification of Latent Mycobacterium Tuberculosis Infection in Lupus Patients. Neslihan Yilmaz, Sibel Aydin, Nevsun Inanc, Haner Direskeneli and Sule Yavuz, Marmara University Faculty of Medicine, Rheumatology, Istanbul, Turkey

Purpose: The tuberculin skin test (TST) might have a low sensitivity for making the diagnosis of tuberculosis (TB) in immunosuppressed patients ,such as connective tissue disease. Quantiferon-TB Gold(QFT-G) is an IFN-gamma-release assay that measures the release of interferon after stimulation in vitro by Mycobacterium tuberculosis antigens using ELISA. The main advantage of this assay with respect to TST is a lack of cross-reaction with bacillus Calmette-Guérin(BCG) and most non-tuberculous mycobacteria. The aim of our study is to compare QTF-G with TST for the detection of latent tuberculosis infection (LTBI) among patients with systemic lupus erythematosus (SLE).

Method: Fifty patients with SLE who fulfilled the ACR criteria and 49 healthy subjects were enrolled. All patients and controls were investigated for a history of tuberculosis, BCG vaccinations and chest x-ray for the presence of any signs of TB infections. QTF-G and TST were performed on both patients and controls. QTF-G results were recorded as positive, negative or indeterminate. A positive TST for SLE was defined as ≥5 mm.

Results: Forty seven of SLE patients (95,9%) had been BCG vaccinated.Thirteen of 50 (26%) patients had positive QTF-G with a similar result to controls (28,5%). One patient had an indeterminate result. The agreement between QTF-G and TST was observed to be 32/48 (66,6%)(κ=0.36). There were fewer positive QFT-G test results than positive TST results (26% vs 56%; $p<0,001$).Fifteen (31%) patients were TST(+)/QTF-G(-) while only 1(2%) patient was TST(-)/QTF-G (+). If 10 mm induration diameter was chosen as the TST cut-off value, the agreement between two tests was 41/48 (85,4%) with a kappa value of 0.65.

Conclusion: In a TB-endemic and BCG vaccinated population, the Quantiferon-TB Gold assay seemed to be a more accurate test for detection of LTBI in SLE patients compared with the TST. Although 5 mm is usually accepted to be the standart cut-off for TST in immunosupressed patients such as SLE, level of agreement between QTF-G and TST was better with a 10 mm cut-off in our population.

287

Impact of Serious Infections in the Morbi-Mortality of a Cohort of Spanish Patients with Systemic Lupus Erythematosus. L. Castro, J. Cortés-Hernández, M. Torres-Salido, S. Buján, M. Vilardell-Tarrés and J. Ordi-Ros, Systemic Autoimmune disease Research Unit. Hospital Vall d'Hebron., Barcelona, Spain

Purpose: Infections remain a serious and important cause of morbidity and mortality in patients with SLE. Despite an early detection and aggressive treatment, severe infections still account for 20-55% of the SLE-related deaths. With the introduction of new immunosuppressant/biological drugs more studies are needed to establish whether there has been a change in the infectious pattern and their

impact in mortality/morbidity. The aim of this retrospective study is to determine the prevalence of infections in our cohort of SLE patients and to establish the impact on mortality and hospitalization as well as to evaluate the risk factors associated to the development of infection

Methods: Database information from the 570 patients attending our specialized SLE clinic between 1969-2009 was reviewed retrospectively to evaluate the incidence and characteristics of the infection, the clinical, treatment received and laboratory of the patients at the time of infection as well as the impact in hospitalization and mortality. Only serious infections were evaluated. Minor infections like urinary and respiratory upper tract infections were not included. Prognostic factors associated to infection development were assessed.

Results: One-hundred thirty-five patients had a serious infection (24%). Ten patients had more than one infection. The mean age at infection was 44±12 years. At the time of the infection the mean disease duration was 30±6 years. Fifty-two patients were receiving immunosuppressive treatment at the time of the infection (38%). Seventy-eight (58%) of them were serious enough to result in hospitalization. Sixteen of those required intensive care admission (16%). Most cases had a community acquired infection (83%). In 25 cases no causative agent was found. Of the rest of 135 infective episodes, 112 (83%) were due to a bacterial infection, 20 (15%) viral and 3 (2%) fungical. Of the bacterial infections, pyelonephritis was the most frequent bacterial infection (27%) being by E Coli in more than 50% of cases, pneumonia occurred in 23% of cases, being the Streptococcus pneumonia antigen positive in 13% of cases. None of those patients had been vaccinated against pneumococcus. Other bacterial infections were soft tissue infection (8%), Tuberculosis (6%), gastroenteritis (4%), meningitis (3%), endocarditis (3%) and osteomyelitis (3%). Of the viral infections, VZH infection was the most frequent (80%). Infection-related mortality occurred in 7 patients (5%), two of them due to miliar tuberculosis. When compared with patients who did not developed infection, the use of high dose of prednisone or other immunosuppressants, disease activity, hypocomplementaemia or hypogammaglobulinaemia did not increased the risk of infection.

Conclusion: Infection is still a problem in patients with SLE. In our series of patients 24% of patients had a serious infection. Infection-related mortality occurred in 7 patients (5%). A major risk factor of infection was not detected.

Reticulocytes Bearing C4d in Patients Hospitalized for Acute Infections. Surabhi Agarwal, Harish Jasti, Susan Manzi, Abdus Sattar, Barbara Paul, Shane Lavin, Joseph M. Ahearn and Amy H. Kao, Lupus Center of Excellence, University of Pittsburgh Schools of the Health Sciences, Pittsburgh, PA

Purpose: Previous studies have shown that complement activation product C4d bound to the surface of reticulocytes (R-C4d) may serve as a biomarker of disease activity in patients with systemic lupus erythematosus (SLE). The goal of this pilot study was to begin to determine if R-C4d levels might be capable of distinguishing flare vs. infection in patients with SLE.

Method: R-C4d levels were measured using flow cytometry in non-SLE and SLE patients who were hospitalized for acute infections. SLE subjects with concurrent active disease defined by SLEDAI >=4 or BILAG A or B were excluded. Both groups were followed longitudinally if baseline levels of R-C4d > 1.9 (0.75 SD of levels in healthy controls). R-C4d levels were compared with historical controls (70 non-SLE and 49 SLE without infection respectively). The historical SLE controls did not have active disease as defined by SLEDAI <4.

Results: The acute infections of 24 non-SLE and 6 SLE subjects included urinary tract infection, pneumonia, Clostridium difficile colitis, cellulitis, peritonitis, pyelonephritis, sepsis, septic joint, impetigo, psoas abscess, osteomyelitis, ascending cholangitis and line infection. R-C4d remained low although slightly increased in non-SLE patients with infection compared to historical non-SLE controls without infection (median: 0.86 vs. 0.53, $p<0.01$ respectively). No significant difference was found in the levels of R-C4d in SLE patients with acute infection compared with historical SLE controls without infection (median: 2.22 vs. 2.65, $p= 0.14$ respectively). In the three non-SLE patients with acute infection that were followed longitudinally, R-C4d levels decreased as the infection cleared. No consistent pattern was observed in the three SLE patients with acute infection.

Conclusion: R-C4d levels are slightly increased in non-SLE patients in setting of acute infection; however, these levels remain below those observed in patients with SLE. There was no significant change in RC4d in the setting of infection in patients with SLE. These initial observations support the potential for RC4d to serve as a biomarker of disease activity in SLE and to facilitate distinction of flare versus infection in lupus patients.

The Size, but Not the Number, of CD-163+ Histiocytes in the Bone Marrow Predicts Macrophage Activation Syndrome in Adults with Systemic Lupus Erythematosus. B. Shakoory[1], R. D. Sanders[2], V. Reddy[2], N. Mccollum[2], G. S. Alarcon[1], W. W. Chatham[1] and R. Q. Cron[3], [1]UAB Rheumatology, Birmingham, AL, [2]UAB Pathology, Birmingham, [3]UAB Pediatric Rheumatology, Birmingham, AL

Purpose and Background: Distinguishing macrophage activation syndrome (MAS) in the setting of active systemic lupus erythematosus (SLE) presents a challenge. The impact of early diagnosis and treatment of MAS on the outcome emphasizes the importance of markers for quick and unequivocal diagnosis. We explored a role for CD-163 staining in identification of bone marrow hemophagocytosis and examined the correlation of number and size of hemophagocytes with diagnosed MAS in patients with SLE.

Methods: Bone marrow biopsy specimens from 18 patients with confirmed SLE (4 ACR criteria) obtained between 2001 and 2008 were evaluated by hematopathologists after conventional staining and re-evaluated after staining for CD-163, a surface marker for activated macrophages (histiocytes). The degree of hemophagocytosis was graded from 0-4 as compared with 6 negative and 9 positive controls. The number and average surface area of the stained macrophages were established using Image J, 1.40 software. The available clinical, radiographic and laboratory data from the charts were reviewed and abstracted. All CD-163 evaluations were independent and blinded to the prior pathology assessments and the clinical and radiographic data. Correlations between CD-163 counts and cell size and clinical/radiographic data were assessed. The association between the number and size of hemophagocytes and the presence of MAS was examined with standard descriptive statistical tests; p was set at <0.05.

Results: The patients were all above 18 years with a mean age of 45.3 years, with 88.9% women and 66.7% African-Americans. Four of the patients (22%) had 5 of the 2004 hemophagocytic lymphohistiocytosis (HLH) criteria required for the diagnosis of hemophagocytic syndrome. The average CD-163 count was 55.5 (95% CI: 48-62) per 40x objective, 285.7 x 214.2 μm field with an average histiocyte size of 75.3 microns (95% CI: 64.5-86.1). The sensitivity of identifying hemophagocytosis increased from 14% in the initial general evaluation using routine H&E staining to 81% in a targeted search by a trained hematopathologists using CD-163 immunostaining. Interestingly, the mean size but not the number of the hemophagocytes was correlated with the presence of MAS in SLE (p=0.02).

Conclusion: CD-163 staining of bone marrow biopsies from patients with SLE allows for detailed characterization and significantly increases the sensitivity of detecting hemophagocytic macrophages in the bone marrow. The size, and not the number, of the hemophagocytic cells is associated with the presence of overt MAS in patients with SLE. Hence, CD-163 bone marrow immunostaining can be used for confirmation of clinically suspected MAS in adults with SLE.

The Relationship of Physical Activity to Lupus Activity and Damage. Stacy D. Kennedy[1], Megan E. B. Clowse[1], Lisa G. Criscione-Schreiber[1], Martin Tochacek[1], Stacy P. Ardoin[2] and Kim M. Huffman[1], [1]Duke University, Durham, NC, [2]Ohio State University Medical Center, Columbus, OH

Purpose: Systemic lupus erythematosus (SLE) places patients at increased risk for cardiovascular disease. Studies have shown exercise lowers cardiovascular risk. U.S. guidelines recommend 30 minutes per day of moderate activity 5 days weekly for optimal health. We aimed 1) to measure the physical activity of women with SLE with a self-report tool, the Stanford Brief Activity Survey (SBAS), 2) to correlate SBAS scores with objectively measured physical activity in this population, and 3) to evaluate relationships between SBAS scores and SLE disease activity and organ damage.

Method: The SBAS was administered to 45 women with SLE between October 2008 and February 2009. Self-reported physical activity on-the-job and during leisure time was determined using the SBAS. Participants were separated into groups based on activity level from inactive

to hard intensity. In 23 participants, physical activity was measured with 7 days of accelerometry. Current disease activity was assessed with the Systemic Lupus Erythematosus-Disease Activity Index (SLEDAI) and overall disease damage was assessed with the Systemic Lupus International Collaboration Clinics (SLICC). Spearman correlation coefficients and one-way frequencies were determined.

Results: Mean age of participants was 36 (SD 11.5) years. A full 76% of participants did not meet recommended physical activity guidelines. SBAS scores were related to the accelerometer data (r=0.45, p=0.03). SBAS scores inversely correlated with organ damage (SLICC r=-0.40, p=0.01), but did not correlate with current SLE disease activity (SLEDAI r=0.12, p=0.45).

Conclusion: The majority of women in this study do not engage in regular exercise. The lack of physical activity was not related to current disease activity, but was related to morbidity associated with SLE. The SBAS appears to be a useful tool to gauge physical activity in this population. Given the increased cardiovascular risk in women with SLE, it is critical to better understand why these individuals do not meet recommended guidelines for physical activity.

Table Objectively Measured Physical Activity, SLE Disease Activity and SLE Disease Damage by SBAS Category (n= 45).

SBAS Categories	Inactive N=17 (37.8%)	Light Intensity N=17 (37.8%)	Moderate Intensity N=6 (13.2%)	Hard Intensity N=5 (11.1%)	r	P values
Accelerometer exercise (min/day)	9.77	14.27	18.86	38.33	0.45	0.03
SLEDAI	1.75	3.44	4.00	0.75	0.12	0.45
SLICC	1.88	1.38	0.20	0.25	-0.40	0.01
ESR (mm/hr)	46.31	49.60	35.29	8.50	-0.35	0.02
Body mass index, (kg/m2)	31.16	36.01	30.33	24.98	-0.13	0.38

Quality of Life in Cutaneous Lupus Erythematosus. Rachel Klein[1], Siamak Moghadam-Kia[1], Jonathan LoMonico[1], Joyce Okawa[1], Katherine Chilek[1], Elizabeth Gaines[1], Chris Coley[1], Lynne Taylor[1], Mary-Margaret Chren[2] and Victoria P. Werth[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of California San Francisco, San Francisco, CA

Purpose: Cutaneous lupus erythematosus (CLE) is a chronic autoimmune disease that can cause significant disfigurement and often requires lifelong treatment with toxic medications. The purpose of this study was to assess the relationship between CLE and quality of life (QOL). We specifically sought to compare QOL in CLE to other diseases and to determine which independent variables are associated with poor QOL.

Method: All patients with CLE or SLE were invited to participate in the study. Subjects were asked to complete the Skindex-29, which assesses QOL in terms of symptoms, emotions, and functioning, with higher scores indicating worse QOL. They were also asked to provide demographic and basic medical history information. Disease severity was assessed with the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). Mean Skindex-29 scores in CLE were compared to norms for other diseases. Mean scores within the CLE population were compared between different genders, ethnicities, and disease subtypes. Pearson's correlation coefficients were calculated for Skindex-29 scores and disease severity, age, and age at diagnosis.

Results: 157 subjects were included in the analysis. Overall, patients with lupus were most affected in the emotions domain (m=48, SD=28) relative to symptoms (m=40, SD=23) and functioning (m=28, SD=25). The subscales were highly intercorrelated, such that a high score in one tended to be associated with high scores in the others (Pearson's r range 0.65-0.78, all $p<0.0001$). Compared to 8 other diseases, QOL in lupus was significantly impaired across all three domains; with respect to symptoms, only vulvodynia (m=50, SD=17) and eczema (m=48, SD=23) had higher scores than CLE (all $p<0.0001$). In the emotions domain, lupus was comparable to dermatomyositis (mean=45, SD=27) and vulvodynia (m=50, SD=20), and the other diseases were all less affected (all $p<0.0009$). For functioning, only patients with vulvodynia

(m=44, SD=22) were more impaired than patients with lupus (p<0.0001). Female gender was associated with poor quality of life in all three domains (all p<0.006), however there was no significant difference in QOL amongst different ethnicities or disease subtypes. There was a correlation between increased disease severity and worse QOL across all three subscales (Pearson's r range 0.27-0.38, all p<0.0006). There was a small correlation between younger age and worse symptoms (Pearson's r -0.16, p=0.04) and emotions scores (Pearson's r -0.22, p=0.005). There was also a small correlation between younger age at diagnosis and worse symptoms scores (Pearson's r -0.19, p=0.04).

Conclusion: CLE has a profoundly negative impact on QOL, particularly in women and individuals with severe disease. Poor QOL has been linked to psychiatric comorbidity (Sampogna et al, Psychosom Med 2004), therefore it is important to acknowledge and address this issue with patients.

Comparison of Psychometric Properties of Health Related Quality of Life (HRQoL) Measures Employed in Adults with Systemic Lupus Erythematosus (SLE) - Review of the Literature. Madhura Castelino[1], Janice Abbott[2], Kathleen McElhone[3] and Lee-Suan Teh[4], [1]SpR, Blackburn, United Kingdom, [2]Psychologist, Preston, United Kingdom, [3]Research Associate, Blackburn, United Kingdom, [4]Rheumatologist, Blackburn, United Kingdom

Purpose: Patients with SLE have impaired HRQoL and thus well validated and reliable measures are needed to determine patient-based outcomes. A systematic review of the literature was carried out to evaluate validation studies of HRQoL measures in adults with SLE.

Methods: Full original papers in English were located with key words 'Lupus' and 'Quality of Life' as search strategy in the following databases; MEDLINE, EMBASE, Web of Science, CINAHL, PsycINFO and Health and Psychosocial Instruments. The psychometric properties of the HRQoL measures identified were evaluated using the checklist published by Bot et al[1].

Results: In total 13 papers were relevant. Six were validation studies for generic instruments and used the Short Form-36 (SF-36) (n=4), Quality of Life Scale (QOLS), EuroQoL-5D (EQ-5D) or the Short Form-6D (SF-6D). The remaining seven papers employed one of the disease-specific measures: SLEQOL, L-QOL, SLE Symptom Check List (SSC), LupusQoL (UK) and LupusQoL (US). Some of the psychometric properties are tabulated.

Measure	Construct Validity	Internal Consistency	Floor and ceiling effects	Test-retest reliability	Responsiveness	Interpretability
Chinese SF-36	+	+	[ ]	+	[ ]	[ ]
SF-36 (Singapore)	+	+	[ ]	+	[ ]	+
SF-36 (UK)	+	+	[ ]	[ ]	[ ]	+
EQ-5D	+	[ ]	+	+	+	+
SF-6D	+	[ ]	+	+	+	+
QOLS	+	+	[ ]	+	[ ]	+
SLEQOL	+	+	-	+	+	+
SSC	+	+	[ ]	+	+	+
L-QoL	+	+	+	+	[ ]	+
LupusQoL (UK)	+	+	+	+	[ ]	+
LupusQoL (US)	+	+	[ ]	+	[ ]	+

+: adequate property

[ ]: no information found

-: inadequate property

Using this checklist, the SF-36 and all the disease-specific measures had good internal consistency. All the measures demonstrated good construct validity, test-retest reliability and interpretability. Floor and ceiling effects and responsiveness (sensitivity to change) were only examined in five instruments. Measures varied in their ease of scoring. All the disease-specific measures had acceptable administration time, comprehensibility and content validity. The minimum clinically important difference was only determined in one paper (SLEQOL).

Conclusion: Generally, the psychometric properties of HRQoL measures employed in SLE are adequate. However, the checklist used in this work may not identify the most appropriate criteria for the evaluation of psychometric quality. It is notable that some properties such as responsiveness, floor and ceiling effects have not been evaluated for some of these measures. Full psychometric evaluation is essential before these instruments can be recommended as patient-based outcome measures in adult SLE patients.

Hydroxy-Chloroquine Use and Disease Specific Health Related Quality of Life in Systemic Lupus Erythematosus. Meenakshi Jolly, Diana Segalite Sandler, Winston Sequeira and Joel A. Block, Rush University Medical Center, Chicago, IL

Purpose: Treatment of Systemic Lupus Erythematosus (SLE) with hydroxy-chloroquine (HCQ) has many known benefits, but its benefits on patient reported health outcomes such as Health Related Quality of Life (HRQOL) has not been previously studied. We have found SLE patients on HCQ to have better HRQOL using generic measures of HRQOL. Hence we hypothesized that HRQOL among SLE patients on HCQ will be better than non HCQ users, utilizing disease specific HRQOL tool (LupusQoL-US) as the outcome measure.

Method: We used a previously established data base on health outcomes in SLE to compare demographics, disease characteristics, and HRQOL among HCQ users and non-users. All patients met the American College of Rheumatology Classification Criteria for SLE. Data were available on 230 SLE patients cross-sectionally, collected using chart reviews, history, physical exam, and HRQOL. HCQ use was determined by patient self-report and confirmed by medical chart review. HRQOL was estimated using generic measures LupusQoL-US which has eight domains: Physical health, Pain, Planning, Intimate Relationships, Burden to Others, Emotional Health, Body Image, and Fatigue. We used chi square test to compare categorical data and Non Parametric Tests (Mann Whitney) compared continuous data not normally distributed. A p value of ≤ 0.05 on two tailed test was considered significant.

Results: Mean subject age was 42 ± 13 years. 60% of subjects were African American, 20% Caucasian, 14% Hispanic, and 6% Asian. Both groups were similar in age and ethnicity. Disease activity was similar in the two groups, however disease damage was lower (Mean ± SD, Median) in the HCQ users: SLEDAI Score (5.7±5.2, 5.0 vs 5.2±5.9, 4.4; p=0.10,) SLICC total score (1.1±1.5, 1.0 vs 1.5±1.6, 1.0; p=0.02.) HRQOL was similar among HCQ users (72% of patients) and non users, using the LupusQoL-US: HCQ users did not have better HRQOL (Mean ± SD, Median) vs. non users: Physical health (50.7±1.9, 53.1 vs 47.7±3.5, 46.4; p=0.8), Pain (48.4±2.4, 50.0 vs 44.6±3.9, 45.8; p=0.4), Planning (56.4±2.3, 58.3 vs 53.2±4.3, 58.3; p=0.8), Intimate Relationships (58.8±2.8, 62.5 vs 65.4±4.5, 75.0; p=0.9), Burden to Others (48.5±2.4, 50.0 vs 43.1±4.6, 45.8; p=0.09), Emotional Health (55.8±2.0, 58.3 vs 58.4±4.1, 66.7; p=0.7), Body Image (56.6±2.4, 56.3 vs 61.3±4.2, 70.0; p=0.8), and Fatigue (42.0±2.3, 43.8 vs 47.9± 4.2, 50.0; p= 0.9.)

Conclusion: Though HCQ use is associated with decreased disease damage accrual, it does not translate into a better HRQOL status on the LupusQoL-US measure. Similar results were seen when LupusPRO (another disease specific measure for HRQOL) was used (Data not included). Larger studies are needed to obtain better insight into this lack of correlation.

Is Cigarette Smoking An Independent Correlate of Health Related Quality of Life in Patients with Systemic Lupus Erythematosus?
Meenakshi Jolly, Ravikumar Patel, Rohit Aggarwal, Winston Sequeira and Joel A. Block, Rush University Medical Center, Chicago, IL

Purpose: To determine if cigarette smoking is an independent determinant of health related quality of life (HRQOL), irrespective of its association with disease activity and damage in patients with systemic lupus erythematosus (SLE).

Methods: The data were extracted from an ongoing study on HRQOL in SLE. Consecutive consenting adult SLE patients seen in the rheumatology clinic at an academic hospital were enrolled from September 2006 to April 2008 and detailed clinical and demographic variables were collected from 216 SLE patients. The HRQOL was assessed by MOS-SF-36 and EuroQol-5D (EQ-5D). The SF-36 has 8 domains: Physical Functioning, Role Physical, Bodily Pain, General Health, Vitality, Social Functioning, Mental Health and Role Emotional. It also provides two summary scores: Physical Component Score (PCS) and Mental Component Score (MCS). The EQ-5D is composed of the following domains: Mobility, Self care, Usual Activities, Pain/Discomfort and Anxiety/Depression. In addition, it includes a Visual Analog Scale (VAS) and an EQ-5D Summary Index. Smoking was defined as present if the subject reported smoking at the time of the study. Chi-Square test and Mann Whitney test were used to make comparisons between the cases 'smoker' and controls 'non-smoker'. Hierarchical linear regression analysis was performed using HRQOL as the dependent variable. In first model, the predictor variable was disease activity (SLEDAI). In second model, disease damage (SLICC) was added to first model. In final model, we added smoking status to second model. R square change for each model was noted. $P < 0.05$ was considered significant on one tailed test.

Results: The mean (±SD) age of participants was 42 ± 13 years and 93 % were females. The ethnic composition was: African American 60%, Caucasian 20%, Hispanic 14% and Asian 6%. Fifteen percent of subjects reported "currently smoking" status at the time of the study. Smokers had worse HRQOL than non smokers: specifically, differences were noted for physical function, bodily pain and vitality domains of SF-36 as well as on PCS (mean ± S.D, median) : physical functioning (45.6 ± 28.3, 50 vs. 56 ± 28.8, 55; p 0.047), bodily pain (38.2 ± 18.5, 41 vs. 54.6 ± 27.6, 51; p 0.001), vitality (38.2 ± 21.4, 45 vs. 49.1 ± 21.6, 50; p 0.012) and PCS (31.1 ± 9.4, 31 vs. 36.1 ± 11.2, 36.6; p 0.017). On EQ5D, smokers had worse functioning on anxiety/depression and visual analog scale: anxiety/depression for extreme problems (10 % vs. 4.5 %, p 0.049), anxiety/depression for some problems (56.6 % vs. 42.3 %, p 0.049) and visual analog scale (61.5 ± 22.4, 60 vs. 68.9 ±20, 70; p 0.048).

On hierarchical regression analysis, disease activity alone explained 3% of the variance in PCS (R square 0.027); disease activity and damage explained similar variance in PCS (R square change 0.028) and addition of smoking variable, increased the variance explained in PCS to 5% (R square change 0.049).

Conclusion: Cigarette smoking is independently associated with worse health outcomes in SLE, although it explains a relatively minor component of variance. Patients with SLE should be screened aggressively and counseled for their smoking history.

What Does Patient-Reported Systemic Lupus Activity Questionnaire (SLAQ) Measure?
Meenakshi Jolly[1], Mariko L. Ishimori[2], Ioana Moldovan[3], Emmanuel P. Katsaros[4], Karina D. Torralba[5], Dilrukshie Cooray[6], Shuntaro Shinada[5], Joel A. Block[1], Daniel J. Wallace[7], Michael H. Weisman[8] and Perry Nicassio[9], [1]Rush University Medical Center, Chicago, IL, [2]Cedars-Sinai Medical Center, LA, CA, [3]Loma Linda Univ Med Ctr, Loma Linda, CA, [4]Loma Linda Univ, Loma Linda, CA, [5]Keck School of Medicine, University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [6]Harbor-UCLA Medical Center, Torrance, CA, [7]Cedars-Sinai Medical Center, West Hollywood, CA, [8]David Geffen School of Medicine at UCLA, Los Angeles, CA, [9]UCLA, LA, CA

Purpose: Systemic Lupus Activity Questionnaire (SLAQ) is a validated 24-item weighted lupus symptom index based on the physician-reported systemic lupus activity measure (SLAM), developed to track disease activity in an economical way for large groups of systemic lupus erythematosus (SLE) patients in clinical studies. It has been validated against SLAM, but its validity against Physician Global Assessment (PGA) and SLE Disease Activity Index (SELENA-SLEDAI) is not known. The objective of this study was to determine the correlation of SLAQ with PGA, SLEDAI and adjusted SLEDAI. The latter is derived by excluding the laboratory based SLEDAI assessment criteria. Also, correlation of SLAQ, PGA and SLEDAI with subject demographics was sought.

Method: Cross sectional Data from 98 SLE subjects collected from the PATROL (Patient-Reported Outcomes in Lupus) study was analyzed. PGA data was available for only 32 subjects. Descriptive, Spearman correlation coefficients were obtained between a) the three

disease activity measures, b) Demographics (Age, ethnicity, education, insurance, marital status, socio-economic status) with the three disease activity measures. Multiple linear regression with SLAQ as the dependent and significant demographic variables as the independent variables was performed. P value of ≤ 0.05 on two tailed tests was considered significant.

Results: 96% of SLE patients were women**.** 48% were Caucasians and 52% were Hispanics. Mean (SD) age was 44.2 (13.4) yrs. Median (IQR) disease activity scores were: SLAQ 12 (17.3), PGA 0.50 (1), SLEDAI 2.0 (4), adj SLEDAI 0 (2). Correlation between SLAQ and SLEDAI, adj SLEDAI and PGA were 0.06 (p=0.6), 0.19 (p=0.08) and 0.19 (p=0.30) respectively. SLEDAI and adj SLEDAI did not correlate with demographics. PGA correlated with age (-0.35, p=0.05) and ethnic minority (-0.40, p-0.02). SLAQ correlated with ethnic minority (-0.51, p=0.000), home ownership (-0.34, p=0.001), income (-0.29, p=0.007), annual household income (0.36, p=0.001), highest grade achieved (0.46, p=0.000) and insurance type (-0.62, p=0.000). These variables collectively explained 46% of the variance observed in the SLAQ score on regression analysis.

Conclusion: Patient reported SLAQ measure does not correlate with SLEDAI or PGA. Furthermore SLAQ scores are significantly influenced by socio-economic variables, especially insurance type and ethnic minority status.

Validation of the SF-36 in Patients with Systemic Lupus Erythematosus (SLE). Jennifer L. Beaumont[1], Jin-Shei Lai[1], David Cella[1], P. Brunetta[2] and Sarika Ogale[2], [1]Northwestern University, Chicago, IL, [2]Genentech, Inc, South San Francisco, CA

Purpose: Systemic lupus erythematosus (SLE) is a multiple organ system autoimmune disease that has an impact on patients' health-related quality of life (HRQOL). The purpose of this study was to validate the SF-36, a widely used measure of HRQOL, for use in moderately-severely active extra-renal SLE patients.

Method: 254 SLE patients, who were participating in a clinical trial of rituximab (the EXPLORER trial), completed the following scales at baseline and weeks 12, 24, and 52: the SF-36, Brief Pain Inventory (BPI), and Patient Global Assessment Visual Analog Scale (PGA). Physicians completed the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and the British Isles Lupus Assessment Group (BILAG) disease activity index at the same time points. We used changes in the BILAG General and Musculoskeletal domains as anchors to evaluate responsiveness and MID of the SF-36 Physical Component Score (PCS). A change in BILAG domain scores from A to B or better, or B to C or better, was classified as improved, and the reverse as worsened. A change from C to D/E or vice-versa was not considered clinically significant and classified as unchanged. PGA scores were categorized as improved or worsened if there was a >30% decrease or increase from baseline respectively, and used as anchors for the PCS and Mental Component Summary (MCS) scores.

Results: All SF-36 scores were 1-2 standard deviations (SD) lower than the US general population at baseline. Internal consistency of most of the SF-36 subscales was supported by Cronbach's alpha > 0.80 at all time points. In cross-sectional analyses, PCS scores successfully differentiated between groups defined by BILAG General and Musculoskeletal domain ratings at most visits. SF-36 had moderate (r = 0.40-0.65) correlations with BPI and PGA scores. Correlations with BILAG and SLEDAI total scores were low (r = 0.12-0.29). Mean changes from baseline in the eight SF-36 domain scores, PCS and MCS, were generally in agreement with improved, unchanged and worsened PGA scores. Patients with improved or unchanged BILAG General and Musculoskeletal status compared to baseline experienced a statistically significant improvement in most SF-36 PCS scores with effect sizes (mean change / SD) in the range of 0.3 to 0.7. Scores remained stable for patients with worsened BILAG ratings compared to baseline with effect sizes generally less than 0.3. Distribution and anchor-based estimates of the minimally important differences (MID) suggested MIDs of approximately 3-6 points.

Conclusion: The SF-36 is a valid and responsive measure of HRQOL in patients with SLE. MIDs in SLE patients are similar to those derived previously in other populations. Since few patients experienced worsening of BILAG General and Musculoskeletal domains and PGA in this study, further research is warranted to evaluate responsiveness of the SF-36 to worsening in this population.

EQ-5D and SF-36 Quality of Life Measures in Systemic Lupus Erythematosus: Comparisons with RA, Non-Inflammatory Rheumatic Disorders (NIRD), and Fibromyalgia (FM). Frederick Wolfe[1], KD Michaud[2], Tracy Li[3] and RS Katz[4], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]U Neb Med Cntr and NDB, Omaha, NE, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Rheumatology Associates, Chicago, IL

Purpose: The SF-36 provides numerical measurement of patient health, but does not include preferences for health states and cannot be used in cost-effectiveness analyses. By contrast the EQ-5D is based on preferences and produces utility scores. However, EQ-5D has not been used before in SLE. In this project we describe the comparative HRQOL of the four groups of rheumatic disease patients according to SF-36 and EQ-5D - EQ-5D VAS results, examine predictors of HRQOL in SLE, and characterize results in term of patients' satisfaction with health.

Methods: We studied 1,316 patients with SLE, 13,722 with RA, 3,623 with NIRD, and 2,733 with FM. We determined SLE damage by the newly developed Lupus Damage Index Questionnaire (LDIQ), a self-report version of the ACR/Systemic Lupus International Collaborating Clinics (SLICC) Damage Index (SDI).

Results: The mean EQ-5D, PCS and MCS scores were 0.72, 36.3, and 44.3 in SLE (Table 1). There was essentially no difference among EQ-5D and PCS scores for patients with SLE, RA, or NIRD. MCS was lower in SLE compared with RA and NIRD (44.3, 49.1, 50.8). All scores were much more abnormal in FM (0.61, 31.9, 41.9). Within SF-36 domains, function was better, but general health, vitality, social function, emotional role, and mental health were more impaired in SLE compared with RA and NIRD. In SLE, QOL was predicted by damage (Figure 1), comorbidity, household income, education, and age. 15% of patients with SLE were very satisfied with their health, and their QOL scores (0.84, 45.4, 50.1) were the similar to those as found in the population for EQ-5D and MCS, but slightly reduced for PCS.

Conclusion: HRQOL in SLE, RA, and NIRD is similar with respect to SF-36 PCS and EQ-5D. SLE patients have the lowest MCS scores of the 3 disorders. Patients with fibromyalgia have the lowest HRQOL scores, regardless of measure. HRQOL in SLE is predicted by damage, comorbidity, age, household income, and educational attainment. About 47% of SLE patients are somewhat (22.1%) or very satisfied (15.1%) with their health.

Table 1. SF-36 and utility scores in SLE, RA, NIRD, and FM.

Health Status Variables	*SLE (N=1,316)*	*RA (N=13,722)*	*NIRD (N=3,623)*	*Fibromyalgia (N=2,733)*
SF-36 domains	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)
Physical function	52.7 (30.6)	49.5 (29.5)	47.6 (28.1)	40.7 (26.3)
Physical role	36.3 (41.5)	39.9 (42.0)	39.5 (41.6)	19.2 (32.3)
Pain total	48.5 (24.1)	50.1 (23.1)	48.3 (21.6)	34.3 (19.5)
General health	37.5 (23.0)	49.4 (23.3)	55.8 (22.5)	39.2 (22.1)
Vitality	35.9 (23.1)	43.4 (23.4)	46.1 (23.1)	27.1 (21.1)
Social function	62.0 (27.9)	69.7 (27.5)	71.6 (26.9)	51.8 (28.2)
Emotional role	54.5 (43.9)	63.5 (42.4)	65.6 (41.4)	43.9 (43.9)
Mental health	67.1 (20.3)	72.9 (18.9)	75.0 (18.2)	62.5 (21.8)
SF-36 Summary Scores				
Physical component score	36.3 (11.5)	36.7 (11.3)	36.4 (10.8)	31.9 (9.6)
Mental component score	44.3 (11.8)	49.1 (11.4)	50.8 (11.4)	41.9 (12.5)

Utilities				
EQ-5D VAS (0-1)	0.64 (0.21)	0.66 (0.21)	0.68 (0.20)	0.57 (0.22)
EQ-5D (US) (0-1)	0.72 (0.21)	0.73 (0.19)	0.73 (0.18)	0.61 (0.22)

Predictors of Osteoporotic Fracture in SLE. Monthida Fangtham[1] and Michelle Petri[2], [1]Good Samaratan Hospital, Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD

Purpose: Osteoporosis and osteoporotic fractures are the most frequent organ damage in systemic lupus erythematosus (SLE). We assessed the association between osteoporotic fractures and SLE clinical features, other organ damage and the impact of treatment, especially corticosteroids.

Method: In this large prospective cohort study of 1799 SLE patients, there were 340 osteoporotic fractures. Variables evaluated were sociodemographic data, disease variables, clinical features, organ damage, the use of corticosteroids and other complications. Clinical associates of fractures were determined by univariate and multivariate analyses.

Results:

Factor	Fracture Positive	Fracture Negative	P-value	Odds Ratio (95% CI)
African-American	32%	42%	0.0021	0.67 (0.52, 0.86)
Smoking ever	45%	37%	0.0092	1.38 (1.09, 1.76)
Raynaud's syndrome	65%	49%	<0.0001	1.93 (1.51, 2.47)
Renal insufficiency	23%	16%	0.0051	1.54 (1.15, 2.06)

Factor	Fracture Positive	Fracture Negative	P-value	Odds Ratio (95% CI)
Lupus anticoagulant	32%	24%	0.0052	1.46 (1.13, 1.90)
Prednisone ever	91%	83%	0.0001	2.15 (1.43, 3.22)
Prednisone use currently	64%	53%	0.0004	1.54 (1.21, 1.97)
Pulse steroid ever	47%	33%	<0.0001	1.79 (1.41, 2.28)
Obesity	50%	38%	<0.0001	1.66 (1.30, 2.10)

In the best multivariable model, African-American ethnicity, smoking ever, Raynaud's syndrome, lupus anticoagulant, prednisone ever, pulse steroid ever and obesity remained significant.

Conclusion: This study identified multiple risk factors for osteoporotic fracture in SLE. Corticosteroid use (ever, current, pulse) was a strong risk factor. For the first time, smoking, Raynauds', renal insufficiency, and antiphospholipid antibodies have been identified as additional risk factors.

Serum Concentrations of 25-OH Vitamin D in SLE Patients Are Inversely Related to Disease Activity- Is It Time to Routinely Supplement SLE Patients with Vitamin D? Howard Amital[1], Zoltá Szekanecz[2], Gabriella Szücs[3], Katalin Dankó[3], Endre Nagy[4], Tünde Csépány[3], Emese Kiss[5], Andrea Doria[6], Nadia Corocher[6], Nancy Agmon-Levin[7], Hedi C. Orbach[8], Gisele Z. Goddard[8] and Yehuda Shoenfeld[9], [1]Sackler Faculty of Medicine, Tel-Aviv University, Kfar-Saba, Israel, [2]University of Debrecen medical and Health Sciences Center, Debrecen, Hungary, [3]University of Debrecen Med Ctr, Debrecen, Hungary, [4]University of Debrecen Medical and Health Science Center, Debrecen, Hungary, [5]5Division of Rheumatology, University of Debrecen Medical and Health Science Center, Debrecen, H-4012, Hungary, Debrecen, Hungary, [6]University of Padova, Padova, Italy, [7]Center for Autoimmune Diseases, Sheba Medical Center, Israel, Ramat Gan, Israel, [8]Wolfson Medical Ctr, Holon, [9]Sheba Medical Center, Ramat Gan, Israel

Purpose: Low serum vitamin D concentrations were reported in several autoimmune disorders. The purpose of this study was to assess whether low serum vitamin D concentrations are related to disease activity of SLE patients.

Method: 378 patients were pooled from several European and Israeli cohorts and their disease activity was measured by two different methods; 278 patients had SLE disease activity-2000 (SLEDAI-2K) scores and 100 patients had European Consensus Lupus Activity Measurement (ECLAM) scores. The disease activity scores were measured on the day their serum samples were drawn. In order to combine the two systems we converted the scores into standardized values (z-scores), this manner enabled univariate summary statistics for the two variables (SLEDAI-2K and ECLAM).

We used the commercial kit, LIAISON® 25 OH Vitamin D Assay (310900-Diasorin) in order to measure serum concentration of 25 OH Vitamin D in 378 patients with SLE. The method for quantitative determination of 25 OH Vitamin D is a direct, competitive chemiluminescence immunoassay.

Results: In this cohort there were 31 male and 347 females patients, vitamin D levels did not differ between genders; the vitamin D serum concentration was 21.7±13.2 vs. 20.5±14.4 ng/ml in males vs. females respectively (p value not significant, p=0.67). A significant negative correlation was demonstrated between the serum concentration of vitamin D and the standardized values (z-scores) of disease activity scores as measured by the SLE-DAI2k and ECLAM scales (Pearson's correlation coefficient of -0.12, p=0.018).

As a comparator we analyzed serum anti-DNA antibodies in these two categories of patients and observed a higher titer according to the chemiluminescence immunoassay units (113.5±212.9 vs. 22.3±38.7, p<0.001). However anti-DNA antibody titers did not correlate with disease activity (Pearson's correlation coefficient of 0.05, p=0.54).

Conclusion: In a cohort of SLE patients originating from Israel and Europe vitamin D serum concentrations were found to be inversely related to disease activity.

Prevalence and Clinical Predictors of Osteonecrosis in Systemic Lupus Erythematosus. Ashima Makol[1] and Michelle A. Petri[2], [1]Michigan State University, East Lansing, MI, [2]Johns Hopkins University, Baltimore, MD

Purpose: Osteonecrosis (ON) is a devastating complication often leading to rapid joint destruction and disability in young women with systemic lupus erythematosus (SLE). We aimed to determine the prevalence, clinical and laboratory predictors of ON in SLE patients from a large prospective cohort to identify patients at risk who could potentially benefit from early therapeutic intervention.

Method: A large prospective cohort was reviewed to identify SLE patients who developed ON at one or more sites. Clinical and laboratory parameters of SLE patients who developed ON were compared versus those who did not. Statistical analysis was done using chi-square test or Fisher's exact test for dichotomous variables and Student's t-test for continuous variables. A P value of less than 0.05 was considered statistically significant in all comparisons in the study. **Results:**

Factor	ON Positive	ON Negative	P-value	Odds Ratio (95% CI)
African-American	63%	37%	<0.0001	2.84 (2.05, 3.92)
Smoking (current)	23%	16%	0.0383	1.50 (1.04, 2.17)
Raynaud's	60%	51%	0.0241	1.43 (1.05, 1.96)
Vasculitis	30%	13%	<0.0001	2.79 (1.97, 3.94)
Lupus anticoagulant	33%	25%	0.0228	1.49 (1.06, 2.08)
Anti-dsDNA positive	66%	56%	0.0095	1.54 (1.12, 2.12)
Low C3	70%	52%	<0.0001	2.15 (1.55, 2.99)
LowC4	61%	46%	0.0001	1.83 (1.34, 2.50)
Deep venous thrombosis	18%	12%	0.0352	1.58 (1.05, 2.36)
Stroke	14%	7%	0.0064	1.95 (1.23, 3.08)
Myocardial Infarction	8%	4%	0.0349	1.96 (1.08, 3.56)
Digital Gangrene	5%	1%	0.0008	4.17 (1.95, 8.91)
Other Venous thrombosis	9%	4%	0.0064	2.23 (1.28, 3.86)
Any Venous thrombosis	28%	17%	0.0002	1.96 (1.39, 2.77)
Any Arterial thrombosis	25%	14%	0.0003	2.03 (1.41, 2.92)
Prednisone (ever)	99%	83%	<0.0001	18.4 (4.54, 74.6)
Pulse steroid	66%	32%	<0.0001	4.19 (3.03, 5.79)
Prednisone highest dose	71.9 ± 40.5	41.3 ± 39.8	<0.0001	

In the multiple variable model, African-American ethnicity, smoking, Raynaud's, vasculitis, lupus anticoagulant, low C3, and venous thrombosis all remained significant.

Conclusion: The association of corticosteroids with ON in SLE is well known. This prospective study also identified other potential mechanisms, including smoking, Raynaud's, low C3 and vasculitis – all of which damage vessels. We found an association with the lupus anticoagulant and with thrombosis. Corticosteroids, smoking, low C3, Raynaud's, and antiphospholipid antibodies are all potentially modifiable risk factors. Whether an antiplatelet therapy would be helpful must be determined in larger databases.

Lupus in Asian Canadians: The 1000 Canadian Faces of Lupus Study. C. A. Peschken[1], Janet E. Pope[2], Earl D. Silverman[3], P. R. Fortin[4], Christian A. Pineau[5], Michel Zummer[6], Murray Urowitz[7], Dafna Gladman[4], M. Hudson[5], Lori B. Tucker[8], G. Chedeville[5], A. Huber[9], S. Bernatsky[10], Ann E. Clarke[11], C. Douglas Smith[12], H. Arbillaga[13], SE. Ramsey[14] and CaNIOS Investigators, [1]Univ of Manitoba, Winnipeg, MB, [2]St Joseph Health Care London, London, ON, [3]Hosp for Sick Children, Toronto, ON, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]McGill University, Montreal, QC, [6]Ch Maisonneuve-Rosemont, Montreal, [7]U of Toronto, Toronto Western Hospital, Toronto, ON, [8]BC Childrens Hospital, Vancouver, BC, [9]IWK Health Centre, Halifax, NS, [10]MUHC, Montreal, QC, [11]McGill University Health Center, Montreal, QC, [12]TOH Riverside Campus, Ottawa, [13]CaNIOS, ON, [14]IWK Health Ctr, Halifax

Purpose: There are few reports of systemic lupus erythematosus (SLE) in North American Asians. We describe differences in disease expression, disease activity and damage between Asian (ASN) and Caucasian (CAU) SLE patients in a large multicentre cohort.

Method: SLE patients were enrolled in a multi-centre cohort and followed annually. Sociodemographic factors, diagnostic criteria, disease activity, treatment, damage, and self-reported disease activity and health were collected using standardized tools. Patients reporting ASN or CAU ethnic origin were abstracted, and results were compared between the two groups. Data from the last annual visit were analyzed, testing for differences in sociodemographic and clinical factors and patient reported measures between the two ethnic groups in univariate analyses; significant variables from univariate analyses were included in multivariate regression models.

Results: 1388 patients were studied, including 1113 CAU and 275 ASN. 330 patients reporting other ethnic backgrounds were excluded. Disease onset was at an earlier age (ASN= 22±12 yrs, CAU 33±15 yrs; $p<0.001$) and disease duration (ASN= 9±8 yrs, CAU 14±11 yrs; $p<0.001$) and age (ASN= 32±15 yrs, CAU 47±16 yrs; $p<0.001$) were lower in ASN compared to CAU. Income was similar, high school completion was higher in ASN (ASN 92%, CAU 84%; $p=0.001$). SLEDAI scores and number of ACR criteria met were similar. ASN had more frequent renal criteria (ASN 60%, CAU 34%; $p<0.001$), less frequent arthritis criteria (ASN 64%, CAU 80%; $p<0.001$). ASN were more frequently treated with prednisone (ASN 80%, CAU 64%; $p<0.001$), cyclophosphamide (ASN 18%, CAU 12%; $p=0.007$) and mycophenolate (ASN 22%, CAU 10%; $p<0.001$). Mean damage scores were higher in CAU but this was no longer significant after controlling for age and disease duration. SLAM scores were higher in CAU (ASN= 5.0±4.2, CAU 6.5±4.7; $p<0.001$). Self-reported flares, fatigue, disease activity and symptom scores (SLAQ) were lower in ASN. SF-36 physical (PCS) and mental (MCS) component scores were higher in ASN. In multivariate analyses, Asian ethnicity remained a significant predictor of better PCS ($\beta=3.3$, 95% CI 0.5,6.1;$p=0.02$) and MCS ($\beta=-2.9$, 95% CI 0.3,5.5;$p=0.03$) and lower SLAQ ($\beta=-5.0$, 95% CI -6.1,0.1; $p=0.01$) when age, disease duration, damage, immunosuppressives, ACR criteria met, education, and SLEDAI were included.

Conclusion: Although lupus was at least as severe in ASN Canadians, (younger age of onset, more renal involvement, and more exposure to immunosuppressives), ASN patients reported fewer disease flares, lower levels of disease activity and fatigue, and better physical and mental health compared to CAU. Cultural attitudes may influence patient perceptions of disease activity and overall health.

302

Michigan Lupus Epidemiology & Surveillance Program (MILES): Increased Proportion of Target-Organ Threatening Involvement Among Male Versus Female SLE Patients. Emily C. Somers[1], Wendy Marder[1], Emily E. Lewis[1], Sheeja Francis[1], Patricia C. Cagnoli[1], Peter DeGuire[2], Caroline Gordon[3], Charles G. Helmick[4], James C. Leisen[5], J. Patricia Dhar[6], W. Joseph McCune[1] and MILES Group, [1]University of Michigan, Ann Arbor, MI, [2]Michigan Department of Community Health, Lansing, MI, [3]University of Birmingham, Birmingham, United Kingdom, [4]Centers for Disease Control and Prevention, Atlanta, GA, [5]Henry Ford Health System, Detroit, MI, [6]Wayne State University, Bloomfield Hills, MI

Purpose: Although SLE disproportionately affects women (female to male ratio ~9:1), anecdotal evidence suggests males with SLE have particularly aggressive disease. We compare SLE characteristics in males vs. females utilizing a population-based registry.

Methods: As part of the ongoing MILES active surveillance program, detailed record reviews are performed for all SLE cases residing in the catchment area (source population ~2.5 million) and meeting eligibility criteria. Two-sided t-tests and chi-squared statistics were performed to compare summary statistics.

Results: Of the n=1928 currently confirmed SLE patients fulfilling >=4 ACR criteria, 183 (9.5%) were male. The total number of ACR criteria was similar between sexes (mean±SD: F 5.6±1.4, M 5.4±1.5; p=NS), as was age at diagnosis (F 33.5±13.1 yrs, M 35.0±16.1; p=NS). However, males on average had a significantly shorter disease duration (defined as time from diagnosis until most recent follow-up: F 12.3 ± 9.0 vs M 9.9 ± 8.2 yrs, p=0.002).

ACR criteria among SLE patients, according to sex

	Female n=1745 no. (%)	Male n=183 no. (%)	P-value
Malar	889 (51.0) *	72 (39.3)	0.003
Discoid	399 (22.9)	51 (27.9)	NS
Photosensitivity	882 (50.6) *	59 (32.4)	<0.001
Mucosal ulcers	795 (45.8) *	46 (25.1)	<0.001
Arthritis	1,329 (76.2) *	122 (67.0)	0.006
Serositis	751 (43.0)	75 (41.0)	NS
Renal	535 (30.7)	78 (42.6) *	0.001
Neurologic	307 (17.6)	47 (25.7) *	0.007
Hematologic	1,041 (59.7)	124 (67.8) *	0.033
ANA	1,639 (94.7)	170 (94.4)	NS
Immunologic	1,125 (64.5)	141 (77.1) *	0.001

* designates sex with significantly greater proportion positive for criterion

Conclusion: Though females had a significantly higher proportion of skin and joint manifestations, males had significantly higher end-organ threatening involvement (renal, neurologic) and both immunologic and hematologic manifestations, which accumulated during a shorter average disease duration. These data support anecdotal evidence that males have more aggressive disease.

Study of Clinical Expression and Morbidity of Systemic Lupus Erythematosus During a 5 Year Follow up After the Diagnosis in Male Patients (THESSALONIKI LUPUS STUDY GROUP). Styliani Stefanidou, Alexios Benos and Alexandros Garyfallos, Thessaloniki, Greece

Purpose: Systemic lupus erythematosus (SLE) is the most clinically and serologically diverse of the autoimmune connective tissue diseases as it may affect any organ of the body. However, some studies suggest that this condition can be divided into more homogenous subsets of pathogenetic, therapeutic, and prognostic significance. For instance, the sex of the patient, among other factors, may influence disease expression. Several studies have been conducted in search of prognostic factors of morbidity and mortality in male patients.

Method: In the present retrospective study we have analyzed the prevalence and the characteristics of the most relevant clinical features at the diagnosis of the disease in 59 male patients out of 594 data of patients with SLE that we collected.

Results: Several differences in the expression of the disease were found in relation to the gender of the patient. Male patients had higher prevalence of thrombosis (O.R.: 5,832 και C.I.: 2,698-12,608), nephropathy (O.R.: 2,806 και C.I.: 1,462-5,384), symptoms from the gastrointestinal system (O.R.:2,237, C.I.:1,043-4,796), strokes (O.R.: 12,289 και C.I.: 3,176-47,545), positive titers of antidsDNA (O.R.:2,226, C.I.:1,009-4,908) and increased values of SGPT (O.R.:3,034, C.I.:1,052-8,752) but tended to appear less often arthralgia (O.R.: 0,425 και C.I.: 0,237-0,719), hair loss (O.R.:0,187 και C.I.:0,044-0,782), Raynaud phenomenon (O.R.:0,386, C.I.: 0,161-0,927) and photosensitivity (O.R.:0,301, C.I.:0,132-0,685) as initial clinical manifestations in comparison to female.

During the five year follow up the predominant symptoms in male were nephropathy, neurologic involvement and arthritis. Positive associations have been found between male sex and the incidence of tendonitis (O.R.:5,594, C.I.:1,593-19,645), myositis (O.R.:5,262, C.I.:1,253-22,106). nephropathy (O.R.:2,959 και C.I.:1,315-6,660) and infections, particularly of the respiratory tract (O.R.:3,925 και C.I.:1,440-10,699), during the 5 year follow up.

Conclusion: This study has shown that SLE has a wide spectrum of manifestations, but still it is possible to recognize relatively homogeneous SLE subsets of clinical significance. Furthermore, our study has provided updated information of SLE morbidity characteristics in male patients. Assessing the incidence rates and delineating the prognostic factors associated with morbidity will be helpful for future management of patients with SLE using evidence-based medicine models.

The Effect of Age-of-Onset On Disease Manifestations in a Large Multi-Ethnic Cohort of SLE Patients. Ryan Webb[1], Emily C. Somers[2], Jennifer A. Kelly[3], Gail R. Bruner[4], Gary S. Gilkeson[5], Diane L. Kamen[6], John B. Harley[7] and Amr H. Sawalha[8], [1]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]University of Michigan, Ann Arbor, MI, [3]Oklahoma Medical Res Fnd, Oklahoma City, OK, [4]OMRF, Oklahoma City, [5]MUSC, Charleston, SC, [6]Medical Univ South Carolina, Charleston, SC, [7]OMRF, OU, VA, Oklahoma City, OK, [8]University of Oklahoma, Oklahoma Medical Research Foundation, Department of Veterans Affairs Medical Center, Oklahoma City, OK

Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with diverse manifestations. Herein, we explored the relationship between the age of disease onset and the clinical and serological manifestations of SLE.

Methods: Our study population included 1317 patients with SLE enrolled in the Lupus Family Registry and Repository at OMRF. We performed univariate analyses on the age of disease onset and the various clinical and serological disease manifestations, and then proceeded to logistic regression modeling with manifestations that had a p-value of <0.20. Next, we fit two logistic regression models for each manifestation: one for childhood-onset (<18 yrs) versus adult-onset disease (≥18 yrs), and one for early adult-onset (18-49 yrs) versus late adult-onset disease (≥50 yrs). Each logistic regression model used the disease manifestation as the dependent variable, and age of onset as the independent variable of interest, while controlling for gender, race and disease duration.

Results: The odds of having proteinuria, malar rash, anti-dsDNA antibody, hemolytic anemia, arthritis, cellular casts and leucopenia were lower in adult-onset compared to childhood-onset SLE (odds ratios = 0.33, 0.47, 0.48, 0.40, 0.53, 0.58, 0.65, respectively, and p-values <0.0001, 0.0004, 0.0005, 0.0024, 0.011, 0.031, 0.045, respectively). Proteinuria, malar rash, anti-dsDNA antibody, and hemolytic anemia all

remained significant after Bonferroni correction for multiple testing. The odds of having proteinuria, cellular casts, anti-nRNP antibody, anti-Sm antibody, anti-dsDNA antibody, and seizures were lower in late adult-onset compared to early adult-onset disease (odds ratios= 0.34, 0.25, 0.55, 0.36, 0.62, 0.35, respectively, and p-values <0.0001, 0.0013, 0.011, 0.013, 0.021, 0.026, respectively). Late adult-onset SLE patients have 1.58 times the odds of developing photosensitivity compared with early adult-onset SLE patients (p=0.0097). Proteinuria and cellular casts remain significant after Bonferroni correction for multiple testing.

Conclusion: Childhood-onset SLE is associated with a more severe disease with higher odds of proteinuria, malar rash, anti-dsDNA antibody, and hemolytic anemia compared to adult-onset disease. In adult-onset SLE, patients with a disease onset at <50 yrs of age are about 3-4 times more likely to develop renal involvement compared to patients with a disease onset ≥ 50 yrs of age.

Variable Health-Related Quality of Life Among African American Cohorts of Patients with Systemic Lupus Erythematosus. Anisha Dua[1], Diane L. Kamen[2], April L. Barnado[3], Gary S. Gilkeson[4], Rachel Mikolaitis[5], Anna Meyer[6], Winston Sequeira[5], Joel A. Block[5] and Meenakshi Jolly[5], [1]Rush University Hospital, Chicago, IL, [2]Medical Univ South Carolina, Charleston, SC, [3]Duke Univ SOM, Durham, NC, [4]MUSC, Charleston, SC, [5]Rush University Medical Center, Chicago, IL, [6]Charleston, SC

Purpose: Systemic Lupus Erythematosus (SLE) predominantly affects young women, affects multiple organ systems, is influenced by genetics, and impacts physical and emotional quality of life. In our previous work, a trend towards greater prevalence of SLE specific serologies were present among urban African Americans (UAA) with more genetic admixture than rural Gullah African Americans (GAA) SLE patients with lower genetic admixture. We now aim to determine if health related quality of life (HRQOL) is significantly different among SLE between different African American cohorts.

Method: Urban African American SLE patients receiving care at a University and County Hospital in Chicago were compared with rural African American subjects from South Carolina. Previously collected demographic, clinical and quality of life data from 137 urban SLE subjects with high genetic admixture (20-30%) and 35 SLE subjects from GAA (with low genetic admixture, 8-12%) were analyzed. The variables analyzed were demographics and health related quality of life (SF-36), domains: Physical Functioning (PF), Role Physical (RP), Bodily Pain (BP), General Health (GH), Vitality (V), Social Functioning (SF), Mental Health (MH) and Role Emotional (RE). It also provides two summary scores: Physical Component Score (PCS) and Mental Component Score (MCS). Data were compared using non-parametric t-tests chi square tests. A p-value of ≤0.05 was considered statistically significant on one tailed tests.

Results: The study population was predominantly female with a median age (IQR) of 43 (21) vs 37(14) yrs in UAA vs. GAA subjects, respectively. Age at diagnosis was significantly older in CAA when compared with SC subjects (Median (IQR) 29.5 (19) vs 28.0 (13), p=0.03) respectively. HRQOL (Median (IQR) was significantly worse in UAA when compared with GAA subjects: RP (24(75) vs 50 (56.3), p=0.01), V (50 (26.25) vs 65.0 (16.3), p=0.00), RE (50(100) vs 75 (66.7), p=0.07), and PCS 35.5 (18.3) vs 40.5 (20.7), p=0.05). Trend towards better SF (62.5 (37.5) vs 50 (21.9), p= 0.06) was observed among UAA vs GAA.

Conclusion: Health related quality of life is significantly worse in UAA as compared to age and gender matched GAA SLE patients. Larger scale studies need to be undertaken to determine the role of genetic vs. social support vs. disease severity on the health-related quality of life in patients with SLE.

306

Ancestral Differences in Associations Between Disease Manifestations and Serum IFN-a. Corinna E. Weckerle[1], Beverly S. Franek[1], Jennifer A. Kelly[2], Gail R. Bruner[2], Judith A. James[2], John B. Harley[2] and Timothy B. Niewold[1], [1]U of Chicago, Chicago, IL, [2]Oklahoma Medical Rsrch, Oklahoma City, OK

Purpose: Interferon alpha (IFN-α) is a primary pathogenic factor in systemic lupus erythematosus (SLE), and high IFN-α levels may be associated with particular clinical manifestations. SLE disease manifestations are highly variable between patients, and the prevalence of individual clinical features differs significantly by ancestry. Additionally, different clinical features in SLE may demonstrate significant associations with each other that may also differ by ancestry. We used logistic regression modeling to establish the network of associations between different clinical manifestations in large SLE cohorts of several different ancestries, and examined the correlation between ACR criteria and serum IFN-α to detect cytokine-phenotype associations in each background.

Methods: We analyzed data reporting presence or absence of ACR criteria as well as IFN-α levels from 724 SLE patients from the LFRR registry at OMRF. IFN-α levels were binned as a high vs. low categorical variable using a cut-off value of 2 standard deviations above the mean of healthy controls. The cohort was first stratified by self-reported ancestral background into 224 African-Americans, 105 Hispanic-Americans and 395 European-Americans. Iterative logistic regression was performed in each background using each of the ACR criteria and the IFN-α variable as an outcome variable serially, with the other variables used as predictor variables. Variables from this initial analysis with a p-value below 0.20 were then used in a repeat logistic regression, and results with $p<0.05$ in this analysis were considered significant. Positive and inverse correlations between different clinical variables were represented visually in a network diagram.

Results: Of over 100 million possible associations between ACR criteria in our background stratified populations, we found 39 unique associations, forming network maps of relatively sparse density in each background. Of those, only 11 associations were shared by more than one different ancestral background. Using Fisher's Exact test, we found that this differed significantly from a model in which associations between clinical manifestations were shared by at least 2 of the 3 ancestral backgrounds ($p<10^{-7}$). The network maps of interactions between clinical features were strikingly different in different ancestral backgrounds. IFN-α showed no common associations with clinical features in different ancestral backgrounds. In European-Americans, high IFN-α was linked to malar rash and hematologic manifestations of SLE. In African-Americans, it was linked to immunological manifestations. In Hispanic-Americans it was linked to oral ulcers, photosensitivity, and the absence of arthritis.

Conclusion: We found strikingly different associations between ACR criteria in different ancestral backgrounds, and IFN-α was associated with different clinical manifestations in each background. These data suggest that both the patterns of clinical manifestations and the underlying molecular pathogenesis of SLE differ significantly by ancestry.

Is Familial SLE Different From Non-Familial SLE?-Data From a Multiethnic US Cohort. Paula I. Burgos[1], Gerald McGwin Jr.[1], John D. Reveille[2], Luis M. Vila[3], Elizabeth Brown[1] and Graciela S. Alarcon[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Univ Texas Health Sci Ctr, Houston, TX, [3]Univ of PuertoRico Schl of Med, San Juan, PR

Purpose: To characterize the clinical features of familial SLE, and its influence on damage accrual and survival using a longitudinal cohort of SLE patients.

Method: SLE patients studied met ACR criteria, were age ≥16 years with disease duration ≤5years (T0) and were African-American, Hispanic (Texan or Puerto Rican) or Caucasian ethnicity. Familial SLE was defined as those with any first degree relative with SLE. Relative risk was estimated using odds ratios (OR) and corresponding 95% confidence intervals (CI) with logistic regression; relative hazards were calculated using Cox proportional hazards for time-dependent data adjusted for potential confounders.

Results: Of the 644 patients evaluated, 32 had familial SLE (mean age 36.7 [±12.5]) and 612 had non-familial SLE (mean age 36.4 [±12.6]). The majority of familial SLE patients were female (90.6% vs. 89.7%; p= 0.8673); first degree relatives were in decreasing order of frequency siblings, parents and children. In multivariable analyses, familial SLE patients were more likely to have a history of oral ulcers (OR = 1.92, 95% CI 0.65-5.70), mitral valve prolapse (OR = 1.74, 95% CI 0.50-6.10), cerebrovascular disease (OR = 4.18, 95% CI 0.98-17.76), oral contraceptive use (ever/never; OR = 2.51, 95% CI 0.88-7.19) and less likely to have had a history of low platelets ($<150{,}000/mm^3$; OR = 0.31, 95% CI 0.08-1.17) and pulmonary disease activity (OR = 0.39, 95% CI 0.14-1.20), albeit not significantly. Familial lupus was associated with a non-significant shorter time to damage accrual and survival (HR 0.77, 95% CI 0.37-1.59, p = 0.4746 and HR 0.20, 95% CI 0.03-1.47, p = 0.202 , respectively).

Conclusion: Although some differences were observed between familial and non-familial patients, no clear clinical pattern emerged suggesting that familial SLE is associated with a significantly greater disease burden than non-familial SLE.

Table 1. Risk factors associated with Familial lupus

Variable	OR	95% CI	P Value
Age	1.01	0.97 – 1.05	0.5751
Male Gender	0.49	0.12 – 2.01	0.3247

Predictors of Rheumatology Clinic Visit Times. Molly M. Larson, Lisa A. Davis and Liron Caplan, Univ of CO Denver School of Med, Aurora, CO

Purpose: Studies have examined the amount of time spent in various parts of non-rheumatology patient visits (Med Group Manage J 1995; 42:18) while others have established that waiting time is a major contributor to patient dissatisfaction with their clinic experiences (Ann Rheum Dis 1992; 51:195 and J Ambulatory Care Manage 2003; 26:138). The purpose of our study was to describe the components of patient visits according to the time they require and their contribution to the overall clinic visit time.

Methods: All data were collected as a part of a Performance Improvement Project (PIP) initiated by the Rheumatology Division. Outpatient visits occurred from January until March of 2008. Check-in and check-out times were stamped on preprinted cards by a tamper-resistant machine clock. Interim visit times were recorded in ink by the staff responsible for each component and confirmed by the staff responsible for the subsequent component. We calculated: patient arrival time relative to scheduled appointment time (amount of time patient checks in late), wait times between check-in and rooming/vitals, wait time between checking of vitals and physician arrival, actual physician visit duration, and time interval from completion of provider's duration and completion of phlebotomy. We also recorded whether the patient was seen in a teaching clinic (resident or fellow) or whether the visit was scheduled for an afternoon appointment (binary variables). We used linear regression to determine whether the amount of time for each component and the characteristics of clinics predicted the visit duration, defined as time elapsed between appointment time and recorded check-out time.

Results: Based on a sample of 130 patients, the amount of time the patient was late to his or her appointment, the waiting room time after check-in, and the amount of time spent taking vitals each prolonged the overall visit duration by equivalent amount (e.g. each minute the patient arrived late prolonged the overall time in clinic by one minute). Being seen by a resident or fellow significantly extended the overall duration of the visit (by 20 and 25 minutes, respectively) while afternoon clinic visits lasted over eight minutes longer than morning clinics. The amount of time during phlebotomy did not predict the overall visit duration.

Conclusion: Teaching and afternoon clinics greatly increased total patient visit duration. The clinic staff is not able to "compensate" for patients arriving late (i.e. every minute that patient arrives lengthens the overall visit duration by an equal amount). These factors should be considered when scheduling patient appointments in order to improve timeliness and patient satisfaction in clinic.

Variable	**P value**	**Coefficient** (effect of variable on total patient visit duration, minutes)	**95% Conf. Interval**	
Days since initiation of the PIP	0.667	-.05	-.34	.22
Patient time in waiting room	**<0.001**	1.13	.78	1.47
Duration of vitals	**0.006**	1.13	.71	1.47
Resident (Y/N)	**0.002**	20.67	7.66	33.69
Fellow (Y/N)	**<0.001**	25.00	11.94	38.0
Phlebotomy duration	0.065	.55	-.03	1.14
Afternoon appointment (Y/N)	**0.038**	8.68	.48	16.88
Amount of time patient checks in late to appointment	**<0.001**	.96	.66	1.27

Improving Osteoporosis Screening through Patient Activation and Self-Scheduling. Ryan C. Outman, Amy H. Warriner, Kenneth G. Saag and Jeffrey R. Curtis, UAB, Birmingham, AL

Purpose: Current U.S. guidelines recommend bone density screening with central dual energy x-ray absorptiometry (DXA) in all women 65 years or older; testing can be repeated as often as every 2 years. However, based on national data, less than one-third of eligible U.S. women have undergone DXA testing. The main barrier in achieving greater rates of osteoporosis screening has been devising a more effective and generalizable way for healthcare providers and patients to most efficiently schedule and receive DXAs.

Method: We conducted a group randomized, controlled trial involving 39 primary care physicians at the University of Alabama at Birmingham (UAB). Women 65 years or older, cared for by these physicians, with no identifiable DXA scan in the past 4 years were identified (n=2999). Approximately 30 patients per physician were randomized to either an intervention group (sent materials in the mail) or the control group (received no mailing). The intervention prompted physicians to review their patients to determine whether a DXA was medically appropriate; if so, an osteoporosis and fracture-risk brochure and a letter providing patients the opportunity to self-schedule a DXA scan were mailed to the patient.

Results: Of 2999 identified women meeting inclusion criteria, 520 women were randomized into the intervention group and 2479 to the control group. Of the 520 women in the intervention group, 135 (26%) women were determined to be medically inappropriate for DXA by their physicians and did not receive the intervention. Of the remaining 385 women, 114 (29.6%) women in the intervention group scheduled a DXA scan. Of these scheduled DXA scans, 64 (56%) were self-scheduled by the patient and 50 (44%) were scheduled by their physician after being prompted by the intervention. In comparison, 150 (6.4%) women in the control group completed a DXA scan (all physician-scheduled). Compared to control, the intervention increased DXA testing by 23.6% (95% CI 19.1 – 28.4%). Under the assumption that a similar proportion of the control group would be medically inappropriate for DXA testing as the intervention group, the intervention increased the proportion of women receiving a DXA by 21.4%, 95% CI (16.9% to 26.3%).

Conclusion: Scheduling and receipt of DXA testing was improved significantly through the use of a simple mailed osteoporosis brochure and the solicited opportunity for patients to self-schedule their own scans. Mailed materials sent directly to patients, in conjunction with minimizing barriers to self-scheduling of DXAs, may be an effective component of a multi-faceted quality improvement program to increase rates of osteoporosis screening.

High Risk Osteoporosis Clinic (HiROC) - Closing the Loop in Clinical Osteoporosis Care. Thomas Olenginski[1], Gwynne Maloney-Saxon[1], Judy Reardon[2], Brian Oppermann[3], Stephanie Morris[1], Lindsay J. Ledwich[4] and Eric Newman[1], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, PA, [3]Geisinger Health System, Danville, PA, [4]Geisinger Medical Center, Danville

Purpose: Ineffective care pathways and process flows continue to hinder osteoporosis care. In an effort to enhance the care of high risk osteoporosis patients across our health system, our rheumatology department created a unique clinical care model – HiROC (High Risk Osteoporosis Clinic).

Method: HiROC utilizes rheumatology physician experts, nurse specialists, electronic tools, and redesigned care processes in an efficient manner to “close the loop” on osteoporotic care. HiROC has both outpatient and inpatient components. Outpatient HiROC is available to primary care physicians and has been operationalized in 9 locations across our health system. Inpatient HiROC involves an auto-consult to the Inpatient HiROC Team on all patients admitted with a low-impact fracture. Patients are logged into a task management database and vitamin D supplementation is initiated. At 4-6 weeks post-fracture, all Inpatient HiROC patients are contacted to re-assess their status. They are then either seen in Outpatient HiROC, or their treating physician is contacted and given a consultative osteoporosis management plan. We report on the first 200 Outpatient HiROC and 100 Inpatient HiROC patients, including baseline demographics, treatment decisions, adherence and financial performance to understand program sustainability.

Results: ***Outpatient HiROC:*** 44.0 % had a previous fragility fracture and 86.5 % were classified as high risk for fracture (Table 1). Vitamin D levels were low in 38 % of patients. 145 patients (80.4% of the high risk group) received treatment. Treatment decisions included IV bisphosphonates (40%), oral bisphosphonates (26%), teraparatide (5%), other agents (1.5%) - 15.5 % of patients refused treatment/remained undecided and 12% did not need treatment. Treatment adherence at 3 months was 98% (94% oral/subcutaneous meds, 100% IV, p=0.051). ***Inpatient HiROC:*** 37 % had previous fragility fractures, yet only 8 % were taking prescription treatment prior to admission. Vitamin D levels were low in 78 %. Admission fracture type included hip (54%), vertebral (14%), pelvic (4%), other (30%). 66 patients reached their 6 week assessment point. The care loop was closed in 92.4% of these patients: 51.5 % transitioning to Outpatient HiROC, 30.3 % returning to their PCP with a consultative osteoporosis care plan, and 10.6 % dying within the 6 weeks of their fracture. ***Financial Performance:*** Inpatient and Outpatient HiROC generated over $110,000 of net revenue for fiscal year 09.

Conclusion: By combining inpatient and outpatient components, well-defined pathways of care, task management, osteoporosis expertise, and electronic tools, our Rheumatology department developed a seamless comprehensive osteoporosis program for our health care system. Provisions were made for inpatients incapable of returning back to the outpatient setting by proactive contact and consultative assistance for their treating provider. HiROC is self-sustainable, and scalable, and may serve as a model for other groups to improve osteoporosis care for the patients they serve.

Table 1. Outpatient and Inpatient HiROC

Outpatient HiROC (n=200) Demographics	
Women	86.6%
Age (mean - years)	67.6 ± 13.4
Risks	
Previous Fracture	44.0%
Chronic Steroids	9.5%
High Risk for Fracture	86.5%
Vitamin D level low	38.0%
Outcomes	
Treatment Started (High Risk Patients)	80.4%
Adherence (at 3 months)	98.0%

Inpatient HiROC (n=100) Demographics	
Women	68.0%
Age (mean - years)	74.1 ± 14.2
Risks	
Previous Fracture	37.0%
Chronic Steroids	9.0%
High Risk for Fracture	78.0%
Vitamin D level low	78.0%
Death	10.6%

311

DXA Testing in Women >65 - Closing the Osteoporosis Quality Care Gap at the Point of Service Using An Electronic Health Record Best Practice Alert. Eric D. Newman[1], Tammy Anderer[2], Fred Bloom[3] and Lester Kirchner[4], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Geisinger Health System, Danville, PA, [4]Geisinger Center for Health Research, Danville

Purpose: Bone density testing (DXA) in women > 65 is uniformly recommended. Nationally <30% of such women have had a DXA in the preceding several years. Electronic Health Record (EHR) systems can be programmed to notify about the need for DXA testing using 2 types of alerts – Health Maintenance reminders (HM) and Best Practice Alerts (BPA). HM are passive – the clinician is given a visual clue that there is a HM present, but needs to proactively seek and address it during the clinic visit. BPAs are active – upon opening the encounter, the clinician is presented with a pop-up box defining the BPA and a simple order set to fulfill the BPA. We studied the secular trends of DXA ordering in our health care system, followed by the sequential effect of turning on a DXA HM then a DXA BPA to ascertain the differential effect of each type of alert.

Method: Our Rheumatology Department and Primary Care Best Practice Team designed and programmed a DXA HM and a DXA BPA for women > 65 using our EHR (Epic). The DXA HM was turned on March 2007 and the DXA BPA was turned on October 2008. Education to all Primary Care Sites included a "fast facts" summary and live web-based training. The percent of women >65 with a previous DXA was calculated for the year prior to the DXA HM reminder to establish a stable baseline, and compared with the same metric for 18 months after the DXA HM reminder was activated and the 6 months after the DXA BPA was activated (for a total of 3 years observation). A Poisson regression model was used to estimate and compare the quality indicators over time (i.e., HM, BPA). To estimate the effect of the interventions the average post-intervention average was compared to the pre-intervention average. Comparisons between BPA versus HM, and between HM versus pre-HM were performed.

Results: Over the course of three years of observation, the number of eligible women >65 increased from 22,309 to 26,735. The percent of women >65 with a DXA showed a clinically insignificant rise (3%) in the year prior to the DXA HM Reminder, indicating very little background secular trend. After the DXA HM Reminder was turned on, the percent of women over 65 with a DXA rose significantly (Table 1). DXA testing rose 31% (from an average of 40.0% pre-intervention to 52.3% post-intervention) for all women >65, as indicated by the intervention effect of 1.31. Each age subgroup also rose significantly – Women 65-74 by 24%, women 75-84 by 29%, and women >84 by 43%. After the DXA BPA reminder, additional significant improvements were noted – 12% for women 65-74, 15% for women 75-84, and 25% for women > 85 – 14% improvement for all women > 65. These improvements were all significant comparing the DXA BPA to the DXA HM Reminder (P<0.0001).

Conclusion: DXA testing in women over 65 is a nationally accepted osteoporosis quality indicator, and usual point-of-care methods are ineffective in improving this measure. However, EHR-based DXA Reminders were highly effective in improving the percent of over 26,000 women > 65 in receiving a DXA. Finally, a BPA (active alert) is additive in effect to a HM (passive alert).

Table 1: Average Pre-HM, HM and BPA DXA Quality Indicator

	Pre-HM	HM	BPA	HM vs. Pre-HM	BPA vs. HM	P-value
Female 65-74	44.70%	67.40%	64.00%	1.28 (1.26, 1.31)	1.12 (1.10, 1.14)	<0.0001
Female 75-84	39.10%	62.80%	60.60%	1.36 (1.32, 1.38)	1.16 (1.12, 1.17)	<0.0001
Female > 85	21.60%	32.60%	40.60%	1.61 (1.44, 1.69)	1.26 (1.19, 1.30)	<0.0001
All	40.00%	62.30%	69.60%	1.31 (1.29, 1.32)	1.14 (1.12, 1.16)	<0.0001

Assessing Care Using New Quality Indicators for Osteoporosis and Cardiovascular Disease Management in SLE. Kristina Demas[1], Brendan T. Keenan[2], Daniel H. Solomon[3], J. Yazdany[4] and K. H. Costenbader[3], [1]George Washington University School of Medicine, Washington, DC, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham & Women's Hospital, Boston, MA, [4]UCSF, SF, CA

Purpose: Quality indicators (QIs) for assessment of health care quality in SLE have been proposed (**Table 1**). We aimed to assess quality of care for osteoporosis (OP) and cardiovascular disease (CVD) among SLE patients at our institution.

Method: We randomly identified 200 patients meeting ACR Criteria for SLE Classification, with ≥ 2 visits to our academic rheumatology practice in 2007-8. We performed a structured electronic medical record review of rheumatologists' notes, medical history, medications, laboratories and bone mineral density (BMD) results. We assessed adherence with proposed SLE QIs for OP and CVD.

Results: 94% of patients were female; 64% were white, mean age was 46.3 years (SD 14.1), mean SLE duration was 15.3 years (SD 11.1). 29% received ≥ 7.5 mg prednisone/day for ≥ 3 months during the year. 57% had received indicated BMD, 62% indicated calcium + vitamin D, and 86% indicated anti-resorptive/anabolic agents. 26% had ≥ 4 and 60% had ≥ 3 CVD risk factors documented in the year. Only 3%, all current smokers, had smoking status documented. Having a primary care physician within our healthcare network was a significant predictor of documented QI adherence (p=0.03 for indicated BMD and p <0.01 for CVD risk factor documentation).

Conclusion: Documented compliance with newly proposed QIs for OP and CVD in SLE was sub-optimal in our center. We found opportunities for improvement in academic rheumatologists' care, and for revisions of proposed QIs to capture the most meaningful clinical data.

Table 1. SLE Quality Indicators (Yazdany et al, A&R 2009; 61:370)
I. Osteoporosis
A. IF SLE patient has received prednisone ≥7.5 mg/d for ≥3 mo, THEN patient should have BMD testing recorded in medical record*, unless patient is c receiving anti-resorptive** or anabolic therapy†.
B. IF SLE patient with SLE has received prednisone ≥7.5 mg/d for ≥3 mo, THEN should receive calcium + vitamin D.
C. IF SLE patient has received prednisone ≥7.5 mg/d for ≥1 mo, and has t-score ≤-2.5 or fragility fracture, THEN should receive anti-resorptive/anabolic agent.
II. CVD
For all SLE patients, CVD risk factors (smoking, blood pressure, BMI, diabetes,slipids) should be documented annually.

313

Adherence with Screening Guidelines for Hepatitis B and C Testing Among U.S. Veterans with Rheumatoid Arthritis (RA). Scott A. Stoerner[1], Ted R. Mikuls[2], Andreas M. Reimold[3] and Grant W. Cannon[4], [1]VAMC and University of utah, Salt Lake City, UT, [2]VAMC and University of Nebraska, Omaha, NE, [3]VAMC and University of Texas Southwestern, Dallas, TX, [4]VAMC and University of Utah, Salt Lake City, UT

Purpose: The Centers for Disease Control and Prevention (CDC) recommend screening for all hepatitis B markers prior to immunosuppressive therapy for rheumatologic disorders. Hepatitis B and C screening is recommended by the American College of Rheumatology (ACR) prior to starting methotrexate or leflunomide in patients with defined risk factors for hepatitis. There have been reports of reactivated hepatitis B with immunosuppression. The purpose of this study was to determine adherence with these screening guidelines in U.S. Veterans with RA and determine the indication for hepatitis testing when undertaken.

Methods: Study subjects included participants in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry from the Dallas, Salt Lake City, and Omaha active collection sites(n=305). The Computerized Patient Record System (CPRS) was used to obtain hepatitis risk factors, ALT/AST values, rheumatologic medications, and hepatitis serologies. When hepatitis serologies were obtained, clinic notes from multiple physicians were reviewed to determine the clinical indication behind this testing. These indications were then classified into the following categories: screening in adherence with the ACR and CDC guidelines, elevated ALT/AST of unknown etiology, and unknown. Hepatitis C had an additional category for those serologies obtained to help diagnose hepatitis C associated arthritis.

Results: Sixty-five (21.3%) patients were tested for a hepatitis B serology. The indications for hepatitis B testing were 35 (53.8%) for screening, 16 (24.6%) for elevated ALT/AST of unknown etiology, and 14 (21.5%) unknown. Hepatitis C testing was done in 136 (44.6%) of patients. The indications for hepatitis C testing included 53 (39.0%) for screening, 19 (14.0%) for elevated ALT/AST of unknown etiology, 53 (39.0%) for diagnosis of hepatitis C arthritis, and 11 (8.1%) for other. The presence and/or absence of risk factors for hepatitis B and/or C infection could not be consistently identified in the current chart review. One hundred and ten (36.1%) patients received biologic therapy, while 267 (87.5%) patients received either methotrexate or leflunomide. One (0.3%) patient tested positive for hepatitis B and 11 (3.6%) patients tested positive for hepatitis C.

Conclusion: Adherence with CDC screening guidelines for hepatitis B in this population was low. Our review could not ascertain the presence of hepatitis B and/or C risk factors to sufficiently determine if ACR guidelines were being followed. The higher rate of testing for hepatitis C in comparison to hepatitis B appeared to the result of increased diagnostic testing for hepatitis C associated arthritis. Hepatitis B was noted to be rare among this population. These results support the need for greater evaluation of these guidelines in clinical practice to determine their best application and impact.

Does My Rheumatologist Know My Pregnancy Risk? Rochelle R. Clementine[1], Bobby J. Dupre[2], Justin S. Lyman[1], William E. Davis[3], Eve Scopelitis[4], Leonard Serebro[4], Tamika Webb-Detiege[1], Jerald M. Zakem[3] and Robert J. Quinet[5], [1]New Orleans, LA, [2]Ochsner Health System, Baton Rouge, LA, [3]Ochsner Clinic, New Orleans, LA, [4]Ochsner Clinic Foundation, New Orleans, LA, [5]Ochsner Med Ctr-New Orleans, New Orleans, LA

Purpose: Many rheumatic diseases occur in women of childbearing age. Most of these diseases require therapy with potentially teratogenic drugs. The objective of the study is to assess the frequency of contraceptive counseling rates among six rheumatology staff physicians during routine clinic visits at Ochsner Department of Rheumatology, a large group practice in New Orleans, LA.

Methods: Retrospective review of ninety charts in women aged 16-40. Diagnoses included systemic lupus erythematosus, rheumatoid arthritis, mixed connective tissue disease, Sjogren's syndrome, scleroderma, antiphospholipid antibody syndrome, fibromyalgia and steroid induced osteoporosis. Routine clinic visits were reviewed during October 2006 through January 2009. The rates of contraceptive counseling, the medications prescribed with respective FDA pregnancy categories and the number of patients prescribed each medication were reviewed and recorded.

Results: Approximately forty different medications were prescribed to the ninety patients reviewed. Four of these medications are classified as FDA pregnancy category X, which has been shown to *cause* fetal abnormalities in either animal or human studies. Six of these medications are classified as FDA pregnancy category D, in which there is positive evidence of human fetal risk. The contraceptive counseling rates in our department ranged from 17-78% among staff physicians. Of the ninety charts reviewed, six of these patients conceived while taking potentially teratogenic medications during this the frame. Of these six patients, two were not counseled on contraception prior to conceiving.

Conclusion: Previous studies have reported that women of childbearing age are frequently not counseled on potentially teratogenic medications. In our department, prescriptions for potentially teratogenic medications were frequently given to women of childbearing age without documentation of contraceptive counseling. It is important to discuss the teratogenic risks of these medications with patients. Each of the six staff physicians reviewed their respective contraceptive counseling rate. Ochsner Department of Rheumatology, in conjuction with Ochsner Quality Assurance department, is in the process of implementing an alert mechanism into the electronic medical record of women of child bearing age in an attempt to prompt physicians to address contraceptive counseling. Further review of contraceptive counseling rates will be obtained pending implementation of the alert system into the electronic medical record.

From Recommendations to Clinical Practice: Experience Applying the 2008 ACR RA Recommendations for the Use of Biologic DMARDs to An Urban, County Hospital Cohort. J. Barton[1], Vladimir Chernitskiy[2], Jonathan Graf[1], John Imboden[1], E.H. Yelin[3] and J. Yazdany[3], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, CA, [3]UCSF, SF, CA

Purpose: In 2008, the ACR developed a clinical algorithm for the use of biological DMARDs in RA. The recommendations provide a framework for clinicians to make treatment decisions. This study examined the feasibility of applying the algorithms to a multiethnic cohort of adults with RA at an urban, county hospital clinic.

Method: We performed a retrospective medical record review from October 2006 to March 2009. Subjects are enrolled in the UCSF RA cohort, a population of adults ≥ 18 years, with confirmed RA who were seen at least twice over a one-year period and were not on a biologic at the time of data extraction. We extracted patient characteristics (age, gender, ethnicity, country of origin) and variables required to follow the algorithms, including: disease duration, prognostic factors (rheumatoid factor or CCP, erosions), assessment of disease activity, and contraindications to treatment.

Results: Among 125 subjects, mean age was 53 ± 13 years, 88% were female, 83% were RF positive, 78% were CCP positive, and 62% had radiographic erosions. Fifty-three subjects were Latino (42%), 51 Asian (41%), 12 African American (10%), 8 White or Other (7%), and 98 (78%) were non-U.S. born. At the time of assessment, 116 (94%) were on a non-biologic DMARD. Of the 125 subjects, 43 (34%) did not meet eligibility criteria for a biologic DMARD due to low disease activity; 41 (33%) met criteria, but were not eligible due to the following: 1) infectious diseases (latent TB, n=33; acute bacterial infection or infection currently on antibiotics, n=4); 2) pregnancy or breastfeeding (n=2); and 3) other (compliance/patient safety, n=2). The remaining 41 (33%) met criteria without contraindication; 21 were prescribed a biologic. Of the eligible subjects, only 11 of 41 were on a biologic at the next visit.

Conclusion: Although applying the 2008 ACR recommendations was technically feasible in our cohort, 33% of subjects were ineligible for the clinical algorithms. In most cases, infectious disease (most commonly latent tuberculosis) rendered a subject ineligible. Clinical practice followed the ACR recommendations in half of the cases; however, only 11 of 41 eligible subjects were on a biologic at follow-up. Understanding such gaps between recommendations and practice will inform the design of future clinical trials that address barriers to care in vulnerable populations.

Monitoring Adherence to Hydroxychloroquine (HCQ) in Childhood-Onset Systemic Lupus Erythematosus (cSLE) and Possible Impact of Successful Self-Management in Improving Medication Adherence. Deepa P. Kudalkar[1], Tracy V. Ting[2], Shannen Nelson[2], Jennifer L. Huggins[2], Avis E. Ware[1], Jamie Eaton[2], Jennifer Rammel[2], Shweta Srivastava[2], Dennis Drotar[2] and Hermine Brunner[2], [1]University of Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Hosp, Cincinnati, OH

Purpose: Prior research suggests that almost half of the cSLE patients do not take their medications as prescribed. Diagnosis and management of sub-optimal adherence is an unsolved problem.HCQ remains the cornerstone drug for cSLE. A commercial bioassay is available to measure blood levels. Successful self-management, as measured by Patient Activation Measure (PAM), relies upon patient ability to play an active role in self-care, which has a positive impact on health outcomes in chronic disease models. Objectives: 1)To assess the value of blood HCQ levels as an objective measure of medication (HCQ) adherence in cSLE; and 2) To determine the relationship between medication(HCQ) adherence and successful self-management as measured by the PAM.

Methods: Adolescents & young adults with cSLE (15-25 yrs) taking HCQ for ≥ 6 months were identified. Medication adherence (0 – 100%) was measured using self-report (Medication Adherence Self-Reported Inventory [MASRI]), pharmacy refill data, and whole blood HCQ levels assayed by HPLC method (lowest detectable level 100mcg/L). HCQ levels < 130mcg/L were considered to reflect non-adherence when taking HCQ at 400mg/day. Non-adherence was defined by MASRI <90% or pharmacy refill <80%, as previously suggested. The PAM questionnaire was also completed.

Results: Among the 39 subjects (93% Female, 67% African American), the HCQ dose ranged from 100-400mg/day. Using the MASRI, 50% of the subjects were non-adherent, while pharmacy refill data suggested non-adherence among 61%. There were 12/39 (30%) subjects with undetectable HCQ levels. HCQ levels reached the suggested target of 1,000 mcg/L in only 8/39 (20%) of the subjects. HCQ levels correlated moderately with adherence by self-report (r=0.45, p=0.006) and pharmacy data (r=0.39, p=0.02). Based on HCQ levels, patients taking 400 mg/day dose were more likely to be non-adherent to HCQ compared to those taking 200 mg/day, which was not affected by frequency of dosing. There was a statistically significant correlation between PAM and both self-reported adherence (r = 0.38; p=0.02) and pharmacy refill adherence (r=0.43; p=0.01).

Conclusion: Whole blood HCQ levels may be used in conjunction with other measures of medication adherence. Ongoing research to assess individual trends in HCQ levels over time may help to more accurately identify patients with poor or non-adherence. Also, patients who are better in self-managing their SLE appear to have higher adherence. Improvement of self- management skills may help improve medication adherence.

Pneumovax Vaccination Among Rheumatology Outpatients On Immunosuppressive Medications: The Development of a Quality Indicator. Sonali P. Desai[1], Alexander Turchin[1], Lara E. Szent-Gyorgyi[1], Michael E. Weinblatt[2], Jonathan S. Coblyn[2], Daniel H. Solomon[1] and Allen Kachalia[1], [1]Brigham & Women's Hospital, Boston, MA, [2]Brigham & Women's Hosp, Boston, MA

Purpose: Providing Pneumovax to immunocompromised patients is recommended by the Centers for Disease Control (CDC), but prior data suggest that rates of vaccination are not optimal. For rheumatology outpatients on immunosuppressive medications (IM), we sought to: 1) develop a quality indicator (QI), 2) measure the proportion of patients up-to-date with Pneumovax prior to starting IM in the past 12 months and the proportion for patients on IM and 3) examine whether years in practice of the rheumatologist influenced performance for this QI.

Methods: Data were aggregated from administrative (billing code data) and clinical (electronic health record [EHR]) sources. We assessed the proportion of patients on IM in our rheumatology practice over a 24-month period (1/1/07 to 1/1/09). We included only patients who had at least 2 visits to the rheumatology clinic within the 24-months and were prescribed an IM by a rheumatologist. Up-to-date with Pneumovax was defined according to CDC guidelines. Two QIs were calculated: 1) up-to-date with Pneumovax prior to starting an IM and 2) up-to-date with Pneumovax while on an IM. Random manual review of patient records confirmed that our methodology accurately captured rheumatology patients on IM who had received Pneumovax and excluded patients not on IM.

Results: We identified 2,471 patients on IM with 634 newly started in the past 12 months. The mean age was 57 and 76% female. The most frequent disease was RA (54%). Corticosteroids (41%) and MTX (32%) were the most common IMs prescribed. 45% on IM were up-to-date with Pneumovax. Among new initiators of IM, 27% (176/634) were up-to-date prior to starting the IM. Provider-level data demonstrated variability between individual rheumatologists and based on years in practice (**Table 1**). Patients treated by rheumatologists in practice for ≤ 10 years were more likely to have received Pneumovax.

Conclusion: Less than half of all patients on IMs were up-to-date with Pneumovax, similar to prior reports. Differences in rates based on years in practice were observed.Future studies will focus on interventions to improve Pneumovax administration prior to initiating IMs.

Table 1. Pnemovax Quality Indicator performance based on years in practice of rheumatologist

	Practicing ≤ 10 years (N)	**Practicing > 10 years** (N)	**p value**
Ongoing immunosuppressive medication	60 ± 9 % (76/127)	44 ± 2 % (1026/2313)	p = 0.0006
Newly initiated immunosuppressive medication	40 ± 14 % (19/48)	27 ± 4 % (157/586)	p = 0.057

318

Erythrocyte Sedimentation Rate (ESR) Is the Least Likely of Core Data Set Measures to Identify An "Abnormal State" in New Patients with RA to Monitor Therapeutic Responses, According to 3 Definitions of "Abnormal State". Theodore Pincus[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: A single "gold standard" measure, such as blood pressure or cholesterol, is not available in rheumatoid arthritis (RA) to assess and monitor each individual patient. Therefore, a Core Data Set of 7 RA measures was developed: 3 from a health professional, swollen joint count (SJC), tender joint count (TJC) and physician/assessor global estimate of status (MDGL); 3 from a patient, physical function (FN), pain (PN) and patient global estimate (PTGL), on a health assessment questionnaire (HAQ) or derivative such as a multidimensional HAQ (MDHAQ); and 1 laboratory test, erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP). Indices of 3-4 of these measures are widely used in clinical research, but not in usual care, in which a laboratory test such as ESR often is the only quantitative measure. We analyzed the capacity of 6 of the Core Data measures to depict an "abnormal state" to monitor 487 new patients with RA seen at a weekly academic rheumatology clinic from 1980-2005.

Method: All patients seen from 1980-2005 completed a patient questionnaire that evolved from a HAQ to a multidimensional HAQ (MDHAQ). The MDHAQ included FN and PN since 1980, and PTGL since 1996. SJC and TJC were assessed in on consecutive patients in certain periods, without selection for severity, but MDGL not until 2005. The proportion of patients in an "abnormal state" was analyzed for 6 of the 7 Core Data Set measures by 3 definitions, "least stringent," "moderately stringent" and "most stringent." Cutpoints for the 3 definitions were >0, >1 and >2 for SJC28 (0-28), TJC28 (0-28), PN (0-10) and PTGL (0-10); for MDHAQ-FN (0-3), >0, >0.25 and >0.5; for ESR, >10 for males/>20 for females, >20 for males/>30 for females, and >28 (commonly used for inclusion in clinical trials). DAS28, RAPID3 (routine assessment of patient index data, composed of only FN, PN and PTGL) and RAPID3-EST (does not include PTGL in patients seen prior to 1996; correlated with RAPID3 at levels rho□0.9), were also analyzed in 3 categories: for DAS28 (0-28), >2.6, □3.2 and >3.2; for RAPID3 and RAPID3-EST (0-30), >0, >3 and >6. The proportion of patients in an "abnormal state" by 3 definitions was analyzed using descriptive statistics.

Results: All measures other than ESR (abnormal in 71%) indicated an abnormal state in >88% of patients, according to the least stringent definition. For the moderately stringent definition, all measures other than ESR (abnormal in 54%) were abnormal in >82% of patients. For the most stringent definition, all measures were abnormal in >79%, other than ESR in 53% and MDHAQ-FN in 67%.

Table. Normal / Abnormal Measurements at First Visit of 487 Rheumatoid Arthritis Patients

Measure	Range	Definition #1	% Abnormal	Definition #2	% Abnormal	Definition #3	% Abnormal
SJC28	0-28	>0	92.3%	>1	86.5%	>2	83.6%
TJC28	0-28	>0	87.6%	>1	84.8%	>2	79.0%
ESR	0-150	Male >10 Female >20	71.3%	Male >20 Female >30	54.4%	>28	52.6%
MDHAQ-FN	0-3	>0	92.8%	>0.25	83.3%	>0.50	66.9%
Pain	0-10	>0	98.4%	>1	92.1%	>2	84.9%
PTGL	0-10	>0	98.6%	>1	91.8%	>2	85.0%
DAS28	0-10	>2.6	92.3%	≥3.2	82.0%	>3.2	82.0%
RAPID3-EST	0-30	>0	99.5%	>3	93.4%	>6	84.5%

Conclusion: Any of 3 definitions identified most new RA patients as in an abnormal state. ESR stood out as considerably less likely to be abnormal than any other Core Data Set measure. Although monitoring of ESR is effective in some RA patients, quantitative measures other than ESR should be collected in clinical care of most patients, to monitor and document responses to therapy of patients with RA.

Disclosure: T. Pincus, None; **C. J. Swearingen**, None.

319

Disease Activity Differences in Patients On DMARD Therapy: Use of the Rheumatology Health Tracker (RHT) An Electronic Data Capture System to Measure Patient Outcomes. Sita A. Narayanan[1], Todd Hofeling[2], Jeffrey R. Lisse[3], Berchman A. Vaz[1], Oscar Furet[3], Alexis A. Alvarez[3], Kari Koerner[3] and Catherine Lo[3], [1]Univ of Arizona, Tucson, AZ, [2]Tucson, AZ, [3]University of Arizona, Tucson, AZ

Purpose: Measurement of disease activity and its response to disease modifying antirheumatic drug (DMARD) therapy is an important component of the decision making process in patients with rheumatoid arthritis. There is however, controversy concerning what measures to use, how to measure them, and the amount of time and effort this entails. Comparisons of the DAS and HAQ scores between drugs may reflect channeling bias due to practitioner preferences, but can be important in detecting outcomes.

Methods: Patients with rheumatoid arthritis were invited to participate in an observational study using a web based electronic capture system. After informed consent, at each visit they were asked to record the following outcome parameters: Involved Joint Count (IJC), Short Form 12 (SF-12), Health Assessment Questionnaire (HAQ), and Visual Analog Scale of their overall disease activity (VAS), demographic information, and information on health care utilization. Practitioners then filled out a Tender Joint Count (TJC), Swollen Joint Count (SJC), and a visual analog scale. Information was also recorded concerning adverse events and medications.

Results: There were 100 patients enrolled in the study who were on biologic DMARDs. Overall HAQ was 0.839, DAS was 4.485, SJC was 5.062, TJC was 6.662, SF-12 was 35.302, and VAS was 24.175. Initial visit HAQ scores for the different biologics was 0.548 for etanercept (n=28), 0.805 for infliximab (n=28), 0.658 for adalimumab (n=29), 0.99 for rituximab (n=9), and 1.1 for abatacept (n=6). The change in HAQ score between the baseline and the first follow up visit was +0.007 for etanercept (over avg 57 days), +0.113 for infliximab (over avg 65 days), -0.017 for adalimumab (over avg 18 days), and +0.08 for abatacept (over avg 18 days). The change in DAS between the initial visit and the first follow up visit was 0.007 for etanercept (over avg 57 days) and 0.035 for infliximab (over avg 65 days).

Conclusion: The Rheumatology Health Tracker (RHT) tracks the outcome in patients with rheumatoid arthritis on different DMARDs. Differences in outcome parameters over time may reflect the use of different biologics in our practice. To date, patients receiving each biologic displayed mostly similar efficacy without a significant change in the DAS or HAQ scores. Use of the RHT is easy, web-based, and takes little practitioner time. In the new era of electronic medical records, it can be an accessible, reproducible source for multiple practitioners to assess their patients over time.

Perceived Barriers to Determine Disease Activity in RA Patients in Daily Clinical Practice: a Qualitative Study. Laura T.C. van Hulst, Jaap Fransen, Nicolien L. Beld, Piet L.C.M. van Riel, Richard Grol and Marlies E.J.L. Hulscher, UMC St Radboud, Nijmegen, Netherlands

Purpose: Several tight control studies and guidelines for the management for RA, recommend that RA patients' disease activity should be assessed with a valid composite score, such as the DAS28. However from surveys and medical record examinations, it is known that a disease activity assessment is infrequently performed in daily clinical practice. The objective of this study was to determine which barriers are perceived for disease activity assessment in daily clinical practice.

Method: A qualitative study was performed with 15 Dutch rheumatologists who were users or non-users of the DAS28, invited based on survey data. Semi-structured interviews were performed, recorded, transcribed verbatim and analyzed with Atlas.ti 6.0.11. according to Grounded Theory. Citations were coded independently by two researchers (LvH and NB) and the final codes were formulated on the basis of consensus. Ultimately, codes were categorized in domains and levels if they discussed similar concepts.

Results: A wide number of perceived barriers to assess the DAS28 in daily clinical practice were identified, covering five domains: the instrument itself, rheumatologist related, patient related, organization features and the social context (see Figure 1.) For example, rheumatologists doubted the reliability and validity of the DAS28 (instrument itself), did not think that DAS28 assessments would lead to another outcome compared with their current given care (rheumatologist related), mentioned that blood markers were not available on time (organization), they were afraid for reimbursement consequences (social context) and felt that patients were not sufficiently familiar with disease activity measures such as the DAS28 (patient related). The complete list of barriers discussed in the interviews is illustrated in Figure 1.

Conclusion: Rheumatologists perceived many barriers, covering 5 domains, for disease activity assessment in daily clinical practice. The organizational barriers usually receive most attention, but several other barriers are experienced as well. Future efforts to improve the use of

disease activity assessment in daily practice should also take into account barriers on the other domains: the rheumatologist, the patient, the social context and the perceived validity and reliability of the assessment itself.

Figure 1. Overview of perceived barriers with respect to DAS28 assessment in daily clinical practice.

Construct Validity, Feasibility and Acceptability of EQ-5D to Assess Physical and Mental Quality of Life in Systemic Sclerosis Patients. Roberta Gualtierotti[1], Luciana Scalone[2], Francesca Ingegnoli[1], Silvana Zeni[1], Paolo Cortesi[2] and Flavio Fantini[1], [1]Istituto Gaetano Pini, University of Milano, Italy, Milano, Italy, [2]Center for Health Technology Assessment and Outcomes Research, University of Milan, Milano, Italy

Purpose: Systemic sclerosis (SSc) is a systemic chronic inflammatory disease and a progressive disabling condition. It compromises ability to perform basic activities. Patients' emotional sphere is also compromised, with anxiety reported as one major aspect negatively affected. EQ-5D, a simple and quickly self-completable tool for quality of life (QoL) assessment, whose reliability and validity have never been tested in SSc, may be useful in evaluating physical and mental state of these patients.

Method: Thirty-five patients aged 27-88 years (median=61), 85.7% female, monthly administered with prostacyclin treatment, were given EQ-5D and Health Assessment Questionnaire (HAQ) for self-completion before the treatment. Acceptability and feasibility were estimated

on the basis of patients' comments/complains on the tool and missing data respectively. The construct validity was tested by computing the Spearman's coerrelation coefficient between response of EQ-5D and HAQ.

Results: Acceptability of EQ-5D was good. With the HAQ, 31.4% of the patients reported difficulties to walk, 42.9% difficulties to arise, 48.6% difficulties to dress, 41.2% difficulties to wash, 57.1% difficulties to eat, 64.7% had difficulties to reach objects, 41.2% difficulties to grip things, 58.8% difficulties to do other common activities. With the EQ-5D, 45.7% had some difficulties to walk, 28.6% some and 5.7% severe difficulties with self-care, 45.7% had some and 8.6% severe difficulties to perform usual activities, 74.3% perceived some and 11.4% severe pain/discomfort, 54.3% were moderately and 2.9% extremely anxious or depressed. Mean VAS was 66.7 (30-90). Correlation coefficients between domains considered conceptually similar were: EQ-5D-mobility with HAQ-walking r=0.614; EQ-5D-self-care with HAQ-dressing r=0.715 and with HAQ-eating r=0.662, with hygiene r=0.443; EQ-5D-usual activities with HAQ-eating r=0.584, with HAQ-reach r=0.544, with HAQ-grip r=0.510 with other common activities r=0.495. The highest correlation of pain/discomfort and anxiety/depression was found with hygiene (0.552 and 0.436, respectively). Correlation coefficient between EQ-5D-VAS and HAQ total disability score was -0.597 ($p<0.001$).

Conclusion: EQ-5D was suitable for self-completion and well accepted in SSc patients; its construct validity was acceptable to good regarding mobility, self-care, usual activities. EQ-5D, differently from HAQ, also includes a mental/psychic domain. Furthermore, compared with other QoL tools such as SF-36, it can be fulfilled quickly and its score can be simply interpreted. Our results suggest that EQ-5D could be included in clinical practice to routinely assess SSc patients' QoL.

Workforce Planning in Paediatric Rheumatology in the United Kingdom (UK). C.E Pain[1], M.J Harrison[2], H.E Foster[3], D.P.M Symmons[2] and E.M Baildam[1], [1]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [2]arc Epidemiology Unit, University of Manchester, United Kingdom, [3]University of Newcastle, United Kingdom

Purpose: The British Society for Paediatric and Adolescent Rheumatology (BSPAR) recommends that all children with rheumatic disease are managed by specialist multidisciplinary teams with appropriate training in paediatric rheumatology (PRh). In the UK and many other parts of the world, adult rheumatologists have historically provided clinical care for children with rheumatic disease and increasingly there has changes been development of multidisciplinary PRh services working in clinical networks with adult rheumatologists or paediatricians. Recent in clinical training in the UK have resulted in PRh becoming a paediatric sub-speciality. Adult rheumatology trainees are no longer being trained in PRh and will be ill-equipped to manage children when incumbent adult rheumatology specialists retire.

Methods: In 2007 a questionnaire was sent to all UK adult rheumatology specialists. One aim was to identify the number of adult rheumatologists seeing children under 16 years, describe the clinical setting for consultations and to estimate numbers due to retire based on a retirement age of 65 years. This information will be used to determine future numbers of PRh consultants.

Results: The questionnaire was sent to 584 adult rheumatology specialists with 403 (69%) responding to questions about PRh service provision. 75/403 (19%) reported seeing patients aged under 16. The median (IQR) number of patients seen per month was 10 (6, 15), accounting for 931 paediatric patients seen in a year. Many rheumatologists will retire in the next 5 and 10 years (13/73 (18%) and 35/73 (48%) respectively). The majority (58/75, 78%) of respondents hold separate clinics for all paediatric patients, often alongside another health care professional (38/58 (57%) consultant paediatrician, 5/58 (9%) PRh specialist, 5/58 (9%) with both present and 7/58 (12%) with another healthcare professional). 3/58 (5%) of adult rheumatologists ran paediatric clinics without another healthcare professional present and 4/75 (5%) of all specialists seeing children did so on their own without paediatric input.

Conclusion: Throughout the UK many adult rheumatologists are involved in managing children with rheumatic disease, and this is similar to that reported in other health care systems. Compared to the US, most adult rheumatologists in the UK see children within a shared care model with paediatric rheumatologists or paediatricians [1]. Over the next 10 years a large number of adult rheumatologists who manage children with rheumatic disease will retire. Their departure will result in a large shortfall in service provision. Unless addressed urgently in workforce planning and training within PRh, along with appropriate expansion of clinical services, these changes will results in marked inequity of access to specialist care for children with rheumatic disease.

The Canadian Arthritis Referral Study (CARS): An Initial Evaluation of the Canadian Arthritis Referral Tool (CART). Andrew Thompson[1], Sara Graydon[2] and Elaine Zibrowski[2], [1]St Joseph's Hlth Ctr, London, ON, [2]St Joseph Hosp/Monsignor Roney, London, ON

Purpose: The importance of triage strategies for rheumatologic referrals is highlighted by the now well-accepted concept that rheumatoid arthritis (RA), in its early stages, is a relative emergency and early intervention may significantly improve outcomes. Given the burden of musculoskeletal disease, as well as the increasing wait times for rheumatologist consultation, various practice management and referral triage strategies have been developed. Success of all triage strategies requires accurate transfer of clinical information between the primary care giver and rheumatologist. We describe the initial evaluation of a prototype single page rheumatology referral form, the Canadian Arthritis Referral Tool (CART), and those factors that improve the ability to accurately triage rheumatology referrals as urgent vs non-urgent.

Method: From September 1, 2007 to August 31, 2008 six rheumatologists at a single academic centre prospectively collected referrals on the CART. All data from the CART was coded and entered into a database. Referrals were prospectively graded on a 4-point scale4 by a single rheumatologist as emergency (1), urgent (2), semi-urgent (3), or elective (4). After the initial rheumatologic consultation a post-hoc grade was assigned to each case based on the clinical information gathered. A binary logistic regression model exploring 17 co-variates was developed using the dependent dichotomous outcome of urgent vs non-urgent at the time of consultation. Agreement between referral and consultation grades was also assessed.

Results: From September 1, 2007 to August 31, 2008, 952 referrals were received on the CART tool. From September 1, 2008 until present 529 of those referrals have been evaluated in consultation and 469 cases were appropriate for this analysis. Using a binary logistic regression model, those factors that were predictive or protective for an urgent vs non-urgent consultation are outlined in Table 1. The probability of assigning an urgent grade at referral for those patients who were deemed to be truly urgent at consultation was 76.9% (sensitivity). The probability of assigning a non-urgent grade at referral among those patients who were deemed to be truly non-urgent at consult was 75.4% (specificity). Factor Odds Ratio, p-value Gender (Male vs Female) 0.62, p=0.05 Patient Reported Joint Swelling (No vs Yes) 2.2, p=0.03 Physician Reported Joint Swelling (No vs Yes) 2.2, p=0.01 History or family history of psoriasis (no vs yes) 1.6, p=0.09 Prior visit to a rheumatologist (no vs yes) 2.3, p=0.002 Rheumatoid factor (negative vs positive) 2.8, p<0.001 Age (<60 vs >60) 0.61, p=0.05 ESR (normal vs elevated) 1.9, p=0.03 CRP (normal vs elevated) 1.8, p=0.05 Duration (<12 months vs >12 months) 1.6, p=0.07

Conclusion: The use of a standardized rheumatology referral tool has significantly increased the ability to detect urgent referrals with our previously measured sensitivity4 increasing from 59% to 76.9%. Using the results of the binary logistic regression model and the analysis of the urgent referrals not identified in the screening process the tool has been further refined. A multi-centre project of the refined referral tool is currently underway.

A Decision Aid for Rheumatoid Arthritis Patients Considering Methotrexate Therapy. Richard W. Martin[1], Patience J. Gallagher[2], Aaron T. Eggebeen[1] and Andrew J. Head[1], [1]Michigan State University, Grand Rapids, MI, [2]Calvin College, Grand Rapids, MI

Purpose: Patient decision aids (PtDA) are tools that medical providers use as a supplement to clinical discussion. PtDAs contain information with choices and outcome probabilities, help patients clarify their values, and provide structured guidance about deliberation. This study sought to develop and pilot test an inexpensive PtDA that could be used during and following a clinical encounter by rheumatoid arthritis (RA) patients considering methotrexate (MTX) therapy.

Method: The PtDA was developed following International Patient Decision Aid Standards Consortium (IPDAS) criteria[1]. Outcome probabilities were identified from the published literature. A preliminary PtDA was pre-tested in 5 RA patients and 10 rheumatology

professionals. After revision, formal pilot testing was conducted in RA patients who had made the decision to start MTX in the past 2 years. Evaluation included visual screening, health literacy screening, time to complete the PtDA, formative and summative questionnaires, and extended structured interviews to illicit feedback to improve the usability of the materials.

Results: The decision aid was developed using plain language (SMOG score of 9.9) and expressing outcome probabilities simultaneously in narrative, natural frequencies, and pictographs. Outcome values clarification and preferred decision making role were elicited with social matching exercises. Deliberation was guided with a modified balance and leaning scale. Of the 17 participants, 76.5% were female, 94.1% were white, 17.6% attained less than high school graduation and 23.5% displayed low or marginal health literacy. Mean completion time was 12.7 minutes (SD 4.0). Persons with lower levels of confidence in ($p<.01$) and satisfaction with ($p<.02$) their previous decision to take MTX took significantly more time to work through the PtDA. Responses about the acceptability, clarity and usefulness of the PtDA were significantly more positive when compared to the neutral value of 3 ($p<.02$) using a one sample t-test for each of the 15 formative evaluation questions. Pre-post PtDA testing of MTX-related knowledge disclosed a significantly increased score from 71.5 to 82.9% correct ($p<.01$), which translates into an effect size of 0.35 for the intervention. Qualitative responses from structured interviews revealed patients felt the PtDA was enjoyable to read, the contents were logical and understandable, and the length was about right. Appraisal with the IPDAS instrument[2] disclosed a quality score of 74 (0-100) which is in the range of existing benchmark decision aids.

Conclusion: Pilot testing suggests that the PtDA is acceptable to patients and effectively informs them of the risks and benefits of MTX. This PtDA could be used as an adjunct to a rheumatology office encounter to encourage shared decision making and increase patients' choice of preference-based care.

Quality Assurance Project: Implementing a Cost-Effective Solution for a Rheumatology Electronic Prescription. Steven J. Katz and Elaine Yacyshyn, University of Alberta, Edmonton, AB

Purpose: Hand written physician prescriptions are fraught with potential medical errors; illegibility, mistakes in dosing, and record keeping are all issues of concern. A prescription error by a pharmacy led to this quality assurance project. With improving patient safety in mind, electronic health records (EHR) and electronic (e) prescription programs are becoming more common, but they remain cost-prohibitive and can be technically difficult to implement. Our aim was to design and implement a cost-effective e-prescription program specifically for the rheumatologist.

Methods: The University of Alberta clinical area is equipped with desktop computers in each room and one central printer. There is no centralized EHR. Microsoft Office 2003 was installed on each computer. Using Microsoft Excel 2003, a prescribing template was created by the rheumatology resident with the 30 most commonly used medications for a rheumatology practice. The password protected program was listed on a website for download, with a link provided to the website on each clinic computer for easy access. A printed copy of the prescription was provided to the patient.

Results: The Edmonton Rheumatology Prescription Software (E-RPS) program was developed in the fall of 2008, with initial programming time under one day. E-RPS was successfully trialed between December 2008 and February 2009 by the division's rheumatology residents, with changes made based on their suggestions, including an automatic second printed copy for the chart and improved esthetics. The program was then expanded to include all rheumatologists on site. Since implementation, no rheumatologist has received a phone call from a pharmacy to clarify an e-prescription and no medication errors have been identified. Ongoing disadvantages of the software include no inclusion of an electronic record of medications prescribed and difficulties prescribing titrating doses.

Conclusion: A rheumatology centered e-prescription program was successfully implemented and is now in use by rheumatologists at our site. We believe this is a cost effective and practical alternative to more expensive EHRs or e-prescribing software to provide quality assurance in improving patient safety. Improvement of the program will be ongoing based on user suggestions and expanded upon request.

The Impact of a Centralized Referral System in Rheumatology. Glen S. Hazlewood, Liam Martin and Susan G. Barr, University of Calgary, Calgary, AB

Purpose: With resources in rheumatology becoming increasingly strained, efficient referral systems are needed. The purpose of this project was to evaluate the success of a centralized rheumatology referral system in our city.

Method: A centralized referral system for rheumatology was implemented in 2006. All rheumatologists in academic and community practice in our city were invited to participate. All referrals are sent to a common referral center, triaged, and distributed amongst the participating rheumatologists. Referring physicians could refer to a specific rheumatologist if they desired. Data on the triage category, wait times and feedback from the rheumatologists on referral quality were collected prospectively in a database. Where appropriate, we compared our results to a pre-implementation practice audit.

Results: Overall, 13/14 rheumatologists (93%) participated in the centralized referral process. During the 2-year study period (Jan 1, 2007-Dec 31, 2008) 9182 referrals were received (383 per month). 80% were booked with the next available rheumatologist, 9% were booked directly with a rheumatologist, 2% were redirected and the remaining 9% were not booked or were waitlisted. Consults were triaged as routine (74%), moderate (19%), or urgent (7%). Feedback was received from the rheumatologist for 3779 referrals (41%). Rheumatologists rated referral quality as moderate or high in 91% of referrals, and the completeness of information as moderate or high in 87% of referrals. The triage category was felt to be appropriate for 90% of referrals. Of the consults triaged inappropriately, 104 (2.8% of all referrals) were "under-triaged" as routine or moderate when they should have been urgent. Of these, referral completeness was deemed "Low" in 31%. There were 14 routine or moderate cases that were "over-triaged" as urgent. There were 254 no-shows (6.7%) which was similar to a prior practice audit. Duplicate referrals were eliminated, which was identified as a significant problem at baseline with a rate of >= 6%. Mean wait times, when compared to baseline, were similar for routine referrals (pre 155±88 days, post 148.9±65, p=0.11), and improved for moderate (pre 110±57, post 77.7±56, p<0.001), and urgent referrals (pre 29±46, post 18.3±22.8 p=0.01). Wait time variability improved significantly, with mean wait times for individual rheumatologists ranging from 44-271 days pre- to 109-178 post-implementation (p<0.01).

Conclusion: A centralized referral system to rheumatology eliminates duplicate consults and improves wait times and wait time variability between rheumatologists. The urgency of referral can be categorized correctly in a high percentage of cases.

Rheumatologists' Practice for Prescribing Pneumocystis Prophylaxis. Deanna Cettomai, Allan C. Gelber and Lisa Christopher-Stine, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Consensus guidelines for *Pneumocystis* pneumonia (PCP) prophylaxis in HIV-negative patients with rheumatologic disorders are lacking. We assessed rheumatologists' practice patterns for prescribing PCP prophylaxis.

Method: Invitations to participate in an online international survey were emailed to 3150 American College of Rheumatology members.

Results: Surveys were retuned by 727 (23.14%) individuals, of whom 505 (69.5%) reported prescribing prophylaxis. In univariate analyses, factors associated with significantly higher odds of prescribing PCP prophylaxis included female gender, US-based and academic practice of <10 years duration, having previously treated a patient with PCP pneumonia, and a practice with a higher proportion of patients on chronic glucocorticoids or other immunosuppressant medications. In multivariate analysis, rheumatologists early in their careers and those with a US-based practice, or a higher proportion of patients treated with chronic glucocorticoid therapy were most likely to prescribe PCP prophylaxis. Among the prescribers, the most important determinant factors for prescribing prophylaxis were treatment regimen (68.6%), rheumatologic diagnosis (9.3%), and medication dosage (8.3%).

	Prescribe PCP Prophylaxis	Univariate Logistic Regression		Multivariate Logistic Regression	
Demographic Characteristic	n (%)[†]	OR (95% CI)	p	OR (95% CI)	p

Female gender	191 (74.9)	1.47 (1.04, 2.08)	0.03	1.01 (0.68, 1.50)	0.97
Male gender	308 (67.0)				
US-based practice	420 (72.0)	1.77 (1.20, 2.61)	0.004	1.974 (1.27, 3.05)	0.003
Internationally-based practice	80 (59.2)				
Academic practice	248 (81.0)	2.75 (1.94, 3.89)	< 0.001	1.81 (1.23, 2.66)	0.003
Non-academic practice	252 (60.9)				
≤ 10 years in practice	206 (86.6)	4.08 (2.69, 6.18)	< 0.001	4.13 (2.62, 6.51)	< 0.001
> 10 years in practice	292 (61.2)				
≥ 10% patients on chronic glucocorticoids	414 (72.8)	2.04 (1.40, 2.96)	< 0.001	2.11 (1.38, 3.23)	0.001
< 10% patients on chronic glucocorticoids	84 (56.8)				
≥ 10% patients on other immunosuppressants	488 (70.5)	3.19 (1.48, 6.86)	0.003	2.26 (0.98, 5.26)	0.06
< 10% patients on other immunosuppressants	12 (42.8)				
Caring for a patient who developed PCP	159 (82.8)	2.62 (1.73, 3.98)	< 0.001	3.04 (1.92, 4.82)	< 0.001
Never caring for a patient who developed PCP	345 (64.7)				
≤ 10 patients with rheumatologic diagnosis under clinical care each week	43 (76.8)	1.48 (0.78, 2.82)	0.23	---*	---*
> 10 patients with rheumatologic diagnosis under care each week	455 (69.0)				

[†]Proportion of respondents with characteristic prescribing PCP prophylaxis.

*Not included in multivariate analysis because variable did not reach statistical significance in the univariate analysis.

Conclusion: Nearly one-third (30%) of rheumatologists surveyed reported that they never prescribed PCP prophylaxis. While the patients for whom physicians would prescribe prophylaxis varied widely, physician demographic characteristics were strongly predictive of prophylaxis use. Consensus guidelines would be helpful to guide clinical decision-making regarding PCP prophylaxis in HIV-negative patients with rheumatologic diagnoses.

Validity of Performance–Based Measures of Physical Functioning in Patients with Ankylosing Spondylitis. Salima F.E. van Weely[1], J. Christiaan van Denderen[1], Martijn P.M. Steultjens[2], Michael T. Nurmohamed[1], Joost Dekker[2], Ben A.C. Dijkmans[3] and Irene E. van der Horst-Bruinsma[2], [1]Jan van Breemen Institute, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands

Purpose: Patients with Ankylosing Spondylitis (AS), gradually experience a reduction in physical functioning and quality of life over time. Physical function is an important domain in core sets of outcome measures in AS research. A widely used outcome measure for this domain is the self-administered Bath AS Functional Index (BASFI) questionnaire, which reflects the patient's point of view. However, it is unclear whether this self-assessment reflects the actual physical performance of patients with AS. Therefore, eight performance-based tests of activities were developed based on BASFI-items.

The objective of this study was to assess the validity of these performance-based tests.

Method: 105 patients with AS completed a BASFI questionnaire and 8 performance tests. The performance tests were extracted from the BASFI. (1.Putting on socks. 2. Bending forward. 3. Reaching up. 4. Getting out of a chair. 5. Getting up off the floor. 6. Climbing 12-15 steps. 7. Looking over the shoulder. 8. Doing physically demanding activities). For tests 1-6 and 8 the time to actually perform the test was measured. For test 7 the ability to look over one shoulder was measured by the range of vision while looking over the shoulder.

Spearman correlation coefficients were calculated and factor analyses were performed to asses the association between the BASFI and the performance tests.

Results: Only modest correlations were found between performance tests and BASFI ranging from 0.25 to 0.57 ($p < 0.05$) Factor analyses including performance tests and corresponding BASFI items produced two independent domains; one for self-reported and one for performed physical functioning. Repeating this analysis and replacing the performance test scores with a compound score comprising time, pain and fatigue resulted in one factor incorporating both self-report and performance.

Conclusion: Self-reported and performance measures of physical functioning in AS produce different outcomes. Consequently, performance tests and self-reported questionnaires on physical functioning measure different constructs of the domain physical functioning. Integrating experienced pain and fatigue in the performance score bridges the gap with self-report and gives relevant additional information on physical function.

Smoking Intensifies Rheumatoid Arthritis Susceptibility in Individuals Carrying the HLA-DRB1 Shared Epitope Regardless of Serologic Markers. So-Young Bang[1], Kyoung-Ho Lee[2], Soo-Kyung Cho[1], Hye-Soon Lee[1], Kyung Wha Lee[3] and S.-C. Bae[1], [1]Hanyang Univ Medical Center, Seoul, South Korea, [2]Seoul National University, Seoul, South Korea, [3]Hallym University Sacred Heart Hospital, Anyang, South Korea

Purpose: Smoking is associated with rheumatoid arthritis (RA) in individuals with the HLA-DRB1 shared epitope (SE). SE alleles have been found to be predominantly associated with anti-cyclic citrullinated peptide antibodies (ACPA)-positive RA. These risk factors have not been identified for ACPA-negative RA. We investigated whether SE-containing HLA-DRB1 alleles, smoking, or the combination contribute to the development of RA depending on the presence or absence of serologic markers in a Korean population.

Method: All RA patients (n =1482) and controls (n = 1119) were Korean.Four-digit HLA-DRB1 typing was performed by a conventional PCR-SBT method. Information about smoking history was obtained through a questionnaire. RA patients were tested for ACPA and rheumatoid factor (RF).

Results: The SE alleles had significant effects on ACPA and RF formation. The DRB1*0901 allele was independently associated with the presence of ACPA (OR 2.49) and RF (OR 2.09). SE alleles and smoking were associated with both ACPA-positive and ACPA-negative RA. The combination of smoking and double SE copies increased the risk for ACPA-positive RA 36.11-fold and ACPA-negative RA 12.29-fold, compared with the risk among nonsmokers not carrying the SE alleles. Gene-environment interactions between SE alleles and smoking were observed for both ACPA-positive and RF-positive RA.

Conclusion: We demonstrated that SE alleles and smoking are associated with RA susceptibility, regardless of ACPA or RF status. The SE-smoking interactions were present in both ACPA-positive and RF-positive RA.

Relationship Between Synovial Blood Flow Signals and Angiogenesis Factors in Patients with Rheumatoid Arthritis by Power Doppler Ultrasonography. Kenichiro Hirai, Daitaro Kurosaka, Makiko Nishioka, Yukio Miyamoto, Ken Yoshida, Isamu Kingetsu, Kunihiko Fukuda and Akio Yamada, The Jikei University School of Medicine, Tokyo, Japan

Purpose: To study the relationship between increases in the blood flow of the synovial blood vessels and vascularization observed in the synovial membrane of patients with rheumatoid arthritis by power Doppler ultrasonography (PDUS).

Methods: The subjects were 70 patients with RA who fulfilled the diagnostic criteria of the American College of Rheumatology. Ten joints: the bilateral wrists, elbows, shoulders, knees, and ankles, were examined by PDUS. The blood flow signals at synovial sites of each joint were scored 0-2, and the total blood flow scores of the 10 joints was calculated as the total signal score (TSS). The vascular endothelial growth factor (VEGF), angiopoietin-1 (Ang-1), angiopoietin-2 (Ang-2), and interleukin-6 (IL-6) levels were determined by ELISA.

Results: Significant correlations were observed between the TSS and serum VEGF, Ang-2, and IL-6 levels but not between the TSS and serum Ang-1 level.

Conclusion: The increases in the synovial blood flow signals in joints of RA patients observed by PDUS are likely to be caused by vascularization in synovial proliferation areas. They are particularly likely to represent the pathology in the period of marked vascularization, in which Ang-2 plays a dominant role.

Richards[10], Lindsey A. Criswell[11], Peter K. Gregersen[12] and Gw Cannon[13], [1]U Nebraska, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Univ of NE Medical Ctr, Omaha, NE, [4]University of Nebraska and NDB, Omaha, NE, [5]VAMC, University of Texas Southwestern Medical Center, Dallas, TX, [6]Department of Veterans Affairs, Dallas, TX, [7]Univ of CO Denver School of Med, Aurora, CO, [8]University of MS Med Ctr, Jackson, MS, [9]VAMC, Georgetown University, Washington, DC, [10]Veterans Affairs Medical Ctr, Washington, DC, [11]University of California, San Francisco, [12]Feinstein Institute for Medical Research, Manhasset, NY, [13]VA and University of Utah, Salt Lake City, UT

Purpose: Approximately half of Caucasians are homozygous for a deletion allele in *glutathione S-transferase Mu-1 (GSTM1-null*), a genotype previously associated with rheumatoid arthritis (RA). The purpose of this study was to examine the associations of *GSTM1* status with anti-cyclic citrullinated peptide antibody (ACPA) positivity and to assess interactions of this genotype with other known RA risk factors.

Methods: Associations of *GSTM1-null, HLA-DRB1 shared epitope (SE),* and smoking with autoantibody positivity were examined in U.S. veterans with RA (n = 595). Additive *gene-gene* and *gene*-smoking interactions were examined by calculating an attributable proportion (AP) due to interaction.

Results: Patients were predominantly men (93%) with a history of ever smoking (79%). Most were positive for ACPA (77%), rheumatoid factor (RF) (81%), and *SE* (75%) while 53% were *GSTM1-null*. *GSTM1-null* (vs. *GSTM1-present*) was associated with a significantly higher odds of ACPA positivity (OR = 1.58; 95% CI 1.07 to 2.32) but not with RF positivity. There were significant additive interactions between *SE*-smoking (AP = 0.56; 95% CI 0.27 to 0.86) and *SE-GSTM1* (AP = 0.49; 95% CI 0.21 to 0.77) in ACPA positivity, the latter most striking in ever smokers (Figure, right panel, O.R. 58.2 [95% CI 7.4 to 456.6] in SE+ 2 copy/GSTM1-null) vs. never smokers (left panel). Study results were not changed after the exclusion of women.

Conclusion: The *GSTM1-null* genotype adds substantially to the risk of ACPA positivity already imposed by *HLA-DRB1 SE* in RA, a risk that is most pronounced in smokers. With an antioxidant function of *GSTM1*, these data suggest that oxidative stress may play an important pathogenic role in ACPA-positive RA.

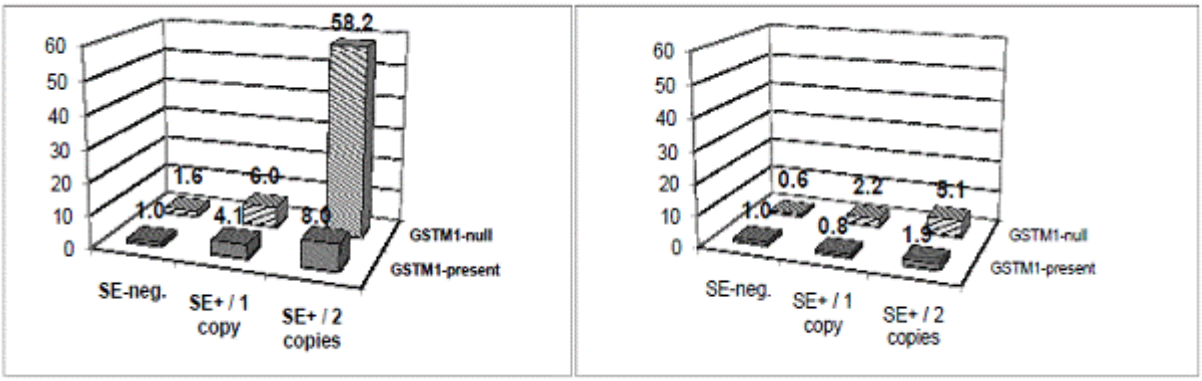

Figure: Odds ratios (ORs) of ACPA positivity based on SE copy number and GSTM1-null status among ever smokers (left panel) and never smokers (right panel)

Citrullinated Proteins Activate IgE-ACPA+ Cells in Rheumatoid Arthritis. Annemie JM Schuerwegh, Andreea Ioan-Facsinay, Annemarie L. Dorjée, Ellen IH van der Voort, Tom WJ Huizinga and René EM Toes, Leiden University Medical Center, Leiden, Netherlands

Purpose: Untill now, the mechanisms on the basis of the chronic inflammation and cartilage destruction in Rheumatoid Arthritis (RA) are unknown. The discovery of antibodies against cyclic citrullinated proteins (ACPA) was a breakthrough. In humans, a direct functional/pathogenic role for ACPA is never shown. The few MCs in the normal synovium of healthy subjects expand to constitute 5% of all synovial cells in RA patients. In this study, it is hypothesized that citrullinated proteins activate immune cells by cross-linking specific IgE-ACPA molecules, bound on FcεRI receptors. The objective of this study is to investigate the presence and the functional role of IgE-ACPA in RA patients.

Method: A sandwich ELISA was performed for anti-citrullinated protein (fibrinogen) IgE antibody detection. The ability of these sera to activate basophils via the human FcepsilonRI was investigated by performing a passive sensitization of human FcεRI transfected Rat Basophil cells (RBL). A basophil activation test was performed with peripheral blood of ACPA-, ACPA+ RA patients and healthy controls to evaluate the potency of citrullinated proteins to directly activate basophils. FACS analysis visualized citrullinated protein (FITC coupled) binding to basophils. IgE and Fc\epsiRI expression were studied by FACS on synovial MC obtained by joint replacement surgery or arthroscopic biopsy in RA and osteoarthritis (OA) patients. Histamin (competitive ELISA) and IgE levels (UniCap) were measured in synovial fluid (SF) of ACPA-, ACPA+ RA and OA patients.

Results: IgE antibodies against citrullinated antigens could be detected in sera of ACPA+ RA patients. No IgE antibodies were found against their uncitrullinated counterparts. Sensitizing human Fc\epsi RI expressing RBL cells with serum from ACPA+ RA patients (but not from ACPA- RA patients) lead to a rapid activation of these cells to ACPA- RA patients and healthy controls, when RBL cells were stimulated by citrullinated antigens but not by uncitrullinated antigens. Non-transfected RBL cells were not activated, showing the specificity of citrullinated antigens to crosslink IgE-ACPA via FcεRI. Direct ex vivo activation (i.e. within 20 minutes) of basophils from ACPA+ RA patients but not from ACPA- RA patients after exposure to citrullinated antigens (but not uncitrullinated control antigens) was observed. This activation was correlated to the binding of citrullinated proteins in basophils and to the presence of immunoglobulins on the surface of these cells. FcεRI and IgE expression was increased in synovial mast cells of ACPA+ patients compared to ACPA- patients and OA patients. Histamine levels correlated with IgE levels in ACPA+ RA SF, but not in ACPA- RA, suggesting degranulation of MC by crosslinking IgE-ACPA.

Conclusion: For the first time, a direct biological response to citrullinated antigens of immune cells is shown in ACPA+ RA patients only. In addition, these results indicate that IgE-ACPA and FcεRI-positive cells (such as mast cells) could be involved in the pathogenesis of RA.

Investigating the Complex Associations of MHC with RA Susceptibility. G. Orozco, W. Thomson, A. Barton, S. Eyre, J. Worthington and Xiayi Ke, arc Epidemiology Unit, Manchester, United Kingdom

Purpose: The major rheumatoid arthritis (RA) susceptibility locus, *HLA-DRB1*, lies within the major histocompatibility complex (MHC) at 6p21. There is evidence of additional RA loci in the MHC, although interpretation of these associations is made difficult by the presence of strong linkage disequilibrium across this region. Our aim was to investigate the complex association pattern of the MHC region with RA susceptibility to identify effects independent of *HLA-DRB1*.

Methods: A total of 1,804 RA cases and 1,474 1958 Birth Cohort controls were included in the study.

High resolution *HLA-DRB1* typing was performed using Dynal RELI^{TM} SSO kits. Subjects were genotyped for 1,546 single nucleotide polymorphisms (SNPs) within the extended MHC region using Affymetrix GeneChip 500K, as part of the Wellcome Trust Case Control Consortium (WTCCC) study. Statistical analysis was carried out using PLINK and Stata.

Results: Shared epitope (SE) alleles were strongly associated with RA (OR 4.25 95% CI 3.52-5.12 and OR 17.44 95% CI 13.18-23.07) for the carriage of one and two copies of the SE, respectively). In particular, the *0101, *0404 and *0408 alleles showed the strongest association with increased RA risk. Therefore, our RA cohort showed a similar pattern of HLA associations to that previously shown for other European populations.

We found 745 SNPs significantly associated with RA (P trend<0.05). Of these, 398 SNPs showed association at a significance level of P trend<0.001. Many of the strongest associations were observed in the vicinity of the *HLA–DRB1* locus.

To avoid confounding by RA-associated DRB1 alleles, we analyzed MHC SNPs using a data set with pairwise matching of cases and controls on HLA-DRB1 genotypes. Analsysis of the 594 case–control pairs with identical HLA-DRB1 genotypes revealed 104 SNPs significantly associated with RA (P<0.05), suggesting that additional effects can be found in the HLA region. Of these, 3 loci showed the strongest associations with RA (P<0.003):

Locus 1: close to *ZNF391* in extended class I

Locus 2: close to *OR2H1* in extended class I

Locus 3: close to *HLA-DPB1/DPB2* class II

Conclusion: This analysis has revealed that multiple independent effects contribute to RA susceptibility in the MHC region. Validation is now being carried out using independent external datasets.

HLA-DRB1*15 Non-Shared Epitope Allele Regulates Production of Very High Levels of ACPA in RA. Judit Laki[1], Emeli Lundström[1], Bo Ding[2], Lars Alfredsson[2], Lars Klareskog[1] and Leonid Padyukov[1], [1]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Purpose: Production of anti-cyclic citrullinated peptide antibodies (ACPA) is an important biomarker for the major subgroup of rheumatoid arthritis (RA). It has been demonstrated that capability to develop these antibodies is associated with HLA-DRB1 shared epitope (SE) alleles. Interestingly, the level of ACPA does not correlate with disease activity. Nevertheless, there is a distinct group of ACPA positive RA patients characterized by very high ACPA levels exceeding the upper limit of the ELISA test. So far there are no data available whether there is a distinct genetic predisposition for this very high ACPA level. Our goal was to determine, whether HLA-DRB1 alleles are involved in regulation of production of very high ACPA in comparison with regular/moderate level in ACPA positive RA.

Methods: In the cohort of 1073 ACPA positive RA patients from the Swedish EIRA study HLA-DRB1 alleles were detected by SSP-PCR genotyping. Baseline DAS28 data from the time of diagnosis were available in 515 patients. Using provisional cut-off with 1,500 units, we found that 283 patients (26.4%) had very high ACPA levels, the rest of patients were considered as with regular ACPA levels.

Results: Though we did not observe any significant differences in baseline DAS28 data between patients with very high and regular ACPA levels, there were marked differences in the genetic background of the two groups. DRB1*15 in combination with smoking was associated with very high ACPA levels (p=0.0002, OR=2.322). Presence of DRB1*03 in combination with shared epitope (SE) alleles was asssociated with moderate or low ACPA levels (p=0.0009, OR=0.3029), however this effect was not independent from DRB1*15. Neither HLA-DRB1 SE alleles nor smoking had any independent effect on production of very high ACPA.

Conclusion: Our data indicate that presence of DRB1*15 may promote very high ACPA levels, in particular in smokers. Our data illustrate the complex nature of the genetic regulation of ACPA levels, and demonstrate the need for additional mechanistic studies on the regulation of ACPA and ACPA-positive RA.

A Functional RANKL Promoter SNP Associated with Younger Age at Onset of Rheumatoid Arthritis. W. Tan[1], H. Wu[1], L. A. Derber[2], D. M. Lee[3], N. A. Shadick[3], E. A. Smith[4], V. H. Gersuk[5], G. T. Nepom[5], L. W. Moreland[6], D. E. Furst[1], S. D. Thompson[7], B. L. Jonas[8], V. M. Holers[9], P. P. Chen[1], D. N. Glass[7], S. L. Bridges[10], M. E. Weinblatt[3], H. E. Paulus[11] and B. P. Tsao[1], [1]UCLA, LA, CA, [2]U Colorado Denver, Aurora, CO, [3]Brigham and Women's Hosp, Boston, MA, [4]MUSC, Charleston, SC, [5]Benaroya Rsch Ini., Seattle, WA, [6]U Pittsburgh, Pittsburgh, PA, [7]Children's Hosp, Cincinnati, OH, [8]UNC-Chapel Hill, Chapel Hill, NC, [9]U Colo Denver, Aurora, CO, [10]UAB, Birmingham, AL, [11]David Geffen School of Medicine at UCLA, LA, CA

Purpose: We previously reported the association of co-occurrence of HLA-DRB1 shared epitope (SE) and R*ANKL* SNPs with younger at onset of RA in 182 RF+ European American (EA) early RA patients, which prompted us to fine map *RANKL* causal SNPs and study additional cohorts: 298 African-Americans (AA) RA (RF+ = 211, CCP+ = 172), 501 EA RA (RF+ = 317, CCP+ = 344) and 80 RF+ EA JIA.

Methods: SNPs were genotyped using TaqMan or pyrosequencing. *RANKL* expression levels in plasma, PBMC and isolated T cells were quantified using ELISA and RT-PCR. In vitro site-directed mutagenesis of rs7984870 within the 2kb *RANKL* promoter was performed to drive the luciferase reporter gene in transfected cells.

Results: Fine-mapping a 64-kb *RANKL* region using 19 SNPs in an extended 210 EA RF+ early RA patients showed association of minor allele homozygotes of 4 *RANKL* SNPs (rs5803141, rs7984870 and rs9525641 in the promoter region, and rs1054016 in the 3'UTR) with 5 yrs earlier mean age at RA onset ($p < 0.05$). The minor allele homozygote frequency for those 4 SNPs had increasing proportions in EA normals (10-11%), RF+ RA (18-20%), and RF+ EA polyarticular JIA (23-26%) patients ($p = 0.02$-0.009). Among those, rs7984870 CC genotype exhibited the strongest statistical significance ($p = 0.009$). This association was confirmed in 172 anti-CCP+ AA patients (7 and 5 yrs earlier for rs5803141 and rs7984870, respectively, $p < 0.05$), and replicated in an independent 344 anti-CCP+ EA early RA patients (4

yrs earlier for rs7984870, $p < 0.05$). Co-occurrence of rs7984870 CC genotype and HLA-DRB1*04 showed a strong younger age (mean 9.2 yrs earlier) at onset in RF+ and anti-CCP+ subgroups of both EA and AA patients ($p = 0.01$-0.00003). Plasma levels of RANKL were 2-fold higher in RF+ RA patients carrying rs7984870 CC vs. GG (10 vs. 13, $p < 0.001$) but not in normals (5 vs. 19). Levels of *RANKL* mRNA in normal PBMCs (17 vs. 21) or T cells (4 vs. 4) were not different in those carrying either homozygous rs7984870 genotypes. However, after 48h incubation with IL-2, significantly elevated *RANKL* mRNAs were observed in normal control T cells carrying the rs798470 CC genotype compared to those carrying the GG genotype (4 vs. 4, $p < 0.05$). Transfection of the rs7984870 CC *RANKL* promoter displayed higher transcription activity than the GG genotype in both stromal and osteoblast cell lines only after stimulation with b-FGF or TNFa ($p < 0.05$).

Conclusion: Association of CC genotype of rs7984870 with younger RA onset has been replicated in several independent cohorts, and confers an elevated promoter activity after stimulation. Elevated inducible *RANKL* mRNA and protein levels may predispose to earlier development of seropositive (RF+ or anti-CCP+) RA in EA and AA patients.

Prevalence of Anti-Cyclic Citrullinated Peptide Antibody and Its Association with Smoking in General Population: A Cross Sectional Study. Shunichi Kumagai, Nobuhide Hayashi, Seiji Kawano, Daisuke Sugiyama, Kunihiro Nishimura, Shimpei Kasagi, Jun Saegusa and Akio Morinobu, Kobe University Graduate School of Medicine, Kobe, Japan

Purpose: We have shown impact of smoking for developing rheumatoid arthritis (RA) by a meta-analysis.Some studies reported anti-cyclic citrullinated peptide antibody (anti-CCP) was related to smoking especially in RA patients with HLA-DR shared epitopes. Aim of this study is to determine the prevalence of anti-CCP and its relationship to RA in a general population and to clarify potential correlations between anti-CCP positivity and smoking.

Methods: Anti-CCP, rheumatoid factor (RF), and CRP were examined in 1,213 residents in a Japanese town. Serum MMP-3 levels were also measured in subjects positive for anti-CCP or RF. Multiple regression analysis was applied to clarify relationships with blood and urine tests results and life habit at physical examinations

Results: Of 1,213 subjects, 29 were positive for anti-CCP (2.4%). Five of seven RA patients were positive for both anti-CCP and RF, one was positive only for anti-CCP, and one was negative for both. Sensitivity and specificity were 85.7% and 98.1% for anti-CCP. Positive predictive value (PPV) of anti-CCP for RA was 20.7% and that of RF was 6.3%. Age and sex adjusted odds ratio (OR) of anti-CCP in current smoking was 4.40 [95% confidence interval (CI); 1.38-14.03] for whole population ($P = 0.012$). Age adjusted OR of anti-CCP was 5.27 [95%CI; 1.06-26.29] for man ($P=0.043$), 3.16 [95%CI; 0.38-26.43] for women ($P=0.28$), although the smoking rate was 43.8% and 2.9% for men (188/428) and women (23/784), respectively. No relation to smoking in past and current/past smoking was found for anti-CCP. In current smoking, age adjusted OR of RF was 1.87 [95%CI; 0.89-3.94] for men ($P=0.098$), 0.81 [95%CI; 0.11-6.25] for women ($P=0.28$).

Conclusion: Prevalence of anti-CCP in a Japanese general population was 2.4%. Anti-CCP was significantly associated with current smoking in the general population, but RF positivity was not.

Different Cartilage Oligomeric Matrix Protein (COMP) Patterns in Untreated Anti-CCP Positive and Negative Rheumatoid Arthritis (RA). AF. Christensen[1], P. Junker[1], H. Lindegaard[1], T. Lottenburger[2], B. Ejbjerg[3], M. L. Hetland[3], K. Stengaard-Pedersen[4], Soren Jacobsen[3], T. Ellingsen[4], Lis S. Andersen[5], I. Hansen[4], H. Skjødt[3], Jk Pedersen[2], UB Lauridsen[3], A. Svendsen[1], U. Tarp[4], J. Pødenphant[3], AG Jurik[4], M. Østergaard[3] and K. Hørslev-Petersen[2], [1]Odense University Hospital, Odense, Denmark, [2]Graasten Rheumatism Hospital, Graasten, Denmark, [3]Copenhagen University Hospital, Copenhagen, Denmark, [4]Aarhus University Hospital, Aarhus, Denmark, [5]Graasten

Purpose: COMP is an extracellular matrix protein, which is primarily localized in cartilage. The protein is believed to regulate collagen fibril formation and matrix assembly. In RA and osteoarthritis there is an altered distribution of COMP in cartilage and COMP release to synovial fluid is increased. The aims were to measure COMP in serum and paired synovial fluid samples in early, untreated RA and to study the predictive value of baseline COMP on structural joint damage at 5 years.

Method: One-hundred-and-sixty patients with DMARD naïve and newly-diagnosed RA were included in the CIMESTRA trial [1]. 90 blood donors served as controls. Disease activity measures (e.g. CRP), x-ray (n=160) and magnetic resonance imaging (MRI) of non-dominant wrist (n=135) were obtained at baseline. In addition, x-ray status was obtained at 5 years. Radiographic progression was defined as the minimal detectable difference from baseline using Sharp/van der Heijde Score. MRI synovitis, oedema and erosion score were assessed according to OMERACT criteria. Anti-CCP was assayed at baseline. COMP was measured in serum and synovial fluids at baseline by ELISA (AnaMar, Sweden). Synovial fluids were collected from 22 patients at baseline.

Results: COMP was increased in RA serum as compared with controls ($p<0.001$). However, anti-CCP positive patients had significantly lower COMP than anti-CCP negative subjects ($p=0.048$), although still elevated compared with controls ($p=0.042$). In both subsets COMP correlated with DAS28 and joint counts. In anti-CCP positive patients COMP was positively correlated to MRI erosion and oedema score ($rho=0.37$, $p<0.001$ and $rho=0.26$, $p=0.02$). In anti-CCP negatives there was a positive correlation between COMP and MRI synovitis score ($rho=0.32$, $p=0.02$). Baseline COMP did not predict x-ray progression at 5 years. Synovial fluid COMP was 3.8 times higher than COMP in serum, but did not correlate to serum values ($p=0.95$).

Conclusion: COMP is increased in early DMARD naïve RA. Anti-CCP negative patients had higher COMP in serum than anti-CCP positives. These findings indicate that anti-CCP antibodies are disease modifiers in RA as also reflected by the differential association of COMP with erosion and synovitis score at baseline in these two subsets.

Uncoupling of Collagen II Metabolism in Newly-Diagnosed Rheumatoid Arthritis (RA) Is Linked to Inflammation and Antibodies against Cyclic Citrullinated Peptides. AF. Christensen[1], P. Junker[1], H. Lindegaard[1], S. Christgau[2], T. Lottenburger[3], M.L. Hetland[4], K. Stengaard-Pedersen[5], Soren Jacobsen[4], T. Ellingsen[5], Lis S. Andersen[6], I. Hansen[5], H. Skjødt[4], Jk Pedersen[3], UB Lauridsen[4], A. Svendsen[1], U. Tarp[5], J. Pødenphant[4], AG Jurik[5], M. Østergaard[4] and K. Hørslev-Petersen[3], [1]Odense University Hospital, Odense, Denmark, [2]Novo Seeds, Novo A/S, Bagsvaerd, Denmark, [3]Graasten Rheumatism Hospital, Graasten, Denmark, [4]Copenhagen University Hospital, Copenhagen, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Graasten

Purpose: Type IIA procollagen is an alternatively spliced collagen II variant, which is present in fetal and diseased cartilage [1]. The N-propeptide of procollagen IIA (PIIANP) is suggested to be a marker of collagen IIA synthesis. The cross-linked C-telopeptide of collagen II (CTX-II) reflects collagen degradation.

The aim was to investigate the relationship between molecular markers of cartilage collagen synthesis and degradation with disease activity measures, auto-antibodies and radiographic outcome in a prospective 5-year protocol on newly diagnosed, DMARD naïve RA.

Method: One-hundred-and-sixty patients with newly-diagnosed, untreated RA entered the CIMESTRA trial [2]. Disease activity, anti-CCP and x-ray status were measured at baseline with additional recordings of synovitis score and radiographic changes after 5 years. CTX-II and PIIANP were measured at baseline by ELISA. PIIANP was also recorded at 2 and 4 years. An uncoupling index for cartilage collagen

metabolism was calculated from *z-scores* for PIIANP and CTX-II defined as numbers of standard deviations from control mean. 120 blood donors served as controls. P-values≤0.05 were regarded as significant.

Results: PIIANP was decreased at diagnosis and 4 years on ($p<0.001$), irrespective of treatment and disease activity. PIIANP was lowest in anti-CCP positive patients ($p=0.006$), and there was a negative correlation between PIIANP and anti-CCP titer (rho=-0.25, $p=0.002$). CTX-II was increased in RA patients ($p<0.001$) and correlated positively with conventional disease activity measures, but not with anti-CCP ($p=0.93$). CTX-II and the uncoupling index were associated with estimated x-ray progression, and joint space narrowing progressors had significantly higher CTX-II and uncoupling index than non-progressors.

Conclusion: Cartilage collagen formation and degradation are un-balanced when RA is diagnosed. The uncoupling of collagen II metabolism is most pronounced in anti-CCP positive patients. Collagen II degradation (CTX-II) is increased and positively correlated to synovitis, while collagen II anabolism (PIIANP) is decreased and negatively correlated with anti-CCP titer.

Association of rs8192284 IL-6 Receptor α Polymorphism and Soluble IL-6 Receptor Plasma Concentration with Disease Activity in Rheumatoid Arthritis. L. Rodriguez-Rodriguez[1], José Ramón Lamas[1], A. González-Vigo[2], P. Lopez-Romero[3], P. Tornero-Esteban[1], L. Abasolo[1], J. Varade[2], N. Perdigones[4], E. Urcelay[4] and Benjamin Fernandez-Gutierrez[5], [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Immunology Service, Hospital Clinico San Carlos, Madrid, Spain, [3]CNIC, Madrid, Spain, [4]Immunology Service, Hospital Clínico San Carlos, Madrid, Spain, [5]Hospital Clinico San Carlos, Madrid, Spain

Purpose: Interleukin 6 soluble receptor α subunit (sIL-6R) is mainly generated by shedding of the membrane-bound form. This process is influenced by the single nucleotide polymorphism rs8192284 (A>C) resulting in an Aspartic acid to Alanine substitution (D358A) located at the proteolitic cleavage site. The aim of this paper is to characterize whether plasma levels of sIL6R may be influenced by rs8192284 in Rheumatoid Arthritis patients and to address the association of sIL-6R plasma levels and SNP with disease activity.

Method: 39 patients were randomly selected from a cohort of RA patients of Spaniard descent. Plasma sIL-6R concentration was measured using an ELISA sandwich. Genotyping of rs8192284 (A>C) polymorphism was done using a Fast Real-Time PCR System. DAS 28 score was used to assess disease activity. Data are indicated as mean (standard deviation).

Results: sIL-6R plasma levels are positively associated to the number of C alleles (AA: 35.27 (3.50) ng/ml, AC: 45.50 (4.58) ng/ml, CC: 52.55 (3.18) ng/ml, $p<0.0001$). DAS28 and sIL-6R plasma levels showed a positive association in the anti-CCP positive subgroup ($r^2=0.4257$, $p=0.0482$) and a negative association in the anti-CCP negative subgroup ($r^2= -0.5466$, $p=0.0284$). Also an association between DAS28 and SNP was showed: C allele carrier was positively related to DAS28 in the anti-CCP positive subgroup (4.68 (1.11) vs. 3.57 (1.12), $p=0.0310$) and it was negatively associated in the anti-CCP negative subgroup (3.36 (1.03) vs. 6.37 (1.10), $p=0.0002$).

Conclusion: Our findings showed that rs8192284 polymorphism is operative in RA patients. The presence of anti-CCP antibodies determines the relationship between sIL-6R concentration, genotype and disease activity. RA anti-CCP positive patients carrying the C allele of rs8192284 SNP would be the ideal target for IL-6R blocking agents.

Altered ADAR2 Gene Expression and Altered Editing of PDE8A1 Gene Transcripts in Rheumatoid Arthritis (RA) T Cells. Dama Laxminarayana[1], Kenneth O'Rourke[2] and Irene Olorenshaw[2], [1]Wake Forest Univ Sch of Med, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC

Purpose: Rheumatoid Arthritis (RA) is an autoimmune disorder of indeterminate etiology characterized by B and T lymphocyte immune effector dysfunctions. The etiopathogenesis of the abnormal immune response in RA is associated with altered gene expressions. Adenosine to Inosine (A to I) editing is the post-transcriptional site-specific modification of precursor mRNAs catalyzed by the members of ADAR family genes. Such RNA editing plays an important role in the regulation of gene expression and produces phenotypic variability. Therefore, we hypothesize that the altered expression and function of ADARs is a mechanism for the immunopathogenesis of RA.

Methods: In the present study, we analyzed expression of ADAR1 and ADAR2 gene transcripts in RA and control T cells by competitive polymerase chain reaction (CPCR). 10 RA subjects and 10 healthy controls were studied. The Cyclic Nucleotide Phosphodiesterase 8A1 (PDE8A1) gene transcripts are edited by ADAR enzymes. Therefore, we assessed the role of altered ADAR2 enzyme expression in editing of PDE8A1 gene transcripts of RA T cells. The base position numbers of PDE8A1 gene transcripts reported here are used from the accession number AK001647. The PDE8A1 gene transcripts from normal and RA T cell samples were amplified and cloned into pCR2.1-TOPO vectors. A total of 100 clones from RA and 100 clones from controls were sequenced using T7 and M13 primers and an automated ABI-377 sequencer.

Results: The results revealed that the mean content of ADAR1 mRNA was 1.84 ±0.41 attomoles/µg total RNA in RA vs 1.79 ± 0.32 attomoles/µg total RNA in controls. The mean content of ADAR2 mRNA was 1.10 ±0.35 attomoles/µg total RNA in RA vs 1.70 ± 0.28 attomoles/µg total RNA in controls (p£0.05). Sequence analyses demonstrated altered A to I editing in the PDE8A1 gene transcripts of RA T cells. There are two hot spots for A to I editing in the PDE8A1 gene transcripts. The first hot spot consists of previously known edited nucleotides 42423 and 42424 and are called site 1. The A to I editing frequency at this site in RA and control samples is 18% and 29% respectively (p£0.001). The second hot spot is found between base positions 42454 and 42457 and called site 2. The A to I editing frequency at the second site was 2% for RA, and 8% for control subjects (p£0.001). In general, A to I editing is impaired in RA T cells compared to normal controls.

Conclusion: It is proposed that, the altered expression of ADAR enzymes tilt the balance of editing machinery and alter editing in RA transcriptome. Such altered editing may contribute to the modulation of gene regulation and ultimately, immune functions in RA patients and play an important role in the initiation and propagation of RA pathogenesis.

Alcohol Consumption Is Inversely Associated with Risk and Severity of Rheumatoid Arthritis. James R. Maxwell[1], Isobel R. Gowers[1], David J. Moore[2] and Anthony G. Wilson[1], [1]University of Sheffield, Sheffield, United Kingdom, [2]Royal Hallamshire Hospital, Sheffield, Sheffield, United Kingdom

Purpose: Studies have suggested that consumption of alcohol associates with a lower risk for rheumatoid arthritis (RA), but the effect of alcohol on disease severity has not yet been investigated. Our objectives were to study the association between alcohol consumption, and susceptibility and severity of RA.

Method: Frequency of alcohol consumption was recorded by patients and controls in a self completed questionnaire. Odds ratios for RA risk were calculated according to alcohol consumption, adjusted for age, gender and smoking status. Median values of all RA severity measures were then calculated according to frequency of alcohol consumption, and the non-parametric trend test was used to assess association. A quantile regression model was used to adjust for potential confounding.

Results: 873 patients with erosive RA, and 1004 healthy controls were included in the study. Risk of RA decreased according to frequency of alcohol consumption, such that non drinkers had an odds ratio for RA of 4.17 (3.01 – 5.77) compared to subjects consuming alcohol on >10 days per month (p for trend <0.0001). All measures of RA severity including C-reactive protein, 28 joint disease activity score, pain visual analogue scale , modified Health Assessment Questionnaire, and modified Larsen score were inversely associated with increasing

frequency of alcohol consumption (p for trend, each <0.0001). After adjustment for potential confounders in a multivariate regression model, frequency of alcohol consumption remained significantly and inversely associated with X ray damage (p=0.002).

Conclusion: This study suggests that alcohol consumption has an inverse and dose related association with both risk and severity of RA, but we would recommend a prospective study to confirm our findings.

Table 1. RA Severity by frequency of alcohol consumption

Severity Marker		Frequency of Alcohol (days / month)				P for trend
		0	**1-5**	**6-10**	**>10**	
LS	All	38 (54)	33 (47)	29 (45)	27 (47)	<0.0001
	Men	41 (44)	30 (46)	21 (45)	19.5 (34)	0.004
	Women	37 (57)	33 (47.5)	32 (52)	30 (54)	0.03
	ACPA+	40 (56)	36.5 (50)	32 (56)	33 (53)	0.02
	ACPA-	27 (52)	22.5 (39.5)	17.5 (23)	16 (35)	0.02
DAS28CRP		4.29 (1.66)	4.01 (1.50)	3.82 (1.63)	3.72 (1.41)	<0.0001

Smoking Rates in Patients with Rheumatoid Arthritis Are Similar to the General Population but Smoking Cessation Rates Are Higher in RA Patients: Data From the QUEST-RA Multinational Database. H. Makinen[1], Tuulikki Sokka[2], Theodore Pincus[3], B. Abelson[3], A. Naranjo[4] and QUEST-RA Investigators, [1]Tampere University Hospital, Tampere, Finland, [2]Central Hospital, Jyvaskyla, Finland, [3]NYU Hospital for Joint Diseases, New York, NY, [4]Hospital Doctor Negrin, Las Palmas GC, Spain

Purpose: Smoking has been implicated in the pathogenesis of rheumatoid arthritis (RA), particularly in association with antibodies to cyclic citrullinated peptides (anti-CCP) and the shared epitope. However, relatively little information is available concerning the proportion of people with RA who smoke and/or discontinued smoking compared to the general population. The QUEST-RA (Quantitative Standard Monitoring of Patients with Rheumatoid Arthritis) multinational cross-sectional database of 8,040 patients from 86 sites in 33 countries provided an opportunity to analyze rates of smoking and smoking cessation in 6,870 RA patients.

Method: QUEST-RA was established in 2005 to promote quantitative assessment in usual rheumatology care and develop a baseline cross-sectional database of consecutive RA patients seen in usual care in many countries. Three or more rheumatologists were asked to enroll 100 consecutive unselected patients in each country, using a standard protocol to evaluate RA (SPERA), with a clinical assessment and 4-page patient self-report questionnaire. Smoking status was assessed by self-report as “never smoked,” “smoked in the past but stopped” and “currently smoking.” Data for the proportions of the general population who smoked and did not smoke were available from all 33 countries. General population data for people who ceased smoking were found for 7 countries: Argentina, Canada, Finland, Germany, Italy, Sweden, and USA. Statistical significance of possible differences was calculated by chi-square analyses.

Results: Overall, 12.8% of 5,436 female QUEST-RA patients and 25.9% of 1,374 males were current smokers, compared to 22.7% of females and 36.8% of males in the general population. Among female QUEST-RA patients, 16.3% had stopped smoking and 70.8% never smoked; in males the proportions were 36.8% and 37.3%, respectively. In the 7 countries for which data concerning ex-smokers were found, 52.9% of patients vs. 52.4% in the general population had never smoked, 18.0% vs 26.6% were current smokers, and 29.1% vs 21.0% were ex-smokers.

	QUEST-RA					General Population			
Country	n	Never smoked	Ever smoked	Ex-smoker	Current smoker	Never smoked	Ever smoked	Ex-smoker	Current smoker
Argentina	243	52.9%	47.1%	25.7%	21.4%	45.5%	54.5%	22.6%	31.9%
Canada	99	31.3%	68.7%	38.4%	30.3%	53.0%	47.0%	26.0%	21.0%
Finland	301	60.2%	39.8%	25.2%	14.6%	49.1%	50.9%	20.8%	30.1%
Germany	222	54.3%	45.7%	32.7%	13.1%	54.0%	46.0%	19.0%	27.0%
Italy	333	58.9%	41.1%	25.2%	15.9%	57.6%	42.4%	18.1%	24.3%
Sweden	257	40.7%	59.3%	40.6%	18.7%	48.0%	52.0%	23.2%	28.8%
USA	296	55.7%	44.3%	24.4%	19.9%	58.2%	41.8%	21.0%	20.8%
TOTAL	1751	52.9%	47.1%	29.1%	18.0%	52.4%	47.6%	21.0%	26.6%

Conclusion: A lower proportion of patients with RA were current smokers than in the general population. The proportions of QUEST-RA patients who ever or never smoked were similar to the general population. Therefore, the likelihood of patients with RA having discontinued smoking was greater than in the general population.

PADI4 Haplotypes Do Not Interact with Smoking, but Interact with Shared Epitope Regardless of Antibodies to Cyclic Citrullinated Pepeptide. So-Young Bang[1], Yoon-Kyoung Sung[1], Kyounghee Jung[1], Tae-Un Han[2], Changwon Kang[2] and S.-C. Bae[1], [1]Hanyang Univ Medical Center, Seoul, South Korea, [2]Korea Advanced Institute of Science and Technology(KAIST), Daejeon, South Korea

Purpose: The association of the peptidyl arginine deiminase 4 (PADI4) gene with rheumatoid arthritis (RA) has been replicated in several Asian populations. Anti–cyclic citrullinated peptide antibodies (ACPA) are most specific serologic markers of RA. We investigated whether PADI4 polymorphisms contribute differently to two subsets of RA depending on the presence or absence of ACPA and whether PADI4 polymorphisms interact with the HLA-DRB1 shared epitope (SE) alleles or with smoking in a Korean population.

Method: All RA patients (n =1313) and controls (n = 1009) were Korean. Four exonic SNPs of the *PADI4* gene (padi4_89, padi4_90, padi4_92, and padi4_104) were genotyped using the MassArray SNP genotyping system. Odds ratios (OR) with 95% confidence intervals (CI) were examined using logistic regression analyses.

Results: The four SNPs and functional haplotype of *PADI4* gene were significantly associated with developing ACPA-positive RA and ACPA-negative RA. No interaction was seen between smoking and *PADI4* polymorphisms. Gene-gene interactions between homozygous GTT haplotypes and SE alleles were observed in the development of ACPA-positive and ACPA-negative RA (attributable proportion 0.44 [95% CI 0.18-0.69], 0.57 [95% CI 0.22-0.91], respectively).

Conclusion: Our findings indicate that PADI4 polymorphisms play a role in the development RA regardless of ACPA status. We could not find a gene-environment interaction between PADI4 polymorphisms and smoking. Gene-gene interaction between homozygous *PADI4* haplotypes and SE alleles occurs in conferring an increased risk of ACPA-positive as well as ACPA-negative RA.

Smoking and Aryl Hydrocarbon Receptor Function in Rheumatoid Arthritis. Marina Kazantseva[1], John Highton[1], Lisa K. Stamp[2] and Paul A. Hessian[1], [1]University of Otago, Dunedin, New Zealand, [2]University of Otago, Christchurch, New Zealand

Purpose: A number of environmental factors are believed to contribute to or protect against the development of rheumatoid arthritis (RA). Tobacco smoking is recognised as the main environmental risk factor for the development RA and is associated with increased incidence of extra-articular manifestations, including the development of subcutaneous rheumatoid nodules. How exposure to cigarette smoke contributes to the pathogenesis of RA remains to be established. The aim of this study was to identify the pathogenic mechanism(s) within inflamed RA tissues, which are triggered by smoking and engagement of the aryl hydrocarbon receptor (AhR).

Method: Total RNA was isolated from 19 synovial membrane samples, obtained at surgery from patients fulfilling ACR criteria for RA. A further 20 subcutaneous nodule samples were also obtained from a separate group of patients with RA. Two nodules were paired with synovial samples from the same patients. All synovial and nodule samples were assessed for AhR, CYP1A1, interleukin (IL)-17A, IL-17F, IL-22 and interferon (IFN)-γ gene expression by quantitative real-time PCR (Applied Biosystems).

Results: AhR was expressed significantly more in joint synovium when compared to rheumatoid nodules (7.10 ± 1.18 vs 2.77 ± 0.34 ng RNA respectively; mean ± SE; $P < 0.001$). To investigate AhR activation, CYP1A1 gene expression was assessed. CYP1A1 transcript was detected in 7/19 synovial membranes (37% CYP1A1+); 6/7 CYP1A1+ synovia were from patients who smoked at the time the sample was obtained, whereas 11/12 CYP1A1- synovia were from patients who never smoked or did not smoke for ≥ 5 years prior (Fisher's exact test; $P = 0.008$). 7/20 nodules (35%) were CYP1A1+ (4/7 smokers) and 13/20 were CYP1A1- (11/13 non-smokers). CYP1A1 expression was significantly higher in synovial tissue from smokers vs non-smokers but there was no such difference in nodule tissue. We investigated whether AhR activation influenced Th1 or Th17 pathways in RA. Contrary to expectation, we found significantly greater expression of IL-17A in CYP1A1- synovia vs CYP1A1+ synovia (0.11 ± 0.03 vs 0.02 ± 0.01 ng RNA; $P < 0.05$). In addition, there was a positive and significant association between IL-17A and AHR gene expression in CYP1A1- synovial tissue ($r = 0.58$; $P < 0.05$). IL-17F expression was restricted to 6/19 CYP1A1- synovia. IL-22 was not detected in synovia and IFN-γ expression was not different between CYP1A1+ and CYP1A1- synovia.

Conclusion: Our results show that in RA, smoking has a demonstrable impact on joint synovial tissue, activating AhR and inducing CYP1A1 expression. The same effect was not seen in rheumatoid nodules. We found that in CYP1A1- synovia from non-smokers, IL-17A gene expression is higher, IL-17F expression is exclusive and that there is a significant positive correlation between AhR and IL-17A expression. The results suggest that smoking induces expression of CYP1A1 (and probably other genes) in an AhR ligand-dependent manner in RA synovial tissue. However smoking appears to have a negative impact on expression of IL-17 related cytokines.

In Early RA, Increased IL-6 Levels Drive B-Cell Activation and Are Associated with Disease Activity and 1-Year Radiographic Progression, Independently From CRP and Other Proinflammatory Cytokines: Results From the ESPOIR Cohort. Jacques-Eric Gottenberg[1], Pascale Roux-Lombard[2], Beatrice Ducot[3], Jean-Michel Dayer[4], Xavier Mariette[5] and Cedric Lukas[6], [1]University Hospital of Strasbourg, Strasbourg, France, [2]Hôpitaux Universitaires de Geneve, Genève, Switzerland, [3]Biostatistics, Bicetre Hospital, France, [4]CMU. Office 9000, Geneva 4, [5]Bicetre Hospital, Paris-Sud University, Le Kremlin Bicetre, France, [6]Lapeyronie hospital, Montpellier, France

Purpose: Serum markers of B-cell activation are increased in early RA compared with undifferentiated arthritis (UA), independently from BAFF secretion. We investigated whether a specific pattern of serum cytokines could explain B-cell activation and correlate with diagnosis, activity and severity of RA.

Method: In the ESPOIR early arthritis cohort, 710 patients were assessed at 1 year and either met the 1987 ACR criteria for RA (n= 578) or had UA (n= 132). Baseline serum samples of patients naïve to corticosteroid and DMARD treatment and 50 healthy controls were assessed

for IL-1beta, IL1-RA, IL-2, IL-4, IL-6, IL-10 IL-17, MCP-1, TNF-alpha, IFN-gamma using Luminex. Radiographic progression was defined as an increase of total Sharp/van der Heijde score (SHS) greater or equal to 1 between inclusion and 1 year.

Results:

- Diagnosis of RA

Levels of all cytokines were significantly higher in patients with RA or UA compared with healthy controls. IL-6 was the only cytokine to discriminate RA from UA, with a significantly higher proportion of detection in RA than UA (70.2 vs 44.3%, $P<0.0001$). Moreover, IL-6 was associated with diagnosis of RA at 1 year on multivariate analysis (OR 1.9, 95%CI [1.2-2.9], $P= 0.004$), along with anti-CCP-positivity (OR 5.1 [2.9-8.7], $P<0.001$) whereas ESR and CRP were not (OR 0.99, [0.9-1.0], $P= 0.6$ and OR 1.0 [0.9-1.1], $P= 0.5$, respectively).

- Disease activity

Baseline detectable IL-6, IL-10 or IFN-gamma were associated with increased disease activity in patients with early RA.

- Serum markers of B-cell activation and autoantibody secretion

Patients with baseline detectable IL-6 had significantly higher levels of beta2-microglobulin, IgG kappa and lamba FLCs and were more frequently RF- or anti-CCP-positive. Patients with detectable IL-10 had higher levels of beta2-microglobulin, IgG, kappa and lambda FLCs and were more frequently anti-CCP-positive.

- Radiographic progression

The proportion of RA patients with baseline erosions and with radiographic progression was higher in patients with detectable IL-6. On multivariate analysis, detectable IL-6 at enrollment (OR 2.5 [1.4-4.3], $P= 0.001$) was associated with 1-year radiographic progression, along with anti-CCP positivity (2.0 [1.1-3.7], $P= 0.02$) and presence of erosions at inclusion (3.3 [2.1-5.3], $P< 0.001$) whereas ESR and CRP were not.

Conclusion: Serum levels of IL-6 are elevated in patients with early RA, compared with UA, independently of inflammation and of TH1/Th17 cytokines secretion. In early RA, increased IL-6 levels are associated with higher disease activity, activation of B-cells and increased 1-year radiographic progression on multivariate analysis. This study suggests that targeting IL-6 might be a useful therapeutic strategy in early RA.

391

Relationship Between Foxp3+ Tregs in Synovium of Rheumatoid Arthritis and Clinical Activity. Zeng Yan[1], Zheng Dong-hui[1], Dai Lie[1], Zhang Bai-yu[1], MO Ying-qian[1] and LI Zhi-xun[2], [1]2nd Affiliated Hospital, Sun Yat-sen University, Guangzhou, China, [2]Department of Pathology, Sun Yai-sen University, Guangzhou, China

Purpose: $CD4^+CD25^+$Tregs play an important role to keep balance of immune system in patients with rheumatoid arthritis (RA). Foxp3 (forkhead box P3/winged-helix transcription factor), the prototypic transcription factor of Tregs, is not only specific but also critical to Tregs function. In this study, Foxp3 was used to identify Tregs and the relationship between synovial $Foxp3^+$Tregs and clinical activity of RA was analyzed.

Method: Synovium from active RA patients was taken by closed needle biopsy. Synovium from patients with OA and non-inflammatory orthopedic arthropathies was chosen as controls. Synovial serial sections were measured by HE staining and immunohistochemistry staining for Foxp3, CD3, CD20, CD34, CD38 and CD68. The cell count of the $Foxp3^+$Tregs and the percentage of $Foxp3^+$Tregs/$CD3^+$Tcells were analyzed. The relationship between $Foxp3^+$Tregs expression in RA synovium and the histological synovitis scores, clinical activity was analyzed. RA patients were divided into two groups according to the DAS28: intermediate active group (DAS28 3.2~5.1, n=12) and severe active group (DAS28 >5.1, n=13).

Results: (1) Foxp3 was expressed in RA synovium , mainly in nuclei of $CD3^+$T cells, and Foxp3 expression was negative in controls. (2)The cell count of $Foxp3^+$Tregs and the percentage of $Foxp3^+$Tregs /$CD3^+$Tcells were less in severe RA group than those in the intermediate group(P=0.005, 0.001).(3)There was an inverse relationship between the cell count of $Foxp3^+$Tregs and the synovitis scores, synovial

hyperplasia, the percentage of CD68 positive cells in intimal lining layer (r=-0.622,-0.916,-0.935, P=0.001,0.000,0.000). (4)There was an inverse relationship between the cell count of Foxp3^{+}Tregs in RA synovium and 28 tenderness joints' indexes or DAS28(r=-0.568,-0.656, P=0.003,0.000).

Conclusion: Foxp3^{+}Tregs invasion in synovium may correlate with rheumatoid synovitis and clinical activity. Synovial Foxp3 expression may be a new diagnostic biomarker for clinical activity of RA patients.

392

Relation of the Pesticide Exposure and the Occurrence of Rheumatoid Arthritis – A Cross Sectional Study of the NHANES 2005 – 2006 Data. Venkata Subhash Gorrepati[1], Ashok Valluri[1] and Pramil Cheriyath[2], [1]Harrisburg Hospital: Pinnacle Health, Harrisburg, PA, [2]Harrisburg Hospital: Pinnacle Health, Harrisburg

Purpose: There is an estimate of 1.2 billion pounds of pesticide use in the United States (US) and about 5 billion pounds worldwide. Deleterious effects of pesticide on the health of the exposed are well known. Rheumatoid Arthritis (RA) is a chronic, autoimmune disorder disabling a considerable amount of US population leading to major burden on the healthcare expenditure. Some studies have shown the incidence of RA to be greater in certain occupations which involves chemical exposure. Here we hypothesize that there is an increased risk of RA in the people who were exposed to pesticide.

Method: The National Health and Nutrition Examination Survey (NHANES) consists of demographic, physical characteristics and laboratory values of a randomly selected non institutionalized civilian US population. Presence of RA was assessed by the questions "Do you have any Arthritis?" and "if so, which type of Arthritis?" Pesticide exposure was evaluated using the questions "Products used in home to control insects?" and "Products used to kill weeds?" The analysis was done using statistical software SAS version 9.1 PROC SURVEY methods.

Results: Out of the 10,348 participants who took part in the survey, our study consisted of 4,680 people after excluding those with age less than 20 and with a missing Body Mass Index (BMI) values. The use of pesticide was positively correlated with RA (odds ratio of 1.43, 95% CI of 1.05 to 1.96). After adjusting the model for age, gender, race, education, smoking and BM, odds ratio was still remained significant (OR of 1.39, 95% CI of 1.03 to 1.88).

Conclusion: Our study showed a positive association between RA and pesticide use. Based on the magnitude of use and variety of products they could be present in, pesticides should be taught to be used in caution. More research is needed to confirm this relationship and to classify the pesticides into groups depending on the strength of the association with RA.

393

T Cell Immunoglobulin and Mucin Domain 3 (TIM3) Genetic Polymorphisms Are Associated with Rheumatoid Arthritis, Independently of Shared Epitope Status. Churl Hyun Im[1], Eun Ha Kang[2], Joonwan Kim[1], Ran Song[1], Jin Hyun Kim[1], Yun Jong Lee[2], Kyung Sook Park[3], Eun Young Lee[1], Eun Bong Lee[1] and Yeong Wook Song[1], [1]Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seongnam, South Korea, [3]Sungshin Women's University, Seoul, South Korea

Purpose: T cell immunoglobulin and mucin domain 3 (TIM3) proteins are T cell surface glycoproteins, and regulate auto- or alloimmune responses. Rheumatoid arthritis (RA) is an immune mediated inflammatory polyarthritis, and defects of TIM3 may have a pathogenic role in immune response during development of RA. TIM3 genetic polymorphism was reported to be associated with RA. We investigated genetic polymorphisms of TIM3 and RA susceptibility according to shared epitope (SE) status.

Method: 368 RA patients and 389 healthy controls were enrolled. 6 single nucleotide polymorphisms (SNPs - rs11742259 (C/T), rs10515746 (C/A), rs35960726 (A/G), rs1036199 (A/C), rs4704846 (A/G), rs11134551 (A/G)) in TIM3 gene were investigated using the

real-time polymerase chain reaction method. SE status of 165 RA patients were investigated. Genetic polymorphisms and their associations were analyzed by SPSS program (ver 12.0). Haplotype associations were analyzed by Unphased program (ver 3.1.2)

Results: TIM3 polymorphisms of rs10515746 (A allele 3.1 % vs 1.4 %, OR 2.249, 95 % CI 1.089 - 4.647, p value = 0.036) and rs35690726 (G allele 4.3 % vs 0.9 %, OR 5.006, 95 % CI 2.196 - 11.415, p value < 0.001) were significantly associated with RA patients compared with healthy controls. These associations were significant in RA patients with (p value = 0.007, < 0.001) or without SE (p value = 0.015, 0.001). Polymorphisms of rs11742259 (p value < 0.001) and rs1036199 (p value = 0.001) were associated in RA patients with SE but not in RA patients without SE. There were no significant associations of polymorphisms in rs4704846 (p value = 0.851), rs11134551 (p value = 0.521). In haplotype analysis, CAAAAA, CCAAAA, CCACAA, CCGAAA, CCGCAA, CCGCAG, TCAAAA haplotypes were significantly associated with RA patients compared with healthy controls.

Conclusion: TIM3 genetic polymorphisms may have a role in development of RA independent of SE status.

Genome Wide Association Analysis of Rheumatoid Arthritis Patients Treated with Anti-TNF Medication. Marieke JH Coenen[1], Erik JM Toonen[1], Annette T. Lee[2], Franak Batliwalla[2], Wietske Kievit[1], Hans Scheffer[1], Timothy RDJ Radstake[1], Pilar Barrera[1], Piet LCM van Riel[1], Dutch Rheumatoid Arthritis Monitoring registry, Peter K. Gregersen[2] and Barbara Franke[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Feinstein Institute for Medical Research, Manhasset, NY

Purpose: Treatment strategies blocking tumour necrosis factor (TNF) have proven very successful in patients with rheumatoid arthritis (RA) showing beneficial effects in at least 60% of the patients. However, a significant subset of patients does not respond for reasons that are unknown, and there is currently no means of identifying these patients.

Method: In this study we performed a genome-wide association (GWA) analysis on 213 patients with RA treated with antibodies directed to TNF (anti-TNF) from the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry. For patient selection, we used an extreme groups approach, limiting inclusion to only very good responders (n=96) and total non-responders (n=117) to anti-TNF, based on the EULAR response criteria. Single nucleotide polymorphisms (SNPs) markers were genotyped using the Illumina HumanHap550-Duo BeadChip. Association analysis was performed using the whole genome association analysis toolset PLINK.

Results: 496.659 SNPs and 207 patients passed quality control. Thirty-three SNPs showed association (uncorrected p-value < 0.0001) with anti-TNF treatment response. The top 10 associated markers were located in regions including the nardilysin (*NRD1*) gene on chromosome 1; the solute carrier family 35, member F3 (*SLC35F3*) gene on chromosome 1; the latrophilin 3 (*LPHN3*) gene on chromosome 4; the translocation associated membrane protein 1-like 1 (*TRAM1L1*) gene on chromosome 4; the ADAM metallopeptidase with thrombospondin type 1 motif, 16 (*ADAMTS16*) gene on chromosome 5; the glutamate receptor, metabotropic 4 (*GRM4*) gene on chromosome 16; and a region on chromosome 14 that includes the beta-spectrin (*SPTB*) gene.

solute carrier family 35, member F3 latrophilin 3 translocation associated membrane protein 1-like 1 (ADAM metallopeptidase with thrombospondin type 1 motif, 16 (glutamate receptor, metabotropic 4 beta-spectrin

Conclusion: The most interesting candidate is *NRD1* for which it is documented that it is involved in TNF alpha shedding. To validate the present results we will extend the GWA analysis with an additional 362 patients from the DREAM registry. Significant findings will be replicated in other patient cohorts. The identified genes may serve as new biomarkers predicting anti-TNF response.

The ACPA Isotype Repertoire Reflects Long-Term Radiographic Progression in Rheumatoid Arthritis. Diane van der Woude[1], Silje W. Syversen[2], Ellen IH van der Voort[1], Kirsten N. Verpoort[1], Guro L. Goll[2], Michael van der Linden[1], Annette H.M. van der Helm-van Mil[1], Désirée M.F.M. van der Heijde[1], Tom W.J. Huizinga[1], Tore K. Kvien[2] and René E.M. Toes[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway

Purpose: The presence of anti-citrullinated protein antibodies (ACPA) is a powerful predictive factor for the development and progression of rheumatoid arthritis (RA). The ACPA response has been shown to consist of various isotypes, but the consequences of differences in isotype-repertoire have not been extensively investigated. In this study, we investigated the relationship between ACPA isotypes and disease outcome.

Method: ACPA isotypes were determined in sera of CCP2-positive patients by enzyme-linked immunosorbent assay (ELISA). To investigate if the ACPA response continues to evolve during disease development, we studied the ACPA isotype repertoire during progression of undifferentiated arthritis (UA) to RA. The association of disease progression with ACPA isotype use was assessed using long-term radiographic follow-up data from RA patients in two independent cohorts.

Results: The ACPA isotype profile did not expand during disease progression from UA to RA, but was relatively stable over time. In both RA cohorts, the baseline ACPA isotype repertoire was a significant predictor of disease severity, with more isotypes indicating a higher risk of radiographic damage (odds ratio for every additional isotype: 1.4 (95% CI: 1.1-1.9) $p<0.001$). ACPA isotypes supplied additional prognostic information to ACPA-status alone, even after correction for other predictive factors.

Conclusion: The magnitude of the ACPA isotype repertoire at baseline reflects the risk of future radiographic damage. These results indicate that not only the presence, but also the constitution of the ACPA response, is relevant for the disease course of RA.

Association of Functional RANKL Promoter Polymorphisms with Subsets of Rheumatoid Arthritis (RA) in Taiwanese. Ji Yih Chen[1], Chin-Man Wang[1] and J. Wu[2], [1]Chang Gung Memorial Hosp, Taoyuan, Taiwan, [2]PhD, Birmingham

Purpose: Rheumatoid arthritis (RA) is a common systemic autoimmune disease involving inflammation and destruction of joints. The aim of the current study was to investigate the functional implication of RANKL promoter polymorphisms and to examine whether RANKL promoter polymorphisms are associated with subtypes of RA in Taiwanese.

Method: RANKL polymorphisms (4-bp deletion/insertion polymorphism and three promoter SNPs) were genotyped in 672 RA patients and 681 age-matched healthy controls from the same geographic region in Taiwan. Genotyping was carried out using gene scan and MALDI-TOF (Mass Array matrix-assisted laser desorption ionisation-time-of-flight mass spectrometry). Genotype distributions, allele and haplotypes frequencies were compared between RA and healthy controls as aggregates or as stratified by X-ray findings, autoantibody profile within patient groups. In addition, EMSA (Electrophoretic Gel Mobility Shift Assay) and promoter reporter assays were carried out to examine whether RANKL SNP -290A>G affects transcription factor binding and promoter function.

Results: RANKL promoter SNP -290A>G significantly affected promoter activities. EMSA (Electrophoretic Gel Mobility Shift Assay) indicates that the SNP -290A>G is within a transcription element C/EBPβ and that -290A allele has higher binding affinity for transcription factor C/EBPβ. Notably, we observed a significant enrichment of -290GG genotype in C-spine involvement positive patients as compared with the C-spine negative RA patients (adjusted $p = 0.012$, OR 1.680 [95% CI 0.998 – 2.547]). Furthermore, the homozygotes -643 TT (adjusted $p = 0.032$ OR 1.967 [95% CI 1.148 – 3.037]) and -693 CC (adjusted $p = 0.05$, OR 1.680 [95% CI 0.998 – 2.547]) were significantly enriched in anti-CCP antibody positive patients compare to the anti-CCP negative RA patients. Haplotype 320/-290A was significantly reduced in RA ($p = 0.034$; odds ratio 0.689 [95% CI 0.488 – 0.973]) and destructive$^+$ RA ($p = 0.039$; odds ratio 0.655 [95% CI 0.437 – 0.981]) patients as compared with normal controls. Haplotype 316/-643C and 316/-693G were significantly reduced in destructive$^+$ RA patients as compared with destructive$^-$ RA patients ($p = 0.026$; odds ratio 0.558 [95% CI 0.331 – 0.939]. Among three RANKL SNPs haplotypes, haplotype -693G/-643C/-290A may have protective roles against CCP antibody production ($p = 0.007$; odds ratio 0.361 [95% CI 0.168 – 0.775]) and against destructive RA ($p = 0.006$; OR 0.354 [95% CI 0.163 – 0.769]).

Conclusion: RANKL promoter SNP affected promoter functions and RA phenotypes. Our data suggest that RANKL may contribute to the complex disease process of RA in Taiwanese.

Rheumatoid Factor and Anti-CCP Antibodies Are Independently Associated with Insulin Resistance in Early Inflammatory Polyarthritis-Results From the Norfolk Arthritis Register (NOAR). H. Mirjafari[1], T. Farragher[1], A. P. Yates[2], D. Bunn[3], T. Marshall[3], D. P. Symmons[1] and I. N. Bruce[1], [1]arc Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Manchester Royal Infirmary, Manchester, United Kingdom, [3]Norfolk and Norwich University Hospital, Norwich, United Kingdom

Purpose: Cardiovascular disease (CVD) is the leading cause of death in patients with inflammatory polyarthritis (IP) and its subset rheumatoid arthritis (RA). Insulin resistance (IR) is predictive of the development of diabetes and CVD disease. IR is increased among patients with long-standing RA. We investigated the associated factors for IR in an early inception cohort of patients with IP.

Methods: Patients with IP (≥2 swollen joints for ≥4 weeks), between 18 and 65 years old, seen within 24 months of symptom onset, were recruited as a nested-cohort study within NOAR; a primary-care-based inception cohort of patients with early IP. At baseline patients provided information on therapy, underwent a joint examination and completed a health assessment questionnaire (HAQ). A fasting blood sample was taken for rheumatoid factor (RF), anti-CCP antibody (ACPA), C-reactive protein (CRP), lipid profile, glucose and insulin levels. IR was defined using the homeostatic model assessment of IR (HOMA-IR). The relationship between IR above the median and parameters known to increase the risk of CVD in the general population (smoking, hypertension, dyslipidaemia, diabetes) and IP related factors (RF, ACPA status, CRP, therapy, DAS28 and HAQ score) was assessed using age and gender adjusted logistic regression. We then used multivariable model analysis to explore the relationship of these associations.

Results: We studied 196 patients with median (IQR) symptom duration of 6.7 (4.6-10.7) months. 137 (70%) were female (Table). IR above the median was associated with higher triglycerides (OR (95% CI) 2.9 (1.7, 5.0). No association was found between IR and smoking, CRP, HAQ score, disease activity, symptom duration or therapy. On multivariable logistic regression modelling RF and ACPA status were each associated with IR, independent of all CVD and IP related factors (OR (95% CI) 3.2 (1.5, 7.0), 3.9 (1.7, 9.3) respectively). Exclusion of patients with diabetes did not alter this association. The relationship was strongest and only significant in those positive for both RF and ACPA, even on adjustment for all other factors (OR (95% CI) 4.7 (1.8, 11.9).

Table: Baseline characteristics.

Variable (n=196)	**Number (%)/mean (SD)/median (IQR)**
Age (years)	49 (40-57)
Female	137 (70%)
RF positive	90/193 (47%)
ACPA positive	61/182 (34%)
HOMA-IR score	2.7 (1.8-3.9)
Diabetic	21 (11%)
Fasting glucose (mmol/L)	4.8 (0.8)

HDL (mmol/L)	4.5 (0.4)
LDL (mmol/L)	3.2 (0.9)
Obese (BMI >30)	57 (30%)

Conclusion: In this inception cohort of patients with early IP, disease phenotype rather than symptom duration or therapy are associated with IR. IR may contribute to the excess CVD mortality found in seropositive IP. Modification of IR may attenuate this risk.

The Predictive Value of the Anti-Cyclic Citrullinated Peptide (anti-CCP): A Study of Actual Test Requests. Christine Peoples[1], Ritu Valiyil[2], Roger Davis[1] and Robert H. Shmerling[1], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Past studies of anti-CCP antibody as a diagnostic test for rheumatoid arthritis (RA) have focused on its performance characteristics primarily among patients with RA and other selected rheumatic diseases. However, information is limited regarding this test's utility in actual practice, when those tested are less highly selected. The purpose of this study was to assess the diagnostic utility of testing for anti-CCP antibody among patients for whom the test was ordered by practicing clinicians.

Method: We reviewed the medical records of all patients for whom anti-CCP testing was requested during the first 6 months of 2005 and the first six months of 2007 in a single academic teaching hospital. Patients with RA were diagnosed by a rheumatologist and/or met ACR criteria. Sensitivity, specificity, and predictive value of anti-CCP results for RA were calculated combining data from both cohorts. In addition, a similar analysis was performed for rheumatoid factor (RF), comparing its performance characteristics with those of anti-CCP.

Results: Clinicians requested anti-CCP testing for 535 patients; 149 were ordered during the 2005 study period and 386 were ordered during the 2007 study period. In total, 90 (16.8%) of these tests were positive; 71 of these patients were diagnosed with RA (positive predictive value (PPV) = 78.9%). Of these 71 patients with RA, 37 had previously been diagnosed with and treated for RA. Among patients without a previous diagnosis of RA, sensitivity was 50.7% and specificity was 95.3%. PPV and negative predictive value (NPV) were 64.2% and 92.1%, respectively. Specificity and PPV were higher for anti-CCP than RF, although the two tests were concordant (both positive or both negative) in 83% of cases. For newly diagnosed RA, the cost per true-positive anti-CCP result was $1250.

Conclusion: The frequency of anti-CCP testing has increased dramatically in recent years, despite clinical utility that may be more limited than previously recognized. For patients without known RA, the PPV was only slightly better than the flip of a coin. In addition, the cost per true-positive anti-CCP result was high. Testing in settings of at least moderate pre-test probability of RA for patients without a prior diagnosis of the disease could improve its diagnostic utility.

Positive and Negative Predictive Value for anti-CCP and RF

	RA Prevalence	PPV		NPV	
		Anti-CCP	RF	Anti-CCP	RF
All patients	24.1%	78.9% (69.0-86.8)	59.5% (50.4-68.2)	87.0% (83.5-90.0)	86.3% (82.4-89.6)
New RA*	14.1%	64.2% (49.8-76.9)	40.0% (29.5-51.2)	92.1% (89.1-94.5)	91.1% (87.6-93.8)
Known RA**	13.2%	66.1% (52.2-78.2)	44.6% (34.2-55.3)	93.9% (91.2-96.0)	94.2% (91.2-96.4)

*New RA excludes patients with known RA **Known RA excludes patients with new RA

Diagnostic Performance of Three Different Anti-Citrullinated Protein Antibodies-Evaluation in the Early Arthritis ESPOIR Cohort.

Pascale Nicaise-Roland[1], Leonor Nogueira[2], Christophe Demattei[3], Sabine Grootenboer-Mignot[1], Luc De Chaisemartin[1], N. Rincheval[4], Philippe Dieudé[1], Alain Cantagrel[5], Olivier Meyer[1], Guy Serre[2] and Sylvie Chollet-Martin[1], [1]Bichat Claude Bernard University Hospital, APHP, Paris, France, [2]Purpan University Hospital, Toulouse, France, [3]Caremeau University Hospital, Nimes, France, [4]Epidemiology unit, Montpellier, France, [5]JE 2510, Purpan University Hospital, Toulouse, France

Purpose: Anti-citrullinated protein antibodies (ACPA) are known to be sensitive and specific markers of rheumatoid arthritis (RA). However, their sensitivity in early RA needs to be better evaluated. We thus investigated the diagnostic sensitivity, individually or in association, of three assays for ACPA detection using different citrullinated antigens: cyclic peptide (CCP), mutated vimentin (MCV) or human fibrinogen (AhFibA) in a French cohort of recent (less than 6 month duration) undifferentiated arthritis (ESPOIR).

Method: 685 patients of the ESPOIR cohort were followed until 2 years after inclusion. Antibodies were determined by enzyme-linked immunosorbent assay at baseline. The cut-off of the different assays was calculated in order to obtain a 98% diagnostic specificity using a control population including healthy controls and other non-RA rheumatic diseases. In the ESPOIR cohort, the sensitivity of the three ACPA assays was determined in the patients classified as RA at 2 years according to the 1987 ACR criteria.

Results: 592 (86.4%) patients were classified as RA at 2 years. Sensitivity of the different assays is given in the table. ROC curve analysis could not detect any significant difference in diagnostic performance between the three ACPA assays. 317 (53.5%) RA patients were positive for at least one ACPA compared to a maximum of 48.5% for an individual ACPA. Interestingly, 8 patients were positive only for anti-CCP antibodies, 17 for anti-MCV antibodies and 16 for AhFibA. 95 of the patients classified as RA at 2 years were not classified as RA at baseline: 30 of them (31.5%) were positive for at least one ACPA assay at baseline. If the positivity of at least one ACPA is included in the criteria, 543 patients are classified as RA (79.3 %) at day 0, instead of 497 (72.5 %) without it.

Table.RA diagnosis sensitivities of the three ACPA assays

	Sensitivity
Anti-CCP	47%
Anti-MCV	47.3%
AhFibA	48.5%
Anti-CCP or anti-MCV	50.8%
Anti-CCP or AhFibA	50.7%
Anti-MCV or AhFibA	52.1%
At least one of the three ACPA	53.5%

Conclusion: Our results show that the performances of the three ACPA assays are very close to each other. However, in undifferentiated arthritis, the detection of the three ACPA subtypes increased the sensitivity of 6% as compared with the assays of only one marker with the risk of a slight decrease in specificity. Moreover, the positivity of one ACPA assay 2 years before the diagnosis, was predictive for RA in 30% of the 95 patients without a diagnosis at day 0. When ACPA were considered as a diagnosis criterion, 7 % more patients were classified as RA at day 0. This confirms that ACPA have to constitute an additional classification criterion for RA.

Associations of Anti-CCP and Rheumatoid Factor Concentrations with Future Disease Activity in Rheumatoid Arthritis. Ben J. Miriovsky[1], Kaleb D. Michaud[2], Geoffrey M. Thiele[3], James R. O'Dell[4], Gw Cannon[5], G.S. Kerr[6], J.S. Richards[7], Dannette S. Johnson[8], Liron Caplan[9], A.M. Reimold[10], R.S. Hooker[11] and T. R. Mikuls[4], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska and NDB, Omaha, NE, [3]Univ of NE Medical Ctr, Omaha, NE, [4]U Nebraska, Omaha, NE, [5]VA and University of Utah, Salt Lake City, UT, [6]VAMC, Georgetown University, Washington, DC, [7]Veterans Affairs Medical Ctr, Washington, DC, [8]University of MS Med Ctr, Jackson, MS, [9]Univ of CO Denver School of Med, Aurora, CO, [10]VAMC, University of Texas Southwestern Medical Center, Dallas, TX, [11]Department of Veterans Affairs, Dallas, TX

Purpose: To examine and compare associations of anti-CCP antibody (aCCP) and rheumatoid factor (RF) concentrations with future disease activity in patients with established rheumatoid arthritis (RA).

Methods: Study participants were U.S. veterans with RA (n = 855). Measures of disease activity included: 1) proportion of observation in remission, 2) remission for ≥ 3 consecutive months, and 3) area under the curve [AUC] for DAS28. Baseline aCCP and RF were examined dichotomously, as ordered categorical variables, and continuously. Associations of autoantibody status with disease activity outcomes were examined using multivariate regression.

Results: Patients were predominantly men (91%) with mean (SD) age of 66 (11) years and 2.3 (1.2) years of follow-up. Most were aCCP (75%) and RF (80%) positive. Associations of aCCP and RF status with sustained remission are shown in the figure below. After multivariate adjustment for age, sex, race/ethnicity, education, disease duration, follow-up time, smoking status, comorbidity, pharmacologic interventions, and disease status (DAS28 ≤ 2.6 vs. DAS28 > 2.6) at enrollment, aCCP and RF concentrations (per 100 unit increments) were associated with a lower proportion of observation in remission (b = -0.004, p = 0.054 and b = -0.002, p = 0.014, respectively), and greater AUC DAS28 (b = 0.02, p = 0.05 and b = 0.01, p = 0.002, respectively). In a sub-analysis of autoantibody discordant groups, higher aCCP concentrations in aCCP+ / RF- patients were associated with an increased likelihood of achieving remission (OR 1.10; 95% CI 1.00-1.20) (data not shown). In contrast, among aCCP- / RF+ patients, higher RF concentrations trended towards an inverse association with remission (OR 0.81; 95% CI 0.58-1.13) (data not shown).

Conclusion: Although higher aCCP concentrations are associated with greater future disease burden in patients with established RA, these associations appear to be related to concomitant elevations in serum RF.

Figure: Age- and sex-adjusted (■) and multivariate (○) ORs of aCCP and RF with the achievement of sustained remission (DAS28 ≤ 2.6). Shapes (■ and ○) correspond to ORs, horizontal bars represent 95%

CIs. ORs and CIs for ‘continuous level' correspond to 100 unit increments.

333

Anti-CCP Antibodies, Rheumatoid Factor and Differences in Clinical Presentation of Early Arthritis: Results From the ESPOIR Cohort. Gaël Mouterde[1], Nathalie Rincheval[2], Cedric Lukas[1], RM Flipo[3], Philippe Goupille[4], Jean-Pierre Daures[2] and Bernard Combe[1], [1]Lapeyronie hospital, Montpellier, France, [2]Epidemiology unit, Montpellier, France, [3]Rheumatology,Lille University, Lille, [4]Université François Rabelais de Tours, CNRS, UMR 6239; CHRU de Tours, Tours, France

Purpose: To compare initial clinical, biological and radiological features of early arthritis patients depending on their positivity for rheumatoid factor (RF) and/or anti-CCP antibodies (anti-CCP). To valid a patient profile based on these serological data.

Method: Patients presenting with synovitis of at least 2 joints for 6 weeks to 6 months were included in the multicenter French ESPOIR cohort. They were tested for IgM RF (Elisa, Ménarini, France ; positive if > 9 UI/ml) and Anti-CCP2 antibodies (Elisa, DiaSorin, France ; positive if > 50 U/ ml) and divided into 4 groups : RF- and anti-CCP-, RF+ and anti-CCP-, RF- and anti-CCP+, RF+ and anti-CCP+. The following data were collected at baseline : clinical features, C-reactive protein, erythrocyte sedimentation rate (ESR), radiographs of hands, wrists, and feet (scored according to modified Sharp score). Quantitative variables were compared across the 4 groups by using Kruskal Wallis test, and the aggregate groups were compared using a Newman-Keuls like method. Khi2 test was performed for qualitative variables across the 4 groups, and recalculated with significant variables in order to constitute new poolings of interest.

Results: The 813 recruited patients had the following features : age 48±13 years, females: 77%, mean disease duration 103+/-52 days, DAS28 5.11±1.3, HAQ score 0.98±0.7, CRP 22.1±33.6 mg/l, HLA-DRB1*01 or 04 genes 57.6%. 406 (50%) were negative for both auto-antibodies (group 1), 91 (11.2%) were RF+ and anti-CCP- (group 2), 34 (4.1%) were RF- and anti-CCP+ (group 3), and 281 (34.6%) were positive for both auto-antibodies (group 4). Mean baseline ESR was higher in anti-CCP+ patients (group 3 and 4) ($p<0.0001$) and van der Heijde modified total Sharp score was higher in group 4 compared with the 3 other groups ($p=0.0018$). Clinical presentation did not show major informative correlation with serological profile. Group 2 and 4 (RF+ groups) had more frequent arthritis of second and third metacarpophalangeal and interphalangeal joints ($p<0.0001$). Group 4 (anti-CCP+ and RF+) had more frequent arthritis of 3 or more joints ($p=0.001$), fulfilled more frequently ACR criteria for RA ($p<0.0001$) compared with the 3 other groups. Group 1 (anti-CCP- and RF-) had less often positive squeeze test on metatarsophalangeal joints ($p<0.0001$), and arthritis of hand joints ($p<0.0001$). There were no differences in morning stiffness, DAS28 and HAQ score across the groups.

Conclusion: The phenotype of early arthritis patients with or without anti-CCP and/or RF was similar with respect to clinical presentation. However at baseline, mean ESR was higher in anti-CCP groups and radiographic damage was more severe in patients with both anti-CCP and RF, suggesting that these auto antibodies may be associated with the inflammatory process and progressive disease in patients with early arthritis.

Levels of Anti-CCP and IgM RF Predict Persistent Arthritis in Patients with Very Early Undifferentiated Arthritis (UA). Maria D. Mjaavatten[1], Désirée M.F.M. van der Heijde[2], Till Uhlig[1], Anne J. Haugen[3], Halvor Nygaard[4], Göran Sidenvall[5], Knut Helgetveit[6] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Østfold Hospital, Moss, Norway, [4]Hospital for Rheumatic Diseases, Lillehammer, Norway, [5]Innlandet Hospital, Kongsvinger, Norway, [6]Martina Hansen's Hospital, Sandvika, Norway

Purpose: To assess the importance of increasing levels of anti-CCP and IgM RF in predicting development of persistent arthritis in UA patients.

Method: Patients with UA included in the Norwegian very early arthritis clinic(NOR-VEAC), which includes adult patients with at least one swollen joint of ≤16 weeks' duration. were assessed after 3, 6, and 12 months for development of persistent arthritic disease (persistent joint swelling or start of disease modifying anti-rheumatic drug). Sera frozen at inclusion were used to analyze anti-CCP2 (Inova Inc.) and IgM RF (in-house ELISA) levels in one batch. Cut-offs used to define a positive status were as recommended by the local laboratory: anti-CCP 25 units/ml, IgM RF 25 units/ml. Patients were divided into categories according to the levels of the respective antibodies (tertiles of patients

with a positive antibody status for anti-CCP and median for IgM RF), thus creating two categorized variables which were entered into univariate logistic regression analyses to determine the impact of increasing antibody levels on development of persistent arthritis.

Results: 376 UA patients were eligible for one year follow-up (58 % females, mean age 46 years, median duration of joint swelling 32 days). 59 (15.7 %) patients were positive for IgM RF, and 62 (16.5 %) for anti-CCP at baseline. 174 (46.3 %) had persistent arthritis after one year. There was a clear increase in the odds ratio and positive likelihood ratio with increasing levels of both anti-CCP and IgM RF.

Conclusion: The likelihood of developing persistent arthritis in UA patients increases with the level of anti-CCP and IgM RF. This finding suggests that patients should be stratified according to levels of these antibodies and not only according to positive or negative status when making risk assessments.

Table. Univariate logistic regression analyses with persistent arthritis as dependent variable.

Anti-CCP (units/ml)	OR (95 % C.I.)	p	LR+	LR-
≤25	1.0		ref	ref
>25-100	4.4 (1.6-12.54)	0.005	4.1 (1.5-11.0)	0.9 (0.9-1.0)
>100-250	9.4 (2.1-42.92)	0.004	8.7 (2.0-38.2)	0.9 (0.8-1.0)
>250	13.64 (4.04-46.04)	<0.001	11.4 (3.5-37.0)	0.8 (0.8-0.9)
IgM RF (units/ml)	OR (95 % C.I.)	p	LR+	LR-

Do First-Year Levels of Autoantibodies Predict Two-Year Outcome Better Than Baseline Autoantibody Status in Early Arthritis Patients? Jennie Ursum[1], W.H. Bos[1], R.J. van de Stadt[2], Ben A.C. Dijkmans[3] and D. van Schaardenburg[2], [1]Jan van Breemen Institute, Amsterdam, Netherlands, [2]Jan van Breemen Intitute, Amsterdam, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands

Purpose: Several studies have demonstrated that the presence of anti-citrullinated protein antibodies (ACPA) or IgM rheumatoid factor (RF) are prognostic for disease activity, functional status and radiographic damage in patients with rheumatoid arthritis. However, data on the association between levels of ACPA or RF and outcome of RA are scarce.

Objectives: To investigate whether levels of autoantibodies provide additional prognostic information over baseline autoantibody status regarding disease activity, functional and radiographic outcome after two years in early arthritis patients.

Methods: In consecutive early arthritis patients with rheumatoid arthritis or undifferentiated oligo-/polyarthritis ACPA and RF levels, disease activity (DAS28), the Health Assessment Questionnaire (HAQ) and Sharp/Van der Heijde Score (SHS) were assessed annually. Baseline status and levels and first-year changes of the autoantibodies were associated with DAS28, HAQ and SHS at two years.

Results: Baseline characteristics of the 545 included patients were: mean age 53 years, 69% female, median disease duration 4 months, 56% ACPA positive, 47% IgM-RF positive. At two years the mean DAS28 was 2.88 and the median HAQ and SHS were 0.38 and 1, respectively. Of the ACPA positive patients at baseline 4% became ACPA negative after one year, whereas 2% of the ACPA negative

patients became positive. Of the RF positive patients at baseline 35% became RF negative after one year, while 3% of the RF negative patients became positive.

Positive baseline ACPA or RF status were both associated with 2-years SHS ($p<0.001$).

In baseline ACPA positive patients, baseline ACPA levels were modestly correlated to 2-year DAS28 and HAQ ($r=0.15$ and $r=0.13$, respectively, $p<0.05$), but not to SHS. No associations were found between baseline RF levels and outcome parameters.

ACPA and RF levels decreased in patients with a positive baseline autoantibody status in the first-year of follow-up with 31% and 56%, respectively. In patients with a positive status of either autoantibody, the first-year changes in ACPA and RF levels were not associated with the 2-year outcome parameters.

Conclusion: Baseline ACPA and RF status are associated with two-year SHS, whereas baseline ACPA levels are mildly associated only with two-year DAS28 and HAQ, and baseline RF levels are not associated with any of these outcome parameters. First-year changes in levels of either autoantibody are substantial, but are not associated with 2-year outcome. Since level changes are not associated with outcome and negative to positive seroconversion seldom occurs, it is not useful to repeat ACPA and RF measurements.

Low Vitamin D Levels Are Associated with Insulin Resistance, Markers of Systemic Inflammation and Endothelial Activation in Rheumatoid Arthritis. Uzma Haque, Joan M. Bathon, Antony Rosen and Jon T. Giles, Johns Hopkins University, School of Medicine, Baltimore, MD

Purpose: Vitamin D deficiency has been identified as a possible risk factor for metabolic syndrome and adverse cardiovascular events in the general population. We investigated the association of vitamin D levels with traditional and non-traditional cardiovascular risk factors in a cohort of RA patients with no prior history of cardiovascular disease.

Method: Data are drawn from RA patients who met ACR criteria and were enrolled in an ongoing observational study of subclinical cardiovascular disease. Serum 25(OH)D levels were used to assess vitamin D status, with a level < 30ng/ml classified as deficient. Additional assessments included sociodemographics, traditional CV risk factors (diabetes, systolic and diastolic blood pressures, HDL, LDL, triglycerides, current and past smoking), body composition (body mass index, waist circumference), markers of systemic inflammation (CRP, fibrinogen), markers of endothelial activation (s-ICAM, E-selectin), and insulin resistance (using the Homeostatic Model Assessment (HOMA-IR). Spearman correlation coefficients were calculated to estimate the correlations between 25(OH)D levels (square root transformed to normality) and continuous CV risk factors (normally transformed where required). The associations of CV risk factors with vitamin D levels were calculated using multivariate linear regression, adjusting for pertinent confounders.

Results: Among the 179 RA patients studied (60% female, 88% White, mean age 61 ± 8 years), 73 (41%) had a 25(OH)D level < 30 ng/mL. Patients with low 25(OH)D levels were more likely to be non-White than those with higher levels (21% vs. 9%; $p=0.019$); however, other sociodemographics (age, gender, education), body composition characteristics, and non-lipid traditional CV risk factors did not differ by 25(OH)D status.

In contrast, significant positive correlations with HDL and inverse correlations with HOMA-IR, LDL, CRP,

s-ICAM, E-selectin, and fibrinogen with 25(OH)D level were observed in unadjusted analyses (Table). With the exception of LDL, these associations remained significant after adjustment for demographics, smoking, and season. 25(OH)D was not associated, in either crude or adjusted analyses, with triglycerides, homocysteine, or serum adipokines.

Conclusion: In this cross-sectional sample of RA patients, vitamin D levels were inversely associated with insulin resistance, markers of systemic inflammation and endothelial activation. These data suggest that vitamin D deficiency in RA may be an independent risk factor for metabolic syndrome and cardiovascular events, implicating a role of vitamin D supplementation in cardiovascular risk reduction.

Table. Crude and Adjusted Associations of Selected Laboratory Parameters with the Square Root of Serum 25-Hydroxy Vitamin D

Risk Factor	Unadjusted			Adjusted*	
	r**	β***	p	β***	p

Relationship of Vitamin D and Parathyroid Hormone to Functional Disability and Disease Activity in RA. Colleen Doherty[1], Tamara Vokes[2], Linda M. Mileti[3], Maria Badaracco[1], Melinda Drum[2] and T.O. Utset[1], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, [3]Northwestern University, Chicago, IL

Purpose: Vitamin D has immunomodulatory effects, and deficiency of this nutrient may impact inflammatory conditions such as rheumatoid arthritis. Conversely, the effect of chronic inflammation on calcium homeostasis is largely unstudied. We sought to determine if 25(OH) vitamin D level correlates with disease activity and functionality in RA, and whether parathyroid hormone (PTH) and calcium levels are impacted by chronic inflammation.

Method: In this cross-sectional study, the levels of 25(OH) vitamin D, calcium, and PTH were measured in postmenopausal women with RA. Disease activity was measured by erythrocyte sedimentation rate (ESR) and functional disability by the Health Assessment Questionnaire-II (HAQ-II). Statistical analysis of relevant clinical variables with ESR, HAQ-II score, and PTH were performed using t tests, and univariate and multivariate linear regression.

Results: Ninety-two subjects were analyzed. Average age was 66 years (SD 9.4), and mean disease duration was 12.1 yrs (SD 10.2); 61% of subjects were African-American, 32% Caucasian, and 8% Latino. Mean HAQ-II score was 0.91 (SD 0.68), and mean ESR was 41.2 (SD 28.4). Mean ESR was higher in African-American subjects (46.0 versus 33.8 mm/hour, p=0.046). Mean 25(OH) vitamin D level was 28.0 ng/mL (SD 11.3, range 2.5-54), and was lower in African-American subjects (25.5 versus 31.9 ng/mL, p=0.01). In univariate analysis, ESR trended closely toward association with 25(OH) vitamin D (p=0.06). After adjustment for age, creatinine, and ethnicity, the association of ESR with 25(OH) vitamin D was significant (p= 0.03). African-American ethnicity no longer significantly associated with ESR when adjusted for 25(OH) vitamin D (p=0.26). HAQ-II score correlated inversely with 25(OH) vitamin D level (p=0.03). Creatinine, African-American ethnicity, and calcium also correlated with HAQ-II score. In multivariate regression, HAQ-II score was positively associated with serum calcium (p=0.01) and serum creatinine (p=0.003), and trended closely toward an inverse association with 25(OH) vitamin D (p=0.06), but no longer varied by ethnicity. PTH level was positively correlated with ESR on both univariate regression (p=0.04) and multivariate regression adjusting for calcium, creatinine and 25(OH)vitamin D (p=0.01).

Conclusion: 25(OH) vitamin correlates inversely with ESR and trends toward correlation with HAQ-II score in RA, after adjustment for covariates. This supports a possible contribution of vitamin D insufficiency to disease activity and functional impairment in RA. The positive association of PTH with ESR suggests that parathyroid hormone production may be increased by a chronic inflammatory state.

What Predicts Homocysteine in Rheumatoid Arthritis? Karen MJ Douglas[1], Vasileios F. Panoulas[1], Jacqueline Smith[1], Giorgos S. Metsios[1], A. Stavropoulos-Kalingolou[1], Tracey Toms[1], Gareth J. Treharne[2] and George D. Kitas[1], [1]Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom, [2]University of Otago, Dunedin, New Zealand

Purpose: Homocysteine (HOM) is a risk factor for Coronary Heart Disease (CHD). High levels of HOM in the general population relate to poor dietary folate intake and the MTHFR polymorphism. Methotrexate (MTX) is commonly used for the treatment of Rheumatoid Arthritis (RA) and, as a folate antagonist, has been implicated in raised HOM levels: this could potentially lead to increased CHD risk in RA, although current data suggests that MTX is protective. To address this apparent paradox, we aimed to determine whether HOM is higher in RA patients than controls, but also to identify predictors of its levels in RA.

Method: Fasting blood was collected for measurement of HOM, multiple other serological assessments and DNA extraction from 141 RA patients and 50 healthy local controls. MTHFR mutations were detected using commercial kits on the Roche Lightcyler™. Within the RA group, HOM levels were then considered in the context of multiple factors, including demographics (age and sex); anthropometrics (weight, BMI, body composition); RA characteristics (activity, seropositivity for rheumatoid factor and anti-CCP, severity (including extraarticular disease-EAD), duration, therapy), and comorbidities (including CHD, hypertension and insulin resistance). **Results:** were analyzed using t-tests, Mann-Whitney tests, Spearman's correlations and linear regression as appropriate. HOM levels were log-transformed for regression analysis; age and sex were controlled for throughout.

Results: HOM was higher in RA than controls (median 11.40mmol/l, IQR 9.08-14.2 vs. 9.0mmol/l, IQR 7.57-11.90, $Z=3.51$, $P<0.001$), and this remained significant after controlling for age and sex ($P<0.01$). Within the RA population, univariate analyses showed HOM to be higher in males and smokers ($P<0.01$), and to increase with age ($r=0.25$, $P<0.001$). HOM correlated significantly with disease activity [ESR ($r=0.19$, $P<0.05$), CRP ($r=0.23$, $P<0.01$), DAS28 ($r=0.18$, $P<0.05$)], but was not related to seropositivity for RF or anti-CCP, or disease severity [HAQ score, presence of erosions or EAD]. HOM levels did not relate to DMARD (including MTX) or NSAID usage but were higher prednisolone users (median 13.5mmol/l, IQR 10.7-16.8 vs. 11.1mmol/l, IQR 8.65-13.8; $Z=2.38$, $P<0.05$). Folate was higher in patients prescribed MTX ($Z = 3.45$, $P=0.001$), and correlated negatively with HOM (Spearmans rho $=-0.474$, $P<0.001$). MTHFR genotype had a major impact, with 677TT homozygotes having significantly higher HOM levels ($F=9.64$, $P<0.001$); within 677TT homozygotes, those taking MTX had non-significantly higher HOM than those who were not on MTX. In multiple regression, HOM levels associated significantly with MTHFR genotype, older age, male sex, smoking, EAD and prednisolone usage.

Conclusion: HOM is increased in RA and its levels are determined by MTHFR polymorphisms, sex, age, smoking, extra-articular disease and use of prednisolone. MTX does not significantly affect HOM, probably due to the co-prescription of folate supplements.

Heavy Chain Hyaluronan in the Serum and Synovial Fluid of Rheumatoid Arthritis Patients as a Possible Marker of Inflammation. Hossam El-Zawawy, Mark Lauer, Vincent Hascall and Elaine Husni, Cleveland Clinic, Cleveland, OH

Purpose: Nonspecific markers of inflammation such as ESR and CRP have been used as an adjunct to the clinical assessment of disease activity in rheumatoid arthritis (RA) but are often imprecise. The synthesis of hyaluronan (HA) is increased by joint inflammation, primarily mediated by IL-1 and TNF-α as well as the amount of HA in the synovial fluid, which is increased in RA. Cells undergoing stress (injury to a knee joint) synthesize and deposit a hyaluronan matrix that is specifically recognized by inflammatory cells that are recruited into the tissue. This pro-inflammatory hyaluronan is modified by a reaction that transfers heavy chain (HC) proteins from a serum molecule named

inter-alpha-trypsin inhibitor. The heavy chain transfer is catalyzed by the TNF-α-induced protein 6, which is up-regulated in inflammation. As this only occurs in inflammatory processes, the heavy chain-hyaluronan complex (HC-HA) is a robust marker for inflammation. The purpose of this study is to test HC-HA in the serum and synovial fluid as a possible marker of inflammation in RA patients.

Methods: Western blot was performed on serum and synovial fluid from 7 RA patients. Approximately 25 µl of 5% serum or 1% synovial fluid was applied to each well of a 10-well SDS-PAGE gel and blotted to nitrocellulose membrane. The blot was blocked with a Li-Cor blocking buffer and probed with antibodies against IαI at 1:1000, or the simultaneous incubation of two HC antibodies at 1:200 dilution in the blocking buffer. The blots were probed with secondary antibodies at 1-15,000 dilution and imaged on an Odyssey infrared imaging system.

Western blot was done in duplicate from each sample. One of the duplicates was done after incubation of the synovial fluid or serum with SD hyaluronidase.

Results: Western blot analysis demonstrated clearly HC-HA in the synovial fluid. However in the serum, western blot did not show any HC-HA (figure, left panel).

Mixing serum and synovial fluid did not affect the reaction. HC-HA could still be detected after mixing the serum with the synovial fluid (figure, right panel).

Conclusion: The above results show that western blot was able to detect HC-HA in the synovial fluid but was unable to detect HC-HA in the serum. Mixing the synovial fluid with the serum did not affect the ability of western blot to detect HC-HA in the synovial fluid. This was done to eliminate the possibility that the serum contains inhibitory enzymes preventing the detection of HC-HA. The amount of HC-HA in the serum does not reflect the amount of HC-HA in the synovial fluid with the current technique. Experiments are underway to test the hypothesis of low sensitivity of western blot to detect “very low concentration” of the HC-HA in the serum. This will include purification and concentration of any HC-HA in the serum.

Unexpectedly High IL-1α Levels in Cerebrospinal Fluid of RA Patients and Correlations with Fatigue Severity. Marie Westman[1], Diana Kadetoff[1], Anna Nordenstedt-Agréus[1], Caroline Gillis-Haegerstrand[2], Magnus Andersson[1], Mohsen Khademi[1], Eva Kosek[1] and Jon Lampa[1], [1]Karolinska Institute, Stockholm, Sweden, [2]Danderyds Hospital, Stockholm, Sweden

Purpose: Fatigue is common in RA patients and often cause substantial distress and reduced work capacity. There is a lack of knowledge of how fatigue is mediated, but central acting inflammatory mechanisms have been suggested in this context. In this pilot study, we investigated cerebral inflammation in RA patients and focused initially on IL-1β, because it has been implicated in sleep regulation and fatigue*.

Methods: Cerebrospinal fluid (CSF) was obtained from 14 female RA patients, 15 age-matched female patients with fibromyalgia (FM), 15 age-matched patients with multiple sclerosis (MS) in clinical remission and 12 age-matched control women without chronic pain undergoing surgery for benign gynecological conditions (before given spinal anesthesia). FM, RA patients and controls had no earlier or present

concurrent neurological disease. Mean DAS28 for RA patients was 3.6 (range 1.5 to 6.5). IL-1 levels were analyzed with ELISA (IL-1β: R&D, high sensitivity Quantikine). In RA and FM fatigue was assessed with visual analogue scale (VAS) as previously described[#] and current pain with VAS.

Results: CSF IL-1β levels was markedly elevated in RA (11.63±12.59 pg/ml) compared with FM (2.57±1.98 pg/ml), MS patients (1.23±1.86 pg/ml) and controls (0.66±1.03 pg/ml) (ANOVA $p<0.0001$; post hoc Bonferroni: $p<0.0006$; $p<0.0001$ and $p<0.0001$ respectively). There was no difference between FM, MS and control IL-1β levels. Pain was increased in FM compared to RA ($p<0.0001$), but there were no differences in fatigue between the diseases. After adjustment for age, disease activity and pain there was a significant positive correlation between RA CSF IL-1β levels and fatigue ($p<0.05$, $F=5.24$) whereas no similar correlation to fatigue was detected in FM ($p=0.23$, $F=1.6$).

Conclusion: This is to our knowledge the first evidence of increased cerebral inflammation in RA. The correlation between intrathecal IL-1β and fatigue in RA, but not in FM, supports involvement of cerebral inflammatory action in RA fatigue, and additionally suggests different mechanisms for fatigue in RA and FM.

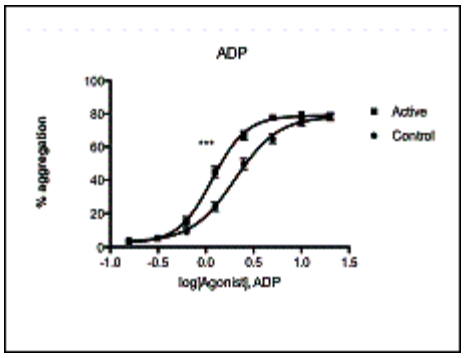
Platelet Hyper-Reactivity in Active Inflammatory Arthritis Is Unique to the ADP Pathway: a Novel Finding and Potential Therapeutic Target. Paul A. MacMullan[1], Aaron J. Peace[2], Anne Madigan[1], Anthony F. Tedesco[2], Dermot J. Kenny[2] and Geraldine M. McCarthy[1], [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland

Purpose: Patients with inflammatory arthritis (IA) have a markedly elevated risk of adverse cardiovascular events. This risk is greatest in those with poor disease control. Platelets play a crucial role in the pathogenesis of atherothrombotic events. To date, platelet function in the IA population has not been well characterised. Therefore, we decided to assess the influence of disease activity on platelet function in patients with IA.

Method: 96 patients with an established diagnosis of IA (rheumatoid, psoriatic, seronegative spondyloarthropathy) were recruited. Patients with a history of cardiovascular disease (CVD), diabetes mellitus, or receiving anti-platelet therapy were excluded. Demographic data, traditional CVD risk factors and medication use were recorded. Patients were characterised as Active disease (n =38) or Control disease (n = 58) groups respectively, based on internationally validated measures of disease activity, {comprising serological markers (ESR,CRP,fibrinogen) , patient measures (VASDA) ,evaluator global assessment, and the DAS-28 score}. Platelet function was assessed using a novel assay of platelet reactivity. Platelet aggregation to multiple concentrations of arachidonic acid, collagen, epinephrine, thrombin receptor activating peptide (TRAP), and ADP were measured simultaneously using a modification of light transmission aggregometry.

Results: The two groups (Active v Control) were similar in terms of demographics and CVD risk factors. Anti-TNFa therapy use was higher in the Control group ($p=0.004$) while NSAID use was higher in the Active group ($p=0.001$).There was a significant difference between the two groups in platelet response to ADP ($p<0.001$). Platelet aggregation in response to submaximal concentrations of ADP was increased in the Active disease group compared to the Control group. There was no difference in platelet reactivity between the groups in response to any of the other agonists.

Conclusion: Patients with active IA demonstrate enhanced platelet reactivity , unique to the ADP pathway. This potential pro-thrombotic bias may contribute to their increased cardiovascular risk.



***** p<0.001 Significantly increased platelet response to ADP in patients with active inflammatory arthritis.**

Screening of Differentially Expressed Serum Proteins for Rheumatoid Arthritis by Proteomic Fingerprinting. Li Long[1], Yongzhe Li[2], Chaojun Hu[1] and Zhanguo Li[3], [1]Bejing Univ People's Hosp, Beijing, China, [2]Peking Union Medical College Hospital, Beijing, China, [3]Peking University People's Hospital, Beijing, China

Purpose: To search for proteomic patterns distinguishing rheumatoid arthritis (RA) patients from healthy controls, biomarker candidates specific for early RA, and proteins reflecting disease activity, by profiling of serum proteins using magnetic bead-based (MB) separation and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS).

Method: Magnetic chemical affinity beads were used to differentially capture serum proteins prior to MALDI-TOF analysis. Seventy serum samples from RA cases fulfilling the American College of Rheumatology (ACR) classification criteria and 50 from healthy controls were analyzed. The samples were randomly allocated to the training set or test set to develop a pattern by means of decision tree algorithm. Nonparametric Mann-Whitney test was utilized to search for potential biomarkers for early RA. Linear correlation analysis was employed to estimate the intensity of the overexpressed peaks in relation to the level of serum C-reactive protein (CRP).

Results: The algorithm identified a pattern based on 3 peaks (m/z 2490, 5910.07 6436.73) that, in the training set, separated RA patients from healthy controls with a sensitivity and specificity of 87.5% and 96.7%, respectively. Blind test data indicated a sensitivity of 86.7% and specificity of 90%. The peaks of m/z 1014.92 and 1061.37671 were raised significantly in early RA group (disease duration<12 months) compared with those in non-early RA group (disease duration>=12 months) and healthy controls. A positive correlation was found between the intensity of peak 1770.16 and the level of serum CRP.

Conclusion: Using MB separation followed by MALDI-TOF-MS enabled rapid diagnosis of RA according to fingerprint pattern, a method which might also help to assess disease activity and identify early RA**.**

Soluble GITR Ligand Is Extremely Elevated in Sera From RA Patients. Kazuhiro Kurasawa, Tetsuya Ohara, Satoko Arai, Takayoshi Owada, Reika Maezawa, Ryosuke Hanaoka and Takeshi Fukuda, Dokkyo Medical University, Mibu, Tochigi, Japan

Purpose: Glucocorticoid-Induced TNF-Related Protein (GITR) and its ligand, GITR ligand (GITRL), are members of the TNF receptor and TNF superfamilies, respectively. GITRL is a membrane protein and expressed on endothelial cells, dendritic cells, and some tumor cells. GITR/GITRL interaction plays important roles in immune response and inflammation, which activates regulatory effects of CD25+ CD4+

regulatory T cells and, on the contrary, stimulates inflammation. However, the role of GITR/GITRL pathway in the development of autoimmune diseases remains to be elucidated. In addition, it is unknown whether a soluble form of GITRL is produced similarly to some members of TNF family such as TNF.

The aim of this study is to determine whether there exists soluble form of GITRL (soluble GITRL) in sera from patients with rheumatic diseases. If so, to clarify the role of GITRL in the development of rheumatic diseases

Method: We developed EIA to detect soluble GITRL using a pair of antibodies against extracellular portion of GITRL. Serum samples from patients from RA (n=76), SLE(n=59), SSc (n=34), bacterial infection(n=21) and healthy controls (n=34) were tested. The soluble GITRL was examined with western blot analysis. Clinical features of patients with soluble GITRL were examined by review of medical records.

Results: Soluble GITRL was detected in sere from some patients with collagen-vascular diseases, particularly with RA .The molecular weight was approximately 15KDa. The patients with soluble GITRL levels above 0.5ng/ml (mean +3 sd of healthy controls) were 53% of RA, 2% of SLE, 18% of SSc, and 0% of infection. Interestingly, serum levels of soluble GITRL in RA were extremely elevated compared to those in other collagen-vascular diseases. Patients with soluble GITRL levels above 10ng/ml and 100ng/ml were 25% and 6.5% of RA, respectively. RA patients with extremely high levels of soluble GITRL (> 10ng/ml) were aged old and had high titers of RF, compared to those with soluble GITRL levels less than10ng/ml or with normal levels. Among RA patients with extremely high, high and normal soluble GITRL levels, no significant differences were found in disease duration, disease activity, levels of CRP and treatment

Conclusion: Soluble GITRL exists in serum of patients with collagen-vascular diseases, particularly with RA and the levels of which were extremely elevated in RA patients. GITR/GITRL system including soluble GITRL might be involved in the development of RA, although further investigations are required.

Biomarkers in Early Rheumatoid Arthritis: Analysis of the Diagnostic Performance. Donatello Pietrapertosa, Barbara Tolusso, Silvia L. Bosello, Anna L. Fedele, Maria C. Papalia, Elisa Gremese and Gianfranco Ferraccioli, Division of Rheumatology – Catholic University of the Sacred Heart, Rome, Italy

Purpose: To test if a combination of biomarkers can increase the classification power of autoantibodies to cyclic citrullinated peptides (anti-CCP) in the diagnosis of early rheumatoid arthritis (ERA).

Method: We tested the levels of anti-CCP2 antibodies, Anti-MCV antibodies, rheumatoid factor (RF) IgM and IgA, Interleukin-6 (IL-6), ESR and CRP by ELISA in serum samples from 83 patients with ERA and 132 control subjects (80 with undifferentiated arthritis and 52 healthy controls). To evaluate the diagnostic performance of different assays, receiver operating characteristic (ROC) curves were constructed. For every parameter we obtained sensitivity and specificity along with 95% confidence interval (95% CI). Differences were tested with McNemar test.

Results: The sensitivity of the bio-markers was evaluated in a panel with cut-offs determined at 95% specificity. When individual tests were considered, sensibility for ERA was highest for the anti-CCP2 (66.7%, 95%CI: 55.3-76.8) and anti-MCV (64.6%, 95%CI: 53.0-75.0), followed by IL-6 (41.5%, 95%CI: 30.7-52.9), RF-IgM (35.1%, 95%CI: 24.5-46.8%), RF-IgA (32.5%, 95%CI: 22.2-44.1), ESR (31.9%, 95% CI: 21.4-44.0) and CRP (16.7%, 95% CI: 8.9-27.3). The difference between anti-CCP2 and anti-MCV was non significant (p=1.0), and both were significantly better than the IL-6 (p<0.01), RF-IgM (p<0.001), RF-IgA (p<0.001), ESR (p<0.001) and CRP (p<0.001).

The combination of markers (at least one of both positive) of anti-CCP2 antibodies and anti-MCV gave a sensitivity of 73.3% (95%CI: 62.7-83.0) and a specificity of 90.3% (95%CI: 84.0-94.7). The combination of anti-CCP2 antibodies and IL-6 gave a sensitivity of 79.0% (95%CI: 68.5-87.3) and a specificity of 90.4% (95%CI: 84.1-94.8). When the other marker combinations along with anti-CCP2 were considered, sensitivity for ERA ranged from 68.7% (RF-IgM) to 74.7% (ESR).

The combination of anti-MCV antibodies and IL-6 gave a sensitivity of 77.2% (95%CI: 66.4-85.9) and specificity of 89.4% (95%CI: 82.8-94.1). When the other marker combinations along with anti-MCV were considered, sensitivity for ERA ranged from 70.1% (RF-IgM) to 77.0% (ESR).

The best marker combination of anti-CCP2 and IL-6 resulted in a significantly sensitivity gain of 12.3% (p=0.001) at a minor loss in specificity of 4.6% compared with anti-CCP as the best single marker. Specificity was significantly higher for the combination of anti-MCV and IL-6 compared with anti-MCV as a single bio-marker (p=0.004).

Conclusion: The inflammation marker IL-6 in support of anti-CCP or anti-MCV has the highest classification power for the diagnosis of early RA.

345

Stepwise Development of a Multi-Protein Biomarker Index of RA Disease Activity. Y. Shen[1], N. Knowlton[2], M. Turner[3], C. Sutton[4], D. Smith[4], D. Chernoff[1], L. Hesterberg[1], R. Roubenoff[5], N.A. Shadick[6], M. E. Weinblatt[6], G. Cavet[1] and M. Centola[3], [1]Crescendo Bioscience, So. San Francisco, CA, [2]NSK Statistical Solns, LLC, Oklahoma City, OK, [3]OMRF, Oklahoma City, OK, [4]Crescendo Bioscience, Oklahoma City, OK, [5]Biogen-Idec, Cambridge, MA, [6]Brigham & Women's Hosp, Boston, MA

Purpose: Studies such as TICORA, CAMERA and FinRACO suggest frequent quantitative monitoring of disease activity with resulting treatment changes improves patient outcomes. ACR and EULAR also recommend ongoing disease activity assessment. Current monitoring tools, while useful for longitudinal tracking, are suboptimal; laboratory tests such as ESR and CRP are non-specific and do not reflect the heterogeneous biology of RA, while symptom-based measures are subjective and have low reproducibility. We are developing a multi-protein biomarker index of RA disease activity using a rigorous, stepwise development program that comprehensively surveys the biological pathways underlying RA.

Method: Candidate serum protein biomarkers were selected from an extensive screen of literature, databases, and experimental data. Quantitative assays for 141 proteins were optimized for reproducibility, RF blocking, sensitivity, and dynamic range, resulting in 121 measurable proteins in RA patient serum.

Three serial studies were performed - only proteins with the strongest associations to disease activity continued to the next. The first study examined 121 proteins in 128 samples, the second 65 proteins in 320 samples, and the third 21 proteins in 255 samples. Associations between candidate biomarker levels and disease activity were assessed using univariate and multivariate statistics and a range of disease activity measures (including joint counts, DAS28ESR, DAS28CRP, CDAI and patient-reported outcomes). Major clinical covariates such as CCP status and treatment were taken into account by inclusion in statistical modeling and by analyzing patients by disease subtype.

Results: The 3 studies were progressively more enriched for proteins associated with disease activity. 8% of proteins had univariate correlations with DAS28 in the first study, 51% in the second and 60% in the third. The top 21 proteins, selected on the basis of univariate multivariate modeling, represent a diverse set of biological pathways implicated in RA pathogenesis. Statistical models with 4-11 protein biomarkers outperformed any individual biomarker at estimating disease activity. These models achieved average accuracy of 70% for assigning patients into low and high disease activity categories, and average correlations of 0.6 with DAS28 in 100 iterations of cross validation. Models developed in one cohort performed well in independent cohorts (correlation of 0.58-0.6 with DAS28).

Conclusion: Serum protein biomarkers contain biologically rich information reflecting RA disease activity. A robust, stepwise development path, using large cohorts from across the spectrum of care, increases likelihood of successfully validating a multi-marker assay. Developing a validated disease assessment biomarker in RA will enhance current measures and can provide value for patient care and outcomes.

Prognostic Factors of Radiological Progression in Rheumatoid Arthritis: a 10-Year Observational Study. Theodora E. Markatseli[1], Yannis Alamanos[2], Paraskevi V. Voulgari[3] and Alexandros A. Drosos[4], [1]Trainee in Rheumatology, Ioannina, Greece, [2]Associate Professor of Hygiene and Epidemiology, Patras, Greece, [3]Assistant Professor of Rheumatology, Ioannina, Greece, [4]Ioannina Medical School, Ioannina, Greece

Purpose: To describe predictive factors of radiological damage at 10-year follow-up in rheumatoid arthritis (RA) patients.

Method: The disease course and outcome of 144 patients, with RA and with X-rays of the hands and the wrists available at baseline and at 5 and at 10 years, were studied, in order to identify predictive factors of radiological outcome. Radiographs were scored using Larsen's criteria. Baseline parameters were initially tested in univariate analysis, and then those presenting a statistically significant association with Larsen score at 10 years were included in a logistic regression model in order to determine relevant independent prognostic factors.

Results: A significant reduction of disease activity score for the 28 joint indices (DAS-28) was noted ($p<0.0001$), associated with a decrease of acute-phase reactants along the three time points in our cohort ($p<0.0001$). On the contrary, Larsen score was increased from 15.3 ± 11.5 at baseline to 25.9 ± 13.7 and 35 ± 17.3 at 5 and at 10 years respectively. The number of erosive joints was also increased from 1.6 ± 2.3 at baseline to 3.3 ± 2.9 and 4.8 ± 3.9 at 5 and at 10 years respectively. At 10 years, 18 (12.5%) patients had no erosions, while 126 (87.5 %) patients had at least one eroded joint and 63 (43.8%) presented with at least five eroded joints. The average annual progression rate was 2.13 ± 1.28 points/year between baseline and five years, and 1.81 ± 1.34 points/year between five and 10 years. Among the clinical and laboratory parameters at 10 years, a significant association with Larsen score was found only with rheumatoid nodules and C-reactive protein (CRP). Larsen score at 10 years was negatively correlated with grip strength. The time-average values of swollen joint count (SJC), erythrocyte sedimentation rate (ESR) and CRP over 10 years were also associated with the final Larsen score. In the univariate analysis, Larsen score at 10 years was significantly associated with baseline radiographic parameters (Larsen score and the number of erosive joints), the presence of autoantibodies [anti-cyclic citrullinated peptide antibodies (anti-CCP) and rheumatoid factor (RF) of IgA and IgM isotype], and disease duration. In the logistic regression analysis Larsen score and the number of erosive joints, as well as anti-CCP antibodies presented a significant and independent association with Larsen score at 10 years.

Conclusion: Despite the clinical improvement, the radiological progression continues over the time due to the underlying inflammatory process. Baseline radiographic damage and autoantibodies constitute the main predictive factors of poor radiological outcome in long term.

Radiographic Severity of Rheumatoid Arthritis in African-Americans: Results From the CLEAR Registry. S. Louis Bridges Jr.[1], Zenoria L. Causey[1], Paula I. Burgos[1], Laura B. Hughes[1], Maria I. Danila[1], Amalia van Everdingen[2], Stephanie Ledbetter[1], Doyt L. Conn[3], Ashutosh Tamhane[1], Andrew O. Westfall[1], Beth L. Jonas[4], Leigh Callahan[4], Edwin A. Smith[5], Richard Brasington[6], Larry W. Moreland[7], Graciela S. Alarcon[8] and Désirée M.F.M. van der Heijde[9], [1]University of Alabama, Birmingham, AL, [2]Medical Center Haaglanden, The Hague, Netherlands, [3]Emory Univ Schl of Med, Atlanta, GA, [4]University of North Carolina, Chapel Hill, NC, [5]Medical University of SC, Charleston, SC, [6]Washington Univ Schl of Med, St Louis, MO, [7]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Leiden University Medical Center, Leiden, Netherlands

Purpose: To describe radiographic changes in African-Americans with rheumatoid arthritis (RA) from the CLEAR (Consortium for the Longitudinal Evaluation of African-Americans with Early Rheumatoid Arthritis) registry, a multicenter observational study.

Methods: RA patients, self-declared African-American were enrolled in CLEAR I (n=357), a longitudinal (disease duration <2 years) cohort from 2000 to 2005, and CLEAR II (n=418), the cross-sectional arm of the registry, from 2006 to the present. Demographic, clinical and radiographic data were obtained. Sets of hand/wrist and foot radiographs were scored for erosions; joint space narrowing (JSN), and total radiographic score using the modified Sharp/van der Heijde scoring system.

Results: Data from CLEAR I and CLEAR II were examined. For the CLEAR I cohort 294 patients had a mean radiographic score of 2.89 at the baseline visit; 32.0% showed either erosions (25.9%) or JSN (19.4%). At the 36-month visit the mean score was 5.65; 44.2% had erosions, 41.5% JSN and 55.4% had either. Among those patients without radiographic damage at baseline, 18.9% had progressed at the 36-month visit, compared to 57.1% of those with baseline damage ($p<0.0001$) and the risk ratio with baseline damage versus no baseline

damage was 3.02 (95% CI: 1.86 -4.88). For the CLEAR II cohort of 167 patients with RA of any duration, 65.3% exhibited joint erosions, 65.3% JSN and 74.8% exhibited either. The mean radiographic score was 33.42. These data are shown in Table 1.

Conclusion: This is the largest radiographic study of RA patients of African American ancestry. Damage occurs early in the disease course and it is associated with radiographic progression at 3 years of disease duration.

Which Subgroups Are at Higher Risk of Rapid Radiographic Progression in Early Rheumatoid Arthritis: Results From SONORA Study. Claire Bombardier[1], Maggie H. Chen[1], Xiuying Li[1], Peter K. Gregersen[2] and Désirée M.F.M. van der Heijde[3], [1]University Health Network, Toronto, ON, [2]Feinstein Institute for Medical Research, Manhasset, NY, [3]Leiden University Medical Center, Leiden, Netherlands

Purpose: Identifying patients with rheumatoid arthritis at high risk for radiographic progression is critical to making appropriate treatment decisions. Data from SONORA (study of new-onset rheumatoid arthritis) was analyzed to explore a prediction model for the high risk of radiographic progression in early rheumatoid arthritis (RA) patients.

Method: A total of 994 patients diagnosed as early RA (symptoms ≥3 and ≤12 months) by a board-certified rheumatologist across North America were recruited in this study. Hand radiographs were obtained at baseline, year 1 and year 2 and scored according to original Sharp method (range 0 to 280) in random order per patient. Radiographic progression was defined by a change of at least 3.2, 2.9 and 3.4 in the erosion score, narrowing score and total Sharp score, respectively[1]. The continuous risk factors were included in the model as categorical variables, which includes CRP (<0.6, 0.6-3 or >3mg/dl), swollen joint count (<10, 10-17, or <17), Rheumatoid factor (≤20 or >20), anti-CCP (≤20 or >20) and baseline sharp score (0, 0-5, 5-10 or >10). Univariate models were used to identify the risk factors for radiographic progression. General estimation equation (GEE) model controlling for disease activity score, baseline sharp score, CRP and anti-CCP was used as the prediction model to identify the subgroups for high risk of radiographic progression.

Results: Patients had a mean age 53 years (SD, 14.81), 72% female and 90% Caucasian with mean disease durations 170 (180) days. The Sharp Score was 5.49 (7.85), 6.38 (8.90) and 6.17 (8.65) at baseline (N=746), year 1 (n=756) and year 2 (n=567) respectively. Among these patients, radiographic progression was observed in 14.7% of the patients at year 1 and 19.4% at year 2. The multivariate GEE model with repeated binary outcomes at year 1 and 2 revealed that a subpopulation with CRP>3mg/dL, baseline sharp score >10, anti-CCP>20 are those ones at highest risk of radiographic progression for early RA patients at year 1 and 2. More details in table 1.

Conclusion: Radiographic progression of RA remains the best method of assessing structural damage associated with the disease. This model predicts the risk of radiographic progression using easily accessible clinical and laboratory variables. These identified subgroups can help guide rheumatologists in making treatment decisions for early RA patients.

Table 1:

Risk factors	Odds ratio	95% CI of OR	P-value
DAS28 (continuous)	1.21	(1.05,1.38)	0.0057
Baseline sharp score >10 vs. 0	3.53	(1.65,7.39)	0.0011
Baseline sharp score >10 vs. 0-5	2.72	(1.49,4.95)	0.0011
Baseline sharp score >10 vs. 5-10	1.43	(0.74,2.77)	0.281
CRP >3 vs. <3	1.65	(1.06,2.51)	0.03
Anti-CCP >20 vs. <20	2.67	(1.67,4.31)	<0.0001

Wrist MRI After 2 Years Treatment of Early Aggressive RA. Veena K. Ranganath[1], Kambiz Motamedi[1], Espen A. Haavardsholm[2], Paul Maranian[3], David Elashoff[3], Fiona M. McQueen[4], Jeffrey Curtis[5], L W. Moreland[6], Stacey S. Cofield[5], Weiling Chen[1] and HE Paulus[1], [1]UCLA, Los Angeles, CA, [2]Department of Rheumatology, Oslo, Norway, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA, [4]University of Auckland, Auckland, New Zealand, [5]The University of Alabama at Birmingham, Birmingham, AL, [6]U Pittsburgh, Pittsburgh, PA

Purpose: Remission is the current goal of RA therapy, but erosive damage may progress despite meeting criteria for clinical remission. Objective: Evaluate relationship of clinical remission criteria to MRI inflammatory scores after 2 or more years of aggressive treatment of RA.

Methods: MRI with gadolinium contrast (1.5 Tesla) of the dominant wrist was obtained 0 to 33.5 months (Mean 5.4) after completing a 2-year controlled clinical trial comparing various combinations of MTX, etanercept, hydroxychloroquine, and sulfasalazine in 115 early (RA duration 4.1 ± 10.8 months) seropositive or erosive RA patients. DAS28/ESR were recorded every 12 weeks during the trial and at the time of MRI. Two experienced readers scored MRIs for tenosynovitis (T: range 0-30), synovitis (S: 0-9), bone marrow edema (BME: 0-42), and erosions (E: 0-140) using published RA MRI (RAMRIS) and tenosynovitis scoring methods; averages of the 2 scorers were used for analysis.

Results: Mean ± SD (subjects with "0" score): S 3.5 ± 1.3 (0); T 5.2 ± 2.7 (3); BME 2.6 ± 4.2 (32); E 10.6 ± 10.7 (0). Significant (Spearman) correlations at time of MRI: DAS with T: r = 0.26. Mean DAS over year 1, year 2, or years 1 and 2, and number of days of sustained DAS remission before the MRI did not correlate significantly with the MRI scores.

Description of Patients by DAS Remission and MRI Inflammatory Scores

	Never in Remission	Ever in Remission (Not Continuous)	Continuous DAS 2.4 R ≤ 1yr
Number of Patients (Total = 115)	34	46	21
DAS 2.4 Remission at time of MRI, N (% of total)	0	0	21 (18.9)
Total Months Ever in Remission (median, range)	0	5.7 (2.4, 19.2)	9.6 (2.4, 21.6)
Index wrist - swell or tender, N (% of category)	6 (19.4)	14 (33.3)	4 (19.1)
Number of Patients in MDA (% of category)	7 (20.6)	15 (35.7)	21 (100)
MRI Scores at MRI, mean/SD (# w/ 0 score)			
Tenosynovitis (T)	5.7/2.3 (1)	5.2/2.7 (1)	5.5/3.3 (1)
Synovitis (S)	3.9/1.4 (0)	3.3/1.4 (0)	3.3/0.98 (0)
Bone Marrow Edema (BME)	3.7/6.5 (8)	2.2/2.9 (14)	1.9/2.5 (7)
Erosions (E)	13.4/14.8 (0)	9.9/10.4 (0)	8.5/6.2 (0)
Composite (T + S + BME)	13.2/9.1 (0)	10.7/4.8 (0)	10.6/4.3 (0)
*p value <0.001 comparing patients never in remission compared with those with sustained remission >1yr MDA= Minimal Disease Activity, DAS<2.85			

Conclusion: After 2 years of aggressive treatment of early seropositive RA, 80% of patients had no pain/tenderness or swelling of the examined wrist, about half had MDA, and some met clinical criteria for DAS28 remission. The duration of clinical remission did not correlate with lower MRI scores. Thus, despite aggressive therapy for at least 2 years, patients were not devoid of evidence of synovitis, tenosynovitis, and bone marrow edema even among people in DAS28 remission.

Predictors of Radiographic Progression in Rheumatoid Arthritis Patients Treated with Methotrexate. Michael E. Weinblatt[1], Edward C. Keystone[2], Marc D. Cohen[3], Bruce Freundlich[4], Juan Li[5], Yun Chon[5] and Scott Baumgartner[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Professor of Medicine/University of Toronto, Toronto, ON, [3]National Jewish Medical Ctr, Denver, CO, [4]Wyeth Research, Collegeville, PA, [5]Amgen, Thousand Oaks, CA

Purpose: To identify prognostic markers associated with radiographic progression at 52 weeks in patients with rheumatoid arthritis (RA) after 12 weeks of methotrexate (MTX) therapy.

Method: The study population consisted of patients from the MTX arm of the Trial of Etanercept and Methotrexate with radiographic Patient Outcomes (TEMPO). Logistic regression analysis was used to identify possible predictors of week 52 radiographic outcome (modified total Sharp score) from clinical and laboratory assessments performed at week 12 of MTX therapy. Classification and regression tree (CART) modeling of the week 12 assessments was used to further determine the subgroups of patients with the best and worst radiographic outcomes.

Results: A total of 169 patients were analyzed. Based on logistic regression analysis, C-reactive protein (CRP) level, erythrocyte sedimentation rate, tender joint count, swollen joint count (SJC), and health assessment questionnaire scores at week 12 were significant predictors of radiographic progression at week 52 ($p < 0.05$ for each assessment). CART modeling showed that patients with CRP > 0.67 mg/dL and SJC > 1, or CRP ≤ 0.67 mg/dL and SJC > 10, at week 12 were likely to show the worst radiographic progression at week 52 (see Figure). The CART model had a sensitivity of 85%, specificity of 60%, and overall classification accuracy of 68%.

Conclusion: In patients with RA, CRP and SJC after 12 weeks of MTX therapy emerged as the best predictors of radiographic progression at week 52.

Baseline RANKL:OPG Ratio and Markers of Bone and Cartilage Degradation Predict Annual Radiological Progression Over 11 Years in Rheumatoid Arthritis. L.H.D. van Tuyl[1], A.E Voskuyl[1], M. Boers[1], P.P.M.M. Geusens[2], R. Landewé[2], B.A.C. Dijkmans[1] and W.F. Lems[3], [1]VU University Medical Center, Amsterdam, Netherlands, [2]University Hospital Maastricht, Maastricht, Netherlands, [3]VUmc, Amsterdam, Netherlands

Purpose: Traditional predictors of radiological progression in rheumatoid arthritis (RA) are mostly markers of inflammation. We investigated to what extent baseline measurements of the ratio of receptor activator of nuclear factor κB ligand (RANKL)/osteoprotegerin (OPG) and C-terminal cross linking of type-I and type-II (CTX-I and CTX-II) in addition to traditional markers of disease severity, could predict annual radiological progression.

Method: A cohort of 155 early, active, untreated RA patients that participated in the COBRA trial was followed for 11 years. Urine was sampled at baseline and after 3 months from start of treatment and analyzed for CTX-I and CTX-II. Baseline serum samples were analyzed for RANKL and OPG. Available traditional markers of disease severity included baseline measurements of erythrocyte sedimentation rate, rheumatoid factor and baseline radiological damage. A digital database of frequent radiographs was available, scored according to the

Sharp/van der Heijde method. Individual annual progression rates were calculated and used as outcome variable. Multiple linear regression analyses identified the strongest predictors of annual radiological progression.

Results: In multivariable analyses the RANKL:OPG ratio and CTX-I or CTX-II proved to be independent predictors of annual radiological damage over 11 years. The prediction of annual radiological progression was strongest when the RANKL:OPG ratio and CTX1 or CTX2 were evaluated in the same model (36 to 39% explained variance). Adding the effect of treatment at 3 months to the baseline models improved the predictive ability of the models up to 44 to 46%.

Conclusion: Unfavorable baseline levels of the RANKL:OPG-ratio as well as CTX-I (markers of bone resorption) and CTX-II (a marker of predominantly cartilage degradation) in patients with early, active, untreated RA are strong independent predictors of rapid and persistent damage progression over 11 years follow up. Early improvement in bone markers on treatment predicts a better outcome.

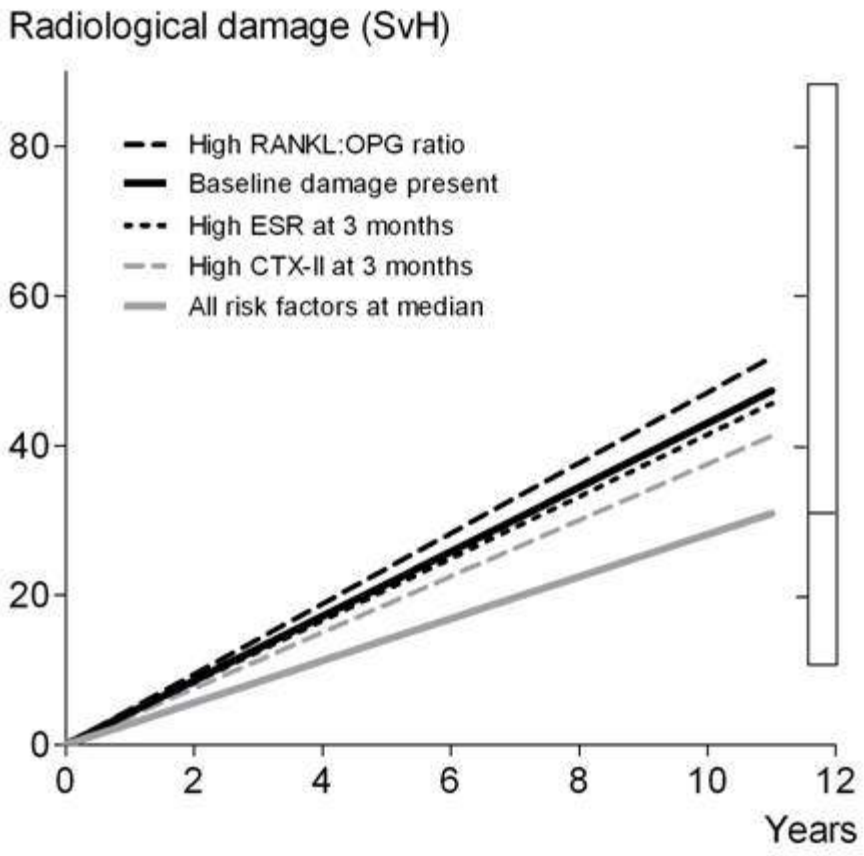

Figure 1*: Radiological progression over 11 years for patients with either an unfavourable RANKL:OPG ratio, ESR level, CTX-II level or baseline damage . This figure is created using the estimations of the model including CTX-II and the RANKL:OPG ratio, predicting 46% of variation in radiological progression determined by a high baseline RANKL:OPG ratio, high ESR at 3 months, high CTX-II at 3 months and presence of baseline damage. The graph shows the radiological progression for the model with one variable at the 90th percentile of the distribution and the other 3 variables at their median value. For example, the highest dotted line represents the radiological progression when CTX-II at 3 months and ESR at 3 months are at their median, baseline damage is absent, but the RANKL:OPG ratio is at its 90th percentile. The vertical box on the right represents the distribution from the 25th to 75th percentile of radiological damage 11 years after inclusion in the COBRA trial, if every patient would have started with zero baseline damage.*

Identification of SNPs Associated with Severe Articular Damage in Patients with Rheumatoid Arthritis. N. Oreiro[1], J. C. Fernández-López[1], J. del Amo[2], J. Mulero[3], A. Balsa[4], R. Cáliz[5], R. Sanmartí[6], F.G. Martínez[7], D. Tejedor[2], M. Artienda[2], J.L. Andreu[3], L. Silva[3], D. Pascual-Salcedo[4], M.D. Collado[5], E. Graell[6], L. Simon[2], A. Martínez[2] and F.J. Blanco[1], [1]Complexo Hospitalario Universitario A Coruña, Coruña, Spain, [2]Progenika Biopharma S.A., Bilbao, Spain, [3]Hospital Puerta de Hierro, Madrid, Spain, [4]Hospital La Paz, Madrid, Spain, [5]Hospital Virgen de las Nieves, Granada, Spain, [6]Hospital Clinic, Barcelona, Spain, [7]Hospital Reina Sofía, Córdoba, Spain

Purpose: Rheumatoid Arthritis (RA) is an inflammatory disease with a very different course in patients. It would be very useful to identify patients at high risk of poor outcome because an early and aggressive treatment could be indicated.

Aim: To study the association of genetic polymorphisms with articular damage (erosions and articular surgery) in RA patients.

Methods: Patients from 6 rheumatology divisions were included in the study. Inclusion criteria were: a) 1987 ACR criteria for RA, b) RA should have started after 1990, c) >5 years of follow-up, d) Onset disease age >18, and e) Caucasian origin. Baseline clinical and analytical variables were collected. As main clinical endpoints, 3 radiographic patterns were defined: RX1: Space narrow and multiple erosions in hands and feet. RX2: Multiple erosions in hands and feet. RX3: Multiple erosions in hands or feet. Joint replacement information was also collected. All patients signed an informed consent. We have developed a DNA microarray that allows the simultaneous detection of 69 SNPs in 49 genes, which have been selected by they potential impact in RA, according to the published literature.

Results: In total 632 patients (465F/167M) were included. From all patients, 129 underwent prosthesis surgery, and the radiographic patterns RX1, RX2 and RX3 were present in 163, 182, and 275 RA patients respectively. Baseline number of painful joints, anti-CCP titers, ESR, RF, and CRP, were all significantly associated with the development of severe articular damage. In addition, carriers of the minor allele of 2 SNPs in SCGB1A1 and MMP-3 genes were more frequent in RA with bone erosions in hand and/or feet (Table 1). In contrast, carriers of the minor allele at 2 SNPs in PDCD1 and IL4R genes were less frequent in patients with articular damage, indicating a protective effect. The statistical analysis also showed that the frequency of homozygous for the minor allele at 2 SNPs in SLC22A4 and SCGB1A1, was higher in patients with articular prosthesis.

Table 1: Univariate analysis of 69 SNPs in 632 patients with RA: SNPs associated to articular damage

Phenotype	Rs ID	Gene	SNPs	Genotype	OR	I.C.95 %	P-value
RX1 Pattern							
	rs3741240	SCGB1A1	A587G	GA or AA	1,5	1,1-2,2	0,02
RX2 Pattern							
	rs3741240	SCGB1A1	G587A	GA or AA	1,6	1,1-2,3	0,01
	rs3025058	MMP3	113-/A	-A or AA	1,5	1,0-2,3	0,04
RX3 Pattern							
	rs2227981	PDCD1	C872T	TT	0,4	0,3-0,7	<0,01

	rs1801275	IL4R	A1969G	AG or GG	0,7	0,5-0,9	0,02
Surgery							
	rs1050152	SLC22A4	C1672T	TT	1,8	1,2-2,9	<0,01
	rs3741240	SCGB1A1	A587G	AA	1,7	1,0-2,9	0,04

Conclusion: We report the association of 5 SNPs with severe articular damage in RA patients. Genetic information, together with other baseline clinical parameters, might be useful to identify patients at high risk of highly erosive RA.

USING VFA to Assess the Prevalence of Vertebral Fractures IN PATIENTS with RHEUMATOID ARTHRITIS: A Case Control Study. Mirieme Ghazi, Sami Kolta, Karine Briot, Simon Paternotte, Maxime Dougados and Christian Roux, Paris-Descartes University, Paris, France

Purpose: Generalized osteoporosis is a well-known complication of rheumatoid arthritis (RA). Clinical consequences of vertebral fractures (VF) in osteoporotic patients are more and more recognized. Vertebral Fracture Assessment (VFA) technology is a convenient method to assess vertebral deformities, with lower radiation and lower costs than standard X-rays.

Objective: To calculate the prevalence of vertebral fractures in female patients with RA using VFA, and to assess risk factors for VF.

Method: Consecutive patients (N= 80, 56.4± 14.7 years, mean RA duration 16 ± 10years) attending the Rheumatology Department were recruited in the study. Clinical, biological status was assessed by Erythrocyte sedimentation rate, C-reactive protein, and rheumatoid factor, health assessment questionnaire, DAS28, and duration of RA. Controls (N= 240) were randomly selected from the general population and were individually matched to each case for age. For both patients and controls, information on general health status, height, weight, smoking habits, history of fracture, and use of oral glucocorticoids, was collected. Bone mineral density was measured by DXA and osteoporosis defined as T score< -2.5 at either spine or hip. Vertebral fractures were defined using VFA during the same exam.

Results: 22.5% and 4.17% of patients and controls had a vertebral fracture respectively. Compared with controls, patients with RA had an increased risk of vertebral fracture: OR [IC 95%]: 6.7 [3.2; 13.8]. Prevalence of non vertebral fractures (low trauma) in RA was 26.25%. Prevalence of osteoporosis was 53.75% and 10.42% in patients and controls respectively. Factors associated with osteoporosis were age, use of steroids, duration of menopause, and prevalent peripheral fractures. Vertebral fractures were associated with age, duration of menopause, prevalent peripheral fractures, and prevalent arthroplasty. No other indicator of RA severity or activity was associated with presence of vertebral fractures. 48.75% patients with RA were receiving anti osteoporotic treatment. By multiple regresion, the presence of vertebral fractures was independently associated only with age (OR=1.13 [1.06; 1.22] and prevalent peripheral fractures (OR= 7.47[1.79; 31.11].

Conclusion: The prevalence of vertebral fractures is 22.5% in our population with RA. RA is a strong risk factor of such fractures (OR= 6.7). Few parameters predict these fractures in this population. Because of the consequences of these fractures, VFA should be a routine procedure in RA.

Hand Bone Densitometry and Bone/Cartilage Markers Failed to Predict Erosion Progression at 5 Years in the Conservatively Community-Based Inceptive Vera (Very Early Arthritis) Cohort. Anne Letierce Vanlerberghe[1], Alain Daragon[2], Michel Brazier[3], Mary Jan[4], Thierry Lequerré[5], Othmane Mejjad[2], Patrick Boumier[6], Alain Gayet[7], François Tron[8], Charles Zarnitsky[9], Olivier Vittecoq[10], Patrice Fardellone[11] and Xavier Le Loët[12], [1]CHU-Hôpitaux de Rouen, France, [2]CHU Hôpitaux de Rouen, France, [3]France, [4]CHU, Rouen, France, [5]CHU Hôpitaux de Rouen, Rouen, France, [6]CHU Amiens, France, [7]CHU de Rouen-Hôpitaux de Rouen, France, [8]INSERM U 905, Rouen, [9]CH Le Havre, France, [10]Rouen, France, [11]CHU d'Amiens, France, [12]CHU Rouen - INSERM U 905, France

Purpose: Ability of bone and cartilage markers and hand bone densitometry to predict progression of structural damage at 5 years in patients with very early arthritis.

Method: Community -based- recrutment (media campaigns) of 310 adults (mean age : 51.8 years ; 68% females) with swelling of 2 or more joints persisting more than 4 weeks, evolving for less than six months (mean : 4.2 months), DMARD and steroids naïve. Then, they were conservatively treated for 5 years. Assessment was made at entry and comprised clinical data (global pain, Ritchie index and swollen joints / 44), CRP, ESR, auto antibodies rheumatoid factors (RF) by agglutination tests and IgM, IgA, IgG, isotypes by Elisa, anti-CCP II, serum pyridinoline (PYD) deoxypyridinoline (DPD), sCTX-I, Cartilage Oligométric Matrix Protéin (COMP), osteoprotegerin (OPG), RANKL, and DKK1. Hand bone densitometry by DXA was performed on both hands every year. All patients with Rheumatoid Arthritis or undifferentiated arthritis were followed but not those classified as having defined rheumatism (DR). Criterion of judgment was progression of erosion score with an increase of at least 1 unit at 5 years (measurement was done according to vdH modified erosion Sharp score by two readers).

Results: At 5 years, 140 patients were assessed (64 refused, 10 lost of follow-up; 5 death, 87 classified as DR, 4 with X ray failure) : 46 (33%) had erosion progression. With univariate analysis, there was a relationship between erosion progression and baseline value of VS (p=0.03), IgA, IgG, IgM FR (p = 0.001), anti-CCP II (p = 0.001), COMP (p= 0,02) and sCTX-I (p=0.001). But OPG, RANKL, OPG/RANKL, DKK1, PYD, DPD, CRP and bone mineral density were not associated with erosion progression. With multifactorial analysis, only anti-CCP II and IgA FR were associated with structural damage. Hand bone mineral density decreased more in the group with erosion progression during the first year, and was correlated with progression of Sharp score within the 5 years.

Conclusion: In patients with very early arthritis, conservatively treated, anti-CPP II and IgA RF are useful to identify patients with structural damage progression at 5 years. sCTX-I and COMP could be also useful, but are associated with RF. Hand bone densitometry could be used within the first year to predict structural progression at 5 years. These patients with structural damage progression could benefit from early aggressive treatment.

Moderate Agreement On the Assessment of Rheumatoid Synovitis Among 18F-FDG-PET, Contrast-Enhanced MRI, and Clinical Examination. Noboru Hagino[1], Tetsuji Sawada[2], Miwako Takahashi[3], Harushi Mori[3], Keishi Fujio[4], Kimito Kawahata[4], Toshimitsu Momose[3], Kuni Ohtomo[3] and Kazuhiko Yamamoto[4], [1]Hospital of the University of Tokyo, Tokyo, Japan, [2]Tokyo Medical University, Shinjuku Tokyo, Japan, [3]Graduate School of Medicine, the University of Tokyo, Tokyo, Japan, [4]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Purpose: 18F-FDG PET imaging is reported to reflect active synovitis in RA, although clinical significance of 18F-FDG PET imaging in the assessment of RA activity is yet to be determined. This study was performed to assess the utility of 18F-FDG PET for visualizing active rheumatoid synovitis, comparing with clinical examinations, serological markers, and contrast-enhanced MRI of the wrist and hand.

Method: We prospectively studied 20 RA patients. Two independent rheumatologists (NH and TS) assessed each patient clinically, and calculated disease activity score that include 28-joint counts (DAS28). Serological data including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and matrix metalloproteinase-3 (MMP-3) were measured. In each patient, the knees, the wrists, the carpometacarpal (CMC) joints and the metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints, the elbows, and the shoulders were imaged with 18F-FDG PET. PET data were analyzed by visual interpretation of radiologists (MT and TM), and 18F-FDG uptake was quantified using the standardized uptake value (SUV).

All patients underwent gadolinium-enhanced MRI of the wrist and hand. MR-images were scored according to the OMERACT-RAMRIS scoring system.

Results: Patients are all female, with mean age 52.3 (range 37-70). Mean disease duration of RA was 9.2 years (range 1-24). Three patients used infliximab, and another 3 patients used etanercept. All other patients were on conventional DMARDs. The mean DAS28-ESR and DAS28-CRP were 4.22 and 3.41 respectively. The joints showing significant uptake of 18F-FDG corresponded moderately with swollen joints on examination with a kappa-coefficient of 0.52. The existence of synovitis of grade 2 or more in contrast-enhanced MRI also showed moderate agreement with the significant uptake of 18F-FDG (kappa coefficient 0.45). There was poor agreement with the uptake of 18F-FDG and joint tenderness. The sum of SUV didn't correlate with DAS28 or DAS28-CRP (correlation coefficient 0.49 and 0.48 respectively) but well correlated with MMP-3 (correlation coefficient 0.77). In one patient, cervical inflammation was visualized via PET imaging.

Conclusion: 18F-FDG PET imaging visualizes active synovial inflammation in RA but its findings of active synovitis only moderately correlated with those of Contrast-enhanced MRI or clinical examinations. In the patients with long-standing RA and joint deformities, 18F-FDG PET imaging can be a powerful tool to assess active rheumatoid synovitis, independently from old synovial thickening without inflammation.

A Prediction Rule for Disease Outcome in Patients with Undifferentiated Arthritis by MRI of the Wrists and Finger Joints and Serologic Autoantibodies: Second Report Regarding to the Utility of Plain MRI. Mami Tamai, Atsushi Kawakami, Masataka Uetani, Kazuhiko Arima, Keita Fujikawa, Naoki Iwamoto, Shin-ya Kawashiri, Junko Kita, Akitomo Okada, Tomohiro Koga, Toshiyuki Aramaki, Makoto Kamachi, Satoshi Yamasaki, Hideki Nakamura, Hiroaki Ida, Tomoki Origuchi, Kiyoshi Aoyagi and Katsumi Eguchi, Nagasaki University, Nagasaki, Japan

Purpose: We have recently reported a prediction rule for disease outcome in patients with undifferentiated arthritis (UA) by MRI of the wrists and finger joints and serologic autoantibodies in Arthritis Rheum (61; 772-778, 2009). In this report, the presence of synovitis, bone edema and bone erosion were considered by both plain and Gd-enhanced MRI. If plain MRI is enough for the consideration, a cost as well as adverse events due to Gd can be reduced. To investigate whether plain MRI of the wrists and finger joints with serologic autoantibodies at entry is equally efficient for the prediction of development of RA at 1 year, as comparison with our recent report obtaining by plain and Gd-enhanced MRI (Arthritis Rheum 2009; 61: 772-778).

Method: The patients population is exactly same as our recent report which contains 129 UA patients. Seventy-five progressed to RA at 1 year (RA group) whereas 54 did not develop in RA at 1 year (non-RA group). The presence of synovitis, bone edema and bone erosion in MRI of the wrists and finger joints of both hands, read by plain MRI, was compared with those read by both plain and Gd-enhanced MRI. We also tried to find a suitability of plain MRI-interpreted features at entry, with serologic autoantibodies, for the prediction toward RA at 1 year.

Results: As compared with the features interpreted by both plain and Gd-enhanced MRI, symmetrical synovitis as well as bone erosion interpreted by plain MRI were more frequently distributed in non-RA group though a significantly high distribution of bone edema in RA group was still found in plain MRI. Accordingly, in UA patients positive with both plain MRI-proven bone edema and anti-CCP antibodies who were considered to have progressed to RA at 1 year, PPV was still in 100% of 24 patients.

Conclusion: Even in plain MRI of the wrists and finger joints, bone edema is a RA-prone feature as compared with symmetrical synovitis and bone erosion. Plain MRI can be an alternative to Gd-enhanced MRI to examine the progression of RA among patients with UA.

357

Hand Bone Mineral Density (BMD) Loss Is Significantly Associated with the Level of Disease Activity in Patients with Rheumatoid Arthritis (RA). M. Güler-Yüksel[1], N.B. Klarenbeek[1], B.A.M. Grillet[2], I. Speyer[3], T.W.J. Huizinga[1], B. A. C. Dijkmans[4], C.F. Allaart[1] and W.F. Lems[4], [1]LUMC, Leiden, Netherlands, [2]Walcheren Hospital, Vlissingen, Netherlands, [3]Bronovo hospital, Netherlands, [4]VUMC, Amsterdam, Netherlands

Purpose: To investigate the differences in changes in hand BMD after 1 year between RA patients with high and low disease activity and patients in remission, with or without anti-rheumatic drugs.

Methods: 145 patients with active early RA, dynamically treated with anti-rheumatic drugs in a DAS<2.4 steered setting in the BeSt study, were included in this study. The patients were divided in 4 groups based on disease activity level during 1 year follow-up: 1. continuous high disease activity (DAS>2.4), 2. moderate disease activity (1.6<=DAS<=2.4), 3. in remission (DAS<1.6) with anti-rheumatic drugs and 4. drug-free remission. Changes in cortical BMD in metacarpals 2-4 of both hands after 1 year were measured by digital X-ray radiogrammetry (Sectra, Sweden). Changes in BMD were divided in 3 groups: 1. accelerated BMD loss (>-0.003 gr/cm^2), 2. stable BMD (-0.003 to 0.003 gr/cm^2) and 3. gain in BMD (>-0.003 gr/cm^2).

Multivariate multinomial regression analyses were performed to examine the differences in changes in hand BMD between the 4 different disease activity groups, adjusted for age, sex, body mass index, smoking status, diagnosis duration, baseline BMD and DAS, anti-rheumatic and anti-resorptive (bisphosphonates, calcium, vitamin D and hormone replacement) treatment and presence of rheumatoid factor and anti-CCP.

Results: Patients (68% women, mean age 57 years) had at baseline a mean disease duration of 63 weeks and 3 erosions in hands and feet. The mean BMD loss in patients in remission, with or without drugs, was significantly lower than in patients with moderate or high disease activity (overall p<0.0001, table). The differences in mean BMD loss between patients in remission with and without drugs were not significant, as well as between patients with moderate and high disease activity. On patient level, patients in remission had significant less often accelerated BMD loss and more often gain in BMD than patients with disease activity (overall p=0.003, table). In multivariate analyses patients in remission had significant more often gain in BMD than patients with high disease activity with an OR (95% CI) of 7.7 (1.2-48) independent of confounders.

Conclusion: Hand BMD loss is substantially lower in RA patients in continuous remission compared to patients with continuous disease activity. Furthermore one third of the patients in remission are gaining in their hand BMD, suggesting that to stop or prevent inflammatory hand BMD loss the target of treatment should be DAS<1.6.

Table. Changes in hand BMD, in mean (SD) and divided in 3 groups, after 1 year in patients with high and low disease activity and patients in remission, with or without anti-rheumatic drugs

	Group 1. DAS>2.4	Group 2. 1.6<=DAS<=2.4	Group 3. DAS<1.6 with anti-rheumatic drugs	Group 4. Drug-free DAS<1.6
Mean (SD) changes in BMD, % of baseline BMD	-0.031 (0.042)	-0.021 (0.025)	-0.0045 (0.020)	-0.0020 (0.013)
Accelerated BMD loss (>-0.003 gr/cm^2), %	70.0	70.3	38.7	48.1
stable BMD (-0.003 to 0.003 gr/cm^2), %	24.0	18.9	29.0	14.8
gain in BMD (>-0.003 gr/cm^2), %	6.0	10.8	32.3	37.0

Does the Age at Onset Influence the Disease Progression in Early Rheumatoid Arthritis? Lena Innala[1], Bozena Möller[2], Lotta Ljung[1], Torgny Smedby[3], Anna Södergren[1], Staffan Magnusson[4], Ewa Berglin[1], Solbritt Rantapää-Dahlqvist[1] and Solveig Wållberg-Jonsson[1], [1]Norrland University Hospital, Umeå, Sweden, [2]Sunderby Hospital, Luleå, Sweden, [3]Östersund Hospital, Östersund, Sweden, [4]Sundsvall Hospital, Sundsvall, Sweden

Purpose: Disease activity and severity contribute to mortality and comorbidity in rheumatoid arthritis (RA). Confounding factors are age at disease onset and sex. In the present study we evaluated potential differences in disease progression and treatment and related prognostic factors in patients with younger vs. later onset of RA.

Method: All patients from the 4 most northern counties of Sweden diagnosed with RA (<12 months symptoms) are consecutively included in a large survey on the progress of the disease and its co-morbidies. Up til now 700 patients have been included. The median age at disease onset was 57 years (range 18-89). All patients were followed clinically on a regular basis, blood was sampled and a survey of co-morbidities was made at inclusion and after 5 years. At regular intervals, measures of disease activity (ESR, CRP, tender joints, swollen joints, VAS pain and VAS global, DAS28, HAQ) were assessed. Disease severity (extraarticular disease, rheumatoid nodules), co-morbidities and pharmacological treatment (DMARDs, corticosteroids, biologics, NSAIDs, COX2-inhibitors) were registered. Autoantibodies (RF, ANA, ACPAs) and HLA-shared epitope were analysed. Data analyses were based on stratification of the patients in groups over/below the median age at disease onset.

Results: Patients with later-onset of RA had significantly higher ESR (36.3 vs. 26.4 mm/h, $p<0.001$), CRP (24.9 vs. 18.9 g/L, $p<0.01$), VAS global (47.8 vs. 42.9, $p<0.05$) and HAQ (1.0 vs 0.8, $p<0.001$) at baseline and significantly higher accumulated disease activity (AUC for DAS28) at 6 ($p<0.001$), 12 ($p<0.001$) and 18 months ($p<0.01$) compared to patients with younger-onset. Patients with younger-onset had significantly more often ACPAs ($p<0.01$), and were numerically more often RF and ANA positive. Presence of extraarticular disease, nodules and frequencies of HLA-shared epitope or PTPN22 T variant did not differ significantly. Patients with later-onset were significantly more often treated with corticosteroids (77.2 vs. 67.8%; $p<0.05$), significantly less treated with methotrexate (76.4 vs. 86.9%; $p<0.001$) and with biologics (9.1 vs. 19.4%, <0.01). Patients with younger-onset were treated with DMARDs earlier (within 3 months from inclusion, 93.5% vs. 84.6%; $p<0.01$).

Conclusion: Patients with onset of RA later in life appear to have higher disease activity in early disease. Despite that, they are less treated with DMARDs and more often with corticosteroids. This may have implications for the development of co-morbidities.

Women with Early Rheumatoid Arthritis Have More Disease Activity and Functional Impairment Than Men, Although Radiographic Damage Is Similar. Jennie Ursum[1], N.B. Klarenbeek[2], Ben A.C. Dijkmans[3], T.W.J. Huizinga[4], C.F. Allaart[2] and D. van Schaardenburg[5], [1]Jan van Breemen Institute, Amsterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands, [4]LUMC, Leiden, Netherlands, [5]Jan van Breemen institute, Amsterdam, Netherlands

Purpose: Women with rheumatoid arthritis (RA) seem to have more disease activity then men with RA[1], whereas reports vary about female gender as a prognostic factor for radiographic damage[2,3]. The aim of this study was to determine whether there are gender differences in patients with early RA concerning disease activity, functional status, radiographic damage and use of medication.

Methods: Patients from the early arthritis clinic of the Jan van Breemen Institute (EAC-JBI) who fulfilled the ACR criteria for RA at baseline (1996-2007) were included, and follow-up data until a maximum of 5 years were analyzed. The annual radiographic progression rate (Sharp-van der Heijde score) per patient was determined using linear regression, while for the disease activity score (DAS) and functional status (HAQ) the weighted mean was used. The same analysis was used for the 5-year data of the two initial monotherapy groups of the BeSt study (early RA): sequential monotherapy and step-up combination therapy.

Results: Women were younger than men (mean 55 vs. 58 year; $p=0.01$ in the EAC-JBI, and 53 vs. 57; $p=0.05$ in BeSt). The annual radiographic progression of women and men was similar (in both cohorts, see table). The number of used DMARDs was higher in women than in men (medians: 2 versus 1 ($p=0.02$) in EAC-JBI en 3 versus 2 in BeSt ($p=0.007$)). In spite of this women in both cohorts had a higher

DAS (mainly caused by tender joints and general health on the visual analogue scale). In the EAC-JBI women had a significantly higher HAQ than men (p<0.001); this was not found in BeSt.

	EAC-JBI	*Follow-up duration until 5 yrs)		BeSt Study	(all patients 5 yrs follow-up)	
	Women n=464	Men n=215	p	Women n173	Men n=74	p
DAS28	3.27 (1.04)	2.79 (1.02)	0.02	-	-	-
DAS44	-	-	-	2.27 (0.75)	2.01 (0.80)	0.01
HAQ	0.69 (0.37-1.13)	0.54 (0.19-0.89)	0.0	0.58 (0.29-1.02)	0.54 (0.25-0.99)	0.49
SHS, progressionrate (b)	0.48 (0-2.28)	0.57 (0-2.79)	0.8	0.29 (0-2.12)	0.76 (0-3.33)	0.07
Number of used DMARDs	2 (1-3)	1 (1-2)	0.02	3 (2-4)	2 (1-4)	0.007

Conclusion: Women have more disease activity and use more medication than men, whereas their radiographic progression rate is similar. Functional impairment was higher in women, but only in one of the two study cohorts. The gender difference is mainly apparent in disease symptoms, with a higher burden of disease in women. Disease Modifying Anti-Rheumatic Drugs Taking Behavior in a Cohort of Early Rheumatoid Arthritis Patients. Impact of Inadequate Medication Taking Behavior On Clinical Outcomes and Prognosticators. Virginia Pascual-Ramos[1], Irazú Contreras-Yáñez[2], Sergio Ponce de León[3], Javier Cabiedes[2] and Marina Rull-Gabayet[2], [1]Instituto Nacional de la Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Mexico CITY, Mexico

Purpose: current management recommendations of rheumatoid arthritis suggest use of disease modifying anti-rheumatic drugs (DMARDs) when disease activity and/or radiographic damage progression are recognized. Inadequate DMARDs taking behavior ranges in occurrence from 20 to 70% of the patients. Study's objectives were: 1.- To determine adherence and persistence with DMARDs during six months of follow-up in a cohort of early rheumatoid arthritis patients. 2.- To investigate their impact on disease outcomes. 3-. To identify prognosticators of nonadherence and nonpersistence.

Methods: patients currently attending the early arthritis Clinic (≤1 year since first symptom) and receiving at least one DMARD (N=94) were invited to participate. Ninety-three patients were enrolled and attended 4 consecutive evaluations, each 2 months apart, during which 28-joint disease activity score (DAS28) and Health Assessment Questionnaire (HAQ) were scored, comorbidities and treatment recorded and a compliance questionnaire and a drug record registry applied. Serum metotrexate was measured in 81 samples. Descriptive statistics, Student´s t and chi-squared testes and logistic regression analysis were used.

Results: at study entry, 80 (86%) patients were females, 62 (66.7%) had rheumatoid factor and patients had (mean±SD) age of 40.8±3.9 years, follow-up at the Clinic of 25±12.2 months, DAS28 of 2.1±1.2, HAQ of 0.09±0.22, and DMARDs/patient Nº of 2.5±0.9. At last evaluation, 47 (50.5%) patients were adherent, 51 (54.8%) persistent and both had more frequently DAS28-remission than their counterparts

(69.4% vs. 30.6% and 74.2% vs. 25.5%, respectively, p≤0.001) and no disability (56.9% vs. 40.3% and 65.3% vs. 34.7%, p≤0.03). Compared to methotrexate-monotherapy, regimens with >3 DMARDs had increased risk of nonadherence and nonpersistence (p≤0.02). Baseline higher DAS28 was associated to nonadherence (OR: 2.7, 95%CI: 1.56-4.56, p≤0.001) and Nº of DMARDs/patient (OR: 1.8, 95%CI: 1.04-2.96, p=0.04) and higher HAQ (OR: 16.22, 95%CI: 1.52-172.95, p=0.02) to nonpersistence. Sensitivity and specificity of the compliance questionnaire and the drug record registry to detect persistence were of 90.6% for both, and of 75% and 71.4%, respectively (serum-quantitative-methotrexate used as validation method).

Conclusion: Early RA patients with inadequate DMARDs taking behavior showed poorer clinical outcomes than their counterparts. Higher disease activity and disability, and more complex therapeutic regimens were baseline prognosticators of nonadherence and nonpersistence.

Lifestyle and Comorbidity Risk Factors for a Poor Prognosis in Very Early Inflammatory Polyarthritis: Results From the STIVEA Trial. S.M.M. Verstappen[1], M.J. McCoy[1], C. Roberts[1], N.E. Dale[1], A.B. Hassell[2], D.P.M. Symmons[1] and STIVEA trial committee, [1]arc Epidemiology Unit, the University of Manchester, Manchester, United Kingdom, [2]National Primary Care Centre, Keele, United Kingdom

Purpose: Medical history and lifestyle factors, such as smoking and diet, may play a role in the aetiology and course of rheumatoid arthritis (RA). However, hardly any data on these factors is available among patients presenting very early in the course of inflammatory polyarthritis (IP). The objective of this study was to identify lifestyle and comorbidity predictors for a poor prognosis in patients with very early IP.

Methods: Patients included in this study were participants in the STIVEA (Steroids In Very Early Arthritis) multi-centre randomised, double blind, placebo-controlled trial. GPs were asked to refer patients with very early IP (4-11 weeks duration) to the rheumatologist. Patients were randomised to receive three IM injections of either methyl prednisolone or placebo given at one week intervals and were followed for 12 months. Assessments were monthly for six months after the first injection, and then at 1 yr. At baseline, patients were asked to complete a questionnaire covering family history, medical history, immunisations, blood transfusion, smoking (ever vs never) and a food frequency questionnaire. Women were also asked about reproductive factors and use of the oral conceptive pill. Baseline predictors of poor prognosis (i.e. the need to start SLT by 6 months or the clinical diagnosis of RA according to the physician at 1 yr) were identified applying adjusted (for treatment group) logistic regression analyses. We present Odds Ratios (OR) with 95% confidence intervals.

Results: Mean disease duration at baseline was 8 weeks. 162 of 253 patients with available SLT data filled out the questionnaire; 107/162 (66%) patients were identified as needing SLT by 6 month after inclusion. 149 of 222 with a diagnosis at one year filled out the questionnaire; 85/149 (58%) were diagnosed as having RA at 1 year. Patients who had hay fever were less likely to be diagnosed with RA at 1 yr (OR 0.33; 0.12 to 0.93, p=0.036). However, hay fever was not associated with the need for SLT. Although not significant, there was a trend for smoking to be associated with a worse outcome (OR need to start SLT 1.91; 0.97 to 3.78, p=0.063; OR diagnosis of RA 1.95; 0.99 to 3.82, p=0.052). A treatment factor interaction was also tested and was significant for smoking (p=0.035) and the diagnosis of RA (OR in placebo group 0.875; 0.32 to 2.40, p=0.795 and OR in steroid group 3.90; 1.50 to 10.13, p=0.005). Pre-menopausal women were less likely to need SLT (OR 0.38; 0.16 to 0.94, p=0.036). Diet and all other factors examined were neither associated with the need for SLT nor with a diagnosis of RA.

Conclusion: Among patients with very early IP, only a few lifestyle factors were associated with a poor prognosis.

The Increased CC Chemokine Ligand 19 (CCL19) at Baseline Is An Independent Predictor of the 5-Year Radiographic Progression in Early Steroid and DMARD-Naive Rheumatoid Arthritis (RA) Patients. Torkell Ellingsen[1], Ib Hansen[1], Jonas Thorsen[2], Bjarne K. Møller[2], Ulrik Tarp[1], Merete L. Hetland[3], Kim Hørslev-Petersen[4] and Kristian Stengaard-Pedersen[1], [1]Rheumatology Universityhospital, Aarhus, Denmark, [2]Clinical Immunology Universityhospital, Aarhus, Denmark, [3]Rheumatology Universityhospital, Copenhagen, Denmark, [4]Rheumatology King Christian X's Hospital, Graasten, Denmark

Purpose: To measure CCL19 in plasma and the CCR7 density on circulating monocytes and CD4+ T-lymphocytes and to analyse for correlation of this chemokine system to long-term radiographic progression in early DMARD-naïve RA patients.

Method: Forty patients with less than 6 months duration sinde appearance of first swollen joint were randomized to receive intraarticular betamethasone in combination with methotrexate/cyclosporine A (MTX/CYA) or methotrexate/placebo (MTX) for 52 weeks and then followed on conventionally shaped DMARD or biological anti-rheumatic treatment..

In house CCL19 ELISA on plasma (healthy controls n=54) and density of CCR7 on monocytes and CD4+ T-lymphocytes by flow cytometry (healthy controls n=15). ELISA and flow cytometric analysis were carried out at baseline and after 52 weeks in RA patients. Radiographic progression was scored by delta total Sharp/van der Heijde score (TSS) from 0 to 5 years. At baseline the median DAS28 was median 5.1 (range 2.5-7.6), at 5 years DAS28 was 1.6 (0.96-5.2).

Results: In DMARD and steroid naive early RA patients the increased CCL19 concentration before treatment ((p=0.005) median 90 pg/mL range 31-1008pg/ml) decreased after 52 weeks of treatment (59pg/ml (31-1030pg/ml), (p=0.051)) but to the level of healthy controls ((p=0.66) (62pg/ml (31-184pg/ml)).

In a univariate analysis the CCL19 koncentration at baseline correlated to delta TSS 0-5 years (p=0.0074 ; r=0.49) but not after 1 year (p=0.70 ; r=0.06). Multiple regression analysis was performed with delta TSS 0-5 years as dependent variable and CCL19 concentration at baseline, crp-levels, anti-CCP and smoking as explanatory variables. CCL19 concentration was the only independent predictor of delta-TSS progression after 5 years (p=0.039). Crp-levels, anti-CCP and smoking at baseline did not predict radiographic progression.

Prior to treatment CCR7 density was increased on monocytes compared to healthy controls (p=0.008) and decreased to normal level after 52 weeks in both the MTX and the MTX/CYA treated group (p=0.002; p=0.02 respectively). The increased CCR7 density on CD4+ T-lymphocytes at week 0 (p=0.018) was unaffected by MTX treatment (p=0.62). The CCR7 density on monocytes and CD4+ T-lymphocytes did not correlate with radiographic progression, neither at year 1 nor at year 5.

Conclusion: In Early steroid and DMARD-naive RA patients increased CCL19 concentration in plasma at baseline was the only independent predictor of delta-TSS radiographic progression after 5 years. Crp-levels, anti-CCP and smoking did not explain radiographic progression. CCL19 in plasma and its receptor CCR7 on monocytes but not on lymphocytes decreased during DMARD treatment. The CCR7 receptor density did not correlate with radiographic progression.

Synovial Tissue Vascularity Is Related to Outcome in Early Undifferentiated Arthritis Patients. Maria J.H. de Hair[1], Marleen G.H. van de Sande[1], Yvonne Schuller[1], Gijs P.M. van de Sande[1], Carla A. Wijbrandts[1], Danielle M. Gerlag[2] and Paul P. Tak[3], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: A subset of the early arthritis patients presenting in the outpatient clinic cannot be classified and are diagnosed as undifferentiated arthritis (UA) patients. About one third of these patients will have self-limiting disease, whereas others will progress to chronic persistent arthritis. Accurate prediction of outcome in these patients will help decision making to start disease-modifying antirheumatic drug (DMARD) treatment. As synovium is the main affected tissue in arthritis, analysis of synovial tissue (ST) might identify biomarkers that can be used to predict outcome. Aim is to evaluate the value of the expression of ST cellular and vascular markers in predicting outcome in early UA patients.

Method: Of the DMARD naive early arthritis patients (arthritis duration < 1 year) enrolled in our prospective cohort we selected the UA patients (n=43) with ST available for analysis. At baseline ST samples were obtained and clinical analysis was performed. Outcome defined as self-limiting disease (no DMARD or joint swelling in past 3 months) or persistent disease was evaluated after 2 years of follow up. Immunohistochemistry was used to evaluate the synovial cell infiltrate and vascularity. Expression of the various cellular and vascular markers was quantified by digital image analysis. Independent predictors of outcome were identified by logistic regression analysis.

Results: After 2 years of follow up 19 patients had self-limiting disease and 24 had persistent arthritis. ST expression of von Willebrand factor (vWF), a measure of vascularity, was significantly related to outcome (P=0.03) with an explained variance of 18% (R^2 according to Nagelkerke= 0.180). However, substantial overlap in expression of vWF was observed between the 2 outcome groups.

Conclusion: vWF expression is in part related to outcome in recent onset UA patients. However, outcome cannot be completely predicted by this marker alone. Therefore, identification of other markers is needed to develop a multivariate prediction model that can be used for personalised treatment decisions in UA.

Interaction Between the PTPN22 620W Risk Allele and Tobacco and Hormonal Treatments Influence the Anti-CCP or RF Status of Rheumatoid Arthritis: Results From the ESPOIR Cohort. Carine Salliot[1], Karen Dawidowicz[2], Pascale Nicaise-Roland[2], Joelle Benessiano[2], Alain Saraux[3], Maxime Dougados[1], Sylvie Chollet-Martin[2], Olivier Meyer[2] and P. Dieudé[2], [1]Paris Descartes University, Medicine Faculty - Cochin Hospital, APHP, Paris, France, [2]Bichat Claude-bernard, Universitary Hospital, APHP, Paris, France, [3]CHU de Brest, Brest, France

Background: Gene-environment interactions play a major role in the pathogenesis of rheumatoid arthritis (RA), such as *HLA-DRB1* shared epitope alleles and smoking.

Purpose: To perform a genotype-phenotype correlation in RA including gene-environment interactions between the *PTPN22* 620W risk allele and tobacco/hormonal treatments in a cohort of early arthritis.

Methods: The ESPOIR cohort included patients with at least 2 synovitis for at least 6 weeks but less than 6 months. 578 patients had RA (defined as the fulfillment of ACR criteria either at baseline, 6 or 12 month follow-up visit) and were genotyped for the *PTPN22* rs2476601 (R620W) SNP. Data regarding anti-CCP and RF status at baseline, HLADR1 and/or DR4 status, demography (age, gender, ethnicity), co-morbidities (BMI, cardiovascular diseases), exposure to tobacco and hormonal treatments (hormonal replacement treatment and/or contraceptives) were collected. Logistic regression was performed to estimate the ORs adjusted for confounding factors including gender, age, ethnicity, BMI, HLADR1 and DR4 status.

Results: At baseline, mean age was 49±12 years, 76.4% were women, 92% were Caucasian, 54% had IgM RF and 47% had anti-CCP antibodies. 56% carried HLADR1 and/or DR4 antigen and 20% carried the *PTPN22* 620W allele. 47% had ever smoked and 69.5% of women had ever received hormonal treatment.

PTPN22 620W risk allele was associated with anti-CCP positive status (11.4% vs 8.4%, OR=2.47, 1.5-4.0 95% CI, p<0.0001) and also correlated with the anti-CCP titter (Mann-Whitney test: mean 335.5 U/ml in 620W+ *vs* 278 U/ml 620W-, p<0.0001).

Gene-environment interaction study found that smoking would increase the risk for anti-CCP and RF positive RA, restricted to individuals who carried the *PTPN22* 620W risk allele. Conversely, hormonal treatment would reduce this risk for anti-CCP seropositive RA in women who carried the 620W risk allele (Tables 1 & 2).

Conclusion: *PTPN22* 620W risk allele interact with tobacco and hormonal treatment for both RF and anti-CCP status in RA population.

A Predictive Algorithm Combining Routine Assessment and Power Doppler Ultrasonography for the Development of Rheumatoid Arthritis From An Early-Onset Undifferentiated Arthritis. Fausto Salaffi[1], Alessandro Ciapetti[1], Stefania Gasparini[1], Emilio Filippucci[1], Marina Carotti[2] and Walter Grassi[1], [1]Department of Molecular Pathology and Innovative Therapies, Università Politecnica delle Marche, Jesi, Ancona, Italy, [2]Department of Radiology, Università Politecnica delle Marche, Ancona, Italy

Purpose: The ability to predict the development of rheumatoid arthritis (RA) in patients with an early-onset undifferentiated arthritis (UA) is highly required if the remission or an adequate response to the treatment are the main goal. The statement of purpose was to develop a predictive algorithm combining clinical variables, serological biomarkers and power Doppler ultrasonography (PDUS) for the progression from an early-onset UA to RA in daily rheumatological practice.

Method: A predictive algorithm was developed after a 12 months study of 149 adult patients with a recent-onset UA and a clinical involvement of the hands. The combination of five routine assessment variables (sex, symptoms duration, morning stiffness, anti-citrulline antibodies and IgM-rheumatoid factor) and PDUS findings was investigated. Logistic regression analysis was performed to identify the independent factors for the development of RA and global predictive score was calculated. The area under the ROC curve (AUC) was used to evaluate the diagnostic performance of the algorithm and a cut off point, maximizing both sensitivity (SE) and specificity (SP), was selected. The post-test probability (post-TP) was evaluated using the Fagan's nomogram.

Results: During the follow up period, 62 patients (41.6%) developed a RA. The score of the global predictive algorithm ranged from 0 to 10, being a higher score indicative of a higher risk to develop RA. The algorithm demonstrated excellent discriminative ability, with an AUC of 0.951 [SE 0.019; 95% interval of confidence (CI) from 0.903 to 0.980]. With the optimal cut-off point of 5 SE was 93.6% (95% CI from 80.1% to 96.3%), SP was 89.9% (95% CI from 81.3% to 95.1%) and positive likelihood ratio (LR+) was 9.39. If a threshold of 7 was applied a higher value of SP (98.1%) was obtained, but SE (58.1%) decreased (LR+ of 31.02). The post-TP value of the two different cut-off points mentioned above were 66% and 87%, respectively.

Conclusion: Our predictive algorithm, which include PDUS assessment, revealed an excellent discriminative ability for assessing the likelihood of development of RA. Further studies are required to confirm the results and to tailor a therapeutic approach in patients with an early-onset UA, according to the values of the predictive algorithm proposed in the present study.

Low Educational Level, Family History of RA and Early Disability Are Associated with Moderate to Severe Disability at 1 Year of Follow-up in Patients with Early RA: Results From the ESPOIR Cohort. Carine Salliot[1], Claire Bombardier[2], Valérie Devauchelle[3], Cedric Lukas[4], Alain Saraux[5], Bernard Combe[6] and Maxime Dougados[7], [1]Cochin Universitary Hospital, Descartes University, APHP, Paris, France, [2]University Health Network, Toronto, ON, [3]CHU Brest, Brest, France, [4]Lapeyronie hospital, Montpellier, France, [5]CHU de Brest, Brest, France, [6]Immuno-Rheumatologie, Hospital Lapeyronie, Montpellier, France, [7]University of Paris V, Cochin Hospital, Paris, France

Purpose: To assess baseline characteristics as associated factors with disability after 1 year of follow-up in a cohort of early arthritis.

Method: The ESPOIR cohort is a multicenter French cohort of patients suffering of at least 2 synovitis for at least 6 weeks but less than 6 months. 579 patients had a diagnosis of RA at 1 year of follow-up (defined as the fulfillment of ACR criteria either at baseline or at 6 or 12month follow-up visit). Data regarding the disease characteristics (clinical, biological, radiological and immunological features), demography (age, gender), socio economy (educational level, family monthly income), family history of RA, comorbidities (smoking status, BMI, cardiovascular disease) were collected at baseline and assessed as associated factors with moderate to severe disability at 1 year (HAQ score $\geq$ 1/3), using univariate and multivariate analyses.

Results: At Baseline, mean age was 49±12 years, 76.4% were women, 48% had IgM Rheumatoid factors (RF) and 54% had anti-CCP antibodies. The mean DAS28 score was 5,3 ±1,2, HAQ score was 1,0 ± 0,7 and the mean modified Sharp score was 6.2 ±8.1. 90% of the patients received at least 1 DMARD during the first year of follow-up. At 1 year, 143 patients had a HAQ score of at least 1 and 436 experienced a low disability.

Logistic regressions were performed with adjustments for several confounding factors (such as gender, age, DAS28 score at baseline, presence of erosion at baseline and treatments received).

Low educational level (compulsory school only), family history of RA and the level of disability at baseline were significantly associated with moderate to severe disability at 1 year (Table). The patients who stopped their trainee after the compulsory school lived more frequently in a rural area ($p<0.000$), had a low monthly income ($p<0.000$), a higher consumption of tobacco ($p=0.05$) and a longer disease duration before the inclusion in the cohort ($p=0.004$)

The presence of RF, anti-CCP, smoking and structural damage at baseline were not associated with disability at 1 year.

Conclusion: In the ESPOIR cohort, early disability was associated with low educational level (compulsory school only), family history of RA and the level of disability at baseline.

At Baseline	**Adjusted ORs for HAQ score ≥1 at 1 year (95% Confidence Interval), *p* values**
Compulsory school only	1.8 (1.1-3.0), p=0.02
Family history of RA	2.6 (1.4-5.0), p=0.003
HAQ score at baseline	
0 to 0.5	1.0 (Reference)
0.5 to 1	3.4 (1.3-9.1), p=0.01
1 to 2	11.8 (4.6-30.4), p<0.0001
≥ 2	21.4 (7.1-64.5), p<0.0001

The Relationship Between Synovial Lymphocyte Aggregates and Diagnosis and Outcome After Follow up in Early Arthritis Patients.

Marleen G.H. van de Sande[1], Rogier M. Thurlings[2], Maartje J. H. Boumans[1] and Paul P. Tak[3], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Background: Synovial lymphocyte infiltration is one of the characteristics of inflammatory joint diseases. Different synovial lymphocyte infiltration patterns, ranging from diffuse infiltration to follicular aggregates that resemble lymphoid germinal centers, can be observed. Germinal center formation has been proposed to play a role in promoting self perpetuating inflammation both by stimulating the humoral immune response to autoantigens and by contributing to T-cell responses and cytokine production. Synovial lymphocyte infiltration patterns have previously been suggested to be a stable feature in time and patient specific. Therefore, lymphocyte infiltration patterns might be of use for patient subclassification and prediction of outcome.

Purpose: To investigate the lymphocyte infiltration pattern in early undifferentiated arthritis patients and its relationship to outcome.

Methods: We analyzed the presence of lymphoid aggregates in synovial tissue (ST) samples from 37 DMARD naive early undifferentiated arthritis (UA) patients (disease duration < 1 year). Patients were selected from our early arthritis cohort based on the diagnosis UA and the availability of ST at baseline. Patients were followed for 2 years to allow confirmation of the diagnosis according to established classification criteria. Furthermore, patients were classified at 2 years as self-limiting, persistent or persistent erosive disease. The presence of lymphocyte aggregates was assessed on anti-CD3-stained sections. Aggregates were counted and graded by size (1-3) (Arthritis Rheum. 2008;58:1582-9). The presence and size of lymphoid aggregates at baseline was compared between the different outcome groups using the Chi^2 test.

Results: After 2 years of follow up 9 patients (24%) fulfilled ACR criteria for rheumatoid arthritis (RA). Furthermore, 16 (43%) patients had self-limiting disease, 14 (38%) persistent disease and 7 (19%) patients had persistent erosive disease. Interestingly, the presence or size of aggregates at baseline was not predictive of the diagnosis RA; there was no difference between patients with RA (34% any aggregate, 22% ≥grade 2) or non-RA (54% any aggregate, 36% ≥grade 2) after 2 years of follow up. Moreover, no difference in presence of aggregates at

baseline was observed between patients with self-limiting (62% any, 31% ≥ grade 2) versus persistent (36% any, 29% ≥grade 2) or erosive disease (43% any, 43% ≥grade 2).

Conclusion: The presence of lymphocyte aggregates at baseline is not specific for RA and not related to outcome in early arthritis patients.

Early Combination Therapy in RA Patients Improves Work Capacity: Results From the SWEFOT Clinical Trial. Sofia Ernestam[1], Johan Bratt[1], Ingemar Petersson[2], Ronald F. Van Vollenhoven[3] and P. Geborek[4], [1]Karolinska University Hospital, Stockholm, Sweden, [2]Lund University, Department of Clinical Sciences, Lund, Lund, Sweden, [3]The Karolinska Institute, Stockholm, Sweden, [4]Lund University, Department of Clinical Sciences, Lund, Sweden

Purpose: In Sweden historically approximately 30% of RA patients are on sick leave/disability pension at their 1st visit to a rheumatologic specialist with no return to working capacity. Similar results have recently been reported from the multinational QUEST study. The SWEFOT study, recruiting patients in an observational open "real life" setting with a randomized procedure from 2003 to 2005, studied early pharmacologic intervention in RA patients with insufficient response to 3-4 months methotrexate (MTX). This part of the investigation included health economic measures such as sick leave to see if early and more aggressive pharmacological intervention could improve work capacity in RA patients.

Method: 258 early RA patients who had not achieved DAS28≤3.2 after 3-4 months treatment with MTX were included in an open, randomized, controlled trial. In arm A (n=130) sulfasalazine and hydroxychloroquine was added and in arm B (n=128), infliximab was added. The Eular good response at 12 months based on intention-to-treat for all randomized patients has been presented previously and showed arm B to be superior to arm A (39% vs. 25%, $p<0.02$). Full time and part time sick leave was computed into total sick leave per 3 month period for patients with working capacity. Last observation carried forward technique was used for dropouts and missing values.

Results: In both groups a similar and steady decrease in sick leave was observed over a two-year period with start after the randomization at 3 months (Figure 1). Mean (SD) total sick leave in days/ 3 months decreased from 32,7 (39,8) and 38,6 (39,3) at baseline to 16,6 (30,1) and 18,3 (31,3) at 2 years for group A and B, respectively. Only one patient progressed to disability pension during the two-year study. In group A 5 patients were on disability pension for other reasons than RA prior to study start and 22 had age pension. The corresponding figures for group B were 7 and 16.

Conclusion: In early RA patients with only partial response to MTX, addition of aggressive pharmacological treatment improve work capacity. No obvious differences in sick leave were found between the treatment strategies.

The Clinical Course, Outcomes, and Treatment of Early Inflammatory Arthritis: Results From CATCH (Canadian Early Arthritis Cohort). W. Katchamart[1], Gilles Boire[2], Janet Pope[3], C. Haraoui[4], Carol A. Hitchon[5], Shahin Jamal[6], Jc Thorne[7], Vivian P. Bykerk[8] and Near, [1]Mount Sinai Hospital, Toronto, ON, [2]Centre hospitalier universitaire de Sherbrooke, Sherbrooke, [3]St Joseph Health Care, London, ON, [4]Institut de Rhumatolgie de Montreal, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]St. Michael's Hospital, Toronto, [7]Newmarket, [8]Mt Sinai Hospital, Toronto, ON

Purpose: To investigate the clinical course, outcomes, and treatments of early inflammatory arthritis (EIA) over time comparing between patients in different disease activity states at presentation

Methods: Patients were recruited to CATCH, a Canadian, multicenter, prospective, observational study of EIA, according to these criteria: >16 years old, symptoms for 6-52 weeks, and ≥2 swollen joints or 1 swollen MCP/PIP joint and ≥1 of: + rheumatoid factor, anti-CCP, morning stiffness > 45 min, a response to NSAIDs, or painful MTP joint squeeze test. Treatment consisted of initial DMARDs based on patient and rheumatologist' discretion to reach a goal of remission. Patients were assessed at baseline, every 3 months for 1st year and every 6 months thereafter. Patients were eligible in this analysis if they had completed DAS28 data at baseline and one year of follow-up.

Results: A total of 234 patients had completed one year of follow-up. At baseline, the proportion of patients who had high (HAD), moderate (MDA), low disease activity (LDA) and were in remission was 52%(121), 35%(83), 6%(15), and 6%(15), respectively. Patients with HAD, MDA, and LDA significantly improved over the time of follow up ($p<0.0001$), while patients presenting with remission had an increased mean disease activity over 1-year of follow-up (mean change of DAS28 ± SD at 3 month 0.5 ± 0.55, 6 month 0.35 ± 1.03, 9 month 0.23 ± 0.73, and 1 year 0.12 ± 0.94 with $p <0.0001$). Patients with baseline LDA (20%) and remission (33%) had a significant higher proportion of clinical progression compared to patients presenting with HAD (2%) or MDA (12%). Patients presenting with remission significantly received less aggressive treatments with MTX, parenteral MTX, and DMARD combinations. They also received a delayed MTX treatment compared to HDA group (53% vs.16%, p 0.006).

Conclusion: In this early arthritis cohort, a significant number of patients presented with very low disease activity. One-third had progressive disease within 1 year despite DMARD treatment. Patients with mild inflammatory arthritis who have a poor prognosis need to be identified early so that more aggressive treatment can be started at the outset.

Tendinitic Involvement Can Precede the Development of Synovial Inflammation in Anti-CCP Positive Patients: Results of US Examination at An Early Arthritis Clinic. Pierluigi Macchioni[1], Mariagrazia Catanoso[1], Luigi Boiardi[1], Irene Modesto[1], Luca Magnani[1], Giuseppe Germanò[1], Sabrina Frigelli[1], Alessandra Ghinoi[1], Giovanna Restuccia[2] and Carlo Salvarani[3], [1]Arcispedale S.Maria Nuova, Reggio Emilia, Italy, [2]Arcispedale S.Maria Nuova, Italy, [3]Arcispedale S Maria Nuova, Reggio Emilia, Italy

Purpose: We describe a form of rheumatic disease characterized by early tendinitic involvement with the presence of anti-CCP antibody and good outcome.

Method: We have evaluated the record of 355 patients seen in 36 months at our early arthritis clinic. All the afferring out-patients were evaluated for clinical and laboratory parameters according to a standardized form which include all the core sets variables of ACR response criteria, the calculation of DAS28 and the determination of serum anti-CCP and RF. All the patients had wrists, hands and feet US examination performed at the same time visit and X-ray hands and feet examination.. **Results:** Eighteen patients (F15 pts/M3 pts, mean age 51+14y, mean disease duration 16+6wks) who presented at rheumatological examination sign and symptoms of peripheral joint involvement (morning stiffness, pain and swollen joints) did not have at US evaluation articular synovitis but only tenosynovitis and/or tendonitis. The distribution of US tendon involvement was : 5 patients wrist flexor (right/left/bilateral 5/4/4), 8 pts wrist extensor (r/l/b 5/7/4), 14 pts digital flexor (r/l/b 12/14/12), 9 pts digital extensor (r/l/b 8/9/8). The most frequent US localization of tendon inflammation was at metacarpal-phalangeal level (15 pts). Fourteen patients had high level of anti-CCP antibody (mean values 306+389 U/ml) and 12 were RF positive. Mean baseline values were : ESR 29.7±18.9 mm/1st h, CRP 0.69±1.1 mg/dl, HAQ 0.76±0.58, DAS28 4.27±0.82, (1 pt low DAS, 3 pts high DAS, 14 patients medium DAS). None of the patients presented joint erosions at X-ray baseline examination.

Because of isolated tendon inflammation none of the patients received any DMARDs and were treated only with AINS and/or low steroid daily dose. After a mean follow-up of 15±7 months 7 patients are in remission without treatment, 8 patients developed synovial joint inflammation (4-8 months later) and were treated with standard MTX weekly dose with good outcome (4 pts remission, one pt LDA, 3 medium disease activity). Only two patients developed radiological erosions. At the last US examination (after 15±7 m) tendonitis/tenosynovitis was still present in 8 pts, 5 pts presented synovial inflammation and 5 had complete US resolution.

Conclusion: US examination is useful for the recognition of an isolated tendinitic involvement in anti-CCP positive patients. The form seems to have a good clinical outcome.

Association of Rheumatoid Arthritis (RA)-Related Autoimmunity and Joint Findings in Unaffected at-Risk Populations. J. R. Kolfenbach[1], K. D. Deane[1], L. A. Derber[1], C. O'Donnell[1], M.H. Weisman[2], J.H. Buckner[3], T. R. Mikuls[4], James R. O'Dell[4], P.K. Gregersen[5], R. M. Keating[6], J.M. Norris[7] and V. M. Holers[1], [1]U Colo Denver, Aurora, CO, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Benaroya Rsch Ini., Seattle, WA, [4]U Nebraska, Omaha, NE, [5]Feinstein Insititute Med Rsch, Manhasset, NY, [6]U Chicago, Oak Park, IL, [7]U Colo Denver

Purpose: The presence of RA-related autoantibodies prior to diagnosis suggests that there is a pre-clinical period in RA. Prospective analysis of *pre-diagnosis RA* may allow for a more complete understanding of early disease pathogenesis. We have established prospective cohorts with subjects at potentially higher risk for RA based on genetic risk factors, with intent to examine RA-related autoimmunity in these populations. The purpose of our current analysis was to identify RA-related autoantibodies within these populations and to examine potential associations with clinical endpoints such as joint disease and systemic inflammation.

Methods: We have created a prospective cohort of first-degree relatives (FDRs) of probands with RA as part of the SERA study (Studies of the Etiology of RA). FDRs *without RA* by ACR criteria are evaluated during a clinical research visit where joint examination and laboratory data are independently obtained. Identical analysis is performed on a second at-risk DR4-enriched population containing parents of children with high risk HLA alleles and/or Type I diabetes (DAISY parents, Diabetes and AutoImmunity Study of the Young). Prevalence of high-risk genetic markers was compared between these cohorts and the general population using control data from the North American Rheumatoid Arthritis Consortium (NARAC). Association analysis was performed by chi-square and Fisher's exact testing.

Results: Data from 1058 FDRs and 627 DAISY parents was analyzed. Prevalence of the shared epitope (SE) (≥1 allele) was higher in the FDR and DAISY cohorts than the general population (55%, 51.6%, and 43% respectively; $p < 0.01$). Prevalence of the PTPN22 polymorphism (≥1 allele) was higher in FDRs than the general population (20% vs. 15.9%; $p < 0.05$). One or more autoantibodies were detected in 15.9% of FDRs and 14.2% of DAISY parents. RF-IgM positivity in FDRs was associated with ≥ 1 tender joint on exam (OR 2.50, 95% CI 1.27-4.89) and elevated CRP (OR 5.31, 95% CI 1.45-19.52). In DAISY parents, RF-IgM was associated with ≥ 1 swollen joint (OR 4.22, 95% CI 1.80-9.93).

Conclusion: Autoantibodies in these at-risk populations are associated with joint swelling and tenderness as well as elevated CRP. Follow-up of subjects with very early signs of clinical disease will be valuable to further understanding the factors associated with transition to a phenotype that meets full ACR or other classification criteria. In addition, these findings support the utility of further prospective analysis of at-risk populations in the study of RA development prior to clinical diagnosis.

Clinical Factors That Predict Erosion-Free Status in Rheumatoid Arthritis. Katherine P. Liao[1], Michael E. Weinblatt[1], Jing Cui[1], Hiroshi Yoshioka[2], Christine Iannaccone[1], Lori Chibnik[1], Bing Lu[3], Jonathan S. Coblyn[1], Nancy A. Shadick[1] and Daniel H. Solomon[3], [1]Brigham & Women's Hosp, Boston, MA, [2]Brigham & Women's Hosp, Boston, [3]Brigham & Women's Hospital, Boston, MA

Purpose: Subsets of rheumatoid arthritis (RA) patients remain erosion-free despite years of disease. Our objective was to characterize this group of RA patients and identify the significant predictors for remaining erosion-free.

Methods: Our study was conducted using data from a prospective observational cohort of RA patients recruited from an outpatient practice of an academic medical center. We included patients with bilateral hand radiographs obtained at recruitment and at 2 yr follow-up whose radiographs had been formally assessed with Sharp scores. The primary outcome was erosion-free status at recruitment and at 2 yr follow-up. We assessed the following characteristics at recruitment: age at RA onset, gender, RA disease duration, DAS28, CRP, tender/swollen joint counts, MDHAQ, smoking status, methotrexate use, anti-TNF use, and the presence of the HLA-shared epitope (SE). Our primary analysis was conducted on subjects with RA duration <10 years to mitigate confounding by secular trends in care. We conducted a

univariate analysis to identify potential predictors. Variables with p<0.20 were selected for the multivariable logistic regression model; significant predictors for erosion-free disease were selected using forward/backward selection. A secondary analysis was conducted on a dataset from the same cohort matched by RA duration.

Results: 222 subjects in our cohort had RA duration < 10 years: 38% were erosion-free at recruitment and 2 year follow-up; 46% of these patients were anti-CCP+ of which 61% were HLA-SE+. 70% of erosion-free patients had an RA duration ≥ 2 years with a mean of 3.7 yrs (SD 3.1) at the time of recruitment. The mean RA duration for patients with erosions either at recruitment or follow-up was 4.7 yrs (SD 3.1). There was no significant difference in baseline methotrexate or anti-TNF use between the two groups in the unadjusted analysis. In our multivariable-adjusted analysis significant predictors of remaining erosion-free were younger age at onset, male gender and shorter RA duration (Table 1). Anti-CCP status was not a significant predictor for erosion-free status. Secondary analyses on a dataset matched by RA duration supported these findings.

Conclusion: In our cohort, the absence of anti-CCP was not a significant factor in predicting erosion-free disease; 46% of individuals who were erosion-free at recruitment and at two year follow-up were anti-CCP+, of which 61% were HLA-SE+. Clinical factors independently predicting remaining erosion free were younger age, male gender and shorter RA duration.

Table 1. Predictors of erosion-free disease in patients with disease duration < 10 years.

Description	Multivariable adjusted (OR)*	p-value	Significant predictors (OR)	p-value
Age at onset (per 5 yrs)	0.81	0.002	0.82	0.0005
Male gender	3.1	0.007	2.9	0.004
Disease duration (per yr)	0.93	0.16	0.89	0.019
Anti-CCP negative	1.5	0.26	-	
SE (1 vs 0 copy)	0.78	0.45	-	
SE (2 vs 0 copies)	0.44	0.08	-	

* Variables with p<0.20 from unadjusted analysis were tested in the adjusted models

The Association Between Focal Bone Loss (erosions) and Generalized Bone Loss (osteoporosis) in Rheumatoid Arthritis. Allen P. Anandarajah[1], Muhammad El-Taha[2], Cheng Peng[2], Jeffrey D. Greenberg[3] and Christopher Ritchlin[4], [1]Univ of Rochester Med Ctr, Rochester, NY, [2]University of Southern Maine, [3]New York University School of Medicine, Millburn, NJ, [4]University of Rochester Medical Center, Rochester, NY

Background: Local and systemic bone loss, that manifest as erosions and osteoporosis respectively, are hallmark findings in rheumatoid arthritis (RA). Relatively little is known, however, about the relationship between these two forms of bone loss.

Purpose: To determine if there is an association between focal bone loss (erosions) and generalized bone loss (osteoporosis) in patients with rheumatoid arthritis.

Method: Patients with RA were selected from the Consortium of Rheumatology Researchers of North America (CORRONA) database. CORRONA is the largest independent database in North America and collects clinical data, from physicians and patients. Multiple logistic regression models were constructed to assess the association between the two key variables, presence or absence of erosions and T-scores in

patients with RA. Adjustment was made for use of steroids, gender, methotrexate, status of using other disease modifying agents, biologics (categorical variables) and weight, age, body mass index (BMI) and disease index (continuous variables).

Results: A total of 16,978 patients with RA were identified in the database. Information on erosions was available in 3898 subjects of which 2085 reported no erosions and 1813 reported the presence of erosions. Values were missing in 13,080. Patients with erosions were significantly younger (mean age 46.9) and had a lower body mass index (BMI) than subjects without erosions (mean age 49.6) ($p<0.0001$ for both). Those with erosions were significantly more likely to have a positive anti-CCP antibody ($p=0.0001$) and have higher disease activity scores (DAS-28) (0.0008) than those without erosions. Additionally the multivariate model revealed that T-scores for the lumbar spine and hips were also significantly lower in RA patients with erosions compared to patients without erosions ($p=0.0002$ and <0.0001 respectively). A significantly larger proportion of patients with erosions were on anti-TNF therapy and osteoporosis medications compared with those without erosions ($p<0.0001$ and 0.0003).

Conclusion: RA patients with erosions were younger, more likely to have an anti-CCP antibody and have more active disease as measured by the DAS-28, compared to subjects without erosions. Interestingly patients with erosions also had a lower BMI compared with RA patients without erosions. The presence of bone erosions in patients with RA was significantly associated with lower T-scores at the lumbar spine and hips. These data suggest a relationship between localized and generalized bone loss in patients with RA.

ACR Poster Session A

Rheumatoid Arthritis Treatment: Steroids, Methotrexate, and Novel Targets

Sunday, October 18, 2009, 9:00 AM - 6:00 PM

397

A Phase 2 Study to Assess the Efficacy and Safety of Maraviroc, a CCR-5 Antagonist in the Treatment of Rheumatoid Arthritis. D. Fleishaker[1], X. Wang[2], S. Menon[2], Bernhardt G. Zeiher[3] and T.C. Stock[2], [1]Pfizer, Inc., Chesterfield, MO, [2]Pfizer, Inc., New London, CT, [3]Pfizer Global Research and Development, New London, CT

Purpose: Maraviroc (MVC) is an antagonist of the human chemokine receptor 5 (CCR5) and has been approved for use in treatment of patients infected with the CCR5-tropic human immunodeficiency virus, Type-1 (HIV). Presence of a nonfunctional receptor of the CCR-5 gene resulting from a 32-base pair deletion has been associated with a reduced incidence and severity of rheumatoid arthritis (RA). Levels of the CCR-5 receptors ligands, RANTES, MIP-1α, MIP-1β are also increased in synovial fluid of RA subjects. Maraviroc 300 mg BID was investigated in this study to determine whether CCR-5 antagonism would prove safe and effective in the treatment of RA patients on background methotrexate (MTX).

Method: This study was divided into two components: Safety/PK (data not shown) and Proof-of-Concept (POC). The Safety/PK component enrolled 16 subjects and demonstrated that MVC 300 mg BID was well tolerated and there was no drug-drug interaction with MTX. The POC component was a randomized, multi-center, double-blind, placebo-controlled, parallel group study. Subjects with active RA, receiving stable weekly MTX (≥ 10 mg and ≤25 mg) for at least 12 weeks were eligible for enrollment if they had at least 6 tender and swollen joints and CRP ≥7.0 mg/L. Subjects were randomized 2:1 to MVC or placebo treatment for 12 weeks and the primary endpoint was ACR20 response. Subjects on background biologic therapy, other oral DMARDs (except antimalarials) and those homozygous for the CCR5Δ32 mutation were excluded from entry.

Results: The study was terminated at the time of a planned interim analysis for futility. 110 subjects were enrolled: 77 (MVC 300 mg BID) and 33 (placebo BID) with similar demographic features across both treatment groups. There was no significant difference between MVC and placebo in ACR20 responder rate utilizing the full analysis set (MVC: 27.27% vs. placebo: 18.18%; p value=0.155); ACR50 and ACR70 were not different. Components of the ACR response, including CRP were not changed. MVC was safe and well tolerated with the majority of AEs mild to moderate in nature. The most common all causality AEs in the MVC-treated group were constipation (7.8%), nausea (5.2%), fatigue (5.2%), urinary tract infection (3.9%) and respiratory tract infection (2.9%) compared to placebo. There were no clinically

significant findings in vital signs, ECG measurements or clinical laboratories including transaminases. There were no SAEs reported in the treated population.

Conclusion: Selective antagonism of CCR-5 using MVC failed to improve the signs and symptoms of RA in subjects with active disease on background MTX. Treatment with MVC was safe and well tolerated in RA subjects over 12 weeks. No impact in transaminases was noted in subjects receiving MVC vs. placebo despite background MTX use in this population.

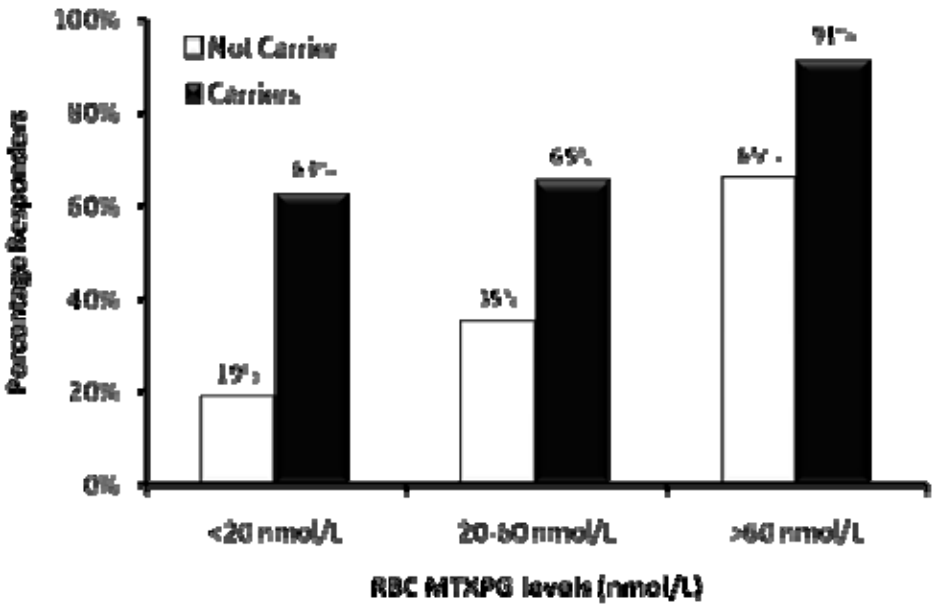
High-Order Epistatic Interactions Between Folate and Adenosine Biological Systems Affect Methotrexate Efficacy in Rheumatoid Arthritis. Thierry Dervieux[1], Judith Wessels[2], Tahar van der Straaten[2], Jason Moore[3], Nadia Penrod[3], Henk-Jan Guchelaar[2] and Joel M. Kremer[4], [1]Cypress Bioscience, San Diego, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Dartmouth-Hitchcock Medical Center, Lebanon, [4]Albany Medical College, Albany, NY

Purpose: No single definitive predisposing genetic marker has emerged as pivotal to the efficacy of Methotrexate (MTX) in rheumatoid arthritis (RA). In this study, we sought to establish that discrete non-linear gene-gene interactions (epistasis) involving multiple low-penetrance single nucleotide polymorphisms in folate, purine and pyrimidine pathways may materialize as combinations modulating MTX effects.

Method: A total of 255 patients treated with low dose MTX were enrolled in a multicentred study at 3 sites. Efficacy to MTX was assessed using the EULAR response criteria or a physician's assessment of patient's response visual analogue scale. A total of 14 single nucleotide polymorphisms were measured together with erythrocyte MTX polyglutamate concentrations (MTXPGs). Detection of non-linear gene-gene interactions was performed using Multifactor Dimensionality Reduction (MDR), a method delineating and deciphering complex interactions among gene networks. MDR reduces the n-dimensions corresponding to the n-genotypes into one dimension by combining high and low predisposing genotypes of efficacy into two separate groups depending on whether they are more common in patients presenting with response or not. The robustness and significance of the model was tested through cross validation consistency (CVC, 10-fold) and 1000-fold permutation testing.

Results: MDR analysis revealed that efficacy (53% responders) was associated with high order epistatic interactions among variants in Inosine Triphosphate Pyrophosphatase (C94A), Amino-Imidazole Carboxamide Ribonucleotide Transformylase (C347G) and Reduced Folate Carrier (G80A) genes. Testing accuracy was 0.638 and CVC was 10/10 (permutation testing $p<0.001$). Significance was achieved independently at all sites ($p<0.05$). Carriers of a predisposing genotype combination were 3.8-fold more likely to respond to MTX than those without (CI95%: 2.2-6.8; $p<0.001$). Sensitivity was 64.7%, specificity was 67.2 % and accuracy was 65.9%. Greater response rates were achieved at low levels of MTXPGs (<20nmol/L) in the presence of predisposing genotype combinations versus in their absence (63% vs. 19% responders) ($p<0.001$). However, the increase of MTXPGs from low to high levels produced greater rates of improvements in the absence of predisposing genotype combinations, (OR: 8.1, CI95%: 2.4-31.8; $p<0.001$) than in their presence (OR= 3.6; CI95%: 1.1-12.5; $p<0.001$). At high MTXPG levels achieved (i.e. >60nmol/L) a convergence in response rates was observed (65% vs. 91% responders), thereby indicating that the disadvantage in the absence of predisposing genotype combinations was reduced as function of increasing MTXPG levels.



Conclusion: These hypothesis generating data indicate that epistatic interactions in folate and purine pathways selectively modulate the effects of MTX in RA.

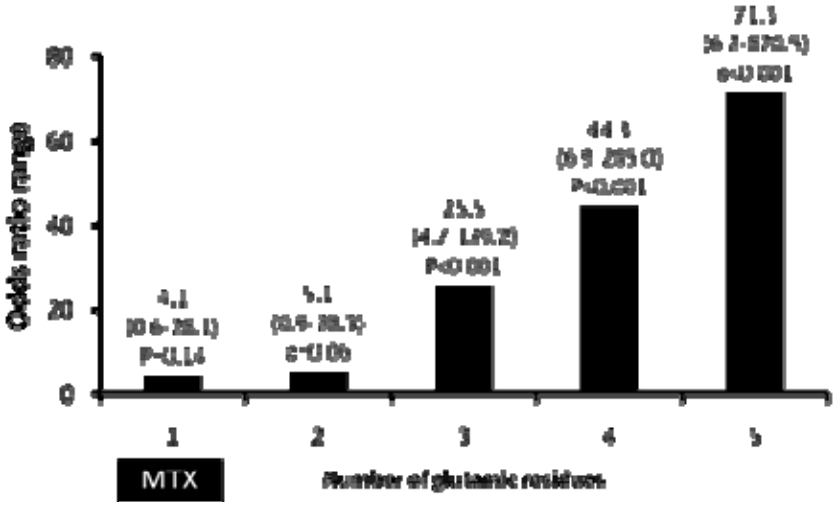
The Sequential Addition of Glutamic Residues On Methotrexate Selectively Potentiates the Efficacy of This Prodrug in Rheumatoid Arthritis. Thierry Dervieux[1], Rong Zablocki[1] and Joel M. Kremer[2], [1]Cypress Bioscience, San Diego, CA, [2]Albany Medical College, Albany, NY

Purpose: Methotrexate (MTX) is an antifolate prodrug activated to MTX polyglutamates (MTXPGs) through a Folylpolyglutamate Synthase mediated sequential addition of glutamic residues added to MTX. In vitro, this process selectively enhances the inhibition of Aminoimidazole Carboxamide Ribonucleotide (AICAR) Transformylase (PNAS 15:4881-5 1985), a *de novo* purine biosynthesis enzyme whose inhibition results in the release of adenosine, a potent anti-inflammatory agent. A relationship between an increasing number of glutamic residues on MTX and its anti-inflammatory/therapeutic effects in rheumatoid arthritis (RA) has yet to be established.

Method: A total of 256 patients treated with low dose MTX for at least three months were enrolled in a multicentred study at 3 sites. MTX efficacy was assessed using the EULAR response criteria or a physician's assessment of patient's response to MTX visual analogue scale as previously described (Arthritis Rheum. 2004 50:2766-74). Red cells MTXPGs concentrations were measured using liquid chromatography with post column photo-oxidation technique (limit of detection 2 nmol/L). Statistical analysis consisted of logistic regression with dose and MTXPGs as independent variables.

Results: There was a large interpatient variability in MTX dosing (median 15 mg/week, range 5-25mg) and MTXPG accumulation. A total of 53% patients were responders. MTXPG levels (median, [range]) were $MTXPG_1$: 23 nmol/L (<2-157), $MTXPG_2$: 19 nmol/L (<2-72), $MTXPG_3$: 37 nmol/L (<2-132), $MTXPG_4$: 8 nmol/L (<2-83) and $MTXPG_5$: <2 nmol/L (<2-51). Poor efficacy was associated with higher dosage administered ($p<0.01$). Long chains $MTXPG_3$ represented 38% of total MTXPGs while very long chains $MTXPG_5$ accounted for only 2.4% of total MTXPGs. Short chains MTXPG ($MTXPG_{1-2}$) were not significantly associated with efficacy ($p>0.06$; Figure). In contrast, the increase in $MTXPG_3$ levels from undetectable levels to 132 nmol/L was associated with a 25.5-fold (CI95%: 4.7-139.2) higher likelihood of response to MTX ($p<0.001$). Further addition of glutamic residues appeared to enhance the efficacy of MTX as an increase in $MTXPG_5$ levels from undetectable levels to 51 nmol/L resulted in a 71.3 fold higher likelihood of response (CI95%: 6.2-820.5; $p<0.001$; Figure).



Conclusion: We have demonstrated for the first time that the sequential addition of glutamic residues on MTX selectively potentiates the efficacy of this prodrug in patients with RA. These in vivo data are consistent with in vitro findings establishing that the increasing number of glutamic residues on MTX produces several fold greater inhibition of AICAR Transformylase, and lends further indirect evidence that AICAR accumulation mediates MTX's anti-inflammatory effects through the release of adenosine.

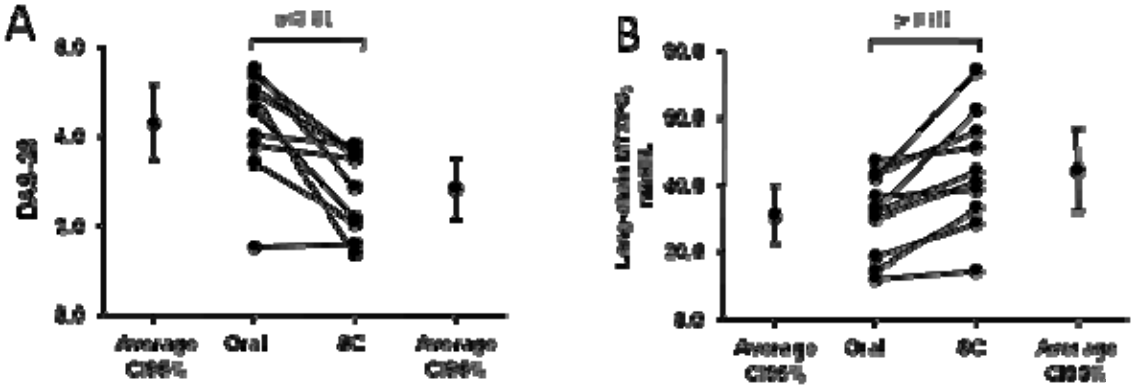
Switching From Oral to Parenteral Methotrexate Administration Produces Clinical Improvements through Selective Accumulation of Long-Chains Methotrexate Polyglutamates. Joel M. Kremer[1], Rong Zablocki[2] and Thierry Dervieux[2], [1]Albany Medical College, Albany, NY, [2]Cypress Bioscience, San Diego, CA

Purpose: Methotrexate (MTX) is effective in rheumatoid arthritis (RA), yet large interpatient variability in MTX absorption and activation to MTX polyglutamates (MTXPGs) often preclude the achievement of appropriate exposure to maximize antiarthritic effects. We evaluated the effects of switching from oral to parenteral MTX on disease activity and MTXPG accumulation in patients with RA.

Method: A total of 10 patients with RA taking oral MTX (dose 17.7±0.8 mg; average±SEM) for 27±3.0 weeks and presenting with a disease activity score (DAS28) of 4.3±0.4 were switched from oral to parenteral administration of MTX to control disease activity. In 4 patients, parenteral administration was also associated with an increase in MTX dose (final average dose 19.0±0.8 mg). At the time of the following visit (average 8.7±1.4 weeks later) DAS28 was determined together with MTXPG levels. Physicians were blinded to MTXPG concentrations. The intrapatient variability in RBC MTXPG levels was assessed in a total of 25 patients receiving a stable oral dose of MTX (range 7.5 to 20 mg/week) for at least 6-weeks. RBC MTXPG levels were determined twice, with the first determination made after 27 weeks (median) therapy (range 13-40 weeks) and the second determination made after 36 weeks (median) therapy (range 21-49 weeks). Long-chains RBC $MTXPG_3$ were measured using liquid chromatography and the change in DAS28 and MTXPG levels between visits were assessed using Wilcoxon paired test or regression analysis.

Results: The intrapatient variability (assessed using the coefficient of variation, CV) was low for MTXPG (median CV=10%) levels when patients were under a stable dose of oral MTX. The Figure (panel A) indicates that switching from oral to parenteral administration of MTX was associated with significant reduction in disease activity (median change -31%; p=0.004). In one patient the decrease in disease activity was only evident after 19 weeks of parenteral MTX. The change in MTX dosage was not associated with reduction in disease activity (p=0.39). In contrast, median percentage increase in RBC MTXPGs levels before and after parental switch was 37% (range 6%-123%) (p=0.002; panel B). The percentage change in the disease activity score was associated with the absolute change in MTXPGs levels (R^2=0.50; p=0.022) thereby indicating that parenteral administration of MTX produced greater antiarthritic effects through greater accumulation of MTXPGs.



Conclusion: These data suggest that switching from oral to parenteral MTX administration produces clinical improvements through selective accumulation of long-chains MTXPGs and are consistent with the observation that parenteral administration is significantly more effective than oral administration (Arthritis Rheum. 2008 58:73-81).

MEDI5117: A Human High Affinity Anti-IL-6 Monoclonal Antibody with Enhanced Serum Half-Life in Development for the Treatment of Inflammation and Rheumatological Diseases. Jacques Moisan[1], Raffaella Faggioni[2], Meina Liang[2], Michael A. Bowen[1], Amy K. Schneider[2], Rozanne Y.W. Lee[2], Inna Vainshtein[2], T. Scott Manetz[1], Lolke de Haan[3], LuAnn McKinney[1], Laura Richman[1], Rob Woods[1], William Dall'Acqua[1], Donna K. Finch[3], Philip R. Mallinder[4], S. Cruwys[4], Steven Lane[3], Matthew Sleeman[3], Lorin K. Roskos[1], Herren Wu[1], Bahija Jallal[1], Anthony J. Coyle[1], Roland Kolbeck[1] and Michael Fung[1], [1]MedImmune LLC, Gaithersburg, MD, [2]MedImmune LLC, Hayward, CA, [3]MedImmune Ltd, Cambridge, United Kingdom, [4]AstraZeneca R&D Charnwood, Loughborough, United Kingdom

Purpose: IL-6 is a pleiotropic pro-inflammatory cytokine linked to the pathogenesis of numerous inflammatory conditions, such as rheumatoid arthritis, lupus, Crohn's disease and cancer.

Method: Here we report the generation and characterization of an affinity-optimized human anti-IL-6 monoclonal antibody IgG1 (MEDI5117) which incorporates YTE Fc modification to extend its plasma half-life.

Result: This modification does not alter the biological potency and specificity of MEDI5117 in comparison with its parent mAb. MEDI5117 binds to recombinant human IL-6 with high affinity in ELISA, consistent with the results from KinExa assays for affinity constant determination (KD < 1 pM). MEDI5117 exhibits potent neutralizing activity against recombinant human IL-6-induced TF-1 cell proliferation (IC50 = 5.2 pM) *in vitro* via inhibition of productive engagement of IL-6 with membrane-bound IL-6Rα (classical signaling mechanism). In addition, MEDI5117 also displays high neutralizing activities (IC50 = 1.2 nM) against native human IL-6-induced VEGF production by fibroblast-like synoviocytes from rheumatoid arthritis patients in the presence of exogenous recombinant soluble IL-6Rα (trans-signaling mechanism). In both assays, MEDI5117 shows similar or slightly better anti-IL-6 neutralizing actvities as compared to a benchmark anti-IL-6 monoclonal antibody (CNTO-136). Mutagenesis studies of human IL-6 show that MEDI5117 binds to an epitope on IL-6 known to be responsible for IL-6Rα interaction. In a pharmacokinetic and pharmacodynamic study in cynomolgus monkeys, MEDI5117 shows approximately 3 fold longer plasma half-life than the parent mAb when given by iv (28 vs 8.5 days) and sc (27 vs 9.1 days) administrations.

Conclusion: Together, our data demonstrate that MEDI5117 is a potent anti-IL-6 human monoclonal antibody with superior pharmacokinetic properties. Therefore, MEDI5117 is an attractive candidate for development to treat IL-6-mediated inflammation, autoimmune diseases, and cancer.

Hypothalamus-Pituitary-Adrenal (HPA)-Axis Function in Rheumatoid Arthritis (RA) Patients Treated with Either Standard or Modified-Release Prednisone. Rieke Alten[1], Gisela Doering[2], Stephan Witte[3], Rainer H. Straub[4], Maurizio E. Cutolo[5], Erika Gromnica-Ihle[6] and Frank Buttgereit[7], [1]Schlosspark-Klinik, Berlin, Germany, [2]Merck KGaA, Darmstadt, Germany, [3]Nitec Pharma GmbH, Mannheim, Germany, [4]University Hospital Regensburg, Regensburg, Germany, [5]University of Genova, Genova, Italy, [6]Berlin, Germany, [7]Charite University Med-Berlin, Berlin, Germany

Purpose: Glucocorticoids (GCs) are effective anti-inflammatory and immunosuppressive drugs for the treatment of rheumatic diseases. Prednisone chronotherapy of RA with a modified-release (MR) tablet, allowing drug release during the rising flank of the circadian cortisol cycle is a novel approach to improve GC therapy. In the CAPRA1 study, the MR formulation was more effective than an identical dose of the immediate release (IR) prednisone administered in the morning (1). As part of this study, we investigated the effects of the two formulations on the HPA axis.

Methods: A total of 32 Corticotropin-Releasing-Hormone (CRH) tests were performed in patients treated with IR prednisone (5.3 mg; 0.82) and 30 tests in patients treated with MR prednisone (5.6 mg; 1.56) during the 12-month study (mean daily dose; SD). Changes of cortisol were assessed and compared to individual patients' efficacy and safety data.

Results: At baseline the increase (mean, SD; highest of two post-injection assessments) of serum cortisol after the injection of corticorelin was 5.5 (4.37) µg/dL in patients on IR prednisone (n=21) and 5.3 (4.07) µg/dL on MR prednisone (n=22) at the end of the study. Normal / suppressed / no response-reactions were similarly frequent in both treatments. Switching from IR to MR prednisone did not influence responses, nor did treatment up to 12 months with MR prednisone. No adverse events indicating an impairment of the HPA-axis such as signs and symptoms of Addison's disease or adrenal crisis were detected during the course of the study.

Conclusion: No differences were seen between the treatments regarding influence on HPA-axis function. Since MR prednisone has been shown to reduce duration of morning stiffness better than IR prednisone, we conclude that chronotherapy with this novel drug improves the risk-benefit ratio of long-term low-dose GC treatment in patients with RA

Sustained Safety and Efficacy of TRU-015 with Continued Retreatment of Rheumatoid Arthritis Subjects Following a Phase 2B Study. S. Stromatt[1], V. Chopiak[2], L. Dvoretskiy[3], G. Koshukova[4], E. Nasonov[5], V. Povoroznyuk[6], M. Stanislavchuk[7] and P. Leith[1], [1]Trubion Pharmaceuticals, Seattle, WA, [2]Lviv Reg Clin Hosp, Lviv, Ukraine, [3]Moscow Med Acad, Moscow, Russia, [4]Republic Hosp Semashko, Simpheropol, Ukraine, [5]Institute of Rheumatology, Moscow, Russia, [6]Institute of Gerontolgy, Kiev, [7]Vinnytsia Nat Med Univ, Vinnytsia, Ukraine

Background: In a Phase 2b double-blind, placebo-controlled randomized clinical trial, 276 subjects with active rheumatoid arthritis received a single infusion of placebo, 200, 400, 800 or 1600mg of TRU-015, a CD20-directed small modular immunopharmaceutical (SMIP ™) protein. Improvement in rheumatoid arthritis disease activity was observed in the 800mg and 1600mg dose groups at 24 weeks. Subjects were eligible to enter an open label retreatment phase and receive 800mg of TRU-015 at 24 week intervals. Further improvement in disease activity was observed after the first retreatment (R1). Data from the second retreatment (R2) are now reported.

Purpose: To evaluate the safety, tolerability, pharmacodynamics (PD), pharmacokinetics (PK) and clinical activity of repeat doses of TRU-015.

Method: All subjects were evaluated for safety. PK parameters were calculated from serum concentration data analyzed by ELISA, and PD, measured by B-cell depletion, was evaluated using CD19+ cell counts. Efficacy assessments were performed on RF+ subjects and included ACR responses (20/50/70) and improvement in DAS28 measured in relationship to baseline values.

Results: 226 subjects (94% of 240 subjects from R1) received R2. Retreatment infusions were generally well tolerated; no subjects experienced a serious adverse event on the day of infusion. 7 subjects (3%) experienced SAEs during the second retreatment period, similar to the incidence observed in the initial double blind phase of the study (placebo 2%, 800mg group 4%) and first retreatment (4%). Subjects treated with 800mg in the initial treatment, R1, and R2 demonstrated comparable PD and PK parameters after each treatment. At 24 weeks after R2, this group achieved ACR 20, 50 and 70 response rates of 72%, 39%, and 21%, respectively, which were similar to the response rates after R1 (70%, 40% and 23%, respectively). Numeric reductions of DAS28, HAQ, and CRP seen at the end of the double-blind treatment period and first retreatment period were maintained or continued to improve during the second retreatment period.

Conclusion: Repeat administration with TRU-015 is generally well tolerated, exhibits pharmacodynamic and pharmacokinetic profiles comparable to initial treatment, and results in sustained improvement in rheumatoid arthritis disease activity.

Corticosteroids Increase Risk for Acute Myocardial Infarction in Rheumatoid Arthritis: The Effects of Careful Modeling of Cumulative Exposure. J. Antonio Avina-Zubieta[1], Michal Abrahamowicz[2], Hyon K. Choi[1], M. Mushfiqur Rahman[1], Marie Pierre Sylvestre[3], John M. Esdaile[1] and Diane Lacaille[1], [1]Arthritis Research Centre of Canada / University of British Columbia, Vancouver, BC, [2]McGill University, Montreal, QC, [3]Samuel Lunenfeld Research Institute., Toronto, ON

Purpose: To determine the effect of corticosteroids (CS) on the risk of acute myocardial infarction (AMI) in rheumatoid arthritis (RA).

Methods: We assembled a retrospective longitudinal cohort of all incident RA cases from Jan 1997 to Dec 2001 followed until March 2006 using administrative data. We excluded cases with prior CS use or AMI at baseline. CS exposure was defined as any dispensed prescription for oral CS during follow up. We used 4 exposure measures to assess the impact of CS on the risk of AMI (Table 1). We used propensity scores (PS) to control for the observed differences between CS users and non users on 12 covariates (age, gender, hypertension, diabetes, angina, hypercholesterolemia, use of other cardiovascular drugs, COPD, Charlson's index, physician responsible of care, and # of medical visits per year), and included them as covariates in the final model because of residual imbalance within PS quintiles. The primary outcome was time to the first AMI event during the study period (hospitalizations or death from AMI). To account for possible cumulative effects of CS use, we used a novel time-dependent Cox model that considers dose and timing of CS exposure. Thus, at any point during the follow-up, cumulative dose is calculated as a weighted mean of past doses, with higher weights assigned to more recent doses (Model 4). We used a 6 months exposure time window for the weighting function (models 3-5). Methotrexate (MTX), NSAID's, and Cox-2 inhibitors use were represented as time-dependent covariates.

Results: 6,981 RA cases provided 42,792 person-years of follow up. Of these 2,789 (40%) were CS users. There were 248 incident AMI events (4 %) during the follow up. CS increased the risk of AMI in all models (Table 1). In each model CS exposure is represented by a different time-dependent covariate. To explore the importance of dose vs duration of use, we included 2 time-dependent exposure measures (Model 5). Weighted cumulative duration of use was not associated with AMI, but current dose was. MTX and care by rheumatologist showed statistically significant protective effects for AMI (HR from **0.42 to 0.44** and **0.48 to 0.53,** respectively in all models).

Conclusion: CS exposure in people with RA is independently associated with a higher risk of AMI, with a 2% increase in risk per 1 mg increase in the mean daily prednisone dose, regardless of the duration of use. Careful modeling of CS exposure history may enhance the understanding of the mechanisms underlying their adverse effects. MTX use and care by rheumatologist were associated with decreased risk of AMI

Model	Exposure measurement	Hazard Ratio (95% CI)			
		Unadjusted	P value	Adjusted	P Value
1	Current use (yes/no)	2.14 (1.49 – 3.08)	0.0001	1.60 (1.08 - 2.43)	0.02
2	Current dose (mg)	1.03 (1.02 - 1.04)	0.0001	1.01 (1.01 – 1.02)	0.001
3	Cumulative duration (month)	1.33 (1.17 – 1.52)	0.0001	1.21 (1.04 – 1.41)	0.01
4	Cumulative dose (per g)	1.01 (1.01 – 1.02)	0.0002	1.01 (1.004 – 1.018)	0.001
5	Current dose +	1.02 (1.01 – 1.04	0.01	1.02 (1.002 – 1.038)	0.03
	cumulative duration	1.25 (1.08 – 1.45)	0.003	1.13 (0.95 – 1.34)	0.15

Characterization of a Potent and Neutralizing Fully Human Anti CD44 Antibody PF 03475952. Herbert A. Runnels[1], Gregory L. Weber[1], Jing Min[1], Elizabeth Kudlacz[2], James Zobel[1], Carol Donovan[2], Mark Thiede[2], Jun Zhang[1], Robbin Alpert[2], Michelle Salafia[2], Douglas Burdette[3], Rosonald Bell[2], Jean Beebe[2] and Xu Xu[2], [1]Pfizer Global Research and Development, Chesterfield, MO, [2]Pfizer Global Research and Development, Groton, CT, [3]Pfizer Global Research and Development, Ann Arbor

Purpose: CD44 is a cell adhesion molecule believed to play a critical role in T cell and monocyte infiltration in the inflammatory process. The reduction of CD44 expression or its ability to properly interact with its key ligand hyaluronic acid (HA) inhibits migration and subsequent activation of cells within sites of inflammation such as synovial tissue and is expected to decrease production of pro-inflammatory cytokines such as TNF-a, IL-6, and IL-1b in the synovium. The genetic knock-out of CD44 expression in mice resulted in a decreased incidence and severity of disease in a mouse arthritis model.

Method: We developed PF-03475952 which is a fully human IgG_2 anti-CD44 monoclonal antibody (mAb).

Results: Binding of PF-03475952 to CD44 inhibits binding of HA, induces loss of CD44 from the cell surface, and inhibits LPS-induced cytokine release from various leukocytes. PF-03475952 also passed a series of safety pharmacology assays designed to assess the risk of the mAb to bind Fc receptors, activate complement, stimulate cytokine release from human whole blood and stimulate cytokine release from peripheral blood mononuclear cells using platebound stimuli. The latter assay was designed specifically to mitigate the cytokine storm potential as seen with TGN1412 (the immunostimulatory CD28 superagonist mAb) and utilized a TGN1412-like mAb as a positive control. PF-03475952 exhibits high affinity binding to both human and cynomolgus monkey CD44, but does not cross-react with rodent CD44. Thus, supporting the rationale of anti-CD44 therapy, a surrogate, rat anti-mouse CD44 mAb (IM7) was utilized to demonstrate a dose-dependent decrease of disease incidence and severity in a mouse collagen-induced arthritis model. Importantly, efficacy was correlated with ≥ 50% loss (measured at 24h post final dose) of cell surface CD44 on circulating cells, which provided a pharmcodynamic marker for both monkey studies and human clinical trials. Loss of CD44 expression on $CD3^+$ lymphocytes was monitored following a single dose in cynomolgus monkeys. The recovery of CD44 expression was found to be dose-dependent. PF-03475952 doses of 1, 10 and 100 mg/kg reduced CD44 expression below 50% for 218, 373 and >504 h, respectively.

Conclusion: Targeting of CD44 is a unique mechanism of action in the treatment of inflammatory diseases and is expected to reduce joint damage induced by inflammatory mediators resulting in disease modification in inflammatory diseases such as RA.

Tetracycline Antibiotics for Treating Rheumatoid Arthritis: A Systematic Review and Meta-Analysis. M. H. Q. Adwan, Wycombe hospital, High Wycombe, United Kingdom

Background: Tetracycline antibiotics have been used in Rheumatoid arthritis (RA) since the late 1940s. Animal and in vitro studies have shown them to modify the inflammatory process in various ways unrelated to their antimicrobial activities. These include effects on matrix metalloproteinases, Nitric oxide, phospholipase A_2, inflammatory cytokines, immunomodulatory and anti-oxidant effect, as well as effects on angiogenesis, apoptosis, MAP kinases, TGF beta and poly (ADP-ribose) polymerase-1.

Purpose: To investigate the effectiveness of tetracycline antibiotics in controlling disease activity in RA.

Methods: The following databases were searched: Medline (1950 to January week 3 2009), The Cochrane Central Register of Controlled Trials (Issue I, 2009) and Embase (1966-2008) for randomised controlled trials (RCTs) investigating the use of tetracycline antibiotics in RA. In addition, the reference lists of included studies were also searched.

All RCTs comparing tetracycline antibiotics to placebo or other disease modifying drugs were included. Data were collected on a pre-designed form. Methodological quality was assessed using the Cochrane 'risk of bias' tool. Outcome measures included ACR20, 50 and 70, components of the ACR core set, radiological changes and adverse effects. Continuous data were reported as weighted mean difference (WMD). Dichotomous data were reported as relative risk (RR).

Results: The search yielded 268 studies, of which 11 studies, including 562 patients, were included in the meta-analysis. The meta-analysis showed a significant improvement in the proportion of patients achieving ACR20 and ACR50 at one and two years compared to placebo or conventional treatment (RR: ACR20 1.87 at 1 year and 1.67 at 2 years, ACR50 1.72 at 1 year and 2.15 at 2 years) . There was no effect on radiological change. Total withdrawals and withdrawals due to lack of efficacy were significantly less for tetracyclines. Withdrawals due to adverse events were more in the antibiotic group than the control group (RR 2.28). But individual adverse effects were not different between treatment and control. The quality of evidence was low to moderate due to the small size of available studies.

Conclusion: Tetracycline antibiotics may be potentially effective and reasonably safe in rheumatoid arthritis.

Functional Polymorphisms within the Folate Pathway Predict Red Blood Cell Folate Concentrations but Are Not Associated with Methotrexate Response in RA. Lisa Stamp[1], J.L. O'Donnell[2], PT Chapman[3], M. Zhang[4], C. Frampton[5], M. Barclay[4], M. Kennedy[5] and R. Roberts[5], [1]University of Otago, Dunedin, New Zealand, [2]Canterbury Health Laboratories, Christchurch, [3]Christchurch Hospital, New Zealand, [4]Christchurch Hospital, Christchurch, New Zealand, [5]University of Otago, Christchurch, New Zealand

Purpose: It is currently not possible to predict which RA patients will achieve adequate control of disease activity with MTX, nor who will develop adverse effects. The aims of this study were to determine whether polymorphisms of genes encoding enzymes in the folate pathway were associated with MTX efficacy and/or toxicity and red blood cell (RBC) folate concentrations.

Method: A cross-sectional study of 200 RA patients on long-term oral MTX was undertaken. Disease activity was assessed by SJC, TJC, CRP, and DAS28. Low disease activity was defined as DAS28≤3.2. A standardised questionnaire regarding common MTX adverse effects was completed. 13 genes encoding enzymes within the folate pathway previously shown to have an effect on gene expression or function were examined (ABCB1, AMPD1, SLC19A1, MTHFR1298, MTHFR677, MTRR, MTR, MTHFD1, ABCC2, ATIC, ITPA, SHMT and TYMS).

Results: Of the 200 patients, an ESR was not obtained in 8 patients and one patient refused to have DNA sampled leaving 191 for analysis. 72.7% were female and mean age was 60.5 years (18-84 years). Mean duration of RA was 10.4 years (0.25 – 53years). 25.1% of patients had rheumatoid nodules, 62.8% radiographic erosions, 80.6% were RF positive and 76.3% anti-CCP positive. There was no significant association between any of the SNPs examined and SJC, TJC, pain VAS, patient global or physician global scores, or DAS28. Similarly there was no association between any of the SNPs and the low and high disease activity groups. There was a weak association between the presence of any CNS adverse effects and AMPD1 (p=0.04) and between the presence of any GI adverse effects and MTHFD1 (p=0.03). RBC folate concentration was significantly higher in patients with high disease activity compared to low disease activity (mean ± SEM: 786.9 ± 31.2nmol/L vs 664.2 ± 27.4 nmol/L, p=0.002). There was a significant association between RBC folate concentrations and MTHFR 677C>T (p=0.002), MTRR (p=<0.0001), MTHFD1 1958 (p=0.001) and SHMT (p=0.01). There was a dose response relationship between genotype and RBC folate concentrations for MTHFR 677C>T, MTRR, and SHMT. Despite this there was no association between the presence of these SNPs and low disease activity after controlling for RBC folate concentrations.

Conclusion: Polymorphisms for genes in the folate pathway were found to be associated with RBC folate concentrations, and less disease activity was seen in patients with lower RBC folate concentrations. Despite this, no relationship was found between folate pathway gene polymorphisms and response to MTX.

Safety, Pharmacokinetics, and Pharmacodynamics of PD-0360324, AHuman Monoclonal Antibody to Monocyte/Macrophage Colony Stimulating Factor, in Healthy Volunteers. Seth Sadis, Arnab Mukherjee, Stephen Olson, Melba Dokmanovich, Robert Maher, Chun-Hua Cai, Vu Le, Megan Crawford, Ronald Fedechko, Lloyd Whitfield, Thomas Stock, Marie-Pierre Hellio le Graverand Gastineau and Bernhardt Zeiher, Pfizer, Inc., New London, CT

Purpose: The monocyte/macrophage cell lineage is required for innate immunity but may also contribute to the pathology of human disease by promoting chronic inflammation. We examined the safety, pharmacokinetics (PK), and pharmacodymanics (PD) of PD-0360324, a novel neutralizing human monoclonal antibody against monocyte/macrophage colony stimulating factor (M-CSF).

Method: Six groups of healthy volunteer subjects received a single intravenous infusion of PD-0360324 or placebo at escalating doses of 3, 10, 30, 100, and 300 mg. The sixth cohort repeated evaluation of the 100 mg dose in an in-patient setting to minimize the influence of lifestyle factors on clinical and laboratory assessments. Safety evaluations and sample collection for PK and PD analyses occurred on days 1, 2, 3, 4, 7, and 14 post-infusion with additional monthly visits to follow PD-0360324 concentrations until below the limit of quantitation.

Results: Forty-eight subjects were enrolled (age 21-55 years). Serum PD-0360324 concentrations increased with escalating doses. The extent of systemic exposure, AUC(0-∞), increased in a greater than dose-proportional manner over the dose range of 3-300 mg. Single doses of PD-0360324 led to rapid dose-dependent suppression of $CD14^{+}CD16^{+}$ monocytes and urinary n-telopeptide of cross-linked collagen I, a marker of bone resorption. Adverse events (AE) were mild to moderate in severity. The most common treatment emergent AEs included headache, elevated blood creatine kinase (CK), upper respiratory tract infection, nasal congestion, oropharyngeal pain, and fatigue. Clinical observations at the highest evaluated dose that were considered potentially dose-limiting included non-pitting edema of the peri-orbital tissue (2 subjects), marked asymptomatic elevation of CK and myoglobinemia (1 subject), and CK elevations of 2.0 to 13.2× ULN (5 subjects). Subjects receiving ≥30 mg of PD-0360324 demonstrated reversible dose-related increases in serum CK and in aspartate transaminase (AST). No subject manifested detectable anti-drug antibody titers.

Conclusion: PD-0360324 exhibited a nonlinear PK profile associated with rapid suppression of PD markers and was generally well tolerated. Because M-CSF regulates the homeostasis of certain tissue macrophage populations, the observed dose-related elevations in CK and AST may reflect the drug's effect on liver macrophages (Kupffer cells), which remove short-lived serum enzymes from the blood. Inhibition of M-CSF is predicted to suppress generalized and focal bone loss and may have less acute infection risk relative to cytokine directed therapies. The safety and efficacy profile of PD-0360324 will be investigated further in a multi-dose study in patients with rheumatoid arthritis.

Prednisone Chronotherapy of Rheumatoid Arthritis: Sustained Efficacy of A Novel Modified-Release Formulation Over 12 Months.

Frank Buttgereit[1], Gisela Doering[2], Christine Knauer[3], Stephan Witte[3], Jacek Szechinski[4] and R. Alten[5], [1]Charite University Med-Berlin, Berlin, Germany, [2]Merck KGaA, Darmstadt, Germany, [3]Nitec Pharma GmbH, Mannheim, Germany, [4]Med. Univ. Dept. of Rheumatology, Wroclaw, Poland, [5]Schlosspark-Klinik, Berlin, Germany

Purpose: Glucocorticoids (GCs), although not free of side effects, are effective drugs for the treatment of rheumatic diseases due to their anti-inflammatory and immunosuppressive effects. It was hypothesized that the timing of GC administration adapted to the circadian rhythms of endogenous cortisol and the typical morning symptoms of RA might improve the risk-benefit ratio. A modified release (MR) tablet has been developed that releases prednisone 4 hours after ingestion. If taken at bedtime, drug release occurs during the night resulting in peak plasma levels in the early morning. The superiority of the MR prednisone tablet over immediate-release (IR) prednisone was shown in a clinical study in patients with RA who were pre-treated with GCs and DMARDs (Lancet 2008; 371: 205-14). Sustained efficacy and safety were followed up in a 9-month open trial.

Method: Prednisone doses during the study (<10 mg/day) were equivalent to pre-study doses. The primary outcome measure was duration of morning stiffness (MS). Secondary endpoints included interleukin-6 (IL-6) as well as RA disease activity and adverse events.

Results: 288 patients were randomized to study treatments (144 per group, mean age 55 yrs, mean disease duration approx. 10 years). During the 3-month double-blind phase, the mean relative reduction of MS duration was significantly higher with MR prednisone than with IR prednisone (p=0.045). 249 patients of the 251 who had completed the double-blind study continued on MR prednisone. Treatment periods on MR prednisone were 12 months in 104 and 9 months in 115 patients, respectively. After 12 months of treatment, the mean relative reduction of morning stiffness was 55 % and 45 % in the patients with 9 months of MR treatment. In addition, after 9 and 12 months a reduction by one count in the DAS 28 as well as a reduction of intensity of pain by 13 or 11 mm on the 100mm-VAS scale, respectively, was observed. Median reductions in IL-6 were about 50% in both groups. At the end of the study, 37 % of the patients achieved improvement according to the ACR20 criteria. The incidence of adverse events was low throughout the study and in line with published data for low dose GC treatment of RA.

Conclusion: Low-dose prednisone chronotherapy of RA via the new MR tablet provides greater efficacy than conventional immediate-release prednisone. The effects on RA symptoms and the favorable safety profile of low dose MR prednisone therapy persist on long-term treatment of RA for at least 12 months.

Benefit of Continuing Treatment Beyond 12 Weeks in Patients with Rheumatoid Arthritis Treated with Tocilizumab and DMARDs Who Had Previous Inadequate Responses to DMARDs or TNF Inhibitors. Edward C. Keystone[1], A. John[2] and K. Wong[3], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Roche, Nutley, NJ, [3]Everest Clinical Research Services Inc, Markham, ON

Purpose: Some patients (pts) with rheumatoid arthritis (RA) achieve rapid responses to treatment with biologic agents, but those who do not respond early may still reach clinical responses if treatment is continued. The objective of this post hoc analysis was to assess the midterm course of pts with no or limited responses to treatment with tocilizumab (TCZ) and DMARDs, including methotrexate (MTX), at wk 12.

Method: This analysis was performed using data from pts who participated in 4 phase 3 clinical trials and who had previous inadequate responses to DMARDs (DMARD-IR; pooled data from OPTION, TOWARD, and LITHE) or tumor necrosis factor-α inhibitors (TNFi-IR, RADIATE). Pts were treated for 24 wks with TCZ (4 mg/kg or 8 mg/kg) and DMARDs/MTX. Proportions of nonresponders (NR) in various disease activity parameters (ACR20/50/70, LDAS [DAS28 ≤3.2], DAS28 remission [<2.6]) at wk 12 but who achieved the respective responses at wk 24 (responders [R]) were determined.

Results: The analysis included 2018 DMARD-IR pts and 331 TNFi-IR pts (Table). Response rates at wk 12 for ACR20/50/70, LDAS, and DAS28 remission were numerically higher for pts in the DMARD-IR and TNFi-IR populations who were randomly assigned to TCZ 8 mg/kg than to TCZ 4 mg/kg. Of DMARD-IR pts, more in the TCZ 8 mg/kg (33%) than in the TCZ 4 mg/kg (25%) group who were ACR20 NR at wk 12 responded by wk 24. Similarly, of TNFi-IR pts, more in the TCZ 8 mg/kg (27%) than the TCZ 4 mg/kg (10%) group who were ACR20 NR at wk 12 responded by wk 24. High-level responses became more apparent after 24 wks of TCZ treatment for pts who had not achieved the respective level of responses at wk 12, with absolute response rates numerically higher for pts in the TCZ 8 mg/kg group than in the TCZ 4 mg/kg group.

Conclusion: Results of this analysis indicated that substantial proportions of DMARD-IR and TNFi-IR pts who do not respond to 12 wks of treatment with TCZ and DMARDs achieve responses if treatment is continued for 24 wks. In the more difficult to treat TNFi-IR population, nearly 30% of pts who do not achieve ACR20 or LDAS after 12 wks of treatment with TCZ 8 mg/kg and DMARDs will reach the respective responses by wk 24 if treatment is continued. Clinicians should be aware that some pts require more than 12 wks of TCZ treatment to achieve clinical benefit.

Benefit of Continuing Treatment Beyond 12 Weeks in Patients with Rheumatoid Arthritis Who Were Treated with Tocilizumab or Methotrexate Monotherapy. Edward C. Keystone[1], A. John[2] and K. Wong[3], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Roche, Nutley, NJ, [3]Everest Clinical Research Services Inc, Markham, ON

Purpose: Some patients with rheumatoid arthritis (RA) achieve rapid responses to treatment with biologic agents, but those who do not respond early may still achieve clinically important disease control if treatment is continued. The objective of this post hoc analysis was to determine the proportions of patients with active RA who achieved ACR responses, LDAS, and DAS28 remission at week 24, if they were nonresponders at week 12, having continued tocilizumab (TCZ) or methotrexate (MTX) monotherapy.

Method: Post hoc analysis was performed using data from patients who participated in the phase 3 clinical trial, AMBITION. Patients included in the trial had not been treated with MTX within 6 months before randomization and had not discontinued MTX treatment because of lack of clinical response or occurrence of clinically important adverse events. Patients were treated for 24 weeks with TCZ 8 mg/kg every 4 weeks or with an initial dose of MTX 7.5 mg/week, titrated up to 20 mg/week within 8 weeks, for 24 weeks. The proportions of patients who were ACR20/50/70, LDAS (DAS28 ≤3.2), and DAS28 remission (<2.6) nonresponders (NRs) at week 12 but who achieved the respective responses at week 24 (Rs) were determined.

Results: Table. The analysis included 286 patients who had been randomly assigned to TCZ 8 mg/kg and 284 patients who had been randomly assigned to MTX (week 8 mean dose, 17 mg/week). Of patients treated with TCZ who were ACR20 NRs at week 12, 40% achieved ACR20 at week 24. Thus, of patients who achieved ACR20 at week 24, 23% achieved it between weeks 12 and 24. Higher level responses became more apparent after 24 weeks of TCZ treatment for patients who were week 12 NRs. For example, of patients treated with TCZ who achieved ACR70 at week 24, 49% achieved it between weeks 12 and 24. Numerically higher proportions of week 24 Rs treated with MTX than of those treated with TCZ were late responders and achieved clinical responses between weeks 12 and 24.

Conclusion: Results of this analysis indicate that continuing TCZ treatment beyond 12 weeks is important because substantial proportions of patients who do not achieve clinical responses by week 12 will achieve them by week 24.

	Monotherapy

Interim Results of the TAMARA Study – Effectiveness and Safety of the Interleukin-6 (IL-6) Receptor Antagonist Tocilizumab After 4 and 24 Weeks in Patients with Active Rheumatoid Arthritis (RA). Andrea Rubbert-Roth[1], Juergen Braun[2], Eugen Feist[3], Herbert L. Kellner[4] and Gerd R. Burmester[5], [1]University of Cologne, Cologne, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Charite University Hospital, Berlin, Germany, [4]Munchen, [5]Charite - University Medicine, Berlin, Germany

Purpose: The IL-6 receptor antagonist tocilizumab was shown to be a safe and effective treatment option for RA-patients with intolerance or inadequate response to conventional DMARDs (1, 2, 3, 4) as well as TNF-blockers in clinical trials (5). This study was performed to assess the effectiveness and safety of tocilizumab in a setting close to real-life medical care.

Method: TAMARA is a German multi-center, open-label, non-controlled Phase IIIb study over 24 weeks with one treatment arm of tocilizumab 8 mg/kg iv q4w. A total of 293 adult RA patients with inadequate response to conventional and/or biological DMARDs were enrolled at 70 sites. Primary endpoint is the proportion of patients achieving a DAS28 "low disease" (defined as ≤3.2) at Week24. Secondary endpoints include further DAS assessments, ACR responses, changes in CDAI, acute phase reactants, HAQ-DI, SF-36, FACIT fatigue scale, prognostic values of several baseline variables in terms of treatment outcome, and adverse events experience including adverse events of special interest according to the risk management plan.

Results: In this week 4 interim analysis, data of 218 patients (75% of women, mean age 55 years, 39% previously on TNF-blockers) were evaluated. As a relevant result, tocilizumab reduced disease activity and improved quality of life and fatigue in patients with RA after 4 weeks (Table 1). The mean CRP level was completely normalized already after 1 week. In 40 patients 49 SAEs were reported as of 1st June 2009. The most often reported SAEs were respiratory tract infections (n=11) followed by increased liver enzymes (n=6). No fatal event was reported so far.

Conclusion: Treatment with tocilizumab achieves rapid improvement of signs and symptoms of RA in a setting mimic real-life medical care. The favorable safety profile of Tocilizumab could be confirmed in this ongoing study. No unexpected or new safety issues were observed.

Table: Results of the Week 4 analyses

Variable	Baseline	Week 4	Change
DAS28	7.5 ± 1.1	4.9 ± 1.5	-2.6 ± 1.3 (N=122)
CRP (mg/L)	23.4 ± 42.8	4.8 ± 13.4	-18.5 ± 41.2 (N=169)

HAQ-DI	1.48 ±0,64	1.14 ± 0,67	-0.33 ± 0.47 (N=217)
FACIT-F (fatigue)	29.2 ± 11.4	35.4 ± 3.0	6.2 ± 9.4 (N=216)

Note: Values are given as mean and standard deviation; N depicts the number of underlying observations for the calculation of changes

Long-Term Efficacy of Tocilizumab in Rheumatoid Arthritis for up to 3.5 Years. J. S. Smolen[1], J. J. Gomez-Reino[2], C. Davies[3], E. Alecock[3], Andrea Rubbert-Roth[4] and Paul Emery[5], [1]Medical University of Vienna, Vienna, Austria, [2]H. Clinico Universitario de Santiago, Santiago de Compostela, Spain, [3]Roche, Welwyn, United Kingdom, [4]University of Cologne, Cologne, Germany, [5]University of Leeds, Leeds, United Kingdom

Purpose: Efficacy and safety of tocilizumab (TCZ) in rheumatoid arthritis (RA) pts have been shown for up to 1 y in phase 3 trials and for up to 2.5 y in long-term extension studies. Efficacy data for up to 3.5 y are reported here.

Method: The analysis includes all pts who received ≥1 dose of TCZ in the randomized controlled studies OPTION, AMBITION, RADIATE, and TOWARD or in the long-term, open-label extension studies GROWTH95 and GROWTH96 (pts from the 4 randomized studies transitioned into GROWTH95 and GROWTH96). Also included are all pts who received ≥1 dose of TCZ in the 2-y controlled (with a 3-y follow-up) phase 3 study, LITHE. Pts were analyzed in 3 groups: inadequate responders to DMARDs (DMARD-IR), anti-TNF-IR pts, and monotherapy pts who never failed MTX (AMBITION). Outcomes, including ACR50/70, DAS28 remission rate (DAS28 ≤2.6), and low disease activity score (LDAS; DAS28 ≤3.2), were assessed every 12 wks from initial TCZ exposure to the cutoff date (Feb 6, 2009). Data are shown for a maximum of 180 wks, after which pt numbers were too low to draw conclusions. High clinical hurdles were examined, such as proportions of pts with HAQ-DI=0, ≤1 SJC, and ≤1 TJC at 96 wks. Pts who withdrew from treatment were categorized as missing for all time points thereafter. Pts with insufficient data at a given time point were excluded from analysis for that time point only.

Results: A total of 3986 pts were included. By the cutoff date, approximately 4% had discontinued due to insufficient therapeutic response and approximately 14% due to safety (including intercurrent illness). Efficacy of TCZ in DMARD-IR pts was demonstrated by increased numbers of pts who achieved ACR50 and ACR70 up to wks 72 and 96, respectively, and who achieved maintenance of ACR70 for 24 consecutive wks, LDAS, and DAS28 remission up to wk 72. Thereafter, proportions increased further or were maintained with continued TCZ up to wk 180 (Table). In anti-TNF-IR and monotherapy pts, the proportions achieving these end points increased or were maintained with continued TCZ treatment (not shown). At 96 wks, proportions in the DMARD-IR, anti-TNF-IR, and monotherapy groups with HAQ=0 were 15%, 8%, and 23%, respectively; the proportions with ≤1 SJC were 46%, 34%, and 55%, respectively; and the proportions with ≤1 TJC were 37%, 23%, and 35%, respectively.

Conclusion: Efficacy of TCZ was demonstrated during long-term treatment of RA pts, as indicated by increasing numbers and/or proportions of pts achieving outcomes. These data support TCZ as an effective, long-term treatment option in pts who are DMARD-IR or anti-TNF-IR or who have not failed MTX.

A Phase II, Randomized, Double-Blind, Placebo-Controlled Study to Evaluate the Efficacy and Safety of MDX-1100, A Fully Human Anti-CXCL10 Monoclonal Antibody, in Combination with Methotrexate (MTX) in Patients with Rheumatoid Arthritis (RA). M. Yellin[1], I. Paliienko[2], A. Balanescu[3], V. Vizir[4], S. Ter-Vartanian[5], J. Tian[1], X. Zhu[1], G. Ignatenko[6] and R. Chirieac[7], [1]Medarex Inc, Bloomsbury, NJ, [2]Bogomolets National Medical University, Kyiv, Ukraine, [3]Sf. Maria Hospital, Bucharest, Romania, [4]Zaporizhya State Medical University, Zaporizhya, Ukraine, [5]Kyiv Central Municipal Clinical Hospital, Kyiv, Ukraine, [6]M. Gorky Donetsk National Medical University, Donetsk, Ukraine, [7]Iasi Rehabilitation Clinical Hospital, Iasi, Romania

Purpose: CXCL10 (IP-10) is a chemokine that promotes directed migration of activated T cells and monocytes by binding to the cell surface receptor CXCR3. Both CXCL10 and CXCR3 are abundantly expressed in rheumatoid arthritis synovium and may play a role in disease pathogenesis. MDX-1100 neutralizes CXCL10 and has been well tolerated in Phase 1 studies. This study evaluated the efficacy and safety of repeat dosing of MDX-1100 in patients with RA who had an inadequate response to methotrexate.

Method: 70 patients with active RA (≥ 6 tender and ≥ 6 swollen joints) on stable doses of MTX (10 to 25 mg weekly) were randomized to receive every other week intravenous doses of either placebo (n=35) or MDX-1100 10 mg/kg (n=35) x 6. The primary endpoint was the ACR20 response rate at Day 85. Patients were followed for safety to study Day 141.

Results: The MDX-1100 and placebo cohorts were well balanced with respect to mean age, sex, disease duration, baseline corticosteroid and MTX doses, and rheumatoid factor (RF) status. All but one subject was anti-TNF treatment naïve and all subjects were white. At Day 85 the ACR20 response rate was significantly higher for MDX-1100 treated patients than for placebo treated patients (54% versus 17%; p-value = 0.0024). The ACR20 response rate showed a statistically significant separation between MDX-1100 and placebo treatment at every time point from Day 43 through Day 85. The ACR50 and ACR70 response rates at Day 85 were numerically higher in the MDX-1100 cohort but did not achieve statistical significance between the 2 cohorts: 9% versus 3% for ACR50 and 3% versus 0% for ACR70. Overall, 51.4% (n=18) of MDX-1100 treated patients and 30.3% (n=10) of placebo treated patients experienced at least 1 adverse event (AE). With 2 exceptions, AEs were mild or moderate in severity (Grade 1 or 2). One patient in the MDX-1100 cohort experienced a grade 3 infusion reaction (bronchospasm) and one patient in the placebo cohort died suddenly, presumably of cardiac causes. The MDX-1100 infusion was

generally well tolerated and did not require pre-medication. The infection rate was similar between the MDX-1100 and placebo cohorts (8.6% vs. 12.1%).

Conclusion: MDX-1100 was well tolerated and associated with a statistically significant increase in ACR20 responses compared to placebo. These results demonstrate that the CXCL10-CXCR3 pathway plays important roles in RA pathogenesis and provide rationale for the continued development of MDX-1100.

LY2439821, a Novel Anti-IL-17 Mab: Safety, Tolerability and Efficacy in Patients with RA On Background DMARDs. MC Genovese[1], F. Van den Bosch[2], SA Roberson[3], S. Bojin[4], M. Biagini[5], P. Ryan[6] and J. Sloan-Lancaster[3], [1]Stanford U, Palo Alto, CA, [2]Univ Hosp, Ghent, Belgium, [3]Eli Lilly, Indianapolis, IN, [4]County Hospital, Covasna, Romania, [5]County Hospital, Bacau, Romania, [6]Nucleus Network, Melbourne, Australia

Purpose: LY2439821 (LY) is an anti-IL-17 antibody that neutralizes the biologic activity of IL-17, a key cytokine in RA pathogenesis.

Method: This was an early phase clinical study to investigate the safety, tolerability, PK, and evidence of efficacy of LY in pts with RA taking at least one DMARD. The study was a randomized, placebo (PBO)-controlled, double-blind study, conducted in 2 parts. The study had dual primary endpoints: safety after single and multiple dosing, and efficacy after multiple dosing. Part A was an initial single dose escalation evaluating safety, which was used to enable multiple dosing. In Part B, 4 treatment groups were dosed IV in parallel every 2 wks for 8 wks (5 treatments per pt), at 0.2, 0.6, or 2.0 mg/kg of LY or PBO, and were evaluated for an additional 8 weeks. The primary efficacy endpoint was the DAS28 at Wk 10.

Results: In Part B, mean baseline characteristics were similar between groups. Mean baseline findings include : age 54.4 to 59.6 yrs; disease duration 6.1 to 10.9 yrs; DAS28 5.8 to 6.1; CRP 1.80 to 2.47 mg/dL; ESR 61.0 to 69.1 mm/hr; Tender Joint Counts (28) 15.7 to 18.2; Swollen Joint Count (28) 11.8 to 13.7; HAQ-DI 1.4 to 1.8. 77 pts were randomized to PBO (18), or LY at 0.2 mg/kg (19), 0.6 mg/kg (20), or 2.0 mg/kg (20). Multiple administrations of LY improved the signs and symptoms of RA (Table). Statistical differences in the mean change from baseline in DAS28 (each dose level compared to PBO) and ACR20 responses (0.2 mg/kg and all LY groups compared to PBO) were detected as early as 1 week after the first dose. At Week 10, statistical differences in the mean change from baseline in DAS28 were detected between the 0.2, 2.0 mg/kg, and all LY combined groups vs. PBO. There were no deaths. Three LY pts (1 at 0.6 and 2 at 2.0 mg/kg) were discontinued from study drug treatment due to AEs, and 1 LY pt was discontinued due to pre-treatment laboratory abnormalities discovered after administration of the first dose. There was 1 reported SAE (skin ulcer in a 0.6 mg/kg pt), classified as unrelated to study drug. No serious infections or malignancies were noted. The incidence of AEs was generally similar between groups.

	PBO	LY 0.2 mg/kg	LY 0.6 mg/kg	LY 2.0 mg/kg
Week 2				
DAS28	-0.5	-1.1*	-1.0*	-1.2*
ACR20 (%)	0	26.3*	30.0*	45.0*
ACR50 (%)	0	5.3	5.0	5.0
ACR70 (%)	0	0	0	0
Week 10				
DAS28	-1.7	-2.3*	-2.2	-2.4*

ACR20 (%)	55.6	73.7	70.0	90.0*
ACR50 (%)	16.7	42.1	40.0	35.0
ACR70 (%)	5.6	26.3	20.0	25.0

NOTE: DAS28 values represent change from baseline.

* Significant at the 0.05 level compared to placebo.

Week refers to number of weeks on active treatment.

Conclusion: IL-17 is a novel cytokine target. IV administrations of LY improved the signs and symptoms of RA early during treatment and confirms the rationale for targeting IL-17. In addition, LY was well-tolerated.

Efficacy and Safety of Baminercept in the Treatment of Rheumatoid Arthritis (RA) - Preliminary Results of the Phase 2B Study in the DMARD-IR Population. John D. Isaacs[1], Mark C. Genovese[2], Paul Emery[3], Morton A. Scheinberg[4], Aj Spindler[5], Charlotte Newman[6], Megan L. Weaver[6], Jeff Browning[6], John O'Gorman[6], Matt Cravets[7], David Hagerty[7], Evan M. Beckman[6] and Ajay Nirula[7], [1]Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Stanford University, Palo Alto, CA, [3]University of Leeds, Leeds, United Kingdom, [4]Center for Clinical Immunology, Sao Paulo SP, [5]Universidad Nacional Tucumán, Tucuman, Argentina, [6]Biogen Idec, Cambridge, MA, [7]Biogen Idec, San Diego, CA

Purpose: The TNF-family lymphotoxin beta receptor (LTBR), present on monocytes and dendritic cells, has been implicated in formation of ectopic organized lymphoid tissues at sites of inflammation. The efficacy and safety of Baminercept, a LTBR-IgG_1 fusion protein, were evaluated in patients with moderate/severe RA with an inadequate response to non-biologic DMARD therapy.

Methods: A blinded, randomized, placebo-controlled, multicenter, Phase 2B trial was performed in patients with moderate/severe RA and inadequate response to non-biologic DMARD therapy, including methotrexate. Patients continued their stable MTX dose and received subcutaneous injections of Baminercept (5mg, 70mg, or 200 mg every other week, 70mg or 200 mg monthly, or placebo for 14 weeks). The primary endpoint was the proportion of subjects with an ACR50 response at Week 14. Secondary efficacy endpoints included ACR20 and ACR70 responses and change from baseline DAS28 at Week 14. Exploratory endpoints included the effect of Baminercept on peripheral blood lymphocyte counts.

Results: 391 subjects were randomized in the study. Treatment groups had similar baseline (BL) demographics and disease activity. Treatment with Baminercept did not result in improvement of ACR 50 (primary endpoint) or secondary endpoints of ACR 20, ACR 70, or change from baseline DAS scores (Table 1). Analysis of individual ACR core parameters showed no significant differences between drug and placebo. Baminercept was overall well tolerated and had comparable rates to placebo for adverse events, serious adverse events, and infections (Table 1). Treatment with Baminercept resulted in a dose-dependent increase in total blood lymphocytes from baseline by Week 2 (Table 1), suggesting effective targeting of the LT-beta pathway. Table 1: Preliminary Efficacy (week 14) and Safety Results in DMARD-IR study.

	Placebo	10 mg mthly	70 mg mthly	140 mg mthly	200 mg mthly	400 mg mthly
Number of patients	79	78	39	39	78	78
ACR50 (% pts)	11	14	8	18	14	10
ACR20	32	36	36	38	40	33

(% pts)						
ACR70 (% pts)	4	4	3	10	8	6
Chg in DAS28 – mean from baseline	-0.91	-0.99	-0.75	-1.23	-1.23	-0.85
Adverse Events (%)	56	53	59	62	58	54
Serious Adverse Events (%)	5	1	13	3	4	3
Infections (%)	22	26	21	28	28	26
Pct chg from baseline in blood total lymphocyte count at Week 2– mean (SD)	15.3 (35.6)	14.3 (28.3)	23.0 (42.4)	35.8* (48.4)	34.9* (30.7)	37.5* (43.5)
* = p-value < 0.01 for comparison versus placebo (post-hoc analysis)						

Conclusion: Baminercept did not exhibit efficacy in patients with RA refractory to oral DMARDs. The drug was overall well tolerated and remains a candidate for clinical study in other autoimmune diseases.

Efficacy and Safety of Baminercept in the Treatment of Rheumatoid Arthritis (RA) – Results of the Phase 2B Study in the TNF-IR Population. M.C. Genovese[1], Maria W. Greenwald[2], Jeff A. Alloway[3], Andrew R. Baldassare[4], Walter Chase[5], Charlotte Newman[6], Megan L. Weaver[6], Jeff Browning[6], Jaya Goyal[6], John O'Gorman[6], Matt Cravets[7], Evan M. Beckman[6] and Ajay Nirula[7], [1]Stanford U, Palo Alto, CA, [2]Desert Medical Advances, Palm Desert, CA, [3]Greenville, NC, [4]St Louis University, St Louis, MO, [5]Austin, TX, [6]Biogen Idec, Cambridge, MA, [7]Biogen Idec, San Diego, CA

Purpose: The TNF-family lymphotoxon beta receptor (LTBR), present on monocytes and dendritic cells, has been implicated in the formation of ectopic organized lymphoid tissues at sites of inflammation. The efficacy and safety of Baminercept, a LTBR-IgG_1 fusion protein, were evaluated in patients with moderate/severe RA with an inadequate response to anti-TNF therapy.

Methods: A blinded, randomized, placebo-controlled, multicenter, Phase 2B trial was performed in patients with moderate/severe RA and inadequate response to ≥1 TNF blocker. Patients were randomized 2:1 to either receive subcutaneous injections of Baminercept (200 mg every other week) or placebo for 14 weeks followed by 12 weeks of observation. The primary endpoint was the proportion of subjects with an ACR50 response at Week 14. Secondary efficacy endpoints included ACR20 and ACR70 responses and change from baseline DAS 28.

Results: 114 subjects were dosed in the study. Both treatment groups had similar baseline (BL) demographics and disease activity. Treatment with Baminercept did not result in improvement of the primary endpoint ACR 50 scores relative to the placebo group at week 14 (11% vs 5%, p=0.3340). Similarly, no significant changes were seen in the Baminercept group relative to placebo for secondary endpoints of ACR 20 (14% vs 13%), ACR 70 (1% vs 3%), or change from baseline DAS scores (-0.64 vs -0.67). Analysis of individual ACR core parameters showed no significant differences between drug and placebo. Baminercept was overall well tolerated and had comparable rates to placebo for adverse events (72% vs 61%) and infections (30% vs 21%); however more serious adverse events (7% vs 0%) were noted.

Exploratory analyses provided evidence strongly suggestive of LTBR pathway inhibition. Baminercept triggered a notable increase in total blood lymphocytes, with percentage changes from baseline at Week 2 (mean ±SD) as follows: placebo (2.2±29.3) and Baminercept (30.9±32.6) (post-hoc $p < 0.0001$). Additionally, reductions of approximately 50% were seen for Baminercept-treated subjects at Week 14 in serum levels of CXCL13, a chemokine regulated by LTBR signaling. Favorable clinical trends were noted at week 6 (subset of subjects) for Baminercept relative to placebo for serum lipid levels, including mean percentage changes from baseline in LDL (-5.3% vs +2.2 %) and HDL (+6.6% vs -1.0%).

Conclusion: Baminercept did not exhibit measurable efficacy in patients with RA refractory to TNF inhibitors. However given its unique mechanism of action, it remains a candidate for clinical study in other autoimmune diseases.

Effects of the Oral JAK Inhibitor CP-690,550 (CP) On Pain, Physical Functioning (PF), Fatigue, and Health-Related Quality of Life (HRQoL) in Patients (pts) with Active Rheumatoid Arthritis (RA). G.V. Wallenstein[1], S. Cohen[2], M. Cutolo[3], D. Gruben[1], K.S. Kanik[1], J.M. Kremer[4], E.B. Lee[5], B. Wilkinson[1], S.H Zwillich[1] and J. Frain[6], [1]Pfizer Inc, New London, CT, [2]Metroplex Clinical Research Centre, Dallas, TX, [3]University of Genoa, Genoa, Italy, [4]Albany Medical College and the Center for Rheumatology, Albany, NY, [5]Seoul National University College of Medicine, Seoul, South Korea, [6]Complete Medical Communications, Macclesfield, United Kingdom

Purpose: To compare effects on pain, PF, fatigue, and HRQoL of (Study 1025) CP v placebo (PBO) for the treatment of active RA in pts with inadequate response to stable background MTX, and of (Study 1035) CP or adalimumab (ADA) monotherapy v PBO for the treatment of RA in pts with inadequate response to DMARDS.

Methods: Data are from two 6-month, double-blind, PBO-controlled Phase 2B studies. Pts with ≥6 tender and ≥6 swollen joints and evidence of inflammation were randomized to: (Study 1025) CP dosed 1, 3, 5, 10, 15 mg BID, or 20 mg QD or PBO; and (Study 1035) CP dosed 1, 3, 5, 10, 15 mg BID, or ADA 40 mg sc QOW, or PBO. Pts receiving CP 1, 3 mg BID, 20 mg QD, or PBO with < 20% reduction from baseline in tender/swollen joint counts at Week 12 were reassigned to CP 5 mg BID.

Results: In Study 1025 507 pts were randomized and received study drug. Significant improvements in pain at Week 2 and PF at Week 12 occurred for several CP groups (Table 1). Pts from the CP groups also showed significant improvements in several domains of the SF-36 at Week 12 ($p < .05$ for PF, Bodily Pain (BP), Vitality (VT), and Mental Health).

In Study 1035 384 pts were randomized and received drug. Pain and PF improved significantly for pts in several CP groups by Week 2 (Table 1). Pts from the CP groups also showed significant improvements in domains of the SF-36 at Week 12 ($p < .05$ for PF, Role Physical, BP, General Health, and VT). Finally, pts from the 10 and 15 mg groups showed significant improvement in fatigue (FACIT-F) by Week 2 ($p < .05$).

Relationship of Tocilizumab Dose and Neutrophil Counts. Peter N. Morcos[1], Xiaoping Zhang[1], Susan Grange[2] and Christophe Schmitt[2], [1]Roche, Nutley, NJ, [2]Roche, Basel, Switzerland

Purpose: Tocilizumab (TCZ) is a humanized IL-6 receptor inhibitor that has demonstrated not only significant improvements in the signs and symptoms of moderate–to-severe rheumatoid arthritis (RA) but also inhibition in the progression of structural joint damage (LITHE Study). In the controlled clinical trials, decreases in neutrophils below 1 x 10^9/ L was observed in 3.4% of patients on TCZ 8 mg/kg plus DMARDs compared to < 0.1% of patients on placebo plus DMARDs. The purpose is to examine the relationship of TCZ dose and neutrophil counts to provide guidance for the management of neutropenia in patients on TCZ therapy.

Methods: In study BP19461, subjects received placebo (N=39), 2 (N=5), 10 (N=36), 20 (N=41) and 28 mg/kg (N=5) TCZ intravenous infusion. In another study, WP18633, 23 patients with RA received 10 mg/kg TCZ infusion. Neutrophil counts were determined from screening until follow up visit.

Results: In healthy subjects, following TCZ infusion, mean neutrophil counts decreased at 2 to 28 mg/kg doses. Median time (T_{min}) to reach mean minimum neutrophil counts (NTT_{min}) was 3 to 5 days (Figure 1). Although not pronounced, there was a trend toward a decrease in mean NTT_{min} with increased dose. The time required for recovery to normal ranges of neutrophil counts was dose dependent (Table 1). Although there was an increase in the observed incidence of markedly low neutrophil counts with increasing dose, there was no dose relationship in the observed incidence of adverse events, specifically the incidence of infections. In patients with RA, patients demonstrated a similar pattern of absolute neutrophil counts following TCZ administration.

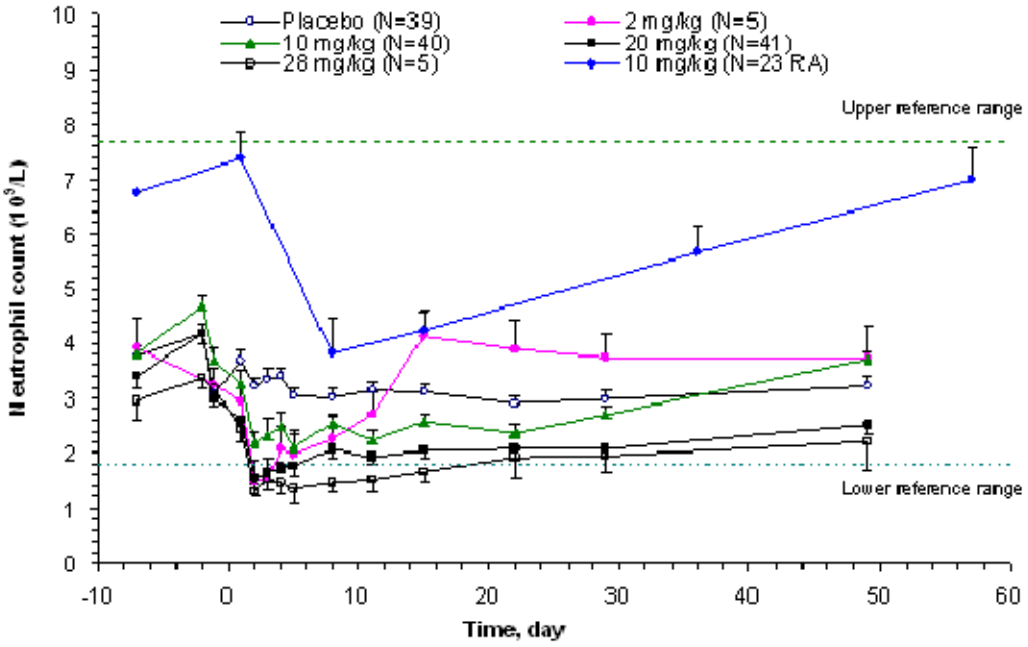
Table 1. Mean (± SD) neutrophil counts (x10^9/L) at baseline, nadir and follow-up in healthy subjects

Dose, mg/kg	Placebo	2	10	20	28
N	39	5	36	41	5
Mean ±SD NTTmin x10^9/L,day	2.43 ±0.64	1.39± 0.86	1.48± 0.79	1.28± 0.64	1.01± 0.10
Median Tmin	11	3	4	3	5

Recovery to Baseline (days)	-	14	39	49	70*

*extrapolated from available data

Figure 1. Mean neutrophil counts over time following single dose TCZ infusion from 2 to 28 mg/kg



Conclusion: In healthy subjects administered TCZ in doses from 2 to 28 mg/kg, absolute neutrophil counts decreased to the nadir 3 to 5 days following TCZ administration. Thereafter, neutrophils recovered towards baseline in a dose dependent manner. RA patients demonstrated a similar pattern following TCZ administration.

Evaluation of Safety, Pharmacokinetics and Pharmacodynamics of a Selective Glucocorticoid Receptor Modulator (SGRM) in Healthy Volunteers. Thomas Stock[1], Dona Fleishaker[1], Arnab Mukherjee[2], Vu Le[2], Jian Xu[2] and Bernhardt Zeiher[2], [1]Pfizer, Inc., Chesterfield, MO, [2]Pfizer, Inc., New London, CT

Purpose: SGRMs were identified preclinically using in vitro and in vivo assays. Compounds that displayed anti-inflammatory activity similar to glucocorticoids (e.g., prednisone) but lesser inhibition of bone formation in animal models were further evaluated in humans. PF-00251802 (C-A), and its phosphate ester pro-drug, PF-04171327 (C-B), were evaluated in separate Phase 1 single-dose studies in healthy volunteers to characterize safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of glucorticoid receptor (GR) agonism.

Method: Single C-A doses (0.3 to 300 mg), and single C-B doses (1 to 300 mg) were evaluated in separate randomized, placebo-controlled, investigator- and subject-blinded clinical studies in 27 and 18 subjects, respectively, using partial cross-over designs. A washout period of 14 days was allowed between dosing. Serial blood samples and safety parameters were collected up to 7 days post-dose for PK, biomarker and safety assessments. C-A plasma concentration, complete blood count with differential, plasma osteocalcin (OC), plasma cortisol, and urinary

N-terminal cross-linking telopeptide of type-1 collagen (uNTX-1) were measured. C-A plasma concentrations were linked to biomarker responses using PK-PD models for estimation of potency (IC50) and maximal effect (Imax). Selectivity of C-A was assessed by model-based comparison to biomarker effects of prednisolone (P), the active metabolite of prednisone, from a previous study.

Results: C-A plasma concentrations increased proportionately with increasing doses of C-A and C-B. C-A PK was similar following equivalent doses of C-A and its pro-drug, C-B, which was not absorbed systemically. Dose-dependent biomarker effects consistent with GR-mediated pharmacology were observed, including cortisol and OC suppression, lymphopenia, eosinopenia, and neutrophilia. The duration of effect was substantially longer than that of P, likely due to the longer elimination half-life and GR binding affinity (Kd) of C-A (24 hr and 0.061 nM, respectively) compared to P (3 hr and 1.3 nM, respectively). The relative potency of C-A for OC suppression versus effects on other markers (cortisol suppression, neutrophilia) was lower compared to P. The Imax for C-A effect on OC was half that of P, but Imax on cortisol and neutrophils was similar to P. PK-PD model-based evaluations indicated that C-A doses up to 10 mg QD would provide OC suppression less than or equal to that of 5 mg QD prednisone, and cortisol suppression and neutrophilia similar to or greater than that of 20 mg QD prednisone. Both compounds were generally well tolerated, with dose limiting nausea and emesis occurring in some subjects at doses greater than 150 and 300 mg for C-A and C-B, respectively. There were no serious or severe adverse events.

Conclusion: Compared to prednisone, C-A was shown to have less impact on OC, a biomarker of adverse effects on bone, with similar effects on other biomarkers of glucocorticoid activity.

Preliminary Results of a Phase I Clinical Trial of Intra-Articular Administration of ARG098, A Novel Anti-Fas IgM Mab, in RA.

Thierry Appelboom[1], Herman Mann[2], Ladislav Senolt[2], David Suchy[3], Petr Nemec[4], Jana Rolova[5] and Marco Matucci Cerinic[6], [1]Erasme University Hospital, Brussels, Belgium, [2]Institute of Rheumatology, Prague 2, Czech Republic, [3]University Hospital Pilzen, Pilzen, Czech Republic, [4]St. Anna's University Hospital Brno, Brno, Czech Republic, [5]Faculty Hospital Ostrava, Ostrava, Czech Republic, [6]University Hospital Florence, Firenze, Italy

Purpose: Activated inflammatory cells including synoviocytes, lymphocytes and macrophages are primary cellular factors which activate inflammation in the joints of rheumatoid arthritis (RA) patients. They contribute to disease progression by producing local inflammatory cytokines. Selective removal of these inflammatory cells directly from inside the joint could represent an innovative therapeutic approach. ARG098 is a novel agonistic anti-Fas IgM mAb which binds to Fas molecule and is in vitro capable of inducing apoptosis in synoviocytes and infiltrating lymphocytes in synovial tissue. Here we demonstrate that ARG098 can be a novel local therapeutics for RA showing clinical benefit as well as safety profile in the clinical phase I study with RA patients in Europe.

Method: This is an open-label dose-escalation study of a single intra-articular administration of ARG098 in patients with RA having safety and tolerability as primary endpoints, and efficacy assessment and pharmacokinetic determination as secondary endpoints. The study included 7 cohorts, each consisting of 6 patients. One mL of formulated ARG098 was administered to the target knee. Safety was assessed by monitoring general findings, serum level of anti-ARG098 antibody and laboratory test over 8 weeks post-administration. Efficacy was assessed by VAS including target knee pain, global efficacy assessment by patient and physician, tender and swollen joint count including target knee, effusion, thickness and erosion by ultrasonography (US) and MRI.

Results: Thirty three RA patients (28 females and 8 males between 37 and 78 years) with knee active synovitis were enrolled for receiving 10 ng/knee through 3 μg/knee. Safety and tolerability were observed in all dosage. Preliminary efficacies were evaluated in 24 patients after injection of 10 ng, 30 ng, 100 ng and 300 ng/knee. Average decrease in VAS scale of pain in the target knee at week 1, 2, 4 and 8 post-administration compared with baseline was 49.5%, 55.1%, 60.7% and 51.8%, respectively. Ten of 23 patients showed high response with more than 80% of decrease in VAS scale of pain at week 4. Around 60% of patients experienced clinical benefit in the target knee including resolution of tenderness and swelling through week 1 to 8. Average of DAS28 of total patients showed slight decrease and in the group of patients with high response, obvious improvement of DAS28 was observed. Tendency of beneficial change was observed by US and MRI analysis.

Conclusion: This is the first report to indicate that an anti-Fas IgM mAb (ARG098) induces improvement of local symptoms and reduction of disease activity in patients with RA.In addition, ARG098 is well-tolerated and has an acceptable safety profile as a local therapeutics in RA.

Effect and Mechanism of Jak Inhibitor as a Possible New Anti-Rheumatic Drug: Analysis From in Vitro and SCID-HuRAg Mouse.
Keisuke Maeshima, Kunihiro Yamaoka, Katsunori Suzuki, Shigeru Iwata, Sonosuke Yukawa, Kazuyoshi Saito and Yoshiya Tanaka, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Purpose: Janus kinase 3 (Jak3) is a tyrosine kinase necessary for lymphocyte differentiation and proliferation, and homozygous deficiency is a cause of severe combined immunodifficiency. Because of its specific expression on hematopoietic cells, inhibitors of Jak 3 have been expected to be immunosuppresive. Recent clinical trials of a Jak3 inhibitor CP-690,550 for rheumatoid arthritis (RA) has been conducted, showing efficacy and acceptable safety. However, CP-690,550 has been shown to possess inhibitory effects not only on Jak3 but also Jak1 and Jak2, both in vitro and in vivo. Thus, it is now considered as a Jak inhibitor. The effects of Jak inhibitors (CP-690,550 and PF-956980) on functions of lymphocytes and synovial cells in vitro and SCID-HuRAg model mouse were assessed in the current study.

Method: Synovium and cartilage from RA patients undergoing joint replacement was implanted into SCID mice (SCID-HuRAg) and Jak-inhibitors (CP-690,550) were administrated via osmotic mini-pump. Serological and histological examinations were performed using the SCID-HuRAg model. Synovial fibroblasts were obtained from RA synovium (RASFs) and were used during passage 2 to 6. RASFs were stimulated with LPS, IL-1, IL-6 or IL-17 under the presence of Jak-inhibitor (CP-690,550). CD4 T cells were negatively purified from RA patients, stimulated with IL-1, IL-6 or IL-23 and were evaluated for the effects of Jak-inhibitor (PF-956980). ,CP690,550 and PF956980 was provided by Pfizer.

Results: CP-690,550 decreased human IL-6, IL-8, and MMP-3 levels in SCID-huRAg mice sera in a concentration-dependent manner. The main source of IL-6 and MMP-3 is known to be synovial frbroblasts. However, CP-690,550 only marginally affected production and proliferation of RASFs. On the other hand, PF-956980 dose-dependently inhibited production of IL-17 and IFN-γ as well as proliferation of peripheral CD4 T cells from peripheral blood.

Conclusion: Recently, CP-690,550 has been described to possess inhibitory effect not only on Jak3 but also on Jak1 and Jak2 and other kinases as well. However, CP-690,550 did not show any effects on RASFs which do not express Jak3, whereas PF-956980 inhibited CD4 T cell proliferation and cytokine production. Our result suggests that CP-690,550 acts on immune cells mainly on CD4 T cells mainly through Jak3 and regulates proliferation and certain cytokine production of CD4 T cells.

Are the Switch to Subcutaneous Administration of MTX or the Addition of Cyclosporine to Oral MTX Useful Steps in a Tight Control Strategy for RA?
Marije F. Bakker, Johannes W.G. Jacobs, Paco M.J. Welsing, Johannes W.J. Bijlsma and Floris P.J.G. Lafeber, University Medical Center Utrecht, Utrecht, Netherlands

Purpose: Methotrexate (MTX) is widely used as the DMARD of first choice in the treatment of rheumatoid arthritis (RA) patients. In an earlier strategy trial (CAMERA) in early RA patients, a tight control MTX strategy proved to be more effective when compared to conventional MTX treatment. However, a substantial number of patients do not respond favorably enough to the maximally (tolerable) dose MTX and need more intensified treatment. Within the CAMERA strategy these intensified treatment steps were defined as subcutaneous (sc) MTX instead of oral MTX treatment; in case this was not effective enough, was contraindicated or caused adverse effects, cyclosporine was added to oral MTX treatment with a simultaneous reduction of the dose MTX to a maximum of 15mg/wk. The aim of this study was to investigate the effectiveness of these two treatment strategy steps.

Method: The change in disease activity (DAS28) over one month after taking the scMTX step was compared to the average 3 monthly change before taking the step. For the cyclosporine strategy step the change in DAS28 over 3 months after taking this step (since cyclosporine has a slow onset of action) was compared to the average 3 monthly change before taking this step. Analyses were performed separately for patients who needed the step because of insufficient effect and for those who needed it because of adverse effects. Additionally, analyses of individual responses and time on treatment were performed.

Results: Of the 151 patients within the tight control strategy arm of the CAMERA study, 57 needed the scMTX strategy step (21 because of adverse events, 36 because of insufficient effect) and 40 the cyclosporine strategy step (20 and 20, respectively). These patients had a mean age of 54 years, 69% was female, and 54% was RF^+. For the scMTX strategy step the DAS28 decreased over the 4 months evaluation period ($p=0.47$ for adverse events, $p<0.01$ for insufficient effect). The decrease in DAS28 between baseline and 4 months was 0.4 and 0.6 points for adverse events and insufficient effect, respectively. For the cyclosporine strategy step no (significant) trend in DAS28 over time was observed. For patients taking the scMTX strategy step because of adverse events, the mean improvement in DAS28 exceeded the mean 3 month improvement in DAS28 before this step by 0.08 units ($p=0.83$); for patients taking the step for insufficient effect this was 0.29 DAS28 units ($p=0.08$). For patients taking the cyclosporine strategy step because of adverse events the DAS28 increased with 0.26 units ($p=0.44$) and for those needing the step because of insufficient effect, the decrease was 0.15 units ($p=0.68$).

Conclusion: Although not statistically significantly (probably due to low numbers), the scMTX strategy step seems to be effective in early RA patients needing this step because of insufficient effect of oral MTX. The cyclosporine strategy step appears not to be effective, possibly due to concomitant lowering of the MTX dose.

The A3 Adenosine Receptor as a Biological Predictive Marker in Rheumatoid Arthritis: Lessons From Phase II Clinical Studies.

MH Silverman[1], S. Aamar[2], T. Reitblat[3], D. Markovitz[4], H. Amital[5], Z. Harpaz[1], S. Fishman[1], M. Farbstein[1], S. Bar Yehuda[1], A. Ochaion[1], S. Cohen[1], F. Barer[1], R. Patoka[1], G. Zozulya[1] and P. Fishman[1], [1]Can-Fite BioPharma, Petach Tikva, Israel, [2]Hadassah University Hospital, Mount Scopus, Jerusalem, Israel, [3]Barzilai Medical Center, Ashkelon, Israel, [4]Rambam Medical Center, Haifa, Israel, [5]Meir Medical Center, Kfar Saba, Israel

Purpose: The Gi protein associated A_3 adenosine receptor (A_3AR) is highly expressed in the inflammatory tissues and peripheral blood mononuclear cells (PBMCs) of patients with Rheumatoid Arthritis (RA). The A_3AR selective agonist CF101 has been shown to possess robust anti-inflammatory effect via de-regulation of the NF-κB signaling pathway and induction of inflammatory cell apoptosis. The purpose of this study was to evaluate the correlation between A_3AR expression at baseline and the response of RA patients to CF101 treatment. CF101 was given as a monotherapy (Phase IIa) or in combination with methotrexate (MTX, Phase IIb).

Method: The trials were multi-center, randomized, double-blind, parallel group dose-ranging (Phase IIa, n=74) or placebo controlled (Phase IIb, n=223) enrolling patients with active RA who failed MTX treatment. In the Phase IIa study, CF101 was given as a monotherapy, at doses of 0.1mg, 1.0mg or 4.0mg, after one month of washout from MTX. In the Phase IIb, CF101 at doses of 0.1mg, 1.0mg or placebo were added to stable doses of MTX. In both trials, CF101 was given orally, twice daily for 12 weeks. The primary efficacy endpoint was ACR20 response and secondary end point were ACR 50/70. To evaluate A_3AR protein expression levels in the PBMCs at baseline, blood samples were withdrawn from 18 patients (Phase IIa) and from 60 patients (Phase IIb). A_3AR expression levels were tested by western blot analysis and compared to that of healthy subjects (control).

Results: The Phase IIa study reached, whereas the Phase IIb study missed the primary efficacy end points. A_3AR expression levels at baseline were up-regulated in the Phase IIa and similar to control in the Phase IIb (2.46±0.0.398 and 1.29±0.125 fold vs. control, respectively).

Conclusion: A_3AR over-expression at baseline in the Phase IIa study was found to be directly correlated to the success of the response, whereas in the phase IIb study low A_3AR expression levels were associated with lack of response. It thus seems that A_3AR can be utilized as a biological marker to predict patient response to CF101.

Decline of Mean Initial Prednisone Dose From 10.3 Mg/Day in 1980-1985 to 3.6 Mg/Day in 2000-2004, with Similar Efficacy Over 12 Subsequent Months. Theodore Pincus[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: To analyze the initial prednisone dose in 308 patients with rheumatoid arthritis (RA) treated between 1980 and 2004, in 5-year periods, and to assess efficacy in patients whose initial prednisone dose was <5 or □ 5 mg/day according to change in scores for functional status, pain and RAPID3 on a multidimensional health assessment questionnaire (MDHAQ) over 12 subsequent months.

Method: A database was maintained from 1980-2006 on all patients seen in a weekly academic rheumatology setting, which includes medications, laboratory tests, and scores at each visit for physical function (FN) and pain (PN) on a MDHAQ. Patient global estimate of status (PTGL) was added in 1996. Most patients took methotrexate or other disease-modifying anti-rheumatic drugs (DMARDs) in addition to low-dose prednisone therapy. All RA patients seen from 1980-2004 were analyzed for the dose at the first visit with recorded prednisone therapy. The proportion of patients whose initial dose was <5, 5 and >5 mg/day was computed in 5-year periods: 1980-84, 1985-98, 1990-94, 1995-99, 2000-04. Mean changes in MDHAQ scores for FN, PN and RAPID3-estimate (RAPID3-EST: FN and PN without PTGL) over 12 months was compared in patients treated with <5 versus □5 mg/day, as few patients received >5 mg/day.

Results: Mean initial prednisone dose was 10.3 mg/day in 1980-84 vs 6.5 mg/day in 1985-89, 5.1 mg/day in 1990-94, 4.1 mg/day in 1995-99, and 3.6 mg/day in 2000-04. The proportion of patients whose initial dose was <5 mg/day was 0, 4%, 23%, 67% and 86% in the 5-year periods, while the proportion initially treated with >5 mg/day was 49%, 16%, 7%, 7% and 3%, and the proportion receiving 5 mg/day was 51%, 80%, 70%, 26% and 10%, in the respective 5-year periods. Overall, scores for FN, PN, and RAPID3-EST fell by 34%, 37% and 37% over 12 months in the group whose initial dose was <5 mg/day, and by 40%, 37% and 38% in patients whose initial dose was □5 mg/day. Substantially better results were seen after 1990, possibly associated with early concomitant methotrexate in most patients.

Year first seen	N	Mean (median) initial dose: mg/d	Percentage of patients taking initial dose: mg/d			Percent clinical change over 12 months*					
						Initial dose <5 mg/d			Initial dose ≥5 mg/d		
			<5	=5	>5	FN	PN	RAPID3-EST	FN	PN	RAPID3-EST
1980-84	37	10.3 (5)	0	51%	49%	--	--	--	+33%	+25%	+28%
1985-89	74	6.5 (5)	4%	80%	16%	–5%	–8%	–24%	+45%	+42%	+43%
1990-94	77	5.1 (5)	23%	70%	7%	+26%	+43%	+38%	+44%	+44%	+42%
1995-99	61	4.1 (3)	67%	26%	7%	+33%	+30%	+37%	+27%	+19%	+25%
2000-04	59	3.6 (3)	86%	10%	3%	+37%	+41%	+39%	+25%	+25%	+30%
TOTAL	308	5.6 (5)	37%	50%	13%	+34%	+37%	+37%	+40%	+37%	+38%

* "+" indicates improvement and "–" worsening in function and pain scores

Conclusion: The mean initial prednisone dose fell by more than 50% over a 25-year period, without significant differences in efficacy between patients receiving <5 versus □ 5 mg/day. Many patients with RA can be treated with doses of prednisone of <5 mg/day.

Disclosure: T. Pincus, None; **C. J. Swearingen**, None.

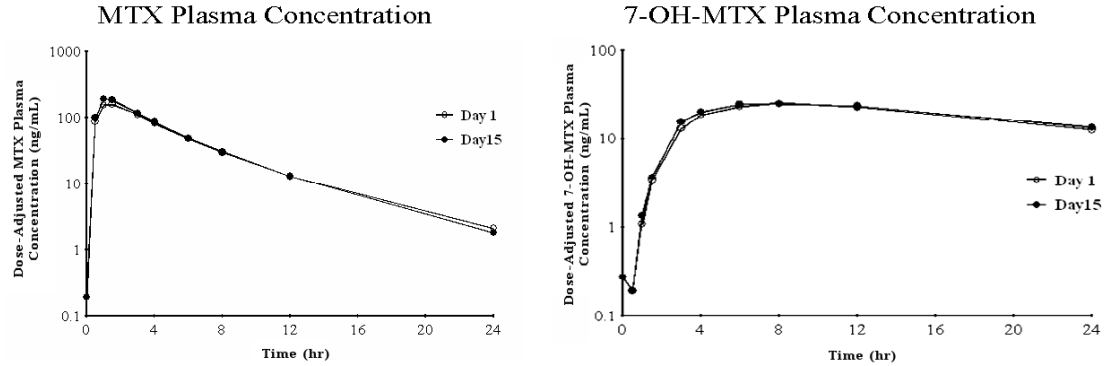
426

Co-Administration of the Oral S1P-Lyase Inhibitor LX2931 with Methotrexate Was Well Tolerated Over 14 Days in Patients with Stable Rheumatoid Arthritis. Roy Fleischmann[1], Kenny S. Frazier[2], Joel Freiman[2], Barbara Brooks[2], Tamas Oravecz[2], David Augeri[3], Michael Kelly[2] and Philip Brown[2], [1]Metroplex Clinical Research Center, Dallas, TX, [2]Lexicon Pharmaceuticals, Inc., The Woodlands, TX, [3]Princeton, NJ

Purpose: Sphingosine-1-phosphate (S1P) is a lipid metabolite affecting lymphocyte trafficking; the major route of S1P degradation is via S1P lyase (S1PL). Mice with reduced S1PL activity have significantly reduced circulating lymphocytes as a consequence of increased S1P content in lymphoid tissues. LX2931 (LX3305), an oral small molecule inhibitor of S1PL, is being developed as a potential therapeutic for autoimmune and inflammatory disorders. LX2931 exhibited significant activity in reducing the inflammatory response in preclinical arthritis models in the mouse and rat. In addition, co-administration of LX2931 with methotrexate (MTX) in the rat model revealed improved pharmacology over monotherapy alone.

Method: LX2931 (120 mg po QD) was evaluated in a randomized, double-blind, placebo controlled, study in 15 subjects (12 active, 3 placebo) diagnosed with stable rheumatoid arthritis (RA) to evaluate the PK, PD, safety and tolerability of co-administration with MTX. The study was conducted at a single center with all subjects receiving MTX at a stable dose between 7.5-25 mg per week.

Results: Co-administration of MTX with LX2931 was well tolerated over 14 days of dosing in patients with stable RA. The most commonly occurring adverse events included headache (26.7%), abdominal pain (20.0%), and nausea (20.0%). Among the abdominal pain events, one was mild and occurred while on study drug, two were mild to moderate and occurred after the last study dose. There were no clinically significant trends observed in laboratory values, vital signs, or electrocardiograms. No clinically significant changes in either MTX or LX2931 kinetics were observed (Figure). Slight increases in MTX $AUC_{(0\text{-last})}$, and C_{max} were observed at Day 15 with no changes in 7-OH-MTX or LX2931 PK.



Conclusion: Co-administration of LX2931 with MTX in patients with stable RA over 14 days was well tolerated with no clinically significant PK, PD, or safety interaction. These observations combined with preclinical and Phase 1 studies in healthy volunteers indicate that inhibition of S1PL by LX2931 may represent a new mechanism for immune modulation and justify further clinical development of LX2931 as a potential small molecule therapy for RA and other autoimmune and inflammatory disorders.

A Randomised, Single-Blind, Placebo-Controlled Dose Escalation Study to Investigate the Safety, Tolerability and Pharmacokinetics of a Single Intravenous Infusion of GSK315234 in Healthy Volunteers. Mark B. Baker[1], Marina Bendit[2], Andrea M. Campanile[2], Maria Feeney[3], Peter Hodsman[4] and John F. Toso[2], [1]GlaxoSmithKline, London, United Kingdom, [2]GlaxoSmithKline, King of Prussia, PA, [3]GlaxoSmithKline, Stevenage, United Kingdom, [4]Nucleus Network, Melbourne, Australia

Purpose: GSK315234 is a humanised IgG1 monoclonal antibody (mAb) against human Oncostatin M (OSM) and is being developed for the treatment of rheumatoid arthritis (RA). GSK315234 blocks the interaction of OSM with its cell surface signaling receptor, gp130. Oncostatin M is a member of the interleukin (IL)-6 family of secreted cytokines and is present in the inflamed synovium and blood of patients with RA. Preclinical data indicated that OSM drives pro-inflammatory responses and induces the production of acute phase reactants. OSM also drives cartilage degradation. This study will provide baseline safety, tolerability, pharmacodynamic and pharmacokinetic information in a healthy volunteer population which will enable the identification of well tolerated effective doses to be used in subsequent clinical studies.

Method: This was a single-blind, placebo-controlled, dose-escalation study in healthy volunteers (males and females of non childbearing potential). Single ascending intravenous doses of GSK315234 (0.003–30 mg/kg) were administered. Assessments included safety/tolerability, pharmacokinetics and pharmacodynamics.

Results: Seventy two subjects were dosed (48 with active and 24 with placebo) and 66 completed the study. There were no remarkable vital signs, electrocardiogram (ECG), hematology and chemistry changes or infusion reactions. There were clinically observed effects on platelets that matched the predictions of models of the preclinical data. A dose response relationship was observed indicating a maximal effect of a 23% reduction in platelets at the highest exposure of GSK315234. A pharmacodynamic analysis showed that the total OSM levels had a non-linear relationship to drug concentrations and could be modeled using an indirect response model (IC_{50} for the relationship to be 5 mg/mL and $t_{1/2}$ ~30min). The pharmacokinetics of GSK315234 was as expected and similar to other monoclonal antibodies of the same class (clearance 3.5mL/day/kg).

Conclusion: GSK315234 showed to be safe and well tolerated in healthy volunteers. Observation of platelet pharmacology clearly defines a broad therapeutic interval allowing a choice of doses that can be determined to cause no haematological adverse effects. It also provides proof that the binding of OSM and the elevation of total OSM has downstream consequences on OSM mediated pharmacology. The low clearance of GSK315234 would allow infrequent dosing and regimes similar to other mAbs in the clinic. This data, in combination with preclinical data, confirms OSM blockade by GSK315234 as a rheumatoid arthritis therapy worthy of further investigation.

Convincing Pharmacological Effects On Inflammation and Pain by Targeting the 5-HT_2 Receptors. C. Wenglén[1], G. Ekström[1], H. Arozenius[1], M. Siller[1], N. Palmqvist[1], A-C. Ryde[1], A. Sjödin[1], C. Klint[1], C. Flood[1], E. Seifert[2], A. Boman[2], P. Lek[2] and T. Lundstedt[2], [1]AnaMar Medical AB, Lund, Sweden, [2]AcurePharma AB, Uppsala, Sweden

Purpose: At inflammatory sites thrombocytes, the major source of peripheral serotonin (5-HT), accumulate and become activated. Thus, in the arthritic joints 5-HT is released into the synovial fluid where it boosts the inflammatory response by binding to 5-HT receptors on synovial cells. We have developed several compounds targeting the 5-HT_2 receptors. The compounds are structurally diverse, have different binding characteristics and pharmacological profiles. They have previously been shown to reduce IL-6 and TNF-α production *in vitro* and to diminish arthritis activity in two different animal models. The objective of the present study was to (1) further give evidence to that the effects of our compounds are mediated by antagonizing the 5-HT_2 receptors, (2) show effects of our compounds during ongoing inflammation in glucose-6-phosphate isomerase (GPI)-induced arthritis in the mouse, a third animal model of RA, (3) evaluate our compounds in an inflammatory pain model. Recently, one of our compounds entered the first tolerability and kinetic evaluation in a phase I clinical trial.

Method: The 5-HT_2 receptor expression pattern on our target cells was evaluated by RT-PCR. *In vitro* our compounds were added to rat synoviocytes together with commercial 5-HT_2 agonists to investigate their effects on IL-6 release. In GPI-induced arthritis, DBA/1 mice were immunized with rabbit GPI. The mice were orally treated with our compound AMAP102 (10 and 30 mg/kg) once daily and scored for arthritis. To investigate the effect of the compounds on inflammatory pain, AMAP102 and AMAP312 (1, 10 and 30 mg/kg) were orally administered to rats before injection of formalin into one of the paws. Nociceptive responses to the formalin injection that occurs in two phases were measured. The first phase is caused by the direct stimulation of nerve ends by formalin and the second represents the pain response to the inflammatory reaction.

Results: *In vitro* target validation experiments showed that the 5-HT_2 receptors are expressed on our target cells and that our compounds reverse the effects induced by selective 5-HT_2 agonists and thus likely act through the 5-HT_2 receptors. AMAP102, was shown to reduce

severity in the GPI-induced arthritis model, even when treatment was initiated after the first manifestations of disease. Finally, compounds from two different chemical classes, significantly reduced the inflammatory pain response at 1-30 mg/kg, without significantly influencing the first part of the nociceptive response.

Conclusion: The present study shows that impressive anti-arthritic effects are established by antagonizing the 5-HT_2 receptors with our proprietary compounds. In addition, the sensitivity to inflammatory pain is diminished. In conclusion, the study supports the clinical development of our compounds targeting the 5-HT_2 receptors.

Drug Survival Time and Safety On Tocilizumab: Does Tocilizumab Differ From Anti-TNF Agents in Routine Practice? Kazuki Yoshida[1], Yasuharu Tokuda[2], Tsuyoshi Iida[1], Kaori Hosaka[1], Masako Utsunomiya[1], Tatsuo Kobayashi[1], Makiko Yamamoto[1], Kazuo Matsui[1] and Mitsumasa Kishimoto[1], [1]Kameda Medical Center, Kamogawa, Chiba, Japan, [2]University of Tsukuba, Tsukuba, Japan

Purpose: To compare the difference between Tocilizumab (TCZ) and anti-TNF agents (TNFs) on safety and drug survival time

Method: We studied a cohort of RA patients participating in the **KA**meda **RA T**NF inhibitor and Tocilizumab **E**ffectiveness and safety (KARATE) registry from Jan/2003 to Jun/2009. We examined the rate of serious adverse events (SAE: defined as use of IV antibiotics or hospitalization) between TCZ and TNFs in patients with at least 3 months follow-up. Baseline characteristics associated with SAE were analyzed by logistic regression model. Kaplan-Meier drug survival estimates at 6 and 9 months of the cohort were analyzed and hazard ratios of discontinuation were determined using Cox proportional hazard model.

Results: Baseline characteristics: We enrolled and analyzed 182 consecutive patients who received TCZ (n=26) and TNFs (n=156, IFX 88, ETN 64, ADA 4) in KARATE. For baseline characteristics, previous TNFs use (TCZ group 65% vs. TNFs group 10%, $p<0.001$) was significantly different between the two groups. There were no significant differences between the two groups for age (59 vs. 58 yrs for the TCZ and the TNFs groups, respectively), RF/anti-CCP positivity (81 vs. 87%), disease duration (8.6 vs. 7.9 yrs), mean baseline DAS28 (3) (3.6 vs. 3.5), mean steroid (PSL equivalent) dose (7.0 vs. 7.3 mg/day), MTX use (96 vs. 88%), diabetes (12 vs. 15%), COPD or ILD (0 vs. 12%, p=0.08), and chronic kidney disease (12 vs 3%, p=0.09).

SAE: No serious adverse events were observed in TCZ users, while 23 patients (15%) in TNFs users developed SAE (p=0.049, vs. TCZ) including 16 infections (7 bacterial pneumonia, 2 UTI, 1 cryptococcal pneumonia, MAC infection, septic arthritis, cellulitis, Listeria bacteremia, sepsis, and PCP), 1 AMI, 4 ILD exacerbation, 1 lung cancer, and 2 GI complications. Among baseline factors, age > 65 yrs (odds ratio, 2.8; 95% CI, 1.0 -7.6) was significantly associated with SAE.

Drug Survival: There was no significant difference in drug survival time between TCZ and TNFs (log rank test, p=0.77). At six and nine months, 90 and 81% of patients remained on TCZ and 83% and 78 on TNFs. The reason for discontinuation in all patients who discontinued TCZ (n=4) was for lack of efficacy. In TNFs users (n=86), the reasons for discontinuation included: lack of efficacy (35%), side effect (29%), MD preference (14%), patient preference (12%), good response (8%), and others 2%. There was a trend for higher risk of discontinuation of both TCZ and TNFs with age >65 yrs (hazard ratio [95% CI] 1.59 [0.97-2.60], p=0.06).

Conclusion: This study on patients treated in routine clinical practice indicates that drug survival time was comparable between TCZ and TNFs. TCZ may be safer than TNFs, although these results require further long term studies.

Improvement of Cardiovascular Risk Markers with Atorvastatin Treatment in Rheumatoid Arthritis. Lotta Ljung[1], Marjatta Leirisalo-Repo[2], Hannele Yki-Järvinen[2], Riitta Koivuniemi[2], Antti Kuuliala[2], Kjell Karp[1], Solbritt Rantapää-Dahlqvist[1] and Robert Bergholm[2], [1]Norrland University Hospital, Umeå, Sweden, [2]Helsinki University Central Hospital, Helsinki, Finland

Purpose: To evaluate the effect of treatment with statin on endothelial function, arterial intima-media thickness, arterial distensibility, disease activity and lipid levels in moderately active, established rheumatoid arthritis (RA).

Method: 51 patients with RA were recruited for the study and received atorvastatin 40 mg daily (n=36, 26 women, 10 men) or placebo (n=15, 10 women, 5 men) for 24 weeks. DMARDs and oral corticosteroid treatments were kept stable during study period. Ultrasound performed measurements of common carotid artery intima-media thickness (IMT) and distensibility, brachial artery flow-mediated dilatation (FMD) and glyceryl trinitrate-dependent brachial artery responses (GTN), as well as clinical activity variables and serum lipid levels were obtained immediately before and after the 24-week period.

Results: The recruited patients had a mean (±SD) age of 60 (± 11) years, a mean disease duration of 17 (±10) years and a mean (± SEM) disease activity score (DAS28) at start of study of 4.20 (± 0.16). The groups were comparable regarding FMD, GTN, distensibility and total cholesterol/high density cholesterol (HDL) ratio at start of study.

FMD improved significantly in the statin treated group (5.5 ± 0.6 vs. 7.3 ± 0.6 %, p=0.02). FMD/GTN increased (0.41 ± 0.05 vs. 0.61 ± 0.09, p=0.04). No change was seen in the placebo group in the FMD or GTN measurements. The distensibility remained unchanged in the treated patients, but decreased in the placebo group leading to a significant difference of delta values between the groups (p=0.01). No change in pulse rate, systolic or diastolic blood pressure was seen in either group. An insignificant tendency towards a decrease in IMT was seen in the statin group (p=0.08).

DAS28 improved significantly in both groups, (-0.78 ±0.14, p<0.001 in statin, vs. -0.59 ±0.27, p=0.05, in placebo), but significant improvement of ESR (-7.5 ±1.7 mm, p<0.001) and CRP (-5.5 ± 1.6 mg/l, p=0.001) were only seen in the treated patients.

The atherogenic index; total cholesterol/HDL ratio, improved in the statin treated group (1.0 ± 0.1, p<0.001), and remained unchanged in the placebo group.

Conclusion: Our data suggests that treatment with atorvastatin may improve several markers of cardiovascular risk or atherosclerosis, as endothelial dysfunction, dyslipidemia and inflammatory laboratory parameters in established, moderately active RA.

Phase I Single and Multiple Ascending Dose Studies to Investigate the Safety, Tolerance and Pharmacokinetics of CH-4051 in Healthy Male Subjects. Aletha Veenendaal[1], John Boland[2] and Lawrence A. Hewitt[2], [1]Kendle International, Utrecht, Netherlands, [2]Chelsea Therapeutics, Charlotte, NC

Purpose: Methotrexate (MTX) is the gold standard treatment for rheumatoid arthritis. However its use is frequently limited by common side effects including hepatotoxicity, nephrotoxicity, and gastrointestinal distress (nausea and diarrhea). It is hypothesized that a significant proportion of the toxicity profile of MTX is attributed to its hydroxylated and polyglutamylated metabolites. Therefore, an antifolate that is metabolically stable, that does not convert to toxic metabolites, yet maintains the efficacy of MTX should prove to be a superior therapy.

CH-4051 is a metabolically stable antifolate and is the more potent “L” isomer of the racemic mixture CH-1504. In a recent double-blind, randomized phase II study in MTX naive RA patients, CH-1504 in the dose range of 0.25 to 1.0 mg QD showed comparable efficacy to MTX and a better safety profile.

It is our proposition that CH-4051 will demonstrate superior efficacy and safety to MTX. As such we conducted a phase I study of the safety, tolerance and pharmacokinetics (PK) of single and multiple doses of CH-4051 in a single-center, double-blind, randomized, clinical trial.

Method: This study was conducted in accordance with ICH/GCP guidelines by Kendle International Utrecht, The Netherlands following favorable opinions from an Independent Ethics Committee and national Competent Authority.

This study consisted of a Single Ascending Dose (SAD) trial followed by a 14 day Multiple Ascending Dose (MAD) trial. In both SAD and MAD portions of the study 4 groups of healthy male volunteers were studied. Six subjects per group in the SAD and 8 subjects per group in the MAD were randomized 5:1 and 6:2 respectively to CH-4051 or placebo p.o. Doses tested were 5, 10, 20 and 40.0 mg in the SAD and 5, 7.5, 10, and 20 mg in the MAD. Subjects remained under clinical supervision for the duration of the dosing and PK collection periods. Dose

escalation occurred following a review of the previous group's safety and tolerance data. Safety assessments included: AEs, hematology, serum biochemistry, urinalysis, vital signs, physical examination and ECG.

Results: There were no serious AEs in either study; no AE was definitively attributed to CH-4051and all possibly related AEs resolved with cessation of dosing. In the SAD study no AEs led to study discontinuation or major intervention. In the MAD study, 7 AEs in 5 subjects led to study discontinuation at higher doses. These AEs included blepharitis, upper abdominal pain and vomiting, increased ALT and AST, and an unconfirmed case of melena. With respect to PK parameters; T_{max} occurred ~1-2h post dose and $T_{1/2}$ was approximately 4 h. C_{max} increased in a greater than dose proportional manner from 5 to 10 mg and a less than dose proportional manner from 10 to 40 mg.

Conclusion: CH-4051 was safe and well tolerated in a single dose up to 40.0 mg and multiple doses up to 7.5 mg daily for 14 days. PK parameters indicate CH-4051 is suitable for daily dosing.

DAS28 and RAPID3 Based On Patient Questionnaire Scores Are More Likely Than ESR to Indicate a Quantitative Abnormality at Initiation of Methotrexate Therapy, to Monitor Improvement in Status in 201 Patients with Rheumatoid Arthritis. Theodore Pincus[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: To identify the likelihood of an abnormal value for 6 quantitative measures in 201 patients with rheumatoid arthritis (RA) at initiation of methotrexate (MTX) treatment in usual care. The 6 measures were: erythrocyte sedimentation rate (ESR); multidimensional health assessment questionnaire (MDHAQ) scores for function (MDHAQ-FN), pain (PN) and patient global estimate (PTGL); RAPID3 (routine assessment of patient index data); and disease activity score (DAS28). We compared the 6 measures at initiation of MTX in 201 patients with RA who began MTX therapy between 1980 and 2004.

Method: All patients seen between 1980-2004 at a weekly academic rheumatology clinic completed a MDHAQ at each visit, which included scores for MDHAQ-FN (0-3, converted to 0-10 for RAPID3) and PN (0-10) since 1980, and after 1996, PTGL (0-10), and capacity to score RAPID3 (0-30). Most patients with RA also had an ESR measured on the date of initiation of MTX therapy, and many unselected consecutive patients at different periods had a swollen joint count and tender joint count to allow calculation of a DAS28. Abnormal values were ESR $\geq$ 28 mm/h, MDHAQ-FN (0-3) >0.5, PN and PTGL (0-10) >2, RAPID3 scores (0-30) >6, indicating moderate or high (>12) severity, and DAS28 scores >3.2, indicating moderate or high (>5.1) activity. RAPID3-EST, i.e., RAPID3 without PTGL (correlated with RAPID3 at rho $\geq$ 0.9), was calculated for patients seen prior to 1996. The proportion of patients with abnormal vs normal values for these measures at the visit when MTX was initiated was analyzed. ESR from the previous visit was available in 64 of the 201 patients, and was examined to determine if an abnormal ESR may have been more likely at that visit than on the date of MTX initiation.

Results: Among 201 RA patients on the date of MTX initiation, abnormal values were seen for ESR in 49% of patients, compared to 70% for MDHAQ-FN, 85% for PN, 82% for PTGL and RAPID3, 83% for RAPID3-EST, and 87% for DAS28. Median ESR was 27, suggesting that ~50% of patients would not meet inclusion criteria for clinical trials. Median DAS28 was 5.0, suggesting that almost 50% of patients had DAS28 high activity (>5.1). Median RAPID3 was 12.9 and RAPID3-EST 13.3, suggesting that slightly more than 50% of patients met the criterion for RAPID3 high activity (>12). No meaningful differences were seen according to ESR at the previous visit.

Measures and indices in 201 RA patients at initiation of MTX: median values, and % of patients with normal vs abnormal values

Measure (range)	Median	Definition of abnormal	% Normal	% Abnormal
ESR (0-150 mm/h)	27	≥ 28	50.8%	49.3%
MDHAQ-FN (0-3)	1.0	> 0.5	29.9%	70.1%
PN (0-10)	5.1	> 2	15.0%	85.0%
PTGL (0-10)	5.0	> 2	17.9%	82.1%
RAPID3 (0-30)	12.9	> 2	18.2%	81.8%
RAPID3-EST (0-30)	13.3	> 2	16.9%	83.1%
DAS28 (0-10)	5.0	> 3.2	13.5%	86.5%

Conclusion: ESR was considerably less likely than any other Core Data Set measure or DAS28 or RAPID3 to be abnormal in patients with RA at the time of initiation of MTX. Textbooks continue to suggest ESR "is increased in nearly all patients with active RA" (Lipsky PE. In: Fauci et al, *Harrison's Rheumatology.* New York: McGraw-Hill; 2006. p 85), although ESR has been reported to be normal in 40% of RA patients at presentation (Wolfe F, Michaud K, *J Rheumatol* 1994;21:1226-37 and Sokka T et al, *J Rheumatol* 2009 epub). Patient MDHAQ/RAPID3 scores are easily collected in standard clinical care, and appear more useful than ESR in many patients to monitor status quantitatively and to document possible improvement in clinical status over time in patients with RA.

Cholesterol 27-Hydroxylase but Not Apolipoprotein E Contributes to A2A Adenosine Receptor Enhanced Reverse Cholesterol Transport. Taiese C. Bingham[1], Saj Parahath[2], Allison Reiss[3], Edwin S. L. Chan[4], Edward Fisher[1] and Bruce N. Cronstein[5], [1]NYU School of Medicine, New York, NY, [2]Winthrop-University Hospital, Mineola, NY, [3]Winthrop University Hospital, Mineola, NY, [4]New York University School of Medicine, New York, NY, [5]New York Univ Med Ctr, New York, NY

Purpose: Unlike other DMARDs methotrexate diminishes the risk of Atherosclerotic Cardiovascular Disease (ASCVD) in patients with Rheumatoid Arthritis and adenosine, acting at adenosine A2A receptors, has been shown to mediate the anti-inflammatory effects of methotrexate. Adenosine inhibits the first step in formation of atherosclerotic plaque, foam cell formation in macrophages and this effect appears to be mediated by enhanced expression of cholesterol 27-hydroxylase, an enzyme involved in reverse cholesterol transport. We therefore asked whether the effect of adenosine A2A receptors on foam cell formation in vitro are mediated by apoE or 27-hydroxylase (27OH'ase), proteins involved in reverse cholesterol transport.

Method: THP-1 cells, a human monocytoid cell line, were infected with lentiviral vectors expressing siRNA for either apoE or 27OH'ase or scrambled RNA and infected cell lines were selected by incubation with puromycin. Foam cell formation was induced in THP-1 cells by incubation with interferon-γ (500U/ml) and % foam cells enumerated in 5 high power fields. 3H-Cholesterol efflux was measured after loading with label.

Results: Specific lentiviral siRNA infection markedly reduces apoE ($p < 0.0001$, apoE siRNA vs. control, n=3) or 27OH'ase mRNA ($p < 0.0001$, 27-hydroxylase siRNA vs. control, n=3) and protein ($p < 0.0107$, 27-hydroxylase siRNA vs. control n= 3) in THP-1 cells. Despite diminished apoE expression CGS-21680 (1μM), an adenosine A2A receptor agonist, inhibits IFNγ-induced foam cell formation ($p < 0.0002$, IFNγ CGS vs. IFNγ alone, n= 4) but has no effect on foam cell formation in 27OH'ase KD cells. CGS21680 increases cholesterol efflux in wild type and apoE1 KD cells (from 9.5% to 17.5+2.5% and from 10.0+2% to 17.5 +2%, respectively) but not 27OH'ase KD cells.

Conclusion: Adenosine A2A receptor-mediated increases in reverse cholesterol transport leading to diminished foam cell formation explains the anti-atherosclerotic effects of methotrexate.

Clinical Control Induced by Epitope Specific Therapy in Rheumatoid Arthritis Is Associated with T-Cell Immune Deviation From Pro-Inflammatory (Th1/Th17) to Regulatory Phenotype (Th2/Treg). Th. van den Broek, N. Schechter, C. Cover, N. Seaver and Salvatore Albani, Arizona Arthritis Ctr, Tucson, AZ

Purpose: Immune therapy in a Phase II, placebo controlled trial in rheumatoid arthritis patients with a pro-inflammatory epitope from the heat shock protein dnaJ (dnaJP1, s5 mg qd op for six months) led to clinical improvement and to a tolerogenic immune deviation. Differences in immune function could be found at trial entry between responders and non responders in the dnaJP1 treatment group. Immune phenotype comprising of the co-expression of anergic/tolerogenic co-stimulatory molecules PD-1, CTLA-4, B7H-1 and FoxP3 was found as a pre-requisite for responsiveness. Clinical efficacy correlated with a reduction in TNFα by T cells to dnaJP1 in vitro. To further dissect the mechanisms of immune deviation, we analyzed the T cell lineage commitment (TH1/TH17 versus TH2/tolerogenic) and suppressive function of isolated T cell populations.

Method: Clinical responders (ACR20 response) treated with dnaJP1 (n=3) or Placebo treated clinical non-responders (n=5) were used. PBMC from time points T0 and Tend were cultured with dnaJP1 or anti-CD3CD28. T cells were enriched by MACS, then FACS sorted by CD4CD127+ (Teff) and CD4CD25+CD127- (Treg). Both populations were used for TaqMan real-time PCR analysis and CFSE suppression assay data. An aliquot of Teff was used for FACS analysis.

Results: DnaJP1 treated clinical responders downregulated TH17 associated markers, IL23R, IL12R and intracellular IL17A, in Teff cells at Tend, as measured by FACS. No differences were seen between T0 and Tend with placebo treated clinical non-responders. With dnaJP1 treated clinical responders, gene expression by TaqMan confirmed the downregulation of TH17 markers, RORC ($p<0.05$) and IL17A. Besides diminished Th17 phenotype, a deviation in cell lineage from a Th1 to a Th2/tolerized cell type was seen in Teff as evidenced by downregulation of Tbet and TNFα, and an upregulation of GATA-3 and IL-10 production. Treg cells from Tend showed superior suppression of Teff over Tregs isolated at T0 from dnaJP1 treated clinical responders (11.88% vs 39.32% Teff suppression, n=2).

Conclusion: Immune therapy with dnaJP1 led to clinical improvement and immune tolerance induction. These data suggest that clinical control in response epitope-specific therapy is mediated by an immune deviation in T cell lineage commitment of Teff from a proinflammatory (TH1/TH17) to a tolerogenic (TH2/tolerized) phenotype, as well as increased suppressive capability of Treg.

Clinical Control in Patients with Rheumatoid Arthritis Is Associated with Restoration of Diverse Subpopulations of Regulatory T Cells, Including a Novel Subtype Relying On the PD1-B7-H1 Pathway. Theo van den Broek, Nicole Schechter, Cathleen Cover, Norma Seaver, Farah Bughio, Nick Shen and Salvatore Albani, Arizona Arthritis Ctr, Tucson, AZ

Purpose: We focused on different subtypes of regulatory T cells discriminated by membrane markers, including the co-expression of PD-1, an otherwise well established marker of anergy. In preliminary studies we found PD-1 to be increased in T cell from patients who respond to the various therapies described here. PD-1 ligand B7H1 was also elevated in APC from the same responsive patients. We employed two systems.

Method: PBMC from 5 rheumatoid arthritis patients treated with epitope specific tolerization to a pro-inflammatory peptide (dnaJP1) in a Phase II trial.,were compared at trial entry (T0) and at the end (Tend). All the patients reached an ACR20 response at the end of the 6 month trial. A second system employed 6 patients on ETN and MTX,(n=3) or MTX alone (n=3). Clinical control was determined as a DAS-score of <3.2 (n=4)

The following T cells were sorted by FACS, CD4CD127+ (Teff), CD4CD25+CD127- (nTreg), CD4CD25+CD127-PD1+ (PD1+ Treg), CD4CD25+CD127-PD1- (PD1- Treg) and CD4CD25-CD127-PD1+ (CD4+PD1+). Gene expression was studied by TaqMan real-time PCR. CFSE suppression assay was used to determine the capability of Treg to suppress Teff proliferation.

Results: In both systems the expression of IL-10 was only upregulated in PD1+ Treg and CD4+PD1+. Clear differences were seen between the different Treg populations, especially in the ETN group and the dnaJP1 treated group. In these groups, PD1+ Treg have a higher expression of TGFBeta, and the opposite is observed for the PD1- Treg.

Suppression did differ between the different Treg groups. PD1-Treg and CD4+PD1+ suppressed the most (86-92% Teff suppression), followed by nTreg (78-82%) and PD1+ Treg (76-79%). With dnaJP1 therapy nTreg suppressed the most (63.74%), followed by PD1+ Treg (57.09%), CD4+PD1+ (26.45%) and PD1-Treg (1.62%).

% of suppression	Etanercept and Methotrexate	dnaJP1 T0	dnaJP1 Tend
CD4CD25+CD127- (nTreg)	78-82%	11.41%	63.74%
CD4CD25+CD127-PD1+ (PD1+ Treg)	76-79%	61.22%	57.09%
CD4CD25+CD127-PD1- (PD1- Treg)	86-92%	1.37%	1.62%
CD4CD25-CD127-PD1+ (CD4+PD1+)	86-92%	1.85%	26.45%

Conclusion: We examined diverse regulatory T cell populations and identified a novel type of Treg cell expressing PD1+ that is not anergic but shows suppressive capability with distinct functional differences between non-PD1 expressing cells. The induced expression of B7-H1 on APCs seen with clinical response might be the trigger for the generation of this specific Treg population. These data suggest the existance of novel circuit of active immune tolerization which seems relevant to clinical improvement.

Glucocorticoids Decrease the Expression of Synovial Citrullinated Proteins in Rheumatoid Arthritis. Dimitrios Makrygiannakis, Shankar Revu, Petra Neregård, Marianne Engström, Lars Klareskog and Anca Irinel Catrina, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden

Purpose: Citrullination has previously been reported to be an inflammation associated process. Peptidylarginine deiminase (PAD) 2 and 4 are the PAD enzymes expressed in the rheumatoid arthritis (RA) synovium, while a mouse monoclonal antibody (F95) has been found to be associated with an intracellular pattern which is specific for RA synovium and which correlates with anti-citrullinated-protein antibody levels. The aim of the current study was to compare the expression of PAD2, PAD4 and citrullinated proteins between RA and healthy synovium and to study the effect of anti rheumatic drugs on synovial expression of CP and PAD enzymes. (MTX), infliximab (IFX) and etanercept (ETA) on PAD2, PAD4 and F95 expression in RA synovium.

Method: Synovial biopsies were obtained from 15 RA patients treated with intra-articular glucocorticoids (IAG), 13 RA patients treated with methotrexate (MTX), 9 RA patients treated with infliximab (IFX) and 13 RA patients treated with etanercept (ETA). Synovial tissue was also obtained from 8 healthy individuals. The presence of PAD2 and PAD4 was immunohistochemically detected with 2 rabbit polyclonal antibodies for each enzyme and the presence of citrullinated proteins with the F95 antibody. Biopsies were evaluated by double blind semi-quantitative analysis on a 4-grade scale (0-3). Additionally synovial tissue from an RA patient obtained during open joint surgery was cultured in vitro to further study the direct effect of the drugs on synovial citrullination. Statistical analysis was performed using the Wilcoxon test.

Results: F95 staining was present in 40/50 RA patients (both extracellular and intracellular) while none of the 8 healthy individuals exhibited an intracellular pattern and only one exhibited an extracellular pattern in low amounts. PAD2 expression was higher in RA in comparison to healthy synovial tissue, while PAD4 expression did not differ.

Treatment with MTX and TNF antagonists did not alter the expression of PAD enzymes and CP, with the exception of a reduction in PAD4 expression (statistical significance with one of the 2 antibodies used) in the IFX treated group. In contrast, IAG treatment resulted in down-regulation of both the expression of intracellular citrullinated proteins (F95) and of the PAD4 enzyme. This finding was confirmed in the cultured biopsy demonstrating no changes in the expression of PAD2 and a decrease of F95 and PAD4 expression following glucocorticoid treatment.

Conclusion: The RA specific pattern of intracellular citrullination is absent in healthy synovium and specific targeted by glucocorticoids.

Open Label Use of Mycophenolate Mofetil in Diffuse Systemic Sclerosis. Max Shenin, Elizabeth Grace, Steffan W. Schulz, Manisha D. Naik, Wen Xiong and Chris T. Derk, Thomas Jefferson University, Philadelphia, PA

Purpose: Mycophenolate mofetil is an inosine monophosphate dehydrogenase inhibitor, that inhibits the proliferative responses of T and B lymphocytes as well as antibody production by B-lymphocytes. Recent studies have also suggested that this agent may also have an anti-fibrotic effect. Based on these actions mycophenolate mofetil appears to be a novel agent for the treatment of systemic sclerosis, especially during early disease where an inflammatory infiltrate precedes the development of fibrosis. We set out to examine the efficacy of this agent in systemic sclerosis.

Method: We recruited 15 patients with early onset diffuse systemic sclerosis to take part in an open label study using mycophenolate mofetil to treat their disease over a 12 months period. The primary outcome measure was the modified Rodnan skin score (mRSS) while secondary outcomes included the Medsger severity score, pulmonary function studies, 2D- echocardiograms and the SF-36 questionnaire.

Result: The mRSS was significantly improved in those patients who tolerated the medication for more than 3 months ($p<0.0001$), and there was statistically significant improvement in the Medsger severity scores of the general ($p=0.05$), peripheral vascular ($p=0.05$) and skin scores ($p=0.0003$). The SF-36 scores were improved ($p=0.05$) and the pulmonary function studies showed a trend towards improvement though not of statistical significance. The mean pulmonary artery pressure by 2D echocardiography did not change.

Conclusion: In this prospective open label study of mycophenolate mofetil for the treatment of early diffuse systemic sclerosis we observed significant improvements in skin scores, peripheral vascular involvement and patient perceived health status. Pulmonary function studies did not worsen as expected but rather showed a trend towards improvement. Controlled trials are needed to further investigate this.

Four-Year Survival in the TRUST Cohort of Bosentan-Treated Patients with Pulmonary Arterial Hypertension Related to Connective Tissue Disease. Christopher P. Denton[1], J. Pope[2], Hans-Hartmut Peter[3], Armando Gabrielli[4], Martin Doelberg[5] and Loic P. Guillevin[6], [1]Royal Free Hospital, London, United Kingdom, [2]St Joseph Health Care, London, ON, [3]Med. Universitätsklinik, Freiburg, Germany, [4]Azienda Ospedaliera Umberto I, Ancona, Italy, [5]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland, [6]Hopital Cochin, Paris, France

Purpose: Pulmonary arterial hypertension (PAH) is a major complication of connective tissue disease (CTD). In the prospective TRUST cohort of 53 patients with PAH-CTD, bosentan therapy was well tolerated and associated with a Kaplan-Meier survival estimate of 92% (95% CI: 85–100) at 1 year, 82% (95% CI: 72–93) at 2 years, and 70% (95% CI: 57–83) at 3 years (1,2). Here we report 4-year survival data from TRUST, which is the last data collection in this cohort.

Methods: Bosentan was administered to patients with PAH-CTD in WHO functional class (FC) III according to product labeling for at least 2 years. Patients were followed for 4 years from treatment start (baseline). Survival and change from baseline in WHO FC (imputed as class IV in case of death) were collected. Probability of survival at different time points was estimated by Kaplan-Meier method.

Results: Of 53 PAH-CTD patients enrolled (mean age 62.7 years, 83% female, 96% Caucasian), 29 patients had limited cutaneous scleroderma (lSSc), 13 diffuse cutaneous scleroderma (dSSc), 6 overlap CTD, and 5 systemic lupus erythematosus. Eight patients had signs of right heart failure at baseline. Mean time from PAH diagnosis was 45.2 weeks at baseline. Twenty-five patients received bosentan monotherapy for more than 2 years from baseline and 15 received bosentan treatment (monotherapy or combination) for at least 4 years. At 4 years, data were available for 36 of the 53 patients. No 4-year data were available for 9 patients who were lost to follow-up (6 of them due to local administrative reasons) and for 8 patients who had their last hospital visit between Year 3 and Year 4. Nineteen patients died by year 4, with an overall survival probability (Kaplan Meier estimate) of 58.3% (95% CI: 43.3–73.2). The percentage of patients with improvement or stabilization of WHO FC from baseline was 40% (95% CI: 23.9–57.9).

Conclusion: A limitation of the present results is that 4-year data were not available for 17 of the 53 patients. Our findings are in accordance with the results reported at the 1-, 2- and 3-year time points of the TRUST cohort (1,2) and are consistent with previously reported data in the PAH-CTD subpopulations of two placebo-controlled trials (3). The observation that all patients were in FC III and some already presented with right heart failure at baseline highlights the PAH severity in this cohort despite potential selection bias. Hence, the observed 4-year survival estimate of 58% in FC III, right heart catheter proven PAH compares favorably with historical data reported after a follow-up of only one year (4).

Progression of Esophageal Dysmotility in Scleroderma. Asia Mubashir[1], Fahd Saeed[2], Mozafareddin Karimeddini[1] and Naomi F. Rothfield[3], [1]University of Connecticut Health Center, Farmington, CT, [2]University of Connecticut Health Center, Farmington, [3]University of Connecticut, Farmington, CT

Purpose: Scleroderma is a multisystem disorder that affects the esophagus in approximately 90 % of the patients. There are no reported studies on the progression of esophageal involvement. The objective of our study was to longitudinally evaluate esophageal transit time in patients with scleroderma.

Method: We did a retrospective chart review of all patients with scleroderma seen by rheumatology faculty at the University of Connecticut Health Center, between 1995 and 2008 .Patients were included if they were greater than 18 years of age and had a total of two or more esophageal transit time (ETT) studies at least one year apart. ETT studies were routinely done yearly on all scleroderma patients. Patients had ETT studies done in upright and supine position and were evaluated for dysmotility in proximal and distal portions for each of the positions. Normal esophageal emptying demonstrates 90% clearance of tracer by 10 seconds and greater than 95% clearance by 30 seconds.

Results: There were 102 patients : Eighty patients (78.4%) had limited scleroderma (LS) and 22 (21.5%) had diffuse scleroderma (DS). 382 esophageal transit time studies were analyzed over 13 years: 293 (76.7%) in LS and 89 (23.3%) in DS. 21 (95.4%) DS patients had worsening dysmotility (mean years 5.6%), 1 patient showed no change. LS, 47 (58.8 %) patients showed progressive worsening (mean years 6), 15 (18.8 %) patients showed no change and 18 (22.5 %) patients had improvement (8.8 mean years).

Conclusion:

Type	Worse	Stable	Improved
Limited	47	15	18
Diffuse	21	1	0

p value (Yates chi square) 0.02

Our study showed a significant difference between limited and diffuse scleroderma. 58.8 % of LS patients worsened whereas 95 % of DS patients worsened. In addition, no DS patient improved and 22.5% of LS improved. (Yates chi square p= 0.02)

A Clinically Defined Subset of dcSSc Is Associated with Elevated Serum IL-6 Level. Voon Ong, Svetlana Nihtyanova, Carol M. Black and Christopher P. Denton, Royal Free Hospital, London, United Kingdom

Purpose: IL-6 is a pleiotropic cytokine and it has been implicated in SSc pathogenesis. We analysed the relationship between serum IL-6 levels and the inflammatory response and modified Rodnan skin score (mRSS) in SSc. Based upon the known stimulatory effect of IL-6 on thrombopoiesis, we also hypothesised that a subgroup of diffuse cutaneous systemic sclerosis (dcSSc) patients with elevated platelet counts might have higher levels of IL-6.

Method: This was a cross-sectional study of SSc patients and healthy controls. These include three subgroups of SSc cases: dcSSc with high platelets (n=20, mean platelet count: 458 x 10^9/L, IQR: 418-508), dcSSc with normal platelets (n=19, mean platelet count: 276 x 10^9, IQR: 242-313), limited cutaneous SSc(lcSSc) (n=22, mean platelet count: 264 x 10^9, IQR: 227-297) and 15 controls. Serum IL-6 and soluble IL-6 receptor (sIL-6r) levels (in pg/ml) were determined by ELISA. Associations between serum IL-6 and CRP, platelet count, peak and concurrent skin score were determined by Pearson's correlation coefficient. IL-6 levels were subdivided into three categories: High (>10 pg/ml), Low (<10 pg/ml and > 3.12 pg/ml) and undetectable (below quantitation limit, < 3.12 pg/ml). Categorical data were analysed by Chi-square test.

Results: A majority of the cases were female: 77% and 96% in dcSSc and lcSSc respectively compared to 53% in controls. The age of the subjects was similar in all cohorts (mean±SD, years): 55.1±10.3 dcSSc, 59.1±11.4 lcSSc and 53.7±11.4 controls. Duration of disease (mean±SEM,months) for lcSSc and dcSSc was 152.6±23.9 and 52.4±7.0 respectively. Disease duration (mean±SEM,months) was longer in dcSSc with elevated platelets (57.0±11.9) than those with normal platelets (47.3±6.9).

IL-6 levels were significantly elevated in 55% of the dcSSc cohort with thrombocytosis compared to only 21% of the dcSSc cohort with normal platelets ($p<0.001$). In contrast, a majority of the lcSSc (75%) and control (87%) cohorts had undetectable IL-6 levels. Moreover, IL-6 levels were positively correlated with platelet count in SSc ($r=0.5$, $p<0.001$). However, there were no significant differences in sIL-6R levels across all cohorts ($p=0.16$) and no correlation was observed between sIL-6R levels and platelet count ($r= -0.15$, $p=0.23$). There was strong association between serum IL-6 and CRP in the total cohort ($r =0.74$, $p<0.001$) and this correlation remained significant in the dcSSc with elevated platelets cohort ($r =0.5$, $p<0.001$). In addition, serum IL-6 levels positively correlate with concurrent mRSS ($r=0.48$, $p=0.02$) but not with peak mRSS ($r=0.19$, $p=0.40$). There was moderate correlation between platelet count and concurrent mRSS ($r=0.33$, $p=0.05$).

Conclusion: These results suggest that IL-6 may be a potential biomarker for skin disease in SSc and that thrombocytosis in dcSSc patients may selectively identify those with high IL-6, and higher mRSS. Together these data support further exploration of the pathogenic role of IL-6 in SSc and suggest that a targeted therapeutic strategy against IL-6 may be worthwhile.

Demographics and Previous Complications/Interventions in Patients with Digital Ulcers and Different Subsets of Scleroderma: Preliminary Findings From the DUO Registry. Christopher P. Denton[1], Loïc Guillevin[2], Thomas Krieg[3], Barbara Schwierin[4], Daniel Rosenberg[4], Mariabeth Silkey[4] and Marco Matucci-Cerinic[5], [1]Royal Free Hospital, London, United Kingdom, [2]Université Paris Descartes, Paris, France, [3]Universität zu Köln, Köln, Germany, [4]Actelion Pharmaceuticals, Allschwil, Switzerland, [5]University of Florence, Firenze, Italy

Purpose: Digital ulcers (DU) are a frequent, persistent and debilitating manifestation of systemic sclerosis (SSc). The DUO Registry is a European, multi-center, prospective, observational cohort study of patients with DU associated with SSc. Here, we describe the history of complications/interventions, and the concomitant medications prescribed for DU, in patients with DU and limited SSc, diffuse SSc or overlap SSc/Mixed connective tissue disease (CTD) at enrolment into the DUO Registry.

Methods: This is a registry in which patients with ongoing DU disease undergo clinical assessments and receive standard medical care, as determined by the patient's physician. All consenting consecutive patients with ongoing DU disease, irrespective of treatment regimen, are enrolled. Since April 2008, data collected has included demographics, relevant SSc and DU medical history, complications of and interventions for DU disease, including relevant medications.

Results: To 19 May 2009, 684 patients have been enrolled, with 47% limited SSc, 41% diffuse SSc, 9% Overlap SSc/Mixed CTD and 3% Other (eg. Lupus erythematosus, SSc type not specified). The patients with limited SSc have a higher age (mean=56.2yrs, SD=13.4) than the patients with diffuse SSc (mean=50.8 yrs, SD=14.0). The following table describes previous complications/interventions and DU-specific concomitant medication reported at enrolment.

	Limited SSc (n/N*, %)	**Diffuse SSc (n/N*, %)**	**Overlap SSc/ Mixed CTD (n/N*, %)**
History of DU complications and DU interventions			
Hospitalization	171/288, 59.4%	132/253, 52.2%	23/52, 44.2%
Soft tissue infection requiring antibiotics	121/272, 44.5%	94/232, 40.5%	19/54, 35.2%
Gangrene	97/279, 34.8%	66/249, 26.5%	17/56, 30.4%
Surgical amputation	39/231, 16.9%	21/194, 10.8%	5/50, 10.0%
DU-specific concomitant medications at enrolment			
Immunosuppressants	8/313, 2.6%	11/273, 4.0%	6/60, 10.0%
Analgesic/anti-inflammatories	67/313, 21.4%	63/273, 23.1%	18/60, 30.0%
Systemic antibiotics	44/313, 14.1%	36/273, 13.2%	8/60, 13.3%
Topical DU treatments	78/313, 24.9%	69/273, 25.3%	11/60, 18.3%
Prostacyclines	109/313, 34.8%	85/273, 31.1%	25/60, 41.7%
Other medications	131/313, 41.9%	105/273, 38.5%	23/60, 38.3%

*The denominator varies according to the number of available observations

Conclusion: DU are a major morbidity across the scleroderma spectrum. Use of DU-specific concomitant medications, complications of infection, gangrene and amputation occur frequently in all major disease subsets. Greater physician awareness and a more consistent approach to management are likely to improve outcomes.

Development of the Scleroderma Disease Activity Index (SDAI). M. Hudson[1], Marilyse Julien[1], Murray Baron[2], Canadian Scleroderma Research Group and Russell Steele[1], [1]McGill University, Montreal, QC, [2]Jewish General Hospital, Montreal, QC

Purpose: Measuring disease activity in systemic sclerosis (SSc) is necessary to provide a conceptual structure to study this poorly-defined disease and as an outcome measure for interventional studies. The purpose of this study was to develop a disease activity index for SSc.

Method: Data from a large, pan-Canadian cohort of SSc patients was reviewed. From 1800 variables available in the database, 61 were retained based on an extensive literature search and review by 2 scleroderma experts working by consensus for face and content validity. The selected variables included 54 independent variables (disease duration, disease subset, physician ID and 51 variables selected as possible indicators of disease activity in SSc) and 7 response variables. Of 745 patients entered into the registry, 191 had complete data on the abovementioned variables and were selected for this analysis. Advanced statistical methods were used to identify the best set of variables for inclusion in a new Scleroderma Disease Activity Index (SDAI).

Results: Baseline characteristics of the patients included for the analysis were as follow: 87% female, mean age 54.5 (± 12.2) years, mean disease duration 10.7 (± 8.9) years; 39% diffuse disease. The mean physician global assessment of disease activity in the last week measured using a numerical rating scale ranging from 0-10 was 2.3 (±1.9). Lasso regression analysis using the physician global assessment of disease activity as response variable performed best and allowed the identification of 11 independent variables predictive of disease activity in SSc. Of these, 4 were patient-reported [severity of Raynaud's phenomenon (RP) in the last week measured using a numerical rating scale ranging from 0-10 (coefficient 0.21), average number of episodes of RP per week in the past month (coefficient 0.24), worsening of scleroderma in the past month (coefficient 0.24), and severity of shortness of breath in the past week measured on a numerical rating scale ranging from 0-10 (coefficient 0.33)], 4 were assessed by physicians [pulse rate per minute (coefficient 0.16), presence of basilar crackles (0.05), modified Rodnan skin score ranging from 0-51 (coefficient 0.75), and swollen joint count ranging from 0-28 (coefficient 0.16)], and 3 were lab-based [weight loss in the past year in lbs (0.13), hematocrit (coefficient 0.03) and forced vital capacity measured as percent predicted (coefficient -0.06)]. These variables accounted for 32.5% of the variance in the physician global assessment of disease activity.

Conclusion: Using data from a large multi-centered cohort of SSc patients, we developed a new and simple measure of disease activity in SSc, the Scleroderma Disease Activity Index (SDAI), with face and content validity. Further testing is underway to verify construct validity and assess sensitivity to change.

The Whole Blood Interferon Score Predicts Progression of Interstitial Lung Disease in Systemic Sclerosis. Shervin Assassi[1], Filemon K. Tan[1], Terry A. McNearney[2], Rosa Estrada-Y-Martin[1], Hilda T. Draeger[3], Jason Anderson[1], Frank C. Arnett[4] and M. Mayes[5], [1]Univ of Texas Houston, Houston, TX, [2]Univ of Texas Med Branch, Galveston, TX, [3]Univ of Texas San Antonio, San Antonio, TX, [4]University of Texas Medical School at Houston, Houston, TX, [5]U.Texas Houston, Houston, TX

Purpose: An upregulation of interferon inducible genes (IFNIG) in the peripheral blood of systemic sclerosis (SSc) patients has been previously reported. *In vitro* studies suggest IFN α and γ might have anti-fibrotic effects. We investigated whether the IFNIG score could predict the rate of decline in forced vital capacity (FVC) among SSc patients.

Method: The peripheral blood gene expression profile of early SSc patients (disease duration <5 years) was examined utilizing whole genome BeadChips. None of the study participants were treated with immunosuppressive agents at the time of blood draw. We calculated a previously described composite score for IFNIG's in all samples. Baseline and follow up FVC values were obtained and annual rate of decline in percent predicted FVC was calculated. We examined the correlation of baseline clinical parameters and IFNIG score with an annual rate of decline in FVC.

Results: A total of 36 patients had two pulmonary function tests that met the ATS/ERS standards for spirometry. The proportion of patients with diffuse disease was 63.89% (23/36). Anti-topoisomerase, anti-centromere and anti-RNA polymerase III antibodies were present in 6, 3, and 10 patients, respectively. Only 2 patients were current smokers. There was a time difference of 1.55 ± 0.6 years between the two FVC measurements. The disease type (p=0.698), disease duration (p=0.448) and presence of anti-topoisomerase antibodies (p=0.976) did not correlate with the annual decline in FVC. There was a trend for association of baseline FVC with the decline in FVC (p=0.054, r= 0.11) whereas the IFNIG score showed a significant negative correlation with the outcome (p=0.011, r= -0.42). Figure 1 demonstrates the reverse relationship between the quartiles of IFNIG score and the annual rate of decline in FVC indicating that higher IFNIG scores may be a marker of protection against progression of interstitial lung disease in SSc. In the bivariate model of baseline FVC and IFNIG score as independent factors, the IFNIG score retained its significantly negative correlation with the decline in FVC (p=0.027).

Conclusion: The interferon score is reversely related to the rate of decline in FVC and may be a useful biomarker to predict the progression of interstitial lung disease in systemic sclerosis patients.

Anti-Topoisomerase I Antibody Develops Simultaneously with Clinical Onset of Systemic Sclerosis through De Novo T Cell-Dependent Process. Masataka Kuwana[1] and Junichi Kaburaki[2], [1]Keio University School of Medicine, Tokyo, Japan, [2]Shin-akasaka Clinic, Tokyo, Japan

Purpose: Anti-topoisomerase I (topo I) antibody is highly specific to patients with systemic sclerosis (SSc), but underlying mechanisms that elicits this autoantibody response still remain unclear. In this study, we have investigated when and how anti-topo I antibody response emerges using blood samples obtained before and after SSc becomes clinically evident.

Method: Eight patients were selected from 98 patients with diffuse cutaneous SSc and anti-topo I antibody in our database, based on availability of serial serum samples including those obtained before onset of first non-Raynaud's phenomenon manifestation of SSc. Autoantibody assays were performed by indirect immunofluorescence and immunoprecipitation (IP) assay using radio-labeled cellular extracts. Levels, isotype distribution (IgG/IgM), and epitope reactivities of anti-topo I antibodies were evaluated by enzyme-linked immunosorbent assay using recombinant topo I fragments as antigen sources. In some instances, topo I-reactive T cells in circulation were quantified by limiting dilution of sorted peripheral blood CD4+ T cells followed by evaluation of a topo I-specific T cell response.

Results: A total of 12 sera obtained at a mean of 33.8 months (range 3-70) before SSc onset were available from 8 patients. All sera showed a positive anti-nuclear antibody at a titer ranging from 1:40 to 1:2560, but none of them was positive for anti-topo I despite use of highly sensitive IP assay. In contrast, anti-topo I was detected in all patients at SSc diagnosis, which was made a mean of 8.6 months (range 1-18) after the onset of first non-Raynaud's symptom. Anti-topo I isotype distribution was further evaluated serially in 2 cases in whom diagnosis of SSc was made within 3 months of the onset. In case #324, IgM anti-topo I alone was weakly positive one month after she noticed puffy fingers, although sera obtained at 3 and 50 months earlier were negative for anti-topo I. Three months later, skin thickness and interstitial lung disease became apparent with a prominent increase in IgG anti-topo I (isotype-switch). In case #336, IgM and IgG anti-topo I were positive three months after onset of puffy fingers despite the absence at 14, 38, and 48 months earlier. IgM anti-topo I became undetectable in one year, but IgG anti-topo I level increased and remained high with prominent expansion of topo I-reactive CD4+ T cells in circulation. Serial analysis of reactivities to epitopes on topo I revealed acquisition of IgG reactivity to previously unrecognized epitopes within one year after the onset (epitope-spreading).

Conclusion: Unlike lupus autoantibodies, development of anti-topo I antibody and clinical onset of SSc are concurrent events in patients with diffuse cutaneous SSc, although positive antinuclear antibody test precedes many years before onset of the disease. In addition, emergence of the anti-topo I antibody response follows a stepwise process of de novo T cell-dependent humoral immune response: production of IgM antibody followed by isotype-switch and epitope-spreading.

Validation of the Qualitative and Semiquantitative Assessment of the Scleroderma Spectrum Patterns by Nailfold Videocapillaroscopy: Preliminary Results. V. Smith[1], Carmen Pizzorni[2], Filip De Keyser[3], Saskia Decuman[3], Jens T. Van Praet[3], Ellen Deschepper[3], Alberto Sulli[2] and Maurizio Cutolo[4], [1]Ghent University Hospital, Ghent, Belgium, [2]University of Genova., Genova, Italy, [3]UGent, Ghent, Belgium, [4]Research Laboratory and Academic Unit of Clinical Rheumatology, Genova, Italy

Purpose: Validation of the qualitative[1] and semiquantitative[2] scoring of nailfold videocapillaroscopy (NVC) scleroderma spectrum patterns in systemic sclerosis (SSc).

Method: Two raters from different centres, blindly assessed the NVC images of 71 consecutive SSc patients qualitatively as NVC scleroderma spectrum patterns ((“early”, “active”, “late” or “scleroderma-like” pattern), or “within normal limits”) and semiquantitatively by calculating the mean score for capillary loss, giant capillaries, microhaemorrhages and capillary ramifications. Inter/intrarater agreement was assessed by calculation of proportion of agreement and by kappa coefficients. Rater agreement of ordered categorical data was assessed by intraclass correlation coefficients.

Results: The inter/intrarater proportion of agreement to qualitatively distinguish the NVC scleroderma spectrum patterns from the “within normal limits” pattern was 90% and 96%, whereas the agreement to distinguish between the scleroderma and the “scleroderma-like” NVC patterns 62% and 81%. The agreement of the semiquantitative scoring, as assessed by intraclass correlation coefficient, was 0.96 and 0.95

for capillary loss; 0.84 and 0.95 for giant capillaries; 0.90 and 0.95 for microhaemorrhages, and 0.64 and 0.95 for capillary ramifications. Mean score classes 2 and 3 of capillary loss were associated with trophic digital skin lesions (pitting scars and skin ulcers) ($p = 0.039$).

Conclusion: This study demonstrates significant reliability of qualitative assessment of NVC scleroderma spectrum patterns and of their semiquantitative scoring between raters of different centres. The clinical associations observed between capillary loss and the clinical finding of pitting scars and skin ulcers in SSc patients underscores the construct validity of the NVC.

Estimated Systolic Pulmonary Artery Pressure Versus Tricuspid Regurgitant Jet Velocity as Screening Tools for Pulmonary Hypertension in Systemic Sclerosis: The PHAROS Experience. Karmela K. Chan[1], Leslie R. Harrold[1], Firas Alkassab[1], Virginia D. Steen[2] and The PHAROS investigators, [1]Univ of Massachusetts Med Schl, Worcester, MA, [2]Georgetown University Medical Center, Washington, DC

Purpose: Pulmonary hypertension (PH) is the leading cause of death in patients with longstanding systemic sclerosis (SSc), with an estimated prevalence of 8-15%. Measurement of the pulmonary arterial pressure via right heart catheterization (RHC) remains the gold standard for establishing this diagnosis. However, given the invasive nature of RHC, other screening modalities have been used, namely echocardiography. The sensitivity of the echocardiographic estimation of systolic pulmonary artery pressure (SPAP) is reported to be 0.79 - 1.00, while the specificity is 0.6 - 0.98. SPAP is dependent upon two variables (based on the Bernoulli equation): estimated right atrial pressure and tricuspid regurgitant velocity (TRV). Since RA pressure estimation is quite subjective, it has been proposed that TRV might be more accurate than SPAP in screening for PH. Therefore, we sought to evaluate the performance of these 2 parameters in predicting PH in an observational cohort of SSc patients.

Methods: PHAROS (Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma) is a multicenter web-based observational registry of SSc patients who are either at risk for, or have an established diagnosis of, PH; with a current total number of 286 enrolled subjects. Patients were included in this analysis if they have had an echocardiogram (reporting both SPAP and TRV) and a RHC within 180 days of each other. Sensitivity and specificity for SPAP and TRV were calculated for different cutoffs, and the area under the ROC curve was calculated using logistic regression analysis.

Results: There were 50 patients who met the inclusion criteria. Of these, 44 (88%) were female. Thirty (60%) had limited cutaneous SSc. Thirty two (64%) patients had PH based on RHC. The table displays the results of the analysis for different cutoffs of SPAP and TRV

Variable	Sensitivity (%)	Specificity (%)	False Positive Rate (%)	False Negative Rate (%)	Correctly Classified (%)
SPAP>35 mmHg	100	28	72	0	74
SPAP>40 mmHg	94	39	50	10	76
TRV> 2.5 m/s	100	33	67	0	74
TRV> 3.0 m/s	81	55	44	19	72

Not surprisingly, increasing the cutoff for either parameter improved the specificity but resulted in decreased sensitivity. When both parameters were considered as continuous variables, the area under the ROC curve for predicting PH was 0.86 (95% CI 0.76-0.96) for SPAP and 0.84 (95% CI 0.73-0.95) for TRV demonstrating the overlap in the predictive capability.

Conclusion: This study suggests that SPAP and TRV provide excellent sensitivity to screen for PH in SSc patients and perform equally well. The low specificity, however, indicates that RHC should remain the gold standard for establishing the diagnosis. Echocardiography is operator- and technique- dependent, so neither parameter can be viewed as an optimal screening tool on its own. Several screening algorithms have been suggested but which of these will provide the best accuracy remains to be determined. This study suggests that incorporating either SPAP or TRV in such algorithm is likely to provide similar predictive capability.

Functional and Morphological Evaluation of the Digital Microcirculation with Laser Doppler Imaging and Nailfold Capillaroscopy in Systemic Sclerosis. Marcelo J.U. Correa, Luis Eduardo C. Andrade and Cristiane Kayser, Universidade Federal de São Paulo, São Paulo, Brazil

Purpose: Laser Doppler imaging (LDI) is a recently developed method for assessing superficial skin blood flow in systemic sclerosis patients (SSc) and Raynaud´s phenomenon. Nailfold capillaroscopy (NFC) is widely used for early diagnosis and for evaluation of structural microcirculation alterations in SSc. This study aimed to investigate the dynamic behavior of fingertip skin microvascular blood flow before and after cold stimulus (CS) using LDI in SSc patients and in healthy controls and to compare functional abnormalities on LDI with morphological microangiopathy evaluated by NFC in SSc.

Methods: 44 SSc patients (26 with limited and 18 with diffuse cutaneous form) with Raynaud´s phenomenon (3 M, 41 F; 47.4±10.5 years old) and 31 healthy controls (1 M, 30 F; 47.5±8.0 years old) were included. Disease duration was 5.9±5.5 years. Vasoactive drugs were discontinued 3 days before the procedure. After acclimatization for 1 hour at 24ºC, all subjects underwent NFC followed by LDI measurement. NFC was performed in a stereomicroscope (Olympus - SZ40) under 10-20 x magnification. The following parameters were analyzed in the ten digits of the hands: (1) number of capillary loops/mm, (2) number of enlarged and giant capillary loops, and (3) vascular deletion score. NFC parameters were calculated as the average obtained in all analyzed fingers. Skin blood flow of the dorsum of 4 fingertips (excluding the thumb) of the left hand was measured using LDI (Moor LDI-VR, Moor Instruments) at baseline and at 1, 4, 10, and 25 minutes after CS (submersion of both hands in water at 15^{o}C for 1 minute). The mean perfusion of the 4 fingertips was considered for analysis. Fingertip blood flow (FBF) was expressed in arbitrary perfusion units (PU) with respect to a calibration standard for the LDI scanner.

Results: LDI showed significantly lower baseline FBF in SSc patients as compared to controls (296.9±208.8 vs 496.6±141.5 PU; $p<0.001$) and also in all time points after CS ($p<0.001$). There was a significant decrease in FBF after CS as compared to baseline in SSc patients and in controls, followed by recovery of the blood flow 25 minutes after CS in healthy controls (FBF 25 min after CS 442.4±174.7 PU; $p=0.996$ vs baseline), but not in SSc (FBF 25 min after CS 209.9±185.1 PU; $p<0.001$ vs baseline). There was no correlation between baseline FBF and the severity of NFC parameters in SSc patients (number of capillary loops, $p=0.556$, $r=0.091$; number of enlarged and giant capillary loops, $p=0.87$, $r=-0.025$; vascular deletion score $p=0.219$, $r=-0.189$).

Conclusion: LDI showed lower digital blood flow before and after CS in SSc when compared to healthy controls and allowed objective measurement of blood perfusion in SSc. There was no correlation between functional and morphological microvascular abnormalities measured by LDI and NFC in SSc. LDI and NFC are complementary tools for evaluation of different aspects of the microangiopathy in SSc patients.

Long-Term Beneficial Effects of Statins On Vascular Manifestations in Patients with Systemic Sclerosis. Masataka Kuwana[1], Yuka Okazaki[1] and Junichi Kaburaki[2], [1]Keio University School of Medicine, Tokyo, Japan, [2]Shin-akasaka Clinic, Tokyo, Japan

Purpose: Microvasculopathy in systemic sclerosis (SSc) mainly affects small arteries, leading to Raynaud's phenomenon and painful digital ulcers. Statins have cholesterol-independent pleiotropic effects, which can improve endothelial functions and/or promote vascular repair through mobilization of endothelial progenitor cells (EPCs). Recent clinical trials suggested potential benefits of statins on vascular manifestations of SSc over a relatively short period (≤ 4 months). In this study, we conducted a 24-month, open-label study to evaluate the long-term effects of statins on vascular symptoms in SSc patients and to examine whether statins promote vasculogenesis as part of their clinical efficacy.

Method: Ten SSc patients were enrolled. All patients took atorvastatin at 10 mg/day for 24 months. A daily Raynaud's phenomenon attack diary and questionnaires for the assessment of global measures of health and psychological scales were assessed in addition to circulating angiogenic factors and endothelial activation/injury markers at 0 (pre-treatment), 1, 3, 12, and 24 months of treatment. EPCs positive for CD34, CD133, and VEGFR2 were serially quantified by cell sorting and 3-color flow cytometry, in accordance with recommendations proposed by the EULAR Scleroderma Trials and Research group expert panel, except the use of a viability marker.

Results: Eight patients (4 diffuse and 4 limited cutaneous SSc) completed the 24-month atorvastatin treatment. Two patients dropped out: one required cyclophosphamide for interstitial lung disease; and the other required bosentan for pulmonary arterial hypertension. None of the patients experienced any adverse events during the atorvastatin treatment. Raynaud's phenomenon improved during atorvastatin treatment, with significant reductions in the Raynaud's condition score ($P = 0.01$) and the patients' assessment by visual analog scale ($P = 0.0003$). The SSc-associated up-regulation of angiogenic factors (VEGF and bFGF) and vascular endothelial activation/injury markers (soluble VCAM-1 and E-selectin) were all reduced ($P < 0.01$ for all comparisons). Improvement in these parameters was best at 12 and 24 months of treatment. In 3 patients who had digital ulcers at the time of entry, the mean number of new digital ulcers prior to enrollment was 4.7/year, but this decreased to 3.3 at the 12-month assessment and 2.7/year at the 24-month assessment. Atorvastatin treatment resulted in a 1.2- to 6.1-fold increase (3.1 ± 1.8) in the EPC number at one month from the baseline ($P < 0.01$). However, the number peaked at one month and decreased thereafter, despite the continuous use of atorvastatin.

Conclusion: This pilot study suggests that statins may be beneficial in treating vascular manifestations of SSc, and these effects persisted for at least for 24 months. Notably, the longer the patients took atorvastatin, the greater the effects we observed. These pleiotropic effects are mediated primarily through improvement of endothelial functions, since statin treatment did not correct the defect in EPC recruitment.

Clinical Usefulness of Anti-RNA Polymerase III Antibody Measurement by Enzyme-Linked Immunosorbent Assay. Masataka Kuwana[1], Takashi Satoh[1], Shinichi Sato[2], Kazuhiko Takehara[3] and Anti-RNAP III Antibody Investigator Group, [1]Keio University School of Medicine, Tokyo, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Kanazawa University Graduate School of Medical Science, Kanazawa City, Japan

Purpose: Autoantibodies reactive with RNA polymerase (RNAP) III were highly specific for systemic sclerosis (SSc) and strongly associated with diffuse cutaneous involvement and renal crisis. In clinical settings, detection of the anti-RNAP III antibody is extremely important, because it helps identify patients with a high risk for developing renal crisis, but routine measurement of the anti-RNAP III antibody has not been feasible in clinical laboratories. Recently, an enzyme-linked immunosorbent assay (ELISA) kit for detecting the anti-RNAP III antibody has become available. This study was undertaken to evaluate the clinical usefulness of measuring anti-RNAP III antibody with a commercially available ELISA in Japanese patients with SSc.

Method: This multicentre study involved 354 patients with SSc, 245 with non-SSc connective tissue diseases (CTDs), and 102 healthy controls. ELISAs were used to detect anti-RNAP III antibody, anti-topoisomerase I (topo I) antibody, and anticentromere antibody (ACA). The presence of anti-RNAP III antibody in selected serum samples was confirmed by immunoprecipitation assay. Severity of individual organ involvements in SSc patients was evaluated using the Medsger's scale that has been modified to conform to Japanese patients, who have less extensive skin and tendon involvement.

Results: By ELISA, anti-RNAP III antibody was detected in 38 (10.7%) patients with SSc, 3 (1.2%) with non-SSc CTD, and no healthy controls. The clinical specificity for SSc was excellent (98.8%), although a small number of false-positives occurred. The sensitivity of the anti-topo I and ACA ELISAs for SSc was 59.9%, which increased to 68.2% without a reduction in specificity when the anti-RNAP III measurement was added. Anti-RNAP III, anti-topo I, and ACA were generally mutually exclusive, but 8 (21%) of the 38 anti-RNAP III-

positive sera had concomitant ACA. Clinical features associated with positivity for the anti-RNAP III antibody were diffuse cutaneous SSc, a high total skin score, and renal crisis, consistent with previous studies that used an immunoprecipitation assay. Furthermore, on clinical severity scales, SSc patients with anti-RNAP III antibody scored worse for general health and higher for skin and joint/tendon involvement than anti-RNAP III antibody-negative patients ($P < 0.05$ for all comparisons).

Conclusion: The measurement of anti-RNAP III antibody by ELISA is useful in routine clinical practice, since it helps diagnose SSc and identify a disease subset with severe skin involvement and a high prevalence of renal crisis.

Close Temporal Relationship Between Onset of Cancer and Scleroderma in Patients with RNA Polymerase I/III Antibodies. Ami A. Shah, Antony Rosen, Laura K. Hummers, Fredrick M. Wigley and Livia Casciola-Rosen, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: A close, at times concurrent, temporal relationship between the development of scleroderma and malignancy has been observed suggesting the immune response to tumor neoantigens may induce the scleroderma disease process in a subset of patients. In this study, we evaluated whether the temporal relationship between scleroderma and malignancy onset differed by autoantibody status among patients with scleroderma and cancer. We further investigated whether the nucleolar antigen RNA polymerase I/III was abnormally expressed in cancerous tissue of scleroderma patients.

Method: Participants were scleroderma patients followed at a tertiary Scleroderma Center who had a new or past diagnosis of malignancy, an available serum sample, and an existing cancer pathology specimen available for histologic confirmation of cancer diagnosis. Scleroderma onset was determined by the date of the first non-Raynaud's symptom. Sera were tested for autoantibodies against topoisomerase I by ELISA and against RNA polymerase I/III by both immunoprecipitation and ELISA. Paraffin sections from cancerous tissue of 3 scleroderma patients who had anti-RNA polymerase I/III antibodies were studied, and normal tissue sections were utilized as controls. Tissue sections were incubated with a monoclonal antibody against RNA polymerase, and staining was visualized with diaminobenzidine. Clinical and demographic characteristics were compared across autoantibody categories using the Kruskal Wallis test and the Fisher's exact test where appropriate.

Results: Twenty four subjects were enrolled. Seven tested positive for anti-RNA polymerase I/III (Group 1), 5 for anti-topoisomerase I (Group 2), and 12 for neither antibody (Group 3). Age, gender, race, smoking status, disease severity indices, and the frequency of ILD or PAH did not differ statistically between groups. The median duration of scleroderma at cancer diagnosis differed significantly between groups: -1 year in Group 1, +13.4 years in Group 2, and +5.1 years in Group 3 ($p=0.011$). The median duration of Raynaud's at cancer diagnosis followed a similar trend with a duration of 0 years in Group 1, +13.2 years in Group 2, and +6.6 years in Group 3 ($p=0.054$). We then examined pathology tissue from the tumors of 3 patients who produced antibodies to RNA polymerase I/III and found robust nuclear RNA polymerase staining. In striking contrast to the prominent staining noted in cancerous tissues, normal tissue paraffin sections showed minimal staining.

Conclusion: There is a close temporal relationship between onset of cancer and scleroderma in patients with antibodies to RNA polymerase I/III suggesting a common etiopathogenesis. Enhanced antigen expression in cancerous tissue from scleroderma patients suggests that malignancy may drive the expression of scleroderma in a subset of scleroderma patients.

An Open Label Trial of the Endothelin Receptor Antagonist Bosentan in Scleroderma Renal Crisis (BIRD-1). Henry Penn[1], Aine Burns[1], Carol M. Black[2] and Christopher P. Denton[3], [1]Royal Free Hospital, London, United Kingdom, [2]Royal Free Hospital, London, [3]UCL Medical School, London, United Kingdom

Purpose: Scleroderma renal crisis (SRC) is a life-threatening complication affecting approximately 5% of cases of systemic sclerosis. Endothelin-1 is a potent vasoconstrictor peptide which has proliferative effects on endothelium and is found at high levels in plasma and in

renal biopsy material in SRC. The non-selective endothelin receptor antagonist (ETRA) bosentan is an established therapy for SSc associated pulmonary arterial hypertension and ischaemic digital ulceration. We have undertaken an open label pilot study of bosentan in SRC (BIRD-1).

Method: Cases within 6 weeks of confirmed of SRC received six months bosentan at a dose of 62.5mg for 1 month then 125mg twice daily for 5 months. 10 cases were screened, and six enrolled. Outcome measures included 1 year mortality, renal function, and blood pressure control. These were compared with a recent historic cohort of 49 SRC cases managed at our centre from 2000-2004.

Results: The mean (SD) age of the BIRD-1 cohort was 52 (11.5) years. 5 were female and only one was classified as lcSSc. The median duration of SSc at time of SRC was 6 months (range 2-72). Demographic and baseline clinical variables were not significantly different for the comparator cohort. All cases were treated with ACE inhibitors at full therapeutic doses. Clinical outcomes are summarised in Table 1. One case withdrew from the study after developing encephalopathy attributable to SRC. One case died at 2 months of multi-organ failure after discontinuing bosentan and dialysis. Bosentan was well tolerated with no significant drug related serious adverse events occurring. Three of five patients developed rebound phenomena on withdrawing bosentan – two with severe Raynaud's phenomenon, and three developed hypertension requiring one or two additional anti-hypertensive agents. Levels of ET-1 were elevated in all cases at SRC (median healthy controls 0.50pg/ml; SRC 1.48 pg/ml; $p<0.0005$), and increased further with bosentan therapy (1.46 pg/ml vs 3.05; t test $p<0.05$). N-terminal pro brain natriuretic peptide levels were also elevated, and high levels prior at presentation were associated with requiring dialysis (log values dialysed 3.61, non-dialysed 2.36, $p=0.028$).

Conclusion: Bosentan appears safe and well tolerated in conjunction with ACEi therapy for SRC. Overall, mortality and dialysis rates were not significantly different to our recent historic comparator cohort. A larger controlled study would be needed to fully assess therapeutic potential.

Table 1		2000-5 cohort (n=49)	BIRD-1 cohort (n=6)
Median (range) BP at presentation		195/114 (130-250/80-180)	194/118 (150-253/90-140)
Median (range) serum creatinine at presentation (microMol/L)		191 (82-1123)	185 (94-251)
Dialysis rates in survivors	at 1 mth	34/49 (69%)	3/6 (50%)
	at 12 mths	21/43 (48%)	2/5 (40%)
eGFR median (range) ml/min for cases not on dialysis	at 3 mths	31 (21-83)	66 (43-85)
	at 6 mths	36.5 (19-66)	68 (59-107)
	at 12 mths	41 (23-70)	72 (62-107)
Mortality at 1 year		6/49 (12%)	1/6 (16%)

Gender and Ethnicity Differences in Patients with Diffuse Systemic Sclerosis Participating in 3 Large Randomized Clinical Trials.

M. Nashid, H. Agrawal, PP Khanna, P. Maranian, D. E. Furst, P. J. Clements and D. Khanna, UCLA, Los Angeles, CA

Purpose: Although non-Caucasian (Non-Cau) are more likely to develop dsSSc compared to Caucasians (Cau), it is not clear whether they have the same disease course after developing dcSSc. In addition, impact of gender on the disease course of dcSSc is unclear. Our objective

was to assess the course of modified Rodnan skin score (MRSS), HAQ-DI, and FVC% predicted between male versus female and Cau versus Non-Cau with dcSSc participating in 3 RCTs.

Method: Data from 3 RCTs (D- Penicillamine, recombinant human relaxin, and type I collagen) were pooled and analyzed. Baseline characteristics were compared in male vs. female and Cau vs. Non- Cau. A linear mixed effects model with patient as random effect was used to model the predictors of MRSS, HAQ- DI, and FVC. The primary independent variables were time-in-study and its interaction with gender (male and female) and ethnicity (Cau and Non- Cau). Other covariates included disease duration and age for MRSS model. For HAQ-DI model, we also accounted for the swollen (SJC) and tender joint count (TJC), digital ulcer, and baseline MRSS. For FVC%, we adjusted for baseline MRSS and BMI as covariates.

Results: On average males were heavier and taller, had a higher serum creatinine, serum hematocrit, but lower HAQI- DI scores compared to females ($p< 0.05$, Table). For ethnicity analysis, Cau were older, had a higher MRSS and FVC% but lower TJC than Non- Cau ($p< 0.05$; Table). In the linear mixed models, the course of MRSS, HAQ-DI, and FVC was not significantly different between males vs. females and Cau vs. Non- Cau. Time in the study was an independent predictor of improvement in MRSS and HAQ-DI.

Conclusion: Our post hoc analysis of RCTs suggests that gender and ethnicity have no influence on the disease course once patients develop dcSSc. These findings should be replicated in larger observational cohorts.

A Disease Damage Index for Canadians with Systemic Sclerosis. Kevin Keen[1], Jenny Walker[2], Marie Hudson[3], Viktoria Bassarguina[1], Murray Baron[4] and Canadian Scleroderma Research Group, [1]University of Northern British Columbia, Prince George, BC, [2]Flinders University, Adelaide, Australia, [3]McGill University and Jewish General Hospital, Montreal, QC, [4]Jewish General Hospital, Montreal, QC

Purpose: Disease activity and damage indices facilitate collection of standardized information and provide an important means of objectively documenting a subject's disease state. A disease severity index is a composite measure of activity and damage. Disease severity indices for systemic sclerosis (SSc) have been developed in the United States and Sweden. An SSc disease activity index has been developed in Europe and another is under development in Canada. The purpose of this ongoing study is to develop a disease damage index for SSc.

Method: A cross-sectional analysis of 654 patients enrolled in the Canadian Scleroderma Research Group Registry was undertaken and after review, 42 variables encompassing 9 organ systems were retained for further study. Rheumatologists' global assessment of damage was chosen as the gold standard in the development of an aggregate damage score (the Canadian Scleroderma Damage Index, or CSDI). Statistical methods included multiple linear regression and multivariate techniques such as principal component analysis and factor analysis.

Results: Among the 654 subjects, the limited-diffuse ratio was 1.3:1. The female-male ratios were 8.6:1 for limited SSc (lSSc) and 4.3:1 for diffuse SSc (dSSc). Mean global damage was 2.50 (SD = 2.19) for 112 lSSc subjects with complete data and 4.12 (SD = 2.51) for 65 dSSc subjects with complete data. Both means are somewhat low with mean global damage for lSSc being significantly lower than that of dSSc ($P < 0.0001$). The 42 explanatory variables in the separate multiple linear regression models for lSSc and dSSc were able to account for 72% and 86%, respectively, of the variation in the rheumatologists' global assessment of damage. The most meaningful among the explanatory variables were the modified Rodnan skin score for the whole body, the number of digits with loss of pulp, whether there had been an SSc renal crisis, the New York Heart Association class, whether the electrocardiogram was abnormal, whether pericardial effusion was present, and whether oxygen was being used at home.

Conclusion: Preliminary damage scales have been developed for patients with lSSc and dSSc. These will be tested among a larger sample of rheumatologists and are presented for peer review.

Atherosclerosis in Patients with Systemic Sclerosis in Stockholm, Sweden. Annica Nordin, Lena Björnådal, Kerstin Jensen-Urstad and Elisabet Svenungsson, Karolinska Institutet, Stockholm, Sweden

Purpose: Previous studies demonstrate that several systemic autoimmune diseases are associated with an increased prevalence of atherosclerosis. Besides traditional risk factors, systemic inflammation seems to be an important factor for atherosclerosis in these patients. We compared atherosclerosis and its risk factors in patients with Systemic Sclerosis and controls.

Methods: 81 consecutive patients (62,4 ± 12,6 years) who fulfilled the American College of Rheumatology criteria for Systemic Sclerosis(SSc) and 80 population-based controls (62,2 ± 12,8 years) matched for sex, age and region of living participated. As a surrogate measure for atherosclerosis we studied the frequency of plaque and the mean IMT (intima media thickness), measured by B-mode ultrasound. Traditional risk factors for cardiovascular disease and biomarkers of systemic inflammation were measured.

Results: Plaques were found in 49,5% of the patients and in 41% of the controls. Mean IMT was 0,69 mm ± 0,11 in patients and 0,69 mm ± 0,14 in controls. Neither plaque occurrence nor IMT differed significantly. The patient with SSc were more likely to be current or former smoker than controls (54% vs. 35%, $p < 0,001$). The patients had more systemic inflammation than controls: Sedimentation Rate 17,6 ± 13,5 mm vs 11,8 ± 6,7mm ($p<0,05$), hsCRP 3,6 ± 4,5 mg/l vs 2,5± 2,8 mg/l ($p=0,05$), alpha-1-antitrypsin 1,6 ± 0,35 g/l vs 1,4 ± 0,2 g/l (<0,001)

and orosomucoid 0,83± 0,16 g/l vs 0,75 ± 0,17 g/l (p<0,01). The patients BMI was lower than controls 24,4 ± 3,3 kg/m² vs 26,1± 3,8 kg/m²(p<0,05).

Lipid levels, blood-pressure, blood glucose or waist hip-ratio did not differ between patients and controls.

In multivariable-adjusted logistic regression models (including age, systolic blood pressure BMI, cholesterol, triglycerides (TG), smoking and hsCRP), independent predictors of plaque among patients was age (p=0.007) and TG(p=0,04) and among controls age(p<0,0001) and smoking (p<0,02).

Conclusion: Atherosclerosis was not more prevalent in SSc patients than in population-based controls. Smoking and markers of inflammation were more common in patients.

Antibodies to Sulfated N-Acetyllactosamine (LacNAc) Are Prevalent in Patients with Systemic Sclerosis and Associated with Pulmonary Hypertension. Thomas Grader-Beck[1], Francesco Boin[1], Stephan von Gunten[2], David F. Smith[3], Antony Rosen[1] and Bruce S. Bochner[4], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Bern, Bern, Switzerland, [3]Emory University School of Medicine, Atlanta, GA, [4]Johns Hopkins Asthma and Allergy Center, Baltimore, MD

Purpose: Differential glycosylation of proteins and lipids plays an important role in the regulation of numerous physiological processes. The endothelium and extracellular matrix, two key tissue components affected in systemic sclerosis (SSc), contain various highly glycosylated structures (glycans). We hypothesized that the immune response in SSc may target distinct glycans, leading to the development of specific anti-glycan antibodies.

Method: A printed glycan array containing 320 glycans was used to screen pooled sera from 40 randomly selected SSc patients and 40 healthy controls for anti-glycan antibodies. Binding was quantified by fluorescence. Antibodies to sulfated LacNac were determined in 181 individual sera from SSc patients and 40 healthy controls by ELISA using an anti-human Fc gamma specific secondary antibody for detection, a high-titer positive SSc serum as standard and a cut-off of 3 SD above healthy controls. Statistical analysis of clinical associations was performed using student's t-test and logistic regression.

Results: Sulfated LacNac was identified as a dominant target of SSc sera initially by printed glycan array screening. Immunogenicity was predominantly conferred by sulfation at position 4 of galactose (4S-LacNAc), but not at position 3 or 6 (13.6 fold; 3.0 fold and 0.9 fold compared to controls; respectively). Subsequently, an anti-sulfated LacNAc specific ELISA was developed to screen individual sera. 27/181 (14.9%) patients were positive for anti-4S-LacNAc antibodies compared to only 1/40 (2.5%) of healthy controls. Anti-4S-LacNAc positive SSc patients had a higher prevalence of pulmonary hypertension as determined by an RVSP > 40 mmHg on echocardiogram (15/27; 55.7% versus anti-4S LacNac negative patients 49/154; 31.8% p=0.02). The odds ratio for pulmonary hypertension was 2.6 (1.1, 6.3) after adjusting for age, gender, race and disease type. Anti-4S-LacNAc positive patients accounted for 23.4% of all patients with pulmonary hypertension. There was no association between anti-4S-LacNAc positivity and disease type (limited versus diffuse SSc) or the presence of anti-topoisomerase I or anti-centromere antibodies.

Conclusion: This is the first study to report that sera from SSc patients contain high titer IgG antibodies targeting glycan structures. 4S-LacNac was identified as a frequent target of the antibody response in SSc and antibody positivity was associated with echocardiographic evidence of pulmonary hypertension. These results suggest that specific posttranslational carbohydrate modifications may act as important immunogens in SSc. Further studies will determine whether these antibodies target 4 sulfated LacNAc expressed on the endothelium or extracellular matrix and thus may play a role in disease pathogenesis.

Factors Associated with Oesophageal Involvement in Systemic Sclerosis: a High-Resolution Manometry Study. Arnaud Hot, Sabine Roman, Jacques Ninet and François Mion, Hopital Edouard Herriot, Lyon, France

Purpose: Oesophageal involvement occurs in about 80% of patients with systemic sclerosis, with a marked diminution of peristaltic pressures in the distal two-thirds of the oesophagus and hypotension of the lower oesophageal sphincter (LES). Manometric techniques have improved in a step-wise fashion from a single pressure channel to the development of high-resolution manometry (HRM) with up to 36 pressure sensors. Our aims were to determine if oesophageal involvement in systemic sclerosis, early detected by high-resolution manometry (HRM), was associated with other organ involvement and with a particular autoantibody profile.

Method: Forty-nine consecutive patients (46 females, mean age 53 years, range 21-80) with systemic sclerosis were included. Oesophageal motility was characterized with HRM. Esophageal aperistaltis was defined as an absence of esophageal waves in the 2 distal thirds of the esophagus and hypoperistaltism as 30% or more of distal esophageal waves with a $\geq$ 2-cm defect in the 30-mmHg isobaric contour. The demographic data, duration of the disease, presence of other organ involvement and autoantibodies (Antinuclear antibodies (ANA), anti-Scl70 antibody (Scl70), anticentromere antibodies (ACA)) were recorded. Chi square test was used to compare the association between these criteria and oesophageal involvement.

Results: Forty patients (81.6%) had a decreased oeso-gastric junction (EGJ) pressure (<10 mmHg). Oesophageal body dysmotility was present in 35 patients (71.5%), with a very monomorphic presentation: aperistaltis in 25 cases, and hypoperistaltism in 10. Hypotensive EGJ and oesophageal dysmotility were associated in 29 patients (60.4%). The velocity of proximal contractions was higher in patients with esophageal body dysmotility compare to patients with normal peristalsis (median 10.8 cm/s vs 5.4, p=0.02) whereas amplitude and duration of proximal waves did not differ. Oesophageal body dysmotility was present in all 14 patients with a diffuse skin involvement (all with positive Scl70) and in 60% of the 35 others (all but 2 with negative Scl70) (p = 0.01). ACA were positive in 51 % of patients with oesophageal body dysmotility and in 93% of patients without oesophageal involvement (p=0.02). No significant association was observed between oesophageal body dysmotility and other organ involvement. Hypotensive EGJ alone was not significantly associated with any of the above-mentioned factors.

Conclusion: This first HRM series confirms the high prevalence of EGJ hypotension and esophageal body dysmotility in systemic sclerosis. The velocity of proximal oesophageal contractions is increased in patients with oesophageal body dysmotility. Oesophageal body dysmotility, strikingly monomorphic when present, is associated with diffuse skin involvement, positive Scl70 and negative ACA antibodies.

Results of A Pilot Randomized Placebo Controlled Trial in Raynaud's Phenomenon (RP) with St. John's Wort (SJW). Deanne Malenfant[1], Kelly Summers[2], Nooshin Samadi[3], Ash Bonner[4] and Janet Pope[5], [1]Schulich School of Medicine & Dentistry, University of Western Ontario, London, ON, [2]University of Western Ontario, London, ON, [3]St. Joseph's Health Care, London, ON, [4]McMaster University, Hamilton, ON, [5]St Joseph Health Care, London, ON

Purpose: Most of the treatments for Raynaud's Phenonomen (RP) cause hypotension which can limit the tolerability of drugs in RP. St. John's Wort (SJW) is a plant extract which works on serotonin receptors as well as other properties. It is proven to be effective in mild to moderate depression. Thus we thought it could possibly affect serotonin receptors of blood vessels and help RP, and one RCT demonstrated that prescription selective serotonin receptor inhibitors (SSRIs) can improve RP.

Method: We performed a double blind RCT with a two week run in where patients had to have at least 14 attacks over two weeks and then they were randomized to SJW or identical placebo for 6 weeks, stratifying by primary and secondary RP (and within secondary by SSc or other CTD). Testing was done to ensure quality of SJW. Serum was collected at each visit and patients kept a diary recording all RP attacks (#/day, duration of each and severity). Tests of vascular mediators included: sE-Selectin, sVCAM-1, sICAM-1, MMP-9, tPAI-1, cytokines, and VEGF were done and between groups comparisons were made with ITT analyses. Data were analyzed blinded to allocation (group A and B).

Results: 27 patients were screened (some withdrew consent or failed due to insufficient number of attacks) and 18 were randomized (2 primary RP, 16 secondary RP of whom 8 had SSc) with 8 on active SJW and 10 on placebo. The between groups differences on # of RP attacks over 1 day (decrease in the mean # of attacks per day) were 0.75 in active and 1.01 in placebo, p=0.06 (favoring placebo). Duration and severity of attacks was not different between the two groups. There were within group differences between the baseline and completion of the study where frequency, severity and duration of attacks improved, some of which were statistically significant, but active SJW did not

alter RP more than placebo. The serum analyses demonstrated that there were no between groups differences on all parameters studied. There was one SAE (a patient with diffuse SSc and atrial fibrillation hospitalized for congestive heart failure on active treatment.)

Conclusion: This study demonstrates that there is not benefit both clinically and from a basic science perspective with SJW in RP.

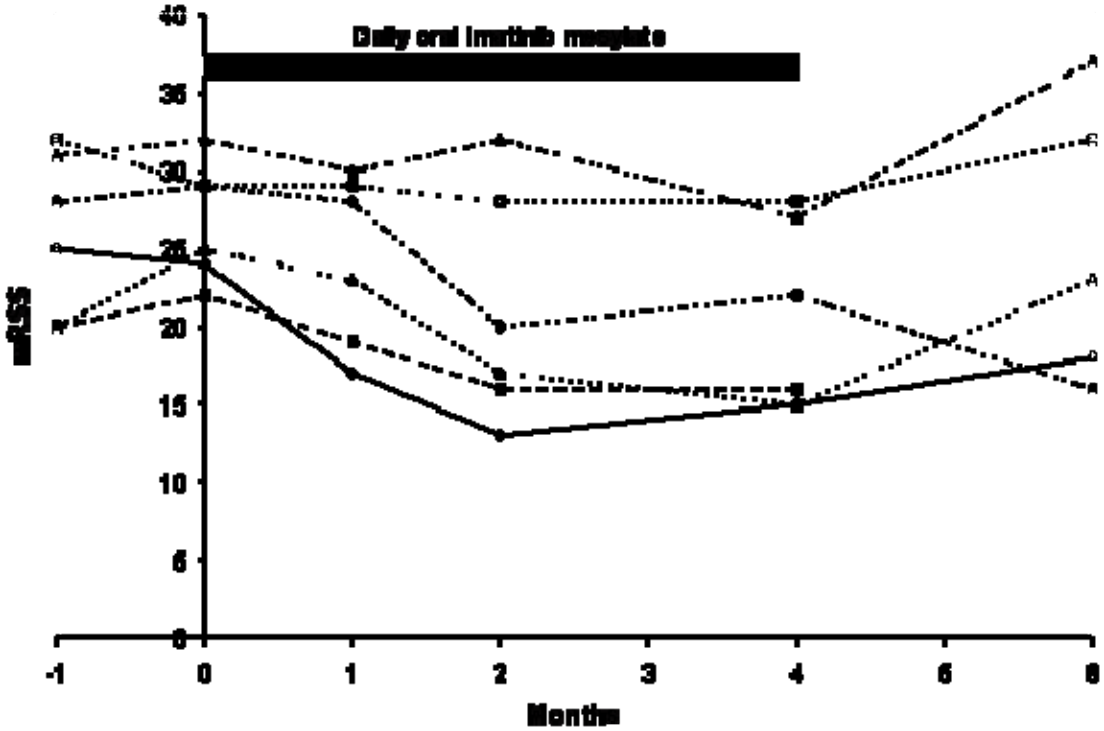
Efficacy and Safety of Oral Imatinib Mesylate in Patients with Nephrogenic Systemic Fibrosis. Jonathan Kay[1], Mary E. Sullivan[2] and Tejas V. Patel[3], [1]University of Massachusetts Medical School, Worcester, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Brigham & Women's Hospital, Boston, MA

Nephrogenic systemic fibrosis (NSF) is an extremely debilitating and painful condition that affects individuals with chronic kidney disease (CKD) following gadolinium exposure during imaging studies. NSF is characterized by rapidly progressive skin hardening, tethering and hyperpigmentation, predominantly on the extremities, often associated with joint contractures and visceral fibrosis. Although no therapy has been proven effective for this prevalent and devastating disorder with increased early mortality, 3 patients with NSF have experienced softening of skin and improvement in joint mobility with oral imatinib mesylate (IM) (J Kay & WA High. *Arthritis Rheum*. 2008;58:2543-8; S Chandran et al. *Am J Kidney Dis*. 2009;53:129-32). This tyrosine kinase inhibitor selectively inhibits signaling mediated by c-Abl, c-kit, and the PDGF receptor, as well as Smad-independent signaling by the TGF-β receptor.

Purpose: This pilot study was undertaken to assess the efficacy of IM in improving skin changes of NSF and the safety and tolerability of IM in patients with CKD and NSF.

Methods: Twelve patients with biopsy-proven NSF were enrolled in a 6-month, open-label clinical trial. One patient died before receiving study drug; 11 patients began treatment with oral IM 400 mg daily, with dose reduction to 200 mg daily allowed for gastrointestinal intolerance. Six patients completed 4 months of IM therapy, and were then observed for 2 months off of IM. The primary outcome measure was change in the modified Rodnan skin score (mRSS) at 4 months. Secondary outcome measures included assessment of safety. Skin biopsies were performed upon initiation and completion of 4 months of drug therapy.

Results: At baseline, subjects were 67% male with mean age 65.5 yrs (range 37-93 yrs); 11 had stage 5 CKD (10 were receiving hemodialysis and 1 had a functioning renal allograft) and 1 had stage 3 CKD. All 6 subjects who had completed 4 months of IM experienced improvement in mRSS from baseline, most markedly within the first 2 months of treatment, with reduction in mRSS of 24% ± 14% (mean ± SD, range 3-40%). Following discontinuation of IM, mRSS worsened in 4 individuals.



All adverse events were expected, of which nausea, vomiting, and diarrhea were the most common. One subject discontinued IM because of neutropenia, another because of skin rash, and 2 others because of anemia. Another subject died of complications following a hip fracture that were unrelated to IM therapy.

Conclusion: This is the first clinical trial to demonstrate reduction in skin tethering in patients with NSF. The improvement observed with IM treatment was evident relatively soon after initiation of therapy. The majority of patients tolerated treatment with IM. Expected adverse events were observed, of which gastrointestinal intolerance was the most common. Because skin changes recurred following discontinuation of IM, a longer duration of treatment may be necessary. Further study of this promising targeted therapy for fibrosis is warranted.

High Prevalence of Left Ventricular Diastolic Dysfunction (LVDD) in Minorities with Systemic Sclerosis (SScl) and Clinical Impact of LVDD Severity. Jina Chung, Soha Dolatabadi, Arsen Hovanesian and George A. Karpouzas, Harbor-UCLA Medical Center, Torrance, CA

Purpose: Cardiac involvement is common in patients (pts) with SScl. Pulmonary hypertension (PH) confers significant mortality. Prevalence and severity of LVDD due to SScl have been challenging to determine due to confounding factors, such as hypertension (HTN), diabetes mellitus (DM) or significant left heart diseases. Accurate assessment of LVDD will allow early diagnosis of myocardial involvement and elucidate its impact on the development of PH. We investigated the prevalence of LVDD and its clinical impact in SScl pts using transthoracic echocardiography (TTE) with pulsed wave spectral and tissue Doppler imaging after excluding the aforementioned parameters.

Methods: We evaluated 56 pts and 83 TTE's fulfilling ACR criteria for SScl, largely minorities, with follow-up in a single academic center. Twenty six pts and 39 TTE's were excluded due to severe lung disease (FVC<60%, TLC<60%), heart disease (LVEF<50%, ≥ moderate mitral or aortic regurgitation or stenosis), HTN or DM. TTE included 2D, M mode, Color, spectral and tissue Doppler techniques. LVDD

severity was classified as: impaired relaxation (I), pseudonormal pattern (II), reversible (III), and irreversible (IV) restrictive pattern. PH was defined as tricuspid regurgitation peak gradient ≥ 31 mmHg (JACC 2009; 54:s55-66). LV hypertrophy (LVH) was defined as septum or inferolateral wall thickness >12 mm. Data was analyzed with Fisher's exact test.

Results: Thirty pts with 44 TTE's were included for analysis (table 1). PH was present in 9.1%. Twenty four of 44 studies (54.5%) had normal diastolic function, 16/44 (36.4%) stage I LVDD, and 4/44 (9%) stage II. No pt had Stages III or IV LVDD. LVH was present in 5/44 (11.4%) likely due to SScl. LVH was significantly higher in stage II LVDD compared to normal (p=0.016). However, functional limitation defined as ≥NYHA class II did not correlate with more advanced LVDD.

Conclusion: LVDD was present in 45.5% of TTE's in our predominantly minority population with SScl and no other confounding factors, suggesting myocardial involvement of SScl. Most showed impaired relaxation. However, 9% had more advanced LVDD and stronger correlation with LVH and PH. The presence of stage II LVDD reflects increased left atrial pressure and may impact diagnosis of PH. Clinical implications of LVDD stages should be explored in larger scale studies.

Table 1: Patient Characteristics and Results.

Topical Application of Vascana, a Novel Nitroglycerin Formulation, Provides 8 Hours of Local Absorption but Limited Systemic Exposure. Jeffrey K. Gregory and Frederick J. Dechow, MediQuest Therapeutics, Inc., Bothell, WA

Purpose: To assess the pharmacokinetic properties of Vascana (formerly MQX-503), a novel topical nitroglycerin (GTN) formulation under study for the treatment of Raynaud's, compared to 2% nitroglycerin ointment under 2 different application scenarios

Method: 2 separate studies comparing the pharmacokinetic properties of Vascana applied to the fingers to those of 2% GTN ointment applied to the chest were performed. The first study of 12 normal subjects measured systemic exposure to GTN when Vascana (mean 2.65 mg GTN) was applied to the dominant hand. Blood was drawn from the antecubital vein of the non-dominant arm for both drug

applications. Thus, GTN levels ($T_{1/2}$ = 1-3 min) were measured after distribution and substantial metabolism had taken place with both drugs. The second study of 6 normal subjects measured local absorption of GTN from the site of Vascana application. Vascana (mean 5.22 mg GTN) was applied to both hands. Blood was drawn from an antecubital vein for both drug applications. Thus, blood was drawn only centimeters from the site of one half of the Vascana application; GTN metabolism would be very limited at that distance. Plasma levels were measured up to 12 and 8 hours after drug application, respectively. In both studies, plasma levels of GTN and its glyceryl dintrate metabolites (1,2 glyceryl dintrate and 1,3 glyceryl dinitrate) were measured using LCMS with negative ion electrospray ionization with a lower level of detection of 40 pg/ml.

Results: In the first study, GTN was detectable at one very low level (41 pg/ml) in only one patient 1 hour after receiving Vascana. The mean GTN area-under-the-curve (AUC in pg·hr/ml) was 2.1 with Vascana and 1111.3 with ointment. The mean GTN T_{max} was 1.0 hr and 4.0 hr, respectively. The mean GTN C_{max} was 3.5 and 173.9, respectively. The mean AUCs for 1,2 glyceryl dinitrate were 675.7 and 15946.3, respectively. The mean AUCs for 1,3 glyceryl dintrate were 69.7 and 3421.2, respectively.

In the second study, the mean GTN AUC (pg·hr/ml) was 7228 with Vascana and 1383 with ointment. The mean GTN T_{max} was 5.25 hr and 4.21 hr, respectively. The mean GTN C_{max} was 2163 and 402, respectively. The mean GTN plasma concentrations at 8 hr were 1163.7 and 212.3. The mean AUCs for 1,2 glyceryl dinitrate were 8755 and 16429, respectively. The mean AUCs for 1,3 glyceryl dintrate were 2273 and 3148, respectively.

Headaches, an adverse event seen in up to 85% of patients treated with nitroglycerin ointment, were seen in 3 Vascana and 8 ointment treatments in the first study and 2 and 4 treatments, respectively, in the second study.

Conclusion: Application of Vascana to the fingers results in substantial local absorption of GTN for at least 8 hours but in minimal systemic exposure, especially when compared to nitroglycerin ointment. This is reflected in Vascana's historically favorable safety profile in which headaches and dizziness were seen at rates (17.5% and 7.4%, respectively) similar to vehicle (15.3% and 6.0%, respectively).

Anorectal Sphincter Function in Systemic Sclerosis (SSc). Karin Franck-Larsson[1], Wilhelm Graf[2], Karin Edebol Eeg-Olofsson[2], Hans Axelson[2] and Anders Rönnblom[2], [1]Uppsala University, Uppsala, Sweden, [2]Uppsala University Hospital, Sweden

Purpose: In a previous population-based study, we have reported that 30% of the SSc patients suffer from fecal incontinence to varying extent (Franck-Larsson et al, Eur J Gastroenterol Hepatol 2009). The aim of the present study is to elucidate the underlying mechanisms.

Method: A cohort of 25 SSc patients with and without fecal incontinence underwent clinical anorectal examination and investigations with proctoscopy, anorectal three-dimensional ultrasound, anorectal manometry, pudendal nerve terminal motor latency, standard EMG and single fiber EMG, and answered questionnaires on symptoms and quality of life (SF-36).

Results: Forty-four % reported incontinence to solid and/or liquid feces. Rectocele was present in 30%, and peri-anal scleroderma skin changes in 30% of the patients.

Sonographic abnormalities, either as thin sphincters or sphincter defects, were present in 17%, all in patients with incontinence to solid and/or liquid feces. These morphologic changes were inversely associated to the resting pressure at 1-2 cm and to squeezing pressure at 2 cm (p=0,035 and 0,028 respectively, Mann-Whitney U), and were also associated to incontinence to solid feces and defecation problems (p=0,017 and 0,026 respectively, Pearson Chi Square).

Failure to increase anal pressure at attempted squeeze was seen in 28%. Increased fiber density was recorded bilaterally in 61% and unilaterally in another 22% of the patients. In patients with increased fiber density, maximum squeeze pressure was significantly lower at 2 and 3 cm (p=0,019 and 0,006 respectively Mann-Whitney U) in comparison with patients with normal fiber density; however, symptoms did not differ between the groups. Distal pudendal nerve latency was increased in 21%.

Conclusion: In patients who reported fecal incontinence, decreased squeeze pressure were recorded in the high pressure zone, and thin or defect sphincters. A majority of the SSc patients had increased fiber density, possibly indicating previous nerve injury with consequent

reinnervation. We concluded, that both structural and neurogenic mechanisms are likely to influence the development of fecal incontinence in SSc patients.

462

Transition FROM "EARLY Systemic Sclerosis" to Definite Systemic Sclerosis. Sheila Melchor[1], Atusa Movasat[1], Beatriz E. Joven[1] and PE. Carreira[2], [1]Hospital 12 de Octubre, Madrid, Spain, Madrid, Spain, [2]Hospital 12 de Octubre, Madrid, Spain

Purpose: To analyze: a) the time between the onset of Raynaud and the diagnosis of systemic sclerosis, according to the 1980 ACR Criteria(1), in a series of consecutive patients diagnosed of early systemic sclerosis, according to the criteria proposed in 2001 for early SSc criteria(2); and b) the clinical differences between patients fulfilling and not fulfilling the 1980 ACR criteria after a follow-up period.

Method: Demographic (birth date, sex) and clinical data (date of Raynaud onset, smoking habit, HBP, hyperlipemia, mRSS, presence of hand edema, ischaemic lesions, arthritis, gastrointestinal, pulmonary or cardiac symptoms, ANA, aScl70, anticentromere (ACA) and aRNP antibodies) of all patients sent for a capillaroscopy to the rheumatology department between 1994 and 2008 because of Raynaud phenomenon were included prospectively in a data base created in 1994. All patients showing typical SSc capillaroscopic findings and/or ANA (+), and no criteria for other autoimmune disease, were diagnosed as early SSc, followed at least yearly, and diagnosed of definite SSc when they presented the 1980 ACR criteria. Time between Raynaud onset and first capillaroscopy, and definite SSc diagnosis or last visit was analyzed. Clinical differences between patients with definite or early SSc diagnosis after the follow-up period were compared with Chi square and t tests.

Results: From 670 patients sent for capillaroscopy during the study period, 74 (10 m, 64 f; 52±16 y) were diagnosed as early SSc(2). At capillaroscopy, median time from Raynaud was 3.3 y (mean 8.2±9.7 y). Forty nine (66%) had pathologic capillaroscopy, 69 (93%) ANA, and 46 (62%) both. Five (7%) had aScl70, 47 (64%) ACA and 9 (12%) aRNP. Thirty two (43%) presented hand edema, 54 (73%) sclerodactily, 7 (10%) ischaemic lesions, 7 (10%) pulmonary fibrosis, and 34 (47%) esophageal involvement. After a median of 3 years (mean 4.3±4.1 y) of follow-up, and a median of 12 years (mean 11±10.3) from Raynaud onset, 31 patients (42%) achieve an SSc definite diagnosis, in all cases as limited cutaneous SSc. The other 43 patients (58%) remained as early SSc. Patients who maintained the diagnosis of early SSc after the follow-up had less ischaemic lesions (OR=0.09; 95%CI 0.01-0.9; p=0.02) and pulmonary fibrosis (OR=0.1; 95%CI 0.01-0.9; p=0.04), than patients who developed the 1980 SSc classification criteria(1), but not other differences between both groups were found.

Conclusion: A large percentage of patients (nearly 60%) with Raynaud phenomenon and clinical findings suggestive of SSc remain undiagnosed after long term follow-up, according to the 1980 ACR classification criteria for SSc(1). In our series, only including the presence of ANA or the capillaroscopic changes characteristic of SSc as minor criteria, as suggested by LeRoy and Medsger in 2001(2), would allow the classification of all our pre-scleroderma patients as definite SSc. This would be important to be able to include these patients in clinical trials.

Prognostic Role of ECG in Pulmonary Hypertension Associated with Systemic Sclerosis (SSc). Cathryn Byrne-Dugan, Elena Schiopu, Ann J. Impens, James R. Seibold and Kristine Phillips, University of Michigan, Ann Arbor, MI

Purpose: To examine whether ECG parameters in patients with systemic sclerosis (SSc) and pulmonary arterial hypertension are associated with survival.

Methods: Consecutive patients in a tertiary care referral center with PAH and a confirmed diagnosis of scleroderma between 2000 and 2009 were assessed. Clinical examination, medications, ECG, echocardiogram, BNP, six minute hallwalk, pulmonary function tests and imaging, and right heart catheterization results were recorded. The following measurements were recorded from each ECG: P-wave amplitude in lead II; mean frontal QRS axis; QRS duration; R-wave and S-wave deflections in leads I and V1-V6; and T-wave configurations in the precordial leads. These ECG variables were correlated with hemodynamic variables on right heart catheterization.

Results: Of the 40 patients included in this study, 35 (88%) were women. In these patients with a diagnosis of SSc and pulmonary hypertension, mortality was high, with most of the 31 deaths occurring within 1-2 years of PAH diagnosis. Patients with improved survival were more likely to have normal ECGs. More than half of the patients in the study had abnormalities of the right ventricle, either structural or physiologic. Twenty-three patients had evidence of right axis deviation (QRS >90 degrees) and sixteen of these patients exhibited right ventricular strain in the precordial leads. Evidence of right ventricular strain by ECG (ST deviation and T wave inversion in V1-V3) was associated with decreased survival ($p<0.05$). Although only one had a complete right bundle branch block, five other patients had incomplete right bundle branch block. Right ventricular hypertrophy was seen with increased frequency, as was an increased p wave amplitude (>0.25 mV in lead II).

Conclusion: ECG results reflecting abnormalities in the right ventricle are associated with a poor prognosis and may be useful for therapeutic decisions in patients with SSc.

Profile of Pre-Scleroderma Evolution. Beatriz Rodriguez-Lozano, Esmeralda Delgado-Frias, Vanesa Hernandez-Hernandez, Maria Angeles Gantes-Mora, Elisa Trujillo-Martín and Sagrario Bustabad-Reyes, Hospital Universitario de Canarias, La Laguna; Tenerife, Spain

Purpose: To describe the pattern of evolution and identify possible predictive risk factors in the pre-scleroderma phase.

Method: Retrospective study of patients diagnosed with pre-scleroderma based on the presence of Raynaud´s phenomenon and positive autoantibodies (nucleolar pattern ANA or anti-Scl-70 or anticentromere antibodies) and/or capillaroscopic findings of scleroderma pattern, during a period of 10 years. These patients were referred to our Rheumatolgy Department for capillaroscopy during the years 1999-2001. Clinical evaluation was performed (degree of cutaneous involvement using a modified Rodnan skin score, ANA and specificities, capillaroscopy performed by the same observer, ECG, chest radiography, respiratory function tests (spirometry/DLCO), echocardiogram, esophageal manometry and renal function) at the baseline and end of the study. At baseline, none of the patients met the criteria for the classification of SSc (ACR 1980).

Results: Of 290 patients undergoing capilloroscopy in the period 1999-2001, 17 patients (7%), all women, median age 52 years (19-62), were diagnosed with pre-scleroderma (7%) and 1 patient with diffuse SSc after the first clinical/immunological/ capillaroscopic evaluation. Reasons for performing capillaroscopy in the selected population were: Raynaud´s (65%), early "puffy" scleroderma (12%) and Raynaud´s with positive Scl-70/ anticentromere antibodies (18%). Baseline capillaroscopic patterns (Maricq) were: Slow escleroderma (5.28%), active scleroderma (3.17%), non-specific pattern of connective tissue disorders (6.34%) and normal (4. 23%). Clinical data included finger edema (12. 62%), dysphagia (11. 62%), pathologic esophageal manometry (47%)(inferior esophageal sphincter hypotonia:7; esophageal aperistalsis: 1), chest radiography with interstitial pattern (4.24 %) with DLCO/VA alteration in 2 patients. At baseline, no patients presented sclerodactyly-type skin involvement associated with lung involvement. Follow-up during 8-10 years was performed in 15 patients (one was lost to follow up and one died after 3 years). Evolution to defined SSc was found in 5 patients (30%) : 4 diffuse (1 being the patient who died) and 1 with SSc sub-type CREST. All these patients at baseline had presented: Raynaud, positive Scl-70 or anticentromere antibodies, cutaneous involvement of the sclerodactyly or visceral (esophageal) type and slow capillaroscopic pattern of scleroderma.

Conclusion: Of all patients referred for capillaroscopy in a 3-year period, 7% were diagnosed with pre-scleroderma.

In this exploratory study, evolution to defined SSc was observed in 30% of these patients after a 10-year follow up period.

Given the infrequency of this disease, multicenter studies are required to be able to draw conclusions with statistical power. However, all those patients who evolved to SSc presented the following at baseline: Raynaud´s, positive anti-Scl-70 or anticentromere, early edematous scleroderma or visceral (esophageal) involvement and slow capillaroscopic pattern of scleroderma.

Nearly Half of the Patients with Severe Primary Pulmonary Arterial Hypertension Associated to Systemic Sclerosis Do Not Fulfill the 1980 ACR Classification Criteria for the Disease. Beatriz E. Joven, M. José Ruiz-Cano, Raquel Almodovar, Pilar Escribano, Miguel A. Gómez-Sánchez and PE. Carreira, Hospital 12 de Octubre, Madrid, Spain

Purpose: To investigate the fulfillment of ACR 1980 Preliminary Classification Criteria for Systemic Sclerosis[(1)] (SSc) in a group of patients with severe primary pulmonary hypertension associated to systemic sclerosis followed in the same University Hospital

Method: All patients with SSc, fulfilling either the 1980 ACR SSc preliminary classification criteria[(1)] or the proposed 2001 classification criteria for early SSC[(2)] were prospectively included in a database created in 1989, containing demographic and clinical information. In the database, severe primary pulmonary arterial hypertension (PAH) was defined as a mean pulmonary arterial pressure (PAP), obtained in right heart catheterization higher than 50 mm Hg, in the absence of pulmonary fibrosis, thromboembolic disease or other known causes of pulmonary hypertension. Severe PAH patients were selected and the presence of the 1980 ACR criteria for SSc classification was analyzed. Odds ratio with 95%CI was used to measure the strength of association between qualitative variables and t test for independent samples to analyze the differences between quantitative variables.

Results: Out of 298 patients included in the SSc database, 24 (8%, 1m, 23f) presented severe PAH. Only 13 (54%) fulfilled the 1980 ACR criteria for SSc classification. Four had diffuse and 20 limited cutaneous disease. ANA were positive in 22 (92%) and ACA in 17/22 (77%). One of ACA positive patients had also aScl70 antibodies. Capillaroscopy was characteristic of SSc in 11 patients in which the technique was performed. All patients not fulfilling the 1989 ACR SSc classification criteria presented Raynaud, sclerodactily and ANA positivity. Besides 7/9 had ACA and 5/5 pathologic capillaroscopy. The only difference between patients fulfilling or not the ACR criteria was the presence of ischaemic ulcers, only present in patients fulfilling them (p=0.002). Thirteen patients died, including 4 not fulfilling ACR SSc classification criteria, 11 because of PAH, after 3.3±4.6 years of PAH diagnosis.

Conclusion: Nearly half of the patients with PAH associated to SSc do not fulfill the 1980 ACR preliminary classification criteria for the disease. All patients with PAH-SSc not fulfilling the classification criteria show clinical symptoms of SSc (Raynaud, sclerodactily, capillaroscopic changes) and present ANA (mainly ACA) in their sera. To be able to include these patients in clinical trials following international guidelines, it would be necessary to revise the actual classification criteria. According to our series, only including the presence of ANA or the capillaroscopic changes characteristic of SSc as minor criteria, as suggested by LeRoy and Medsger in 2001[(2)], would allow the classification of all our PAH patients as SSc.

Elevated sVEGFR-1 Is a Candidate Biomarker for Pulmonary Dysfunction in Patients with Systemic Sclerosis. Ziad A. Taimeh, Jessica Gordon, Emma J. MacDermott, Lilliana Barillas, Jamie Mersten, Roland Duculan, Robert Spiera, Mary K. Crow and Kyriakos A. Kirou, Hospital for Special Surgery, New York, NY

Purpose: Circulating mediators of angiogenesis include vascular endothelial growth factor (VEGF) and its soluble receptor (sVEGFR-1), which binds VEGF and inhibits its biologic activities in vivo. These factors may reflect and contribute to dysregulated angiogenesis in patients with Systemic Sclerosis (SSc). In the present study, we measured levels of VEGF and sVEGFR-1 in a cohort of patients in the scleroderma registry at our institution and related these findings to clinical and laboratory parameters.

Method: Sera from 80 patients with SSc, 20 patients with systemic lupus erythematosus (SLE) and 20 healthy donors (HD) were obtained along with data from histories, physical exams, and medical records. Sera were assayed for VEGF and sVEGFR-1 using ELISA kits per the manufacturer's protocol, and values were expressed in pg/ml. Bivariate statistical analysis was performed to compare levels between SSc and control groups, and between subgroups of SSc patients with respect to differences in disease duration (early vs late disease) and key disease manifestations [presence or absence of digital tip ulcers (DTU), interstitial lung disease (ILD) and pulmonary hypertension (PAH)].

Results: Median circulating levels of VEGF were higher in patients with SSc (493) than in those with SLE (348; p=0.0016) or healthy donors (HD) (360; p=0.019). Median levels of sVEGFR-1 were also significantly higher in the SSc group (115) relative to HD (99; p=0.01), but were similar to SLE (110). VEGF levels positively correlated with sVEGFR-1 levels (r=0.39; p=0.0004). Patients with early disease (<5 years) had significantly higher levels of VEGF (548) compared to patients with late disease (376), and VEGF/sVEGFR-1 was higher in early disease (5.23 vs 3.63; p=0.033). Patients with a history of DTU tended to have lower levels of VEGF (497) compared to those with no ulcers (621; p=0.2), and no differences in sVEGFR-1 levels. In contrast, patients with Interstitial Lung Disease (ILD), defined by lung fibrosis (by X-Ray or CT Scan) or pulmonary function tests [forced vital capacity (FVC) and carbon monoxide diffusion capacity (DLCo) less than 80% of predicted, showed higher values of sVEGFR-1 (121) than patients without ILD (109; p=0.04), with no difference in VEGF levels. In addition, serum levels of sVEGFR-1 negatively correlated with FVC (r=-0.39; p=0.013) and DLCo (r=-0.33; p=0.03).

Conclusion: Levels of serum VEGF and sVEGFR-1 were elevated in patients with SSc. Higher levels of VEGF occurred in early SSc. In contrast, levels of sVEGFR-1 were high in both early and late disease. Increased sVEGFR-1 in SSc patients with important pulmonary disease raises the question of whether this is a hypoxia-induced phenomenon or whether sVEGFR-1 directly contributes to the pathogenic process. sVEGFR-1 may be a candidate biomarker useful for predicting or detecting pulmonary dysfunction.

Gynecologic and Obstetric History IN Systemic Sclerosis (SSC) PATIENTS IN Spain: A Case Control Study. N. Dorado, M. Pérez, MA Roldán, SI Piedrabuena, BE Joven and PE. Carreira, Hospital 12 de Octubre, Madrid, Spain

Purpose: To analyze: 1.gynecologic and obstetric (gyn-obs) history in systemic sclerosis (SSc) patients, compared with healthy controls; 2.the influence of SSc in patients gyn-obs history; and 3.if this influence is different in SSc subgroups.

Method: A semistructured questionnaire on gyn-obs history was sent to all SSc women followed between 1995-2008 in the rheumatology department of a University Hospital, and to an age-matched control group, comprised by women seen in rheumatology because of mechanical problems, without any evidence of autoimmune disease. SSc patients information: age at onset, SSc subgroup (diffuse or limited), clinical data (lung, renal or cardiac involvement, pulmonary hipertension (PH), antibodies (ANA, anticentromere (ACA), a-Scl70)), had been previously included in a prospective database containing demographic and clinical information. The following groups were analyzed: whole SSc and control group; patients and control older than 45; control group with SSc subgroups (diffuse, limited, ACA (+), aScl70 (+), with interstitial lung disease); control group with SSc patients with disease onset before 35; SSc diffuse and limited; SSc ACA (+) and (-); SSc aScl70 (+) and (-). Chi square and t test were used to analyze differences between groups. Univariate logistic regression was used to analyze the influence of SSc presence in gyn-obs history.

Results: Questionnaire was answered by 98/150 SSc patients and 94/150 controls, with a mean age of 55±15 and 52±12 years, respectively. In the SSc group, 63(64%) had limited and 35(36%) diffuse disease, 25(27%) had lung involvement, 26(28%) had aScl70 and 41(43%) had ACA. The only difference in the gynecologic history was less frequent use of postmenopausal hormonal substitutive therapy (HST) in SSc group (OR=0.3; 95%CI 0.1-0.7; p= 0.005). In obstetric history, SSc patients have been ever pregnant (OR=0.44; 95%CI 0.2-0.9; p= 0.02), and have had the intention to become pregnant less frequently (OR= 0.5; 95%CI 0.2- 0.9; p= 0.04) than controls. There were no differences between ever pregnant women in number of pregnancies or percentage of alive new-born. Similar results were obtained when women older than 45 years were analyzed. These differences were higher when only diffuse SSc or aScl70 (+) patients were analyzed, but were not present when only limited or ACA (+) patients were analyzed. Patients with SSc onset before 35 years were less frequently pregnant (OR=0,2; 95%CI=0.1-0.6; p=0.004), and have had ever the intention to become pregnant (OR=0.3; 95%CI=0.1-0.6; p=0.004), than age

adjusted controls. When analyzing subgroups of SSc patients, diffuse and aScl70 (+) patients showed similar results. Menopause happened at earlier age (p=0.001) and was not natural more often in the diffuse and aScl70 subgroups (OR=0.1; 95%CI= 0,03-0,5; p=0,003)

Conclusion: SSc patients, especially those with diffuse disease or aScl70 antibodies, are less often ever pregnant and have less intention to become pregnant than healthy controls. These is confirmed for patients with disease onset before 35 years. SSc patients are less frequently treated with HST after menopause. Menopause occurs earlier and is more often not natural in SSc patients with diffuse disease and aScl70 antibodies.

CANCER Incidence In Systemic Sclerosis In Spain: A Case Control Study. Beatriz E. Joven, Regina Fare, Francisco J. Colina, Belen Ramos and PE. Carreira, Hospital 12 de Octubre, Madrid, Spain

Purpose: To analyze: 1) the incidence of cancer in a large series of SSc patients, followed a University Hospital during the last 28 years; 2) to compare with a control group, and 3) to compare disease presentation in SSc patients with and without cancer.

Method: Demographic and clinical data from all SSc patients regularly followed in the rheumatology department of our Hospital were prospectively included in a data base created in 1989. A sex and age-matched control group of patients seen in the rheumatology department because of mechanical problems during the same period, was randomly selected. Patients with cancer were obtained from the cancer registry in our hospital. Type of cancer, extension, know risk factors for cancer development (family history, smoking habit, other toxics), cancer treatment and outcome were obtained from the patients charts. For SSc patients, temporal relationship with SSc was also obtained. Chi square, t test, bivariate logistic regression was used to analyze differences in cancer incidence between both groups and differences between SSc patients with and without cancer.

Results: From 270 SSc patients (86% females), 28 (24 f, 5 m) had any type of cancer: 8 breast, 1 lung, 2 colon, 11 skin (1 melanoma, 7 basal cell carcinoma, 1 lip ductal terminal carcinoma, 2 epidermoid). Five patients (3 basal cell carcinoma, 1 colon, 1 breast) presented a second cancer (basal cell carcinoma in all cases). From 317 control patients (86% females), 20 (14 f, 6 m) had any type of cancer: 3 breast, 4 skin, 3 prostate, 10 others. Cancer incidence was higher in SSc patients, without statistical significance (p=0.09), but skin cancer was more frequent in SSc patients (OR=3.3; 95%CI 1.05-10.6; p=0.04), especially in female group (OR=6; 95%CI 1.3-27.8; p=0.02). Although breast cancer was also more frequent in SSc patients, this difference was not significant (p=0.1). No other differences were found between SSc and control group in cancer incidence. Within the SSc group, 8 patients were smokers and 5 had family history of cancer. Mean age at cancer diagnosis was 59±13. Neoplasia was localized in 24 and metastatic in 4. Cancer treatments included surgery (26 cases), quimiotherapy (10) and radiotherapy (4). Cancer was considered cured in 22, and 6 patients died from the neoplasia. Six patients had a cancer recidiva. Cancer was previous to SSc development in 9 (7±5 y), coincidental with SSs (less than 12 months) in 2, and posterior in 17 (20±15 y). Skin cancer presented after SSc diagnosis in 73% of cases. Eleven patients had diffuse and 17 limited disease. ANA was positive in 86%, ACA in 40% and Scl70 in 13%. Patients with cancer tended to be older at first SSc symptom (p=0.04), but there were not any other clinical differences between SSc patients with and without cancer.

Conclusion: The incidence of skin cancer in Spain is higher in SSc patients after SSc diagnosis than in control population, especially in females. This finding suggests that SSc patients should receive special advice about sun exposure. Although other types of cancer, as breast cancer, might be more frequent in SSc patients, our study is unable to confirm these data. Cancer does not seem to have a worse outcome in SSc than in control population, and does not seem to be associated to special features in SSc patients.

Autoantibody Profiles in Systemic Sclerosis More Predictive of Clinical Outcomes Than Disease Subset Classification. Laisvyde Statkute[1], Mary Carns[1], Spencer Huang[1], Monique E. Hinchcliff[1] and John Varga[2], [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Systemic sclerosis (SSc) clinical subtypes, diffuse (dcSSc) and limited (lcSSc), have been associated with specific autoantibodies (autoAb): anticentromere (ACA) for lcSSc and topoisomerase 1 (topo-1) for dcSSc. Patients with lcSSc/topo-1 and patients with dcSSc/ACA could be referred as "atypical". Additionally, patients lacking ACA or topo-1 likely express 1 of less common SSc-specific autoAb (double negative, DN). We compared different subsets of patients (by clinical subtype and autoAb) to determine if specific autoAb or clinical subtype is more predictive of particular SSc manifestations.

Methods: 254 consecutive patients with SSc seen at the Northwestern Scleroderma Program between 2005 and 2008 were evaluated retrospectively. Subjects were assigned into 1 of 6 groups based on clinical classification and autoAb (determined by ELISA). T and Chi square tests were utilized, $p<0.005$ was used for level of significance.

Results: 167 patients (66%) had lcSSc and 87 (34%) had dcSSc. 27% of lcSSc patients were ACA+ and 23% were Topo-1+. 5% of dcSSc patients were ACA+ and 35% were Topo-1+. 50% of lcSSc, 60% of dcSSc and 53% of total were DN.

Patients with lcSSc who had topo-1 were more likely to have pulmonary fibrosis (PF) and less likely to have pulmonary hypertention (PH) compared to other lcSSc patients with either ACA or DN. No patients with topo-1 or ACA developed scleroderma renal crisis (SRC). Within 1st group of comparison (dcSSc/topo-1 vs lcSSc/topo-1) presence PF was comparable (97 vs 83%, p=0.073). In group 2 (dcSSc/ACA vs lcSSc/ACA), PF was present in 50 vs 24%, isolated PH in 25 vs 28%, not statistically significant. For group 3 (dcSSc/topo-1 vs dcSSc/ACA), rate of PF (97 vs 50%) and isolated PH (0 vs 25%) differed significantly. Group 4 (dcSSc/DN vs dcSSc/ACA) showed no differences in PF, PH or isolated PH. dcSSc/DN had 4 SRC cases (8%); 23% had severe cardiac involvement and 9 patients (17%) died. Within group 5 (lcSSc/topo-1 vs lcSSc/ACA), PF (83% vs 24%, $p<0.001$) including severe (16 vs 4%) was more prevalent in patients with topo-1. Group 6 (lcSSc/topo-1 vs lcSSc/DN) showed similar significant differences in rates of PF (83 vs 54%) and isolated PH (0 vs 13%). lcSSc/DN demonstrated another 3 SRC cases (4%) and frequent (15%) severe cardiac involvement.

Conclusion: While ACA is rare in patients with dcSSc, topo-1 is frequent in patients with lcSSc.Topo-1 positive lcSSc patients are at higher risk for PF than other lcSSc patients. However, no patients with topo-1 developed SRC. These results indicate that while ACA is useful in delineating clinical subsets of SSc, topo-1 is less predictive. Furthermore, autoantibodies are more predictive of severity and disease outcomes than clinical subsets. In particular, disease manifestations and severity in lcSSc patients who are topo-1 positive are comparable to those in dcSSc patients.

470

Pharmacokinetics of Oral Treprostinil in Patients with Systemic Sclerosis (SSc) and Digital Ulcer Disease. Elena Schiopu[1], Kristan Rollins[2], Michael Wade[2] and James R. Seibold[1], [1]University of Michigan, Ann Arbor, MI, [2]United Therapeutics Corp, Research Triangle Park, NC

Purpose: Fibrotic arteriosclerosis with endothelial dysfunction is the hallmark of SSc (scleroderma) and is the underlying cause of clinical complications including Raynaud's phenomenon, digital ulcers, pulmonary hypertension and renal crisis. Prostacyclins are proven effective therapies for pulmonary hypertension, but delivery systems can be either cumbersome (IV, SQ) or targeted (inhalation). Treprostinil diethanolamine (TDE), an oral prostacyclin ($PGI_{2)}$ analogue, is in development as an oral sustained release (SR) tablet. The availability of a formulation permitting convenient systemic delivery might have applicability to non-pulmonary SSc vascular complications. The objective of this study was to evaluate the disposition of TDE SR in patients with systemic sclerosis with peripheral vascular complications.

Methods: Patients with SSc (as defined by the ACR criteria) and evidence of peripheral vaso-occlusive disease (defined as presence or history of an active digital ulcer within the past 6 months) participated in this study. Subjects with PAH were excluded. A single 1 mg TDE SR oral dose was administered in the morning following a standardized 500 kcal breakfast. Fourteen blood samples were obtained over 24 hrs and plasma concentrations of treprostinil quantified by liquid chromatography/mass spectrometry. Pharmacokinetic (PK) parameters were calculated using non-compartmental analysis.

Results: Eight subjects were recruited (7 females / 1 male). The mean age was 48.5 years and the mean disease duration was 12.8 years. Five subjects had limited SSc and three had diffuse SSc. We compared the PK data to those obtained from a pool of healthy volunteers. Results are shown as geometric mean (CV%).

Parameter	SSc N=8	Healthy Volunteers N=128
$AUC_{0\text{-}24hr}$ (hr*pg/mL)	3908 (62%)	2974 (49%)
Cmax (pg/mL)	671 (42%)	601 (48%)
Tmax (hr)	4.2 (42%)	4.1 (48%)
Total Clearance (L/hr)	247 (59%)	325 (48%)
$T_{1/2}$(hr)	3.96 (87%)	3.38 (63%)

SSc exhibited similar mean maximum plasma concentrations and modestly higher AUC values (by mean factors of 1.1 and 1.3). Headache and nausea were the most commonly reported adverse events in three and two SSc subjects, respectively.

Conclusion: TDE SR is absorbed and had no unexpected adverse effects following administration of a single 1 mg dose in SSc patients with peripheral vascular disease. Although the study population was expected to display a variable degree of absorption due to SSc-related gastro-intestinal complications, the pharmacokinetic profile was comparable to that observed in healthy volunteers. Multiple dose PK studies are in progress and will support dosing guidelines in controlled trials in SSc patients.

C-Reactive Protein (CRP) Is Associated with High Disease Activity in SSc. Results From the Canadian Scleroderma Research Group (CSRG). J. Pope[1], Sarah Harding[2], Sarit Khimdas[3], Ash Bonner[4] and Murray Baron[5], [1]St Joseph Health Care, London, ON, [2]University of Western Ontario, London, ON, [3]Schulich School of Medicine & Dentistry, University of Western Ontario, London, ON, [4]McMaster University, Hamilton, ON, [5]Jewish General Hospital, Montreal, QC

Purpose: It has been reported that elevated ESR in SSc increases morbidity and mortality. Little is known about the predictive value of the CRP in SSc.

Method: The CSRG is a large multi-site dataset comprised of annually assessed SSc patient physical exam and laboratory parameters. Statistical comparisons were made for CRP in early vs late SSc, diffuse vs limited, association with skin score and disease activity (MD and patient assessment of disease activity). CRP was drawn annually and normal is up to 8.0mg/L.

Results: 938 patients were analyzed of whom 47% (413) had diffuse SSc and 41 were early diffuse patients (<3 years from first non-Raynaud's symptom). Patient baseline characteristics are reported below:

	Total	All Limited	All Diffuse	Early diffuse <3yrs	Late diffuse >3years
N	938	455	413	41	366
% Female	86	88	83	78	83
Mean Age	55.4 (12.3)	57.6 (12.0)	53.1 (12.2)	52.2 (12.32)	53.1 (12.21)
Mean CRP (mg/L)	9.76 (19.3)	9.39 (18.05)	10.18 (20.54)	17.17 (29.82)	9.27 (19.05)
% with Elevated CRP(>8mg/L)	26.8	25.5	28.6	37.8	26.7
Mean ESR (mm/h)	22.69 (21.5)	20.92 (20.29)	24.74 (22.8)	27.94 (28.63)	24.10 (21.58)
% with Elevated ESR(>20mm/h)	39.5	36.0	43.8	36.1	44.3
Mean (SD) mRSS	10.29 (9.5)	5.52 (4.37)	16.39 (10.5)	21.8 (10.41)	15.74 (10.28)

% mRSS >10	36.1	12.7	65.3	87.8	62.6
Correlation (r): CRP vs mRSS	.197**	.144**	.315**	.040	.326**
Correlation (r): CRP vs MD Global Assessment	.282**	.222**	.389**	.486**	.363**
Correlation (r): CRP vs Patient Global Assessment	.199**	.118*	.279**	.016	.285**
Mean difference in CRP between Tendon Friction Rubs yes – no	2.43	3.49	7.21*	19.19	5.16
Correlation (r): CRP vs ESR	.348**	.324**	.372**	.550**	.341**

Baseline characteristics reported as mean (SD) and Spearman's rho. P-values for comparison with CRP based on 2-tailed T-test *p<0.05, **p<0.01

Though some of the data may not be consistent in all subsets, CRP was significantly associated overall with modified Rodnan Skin Score (mRSS), MD and patient global assessments and ESR. The mean difference in CRP between tendon friction rubs (yes and no) was significant for diffuse SSc.

Conclusion: It appears that CRP is elevated in many SSc patients especially early diffuse SSc. It is associated with other active signs of disease such as tendon friction rubs and MD and patient global assessments. Interventions that lower CRP may be worth pursuing in active SSc.

Modified-Release Sildenafil Reduces Raynaud's Attack Frequency in Systemic Sclerosis. Ariane L. Herrick[1], Frank van den Hoogen[2], Armando Gabrielli[3], Nihad Tamimi[4], Carol Reid[4], Damian O'Connell[4], Maria-Dolores Vazquez-Abad[4] and Christopher P. Denton[5], [1]University of Manchester, Salford Royal Hospital, Salford, United Kingdom, [2]Rheumatology, Nijmegen, Netherlands, [3]Università politecnica delle Marche, Ancona, Italy, [4]Pfizer Ltd, Sandwich, United Kingdom, [5]UCL Medical School, London, United Kingdom

Purpose: To examine the effect of sildenafil in patients with Raynaud's phenomenon (RP) secondary to limited cutaneous systemic sclerosis (SSc).

Methods: This double-blind, placebo-controlled study randomized 57 patients with RP/SSc to receive modified-release (MR) sildenafil 100 mg once daily for 3 days followed by MR sildenafil 200 mg once daily for 25 days or placebo. The primary endpoint was the change in the number of Raynaud's attacks per week, expressed as a percentage change from baseline, assessed using analysis of covariance (ANCOVA) with treatment as a factor and baseline as a covariate. Secondary endpoints included Raynaud's condition score (RCS) and pain score (assessed using ANCOVA), serum biomarkers (soluble vascular and intercellular adhesion molecules and pro-collagen type I N-terminal peptide) and endothelial dysfunction assessed by a peripheral arterial tone (PAT) device (summaries only). Efficacy was assessed in the per-protocol (PP) population (patients who received all treatments, completed diaries, and did not violate protocol). Digital ulcers and dyspepsia were exploratory endpoints.

Results: The PP population included 45 patients (sildenafil, n=20; placebo, n=25). The mean percentage change from baseline to day 28 in number of attacks per week was greater with sildenafil than placebo (–44.0% vs –18.1%, *P*=0.034); the mean number of attacks per week improved from 25.0 at baseline to 19.3 after placebo treatment, and from 30.5 to 18.7 after sildenafil treatment. Decreases from baseline in

RCS, duration of attacks, and Raynaud's pain score were not statistically significantly different between groups. Mean values and changes from baseline in PAT responses and serum biomarkers were similar between groups. The number of patients with digital ulcers improved with sildenafil from 5 (25%) at baseline to 4 (20%) at day 14 and to 3 (15%) at day 28; with placebo, the number of patients with digital ulcers was 3 (12%) at baseline, 4 (16%) at day 14, and 5 (20%) at day 28. The number of patients with dyspepsia was 5 (25%) at baseline and 9 (45%) at day 28 for sildenafil compared with 5 (20%) at baseline and 5 (20%) at day 28 for placebo. The most frequent treatment-emergent adverse events were headache and dyspepsia; the majority of adverse events were mild or moderate.

Conclusion: Sildenafil reduced attack frequency in patients with RP secondary to limited cutaneous SSc and was well tolerated. Sildenafil may be a treatment option in this patient population.

Differences in Overall Disability as Measured by the Health Assessment Questionnaire (HAQ) Between Patients with and without Digital Ulcers in Systemic Sclerosis (SSc): A Post Hoc Analysis of Pooled Data From Two Digital Ulcer Randomized Controlled Trial. J. Pope[1] and Caleb Zelenietz[2], [1]St Joseph Health Care, London, ON, [2]University of Western Ontario, London, ON

Purpose: We studied patients with SSc enrolled in two RCTs using bosentan which has been shown to prevent DU. Patients completed the Health Assessment Questionnaire (HAQ) at each study visit

Methods: Data from the studies were pooled to determine the within patient differences of the HAQ between groups with and without DU; where 309 were enrolled in the two trials of whom 133 were on placebo and 176 received bosentan. Patients were pooled irrespective of drug allocation. The patients were grouped by DU status at baseline and study end into: no DU at baseline and no DU at trial end, no DU at baseline and DU at trial end, DU at baseline and no DU at trial end, DU at baseline and DU at trial end. The components of the HAQ scores that are compared are overall disability, hand function, dressing, hygiene, and grip. The main outcome was difference in HAQ score between baseline and trial end in the 4 categories in a post hoc analysis (HAQ at baseline – HAQ at end of study) was calculated for each group. A negative change in HAQ is an improvement; whereas a positive is worsening.

Results: The groups that had a different DU status at baseline than at end had greater change scores for the majority of the HAQ components compared to groups whose DU status remained constant throughout the trial. Those who had a baseline DU and none at end improved their HAQ scores. (See table)

Changes in the Health Assessment Questionnaire in SSc with and without digital ulcers.

Group	Time Course	Overall Disability Index (SHAQ)	Hand Function Score	Dressing and Grooming Score	Hygiene Score	Grip Score
DU at baseline and end (N= 175)	Start	0.95 (0.65)	1.13 (0.76)	1.25 (0.88)	1.03 (1.00)	1.10 (0.88)
	End	0.92 (0.71)	1.04 (0.80)	1.23 (0.92)	0.90 (1.00)	0.98 (0.87)
	Change	-0.01 (0.37)	-0.06 (0.53)	0.02 (0.86)	-0.09 (0.72)	-0.10 (0.70)
No DU at baseline, no DU at end (N= 32)	Start	0.65 (0.69)	0.69 (0.68)	0.77 (0.69)	0.60 (1.00)	0.69 (0.83)
	End	0.69 (0.73)	0.70 (0.74)	0.81 (0.69)	0.66 (1.04)	0.63 (0.79)
	Change	0.02 (0.34)	0.01 (0.41)	0.03 (0.54)	0.03 (0.47)	-0.03 (0.70)
DU at baseline, no DU at end (N= 84)	Start	0.89 (0.67)	0.99 (0.73)	1.31 (0.86)	0.86 (0.98)	0.81 (0.78)
	End	0.74 (0.72)	0.77 (0.75)	0.90 (0.79)	0.69 (0.97)	0.73 (0.81)
	Change	-0.14 (0.43)	-0.22 (0.56)	-0.42 (0.80)	-0.16 (0.69)	-0.08 (0.66)

No DU at baseline, DU at end (N= 10)	Start	0.54 (0.57)	0.43 (0.45)	0.80 (0.63)	0.30 (0.48)	0.20 (0.42)
	End	0.65 (0.60)	0.70 (0.64)	0.80 (0.79)	0.90 (1.10)	0.40 (0.97)
	Change	0.11 (0.21)	0.27 (0.52)	0.00 (0.67)	0.60 (0.97)	0.20 (1.0)

* Digital Ulcers, Improvement on change is -; worsening change is +

Conclusion: Patients with a DU at baseline and no DU at trial end had improvements in all components of the HAQ. The cohort of patients with no DU at baseline and a DU at trial end had worsening of all but the grooming score; but numbers were small (N=10). The overall change in HAQ did not meet the minimal important difference (MID) of 0.22, but the Hand Function part of the HAQ seemed to be above the MID when DU were present and then healed. As expected, those patients with no change in DU status from baseline to trial end had no changes in HAQ.

Circulating Inhibitors of Angiogenesis in Scleroderma. Laura K. Hummers[1], Michael Simons[2], Fredrick M. Wigley[1] and Mary Jo Mulligan-Kehoe[3], [1]Johns Hopkins University, Baltimore, MD, [2]Yale University School of Medicine, New Haven, CT, [3]Dartmouth-Hitchcock Medical School, Lebanon, NH

Purpose: Multiple studies have suggested that an imbalance of pro-and anti-angiogenic factors may be a contributing factor leading to more significant vascular disease in scleroderma. In this study we examine a panel of circulating inhibitors of angiogenesis in a cross-section of patients with scleroderma.

Methods: Plasma samples for subjects and controls were obtained and ELISAs performed for soluble VEGF receptors 1 and 2, soluble endoglin, FGF receptor 1, PDGF, IL-4, angiostatin, decorin, endostatin, PEDF, thrombospondin-1, platelet factor-4. Clinical characteristics of scleroderma patients were obtained from a comprehensive clinical database and correlations between measured factors and clinical features were assessed by univariate and multivariate analysis.

Results: Scleroderma subjects (N=94) were mostly female (88%), Caucasian (82%), limited subtype (67%) and had a mean disease duration of 10.8 years. Levels of sVEGFR1, angiostatin, and TSP1 were all markedly higher in scleroderma subjects compared with controls even when corrected for multiple comparisons (Table). Interestingly, we also found levels of endostatin, sVEGFR2 and PEDF to be lower in scleroderma. When assessing for correlations between these factors and clinical features of the scleroderma, we found that sVEGFR1 was higher in patients with diffuse disease and sVEGFR2 showed an inverse relationship with measures of pulmonary vascular disease. Endoglin levels correlated with severity of Raynaud's phenomenon, the presence of centromere antibodies and inversely correlated with DLCO, but not other measures of pulmonary disease. Endostatin showed an inverse relationship with age, but a positive association with disease duration. PEDF levels were lower in those with more severe Raynaud's phenomenon. TSP-1 was higher in those with limited vs. diffuse disease and lower in those with ILD and PAH and a positive association with FVC.

Conclusion: Patients with scleroderma have marked and varied levels of circulating inhibitors of angiogenesis suggesting that the imbalance of these and other pro-angiogenic factors may be important in the development of scleroderma vascular disease.

Factor	Normal N=30	Scleroderma N=94	P value	Mult Comp
sVEGFR1, pg/ml	0	13.3	<0.00001	0.00012
sVEGFR2, pg/ml	393.9	326.2	0.002	0.024

Patients with Diffuse Cutaneous Systemic Sclerosis (dc SSc) Treated with Oral Type I Collagen (CI) Who Experienced, d 25% Improvement in Modified Rodman Skin Score (mRSS) Upregulated IL-10 Production to Specific Cyanogen Bromide (CB) Fragments of CI. Arnold E. Postlethwaite[1], Weng Kee Wong[2], Philip J. Clements[2], Andrew H. Kang[1], Jesse Ingels[1], D. E. Furst[2] and Investigators of the SSc Phase II Oral CI Clinical Trial, [1]UTHSC, Memphis, TN, [2]UCLA, Los Angeles, CA

Purpose: A recent placebo controlled trial of oral CI showed that Late Phase (3-10 yrs duration) dcSSc patients who completed the study and took oral CI for up to 12 months (mo.) had significant improvement in the mRSS at 15 months compared to those treated (Rx) with placebo (Arthritis Rheu 58: 1810-1822, 2008). IL-10 is a potent anti-fibrotic Th2 cytokine that is expressed by T regulatory type 1 (Tr 1) cells and is induced in some laboratory models of oral immune tolerance. The present study was designed to determine whether oral CI induced IL-10 production by PBMC stimulated by purified CB fragments of bovine CI.

Methods: PBMC at baseline and after 12 mo. daily oral CI or placebo treatments were cultured with purified CB fragments of bovine α1(I) and α2(I) and mRSS was determined at these and other times including at month 15 of the trial (3 months off study medication). Patients were grouped into four categories based on whether they were Rx with CI or Placebo and whether or not they had ≥ 25% improvement at month 15 from baseline in their mRSS. Paired t test were used to analyze data.

Results: Of the 168 enrolled in the original clinical trial, 113 completed assigned 12 mo. of treatment and had IL-10 and mRSS data at both baseline and at 15 mo. As a group, all 59 placebo patients did not have significant changes in 12 month IL-10 levels in supernatants from PBMC cultured with a1(I) or a2(I) CB peptides. In contrast, as a group, the 54 patients Rx with oral CI for 12 months had significant increases at 12 months from baseline in IL-10 in supernatants from PBMC cultured with a1(I) CB 2 (Δ=+134 pg/ml, p=0.0365); a1(I) CB3 (Δ=+ 93 pg/ml, p=0.0402); a1(I) CB7 (Δ=+127 pg/ml, p=0.0198), and a2(I) CB2 (Δ=+76 pg/ml, p=0.0402). Further subset analysis revealed that ≥ 25% CI Rx mRSS "responders" had significant 12 month increases in IL-10 in supernatants from PBMC cultured with α1(I) CB4 (p=0.0414), α1(I) CB5 (p=0.0414), α1(I) CB7 (p=0.0414) and α2(I) CB2 (p=0.0414). Patients who had < 25% increase in mRSS had significant elevations of IL-10 in supernatants from PBMC cultured with a1(I) CB2 (p=0.0351) and α1(I) CB3 (p=0.0090). The placebo

treated group did not have increase in IL-10 in supernatants from cultures of their PBMC with α1(I) CB peptides. Increased IL-10 was observed with α1(I) CB2 in placebo Rx mRSS non-responders.

Conclusion: Patients with dcSSc Rx with oral CI who had ≥ 25% in mRSS had an associated upregulation of the anti-fibrogenic cytokine IL-10 to specific epitopes in regions of α1(I) and α2(I) and provides a theoretical explanation of how oral CI may improve mRSS in some patients with dcSSc.

ACR Poster Session A

Sjögren's Syndrome

Sunday, October 18, 2009, 9:00 AM - 6:00 PM

476

Lymphomas in a North American Sjögren's Syndrome Population. Jane Kang, Lytia Fisher and Frederick B. Vivino, University of Pennsylvania, Philadelphia, PA

Purpose: To describe lymphomas in a North American population with 1° or 2° Sjögren's syndrome (SS).

Method: Using a database of 527 patients with 1° or 2° SS diagnosed according to the American European Consensus Group (AECG) criteria and followed from 1/2/2003 to 2/30/2009, those with a concurrent diagnosis of lymphoma were selected and retrospectively studied. Information on demographics, sicca symptoms, extraglandular manifestations, and lymphoma presentation, year of diagnosis, cell type, and prognosis were obtained through review of electronic and paper charts.

Results: Nineteen patients had both lymphoma (prevalence 3.6%) and 1° or 2° SS. The mean age was 57.3 ± 15.2 years (18 – 79 years) at the first visit. Most patients were female (78.9%), Caucasian (94.7%), and had 1° SS (89.5%). The patient with 2° SS had CREST. The majority were ANA (94.7%) and SSA (68.4%) positive, with less being SSB (31.6%) positive. Six were SSA and SSB negative (31.6%). All had extraglandular involvement.

The mean age at lymphoma diagnosis was 56.1 ± 18.2 years (20 – 82 years). All but one patient developed sicca symptoms prior to their lymphoma diagnosis; this patient had Hodgkin's lymphoma diagnosed 33 years prior to the onset of sicca symptoms, and received chemotherapy and radiation. Eighteen of 19 patients had a single course with no evidence of recurrence during follow up. One patient had a right parotid gland MALT lymphoma, followed by recurrence on the contralateral side 6 years later. Most lymphomas presented as persistent salivary gland swelling (52.6%) or adenopathy (31.6%). MALT lymphoma was most common (57.9%), all of which were extranodal except one. No fatalities were noted during the study period. Detailed results are summarized in Table 1.

Table 1. Results

	MALT	Diffuse large B cell	Undifferentiated NHL	Small B cell	Hodgkin's	All lymphomas
Total	11 (57.9)	4 (21.0)	2 (10.5)	1 (5.3)	1 (5.3)	19
Age at lymphoma diagnosis	52.5 ± 16.7	64.5 ± 16.5	69.5 ± 4.9	72	20	56.1 ± 18.2
Lymphoma presentation						
Parotid gland swelling	7	0	0	0	0	7

Submandibular gland swelling	2	0	0	0	0	2
Cervical lymphadenopathy	1	3	0	0	1	5
Pelvic lymphadenopathy	0	1	0	0	0	1
Diffuse lymphadenopathy	0	0	1	0	0	1
Weight loss	1	0	0	0	0	1
Respiratory failure	0	0	1	0	0	1
Left anterior orbit mass	0	0	0	1	0	1
Years to lymphoma*	5.7 ± 3.3	13 ± 2.7	26 ± 15.6	12	-33	9.9 ± 8.1†

* From onset of sicca symptoms to lymphoma diagnosis

† Excluding patient who developed sicca symptoms after lymphoma diagnosis

Conclusion: These findings are the largest description to date of lymphomas in a North American SS population defined by the AECG criteria. Consistent with other reports, MALT and diffuse large B cell lymphomas were most commonly observed. T cell lymphomas or fatalities were not noted. Pathologic diagnoses usually paralleled the initial organs involved. Patients with salivary gland swelling usually had MALT lymphoma while those with localized or diffuse lymphadenopathy usually did not. Although lymphomas are a significant and at times fatal complication of SS, awareness of warning signs and prompt diagnosis may ensure a good prognosis in the North American SS population.

A Double-Blind, Placebo-Controlled, Crossover Study Using a Latin Square Design to Evaluate the Safety, Tolerability, and Efficacy of NGX267 Oral Capsules in Patients with Xerostomia Associated with Sjögren's Syndrome. Naoto Yokogawa[1], Jonathan S. Dunham[1], Lytia Fisher[1], Sue Mellberg, Frederick B. Vivino[1], Walter Chase[2], A. Kivitz[3] and Michael Murphy, [1]University of Pennsylvania, Philadelphia, PA, [2]Austin, TX, [3]Altoona Arthritis & Osteo Ctr, Duncansville, PA

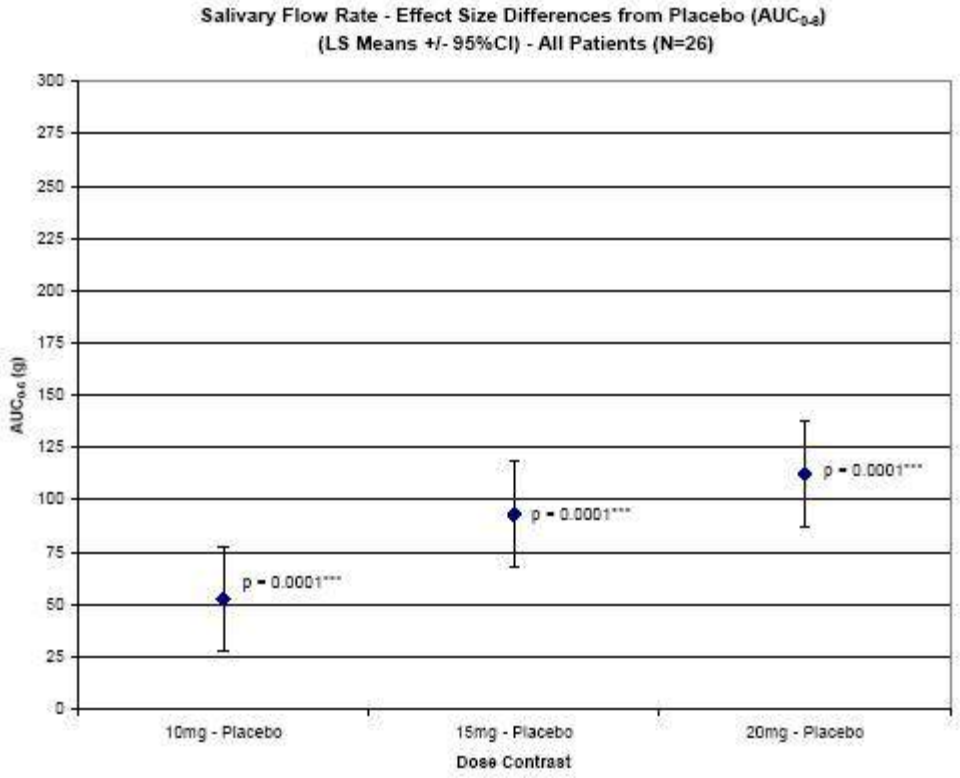
Purpose: To evaluate the efficacy and safety of NGX267 oral capsules for treatment of xerostomia due to Sjögren's syndrome.

Background: Muscarinic agonists may stimulate salivary flow and improve oral symptoms in patients with Sjögren's syndrome. However, the clinical utility of these agents is sometimes limited by dosing frequency and cholinergic side effects. NGX267 (Torrey Pines Therapeutics, Inc., La Jolla, CA) is a novel acetylcholine analog that is relatively M1 receptor selective (M1> M3>> M5> M4> M2). Prior phase I clinical studies documented increased salivary flow and tolerability of doses up to 20 mg/ day in normal elderly (age ≥ 65 years) men and women and, in doses up to 35 mg/ day in normal young adult males.

Methods: Twenty-six patients, aged 21 to 55 years with 1º or 2 º Sjögren's syndrome, diagnosed by American European Consensus Group criteria with subjective/objective salivary gland hypofunction were enrolled at 3 different centers for this 6 week protocol. After screening, patients were randomized to one of four different treatment sequences to receive single doses of NGX267 10mg, 15mg, 20mg or placebo in four separate 24 hour treatment periods interspersed by washout periods (6±2 days). A 4 x 4 Williams Latin Square crossover design was balanced for treatment order and carryover effects. Following an overnight fast, whole mouth sialometry was performed at baseline and 0.5, 1, 2, 4, 6, 12, 14 and 24 hours post dose. Subjects remained NPO except for water for the first 4 hours post dose. Unanesthetized Schirmer's tests were measured at baseline and 2, 12, 14 and 24 hours post dose. Oral symptoms including xerostomia, dry throat, dysphonia, dysphagia, cheilosis, dry tongue, level of thirst and sensation of saliva in the mouth were assessed with 100 mm visual analog scales (VAS). Safety was monitored by vitals, labs, EKGs/Holter monitors and patient diaries. The primary outcome was the cumulative salivary flow during the first six hours post-dosing of the study drug, AUCpd 0-6 (g).

Results: All doses of NGX267demonstrated a statistically significant dose-dependent ƒ¢ salivary flow over baseline compared to placebo for AUCpd 0-6 (g) (p=0.0001) **(Fig. 1):** 10mg- 52.5 (27.5-77.6), 15 mg- 93 (67.9-118.1), 20 mg-112.5 (87.3-137.7) that persisted for 24 hours: AUCpd 0-24 (g) (p=0.0025). All symptoms (24 hour post dose pooled- contrast VAS data) using the 15 and 20-mg doses improved over baseline compared to placebo. Lacrimal flow did not significantly change.

Figure 1



There were no dropouts for adverse effects or other reasons. Side effects included headaches, cold sweats, hyperhidrosis, nausea, flushing and URI's. Only one serious adverse event was noted in a patient who developed appendicitis after protocol completion.

Conclusion: NGX267 is safe and efficacious in Sjögren's syndrome patients during short-term use. Further, long-term placebo controlled trials are justified.

Diagnostic Algorithm for Pediatric Sjögren's Syndrome. Naoto Yokogawa[1], Scott M. Lieberman[2], Sharon Bout-Tabaku[3], Faizan Alawi[1], Juan P. Palazzo[4], Marta Guttenberg[2], Frederick B. Vivino[1] and David D. Sherry[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, Philadelphia, [4]Thomas Jefferson University, Philadelphia

Purpose: To develop a new diagnostic algorithm for childhood Sjögren's syndrome (SS).

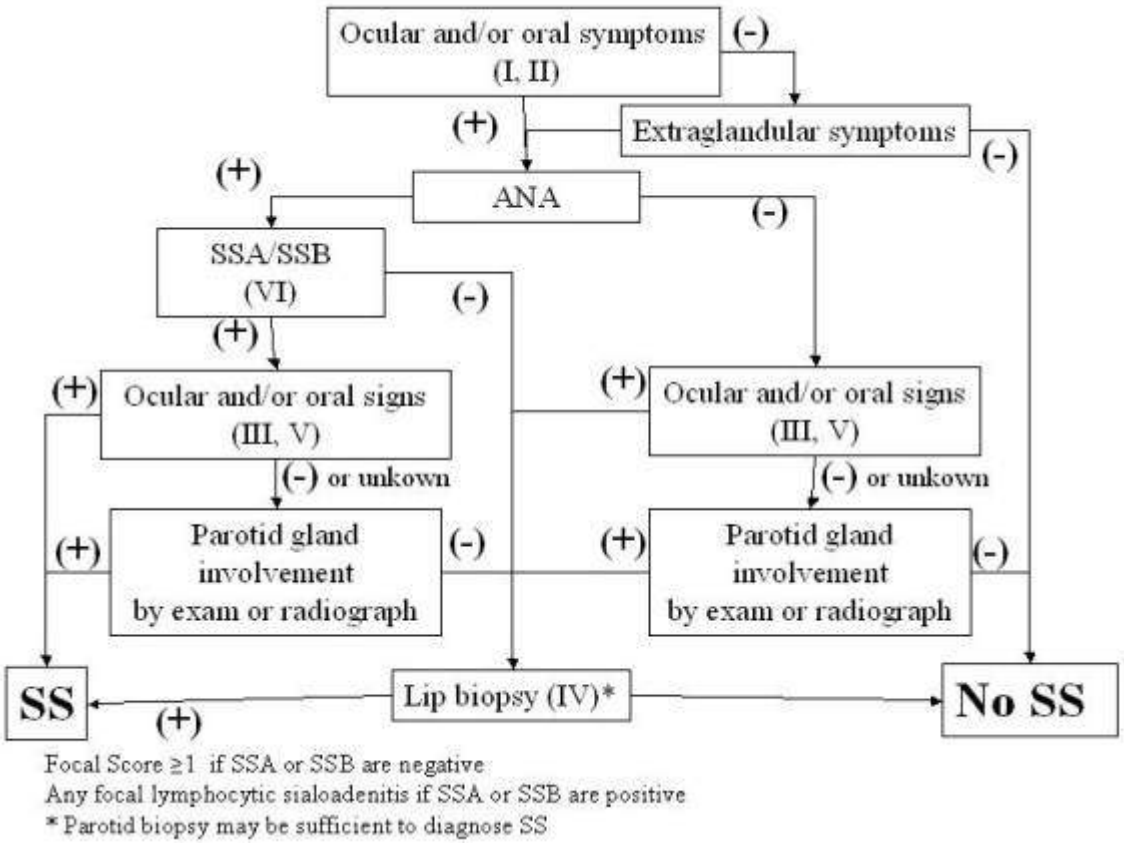
Background: The diagnosis of pediatric SS is challenging because sicca symptoms such as dry mouth/ dry eyes are often absent at the time of initial presentation. Adult classification criteria have not been validated in children and currently proposed pediatric criteria lack diagnostic sensitivity.

Methods: Retrospective review of medical records was performed at Children's Hospital of Philadelphia and the Penn Sjögren Center to identify patients (pts) with suspected pediatric SS. Inclusion required 1) diagnosis or symptom onset at age <20 yrs, 2) consensus agreement on diagnosis by pediatric and adult rheumatologists and 3) exclusion of other diseases based on diagnostic testing and/or long-term follow-up. Pts with overlapping autoimmune disease were not excluded. Information on clinical presentation, serologies, objective tests for sicca and histopathology was reviewed. All available salivary gland biopsies were blindly reviewed by oral pathologists to calculate a focus score (FS) and compared to biopsy findings from nonSS pts. Pts were classified as pediatric SS, nonSS or unclassifiable according to three criteria sets: 1) American-European Consensus Group (AECG) criteria (Vitali et al, 2002), 2) Japanese Criteria (Fujibayashi et al, 2004) and 3) pediatric criteria (Bartunkova et al, 1999) . A novel diagnostic algorithm was devised based on a modification of the adult AECG criteria. Sensitivity of various classification schemes was compared.

Results: Thirty-five children followed over a 10-15 year period met inclusion criteria. Pts met varying % of the 6 diagnostic categories for AECG criteria: I xerophthalmus 63% (22/35), II xerostomia 71% (25/35), parotid swelling 66% (23/35), III abnormal Schirmer's test 36.4%(8/22), abnormal corneal staining 23% (5/22), IV histopathology FS≥1/4 mm^2 75%(18/24), V abnormal salivary flow 46% (7/13), abnormal scintigraphy 100%(7/7), VI positive SSA or SSB (83%).

Antinuclear antibodies (ANAs) were the most sensitive diagnostic test (91%). Salivary gland biopsies demonstrated focal lymphocytic sialadenitis (FLS) in 84%(21/24). Modification of AECG criteria by inclusion of ANA positivity, parotid gland involvement and FLS irrespective of FS improved sensitivity (97%) compared to other classification schemes.

Pediatric SS, n=35	SS	Non SS	Unclassifiable	Excluded
Philadelphia algorithm	97%(34)	3%(1)	0%(0)	0%(0)
AECG criteria	54%(19)	3%(1)	42%(15)	0%(0)
Japanese criteria	60%(21)	3%(1)	37%(13)	0%(0)
Pediatric criteria	77%(27)	6%(2)	0%(0)	17%(6)



Conclusion: Criteria for childhood SS can be modified to maximize diagnostic sensitivity (97%) in order to facilitate earlier treatment and prevent long-term complications. The presence of ANAs and any FLS is more clinically significant in children than adults.

Manifestations of Pediatric Sjögren's Syndrome: Comparison to Adult Sjögren's Syndrome. Naoto Yokogawa[1], Sharon Bout-Tabaku[2], Scott M. Lieberman[3], Faizan Alawi[1], Juan P. Palazzo[4], Lytia Fisher[1], Frederick B. Vivino[1] and David D. Sherry[3], [1]University of Pennsylvania, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Thomas Jefferson University, Philadelphia

Purpose: To compare clinical and serologic features of childhood and adult Sjögren's syndrome (SS).

Methods: A retrospective chart review was performed at the Children's Hospital of Philadelphia (CHOP) and Penn Sjögren's Syndrome Center (PSSS) to identify patients (pts) with childhood SS. Diagnosis (DX) of pediatric SS was based on: 1) Dx or symptom onset at age <20 yrs 2) consensus agreement on DX by pediatric and adult rheumatologists and 3) exclusion of other DX based on other testing and long term follow-up. We compared clinical manifestations, serologies and SS Disease Damage Index (Vitali, et al, 2007) of the pediatric pts to adult pts from the PSSS database.

Results: The pediatric cohort included 30 cases from CHOP, the largest single institution series, and 5 pts from the PSSS diagnosed from 1994-2008. Twenty-eight had 1°SS and 7 had 2° SS (3 SLE, 3 UCTD, 1 JIA). Presenting manifestations included parotid swelling 43%, polyarthralgias 20%, neurological symptoms 11%, and sicca 11%. Sicca symptoms were present in 37% at time of diagnosis and occurred in 44% during follow-up. Complications included fetal heart block during teen pregnancy (n=1) and non Hodkins B cell lymphoma (n=1).

Adult pts (n=410, DX by AECG criteria) included 378 with 1°SS and 32 with 2° SS (13 CREST, 10 RA, 4 SLE, 2 UCTD, 1 Diffuse SCL, 1 MCTD, 1 DM). Sicca symptoms were more common in adults but parotitis was more common in children. Extraglandular manifestations such as fever, lymphadenopathy, neurological, renal disease, cutaneous vasculitis, inflammatory eye disease and, serological abnormalities such as SSA/SSB, ANA, RF, and □« C3/C4 were all more common in pediatric than adult SS. The SS Disease Damage Index was not statistically different between the two groups.

Parameter	**Pediatric (n=35)**	**Adult (n=410)**	**p**

Uncoupling Salivary Gland Dysfunction From Inflammation in a Large Cohort of Primary Sjögren's Syndrome Patients. Nikolay P. Nikolov[1], Ilias Alevizos[1], Margaret Grisius[1], Jane Atkinson[1], Ana Cotrim[1], Bruce J. Baum[1], Jaime Brahim[2], David Kleiner[3], Lolita Bebris[1] and Gabor G. Illei[4], [1]NIH/NIDCR, Bethesda, MD, [2]University of Maryland, Baltimore, MD, [3]NCI, Bethesda, MD, [4]NIDCR, NIH, Bethesda, MD

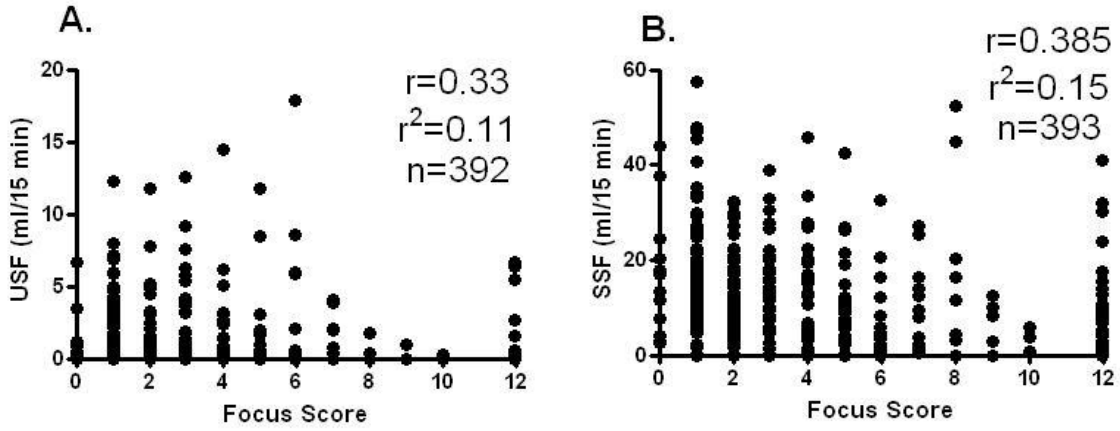
Purpose: To evaluate the association between salivary gland inflammation and hypofunction in a large cohort of primary Sjögren's syndrome (pSS) patients.

Background*:* Many theories of SS pathogenesis embrace the concept that glandular inflammation is the central event that leads to loss of glandular function even though the evidence for this assumption is circumstantial.

Method: A cohort of 393 well characterized patients with pSS underwent concomitant evaluation of salivary gland inflammation and function. Salivary gland inflammation was quantified by focus score (FS) on minor salivary gland (MSG) biopsy. Salivary gland function was quantified by calculating salivary flow rates (ml/15min) after standardized collection from individual parotid, submandibular and sublingual glands in the unstimulated state (total glandular unstimulated salivary flow, USF) and after 2% citric acid stimulation (total glandular stimulated salivary flow, SSF). Data were analyzed using Spearman correlation test. To account for confounders such as concomitant medications, duration of sicca symptoms and age a multiple regression model was used (SAS Institute, Cary, NC).

Results: A statistically significant but very weak negative correlation was observed between FS and glandular USF (r^2=0.11, p<0.0001, Figure 1A) and stimulated salivary flow (r^2=0.15, p<0.0001, Figure 1B). A similar negative correlation was observed between whole unstimulated salivary flow and FS (r^2=0.21, p<0.0001, n=87). These results demonstrate that salivary gland inflammation as measured by minor salivary gland focus score explains only 11-21% of the loss of glandular function. Multiple regression analyses showed no significant contribution of the potential confounders to the model.

Figure. Scatterplot of FS vs USF (A.) and SSF (B.) Abbreviations: r-coefficient of correlation; r^2-coefficient of determination, n-number of observations



Conclusion: Our findings show a statistically significant, but not clinically meaningful, negative correlation between the degree of salivary gland inflammation, as measured by FS on MSG biopsy, and glandular dysfunction, as measured by both USF and SSF, in a large cohort of pSS patients. These data suggest that salivary inflammation and dysfunction may be two different processes in the pathogenesis of SS. This observation may have significant implications for evaluating disease models, selecting appropriate outcome measures and designing clinical trials of pSS.

Increased Immune Reactivity towards Human hsp60 in Patients with Primary Sjögren Syndrome Is Associated with Increased Cytokine Levels and Glandular Inflammation. Huib de Jong[1], Wilco de Jager[1], B. Prakken[2], Aike A. Kruize[1], Floris P.J.G. Lafeber[1], Johannes W.J. Bijlsma[1] and Joel A.G. van Roon[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University Medical Center, Utrecht, Netherlands

Purpose: Although the etiology of primary Sjogren syndrome (pSS) is largely unknown a predominant role for T cells and B cells in the immunopathology of pSS is indicated. Since self heat shock proteins are immunogenic proteins that are involved in different auto-immune diseases, the expression of and immune response to human hsp60 in patients with pSS compared to patients with non-SS sicca syndrome (nSS) was analyzed

Method: Hsp60 expression in glandular tissue of patients with pSS (n=7) and nSS (n=9) was assessed by immunohistochemistry. Anti-hsp60 specific antibodies in serum of pSS and nSS patients (both n=10) were assessed and correlated to disease parameters and circulating cytokines (assessed by Luminex). In addition, the capacity of hsp60 molecules to induce in vitro proliferation and cytokine production by PBMC of patients with pSS and nSS were measured.

Results: Hsp60 expression in salivary gland biopsies of pSS patients was increased compared to nSS sicca patients. Hsp60 expression significantly correlated with a decreased % of IgA+ plasma cells ($r=0.775$, $p=0.041$). Total serum IgG and IgG1 anti human hsp60 levels were significantly increased in pSS (both $p<0.05$), while the opposite was true for IgG2. The increased anti-hsp60 IgG and IgG1 titers and the decreased IgG2 titers correlated significantly with increased local and systemic disease parameters (all $p<0.01$). Human hsp60 induced IL-1β, IL6 and IL10 production by mononuclear cells (all $p<0.01$). Serum IL-1β, IL-6 and IL-10 concentrations significantly correlated with increased anti-human hsp60 IgG1 but decreased IgG2 levels. In addition serum IL1α, IL10, IL12, IL15, MIG, IP10, sRANKL and sVCAM levels in pSS patients were significantly increased and correlated with increased anti-hsp60 IgG1 and decreased anti-hsp60 IgG2 levels (all $p<0.05$).

Conclusion: The local expression of hsp60, the increased anti-human hsp60 antibody levels and the correlation of these antibodies with cytokine levels and disease parameters in patients with pSS suggest that immune reactivity towards this self antigen significantly contributes immunopathology in pSS. As previously demonstrated this immune reactivity might be exploited to regulate the local inflammatory response, e.g. by nasal or oral tolerization towards human hsp60 or hsp60-derived epitopes.

Association of C8orf13-BLK and TNFSF4 Gene Variants with Primary Sjögren's Syndrome. Gunnel Nordmark[1], Gudlaug Kristjansdottir[2], Silke Appel[3], Lilian Vasaitis[1], Marika Kvarnström[4], Per Eriksson[5], Elke Theander[6], Per Lundmark[2], Christopher Sjöwall[5], Johan G. Brun[3], Peter Söderkvist[7], Erna Harboe[8], Lasse Gøransson[8], Leonid Padyukov[4], Maija-Leena Eloranta[1], Gunnar Alm[9], Eva Baecklund[1], Marie Wahren-Herlenius[4], Roald Omdal[8], Lars Rönnblom[1], Roland Jonsson[3] and Ann-Christine Syvänen[2], [1]Rheumatology clinic, Uppsala, Sweden, [2]Molecular Medicine, Uppsala, Sweden, [3]Broegelmann research laboratory, Bergen, Norway, [4]Rheumatology unit, Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology clinic, Linköping, Sweden, [6]Rheumatology clinic, Malmö, Sweden, [7]Cell biology, Linköping, Sweden, [8]Clinical Immunology unit, Stavanger, Norway, [9]Biomedical Sciences, Swedish University of Agricultural sciences, Uppsala, Sweden

Purpose: Genetic factors are thought to contribute to the etiology of primary Sjögren's syndrome (pSS). The aim of this investigation was to perform a large scale candidate gene association study in patients with pSS from Sweden and Norway, to identify single nucleotide polymorphisms (SNPs) in genes with a putative role in the immune pathogenesis of pSS and in genes that have shown an association with SLE in genome wide association studies (GWA).

Method: Genotyping was performed with the GoldenGate assay from Illumina Inc., San Diego, USA, and 1121 SNPs in 83 genes passed quality control filters and remained for association analysis. A total of 541 patients, 345 Swedish and 196 Norwegian, and 531 controls, 318 Swedish and 213 Norwegian, had a genotype success rate of >90% and were analyzed. All patients fulfilled the AECC criteria and all were Caucasians. Allele counts and genotype frequencies were compared between patients and controls by Fisher's exact test and combined p-values and OR for the Swedish and Norwegian cohorts were calculated with Cochran-Mantel-Haenzel Chi square test.

Results: We found an association between pSS and SNPs in the C8orf13-BLK gene region and the TNFSF4 gene with a p-value of < 0.001 in the combined Swedish and Norwegian cohorts. The SNP rs12549796 in C8orf13-BLK showed an association with $p = 5.8 \times 10^{-4}$ and OR 1.36 (95% CI 1.15-1.63) and the SNP rs1234315 in TNFSF4 was associated with $p = 7.2 \times 10^{-4}$ and OR 1.35 (1.14-1.59). In addition we found an expected association between the TNPO3 gene SNP rs13246321, $p = 1.2 \times 10^{-5}$, OR 1.67 (1.33-2.10) which is in perfect LD with the IRF5 3´SNP rs10488631 and confirms our previous results. We found no association of these SNPs in C8orf13-BLK, TNFSF4 or TNPO3 with autoantibody status. There was no association with the BANK1, ITGAM-ITGAX, KIAA1542 or PXK genes that have shown an association with SLE in GWA studies.

Conclusion: We identified new candidate genes for pSS. Since BLK (B lymphoid tyrosine kinase) is only expressed in B-cells and activates nuclear transcription factors upon B cell receptor signaling and TNFSF4 (Tumor necrosis factor superfamily 4) = Ox40L, is expressed on antigen presenting cells including B cells and plasmacytoid dendritic cells, we conclude that genes involved in B cell activation are important in the pathogenesis of primary SS.

Development and Preliminary Validation the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI): A New Consensual Disease Activity Index That Detects Changes Accurately. Raphaèle Seror[1], Philippe Ravaud[1], Simon J. Bowman[2], Gabriel Baron[1], Athanasios G. Tzioufas[3], Elke Theander[4], Jacques-Eric Gottenberg[5], Hendrika Bootsma[6], Xavier Mariette[7], Claudio Vitali[8] and EULAR Sjögren's Task Force, [1]University of Paris VII, Bichat Hospital, Paris, France, [2]University Hospital Birmingham, Birmingham, United Kingdom, [3]Medical School-Univ of Athens, Athens, [4]Rheumatology clinic, Malmö, Sweden, [5]University Hospital of Strasbourg, Strasbourg, France, [6]University Medical Center Groningen, Groningen, Netherlands, [7]Bicetre Hospital, Paris-Sud University, Le Kremlin Bicetre, France, [8]"Villamarina" Hospital, Piombino, Italy

Purpose: To develop and assess sensitivity to change the EULAR Sjögren's Syndrome (SS) Disease Activity Index (ESSDAI).

Methods: Thirty-nine SS experts identified 12 organs (domains) contributing to disease activity. For each domain, features of disease activity were classified in 3 or 4 levels (items) according to their severity. 96 real profiles of patients with systemic complications of SS, including 3 successive visits were abstracted from medical charts. These data were used to generate 702 realistic vignettes. Real patient profiles were scored with the ESSDAI, the SS disease activity index (SSDAI) and the Sjögren's Systemic Clinical Activity Index (SCAI). Each expert, blinded to disease activity scores, assessed disease activity of 5 real profiles and 20 realistic vignettes using the 0-10 physician global assessment (PhGA), and determined for real profiles whether disease activity had improved, worsened or remained stable at visits 2 and 3. Realistic vignettes were used to develop the ESSDAI; domain weights were estimated using multiple regression modelling, with PhGA as gold standard. Real patient's profiles were used for validation; sensitivity to change was assessed by the standardized response mean (SRM) in each sub-group of improved, worsened, or stable patients.

Results: All 12 domains were significantly associated with disease activity in the multivariate model, domain weights ranged from 1 to 6. The ESSDAI scores were significantly correlated with PhGA in real patient profiles ($r=0.61$;, $p<0.0001$). For improved patients, the SRMs for all scores did not differ, and ranged from -1.08 to -1.38 between visits 1 and 2 and from -0.50 to -0.76 between visits 2 and 3. For patients with worsened activity, the SRMs, between visits 1 and 2 and between visits 2 and 3, were, respectively, +0.46 and +1.10 for the ESSDAI, -0.03 and +0.79 for the SSDAI, and +0.17 and +1.02 for the SCAI. For patients with stable activity, the SRMs, between visits 1 and 2 and between visits 2 and 3, were, respectively, 0.00 and -0.13 for the ESSDAI, -0.44 and -0.11 for the SSDAI, and -0.36 and +0.34 for the SCAI.

Conclusion: The ESSDAI is a consensual clinical index designed to measure disease activity in patients with primary SS. For patients with improved disease activity, ESSDAI has large sensitivity to change similar to that of SCAI and SSDAI. However, the ESSDAI detects changes in activity more accurately than other disease activity indexes, notably, for patients with stable disease activity.

Autonomic Nervous Dysfunction Development in Patients with Primary Sjögren's Syndrome – a 5 Year Follow-up. Thomas Mandl, Malmö University Hospital, Malmö, Sweden

Purpose: To investigate autonomic nervous dysfunction development over a 5-year period in patients with primary Sjögren's syndrome (pSS).

Materials: 15 pSS patients, previously studied for autonomic dysfunction, were included. Autonomic nervous function test (ANT) and Autonomic Symptom Profile (ASP) controls consisted of 56/80/238/200 previously investigated individuals.

Methods: The patients were studied at baseline and after a 5 year follow-up by 5 ANTs (deep-breathing test (E/I-ratio), orthostatic heart rate test (AI), finger-skin blood flow test (VAC-index), and orthostatic blood pressure test (SBP & DBP-ratios)). Patients also filled out the ASP questionnaire on autonomic dysfunction symptoms.

Results: The E/I-ratio and SBP- & DBP-ratios were decreased in pSS patients both at baseline and follow-up.The orthostatic intolerance, urinary dysfunction, gastroparesis, secretomotor, pupillomotor and ASP total score were increased in pSS patients both at baseline and at follow-up. When comparing ANT and ASP results between baseline and at follow-up, the E/I- and DBP-ratios were decreased and the vasomotor score increased at follow-up.

Conclusion: Both objective and subjective signs of a parasympathetic and a sympathetic dysfunction were seen in pSS patients at baseline and after a 5 year follow-up. The E/I- and DBP-ratios and vasomotor score were found to significantly deteriorate during the 5-year follow-up.

Table 1 – Results of the ANTs and ASP, at baseline and after a 5 year follow-up. ANT results were age-corrected and expressed as z-scores (SD). Most ASP scores were age-, gender-, height- and weight-corrected and expressed as z-scores (SD).

	pSS patients Baseline	pSS patients Year 5	Controls	p-value pSS patients Baseline vs Year 5

Utility of Whole Versus Total Glandular Unstimulated Salivary Flows for the Classification of Sjögren's Syndrome. Nikolay P. Nikolov[1], Margaret Grisius[1], Ilias Alevizos[1], Jane Atkinson[1], Ana Cotrim[1], Bruce J. Baum[1], Lolita Bebris[1] and Gabor G. Illei[2], [1]NIH/NIDCR, Bethesda, MD, [2]NIDCR, NIH, Bethesda, MD

Purpose: American-European Consensus Group (AECG) classification criteria for Sjögren's syndrome (SS) include documentation of objective signs of xerostomia such as salivary hypofunction defined as whole unstimulated salivary flow (WUSF) of ≤1.5 mL in 15 minutes. However, WUSF is contaminated with non-salivary fluids and proteins. Historically our clinic has used total glandular unstimulated salivary flow (TGUSF) as the standard method of saliva collection but TGUSF does not include saliva from minor salivary glands. This study compared TGUSF and WUSF to determine their impact on the SS classification.

Method: Salivary gland function was quantified in 292 consecutive subjects (156 pSS, 21 secondary SS and 115 non-SS) by calculating salivary flows using the WUSF method followed by standardized unstimulated collections from individual parotid, submandibular and sublingual glands (TGUSF). Data were analyzed using the non-parametric Spearman correlation test. To account for confounders such as concomitant medications, duration of sicca symptoms, age and glandular inflammation (focus score) a multiple regression model was used (SAS Institute, Cary, NC).

Result: Collections from all 292 subjects were analyzed. Good correlation between WUSF and TGUSF was observed (Figure, r=0.66, p<0.0001, n=292) but 18% (54/292) were discordant using 1.5 mL/15 minutes as a cutoff (AECG classification criteria). The discrepancy went equally in both directions: in 54% (29/54) WUSF overestimated and in 46% (25/54)-underestimated the TGUSF. Among the discrepant cases, documenting objective salivary hypofunction was critical for the SS classification of only 12 subjects (4% of the cohort) (Table). Of these, 11 would have met AECG criteria for SS using WUSF and 1-using TGUSF. In the multiple regression model, only focus score remained significantly associated with both WUSF and TGUSF.

Figure. Scatterplot of WUSF and TGUSF; r-coefficient of correlation, n-number of observations; AECG cutoff of 1.5 ml/15 min (dashed line).

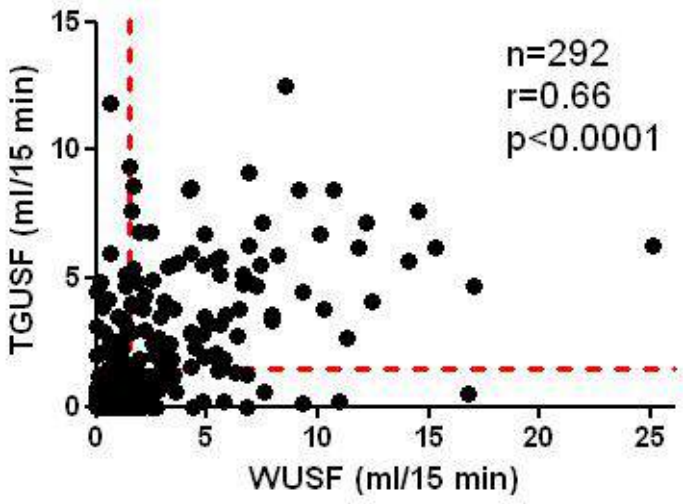

Table. Subject characteristics and impact of TGUSF and WUSF on the SS classification. n-number of observations.

	Primary SS	
Saliva collection method	**TGUSF (n=156)**	**WUSF (n=146)**
Age, years (mean, ±SD)	**51 (±14.2)**	**51 (±14.4)**
Females, %	**90**	**90**
Symptoms Duration, y (median, ±SD)	**6 (±9)**	**6 (±9)**
TGUSF, mL/15 min (mean, ±SD)	**1.092 (±1.877)**	**1.107 (±1.94)**
WUSF, mL/15 min (mean, ±SD)	**1.731 (±3.15)**	**1.552 (±2.95)**
Focus Score (median, ±SD)	**3 (±3)**	**3 (±3)**
Concomitant Meds, n (median, ±SD)	**2 (±3)**	**2 (±3)**

Conclusion: This is the first study to compare WUSF and TGUSF data for evaluation of salivary dysfunction and assess their utility for the classification of SS. Our results demonstrate a statistically significant and clinically meaningful correlation between whole and total glandular unstimulated salivary flows. The observed discrepancies did not suggest that one method is superior to the other in the assessment of salivary gland function. Ultimately the discordance between WUSF and TGUSF did not have a significant impact on the classification of SS.

Degree of Modification of Ro 60 by the Lipid Peroxidation Byproduct 4-Hydroxy-2-Nonenal May Differentially Induce Sjögren's Syndrome or Systemic Lupus Erythematosus in BALB/c Mice. Biji T. Kurien[1], Andrew Porter[2], Yaser Dorri[2], Saqib Iqbal[2], Sima Asfa[3], Anil Dsouza[2], Kenneth Hensley[2] and R. Hal Scofield[4], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]OMRF, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]Oklahoma Med Res Foundation, Oklahoma City, OK

Purpose: Our earlier studies showed that immunization of rabbits with 4-hydroxy 2-nonenal (HNE) modified Ro 60 (SS-A) resulted in accelerated epitope spreading and autoimmunity. We determined to extend this model into mice and hypothesized that the degree of modification of Ro 60 with HNE might determine severity of disease and possibly bring about differential induction of Sjögren's syndrome (SS) and SLE in BALB/c mice.

Materials and Methods: Fifty BALB/c mice were divided into five groups with 10 mice in each group. Group I was immunized with purified Ro 60 treated with 1 mM sodium cyanoborohydride ($NaCNBH_3$) alone. Groups II to IV were immunized with Ro 60 modified with 0.4 mM (low HNE), 2 mM (medium HNE) and 10 mM (high) HNE respectively in the presence of 1 mM $NaCNBH_3$. Group V control mice received only Freund's adjuvant. Primary immunization was with Freund's Complete Adjuvant, with subsequent boosts in Freund's Incomplete Adjuvant. The first, second and third boosts were given on day 14, 35 and 63. Post-immune sera were collected on day 21, 42, 56, 70, 84, 98, 105, 126 and a final exsanguination bleed two days later. The anti-sera were used to determine binding to Ro60, HNE-modified Ro 60, La and dsDNA (*C. Lucillae*).

Results: Antibodies to ds DNA were found only in mice immunized with medium HNE-modified Ro 60 (Group III) in bleeds 7 and 9 (4/4 mice in each bleed). Anti-dsDNA was not present in any of the groups in the 6th bleed. Salivary flow, collected 120 days after immunization, decreased 31, 11 and 37% in Groups II, III and IV respectively compared to Freund's immunized controls while Group I mice did not have any reduction in salivary flow. Lymphocytic infiltration was seen in (Group IV-1/1) but not in Freund's immunized group. A rapid abrogation of tolerance to Ro 60 and La antigens was observed in mice immunized with HNE-modified Ro, especially the low and medium HNE-Ro immunized groups. Control mice immunized with Freund's did not make antibodies to Ro, La or other autoantigens studied. Anti-Ro 60 and anti-HNE Ro 60 was detected in the saliva of mice in Groups 1-4, but not in the control Group V mice. Anti-HNE Ro was highest in the saliva of the group immunized with medium HNE-Ro 60.

Conclusion: Immunization with oxidatively modified Ro60 accelerates autoimmunity. Immunization with Ro 60 modified with medium HNE induces an SLE like phenotype while high HNE Ro60 induces a Sjogren's like syndrome in experimental mice.

Population-Based Prevalence of Primary Sjögren's Syndrome: A 5-Source Capture–Recapture Estimate. Carla Maldini[1], Raphaèle Seror[1], Olivier Fain[2], Robin Dhote[3], Xavier Mariette[4], Michel De Bandt[5], Jean-Luc Delassus[5], Géraldine Falgarone[3], Véronique Le Guern[1], François Lhote[6], Olivier Meyer[7], Jacky Ramanoelina[8], Karim Sacré[7], Yurdagül Uzunhan[3], Jean-Louis Leroux[9], Loïc Guillevin[1] and Alfred Mahr[1], [1]Hospital Cochin, Paris, France, [2]Hospital J. Verdier, Bondy, France, [3]Hospital Avicenne, Bobigny, France, [4]Hospital Bicêtre, Kremlin-Bicêtre, France, [5]Hospital R. Ballanger, Aulnay-sous-Bois, France, [6]Hospital Delafontaine, Saint-Denis, France, [7]Hospital Bichat, Paris, France, [8]Hospital Montfermeil-Le Raincy, Montfermeil, France, [9]Service médical Assurance-Maladie, Bobigny, France

Purpose: The prevalence of primary Sjögren's syndrome (pSS) is not well known. Most earlier studies based on small numbers of identified pSS cases yielded widely divergent prevalence estimates of 0.02–3% for general populations. This population-based study aimed at estimating the year 2007 prevalence of pSS.

Method: The cross-sectional study concerned Seine–Saint-Denis County, a Parisian suburb (France), with 1,093,515 adult inhabitants (□15 yr old). Case ascertainment used 5 sources: 1) hospitals; 2) community-based practitioners; 3) positive anti-SSA/SSB antibody testing by private laboratories; 4) a nationwide patient support group; and 5) a national health insurance database. Recorded case diagnoses were verified against the American–European Consensus Group (AECG) criteria; to account for inconsistent availability of information on objective ocular or oral dryness, we also defined "enlarged AECG criteria" (based on the presence of □3/4 remaining AECG items). Five-source capture–recapture analyses (CRA) using log-linear modeling was performed to estimate the number of cases missed by any source. Confidence intervals were calculated using the Poisson method.

Results: The 5 sources yielded 1,385 notifications of potential pSS cases; among them, 343 charts could not be accessed for detailed examination. After exclusion of non-pSS diagnoses, pSS cases diagnosed after 2007, and cases not meeting classification criteria, residing outside the study area or for whom no follow-up data were available for the study period and thereafter, we retained 122 subjects meeting the

AECG criteria and 183 subjects meeting the enlarged AECG criteria. Numbers of missed cases calculated by CRA were 18.0 and 37.6, respectively. The year 2007 prevalence estimate, adjusted for missed cases, was 128.0 per million adults (95% CI: 107.7–150.1) for AECG criteria and 201.7 per million adults (95% CI: 176.3–229.6) for enlarged AECG criteria.

Conclusion: This population-based study estimated pSS prevalence at 128–202/million (0.013–0.020%) adults. Although this rate must be interpreted with the possibility of undiagnosed pSS in mind, it agrees with the low prevalences obtained by the few other large population-based surveys and might represent a more accurate indication of the true pSS prevalence.

Rheumatoid Factor and High Titer ANA Are More Strongly Associated with Focal Lymphocytic Sialoadenitis Than SS-A Antibodies. Alan N. Baer, Don R. Martin, Esen K. Akpek, Julius Birnbaum, James M. Christian and Gary R. Warnock, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: The diagnosis of Sjögren's syndrome (SS) requires the presence of SS-A/SS-B antibodies or a labial gland biopsy showing focal lymphocytic sialoadenitis (FLS) with a focus score ≥1. However, SS-A/SS-B antibodies are present in only 40-50% of SS patients. We sought to determine whether there are clinical or laboratory abnormalities that are more strongly associated with a "positive" labial gland biopsy in SS than SS-A antibodies.

Method: During the period of 2002-2009, 117 patients seen in the Rheumatology Clinics at Johns Hopkins University had labial gland biopsies performed at the discretion of the clinician to establish a diagnosis of primary SS. The biopsies were graded as to the presence of FLS with a focus score ≥1 (positive, n=63) or <1 (negative, n=54). The charts of these pts were reviewed to determine positive Schirmer's I (≤5 mm wetting) test results, the highest recorded ANA titer and "ever" presence of positive tests for SS-A or SS-B antibodies, rheumatoid factor (RF), and hypergammaglobulinemia.

Results: The group of patients with positive biopsies did not differ significantly from the group with negative biopsies in terms of age (53.4 vs 52.5 yrs) or female gender (92 vs 87%). There were a significantly greater number of African-American patients in the group with positive biopsies (9 vs 0, p=0.004). Among the 107 patients who had objective measures of sicca, 50 met the American-European Consensus criteria for SS.

Correlates	No. positive/ Total available (%)	Odds Ratio (95% CI)	P value[1]	Sens.	Spec.	+LR[2]
SS-A	19/27 (70)	2.5 (1.0-6.4)	0.05	0.31	0.85	2.1
SS-A or SS-B	19/29 (66)	1.9 (0.8-4.7)	0.20	0.31	0.82	1.7
ANA≥1:640	17/22 (77)	4.5 (1.5-13.4)	<0.01	0.33	0.90	3.3
ANA≥1:320	24/34 (71)	3.6 (1.5-8.8)	<0.01	0.47	0.80	2.4
RF	18/20 (90)	9.5 (2.1-43.6)	<0.01	0.32	0.95	6.8
Hypergammaglobulinemia	14/18 (77)	2.98 (0.9-9.9)	0.11	0.26	0.9	2.5
Abnormal Schirmer's	34/60 (56)	1.1 (0.3-3.7)	1.0	0.83	0.19	1.0
SS-A or RF	26/34 (76)	3.7 (1.5-9.4)	<0.01	0.46	0.81	2.4
SS-A or ANA≥1:640	21/29 (72)	3.8 (1.5-9.8)	<0.01	0.42	0.84	2.6

ANA≥1:640 or RF	22/28 (79)	5.7 (2.0-16.2)	<0.01	0.50	0.85	3.3
[1]Fisher exact test, with p<0.05 considered statistically significant [2]positive likelihood ratio						

Conclusion: In patients suspected of having SS, rheumatoid factor, a high titer ANA test, or the combination of these two were more strongly associated with a positive lip biopsy than SS-A antibodies alone. Additionally, these tests had greater sensitivity and specificity than SS-A antibodies. Rheumatoid factor and high titer ANA tests should be considered important serologic markers of SS and may serve as an adjunct to SS-A antibodies in future diagnostic criteria.

Salivary Gland Tissue Expression of Interleukin-21 in Patients with Primary Sjögren's Syndrome. Kwi Young Kang[1], Hyun-Ok Kim[2], Sung Soo Kim[3], Ji-Min Kim[1], Ho-Sung Yoon[1], Chang-Hun Lee[1], Seung-Ki Kwok[1], Ji-Hyeon Ju[1], Kyung-Su Park[4], Sung-Hwan Park[5] and Ho-Youn Kim[1], [1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [2]Gyongsang University, Jinju, South Korea, [3]Ulsan Univ Med Sch Gangneung, Gangneung, [4]Seoul St Mary's Hospital, Seoul, South Korea, [5]Kangnam St Mary's Hosp, Seoul, South Korea

Purpose: To assess the levels of serum interleukin (IL)-21 in patients with primary Sjogren's syndrome (pSS) and to investigate salivary gland expression of IL-21 in pSS patients.

Method: The serum IL-21, IL-17, IL-23 and IL-6 in 40 pSS, 40 RA, 38 SLE patients and 20 healthy controls were measured by sandwich enzyme-linked immunosorbent assay. Laboratory data such as anti-nuclear antibody (ANA), anti-Ro/La antibody, anti-dsDNA antibody, rheumatoid factor (RF), erythrocyte sedimentation rate (ESR) and globulin were tested. The relationship between serum IL-21 level and other laboratory data was analyzed. Minor salivary glands from 16 patients with pSS and 4 control with sicca symptom were evaluated for IL-21 and IL-21 receptor (IL-21R) expression by immunohistochemistry.

Results: The level of serum IL-21 in patients with pSS (646±637 ng/l) was higher than that in healthy control (71±132 ng/l) ($p<0.001$). The serum IL-21 in pSS patients was higher than that in RA patients (342.6±322 ng/l, $p=0.01$), but it was not significantly different with that in SLE patients (454.32±534 ng/l, $p=0.147$). The serum level of IL-21 was not correlated with that of IL-17, 23 and 6. There was no significant correlation between level of IL-21 and ANA, anti dsDNA antibody, RF and ESR. The level of serum IL-21 in pSS patients showed positive correlation with globulin ($r=0.482$, $p=0.002$) and immunoglobulin G (IgG) ($r=0.438$, $p=0.009$). Immunohistochemical staining of minor salivary glands biopsy specimens from pSS patients revealed positive staining for both IL-21 and IL-21R within lymphocytic foci and periductal area whereas only minimal expression was seen in samples from control. IL-21 was more strongly stained than IL-21R.

Conclusion: The elevated level of IL-21 in pSS patients has positive correlation with that of globulin and IgG. IL-21 and IL-21R is expressed in Salivary gland from pSS patients, which suggests that IL-21 may play a critical role in the pathogenesis of pSS.

Establishment of New Murine Model for Sjögren's Syndrome Like Sialoadenitis Using M3 Muscarinic Acethylcholine Receptor Knockout Mice. Mana Iizuka, Ei Wakamatsu, Isao Matsumoto, Hiroto Tsuboi, Yumi Nakamura, Taichi Hayashi, Daisuke Goto, Satoshi Ito and Takayuki Sumida, University of Tsukuba, Tsukuba, Japan

Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disease characterized by lymphocytic infiltration of salivary glands, in which $CD4^+$ T cells are predominant. These infiltrating T cells play a crucial role in the generation of SS. Previous studies showed that autoantibodies and auto-reactive T cells against M3 muscarinic acethylcholine receptor (M3R) were detected in patients with SS. In this

study, to reveal the pathological mechanisms underlying immune response against M3R, we tried to establish the new murine model for SS like sialoadenitis as a target of M3R.

Method: 1) C57BL/6J mice and M3R knockout mice were immunized intradermaly with synthesized peptides, which were coded the extracellular domains of murine M3R (N-terminus, 1st, 2nd, and 3rd extracellular loops), in CFA. On day 10, these mice were boosted with intradermal injection. Ten days after booster immunization, spleens were isolated, the immune response to M3R was examined in vitro, and them were transferred to Rag1 knockout mice (C57BL/6J → $Rag1^{-/-}$ and $M3R^{-/-}$ → $Rag1^{-/-}$). 2) After inoculation, anti-M3R antibodies and amount of saliva flow were measured on day 0, 15, 45. 3) Salivary glands were investigated histologically by H&E staining on day 45 after the cell transfer to Rag1 knouckout mice. Infiltrated lymphocytes in the salivary glands were evaluated using anti-Thy1, anti-B220, anti-CD4 and anti-CD8 antibodies by immunohistochemical study.

Results: 1) IL-17 and IFNg were highly produced in splenocytes of immunized M3R knockout mice compared with C57BL/6J mice. 2) In $M3R^{-/-}$ → $Rag1^{-/-}$ mice, anti-M3R antibodies was increased and saliva flow were decreased. 3) On day 45, the sialoadenitis with remarkable mononuclear infiltration was observed in the salivary glands of $M3R^{-/-}$ → $Rag1^{-/-}$ mice, but not in the C57BL/6J → $Rag1^{-/-}$ mice. Moreover, $Thy1^{+}CD4^{+}$ cells predominantly infiltrated in salivary glands of $M3R^{-/-}$ → $Rag1^{-/-}$ mice .

Conclusion: We established the new murine model for SS like sialoadenitis using M3R knockout mice immunized with M3R. These findings support the possibility that autoimmune response to M3R molecule plays a crucial role in the generation of sialoadenitis in patients with SS.

Novel Brain Biomarkers for Fatigue and Cognitive Function in Primary Sjogren's Syndrome. Barbara M. Segal[1], Bryon A. Mueller[1], Brian Pogatchnik[2], Erin Holker[2], Xiaochun Zhu[2], Rachel Prosser[3] and Sriharsha Veeramachaneni, [1]Univ of Minnesota, Minneapolis, MN, [2]University of Minnesota, [3]Hennepin County Medical Center

Purpose: To assess the degree of brain tissue injury in primary Sjogren's syndrome (PSS) subjects with minimal cognitive dysfunction. We hypothesized that microstructural abnormalities detectable with quantitative high resolution brain MR imaging would be correlated with neuropsychological measures.

Methods: Female PSS subjects who met AECG criteria were compared with age and education matched healthy volunteers. Subjects were evaluated who had no history of CNS disorder other than “mental fatigue" (subjective memory and concentration difficulties.) Subjects underwent an extensive neuropsychometric evaluation and completed validated questionnaires to assess symptoms of fatigue (FSS), pain (BPI), depression (CES-D), sleep quality (PSQI) and subjective cognitive function (Prof-M). Based on the results of cognitive tests, PSS subjects were classified as impaired or non-impaired. 7 PSS subjects with evidence of cognitive impairment, 7 PSS subjects with no impairment and 7 controls underwent MR imaging. MRI parameters assessed included diffusion tensor fractional anisotropy (FA) and mean diffusivity (MD), FLAIR imaging for white matter (WM) hyperintensities and T1 weighted MP-Rage lobar volume and cortical thickness. Analysis of variance was used to compare cognitive test scores, symptom measures and MR parameters between groups (significance threshold p=.05.) Mancova with Tukey correction for multiple comparisons was used to compare groups on MR measures of brain pathology. Spearman correlation coefficients were calculated to test for correlations between neuropsychological outcomes and MR parameters.

Results:19 female PSS patients mean age 47.6(10.8) and 18 controls mean age 50.9(5.4) were evaluated with a neuropsychometric battery. 18% of patients versus 6% of controls were impaired on measures of attention, 21 % of the PSS patients and 5.6% of the controls were <1.5 SD below age adjusted norms one or more measures of verbal learning. Impaired PSS subjects differed significantly from non-impaired PSS and control groups in DTI parameters localized to the inferior frontal lobe WM. There was no difference in regional cortical thickness,volume, WM lesion severity or lesion load between PSS subjects and controls. Pychological measures and tests of verbal memory correlated with DTI parameters in the inferior frontal region.

Conclusion: The present study suggests that DTI could be a sensitive biomarker for CNS pathology and mild cognitive dysfunction in pSS. Larger studies are needed to assess the contribution of microstructural brain abnormalities to neuropsychological symptoms and cognitive performance in PSS.

The Role of Anti-2nd Extra-Cellular Loop-M3R Polypeptide (anti-M3R) in Sjogren's Syndrome. He Jing[1] and Li Zhanguo Sr.[2], [1]Peking University People's Hospita, Beijing, China, [2]Professor, Beijing, China

Purpose: M3 muscarinic acetylcholine receptor (M3R) plays a crucial role in Sjogren's syndrome. Resent studies have shown that autobodies against the 2 nd extra-cellular loop in M3R were detected in serum from Primary Sjogren's syndrome (pSS) patients.

Objective: To determine the role of 2 nd extra-cellular loop-M3R polypeptide antibodies in diagnosis of patients with pSS.

Method: (1)We synthesized 2 nd extra-cellular loop-M3R polypeptide by two ways: Linear and cyclic. (2) The prevalence of anti-M3R antibodies was examined by ELISA in 148 patients with pSS, 84 patients with systemic lupus erythematosus (SLE), 95 patients with rheumatoid arthritis (RA), and 64 healthy subjects. (3) The association between anti-M3RP antibodies and other autoantibodies of SS was also investigated.

Results: (1)The prevalence of anti-cycle-M3RP antibodies in the SS, SLE, RA, and health controls were 62.2%, 7.1%, 5.3% and 1.6%. The prevalence of anti-lined-M3RP antibodies in the SS, SLE, RA, and health controls were 56.1%, 20.0%, 14.7% and 9.4%. (2) The specificity of the anti-cycle-M3R antibodies in the diagnosis of SS was 95.1%, much higher than lined polypeptide (84.7%). (3) Anti-M3R antibodies were highly prevalent even in SS patients lacking anti-SSA, anti-SSB antibodies.

Conclusion: 2nd–M3RP may be the most important epitome in M3R, which may play the pathogenic role in SS. Anti-2nd–cycled M3RP antibody may be a good diagnositic marker in serum of SS patients.

493

New Epitopes and Functions of Anti-M3 Muscarinic Acetylcholine Receptor Antibodies in Patients with Sjögren's Syndrome. Hiroto Tsuboi, Isao Matsumoto, Ei Wakamatsu, Yumi Nakamura, Mana Iizuka, Taichi Hayashi, Daisuke Goto, Satoshi Ito and Takayuki Sumida, University of Tsukuba, Tsukuba, Japan

Purpose: M3 muscarinic acetylcholine receptor (M3R) plays a crucial role in the secretion of saliva from salivary glands. Data from a recent study have suggested some patients with Sjögren's syndrome (SS) carried inhibitory auto-antibodies (Abs) against M3R. We reported a subgroup of SS patients had anti-M3R Abs recognizing the 2nd extracellular loop of M3R. In functional assays using salivary gland cells, IgG fractions from SS patients (SS-IgG) inhibited the rise in intracellular Ca^{2+} concentrations ($[Ca^{2+}]_i$) induced by carbachol. The precise epitopes of anti-M3R Abs and the relationship between the functions and epitopes are currently unknown. To clarify the precise B cell epitopes and the functions of anti-M3R Abs in patients with SS, we carried out this study.

Methods: 1) We synthesized four different peptides encoding the extracellular domains of human M3R such as N terminal region, 1st, 2nd, and 3rd extracellular loops. Abs against those regions of M3R were examined by ELISA in the sera from 42 SS patients and 42 healthy controls (HC). We assessed the correlation between anti-M3R Abs and various clinical features.

2) Human salivary gland (HSG) cells were pre-cultured with IgG fractions (1.0 mg/ml) separated from sera of anti-M3R Abs positive SS, negative SS, and HC for 12 h. After loading with Fluo-3, HSG cells were stimulated with cevimeline hydrochloride (20 mM), and then $[Ca^{2+}]_i$ was measured by the fluorescence plate reader.

Results: 1) Abs to N terminal region were detected in 42.9% (18/42) of SS patients and 4.8% (2/42) of HC. Abs to 1st extracellular loop were detected in 47.6% (20/42) of SS and 7.1% (3/42) of HC. Abs to 2nd were found in 54.8% (23/42) of SS and 2.4% (1/42) of HC. Abs to

3rd were detected in 45.2% (19/42) of SS and 2.4% (1/42) of HC. The titers of anti-M3R Abs against all extracellular domains were significantly higher in SS patients than HC. Some SS patients carried anti-M3R Abs that recognized several extracellular domains of M3R. The positivity for anti SS-A antibody was significantly higher among anti-M3R Abs positive SS than negative SS ($P<0.05$). In contrast, there was no difference in other clinical features between anti-M3R Abs positive and negative SS.

2) Anti-M3R Abs to the 2nd extracellular loop positive SS-IgG inhibited the increase of $[Ca^{2+}]_i$ induced by cevimeline hydrochloride. Abs to the N terminal positive SS-IgG and Abs to the 1st extracellular loop positive SS-IgG enhanced it, while Abs to the 3rd extracellular loop positive SS-IgG showed no effect on $[Ca^{2+}]_i$ as well as anti-M3R Abs negative SS-IgG.

Conclusion: These findings indicated the presence of several B cell epitopes on M3R in SS patients and some SS patients were reactive to several extracellular domains of the M3R. Influence of anti-M3R Abs on the secretion of saliva might differ with these B cell epitopes on M3R.

Development of P552-02 to Treat Xerostomia in Sjögren's Syndrome. M.L. Singh[1], A.S. Papas[1], P.C. Fox[2], A.L. Stevens[3], R.C. Boucher[4], B.T. Thelin[3] and M.R. Johnson[3], [1]Tufts University, Boston, MA, [2]PC Fox Consulting, LLC, Spello (PG), Italy, [3]Parion Sciences, Durham, NC, [4]University of North Carolina at Chapel Hill, NC

Purpose: Sjögren's syndrome (SS) is an autoimmune inflammatory disorder characterized by diminished exocrine secretions, xerostomia and oral health deterioration. Evidence suggests that oral mucosal hydration is regulated, in part, via transepithelial salt (and water) transport. Transepithelial absorption of sodium through the epithelial sodium channel (ENaC) drives absorption of water through the oral mucosa reducing mucosal hydration. We predict inhibition of ENaC in the oral mucosa will increase oral hydration and improve xerostomia symptoms. A novel potent small-molecule inhibitor of ENaC, P552-02 (552), is being developed by Parion Sciences and Kainos Medicine for treatment of xerostomia. It is designed to be a safe and effective topical agent with little to no oral bioavailability.

Method: Safety and exploratory efficacy of 552 were evaluated in a randomized, double-blind, placebo-controlled, crossover study of 552 oral rinse vs. placebo (PBO) in 30 subjects with primary SS (study 205S). Subjects received 6 doses of 552 oral rinse (10mL of 5µg/mL solution) or PBO daily for 28 days. Visual analogue scales (VAS) were used to assess xerostomia symptoms on days 7 and 28. Also, a pharmacokinetic (PK) study evaluating systemic exposure of 552 was completed as part of an ongoing randomized, double-blind, placebo-controlled, parallel clinical trial evaluating safety and efficacy of a higher dose of 552 oral rinse (25 µg/mL solution) in 120 subjects with SS (study 207S). Blood samples were taken 15 minutes before the last dose on Treatment Day 7 and at 5 time points during the 2-hour steady-state dosing interval. A validated LC/MS/MS method was used to determine concentrations of 552.

Results: In study 205S, significant improvements from baseline were seen between 552 and PBO for mouth dryness on Days 7 and 28 ($p=0.039$, 0.033, respectively) and the ability to sleep on Day 28 ($p=0.042$). The differences between treatments in global assessment of dry mouth and tongue dryness approached statistical significance ($p=0.056$, both variables) on day 28. No clinically relevant differences between 552 and PBO were seen for adverse events, clinical laboratory parameters, vital signs, or physical examination findings. In the PK study, 552 was "below limit of quantification" (<20 pg/mL) in all samples from all subjects (8 active; 8 PBO), confirming lack of oral bioavailability when administered by oral rinse.

Conclusion: 552 (5 µg/mL) was well tolerated when given 6 times daily for 28 days to subjects with SS. Despite a small sample size, subjects' assessment of changes from baseline indicated that 552 was effective in improving the key symptoms of oral dryness and the ability to sleep. Furthermore, the PK sub-study of a larger second study found no systemic exposure following oral rinsing with 552 (25µg/mL).

Frequency of Neurologic Disease in Sjogren's Patients Versus Controls. Julius Birnbaum, Douglas Kerr and Alan N. Baer, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Neurologic disease is a devastating extraglandular manifestation of Sjögren's syndrome. Comparing the frequency of neurologic syndromes in Sjögren's versus non-diseased controls can highlight specific syndromes highly relevant to Sjögren's patients. Therefore, we sought to assess the frequency and potential diagnostic utility of different neurologic syndromes in discriminating between Sjögren's patients and clinically relevant controls.

Method: Retrospective, case-control study, characterizing the frequency of neurologic syndromes, seen in 268 consecutively evaluated outpatients, referred for diagnostic suspicion of Sjögren's syndrome.

Results: Neurologic Syndromes in Sjögren's patients versus non-diseased controls

Variable	Sjögren's syndrome (N=157)	Controls (N=111)	Sensitivity/ Specificity	Positive/Negative Predictive value for neuropsychiatric syndromes	p-value[1]
DEMOGRAPHICS					
Age onset Neuro Sx, years	46.2	42.5	N/A	N/A	p=0.91

Multiple Sclerosis (MS)-type Demyelinating Syndrome % (#)	10% (16)	2% (2)	10%/98%	83%/43%	P=0.02
Focal Syndromes					

Cerebrovascular Disease % (#)	5% (7)	4% (4)	4%/96%	64%/42%	p=1.00
Seizures % (#)	4% (6)	1% (1)	4%/99%	85%/42%	p=0.25
PNS Syndromes					
Small-fiber neuropathy % (#)	7% (11)	1%(1)	7%/99%	92%/43%	p=0.02
Ganglionopathy % (#)	3% (5)	0% (0)	3%/100%	100%/42%	p=0.08
Axonal, symmetric polyneuropathy % (#)	1% (2)	1% (1)	1%/99%	67%/42%	p=1.00

(1) Assessed by student's t-test for continuous variables, and by chi-squared analysis or Wilcoxon rank sum test for categorical variables

Conclusion: (1) The frequency and positive predictive value (PPV) of neurologic disease in discriminating between Sjögren's versus controls, was similar to the seroprevalence and predictive value of the SS-A and SS-B antibodies.

(2) In contrast to lupus, "focal" CNS syndromes (strokes, seizures) are uncommon and not statistically associated with Sjögren's patients.

(3) Although demyelinating syndromes and neuropathies are uncommon, these syndromes are statistically associated with Sjögren's, and exhibit high PPV in distinguishing between Sjogern's patients versus controls.

(4) As a major, multi-center, NIH funded study is underway to revise diagnostic criteria for Sjogren's syndrome, this study suggests that the aggregated presence of neurologic disease, as well as the presence of demyeinating syndromes and neuropathies, may have potential diagnostic utility in discriminating between Sjogren's versus controls.

Proteomic Analysis of Whole Saliva as a Promising Tool to Identify Novel Disease Biomarkers in Primary Sjögren's Syndrome.

Chiara Baldini, Laura Giusti, Camillo Giacomelli, Federica Ciregia, Francesca Sernissi, Rosaria Talarico, Laura Bazzichi, Marta Mosca, Gino Giannaccini, Antonio Lucacchini and Stefano Bombardieri, University of Pisa, Pisa, Italy

Purpose: To characterize the salivary proteomic profile of patients affected by primary Sjögren's syndrome (pSS) in order to identify novel diagnostic biomarkers for the disease.

Method: Forty patients with a diagnosis of pSS made according to the AECC criteria (50.86 ± 9.41 years, mean age ±SD) were enrolled in this study. Forty healthy subjects, sex and age matched (48.45 ± 7.56 years, mean age ±SD) were included as controls. Unstimulated whole saliva was collected by draining under standard conditions, and samples were analysed by two-dimensional electrophoresis (2DE) combined with matrix-assisted laser desorption ionisation time of flight mass spectrometry (MALDI-TOF-MS) The same samples were also analysed by surface enhanced laser desorption ionisation time of flight mass spectormetry (SELDI-TOF-MS) which was carried out on different chip arrays (CM10, Q10, IMAC30, H50).

In order to verify the ability of the candidate potential biomarkers to distinguish pSS from other non-SS sicca syndromes, serial salivary samples from 24 patients who were routinely subjected to minor salivary gland biopsy (MSGB), were also analyzed. MSGB was employed as the gold standard test to differentiate pSS from other non-SS sicca syndromes.

Results: Eleven proteins resulted differently expressed in the 2DE-MALDI-TOF-MS analysis of pSS vs healthy subjects. Poly-Ig receptor, alpha-salivary amylases, carbonic anhydrase VI, cystatin SN and prolactine-inhibitor protein precursor were significantly reduced, while enolase, Ig kappa light chain, beta-2-microglobulin, Zn alpha 2 glycoprotein, calgranulin A and B resulted increased. SELDI-TOF-MS detected 57 peaks differently expressed in pSS vs healthy controls. The longitudinal prospective study of the biopsied patients revealed that 36 peaks were also differently expressed in pSS patients compared with non-SS sicca sydrome patients. Noteworthy, 9/36 increased peaks corresponded exactly to 9/57 peaks increased in the comparison between pSS and healthy subjects (m/z 3371, 7511, 10852, 11586, 11740, 12697, 13470, 21721, 77961). Moreover, 3/36 decreased peaks were identical to 3/57 peaks (m/z 4928, 13825, 14266) which were decreased in pSS vs healthy volunteers. The EPO-KB database identified the m/z 3371 and the m/z 11740 peaks as corresponding to neutrofil defensin

1 and beta-2-microglobulin respectively. In addition, the m/z 10852, 11586, 13470 resulted vey close to the molecular weight of calgranulin A, Ig kappa light chain and calgranulin B, apparently validating the results obtained by using 2DE-MALDI-TOF-MS.

Conclusion: This study demonstrated that 2DE-MALDI-TOF-MS and SELDI-TOF-MS might be valid complementary techniques able to identify a pannel of potential novel diagnostic biomarkers for pSS.

Heat Solubilized Curcumin/Turmeric Inhibits Autoantigen-Autoantibody Interaction in Sjögren's Syndrome (SS)/SLE and in a Mouse Model of SS. Biji T. Kurien[1], Anil Dsouza[2] and R. Hal Scofield[3], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]OMRF, Oklahoma City, OK, [3]Oklahoma Med Res Foundation, Oklahoma City, OK

Purpose: Curcumin, derived from Curcuma longa, is the most active component in the Indian curry spice turmeric. Curcumin has emerged as a new "nutraceutical" agent that can ameliorate multiple sclerosis, RA, psoriasis, and inflammatory bowel disease in human or animal models by regulating inflammatory cytokines and related signaling pathways in immune cells. Curcumin levels upto 8 g/day is non-toxic to humans. Insolubility of curcumin limits its biological utility. However, we found that heat treatment increased curcumin solubility 12-fold. We report here that heat-solubilized curcumin/turmeric binds to proteins. We therefore hypothesized that heat-solubilized curcumin/turmeric would bind to antigen and/or antibody and thus inhibit their interaction. Such an intervention would be of therapeutic potential to prevent autoantibody targeting of cognate antigen to ameliorate autoimmune diseases.

Method: BSA or HeLa cell antigens were resolved by SDS PAGE and stained with heat-solubilized curcumin. Antibody/antigen (Ro60, Ro multiple antigenic peptide (MAP)-274 or human spectrin) was determined by ELISA in SLE/SS patients and a mouse model of SS in the absence or presence of heat-solubilized curcumin/turmeric. Surface plasmon resonance was used to determine binding of curcumin to Ro MAP 274antigen interaction as well as inhibition of autoantibody binding to specific antigens. Primary SS (n=20) and SLE (n=20) sera were used in this study along with age and sex matched controls. In addition sera were obtained from 5 mice each immunized with Ro 274 peptide (LQEMPLTALLRNLGKMT) or Freund's.

Results: Curcumin was found to interact significantly with proteins. Anti-Ro 60 antibodies or anti-Ro 274 peptide antibodies bound significantly ($p < 0.001$) to Ro 60 or Ro 274 MAPs compared to controls. Anti-Ro 60 binding to Ro 60 (in SS patients with significant anti-Ro 60 activity) was inhibited 24-43% (35 ± 5.8%; n=9) by curcumin. However the inhibition ranged from 26-74% in SS patients (58 ± 13.5%; n=9) when turmeric extract was used. In the case of SLE patients the range was 36-52% (43 ± 6.6; n=4) and 61-70% (65 ± 4) respectively when curcumin or turmeric respectively was used. Anti-Ro 274 mice sera bound significantly to Ro MAP 274 (p=000) compared to Freund's immunized. Curcumin inhibited binding of anti-Ro 274 antibodies to Ro MAP 274 by 35-50% (46 ± 8.9; n=5) while turmeric inhibited by 55 to 60% (58 ± 2.7%; n=5). Heat-solubilized curcumin/turmeric also inhibited binding of polyclonal anti-spectrin to spectrin by 50/56 % respectively.

Conclusion: Heat mediated curcumin and turmeric significantly inhibited the interaction of human anti-Ro 60, anti-Ro 274 or anti-spectrin peptide antibodies with respective cognate antigens. Turmeric inhibited better than curcumin. Curcumin/turmeric could prove useful as a therapeutic intervention in SS or SLE to minimize autoantibody/antigen interaction and reduce severity of disease manifestation.

Perturbations in B-Cell Homeostasis in Primary Sjögren's Syndrome. Mustimbo Roberts[1], Chungwen Wei[2], James Roger[3] and Iñaki Sanz[4], [1]University of Rochester, Rochester, NY, [2]University of Rochester, [3]University of Rochester School of Medicine and Dentistry, Rochester, NY, [4]University of Rochester School of Medicine and Dentistry., Rochester, NY

Purpose: To elucidate abnormalities in B cell homeostasis with pathophysiological and diagnostic implications for primary Sjogren's Syndrome (pSS). Multicolor flow cytometry was used in a cross-sectional analysis of patients that meet AECG criteria for the diagnosis of pSS as compared to patient with a clinical diagnosis of pSS and patients with sicca symptoms referred to our Rheumatology clinics for the evaluation of possible pSS. We also initiated longitudinal analysis to identify biomarker candidates that could be then validated for their predictive value for the development of full-blown pSS.

Method: B-cells from pSS (n=17), SLE (n=26), RA (n=26), healthy controls (n=24) and longitudinal pSS (n=11) patients were analyzed by multicolor flow cytometry for expression of CD24, CD27, CD38, IgD, B220, CXCR3 and CXCR5 in C19+ B cells.

Results: As reported by others, pSS patients feature decreased frequencies of switched memory (SM) (IgD-/CD27+) and unswitched memory (UM) (IgD+/CD27+) cells as compared to healthy controls (HC) ($p=0.0007$, $p=<0.0001$). In contrast CD27-/IgD- switched cells, a population we reported expanded in SLE, were significantly increased in pSS ($p=0.0142$). We also report that similar to SLE, there is a significant decrease of UM cells in pSS but not RA. Our use of multicolor flow cytometry revealed a relative expansion within the IgD-, CD27+ and CD27-, population of a novel B220+/CXCR3+/CXCR5- subset with a phenotype suggestive of effector B cells. Our preliminary data also indicate that the reported expansion of pre-GC cells (Bm2') may be explained partly by increased transitional B cells (CD24hi/CD38hi). Finally, longitudinal analyses indicate that a decrease in the frequency of UM cells may constitute a valuable indicator of clinical progression to pSS.

Conclusion: Our data provide greater understanding of B-cell homeostasis in pSS and identify more discreet memory subsets that might be implicated in the pathogenesis of the disease and serve as biomarkers for diagnosis and disease progression. The decrease in UM B-cells appears to be the earliest change in the progression to pSS and may bear substantial pathophysiological significance as equivalent marginal zone-like cells have been postulated to play protective roles against autoimmunity in animal models. The CXCR3+/CXCR5-/B220+ population of B-cells is hypothesized to represent effector B cells with enhanced ability to migrate to inflamed target tissues and contribute to disease. Our data suggest a model of clinical autoimmunity onset triggered by an imbalance of regulatory/effector B cell functions mediated by a decrease in regulatory B-cells which may represent an early biomarker in the development of pSS. The presented results also identify the expansion of new candidate effector B cells.

Blocking LFA-1 with Efalizumab Promotes Inflammation, T Cell Activation and Autoimmunity in Primary Sjögren's Syndrome (pSS). Nikolay P. Nikolov[1], Kanneboyina Nagaraju[2], Svetlana Ghimbovschi[2], Maria Alba[1], Larissa Lapteva[3], David Kleiner[4], Janine Clayton[5], Ilias Alevizos[1], Margaret Grisius[1], Lolita Bebris[1] and Gabor G. Illei[6], [1]NIH/NIDCR, Bethesda, MD, [2]Children's National Medical Center, Washington, DC, [3]FDA, Silver Spring, MD, [4]NCI, Bethesda, MD, [5]NIH, Bethesda, MD, [6]NIDCR, NIH, Bethesda, MD

Purpose: The LFA-1/ICAM-1 interaction is important in lymphocyte migration to inflammatory sites, T cell activation and antigen presentation. In SS, activated lymphocytes have increased expression of LFA-1 whereas activated endothelial cells in the salivary and lacrimal glands have increased ICAM-1 expression. In this pilot study we evaluated the safety, clinical efficacy and biology of blocking this interaction in primary SS (pSS) subjects with weekly efalizumab (EFLZ) (1mg/kg), a recombinant humanized monoclonal antibody against the alpha subunit of LFA-1.

Method: The study had three phases (Table). Primary outcome was measured by objective improvement in salivary and lacrimal flows and minor salivary gland (MSG) inflammation (focus score) at the end of Phase 1. Gene expression was profiled from PBMC total RNA collected at baseline and at the end of the double blinded, open label and follow-up phases. Data were analyzed using GeneSpring GX and Ingenuity Pathways Analysis (IPA) software.

Results: After 9 pSS subjects were enrolled (Table) the study was terminated due to reports of fatal JC viral infection in psoriasis patients.

Table. Summary of study accrual and outcomes:

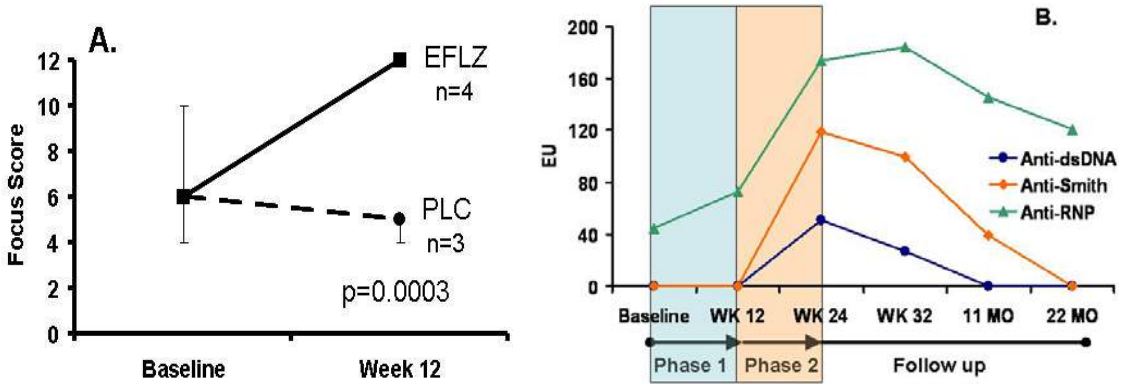
Phase 1 (Week 1-12), Randomized, Double Blinded, Placebo Controlled	**EFLZ , (n=6)**	**Placebo, (n=3)**
Gender	5 Females	All Females

Age, years (median, ±SD)	54 (±4)	54 (±14)
Completed Phase 1	4	3
Responded	0	1
Withdrawn, study terminated	1, Week 08	0
Withdrew, personal reasons	1, Week 09	1, Week 12
Phase 2 (Week 13-24), Open Label	**EFLZ , (n=4)**	**EFLZ , (n=2)**
Responded	0	0
Withdrawn, worsening of SS	1, Week 13	0
Withdrawn, worsening of SS and study termination	1, Week 21	0
Completed Phase 2	2	2

Phase 3 (Week 25-32), Follow up

Repeat MSG biopsy at the end of Phase 1 showed significant increase in inflammation in EFLZ treated subjects (Figure A). Two subjects developed anti-dsDNA antibodies (Abs) during EFLZ treatment one of whom developed multiple auto-Abs and lupus like syndrome which resolved after EFLZ discontinuation (Figure B). Serum Immunoglobulins (IgG) increased significantly in 3 subjects, 2 developed IgG monoclonality and one oligoclonality.

Figure. EFLZ-induced exacerbation of MSG inflammation (A) and de novo auto-antibody secretion (B)



GeneSpring analysis showed 582 genes significantly differentially expressed after EFLZ treatment. IPA identified CD86-CTLA4, IL-2 and Wnt/Beta-catenin signaling pathways to be the most significantly altered in EFLZ treated subjects.

Conclusion: EFLZ exacerbates SS and induces significant increase in local inflammation and systemic autoimmunity. The gene expression data suggest that hyperactivation of peripheral T cells may be responsible for the systemic B cell activation and auto-Abs generation. Further studies may elucidate how inhibition of LFA-1/ICAM-1 signaling drives this profound immune system perturbation.

Differential Expression of MicroRNAs Not Related to Inflammation in Minor Salivary Glands of Primary Sjögren's Syndrome Identify Novel Pathogenesis Related Pathways. Ilias Alevizos[1], Siddhartha Bajracharya[2], Roy J. Turner[3] and Gabor G. Illei[2], [1]NIH/NIDCR, Bethesda, MD, [2]NIDCR, NIH, Bethesda, MD, [3]Bethesda, MD

Purpose: The etiology of salivary gland dysfunction (SGDF) in Sjögren's syndrome (SS) is poorly understood but most likely includes both inflammatory and non-inflammatory mechanisms. It is likely, that changes in the regulation of gene expression may also play a role. MicroRNAs (miRNAs), are master regulators of gene expression. They exert their effects by mRNA degradation and inhibition of translation. A single miRNA is capable of regulating the translation of a multitude of genes involved in certain functions. We hypothesized that miRNA patterns, which are different from healthy controls but do not correlate with inflammation may identify potentially pathogenic processes underlying SGDF.

Methods: Minor salivary gland (MSG) microRNA expression profiles were compared between healthy volunteers (n=8) and primary SS patients (n=16) with minimal (n=8, focus score 1 or 2) or extensive inflammation (n=8, focus score 12). Half of the patients in both pSS groups had preserved and half had decreased salivary flow. MicroRNA expression profiles of minor salivary glands were generated using Agilent microarrays. We developed a novel method to normalize the array data by identifying a set of housekeeping miRNAs. We used validated and bioinfomatically predicted mRNA targets to identify networks and pathways altered by the differential expression of the microRNAs with the Ingenuity Pathway Analysis software.

Results: We identified 30 miRNAS which were overexpressed in the entire SS cohort compared to controls but did not correlate with inflammation. To test if they targeted pathways that are related to non-immunologic aspects of the disease process we used the Ingenuity Pathway Analysis to predict the networks and pathways they might be targeting. Because each microRNA has potentially hundreds of mRNA targets, to reduce the chance identification of pathways that may result from the multiple predicted targets of each microRNA, we only included those predicted mRNAs which were targeted by at least 25% of miRNAS. Pathway analysis identified 20 statistically significant canonical pathways. The six most significant ($p<0.01$) included FGF signaling, pathways related to signaling in neurons (ephrin receptor signaling, reelin signaling in neurons), O-glycan biosynthesis, T cell receptor signaling and proteasomal degradation (PTEN signaling).

Conclusion: Pathway analyis of differentially expressed microRNAs not related to inflammation in MSG of SS patients predicted target pathways related to neurogenesis, FGF signaling and lysosome degradation as the top targets of microRNAs. These pathways may play an important role in the pathogenesis of SS.

MicroRNA Differential Expression in Minor Salivary Glands of Primary Sjögren's Syndrome with High Focus Scores and Normal or Decreased Function Identifies Altered Salivary Gland Function Related Pathways. Ilias Alevizos[1], Siddhartha Bajracharya[2], Roy J. Turner[3] and Gabor G. Illei[2], [1]NIH/NIDCR, Bethesda, MD, [2]NIDCR, NIH, Bethesda, MD, [3]Bethesda, MD

Purpose: Salivary gland dysfunction in Sjögren's syndrome (SS) is poorly understood as it is not always associated with structural damage of the salivary gland parenchyma by lymphocytes. It is likely, that changes in the regulation of gene expression in the lymphocytic infiltrate may also play a role. MicroRNAs (miRNAs), are master regulators of gene expression. They exert their effects by mRNA degradation and inhibition of translation. A single miRNA is capable of regulating the translation of a multitude of genes involved in certain functions. We hypothesized that miRNA expression differences exist between the functional and non-functional minor salivary glands with very high focus score (FS of 12) and that those differences can reveal differences in the type of infiltrating cells

Methods: Eight minor salivary glands from primary Sjögren's syndrome patients with high focus score were used for this study. Half of the patients had normal and half had decreased salivary flow. microRNA expression profiles of minor salivary glands were generated using Agilent microarrays. We developed a novel method of normalizing microRNA microarrays by generating minor salivary gland specific housekeeping miRNAs.. We used validated and bioinfomatically predicted mRNA targets to identify networks and pathways altered by the differential expression of the microRNAs with the Ingenuity Pathway Analysis software.

Results: We identified 21 miRNAs upregulated in the samples with normal salivary flow. Using Targetscan we identified the predicted mRNA targets of those miRNAs and kept only the mRNAs that are targeted by 7 or more of the miRNAs. The list of those genes was then

explored with the Ingenuity Pathway Analysis software and revealed 28 statistically significant pathways. The top 5 of those pathways are: PPARα/RXRα Activation, Glycosphingolipid Biosynthesis – Neolactoseries, Aldosterone Signaling in Epithelial Cells and Clathrin-mediated Endocytosis.

Equally important was the discovery that three of the 21 microRNAs, namely hsa-mir-18a, hsa-mir-19a and hsa-mir-19b, belong to the mir-17-92 cluster which has been associated with specific types of lymphocytes and lymphocytic pathologies. More specifically, decrease of the mir-17-92 has been associated with accumulation of pro-B cells with a marked reduction of pre-B and more mature B cells, and overexpression of it has been linked to lymphoproliferative disease and autoimmunity.

Conclusion: MicroRNA expression differences between MSGs with high focus score suggest that qualitative rather than quantitative differences in the infiltrating lymphocytes are associated with loss of function. Further exploration of the pathways associated with decreased salivary flow will provide insight in the pathophysiology of SS and may identify novel therapeutic targets.

Aquaporin Expression in Interstitial Lung Diseases Related to Sjögren Syndrome. Carmen Navarro[1], Alfonso Salgado[2], Miguel Gaxiola[3], Mayra Mejia[3] and Moises Selman[3], [1]National Institute of Respiratory Diseases, Mexico City, Mexico, [2]National Institute of Respiratory Diseases, [3]National Institute of Respiratory Diseases, Mexico

Purpose: Aquaporins (AQP) are molecular water channels expressed in many epithelia and endothelia involved in fluid transport, such salival and lacrimal gland or lung. It has been shown down-regulation of AQP in salivary glands in patients with Sjögren´s syndrome (SS) and altered expression on lacrimal gland in animal models of the disease suggesting AQP may play a crucial role in the pathology and clinical manifestations of the disease. To assess abnormalities in the expression of AQP in lung tissue of SS patients who develop interstitial lung disease (ILD).

Method: We analyzed 7 lung biopsy obtained with diagnosis proposal from SS patients who develop ILD. Pattern of AQP 1, 4 and 5 mRNA expression in both, total lung tissue and epithelial cells obtained by laser captured microdissection, were examined by quantitative real-time PCR. We used RNA from normal lung commercial available (StratageneÒ, ClontechÒ, AmbionÒ) as control group.

AQP localization in lung tissue was evaluated by standard immunohistochemistry using antibodies commercial available (Santacruz Ò). Clinical data were collected from clinical charts.

Results: The data we have obtained showed that 5 of the 7 SS-ILD patients had lower expression of AQP-1 than the average expression in the control group; 6 of the 7 SS-ILD patients had lower expression of AQP-4 than the control group; and all the patients had higher expression of AQP-5 than the control group. Similar results were found on the mRNA obtained from epithelial cells and total lung tissue. Localization of AQP-1 and AQP-4 were similar to normal tissue. However expression of AQP-5 was diminished compared with normal tissue.

Conclusion: Expression of AQP is modified in lung parenchyma of SS patients who develop interstitial lung diseases. Although the full implications of these findings remain to be determined, may be AQP could be involved in the lung damage of SS patients.

Disclosure: C. Navarro, None; **A. Salgado**, None; **M. Gaxiola**, None; **M. Mejia**, None; **M. Selman**, None.

Anti-Aquaporin-4 Antibodies Are Highly Specific for Neuromyelitis Optica and Show No Association with Sjögren's Syndrome and Other Autoimmune Diseases. Alessandra Dellavance[1], Rossana R. Alvarenga[2], Silvia H. Rodrigues[2], Fernando Kok[3], Alexandre W. S. Souza[2] and Luis Eduardo C. Andrade[2], [1]Fleury Health and Medicine, São Paulo, Brazil, [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [3]Universidade de Sao Paulo, Sao Paulo, Brazil

Purpose: Neuromyelitis optica (NMO; Devic's syndrome) is a severe CNS demyelinating syndrome characterized by optic neuritis (ON) and acute myelitis. Anti-aquaporin 4 antibodies have been recently reported as a biomarker for NMO with specificity over 90% in patients with optic-spinal syndrome and other demyelinating conditions. The specificity of anti-aquaporin 4 antibodies for NMO has not been tested

against a wider spectrum of systemic autoimmune diseases but a recent report has suggested that patients with Sjögren's syndrome may present anti-aquaporin 4 antibodies. Therefore we set to screen anti-aquaporin 4 antibodies in a wide clinical spectrum of systemic and organ-specific autoimmune diseases, demyelinating neurological diseases and infectious diseases.

Method: Serum was obtained from patients regularly followed at specialized outpatient clinics at Federal and State University of São Paulo, Brazil: 37 with NMO, 22 with other demyelinating conditions, 28 with primary Sjögren's syndrome, 32 with rheumatoid arthritis, 80 with systemic lupus erythematosus, 38 with systemic sclerosis, 40 with myasthenia gravis, 37 with primary biliary cirrhosis, 23 with hepatitis C virus, 12 with miscellaneous infectious disease (CMV, dengue, herpes simplex), and 200 samples from patients from the general outpatient clinic without any suspicion of neurological disease. IgG anti-aquaporin 4 antibodies were determined by indirect immunofluorescence on rat cerebellum at a screening dilution of 1/10 as previously established (Lennon VA et al, JEM 2005, 202:473). Slides were read by two blinded independent observers at x200 and x400 magnification.

Results: The characteristic staining pattern of anti-aquaporin 4 antibodies was observed in 30 of 37 samples from patients with neuromyelitis optica (81% sensitivity) and in none of 549 samples not related to this disease (100% specificity). Detailed clinical data was available for 15 patients with documented primary Sjögren's syndrome and revealed neurologic involvement in 4 of them. Peripheral polyneuropathy occurred in two and cranial neuropathy in two other patients. No patient had central nervous system involvement. Cutaneous small vessel vasculitis was observed in two patients and in one of them it was associated with cryoglobulinemia.

Conclusion: Anti-aquaporin 4 antibodies are highly specific for the diagnosis of NMO in the context of several autoimmune and infectious diseases. There was no association of anti-aquaporin 4 antibodies with neurological manifestations in Sjögren's syndrome.

Clinical, Radiographic, and Autoantibody Features Are Associated with Distinct Patterns of Demyelinating Syndromes in Sjögren's Patients. Julius Birnbaum, Douglas Kerr and Alan N. Baer, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Demyelination in the Central Nervous System (CNS) can be a severe neurologic manifestation of Sjögren's syndrome. In recent years, "idiopathic" demyelinating syndromes (i.e. Multiple Sclerosis versus Neuromyelitis Optica/NMO) are increasingly recognized as heterogeneous entities, which exhibit distinct demographic, clinical, radiographic, and autoantibody patterns. We sought to characterize whether the demyelinating syndromes in Sjögren's may similarly exhibit distinct clinical and radiographic features, and to characterize the autoantibody patterns in these CNS demyelinating syndromes.

Method: We reviewed the medical records of 157 consecutive patients with Sjögren's syndrome, presenting for evaluation between January, 2002 and May 2009. Demyelinating attacks required both symptoms and exams suggestive of a clinically relevant lesion, with evidence of demyelination on spine or brain MRI neuroimaging.We investigated whether demyelinating episodes satisfied revised diagnostic criteria for Neuromyelitis Optica/NMO, the Neuromyelitis Optica-Spectrum of Syndromes (NMOS), or had multifocal brain lesions similar to Multiple Sclerosis.

Results: Of 157 patients, 25 experienced CNS demyelinating syndromes. Patients with demyelinating syndromes reported earlier onset of sicca symptoms (mean 39.7 years, compared to 47.3 years, $p<0.01$). Sjögren's patients with demyelinating attacks, were also younger at time of first flare, compared to Sjögren's patients experiencing other neurologic syndromes (mean of 38.8 years, versus 48.3 years $p<0.01$).

Two patients satisfied diagnostic criteria for NMO; 7 patients satisfied suggested criteria for NMOS, having recurrent myelitis attacks without optic neuritis, but with inflammation on spinal cord MRI spanning at least 3 vertebral segments. Seven of the nine patients (77%) with NMO/NMOS were seropositive for the NMO-IgG autoantibody. Sixteen patients had symptomatic and/or radiographic multifocal brain disease which was phenotypically similar to Multiple Sclerosis. Patients with demyelinating episodes had a non-statistically higher seroprevalence of anti-Ro antibodies (75% versus 64%, $p=0.35$), but a lower seroprevalence of anti-La antibodies (17% versus 37%, $p=0.06$)

Conclusion: Demyelinating syndromes in Sjögren's syndrome are clinically and radiographically heterogeneous syndromes, which can be distinguished as being more similar to NMO/NMOS versus MS. Patients with demyelinating syndromes are younger, and are more likely to have an autoantibody profile showing isolated SS-A positivity with SS-B negativity

505

Effect of Rituximab Treatment On Cytokine/ Chemokine Profile in Patients with Primary Sjögren's Syndrome. R.P.E. Pollard, W.H. Abdulahad, J.M. Meijer, M.G. Huitema, F.K.L. Spijkervet, C.G.M. Kallenberg, A. Vissink and H. Bootsma, University Medical Center Groningen, Groningen, Netherlands

Purpose: To assess the effect of rituximab (anti-CD20) treatment on the cytokines/ chemokines profile in patients with primary Sjögren's syndrome (pSS)**.**

Method: In a randomised double-blinded placebo-controlled trial patients were treated on days 1 and 15 with either rituximab (n= 20) or placebo (n= 10). Fresh blood samples were collected at various time points (before, 5, 12, 36 and 48 weeks following treatment). In addition, age- and sex-matched blood samples were collected from healthy controls (n=10). B and T-cells were examined by four-color cytometry. A multiplex-25 bead array cytokine assay was used enabling simultaneous measurement of (1) proinflammatory cytokines (GM-CSF, IL-1β, IL-1RA, IL-6, IL-8, TNF-α); (2) Th1/Th2 distinguishing cytokines (IFN-γ, IL-2, IL-2R, IL-4, IL-5, IL-10); (3) nonspecific acting cytokines (IFN-α, IL-7, IL-12p40/p70, IL-13, IL-15, IL-17); and (4) chemokines (Eotaxin, IP-10, MCP-1, MIP-1α, MIP-1β, MIG, RANTES).

Results: Depletion of B-cells was observed in the rituximab treated group after first infusion, while B-cell levels remained unchanged after placebo treatment. The B-cells reappeared in the rituximab treated group within 24 to 48 weeks after treatment. Regarding CD4+ and CD8+ T cells no changes were observed between the rituximab and placebo treated patients at all time points. When compared to healthy controls, except for IL-8 and IFN- γ, an increase was seen in the levels of the other cytokines at baseline. After rituximab treatment, a decrease and subsequent (partial) recovery within 24 to 48 weeks was observed for IL-1β, IL-1RA, IL-2R, IL-4, IL-5, IL12, IL-15, IL-17, TNF-α, GM-CSF, MIP-1α, MIP-1β, MIG, Eotaxin, MCP-1. As compared to placebo, the most striking early decrease was observed in IL-10 levels.

Conclusion: These preliminary data show a variation in cytokine/ chemokine profile before and after rituximab therapy in conjunction with a depletion and reappearance of B-cells. Related to the observed changes in cytokine profiles, specific cytokines are noted that may play a role in pathogenesis of pSS. This observation will be correlated with clinical data. Extended data are in progress.

506

Peripheral Neuropathy Is An Uncommon Cause of Neuropathic Symptoms in Sjögren's Patients. Julius Birnbaum, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Sjögren's patients frequently describe sensory symptoms, ranging from numbness to excruciating, lancinating pain. Different cohorts have reported discrepant rates of peripheral neuropathy in Sjogren's syndrome, ranging from 3 to 60 percent. We sought to understand the frequency of sensory symptoms in Sjogren's patients, the attribution of these symptoms to peripheral neuropathies, and to understand the autoantibody patterns of Sjogren's patients with sensory symptoms and peripheral neuropathies

Method: We reviewed the medical records of 157 patients presenting with Sjogren's syndrome. We considered the patients as having neuropathic symptoms if they complained of numbness, or other sensory descriptors contained in the LANSS neuropathy questionnaire. Patients were considered as having neuropathic pain if they satisfied the 2007 consensus redefinition for neuropathic pain, which requires pain in a plausible neuroanatomic distribution; a potential history of a CNS or PNS cause of such neuropathic pain; and confirmation (either by neurologic exam, or other corroborating studies) of both topographic distribution and cause of neuropathic pain.

Results: A considerable number of Sjögren's patients (55%, 86/157) had neuropathic symptoms. However, of these 86 patients with sensory symptoms, a diagnosis of neuropathic pain was only achieved in 66% (57/86) patients. In Sjögren's patients with neuropathic symptoms, only 21% (18/86) had peripheral neuropathies: CNS structural disease (i.e. cervical spondylosis) and demyelinating syndromes were causes of neuropathic symptoms in 16% (14/86) and 29% (25/86) of patients. Seropositivity to anti-La was seen less commonly in Sjögren's patients with neuropathic symptoms (24% versus 43%, OR=.41 [95% CI [0.20, 0.83], p=0.02) There was no difference in seropositivity for SS-A, comparing Sjögren's patients without versus having neuropathic symptoms (63% versus 70%)

Conclusion: A considerable number of Sjogren's patients with neuropathic symptoms, will not have plausible CNS or PNS identifiable etiologies allowing the diagnosis of neuropathic pain. Only a minority of Sjogren's patients with neuropathic symptoms will have a neuropathy. The lower seroprevalence of anti-La antibodies in Sjogren's patients with neuropathic symptoms suggests that immunologic mechanisms may modulate the perception of neuropathic pain in Sjogren's patients.

B-Cell Reconstitution and T-Cell Balance After Rituximab Treatment of Active Primary Sjögren's Syndrome. Wayel H. Abdulahad[1], Jiska Meijer[1], Rodney Pollard[1], F.K.L. Spijkervet[1], C.G.M. Kallenberg[1], A. Vissink[1], Frans Kroese[2] and Hendrika Bootsma[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]Groningen, Netherlands

Purpose: To analyze the phenotype and the state of activation of reconstituting B-cells after B-cell depletion, and to assess the effect of reconstitution on regulatory (T_{Reg}) and effector (T_{eff}) T-cell numbers in patients with active primary Sjögren's syndrome (pSS).

Method: Twenty-nine patients with pSS were treated on days 1 and 15 with either rituximab (RTX, n=20) or placebo (PLC, n=9). B-cell numbers and phenotypes were examined in fresh blood samples by four-color cytometry at baseline and at 5, 12, 24, 36, and 48 weeks after infusions. The distribution of plasma cell/blast ($CD38^{High}CD27^{High}CD19^{+}$), post-switches memory ($IgD^{-}IgM^{-}CD27^{+}CD19^{+}$), pre-switches memory ($IgD^{+}IgM^{+}CD27^{+}CD19^{+}$), naïve ($CD38^{-/Low}CD27^{-}$), and transitional ($CD38^{High}CD27^{-}$) B-cells subsets were examined. In addition, numbers of both T_{Reg} cells ($CD3^{+}CD4^{+}CD25^{High}CD127^{-}$) and T_{eff} cells ($CD3^{+}CD4^{+}CD25^{+}CD127^{+}$) were also analyzed at all time points.

Results: At baseline, patients with pSS displayed several abnormalities in B-cell homeostasis, including a significant reduction of pre-switched memory B-cells and expansion of immature- and mature naïve B-cells, compared with healthy controls (n=10). Following RTX-treatment (at week 48), a majority of emerging B-cells revealed a phenotype of transitional B-cells. Although the recovery of memory B-cells was delayed, a significant increase in post-switched and a significant decrease in pre-switched memory B-cells was observed in post-RTX when compared with pre-RTX and post-PLC. Remarkably, no significant differences in the percentages of plasma cells were found at 48 weeks compared to pre-RX-treatment. Furthermore, percentages and absolute counts of T_{Reg} and T_{eff} cells, as well as T_{Reg}:T_{eff} ratios, showed no significant changes after RTX compared to baseline.

Conclusion: B-cell reconstitution after RTX-treatment starts with transitional B-cells followed by post-switched memory B-cells that probably include autoreactive B-cells. RTX-treatment did not alter the numbers of circulating T_{Reg} and T_{eff} cells.

Associatioin of Primary and Secondary Sjögren's Syndrome in Lupus Families. Rachna Aggarwal[1] and R. Hal Scofield[2], [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, University of Oklahoma HSC, Dept Veterans Affaris Med Cnt, Oklahoma City, OK

Purpose: Systemic lupus erythematosus (SLE) and Sjögren's syndrome are closely related diseases, but the relationship of primary and secondary Sjögren's syndrome within families with SLE is not known. We undertook this study to determine whether primary Sjögren's syndrome is increased among SLE-unaffected, and whether primary and secondary Sjögren's syndrome are associated within families with SLE.

Methods: Families were collected through the Lupus Family Registry and Repository. All SLE patients met the 1982 revised classification criteria for SLE, and all families had at least one member with SLE.. All subjects completed a standardized questionnaire, and had autoantibodies determined by ELISA and double immunodiffusion. Sjögren's syndrome was considered present when subjects met the combined US-European Sjögren's classification criteria for dry mouth as well as dry eyes and had anti-Ro (or SSA).

Results: Among a total of 2537 SLE patients, there were 505 (19.9%) SLE patients with secondary Sjögren's syndrome. There were 65 SLE-unaffected relatives of SLE patients who had primary Sjögren's syndrome, while none of 1304 age and sex matched healthy controls

had Sjögren's ($\chi 2$=12.7, p=0.02). Seventeen (26.2%) of the 65 subjects with primary Sjögren's had an SLE-affected relative with secondary Sjögren's syndrome, compared to 493 (7.1%) of 6922 SLE-unaffected family members without primary Sjögren's ($\chi 2$=34.8, p<0.00001, odds ratio=5.0).

Conclusion: We find that primary Sjögren's is found among relatives of SLE patients statistically more often than in healthy controls. Furthermore, within these SLE families primary Sjögren's syndrome in SLE-unaffected members was associated with secondary Sjögren's. That is, there was a familial distribution of primary and secondary Sjögren's. Primary Sjögren's affected family members were about 5 times more likely to have an SLE-affected relative with secondary Sjögren's than family members without primary Sjögren's. These data suggest common susceptibility factors, possibly genetic, for primary and secondary Sjögren's syndrome.

Memory T Cells Require the Continuous Presence of B Cells in a Mouse Model of Sjögren's Syndrome. Yongmei Li[1], Robert Dunn[2], Marilyn R. Kehry[2], Jennifer Resling[1], Ammon B. Peck[3], Robert A. Eisenberg[4] and Philip L. Cohen[1], [1]Temple University, Philadelphia, PA, [2]Biogen Idec, San Diego, CA, [3]University of Florida College of Dentistry, Gainesville, FL, [4]University of Pennsylvania, Philadelphia, PA

Purpose: To use B-cell depletion with a monoclonal anti-mouse CD20 as a tool to understand the mechanism of T-cell activation in C57BL/6.NOD.Aec1Aec2 (AEC) mice, which spontaneously develop Sjögren's syndrome.

Method: Splenic B and T cell subsets were analyzed in B-cell depleted and untreated 10 week, 16 week and 14 month-old AEC mice and B6 controls.

Results: We found expanded numbers of CD3+ T cells in spleens of AEC mice starting at 10 wk of age, mostly reflecting an increase in CD4+ memory T cells ($CD62L^{lo}$ $CD44^{hi}$). Na•ve and activated CD4+ subsets, as well as CD8 T cells, were not different between AEC and B6 controls. B-cell numbers were initially lower in AEC mice at 10 wk of age but became comparable to B6 controls at 16 wks of age. To investigate the role of B cells in this accumulation of CD4+ memory T cells, we depleted B cells in 9-12 month old AEC females by injecting i.p. anti-mouse CD20 (0.25mg, clone 18B12 IgG2ak, weekly, for three or four weeks). In two separate experiments, anti-mCD20 significantly reduced peripheral blood B cells, and splenic follicular, marginal zone B cells, as well as spontaneous IgM- and IgG-antibody forming B cells. Anti-mCD20-treated AEC mice also had significantly reduced numbers of CD4+ memory T cells (46% reduction, p=0.025) compared to mice treated with control antibodies or PBS. Other T-cell subsets were unaffected.

Conclusion: Our findings suggest that the proliferation of a substantial number of CD4+ memory T cells is dependent on the continuous presence of B cells. The perpetuation of a T-cell immune response, which seems to be of critical importance in mediating SS tissue damage, may require B-cell presentation of autoantigens and/or B-cell derived cytokines. These studies provide an experimental framework for ongoing trials of B-cell depletion in human SS.

Comparison of RAPID3, BASDAI and BASFI in Ankylosing Spondylitis Patients in Routine Care: RAPID3, Composed of Patient Measures Only, Is Strongly Correlated with BASDAI and BASFI. Duygu Kurtulus[1], Cengiz Bahadir[1], C.J. Swearingen[2] and Yusuf Yazici[3], [1]Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey, [2]MUSC, Charleston, SC, [3]NYU Hospital for Joint Diseases, New York, NY

Purpose: The Bath ankylosing spondylitis disease activity index (BASDAI) and Bath AS Function Index (BASFI) were developed as outcome measures to assess and monitor patients with ankylosing spondylitis (AS). Although widely used in clinical trials and other clinical research, these questionnaires are not commonly used in routine clinical care. It is complex to distribute multiple questionnaires to different patients in a reception area. A single questionnaire for all patients with rheumatic diseases may present advantages to introduce quantitative measurement into routine care. A multidimensional health assessment questionnaire (MDHAQ) has been developed to be used as part of the infrastructure of routine care and has been used in the clinics of the senior author for close to 10 years in every patient with any diagnosis. Routine assessment of patient index data 3 (RAPID3) is a composite index based on 3 MDHAQ components, patient function, pain and patient global assessment, each scored 0-10 for a total of 0-30. The MDHAQ has been shown to be useful in RA, OA, fibromyalgia and Behçet's syndrome.

Method: Consecutive AS patients seen at Haydarpasa Numune Training and Research Hospital, Physical Medicine and Rehabilitation Outpatient Clinic in Istanbul, Turkey, between May 18 and June15, 2009 were enrolled. All patients completed a BASDAI (score range 0-10), BASFI (score range 0-10) and MDHAQ and had medical records reviewed for additional demographic information, disease characteristics, medication use and selected laboratory test results. Spearman correlations were computed for components of MDHAQ and RAPID3 (score range 0-30) with BASDAI and BASFI.

Results: 51 AS patients were assessed (mean (SD) age:30 (10.9) 69% male, disease duration: 5.0 (6.7) years). Mean scores for BASDAI, BASFI and RAPID3 were 4.9 (2.5), 3.6 (2.5) and 12.9 (7.0), respectively. RAPID3 was strongly correlated with BASDAI and BASFI (r:0.77, and 0.72, $p<0.001$). Individual components of the MDHAQ (pain r:0.72, 0.6) patient's global assessment (r:0.8, 0.65), function (r:0.5, r:0.73), MD global assessment (r:0.7, r:0.76) and fatigue (r:0.62, r: 0.53) (all $p<0.01$), were also correlated significantly with both BASDAI and BASFI, respectively.

Conclusion: RAPID3, on an MDHAQ was strongly correlated with the outcome measures of BASDAI and BASFI in AS patients. Additional measures in the MDHAQ were also correlated. This extends findings that an index of patient measures, RAPID3, may provide a user-friendly index and an effective measure in clinical care of individual patients with AS.

Maintained Clinical Response of Infliximab Treatment in Ankylosing Spondylitis: A 6-Year Long-Term Study. Ioanna Saougou[1], Theodora E. Markatseli[1], Paraskevi V. Voulgari[2], Niki Tsifetaki[2], Evripidis Kaltsonoudis[2] and Alexandros A. Drosos[3], [1]Trainee in Rheumatology, Ioannina, Greece, [2]Assistant Professor of Rheumatology, Ioannina, Greece, [3]Ioannina Medical School, Ioannina, Greece

Purpose: To investigate the efficacy, safety and drug discontinuation in patients with ankylosing spondylitis (AS) treated with infliximab, as well as the drug survival over a period of 6 years.

Method: Forty patients with AS treated with infliximab were included in this prospective, open label study. All patients fulfilled the New York revised criteria for AS. Infliximab was given intravenously (5 mg/kg/body weight) at weeks 0, 2, 6 and every 8 weeks thereafter for a period of 6 years. Data concerning infliximab efficacy, tolerability, adverse events and drug discontinuation, were recorded. Clinical improvement according to the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) 50% and the Ankylosing Spondylitis Assessment Study Group (ASAS) 20% and 40% were also recorded.

Results: A significant improvement in the BASDAI and ASAS scores was noted in the first year which sustained through the sixth year of treatment. More specifically, after the sixth year of treatment, BASDAI 50% was achieved by 65% of patients (26/40), ASAS 20% by 72.5% (29/40) and ASAS 40% was reached by 70% (28/40) of patients. Clinical improvement was associated with the reduction of acute phase reactants, such as C-reactive protein levels. After the first and the second year of treatment, the survival rate of infliximab reached 95%, after the third year it was 80%, while after the fourth year it was 72.5%, which was maintained throughout the fifth and sixth year of therapy. Five patients were increased the dose of infliximab and 3 of them had shortened the interval infusion. Overall, 11 patients were withdrawn during the observational period, 3 because of adverse events, 2 because of lack of efficacy, while 6 were lost from follow-up.

Conclusion: Infliximab was effective, safe and well-tolerated in patients with AS. The clinical response was maintained for a period of six years, with high infliximab survival rate, reaching the percentage of 72.5% .

Golimumab, ANew, Human, TNF Alpha Antibody, Administered Subcutaneously Every 4 Weeks in Psoriatic Arthritis Patients: 104-Week Efficacy and Safety Results of the Randomized, Placebo-Controlled GO-REVEAL Study. A. Kavanaugh[1], P. Mease[2], G.G. Krueger[3], D. Gladman[4], J. Zrubek[5], A. Beutler[5], B. Hsu[5], S. Mudivarthy[5], M. Mack[5] and Iain B. McInnes[6], [1]UCSD, San Diego, CA, [2]Swedish Med Ctr/U of Washington, Seattle, WA, [3]U of Utah Hlth Sciences Ctr, Salt Lake City, UT, [4]The Toronto Western Hosp., Toronto, ON, [5]Centocor R&D, Inc, Malvern, PA, [6]University of Glasgow, Glasgow, United Kingdom

Purpose: To assess long-term efficacy & safety of golimumab (GLM) in active PsA.

Methods: PsA pts with ≥3 swollen and ≥3 tender joints and psoriasis were randomized to SC PBO or GLM (50 or 100 mg) q4wks. At wk 16, pts with inadequate arthritis response entered early escape (EE). All pts received GLM from wk 24. Investigators could dose-escalate pts receiving GLM 50 mg to 100 mg based on clinical judgement after all pts reached wk 52. The results for pts who remained on the same dose of GLM 50 to 100 mg are described. Analyses were based on observed data.

Results: 405 pts with active PsA were randomized (113 PBO, 146 GLM 50 mg, 146 GLM 100 mg). GLM was significantly better than PBO in improving signs and symptoms of PsA at wk 24, and GLM efficacy was maintained through wk 52.Through wk 104, pts continuing on the same dose of GLM 50 or 100 mg maintained high levels of response. GLM 50 mg pts who switched to 100 mg in EE or via dose escalation also achieved clinically meaningful responses (Table). 8.6% (34/394) of GLM-treated pts experienced SAEs through wk 104. Injection site reactions occurred in 8.9% (35/394) of pts. There was 1 case of histoplasmosis in a pt (GLM 100 mg) that was successfully treated. Malignancies reported through wk 104 include basal cell skin (1 pt), colon (1 pt), and small cell lung cancer (1 pt) in pts receiving GLM 50 mg, and basal cell skin (3 pts), prostate (1 pt), and small cell lung cancer (1 pt; fatal) in pts receiving GLM 100 mg. An additional pt died due to a climbing accident (GLM 50 mg).

Table:

Summary of efficacy in GO-REVEAL through wk 104

	GLM 50mg only[1]	**GLM 50 ≥100mg[2]**	**GLM 100mg only[3]**
Wk 52 ACR20	80/102(78.4%)	11/26(42.3%)	93/115(80.9%)
HAQ score, mean (SD) improvement	n=100, 0.49 (0.55)	n=26, 0.20(0.49)	n=113, 0.50 (0.54)
ACR50	58/102(56.9%)	7/26(26.9%)	68/115(59.1%)
ACR70	44/102(43.1%)	3/26(11.5%)	41/115(35.7%)
PASI75[4]	44/71(62.0%)	17/23(73.9%)	60/86(69.8%)
Wk 104 ACR20	64/70 (91.4%)	43/76 (56.6%)	95/130 (73.1%)
HAQ score, mean(SD) improvement	n=69, 0.54 (0.55)	n=76, 0.36 (0.57)	n=127, 046 (0.57)
ACR50	46/70 (65.7%)	27/76 (35.5%)	70/130 (53.8%)

ACR70	31/70 (44.3%)	17/76(22.4%)	48/130(36.9%)
PASI75	33/48 (68.8%)	35/56 (62.5%)	73/96 (76.0%)

[1] *Includes pts randomized to GLM 50mg and did not change dose;* [2] *Includes pts on PBO at baseline who entered EE or crossed over to GLM 50mg and later dose escalated to GLM 100mg and pts randomized to GLM 50mg who entered EE or dose escalated to GLM 100mg;* [3]*Includes pts randomized to GLM100 mg and did not change dose;* [4]*Among pts with ≥3% body surface area psoriasis involvement at baseline.*

Conclusion: Pts with active PsA treated with GLM 50 and 100mg SC q4 wks maintained high levels of improvement through wk 104. GLM was generally well-tolerated, with a safety profile similar to that observed for other anti-TNF agents.

Both Structural Damage of the Spine (X-Rays) and Spinal Inflammation (MRI) Contribute to Impairment of Spinal Mobility in Patients with Ankylosing Spondylitis.

Pedro Machado[1], Robert Landewé[2], Jürgen Braun[3], Kay-Geert Hermann[4], Benjamin Hsu[5], Daniel Baker[5] and Désirée M.F.M. van der Heijde[6], [1]Coimbra University Hospital, Coimbra, Portugal, and Leiden University Medical Center, Leiden, Netherlands, [2]University Hospital Maastricht, Maastricht, Netherlands, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Charité Medical School, Berlin, Germany, [5]Centocor Inc., Malvern, PA, [6]Leiden University Medical Center, Leiden, Netherlands

Purpose: Structural damage in ankylosing spondylitis (AS) has been shown to impair spinal mobility. However, the contribution of spinal inflammation to potentially reversible impairment of spinal mobility is not well established. Our aim was to study the relationship between radiographic damage of the spine, spinal inflammation (MRI) and spinal mobility in patients with AS.

Method: In this investigator-performed sub-analysis of the ASSERT database at baseline, in total 214 patients, representing an 80% random sample, were investigated. MRI inflammation was assessed by the ASspiMRI-a score, structural damage by the mSASSS and spinal mobility by the linear definition of the BASMI (BASMI-lin). Independent associations between the variables of interest were investigated by linear regression analysis on van der Waerden-normalised variables. Because of a relevant statistical interaction between disease duration (in quartiles) and ASspiMRI or mSASSS, sub-analyses are presented in patients with low (≤3 years) *vs* high (>3 years) disease duration.

Results: BASMI-lin correlated moderately well with mSASSS (Spearman's rho=0.60) but only weakly with ASspiMRI-a (rho=0.30). A best-fit model for BASMI-lin included the variables presented in table I (sex included by default).

Table I: Best-fit model for BASMI-lin

	Beta	**B**	**95% CI**	**p-value**
mSASSS	0.544	0.863	0.675 to 1.052	<0.001
ASspiMRI-a	0.142	0.235	0.040 to 0.431	0.019
Sex (male)	-0.08	-0.303	-0.735 to 0.130	0.169

In patients with a disease duration ≤3 years, ASspiMRI-a (but not mSASSS) was the only contributory variable (B=0.594 (0.171 to 1.017); p=0.007), while in patients with a disease duration >3 years mSASSS (but not ASspiMRI-a) was contributory (B=0.923 (0.713 to 1.132); p<0.001).

Conclusion: Spinal mobility impairment in AS is independently determined both by irreversible spinal damage as well as by reversible spinal inflammation. Spinal mobility impairment is dominated by spinal inflammation in early disease, and by irreversible structural damage in later disease, which may imply that spinal mobility can better be maintained by early as compared to late intervention.

514

The Prevalence of Co-Morbidities in a Psoriatic Arthritis Cohort. Majed M. Khraishi[1], Nadia Longo[2], Anthony Pellegrino[2] and John S. Sampalis[2], [1]Nexus Clinical Research, St Johns, NF, [2]JSS Medical Research, Westmount, QC

Purpose: Psoriatic arthritis (PsA) is a serious chronic condition that affects 10-35% of patients with skin psoriasis (PSO) and is associated with progressive joint damage and significant morbidity. Co-morbidities associated with PsA are still not fully defined specifically in early stages of the disease compared to the general population.

Method: Data was collected from a rheumatology clinic specializing in patients with PSO and PsA diagnosed greater than 2 years (Established PsA) compared to cohort of PsA patients diagnosed less than 2 years (Early PsA) in Newfoundland. Data for controls with no history of PSO or PsA were collected from the Newfoundland and Labrador Center for Health Information (NLCHI). Controls were matched 3:1 to the Established PsA cohort. Co- morbidities associated with PsA will be compared to the general population using age adjusted standardization rates by gender.

Results: 148 patients with PsA were identified, of which 38 were in the Early PsA group. Mean (SD) age of the established group was 53 (11.0) and 48 (11.3) for the early group. Mean (SD) duration of PsA was 12.6 (9.4) months for the Early PsA cohort and 8.0 (9.1) years in the Established PsA cohort. There were more females in the Early PsA group compared to the Established PsA (60.5% vs. 42.6%) respectively. The table summarizes the prevalence rates of co-morbidities, showing that hypertension, obesity, diabetes and depression are more prevalent in the PsA population in comparison to the general population.

Gender	Co- morbidities	Early PsA Cohort			Established PsA Cohort		
		Observed (PsA cohort)	Expected (Control cohort)	Prevalence Rate	Observed (PsA cohort)	Expected (Control cohort)	Prevalence Rate
Males	Hypertension	5	0.6	8.2	17.5	3.6	4.9
	Coronary Heart Disease	0	0.6	0	6	3.7	1.6
	Diabetes	1	1	1	6	5.9	1
	Obesity	0	1	0	14	5.9	2.4
	Depression	1	0.2	5.1	3	0.6	4.9
Female	Hypertension	7	0.4	16.9	24	1.3	17.8
	Coronary Heart Disease	1.0	0.4	2.3	1	1.4	0.7
	Diabetes	5	1.1	4.4	6	3.6	1.7
	Obesity	7	0.4	18.2	18	1.3	14.1
	Depression	1	1.1	0.9	8	3.5	2.3

Conclusion: Patients with PsA have a high prevalence of cardiovascular disease and metabolic abnormalities even when age is adjusted to the general population. These co-morbidities are present in patients with short disease duration suggesting that the predisposition of cardiovascular and metabolic abnormalities in PsA patients may precedes the development of joint disease.

515

The Impact of Psoriatic Arthritis (PsA) According to the International Classification of Functioning, Health and Disability (ICF).
William J. Taylor[1], Dafna D. Gladman[2], Philip J. Mease[3], Adewale Adebajo[4], P. Nash[5] and Marie Feletar[6], [1]University of Otago, Wellington, New Zealand, [2]University of Toronto, Toronto, ON, [3]Seattle Rheumatology, Seattle, WA, [4]Barnsley Hospital, Sheffield, United Kingdom, [5]University of Queensland, Brisbane, Australia, [6]Rheumatology, Dandenong, Australia

Purpose: To determine the categories of the ICF-Checklist (an abbreviated form of the ICF augmented by categories in the ICF Core-sets of rheumatoid arthritis and ankylosing spondylitis), affected in at least 30% of people with PsA and to compare the number of affected categories with scores on self-report measures of disability and health related quality of life.

Method: Data was collected from 94 patients with PsA attending rheumatology clinics in Wellington, Maroochydore, Melbourne, Barnsley, Toronto and Seattle using the extended ICF-Checklist interview. For ICF categories affected by PsA in at least 30% of patients, the percentage of patients affected were determined under the headings of Body Structures, Body Functions, Activities & Participation and Environmental Factors. A count of affected categories in the Activities & Participation section was compared to the SF-36 scales, HAQ, and PsAQOL using Spearman correlation.

Results: Thirty-eight percent were male, mean (SD) age was 51 (11) years and the mean (SD) disease duration was 10 (8) years. There were 25 categories in the Body Functions section, 6 categories in the Body Structures section and 51 categories in the Activities & Participation section that were affected by PsA in at least 30% of participants. There were 13 facilitating Environmental Factors and 1 Environmental Factor (climate) that was a barrier in at least 30% of participants. The number of affected Activities & Participation categories correlated highly ($r>0.6$) with SF-Physical Function, SF-Role Physical, SF-Social Functioning, HAQ-DI, and PsAQOL.

Conclusion: PsA is associated with a wide range of impairments, limitations and restrictions across the ICF categories. People with PsA find Environmental Factors more often to be helpful than a barrier to good health. Standardised self-report measures of functioning correlate highly with the number of affected Activities & Participation categories, suggesting that these instruments measure a similar concept to the ICF concept of functioning. The large number of affected categories in the Activities & Participation domain (51 of 97 categories that were assessed, 53%) highlight the importance of this concept in PsA and compares with 16 of 48 (33%) categories listed as affected in a methodologically similar study of patients with rheumatoid arthritis and 35 of 78 (45%) in ankylosing spondylitis.

Increased Prevalence of Obstructive Sleep Apnea in Patients with Psoriatic Arthritis and Ankylosing Spondylitis.
Jessica Walsh[1], Daniel O. Clegg[2] and Kristina Callis Duffin[3], [1]Salt Lake City Veterans Affairs, Salt Lake City, UT, [2]Salt Lake City Veteran Affairs, Salt Lake City, UT, [3]University of Utah, Salt Lake City, UT

Purpose: To determine the prevalence of Obstructive Sleep Apnea (OSA) in psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients in the Salt Lake City Veterans Affairs rheumatology clinics.

Methods: Polysomnography (PSG) data was collected from consecutive AS (n=13) and PsA (n=17) Salt Lake City veterans enrolled in the Program to Understand the Longterm Outcomes in Spondyloarthritis registry between July 2008 and April 2009. Home four channel PSG was used in 23 of 30 patients. Seven patients received conventional sleep lab studies. The apnea hypopnea index (AHI) at 4% was used to

measure the severity of OSA. Fisher's exact test and 2 tailed t-tests were used to compare variables. Patients were excluded if they smoked in the week prior to PSG or if they refused PSG.

Results: OSA was diagnosed in 23 of 30 (77%) patients, and 14 (47%) patients had moderate to severe OSA. The prevalence of OSA in patients taking TNF-inhibitors was significantly lower compared to those not taking TNF-inhibitors. There was a trend toward higher disease activity measures in the OSA group compared to the no OSA group. There were no statistically significant differences in patient characteristics or disease features between the OSA and no OSA groups. Demographics and AHI were similar in the PsA and AS groups.

Conclusion: The prevalence of OSA in these patients was substantially higher than both the 1-9% prevalence reported in the general population and the 12% and 23% prevalence reported in two small AS studies[1,2]. The age, BMI, and male predominance were higher in this study than in the general population and the aforementioned AS studies. However, these differences were not statistically significant between the OSA and no OSA groups. The lower prevalence of OSA in patients taking TNF-inhibitors is consistent with data demonstrating elevated serum levels of TNF-α and IL-6 in OSA patients and with a pilot study showing improvement in AHI after treatment with etanercept[3]. OSA is under-recognized in veterans with PsA and AS, and alterations of inflammatory cytokines with biologic therapy may positively impact OSA.

Value of PET/CT in Clinical Practice in Patients with Possible Spondyloarthropathy. Hiroyuki Yamashita, Kazuo Kubota, Yuko Takahashi, Junwa Kunimatsu, Arisa Shimizu, Toshiki Eri, Kenji Itoh and Akio Mimori, International Medical Center of Japan, Tokyo, Japan

Purpose: Seronegative spondyloarthropathy (SNSA) is a disease group characterized by enthesopathy, sacroiliitis, synovitis, and spinal inflammation. Its diagnosis based on clinical and plain x-ray findings is not always easy, especially at early stages or in cases of undifferentiated spondylitis. We aimed to evaluate the utility of 18-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) for diagnosing SNSA, which to our knowledge has been little described in the literature of rheumatology.

Method: Nine patients suspected of having SNSA were hospitalized at our institute between 2006 and 2008 for diagnosis or to start initial therapy for the diseases. The mean age of the patients was 48.9+/-20.3 (range 19-73) years old. All 9 patients were examined by PET/CT, magnetic resonance imaging (MRI), and bone x-rays. We evaluated whether or not each patient met the European Spondyloarthropathy Study Group criteria of SNSA (ESSG), Amor's criteria of SNSA (Amor), or the modified New York criteria of ankylosing spondylitis (NY/AS). The evaluation was based on either clinical and plain x-ray findings or on those findings combined with PET/CT findings. Some of the patients received additional imaging tests, including x-ray CT and/or bone scintigraphy.

Result: PET/CT revealed positive results (the number of patients) in all 9 patients including enthesopathy (7), spondylitis (6), and/or sacroilitis (3). These lesions were partially detected by MRI in 7 patients but totally negative in 2 patients, and were never detected by bone x-ray. The ratios of positive results were 1/3 in bone scintigram and 0/1 in x-ray CT. More patients met the diagnostic criteria of SNSA when the positive results of PET/CT were considered, as shown in Table, and PET/CT was more sensitive than MRI to detect lesions.

Conclusion: PET/CT is quite useful for diagnosing seronegative spondyloarthropathy (SNSA) by virtue of its high sensitivity in detecting inflammation at SNSA disease-specific sites.

Table: Diagnosis according to the criteria of SNSA in reference to PET/CT

case	1	2	3	4	5	6	7	8	9
Dx	USpA	USpA	USpA	USpA	ReA	ReA	ReA	AS	AS

Analysis of Factors Associated with Obesity in Psoriatic Arthritis. Allen P. Anandarajah[1] and Christopher T. Ritchlin[2], [1]Univ of Rochester Med Ctr, Rochester, NY, [2]University of Rochester, Rochester, NY

Purpose: To examine the relationship between environmental factors and obesity in psoriatic arthritis (PsA) and rheumatoid arthritis (RA) and to determine factors associated with the outcome variable body mass index (BMI).

Method: Patients were selected from the Consortium Of Rheumatology Researchers Of North America (CORRONA) database and matched for age, sex and disease duration. Univariate analysis was performed to determine if the matched PsA and RA cohorts differ in their

association with several variables. These same covariates were examined in matched PsA and RA patients stratified by the categorical outcome variable BMI (<30 or >30) and logistic regression was then performed in the two cohorts using the same covariates.

Results: Frequency matching (age, sex and disease duration) yielded 2389 RA and PsA pairs. Logistic regression revealed that the number of tender joints, non-smoking status, absence of exercise, depression, age, shorter disease duration and female gender were associated with an elevated BMI in PsA whereas only lack of exercise, non-smoking status and shorter disease duration were associated with obesity in the RA cohort. Stepwise logistic modeling revealed that after controlling for exercise, older age, shorter disease duration, depression and the presence of PsA were associated with an elevated BMI. Increased tender joint counts and female gender also increased the likelihood of obesity in the PsA but not the RA cohort.

Conclusion: These findings support a multiplicative model of obesity in PsA that results from interplay between the environment and factors related to the disease process that remain to be identified.

Adalimumab in Crohn's-Related Spondylitis Patients Resistant or Intolerant to Infliximab. Marco Antivalle, Luca Bertani, Michele Battellino, Alberto Batticciotto, Alessandra Mutti, Fabiola Atzeni and Piercarlo Sarzi-Puttini, L. Sacco University Hospital, Milano, Italy

Purpose: : Limited evidence shows that switching anti-TNF therapy in ankylosing spondylitis may be effective. However, there are no data on the switch from infliximab (IFX) to adalimumab (ADA). In Crohn's patients, ADA therapy in patients resistant or intolerant to IFX has been studied by several authors. Aim of the study was to assess the clinical response to the treatment with ADA in Crohn's-related spondylarthritis in patient resistant or intolerant to IFX.

Methods: ADA was administered 40 mg sc eow in patients diagnosed with Crohn's disease and spondylarthritis, who had stopped the treatment with IFX due to intolerance or non-responsiveness, starting at least after 8 weeks from the last injection of IFX. Concurrent therapies were continued during the study, and dose adjustments allowed. Patients were followed-up to one year, and clinic visits were performed at baseline, and after 4, 12, 24, and 52 weeks of treatment with ADA. At each visit spondylitis activity and function were assessed by the BASDAI, and the BASFI scores. The response to treatment was evaluated by the ASAS20 score. Crohn's disease activity was assessed by the CDAI score, and quality of life by the SF-36 questionnaire. The variation of clinical measures was evaluated by Wilcoxon test, and differences in proportions by chi-square test.

Results: 18 patients entered the study (12 F 6 M, mean age 43.55 ± 13.1 yrs). Mean duration of IFX treatment was 92.09 (range 2 - 256) weeks. Reason for IFX discontinuation were inefficacy (N=12) or intolerance (N=6). Crohn's disease activity was low in all patients (CDAI < 150). 13 patient had active spondylitis, (BASDAI score > 4). 15 patients completed the week 24 visit, and 12 the week 52 visit. ADA was discontinued in 3 patients, due to Crohn's related complications or articular flare-up (N=1). The variation of BASDAI and BASFI clinical scores are reported in Figures 1 and 2. During the study, both the BASDAI and the BASFI improved as compared to study entry levels, significant differences vs baseline values being recorded only up to the 6^{th} month for BASDAI, and up to the 3^{rd} month for BASFI. BASDAI reduction > 50% and ASAS20 responses were recorded in 3/18, 7/18, 3/15, and 2/15 patients, and in 3/18, 4/18, 3/18, and 2/18 patients at month 1, 3, 6, and 12 respectively. Only patients with BASDAI > 4 at entry showed ASAS20 responses. However, the proportion of responders was not statistically significant by chi-square test. CDAI and SF-36 scores changed little during the study. Overall, the effect of treatment on all considered variables, reached a maximum at the 3^{rd} month, but was not maintained at subsequent assessments, being minimal at the 12^{th} month.

Fig. 1. Mean BASDAI variation during treatment with Adalimumab

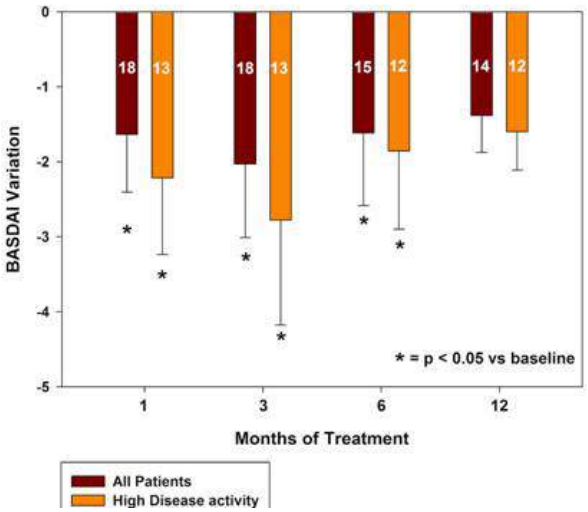

Fig. 2. Mean BASFI variation during treatment with Adalimumab

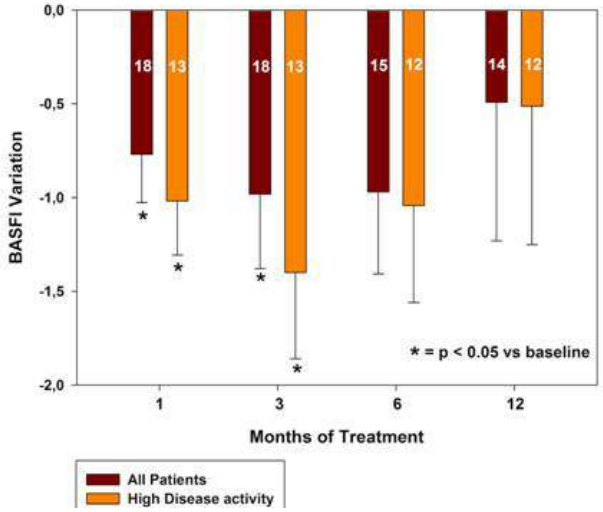

Conclusion: Our study is, to our knowledge, the first addressing the effectiveness of adalimumab in Crohn's-related spondylarthritis after failure of infliximab. Our results suggest that treatment with ADA may be a suitable option in these patients. However, the magnitude and duration of therapeutic effect should be further investigated.

European Ankylosing Spondylitis Infliximab Cohort (EASIC): Long-Term (5 years) Efficacy of Infliximab On Disease Activity and Function - A Real Life Experience After the End of ASSERT. Frank Heldmann[1], Jan Brandt[2], Jürgen Braun[3] and EASIC study group, [1]Centre of Rheumatology, Herne, Germany, [2]Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany

Purpose: The knowledge about the clinical efficacy of long-term anti-TNF therapy in patients with ankylosing spondylitis (AS) is rather limited. This study has been performed to demonstrate that treatment with infliximab in patients with AS is efficacious after more than 5 years of therapy.

Method: AS patients from 6 European countries who had taken part in the 2 year RCT ASSERT were invited to take part in the open label investigator driven study EASIC where they were followed every 6-8 weeks. For pragmatic reasons patients could only be included several months after the end of ASSERT. In the meantime they were treated by the local standard of care. There were mainly two groups of patients: patients allocated to group 2 had received infliximab between ASSERT and EASIC, patients allocated to group 1 had not, these were divided into two subgroups: to group 1a in case of relapse (BASDAI > 4 and physician global VAS > 4) and to group 1b in case of remission. All patients of group 1a and group 2 were continuously treated with infliximab during EASIC (96 weeks) in a mean dosage of about 5 mg/kg and intervals of 6-8 weeks, this decision was left to the discretion of the investigator.

Results: A total of 103 of 149 (69.1%) ASSERT patients were included in EASIC 1.3 ± 0.9 years after ASSERT (9 in group 1a, 5 in group 1b, 89 in group 2). Data from 97 patients (14 in group 1, 83 in group 2) could be analyzed. The patients were 82.5% men and 17.5% women and had a mean age of 43.5 years (39 in group 1, 44 in group 2). There was no major difference to the ASSERT population. 81 patients completed the 96 weeks of the trial, 5 in group 1 (33.3%) and 76 in group 2 (86.4%). There were 6 drop-outs due to adverse events, 4 due to lack of efficacy, 3 due to a planned pregnancy, 7 due to other and 2 due to unknown reasons. The table summarizes the responses for the completers of group 2. The values of BASDAI, BASFI, BASMI, Patient VAS, CRP, Swollen joint count and enthesitis index were at week 96 significantly improved compared to the ASSERT baseline data. At the end of ASSERT 78.4% of patients had no arthritis and 84.9% had no enthesitis.

	Baseline ASSERT	End of ASSERT	Week 0	Week 48	Week 96
BASDAI 50 (%)	NA	68.4	59.5	60.5	67.1
ASAS 20 (%)	NA	82.9	78.9	84.2	82.9
ASAS 40 (%)	NA	67.1	57.7	67.1	61.8
ASAS partial remission (%)	NA	30.3	23.9	27.6	27.6
CRP (mg/dl)	2.9	0.6	0.7	0.6	0.5
BASDAI	6.4	2.4	2.9	2.7	2.5
BASFI	5.9	2.9	3.2	3.1	3.1
BASMI	4.0	2.7	2.1	2.0	2.2
Patient global disease VAS	7.0	2.7	3.3	2.7	2.8
Swollen joint count	1.6	0.6	0.6	0.4	0.6
Enthesitis Index	9.0	3.7	0.6	0.3	0.4

Conclusion: The majority of patients was continuously treated with infliximab between ASSERT and EASIC and during EASIC in a total of 5 years therapy. Attrition rates for any reason were lower than 10% per year in these patients. In the completer analysis, this was associated with a sustained high response rate, low disease activity, a good functional state, a very low prevalence of arthritis and enthesitis and a low CRP. Anti-TNF therapy with infliximab was clinically efficacious on a long-term basis.

Diagnostic Utility of MRI in Early Spondyloarthritis: Do Rheumatologists Omit Diagnostic Information Provided by the T1-Weighted Sequence? Mikkel Ostergaard[1], Ulrich Weber[2], Susanne J. Pedersen[1], Juerg Hodler[2], Robert GW Lambert[3] and Walter P. Maksymowych[3], [1]Copenhagen University Hospitals, Copenhagen, Denmark, [2]University Clinic Balgrist, Zurich, Switzerland, [3]University of Alberta, Edmonton, AB

Purpose: There is increasing acceptance that MRI has diagnostic utility in early spondyloarthritis (SpA). Prior studies and a recent ASAS consensus-driven proposal have focused only on the presence of bone marrow edema on fat-suppressed (FS) sequences as the principle diagnostic feature and ignore the potential contribution of diagnostic abnormalities seen on T1-weighted (T1W) sequences. We aimed to compare the diagnostic utility of FS and T1W MRI in early SpA using a standardized approach to the evaluation of the sacroiliac joints (SIJ).

Method: Six experienced readers (4 rheumatologists, 2 radiologists) from 3 international centres, blinded to patient and diagnosis, independently assessed MRI scans (T1W and STIR) from the following subjects: 77 patients with AS and symptom duration < 10 years; 26 patients with mechanical low back pain, age <45 years and symptom duration < 10 years; 25 patients with pre-radiographic inflammatory back pain (IBP), mean symptom duration 26 months; and 59 healthy controls, age < 45 years. MRI scans of the SIJ were read systematically as described in a standardized online training module. We recorded bone edema, fat replacement, joint erosions, and ankylosis according to standardized definitions using an online data entry system. In addition to deciding on the presence/absence of SpA readers were asked to

record the following: 1. Whether their diagnostic conclusion was primarily based on abnormalities observed on the STIR, T1W, or both. 2. Which type of lesion was the primary basis for the diagnostic conclusion.

Results: Diagnostic utility of MRI in early AS was better for concordant data from radiologist (sensitivity 85.7%, specificity 100%) as compared to rheumatologist (sensitivity 79.6%, specificity 94.9%) reader pairs. The better performance of radiologists (sensitivity 48%/specificity 100%) as compared to rheumatologists (sensitivity 48%/specificity 94.9%) was also noted for pre-radiographic SpA. Although all readers considered both sequences as more important to the diagnosis of early AS than either T1W or STIR sequence alone, rheumatologists based their diagnostic conclusion on the STIR significantly more frequently than radiologists for both early AS and pre-radiographic SpA ($p<0.0001$ for both) and this difference was associated with a greater recognition of the importance of erosions on TIW by the radiologists.

	Sequence the diagnosis is based on (% of patients)			Primary feature the diagnosis is based on (% of patients)			
	STIR	**T1**	**T1+STIR**	**Bone edema**	**Fat**	**Erosion**	**Ankylosis**
AS/All readers	19.4	22.8	60.4	51.9	6.2	24.2	17.3
AS/Rheumatologists	27.7	18.9	57.4	68.1	4.1	10.6	17.2
AS/Radiologists	2.9	30.7	66.4	27.8	9.5	44.6	17.6
IBP/All readers	60.0	5,2	34.7	88.2	3.8	8.1	0
IBP/Rheumatologists	72.7	4.0	23.3	91.2	3.7	5.1	0
IBP/Radiologists	34.7	7.7	57.7	83.7	3.9	12.5	0

Conclusion: Rheumatologists rely primarily on the diagnostic information by the STIR sequence and de-emphasize the contribution of abnormalities on the T1W, such as erosions, which radiologists consider important to the diagnosis of SpA by MRI.

Ultrasound-Guided Sacroiliac Joint Injection in Patients with Sacroiliitis: Precise i.a. Injection Does Not Predict Outcome. Wolfgang Hartung[1], Jürgen Schölmerich[2], Rainer H. Straub[2], Thomas Herold[3], Christian J. Ross[3], Stefan Feuerbach[3] and Martin Fleck[2], [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, Bad Abbach, Germany, [2]University Hospital Regensburg, Regensburg, Germany, [3]University Medical Center Regensburg, Regensburg, Germany

Purpose: Intraarticular injections of sacroiliac joints (SIJ) with corticosteroids are often performed in patients suffering from low back pain due to active sacroiliitis. However, SIJ injections are technically demanding, and therefore the clinical outcome of ultrasound-guided corticosteroid SIJ injections was analyzed in relation to the accuracy of the injection.

Method: Ultrasound-guided injections were performed with 40 mg triamcinolone and 0,78 mg gadolinium in 20 SIJ of 14 consecutive patients suffering from active sacroiliitis. Immediately following SIJ injection, MRI scanning was initiated to verify the correct placement of the drug. Clinical outcome of the intervention was determined using a numerical pain rating scale (NRS) at day 1 and 28.

Results: Despite ultrasound guidance, only 8 injections (40%) were exactly positioned into the SIJ-space, whereas the other 12 injections (60%) missed the SIJ. However, there were no significant differences observed in the clinical outcome between the intraarticular-injected group and the periarticular-injected group. There was a similar pain relief observed in both groups 24h and 28 days following the intervention (intraarticular injection group: mean NRS-baseline: 6,8 [range 4 - 9], NRS-24h: 4,3 [range 1 - 7], NRS-day 28: 3,5 [range 1 - 5]; periarticular injection group: mean NRS-baseline: 7,0 [range 5 - 10], NRS-24h: 4,1 [range 1 - 10], NRS-day 28: 4,5 [range 1 - 8]).

Conclusion: These results demonstrate that intraarticular SIJ-injections remain technically challenging despite ultrasound guidance. However, periarticular deposition of triamcinolone appears sufficient for pain and symptom control in patients suffering from inflammatory low back pain due to active sacroiliitis.

Etanercept Benefits Skin, Joint, and Entheseal Symptoms in Patients with Psoriasis and Psoriatic Arthritis: The PRESTA Trial.

Bruce W. Kirkham[1], W. Sterry[2], A. Ormerod[3], Stefan Schewe[4], Debbie H. Robertson[5], Arthur Zbrozek[6], Charles T. Molta[7] and Bruce Freundlich[7], [1]4th Fl Thomas Guy House, London, England, [2]1Klinik für Dermatologie, Venerologie und Allergologie,, Berlin, Germany, [3]University of Aberdeen, Aberdeen, United Kingdom, [4]Ludwig-Maximilian Universitaet, Munchen, Germany, [5]Wyeth Pharmaceuticals, Collegeville, PA, [6]Wyeth Pharmaceuticals, Philadelphia, PA, [7]Wyeth Research, Collegeville, PA

Purpose: Etanercept (ETN) has been approved for the treatment of both psoriatic arthritis (PsA) and moderate-to-severe plaque psoriasis (PsO) based on its efficacy in treating both joint and skin symptoms. ETN can be used at 50mg twice weekly (BIW) in PsO *v* 50mg once weekly (QW) in PsA. Efficacy of 50 mg BIW for joint symptoms in PsA has not been previously investigated. The objective of this study was to determine the efficacy of 2 ETN regimens on skin, joint, and entheseal manifestations in subjects with both PsO and PsA at 12 and 24 weeks.

Methods: Subjects (n= 752) received either ETN 50mg BIW (n=379) or 50mg QW (n=373) for 12 weeks double-blind followed by open-label 50mg QW for 12 weeks. Eligibility criteria included stable, moderate-to-severe plaque PsO assessed by dermatologist and active PsA (≥2 swollen/painful joints) assessed by rheumatologist. Primary endpoint was % subjects achieving Physician Global Assessment (PGA) of psoriasis of clear/almost clear at week 12. Improvement in skin, joint and enthesitis/dactylitis manifestations of PsA were also evaluated. Subject assessed physical function and symptoms.

Results: See Table for efficacy results. In addition, subjects with enthesitis at baseline were found to have more extensive skin and joint involvement with more swollen/painful joints and higher mean PASI at baseline. The regimens had similar safety profiles with no new safety signals.

Conclusion: In this population of subjects with PsO and PsA, etanercept 50 mg BIW/QW provided faster relief of skin symptoms than 50 mg QW/QW at week 12, while either regimen appeared appropriate for relief of joint and soft tissue rheumatic symptoms at weeks 12 & 24. Both regimens were safe and effective at 24 weeks.

Efficacy of Etanercept On Rheumatic Signs and Pulmonary Function Tests in Advanced Ankylosing Spondylitis. Results of a Randomized Double Blind Placebo-Controlled Study (SPINE). Maxime Dougados[1], J. Braun[2], S. Szanto[3], B. Combe[4], M. Elbaz[5], P. Geher[6], G. Thabut[7], V. Leblanc[8] and I. Logeart[8], [1]Hôpital Cochin, Paris, France, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]University of Debrecen medical and Health Sciences Center, Debrecen, Hungary, [4]Immuno-Rheumatology, Montpellier, France, [5]Medical center, Avignon, France, [6]Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, Hungary, [7]Paris Diderot University, Bichat Hospital,Paris, [8]Wyeth Pharmaceuticals France

Purpose: TNF blockers have demonstrated their benefit in patients with active Ankylosing Spondylitis (AS) (1). Advanced AS patients are disabled because of reduced spinal mobility and respiratory functional impairment.

This study evaluated the effect of etanercept (ETN) not only on the rheumatic symptoms (pain, function) but also on signs (spinal mobility) and respiratory function tests.

Method: *Patients*: Definite AS patients (modified New York criteria) with active (BASDAI ≥40), refractory (at least 2 NSAIDs), severe (at least 2, 3 or 3 inter-vertebral radiological consecutive bridges at the lumbar, thoracic or cervical level respectively), anti-TNF naive. *Study design*: Multi-center, randomized, double blind, placebo-controlled trial of 12-week duration. *Study drugs*: ETN 50 mg OW and identical placebo (PBO). *Outcome measures*: BASDAI, BASFI, BASMI, CRP and respiratory function tests.

Results: Of the 95 screened patients, 82 (males: 95%, age: 47.3±10.4 y, disease duration: 16±10.4 y, B27 positive: 81.7%) were randomized to receive either ETN (n=39) or PBO (n=43). At baseline, patients had an active (BASDAI: 61±13.4, CRP: 20.7±25.5 mg/l) and severe (BASMI: 5.7±1.3, mSASSS: 36.5±20.5) disease. During the 12 weeks of the trial, 5 patients discontinued the treatment (4 in the PBO arm [due to lack of efficacy: 2, lost to follow-up:1, withdrawal of consent: 1) and 1 in the ETN arm [due to serious adverse event]). The adjusted mean BASDAI (primary outcome: normalized net incremental Area Under the Curve between baseline and W12) was significantly greater in the ETN vs PBO group: -19.8±16.5 vs -11.0±16.4, (p=0.019). Moreover, all the analyses evaluating the changes observed at 12 weeks were in favor of ETN (BASDAI -26.4±19.7 *vs* -14.4±19.7, p=0.008; Total back pain -29.2±24.0 vs -14.9±24.0, p=0.010; BASFI -21.7±17.6 *vs* -10.1±17.6, p=0.004; BASMI -0.6±0.6 *vs* -0.2±0.6, p=0.011; CRP -15.7±14.2 *vs* -1.3±14.2, p<0.001); pulmonary vital capacity +0.14±0.26 *vs* -0.05±0.26, p=0.003.

Conclusion: This prospective study conducted in advanced AS patients confirms the short term symptomatic efficacy of ETN previously reported in less advanced disease. Such efficacy has been observed on the main symptoms of the patients (*e.g.* pain) and on the markers of inflammation (*e.g.* CRP); this study also shows a significant effect on signs related to the severity of the disease such as spinal mobility and pulmonary capacities.

Folate Pathway Enzyme Gene Polymorphisms and the Efficacy and Toxicity of Methotrexate in Psoriatic Arthritis. Vinod Chandran[1], Fotios Siannis[2], Proton Rahman[3], Catherine T. Schentag[1], Vernon Farewell[4] and Dafna D. Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Athens, Greece, [3]St Clare's Mercy Hospital, St Johns, NF, [4]Medical Research Council (MRC) Biostatistics Unit, Cambridge, United Kingdom

Purpose: Our aim was to determine whether polymorphisms of genes coding enzymes of folate pathway are associated with effectiveness, toxicity and drug survival of methotrexate (MTX) in psoriatic arthritis (PsA).

Methods: Data was obtained from a longitudinal cohort of PsA patients. Patients are evaluated every 6 months according to a standard protocol. Data on drugs taken with start and stop dates, dose, side effects and reasons for discontinuation are systematically recorded. Response to MTX treatment was assessed at 6 months and was categorized as excellent if there was ≥50% decrease in joint counts from baseline at dose of ≤15 mg/wk, good if there was ≥50% decrease in joint counts from baseline at dose of >15 mg/wk and none if there was <50% decrease, no change, or an increase in joint counts. Patients treated with MTX after clinic entry and who had ≥3 swollen joints prior to initiating MTX therapy were selected for effectiveness evaluation. Data from all patients treated in the clinic with MTX was used in evaluation of toxicity and drug survival. The following SNPs were measured using the Sequenom platform from DNA isolated from peripheral blood: MTHFR 677C>T (rs1801133), MTHFR 1298A>C (rs1801131), DHFR –473T>C (rs1650697), DHFR 35289A>G (rs1232027), and RFC 80G>A (rs1051266). Fisher's exact test and logistic regression was used to determine association between heterozygote and homozygote of the minor allele of the SNPs tested with effectiveness, and toxicity of MTX. Cox proportional hazards analysis was used to determine association between these SNPs and drug survival.

Results: 281 patients (165 males, mean age 44 years, mean disease duration 10 years) treated with MTX were identified from the database. 119 patients (67 males) were included in the effectiveness analysis. After 6 months of therapy with MTX 52.4% patients had 50% reduction in their actively inflamed joint count. 31% had an excellent response, 16% had a good response and 53% had no response to MTX. The minor 'A' allele of DHFR gene at +35289 was the only SNP associated with an increased odds of 50% reduction in actively inflamed joint count (OR = 3.03, p=0.02) as well as an excellent/good response to MTX after 6 months of therapy (OR= 2.7, p=0.03). 156/281 (55.5%) experienced side effects to MTX. 45 (16%) had liver function test abnormalities and in 103 (36.7%) side effects led to drug discontinuation. Patients homozygous for the minor allele of MTHFR 677C/T (677TT) had more liver toxicity (Fisher p=0.04). None of the other SNPs tested were associated with response to MTX, toxicity or drug survival.

Conclusion: Polymorphisms of the DHFR gene are associated with MTX efficacy and that of the MTHFR gene are associated with MTX induced liver toxicity in PsA.

The Fatty Romanus Lesion- A Non-Inflammatory Spinal MRI Lesion Specific for Axial-Spa. Alexander.N. Bennett[1], Amer Rehman[2], EM Hensor[3], Helena Marzo-Ortega[3], P. Emery[3] and Dennis McGonagle[3], [1]Defence Medical Rehabilitation Centre, London, United Kingdom, [2]American Hospital, Dubai, United Arab Emirates, [3]University of Leeds, Leeds, United Kingdom

Purpose: Fatty changes at vertebral corners have been reported on MRI in axial-SpA but the distribution or specificity of these lesions to axial-SpA has not been determined. This study assessed the diagnostic utility of Fatty Romanus Lesions (FRLs) for axial-SpA in a chronic back pain population.

Method: Axial-skeleton TI SE and fat-suppressed MRI were performed on 174-patients with back pain and 11-controls. MRI lesions including FRLs were scored blind. An imaging diagnosis was given on MRI findings alone and compared to the gold-standard treating physician diagnosis.

Results: Twenty-nine patients had FRLs. Thirty-one percent (20/64) of SpA, 13% (6/45) of degenerative arthritis, 4% (2/45) of spinal malignancy, 5% (1/20) of "other" diagnoses and 0/11 normals. . The majority of FRLs in SpA 59%(135/226) were present in the thoracic-spine. The diagnostic utility of FRLs for SpA(LR=4.7) was significantly ($p<0.05$) greater than for other diagnoses and increased further (LR=12.6,$p<0.05$) when >5 FRLs were present. Of note 5/20 (25%), of SpA patients with FRLs had no diagnostic bone-oedema lesions on fat-suppressed MRI suggesting that FRLs may be useful diagnostically in axial-SpA.

Conclusion: This study defines the FRL as a diagnostic imaging feature of axial-SpA which may be useful where inflammatory changes are absent on fat-suppression MRI and where radiography is normal.

TNF Inhibitors in Ankylosing Spondylitis (AS) in the NOR-DMARD Register: Is Switching Useful? Elisabeth Lie[1], Désirée M.F.M. van der Heijde[2], T. Uhlig[1], M.S. Heiberg[1], E. Rødevand[3], C. Kaufmann[4], K. Mikkelsen[5], W. Koldingsnes[6] and T.K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]St Olavs Hospital, Trondheim, Norway, [4]Buskerud Central Hospital, Drammen, Norway, [5]Lillehammer Hospital for Rheumatic Diseases, Norway, [6]University Hospital of Northern Norway, Tromsø, Norway

Purpose: To assess the efficacy of switching to a second TNFi in patients failing the first TNF inhibitor.

Method: Data were extracted from a multi-center treatment registry where patients (pts) with inflammatory arthropathies starting treatment with DMARDs and biologicals are assessed at baseline and followed longitudinally. BASDAI and BASFI were included from 2006. Pts with AS who started on their 1st or 2nd TNFi were eligible for the current analyses. Mann-Whitney U and Chi-square tests were used to compare the effectiveness between patient groups and Wilcoxon signed rank and McNemar's tests were applied for the comparison within the same patient group.

Results: We identified a total of 514 pts with AS who started their first TNFi (etan(ercept) n=264, infl(iximab) n=180, ada(limumab) n=70). 71% were male, 92% HLA-B27 positive, median (IQR) age was 42 (35-50) yrs and disease duration 11 (4-20) yrs. A subgroup of 79 pts (etan n=32, infl n=43, ada n=4; switchers 1st TNFi) switched to a second TNFi (etan n=31, infl n=20, ada n=28; switchers 2nd TNFi). Median (IQR) time between stop of 1st and start of 2nd TNFi was 72 (0-308) days. Baseline variables and 3-month responses in non-switchers and the 1st and 2nd TNFi in switchers, respectively, are shown in the table. BASDAI/BASFI data were available for 58, 38 and 73% of pts in the respective groups. Switchers were on 1st TNFi for 252 (98-592) days, and for these pts the last recorded BASDAI/ASDAS/Patient global before switch were 6.1(3.1-7.5)/3.5(1.7-4.2)/59(27-75). Reasons for discontinuation of the 1st TNFi were insufficient response (IR) in 31, adverse events (AEs) in 45 and not reported in 3 pts. Baseline disease activity level and 3-month responses in IR-switchers and AE-switchers did not differ. As of Feb 2009, 40 of the 79 switchers were still on their 2nd TNFi after 533 (244-908) days, 32 pts had discontinued therapy (reason: 17 IR, 13 AEs, 2 other) while 7 pts were lost to follow-up.

Conclusion: Responses to the 2nd TNFi were generally similar to responses of the 1st TNFi within the same patient group and also similar to responses in pts who did not switch. This study supports that switching to a 2nd TNFi can be effective in AS pts and can be as useful as in RA pts.

Psoriatic Arthritis in a Diverse Ethnic Cohort. Gail S. Kerr[1], John S. Richards[2], Hashem Vahabzadeh-Monshie[3], Chesahna Kindred[4], Iraj Sabahi[5], Annyce Treherne[3], Michael D. Alpert[3], George Cohen[6] and Richard Amdur[3], [1]VAMC, Georgetown and Howard University Hospitals, Washington, DC, [2]VAMC, Geogetown University Hospital, Washington, DC, [3]VAMC, Washington, DC, [4]Howard University Hospital, Washington, DC, [5]Washington Hospital Center, Washington, DC, [6]VAMC, Howard University Hospital, Washington, DC

Purpose: Present literature is sparse concerning psoriasis (PSO) and psoriatic arthritis (PsA) in minority populations, often retrospective and lacking current measures of disease burden and activity. Our objective was to determine the prevalence, disease severity and activity and quality of life of PsA in a diverse ethnic cohort of patients with PSO.

Method: Patients with confirmed PSO or PsA seen in dermatology and rheumatology clinics at 2 institutions during a12 month period were enrolled. Patient demographics, disease duration, smoking (never, former, current), anti-TNF therapy, and body mass index (BMI) were recorded. Patients were examined to ascertain type of psoriasis (plaque, guttate, pustular), psoriasis area and severity index (PASI), arthritis pattern (appendicular, axial) and tender, swollen joint counts. ESR, CRP, uric acid were obtained, and DAS28 calculated. Questionnaires were administered for functional status (MD-HAQ) , quality of life (SF-36, PSORIQoL, PsAQoL) and fatigue (Multidimensional

Assessment of Fatigue-MAF). Employment status (yes, no), education level (high school, college) and insurance coverage information (yes, no) were obtained.

Results: Eighty-four PSO patients (39 African Americans (AA), 45 Caucasians), predominantly males (91%), of mean age 59.9, years (11.7) were enrolled. PsA occurred in 27.9%, with mean disease duration of 21.6 (14.8) years. PsA followed the diagnosis of PSO by a mean of 6 years, but occurred earlier in AA (3.5 yrs vs 8.4 yrs). PsA was one third less prevalent in AA compared to Caucasians (13.9% vs 39.5%, p<.01). Appendicular arthritis and plaque psoriasis were the predominant patterns. AA and Caucasians differed significantly in PSO disease duration (20.6 ± 17.4 vs 32.4 ± 21.5, p<.05), insurance coverage (57.6 % vs 80.5%, p<.05), alcohol use (29.4% vs 69.3%, p<.01) and trended to lower mental component of SF-36 scores (38.7 ± 7.0 vs 41.7 ± 7.1, p=.06). Smoking, education level, employment status, BMI, uric acid levels, MAF and PSORIQoL were similar in both groups. In those with PsA, there was no ethnic difference in MD-HAQ, DAS28, or PsAQOL scores. Anti-TNF therapy was prescribed in 27.4% of the cohort, and despite less insurance coverage in AA, was not statistically different from Caucasians (20% vs 32.6%). PSO with and without PsA were similar in all variables.

Conclusion: In this study cohort, psoriatic arthritis occurred in approximately one third of patients with psoriasis. Psoriatic arthritis in African Americans was one third less prevalent than in Caucasians, but of equal disease burden. The diagnosis of psoriasis in African Americans appeared to have less psychological impact and the lack of medical coverage was not an impediment to receive biologic therapy. Enrollment continues to examine the validity of these findings.

Predicting Major Quality of Life Improvement Via PASI or HAQ in Psoriatic Arthritis Patients. Bruce W. Kirkham[1], Wenzhi Li[2], Charles T. Molta[2], Amitabh Singh[2] and Arthur Zbrozek[2], [1]Thomas Guy House and University of New South Wales-Sydney, London, England, [2]Wyeth Research, Collegeville, PA

Purpose: Patients with psoriatic arthritis (PsA) suffer significant morbidity from both skin and joint disease. Biologic therapy has benefited both areas. However, the relative effects of skin or physical function morbidity reduction on the enhancement of health status is not presently understood, reducing our understanding of the value of clinical improvement. The objective of this analysis was to compare the predictive power *post hoc* of skin sign and physical function in major quality of life improvement ie, to the general population level, in a population with active PsA.

Method: A 12-week randomized double-blind study followed by a 12-week open-label extension; subjects received etanercept 50 mg BIW or 50 mg QW during the double-blind period followed by 50 mg QW during the open-label period. Key eligibility criteria included: age >18 y; stable, moderate-to-severe plaque psoriasis with ≥2 swollen/painful joints, and no previous anti-TNF therapy. PASI for psoriasis signs, HAQ for physical function, and EQ-5D VAS were measured at baseline, and Weeks 12 and 24. Logistic regressions predicted a change in EQ-5D VAS to at least 82 (0-100 scale), a level consistent with the general population. Meaningful changes from baseline as predictors: HAQ= 0.375, 0.5; PASI= 50%, 75%.

Results: At baseline, subjects (n=752) had a mean age 47 y, were 63% male, and 89% white. Mean number of tender joints= 19.2, and swollen joints= 12.5. Mean durations of psoriasis and PsA= 19 and 7 years, respectively. Baseline scores were not significantly different between the 2 groups; pooled baseline (mean±s.d.) PASI= 19.43 ±10.28, HAQ= 0.91±0.69, and EQ-5D VAS= 55.55 ±20.73. Only PASI change from baseline at Week 12 differentiated treatment groups. Pooled reductions from baseline to W24 (LOCF) were: PASI= 75.9%, and HAQ= 52.0%. Proportion achieving EQ-5D VAS (≥82)= 44.4%. HAQ change from baseline of ≥0.375 was most consistent change predictor in improving the quality of life score to the general population level, with HAQ change ≥0.375 at Week 12 being the strongest single predictor. Higher baseline HAQ scores reduced the odds for major quality of life improvements at both Weeks 12 and 24.

Odds ratios* of EQ-5D VAS to ≥82

Week 12 (N= 723) Week 24 (N= 723)

	Estimate (95% C.I.)	Estimate (95% C.I.)
EQ-5D VAS baseline	1.04 (1.03 – 1.05)	1.03 (1.02 – 1.04)
HAQ baseline	0.39 (0.26 – 0.59)	0.47 (0.32 – 0.67)
HAQ change ≥0.375	2.68 (1.37 – 5.25)	2.25 (1.20 – 4.24)
HAQ change ≥0.50	2.09 (1.10 – 3.98)	
PASI change ≥50%	2.03 (1.16 – 3.55)	
PASI change ≥75%	1.88 (1.25 – 2.85)	2.40 (1.54 – 3.75)
Asian		0.22 (0.08 – 0.62)

*Factors reported were those significant ($p<0.05$).

Conclusion: Patients with less advanced PsA could have better odds of achieving an improvement in quality of life to the level consistent with that of the general population when treated to reduce both skin and joint morbidity.

Cross-Sectional Evaluation of Different Retreatment Schedules with Infliximab in Daily Practice Treatment of Patients with Ankylosing Spondylitis. M. Devinck[1], H. Mielants[2] and F. Van den Bosch[3], [1]University hospital, Gent, Belgium, [2]University Hospital, Gent, Belgium, [3]Univ Hosp, Ghent, Belgium

Purpose: Since 2004, TNF blocking agents became available in Belgium for patients with active, NSAID-refractory ankylosing spondylitis (AS). The reimbursement criteria for infliximab stipulate that after a conventional loading dose regimen, all patients should be retreated with a dose of 5 mg/kg and an interval of 8 weeks. Only in case of repeated (on 2 consecutive retreatment visits) and significant raise of the BASDAI (increase with at least 50% or 20 points on a 0-100 scale), the retreatment interval can be decreased to every 6 weeks. To our knowledge, Belgium is the only country where this stepwise reimbursement system is used; in most other countries the decision on the retreatment interval is at the discretion of the treating rheumatologist. The objective of this study is to evaluate the efficacy of infliximab in daily practice treatment of patients with AS. **Methods:** A cross-sectional evaluation of all AS patients currently treated at our department was performed from the 1st of March until the 30th of April 2009. Values for BASDAI and BASFI were collected for all patients at time of retreatment. Retreatment regimen (every 8 weeks (q8w), every 6 weeks (q6w), other), age of the patient, and duration of treatment with infliximab (weeks) was recorded.

Results: A total of 102 patients was evaluated : 85 patients are retreated with an interval of 8 weeks, whereas only 15 patients are retreated with a shorter interval of 6 weeks. Of interest is the fact that there are 2 patients that are retreated with a longer interval (10 or 12 weeks). Results are summarised in the table (median value and range are presented). Both with regard to the BASDAI and the BASFI, a higher median value was observed in the patients that are retreated every 6 weeks. Of the 15 patients, 7 had a BASDAI value greater than 40.

	Q6w	Q8w	Q10/12w
Nr of patients	15 (15%)	85 (83%)	2 (2%)
Age (years)	52 (30/71)	47 (22-75)	44 (41-47)
Male/female ratio	10/5	70/15	2/0

Duration of treatment	204 wks (17-491)	243 wks (13-500)	355 wks (287-422)
BASDAI (0-100)	36 (3-70)*	20 (0-75)	24 (10-37)
BASFI (0-100)	49.5 (0-96)**	20 (0-85)	33 (0-65)

*p=0.084, ** p=0.008 comparison between q6w en q8w, using T-test

Conclusion: Low BASDAI and BASFI scores are observed in AS patients chronically retreated with infliximab every 8 weeks. Pharmacoeconomically, these data support the stepwise reimbursement approach where patients are only treated with the more intensive q6w regimen in case of documented high disease activity. In the group retreated every 6 weeks, the median values for these assessments are higher, reaching statiscal significance for the BASFI. Several interpretations are possible. The higher BASFI might suggest more structural damage, pointing towards a subgroup possibly needing more frequent treatment. On the other hand, the higher BASDAI could suggest that even with a shorter retreatment interval, the disease is still not adequately controlled in a number of patients, and that other treatment options should be considered.

Higher Remission Rates in Psoriatic Arthritis: Cause and Effect. Tajvur P. Saber[1], Chin Teck Ng[1], Guillaume Renard[1], Bernadette M. Lynch[1], Alexia Grier[1], Patricia Minnock[2], Madeline O'Neill[2], Louise Moore[2], Marian Molloy[1], Barry Bresnihan[1], Oliver M. FitzGerald[1], Ursula Fearon[1] and Douglas J. Veale[1], [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Rheumatology Rehabilitation, Our Lady's Hospice, Dublin, Ireland

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis with a higher male prevalence.TNF targeted drugs have proven efficacy in randomised controlled trials. Previous studies highlight an association between Testosterone and HLA B 27.

Purpose: To assess remission in a PsA compared to an RA cohort matched for disease activity and to identify possible factors associated with remission.

Methods: A prospective analysis of a biologic database 2004-08 was performed. Patients attend prior to commencing biologic therapy and at 3, 6 and 12 months. Baseline characteristics collected included age, gender, disease duration, smoking status, rheumatoid factor, previous DMARDS, 28 joint count, patient global assessment VAS, CRP, DAS 28 using CRP and HAQ score. Values are expressed as median, analysis used Wilcoxin Rank Sum, Oneway Anova and Chi-Square tests.

Results: 152 PsA patients completed 1 year follow up, 47% were male. Measures of disease activity significantly improved in PsA patients from baseline to 12 months post treatment (see table) TJC ($p<0.01$), SJC ($p<0.01$), CRP ($p<0.01$), HAQ ($p<0.01$). DAS28 remission (<2.6), validated for PsA, was achieved in 58% of PsA patients from baseline 4.86 to 2.23 ($p <0.001$). Male PsA patients attained significantly lower DAS28 scores than females 1.88 vs 2.65 at 1 year ($p <0.05$). To compare remission rates in PsA vs RA, we analysed a subset of patients matched for disease activity at baseline (n=41, in each group). Remission rates defined by DAS28 were significantly greater in PsA patients ($p=0.01$), 59% PsA patients vs 44% RA patients at 12 months.

Conclusion: PsA patients with significant disease activity at presentation achieved high levels of remission at one year. Male gender is significantly associated with a favourable outcome, this may be further evidence of an important association between testosterone, HLA B27 and spondyloarthropathy which deserves further study. Remission was significantly higher in PsA than RA patients in a disease activity matched cohort.

The Sensitivity of National Criteria to Assess Eligibility for Biologic Therapy in Patients with Ankylosing Spondylitis. Sarah M. Keidel[1] and Antoni Chan[2], [1]Dept. of Rheumatology, Royal Berkshire Hospital NHS Foundation Trust, Reading RG1 5AN, United Kingdom, [2]Royal Berkshire Hospital, NHS Foundation Trust, Reading RG1 5AN, United Kingdom

Background: Ankylosing spondylitis (AS) is an inflammatory arthritis primarily affecting the vertebrae. Anti-TNF therapy has been shown in randomized controlled trials to reduce composite measures of disease activity and is assumed to prevent the accumulation of structural damage. In the United Kingdom, the National Institute of Clinical Excellence (NICE) has developed guidelines for the treatment of AS with anti-TNF agents (May 2008, TA 143).

Purpose: To determine the cohort of AS patients in our hospital who would qualify for anti-TNF therapy under the NICE guidance, and to determine if this guidance is sensitive in selecting patients who would benefit from anti-TNF therapy.

Method: Patient cohort identified (251 AS patients) in August 2008 via patient database and updated by a review of clinic letters. Available case notes (174 patients, 69%) were reviewed retrospectively. Patient demographics, radiographic data and assessment scores (Bath AS scores) were recorded.

Results: 174 patients with AS were studied. Mean age was 46.8 years (SD 13.7) and disease duration 12 years. 13 patients (7%) were already on anti-TNF agents (n= 3 patients on Infliximab, 5 on Etanercept and 5 on Adalimumab). 4 patients (2%) fulfilled all 3 NICE criteria and were therefore eligible for anti-TNF therapy. 3 patients (2%) had a contraindication to anti-TNF therapy (coexistent multiple sclerosis and chronic sepsis). 53 patients (30%) did not qualify for anti-TNF therapy due to outright failure of at least 1 NICE criterion. Of these patients, 18 (10%) failed to satisfy the New York (NY) criteria due to normal sacroiliac radiographs, despite evidence of sacroiliitis on MRI.

28 patients (16%) fulfilled 2 out of 3 NICE criteria (26 patients met NY criteria and ≥ 2 NSAIDs, 2 patients met NY criteria and BASDAI ≥4). 65 patients (37%) fulfilled 1 out of 3 NICE criteria (56 patients met NY criteria, 9 patients were treated with ≥2 NSAIDs). These 101 patients are undergoing further assessment in a specialist AS clinic to determine whether the remaining NICE criteria are satisfied.

Conclusion: In our study, 4 patients with ankylosing spondylitis were eligible for anti-TNF therapy in accordance with the NICE guidelines, in addition to 13 patients already on treatment. These NICE-compliant patients represent 23% of our AS population where complete data are available. 58% of our patients require further assessment including follow-up Bath AS indices to determine their status against the NICE guidance. It is expected that approximately 23% of these patients will also qualify for anti-TNF therapy.

A significant proportion of our patients (10%) were ineligible for anti-TNF treatment due to failure to fulfill NY criteria despite sacroiliitis on MRI. This included patients with early AS. New diagnostic criteria for AS should include MRI to increase the sensitivity of screening for patients who may qualify for anti-TNF therapy, as radiographic change may take years to develop[1,2].

Are Clinical and Radiologic Outcomes the Same for Patients with Moderate Vs. Severe Disease Activity at Baseline in Patients with Psoriatic Arthritis? - *Post-Hoc* Analysis of ADEPT. Philip Mease[1], Arthur Kavanaugh[2], Renee Perdok[3], Hartmut Kupper[4] and Frédéric Lavie[5], [1]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [2]University of California San Diego, La Jolla, CA, [3]Abbott Laboratories, Abbott Park, IL, [4]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [5]Abbott Laboratories, Rungis, France

Purpose: Patients (pts) in psoriatic arthritis (PsA) trials usually have severe disease activity at baseline, yet most pts in clinical practice have more moderate disease. This *post-hoc* analysis compared clinical and radiographic responses to placebo (PBO) and adalimumab (ADA) for pts with moderate vs. severe PsA.

Methods: Observed clinical data at Weeks 2, 12, 24, and 48 and radiographic data at Weeks 24 and 48 of the ADEPT study were analyzed.[1] Pts were classified by the 28-joint Disease Activity Score (DAS28) as having moderate (<5.1) or severe (≥5.1) PsA at baseline. Outcomes included ACR20, 50, and 70 responses at Weeks 2, 12, 24, and 48, and mean change in modified total Sharp score (ΔmTSS) between baseline and Weeks 24 and 48. Data from pts who received PBO or ADA during the first 24 weeks of ADEPT were analyzed separately. All pts were switched to ADA in an open-label extension after Week 24.

Results: Data from 288 ADEPT pts were analyzed (ADA, N=145; PBO, N=143). Of these 288 pts, 172 pts (ADA, n=86; PBO, n=86) had moderate PsA and 116 pts (ADA, n=59; PBO, n=57) had severe PsA at baseline. At Weeks 12, 24, and 48, no differences were observed in ACR20 and ACR50 responses between pts with moderate vs. severe PsA at baseline. Conversely, at Weeks 24 and 48, a statistically significantly greater ACR70 response was observed in the ADA-treated pts with moderate PsA at baseline ($p<0.05$). Similarly, we observed a trend for a greater radiographic outcome at Week 48 in pts with moderate PsA at baseline in both treatment groups. Results of clinical and structural evaluations at Week 48 are presented in the table.

Clinical and Radiographic Responses to ADA and PBO for Pts With Moderate vs. Severe PsA

Outcome at Week 48		**Baseline DAS28 <5.1**	**Baseline DAS28 ≥5.1**
ACR20, n (%)	ADA	77 (68.8)	51 (68.6)
	PBO/ADA	83 (54.2)	55 (58.2)
ACR50, n (%)	ADA	77 (53.2)	51 (51.0)
	PBO/ADA	83 (39.8)	55 (38.2)
ACR70, n (%)	ADA	77 (42.9)[a]	51 (23.5)
	PBO/ADA	83 (21.7)	55 (23.6)
ΔmTSS, mean (SD) [n]	ADA	–0.1 (1.35) [69]	+0.4 (2.66) [44]
	PBO/ADA	+0.3 (3.52) [75]	+1.7 (5.13) [50]

[a]$p<0.05$ compared with ADA-treated patients with severe PsA (DAS28>5.1) at baseline using Fisher's exact test.

Conclusion: Treatment with ADA resulted in greater ACR70 response rates and in a trend for greater inhibition of radiographic progression for pts with moderate disease activity at baseline compared with patients with severe disease activity at baseline.

Comparison of Conventional X-Ray with CT Using SASSS for as Patients. Sang-Hoon Lee[1], So-Hee Park[1], So-Young Park[2], In-Ah Choi[1], Ji-Na Park[1], Seong-Su Nah[3], Yeon-Ah Lee[1], Seung-Jae Hong[1], Wook Jin[2] and Hyung-In Yang[1], [1]Internal Medicine, School of Medicine, Kyung Hee University, Seoul, South Korea, Seoul, South Korea, [2]School of Medicine, Kyung Hee University, Seoul, South Korea, EAST-WEST Neo Medical Center, Sagngil-dong, Gangdong-gu, Seoul, South Korea, Seoul, South Korea, [3]Soonchunhyang University College of Medicine, Cheonan, South Korea

Purpose: To compare conventional radiography and Computed tomography for evaluation of radiolographic progression in ankylosing spondlitis

Methods: All patient fulfilled the modified New York diagnostic criteria for AS and visited at Neo Medical Center of Kyung Hee university from March. 1, 2008 to February .1 2009. Assessment of radiolographic progression in conventional x-ray and computed tomography was performed with Stoke Ankylosing Spondylitis Spinal Score. All images were read twice and blindly by two readers.

Results: total 339 patients with AS were examined. Disease duration is less than 10 years and the mean age is 30.5±5.7 years. The proportion of male to female is 3:1 and 90.1% was HLA-B27 positive. Total SASSS is 15.9± 11.6 in X-ray and 19.7 ± 8.3 in CT. In sclerosis, syndesmophyte and bridging CT detected more than X-ray, but did not in erosion and squaring, significantly. There were significant differences in SASSS of conventional radiography versus those of CT in all L-spine level. Especially bone bridge and syndesmophyte was significantly detected when 3 dimensional reconstruction.

Conclusion: Conventional X-ray overestimates Erosion and squaring and underestimates sclerosis, syndesmophyte and bridging. Our study suggests that the CT is more appropriate method than X-ray for assessing radiographic change in AS.

Effect of Anti-Tumor Necrosis Factor–α Treatment On the Arterial Stiffness, Carotid Intima-Media Thickness and Rheological Parameters of Blood in Active Psoriatic Arthritis. Tatiana V. Korotaeva[1], Elena Yu. Loginova[1], Diana S. Novikova[1], Evelina S. Mach[1], Lev N. Denisov[1], Nadezhda V. Klimova[1], Shandor Erdes[1], Evgeniy L. Nasonov[1] and Nikolay N. Firsov[2], [1]Institute of Rheumatology of Russian Academy of Medical Sciences, Moscow, Russia, [2]Russian State Medical University, Moscow, Russia

Systemic inflammation may play an important role in the increased cardiovascular mortality of psoriatic arthritis (PsA). Suppression of inflammation with TNF antagonists may improve vascular function in PsA.

Purpose: We examined the changes of mean/maximum carotid intima-media thickness (m-c-IMT/max-c-IMT), arterial stiffness (AS) and parameters of red blood cell aggregation (RBCA) for Adalimumab (ADA) treatment in psoriatic arthritis (PsA) patients (pts)**.**

Method: 18 active PsA pts, age range 24-56 y.o., were treatment ADA 40mg s/c eow for 12 weeks. DAS_4, parameters of RBCA [T_1, Kt, $I_{2,5}$, β] were evaluated at baseline, 4, 12 weeks in erythroagregometer; c-IMT by ultrasound and AS by Pulce Trace Device (PT2000, Micro Medical, UK), carotid-femoral pulse wave velocity (PWVcf) with a 4MHz Doppler probe, stiffness index (SI) and resistance index (RI) with a digital volume photoplethysmography transducer were measured at baseline and 12 weeks. Statistical analyses were performed with Me (Q25; Q75) and Friedman/Wilcoxon tests (t.). All $p<0.05$ were considered to indicate statistical significance.

Results: At the baseline parameters of RBCA and PsA activity are shown: T_1=5.98 (5.42; 6.99), Kt=0.39 (0.33; 0.53), $I_{2,5}$= -8 (-9; -7), β=58.32 (47.0; 77.3), DAS_4 =4,79 (4.0;5.45). RBCA and DAS_4 improved significantly at week 4 [T_1=8.77 (7.9; 10.1), Kt=0.22 (0.17; 0.28), β=32.46 (20.7; 42.5), $I_{2,5}$= -26 (-29; -20); DAS_4=2.8 (2.1;3.1)]. These results were maintained at week 12 [T_1=9.2 (8.4; 11.4), Kt=0.22 (0.2; 0.27), β=34.0 (26.5; 41.9), $I_{2,5}$= -27.5 (-32; -22); DAS_4=1.6 (1.33;2.03)]. All parameters improved significantly (Fr. t., $p<0.002$). ADA treatment resulted significant reduced of m-c-IMT/max-c-IMT [from 0.78 (0.74; 0.84) to 0.73 (0.61; 0.74), W. t., $p<0.001$ and from 0.95 (0.95; 1.03) to 0.80 (0.66; 0.89) W. t., $p<0.002$ respectively], mostly parameters of AS: RI [from 69.5 (58; 74) to 49.5 (44; 64), W. t., $p<0.05$] and PWV cf [from 9.9 (7.7; 17.7) to 9,2 (7.4; 10.6), W. t., $p<0.005$].

Conclusion: ADA significantly improved PsA activity, AS, RBCA and c-IMT as marker of subclinical atherosclerosis.

EQ-5D and SF-6D Perform Differently in Ankylosing Spondylitis (AS): A Follow-up Study of Patients Receiving Disease Modifying Therapy. Elisabeth Lie[1], Siri Lillegraven[1], Désirée M.F.M. van der Heijde[2], Maria K. Kvamme[3], Till Uhlig[1] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Inst of Health Management and Health Economics, University of Oslo, Norway

Purpose: Biological therapy has constituted a major advance in the treatment of AS, but therapy is costly and this has raised an interest in the economics of treatment. Preference based instruments like EQ-5D and SF-6D are used to obtain health state utility values which are needed in cost-utility analyses of treatment interventions. In this study we wanted to examine how these measures relate to each other and to BASDAI and BASFI in AS patients (pts) treated with DMARDs or biologicals.

Methods: AS patients were extracted from a multi-center treatment registry where pts with inflammatory arthropathies starting treatment with DMARDs and biologicals are followed longitudinally. 448 pts (67% male, 90% HLA-B27 pos, biologicals n=373, DMARDs n=75) were included for analyses of baseline data. 309 pts had available 3-month data. Baseline and 3-month changes for BASDAI, BASFI, EQ-5D and SF-6D were analysed descriptively and by Spearman correlation coefficients. Baseline BASDAI and BASFI and the 3-month changes of these measures were divided into quartiles, and EQ-5D/SF-6D values/changes were plotted against these quartiles.

Results: At baseline pts had mean/median BASDAI 5.6/5.8, BASFI 4.5/4.5, SF-6D 0.59/0.58 and EQ-5D 0.42/0.59. EQ-5D showed a bimodal distribution. Table 1 shows the utility values across quartiles of baseline BASDAI/BASFI. Pts had the following mean(SD) 3-month changes: BASDAI -2.0(-2.3), BASFI -1.3(-2.0), EQ-5D 0.18(0.34), SF-6D 0.09(0.13). We found significant, moderate correlations (rho range -0.59 to -0.66) between 3-month changes in EQ-5D/SF-6D and BASDAI/BASFI, and between changes in the two utility measures. The figure displays mean changes in EQ-5D/SF-6D in relation to quartiles of BASDAI change. Analysis with quartiles of BASFI change (data not shown) yielded a very similar result.

	BASDAI <4.2	**BASDAI 4.2-5.8**	**BASDAI 5.8-7.1**	**BASDAI >7.1**
Mean/median EQ-5D	0.69/0.73	0.52/0.66	0.34/0.26	0.12/0.00
Mean/median SF-6D	0.68/0.67	0.61/0.60	0.57/0.55	0.50/0.51
	BASFI <2.6	**BASFI 2.6-4.5**	**BASFI 4.5-6.3**	**BASFI >6.3**
Mean/median EQ-5D	0.68/0.73	0.52/0.66	0.36/0.52	0.12/0.00
Mean/median SF-6D	0.68/0.68	0.60/0.60	0.56/0.56	0.50/0.51

Conclusion: EQ-5D is better able to discriminate between different levels of disease activity as compared to SF-6D, which shows a much narrower range. In pts with most improvement in BASDAI, EQ-5D gave twice the utility gain of SF-6D. These data demonstrate that changes in EQ-5D and SF-6D can differ considerably during treatment in AS and subsequently may yield quite different cost-utility results.

Application of a New Composite Measure of Minimal Disease Activity in Patients with Psoriatic Arthritis Treated with Adalimumab: Subanalysis of the ADEPT Trial. Philip Mease[1], Renee Perdok[2], Sonja Kary[3] and Hartmut Kupper[3], [1]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [2]Abbott Laboratories, Abbott Park, IL, [3]Abbott GmbH & Co. KG, Ludwigshafen, Germany

Purpose: TNF antagonists are highly effective in treating patients (pts) with psoriatic arthritis (PsA), usually within 12 weeks.[1] Most recently, a new outcome score measuring a minimal disease activity (MDA) state was developed for that incorporates various clinical manifestations of PsA. We performed a *post-hoc* analysis of MDA achievement in pts with active PsA treated with adalimumab (ADA) or placebo (PBO) in a 24-week randomized controlled trial (ADEPT).[2]

Methods: MDA is defined as achievement of 5 of the 7 following criteria: tender joint count (TJC, 0–78) ≤1, swollen joint count (SJC, 0–76), Psoriasis Activity and Severity Index (PASI) ≤1 or body surface area (BSA) ≤3%, pt pain on a visual analog scale (VAS, 0–100 mm) ≤15, Patient's Global Assessment of disease activity (PaGA; VAS 0–100 mm) ≤20, Health Assessment Questionnaire (HAQ) ≤0.5, and tender entheseal points (no definition of enthesitis scoring methodology, 0–13) ≤1.[3] Adults with active PsA (≥3 TJC and ≥3 SJC) self-administered ADA 40 mg or PBO every other week for 24 weeks. For calculation of MDA at Weeks 12 and 24, we used the PASI and a heel-limited enthesitis score (0–4). We alternatively evaluated MDA by 5 of 6 criteria (omitting the enthesitis score). Only pts with PsA and active psoriasis (Ps) (i.e., BSA ≥3% affected) were included.

Results: Of the 313 pts with active PsA enrolled in ADEPT, 140 pts had Ps with ≥3% BSA affected and data for all other required criteria of the MDA definition (70 pts received PBO and 70 received ADA). Baseline characteristics in ADA/PBO-treated pts were mean age, 50/48 years; female, 41%/44%; median TJC, 21/26; median SJC, 13/12; median PaGA 49/48; median pain, 53/48; median PASI, 5.5/6.4; median HAQ, 1/1.06; and mean enthesitis, 0.8/1. At Week 24, data were available from 61 (87%) PBO- and 65 (93%) ADA-treated pts. At Week 12, 33.3% of ADA- and 3.1% of PBO-treated pts achieved MDA based on 5 of 7 criteria ($p<0.001$). At Week 24, the percentages were 40.0% (ADA) and 6.5% (PBO) ($p<0.001$). When using 5 of 6 criteria for MDA, 24.2% and 1.6 % of ADA- and PBO-treated pts achieved MDA at Week 12 ($p <0.001$) and 32.3% and 1.6% of ADA- and PBO-treated pts achieved MDA (5 out of 6) at Week 24 ($p<0.001$). Fulfillment of individual MDA components are also summarized (table).

Observed Percentages of Pts Who Fulfilled Individual MDA Criteria at Baseline, Week 12, and Week 24

	Baseline		Week 12		Week 24	
MDA Criterion Fulfilled	**ADA (n=70)**	**PBO (n=70)**	**ADA (n=66)**	**PBO (n=64)**	**ADA (n=65)**	**PBO (n=61)**
TJC≤1, %	0	0	33.3	7.8	40.0	9.8
SJC≤1, %	4.3	1.4	28.8	12.5	35.4	14.8
PaGA≤20, %	20.0	14.5	55.4	10.9	50.8	18.0
Pain≤15, %	7.1	8.7	47.4	6.3	49.2	11.5
PASI≤1, %	1.4	4.3	45.5	3.2	58.5	3.3
HAQ≤0.5, %	25.7	27.1	56.9	34.4	52.3	34.4
Enthesitis ≤1, %	75	68.6	83.1	64.1	82.8	67.2

Conclusion: This study demonstrates the application and utility of a new composite measure of MDA in PsA. Approximately one-third of pts with PsA who had both active arthritis and active Ps experienced MDA after 12 and 24 weeks of ADA treatment.

Development of a Composite Psoriatic Disease Activity Index. Aizad Mumtaz[1], Phil Gallagher[2], Brian Kirby[1], Laura C. Coates[3], Robin Waxman[4], Tom O'Hara[5], Douglas J. Veale[6], Philip S. Helliwell[3] and Oliver FitzGerald[7], [1]St Vincents University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]University of Leeds, Leeds, United Kingdom, [4]Leeds, United Kingdom, [5]Trinity College, Dublin, Ireland, [6]St.Vincent's University Hospital, Dublin, Ireland, [7]St Vincent's University Hospital, Dublin, Ireland

Purpose: To develop a composite disease activity index for Psoriatic disease and to further test its ability as a responder index in patients undergoing treatment.

Method: All patients included were recruited from our rheumatology out- patients and satisfied the CASPAR criteria for diagnosis of Psoriatic Arthritis . Five domains were assessed including joint, skin, dactylitis, enthesitis and back involvement to formulate the Composite Psoriatic Disease Activity Index (CPDAI). Specific instruments were employed to determine the extent of domain involvement and their effect on quality of life/function: joint (68 tender, 66 swollen joint counts, HAQ), enthesitis (Leeds enthesitis index, HAQ), spine (BASDAI, ASQOL), skin (PASI, DLQI) and dactylitis (Digit count and HAQ). Disease activity was then graded as mild, moderate and severe using these instruments on a severity score of 0 to 3. The maximum attainable score was 15. Patient and physician related global disease activity measures were also recorded and a physician was independently asked to indicate if treatment change was required. Spearman's rank correlation coefficient was applied to check for correlation between the CPDAI, patient and physician global assessments. A tree analysis to depict the cut off values of the CPDAI predicting a treatment change was also derived.To explain maximum variability in the data,factor analysis with component extraction was done. To overcome the problem of patients without involvement of a particular domain, weighted linear scale regression analysis was performed. Finally binary logistic regression analysis was used to evaluate which factors most predict the treatment change.

Results: In total 92 patients were analysed; median age was 46 years with a range of 52 (20-72); mean duration of arthritis before the first assessment was 10 months.In total treatment change was thought indicated in 33 patients. The median CPDAI score consistent with change of treatment required was 9 (n=92) ($p<0.05$);in patients not requiring treatment change the median of CPDAI values was 3. The tree analysis revealed that 96.3 percent of patients had their treatment changed if their CPDAI values were greater than 6;none of the patients had their treatment changed when CPDAI values were <5. The CPDAI showed significant correlation with the patient($r=0.834$) and physician($r=0.825$) derived global assessments($p=0.01$).The linear regression model demonstrated that the HAQ, LEI, PASI, swollen joint count and dactylitis are the factors contributing most to the CPDAI . Binary logistic regression analysis revealed the HAQ, tender joint count and dactylitis as most closely predicting a need for treatment change.

Conclusion: The CPDAI is an effective tool which correlates with patient and physician global health assessments and which clearly distinguishes those who require a treatment change from those who do not. Further testing of the CPDAI in patients undergoing treatment change is underway.

High-Field MRI in Patients with Ankylosing Spondylitis Under Etanercept Treatment. Maria Hoehle, Rheumatology, Hamburg, Germany

Purpose: Data on efficacy were collected in axial AS patients who received etanercept (ETA) monotherapy for up to 7 ys. High-field MRI was used to measure disease activity.

Method: A retrospective investigation was undertaken in 20 patients with axial AS who had received ETA monotherapy continuously since 2001. Diagnosis was based on clinical parameters according to the modified New York and/or European Spondylarthropathy Study Group preliminary criteria. BASFI, BASDAI, CRP, ESR and AS DAS were measured as clinical and paraclinical parameters of disease activity. For reasons of radiological protection, high-field MRI was used as the imaging technique for the cervical, thoracic and lumbar spine with imaging of the iliosacral joint in native T1, T1 fat saturation/fat saturated T2-weighting (STIR), as well as a fat-saturated T1-weighting before and after i.v. application of contrast medium (gadolinum). If clinical symptoms were present, MRI of hip joints was also carried out. MRI scans were interpreted analogous to the known m-SASSS and supplementary to the additional possibilities of MRI in terms of the early detection of inflammatory activity with contrast medium enhancement. The axial AS patients were divided into 3 groups. First group early axial AS: at the start of treatment, high AS criteria and/or AS DAS, in CM high-field MRI: Grade 1 sacroiliitis with/without spinal

activity (possible hip joints) without bony remodelling processes and/or erosions. Second group active established axial AS: at the start of treatment, high AS DAS criteria, Grade 2 sacroiliitis with/without spinal involvement and bony remodelling processes and/or erosions less than 50%. Third group chronic established axial AS: at the start of treatment, high AS DAS criteria, Grade 3 and upwards sacroiliitis with inflammatory activity and bony remodelling processes with syndesmophyte formation more than 50%.

MRI examination took place according to the scheme: baseline, 6 months, annually after the start of therapy and individually after clinical and radiological complete remission.

Results: 20% of patients were assigned to Group 1, 60% of patients to Group 2 and 20% of patients to Group 3.

In all patients in Group 1 a clinical and MRI-recorded complete remission occurred after a period of at least 2 but not more than 3 ys, so that the ETA therapy could be ended. 4 further annual controls continued to show a remission. In Groups 2 and 3, a reduction in MRI-measured disease activity criteria (m-SASSS) from 3 to 0, and a score as low as Grade 1 in the ASspiMRI-a, as well as bony remodelling processes and an improvement in functional parameters, were recorded. Attempts to discontinue ETA led, however, to reactivation of the inflammatory disease.

Conclusion: Continuous monotherapy with ETA led to a clinical and MRI-recorded complete remission within 3 ys in the patients with high clinical activity and Grade 1 sacroiliitis in high-field MRI (with CM) with and without spinal activity without bony reaction, remodelling processes and erosions (corresponds to the group with early AS). In this group of patients, ETA could be stopped. A further 4 years of follow-up showed no return of symptoms. Due to its sensitivity, high-field MRI with CM enhancement should be used as a diagnostic tool for the early detection of axial AS.

Rheumatologist Training to Recognize Lesions On T1-Weighted MRI Enhances Diagnostic Utility of MRI in Patients with Ankylosing Spondylitis. Walter P. Maksymowych[1], Ulrich Weber[2], Juerg Hodler[2], Mikkel Ostergaard[3], Susanne J. Pedersen[3] and Robert GW Lambert[1], [1]University of Alberta, Edmonton, AB, [2]University Clinic Balgrist, Zurich, Switzerland, [3]Copenhagen University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark

Purpose: In using MRI to diagnose AS, we have shown that rheumatologists rely primarily on diagnostic information from fat-suppressed sequences where inflammation is readily discernable and de-emphasize the contribution of abnormalities on T1-weighted sequences (T1W) which may reflect difficulty in interpreting complex structural abnormalities such as erosions and sclerosis and the uncertain diagnostic significance of fat infiltration. We aimed to test the hypothesis that systematic calibration of readers directed at recognition of abnormalities on T1W MRI would enhance the diagnostic utility of MRI in early AS.

Method: Six experienced readers (4 rheumatologists, 2 radiologists) from 3 international centres, blinded to patient and diagnosis, independently assessed MRI scans (T1W and STIR) from the following subjects all aged < 45 years: 77 patients with AS; 85 controls (26 with mechanical low back pain (mLBP) and 59 healthy individuals). MRI scans of the SIJ were read systematically as described in a standardized online training module. We recorded bone edema, fat infiltration, erosions, and ankylosis according to standardized definitions using an online data entry system. In addition to deciding on the presence/absence of SpA, readers were asked to record the following: 1. Whether their diagnostic conclusion was primarily based on abnormalities observed on the STIR, T1W, or both. 2. Which type of lesion was the primary basis for the diagnostic conclusion. The exercise was repeated 6 months later on a random selection of 30 AS patients (symptom duration ≤ 5 years) and 34 controls (26 with mLBP and 8 healthy) from the original cohort after 2 training exercises directed at abnormalities on T1W MRI and development of a reference image set developed by group consensus.

Results: Diagnostic utility of MRI improved for both concordant as well as individual readers following calibration. Rheumatologist readers also based their diagnostic conclusion on the T1W MRI and recorded erosions as the principal diagnostic feature significantly more frequently after calibration ($p = 0.013$ and <0.0001, respectively). However, this was not accompanied by significant improvement in the inter-reader agreement of detection of erosions as recorded in individual SIJ quadrants.

	Pre-Calibration				**Post-calibration**			
	Sensitivity	**Specificity**	**LR+**	**LR-**	**Sensitivity**	**Specificity**	**LR+**	**LR-**

Individual reader (mean (range))	92.2% (76.7-100)	93.6% (79.4-100)	14.4	0.08	97.9% (96.7-100)	95.6% (88.2-100)	18.1	0.02
All Rheumatologists (mean (range)	91.7% (76.7-100)	91.2% (79.4-100)	10.4	0.09	97.8% (96.7-100)	94.1% (88.2-97.1)	16.6	0.02
Concordant data (all 6 readers)	66.7%	76.5%	2.8	0.44	90.0%	82.4%	5.1	0.12

Conclusion: Rheumatologist training directed specifically at detection of MRI abnormalities on T1W scans enhances diagnostic utility by increasing overall interpretation of the T1W scan.

Does Fat Infiltration in the Sacroiliac Joint Contribute to the Diagnostic Utility of MRI in Ankylosing Spondylitis? Ulrich Weber[1], Susanne J. Pedersen[2], Juerg Hodler[1], Mikkel Ostergaard[2], Robert GW Lambert[3] and Walter P. Maksymowych[3], [1]University Clinic Balgrist, Zurich, Switzerland, [2]Copenhagen University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark, [3]University of Alberta, Edmonton, AB

Purpose: Fat infiltration in bone marrow of the sacroiliac joint (SIJ) and spine is frequently detected on T1-weighted (T1W) MRI in patients with AS but also in healthy individuals and those with other causes of back pain. There have been no systematic studies to address its diagnostic utility in AS. We aimed to evaluate the diagnostic utility of fat infiltration in the SIJ per se and to determine whether any morphological features characterize pathological infiltration.

Method: Six experienced readers (4 rheumatologists, 2 radiologists) from 3 international centres, blinded to patient and diagnosis, independently assessed MRI scans (T1W and STIR) from the following subjects all aged < 45 years: 30 patients with AS and symptom duration 5 years or less; 34 controls (26 with mechanical low back pain (mLBP)). MRI scans of the SIJ were read systematically as described in a standardized online training module using an online data entry system. In addition to deciding on the presence/absence of AS readers were asked to record the following: the primary MRI feature on which the diagnosis of AS was based, the presence/absence of fat infiltration, the degree to which fat infiltration was considered due to AS (0-10 scale), its location (sacral, iliac, both), and associated morphological features (bone edema, erosion, sclerosis, ankylosis, distinct border, infiltration adjacent to iliac/sacral joint surface, homogeneity of infiltration). We calculated sensitivity, specificity, and likelihood ratios.

Results: Fat infiltration was considered present in 28/30 (93.3%) of AS patients by a majority (≥4) of readers and in 29/30 (96.7%) by at least 2 readers but stated to be the principal diagnostic feature by only 2 readers in only 3 patients. Only one AS patient was considered to have no infiltration by any reader. It was also present in 6/34 (17.6%) of controls by a majority (≥4) of readers and in 13/34 (38.2%) by at least 2 readers (sensitivity 96.7%, specificity 61.8% for AS as recorded by at least 2 readers). Only 20/34 (58.8%) of controls were considered to have no fat infiltration by any reader. Applying a pre-specified definition of any 2 readers recording fat infiltration and each reader scoring ≥7 for fat infiltration considered due to AS gave a sensitivity of 80% and specificity of 97.1%. At least 1 associated feature was recorded in all patients by all readers. Table values represent concordant data from at least 2 readers.

Morphological Features	**Sensitivity**	**Specificity**	**LR+**	**LR-**
Both sacral and iliac	70%	94.1%	11.9	0.32
Bone edema	60%	100%	nc	0.4
Sclerosis	70%	97.1%	24.1	0.31
Erosion	83.3%	97.1%	28.7	0.17
Ankylosis	6.7%	100%	nc	0.93

Distinct margin	60%	97.1%	20.7	0.41
Homogeneity	43.3%	94.1%	7.3	0.60
Adjacent to sacral/iliac endplate	90%	88.2%	7.6	0.11

Conclusion: . Fat infiltration in the SIJ per se has high sensitivity but low specificity for AS. Its diagnostic utility primarily reflects the presence of associated abnormalities, especially erosions, characteristic of AS.

Efficacy of Switching Between Anti-Tnf Agents in Spondylarthropathies. Julien Paccou Sr. Hôpital Roger Salengro, CHRU de Lille, Lille cedex, France

Purpose: TNF alpha antagonists are remarkably effective in the treatment of spondylarthropathies. However, 20% of patients will have to interrupt their treatment prematurely due to primary non-response, and 10 to 20% due to loss of efficacy. The objective of this study was to assess, in a large cohort of patients, the response to a 2nd and a 3rd TNFα antagonist in the event of failure, and to determine whether or not the cause of failure influenced the response.

Method: Retrospectively, we included all patients with spondylarthropathies who had received at least 2 TNFα antagonists or more. In patients in whom the treatment failed, the initial therapeutic response and the reason for the withdrawal of the TNFα antagonists were analyzed with respect to reason for failure and disease subtype. Patients were evaluated for response to the change in anti-TNF alpha therapy after 6 to 12 weeks. The reasons for withdrawal were (i) primary non-responder, (ii) loss of efficacy and (iii) occurrence of side effects over the follow-up period. An attempt was made to identify response-predictor factors using univariate and multivariate analysis.

Results: 103 patients with spondylarthropathies were included in this study (41 women and 62 men; mean age was 46 years and average duration of disease was 13 years). One switch was made in 73 patients and 2 switches in 30 patients. Following the failure of a first TNF alpha antagonist, the response to a 2nd agent was satisfactory (81% of the patients responded 6 to 12 weeks after starting treatment). The response to the second agent was not conditioned by the reason for withdrawal of the first TNF alpha antagonist. Patients who had received a 3rd TNF alpha antagonist following failure of the first 2 also showed a satisfactory response (79% of the patients responded 6 to 12 weeks after starting treatment). The reason for withdrawal of the 1st or 2nd agent did not conditioned response. Logistic regression analysis failed to distinguish response predictors.

Conclusion: In the event of failure or intolerance to TNF alpha antagonists in the treatment of spondylarthropathies, performing a first or a second switch produces a satisfactory therapeutic response, regardless of the reason for discontinuing previously prescribed TNF alpha antagonists.

Does Clinical Examination Overestimate the Amount of Active Enthesitis in Early Psoriatic Arthritis? - A Comparison with Power Doppler Ultrasound. Jane E. Freeston[1], Laura C. Coates[1], Philip S. Helliwell[1], Elizabeth M. A. Hensor[2], Richard J. Wakefield[1], Paul Emery[1] and P. Conaghan[3], [1]University of Leeds, Leeds, United Kingdom, [2]LIMM, University of Leeds, Leeds, United Kingdom, [3]U of Leeds, Leeds, United Kingdom

Purpose: Enthesitis is thought to be important in the spondyloarthropathy (SpA) group of diseases, including psoriatic arthritis (PsA). Some groups have proposed enthesitis as the primary pathological abnormality in PsA, therefore enthesitis should be a prevalent finding in early PsA. The accuracy of clinical examination (CE) for enthesitis has been shown to be inferior to imaging assessment in established SpA cohorts, and a significant proportion of patients have been found to have sub-clinical enthesitis using ultrasound (US) imaging. However there is no data on the use of US in early PsA. The aim of this study was to compare CE and US findings in an early PsA cohort.

Method: 40 patients with new onset PsA, according to the CASPAR criteria, were recruited. They were all DMARD naïve and had a median disease duration of 10 months. All patients underwent CE of 66/68 joints and an entheseal assessment for tenderness and swelling as well as grey scale (GS) and power doppler (PD) US of the corresponding entheses. Bilateral lateral epicondyles of the elbow, Achilles tendons and plantar fascia were examined. GS and PD were scored separately on a 0-3 semi-quantitative scale for each enthesis imaged. A GS score of ≥2 and/or a PD score >0 were used to identify active US enthesitis.

Results: On CE, 34/202 entheses were tender, but none were clinically swollen. Using combined GS and PD, 14/202 had active enthesitis on US. Of all entheses examined, 85% had imaging findings consistent with CE. A substantial correlation (prevalence and bias-adjusted Kappa = 0.70) was identified between clinical assessment of activity (tender and/or swollen) and imaging assessment of activity.

In this early cohort, there was little evidence of sub-clinical disease with only 2% (5/202) of non-tender entheses showing significant US changes. Interestingly, all of the 5 non-tender, US active entheses were in the lower limb, and there was no sub-clinical disease seen at the lateral epicondyles. However, CE over-estimated activity in 12% of entheses. Of the 25 tender but US inactive entheses, 7 were adjacent to clinically tender joints. Bony erosion was only present in 8 of 202 entheses.

Table – Comparison of clinical and ultrasound assessment of disease activity by individual enthesis.

Type of assessment	US active	US inactive	Total
Tender	9	25	34
Non-tender	5	163	168
Total	14	188	202

Conclusion: These data have shown that the prevalence of enthesitis in early PsA is relatively low compared with previous studies of established disease. CE over-estimated the amount of enthesitis in this study, possibly due to pain from adjacent joint disease. There is no significant burden of sub-clinical enthesitis seen in this cohort of early PsA, and the few sub-clinically inflamed entheses were in the lower limb, where mechanical stress through entheses is likely to be more significant. These preliminary data have implications for research into pathogenesis, particularly as studies attempt to elucidate the primary pathology in PsA.

Disclosure: J. E. Freeston, None; **L. C. Coates**, None; **P. S. Helliwell**, None; **E. M. A. Hensor**, None; **R. J. Wakefield**, None; **P. Emery**, None; **P. Conaghan**, None.

To Verify the Clinical Value of the New Ankylosing Spondylitis Disease Activity Scores (ASDAS) in Chinese as and USpA Patients.

Jieruo Gu, Manlong Xu, Zhiming Lin, Zetao Liao, Shuangyan Cao and Qiujing Wei, 3rd Affiliated Hospital of Sun Yat-Sen Uni, Guangzhou, China

Background and Purpose: Nowadays, the most widely used measure for assessing the disease activity of AS is Bath Ankylosing spondylitis Disease Activity Index (BASDAI). However, it is a self-administered instrument and does not include any objective index. In July 2008, the Assessment of SpondyloArthritis international Society (ASAS) developed a new assessment tool of disease activity in AS: ankylosing spondylitis disease activity score (ASDAS). This study is to assess the clinical value of ASDAS in Chinese AS and USpA patients, in comparison to BASDAI, the individual components of it as well as patient global and the acute inflammation score of MRI.

Method: All the AS and USpA patients in the study included two cohorts: 1) patients participated in double-blind placebo-controlled randomized clinical trials with Etanercept (n=117), 2) the out-patients who were receiving the treatment of Infiximab (n=90). The data about every patient at baseline and a following up visit at 6 weeks later as well as the data including the results of MRI of the lumbar and sacroiliac joints about some patients at a following up visit at 12 weeks later were collected. The disease activity and treatment effect were assessed by ASDAS and BASDAI. Discrimination between patients in low versus high disease activity according to various definitions, and between various levels of changes was analyzed as standardized mean difference (difference of the group means divided by the pooled SD of the group means).

Results: 1. On the disease activity assessment: (1)All the four ASDAS and BASDAI correlated significantly with patient global. The results of them were similar. However, the four ASDAS performed much better than BADAI in correlating with ESR and CRP in both AS and

USpA groups. (2) The four ASDAS outperforms BASDAI in discriminating the different status of disease activity, in the settings of ESR based. The SMDs of the four ASDAS were: 1.52, 1.55, 1.24 and 1.51 in AS group respectively and 1.41, 1.48, 1.38 and 0.43 in USpA grouprespectively. The SMDs of BASDAI were0.62 in AS group and 0.43 in USpA group. 2. On assessing the different levels of change of disease activity according to the treatment of TNF-α blockers, the SMDs of ASDAS in discriminating the changes of disease activity between baseline and 6 weeks after treatment were 1.16, 1.09, 1.09 and 1.15 in AS group respectively and 1.38, 1.48, 1.32 and 1.37. in USpA group respectively. While the SMDs of BASDAI were 0.88 in AS group and 1.06 in USpA group. Obviously, the discriminatory power of the ASDAS proved to be better than the BASDAI. 3. The four ASDAS outperforms the total acute inflammation score of the MRI of lumbar and sacroiliac joint in correlating with patient global assessment , ESR and CRP.

Conclusion: In comparison to the BASDAI and the other conventional indices, the four new ASDAS are more sensitive in discriminating the disease activity and the efficacy of TNF-αblocker treatment at 6 weeks in AS patients. Furthermore, ASDAS will be value to be used for assessing disease activity and the treatment effect of TNF-αblocker in USpA patients.

Evaluation of the ASAS Classification Criteria for Axial Spondyloarthritis, A Diagnostic Algorithm and the Probability Approach (likelihood ratio product) in Diagnosing Axial Spondyloarthritis. M. Rudwaleit, J. Vahldiek, H. Brandt, H. Appel, H. Haibel, I.-H. Song, S. Zinke, K. Karberg, I. Spiller and J. Sieper, Charité - Campus Benjamin Franklin, Berlin, Germany

Purpose: The diagnosis of non-radiographic axial spondyloarthritis (i.e. axial SpA in the absence of definite radiographic sacroiliitis as required for ankylosing spondylitis (AS)) has been and still is a challenge. The objective of this study was to evaluate the diagnostic accuracy of a recently proposed diagnostic algorithm (1), the likelihood ratio (LR) product approach (2), and the new ASAS classification criteria for axial SpA (3) in patients with chronic back pain presented to a single rheumatology center.

Method: Patients were referred to our rheumatology department because of chronic back pain of unknown origin and already some suspicion of SpA such as inflammatory back pain (IBP), or positivity for HLA-B27, or any other SpA feature. Upon routine diagnostic work up, the diagnosis was made by the treating rheumatologist (n=9 in total), often after consultation of the team. The clinical diagnosis (SpA vs no SpA) served as gold standard in this study.

Results: In total, 374 patients were analysed. Of these 200 were diagnosed as axial SpA (53.5%) and 174 as no SpA (mechanical low back pain: median age 43 yrs, median symptom duration 6 yrs). Definite radiographic sacroiliitis was present in 101 of the 200 axial SpA patients (median age 39 yrs, median symptom duration 7.5 yrs), and 99 patients had non-radiographic axial SpA (median age 34 yrs, median symptom duration 3.0 yrs). IBP was present in 91.5% vs 49%, HLA-B27 positivity in 86% vs 39%, and elevated CRP in 55% vs 30% of SpA vs no SpA patients, respectively. MRI investigation of the sacroiliac joints was performed in 76% of patients diagnosed as non-radiographic axial SpA, and 86% of these patients had active sacroiliitis on MRI. In the 374 back pain patients the new ASAS classification criteria for axial SpA had a sensitivity/ specificity of 97.0%/ 74.7%, the diagnostic algorithm of 82.8%/ 74.7%, and the LR product approach (with a threshold of 90% for definite diagnosis) of 83.8%/ 85.1%, respectively. In patients diagnosed as non-radiographic axial SpA the imaging arm of the ASAS classification criteria (i.e. sacroiliitis on radiographs or MRI plus at least 1 SpA parameter) was fulfilled by 64.6% but only 1.1% of no SpA (specificity 98.9%).

Conclusion: All three diagnostic approaches seem suitable for establishing a diagnosis. The new ASAS classification criteria for axial SpA revealed an excellent sensitivity and a reasonable specificity, the latter was also excellent if the imaging arm only of the criteria was applied. In comparison to the LR product approach the ASAS criteria are easy to use in daily rheumatology practice.

Comparison Between Inspire and Domjan Method for Measuring Lumbar Lateral Flexion in Patients of Psoriatic Arthritis (PsA) and Correlation with Radiographic Damage. Anupam Wakhlu[1], Veerapong Phumethum[1], Vinod Chandran[1], Catherine T. Schentag[1], Hua Shen[2], Richard J. Cook[2] and Dafna Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON

Purpose: Assessment of spinal lateral flexion is important in the assessment of spondyloarthritis (SpA). The INSPIRE method of measuring spinal lateral flexion requires one set of measurements, is faster, feasible and correlated with the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) in patients with ankylosing spondylitis. The purpose of the present study is to compare the INSPIRE method of measuring lumbar lateral flexion to Domjan method in PsA patients and correlate it with radiographic changes.

Method: Patients were selected from a longitudinal cohort followed in a PsA clinic since 1978. Detailed demographic and clinical data are obtained every 6-12 months and are tracked on a computerized database. Patients satisfying CASPAR criteria for PsA and axial disease were identified using radiological criteria, which included the presence of at least grade 2 sacroiliitis. Clinical features recorded systematically included the following: age, gender, ethnicity, age at symptom onset, age at diagnosis, arthritis pattern, family history, extra-articular manifestations and medications. The physical examination includes general physical examination, musculoskeletal examination and full spinal clinimetrics including measurement of INSPIRE and Domjan methods of spinal lateral flexion by trained rheumatologists. Spine radiographs, obtained every 2 years included AP pelvis, lateral view of cervical spine, AP and Lateral views of lumbar spine. These were scored by consensus for mSASSS by 2 assessors. Pearson correlation was used to correlate the values of spinal mobility measures and radiographic scores.

Results: 229 patients were included in the study of whom 43% were female. The mean age at study entry was 51 years (16-83) and mean age at onset of PsA was 37 years. The mean disease duration was 15 years (0.5-49). 54% of patients had radiological evidence of sacroiliitis and 45% had evidence of degenerative spinal disease. The spinal mobility and radiographic scores were as follows [mean (minimum, maximum)]: Occiput-to-wall distance (cm)=1.0 (0-17), Tragus-to-wall distance (cm)=12 (7-25), Cervical rotation (degrees)=71 (5-90) , Chest expansion (cm)=6 (2-12), Modified Schoeber (cm)=4.5 (1-8), Lateral spinal flexion-Domjan (cm)=16.5 (3.5-40), Lateral spinal flexion-INSPIRE (cm)=32 (8-60), mSASSS score=2 (0-48). Correlation (95% confidence interval) between INSPIRE and Domjan method was 0.86 (0.82,0.89), between INSPIRE, Domjan methods and mSASSS were -0.28 (-0.40,-0.16) and -0.27 (-0.39,-0.14) respectively. All correlations had a p value of <0.0001. Comparable correlations were obtained when comparisons were made in patients of PsA with axial disease only.

Conclusion: The study demonstrates that both INSPIRE and Domjam methods correlate well as measures of spinal lateral flexion in PsA and correlate well with radiographic damage**.** If the two show a similar sensitivity to change, they may be used interchangeably.

A Comparison of Cardiovascular Risk in Patients with Spondyloarthropathies and Rheumatoid Arthritis. Laura Grant[1], Kimberley A. Bailey[1] and Namita Kumar[2], [1]Medical School, University of Newcastle, Newcastle upon Tyne, United Kingdom, [2]University Hospital of North Durham, Durham, United Kingdom

Purpose: The management of cardiovascular disease (CVD) and its risk factors play an important role in the multi-factorial management of patients with inflammatory arthritis (IA). The British Society for Rheumatology and NICE all recommend that patients with IA should be offered annual CVD review.

A suggested multiplier of risk in Rheumatoid Arthritis (RA) is 1.5 greater than the general population and we have shown this significantly increases numbers of patients requiring primary prevention (1). This is also a fair estimate of CVD burden in Seronegative Spondylarthropathies (SpA) also (2). We wished to establish the number of SpA patients who reached primary prevention treatment threshold prior to establishing a CVD screening service .

Method: Consecutive RA patients and SpA patients, both without diabetes or CVD were recruited over a five week period in 2 consecutive years. Ten year CVD risk was calculated using the Joint British Societies risk calculator and comparisons were made between the 2 groups. Both sets of data were multiplied by 1.5. Paired t tests were then used to compare risk scores within each disease group.

Results: 45 RA patients were assessed 26 female, 18 male. Mean age was 57.53 years (range 39-74 years). Mean systolic BP 136.4mmHg (SD 13.6), diastolic 86.3mmHg (SD 14.0) 51 SpA patients were assessed, 20 male, 31 female. The mean age was 49.5 years (range 30-72 years). Mean systolic BP was 140.4 mmHg (SD 18.3) and mean diastolic BP was 86.1 (SD 10.7). All patients had a diagnosis of one year or longer.

Table 1: Projection of 10 Year Cardiovascular Risk

	RA		**SpA**		**P**
N	**45**		**51**		
	Actual risk greater than 20%	**Risk X1.5**	**Actual risk greater than 20%**	**Risk X1.5**	
	6*	18*	7[#]	15[#]	*[#]0.001

Conclusion: CVD is an important cause of mortality and morbidity in IA. Disease burden is underestimated by standard risk assessment. Multiplying by 1.5 is an acceptable estimation of true risk. This however significantly increases the number of patients requiring primary prevention in this work twofold. This should be recognised when establishing such services and results of studies such as TRACE RA will guide Rheumatologists in whether primary prevention has a significant impact in patients with IA.

Genome-Wide Association Study of Systemic Sclerosis in a Large US Cohort of Over 1,500 Cases. Olga Gorlova[1], Shih-Feng Weng[1], Jun Ying[1], Fredrick M. Wigley[2], Laura K. Hummers[2], Peter K. Gregersen[3], AnnetteT Lee[3], Christopher Amos[1], Frank C. Arnett[4], Shervin Assassi[4], Pravitt R. Gourh[5], Filemon K. Tan[4], John D. Reveille[6], J. Lee Nelson[7], Terry A. McNearney[8], Michael Fischbach[9] and M. Mayes[10], [1]M.D. Anderson Cancer Center of the University of Texas, Houston, TX, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]University of Texas Medical School at Houston, Houston, TX, [5]UTHSC-Houston Medical School, Houston, TX, [6]Univ Texas Health Sci Ctr, Houston, TX, [7]Fred Hutchinson Cancer Rsch, Seattle, WA, [8]Univ of Texas Med Branch, Galveston, TX, [9]Univ Texas Hlth Sci Ctr, San Antonio, TX, [10]U.Texas Houston, Houston, TX

Purpose: Systemic Sclerosis (SSc) is a rare and severe rheumatologic disease. Multiple lines of evidence suggest that genetic factors play a role in SSc susceptibility and disease expression. To analyze the genetic component of SSc risk we performed a genome-wide association study comparing 1,617 Caucasian SSc cases to data from 3,597 Caucasian controls utilizing the Ilumina 550k gene chip.

Methods: Cases were obtained from three U.S. centers Cases (initial n=1,678) were obtained from three U.S. centers: the University of Texas (UT) Health Science Center-Houston, Johns Hopkins University Medical Center in Baltimore and the Fred Hutchinson Cancer Research Center in Seattle. Control data were obtained from 3 publicly available databases: (1) breast cancer controls CGEMS; (2) prostate cancer controls CGEMS; and (3) Illumina controls. After eliminating duplicates, gender discrepancies and call rates <95%, the final case population consisted of 1,534 individuals (182 men and 1,352 women). After similar quality control and gender matching by randomly eliminating male controls to adjust M:F ratio to that in cases, the final control population consisted of 3,597 individuals (464 men; 3,133 women).

Results: Thirty-three SNPs representing 12 genes were significantly associated with SSc with p-values from $9.9 \cdot 10^{-15}$ to $5 \cdot 10^{-8}$. The most significantly associated genes were those in the MHC region (6p21), including, but not limited to, HLA-Class II alleles. Aside from the MHC region, 4 gene regions were identified as significantly associated with SSc. These include TNPO3 ($p= 1.2 \cdot 10^{-9}$ for the most significant SNP) which is in linkage disequilibrium with IRF5 and previously associated with SSc in candidate gene studies, XKR4 on chromosome 8 ($p= 5.15 \cdot 10^{-9}$), TSSC1 on chromosome 2 ($p=2.53 \cdot 10^{-9}$), and TUBA3C (tubulin alpha 3 C) on chromosome 13 ($p= 3.73 \cdot 10^{-8}$). The p-values for T-cell signaling related genes (CD3Z p=2.37E-06), cytokine receptors (IL21R) and other previously studied candidate loci were in the range of 10^{-7} to $10^{-6.}$

Conclusion: We confirm the association with HLA alleles thus firmly establishing that this disease has a strong autoimmune component. In addition, multiple other gene regions have been identified. Our study is the largest GWAS yet reported and one of the few where multiple candidate genes with P-values as low as 10^{-15} were identified.

dsRNA Drives Type I and Type II Interferon-Mediated Inflammation, Fibroblast Activation and Dermal Fibrosis through TLR3-Dependent and Independent Signaling. Giuseppina Alessandra Farina, Mike Di Marzio, Cindy Collins, Michael R. York and Robert A. Lafyatis, Boston University School of Medicine, Boston, MA

Purpose: The goal of this study was to better understand innate immune regulation and associated IFN responsive gene expression in systemic sclerosis (SSc). We also sought to better understand the role of innate immune activation of dermal fibroblasts and in particular the effect of different Toll-like receptor (TLR) ligands on dermal fibroblast expression of type I and type II IFN responsive genes. Finally we wanted to develop a murine model for chronic innate immune stimulation for studying TLR-regulated dermal inflammation and the effect of type I IFNs on dermal fibrosis.

Method: Skin biopsies from Lesional (L/SSc) (n=36), Non Lesional (N/LSSc) (n=15), and healthy control skin (n=6), and SSc (n=6) and normal (NL) (n=4) dermal fibroblasts were studied for mRNA expression of IFN responsive genes using real-time PCR. Dermal fibroblasts were stimulated with different TLR ligands (TLR2, TLR3, TLR4, TLR7, TLR8, TLR9), IFNa,b,g or TGFb. Groups of C57BI/6, and type I IFN receptor deleted mice (IFNAR1-/-), were implanted with osmotic pumps designed to deliver the TLR3 agonist PolyIC or control (PBS). Skin was taken after a week of treatment and then analyzed for gene expression using real-time PCR, and examined by H&E staining.

Results: Both type I and II IFN responsive genes were found significantly increased in L/SSc compared to control skin (OAS2: average 3.3 fold increase in L/SSc, 2.9 fold in SSc N/L); (CXCL9: average 7.03 fold increase in L/SSc, 5.80 fold in N/LSSc). Moreover, expression of genes known to be related to TLR activation was also overexpressed in SSc skin (IRF7: average 3.71 fold increase in L/SSc; SOCS3: average 3.07 fold increase in L/SSc). Of the TLR ligands tested PolyIC most potently stimulated SSc and NL fibroblasts showing marked induction of IFN responsive genes. Mice treated with PolyIC developed striking skin inflammation and fibrosis. PolyIC treated skin also showed highly upregulated expression of Mx-2, a type I IFN-responsive gene and CXCL9, a type II IFN responsive gene, as well as increased expression of TGFb responsive genes, PAI-1 and Thrombospondin (TSP1).

PolyIC treatment of IFNAR-/- mice did not induce Mx-2 gene expression, and CXCL9 expression was partially reduced compared to WT mice. In contrast deletion of IFNAR showed no effect on TGFb responsive gene expression.

Conclusion: Type I and II responsive gene expression is increased in SSc skin. Chronic immune stimulation by TLR3 agonist stimulates inflammation, fibrosis, and IFN and TGFb responsive gene expression. IFNAR plays a relatively modest role in regulating TGFb activation in skin by the TLR3 agonist, PolyIC.

Rituximab Versus Cyclophosphamide for Induction of Remission in ANCA-Associated Vasculitis: A Randomized Controlled Trial (RAVE). J.H. Stone[1], P.A. Merkel[2], P. Seo[3], R. Spiera[4], C.A. Langford[5], Gary S. Hoffman[5], C.G.M. Kallenberg[6], E. William St. Clair[7], B.J. Fessler[8], N. Tchao[9], L. Ding[10], L.V. Webber[10], D. Ikle[11], D. Weitzenkamp[11], W. Wu[12], P. Brunetta[13], L. Seismundo[3], F.C. Fervenza[14], K.A. Keogh[14], E. Y. Kissin[2], K.S. Mieras[14], P.A. Monach[2], T. Peikert[14], C. Stegeman[15], S.R. Ytterberg[14], U. Specks[14] and The RAVE-ITN Research Group[9], [1]MGH, Boston, MA, [2]BU, Boston, MA, [3]Johns Hopkins, Baltimore, MD, [4]HSS, New York, NY, [5]Cleveland Clinic, Cleveland, OH, [6]University Medical Center Groningen, Groningen, Netherlands, [7]Duke University Medical Center, Durham, NC, [8]UAB, Birmingham, AL, [9]ITN, San Francisco, CA, [10]NIH, Bethesda, MD, [11]Rho, Chapel Hill, NC, [12]PPD, Wilmington, NC, [13]Genentech, Inc., S. San Francisco, CA, [14]Mayo Clinic, Rochester, MN, [15]Med.Univ., Groningen, Netherlands

Purpose: Combined use of cyclophosphamide (CYC) and glucocorticoids (GCS) has been the standard of care for remission induction for ANCA-associated vasculitis (AAV) for decades. Uncontrolled studies suggest rituximab (RTX) may be effective for AAV, and its use may avoid some of the toxicities associated with CYC therapy. This trial compares the efficacy of RTX to that of CYC for AAV.

Method: A multicenter, randomized, double-blind, placebo-controlled trial was conducted to determine if treatment with RTX (375 mg/m^2 i.v. weekly x 4) was not inferior to CYC (2 mg/kg/d p.o.) for inducing remission in severe AAV. Once remission was achieved, CYC was replaced by azathioprine between months 3-6. All patients received the same GCS treatment protocol: 1-3 g i.v. methylprednisolone followed by prednisone 1 mg/kg/d p.o. reduced to 40 mg/d by month 1, and then tapered and discontinued completely by month 6. The primary endpoint was disease remission in the absence of prednisone therapy at month 6. Remission was defined as a Birmingham Vasculitis Activity Score for Wegener's granulomatosis (BVAS/WG) of 0.

Results: Nine centers enrolled a total of 197 patients with severe Wegener's granulomatosis or microscopic polyangiitis (3:1), all positive for PR3-ANCA or MPO-ANCA (2:1). The mean BVAS/WG at enrollment was 8.4 (range 3-19). Disease severity, organ involvement, proportion of newly diagnosed disease (49%), AAV type, and ANCA type were similar in both treatment arms. All results reported refer to the initial 6 months of study participation for each patient. Eighty-four (85%) of the 99 patients in the RTX arm and 81 (83%) of the 98 in the CYC arm completed 6 months of follow-up. Sixty-three (64%) of the patients assigned to RTX achieved the primary outcome, compared with 52 (55%) in the CYC arm (P=0.21). Seventy patients (71%) in the RTX arm achieved a BVAS/WG of 0 and a prednisone dose < 10 mg/day at six months, compared with 61 patients (62%) in the CYC arm (P=0.22). No differences were observed between the groups in the rates of disease flares. The rates of protocol-defined selected adverse events were similar between the RTX and CYC groups (0.06 versus 0.08; P=0.29), but fewer patients in the RTX group experienced one or more of these events (19 vs 32 patients; P=0.03). There was no difference in treatment response within the subgroups with major renal involvement (n=99) or alveolar hemorrhage (n=50).

Conclusion: RTX is not inferior to CYC for the induction of remission in severe AAV. These results provide strong support for the use of RTX as an alternative to CYC in AAV.

Towards a Risk-Adapted Therapy to Maintain Clinical Remission in Juvenile Idiopathic Arthritis: Results of a Randomized Trial of 6 Versus 12 Months Withdrawal of Methotrexate. Dirk Foell[1], Nico Wulffraat[2], L. R. Wedderburn[3], Nicola Ruperto[4], Helmut Wittkowski[1], Michael Frosch[1], A. Martini[5], Johannes Roth[1] and Printo, [1]University of Muenster, Muenster, Germany, [2]University Medical Centre Utrecht, Utrecht, Netherlands, [3]UCL Institute of Child Health, London, United Kingdom, [4]IRCCS Istituto G. Gaslini, Universita' di Genova, Genova, Italy, [5]Pediatria-II PRINTO, IRCCS G. Gaslini, Genova, Italy

Purpose: Methotrexate (MTX) is effective in juvenile idiopathic arthritis (JIA), but about half of the patients experience a relapse after withdrawal. Thus prolonged treatment for at least another year in remission was recommended. We analyzed 1) whether the duration of treatment after reaching inactive disease status influences the risk of flares and 2) whether patients at risk for flares may be identified by molecular biomarkers.

Methods: A total of 364 JIA Patients with inactive disease for at least 3 months were randomized to discontinue MTX either 6 months (Group 1, n=183) or 12 months (Group 2, n=181) thereafter. At baseline, demographic and clinical characteristics were well balanced. At the time of withdrawal, Myeloid-Related Proteins 8 and 14 (MRP8/14) were analyzed.

Results: Six patients were lost to follow-up, and in 61 (16.8%) flare occurred before MTX stop (19 within 6 months in group 1 and 42 within 12 months in group 2). In the remaining 297 patients, there were 88/162 [54.3%] flares in group 1 and 59/135 [43.7%] in group 2). The flare rates were 28.8 *per* 1000 person-months in group 1 and 27.4 *per* 1000 person-months in group 2 (p=0.83). Clinical (disease subtype, duration or dosage of therapy, time of continuous MTX therapy in inactive disease) or standard laboratory (CRP, ESR) parameters could not differentiate between patients at risk for relapse and those without. In contrast, MRP8/14 levels were significantly higher in those patients who subsequently developed relapses (715±140 ng/ml) compared to patients with stable remission (400±105 ng/ml; p=0.003). MRP8/14 was even higher in patients with relapses occurring within 6 months (955±270 ng/ml; p<0.001). A Log-rank analysis confirmed the prediction of relapse risk at cut-off 690 ng/ml (p<0.001). **Conclusion:** Longer treatment with MTX in inactive disease does not in general improve the stability of remission. Clinical and therapeutic characteristic do not influence the risk of relapse. Subclinical disease activity may result in instable remission, e.g. a status of clinical but not immunologic remission. MRP8/14 as marker of phagocyte activity indicates subclinical inflammation and identifies patients with increased risk of relapse in whom therapy may not be safely stopped.

Tracking JIA Predisposition Genes From Genome-Wide Association Studies to Next Generation Sequencing to Functional Relevance. Terri H. Finkel[1], Edward M. Behrens[1], Yongwon Choi[2], Robert A. Eisenberg[2], Johannes Dapprich[3], Dimitrios S. Monos[1] and Hakon Hakonarson[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Generation Biotech, Lawrenceville, NJ

Purpose: Juvenile Idiopathic Arthritis (JIA) is the #1 cause of acquired disability in children. We recently identified TRAF1-C5 as a genetic locus associated with JIA, and have undertaken a comprehensive translational approach to elucidate the genetic contributions to this disease. Here, we identify single nucleotide polymorphisms (SNPs) associated with JIA by a genome-wide (GW) screen of a large well-phenotyped patient cohort; resequence loci with GW significant association; and for one candidate, TRAF1, employ a mouse model of inflammatory arthritis to probe the mechanisms by which the locus and its variants contribute to disease.

Method: We define genes and genomic regions with evidence for association with JIA in a discovery cohort of 1,500 cases (diagnosed by revised ILAR criteria) recruited from greater Philadelphia and internationally (Stage 1). In Stage 2, we selectively genotype an additional 1,000 existing samples from well-phenotyped JIA cases recruited by other collaborating sites. This database is leveraged against matched samples from >8,000 genotyped controls. In parallel studies, we use novel methodology to target and isolate regions of interest, and resequence genomic regions containing or in high linkage disequilibrium (LD) with TRAF1 and other putative disease variant SNPs in cases with polyarticular subtype JIA. To confirm functional relevance of a candidate locus, we assess onset and severity of arthritis after K/BxN serum transfer to TRAF1 mutant mice.

Results: We genotyped a cohort of >400 children with JIA and >80,000 other subjects (adults and children), using the Illumina HumanHap550/610Q BeadChip to track 600,000 polymorphisms. Our candidate gene analysis of JIA identified a predisposition locus in LD with the TRAF1-C5 locus (p=0.031, OR=1.38), and we identified multiple SNPs that tag a novel locus on 3p12.3 and achieve GW

significance ($p=4.94x10^{-8}$; OR=2.32). We utilized 'Region Specific Extraction' (RSE), a simple, automated method of enriching large chromosomal regions of genomic DNA that can be used directly in next generation sequencing platforms. We applied this technology to resequence the TRAF1 and PTPN22 genomic regions in high LD with putative disease variant SNPs in cases with polyarticular JIA. In a single RSE, we used 67 oligos to target 3 separate gene regions over 0.5 Mb total. >95% of all 3 target regions were successfully sequenced, with 100% concordance between sequencing and SNP genotyping data. We developed and characterized TRAF1-KO and –GFP-KI mice.

Conclusion: TRAF1-C5 and a novel locus on 3p12.3 are associated with all forms of JIA and could represent "master switches" predisposing to arthritis. The functional role of TRAF1 is assessed for the first time in a murine model of inflammatory arthritis (K/BxN). RSE can be used to target, sequence, and identify genomic variation in regions defined by significantly associated SNPs, with the goal of identifying genomic variations associated with JIA and elucidating potential pathogenic mechanisms.

555

The Association of Parity with Knee Osteoarthritis (OA) and Total Knee Replacement in the MOST Cohort. B.L. Wise[1], J. Niu[2], Y. Zhang[2], David T. Felson[3], Laurence A. Bradley[4], J. Torner[5], M. Nevitt[6] and N.E. Lane[1], [1]UCDMC, Sacramento, CA, [2]BUSM, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]UAL, Birmingham, Birmingham, AL, [5]UIowa, Iowa City, IA, [6]UCSF, SF, CA

Purpose: A recent study found that risk of total knee replacement (TKR) among women increased on a per-birth basis. The purpose of this study was to further evaluate the association of TKR and knee OA with parity.

Method: The NIH-funded Multicenter Osteoarthritis Study (MOST) is a longitudinal observational study of persons age 50 to 79 years with either symptomatic knee OA or at high risk of disease. Women in the study reported their number of births at the 30 month visit. Baseline and 30 month knee radiographs were collected and read, and radiographic OA (ROA) was defined as Kellgren/Lawrence (K/L) grade>=2. Women were grouped based on their number of children: 0, 1-3 births, and 4 or above. We examined the relation of parity to the prevalence of baseline ROA and TKR, to incident ROA and to incident TKR over the 30 month follow-up as well as to prevalent TKR at 30 months using a Poisson regression model. Generalized estimating equations were used to control for correlation between two knees within a subject. We adjusted for age, BMI, race, education, labor occupation versus non-labor versus “other”, WOMAC pain subscale at baseline, pain medication, and baseline K/L grade (WOMAC, medication, and K/L grade not used in the prevalent TKR analyses; prevalent and incident OA analyses also adjusted for history of knee injury or surgery).

Results: 1820 women reported parity information at the 30 month visit (mean age 62.6, mean BMI 30.7, mean WOMAC pain subscale score 3.7). Women who had 4 or more children were older, were more likely to have a labor occupation, and had lower education levels than women with 0 or 1-3 children. After adjusting for covariates, compared to nulliparous women, those with 1-3 children had a 70% increased risk of incident TKR (RR=1.7, 95% CI 0.8, 4.0), while women with 4-12 children had a 2-fold increased risk for incident TKR (RR=2.0, 95% CI 0.8, 4.9) (p for trend=0.03). At baseline there were only 45 prevalent TKRs, which was not enough to achieve significance. After adjusting for covariates, compared to nulliparous women, those with 1-3 children had a relative risk of 30 month prevalent TKR of 2.4 (95% CI 1.2, 4.8), while women with 4-12 children had a relative risk for prevalent TKR of 2.3 (95% CI 1.1, 4.9). No association was observed between parity and baseline ROA, but incident tibiofemoral ROA was slightly increased in women with 4-12 children (RR 1.5; 95% CI 0.8, 2.8), although this observation did not reach significance.

Conclusion: Parity in women is associated with incident and prevalent TKR, but we did not find an association with prevalent or incident radiographic OA. This suggests that the effect of parity on risk of TKR is not an artifact of an association between parity and ROA, but instead may be mediated by social, neurological, hormonal or other factors.

Relationship of Weight and Weight Change with Knee Pain and Function in Persons with Symptomatic Radiographic Knee Osteoarthritis: Two-Year Data From the Osteoarthritis Initiative. Danuta I. Bujak, Knachelle Favors, John D. Sorkin and Marc C. Hochberg, University of Maryland School of Medicine, Baltimore, MD

Purpose: Overweight is a major risk factor for the development and progression of knee osteoarthritis (OA) and weight loss is recommended as part of the non-pharmacologic management of patients with knee OA. This analysis examined the relationship between weight and weight change and change in self-reported symptoms and function and physical performance in adults with symptomatic radiographic knee OA over two years.

Method: Data for this analysis were obtained from the Osteoarthritis Initiative (OAI) public access database (http://www.oai.ucsf.edu). Specifically, we examined data from the baseline, 12- and 24-month follow-up visits for subjects with symptomatic radiographic knee OA enrolled in the OAI Progression subcohort. Subjects completed the Western Ontario McMaster Osteoarthritis Index (WOMAC) and the Knee Osteoarthritis Outcome Score (KOOS) at all visits and the Physical Activity Scale for the Elderly (PASE) at the baseline and 24-month follow-up visits. Weight was measured with a balance beam scale and physical performance was measured with a timed 20-meter walk at all visits and a timed 400-meter walk at baseline and 24-month follow-up visits; height was measured with a stadiometer at baseline. Names and dosages of medications and dietary supplements were recorded at all visits by trained personnel. Correlations between weight and weight change and change in outcomes were examined in multiple variable adjusted models using repeated measures analysis and generalized estimating equations to control for the correlation between knees in subjects with both knees involved at baseline.

Results: Of 1388 subjects with symptomatic radiographic knee OA in one or both knees enrolled in the Progression subcohort, 1189 (85.7%) and 1109 (79.9%) completed 12- and 24-month follow-up visits, respectively. The mean (SD) age at baseline was 61.4 (9.1) years; 791 (57.1%) were women and 972 (70.2%) were white. The mean (SD) weight and body mass index (BMI) at baseline were 86.1 (16.2) kg and 30.2 (4.9) kg/m^2, respectively. Mean (SD) weight change from baseline to 12 months and from 12 to 24 months were -0.31 (4.2) and -0.06 (3.8) kg, respectively. In analyses adjusted for age, sex, race and use of analgesic and/or antiinflammatory drugs at each visit, weight change was significantly correlated with WOMAC stiffness, function and total score (but not pain score), PASE score and 20-meter walk speed. In similar multiple variable adjusted analyses, absolute weight was significantly correlated with all clinically relevant outcomes with heavier persons having more pain and worse function.

Conclusion: These data support an association between weight loss and improvement in function assessed by both self-report and performance measures but not pain in persons with symptomatic radiographic knee OA. In addition, greater absolute weight was significantly associated with higher pain scores and worse function at all visits. These data support recommendations for weight loss in persons with symptomatic knee OA.

Patterns of Compartment Involvement in Tibiofemoral Osteoarthritis (TFOA) in Men and Women and in Caucasians and African Americans: The MOST Study. B.L. Wise[1], M. Yang[2], J. Niu[2], N.E. Lane[1], W.F. Harvey[3], David T. Felson[4], M. Nevitt[5], J. Hietpas[5] and Y. Zhang[2], [1]UCDMC, Sacramento, CA, [2]BUSM, Boston, MA, [3]NEBH, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]UCSF, SF, CA

Purpose: Previous studies have reported ethnic differences in radiographic OA and malalignment for medial versus lateral compartment TFOA. We conducted a cross-sectional study to describe the compartmental patterns of TFOA between men and women as well as between Caucasians (CC) and African Americans (AA), and assess whether the difference, if present, was related to differences in knee malalignment between comparison groups.

Method: The NIH-funded Multicenter Osteoarthritis Study (MOST) is an observational study of persons age 50 to 79 years with either symptomatic knee OA or at high risk of disease. In knees with radiographic OA (ROA; Kellgren/Lawrence grade>=2), we defined medial compartment involvement as maximum medial joint space narrowing (JSN) on baseline radiograph PA view greater than maximum lateral JSN, and lateral compartment involvement as maximum lateral JSN greater than maximum medial JSN; if a knee had equal maximum JSN, it was considered to have both compartments involved if JSN>0 and neither involved if JSN=0. Using long limb films, valgus malalignment was defined as mechanical axis angle >181 degrees, while varus malalignment was defined as < 179 degrees. We compared the proportion of JSN in lateral and medial compartments among subjects with ROA between men and women as well as CC and AA using a logistic regression model adjusting for age, BMI, education, and prior injury to the knee. We also explored whether knee alignment was related with any difference in prevalence of lateral and medial JSN by adding this variable to the model. We used generalized estimating equations to account for correlation between two knees within a subject.

Results: Of 2014 knees with TF ROA, 1554 knees (77.2%) had medial JSN, and 414 knees (20.6%) had lateral JSN (107 knees had neither). Lateral JSN was more prevalent in women than in men (OR=1.84, 95% CI 1.40-2.42) and was also more prevalent in AA than in CC (OR=2.22, 95% CI: 1.59-3.11). The differences in proportion of lateral JSN between men and women as well as between CC and AA were consistent across K/L grades. Among knees without ROA, women were more likely than men to have valgus alignment, but there was no difference in malalignment between AA and CC. After further adjustment for knee alignment, we found no difference between women and men in proportion of lateral JSN (OR=0.74, 95% CI: 0.51-1.07), but continued to find a difference between AA and CC (OR=3.04, 95% CI: 1.96-4.74).

Conclusion: Women and AA with TF ROA are more likely to have lateral JSN. After adjusting for malalignment this difference disappeared between men and women but remained significant between AA and CC. These findings suggest that factors other than alignment may account for observed compartment specific differences in OA by race.

A Biomechanical Approach Predicts Hip Fracture Independent of Bone Mineral Density (BMD) in Women: The Framingham Osteoporosis Study. Alyssa B. Dufour[1], Benjamin Roberts[2], Douglas P. Kiel[3], Mary L. Bouxsein[2] and Marian T. Hannan[3], [1]IFAR, Boston, MA, [2]BIDMC, Boston, MA, [3]Hebrew SeniorLife & Harvard Medical School, Boston, MA

Purpose: Hip fractures are disabling events for older persons. Studies have identified low BMD as a major risk factor, yet up to half of those suffering a hip fracture do not have low BMD; thus, alternative methods of assessing fracture risk are needed. One such method is the biomechanical Factor-of-Risk (Φ), defined as the ratio of force applied to the hip from a sideways fall to femoral bone strength. We examined the relation between Φ and risk of hip fracture in men and women of the population-based Framingham Study.

Method: Subjects included 1100 Framingham Original Cohort members who had hip BMD scans (LUNAR DPA) in 1988-89 (baseline). Body weight, height (used to calculate BMI (kg/m^2)) and age were measured at baseline. Incident hip fractures were ascertained and confirmed by interview and review of medical records through 12/31/05. We calculated Φ in two ways: using the ratio of either the estimated peak force or the attenuated (atten) force applied to the hip in a sideways fall from standing height divided by the femoral strength. Peak force (N) was calculated from height (m) and weight (kg). The attenuated force incorporated the cushioning effect of trochanteric soft tissue thickness (mm), as estimated by BMI, using published sex-specific regressions. Femoral strength (N) was estimated from femoral neck BMD, using a relation derived from published cadaveric femoral strength testing. Sex-specific crude, age- and BMD-adjusted Cox Proportional Hazards regressions were used to calculate hazard ratios (HR) and 95% confidence intervals (CI) for the relation between hip fracture risk and both Φ_{peak} and Φ_{atten}.

Results: In the 425 men and 675 women (mean age 76 yrs) mean BMI was 26.8 kg/m^2. Median follow-up was 11.3 yrs and 155 hip fractures occurred (28 in men). Φ_{peak} and Φ_{atten} were associated with increased risk of hip fracture, adjusting for age (Table). A 1 SD increase in Φ_{peak} was associated with a HR of 1.88 in men and 1.23 in women. Similarly, for Φ_{atten}, the HR for hip fracture was 1.78 in men and 1.41 in women. After adding BMD to the model, Φ_{atten} remained predictive of hip fracture in women. In men, we could not adjust for BMD due to collinearity with Φ.

Conclusion: In summary, both Φ_{peak} and Φ_{atten} predict subsequent hip fracture in men and women. In women, we showed for the first time that Φ_{atten} predicts hip fracture independent of hip BMD. These findings provide strong rationale for additional studies testing the ability of this biomechanical approach to predict hip fracture.

Table: Adjusted hip fracture hazard ratios (95% CI) in men and women for a 1 standard deviation (SD) increase.

Model	**Men**	**Women**
Age-adjusted		
Factor-of-Risk$_{peak}$	1.88 (1.38, 2.55)	1.23 (1.10, 1.37)
Factor-of-Risk$_{attenuated}$	1.78 (1.30, 2.44)	1.41 (1.26,1.58)
Age- and BMD-adjusted		
Factor-of-Risk$_{peak}$	– *	0.80 (0.51, 1.27)
Factor-of-Risk$_{attenuated}$	– *	1.20 (1.01,1.41)

*In men, Factor-of-Risk$_{peak}$ and Factor-of-Risk$_{attenuated}$ were collinear with BMD. Therefore, we were unable to examine this association.

Predicting Arthritis-Related Work-Transitions within One Year: Which at-Work Disability Measure Is Best? Kenneth Tang[1], Dorcas E. Beaton[1], Monique A. Gignac[2], Diane Lacaille[3], Elizabeth M. Badley[2], Aslam H. Anis[3] and Claire Bombardier[4], [1]St. Michael's Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of British Columbia, Vancouver, BC, [4]University Health Network, Toronto, ON

Purpose: To cope with the effects of arthritis, workers may opt to reduce work hours, take a disability leave of absence, or change jobs. Evidence of such "work-transitioning" is a concern, and may indicate a risk for future work loss. The ability to predict arthritis-related work-transitions would be useful for early identification of workers at-risk. Our aim is to assess and compare the ability of three at-work disability measures to predict arthritis-related work-transitions over a 1 year period.

Method: Workers with arthritis (*n*=250, OA=130, RA=120) recruited from community or clinical settings were followed for 1 year (four timepoints: baseline & 3, 6, 12-month follow-up). Measures tested as predictors include the *Workplace Activity Limitations Scale* (WALS, range=0-33), *Work Instability Scale for Rheumatoid Arthritis* (RA-WIS, range=0-23), and *Work Limitations Questionnaire* (WLQ, index range=0-28.6), all with previous validation in both OA and RA. To compare their predictive ability, 3 parallel multivariate logistic regressions were performed with work-transitioning expressed as a dichotomized outcome (occurrence vs. non-occurrence within 1 year). Each model featured 1 of the 3 measures to be compared, in addition to statistically-relevant covariates (e.g. pain intensity, HAQ) controlled across parallel models. Statistical indictors of model fit and predictive ability (AIC, Cox & Snell's pseudo R^2, standardized coefficient [std β]) were directly compared across models, as well as adjusted odds ratio (OR) associated with the 3 measures. In addition, area under the receiver operating characteristic curve (AUROCC, 95%CI) was also assessed for each measure for further comparisons of discriminative ability.

Results: Within 1 year, 20.4% of the sample had made a work-transition. Although all 3 regression models showed some ability to predict this outcome, the lowest AIC and highest pseudo R^2 were observed when the RA-WIS was the predictor measure. An increase in RA-WIS score (std β=0.24, OR=1.1 [95%CI: 1.0-1.2]) was also shown to have greater predictive ability than any of the covariates assessed (std β=0.05-0.15). Notably, HAQ scores were consistently found to contribute little to the prediction of a work-transition. Between the 3

measures, the RA-WIS also demonstrated the largest AUROCC associated with specific forms of work-transitions assessed (disability leave: 0.74 [0.58-0.89]; reduced work hours: 0.81 [0.72-0.89]; job change: 0.61 [0.45-0.78]), indicating superior discriminative ability.

Conclusion: Overall, all 3 measures were found to contribute to the prediction of arthritis-related work transitions, with the RA-WIS emerging as the slightly better performer. Constancy of the predictive effects of the scales was also found to be independent of the influence of HAQ scores.

Berg Balance and Risk of Indoor and Outdoor Falls in Elderly Men and Women. Uyen-Sa DT Nguyen[1], Lien Quach[1], Jennifer L. Kelsey[2], Douglas P. Kiel[1], Andrew M. Galica[1], Carol A. Oatis[3] and Marian T. Hannan[1], [1]IFAR HSL, Boston, MA, [2]UMass, Worcester, MA, [3]Arcadia Univ, Glenside, PA

Purpose: Falls occur frequently, 1/3 of older adults have a fall each year. Balance, as measured with the Berg Balance Scale (BBS), has been shown to be a risk factor of falls in nursing home patients but its association with falls in community-dwelling older adults is less clear. Furthermore, little research has examined the association of balance with indoor and outdoor falls. The goal of this study was to examine the association of BBS with risk of falls separately for indoor and outdoor falls in community-dwelling older adults.

Method: We studied the 765 participants from MOBILIZE Boston, a population-based prospective cohort study of elderly men and women living in the Boston area. We assessed balance using the BBS (range: 0 – 56), and followed the cohort for falls using monthly falls calendars (mean follow-up: 1.8 years). We dichotomized BBS using the clinical cut-point for poor balance of 45 (BBS <= 45 vs. BBS > 45), and calculated annualized fall rates (number of falls/year of follow-up) separately for indoor and outdoor falls. We used negative binomial regression to estimate incidence rate ratios (RRs) and 95% confidence intervals (CIs), and controlled for factors related to both falls and balance including age (years), college education (y/n), fall in the past year (y/n), depression symptoms (CESD-R), number of medications, physical activity (PASE), and vision (> 40/100).

Results: Poor balance (BBS <= 45) occurred in 16% of participants. Those with poor balance had an annualized fall rate of 0.83 per person year (ppy) for indoor and 0.24 ppy for outdoor falls. Those with BBS > 45 had an annualized fall rate of 0.35 ppy for indoor and 0.39 ppy for outdoor falls. Baseline characteristics are shown in Table 1. Adjusting for confounders (Table 2), those with BBS <= 45 compared to BBS > 45 had a 70% increased rate of indoor falls (95% CI: 1.2, 2.4) and a 30% decreased rate of outdoor falls (95% CI: 0.4, 1.0).

Conclusion: Poor balance was associated with an increased rate of indoor falls, and was inversely associated with the rate of outdoor falls in our population-based cohort of older adults. Our results indicate that poor balance is related differently to indoor and outdoor falls and that these outcomes should be examined separately.

Table 1. Baseline Characteristics of Study Population

	Mean ± SD or N (%)*	
Characteristics	**BBS <= 45 (n=126)**	**BBS > 45(n=638)**

ACR Concurrent Abstract Sessions

Clinical Aspects of Systemic Lupus Erythematosus

Sunday, October 18, 2009, 2:30 PM - 4:00 PM

561

A Randomised Controlled Trial of Mycophenolate Mofetil Versus Placebo On Surrogate Markers of Atherosclerosis in Systemic Lupus Erythematosus. R. Davies, SR. Sangle, V. Murru, ML. Bertolaccini, Munther A. Khamashta and David P. D'Cruz, Lupus Research Unit, The Rayne Institute, King's College London School of Medicine, St Thomas' Hospital, London, United Kingdom

Purpose: Systemic lupus erythematosus (SLE) is an independent risk factor for atherosclerosis. Endothelial dysfunction is the earliest marker of atherosclerosis and is measured by flow mediated dilation (FMD) of the brachial artery. The purpose of the study was to measure FMD in mild, stable SLE patients and look for change in FMD with the immunosuppressant drug mycophenolate mofetil (MMF).

Method: A prospective, double-blind, randomised, placebo-controlled trial evaluating MMF on surrogate markers of atherosclerosis in mild SLE. 70 females fulfilling ACR criteria were recruited and allocated by minimisation to either placebo or MMF 1gm bd for 8 weeks. The primary end point was change in FMD assessed on an intention to treat basis. Other inclusion criteria were mild and stable disease, 18-60 years, on hydroxychloroquine and/or ≤15mgs prednisolone od. Exclusions were severe active disease, other immunosuppressants, smokers, diabetes mellitus and ischaemic heart, cerebrovascular or end stage renal disease. A minimum of 30 subjects per group were required to detect a change in FMD with a power of 90% at a 5% significance level.

Results: Seventy patients were recruited and 63 completed the study. The FMD for both groups was within the normal range at baseline and failed to change significantly post treatment. There was a significant decrease in BILAG score within the treatment group and this was reflected by a downward trend in Hs-CRP levels, although not reaching statistical significance. The Hs-CRP rose significantly during the study period in the placebo group. Secondary end points looked at change in levels of serum biomarkers previously shown to be associated

with increased cardiovascular risk (ADMA) and endothelial dysfunction (tPA and PAI-1), however levels failed to change in either group and using multiple regression analysis there were no assoiciations with reduced FMD or traditional cardiovascular risk factors.

Table 1

	Placebo visit 1	Placebo visit 2	p values	MMF visit 1	MMF visit 2	p value
FMD%	7.61 (±3.48)	7.29 (±3.21)		8.36 (±4.11)	8.98 (±5.47)	
BILAG	9.8 (±4.2)	9.5 (±4)		10.1 (±4.5)	8.5 (±3.9)	p=0.03
HsCRP	5.1 (±5.8)	7.4 (±9.7)	p=0.05	6.3 (±8.6)	5.8 (±7.4)	
ADMA	0.39 (±0.23)	0.38 (±0.16)		0.36 (±0.22)	0.35 (±0.17)	
tPA	16.03 (±	19.83 (±		29.33 (±	18.39 (±	
PAI-1	23.07 (±20.12)	23.08 (±19.98)		21.35 (±14.56)	23.29 (±12.55)	

Values; mean(±sd), BILAG; British Isles Lupus Assessment Group disease activity score, HsCRP; high sensitivity C-reactive protein (mg/l), ADMA; Asymmetric dimethylarginine (µmol/l), tPA; Tissue plasminogen activator (ng/ml), PAI-1; Plasminogen activator inhibitor 1 (ng/ml).

Conclusion: Endothelial function is well preserved In SLE patients with mild, stable disease on hydroxychloroquine and with few or absent traditional cardiovascular risk factors. It is likely that aggressive immunosuppressive treatment to suppress vascular inflammation may not be warranted in these patients.

Low Mycophenolic Acid Area Under the Curve Is a Major Parameter of Systemic Lupus Erythematosus Activity. Laurent Arnaud[1], Noël Zahr[2], Julien Haroche[1], Jean-Sébastien Hulot[2], Pierre Marquet[3], Christian Funck-Brentano[2], Jean-Charles Piette[1] and Zahir Amoura[1], [1]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [2]Department of Pharmacology, Pitié-Salpêtrière Hospital, Paris, France, [3]INSERM U850, Limoges, France

Purpose: Mycophenolate Mofetil (MMF) is widely used for the treatment of Systemic Lupus Erythematosus (SLE). Mycophenolic Acid (MPA) is the active metabolite of MMF. In transplantation, MPA Area Under the plasma Concentration-time Curve from 0 to 12 hours (MPA AUC_{0-12}) is the most reliable assessment of MPA exposure and is correlated with the clinical outcome. We assessed possible relationships between SLE activity and MPA AUC_{0-12}.

Method: Seventy-one consecutive SLE patients, 61 women and 10 men, mean (± SD) age at sampling 34 ± 10 years, with stable MMF dose, were enrolled in the study. On the same day, SLE activity was assessed with the SLEDAI and the BILAG (SLEDAI-active and BILAG-active SLE were defined, respectively, as SLEDAI ≥ 6 or BILAG A or B). MPA AUC_{0-12} was determined by using a Bayesian estimator developed for SLE.

Results: Two groups were studied: active SLE (n=26; mean SLEDAI: 11.6 ± 4.4) and inactive SLE (n=45; mean SLEDAI: 1.9 ± 1.6), that were similar for sex-ratio, mean age at sampling, mean weight, mean Body Mass Index, mean daily doses of MMF, of steroids, and mean hydroxychloroquine blood levels. MPA AUC_{0-12} correlated weakly with the daily dose of MMF (r=0.33, p=0.005). Mean (±SD) MPA AUC_{0-12} of the active SLE group was significantly lower than that of the inactive SLE group (26.8 ± 13.6 µg.h/ml vs 46.5 ± 16.3 µg.h/ml, respectively; p<0.0001). MPA AUC_{0-12} negatively correlated with the SLEDAI (r=-0.64, p<0.0001), with anti-dsDNA levels (r =-0.25,

p=0.04), and correlated positively with C3 levels (r=0.38, p=0.001). Similar results were obtained when comparing BILAG-active and BILAG-inactive patients. In multivariate analysis, MPA AUC_{0-12} was the sole independent parameter associated with SLE activity (odds ratio = 0.893; 95% CI = 0.834-0.956; p = 0.001). By ROC curve analysis, we determined that the MPA AUC_{0-12} value of 35 µg.h/ml provided the best trade-off between sensitivity and specificity associated with the lowest risk of SLEDAI- or BILAG-active SLE on the day of sampling.

Conclusion: SLE activity is strongly correlated with MPA AUC_{0-12} in SLE. Individualized dosing regimen of MMF, with a recommended target AUC threshold of 35 µg.h/ml has to be considered to improve the efficacy of MMF in SLE. Because there is a high inter-individual variability of MMF pharmacokinetics, it is now mandatory to include MPA AUC_{0-12} in future clinical trials evaluating MMF in SLE.

563

Validation of Interferon-Regulated Chemokines as Predictors of Lupus Flare. Jason W. Bauer[1], Michelle Petri[2], Franak Batliwalla[3], Joseph C. Wilson[1], Thearith Koeuth[1], Marlene Hyer Kern[3], Sukhminder Singh[2], Hanna Tesfasyone[2], Peter K. Gregersen[3], Timothy W. Behrens[4] and Emily C. Baechler[1], [1]University of Minnesota, Minneapolis, MN, [2]JHU, Baltimore, MD, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]Genentech, South San Francisco, CA

Purpose: We previously showed that serum levels of interferon (IFN)-regulated chemokines are biomarkers of systemic lupus erythematosus (SLE) disease activity. In a cohort of 267 SLE patients, high baseline chemokine levels were predictive of flare. Here we have measured serum levels of IP-10, MCP-1, and MIP-3b in an independent group of 373 SLE patients in a replication study.

Method: We studied 373 SLE patients enrolled from the Hopkins Lupus Cohort via the Autoimmune Biomarkers Collaborative Network. Clinical and laboratory data were available for 1 year of follow-up (1815 visits). Multiplex sandwich-based immunoassays were used to measure serum levels of IP-10, MCP-1, and MIP-3b. A normalized chemokine score was used to reflect the combined levels of all 3 chemokines. For flare prediction, we selected baseline visits from 257 patients with mild or inactive disease (SLEDAI≤4) and tabulated flares within 1 year (increase in SLEDAI≥3). ROC curves were used to identify the chemokine concentration with optimal sensitivity and specificity for flare prediction. These concentrations were used to stratify patients into chemokine-high and –low groups, and flare rates were compared by Kaplan-Meier (KM) analysis. Univariate Cox regression was performed with chemokines and laboratory tests with flare-free survival as the dependent variable. Significant variables were subjected to stepwise multivariate Cox regression.

Results: As expected, patients with active SLE (SLEDAI≥6; n=50) had elevated chemokine levels vs. inactive SLE (SLEDAI≤2, PGA=0; n=94) ($p<2x10^{-10}$). In KM analysis, flare rates were significantly higher in patients who had high baseline levels of IP-10, with 41% of IP-10 high patients and 23% of IP-10 low patients having a flare (p=0.002). Similar results were obtained with MIP-3b (46% of MIP-3b high vs. 27% of MIP-3b low patients; p=0.006), but not MCP-1 (29% of MCP-1 high vs. 32% of MCP-1 low; p=0.49). The composite chemokine score reached greater significance than any single chemokine (42% of chemokine-high vs. 23% of chemokine-low; p=0.001). Significant flare predictors from univariate Cox regression were IP-10 (p=0.001), chemokine score (p=0.002), MIP-3b (p=0.01), anti dsDNA Abs (p=0.02), ESR (p=0.04) and C3 (p=0.04). These variables was subjected to a multivariate analysis in which only IP-10 levels were significant (p=0.002)

Conclusion: This is the first validation, in an independent group of 257 SLE patients, of our previous report that chemokine levels are predictive of flare. Our data suggest that IP-10 may have the greatest predictive power, and further studies are needed to determine whether models containing both chemokines and laboratory results will prove optimal.

Urine Cyto/Chemokines Correlate with Renal Histopathology in Systemic Lupus Erythematosus. C. Landolt-Marticorena[1], H. Reich[2], S. Morrison[3], E. Aghdassi[3], C. A. Pineau[4], J. Scholey[5], D. Gladman[3], M.B. Urowitz[1], A. Herzenberg[5], P. R. Fortin[6], J. E. Wither[1] and CaNIOS LuNNET Investigators, [1]U of Toronto, Toronto Western Hospital, Toronto, ON, [2]University Heath Network, Toronto, ON, [3]Toronto Western Hospital, Toronto, ON, [4]MUHC, Montreal, QC, [5]University Health Network, Toronto, ON, [6]U. Toronto, Toronto, ON

Purpose: Renal biopsies are the gold standard for the assessment of renal activity and chronicity in SLE patients. Urinary biomarkers may serve as a less invasive alternative in the management of lupus nephritis (LN). In an initial screen of 20 cyto/chemokines urine concentrations of IP-10, MCP-1, adiponectin, IL-15 and sVCAM were found to be elevated in patients with active LN. We therefore examined the relationship between renal histopathology and the urine concentration of these 5 analytes at the time of biopsy.

Methods: Patients (n = 22) satisfying 4 or more ACR criteria undergoing renal biopsy were recruited from a longitudinal clinical cohort. Plasma and urine were obtained coincident with biopsy. 19 healthy controls were also recruited. The plasma and urine concentrations of 5 analytes was determined by a Luminex assay with urine concentrations corrected for creatinine excretion. Patients were segregated into active (ISN/ASN; III to V; n = 19) and inactive (chronic, n = 3) based on renal histopathology. Elevated urine analyte concentration was defined as values ≥ 2 standard deviations above the mean in controls. Mann Whitney non-parametric test was used for comparisons between groups. The statistical significance of correlations was determined by linear regression analysis.

Results: The urine concentration of IP-10 ($p < 0.0001$), MCP-1 ($p < 0.0001$), adiponectin ($p = 0.0004$), IL-15 ($p = 0.0006$) and sVCAM ($p = 0.007$) were significantly elevated in SLE patients versus controls. There was a moderate positive correlation between the urine and plasma concentration of IP-10 ($r = 0.54$, $p = 0.009$) but none of the other analytes. Elevated urine concentrations of MCP-1, IP-10, adiponectin and IL-15 were seen in 82.3%, 68.1%, 54.5% and 40.9% respectively. As only 22.7 % of patients had elevated urine sVCAM this analyte was excluded from further analysis. To assess if increased urinary analyte concentrations discriminate between active and inactive LN, the absolute number of elevated values for all 4 analytes were summed to create a global score (maximum = 4). Patients with active renal lesions had a statistically significant increase ($p = 0.03$) in the global score versus patients with established fibrosis. All 3 patients with fibrosis had scores ≤ 1 whereas the majority (73.8 %) of patients with active renal lesions had scores ≥ 2. In patients with proliferative lesions (ISN III or IV) 85.7% patients (n = 14) had scores of 2 or greater whilst 75 % (n = 4) patients with membranous LN (ISN V) had scores of 1 with a single patient having a score of 4.

Conclusion: Urinary elevation in selected cyto/chemokines effectively discriminate between active and chronic renal lesions. The elevation of 2 or more analytes was sufficient to identify proliferative renal lesions. These results suggest that urinary cyto/chemokines reflect underlying renal pathology and may serve as alternatives to renal biopsy.

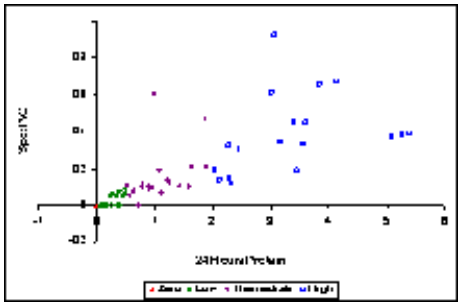
Expressing Urinary Protein Excretion in Lupus Nephritis. Debra Dye-Torrington[1], Emily Siu[2], Dominique Ibañez[1], Murray B. Urowitz[1] and Dafna D. Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON

Purpose: Lupus nephritis is seen in more than 50% of patients with SLE and is one of the most serious manifestations of this disease. Kidney involvement in these patients is monitored by the amount of proteinuria. This is ordinarily done by measuring total protein in a 24hr urine collection. A more convenient way of measuring proteinuria is the protein-to-creatinine ratio in an untimed urine (spot p/c ratio).Whether this is an accurate measure of high proteinuria is still not clear. The objective of this study was to determine the correlation between p/c ratio and 24 hr urine protein among patients with SLE over a range of proteinuria.

Method: SLE patients recruited from a single centre were asked to collect a spot urine within 24 hrs after the end of the 24 hr urine collection. 24 hr protein excretion was categorized into three groups: Low <0.5g/24h, intermediate 0.5-2g/24h, high >2.0g/24h. Comparison of P/C ratio with levels of proteinuria was done through correlation coefficients.

Results: 76 samples of 24hr urine and spot urines were collected. (86%) of the patients were female, 50% Caucasian, 19% Black, 18% Chinese and 12% Other. Age (± std) at SLE diagnosis was 28.8 ± 12.4 years and disease duration at the time of sampling was 11.8 ± 6.9 years. 84% of the samples were positive for protein. 25(33%) were in the low range, 21(28%) were intermediate and 18(24%) were high. The mean Spot P/C (± std) by protein levels was; for no protein, Spot P/c 0 ± 0; for low protein, Spot P/C 0.02 ± 0.03; for intermediate

protein, spot P/C 0.15 ± 0.14; for high protein, spot P/C 0.39 ± 0.21 Overall, the correlation coefficient between all 24 hours protein and spot P/C was 0.79 (p<0.0001). For each of the protein level, the correlation coefficient with spot P/C was; for low protein, r=0.69 (p=0.0001); for intermediate protein, r=0.44 (p=0.05); for high protein, r = 0.34 (p=0.16). *Plot of 24 hours protein with Spot P/C by protein levels.*



Conclusion: There is a poor correlation between spot P/C ratios and 24 hour urine protein excretion at levels of proteinuria of 2 grams or more. P/C ratios should not be used to monitor protein excretion in patients with lupus nephritis.

Impact of Clinical and Demographic Features On Influenza Vaccination Responses in Human Systemic Lupus Erythematosus.

Sherry R. Crowe[1], Jourdan R. Anderson[1], Amy B. Dedeke[2], Virginia C. Roberts[1], Gillian M. Air[2], Linda F. Thompson[1] and Judith A. James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma University Health Sciences Center, Oklahoma City, OK

Purpose: Infectious diseases are a serious cause of morbidity and mortality in immunocompromised individuals, such as those with systemic lupus erythematosus (SLE). Vaccination against common infections, such as influenza, is recommended for SLE patients to decrease infections and improve health. However, few reports detail how SLE patients respond to this common vaccination. The goal of this study is to understand the clinical, serological, therapeutic, and demographic factors which influence the immune response to influenza vaccination in SLE patients.

Method: Over three influenza seasons (October 2005 to February 2008), 72 SLE patients and matched controls were enrolled. Each individual provided detailed clinical (medication usage, previous vaccinations, etc) and demographic (age, race, etc) information. Blood was collected from each individual on the day of influenza vaccination, as well as two, six, and twelve weeks post vaccination. Influenza-specific antibody responses were evaluated by standard ELISAs, relative antibody affinities, and hemagglutination inhibition levels. Based upon these data, individuals were grouped into high and low responders. Autoantibody levels were evaluated at each time-point by immunoflourescence and standard ELISAs.

Results: Poor responders to influenza vaccination were more likely to have hematologic criteria (p = 0.009), exhibit more ACR criteria (p = 0.05), and be receiving prednisone treatment (p = 0.037). No significant differences in the initial autoantibodies between the high and low responders were found, although low responders were more likely to have serum anti-cardiolipin antibodies. Interestingly, the high influenza responder group was enriched for African Americans (p = 0.03) and in fact low responders were 3 times more likely to be Caucasian than African American. All measures of disease activity significantly increased following vaccination: SLEDAI (p = 0.012), PGA (p = 0.007), and SLAM (p = 0.001), but disease activity changes were not enriched in either the high or low responders. Finally, low responders were more likely to increase ANA titers following vaccination (p = 0.045).

Conclusion: In summary, influenza vaccination impacts a significant fraction of SLE patients by increasing autoantibody production and/or disease activity. Poor responders have more ACR criteria, use prednisone and have hematological criteria, suggesting that studies of split doses or withholding prednisone on day of vaccination in some patients may be warranted.

ACR Concurrent Abstract Sessions

Fibromyalgia and Soft Tissue Disorders I: Diagnosis and Management

Sunday, October 18, 2009, 2:30 PM - 4:00 PM

567

Clinical Diagnostic and Severity Criteria for Fibromyalgia. F. Wolfe[1], Daniel Clauw[2], MA Fitzcharles[3], Don L. Goldenberg[4], KA Harp[1], RS Katz[5], PJ Mease[6], KD Michaud[7], Anthony S. Russell[8], IJ Russell[9], JB Winfield[10] and MB Yunus[11], [1]National Data Bank, Wichita, KS, [2]University of Michigan, Ann Arbor, MI, [3]MGH, Montreal, QC, [4]Newton-Wellesley Hosp, Newton, MA, [5]Rheumatology Associates, Chicago, IL, [6]Seattle Rheumatology, Seattle, WA, [7]U Neb Med Cntr and NDB, Omaha, NE, [8]U Alberta, Edmonton, AB, [9]U TX Hlth Sci Ctr, San Antonio, TX, [10]UNC, Chapel Hill, NC, [11]U IL Coll of Med, Peoria, IL

Purpose: Among the criticisms of current ACR fibromyalgia criteria is their reliance on the tender point (TP) examination, which is largely ignored in primary care, and the absence of criteria items, beyond pain, that relate to key fibromyalgia symptoms by which patients are identified and diagnosed clinically. However, ACR criteria represent the gold standard, and any modified criteria must move away from the ACR definition to some extent. We performed a multicenter study to develop clinical diagnostic criteria while remaining generally true to the ACR classification criteria.

Methods: We performed a two-stage 55-site multicenter study of 1,002 FM patients and pain controls to develop simple clinical criteria for fibromyalgia. Physicians and patients were evaluated separately. Patients underwent a detailed interview and examination, including TP examination and assessment of the extent of widespread pain using a 0-19 widespread pain index (WPI), and also completed a detailed questionnaire. We used Random Forest data mining methods in a series of analyses that included a maximum of 134 variables to identify best variables for FM criteria, not including tender points. Some variables (e.g., fatigue) were included in continuous and categorical forms.

Results: The WPI was the best predictor of FM. Analyses excluding WPI identified unrefreshed sleep, fatigue, cognitive difficulties, and the extent of somatic symptom reporting as the key FM predictors. We combined the 4 categorical symptom variables into a 0-12 Symptom Severity (SS) scale. The SS scale correlated with the TP count (r=0.688) and the WPI (0.733). We propose that FM may be diagnosed when (WPI >6 AND SS >4) OR SS >=9. These criteria correctly identified 80.9% of ACR (+) cases while physician diagnosis agreed with ACR criteria in 84.1% of cases. New diagnostic criteria agreed with an SS scale >=7 in 93% of cases. The SS scale correlated with a wide series of FM severity measures and was effective in describing FM severity and severity status of persons previously diagnosed with FM, but now not satisfying ACR criteria. In the 2nd phase of the study, a simple categorical form, suitable for use in the clinic, was used and performed as well as Phase 1 variables.

Conclusion: We have proposed simple clinical criteria for FM that do not require the use of tender points. These criteria expand the definition of fibromyalgia to include symptoms other than pain, and provide a measure to assess FM symptom related severity. The agreement with ACR criteria of 80.9% reflects disagreement related to the expanded definition and removal of the tender point criterion. We propose that the 1990 ACR classification criteria continue to be used for their intended purpose (to identify individuals for research studies), but that these new criteria may be more applicable in clinical settings, or research settings (e.g. epidemiological studies) where a TP count is not feasible.

Chronic Widespread Pain Predicts Higher Levels of Fatigue: Results From a Population Based Prospective Survey. John McBeth and Barbara I. Nicholl, University of Manchester, Manchester, United Kingdom

Purpose: Chronic widespread pain (CWP) is associated with numerous co-morbidities including high levels of fatigue. It is unclear whether this relationship is explained by other factors associated with pain, which may act to increase the likelihood of becoming fatigued or whether there is a direct relationship between pain and fatigue. The aim of this study was to test the hypothesis that individuals with CWP would have an increased risk of becoming fatigued, independently of putative confounders.

Method: We conducted a population based prospective cohort study. 1953 adult subjects, selected from a population register, completed a detailed questionnaire which included a pain drawing. Based upon their reports subjects were classified into one of three groups: those reporting no pain, those with some pain but not CWP, and those satisfying the ACR criteria for CWP. Baseline levels of fatigue were assessed using the 11 item Fatigue Questionnaire. Subjects also completed measures of psychological distress (General Health Questionnaire), somatisation (Somatic Symptom Checklist), and Illness Behaviour and Health Anxiety scales. All subjects who participated at baseline were followed up 12 months later at which time they completed another questionnaire that assessed levels of fatigue using identical instruments. The relationship between pain status at baseline and levels of fatigue (in tertiles) at follow up was assessed using multinomial regression and the results are expressed as relative risk ratios (RRR) with 95% confidence intervals (CI). All analyses were adjusted for age and gender.

Results: A total of 1910 subjects provided pain data at baseline and were eligible for follow up. Of those 1681 (88.0%) returned the follow up questionnaire, 1482 (77.6%) completed the fatigue questionnaire and 1384 (72.5%) provided full data and were included in the current analysis. Compared to those reporting no pain at baseline, those reporting some pain were more likely to have fatigue levels at follow up in the highest third of the scale (12.2% v 19.8% respectively) and those with CWP were most likely (36.0%). After adjusting for age and gender, subjects with some pain (OR = 2.3, 95% CI (1.6, 3.2)) and CWP (5.8 (3.8, 8.9)) had a higher risk of being in the top third of fatigue score. These relationships were attenuated when adjusted for baseline psychosocial factors (some pain: 1.6 (1.1, 2.3) and CWP: 3.0 (1.9, 4.8)). Only the relationship with CWP persisted after adjusting for baseline levels of fatigue (1.9 (1.1, 3.2)).

Conclusion: CWP is strongly associated with higher levels of fatigue. Future studies should explore potential mechanisms including behavioral factors such as physical inactivity and diet.

Genetic Polymorphisms of the Beta 2-Adrenergic Receptor Relate to Gs Protein Dysfunction in Fibromyalgia Syndrome. Yangming Xiao, I. Jon Russell, Wanda L. Haynes and Joel E. Michalek, The University of Texas Health Science Center at San Antonio, San Antonio, TX

Purpose: The beta 2-adrenergic receptor (β_2AR) is a G protein-coupled receptor (GPCR) that mediates the actions of catecholamines in multiple tissues. We previously documented a GPCR stimulatory (Gs) dysfunction in patients with fibromyalgia syndrome (FMS). The aims of the present study were to determine the frequencies of β_2AR gene polymorphisms in FMS compared with healthy normal controls (HNC) and to determine whether polymorphisms in the β_2AR gene might contribute to the Gs dysfunction in FMS.

Method: The study was conducted with ethics committee approval and study subjects signed informed consent to participate. Morning blood samples were obtained from primary FMS (1990 ACR criteria) and demographically-matched HNC in what was intended to be a ratio of 2:1. Peripheral blood mononuclear cells (PBMC) were isolated by density gradient centrifugation. The Gs functions of PBMC were tested using isoproterenol (ISO) as the adrenergic Gs ligand and measuring intracellular cAMP levels (second message) by enzyme linked immunosorbent assay (ELISA). The β_2AR genotypes at amino acid position 16 and 27 were determined for each subject using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Differences between the genotype frequencies of FMS and HNC were evaluated using a chi-square test.

Results: Study subjects included 97 FMS patients and 59 HNC. The frequency of the β_2AR gene polymorphism Arg16Gly (45.1%) in FMS was significantly lower ($p = 0.035$) than in HNC (62.7%). Conversely, the Gly16Gly genotype in FMS (37.1%) was marginally more frequent than in HNC (25.4%, $p = 0.06$). The frequencies of other tested β_2AR genotypes, such as Arg16Arg, Gln27Gln, Glu27Glu, and Gln27Glu did not differ between FMS and HNC. FMS patients carrying the β_2AR polymorphism Arg16Arg exhibited significantly lower PBMC basal cAMP levels ($p<0.025$) and lower ISO-stimulated cAMP levels ($p<0.025$) than FMS carrying Gly16Gly or Arg16Gly.

Conclusion: These data show that *in vitro* testing of GPCR function of PBMC can be fruitful in FMS. Several associations were found between FMS and β_2AR genetic polymorphisms at codon 16. Indeed, this is the first study to demonstrate β_2AR polymorphism-related differences in intracellular cAMP levels within FMS PBMC before and after beta adrenergic stimulation. These findings imply that β_2AR polymorphism in FMS may influence responses to a variety of beta adrenergic ligands. This concept may help to explain some of the differences in responsiveness of FMS subgroups to the adrenergic agonist medications currently approved for FMS treatment. Finally, one could speculate that these findings may directly relate to the adrenergic autonomic nervous system dysfunction documented in FMS.

Chronic Widespread Pain Is Associated with Reduced Psychomotor Processing Speed in Middle-Aged and Older Men: Results From the European Male Ageing Study (EMAS). David M. Lee[1], Abdelouahid Tajar[1], Neil Pendleton[1], Gyorgy Bartfai[2], Gianni Forti[3], Aleksander Giwercman[4], Dirk Vanderschueren[5], Frederick CW Wu[1] and John McBeth[1], [1]The University of Manchester, Manchester, United Kingdom, [2]Albert Szent-Gyorgy University, Szeged, Hungary, [3]University of Florence, Florence, Italy, [4]Malmö University Hospital, Malmö, Sweden, [5]Katholieke Universiteit Leuven, Leuven, Belgium

Purpose: There is evidence from clinic based studies that fibromyalgia is associated with impairment in cognitive function though the mechanism is unclear. The aim of this analysis was to determine whether there is an association between chronic widespread pain (CWP), a cardinal feature of fibromyalgia, and impaired cognition in a community setting.

Method: 3,369 men aged 40 to 79 years were recruited from population registers in eight centres for participation in the European Male Ageing Study (EMAS). Subjects completed a postal questionnaire which included questions about the occurrence of pain experienced in the past month and were asked to draw on a body manikin the site of any pain. Based on the pain questionnaire and body manikin the presence of CWP was defined using the ACR criteria. Self-report data on age on leaving education, smoking, physical function and a range of co-morbidities were also collected. Subjects were then invited to attend a clinic visit which included assessments of depressive symptomology and physical function in addition to several cognitive function tests: the Rey-Osterrieth Complex Figure test (ROCF) to assess visuospatial construction (copy score) and memory (recall score), the Camden Topographical Recognition Memory test (CTRM) to assess non-verbal recall and the Digit Symbol Substitution test (DSST) to measure psychomotor processing speed. For all these tests higher scores reflect better cognitive performance. The relationship between the occurrence of CWP and the various cognitive tests was assessed using linear regression with the cognitive test as the outcome and the results expressed as β coefficients and 95% confidence intervals (CI).

Results: We restricted our analysis to those subjects reporting no pain, those reporting pain that satisfied the ACR criteria for CWP and in whom complete data on cognition was available. Of these 1,540 men [mean (SD) age 60 (11) years], 266 (17.3%) had CWP. The mean (SD) for the ROCF copy was 33.5 (4.3), ROCF recall 17.7 (6.6), CTRM 22.9 (4.7), and DSST 27.9 (8.7). All test scores were negatively associated with age ($p<0.05$). In age-adjusted linear regressions, compared to those without CWP, those with CWP had a lower DSST score (β coefficient = -2.4; 95%CI -3.4 to -1.5). After additional adjustment for other putative confounders (age leaving education, depression, physical function, smoking, alcohol, presence of morbidities, and centre), the association between pain status and the DSST score was attenuated but remained significant (β coefficient = -1.4; 95%CI -2.7 to 0.00). There was no association between CWP and the ROCF copy, ROCF recall or CTRM scores.

Conclusion: CWP is associated with reduced psychomotor processing speed among middle-aged and older European men. Prospective studies are required to confirm this observation and to explore possible mechanisms for the association.

571

Typology of Patients with Fibromyalgia: Cluster Analysis of Duloxetine Study Patients. Laurence A. Bradley[1], Ernest H. Choy[2], Peter Van Wembeke[3], Ilya A. Lipkovich[4] and Walter Deberdt[5], [1]UAL, Birmingham, Birmingham, AL, [2]Kings College London, London, United Kingdom, [3]Univerity Hospitals Leuven, Leuven, Belgium, [4]Eli Lilly and Company, Indianapolis, IN, [5]S.A. Eli Lilly Benelux N.V., Brussels, Belgium

Purpose: To identify distinct groups of subjects with fibromyalgia across multiple outcome measures and to evaluate their predictors.

Method: Eighteen variables from 7 scales covering areas of pain, mental and physical impairment, global impression, and overall functioning from 631 duloxetine-treated females collected post-treatment (endpoint within >2-12 weeks; last observation carried forward [LOCF]) in 4 randomized placebo-controlled duloxetine trials were included in a cluster analysis (k-means method) to identify distinct

patient groups. Classification rules were derived using a classification tree algorithm to define categories that mimic the clusters. Probabilities for transitioning from baseline to endpoint category were evaluated using logistic regression.

Result: Five clusters were identified, ranging from "worst" with high pain levels and severe mental/physical impairment to "best" with low pain levels and nearly normal mental/physical function:

Cluster characteristics (selection) and classification rules

		Endpoint mean score					
Cluster	**N**	**BDI total**	**BPI pain intensity**	**BPI pain interference (BPIAI)**	**FIQ interference with work (FIQ14)**	**FIQ depression (FIQ20)**	**Classification rule**
1 (worst)	78	25.08	7.58	7.89	8.26	6.91	BPIAI ≥7.14
2 (physically poor)	135	7.93	5.93	4.77	6.29	1.45	3.29 ≤BPIAI <7.14, FIQ20 <5
3 (mentally poor)	104	15.81	4.12	4.21	4.82	5.09	3.29 ≤BPIAI <7.14, FIQ20 ≥5
4 (moderate)	185	5.99	3.55	2.23	3.16	1.12	BPIAI <3.29, FIQ14 ≥2
5 (best)	129	3.46	1.43	0.60	0.77	0.57	BPIAI <3.29, FIQ14 <2
BDI=Beck Depression Inventory; BPI=Brief Pain Inventory; FIQ=Fibromyalgia Impact Questionnaire							

Classification rules for categories that mimic the clusters were derived (see table) and used to classify duloxetine- and placebo-treated females at baseline and endpoint (N=1199). Patient characteristics and category frequencies at baseline were similar between treatments; >80% of patients were in the 3 worst categories ("worst": 30.6% overall; "physically poor": 32.8%; "mentally poor": 21.2%). Frequencies for the 2 best categories combined changed from 15.7% at baseline to 51.6% at endpoint with duloxetine and from 14.8% to 35.6% with placebo. The analysis of probabilities for transitioning from baseline to endpoint category showed that duloxetine patients were significantly more likely to improve the outcome category than placebo patients. Baseline category and treatment were the best predictors for endpoint outcome category.

Conclusion: Fibromyalgia patients are heterogeneous and can be classified into distinct subgroups based on overall severity and by differentiating between mental and physical impairment. Such classification facilitates outcome prediction and thus may have implications for individual patient management.

572

Gonadotrophins Are Associated with Chronic Widespread Pain in Middle-Aged and Older Men. Abdelouahid Tajar[1], John McBeth[1], Gyorgy Bartfai[2], Felipe F. Casanueva[3], Gianni Forti[4], Krzysztof Kula[5], Margus Punab[6], Alan J. Silman[7], Dirk Vanderschueren[8], Frederick CW Wu[1] and Terence W. O'Neill[1], [1]The University of Manchester, Manchester, United Kingdom, [2]Albert Szent-Gyorgy Medical University, Szeged, Hungary, [3]Santiago de Compostela University, Santiago, Spain, [4]University of Florence, Florence, Italy, [5]University of Lodz, Lodz, Poland, [6]United Laboratories of Tartu University Clinics, Tartu, Estonia, [7]Arthritis Research Campaign, Chesterfield, [8]Katholieke Universiteit Leuven, Leuven, Belgium

Purpose: The role of sex hormones in the aetiology of chronic musculoskeletal pain is unclear. The aim of this study was to determine the influence of hypothalamic pituitary testicular axis (HPT) hormones on the occurrence of chronic widespread pain (CWP).

Methods: Men aged 40-79 years were recruited from population registers in eight centres for participation in the European Male Aging Study (EMAS). Subjects were asked to complete a postal questionnaire which included questions about lifestyle, co-morbid illnesses and musculoskeletal pain experienced in the past month. They were asked to highlight on a body manikin the sites of any pain they had

experienced. Subjects subsequently attended for assessment which included an interviewer assisted questionnaire and fasting blood sample from which total testosterone (TT), sex hormone binding globulin (SHBG), luteinising hormone (LH), and follicle-stimulating hormone (FSH) were assayed. Free testosterone (FT) was calculated from TT and SHBG using an established formula. Subjects were classified into one of three groups according to their pain reports: those reporting no pain, those with CWP, as classified using the ACR criteria, and those reporting some pain (non CWP). The association between pain status and sex hormone levels was assessed using multinomial logistic regression with results expressed as relative risk ratios (RRR) and 95% confidence intervals (CI). In all analyses the "no pain" group was the referent category.

Results: A total of 3,184 men [mean (SD) age 60 (11) years] had complete data on sex hormones and pain status. Of these 1,304 (41.0%) reported no pain, 1,605 (50.4 %) had some pain and 275 (8.6%) had CWP. The mean (SD) for TT was 16.5 (5.9) nmol/L, FT 292.0 (93.2) pmol/L, LH 6.2 (4.5) U/L , FSH 8.7 (9.2) U/L and SHBG 42.9 (19.8) nmol/L.After adjustment for age and other putative confounders including body mass index, smoking, alcohol intake, number of co-morbidities, depression and centre, the association between higher levels of LH and FSH and pain persisted. Being in the highest tertile of LH was associated with an increased risk of having some pain (RRR = 1.3; 95% CI, 1.1, 1.5) and CWP (RRR = 1.6; 95% CI, 1.1, 2.2). Similarly, being in the highest tertile of FSH was associated with an increased risk of having some pain (RRR = 1.3; 95% CI 1.01,1.5) and CWP (RRR = 1.5; 95% CI 1.2, 2.0).

Conclusion: Testosterone levels were similar among the pain groups with high levels of gonadotrophins (LH and FSH) among those with pain (some pain and CWP). This relationship may indicate that deficits in testicular function can be adequately compensated for in the presence of musculoskeletal pain. Further studies appear warranted to investigate these findings.

ACR Concurrent Abstract Sessions

Genomics of Rheumatoid Arthritis

Sunday, October 18, 2009, 2:30 PM - 4:00 PM

573

Genome-Wide Association Study of Genetic Predictors of Anti-Tumour Necrosis Factor (TNF) Treatment in Rheumatoid Arthritis (RA) Identifies Associations with Polymorphisms at Five Loci. Laura J. Gibbons[1], Catherine Potter[2], K. L. Hyrich[1], Ann W. Morgan[3], Anthony G. Wilson[4], John D. Isaacs[2], Braggss and A. Barton[1], [1]arc Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Musculoskeletal Research Group, Newcastle University, Newcastle Upon Tyne, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Sheffield Uni /Medical School, Sheffield, United Kingdom

Purpose: Anti-tumour necrosis factor (TNF) agents are successful therapies in rheumatoid arthritis (RA); however, inadequate response occurs in 30-40% of patients treated. Knowledge of genetic factors influencing response may facilitate personalised therapy. The aim of this study was to identify genetic predictors of response to anti-TNF therapy in RA and to validate our findings in independent cohorts.

Method: Genome-wide association (GWA) data from the WTCCC[1] was analysed in terms of treatment response for 595 anti-TNF-treated RA patients. Multivariate linear regression analysis of change in 28 joint count disease activity score (DAS28) at 6 months was conducted at each single nucleotide polymorphism (SNP) using an additive model. Associated markers ($P < 10^{-3}$) were genotyped in two independent validation cohorts (n = 403 and n = 332) and a combined analysis was performed.

Results: Of 193 markers associated with treatment response in the GWA data, 5 were replicated in both validation cohorts. In the combined analysis, the strongest effect was at rs9292156, an intergenic SNP on chromosome 5q11.2: the minor allele conferred improved response (Table 1), with a clinically relevant improvement of 0.61 units between the minor and major allele homozygotes. Association was also replicated at intronic SNPs in *PDZD2* and *EYA4*, and at intergenic SNPs at chromosomal regions 1q23.3 and 12p12.3.

Purpose: Genetic studies in RA have identified 16 loci containing genes involved in key immunologic processes. We hypothesized that undiscovered RA risk loci likely contain genes functionally related to previously validated gene loci, and that a systematic approach to establishing those functional relationships will effectively help identify novel RA loci from genome-wide association studies (GWAS).

Method: To test this hypothesis, we examined 370 SNPs from 179 independent loci with $p<0.001$ in a published meta-analysis of three RA GWAS (Raychaudhuri et al, Nat Genet 2008), most of which likely represent spurious associations. We developed and applied *GRAIL* (Gene Relationships Across Implicated Loci, Raychaudhuri et al PLOS Genet), a computational method that automatically assesses functional relationships between genes by applying statistical text mining to PubMed abstracts. We scored these 179 loci for functional relationships to genes in 16 known RA disease loci. We genotyped representative SNPs from loci with the highest scores in an independent set of 8,096 autoantibody positive RA cases and 11,822 matched controls.

Results: We identified 22 loci with a high degree of functional connectivity as determined by high GRAIL scores. Three of these validate convincingly: *CD2/CD58*, *PRDM1*, and *CD28* (see Table 1). In addition, four loci replicate at $p<0.0023$ (=0.05/22), indicating that these almost certainly represent true RA risk loci: *PTPRC*, *TAGAP*, *TRAF6/RAG1* and *FCGR2A*. Many of these loci are already associated to other immunologic diseases.

Conclusion: We present novel RA risk loci, discovered by utilizing pathway-based approaches; these loci could indicate key immunologic processes in pathogenesis.

Table 1. 7 of 22 SNPs tested replicate in independent samples (p<0.0023).

Cumulative Association of Twenty-Two Genetic Variants with Seropositive Rheumatoid Arthritis Risk. Elizabeth W. Karlson[1], Lori B. Chibnik[1], Peter Kraft[2], Jing Cui[1], Brendan T. Keenan[1], Bo Ding[3], Soumya Raychaudhuri[1], Lars Klareskog[4], Lars Alfredsson[5] and Robert M. Plenge[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Channing Laboratory, Brigham & Women's Hospital and Harvard Medical School, [3]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska University Hospital, Stockholm, [5]Karolinska Institutet, Stockholm, Sweden

Purpose: Recent discoveries of risk alleles have made it possible to define genetic risk profiles for RA. We examined whether a cumulative score based on 22 validated genetic risk alleles for seropositive RA would identify high-risk individuals who might benefit from preventive interventions.

Methods: We genotyped 14 single nucleotide polymorphisms (SNPs) at 13 validated RA risk loci based on published GWAS, or meta-analysis and 8 HLA alleles among (1) 289 Caucasian seropositive (CCP+ and/or RF+) cases and 481 controls from the U.S. Nurses' Health Studies (NHS), and (2) 630 Caucasian CCP antibody positive cases and 623 controls from the Swedish Epidemiologic Investigation of RA (EIRA). We created a weighted genetic risk score (GRS), where the weight for each risk allele is the log of the published odds ratio (OR). We used logistic regression to study associations between incident RA and GRS grouped in 7 categories based on the GRS distribution among the controls, using the median (group 4) as the referent group. We compared area under the ROC curve (AUC) from a clinical-only model and clinical + genetic model in each cohort. Clinical models included year of birth and pack-years of smoking for NHS and age, pack-years of smoking, sex, and residential area in EIRA. To determine the clinical utility of our GRS in individual patients, we calculated risk-score specific absolute risks within each cohort.

Results: Subjects in group 7 with the highest GRS (> 1.25 standard deviations from the mean) had a significantly higher OR for seropositive RA in both NHS (OR=2.9, 95% CI 1.8-4.6) and EIRA (OR=3.4, 95% CI 2.3-5.0) referent to the population average. After removing HLA alleles from the GRS, subjects in group 7 with the highest GRS had a significantly higher OR for seropositive RA in both NHS (OR=2.5, 95% CI 1.5-4.3) and EIRA (OR=2.8, 95% CI 1.7-4.7) referent to the population average. The AUC for a clinical model was 0.566 and for a clinical + genetic model was 0.660 in NHS (p=0.0001), and 0.626, 0.752 in EIRA (p=0.0001), respectively. In the NHS cohort, the absolute risk of sero+ RA was 0.3%. Having a GRS in group 7 increases the absolute risk to 0.7%. In EIRA, the absolute risk of CCP+ RA was 0.4% for women and 0.2% for men. Having a GRS score in group 7 increases these absolute risks to 1.3% for women and 0.7% for men, respectively.

Conclusion: The combination of 22 risk alleles into a weighted genetic risk score significantly improves prediction for RA risk beyond clinical risk factors alone. However, given the low absolute risk of RA, the clinical utility of a weighted genetic risk score is still to be determined.

Receiver Operator-Characteristic (ROC) Curves for Cumulative Genetic Risk Score Predicting Seropositive RA in NHS and CCP Positive RA in EIRA

Association and Linkage Proof for IRF5 as a Rheumatoid Arthritis Susceptibility Gene. Karen Dawidowicz[1], Yannick Allanore[2], Céline Pierlot[3], Vitor-Hugo Teixeira[3], Elisabeth Petit-Teixeira[3], Francois Cornelis[3], P. Dieudé[1] and the ECRAF, [1]Bichat Claude-bernard, Universitary Hospital, APHP, Paris, France, [2]Paris Descartes Univ, Paris, France, [3]Evry University, Evry-Genopole, France

Background: Type 1 IFNs play a key role in autoimmunity when tolerance is lost and autoreactivity appears. Increased expression of type 1 IFN genes, also referred as an IFN signature, has been detected in various autoimmune diseases such as systemic lupus erythematosus, rheumatoid arthritis (RA), Sjögren's syndrome and in a subgroup of systemic sclerosis patients. Interferon regulatory factors, such as IRF5, coordinate type I IFNs expression. To date, multiple *IRF5* variants were suggested as susceptibility genetic factors of various autoimmune diseases, including RA.

Purpose: As the linkage proof remains important to fully establish *IRF5* as genetic RA susceptibility factor, we aimed at providing it, tacking advantage of the largest reported European family resource dedicated to RA linkage studies.

Method: Overall, 1014 European Caucasian individuals from 338 RA trio families were genotyped for *IRF5* rs3757385, rs2004640 and rs10954213 single nucleotide polymorphisms (SNPs).

Results: Single marker analysis provided linkage evidence for each *IRF5* SNP investigated. *IRF5* linked to RA with two significant haplotypes out of 8. The IRF5 C-T-A susceptible haplotype "S" (T = 62.2%, $P = 2.9 \times 10^{-4}$) and the A-G-G protective haplotype "P" (T = 38.7%, $P = 1.86 \times 10^{-3}$). Linkage was significantly stronger in non-erosive disease for both *IRF5* S and P haplotypes: T = 82.2%, $P = 1.34 \times 10^{-5}$ and T = 19.4%, $P = 2.46 \times 10^{-4}$, respectively. No other significant independent clinical, including ACPA status, nor genetic factor influencing linkage was detected. *IRF5* homozygous haplotypic genotypes SS and PP were strongly associated with RA: P = 0.0026, OR1.88, 95%CI [1.24-2.84], P = 0.006, OR 0.71 95%CI [0.55-0.91], respectively. leading us to purpose a practical approach according to the *IRF5* SS, PP and XX haplotypic genotype individual status (X being non-S and non-P haplotypes).

Conclusion: This study provides the final piece of the "association and linkage proof" for *IRF5* as a RA susceptibility gene and led to the identification of a potential factor which could influence the rheumatoid erosive phenotype. Further studies in inception cohorts are required to clarify the role played by *IRF5* in the rheumatoid arthritis erosive phenotype.

RA Susceptibility Is Associated with An Epistatic Interaction Between Shared Epitope Alleles and MMEL1-TNFRSF14. Hani S. El-Gabalawy[1], Nina A. Daha[2], David B. Robinson[1], Kiem G. Oen[1], Irene Smolik[1], Donna Hart[1], Annemiek Willemze[2], Wendimagegn Ghidey[2], Jeanine J. Houwing-Duistermaat[2], René E.M. Toes[2], Tom W.J. Huizinga[2] and K.A. Siminovitch[3], [1]University of Manitoba, Winnipeg, MB, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Toronto, Toronto

Purpose: North American Native (NAN) populations have a high prevalence rates for RA. We have studied a Cree/Ojibway population in Central Canada for disease risk, and our previously published data indicate an early age of onset, high rates of multi-case families, high prevalence and titers of anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF), and prevalent shared epitope (SE) alleles in the background control population. We therefore asked the question of whether additional genetic factors may interact with SE alleles in predisposing this population to the development of RA

Method: RA patients (n=317), their first degree relatives (FDR, n=295), and unrelated controls (C, n=300) were tested for 21 single nucleotide polymorphisms (SNP) that have been shown to be associated with RA in whole genome scans, including PTPN22, TRAF1-C5, CTLA4, PADI4, STAT4, FCRL3, CCL21, MMEL1-TNFRSF14, CDK6, PRKCQ, KIF5A-PIP4K2C, IL2RB, TNFAIP3, IL10 -1082G/A, REL. HLA-DRB1 alleles were tested by sequencing. Significant SNP associations detected in the NAN population were tested for replication in a Dutch RA population (n= 880) and controls (n= 546)

Results: The prevalence of SE alleles in the NAN population was RA = 85%, FDR = 79%, and C = 66%. The most common SE alleles were *0404 (38%) and *1402 (28%). With the exception of rs3890745 (MMEL1-TNFRSF14), there were no significant associations with any of the RA SNP tested, including the 1858T allele of PTPN22, which was present at a frequency of 9% in all groups. The data indicate that homozygosity for the major allele of MMEL1-TNFRSF14 was significantly higher in RA compared to both the C and FDR groups (OR 1.31, CI 1.05 -1.63, p=0.02). Further analysis indicated that this association was present only in SE+ individuals (OR 1.46 CI 1.15 -1.89, p=0.004),

with no association detectable in SE- individuals. Binary logistic regression indicated that SE and MMEL1-TNFRSF14 were both independently associated with an RA diagnosis. Using a recessive model for the major allele of MMEL1-TNFRSF14 (AA vs AG or GG), there was clear evidence of an interaction between MMEL1-TNFRSF14 and SE (OR 1.84 p<0.0001 in SE+, and OR 0.75, p=NS in SE- individuals). Analysis in the Dutch population using the rs6684865 SNP (MMEL1), which is in complete linkage disequilibrium with rs3890745, demonstrated a similar trend in RA association (OR 1.16 CI 0.89-1.52), but there was no statistical evidence for interaction with SE.

Conclusion: The MMEL1-TNFRSF14 SNP has recently been shown to be associated with RA in a large genome wide analysis of primarily Caucasian populations. Here we demonstrate a novel interaction between SE and MMEL1-TNFRSF14 that is highly associated with RA susceptibility in the NAN population. This epistatic interaction is particularly important since SE alleles are prevalent in this population yet most individuals remain disease free.

Effect of Glutathione S-Transferase T1, M1, P1 and Heme Oxygenase-1 Gene Promoter Polymorphisms Interactions with Heavy Smoking On the Risk of Rheumatoid Arthritis. Brendan T. Keenan, Lori B. Chibnik, Jing Cui and Elizabeth W. Karlson, Brigham and Women's Hospital, Boston, MA

Purpose: Glutathione S-transferase (GST) and heme oxygenase-1 (HMOX1) genes encode enzymes that detoxify carcinogens and protect against oxidative stress. Variations in these genes may be associated with increased susceptibility to carcinogens in tobacco smoke. We studied the effect of interactions between these genetic variations and smoking (a risk factor for RA) on the risk of RA using a nested case-control sample from 2 large prospective female cohorts.

Method: Blood was obtained from 32,826 women in the Nurses' Health Study (NHS) and 29,611 women in the Nurses' Health Study 2. Buccal cell samples were provided by 33,040 additional women in NHS. Cases and controls with available DNA were selected. Incident RA was confirmed by record review for ACR criteria. Controls were matched on age, menopausal status, and postmenopausal hormone use. Genotyping by Taqman was performed for GSTM1, GSTT1 homozygous deletions (null) and GSTP1 (rs1695), HMOX1 (rs2071746) alleles. Heavy smoking was defined as >10 pack-years (packs per day X years smoked). We studied gene-environment (GxE) interactions between genetic variations of GST genes or HMOX1 and heavy smoking for the risk of all RA and seropositive (sero+) RA (CCP+ and/or RF+) in separate logistic models adjusted for matching factors. We calculated multiplicative interactions by including a GxE product term in the logistic model and additive interactions using the attributable proportion due to interaction (AP).

Results: 549 matched Caucasian pairs were included. Mean age at diagnosis was 56.9 ± 10.3 years and 325 (59%) were sero+ cases. For all RA risk, we observed a significant multiplicative interaction (p=0.03) between HMOX1 and heavy smoking; we observed significant multiplicative (p=0.05) and strong additive (AP=0.51, p=0.0008) interactions between GSTT1-null and heavy smoking. For sero+ RA risk, we found a significant additive interaction (AP=0.41, p=0.03) but not multiplicative interaction between HMOX1 and heavy smoking; we observed significant multiplicative (p=0.01) and strong additive (AP=0.63, p<0.0001) interactions between GSTT1-null and heavy smoking. GSTM1-null and GSTP1 did not show significant interactions with heavy smoking for all RA or sero+ RA risk.

Conclusion: We observed significant gene-environment interactions between HMOX1 and heavy smoking and strong interactions between GSTT1-null and heavy smoking for the risk of all RA and seropositive RA. Future studies are needed to assess the impact of these interactions on RA prediction.

Proteasome Inhibitors Block Production of Alpha Interferon and B Cell Activation. R. J. Looney, Thomas Conley, James Kobie and Jennifer H. Anolik, University of Rochester, Rochester, NY

Purpose: Proteasome inhibitors have been proposed as a new therapy for SLE because of their effects on plasma cells. Animal studies have shown that bortezomib, a dipeptide boronate that targets the constitutive and immunoproteasome, induces apoptosis of short-lived and long-lived plasma cells via induction of the unfolded protein response, and is also able to decrease autoantibody production and prolong survival. Since proteasome inhibitors block activation of NFkappaB by preventing degradation of IkappaB, they should also have effects on cellular activation such as alpha interferon production after stimulation of toll-like receptors. Bortezomib is approved for the treatment of multiple myeloma but its use in non-malignant conditions may be limited due to unacceptable toxicities such as painful peripheral neuropathy. Because of this problem, new proteasome inhibitors are being developed. Carfilzomib is a peptide epoxyketone proteasome inhibitor that has greater selectivity for the proteasome than bortezomib and is currently in phase 2 clinical studies in myeloma. PR-957 is a novel, immunoproteasome selective inhibitor of the same chemical class as carfilzomib.

Methods: The effects of carfilzomib and PR-957, were compared to bortezomib in PBMCs and B-cells. Alpha interferon was assayed by ELISA, immunoglobulin production by ELISPOTS, and proliferation by CFSE/flow cytometry.

Results: Induction of alpha interferon production by PBMCs treated with polyIC or with ODN2216 activating respectively TLR-3 or TLR-9 was dramatically inhibited by all three proteasome inhibitors. (See below.) The effects of these proteasome inhibitors on B cell activation by IL-2 and CpG were also examined. B cell proliferation and IgM or IgG antibody secreting cells were inhibited by all three proteasome inhibitors. (Data not shown.).

Conclusion: These results demonstrate for the first time that proteasome inhibitors are able to block production of alpha interferon induced by stimulation of toll-like receptors, and also show that proteasome inhibitors can block B cell proliferation and differentiation. Furthermore, activity with PR-957 suggests that the effects of carfilzomib and bortezomib are mediated through immunoproteasome inhibition. Thus, the potential beneficial effects of proteasome inhibitors in SLE may work through multiple mechanisms.

Vitamin D Deficiency Is Associated with B Cell Hyperreactivity in Systemic Lupus Erythematosus. Lauren R. Cole[1], Susan Macwana[2], Rufei Lu[2], Wendy Klein[2], Virginia Roberts[2], Amy Dedeke[1], Sherry R. Crowe[2], Gillian M. Air[1], Linda F. Thompson[3], Joel M. Guthridge[2] and Judith A. James[3], [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]OMRF & OUHSC, Oklahoma City, OK

Purpose: Autoimmune diseases have complex etiologies, likely including variable interactions between genetic predispositions and environmental risks. Vitamin D (Vit D) deficiency has recently been linked with many autoimmune disorders, including systemic lupus erythematosus (SLE). Vit D inhibits antibody secretion and autoantibody production in B cells of animal models; however, the influence of Vit D deficiency on autoantibody production and antigen specific immune responses in SLE patients is unknown. Our study tests whether Vit D deficiency is associated with SLE B cell hyperreactivity or improved antigen-specific antibody responses.

Method: This study enrolled 92 SLE patients who met ACR criteria and matched controls. 25-hydroxyvitamin D (25D) levels, lupus-associated autoantibodies (Ro, La, Sm, nRNP, ribosomal P, dsDNA, ANAs and phospholipid antibodies) and influenza humoral immune response parameters including Bmax (relative amounts of anti-influenza antibodies against native or denatured antigen, measured separately), Ka (relative affinity), and hemagglutination inhibition (relative protective antibody response) were measured. Isolated PBMCs were used for multiparameter PhosFlow analysis of downstream B cell activation markers such as phospho-LYN (pY_{397} and pY_{508}) and phospho-ERK1/2 (pERK1/2).

Results: SLE patients and autoantibody-positive controls were significantly more likely to be Vit D deficient than autoantibody-negative controls, 75% vs 65% vs 25%, respectively (p=0.0003 and p=0.0124). Additionally, anti-Ro positive SLE patients had significantly lower 25D levels than anti-Ro negative SLE patients (p=0.0311). In SLE patients, we saw a significant negative correlation between 25D levels and their humoral immune response to influenza vaccination (p=0.004, r^2=0.189). Furthermore, decreased vitamin D levels in SLE patients were correlated with hyperreactive B cells as measured by pY_{508}LYN and pERK1/2. This correlation with 25D was seen in anti-IgM F(ab)'2 and PMA stimulated B cells ([PMA: pY_{508}LYN p=0.002, pERK1/2 p=0.014] [anti-IgM F(ab)'2: pY_{508}LYN, p=0.018]), as well as in unstimulated B cells (pY_{508}LYN p=0.019, pERK1/2 p=0.029).

Conclusion: Our evidence suggests a role for Vit D deficiency in human B cell hyperreactivity and autoantibody production. We saw an increase in Vit D deficiency in autoantibody-positive controls that is similar to what is seen in SLE patients. Supporting the idea that Vit D deficiency leads to increased B cell activity, we saw a negative correlation between Vit D levels and the ability to mount a humoral immune response to the flu vaccine. The increase in B cell activity was corroborated by flowcytometric data indicating increased phosphorylation of LYN and ERK1/2 in Vit D deficient patients.

Gadd45a Overexpression Contributes to Autoimmunity by Demethylating DNA in Lupus T Cells. Yaping Li[1], Ming Zhao[1], Yongqi Luo[1], Sha Zhao[1], Xiujuan Zhang[1], Heng Yin[1], Hai Long[1], Yuwen Su[1], Bruce C. Richardson[2] and Qianjin Lu[1], [1]The Second Xiangya Hospital, Central South University, Changsha, China, [2]University of Michigan, Ann Arbor, MI

Purpose: Demethylation of CD11a (ITGAL) and CD70 (TNFSF7) regulatory regions in $CD4^+$ T cells contributes to the development of autoreactivity and the overstimulation of autoantibodies. Gadd45a reduces epigenetic silencing of genes by removing methylation marks. Ultraviolet (UV) irradiation upregulates Gadd45a expression and also aggravates systemic lupus erythematosus (SLE). In this study, we explored whether Gadd45a may contribute to the development of autoimmunity by promoting DNA demethylation in $CD4^+$ T cells from SLE patients.

Methods: $CD4^+$ T cells from 17 SLE patients and 10 healthy controls were isolated using Miltenyi beads. Expression of Gadd45a mRNA and protein were detected by real-time RT-PCR and Western blotting. Global methylation was evaluated by Methylamp™ global DNA methylation quantification kits. Gadd45a-expressing plasmids and Gadd45a siRNA constructs were transfected into $CD4^+$ T cells by transient electroporation. CD11a and CD70 expression were detected by real-time RT-PCR and flow cytometry. $CD4^+$T cell proliferation and autologous B cell IgG antibody detection were performed using commercially available kits. Methylation of CpG pairs in CD11a promoter regulatory elements was detected by sodium bisulfite sequencing.

Results: Compared to controls, $CD4^+$ T cells from SLE patients exhibited elevated levels of Gadd45a mRNA (p=0.006) and protein (p=0.026), and reduced global DNA methylation (p=0.024). Gadd45a mRNA expression correlated negatively with global methylation levels (R=-0.676, p=0.002), and positively with disease activity in our SLE patient cohort (R= 0.568, p=0.015). Gadd45a expression in $CD4^+$T cells was significantly upregulated 6, 24 hours and 48 hours after UVB irradiation, with concomitant increases in CD11a and CD70 mRNA expression at each time point. Global methylation was significantly decreased 48 hours after irradiation. Transfecting $CD4^+$ T cells with Gadd45a led to significant increases in CD11a and CD70 expression, as well as autoreactivity and B cell stimulation. Furthermore, methylation of CpG pairs in the CD11a promoter region was reduced in Gadd45a-transfected cells. In contrast, siRNA-mediated knockdown of Gadd45a in SLE $CD4^+$ T cells significantly reduced autoreactivity and B cell stimulation, and increased CD11a promoter methylation.

Conclusion: Our findings indicate that Gadd45a expression is increased in $CD4^+$ T cells of SLE patients, promoting DNA demethylation and thereby leading to autoimmune responses.

Type I Interferon Gene Signatures Are Associated with Vascular Risk and Atherosclerosis in Systemic Lupus Erythematosus. Wenpu Zhao, Emily C. Somers, W. Joseph McCune and Mariana J. Kaplan, University of Michigan, Ann Arbor, MI

Purpose: Patients with SLE have a striking increase in cardiovascular (CV) risk due to accelerated atherosclerosis, which can not be fully explained by traditional risk factors. We and others have proposed that type I Interferons (IFN) induce premature vascular damage in lupus at least in part by promoting an imbalance between vascular damage and repair. We have now assessed if the induction of type I IFN signatures by SLE serum is associated with functional and anatomical evidence of vascular damage, atherosclerosis and with biomarkers of CV risk in a well characterized Lupus Cohort.

Method: Serum samples from 75 SLE and 20 control females without previous CV events were analyzed to assess their capacity to induce type I IFN signatures on an epithelial cell line using a validated bioassay. IFN scores were calculated. The quantified IFN-inducible genes were *MX-1, PRKR, IFI44L* and *IFIT1*. Flow mediated- and nitroglycerin mediated- dilatation of the brachial artery (FMD and NMD) were quantified by ultrasound to measure endothelial dependent and independent function, respectively. Carotid intima media thickness (CIMT) and plaque were determined by ultrasound and coronary calcification was measured with electron beam CT. Circulating apoptotic

endothelial cells (CAECs) and endothelial progenitor cells (EPCs) were quantified by FACS and serum ICAM-1, VCAM-1, tissue factor (TF), PAI-1, TPA, MCP-1, VEGF and CRP were quantified by ELISA.

Results: IFN scores were higher in SLE patients than in controls and correlated with SLEDAI ($p=0.04$). In SLE, IFN scores significantly correlated with CIMT and with carotid plaque ($p=0.0009$ and $p=0.033$, respectively). In addition, levels of ICAM-1, tissue factor, MCP-1 and CAECs correlated with IFN scores and individual type I IFN scores ($p<0.05$). In multivariable analysis accounting for SLEDAI, Framingham score and CAECs, type I IFNs showed significant association with CIMT and carotid plaque. In addition, levels of CAECs at baseline predicted progression of coronary artery calcification ($r=0.33$, $p<0.05$).

Conclusion: Type I IFNs are associated with atherosclerosis development in a cohort of SLE patients with low Framingham risk factors. This study further supports the hypothesis that type I IFNs promote premature vascular damage in SLE.

Antiribosomal P Protein Antibody Induces Th1 Responses by Enhancing the Production of IL-12 in Activated Monocytes. Tatsuo Nagai[1], Tamiko Yanagida[2] and Shunsei Hirohata[1], [1]Kitasato University School of Medicine, Kanagawa, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan

Purpose: Autoantibodies to ribosomal P proteins (anti-P) are detected in 12-16% of patients with SLE, and have been found to be associated with a variety of manifestations of the disease, including lupus psychosis, nephritis and hepatitis. We have recently disclosed that anti-P react with activated human peripheral blood monocytes, and enhance their production of TNFα and IL-6. It is also possible that anti-P might regulate other monocyte functions, including regulation of helper T cell (Th) responses. It has been recently shown that serum levels of IL-12 and IFNγ are higher in patients with lupus nephritis (LN) and peripheral cells from LN patients show a Th1 phenotype. The current study was therefore undertaken to explore the effects of anti-P on the induction of Th1 responses.

Method: IgG anti-P were affinity-purified from sera of anti-P positive lupus patients. Peripheral blood mononuclear cells (PBMCs) from healthy donors were cultured with anti-P or control IgG in round-bottomed polystyrene tubes for 120 hours. Highly purified peripheral blood monocytes were cultured in a 96-well microtiter plate with IFNγ in the presence of anti-P or control IgG for 120 hours. The concentrations of IFNγ and IL-12 in the culture supernatants were measured using ELISA.

Results: Anti-P significantly enhanced the production of IFNγ by PBMCs, compared with normal IgG or IgG from SLE patients devoid of anti-P. Of note, the up-regulation of IFNγ production by anti-P was abrogated by anti-IL-12 monoclonal antibodies. Accordingly, anti-P significantly enhanced the production of IL-12 by peripheral blood monocytes activated with IFNγ.

Conclusion: These results indicate that anti-P induce Th1 responses by up-regulating the production of IL-12 by activated monocytes. The data therefore suggest that anti-P play an important role in the pathogenesis of SLE through promotion of Th1 responses.

IgG Anti-NR2 Glutamate Receptor Antibodies From Patients with SLE as Causative Auto-Antibodies of Damage to the Blood-Brain Barrier. Taku Yoshio[1], Shoji Yamazaki[2], Hiroshi Okamoto[3], Sachiko Onishi[1], Shunsei Hirohata[4] and Seiji Minota[1], [1]Jichi Medical University, Shimotsuke, Japan, [2]Jichi Medical University Hospital, Shimotsuke, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Kitasato University School of Medicine, Sagamihara, Japan

Purpose: To determine whether IgG anti-NR2 glutamate receptor antibodies derived from patients with systemic lupus erythematosus (SLE) bind to endothelial cells (EC) causing up-regulation of adhesion molecule expression on and cytokine production.

Methods: EC were established from human umbilical veins. Purified IgG anti-NR2 glutamate receptor antibodies from 14 patients with SLE were tested for to the following: 1) binding to EC, 2) modulation of endothelial adhesion molecule expression, 3) cytokine production from

EC and 4) stimulation of nuclear translocation of NF-kappaB through the degradation of cytoplasmic IkappaB. Purified IgG from 5 healthy individuals were used as negative controls.

Results: Purified IgG anti-NR2 glutamate receptor antibodies bound to EC, and up-regulated the expression of endothelial leukocyte adhesion molecules-1, vascular cell adhesion molecules-1, and intercellular adhesion molecules-1 on EC surface. In addition, these antibodies also increased IL-6 and IL-8 production from EC when compared to IgG from normal controls. However, the anti-NR2 glutamate receptor antibodies failed to induce tumor necrosis factor-alpha or IL-1beta secretion from EC. These auto-antibodies stimulated nuclear translocation of NF-kappaB through the degradation of cytoplasmic IkappaB.

Conclusion: These results suggest that circulating anti-NR2 glutamate receptor antibodies may lead to vascular inflammation and damage to the blood-brain barrier (BBB) thereby resulting in the penetration of these antibodies through BBB and resulting in neuronal damage. This neuronal damage might cause the cognitive disturbance and memory loss, commonly observed in patients with SLE.

Expanded Proinflammatory T Cells in Inclusion Body Myositis. Jayesh Pandya, Andreas Fasth, Snjolaug Arnardottir, Eva Lindroos, Vivianne Malmström and Ingrid E. Lundberg, Karolinska Institute, Stockholm, Sweden

Purpose: Inclusion body Myositis (IBM) is a chronic, inflammatory myopathy of unknown cause, which is characterized clinically by muscle weakness and muscle atrophy, particularly of the quadriceps and finger flexor muscles, and by being resistant to conventional immunosuppressive drugs. Muscle tissue of IBM patients is characterized histopathologically by leukocyte infiltrates, preferentially T cells and macrophages. We have previously demonstrated the accumulation of a specific phenotype of T cells, so called $CD28^{null}$ T cells in muscles of patients with dermatomyositis and polymyositis. The $CD28^{null}$ T cells are apoptosis resistant, pro-inflammatory and cytolytic cells that hypothetically also may have a role in disease mechanisms of IBM. The aim of present study is to investigate the frequency and effector functions of $CD28^{null}$ T cells in IBM and whether this subset of T cells is clonally expanded. Functional characterization of proinflammatory T cells will provide important clues for designing new T cell-targeted therapeutics for inflammatory myopathies.

Patients and Methods: A cohort of 20 patients with IBM were analyzed for the frequency of circulating $CD4^{+}CD28^{null}$ and $CD8^{+}CD28^{null}$ T cells in peripheral blood and muscle biopsies were taken at different time points during disease course. The TCR-Vβ usage was determined by the flow cytometry based IOTest1 B Mark kit (n=6). For functional analysis, peripheral blood mononuclear cells (PBMC) were polyclonally stimulated with plate bound anti-CD3 for 6 and 72 hrs (n=5) and the frequencies of intracellular IFNγ and CD107a (a marker of degranulation and cytotoxicity) containing T cells were recorded by multicolour flow cytometry.

Results: $CD28^{null}$ T cell populations were clearly expanded in peripheral blood of IBM patients and both the $CD4^{+}$ $CD28^{null}$ and $CD8^{+}$ $CD28^{null}$ T cell populations were highly TCR Vβ restricted compared to the $CD28^{+}$ subsets from the same patient. Different patients displayed different TCR Vβ restrictions, and the expansions were consistent over time. Anti-CD3 stimulation of PBMC resulted in a fast and high frequency of $CD28^{null}$ T cells of both the $CD4^{+}$ and $CD8^{+}$ subsets significantly more positive for IFNγ and CD107a compared to $CD28^{+}$ subsets. Both the TCR Vβ dominant and non dominant $CD28^{null}$ subsets were equally activated under these conditions.

Conclusion: The TCR Vβ restriction of $CD28^{null}$ T cells in IBM patients suggest that a limited numbers of antigens are involved in driving the expansion and high TCR Vβ restriction of $CD28^{null}$ T cells in IBM patients. Functional evaluation experiments revealed that $CD28^{null}$ T cells in both the $CD4^{+}$ and $CD8^{+}$ compartment are devoted proinflammatory and cytotoxic effector cells. Interestingly, the TCR Vβ dominant and non-dominant $CD28^{null}$ T cell subsets displayed equal quality and quantity of effector function. Further analysis is ongoing to evaluate antigen specificity of these $CD28^{null}$ T cells and their presence in skeletal muscle infiltrate of IBM patients.

Evidence for the Implication of Th-1 and Treg Cells but Not Th-17 in Inclusion Body Myositis. Yves Allenbach Jr.[1], Julia Wanschitz Sr.[2], Michelle Rosenzwajg Sr.[1], Coralie Bloch-Queyrat Sr.[3], Serge Herson[4], David Klatzmann Sr.[1] and Olivier Benveniste[4], [1]UMR 7211, CNRS,Université Pierre et Marie Curie, University of Paris 06, Paris, France, [2]UMR 974, CNRS, Université Pierre et Marie Curie, University of Paris 06, Paris, France, [3]Hôpital Pitié-Salpêtrière, [4]Hôpital Pitié-Salpêtrière, Paris, France

Purpose: Inclusion Body Myositis (IBM) is the most common acquired myopathy in patients above the age of 50 years. This disabling disease is an inflammatory myopathy characterized by CD8+ cytotoxic infiltrates and amyloid deposits. IBM remains resistant to conventional treatment. To date, only severe T cell depletion by Anti-thymocyte Globulin or Alemtuzumab can slow down the course of the disease underlining the role of adaptative immune system. Regulatory T cells (Treg) are key regulators of this system. We described Treg in 22 IBM patients, but also Th1/Th2/Th17 and inflammatorys responses, in attempt to develop new therapeutic approaches.

Method: We included 22 IBM patients (mean age; 70.1) and 22 sex and age matched controls. All were not treated with immunosuppressive drugs, nor presented active infection or other autoimmune diseases. Peripheral blood mononuclear cells (PBMC) were analyzed using flow cytometry. PBMC were tested in vitro for their ability to produce IFNg and IL-17 upon stimulation with PMA and Ionomycin. Using a multiplex assay, the concentrations of 25 cytokines and chemokines was determined in the supernatant of stimulated PBMC and in the sera. Muscle biopsies of 7 among the 22 IBM patients were tested by immunohistochemistry for presence of CD4+, CD8+ T cells and Treg.

Results: In blood, mean percentage of activated CD4+ T cells (CD3+CD4+DR+) was higher in IBM patients than in controls (16.2±13.7% vs 8.7±4.2%; p=0.04). Moreover, terminally differentiated CD8+CD28- T cells was increased in IBM patients compare to controls (61±23.9% vs 44±20%, p=0.023). The mean percentage of CD3+CD4+IFNg+, CD3+CD8+IFNg+ and CD3+CD4+IL-17+ was not statically different in both groups. The supernatant concentration of IFNg and IL-17 was not statically different in the two groups. Whereas, we observed an increase of IL-12 concentration in the sera of IBM patients (301.36±142.08 pg/ml vs 154.25±-28.41 pg/ml p=0.0002) and of the chemokine IP-10 (377.73±296.72 pg/ml vs 61.147±44.64 pg/ml; p<0.0001).

The percentage of Treg (CD3+CD4+CD25+CD127-FOX3+) among CD4+ T cells was lower in IBM group compare to controls (5.5 ± 0.3% vs 6.6 ± 0.4% p= 0.043). Treg cells (FOXP3+) were detected in 6/7 muscle biopsies at a low frequency among CD4+ T cell infiltrates.

Conclusion: Together these results suggest that CD4+ and CD8+ T cells are more activated and engaged in a Th1 lineage (and not a Th17 one). Effector Th1 and activated CD8 cells may home the muscle attracted by IP-10. Treg cells are decreased in blood whereas they are present in the muscle, where they seem unable to control effector cells.

Relationship Between Disease Activity and Type 1 Interferon- and Other Cytokine-Inducible Gene Expression in Blood in Dermatomyositis and Polymyositis. Steven A. Greenberg[1], Brandon W. Higgs[2], Christopher Morehouse[2], Philip Brohawn[2], Wei Zhu[2], Ronan J. Walsh[1], Sek Won Kong[1], Jiaqi Huang[2], Anthony Amato[3], Barbara White[2], Peter A. Kiener[2], Bahija Jallal[2] and Yihong Yao[2], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]MedImmune, Gaithersburg, MD, [3]Harvard University

Purpose: A longitudinal study evaluated a group of cytokines including type 1 interferon (IFN) that are potentially involved in the pathogenesis of dermatomyositis (DM) and polymyositis (PM) pathogenesis before and during treatment. Peripheral blood of 42 patients with DM or PM was subjected to gene expression profiling using Affymetrix human genome U133 plus 2.0 GeneChips® in an initial study to identify the prevalence of patients exhibiting periphery overexpression of type 1 IFN-inducible genes. To gain further scientific insight on type 1 IFN as a potential therapeutic target for DM and PM, 24 patients with DM or PM were then prospectively enrolled and followed for up to 6 years (mean of 1.9 years) while receiving standard clinical care.

Methods: Clinical courses including MITAX scoring of disease activity were assessed across 150 patient visits. Peripheral blood samples collected at 80 patient visits were used for microarray analysis of , GM-CSF,β, IL-1αcytokine-induced gene expression for type 1 IFN, TNF-IL-10, and IL-13 signaling pathways.

Results: 35 of 42 (87%) DM and PM patients had moderate/strong overexpression of type 1 IFN-inducible genes in the periphery blood. In the longitudinal study during the course of treatment, 21 of 24 patients showed overexpression of a type 1 IFN-inducible gene signature in peripheral blood. Overexpression of type 1 IFN-inducible genes IFI27, IFI44, IFI44L, and RSAD2 and a type 1 IFN-inducible 13-gene composite signature correlated highly with disease activity during treatment. For 3 patients, type 1 IFN-inducible gene overexpression during treatment preceded disease , GM-CSF, IL-10, andβ, IL-1αrelapse within approximately 1 month. TNF- IL-13 inducible gene signatures were also overexpressed in DM and PM patients but were not correlated with disease activity.

Conclusion: Targeting type 1 IFN is likely to provide clinical benefit in DM and PM patient populations with overexpression of type 1 IFN-inducible genes in the periphery. Type 1 IFN-inducible gene overexpression in the periphery blood merits further study for use as a pharmacodynamic and predictive biomarker for developing anti-type 1 IFN therapy for these patients.

Discordance Between Cardiac Troponin T Elevation in Patients with Inflammatory Myopathies Vs. Other Muscle Disease. John P. Case[1], Augustine M. Manadan[2] and Rohit Aggarwal[3], [1]Stroger Hospital of Cook County, Chicago, IL, [2]Rush Univ Med Ctr, Chicago, IL, [3]John H. Stroger, Jr. Hospital of Cook County and Rush University Medical Center, Chicago, IL

Purpose: Patients commonly present with malaise and fatigue associated with elevated creatine kinase (CK), or a CK is determined early in the course of evaluation for musculoskeletal disease. Some are ultimately diagnosed with inflammatory myopathies (IM). In many however, the CK elevation is unrelated to IM but rather to non-IM causes (non-IM). We have previously determined (ACR 2007 and J. Rheum, in press) that cardiac troponin T (cTnT), but not cardiac troponin I (cTnI) is frequently elevated in patients with IM and that cTnT and CK are correlated. We undertook the present study to determine whether cardiac troponins are elevated in non-IM and their relationship to CK.

Methods: We performed a retrospective study using a computerized database to identify patients who were evaluated for non-IM CK elevation, myopathy, or rhabdomyolysis between January 2004 and December 2008 by the Rheumatology service of Cook County Hospital. We compared these patients to those with IM described earlier. In each group, we excluded patients who had chronic kidney disease (CKD) or acute coronary syndrome (ACS). Statistical comparisons were done with Pearson's chi-square test.

Results: The records of 56 patients with a non-IM diagnosis were retrieved. The CK was assayed in 54 (96%) and was elevated in 47 (89%). The etiology of the CK elevation was statin myopathy (16); neuromyopathy (6), metabolic myopathy (2), HIV (2), and viral syndrome (2). Non-statin medication toxicity, muscular dystrophy, alcohol, cardiomyopathy, and hyperthyroidism accounted for one case each. In one case the cause was multifactorial. In 13 cases the diagnosis was not determined. In the 9 patients with normal CKs (17%), the final diagnoses were steroid myopathy (3); and in one case each, alcohol, statin myopathy, cardiomyopathy, and myopathy from a non-statin medication. In two cases (4%) the CK was not assayed. One had cardiomyopathy, another had steroid myopathy. In the 47 patients who had elevated CK and had cTnT or cTnI assayed, cTnT was elevated in 3 of 19 (16%) and cTnI in 0 of 18 (0%). Inclusion body myositis was suspected in two of the patients with elevated cTnT, but biopsy was not done and formal diagnosis not made. In the third patient, elevated cTnT was attributed to the combination of cyclosporine and ezetimibe. cTnT was assayed in four patients with rhabdomyolysis. It was elevated in only one patient (cyclosporine/ezetimibe combination). Overall, cTnT elevation was not associated with CK elevation ($p=0.445$). By comparison (and as previously reported), in patients with IM who had elevated CK the cTnT was elevated in 18 of 23 (78%) and was highly associated with the CK ($p=0.005$). The percent frequency of cTnT positivity in IM patients with elevated CK is significantly higher, almost 5 fold, than in patients with non-IM ($p<0.001$).

Conclusion: An elevated cTnT is not associated with non-IM CK elevation. In evaluating a patient with possible IM in the non-ACS, non-CKD setting, obtaining the cTnT level may help in the diagnosis, since it is usually elevated in IM but rarely elevated in non-IM. The reason is unclear.The cTnI is not elevated in IM or in non-IM.

589

Anakinra in Patients with Refractory Idiopathic Inflammatory Myopathies. Christina Dorph[1], Maryam Dastmalchi[1], Helene Alexanderson[2], Christina Ottosson[3], Eva Lindroos[3], Inger Nennesmo[4] and Ingrid E. Lundberg[1], [1]Rheumatology Unit, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine and Department of Physical Therapy, Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Division of Pathology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Purpose: Earlier studies have shown an increased interleukin-1 (IL-1) expression in muscle tissue from patients with polymyositis (PM), dermatomyositis (DM) and inclusion body myositis (IBM). The objective of this study was to investigate the efficacy and tolerability of treatment with the IL-1 blocking agent, anakinra, in patients with treatment-resistant inflammatory myopathies.

Method: 15 patients with refractory PM (6), DM (4) or IBM (5) were included in a 12-month open-label study and treated with 100 mg anakinra subcutaneously per day. All patients had stable concomitant immunosuppressive treatment such as prednisolone and methotrexate or azathioprine. Outcome measures included myositis disease activity score with improvement defined according to The International Myositis Assessment and Clinical Studies Group (IMACS) and for muscle performance, the functional index of myositis (FI) at 3, 6 and 12 months. Repeated muscle biopsies (months 0 and 6) were investigated for cellular infiltrates, major histocompatibility complex (MHC) class I, IL-1α, IL-1β and IL-1 receptor antagonist (IL-1Ra).

Results: 8 women and 7 men who had definitive diagnosis of PM, DM or IBM with disease duration of 2-18 years were included. 9 patients completed the 12 month study. 11 patients completed 6 months, and 13 patients concluded 3 months. 7 patients fulfilled improvement criteria for disease activity (responders) according to IMACS definition (3 DM, 3 PM, 1 IBM). 5 had improved by 3 months (1 sustained until 6 months), 1 by 6 months (sustained until 12 months) and 1 by 12 months. Five were unchanged and three worsened (non-responders). FI improved ≥20 % in 4 of the 7 responders (1 DM, 2 PM, 1 IBM). Two patients withdrew due to a local skin rash at the injection site. Other reasons for premature ending of the study were increased muscle symptoms in 2, headache in 1 and lack of efficacy in 1. Repeated biopsies were available in 14 patients. There were no statistically significant changes in mononuclear inflammatory cells, T cells, IL-1α, IL-1β and MHC class I between pre-treatment and post-treatment biopsies. All responders had IL-1Ra expression in the post-treatment biopsy but only 3 of 8 non-responders.

Conclusion: Treatment with anakinra had beneficial effects on clinical outcome measures including disease activity and muscle performance in some patients in this pilot study of previously treatment-resistant myositis. The clinical positive effects together with the observation of IL-1Ra expression in muscle tissue in more post-treatment biopsies of responders than non-responders need to be confirmed in a larger placebo-controlled trial.

Effectiveness of Mycophenolate Mofetil (MMF) as Secondary Therapy for Idiopathic Inflammatory Myopathy (IIM) & Interstitial Lung Disease (ILD): Case Series of 11 Patients. Richard CJ Campbell[1] and Patrick A. Gordon[2], [1]King's College London, London, United Kingdom, [2]Kings College Hospital, London, United Kingdom

Purpose: Controlled trials for treating IIM (and IIM associated with ILD) are limited although corticosteroids and imunosuppressants are standard therapies. A few small case series are beginning to emerge to suggest that MMF may be efficacious and well tolerated in these patients. We present a case series of 11 patients with IIM (5 with ILD) with long-term follow up.

Methods: In this retrospective observational study we examined case notes for 11 patients with IIM treated with MMF. We recorded outcomes before introduction of MMF and at 6 months, 1 and 2 years. We measured muscle strength (IMACS MMT 260 score), change in CK and change in mean steroid dose to assess for successful steroid taper. For the patients with associated ILD, percentage change in predicted TLCO/VC were recorded at 6 months and 1 year. Adverse event data thought to be directly attributable to MMF were also recorded.

Results: 11 patients (8 female) were treated for 257 patient-months. 10 had dermatomyositis, 1 had polymyositis and 5 had associated ILD. 10/11 patients had received steroids and at least one other DMARD prior to MMF.

8 patients had muscle weakness (MMT >260) prior to MMF. 7/8 of these patients with weakness (range 229-258/260, mean 249/260) improved by 6 months (range 256-260/260, mean 258.3). All those on MMF for 2 years (n=4) showed improvement from baseline (range 256-260/260, mean 259/260). 3 patients had a CK>300 prior to MMF but all had normalised by 6 months. Mean steroid dose reduced from 23.9mg to 15.8mg over 1 year (dose reduction was possible in 8/11).

Mean percentage predicted TLCO and VC improved by 13% and 12% respectively by 6 months (n=5) and 14.2% and 13.7% at 1 year (n=4). One patient required rituximab before progressive decline in lung function was halted. Out of 3 patients who had severe dysphagia (including one who required PEG feeding), all improved significantly.

Adverse events for the group, thought to be directly related to MMF, were already known to be associated with its use: TB, shingles, campylobacter diarrhoea, migraine, mania and sleep disturbance. There was one case of penile carcinoma but symptoms were already being investigated prior to introduction of MMF.

Conclusion: For this population, MMF is effective as a second or third line treatment in improving muscle power and for tapering steroids in IIM. It is also efficacious for ILD associated with IIM. Some adverse events including opportunistic infection were noted in this group.

Effects of Once-Yearly Zoledronic Acid 5mg in Combination with Teriparatide (PTH) On Postmenopausal Women with Osteoporosis. Cosman Felicia[1], Kenneth Saag[2], Erik Eriksen[3], Chris Recknor[4], Paul Miller[5], Susan L. Greenspan[6], Philemon Papanastasiou[7], Hanumantha Rao[8], Juerg Gasser[7], Christina Bucci-Rechtweg[9] and Steven Boonen[10], [1]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, [2]University of Alabama, Birmingham, AL, [3]Aker University Hospital, Oslo, Norway, Oslo, Norway, [4]United Osteoporosis Centers, Gainesville, FL, USA, Gainesville, FL, [5]Colorado Center for Bone Research, Lakewood, CO, [6]University of Pittsburgh, Pittsburgh, PA, [7]Novartis Pharma AG, Basel, Switzerland, [8]Novartis Healthcare Pvt. Ltd, Hyderabad, India, [9]Novartis Pharmaceuticals Corp, East Hanover, NJ, [10]University of Leuven, Leuven, Belgium

Purpose: The role of combination therapy with hrPTH (1-34) (PTH) and bisphosphonates (BPs) is unclear and although there does not appear to be an additive effect in terms of bone mineral density, certain BPs may blunt the PTH anabolic effect when administered simultaneously. Zoledronic acid (ZOL) does not blunt the PTH effect in rodent models (*Gasser et al. 2006*), and we sought to determine the effects in humans of combination therapy with once-yearly i.v ZOL 5mg and daily sc PTH 20mg *vs.* either agent alone on spine and hip BMD (DXA) and bone turnover markers [serum C-telopeptide, (β-CTx), and N-terminal propeptide of type I collagen, (P1NP)].

Method: This 1-year, partial double-blinded, multicenter study randomized 412 postmenopausal osteoporosis women aged 45–87 yrs, (65±9 yrs) to receive either a combination of ZOL and PTH (n=137), ZOL alone (n=137) or PTH alone (n=138). Between-treatment comparisons for the percent change in lumbar spine (LS) and total hip BMD relative to baseline were performed at weeks 13, 26 and 52 based on the difference of least square means (LSM) from a two-way ANOVA model including all 3 treatments.

Results: 388 women (94.2%) completed the study. At week 52, the LSM estimates of the percent increase in spine BMD were 7.51%, 7.05%, and 4.37% in the combination arm, PTH and ZOL groups, respectively (NS for combination *vs.* PTH , p<0.001 for combination and PTH *vs.* ZOL). The combination therapy significantly increased LS BMD at weeks 13 and 26 and total hip BMD at weeks 13, 26, and 52 *vs.* PTH alone (all p<0.005) (Figure). In the combination arm, β-CTx declined within 4 weeks and rose progressively thereafter, with levels above baseline within 39 weeks; P1NP increased for up to 4 weeks, declined to a nadir at week 8 and then rose progressively with levels above baseline by week 26. Both β-CTx and P1NP levels were lower with combination arm *vs.* PTH alone throughout the trial (all p<0.002). Overall incidence of serious adverse events was 9.5%, 14.6 % and 10.9% in combination, ZOL and PTH arms, respectively. Most frequent adverse events in the combination and ZOL arms *vs.* PTH were transient post-infusion flu-like symptoms.

Conclusion: The concomitant administration of once-yearly i.v ZOL 5mg and daily sc PTH 20mg does not blunt the PTH effect on lumbar spine BMD and results in a significantly greater increment in total hip BMD than PTH alone. Combination therapy could be considered in patients at high risk for hip fracture or those with very low hip BMD.

The Effects of 6 Years of Continuous Denosumab Treatment On Bone Mineral Density and Biochemical Markers of Bone Turnover.

P. Miller[1], Michael Bolognese[2], EM Lewiecki[3], M. McClung[4], R. Weinstein[5], B. Ding[6], RB Wagman[7] and J. San Martin[6], [1]Colorado Center for Bone Research, Lakewood, CO, [2]Bethesda Health Research Center, Bethesda, MD, [3]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, [4]Oregon Osteoporosis Center, Portland, OR, [5]Diablo Clinical Research, Inc., Walnut Creek, CA, [6]Amgen Inc., Thousand Oaks, CA, [7]Amgen Inc. and Stanford University School of Medicine, Thousand Oaks and Stanford, CA

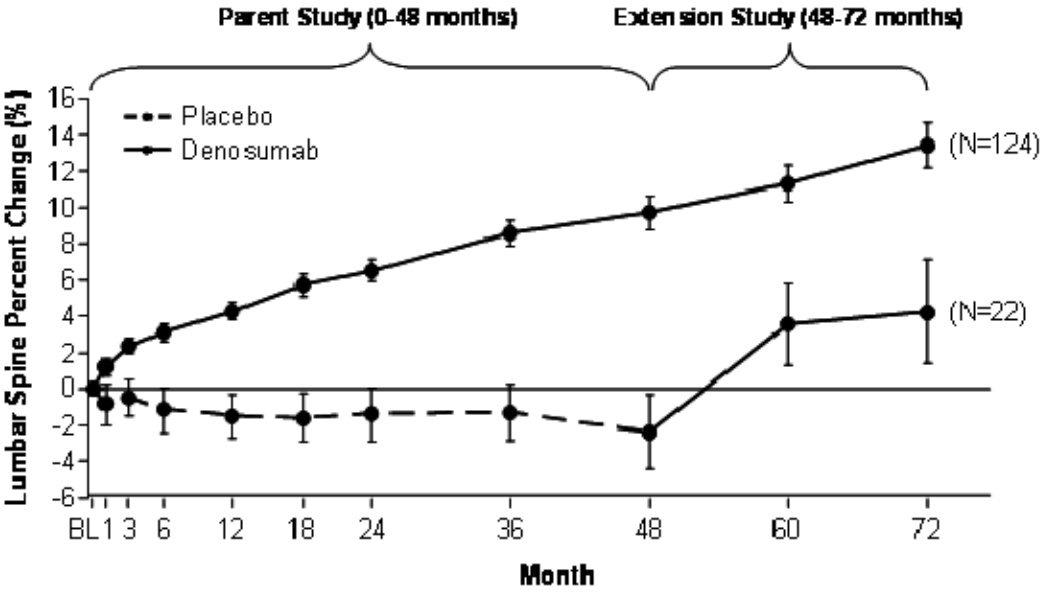
Purpose: Denosumab (DMAb), an investigational fully human monoclonal antibody that inhibits RANKL, significantly reduced the risk of new vertebral, hip, and nonvertebral fractures in a Phase 3 trial at 3 years (Cummings et al., OI 2009;20:S16). In a Phase 2 study, DMAb treatment for 4 years increased bone mineral density (BMD) and reduced bone turnover markers (BTM) (Miller et al., Bone 2008;43:222). Here we present the effects of 6 years of DMAb treatment on BMD and BTM.

Methods: In the Phase 2 parent study, postmenopausal women with a T-score between –1.8 and –4.0 (lumbar spine), or –1.8 and –3.5 (total hip or femoral neck), were randomized to receive placebo (Pbo), alendronate (ALN), or 1 of 7 different doses of DMAb. After 2 years, subjects were reallocated to maintain, discontinue, or discontinue and reinitiate DMAb; discontinue ALN; or maintain Pbo for 2 more years (Miller et al., Bone 2008;43:222). In the extension phase of this study, all subjects received open-label DMAb 60 mg subcutaneously every 6 months (Q6M). Our results focus on subjects who received DMAb treatment for 6 years and those who received Pbo for 4 years followed by DMAb for 2 years.

Results: Of 262 subjects who completed the parent study, 200 enrolled in the extension study and of these, 164 (82%) have completed the first 2 years at the time of this submission. For the 93 subjects who received 6 years of DMAb treatment, BMD at the lumbar spine increased 13.4% compared with their parent study baseline and 2.7% compared with their extension study baseline (Figure). For the 16 subjects in the previous Pbo cohort, 2 years of DMAb treatment resulted in gains in BMD comparable to those observed during the first 2 years of DMAb in the parent study (Figure). Reductions in serum CTX were sustained over the course of continuous DMAb treatment and observed values were comparable to the premenopausal reference range. Reductions in these BTMs also were observed when the Pbo group transitioned to DMAb treatment. The types and rates of adverse events during the extension study were balanced and similar to those observed during the parent study.

Conclusion: Data collected from the 4-year parent study and the 2-year extension study demonstrated that DMAb was safe and effective for 6 continuous years of treatment. There was an increase in BMD in the previous Pbo and continued treatment groups along with reduction of bone turnover markers.

Figure: Percent Change in Lumbar Spine BMD From Parent Study Baseline



Least squares mean (95% CI). N=subjects with at least one parent study baseline and at least one post-baseline measurement. 1 subject who had new vertebra deletion during the extension study was excluded from this analysis.

The Effects of Denosumab On Fracture Risk Reduction Related to Baseline Bone Resorption. M. McClung[1], D. Bauer[2], C. Christiansen[3], P. Ebeling[4], A. Grauer[5], P. Lakatos[6], W. Lems[7], C. Libanati[5], I. Reid[8], C. Roux[9], P. Sambrook[10], A. Wang[5], S. Cummings[11] and R. Eastell[12], [1]Oregon Osteoporosis Center, Portland, OR, [2]UCSF, San Francisco, CA, [3]CCBR, Ballerup, Denmark, [4]University of Melbourne, Melbourne, Australia, [5]Amgen Inc., Thousand Oaks, CA, [6]Semmelweis University, Budapest, Hungary, [7]Vrije Universiteit medical Centre, Amsterdam, Netherlands, [8]University of Auckland, Auckland, New Zealand, [9]Paris Descartes University, Paris, France, [10]University of Sydney, Sydney, Australia, [11]SFCC, CPMC Research Institute & UCSF, San Francisco, CA, [12]University of Sheffield, Sheffield, United Kingdom

Purpose: Denosumab, an investigational human monoclonal antibody to RANKL, significantly reduced the risk of new vertebral, nonvertebral, and hip fractures in the FREEDOM trial. However, it is not known whether the reduction in fracture risk with denosumab is related to the level of bone resorption at baseline.

Methods: FREEDOM was a 3-year, randomized, placebo-controlled trial in women 60-90 yrs old with postmenopausal osteoporosis defined as a T-score <-2.5 at the spine or hip but not <-4 at either site. Treatment was sc injection of denosumab (60 mg) or placebo every 6 months, along with daily calcium (1000 mg) and vitamin D supplement (400 to 800 IU). We measured 2 bone resorption markers, CTX (ELISA,

Osteometer) and TRACP 5b (immunocapture activity assay, Suomen Bioanalytiikka Oy) in baseline fasting serum samples (n=3906 placebo, n=3902 denosumab).

Results: New vertebral fractures were identified as an increase of ≥1 semiquantitative grade from a baseline grade of 0 on spinal radiographs taken annually, and nonvertebral fractures were confirmed radiologically. Overall, denosumab decreased new vertebral fracture risk by 68% (RR=0.32, *P*<0.0001) and nonvertebral fracture risk by 20% (HR=0.80, *P*=0.01). We divided the study population by quartiles of baseline bone turnover marker levels and examined the denosumab vs placebo risk/hazard ratios for each fracture type and tested for a trend across quartiles in the denosumab group (Table). Denosumab reduced new vertebral fracture risk in all quartiles for CTX and TRACP 5b (*P*<0.001). A greater effect of denosumab on risk of new vertebral fractures was seen in patients with higher baseline serum levels of CTX (*P*=0.01). For nonvertebral fractures, there was a similar trend that did not reach statistical significance (*P*=0.09).

Conclusion: Denosumab reduced the risk of new vertebral fractures regardless of the level of baseline bone resorption. Denosumab-treated patients with higher levels of CTX had a greater reduction in new vertebral fracture risk. The effect of denosumab to reduce nonvertebral fracture risk was not statistically associated with baseline bone turnover.

	CTX, New Vert, RR	CTX, Nonvert, HR	TRACP 5b, New Vert, RR	TRACP 5b, Nonvert, HR

Active Shape Modeling of the Hip and Incident Osteoporotic Hip Fractures. K.R. Luker[1], John A. Lynch[2], R.K Chaganti[3], N. Parimi[4], M. Nevitt[2], J.S. Gregory[5], T. Hillier[6] and N.E. Lane[7], [1]UCSD, San Diego, CA, [2]UCSF, San Francisco, CA, [3]UCSF, SF, SF, CA, [4]CPMC, SF, CA, [5]Aberdeen, United Kingdom, [6]KPMG, Portland, OR, [7]UCDMC, Sacramento, CA

Purpose: Variations in femoral head shape have been reported to predict incident hip fractures. This study evaluated the proximal femur shape as a risk factor for incident hip fractures in a cohort of elderly women through the method of active shape modeling (ASM).

Methods: This analysis was performed using prospectively collected data from a cohort of white women ≥65 years of age at baseline enrolled in the Study of Osteoporotic Fractures (SOF). Supine pelvic radiographs were obtained at the baseline SOF visit. A nested case-

control study was performed. Hips were eligible for inclusion if they had no prevalent radiographic osteoarthritis (RHOA) or fracture in either hip at baseline. Case subjects had no RHOA baseline and had an incident hip fracture after the baseline visit (n=168). Control subjects were a random selection of subjects (n= 231) without RHOA in either hip at baseline or incident hip fractures during the follow-up period. The shape of the right proximal femur was outlined on a digitized baseline radiograph by two readers (KL, KC) using a statistical image analysis technique. Active shape modeling (ASM) was performed to generate 10 unique and independent modes of variations in the proximal femur shape, accounting for 95% of the variance in the shape of the proximal femurs (Gregory et al, Osteo. Inter, 2004). Three other measures of hip geometry associated with hip fracture, namely femoral neck width and length and femoral head diameter, were also measured. The association of proximal femur shape by ASM and other geometric measures were analyzed by logistic regression as independent predictors of incident hip fracture adjusting for covariates.

Results: The incident hip fracture cases were older, weighed less and had lower hip bone mineral density than the control subjects ($p<0.05$). Point-to-point correlations between each film and the composite average shape were computed for the entire set of 399 images and were used to describe 10 modes of variation. Modes 1 (OR 1.62,95% CI: 1.26-2.07 $p<0.001$, per SD change in mode score) and 4 (OR 2.13, CI: 1.63-2.77, $p<0.001$) were found to carry a significantly increased risk for future hip fractures while modes 6 (0.49 95% CI: 0.38-0.65 , $p<0.001$) and 10 (0.60, 95% CI: 0.47-0.78), $P<0.001$) were shown to have a significantly lower risk for incident hip. Femoral neck length was also associated with incident hip fracture, while femoral head diameter and femoral neck diameter were not significantly correlated.

Conclusion: These results suggest that variation in the relative size of the femoral head and neck are moderate determinants of incident hip fractures. The combination of hip shape, femoral neck length, and BMD may improve our ability to identify patients who may be at increased risk for osteoporotic hip fractures and implement appropriate therapy.

Fracture Risk Among a Very Large Cohort of RA: Age and Gender-Specific Results. Daniel H. Solomon[1], Gregory Daniel[2], Gina Chang[2], Jun Liu[3] and Sebastian Schneeweiss[3], [1]Brigham & Women's Hospital, Boston, MA, [2]HealthCore, Wilmington, DE, [3]Pharmacoepidemiology, Boston, MA

Purpose: While osteoporosis is known to be more common in persons with RA, little is known about the incidence rates (IRs) for fractures by anatomic site and stratified by age and gender. We compared fracture rates for RA versus age and gender-matched controls.

Methods: Adult beneficiaries of Blue Cross Blue Shield health plans served as the source population. Persons with at least 2 diagnoses of RA with 12+ months of plan eligibility before and after cohort entry date were included. A group of non-RA controls with similar eligibility criteria who were matched on state, plan type and year of cohort entry were also included. Fractures were defined from health care utilization data based on established algorithms. In addition, potential confounders were defined based on data from the 12 months prior to cohort entry. These include age, gender, use of relevant medications (steroids, bisphosphosphonates, benzodiazepines, SSRIs, beta blockers, anti-convulsants, thiazides), co-existence of conditions associated with falls and fractures, and prior diagnoses of a fracture or osteoporosis. IRs and incidence rate ratios (IRRs) were calculated. As well, adjusted Cox proportional hazards models were constructed to estimate the hazard ratio of fracture in subjects with RA compared with controls, adjusting for all of the above confounders.

Results: 47,034 subjects with RA were included along with 828,606 controls. The median age of subjects with RA was 55 years and 45 years for controls. 73% of those with RA were female compared with 71% for controls. The age- and gender-specific IRs for any fracture and by individual anatomic sites were elevated in RA compared with controls (**see Table** for IRs and IRRs). As expected, the IRs across all age strata were higher for women than men in both cohorts (RA and non-RA) and increased with older age. When comparing RA with non-RA across common anatomic sites for osteoporotic fractures, the IRR was consistently elevated for RA: hip IRR 2.07 (95% CI 1.84 – 2.33), wrist IRR 1.19 (95% CI 1.04 – 1.35), pelvis IRR 2.64 (95% CI2.33 – 2.97), and humerus IRR 1.80 (95% CI 1.52 – 2.15). After multivariable adjustment in a Cox regression model, RA was associated with an increased relative risk for any fracture (HR 1.13, 95% CI 1.04 – 1.22).

Conclusion: These analyses demonstrate an elevated relative risk of typical osteoporotic fractures for RA patients compared with non-RA. This trend held up across age and gender strata, as well as across anatomic sites.

Table: Risk of Fracture Comparing Patients with RA to Controls

	RA	Non-RA	Incidence rate ratio, RA vs non-RA(95% CI)
	Incidence rate per 1,000 person-years, (95% CI)		
WOMEN			
< 50 years	3.14 (2.42 – 3.86)	1.73 (1.62 – 1.84)	1.82 (1.43 – 2.30)

Association Between Bone Mineral Density and High-Sensitivity CRP in a Large Population-Based Sample. Paola de Pablo and Christopher Buckley, University of Birmingham, Birmingham, United Kingdom

Purpose: Several studies suggest that bone mineral density (BMD) is reduced in chronic inflammatory diseases. Higher serum levels of hs-CRP have been associated with lower BMD in women and older adults. However, whether this association holds in a representative sample of the general population is unclear. The purpose was to examine the relationship between BMD and hsCRP in a large representative US population-based sample from the National Health and Nutrition Examination Survey (NHANES) conducted between 1999 and 2004.

Method: We selected subjects over age 20 with BMD (total and subregions) measured by dual-energy x-ray absorptiometry scans from NHANES 1999-2004. The association between CRP concentrations and BMD was evaluated using multivariable linear regression models adjusting for potential confounders. Sensitivity analyses included further adjustment for vitamin D levels, participants taking prescriptions medications, or comorbid diseases, such as arthritis, COPD, CVD, CHF, and stroke.

Results: The study sample included 11,065 participants with a mean age of 50 years (range 20-85). Of those, 53% were Caucasians, 22% were Mexican-American, 18% were African-American, and 7% other races, and 52% were women. Men had higher BMD and lower hs-CRP concentrations than women. BMD (total, subtotal, extremities, ribs, and trunk) was inversely associated with CRP quintiles both in men and women in a dose-dependent fashion (total BMD p for trend <0.001 for men and 0.001 for women). Lumbar spine BMD was inversely associated with CRP in women but not in men and there was no association at the thoracic spine and pelvis BMD subregions. The associations were independent of prescriptions medications use, comorbidities, and other potential confounders. Sensitivity analyses with further adjustment for vitamin D levels confirmed the results (Figures).

Conclusion: Among men and women in a large representative population-based sample, hs-CRP is inversely and independently associated with BMD (total and some subregions) in a dose-dependent fashion.

Rates and Predictors of Influenza, Pneumococcal, and Herpes Zoster Vaccination in Adult Patients with Rheumatic Diseases.

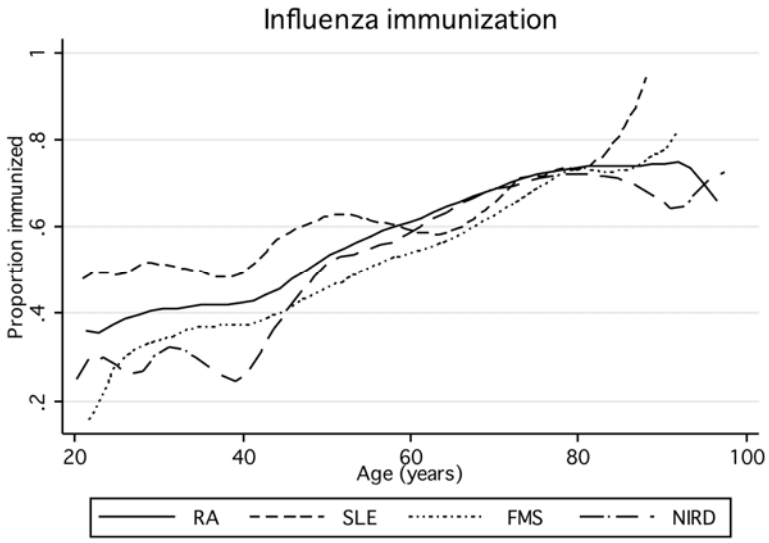
Frederick Wolfe[1] and Kaleb D. Michaud[2], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Nebraska Medical Center and NDB, Omaha, NE

Purpose: Patients with chronic illnesses are at increased risk for, and have increased consequences of, illnesses such as influenza, pneumonia, and Herpes Zoster (Zoster). Public health authorities recommend immunization against influenza and pneumonia in the chronically ill, those over age 50 (influenza), and those who are immunocompromised; but there are not yet recommendations for the newer, expensive zoster vaccine. We studied rates and predictors of immunization in rheumatoid arthritis (RA) and other rheumatic diseases in light of public health recommendations and observed general population rates.

Methods: We studied 25,559 observations from 10,381 patients with RA, SLE, fibromyalgia, and non-inflammatory rheumatic disorders (NIRD) over a 2-year period ending in 2008. Patients self-reported immunizations for influenza (IV), pneumonia (PV), pneumonia in last 5 years (PV5), and zoster (ZV) in semi-annual questionnaires. We analyzed a series of predictors of immunization using Generalized Estimating Equations (GEE).

Results: In the most at risk group, age >=65, immunization rates for all patients were IV 70.2%, PV/PV5 78.8%/66.3%, and ZV 9.1% (table 1). Compared with RA, the SLE immunization rate was increased by 20% and the fibromyalgia rate was decreased by 30% after adjustment for age and sex. For PV5 these values were 42% increase and 56% decrease. For IV and PV5, rate differences between diagnostic groups were mostly in the <65 year age group (figure1). In multivariable analyses across all immunizations, rates increased by age, presence of diabetes, cardiovascular and pulmonary diseases, education level, household income, and majority ethnicity. In the multivariable RA analyses described above, prednisone (OR 1.14 (1.04, 1.25)) and biologic use (OR 1.27 (1.16, 1.39)) increased PV5 probability and biologic use increased IV probability (OR 1.21 (1.11,1.31)).

Age group	IV (Annual) %	PV (ever) %	PV (last 5 yrs) %	ZV (ever) %
<40	41.3 (37.4, 35.2)	29.5 (25.8, 33.2)	23.6 (20.2, 27.0)	-
40-65	56.3 (54.9, 57.6)	45.1 (43.7, 46.4)	37.1 (35.8, 38.4)	-
>=65	70.2 (68.9, 71.6)	78.8 (76.7, 79.2)	66.3 (64.9, 67.7)	9.1 (8.3,9.9)



Conclusion: Rates of immunization among rheumatic disease patients are similar to those of published studies of the general population but substantially lower than recommended by public health authorities. The use of ZV remains rare. Rheumatologists should pay more attention to immunization status of rheumatic disease patients.

Inadequate Performance of Diagnostic Tests for Latent TB Infection in Elderly Rheumatoid Arthritis Patients: Study in a Population with a High Prevalence of Tuberculosis. Dario Ponce de Leon[1], Eduardo Acevedo-Vasquez[1], Sergio Alvizuri[1], Cesar Gutierrez[2], Mariano Cucho[1], Jose Alfaro[1], Risto Perich[1], Alfredo Sanchez-Torres[1], Cesar Pastor[1], Cesar Sanchez-Schwartz[1], Mariela Medina[1], Rocio Gamboa[1] and Manuel Ugarte-Gil[3], [1]Hospital Nacional Guillermo Almenara Irigoyen, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Universidad Cientifica del Sur, Lima, Peru

Purpose: More than 80% of Tuberculosis cases associated with biologic therapy are reported in patients older than 60 years being, in most cases the result of reactivation of latent tuberculosis infection (LTBI). The objective is to determine the performance of the tuberculin skin test (TST) and Quantiferon TB-Gold ® In Tube version (QFT-IT) (one of the two commercially available Interferon-g release assays) for detection of latent TB infection in elderly patients with rheumatoid arthritis (RA) and matched controls in an endemic TB population

Method: A controlled cross-sectional study of 101 consecutive RA patients and 93 immunocompetent controls was conducted at the Hospital Guillermo Almenara, where the incidence of TB in RA is 216/100,000. TST was deemed positive at ≥5mm (RA) and ≥10mm (Controls).The patients were stratified according to age groups in 20-40 years, 40-60 years and older than 60 years

Results: TST. We found a much lower TST positivity in RA patients older than 60 years (8/45; 17%) compared to controls from the same age group (29/41; 71%) (P<.001); this difference persisted for patients aged 40 to 60 (P<.001) but not in younger patients (aged 20–40) (45% vs 36%; P = 0.62).Fig 1

QFT-IT. We found a lower QFT positivity (18/45;40%) in RA patients older than 60 years compared to controls from the same age group (29/41;71%) (P =0.004).There was no difference between patients and controls in the younger age group. Fig. 2.

Conclusion: A decreased reactivity to the TST and the Quantiferon In Tube test is found in older RA patients compared to matched controls. Therefore, these results must be taken into account for decision making before initiation of biologic therapy in elderly RA patients, particularly in areas highly endemic for TB. These findings could be related to premature immunosenescence described in RA patients.

Prevalence and Determinants of Vitamin D Insufficiency/Deficiency in U. S. Veterans with Rheumatoid Arthritis. Gail S. Kerr[1], John S. Richards[2], T. R. Mikuls[3], Iraj Sabahi[4], A.M. Reimold[5], Gw Cannon[6], Dannette S. Johnson[7] and Liron Caplan[8], [1]VAMC, Georgetown and Howard University Hospitals, Washington, DC, [2]VAMC, Geogetown University Hospital, Washington, DC, [3]U Nebraska, Omaha, NE, [4]Washington Hospital Center, Washington, DC, [5]VAMC, University of Texas Southwestern Medical Center, Dallas, TX, [6]VA and University of Utah, Salt Lake City, UT, [7]University of MS Med Ctr, Jackson, MS, [8]Univ of CO Denver School of Med, Aurora, CO

Purpose: 25-hydroxy vitamin D (VitD) insufficiency/deficiency is increasingly reported in chronic diseases; rheumatic entities not exempted. However, its non-calcitropic and immunomodulatory role in rheumatoid arthritis (RA) disease severity, activity and outcomes remains to be defined. The purpose of this study was to evaluate the prevalence of VitD insufficiency/deficiency and their associations with disease activity, severity, body mass index (BMI), and all-cause mortality in a cohort of United States Veterans with rheumatoid arthritis (RA).

Method: Enrollment clinical data and banked plasma from RA patients entered in the Veterans Affairs Rheumatoid Arthritis Registry (VARA) (n=1,160), were available for study. Time of enrollment was stratified to season. VitD insufficiency was defined as < 30 ng/ml, deficiency as < 20 ng/ml. Demographics, body mass index (BMI), and parameters of disease severity and activity, were examined. Comorbidities and mortality were recorded. Chi-squared tests were performed for dichotomous variables, Student's t-test for continuous variables and Cox proportional hazards regression for mortality risk. Multivariate associations of patient factors with VitD status were examined using logistic regression, adjusting for age, gender, season of enrollment, and race.

Results: Patients (1,049 men, 77% Caucasian) had a mean (SD) age 64 (11) yrs. The prevalence of VitD insufficiency and deficiency were 84% and 45%, respectively (mean = 22.2 ng/ml, SD=25.9 ng/ml), and neither correlated with any season. There were 116 deaths with 2,067 patient-yrs of follow-up (mean follow-up period of 1.9 yrs.). Both VitD insufficiency (90% vs. 83%, p = 0.003) and deficiency (65% vs. 40%, p < 0.001) were more prevalent in non-Caucasians than Caucasians. Low VitD status (insufficiency and deficiency) was also more common among aCCP positive patients (85% vs 79%, p = 0.016, 48% vs 38%, p = 0.004, respectively), and was unchanged after adjustments for age, gender, race, and season of enrollment. VitD deficient patients were also significantly younger (62.9 vs. 65.2, p = 0.0009), while insufficient patients had a higher BMI (28.6 vs. 27.2, p = 0.013). There were no associations of other measures of RA disease activity or severity, nor select comorbidities or overall mortality, with VitD status.

Conclusion: In an elderly male RA population, VitD insufficiency was nearly universal, with deficiency affecting almost a half of the patients. With the increasing adverse health outcomes associated with VitD insufficiency/deficiency, screening and supplementation, particularly amongst young, minority and aCCP positive RA patients, should be performed.

Carotid Intima Media Thickness in Rheumatoid Arthritis as Compared to Control Subjects: a Meta-Analysis. Alper M. van Sijl[1], Mike J.L. Peters[1], Dirk L. Knol[1], HC de Vet[1], Miguel A. Gonzalez-Gay[2], Yvo M. Smulders[1], Ben A.C. Dijkmans[1] and Michael T. Nurmohamed[3], [1]VU Medical Centre, Amsterdam, Netherlands, [2]Hospital Xeral-Calde, Lugo, Spain, [3]Jan van Breemen Institute, Amsterdam, Netherlands

Purpose: Rheumatoid arthritis is associated with an increased risk of cardiovascular disease. Carotid intima media thickness (cIMT) is a frequently used measure to identify populations at risk for cardiovascular disease. A systematic literature search and meta-analysis were performed to evaluate the difference in cIMT between rheumatoid arthritis (RA) and control subjects.

Methods: The literature was screened to identify all available studies comparing cIMT in RA patients and control subjects. A random effects model meta-analysis was performed to estimate the overall mean difference in cIMT between both groups. Meta-regression was performed to assess the influence of the degree of comparability with regard to established cardiovascular risk factors, age, RA disease duration, and the disease activity score (DAS28) on the difference in cIMT.

Results: From 22 studies, cIMT data was obtained from 1,384 RA patients and 1,147 control subjects. In 17 out of 22 studies, RA patients had a significantly greater cIMT relative to controls. The overall mean cIMT difference was 0.09mm (95%-CI: 0.07-0.11). The degree of comparability of cardiovascular risk factors at baseline did not explain the observed heterogeneity of the cIMT difference between RA patients and controls. In addition, neither age nor RA disease duration had a significant influence on the cIMT difference among RA patients. With respect to disease activity, we found a borderline association of DAS28 with cIMT (b regression coefficient; 0.052, p-value; 0.05), which indicates that a higher DAS28 is associated with a greater cIMT. The funnel plot showed a typical inverse funnel shape suggesting publication bias (Egger's test, p = 0.07).

Conclusion: The findings of this systematic review indicate that cIMT is significantly higher in RA patients than in controls, supporting the current evidence base for an increased CV burden in this population.

Discordance in the Association of Carotid with Coronary Atherosclerosis in Rheumatoid Arthritis Compared with Controls. Jon T. Giles[1], Wendy Post[1], Moyses Szklo[1], Roger S. Blumenthal[1], Michelle Petri[1], Allan Gelber[1], Joseph Polak[2] and Joan M. Bathon[1], [1]Johns Hopkins Univ, Baltimore, MD, [2]Tufts-New England Medical Center, Boston, MA

Purpose: Measures of carotid atherosclerosis have been used as surrogates for coronary atherosclerosis in many studies of cardiovascular disease (CVD) in RA. However, no studies have heretofore explored whether these measures are predictive of coronary atherosclerosis in RA patients to the same extent as in non-RA controls.

Methods: Men and women with RA enrolled in ESCAPE RA, a cohort study of subclinical CVD in RA, underwent ultrasonography of both common (CCA) and internal (ICA) carotid arteries and cardiac computed tomography (CT). The presence of carotid plaque, maximal intima-medial thickness (IMT) of the CCA and ICA, and extent of coronary arterial calcification (CAC) were compared to non-RA controls frequency matched on age, gender, and ethnicity from the Multi-Ethnic Study of Atherosclerosis. The associations of carotid measures with moderate subclinical atherosclerosis [CAC>100 (a cutpoint highly associated with CV events)] were compared between groups, with prevalence ratios (PRs) and 95% confidence intervals (CIs) calculated using multivariate Poisson regression with robust variance estimation.

Results: We compared 195 RA patients (60% female, 86% Caucasian, mean age 59 years) to 198 frequency matched non-RA controls. CV risk factors were similarly distributed, except for slightly higher mean systolic and diastolic blood pressures in the RA group. The prevalences of any CAC and carotid plaque, and median CAC and ICA-IMT values were significantly higher in RA patients vs. controls. Test characteristics (sensitivity, specificity, positive and negative predictive values) for carotid measures to predict CAC>100 were all lower in RA patients compared to controls. The weaker associations in the RA group were due to higher prevalences of CAC>100 for patients without plaque and with the lowest IMT values (Table); however, having plaque and higher IMT values were similarly associated with CAC>100 in the RA and control groups.

Conclusion: While the presence of plaque and increased IMT were similarly predictive of CAC>100 in RA patients and controls, RA patients without plaque or with low IMT were more likely to demonstrate CAC>100 than controls, suggesting that the absence of carotid atherosclerosis cannot rule out coronary atherosclerosis in RA. These findings may reflect differences in the underlying mechanisms of atherosclerosis between RA patients and controls.

Table. Crude and Adjusted Prevalences of CAC>100 According to Carotid Measures, RA vs. Control							
	Prevalence of CAC > 100 (%)		Prevalence Difference (%) RA vs. Control (Unadjusted)	RA vs. Control (Unadjusted)		RA vs. Control (Adjusted**)	
Carotid Measure	RA n = 195	Control n = 198		PR*	p	PR*	p
Plaque

The Apolipoprotein Complex LpAII:B:C:D:E Is Increased in Rheumatoid Arthritis and Is Associated with Carotid Atherosclerosis.

Petar Alaupovic[1], Jon T. Giles[2], Nicholas Knowlton[3], Adam Payne[1], G. Cavet[4], Micheal Centola[3] and Joan M. Bathon[2], [1]Oklahoma Medical Research Foun, Oklahoma City, OK, [2]Johns Hopkins University, School of Medicine, Baltimore, MD, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Crescendo Bioscience, Inc., South San Francisco, CA

Purpose: Conventional lipid measures do not account for the higher rates of cardiovascular disease (CVD) events and mortality in rheumatoid arthritis (RA). However, novel lipid parameters, such as loss of appropriate equilibrium among apolipoprotein complexes that traffic cholesterol, triglycerides, and fatty acids, may lead to atherogenic consequences in RA.

Method: Clinical and lab measures were assessed in 2 cohorts: 1) 94 RA patients and 79 age and sex matched controls (Cohort 1); 2) 39 RA patients from the ESCAPE RA CVD cohort study (Cohort 2). Cohort 2 patients were screened by carotid artery ultrasound to assess maximal intima-medial thickness (IMT) and plaque as surrogates of coronary atherosclerosis. Univarate comparisons were made using t-tests. Multivariate analyses were performed using linear and logistic regression.

Results: As previously observed, traditional risk factors, and plasma HDL and LDL, were not significantly increased in RA patients relative to age and sex matched controls (Cohort 1) and total cholesterol was only marginally increased. However, significant increases in the triglyceride carrier apolipoprotein complex LpAII:B:C:D:E and total triglyceride levels were observed in RA patients relative to controls (Table). For Cohort 2 patients, after adjusting for age, gender, and the anti-atherogenic apolipoprotein A-1, each standard deviation increase in LpAII:B:C:D:E was associated with a 0.15 unit increase in log-IMT ($p = 0.029$) and with a 4-fold increase in the odds of carotid plaque (OR 3.94; $p=0.048$). The magnitude and significance of the associations were unaffected by adjustment for Framingham score, or HDL, LDL, and triglyceride levels.

Table. Plasma Lipid, Apolipoprotein, and Apolipoprotein Complex Levels

	RA	Control	P-Value		RA	Control	P-Value
Lipids/Apolipoproteins				Apolipoprotein Particles			
HDL	59.5 (17.8)	56.9 (16.9)	0.422	LpA-I	35.7 (4.1)	35.1 (4.4)	0.432
Cholesterol	201.7 (46.9)	186.8 (36.8)	0.042	LpA-I:A-II	97.3 (11.6)	102.1 (14.6)	0.038
Triglycerides	163.1 (81.7)	113.1 (42.8)	<0.001	LpB	60.8 (7.6)	59.4 (7.4)	0.362
ApoA-I	133 (14.5)	138.7 (17)	0.039	LpB:C	8.7 (4.2)	10.5 (5.6)	0.038
ApoB	98.2 (15.5)	89.9 (12.8)	0.001	LpB:E+LpB:C:E	10.6 (5.1)	10 (5.5)	0.52
ApoC-III	12.1 (4.8)	10.2 (2.8)	0.007	LpA-II:B:C:D:E	18.2 (8.1)	10 (6)	<0.001

Values depicted are mean (standard deviation)

Conclusion: Compared to controls, RA was associated with a number of abnormalities in lipids, lipoproteins, and apolipoproteins known to be associated with atherogenesis. Among these, the apolipoprotein complex LpAII:B:C:D:E was the most strongly associated with measures of carotid atherosclerosis, suggesting that defects in apolipoprotein complex metabolism and triglyceride transport may mediate CVD in RA over and above the effects of commonly assessed lipoproteins (i.e. LDL, HDL). Moreover, this complex could form the basis of a standardized assay to detect patients at high risk of cardiovascular disease, thus targeting them for therapeutic intervention.
