Results: We recruited 467 (86% females) and 698 (90%) from France and Italy respectively. The mean age was 57±13 and 62±14 years old in the French and Italian cohort respectively ($p<0.0001$) and the mean disease duration was 11±9 and 14±8 years respectively ($p<0.0001$) in the French and Italian cohort. The prevalence of PHs was 25/467 (5%) and 39/698 (6%) in French and Italian SSc patients respectively, providing a frequency of 5% in the combined populations. This group was constituted of 42 pulmonary arterial hypertension (PAH) and 22 PH related to interstitial lung disease (ILD). In multivariate analysis, decreased DLCO/VA (OR [CI95%]: 12.9 [4.7-33.3], $p<0.0001$), decrease forced vital capacity <75% (4.3 [2.2-8.2], $p<0.0001$) and age (1.1 [1.0-1.2], $p=0.0002$) were independent associated factors. The proportion meta-analysis of five studies that included 3818 SSc patients was based on random effects (DerSimonian-Laird) because of heterogeneity between the studies and gave a pooled proportion of 9% (CI95%: 6-12%). Among the PHs population, the mean age was 66±12 years, the mean disease duration: 13±9 years; 72% (CI95%: 66-77%) had the limited cutaneous subtype, 32% (CI95%: 26-38%) had pulmonary fibrosis, 63% (CI95%: 55-72%) had PAH and 36% (CI95%: 28-45%) had PH related to ILD.

Conclusion: Our study shows that 5% of this large series of European Caucasian patients affected by SSc have developed PHs, as defined by RHC. Among these patients, about 2/3 had PAH and 1/3 PH related to ILD. Our study supports that SSc patients with PHs were significantly older and confirm the association between PH and decreased DLCO/VA.The proportion meta-analysis of 5 studies found a pooled PH point prevalence of 9%. It confirms that PAH was predominant in comparison to PH related to ILD. Moreover, SSc-PHs appear to be a late complication within disease course, occurring in older patients and predominantly within the limited cutaneous subtype.

Myocarditis in Systemic Sclerosis Diagnosed through Endomyocardial Biopsy. Gaetano Zizzo[1], Maria De Santis[1], Silvia Bosello[1], Giusy Peluso[1], Stefano Alivernini[1], Michela Pinnelli[1], Mario Bocci[1], Giacomo De Luca[1], Luigi Natale[2], Maurizio Pieroni[3], Filippo Crea[3], Lorenzo Bonomo[2] and Gianfranco Ferraccioli[1], [1]Division of Rheumatology, Rome, Italy, [2]Department of Radiology, Rome, Italy, [3]Institute of Cardiology, Rome, Italy

Purpose: Heart involvement in Systemic Sclerosis (SSc) is estimated to be present in almost all patients, although most often asymptomatic. To what extent ischemic injury, flogosis and fibrosis respectively contribute to myocardial damage is not clear. We describe 6 patients with biopsy-proven myocarditis.

Method: Among 189 scleroderma patients undergone ECG, the ones who showed ECG alterations (arrhythmias and conduction disturbances, with or without signs of ischemia) together with serum increase of cardiac enzymes were recruited, and studied by echocardiography, myocardial perfusion scintigraphy, late gadolinium-enhanced cardiac magnetic resonance imaging (MRI), coronarography and myocardial biopsy.

Results: 46 patients out of 189 (24.3%) showed ECG findings of conduction and/or rhythm disturbances: first degree atrioventricular block in 13%, right bundle branch block (RBBB) in 6.5%, left anterior fascicular block (LAFB) in 28.2%, sinus bradycardia in 17.3%, sinus

tachycardia in 2.1%, supraventricular ectopic beats in 17.3%, ventricular ectopic beats (VEB) in 19.5%. Among these, 7 (6 F, 1 M; 3.7% of all) also presented increased cardiac enzymes (CK-MB in all, troponin T in 5, total CK in 3). 2 showed VEB, 1 RBBB and VEB at times organized in bigeminal rhythm, 2 bradycardia, 1 tachycardia, 1 LAFB. 5/7 accused dyspnea. 4/7 showed positive late-gadolinium enhancement (LGE) on MRI (subepicardial pattern in 2, subepicardial and subendocardial in 1, midwall in 1); 1 among the others had pericarditis. Coronarography documented uninjured coronaries in all patients. In 6/7 endomyocardial biopsy proved myocarditis, according to Dallas Criteria, demonstrating myocyte necrosis and mononuclear cell infiltrate, associated to interstitial and perivascular fibrosis, subendocardial thickening with prominence of smooth muscle cells; none presented vasculitis; extended areas of substitutive fibrosis were observed in 2, the ones who also showed ECG changes for previous myocardial infarction, echocardiographic and MRI assessment of wall motion abnormalities and scintigraphic perfusion defects. Histology was normal in the patient with pericarditis. Among the 6 patients with biopsy-proven myocarditis, 4 had diffuse SSc, 3 were positive to antiSCL70, 3 to c-ANCA, 3 to antiphospholipids, 1 to p-ANCA.

Conclusion: Although cardiac MRI is considered the gold standard in the diagnosis of myocarditis, it was controversial (LGE midwall pattern) or falsely negative in half of patients with biopsy-proven myocarditis. c-ANCA positivity correlated with myocardial involvement, as it occurred in 57.1% of the patients with ECG and cardiac enzyme alterations, in 50% of those with myocarditis and in 3.1% of the whole cohort.

ARHP Concurrent Abstract Sessions

Outcome Measures in Arthritis

Monday, October 19, 2009, 2:30 PM - 4:00 PM

1202

What Aspects Do Outcome Measures Used in Team Rehabilitation Really Measure? Sofia Hagel[1], Elisabet Lindqvist[2], Ingemar F. Petersson[3] and Ann B. Bremander[4], [1]Department of Rheumatology, Lund University Hopsital, Lund, Sweden, [2]Department of Rheumatology, Lund University Hospital, Lund, Sweden, [3]Section of Orthopedics and Section of Rheumatology, Department of Clinical Sciences, Lund University, Lund, Sweden, [4]R & D Center, Spenshult Hospital for Rheumatic Diseases, Halmstad, Sweden

Purpose: To study the ability of well used and validated outcome measures for patients with chronic inflammatory arthritis to cover the ICF domains (International Classification of Functioning, Disability and Health), and the agreement and sensitivity to change among the included measures.

Method: HRQoL was measured by the Nottingham Health Profile (NHP), the EuroQol (EQ5D) and the Short Form-36 Health Survey (SF-36). Physical function was evaluated with the Health Assessment Questionnaire (HAQ), aerobic capacity (VO_{2max}), the Shoulder-arm-hand functioning test, grip strength, and the Signals of Functional Impairment test. The outcome measures were classified according to the ICF. Spearman correlations (r_s) were then performed between the measures belonging to the same ICF domain and in groups of HRQoL and physical function. Standardized response mean (SRM) was used to calculate responsiveness. Analyses were based on results from 216 patients participating in a multidisciplinary daycare rehabilitation program for 18 days, 149 (122 females) with peripheral arthritis median age 54 years (IQR 18), and 67 (31 females) with spondylarthritides (SpA) median age 44 years (IQR 21). Evaluations of agreement and sensitivity to change were performed at inclusion, after 18 days and after 12 months.

Results: The ICF domains body function, activity and participation were all covered by SF 36, EQ5D and NHP. All other instruments covered only one domain, while none covered ICF environmental. EQ5D showed correlations of $r_s<0.3$, with the other HRQoL instruments (baseline and change values). Correlations between NHP and SF36 subscales measuring similar aspects was the highest for SF36 MH and NHP emotion $r_s>0.7$, all other correlations varied between r_s 0.001and 0.7. Aerobic capacity had correlations of $r_s<0.2$, at all time points, with all other outcome measures on observed physical function, for all included patients. Aerobic capacity also had an SRM of 0.8 or higher at all time points for all patients while the SRM for HRQoL instruments was 0.4 or lower.

Conclusion: ICF environmental aspects were not covered by commonly used rehabilitation outcome instruments. For accurate comparison between studies HRQoL needs to be evaluated with the very same instrument, due to poor agreement between the different outcome measures. Aerobic capacity, when appropriate, should accompany other measures on the ICF domain body function, since it showed low correlations to all other outcome measures, indicating that it captures a different aspect, yet with a high SRM. The results of this study emphasis the need of consensus on a core set of outcome instruments to make comparison among rehabilitation programmes possible.

Development and Validation of the Osteoarthritis Burden Questionnaire (OA-Quest). Lucy Busija[1], Rachelle Buchbinder[2] and Richard H. Osborne[3], [1]The University of Melbourne, Melbourne, Australia, [2]Cabrini Medical Center, Malvern, Australia, [3]Deakin University, Melbourne, Australia

Purpose: This study describes the development and validation of the Osteoarthritis Burden Questionnaire (the OA-Quest), a new tool designed to measure the overall potentially modifiable burden of OA in a single measure. It is intended for use in a wide range of settings, particularly where the assessment of the full range of osteoarthritis-related consequences would be required. The questionnaire is non-joint specific and suitable for use in osteoarthritis of any joint.

Method: Item development for the OA-Quest was guided by concept mapping (CM) workshops with patients (N=26) and health professionals (N=27) conducted in Australia and in Sweden. Construction (N=394), evaluation (N=398) and validation (N=296) samples were drawn from community and clinical settings. The properties of the new questionnaire were investigated using exploratory and confirmatory factor analysis and Rasch analysis. The construct validity of the OA-Quest was assessed using correlations with existing measures of theoretically related concepts, including the WOMAC and the SF-36. The development and validation procedures meet recent FDA requirements for questionnaire development.

Results: 123 candidate items were generated from the results of CM, with 42 items selected for inclusion into the questionnaire. Each item underwent cognitive testing to ensure it was understood as intended. The OA-Quest was found to be comprised of seven independent dimensions of osteoarthritis burden, including Physical distress (7 items, Cronbach's α=0.93), Physical limitations (11 items, α=0.95), Psychosocial distress (7 items, α=0.93), Physical de-conditioning (4 items, α=0.87), Financial hardship (4 items, α=0.93), Sleep disturbances (5 items, α=0.96), and Lost productivity (4 items α=0.90). The concepts represented in the Financial hardship and Physical de-conditioning scales have not been previously measured in osteoarthritis. The construct validity of the OA-Quest scales was strongly supported by the expected pattern of correlations with existing questionnaires and these scales were able to distinguish the individuals who self-rated the severity of their osteoarthritis as mild or moderate from those who self-rated their osteoarthritis as severe or extremely severe. On all scales, the group with higher severity of osteoarthritis received significantly higher scores than the lower severity group, further supporting the construct validity of the OA-Quest.

Conclusion: The OA-Quest is a new measure of osteoarthritis burden, with strong evidence of face validity, reliability and construct validity. It provides very precise information (high reliability) efficiently (few items) across 7 areas important to patients, clinicians, and clinical trialists. The high precision of the scales will permit trial sample sizes to be minimized, thus reducing costs. The OA-Quest can be used flexibly, i.e., one or all scales can be used in a particular study. The OA-Quest delivers information that is pertinent to patients and clinicians on potentially modifiable domains linked to individual and society burden due to osteoarthritis.

Development and Initial Validation of the Bristol RA Fatigue Multi-Dimensional Questionnaire (BRAF-MDQ). Joanna Nicklin[1], Fiona Cramp[1], Jr Kirwan[2], Marie Urban[3] and Sarah E. Hewlett[1], [1]University of West of England, Bristol, United Kingdom, [2]University, Bristol, United Kingdom, [3]Bristol Royal Infirmary, Bristol, United Kingdom

Purpose: As current fatigue scales do not adequately reflect the experiences of rheumatoid arthritis (RA), we developed a new scale based on patient interviews, focus groups and "think aloud" methods. From these previously reported studies we devised a 45 item draft questionnaire. Here we report the results of item reduction and initial validation of the final scale.

Method: These 45 items contained 12 fatigue concepts previously identified from patient interviews. RA patients with fatigue (≥5/10 on a VAS) completed the questionnaire and comparator fatigue scales with some validity in RA (FACIT(F), MAF, POMS, SF36) and scales measuring disability (HAQ), anxiety & depression (HAD), helplessness (AHI) and pain (VAS). A series of analyses (Cronbach's Alpha for internal consistency, factor analysis for dimensions, bootstrapping for stability of the factor analysis (50 repeat random sets of analyses)) and clinical judgements informed removal of less informative items and retention of more informative items. The resulting BRAF-MDQ was tested for criterion and construct validity (Spearman's correlation with other scales).

Results: 229 patients completed the study (54 males, mean VAS fatigue 7.2). Cronbach's alpha was very high (>0.9) and changed little with removal of the first 20 items. A further 5 items were removed to enhance the stability of repeated subset factor analysis. The resultant 20 item questionnaire retained excellent overall internal consistency (Cronbach's alpha 0.932). The BRAF-MDQ global score has criterion validity, showing good correlation with other fatigue measures: FACIT(F) r=-0.813, MAF r=0.815, POMS r=0.712, SF36 Vitality r=-0.643. Construct validity was shown by moderate associations with related constructs (HAQ r=0.501, Anxiety r=0.517, Depression r=0.627, AHI r=0.563, Pain VAS r= 0.334). Factor analysis consistently showed 4 dimensions: Cognition, containing forget things, concentration, think clearly, lack of mental energy, make mistakes (Cronbach's alpha 0.915); Emotion, containing upset, down / depressed, less control over life, embarrassment (Cronbach's alpha 0.889); Living, containing getting dressed, bath/shower, work/daily activities, social life, refuse invitations, avoid making plans, cancel plans (Cronbach's alpha 0.906); and Physical, containing level, duration and frequency of fatigue, lack of physical energy (Cronbach's alpha 0.713). Correlations between the BRAF-MDQ dimensions and MAF were also good: Cognition r=0.548, Physical r=0.834, Emotion r=0.658 and Living r=0.664.

Conclusion: The BRAF-MDQ is RA-specific was developed from language and concepts generated by patients, has criterion and construct validity, and four dimensions which can be measured separately. Each individual's fatigue experience may be unique. This questionnaire may assist the development of individually tailored fatigue management programmes, focusing on the dimensions of personal importance.

An Additional Core-Set Generated by People with Rheumatoid Arthritis: RA Patient Priorities for Pharmacological Interventions (RAPP-PI). Tessa Sanderson[1], Marianne Morris[2], Michael Calnan[3], Pamela Richards[4] and Sarah Hewlett[2], [1]University of West England, Bristol, United Kingdom, [2]University of West of England, Bristol, United Kingdom, [3]University of Kent, Canterbury, United Kingdom, [4]University of Bristol, Bristol, United Kingdom

Purpose: Existing core sets of outcomes in RA clinical trials and treatment decisions comprise function, patient global assessment and pain. This study aimed to determine RA patient priorities for treatment outcomes in drug interventions.

Method: A survey comprising 32 outcomes generated and prioritized by patients using interviews and nominal groups[1,2] was posted to RA patients, identified through 3 diverse databases at 3 different UK hospitals, and to people randomly selected from the National RA Society (NRAS) membership database. Patients were asked to rate the importance of each outcome (1-5) for a pharmacological intervention, and to rank their top 6 outcomes (1-6). Demographics, disease activity (DAS patient global VAS, pain Numerical Rating Scale, fatigue NRS and HAQ), self-efficacy (NRS for managing your RA, RASE scale) and well-being (NRS) were measured. Importance and priority scores were calculated, and chi squared tests computed.

Results: 254 surveys were returned, with a mean age of 62.41 yrs (SD 12.39), disease duration of 12.76 yrs (SD 10.64). 51.6% of patients were taking DMARDS, and 39.4% biologic therapies. Using the rankings of top 6 items, the RAPP-PI core set comprises 8 outcomes most highly prioritised by patients: pain, activities of daily living, visible joint damage, mobility, life enjoyment, independence, fatigue, and valued activities. In addition, 3 global outcomes were identified as important to measure from the patient perspective: quality of life, well-being and normality.

Priorities differed across patient and disease characteristics. For example, severe disability was significantly associated with the prioritisation of 'More mobility' (X^2= 24.80) and 'Able to do everyday things' (X^2=11.74), whereas mild disability was associated with the selection of 'Enjoy life' (X^2= 7.67), 'Able to work' (X^2= 17.28), and 'Valued activities' (X^2= 6.98, all $p<0.05$).

Conclusion: The RAPP-PI, a core-set of outcomes generated and prioritized by people with RA, indicates that current drug trials and clinical practice using existing core sets may be leading to treatment decisions based on data that excludes outcomes patients consider important. It is suggested consideration be given to using the additional outcomes of the RAPP-PI. An ongoing study will identify appropriate instruments to measure the RAPP-PI and determine the relative contribution of each outcome to global patient well-being.

Economic Modelling in Rheumatoid Arthritis in Real World Practice: The DAS Has Minimal Impact On Hrqol Data Categorized by the HAQ Score. Arto Ohinmaa[1], Liam Martin[2], Anthony S. Russell[3], Susan G. Barr[2] and Walter P. Maksymowych[4], [1]Institute of Health Economics, Edmonton, AB, [2]University of Calgary, Calgary, AB, [3]U Alberta, Edmonton, AB, [4]University of Alberta, Edmonton, AB

Purpose: Little information is available on cost-effectiveness of anti-TNF medications in real world clinical practice. A Provincial prospective observational cohort study of consecutive RA patients starting anti-TNF therapy (infliximab, etanercept or adalimumab) was started in 2004. In many jurisdictions, access to biologics and economic modeling is based on DAS scores. We aimed to assess the relationship between Health Related Quality of Life (HRQOL), the Health Assessment Questionnaire (HAQ), and the Disease Activity Score (DAS28) for use in economic modelling of HRQOL outcomes using data from real world practice.

Methods: Data in the registry is collected at baseline, 3 months, and every 6 months thereafter on patients receiving anti-TNF. Health-related quality of life is measured with the EQ-5D and single index scores were calculated using US value sets. For this analysis, clinical status was categorized into 0.5 units of the HAQ while the DAS28 was categorized according to 0 – 3.19, 3.2 – 5.1 and over 5.1 scores. We analyzed change in the mean EQ-5D index score in HAQ categories over time and determined if the DAS28 affects the distribution of the EQ-5D index in the HAQ categories. An intention-to-treat analysis was conducted up to 21 months of follow-up.

Results: 778 patients started on anti-TNF with mean age 54.4 (SD 14.6) years 69.8% of them being females. Twenty one month outcome data was available from 563 patients. At baseline the EQ-5D index score in the anti-TNF group was 0.483 and improved 0.281 units ($p<0.001$; t-test) during follow up. The results show that the EQ-5D index was consistently higher the better the HAQ index category the patient was in except for category 0 at baseline (Table 1). After baseline the EQ-5D index decreased by increasing DAS28 categories. Within HAQ categories the DAS28 categories did not consistently affect on the mean EQ-5D index scores.

Table 1. Mean EQ-5D index scores in biologics group at baseline and 21 month follow-up by HAQ categories.

HAQ categ.	0	0.01-0.5	0.51-1.0	1.01-1.5	1.51-2.0	2.01-2.5	2.51-3.0	Total
EQ-5D at	0.486	0.775	0.671	0.571	0.449	0.376	0.237	0.483
Baseline	n=7	n=22	n=48	n=91	n=154	n=93	n=33	n=448
EQ-5D at	0.908	0.840	0.758	0.713	0.606	0.540	0.398	0.763
21 months	n=71	n=96	n=95	n=67	n=49	n=14	n=8	n=400

Conclusion: Our data shows a significant shift of the EQ-5D values in different HAQ categories which indicates that it is inappropriate to use the same utility index (EQ-5D) values to measure Quality Adjusted Life Year outcomes at baseline and after starting anti-TNF therapy. The DAS28 has minimal additional impact on HRQOL data categorized by the HAQ score and is therefore much less relevant for economic modelling than the HAQ.

1207

Rheumatoid Arthirtis Patients' Interpretation of the DAS Patient Global Used at Bristol Royal Infirmary. Tessa Sanderson[1], Marianne Morris[2], Michael Calnan[3], Pamela Richards[4] and Sarah Hewlett[2], [1]University of West England, Bristol, United Kingdom, [2]University of West of England, Bristol, United Kingdom, [3]University of Kent, Canterbury, United Kingdom, [4]University of Bristol, Bristol, United Kingdom

Purpose: The Disease Activity Score (DAS) provides evidence of clinical need for anti-TNF therapy in the UK, and is a composite score including patient opinion. However, the formulation of the patient VAS may vary between departments and may not capture the intended data. This abstract describes how RA patients interpreted the DAS patient VAS as routinely used at one busy outpatient clinic.

Method: Five focus groups (n=26) were held as part of a larger study for the development of a patient-generated core set of outcomes, purposively sampled for disease duration, disease severity, medication, age, gender and work status. The DAS patient VAS used in the clinic is “Considering all the ways your arthritis affects you, please mark the line to show how well you are doing”. Patients were asked their opinion of what the VAS was intended to measure, and subsequently, whether there was a better way of asking about global health/disease activity from the patient perspective. The discussions were tape recorded, transcribed verbatim and analysed for relevant items.

Results: Patients reported a range of interpretations of what the DAS patient VAS was measuring: general health, coping, emotions, function, and physical status. Speaking generally, one woman said “I think it's taking everything into consideration”. However, most patients gave uni-dimensional responses. Many participants interpreted the VAS as asking about coping or emotion: e.g. “How do you cope with it?” and “For me it's always an emotional thing”. Other patients interpreted the VAS as asking about function or physical status, e.g. “Day to day living”, “How much you can do”, and “If you've got a lot of pain or whatever”.

Many participants felt that a single global question would give an inaccurate answer because it was difficult to assess that global status from dimensions: “You could be alright physically, but not emotionally and you could be different with finances”. Overall, the preference was to have separate questions for different aspects of health: physical, emotional, adaptation, and impact of external stresses. Those on anti-TNF therapy were surprised that the patient opinion in the DAS was not more detailed if their clinical need was to be partially assessed in this way. In relation to the physical scale, one group suggested using the specific words “disease activity” with examples, such as pain, stiffness, swelling, fatigue and ability to carry out everyday activities.

Conclusion: There is evidence that patients interpret the DAS patient global used in this clinic in a range of ways, which may affect their response. The originators of the DAS have states that either the patient’s opinion of general health or disease activity can be used in calculating the DAS28. Efforts should be made to standardise the scale in all clinics and research studies.

Absence of Sphingosine Kinase 1 Alters Erosions in TNF-Alpha Induced Arthritis. DeAnna A. Baker, Lina M. Obeid and GS Gilkeson, Medical University of South Carolina, Charleston, SC

Purpose: Sphingolipids are constituents of the plasma membrane. Variations in their cellular levels lead to alterations of cellular functions. Sphingosine 1 phosphate (S1P) *in vitro* is required for TNFa induced production of COX-2 and PGE_2. Additionally, stimulation with TNFa

and S1P together leads to higher production of COX-2 and PGE_2 than either alone. Both sphingosine kinase (SphK) 1 and 2 are upregulated in the rheumatoid synovium compared to osteoarthritis synovium. $S1P_1R$ (EDG1), one of the receptors for S1P, is also upregulated in the joints of rheumatoid arthritis patients. Fibroblast-like synoviocytes (FLS), found in the synovial lining, proliferate in response to proinflammatory cytokines and produce COX-2 and PGE_2 in response to TNFa and S1P. We hypothesized that S1P, induced by TNFa, is a critical mediator of inflammation and joint damage in the rheumatoid joint. The following experiments were performed to test this hypothesis

Method: Transgenic hTNFa mice were crossed with SphK1-/- mice and genotyped by PCR. Arthritis in these mice develops independent of antigen, T cells or B cells. The mice were observed weekly for disease activity, while CT images and microarray analysis were used to evaluate disease activity in the joint and evaluate genetic profiles respectively. Mouse synoviocytes were isolated from the knee joints of WT and SphK1-/- mice, cultured, and stimulated with TNFa. OA and RA human synoviocytes were cultured, and stimulated with hTNFa.

Results: hTNF/Sphk1-/- mice (n=15) had significantly decreased clinical joint disease compared to hTNF/SphK1+/+ mice (n=18), with average arthritis scores of 1+/-0.5 vs. 5+/- 1.2 respectively at 5 months (based on joint swelling and deformity). An erosion Index, measured quantitatively from 3D CT images of the ankles was significantly decreased in hTNF/SphK1-/- mice at 4 and 5 months, with a 2 fold decrease in erosions in hTNF/SphK1-/- vs. hTNF/SphK1+/+ mice. Microarray analysis of ankle joint synovium, with RT-PCR confirmation, demonstrated significant modulation of a cluster of genes regulated by SOCS3 in hTNF/SphK1-/- mice compared to hTNF/SphK1+/+ mice. Synoviocytes from SphK1-/- mice, stimulated with TNFa, produced significantly less IL-6 and PGE_2 than synoviocytes from WT mice. Similarly, human RA synoviocytes stimulated with TNFa and treated with a specific SphK inhibitor produced significantly less IL-6 and PGE_2 than cells treated with TNFa alone.

Conclusion: Genetic deletion of SphK1 significantly decreased the severity of hTNFa induced arthritis, decreased erosions and led to upregulation of SOCS3 with impact on expression of SOCS3 related genes. Lack of SphK1 resulted in decreased PGE_2 and IL6 production by mouse and human synoviocytes in response to TNFa. These data indicate that S1P plays a key role in TNFa induced joint inflammation and erosions and is a potential target for therapeutic intervention in inflammatory arthritis.

Effective Anti-CD20 Therapy for Arthritis Is Associated with Increased Lymphatic Flow and B-Cell Depletion in Lymph Nodes. J. Li[1], S.T. Proulx[1], Q. Zhou[1], I. Kuzin[1], Robert Dunn[2], R. J. Looney[1], Christopher T. Ritchlin[1], Jennifer H. Anolik[1], I. Sanz[1], A. Bottaro[1], L. Xing[1] and E.M. Schwarz[1], [1]University of Rochester, Rochester, NY, [2]Biogen Idec, San Diego, CA

Purpose: B cell depletion therapy (BCDT) with anti-CD20 is effective for some RA patients; however, questions remain regarding mechanism of action and variability of response. Previously we utilized contrast enhanced (CE) MRI and near infrared (NIR) imaging of footpad injected indocyanine green (ICG) to evaluate arthritis in TNF-Tg mice. The results showed that “expanding” popliteal lymph nodes (PLN) with high lymphatic drainage capacity (LNcap) protect the afferent knee from inflammatory-erosive arthritis. Prior to the onset of synovitis, the PLN “collapses” and this volume change is associated with translocation of B cells into the sinus space, which decreases LNcap and triggers synovitis. Here we test the hypothesis that anti CD20 therapy restores lymphatic function by depletion of B cells from the sinuses of the PLN.

Method: TNF-Tg mice with ankle arthritis, collapsed PLN and baseline NIR-ICG foot pad clearance (Tclear) were treated with anti-CD20 (n=5; 10 knees) (10mg/kg/i.v. every two weeks) or placebo (n=4; 4 knees) for 6 weeks, with CE-MRI every 2-weeks, and terminal Tclear test. Some PLNs were harvested for flow cytometry, and others were analyzed by IHC for IgM, CD20, active caspase-3 and the lymphatic endothelium vessels marker LYVE-1.

Results: CE-MRI revealed two different responses to the anti-CD20. Responders (no synovitis @ 6-weeks; n=7 knees) had sustained LNcap, while non-responders (synovitis @ 6-weeks; n=3 knees) displayed a dramatic decrease in LNcap. Despite this variability, anti-CD20 significantly decreased synovial volume (p=0.02) at 6-weeks, and synovitis over time (p=0.0003), vs. the placebo group, which demonstrated a significant (p=0.0001) 0.81mm3/week increase in synovitis. Effective BCDT also increased lymphatic function (3.3-fold increase in Tcear). Flow cytometry confirmed effective (85-90%%) BCDT in PLN of both responders and non-responders, and staining for various surface markers failed to identify any significant differences in the remaining B cell populations. However, IHC revealed the presence of large numbers of IgM+/CD20-B cells/mm2 in the sinus spaces of placebo (22.1 +/- 5.1) and non-responder (20.9 +/- 1. 9) PLN, while the

sinuses of responder PLN were largely free of B cells (8.3 +/- 2.0; p<0.001). Staining for active caspase-3 demonstrate an 8.6-fold vs. 13.1-fold increase in the number of apoptotic cells in non-responder vs. responder PLN compared to placebo.

Conclusion: These results are consistent with our previous findings indicating that arthritic flares are mediated by centripetal B cell translocation in efferent LN, which obstructs draining lymph from the proximal joint. We also demonstrate a novel mechanism of action for BCDT in which effective clearance of B cells from the LN sinuses restores lymphatic drainage, while inadequate BCDT that fails to clear B cell from the LN sinuses has no effect on lymph drainage or arthritic progression.

1210

Suppression of Rat Collagen-Induced Arthritis by Lentiviral Vector-Mediated Delivery of Toll-Like Receptor 7 Short Hairpin RNA Gene. Chrong-Reen Wang, Ai-Li Shiau, Shih-Yao Chen, Yi-Syuan Lin and Chao-Liang Wu, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan

Purpose: The effects of Toll-like receptor 7 (TLR7) gene knockdown were examined in a rat collagen-induced arthritis (CIA) model by intra-articular (i.a.) delivery of lentiviral vector-mediated TLR7 short hairpin (sh) RNA gene.

Method: After screenings, the pSuper/TLR7 shRNAs were further cloned into the lentiviral plasmid (Lt.shTLR7). After being immunized with type II collagen on days 0 and 7, SD rats received i.a. injection of Lt.shTLR7 into right ankles and scramble vectors (irrelevant oligonucleotides unable to suppress TLR7 expression) into left ankles on days 7 and 10. Ankle circumference and articular index were evaluated, and joint radiographic examination was done upon sacrifice of rats on day 16. Ankles joints were subjected to H&E stain and immunohistochemical analyses including small vessels and T cells. Western blot and immunohistochemical stain were performed for TLR7 expression on synovium tissues. ELISA was used for quantitation of proinflammatory cytokines (IL-1b, IL-6 and TNF-alpha) and VEGF in joint extracts and culture supernatants from TLR7-transfected synovial fibroblasts (SFs) stimulated with imiquimod or joint extracts containing endogenous TLR7 ligands. RT-PCR of IP-10, a chemokine attracting Th1 cells, was performed for imiquimod-stimulated SFs.

Results: Western blot revealed increased TLR7 expression from day 11. Immunohistochemical stain demonstrated notable TLR7 on synovium tissues and cultured SFs. Significant reductions in ankle circumference and articular index were detected in Lt.shTLR7-treated joints as compared with scramble vector-injected ankles. Radiological and histological scores on day 16 were significantly decreased in Lt.shTLR7-injected ankles. Microvessel densities and VEGF concentrations wthin synovium tissues were significantly lower in Lt.shTLR7-treated joints. VEGF production from imiquimod-stimulated SFs was significantly suppressed in the Lt.shTLR7 transfection group. IL-1beta and IL-6 concentrations were significantly reduced in Lt.shTLR7-injected ankles. IL-6 production from imiquimod-stimulated SFs was significantly decreased in the Lt.shTLR7 transfection group. Addition of ankle joint extracts could significantly up-regulate the production of IL-1beta and IL-6, and treatment with benzonase (a RNase) could significantly down-regulate their production. Furthermore, significantly lower T cell numbers were noted in Lt.shTLR7-treated joints, and the IP-10 induction in imiquimod-stimulated SFs was clearly demonstrated by RT-PCR.

Conclusion: These data demonstrated the effects of local injection of lentiviral vector-mediated delivery of shTLR7 RNA gene on inhibiting ankle arthritis of CIA rats. Our *in vivo* animal studies reveal the potentiality of TLR7 molecule as a future target for RA therapy.

Suppression of Collagen-Induced Arthritis by Natural Killer T Cell Activation with α-Carba-GalCer, a Novel Synthetic Glycolipid Ligand. Yohei Yoshiga, Daisuke Goto, Seiji Segawa, Makoto Sugihara, Taichi Hayashi, Yusuke Chino, Isao Matsumoto, Satoshi Ito and Takayuki Sumida, University of Tsukuba, Tsukuba, Japan

Purpose: Alpha-carba- galactosylceramide (GalCer), a novel synthetic analog of α-GalCer, stimulates natural killer T (NKT) cells to produce predominatly interferon (IFN)-γ. IFN-γ has been known to suppress T helper (Th) 17 cells differentiation. Thus, we think that α-carba-GalCer may be a potential agent for the treatment of Th17-mediated autoimmune diseases. This study was designed to evaluate the protective effects of α-carba-GalCer on collagen-induced arthritis (CIA) in mice.

Methods: 1) We injected glycolipid ligand into naïve DBA/1 mice, and cytokines in the serum were analyzed by enzyme-linked immunosorbent assay (ELISA). Naïve splenocyes were stimulated with glycolipid ligand and cytokine levels in cultures were determined by ELISA. 2) To clarify the effect of α-carba-GalCer on CIA, DBA/1 mice were immunized with bovine type II collagen (CII) with glycolipid, and we monitored the incidence and clinical symptom of disease. 3) To neutralize IFN-γ, anti-IFN-γ monoclonal antibody (mAb) was administered intraperitoneally (i.p.) at the same time of CII/glycolipid injection. 4) To examine CII-reactive T cell response, draining lymph node (DLN) cells from glycolipid treated mice were re-stimulated with CII in vivo. Anti-CII Ab titer in the serum from glycolipid treated mice were determined by ELISA. Frequency of memory/activated and Foxp3+ regulatory T cell were determined by flow cytometory. The function of antigen-presenting cells (APCs) was analyzed by the capacity of stimulation of CD4 T cells in vitro.

Results: 1) Alpha-carba-GalCer selectively induced IFN-γ compared with α-GalCer in CIA-susceptible DBA/1 mice in vivo/in vitro. 2) The mice treated with α-carba-GalCer exhibited lower incidence and clinical score of CIA. In addition, lower anti-CII antibody production was observed in α-carba-GalCer treated mice. 3) Interferon-γ neutralization at the time of CII immunization abolished the suppressive effect of α-carba-GalCer 4) We found the decreased number of Th1 and Th17 cells in DLN cells from α-carba-GalCer treated mice. However, the number of memory/activated and Foxp3+ regulatory T cells, and the function of APCs were not affected by α-carba-GalCer treatment.

Conclusion: These findings suggest that α-carba-GalCer activated NKT cells could protect CIA via the selective production of IFN-γ.

FLIP: The Master Regulator of Myeloid Differentiation and Survival-A Novel Therapeutic Target in Chronic Inflammation. Qi Quan Huang[1], Zan Huang[1], Robert Birkett[1], Lixin Kan[1], Sandeep Gurbuxani[2], John Crispino[1], Harris R. Perlman[1] and Richard M. Pope[1], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]University of Chicago, Chicago, IL

Purpose: Macrophages are important mediators of chronic inflammation, and in rheumatoid arthritis synovial tissue macrophage apoptosis is inappropriately reduced. FLIP, an anti-apoptotic molecule induced by chronic inflammation, protects against death receptor mediated apoptosis. However, its essential *in-vivo* functions in the myeloid cell lineage have not been characterized. We have generated and characterized a mouse line with FLIP conditionally deficient in the myeloid lineage.

Method: Mice bearing floxed *flip* (*flip*^{f}) were employed to generate one allele of *flip* deleted (*flip*^{d}) and one floxed (*flip*$^{d/f}$). These animals were then crossed with LysM-cre mice to generate *flip*$^{f/d}$LysMcre$^{+/-}$ mice with FLIP knockout (KO) in myeloid cells. The mice were examined for complete blood count, serum cytokine concentrations, FLIP expression, linage-restricted colony-forming progenitors. Tissues were examined by flow cytometry, immunohistochemistry, and bacterial culture. Granulocytes were analyzed for apoptosis by Annexin V and Rhodamine 123. Serum transfer mouse model of arthritis was induced with anti-GPI serum.

Results: Myeloid specific KO mice exhibited severe postnatal growth retardation and premature death, but no indication of embryonic lethality. KO mice had significantly reduced body weight (50% that of control group), and 50% died before 7 months of age. There was a dramatic increase in neutrophils (>10 fold) in the peripheral blood, which was accompanied by multi-organ neutrophil infiltration. The neutrophils demonstrated a mature morphology and underwent normal apoptosis and oxidative burst response. The F4/80^{high} subset of macrophages was greatly reduced in the spleen and peritoneal cavity, both spontaneously and induced. KO mice exhibited splenomegaly with altered architecture, a marked reduction of B cells and extramedullary hematopoiesis. 30% of KO mice exhibited systemic infection with commensal intestinal flora such as entercocci and proteius species. Serum from KO mice exhibited significantly increased G-CSF (14.5 fold) and inflammatory cytokines TNF-alpha (10 fold) and IL-6 (25 fold). Nonetheless, when induced by anti-GPI serum, KO mice developed significant less severe arthritis.

Conclusion: The myeloid specific deletion of FLIP results in a massive systemic increase of neutrophils, a reduction of macrophages in the spleen and peritoneal cavity, and a reduction of serum transfer arthritis. These studies identify FLIP as a master regulator of myeloid cell differentiation and survival and identify macrophage expressed FLIP as a therapeutic target in chronic inflammation.

1213

Specific Targeting of TNF Receptor I in Synoviocytes or Antigen-Presenting Cells in Secondary Lymphoid Organs Ameliorates Collagen-Induced Arthritis. Onno J. Arntz, Jeroen Geurts, Sharon Veenbergen, Miranda B. Bennink, Wim B. van den Berg and Fons A. van de Loo, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Purpose: TNFα is a pleiotropic cytokine that plays a key role in RA and TNF blockade serves as the main biological therapy in RA patients. Signaling is mediated via two receptors (TNFRI/II) and the relative abundances of these determine the effects on different cell types. Recently it is shown that targeting of TNFRI in hematopoietic cells, i.e. leukocytes, aggravates disease in collagen-induced arthritis (CIA) [1]. Using RNA interference as a gene therapeutic strategy we investigated the role of TNFRI specifically in synoviocytes and antigen-presenting cells (APCs) in liver and spleen during experimental arthritis.

Methods: An adenoviral vector containing a short hairpin (sh) RNA was constructed and the functionality was evaluated *in vitro* and *in vivo* using qPCR and reporter assays. For targeting of synoviocytes or APCs viruses (scrambled- and TNFRI-shRNA) were injected intra-articularly or intravenously, respectively, shortly before CIA onset. Effects of TNFRI targeting were evaluated using macroscopic scoring of CIA progression, qPCR, histological and cytokine analyses and T-cell assays..

Results: *In vitro* TNFRI expression (mRNA) was three-fold downregulated resulting in a 70% reduction of TNF-induced activation of the pivotal pro-inflammatory transcription factor NFκB. Expression in synoviocytes and APCs was three- and eight-fold diminished, respectively. TNF-induced production of IL-6 was significantly reduced in splenic APCs. Targeting of TNFRI in synoviocytes resulted in a local protection against CIA, supported by a strongly reduced mRNA and protein levels of TNFα, IL-1β and IL-6. Knockdown of TNFRI in splenic and hepatic APCs led to an impressive amelioration of CIA. This led to a significant decrease of joint inflammation and cartilage erosion. Expression of IL-1β, IL-6 and the acute phase protein Saa1 were strongly reduced (75%) in liver. In the spleen, we observed a decreased expression of Th1/2/17-specific transcription factors T-bet, GATA-3 and RORγT. FACS analysis confirmed a reduced amount in the numbers of IFNγ (Th1), IL-4 (Th2) and IL-17 (Th17) producing cells in spleen.

Conclusion: In this study we showed that TNFR1 signaling mediates a clear pro-inflammatory response in synoviocytes and APCs in secondary lymphoid organs. This highlights that cell-specific targeting is of crucial importance for therapeutic strategies aimed at blockade of TNFRI-mediated signaling.

ACR Concurrent Abstract Sessions

Clinical Aspects of the Antiphospholipid Syndrome

Monday, October 19, 2009, 4:30 PM - 6:00 PM

1214

Antiphospholipid Antibodies Predict Future Arterial Events. Carolyn Neville[1], Joyce Rauch[1], Jeannine Kassis[2], Susan Solymoss[1], Lawrence Joseph[3], P. Belisle[3] and P. R. Fortin[4], [1]McGill University, Montreal, QC, [2]Université de Montréal, Montreal, QC, [3]MUHC, Montreal, QC, [4]U. Toronto, Toronto, ON

Purpose: To determine the role of antiphospholipid antibodies (aPL) in predicting new arterial (VE-A) and venous (VE-V) vascular events in an ongoing prospective cohort of individuals.

Method: Demographic and clinical data were obtained at baseline and semiannually. All events were confirmed by consensus with medical record review by a panel of physicians. Blood samples were collected at baseline and annually for four years, and stored frozen at -70°C. Assays performed included: IgG/IgM anticardiolipin antibodies (aCL), lupus anticoagulant (LA), and IgG/IgM anti-b2-glycoprotein I antibodies (aβ2GPI). Kaplan-Meier and proportional hazard survival analyses were used to compare the time to new VE-A or VE-V in aPL-positive (defined as aCL IgG/IgM >40, LA, and/or aβ2GPI positive) versus aPL-negative individuals. Multivariate regression analyses were performed using new VE-A or VE-V as outcome variable and aPL positivity as predictor variable. Covariates for outcome VE-A were age, gender, family history of CVD (FMH), smoking, systemic lupus erythematosus (SLE), hypertension (HTN), diabetes mellitus (DM), smoking, previous VE-A, activated protein C resistance (APCR), and hyperhomocysteinemia. Covariates for outcome VE-V were age, gender, SLE, previous VE-V, anticoagulation therapy (ACT), APCR, antithrombin III, factor V Leiden mutation and MTHFR mutations.

Results: 414 persons enrolled in 1997 with mean (SD) age 46.4 (14.1) years, 83.1% female; 53.3% had FMH, 20.5% had SLE, 27.8% were smokers, 15.9% had HTN, 5.6% had DM, and 16.4% had had previous vascular events (VE). Fifty-nine (14%) individuals were aPL-positive at baseline, and 38 more became aPL-positive during follow-up for a total of 97 (23.4%). During 11 years of follow-up (median 9.5 [IQR=4.0, 10.6] years), 52 (12.6%) individuals sustained 78 new events (36 had VE-A; 17 had VE-V; 2 had both). The proportion of VE-free survivors at 10 years was 88% (95%CI=84%, 92%) for aPL-negative and 67% (95%CI=54%, 81%) for aPL-positive individuals. The proportion of VE-A-free survivors at 10 years was 91% (CI = 88%, 95%) for aPL-negative and 76% (CI = 65%, 89%) for aPL-positive individuals. For VE-V-free survivors, the proportions were 97% (CI = 95%, 99%) for aPL-negative and 83% (CI = 73%, 95%) for aPL-positive individuals. Multivariate regression analyses revealed that VE-A were predicted by aPL positivity [HR= 2.52 (CI=1.17, 5.47)], age [HR=1.05 (CI=1.02, 1.07)], DM [HR=3.93 (CI=1.66, 9.32)], smoking [HR=2.31 (CI=1.15, 4.64)], and previous VE-A [HR=4.77 (CI=2.32, 9.82)]. While the effect of aPL positivity on VE-V cannot be accurately estimated from our data [HR=1.86 (CI=0.67, 5.20)], VE-V were predicted by previous VE-V [HR=4.00 (CI=1.35, 11.87)], ACT [HR=4.60 (CI=1.50, 14.08)], and APCR deficiency [HR=5.21 (CI=1.95, 13.90)].

Conclusion: aPL positivity independently predicts VE-A, whereas the effect of aPL on VE-V is less clear.

1215

Association of Traditional and Novel Antiphospholipid Antibody Assays with Thrombosis in SLE. Ehtisham Akhter[1], Walter L. Binder[2], Zakera Shums[2], Laurence Magder[3] and Michelle Petri[4], [1]Johns Hopkins University, Baltimore, MD, [2]Inova Diagnostics Inc, San Diego, CA, [3]University of MD, Baltimore, MD, [4]Johns Hopkins Univ, Baltimore, MD

Purpose: The current APS classification criteria recognize the lupus anticoagulant, anticardiolipin (aCL) and anti-beta2 glycoprotein I (anti-beta2). We determined the association of anti-phosphatidylserine-prothrombin (PSPT) and D4/5 IgA (directed against the domain 4/5 fragment of beta2-GPI), as well as anti-beta2 and aCL, with thrombosis in SLE.

Method: Stored sera from 314 SLE patients in a prospective database were studied. 206 had a history of thrombosis (87% female, 43% African-American, 50% Caucasian) and 108 did not (45% female, 31% African-American, 53% Caucasian). Assays were performed at INOVA Diagnostics, Inc. **Results:** Comparison of those with and without history of any type of thrombosis with respect to the percent positive for each antibody.

	Thrombosis (n = 206)	No thrombosis (n = 108)	P-value	P-value when age, sex, and race are controlled
Assay	Number (% positive)	Number (% positive)		
anti-beta2 IgA	45 (22 %)	16 (15%)	0.18	0.23
anti-beta2 IgG	24 (12%)	3 (3%)	0.010	0.021

anti-beta2 IgM	18 (8%)	4 (4%)	0.11	0.12
aCL IgA	9 (4 %)	1 (1%)	0.171	0.21
aCL IgG	30 (15%)	5 (5%)	0.008	0.016
aCL IgM	27 (13%)	7 (6%)	0.086	0.11
anti-PSPT IgG	47 (23%)	10 (9%)	0.003	0.001
anti-PSPT IgM	43 (21%)	8 (7%)	0.002	0.011
D4/5 IgA	36 (18%)	16 (15%)	0.63	0.71

Comparison of those with and without a history of venous thrombosis with respect to the percent positive for each antibody.

	Venous Thrombosis (n = 123)	No venous thrombosis (n = 191)	P-value	P-value when age, sex, and race are controlled
Assay	Number (% positive)	Number (% positive)		
anti-beta2 IgA	29 (24 %)	32 (17%)	0.14	0.20
anti-beta2 IgG	19 (15%)	8 (4%)	0.001	0.005
anti-beta2 IgM	11 (10%)	10 (5%)	0.17	0.20
aCL IgA	5 (4 %)	5 (3%)	0.52	0.53
aCL IgG	22 (18%)	13 (7%)	0.003	0.006
aCL IgM	15 (12%)	19 (10%)	0.58	0.63
anti-PSPT IgG	34 (28%)	23 (12%)	0.001	0.001
anti-PSPT IgM	27 (22%)	24 (13%)	0.041	0.13
D4/5 IgA	20 (16%)	32 (17%)	1.00	0.94

No assay was significantly associated with history of arterial thrombosis.

Conclusion: For any thrombosis, the anti-PSPT assay performed the best after adjustment for age, sex, and race. For venous thrombosis, anti-beta2 GPI, aCL, and anti-PSPT IgG assays performed equivalently. For IgM assays, only the anti-PSPT was significantly associated with thrombosis. This study suggests that anti-PSPT may have value in APS in SLE, and that only IgG assays may be cost-effective.

Antiphospholipid Score (aPL-S) in the Antiphospholipid Syndrome: Diagnostic Significance and Predictive Value for the Development of Thrombotic Events in Autoimmune Diseases. Kotaro Otomo, Tatsuya Atsumi, Yuichiro Fujieda, Masaru Kato, Eriko Miyamoto, Kenji Oku, Olga Amengual, Hiroshi Kataoka, Tetsuya Horita, Shinsuke Yasuda and Takao Koike, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: 1) To define the Antiphospholipid Score (aPL-S) by testing multiple antiphospholipid antibodies, and 2) to evaluate its efficacy for the diagnosis of antiphospholipid syndrome (APS) and predictive value for the development of thrombotic events in autoimmune diseases

Method: 1) From our database of autoimmune disease clinic, the results of antiphospholipid antibodies in 233 patients were used to define aPL-S. Five clotting assays (the mixing studies: activated partial thromboplastin time (APTT), kaolin clotting time, the dilute Russel's viper venom test (dRVVT), and the confirmatory tests: APTT and dRVVT) and 6 ELISAs (IgG/M anticardiolipin antibodies, IgG/M anti-beta2-glycoprotein I antibodies and IgG/M phosphatidylserine dependent antiprothrombin antibodies) were analyzed. The aPL-S was calculated according to the number of positive tests and their titers (range 0-83), and compared with the history of thrombosis/pregnancy morbidity. 2) For further analysis, we retrospectively explored the predictive value of aPL-S for thrombotic events. This part of the study comprised 221 patients with autoimmune diseases (12 primary APS, 16 APS with systemic lupus erythematosus and 193 other autoimmune diseases). The aPL-S in 2002 was evaluated in all subjects. Among all the patients, 174 (78%) were followed-up with a mean duration of 66 ±16 months. To calculate the predictive value, the aPL-S was compared with the development of thrombotic events during the follow-up period.

Results: 1) The aPL-S was higher in patients with thrombosis/pregnancy morbidity (n=46) than in those without (22.3±26.3 vs. 4.13±10.8, p=0.00001). For the diagnosis of APS, the receiver operating characteristics (ROC) curve of aPL-S showed hyperbolic, and the area under the ROC curve (ROC AUC) are 0.752 and 0.686 for the aPL-S and for the Sydney revised Sapporo criteria, respectively. The prevalence of thrombosis/pregnancy morbidity was correlated with the levels of aPL-S (Figure). 2) Seventeen patients newly developed thromboses; 10 arterial and 10 venous thromboses. Although 18 out of 19 patients with aPL-S >30 received antithrombotic therapy (4 anticoagulant therapies, 14 antiplatelet therapies and 2 both therapies), six of them developed 8 thrombotic events during the follow-up. Patients with aPL-S >30 had a higher risk of thrombosis than those without (Odds-Ratio: 6.04[95%CI: 1.92-18.99, p=0.004]).

Conclusion: The aPL-S is a useful quantitative index for diagnosing APS, and may be a predictive marker of thrombosis in autoimmune diseases.

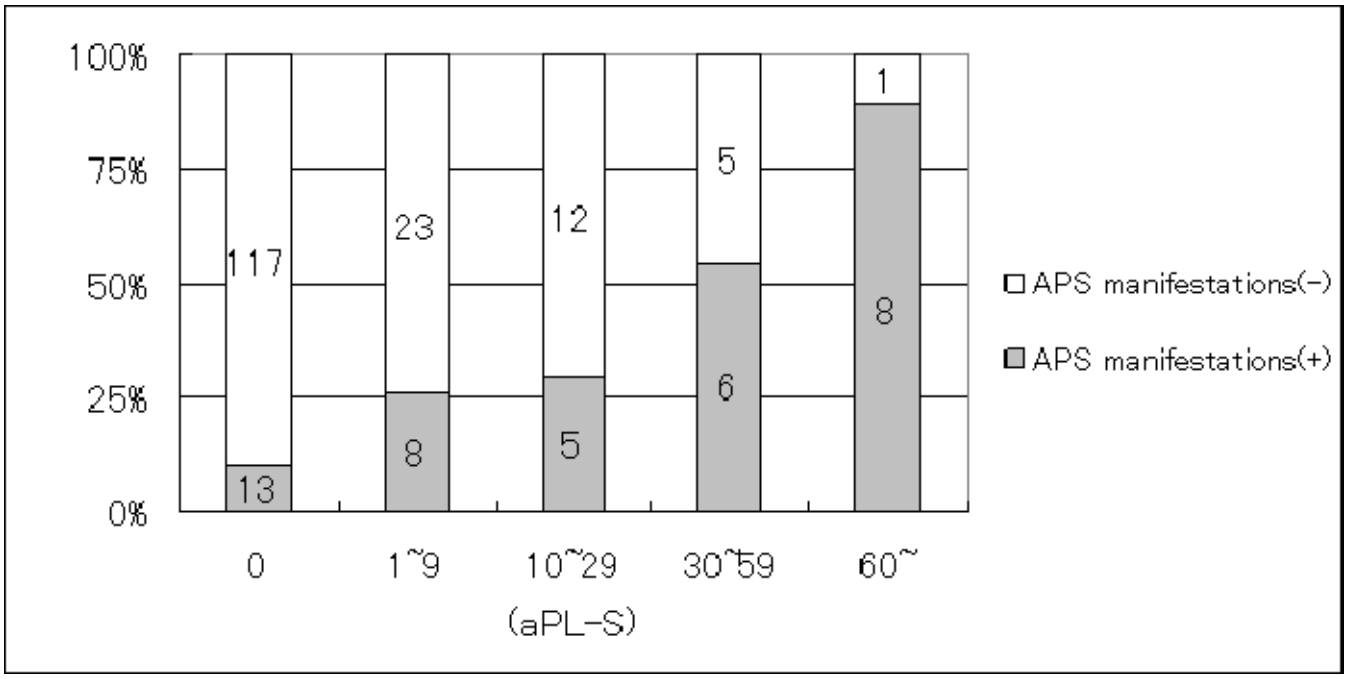

Figure: The bar charts indicate the percentages of the prevalence of APS manifestations in each groups of aPL-S. The values inside the bar indicate the number of the patients.

1217

End-Stage Organ Damage and Mortality in Patients with Antiphospholipid Syndrome (APS): Prognostic Models for Serious Clinical Outcomes. Eleftheria P. Grika[1], Elias Zintzaras[2], Haralampos M. Moutsopoulos[3] and Panayiotis G. Vlachoyiannopoulos[3], [1]School of Medicine,National University of Athens, Greece, [2]School of Medicine, University of Thessaly,Larissa, Greece, Greece, [3]School of Medicine, National University of Athens, Athens, Greece

Purpose: APS is characterized by the presence of anti-phospholipid antibodies and recurrent venous (VT) and/or arterial thrombosis (AT) and/or pregnancy morbidity (PM). Prognostic factors for serious clinical outcomes; description of end-stage organ damage, mortality and reasons for death in consecutive patients with APS.

Method: Descriptive analysis of 135 patients (100 female, 35 male), 89 with primary and 46 with APS secondary to systemic lupus erythematosus (SLE) (average follow-up = 7.5 years, mean age ± SD=33.6± 11.8 years). Patterns of evolution according to initial event and the prevalence of organ damage were studied. Categorical data were compared between groups by Chi-square test and continues data with one-way analysis of variance with post-hoc test and Bonferroni's correction. Associations between initial and second event were tested using a log-lineal model and expressed as odds ratios (ORs) with their respective 95% confidence interval. Differences between initial events in proportion of undesired events over time were compared using a Kaplan-Meier survival analysis with an extension of Gehan's generalized Wilcoxon test.

Results: The patients were clustered according to their initial event relevant to APS; AT (n=15), VT (n=53), Stroke (S) (n=31) or PM (n=36). The diagnosis of SLE was rather common in those with S (52%) and PM (36%) vs those with VT (28%) and AT (13%) (p=0.051).Major organ involvement accounts mainly for patients with S (29%) vs those with PM (5%), VT (6%) and AT (13%) (p=0.008).The time for presentation of a second unwanted event did not differ if the first event was VT, AT or S or any other event. Patients with AT/S, as an initial event have a 5-fold chance to experience AT in the future [OR=5.091(1.120, 23.142) (p=0.035)] while patients with VT have a 6-fold chance to experience VT [OR=5.571(1.325, 23.435) (p=0.019)]. The prevalence of traditional risk factors for arterial occlusion in AT patients did not differ from that of the remaining patients. Twenty out of 46 patients with AT/S (43%) and 26 out of 53 patients with VT (49%) experienced a second thrombotic event; 17% and 19% of whom respectively occurred under intense anticoagulation. Anticoagulation after initial events lengthened thrombosis free survival (p< 0.008) as compared to no therapy. A total of 34 patients (25%) experienced end stage organ disease or died as follows: heart failure (n=2), renal failure (n=5), severe pulmonary arterial hypertension (n=3), movement or gait disability (n=22), cognitive dysfunction and dementia (n=8), amputation (n=3) and death [(n=5), catastrophic APS (n=3), pulmonary emboli (n=1) and acute pulmonary oedema (n=1)].

Conclusion: The pattern of initial involvement predicts the outcome of patients with APS . The syndrome is a cause of high morbidity and mortality among young individuals, despite current therapy.

Simvastatin and Hydroxychloroquine Can Prevent the Procoagulant/Thrombogenic Properties of Antiphospholipid Antibodies in Monocytes. Anastasia Lambrianides[1], Katie Bell[2], Silvia S. Pierangeli[3], David S. Latchman[4], David A. Isenberg[1], Anisur Rahman[1] and Ian P. Giles[1], [1]University College London, London, England, [2]University College London, London, United Kingdom, [3]University of Texas Medical Branch, Galveston, TX, [4]DSc, FRCP, London, United Kingdom

Purpose: A major mechanism of hypercoagulability in the antiphospholipid syndrome (APS) is antiphospholipid antibody (aPL)-mediated up-regulation of tissue factor (TF) on monocytes. Recent attention has been focused on other therapeutic tools for the APS to ameliorate the risk of the hemorrhagic compications associated with the use of anticoagulant drugs currently used for treatment. Statins are potent inhibitors of cholesterol synthesis and have been shown to modify the function of endothelial cells and platelets by decreasing the expression of adhesion molecules, inhibiting TF expression and down-regulating inflammatory cytokines after treatment with aPL. Similarly, hydroxychloroquine (HCQ) has been shown to reduce the extent of thrombosis in an animal model of injury-induced thrombosis in APS and reversed aPL-induced platelet activation. The aim of this study was to determine whether simvastatin and HCQ have an effect on the APS-IgG-mediated up-regulation of p38MAPK and NFκB signalling pathways and TF activity in monocytes.

Method: We purified IgG from 7 APS patients with vascular thrombosis (VT) and 7 healthy controls. A human monocyte cell line was treated with 100μg/ml IgG for 6 hours. In some experiments, cells were pretreated with simvastatin or pravastatin (5μM) with or without mevalonate (100μM) or with HCQ (1μg/ml). The cell extracts were examined by immunoblot using total and phospho-specific antibodies to p38MAPK and NFκB p65. TF was extracted from the cell lysates and monocyte TF activity was determined using a chromogenic assay that measures factor Xa after activation by the TF-factor VII complex.

Results: IgG from patients with VT increased the up-regulation of p38MAPK, NFκB and TF activity in monocytes. Simvastatin and HCQ decrease the APS-IgG-mediated phosphorylation of phospho-p38MAPK and phospho-NFκB. Simvastatin inhibited the effects of APS-IgG on TF activity by 60% and 50% respectively, to levels comparable with healthy control IgG. Mevalonate only partly abrogated the inhibitory effects of simvastatin and the APS-IgG-mediated TF activity was restored to 75%. HCQ completely inhibited the up-regulation of TF activity produced by APS-IgG from patients with VT.

Conclusion: Our findings demonstrate, for the first time, that statins and HCQ inhibit the APS-IgG-mediated up-regulation of p38MAPK and NFκB and TF activity in monocytes and support the possibility that these drugs may offer an alternative nonanticoagulant therapeutic approach for treating APS.

Combination of Heparin and Aspirin Is Superior to Aspirin Alone in Enhancing Live Births in Patients with Recurrent Pregnancy Loss and Positive Antiphospholipid Antibodies: a Meta-Analysis of Randomized Controlled Trials and Meta-Regression. Anselm Mak[1], Alicia AC Cheak[1] and Roger CM Ho[2], [1]National University of Singapore, Singapore, Singapore, [2]National University of Singapore, Singapore

Purpose: The combination of heparin and aspirin was regarded as the "standard therapy" for patients with recurrent pregnancy loss and positive antiphospholipid antibodies but it largely stems from expert opinion. We performed a meta-analysis of randomized controlled trials (RCTs) to assess whether such a combination works better than aspirin alone in enhancing live births and reducing obstetrical complications in these patients.

Method: RCTs investigating the safety and efficacy of heparin and aspirin versus aspirin alone were searched in electronic databases using the keywords "antiphospholipid", "pregnancy", "heparin", "aspirin", "antiplatelet", "lupus" and "anticoagulants". The primary outcome was proportion of live births. The secondary outcomes were obstetrical complications and birth weight. Outcomes were pooled for relative risks (RR) [and 95% confidence interval (CI)] for live births and obstetrical complications while standardized mean difference (SMD) was pooled for birth weight, using the random effects model. Meta-regression was performed to identify factors associated with the primary outcome.

Results: Five trials involving 334 patients were analyzed in this meta-analysis. Of these patients, 171 received heparin and aspirin while 163 took aspirin only. The overall live-birth rates were 74.27% and 55.83% in patients who received heparin/aspirin combination and aspirin alone respectively. Using the random effects model, patients who received heparin and aspirin had significantly higher live-birth rate (RR 1.301; 95% CI 1.040-1.629) than those on aspirin alone (see Figure for Forest Plot). The number needed to treat by adding heparin to aspirin to achieve one live birth was 5.6. There were no significant differences in birth weight (SMD 0.084; 95% CI -0.239-0.408) and the risks of preeclampsia (RR 0.471; 95% CI 0.096-2.314) and preterm labour (RR 1.027; 95% CI 0.399-2.645) between both groups. Meta-regression using age at randomization, previous history of live births and early and late miscarriages as covariates failed to predict the RR of live birth.

Conclusion: Combination of heparin and aspirin is superior to aspirin alone in achieving more live births in patients with positive antiphospholipid antibodies and recurrent pregnancy loss.

Training, Practice and Assessment of Arthrocentesis Procedure Skills without Risk to a Patient. Richard Brasington[1], Jane Miller[2], Vic Spitzer, V. M. Holers[3], Ann Sherzinger, Adam Lawson and Maren L. Mahowald[4], [1]Washington Univ Schl of Med, St Louis, MO, [2]University of Minnesota, [3]U Colo Denver, Aurora, CO, [4]Univ of MN, Minneapolis, MN

Purpose: The 'See One, Do One, Teach One' method for learning arthrocentesis is no longer acceptable because of risk to patients. However, trainees are not able to practice these procedures with sufficient repetition and supervision on patients to become proficient (Roberts et al 2002), and there is no objective, standardized method to document that the trainee is competent to perform these procedures independently. We developed a Virtual Reality-Based Joint Injection Simular (VR-JIS) (Touch of Life Technologies, Inc.) with haptically enabled virtual palpation and needle insertion for repeated simulated arthrocenteses.

Methods: As part of a systematic process of simulator validation and development of an Arthrocentesis Competency Level Assessor, we designed a "mini-Arthro CEX to use with the VR-JIS. A field test was carried out with 15 trainees in a regional ROSCE for 5 US rheumatology training programs. Using a haptically enabled virtual syringe and palpation device, the trainee attempted to locate the landmarks for anterior entry into the glenohumeral joint, to advance the needle into the virtual joint, and withdraw virtual fluid. Pre-specified performance metrics were assessed by the computer and by observational assessment. Each metric was scored on a 9 point Likert scale by a senior rheumatologist with extensive experience with arthrocentesis and using the simulator.

Results: Two clinical evaluators piloted a 13-item dichotomous checklist to establish a performance baseline as part of a validation study of the VR-JIS. An educational consultant collected field notes describing the conditions of each of the 15 residents' encounters with the simulator. Each of the residents was oriented briefly to the simulator. Nine of 15 fellows needed direction during each procedure. Most expressed discomfort and/or confusion over the virtual anatomical landmarks as represented on the simulator. Expert evaluators concluded that trainees would need more time practicing on the simulator prior to competency assessment and more time for immediate feedback and opportunity to repeat the procedure if they fail. Future field tests will include a revised assessment tool for clinical evaluators, modification of the tactile reality and more robust evaluation of the simulator by trainees.

Conclusion: The VR-JIS is a unique technology for arthrocentesis training and and practice as well as a method for objective competency testing without concern for patient disomfort. The simulator provides an objective consistent testing paradigm for multiple trainees and the Arthro-CEX contains a set of standard procedure metrics for preceptor assessment. Problems encountered included: 1)electronic complexity of the VR-JIS, 2)time required for the trainee to become oriented to using the VR-JIS, and 3) expense and fragility of the haptic devices. Thi work was supported by an NIH/SBIR Grant

An Evaluation of Knee Arthrocentesis Videos On YouTube for Content, Technical, and Instructional Quality. Paul Sufka[1] and Anne G. Minenko[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, MN

Purpose: The Internet is a growing resource of instructional medical procedural videos. Unrestricted by time or place, viewers can access knee arthrocentesis videos as unregistered users on non peer-reviewed public websites e.g. YouTube. To our knowledge, there is no instructional arthrocentesis video evaluation instrument. The purpose of this project is to review arthrocentesis videos currently on the Internet and evaluate them for content, technical, and instructional quality.

Method: YouTube, the public video sharing website, was searched on June 15, 2009, using the terms "knee arthrocentesis" or "knee aspiration". Data for determination of video length, viewership rate, and author credential were collected.

Videos were independently evaluated by one medical resident and one Rheumatology faculty:

a) **for content** using a 16 item checklist based on the New England Journal of Medicine[1] (NEJM) website knee arthrocentesis video (indications, contraindications, equipment needed, obtaining consent, limb positioning, identification of anatomy, skin cleansing, draping, anesthetics, needle direction/insertion, removal of fluid, instruction on "milking" the knee effusion, needle removal/safety, post-procedure care, fluid handling, complications)

b) **for instructional quality** by assigning the highest level achieved on Bloom's taxonomy/cognitive domain (from lower to higher levels of behavior: knowledge, comprehension, application, analysis, evaluation, creation)

c) **for technical visual and audio quality**.

Results:

The **NEJM video** was longest at 6:23, and was assigned the highest learning behavior category level of "analysis".

Seven **YouTube videos** (Table) were evaluated after excluding 2: one copied from NEJM, a second without audio. Compared to the video on NEJM, the 7 videos on YouTube vary in length (0:31–4:51), viewership (1–33.6 views/day), author credential (commercial, physician,

university residency), number of content items addressed (3–11), and highest level of cognitive learning behavior achieved. One commercial video, 1:32 in duration addressing 5/16 content items, reached the same level (analysis) of cognitive learning behavior as the 6:23, 16 item NEJM video.

Video technical quality was fair-good. Consistency of evaluation between the 2 resident/faculty raters was excellent.

Video	Length	Views/day	Author Credential	Content Items	Highest Learning Behavior Level
1	0:38	6.5	Commercial	4	Comprehension
2	0:31	1.0	Commercial	3	Application
3	4:51	4.1	University Residency	11	Application
4	0:35	2.9	Physician	4	-
5	1:32	6.7	Commercial	5	Analysis
6	0:25	9.7	Physician	3	-
7	0:34	33.6	Physician	3	-
8					Excluded (copied from NEJM)
9					Excluded (no audio)
NEJM	6:23		University Residency	16	Analysis

Conclusion: This sample of knee arthrocentesis videos published on the NEJM and YouTube websites are at best of moderate instructional quality. For the Internet's potential as a learning resource beyond convenience to be realized, authors of procedural videos should challenge themselves to produce higher quality instructional materials.

1222

Immediate Station Feedback During the Annual New York Rheumatology Objective Structured Clinical Examination (NY-ROSCE) Increases Intra-Exam Scores. Jessica Berman[1], Theodore Fields[1], Anne R. Bass[1], Deana M. Lazaro[2], Svetlana Krasnokutsky[3], Elena S. Weinstein[4], Edward Dwyer[5], Huong Do[1], Stephen Paget[1] and Michael H. Pillinger[3], [1]Hospital for Special Surgery, New York, NY, [2]SUNY Downstate Medical Center, Brooklyn, NY, [3]NYU Hospital for Joint Diseases, New York, NY, [4]Albert Einstein College of Medicine, White Plains, NY, [5]Columbia U. College of P & S, New York, NY

Purpose: We have reported that the ROSCE is an effective tool for assessing competencies such as professionalism among rheumatology fellows. Our prior ROSCEs have excluded immediate feedback to participants due to concerns that station scores might be skewed by intra-exam effects on fellow performance. However, fellows have voiced a desire for immediate feedback, stating that it would improve the

ROSCE's educational value. This year we instituted immediate feedback, and assessed its impact on fellows' performance/ratings as they progressed through the ROSCE stations.

Methods: The 2009 NY ROSCE included four patient-centered stations focusing on rheumatic disease. Rheumatology trainees (n=22) and faculty MD-evaluators (n=24) participated from 6 NY rheumatology training programs. To accommodate feedback time, the 2009 NY ROSCE included fewer stations than prior ROSCEs (reduction of 2-3 stations). Professional actors were trained to role-play patients. At each station, fellows were evaluated by patient- and MD-evaluators (9-point Likert scales for patient care, interpersonal skills and professionalism). After each station fellows received immediate feedback from both evaluators, who were instructed to emphasize constructive criticism. Fellows also rated their own overall performance (immediately after each station but prior to receiving feedback). Following the exam, the average scores obtained as fellows moved from their initial to final stations were determined, and compared to station scores from the 2008 NY ROSCE, in which no immediate feedback was given.

Results: During the 2009 ROSCE, physician global assessments of fellows (n=22) increased progressively from first (mean 6.727) to last (mean 7.149) stations (p=0.05). Patient assessments of fellows demonstrated a similar increase (from 6.015 to 6.419), though this trend did not achieve statistical significance (p=0.14). In contrast, the 2008 ROSCE showed no progressive score improvements across stations. Fellows' self-assessments for individual stations (2009) showed progressive improvement for only 7/22 fellows. In a post-exam questionnaire, fellows reported satisfaction with the immediate feedback process.

Conclusion: A potential strength of the ROSCE is the opportunity for immediate feedback. However, our data indicate that giving immediate feedback improves trainee performance as the ROSCE progresses. Educators considering incorporating feedback into the ROSCE should be aware of both the positive benefits of feedback as a teaching tool, and the possibility that feedback may alter the performance of the ROSCE as an assessment instrument.

1223

Rheumatology Fellows Report Higher Satisfaction with VA-Based Training in Comparison to Other Internal Medicine Subspecialty Fellows. Grant W. Cannon[1] and T. Michael Kashner[2], [1]VAMC and University of Utah, Salt Lake City, UT, [2]VA Office of Academic Affiliations and University of Texas Southwestern, Dallas

Purpose: The Learners' Perception Survey (LPS) has been administered to trainees at Veterans Affairs (VA) medical centers since 2001. This validated survey assesses overall trainee satisfaction (OTS) on a 100 point scale with the higher score representing higher satisfaction. Using five point Likert scales, trainees also rated their experience in six domains listed in table 1. Each domain contained between 12 and 15 items (total 81). Domains and items were assessed as 1 = very satisfied, 2 = somewhat satisfied, 3 = neither, 4 = somewhat dissatisfied, 5 = very dissatisfied. Lower scores represent higher levels of satisfaction.

Methods: This analysis compared the LPS results for rheumatology (Rheum) fellows to other internal medicine subspecialty (Other) fellows during VA-based training for OTS, domain scores, and items scores. These results were adjusted for year of survey, year of training, and VA facility. Ratings are shown as mean ± standard error.

Results: The OTS for Rheum fellows (n= 109) was 84.1±1.3 in comparison to other fellows 81.3±1.3 (n=2,112) ($p<0.03$). For each of the domains, rheumatology fellows reported higher levels of satisfaction (Table 1).

	Rheum Fellows	Other Fellows	p-value
Clinical Faculty (CF)	1.50±0.08	1.62±0.09	0.166
Personal Experience (PEx)	1.53±0.08	1.70±0.08	0.037
Learning Environment (LE)	1.69±0.09	1.86±0.09	0.053
Working Environment (WE)	1.70±0.09	1.94±0.09	0.013
Clinical Environment (CE)	1.75±0.10	2.05±0.10	0.004

Physical Environment (PEn)	1.81±0.09	2.01±0.09	0.027

Rheum fellows reported higher satisfaction with 78 (96%) of the 81 elements within the 6 domains. The ten elements with highest satisfaction for Rheum fellows during VA training are listed in table 2.

	Rheum Fellows	Other Fellows	p-value
CF- Clinical Skills	1.31±0.07	1.52±0.07	0.005
CF-Patient-oriented	1.34±0.08	1.55±0.08	0.010
CF- Approachability/Openness	1.35±0.08	1.44±0.08	0.235
CF-Quality of faculty	1.35±0.09	1.57±0.09	0.012
PEx-Relationship with patients	1.37±0.07	1.44±0.07	0.310
CF-Teaching ability	1.39±0.07	1.61±0.07	0.011
CE-Hours at work	1.41±0.08	1.61±0.08	0.013
LE-Degree of autonomy	1.41±0.07	1.44±0.07	0.690
CF-Interest in teaching	1.43±0.09	1.61±0.09	0.044
PEx-Appreciation by patients	1.43±0.07	2.14±0.07	0.339

In an analysis of the impact of changes in domain scores and items scores on OST, all domains and items showed association with satisfaction score. The domains changes associated with the greatest OTS scores were personal experience, working environment and clinical environment.

Conclusion: Rheumatology fellows report higher training satisfaction with VA based training than other subspecialty fellows. Satisfaction with clinical faculty and personal experience was highest for the domains tested. Since working environment, personal experience, and clinical environment are most strongly associated with trainee satisfaction, these domains may have high potential for improving trainee satisfaction.

An Instrument to Provide Documentation (iPROD) of Practice-Based Learning and Improvement (PBLI): A Pilot Trial Conducted by the Carolinas Fellows Collaborative. Kenneth S. O'Rourke[1], Marcy B. Bolster[2], Lisa G. Criscione-Schreiber[3] and Beth L. Jonas[4], [1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]MUSC, Charleston, SC, [3]Duke University Med Ctr, Durham, NC, [4]Univ of North Carolina, Chapel Hill, NC

Purpose: Since 1999 the ACGME Outcome Project has required programs to assess trainee skills in PBLI – the ability of the fellow to improve patient care practices and appraise and assimilate scientific evidence into practice. Assessment of these activities has typically required mining information from multiple tools (e.g. patient logs, performance ratings, records review) as few individual tools evaluate all the essential components of PBLI: independent learning, self-evaluation of performance, and incorporation of feedback into improvement of clinical activity.

Method: Our collaborative group created a one-page, online form (iPROD) for fellow self-completion of PBLI activity. The form is divided into three sections: (1) summarization of the issue being addressed and site where it developed (e.g., clinic patient encounter), (2) results and resources used to resolve the issue, and (3) a description of how the results were applied. The form was piloted at a single institution over 7 weeks. Participants were to complete at least one form per week. A seminar was held once weekly during which all participants each presented the contents of one completed form over 3-5 minutes followed by a short 1-2 minute discussion with annotation. Hard copies of

the forms were (1) indexed and placed in a binder as a resource for future use, and (2) incorporated into the fellow's portfolio. Issues raised in the iPRODs will serve as a source for locally-generated 'inservice' questions.

Results: Three fellows and two faculty submitted a total of 23 forms. Issues involved questions of clinical manifestations or disease pathophysiology (n=9), pharmacology (5), diagnostic testing (4), therapy (4) and differential diagnosis (2). Two forms incorporated a systems-based practice concern. The majority (17/23) of issues originated from clinic encounters, and information learned in all cases was applied directly to patient care. Completion of the iPROD was straightforward and relatively rapid. Group discussion provided for feedback and reinforcement of major teaching points.

Conclusion: This pilot trial demonstrated the feasibility of a simple online tool, supplemented by presentation and discussion, to document and evaluate all essential components of PBLI. A larger study among all sites in our collaborative is planned.

1225

Medical Education Preferences Among North American Rheumatologists: A 2009 Survey. John J. Cush, Baylor Research Institute, Dallas, TX

Purpose: Practicing rheumatologists (Rheums) regularly deal with changing therapies, limited time/resources for medical education and an ever expanding information glut. These hurdles are compounded by revisions in medical education imposed by ACGME, academic institutions and the pharmaceutical industry. This study intends to assess the current preferences and objections of Rheums with regard to professional and medical education.

Method: 2123 adult and pediatric Rheums from the USA and Canada (160) were invited (via 2 emails) to an online survey in June 2009. The survey included 16 questions regarding respondent demographics, practice type, educational opportunities and preferences regarding venue, attendance, educational resource evaluation, learning formats and preferred topics.

Results: There were 435 respondents (21% response rate), 74.5% male, with a mean age of 55.5 yrs. Responses came from private practice (51%), academic (34%), government/military (4%), Pediatric Rheums (6%); with an overall mean of 23 years in practice (43% > 25 yrs). 63% were engaged in full time patient care, 28% part-time patient care, 32.4% supervise resident/fellow run clinics and 11% are engaged in a single disease specific-only clinic (eg, PSS patients). Most devote either 1-3 hrs (38%) or >3 hrs (40%) per week to education with most online education being sought by private practitioners (>20%). 56% of academicians lecture at least 1 hr/week. Attendance at live meetings (26%) was more popular than on-line education (15%). Whereas the highest rated education sources included Rheum journals (76%), ACR meetings (52%), medical literature searches (45%); the least valued sources included free CME monographs/CDROMs (53%) and Dinner programs (42%). Nonetheless, most attend dinner programs (CME and non-CME) with a 10% high rating and 56 moderate rating. Factors most influencing meeting attendance included topic (79%), time away from practice (72%), site/venue (68%), 66% (cost), speaker reputation (58%) and CME credit (55%). Factors less important (20-25%) included title, evening vs Saturday programming, medical school affiliation and dinner programs. Top ranked meetings included ACR annual mtg (1), Review courses (2), meet the professor groups (3), advisory meetings (4) and post-ACR/EULAR reviews (5). Lowly ranked meetings included webcasts, podcasts and speakers who visit the clinics. Top ranked proposed changes for the future included topic reviews, year in review, case-based conferences, programs with more Q&A time and shorter lectures. Lastly nearly 2/3 of respondents would pay $10-50 per hour of CME but 20% refuse to pay for CME.

Conclusion: Regardless of age, type/focus of practice or country, N. American Rheums are demanding with regard to educational needs. Dinner programs, pharma promotional materials and online webcasts remain unpopular. However interest in convenient, local or regional, affordable education remains strong especially when review courses, post-meeting reviews, basic science reviews or advances in drug therapy are the focus.

Genetic Interactions Reveal a Novel B-Cell Pathway in Systemic Lupus Erythematosus. Casimiro Castillejo-Lopez[1], Angelica M. Delgado-Vega[1], Jerome Wojcik[2], Sergey Kozyrev[1], Juan R. Lopez Egido[1], Elena Sánchez[3], David Pöllmann[1], Serena Fineschi[1], Nicolas Dominguez[4], Rufei Lu[4], Judith A. James[4], Joan T. Merrill[4], Jennifer A. Kelly[4], KM. Kaufman[4], Kathy L. Moser[4], GS Gilkeson[5], Bernardo Pons-Estel[6], Nadia Barizzone[7], Torsten Witte[8], Jose Luis Callejas[9], Jb Harley[4], Patrick M. Gaffney[4], Javier Martin[3], Joel M. Guthridge[4] and Marta E. Alarcon-Riquelme[1], [1]Uppsala University, Uppsala, Sweden, [2]Merck Serono International, Geneva, Switzerland, [3]Instituto de Biomedicina y Parasitología López-Neyra, Granada, Spain, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Medical University of South Carolina, Charleston, SC, [6]Sanatorio Parque, Rosario, Argentina, [7]University of Eastern Piedmont, Novara, Italy, [8]Hannover Medical School, Hannover, Germany, [9]Hospital Clinico San Cecilio, Granada, Spain

Purpose: Epistasis, or genetic interactions, might explain larger genetic effects than single-gene associations on the susceptibility to diseases, and help to define functional pathways with potential therapeutic targets. We aim to identify genes that modify the susceptibility to SLE through their interaction with the B-cell scaffold protein with ankyrin repeats gene (*BANK1*).

Method: We searched for genetic interactions in an Affymetrix 100k genome-wide scan performed in 256 cases and 515 controls from Sweden. A subsequent replication study included two independent multi-center cohorts of European-Americans (n=676 cases and 850 controls) and Europeans (n=1265 SLE cases and 1506 controls). We developed a genotype interaction test based on contingency tables for all possible genotype combinations between pairs of SNPs with $r^2 < .80$ and calculated a Pearson *S* score of interaction association and its X^2 *P* value. Each interacting combination was tested against the hypothesis of independence to derive an epistasis score (S_e) and a *P* value (P_e) was obtained through permutation.

Results: *BANK1* showed genetic interactions with 29 genes, including the B-cell tyrosine kinase (*BLK*) and the inositol 1,4,5-triphosphate receptor 2 (*ITPR2*). One fifth of SLE patients (21%) vs. 8 % of controls were homozygous for the risk alleles of polymorphisms in these three genes with a significant epistatic effect ($P_e < 0.0002$). The interactions *BANK1xITPR2* and *BANK1xBLK* were replicated in two independent European-American ($P = 2.1 \times 10^{-6}$) and European sets ($P = 4.11 \times 10^{-9}$). The data was verified using multifactor dimensionality reduction (MDR) and logistic regression analysis. Moreover, BLK co-immunoprecipitated and co-localized with BANK1 in co-transfected HEK-293T. Exogenous expression of BANK1 in human Daudi B cells curbed BLK from reaching the plasma membrane with the subsequent accumulation in cytoplasmic compartments. Expression of BANK1 and BLK but not ITPR2 was modulated by IFNα

Conclusion: *BANK1*, *BLK* and *ITPR2* are genetically and functionally interacting partners and through their protein-protein interactions might results in a novel B-cell signaling pathway regulated by type I interferon α. This pathway may affect B-cell responses to self-antigens in human lupus.

[5]Rheumatology and Clinical Immunogenetics, University of Texas

Health Science Center at Houston, USA. [6]Botnar Research Centre, University of Oxford, UK. [7]Royal National Hospital for Rheumatic Diseases NHS Foundation Trust and University of Bath, UK.

Purpose: Inflammatory bowel disease (IBD) occurs in ~10% of AS cases and 70% of AS cases have subclinical terminal ileitis. Spondyloarthritis is also common in patients with IBD. We sought to test whether genes involved in Crohn's disease (CD) are also associated with ankylosing spondylitis (AS), potentially explaining the co-occurrence of the two conditions.

Method: Using Taqman and Sequenom technologies, we genotyped 1262 US and UK AS cases of white European descent for 37 established CD loci. Because 3 loci were in strong candidates, genes were typed using tagSNPs across all exons. Control genotypes were obtained from a white European ancestry historical dataset (n=1295, from the 1958 British Birth Cohort, typed by the Wellcome Trust Case Control Consortium), and imputation was carried out using MACH whenever control marker data was unavailable. Statistical analysis was carried out using a Cochran-Armitage test for trend and all associated markers ($P<0.1$) were genotyped on US and UK cases (n=854) and controls (n=858) for replication on the OpenArray platform (AB). P-values for the combined analysis are presented.

Results: Out of 62, 26 markers ($P<0.1$) were taken for genotyping in the 2nd phase and 9 achieved association ($P<0.05$) in the replication phase with P values ranging from 0.01 to $7.7x10^{-29}$ in the combined analysis. Association was confirmed for *IL23R* (rs11465804, $P=1.0x10^{-4}$) and MHC (rs3763313, $P=7.7x10^{-29}$). Outside the MHC, strongest association was detected at chromosome 1q32.1 (rs11584383, $P=8.2x10^{-8}$), in an intergenic region. Association was also confirmed for 3 markers in *STAT3* (rs6503695, $P=5.7x10^{-3}$; rs4103200, $P=1.1x10^{-2}$; rs744166, $P=1.5x10^{-3}$). Finally, association was identified in both datasets for markers in *MST1* (rs3924462, $P=2.7x10^{-3}$), *CDKAL1* (rs6908425, $P=1.4x10^{-3}$), and *LRRK2/MUC19* (rs11175593, $P=3.6x10^{-3}$). These associations did not significantly change when AS cases with clinical IBD were excluded.

Conclusion: Evidence has been demonstrated for strong association with an intergenic region on chromosome 1q32.1, and with *STAT3*. *STAT3* is a key gene involved in Th17 lymphocyte differentiation, and further enhances the case for a major role of this T-lymphocyte subset in AS pathogenesis. Finally these findings suggest a common aetiopathogenesis for AS and CD and further highlight the involvement of common risk variants across multiple diseases.

Complete T- and B-Cell Receptor Repertoire Analysis in Rheumatoid Arthritis Using Massive Parallel Sequencing. P.L. Klarenbeek[1], M.E. Doorenspleet[1], B.D.C. van Schaik[1], M.M. Herenius[1], M.E. Jakobs[1], Tineke Cantaert[2], D.L.P. Baeten[1], A.H.C. van Kampen[1], F. Baas[1], Paul P. Tak[3] and N. de Vries[1], [1]Academic Medical Center/Univ. of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: T-cells and B-cells are likely to play important roles in the pathogenesis of rheumatoid arthritis (RA). Previous attempts to investigate the roles of T- and B-cell clones in RA by screening the T-/B-cell receptor (TCR/BCR) repertoires were hampered by the sheer size and complexity of the repertoires. Current techniques are unable to analyse the whole repertoire in sufficient detail, are vulnerable to artefacts, and do not provide quantitative data. Here, we used our newly developed protocol based on massive parallel sequencing which overcomes current limitations and produces the DNA-sequence of >100.000 receptors in a single experiment. Using this technique we performed the first quantitative, high- resolution analysis of the complete TCR and BCR repertoires in an RA patient. **Objectives:** Describe the complete BCR and TCR repertoires in synovial tissue (ST) and peripheral blood (PB) samples of an RA-patient and screen for dominant T- and B-cell clones.

Method: mRNA was isolated from paired PB and ST samples from an ACPA+ RA-patient with active disease despite treatment with methotrexate. A linear amplification with multiplex primers for all V(ariable)-families of the receptor beta-chain (TCR) or heavy-chain (BCR) was performed. The samples were analyzed on a Genome Sequencer FLX (Roche) resulting in 14000 reads/samples for TCR and 35000 for BCR analysis respectively, each containing the full CDR3 sequence. Bioinformatic algorithms were used to identify gene segments and correct for sequencing errors.

Results: *TCR-repertoire*: in ST most TCRs contained a Vbeta6(46%), 10(19%), and 27(13%) gene segment, while in PB V29(32%) and 7(26%) were most frequent. The TCR repertoire was dominated by low-frequency clones (>95%), both in the PB and ST. Several clones were clearly expanded (up to 217 and 121 copies/clone for PB and ST). However, the dominant clones in ST were different from those in

PB, as compared by V-segment and CDR3 sequence. *BCR-repertoire*: the ST sample showed preferential usage of the small V2,5,6,7 families (total 50%) when compared to published data in PB[1](20%). Several clearly expanded clones (up to 1892 copies) were found against a background of low-frequency clones.

Conclusion: This is the first high-resolution analysis of the TCR and BCR repertoire in RA, providing detailed insight into the presence of T- and B-cell clones. We found clear differences between the TCR-repertoire in ST compared to PB in an RA-patient. Several expanded clones were found only in ST, suggesting proliferation or local retention of T-cells. The BCR-repertoire also showed expanded clones within the ST. Further studies will elucidate the role of these clones in RA.

The Coding Variant within ITGAM Influences Lupus Nephritis. Xana Kim-Howard[1], Amit K. Maiti[1], Juan-Manuel Anaya[2], Gail R. Bruner[3], J. T. Merrill[4], Jeffrey C. Edberg[5], Michelle A. Petri[6], John D. Reveille[7], Elizabeth Brown[5], Graciela S. Alarcon[5], Rosalind Ramsey-Goldman[8], Timothy J. Vyse[9], GS Gilkeson[10], Robert P. Kimberly[5], Judith A. James[3], Joel M. Guthridge[1], John B. Harley[11] and Swapan K. Nath[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]CIB-Rosario University, Medellin, [3]Oklahoma Medical Rsrch, Oklahoma City, OK, [4]OMRF, Oklahoma City, OK, [5]University of Alabama at Birmingham, Birmingham, AL, [6]JHU, Baltimore, MD, [7]University of Texas Medical School at Houston, Houston, TX, [8]Northwestern University, Chicago, IL, [9]Imperial College, London, United Kingdom, [10]Medical University of South Carolina, Charleston, SC, [11]OMRF, OK, OK

Purpose: We recently demonstrated genetic association between a novel non-synonymous (R77H) variant (rs1143679) at exon-3 of *ITGAM* and systemic lupus erythematosus (SLE), a clinically heterogeneous disease. The relationship between this variant and clinical sub-phenotypes have not been studied. We hypothesized that rs1143679 could predict specific clinical outcomes (sub-phenotypes).

Method: We used 2366 SLE cases and 2931 unaffected controls of European descent to assess association between this coding variant and clinical sub-phenotypes. SLE patients were classified by the presence or absence of individual ACR criteria. Logistic regression and Pearson chi-square tests were used to assess statistical significance with rs1143679 in case-control and case-only analyses.

Results: First, for overall case-control analysis between SLE and rs1143679, we detected highly significant ($P = 2.22x10^{-21}$, OR = 1.73) genetic association. Second, we performed case-only analysis between individual ACR criteria positive cases and negative cases. This variant was significantly associated with lupus nephritis (P = 0.0003, OR = 1.39), discoid rash (P = 0.02, OR = 1.27) and immunologic criteria (P = 0.04, OR = 1.30). Third, to further assess the magnitude of associations between significant ACR criteria, we compared them with normal controls. The strongest statistical association was with lupus nephritis versus controls ($P = 4.69x10^{-22}$, OR = 2.15), and immunologic manifestations versus controls ($P = 3.49x10^{-22}$, OR = 1.86); both were more significant than all SLE cases together versus controls. Conversely, significant associations were also detected with ACR-negative versus controls for nephritis ($P = 4.05x10^{-7}$, OR = 1.50) and discoid rash negative ($P = 2.58x10^{-6}$, OR = 1.55). However, significantly different ORs were only detected between nephritis positive and nephritis negative cases when compare with all controls. The minor allele frequency increased from 10.6% (controls) to 17.0% (SLE cases) and 20.4% (lupus nephritis). All associations remained significant after 10,000 permutations.

Conclusion: Clinical sub-grouping yielded the strongest association with rs1143679 in SLE patients with lupus nephritis, both in case-only and case-control analyses. SLE nephritis patients were highly enriched with the risk allele. These results suggest a correlation between a coding variant of *ITGAM* (rs1143679) and lupus nephritis.

Towards Genetic Correlates of Cardiac Manifestations of Neonatal Lupus: A Genome-Wide Association Study. Robert M. Clancy[1], Miranda C. Marion[2], Kenneth M. Kaufman[3], Adam Adler[3], John B. Harley[4], Carl D. Langefeld[2] and Jill P. Buyon[1], [1]NYU School of Medicine, New York, NY, [2]Wake Forest University Health Sciences, Winston-Salem, NC, [3]Oklahoma Medical Research Foundation, OK, OK, [4]Oklahoma Medical Research Foundation, OK

Purpose: Maternal anti-Ro antibodies are highly associated with heart block and/or cardiomyopathy (cardiac neonatal lupus (NL) in an offspring. Monozygotic twin studies and the 10 fold increased recurrence rate of cardiac NL in a subsequent pregnancy implicate a strong genetic influence on risk of disease. Here, we report the first genome-wide association study of cardiac NL.

Methods: Caucasian children (n=117) with cardiac NL were identified from an extensive collection of DNA in the U.S. Research Registry for Neonatal Lupus (RRNL). Two criteria were required: 1) cardiac NL defined as heart block (1st, 2nd ,3rd, degree) documented by electrocardiogram (if 1st degree), echocardiogram, history of pacemaker, or statement in the medical record; and/or presence of cardiac injury which included autopsy evidence of a mononuclear infiltrate in the endocardium, myocardium and pericardium and/or endocardial fibroelastosis on echocardiogram always associated with cardiac dysfunction 2) maternal antibodies to 52kD SSA/Ro, 60kD SSA/Ro, or 48kD SSB/La. In 96%, 2nd or 3rd degree block was present. Cardiac NL subjects were genotyped using the Illumina 370K SNP platform and merged with 3351 Illumina "out-of-study" controls from SLEGEN (Harley 2008). Standard quality control and admixture adjusted tests of association were computed.

Results: The HLA region (6p21) showed strong evidence of association. Two HLA SNPs in high linkage disequilibrium were rs3135353 (p_{dom} = 3.99E-08; OR = 2.87; 2.8 kb from HLA-DRB5) and rs3129963 (p_{dom} = 8.96E-07; OR = 2.57; 75 kb from HLA-DRA). Outside the HLA region, rs1810636 near 20p13 showed significant association to cardiac NL (p_{rec} = 1.53E-12, OR = 4.07). In proximity to this region are the DNA sequences of five noncoding RNAs that associate with the spliceosome. An additional suggestive association at 5q11.2 includes rs 2432143 (p_{dom}=5.87E-05, OR=2.28) within the integrin, alpha 1, a receptor involved in cell-cell adhesion, which may play a role in inflammation and fibrosis. Importantly, none of the fifteen prominent non-HLA polymorphisms reported in SLE association studies were associated with cardiac NL at less than 1E-5.

Conclusion: These analyses are the first genome-wide association study for cardiac NL and identify several strong statistical associations. These associations, including the HLA region, corroborate the genetic influences on cardiac NL and may provide a basis for exuberant fibrosis of the conduction system.

Genomewide Scan in Acute Anterior Uveitis: Similarities and Differences with Genes Associated with Ankylosing Spondylitis.
Tammy M. Martin[1], David M. Evans[2], Patrick Danoy[3], Justine R. Smith[1], Michael M. Ward[4], Michael H. Weisman[5], The Australo-Anglo-American Spondylitis Consortium, John D. Reveille[6], Matthew A. Brown[3] and James T. Rosenbaum[1], [1]Oregon Health & Science Univ, Portland, OR, [2]University of Bristol, Bristol, United Kingdom, [3]Diamantina Institute, University of Queensland, Brisbane, Queensland, Australia, [4]NIH/NIAMS, Bethesda, MD, [5]Cedars-Sinai Med Ctr, LA, CA, [6]University of Texas Medical School at Houston, Houston, TX

Purpose: Acute anterior uveitis (AAU) or iritis, complicates ~40% of cases of ankylosing spondylitis (AS), and can occur in the absence of AS. Both AS and AAU are associated with HLA-B27, and there is evidence to suggest that other genes are involved in each disease. This study aimed to identify genes involved in AAU and to compare those genes with the known genes involved in AS.

Method: 952 cases with uveitis (with or without AS) and 1380 AS cases without uveitis were available for study. These were identified from cases enrolled in the TASC AS genomewide association study (n=2082), or were recruited separately having presented with AAU (n=250). TASC cases were genotyped with lllumina 370CNV chips and non-TASC samples with Illumina 610 chips. Healthy controls used were from the Illumina iControl database, and had been cleaned for white European ancestry using ancestry informative markers. Datasets were compared using the Cochrane-Armitage test for trend as implemented in PLINK. Study activities were conducted under approved human subjects protocols.

Results: Comparing uveitis cases with AS cases without uveitis, association was observed at chromosome 1p35.1 with SNPs in the gene *CSMD2* (CUB and Sushi multiple domains 2; rs732889, P= 1.8x10-7). Association was also observed with SNPs in the chromosomal regions

4q32.3 (rs11100530, P=2.0x10-6) and 15q22.1 (rs1122208, P=5.7x10-7). No genes are encoded in these regions. No association was seen between *CSMD2*, or the chromosome 4 or 15 regions, with AS in comparisons of AS cases vs healthy controls, suggesting that the associations observed are with AAU rather than primarily with AS. The CSMD2 protein is expressed primarily in brain and related tissues, including the ciliary ganglia. It has unknown function and belongs to a family of transmembrane proteins with large extracellular domains containing alternating CUB and Sushi motifs. Based on the absence of differences between uveitis compared to AS without uveitis at known AS loci, these data also support uveitis associations with MHC, *IL23R*, *ERAP1*, chromosome 2p15, 21q22, *IL1R2* and *ANTXR2*.

Conclusion: This study suggests that there is great similarity between the genes involved in AS and in AAU, and that the major genes involved in AS that are known thus far are similarly associated with AAU. In addition, three loci were identified, including the gene *CSMD2*, which have a greater association in AAU cases than in AS alone, suggesting that these genes are independent risk factors for AAU. Funding: NIH, RPB, NHMRC.

Is Infliximab Effective and Safe for the Treatment of Refractory Non Infectious Inflammatory Uveitis?-A Systematic Literature Review. Ana M. Ortiz[1], Estibaliz Loza[2], Miguel Abad[3], Felix Francisco[4], Jesús Maese[2], Santiago Muñoz-Fernández[5], Loreto Carmona[2] and Esperanza Pato[6], [1]Hospital Universitario de la Princesa, Madrid, Spain, [2]Fundación Española de Reumatología, Madrid, Spain, [3]Hospital Virgen del Puerto, Plasencia, Cáceres, Spain, [4]Hospital Doctor Negrin, Las Palmas de Gran Canaria, Spain, [5]Hospital Infanta Sofía, Madrid, Spain, [6]Hospital Clínico San Carlos, Madrid, Spain

Infliximab (INF) has successfully been used for the treatment of different inflammatory diseases. Non infectious inflammatory uveitis (NIIU) might develop a severe course with poor visual prognosis if an adequate control of the disease is not achieved. INF has been used for the treatment of these patients.

Purpose: To systematically review the published evidence regardingthe efficacy and safety of INF in NIIU refractory to conventional immunosuppressive drugs.

Method: Systematic review of studies retrieved by a sensitive search strategy in Medline (1961-October 2007), Embase (1961-October 2007), Cochrane Library (up to October 2007). Selection criteria: (population) studies analyzing patients with uncontrolled NIIU in spite of immunosuppressive drugs; (intervention) studies had to test INF; and (outcomes), studies reporting visual acuity, Tyndall, vitritis, retinal vasculitis, macular edema, pars planitis and adverse events. Randomized controlled trials, observational studies and case series were included. Three reviewers screened the titles and abstracts of the retrieved articles for selection criteria independently and collected the data by using *ad hoc* standard forms. One of them also graded the quality of the selected studies using a modification of the Oxford Centre for Evidence-based Medicine Levels of Evidence in its May 2001 update. A hand search was completed by reviewing the references of the included studies.

Results: A total of 105 articles were studied in detail, of which 40 were included (7 open studies, 1 cohort study, 10 retrospective studies, 16 cases series and 1 literature review). A total of 409 patients with NIIU were analyzed (139 associated with Beçhet disease, 90 with idiopathic juvenile arthritis and 180 with other diagnoses). Although the great variability in the study design, study samples, drug dosing and treatment duration and outcomes, most patients on INF showed an important improvement in the visual outcomes. Few major adverse events were reported.

Conclusion: Treatment with INF is effective and safe for the treatment of patients with NIIU refractory to conventional immunosuppressive drugs (level of evidence 4, grade of recommendation C).

1233

Cardiac Sarcoidosis: Clinical, Diagnostic, Therapeutic and Outcome Features From a Series of 126 Patients. Damien Sène, Catherine Chapelon-Abric, David Saadoun, Alexis Mathian, Nathalie Costedoat-Chalumeau, Julien Haroche, Du Li Thi Huong-Boutin, Jean -Charles Piette, Patrice P. Cacoub and Zahir Amoura, Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France

Purpose: To analyze clinical, diagnostic and therapeutic features and the outcome of 126 patients with a cardiac sarcoidosis (CS).

Methods: Patients with a definite CS, prospectively followed in a single centre, were included. SC was diagnosed using the following procedures: electrocardiogram, myocardial echography, MRI and scintigraphy. The diagnosis of CS was defined by the evidence of myocardial abnormalities to at least two different procedures. Patients with a CS were analyzed regarding their clinical, diagnostic, therapeutic and outcome features.

Results: Out of a cohort of 502 patients with a systemic sarcoidosis, 126 patients (25%) presented a CS: mean age 41 ± 12 years; male gender 59%; Caucasian 70%; Black 28% and Asiatic 2%. Extracardiac sarcoidosis involvement included: chest 79%, central nervous system (CNS) 44%, peripheral lymph nodes 31% and skin 25%. **Diagnosis**: Dyspnea was present in 19% of patients. ECG abnormalities were present in 64% of patients including conduction (54%) and rhythm (63%) disturbances. The echocardiography (n = 125) showed pathological signs for 88 patients (70%): hypokinesia (33%), low *left ventricular ejection fraction* (22%), interventricular septum thickness (10%). Myocardial scintigraphy (n = 112) was pathological for 81 patients (72%) with localized (61%) and diffuse (12%) defects. Cardiac MRI (n = 64) showed abnormal signals and gadolinium uptake in 37 patients (58%). Morphological and electrocardiographic troubles were both present in 80 patients (63.5%) and 46 patients (36.5%) had isolated morphological abnormalities. The highest diagnostic accuracy was reached between MRI and echocardiography (67%), followed by MRI and scintigraphy (63%) and echocardiography and scintigraphy (56%).**Treatment and Outcome**: A first line treatment with steroids was initiated for 111 patients (88%), among whom 48 patients (43%) received an additional immunosuppressive drug (ISD) including methotrexate (71%), cyclophosphamide (23%), mycophenolate mofetil (6%). After a mean follow-up of 74.8 ± 63 months, 122 patients were evaluable: 89 patients (73%) recovered, 28 patients (23%) were stable, and 5 patients (4%) worsened. After multivariate analysis, two factors were associated with the absence of CS recovery: CNS involvement (OR = 3.2; 95%CI: 1.3-7.5; P = 0.0025) and a left heart insufficiency (OR = 2.5; 95%CI = 1-6; P = 0.05). Thirteen patients (10%) died and only two deaths (1.6%) were imputable to CS.

Conclusion: Our results show that CS has a good prognosis under steroids alone or in association with an ISD. Up to 70% of patients may recover and the CS related death rate is less than 2%. The absence of a stable recovery is associated with the severity of systemic sarcoidosis, i.e. left heart insufficiency and CNS involvement.

Wrist Pain in 7-12 Year Olds Playing with Game Consoles/Handhelds: Younger Children Have More Pain, Independent From Time Spent Playing. Deniz C. Ince[1], C.J. Swearingen[2] and Yusuf Yazici[3], [1]Rossman Elemantary School, St Louis, MO, [2]MUSC, Charleston, SC, [3]NYU Hospital for Joint Diseases, New York, NY

Purpose: Game consoles such as Xbox, PS3 and Wii, in addition to handheld unit PSP, iTouch and iPhone are used by many children. Data regarding wrist and finger pain that may be caused by excessive use of these devices do not exist, especially in young children. We examined the possible association device type, age of children and hours played may have with wrist and finger pain.

Method: 7-12 year olds attending Rossman Elemantary School in St Louis, MO, were administered a questionnaire asking about game consoles and hand-held devices used, hours played, and wrist or finger pain as reported on a 10cm VAS. Summary statistics of playing habits, devices played and pain levels were estimated. Multivariable generalized linear models associating consoles played, age and hours played to pain were constructed using standard backward selection techniques, determining the most significant independent predictors for pain.

Results: 171 children completed the survey (mean age 9.7 years, 93 were female (54.4%). 84 (49.1%) reported 0-1 hours of play a day, 58 (33.9%) 1-2 hours, 12 (7%) 2-3 hours and 11 (6.4%) over 3 hours. 20 (11.7%) children reported finger pain and 17 (9.9%) reported wrist pain limiting their playing time. The mean (SD) pain level was 0.83 (1.82). Among the consoles Wii was the most commonly used (n=77, 45%), followed by Xbox/PS3 (n=9, 5.3%). 28 (16.4%) children played with none and 57 (33.3%) played both. For handhelds, Gameboy/PSP were played by 103 (60.2%) and iTouch/iPhone by 10 (5.8%). 39 (22.8%) played both and 19 (11.1%) played with neither. In beta regression, increasing age was independently associated with decreased odds of reporting pain (OR=0.65 (95% CI 0.57 – 0.75)); increasing hours played was associated with increased odds of reporting pain (OR=1.52 (95% CI 1.16-2.00)). Playing the Wii only was also independently associated with increased odds of reporting pain (OR=2.39 (95% CI 1.81-3.73)). In logistic regression, age was the only significant predictor of wrist pain (OR=0.68 (95% CI 0.48-0.96).No significant predictor of finger pain was observed.

Conclusion: In children aged 7-12, 80% of which played with a console or handheld, younger age was associated with more wrist pain. Wii use was associated with more self-reported pain independent of age and hours played. Seven year olds reported the most pain as compared the other age groups. These findings may have implications for which age children should start playing with gaming consoles and handheld devices and possibly some limits in the hours they play.

Efficacy and Safety of Canakinumab (Ilaris) in A Large Cohort of Patients Across Different Severity Phenotypes of Cryopyrin Associated Periodic Syndrome (CAPS). J.B. Kuemmerle-Deschner[1], H.J. Lachmann[2], E. Hachulla[3], J. Hoyer[4], J. Smith[5], K. Leslie[6], I. Kone-Paut[7], J. Braun[8], A. Widmer[9], N. Patel[10], R. Preiss[10] and P.N. Hawkins[2], [1]Universitätsklinikum Tübingen, Klinik fuer Kinder-und Jugendmedizin, Germany, [2]Royal Free and University College Medical School, London, United Kingdom, [3]Hopital Claude Huriez, Lille Cedex, France, [4]Univ.-Klinikum Gießen und Marburg, Marburg, Germany, [5]University of Wisconsin Hospital and Clinics, Madison, WI, [6]UCSF, School of Medicine, San Francisco, CA, [7]Hopital Kremlin Bicetre, Le Kremlin Bicetre, France, [8]Rheumazentrum Ruhrgebiet, Herne, Germany, [9]Novartis, Basel, Switzerland, [10]Novartis, East Hanover, NJ

Purpose: CAPS (disease spectrum consisting of FCAS, MWS, NOMID) is a rare hereditary, autosomal dominant, systemic inflammatory disease associated with excessive production of IL-1β. The fully human monoclonal antibody canakinumab provides prolonged selective blockade of IL-1β.

Method: Patients enrolled in this open-label multi-center study were canakinumab naïve or rolled over from earlier Phase II/III studies. Patients received canakinumab 150 mg s.c. or 2 mg/kg s.c. (≤40 kg) every 8 weeks. The primary objective of this ongoing trial is to assess the long-term safety and tolerability of canakinumab in CAPS patients. Secondary objectives included assessment of response (for naïve patients), maintenance of response, percentage of patients requiring dose adjustment, and immunogenicity of canakinumab. A relapse was defined as: serum levels of CRP and/or serum amyloid A protein (SAA) >30 mg/L and physician's global assessment of disease activity >minimal or physician's global assessment of disease activity =minimal along with the assessment of skin disease >minimal.

Results: Out of 98 patients (19 FCAS; 69 MWS; 9 MWS/NOMID; 1 cold urticaria/protocol deviation; 19 pediatric) aged 5-69 years enrolled in the study, 44 patients were canakinumab-naïve, while 54 had previously received canakinumab in another study. The median duration of exposure to canakinumab was 113 days (range 9-232 days) and the mean number of injections per patient was 2.9 (range 1-9) at the time of this interim analysis. A complete response by Day 8 was seen in 41/44 (93.2%) canakinumab-naïve patients. 13 patients had missing relapse assessment data at the interim analysis cut off. Of the remaining 85 patients, 77 had no relapse (90.6%), 5 experienced a relapse (5.9%), and 3 naïve patients did not achieve a complete response. At least one dose adjustment was required in 16 patients (16.3%). AEs were predominantly mild to moderate in severity, the most frequent AE was nasopharyngitis. Two patients discontinued due to AEs (1 due to worsening of multiple sclerosis like lesions and another due to MWS flare). Serious AEs were reported in 5 patients and resolved while on treatment. The majority of patients (94.9%) had no injection site reactions, 5.1% reported reactions, which were all mild. No anti-canakinumab antibodies were observed.

Conclusion: For CAPS patients, canakinumab administered every 8 weeks, provided rapid improvement of symptoms and sustained remission in a large cohort of patients across all disease severity phenotypes.

Familial Mediterranean Fever (FMF)-Associated B30.2 (PRYSPRY) Mutations Activate a NLRP3-Independent Inflammasome and Induce Autoinflammatory Disease in Mice. Jae Jin Chae[1], Young-Hun Cho[2], Jun Cheng[3], Maria Mosaico[4], P. Paul Liu[3], Lionel Feigenbaum[4], Stephen I. Katz[2] and Daniel L. Kastner[1], [1]Inflammatory Biology Section, Laboratory of Clinical Investigation, NIAMS, NIH, Bethesda, MD, [2]Dermatology Branch, NCI, NIH, Bethesda, MD, [3]Genetics and Molecular Biology Branch, NHGRI, NIH, Bethesda, MD, [4]Laboratory Animal Sciences Program, SAIC-Frederick, NCI, NIH, Frederick, MD

Purpose: Familial Mediterranean fever (FMF) is the prototype and the most common of a group of disorders, termed systemic autoinflammatory diseases, that are characterized by recurring spontaneous episodes of fever and localized inflammation. FMF is caused by mutations of a 781-amino acid protein denoted pyrin. Most patients carry missense mutations in the C-terminal B30.2 domain of pyrin. However the molecular pathogenesis of FMF remains poorly understood. In order to study the pathogenesis of FMF *in vivo*, we have generated various knock-in (KI) mouse models with FMF-associated B30.2 mutations.

Method: KI mice were generated by inserting the B30.2 domain of wild-type (WT) or FMF-associated M680I, M694V, and V726A mutant pyrin into mouse pyrin that ordinarily does not include a B30.2 domain. The KI mice were analyzed by histology, flow cytometry, multiplex cytokine assay, and Western blot. The KI mice were also used in bone marrow (BM) transplantation and crossed with Pyrin KO, Rag-1 KO, IL-1R KO, ASC KO, and NLRP3 KO mice.

Results: While the WT B30.2 KI mice were embryonic lethal, the KI mice for FMF mutations exhibited a phenotype similar to the human disease, but more severe, with growth retardation, spontaneous dermatitis and arthritis, and increased CD11b+ cells (especially granulocytes) in the blood. These inflammatory phenotypes could be observed only in homozygotes, but not in heterozygous KI, pyrin KO, and hemizygous KI mice expressing only mutant pyrin from a single allele. BM cells of KI mice transferred the KI phenotype into WT mice, and WT BM cells rescued the diseased KI mice. Rag-1 deficient KI mice showed phenotypes similar to Rag-1 sufficient KI mice. Pro-inflammatory cytokines, such as IL-1beta, are significantly increased in KI mouse sera. In the steady state, the inflammasome is constitutively activated in CD11b+ cells in KI mice, and subsequently CD11b+ cells secrete active IL-1beta when stimulated with LPS alone without ATP *in vitro*. Moreover, the autoinflammatory phenotype was abrogated when KI mice were crossed with IL-1R KO or ASC KO mice. On the other hand, NLRP3 deficient KI mice exhibited the autoinflammatory phenotype.

Conclusion: Taken together, these results suggest that the pathogenesis of FMF can be explained by gain of function of the mutant B30.2 domain with gene dosage effects, and BM derived cells are necessary and sufficient for the induction of FMF inflammation characterized by increased CD11b+ cells. Moreover, in addition to confirming earlier data implicating IL-1beta in pathogenesis of FMF, our results provide evidence for a heretofore unrecognized ASC-dependent, NLRP3-independent, pyrin inflammasome.

Rilonacept: Long-Term Safety Profile in Patients with Cryopyrin-Associated Periodic Syndromes (CAPS). Hal M. Hoffman[1], Douglas R. Nadler[2], Warren P. Brooks[2] and Steven P. Weinstein[2], [1]University of California at San Diego, La Jolla, CA, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Purpose: IL1-β inhibition with weekly rilonacept (IL-1 Trap) provided marked, durable improvement in clinical and laboratory signs and symptoms associated with CAPS (Familial Cold Auto-inflammatory Syndrome (FCAS) and Muckle-Wells Syndrome (MWS)) while exhibiting a generally well-tolerated profile during a 24-wk double-blind, placebo-controlled pivotal study and a subsequent single arm, 24-

wk, open-label extension (OLE) study. The results described herein report on the safety profile in patients throughout the OLE and subsequent 64-week long term extension (LTE).

Methods: Patients enrolled into the consecutive OLE and LTE by either continuing from the pivotal study (44 patients) or entering directly (57 patients). All patients received SC rilonacept 160 mg/week (for a maximum of 112 wks). Safety assessments were performed at baseline and periodically throughout the study, including physical examinations, vital signs, documentation of adverse events (AEs), routine laboratory tests ,and assays to detect anti-rilonacept antibodies.

Results: Safety data were available for 104 pts with more than 125 patient exposure years (mean age 43.6 years; 66.3% female). The most common treatment-emergent AEs were injection-site reactions (erythema, swelling, pruritis, bruising), which occurred in 60.6% of patients; these were mild to moderate in severity and did not cause patient withdrawal. The most common treatment-emergent infections were: nasopharyngitis (10.6%), sinusitis (11.5%), upper RTIs (11.5%), UTIs (8.7%) and bronchitis (6.7%) which occurred in 32.7% of patients. None of the serious AEs (sciatica, cholelithiasis, hyponatremia, hypokalemia, pulmonary embolism, GI reflux, renal colic) were considered drug-related. During the OLE/LTE, one patient withdrew due to pregnancy and one due to chronic sinusitis. One death occurred due to pneumococcal meningitis and one to coronary atherosclerosis, respectively; the causes of death were assessed by the treating physician and considered not to be treatment-related. Through Week 56 (up to 80 weeks of rilonacept treatment) small to modest mean reductions in platelet (67K/mm3) counts occurred, but levels were stable throughout and did not fall below reference range. Mean neutrophil counts decreased (-1.9 K/mm3); no patients reported with neutropenia (<1.0 K neutrophils/mm3). Small and expected increases (16.9 mg/dL) in mean total cholesterol occurred. Change in weight and BMI was 2.9kg and 1.0 kg/m2, respectively, at Week 72. Other vital signs were without notable changes. Among the 96 patients who received at least 6 weeks of treatment through Week 72 of the OLE, 39 (40.6%) and 20 (20.8%), respectively, were anti-rilonacept Ab positive or positive at last assessment. Titers were generally low to moderate and had no apparent impact on rilonacept levels.

Conclusion: Rilonacept is generally well tolerated in both the long- and short-term when administered as a weekly SC injection of 160 mg.

Molecular Modulation of Gene Expression

Monday, October 19, 2009, 4:30 PM - 6:00 PM

1238

Suppressive Influences of IFN-α On IL-17 Expression and Th17 Differentiation. Shunsei Hirohata[1] and Hideki Shibuya[2], [1]Kitasato Univ School of Med, Kanagawa, Japan, [2]Tokyo Teishin Hospital, Tokyo, Japan

Purpose: T cells secreting IL-17 (Th17) have been implicated in the pathogenesis of a variety of inflammatory diseases, including inflammatory bowel disease, multiple sclerosis and Behçet's disease. Since IFN-α has been shown to have beneficial effects in the treatment of ulcerative colitis and uveitis in Behçet'sdisease, it is possible that IFN-α might regulate the development of Th17. The current studies were therefore undertaken to explore the direct effects of IFN-α on the development of Th17 with a system using immobilized anti-CD3, which permits activation of CD4+ T cell in the complete absence of accessory cells.

Method: Highly purified CD4+ T cells obtained from healthy volunteers were stimulated with immobilized anti-CD3 with or without IFN-α. The production of IL-17 and TGF-β was measured by ELISA, and that of IL-6 was determined using a bioassay with IL-6 dependent murine hybridoma MH60.BSF2 cells. The expression of mRNA for IL-17 and retinoic acid receptor-related orphan receptor C (RORC) was evaluated by using quantitative PCR.

Results: The production of IL-17 could not be dtected at 24 h of cultures, but markedly increased between 24 h and 72 h and appeared to reach the peak at 72h of cultures with immobilized anti-CD3. IFN-α suppressed the production of IL-17 of immobilized anti-CD3-stimulated CD4+ T cells at 72 h of cultures in a dose-response manner. Accordingly, IFN-α inhibited IL-17A mRNA expression in immobilized anti-CD3-stimulated CD4+ T cells from 7 healthy individuals as early as at 3 h of cultures. TGF-β and IL-6 have been shown to play a critical

role in the development of Th17. However, IFN-α did not affect the production of TGF-β or IL-6 at 24h or 72 h of cultures. Of importance, IFN-α inhibited the expression of mRNA for RORC (a key transcription factor for Th17 development) in anti-CD3-stimulated CD4+ T cells as early as at 3 h.

Conclusion: The data indicate that IFN-α suppresses IL-17 expression and Th17 differentiation through direct actions on CD4+ T cells, resulting in down-regulation of RORC mRNA expression without influencing the production of TGF-β or IL-6. It is therefore suggested that these effects might be involved in the mode of action of IFN-α in the treatment of various inflammatory diseases, in which Th17 plays an important role in the pathogenesis.

Essential Role for the ER Stress Induced Transcription Factor, CHOP10 in IL-23 Gene Expression. Jane Goodall[1], Changxin Wu[1], Lou Ellis[1], Louise O'Brien[1] and J. S. Hill Gaston[2], [1]University of Cambridge., Cambridge, United Kingdom, [2]Univ of Cambridge/Clin Med, Cambridge

Purpose: We have previously shown that ER stress and TLR signalling synergistically enhance IL-23 p19 expression in myeloid cells. Furthermore these combined stimuli substantially enhance the secretion of IL-23 but not IL-12 by dendritic cells. The aim of this study is to investigate the mechanism of this synergy.

Method: We examined the human *IL-23* promoter for potential binding sites for ER stress induced transcription factors and identified a putative site for CHOP10. U937 cells were stimulated with LPS or the ER stress inducing chemical thapsigargin (TP), alone or in combination for 1, 3 and 5 hours and nuclear lysates were isolated. Immunoprecipitation (ChIP) assays using anti CHOP10 and isotype control Mab were performed and IL-23 promoter DNA was detected by qPCR. To confirm the role of CHOP10 in IL-23 gene transcription, U937 cells expressing shRNA's specific for CHOP10 or non specific gene target were tested for their ability to express IL-23 following TLR and ER stress stimulation for 8 hours. Live or γ-irradiated *Chlamydia trachomatis* (CT) was used to infect U937 cells at a multiplicity of infection of 10:1 for 12 hours.

Results: CHOP10 binding on the *IL-23* promoter was detected following stimulation of U937 cells with LPS or TP alone, but this was significantly enhanced when ER stress and TLR stimuli were combined. Maximal CHOP10 binding was detected at 5 hours post stimulation with LPS and TP. IL-23 promoter DNA was not detectable following ChIP with a isotype control antibody. U937 expressing three independent shRNA targets for CHOP10 exhibited a significant reduction in IL-23p19 mRNA (up to 87% reduction of the response to LPS+TP) compared to U937 expressing a control shRNA. CHOP10 shRNA expression did not affect the expression of other LPS induced genes including IL-1, IL-8, CCL3 and SOD2.

To identify if ER stress induction of IL-23 mediated by CHOP10 expression plays a role in a more physiological setting, we examined the role of CHOP10 in the induction of IL-23p19 gene expression following CT irradiated–infection. The infection of U937 cells with live but not γ- CT induced the expression of ER stress response genes, including CHOP10. U937 infected with live CT exhibited increased IL-23p19 mRNA expression compared to U937 infected with nonviable bacteria. CHOP10 silencing substantially reduced the ability of live CT to induce IL-23p19mRNA, confirming the important role of CHOP10 in the response to infection.

Conclusion: We have shown that ER stress signals make a significant contribution to the control of IL-23 expression. Here we show that the ER stress induced transcription factor, CHOP10, is a critical factor that regulates IL-23p19 gene expression. These data suggest that the initiation of ER stress by infection or other physiological processes would contribute significantly to the pathology associated with diseases where IL-23 plays an important role in their pathogenesis.

Receptors for TSLP and IL-7 Strongly Promote Proteoglycan-Induced Arthritis. Sarita A.Y. Hartgring[1], Cynthia R. Willis[2], Johannes W. J. Bijlsma[1], Femke Broere[3], Floris P.J.G. Lafeber[1] and Joel A.G. van Roon[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Amgen Inc., Seattle, WA, [3]University Utrecht, Utrecht, Netherlands

Purpose: IL-7 is a potent T cell activating cytokine that can lead to T-cell-dependent activation of monocytes, B cells, and osteoclasts. IL-7 effects are mediated through the high affinity IL-7 receptor-alpha chain (IL-7Rα) in conjunction with the common-gamma chain. Another cytokine, thymic stromal lymphopoietin (TSLP), shares the IL-7Rα for signaling, but has a distinctive receptor subunit, the TSLP receptor. TSLP acts on dendritic cells, mast cells, and CD4 T cells and plays a key role in Th2-type inflammatory responses. We used the proteoglycan-induced arthritis (PGIA) model to determine whether there are distinct roles for IL-7Rα and TSLPR in the immunopathology of arthritis.

Method: PGIA was initiated by immunizing aged female wild type BALB/c (WT) or TSLPR knockout BALB/c (TSLPR-/-) mice with human PG. Mice were treated with PBS as a control, or with an anti-IL-7Rα antibody. Clinical arthritis was determined by visual examination of swelling and redness of the paws. Joint destruction on day 33 was assessed on basis of radiographs and histological examinations of the ankle joints. Cellularity of thymus and spleen and numbers of T-cell subsets, and B cells were assessed. Proinflammatory mediators were assessed by multi-analyte profiling in serum and paw protein lysates.

Results: Anti-IL-7Rα treatment in WT mice significantly reduced arthritis, compared with PBS WT (mean inhibition 55%, $p=0.007$). The TSLPR-/- mice also showed decreased arthritis severity compared with PBS WT (56%, $p=0.019$). Ablation of the TSLPR toghether with IL-7Rα blockade showed an even stronger reduction of arhritis (70%, $p=0.002$). Total numbers of thymocytes or splenocytes in TSLPR-/- mice were not different compared with the PBS WT mice. Splenic CD4 and CD8 T cells were modestly decreased by treatment with anti-IL-7Rα as compared with the non treated mice (PBS WT vs anti-IL-7Rα treated WT 22% decrease; PBS TSLPR-/- vs TSLPR-/- anti-IL-7Rα treated 26% decrease, both $p<0.01$ for CD4 T cells). The additive effect of blocking both IL-7 and TSLP signaling was clearly shown by radiological scoring of joint damage (PBS WT vs anti-IL-7Rα treated WT 59% decrease, PBS WT vs PBS TSLPR-/- vs 75%, and PBS WT vs anti-IL-7Rα treated TSLPR-/- 94%, all $p<0.01$). This was consistent with the histological joint damage, showing additive ($p<0.05$) reduction of cell infiltrates, bone and cartilage erosions. Furthermore, multi-analyte profiling of serum and paw lysates showed decreased (at least $p<0.05$) concentrations of cytokines, chemokines, acute phase reactants, and factors associated with tissue destruction.

Conclusion: Our data show that both IL-7Rα and TSLPR signaling promote arthritis and joint destruction. Blocking both pathways results in additive disease suppression indicating the distinct contributions of TSLPR and IL-7Rα in arthritis and the potential of targeting these receptors in arthritic conditions, including RA.

Dendritic Cell-Specific Transmembrane Protein (DC-STAMP) Is An Immunoreceptor Tyrosine-Based Inhibitory Motif (ITIM)-Bearing Molecule Regulating Osteoclast Development Thru the SHP-1 Signaling Cascade. Yahui Grace Chiu, Yawen Ju, Kofi A. Mensah, Changyong Feng, Edward. M. Schwarz and Christopher T. Ritchlin, University of Rochester, Rochester, NY

Purpose: DC-STAMP is a 7-pass transmembrane protein required for cell-to-cell fusion during osteoclastogenesis. Our previous studies showed that DC-STAMP can serve as a biomarker for osteoclast precursors (OCP), and importantly, the expression patterns of DC-STAMP differ significantly between healthy individuals and PsA patients. Herein, we examined the molecular mechanism underlying the regulation of osteoclast (OC) formation by DC-STAMP. We evaluated the role of DC-STAMP as a signaling molecule in the receptor activator of NF-kB ligand (RANKL)-induced osteoclastogenesis pathway. Moreover, we investigated the effects of a novel monoclonal anti-DCSTAMP antibody 1A2 on OC formation.

Methods: We compared the sequence of DC-STAMP with the ITIM consensus sequence (I/V/L/S)-X-Y-X-X-(L/V) where X denotes any amino acid. Proteins isolated from fresh human monocytes, monocyte-derived OC or dendritic cells (DC) were immunoprecipitated and immuno-blotted with either anti-DCSTAMP, anti-SHP-1 or anti-phosphorylated tyrosine antibodies. To test the effect of a monoclonal anti-DC-STAMP antibody 1A2 on osteoclastogenesis, human monocytes were cultured in the presence or absence of 1A2 and were TRAP-stained for OC quantification on day 8. The permutation test was performed on the data for 1A2 inhibition for statistic analysis.

Results: We identified an important immuno-regulatory motif ITIM on the cytoplasmic tail of DC-STAMP. By immunoprecipitation and western blotting, we showed that DC-STAMP is phosphorylated thru its tyrosine residues and interacts with SHP-1, a SH2 domain-

containing tyrosine phosphatase 1 and an inhibitory element for osteoclastogenesis. Interestingly, we found DC-STAMP also associates with CD16, a molecule bearing the counteracting immunoreceptor tyrosine-based activation motif (ITAM). Monocyte-derived DC showed less phosphorylation on DC-STAMP than OC. Addition of 1A2 to the monocyte cultures significantly inhibited OC formation (489±284 vs. 61±107 OC without or with 1A2 per 10^6 monocytes, respectively, p=0.013), and staining revealed that the majority of monocytes were arrested at the TRAP-positive pre-OC stage.

Conclusion: In addition to its current role considered as a fusogen in mediating the cell-to-cell fusion during osteoclastogenesis, our finding of ITIM on the cytoplasmic tail of DC-STAMP defines its new role in OC development as a signaling molecule. Our data show that DC-STAMP regulates osteoclastogenesis possibly by interacting with SHP-1 thru its tyrosine residues on ITIM. Intriguingly, the levels of DC-STAMP phosphorylation differ in DC and OC. Most importantly, the observation that the anti-DC-STAMP antibody 1A2 can inhibit OC formation in vitro emphasizes the potential of 1A2 in therapeutic application for prevention of inflammatory and metabolic bone loss.

MiR-155 and Mir-34a Regulate TNF-Alpha Production by Human Monocytes. Mariola Kurowska-Stolarska, Lucy E. Ballantine, Bartosz Stolarski, J. Alastair Gracie, Foo Y. Liew and Iain B. McInnes, University of Glasgow, Glasgow, United Kingdom

Purpose: Dysregulated pro-inflammatory activation of synovial monocyte and macrophage is of fundamental importance in pathogenesis of rheumatoid arthritis (RA). Recently microRNA (miRNA) have been identified as critical post-transcriptional regulators of many components of immune responses. The aim of our study was to investigate the role of candidate miRNAs, miR-155 and mir-34a in the activation of RA synovial fluid (SF) and blood monocyte / macrophages.

Method: CD14+ cells from SF or peripheral blood (PB) of RA patients (n=7) and CD14+ cells from PB of healthy controls (n=6) were isolated using CD14 MACS MicroBeads. PB CD14+ cells were stimulated with LPS (100 ng/ml), Pam3CSK4 (300 ng/ml), PolyI:C (50 μg/ml), CPG (3 μg/ml), control CPG (3 μg/ml) or protease activated receptor-2 (PAR2) agonist (SLIGKV-NH2; 50μM) for 24h. PB CD14+ cells were transfected with miR-155, miR-34a or scramble mimics (all 3.5 mg/3x10^6 cells) by electroporation (Amaxa). Expression of AXL (receptor tyrosine kinase) and TNF production were tested 36 h later. Total RNA was isolated by miRNeasy kit. TaqMan miRNA and mRNA assays were used for semiquantitative determination of the expression of miR-155, miR-34a and AXL, respectively. The expression of U6B small nuclear RNA and beta-actin were used as endogenous controls. To identify the cellular targets of candidate miRs, multiple target prediction programs and mRNA transcriptomic signatures of SF CD14+ cells were employed.

Results: Synovial fluid CD14+ cells expressed higher levels of miR-155 (64 fold, $p<0.05$) and miR-34a (4.5 fold, $p<0.05$) than PB matched CD14+ cells. Expression of miR-155 was up-regulated by TLR2, TLR3, TLR4 and TLR9 ligands ($p<0.05$) but not by PAR2 agonist in PB CD14+ cells. In contrast, miR-34a expression was either not affected (Pam3CSK4, SLIGKV-NH2) or down-regulated (LPS, PolyI:C, CPG; $p<0.05$) under the same conditions. Overexpression of miR-155 and miR-34a mimics in PB monocytes induced TNF production (10170 ± 385 pg/ml) and (991 ± 33), respectively. Using computational target ranking system combined with mRNA transcriptomic data we identified a negative regulator of TLR/IL-1R signalling, AXL, to be targeted by miR-34a. Overexpression of miR-34a and miR-155 mimics decreased the expression of AXL in PB monocytes by (48 ± 3%) and (38 ± 16%), respectively.

Conclusion: These data suggest that overexpression of miR-155 and miR-34a in CD14+ cells can result in downregulation of AXL expression which in turn can lead to the overproduction of TNF. We provide a novel mechanism for deregulated TNF production in RA synovial macrophages amenable to therapeutic intervention in due course.

IL-17 Acts through Act1 and TRAF6 to Mediate the Canonical NF-κB Signaling Pathway to Upregulate RGS16 Expression in Autoimmune B Cells of BXD2 Mice. Shutao Xie[1], Hui-Chen Hsu[1], John Wang[1], Qi Wu[1], Jun Li[1], Lesley E. Smythies[1] and John D. Mountz[2], [1]The University of Alabama at Birmingham, Birmingham, AL, [2]The University of Alabama at Birmingham and Birmingham VAMC, Birmingham, AL

Purpose: BXD2 mice spontaneously develop erosive arthritis and lupus that progresses as the mice age. We previously found that BXD2 mice express high levels of IL-17, which correlate with upregulated expression of *Rgs* genes and results in suppression of B cell migration in response to CXCL12 and CXCL13, leading to the development of spontaeous germinal centers. This study is to elucidate the signaling mechanisms underlying this regulation mediated by IL-17 in autoimmune B cells of BXD2 mice.

Method: Purified splenic B cells from BXD2, BXD2-*Il17r*$^{-/-}$ or B6 mice and pre-B cell line 70Z/3 were incubated with or without IL-17 for varying times. Intracellular location of phosphorylated p65 (P-p65) was determined by fluorescent microscopy. Antibodies against phosphorylated IκBα (P-IκBα), P-p65, p65, p50, phosphorylated p100 (P-p100), p52, RelB, and RGS16, GAPDH and SP1 were used for western blotting analysis. siRNAs for *Act1*(*Traf3ip2*) or *Traf6* were transfected into 70z/3 pre-B cells to knockdown them respectively. Expression of *Rgs* genes, *Act1* and *Traf6* were determined by quantitative real-time PCR.

Results: Treatment of isolated splenic B cells with IL-17 resulted in rapid phosphorylation of IκBα and p65 (>2.5-fold, $p<0.01$) and lead to P-p65 nuclear translocation. IL-17 did not affect the non-canonical NF-κB pathway, as indicated by no significant increase or nuclear translocation of P-p100, p52 or RelB in either splenic B cells or 70Z/3 cells. Compared to B6 or BXD2-*Il17r*$^{-/-}$ B cells, BXD2 B cells exhibited dramatically higher endogenous P-p65 (>5.0-fold, $p<0.01$), and this was suppressed after blockade of IL-17 signaling *in vivo* via administration of AdIL-17R-Fc. Pretreatment of BXD2 B cells or 70Z/3 pre-B cells with a permeable peptide inhibitor of p65-ser276 phosphorylation resulted in significant inhibition of IL-17 induced RGS16 (>4-fold, $p<0.01$) and abrogated the IL-17 mediated chemotactic arrest of B cells. Suppression of TRAF-6 and Act-1 using siRNAs of *Traf6* or *Act1* led to decreased induction of *Rgs* genes in 70z/3 pre-B cells by IL-17 (>1.5-fold, $p<0.05$).

Conclusion: IL-17 activates the canonical NF-κB signaling pathway to upregulate *Rgs* genes expression in B cells. The activation of NF-κB signaling by IL-17 is especially evident in autoimmune B cells of BXD2 mice. In addition, TRAF6 and Act1 may be important factors in the upstream signaling for the IL-17 mediated activation of NF-κB pathway in B cells. Our findings suggest that blockade of IL-17 receptor recruitment of TRAF-6 and Act-1 or IL-17 mediated NF-κB P-p65 activation and translocation may provide important mechanisms to block the IL-17-mediated production of pathogenic autoantibodies, lupus, and erosive arthritis.

Fatigue Is Not An Inflammatory Marker of RA. Martin J. Bergman[1], Shadi H. Shahouri[2], Timothy S. Shaver[2], James D. Anderson[3], David N. Weidensaul[2], Ruth E. Busch[2], Shirley Wang[2], Kaleb D. Michaud[4] and F. Wolfe[5], [1]Drexel University College of Medicine, Ridley Park, PA, [2]Arthritis & Rheum Clinics KS, Wichita, KS, [3]Arthritis & Rheum Clinics KS, Leawood, KS, [4]University of Nebraska Medical Center and NDB, Omaha, NE, [5]National Data Bank, Wichita, KS

Purpose: To investigate whether fatigue is an inflammatory (RA) variable, the contributions of RA variables to fatigue, and the levels of fatigue in RA and osteoarthritis (OA).

Method: We studied 2096 RA patients (1577 with DAS-28 scores) and 1440 OA patients in a clinical setting, and 14607 RA and 3173 OA patients in survey research. Individual components of the DAS28 and ACR core data set were obtained and analyzed for individual

correlations. We partitioned variables into inflammatory and non-inflammatory factors using a 2-factor analysis and examined variable contribution to VAS fatigue.

Results: There were significant correlations between the levels of pain in patients with RA as compared to patients with OA. The mean clinic fatigue scores were RA= 4.9 and

OA= 4.8 on a 0-10 scale; mean survey pain scores were RA =4.5 and OA=4.4. Mean pain differences for both the clinical group and the survey group were 0.1 units (scale 0-10). Adjusted for age and sex, RA and OA fatigue scores were not significantly different. Factor analysis identified DAS-28 and swollen (SJC) and tender joints (TJC) as a physician-inflammation factor, and patient global, pain, HAQ, and fatigue as patient components. Fatigue demonstrated weak correlations with ESR (r=0.071) and SJC (r=0.112), weak to fair correlations with TJC (r=0.294), physician global (r=0.384), and DAS-28 (r=0.399), but strong correlation with patient global (r=0.567). In hierarchical regression analysis, patient global explained 43.1% of DAS-28 fatigue variance; when SJC, TJC, and ESR were entered the explained variance increased to 43.7%. In reverse order, SJC, TJC, and ESR explained 9.2% of the variance, but explained variance increased to 43.7% when patient global was added.

Conclusion: Inflammatory components of the DAS-28 contribute minimally to fatigue. RA and OA fatigue levels do not differ. Fatigue is not an inflammatory variable and has no unique association with RA or its therapy. Although the impact of fatigue on patients with RA cannot be understated (mean Pain=4.9 in the clinical setting),t he need to measure fatigue in clinical trials, as an independent marker of disease activity, has to be questioned.

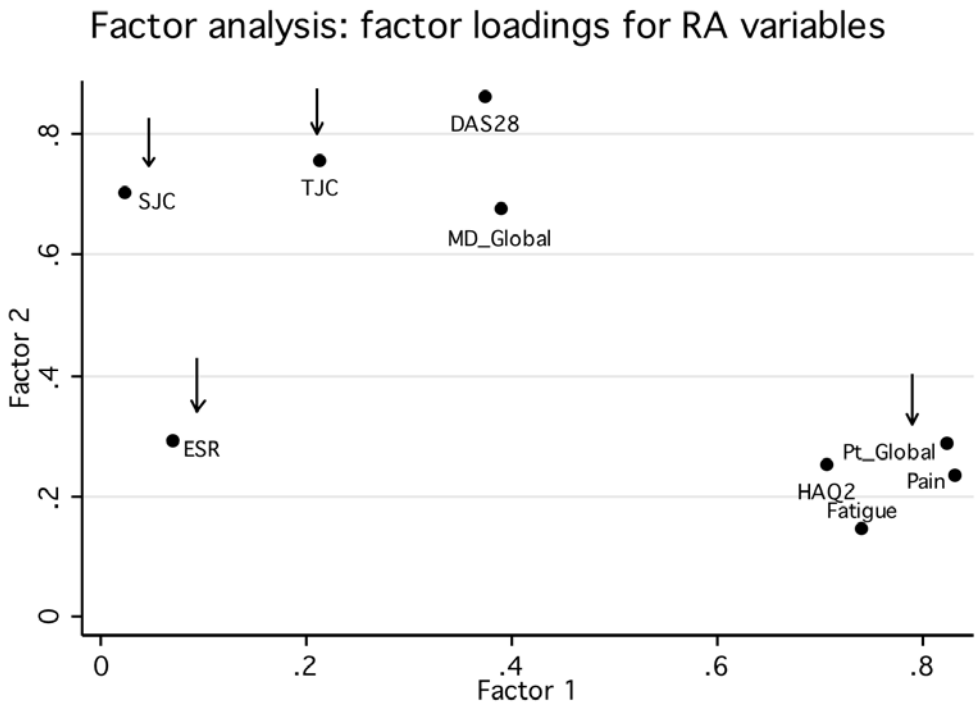

Figure 1. Factor loadings. Arrows indicate components of DAS-28. Fatigue clusters with patient variables, not with inflammatory (physician) variables. SJC = swollen joint count; TJC = tender joint count; ESR = erythrocyte sedimentation rate; DAS28 – Disease Activity Scale-28; MD_global – physician global activity; Pt_global = patient global severity; HAQ2 = Health Assessment Questionnaire II.

Patient's Global Assessment of Disease Activity and Patient's Assessment of General Health in Rheumatoid Arthritis: Are They Equivalent? Nasim A. Khan[1], Tuulikki Sokka[2] and QUEST-RA Investigators, [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [2]Central Hospital, Jyvaskyla, Finland

Purpose: Patient's global assessment of disease activity (PGA) and patient's assessment of general health/global health (GH) are part of several composite indices used to assess rheumatoid arthritis (RA) disease activity. Though originally each composite index used either PGA or GH, subsequently they have been used interchangeably for calculating indices that they were not a part of . We assessed whether PGA and GH are equivalent as individual variables, and if they can be used interchangeably in calculating common composite indices used for RA activity assessment.

Method: This analysis is based upon 7568 (6949 with complete data) patients in the Quantitative Standard Monitoring of Patients with RA (QUEST-RA) database who received usual care from rheumatologists in 83 sites in 30 countries. PGA and GH were assessed by patient self report questionnaire with 0-10 cm visual analog scales. Bland Altman 95% limits of agreement (BALOA) were calculated to assess equivalence of GH and PGA. The impact of using PGA and GH interchangeably was assessed by calculating disease activity score (DAS28), clinical disease activity index (CDAI) and routine assessment of patient index data 3 (RAPID3) and looking at the level of agreement in classifying RA activity in 4 states (remission, low, moderate & high) using Kappa statistics.

Results: The mean (SD) value for PGA and GH were 4.01 (2.70) and 4.04 (2.59) respectively. As individual measures, GH and PGA had good correlation (r = 0.64). The BALOA was - 4.41 to 4.54 and is too wide an interval for a 0-10 scale indicating that PGA and GH are not equivalent. Both DAS28 (absolute agreement: 98.5 to 99.5%, kappa = 0.98) and CDAI (absolute agreement: 81.2 to 96.2% kappa = 0.83) showed excellent agreement between RA activity categories calculated using PGA and GH. However, the level of agreement was lower for RAPID3 (absolute agreement: 68.7 to 91.4%, kappa = 0.75).

Conclusion: Though, individually PGA and PGH are not equivalent, they may be used interchangeably for calculating composite index like DAS28/CDAI for RA activity assessment.

A Comparison Between the Simplified Erosion and Narrowing Score (SENS) and the Sharp-Van Der Heijde Score (SHS) in Assessing Radiological Damage in RA Patients During 5 Years of Follow-up. N.B. Klarenbeek[1], M. Güler-Yüksel[1], Désirée M.F.M. van der Heijde[2], P.J.S.M. Kerstens[3], C. Mallée[4], M.L. Westedt[5], T.W.J. Huizinga[1], B. A. C. Dijkmans[6] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]JBI, Amsterdam, Netherlands, [4]Kennemer Hospital, Haarlem, Netherlands, [5]Bronovo Hospital, The Hague, Netherlands, [6]VUMC, Amsterdam, Netherlands

Background: The Simplified Erosion and Narrowing Score (SENS) is an easy to learn and quick method to assess the number of joints with erosions and/or joint space narrowing on radiographs of hands and feet in patients with RA. Since SENS does not take severity of damage per joint into account, sensitivity to change may decrease over time.

Purpose: To compare the reliability and sensitivity to change of SENS and SHS during 5 years of follow-up in a large number of recent onset RA patients.

Methods: Annual radiographs of year 0 to 5 of 508 patients participating in the BeSt study were scored in one session per patient by two readers independently using SHS. X-rays were scored in random order, blinded for patient identity. The SENS scores were derived from the SHS scores. Interobserver reliability (intra-class correlation coefficients (ICCs)) was calculated for different time intervals. Sensitivity to change was compared using the ratio of Standardized Response Means (SRMs) of SHS and SENS and Effect Size (ES) ratios. Progression % > smallest detectable change (SDC, calculated each time interval) between the methods were compared. Sensitivity and specificity of SENS were defined, with SHS as gold standard. Non-parametric tests were used to assess the discriminative ability between treatment arms.

Results: Mean baseline scores for SHS and SENS were 7.1 and 3.8. The interobserver ICCs of SENS and SHS were comparable and constant over time (ICC of progression between annual SHS and baseline: 0.91, 0.91, 0.90, 0.91, 0.91 for SENS and 0.93, 0.93, 0.93, 0.91, 0.95 for SHS). Using change scores with time intervals of 1 year, the ICCs of SENS and SHS highly correlated as well, although the ICCs of both methods were lower after year 1, when there was less progression (ICCs for year 1-5 SHS vs SENS: 0.93 vs 0.91, 0.65 vs 0.57, 0.69 vs 0.59, 0.66 vs 0.51, 0.68 vs 0.62). SRM ratios ranged from 0.73 to 1.18 without a clear pattern over time. ES ratios showed similar results. Percentages with progression >SDC for both methods were comparable over time. Specificity and sensitivity of SENS varied between 92% and 99% for change scores between each follow-up year and baseline. For change scores with a 1 year time interval, specificity was high at all years (94-99%), but sensitivity was lower with more variance over time (86%, 84%, 62%, 70%, 81% in year 1-5 for reader 1, 93%, 90%, 57%, 66%, 89% for reader 2). The ability to discriminate between the treatment arms was comparable in both methods.

Conclusion: The properties of SENS are comparable to SHS. There is no decrease in sensitivity to change over 5 years time. Therefore SENS seems a valuable method for assessing radiological joint damage in daily practice.

The BeSt Matrix Model in Recent-Onset Rheumatoid Arthritis Patients: Individual Prediction of Rapid Radiographic Progression and Numbers-Needed-to-Treat with Initial Combination Therapy. K. Visser[1], Y. P. M. Goekoop-Ruiterman[1], J.K. De Vries-Bouwstra[1], H.K. Ronday[2], P.E.H. Seys[3], P. Kerstens[4], T.W.J. Huizinga[1], B. A. C. Dijkmans[5] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]HAGA hospital, The Hague, Netherlands, [3]Franciscus hospital, Roosendaal, Netherlands, [4]JBI, Amsterdam, Netherlands, [5]M.D., PhD, Amsterdam, Netherlands

Background: Early treatment and the initial treatment choice determine the chance of a favorable outcome in patients with rheumatoid arthritis (RA). At the group level, initial combination treatment is superior to initial monotherapy. For individual patients, physicians may find it difficult to choose the initial treatment.

Purpose: To develop a matrix model for the prediction of rapid radiographic progression (RRP) in recent-onset RA patients with specific combinations of risk factors, if treated with different dynamic treatment strategies. To calculate numbers needed to treat with initial combination therapy versus initial monotherapy.

Method: Data from 465 recent-onset RA patients, randomized in the BeSt study to initial monotherapy with methotrexate (groups 1 and 2) or initial combination therapy including either prednisone (COBRA) or infliximab (group 3 and group 4) were used. Treatment was dynamically adjusted, aiming at a disease activity score (DAS) of =<2.4. Predictors for RRP, defined as a change in Sharp-van der Heijde (SvdH) score α 5 after one year, were identified with logistic regression analysis. From the fitted multivariate model, the predicted risk for RRP for patients with a specific combination of risk factors per treatment group was visualized in a matrix. A receiver operating characteristic (ROC) curve was fit and the positive (PPV) and negative predictive value (NPV) of the model were calculated. Compared with initial monotherapy, the number needed to treat (NNT) with initial combination therapy to prevent one patient from RRP was calculated and likewise presented in a matrix.

Results: The presence of rheumatoid factor (RF) and/or anti-citrullinated peptide antibodies (ACPA), C-reactive protein (CRP), the baseline SvdH erosion score and treatment group were significant independent predictors of RRP. With cut-offs at 20% (low risk), and 50% (high risk), the matrix shows a low risk for 23% of the patients treated with initial monotherapy (NPV 91%), a high risk for 25% of the patients (PPV 62%), leaving a midgroup of patients with intermediate risk (20-50%). In the combination therapy groups the risk of RRP was markedly reduced. The area under the ROC curve was 0.81 (0.77-0.86). The NNT with initial combination therapy including prednisone or infliximab to prevent one patient from RRP with monotherapy ranged from 2 for patients with unfavorable prognostic characteristics to 25 for patients with more favorable prognostic factors.

Conclusion: Based on dynamic treatment outcomes of the BeSt study, a matrix risk model was developed, which visualizes the risk of RRP for patients with recent-onset RA, with specific combinations of prognostic factors, if treated with initial mono or combination therapy, and which illustrates the risk for over- and undertreatment. Rheumatologists might use the matrix for weighing their initial treatment choice.

Changes in the Rates of Joint Surgery Among Patients with Rheumatoid Arthritis in California, 1983-2007. Grant H. Louie and Michael M. Ward, National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD

Purpose: Treatment of rheumatoid arthritis (RA) has improved markedly over the past 25 years. We previously reported that rates of total knee arthroplasty, a long-term sequela of poorly-controlled RA, decreased among patients with RA in California in 1998-2001 after peaking in the 1990s. Because it is uncertain whether these rates have continued to decrease, we examined rates of total knee arthroplasty through 2007, and investigated whether rates of other joint surgery decreased between 1983 and 2007.

Methods: In this population-based, serial cross-sectional study of California residents aged 40 years and older with RA, we analyzed trends in annual rates of total knee arthroplasty, total hip arthroplasty, total ankle arthroplasty or arthrodesis, and total wrist arthroplasty or arthrodesis from 1983-2007. We computed age-, sex-, and race-adjusted rates of joint surgery and pooled data in 5-year intervals to provide more stable estimates of rates. We used Poisson regression models to compare changes in adjusted rates across time periods, and performed stratified analyses by age and sex.

Results: Rates of joint surgery peaked in the 1990s and since have decreased (Table). Among patients aged 40-59 years, rates of total knee arthroplasty in 2003-2007 were 19% lower than in 1983-1987 (adjusted rate ratio 0.81; 95% confidence interval (CI) 0.74 – 0.87, $P <$ 0.0001), while rates of total hip arthroplasty in 2003-2007 were 40% lower than in 1983-1987 (adjusted rate ratio 0.60; 95% CI 0.54 – 0.66, $P < 0.0001$). Rates of total knee arthroplasty and total hip arthroplasty in 2003-2007 did not decrease in patients aged ≥ 60 years but increased by 4% ($P = 0.19$) and 26% ($P < 0.0001$), respectively. Similar trends were observed in the general population. Compared with rates of ankle and wrist surgery in the mid-1980s, rates in the mid-2000s decreased significantly in both age groups. For all four procedures, trends were similar in men and women.

Table. Age-, sex-, and race-adjusted rates of joint surgery among 100,000 persons with rheumatoid arthritis from 1983-2007

	1983-1987	**1988-1992**	**1993-1997**	**1998-2002**	**2003-2007**

Total					
Total knee arthroplasty	478.3	486.9	524.1	444.3	460.4
Total hip arthroplasty	311.6	377.3	417.4	363.4	323.5
Ankle surgery	39.8	47.2	48.2	32.7	23.7
Wrist surgery	7.8	15.1	12.8	8.2	3.1
Age 40-59 years					
Total knee arthroplasty	381.6	366.6	381.2	301.9	309.3
Total hip arthroplasty	286.4	276.9	268.1	223.6	172.0
Ankle surgery	52.3	56.9	52.5	33.1	20.8
Wrist surgery	8.3	15.4	10.4	8.0	3.5
Age ≥ 60 years					
Total knee arthroplasty	553.9	581.2	636.0	555.2	577.8
Total hip arthroplasty	331.5	456.2	534.0	472.4	441.3
Ankle surgery	30.2	39.8	44.9	32.4	25.9
Wrist surgery	7.4	15.0	14.6	8.5	2.7

Conclusion: Rates of joint surgery in patients with RA peaked in the 1990s and have declined thereafter, suggesting that long-term outcomes of RA are improving.

Decrease of Hip Replacement Surgery in Patients with Rheumatoid Arthritis - Results From a Well Defined Population in Southern Sweden. Korosh Hekmat[1], Lennart TH Jacobsson[1], Jan-Åke Nilsson[1], Ingemar F. Petersson[2], Otto Robertsson[2], Göran Garellick[3] and Carl Turesson[1], [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Orthopedics, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden, [3]Department of Orthopaedics, Swedish Hip Arthroplasty Register, Institute of Clinical Sciences at Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Purpose: Major joint arthroplasty is used effectively in many patients with severe rheumatoid arthritis. The aim of modern pharmacologic treatment is to prevent joint destruction and reduce the need for orthopedic surgery. The purpose of our study was to investigate trends in the incidence of primary total hip and knee replacements in a well defined sample of patients with RA.

Method: Patients were recruited from a community based register established in 1997, which includes patients from a single University Clinic and collaborating private practitioners. Prevalent cases of RA in 1997 and incident cases 1997-2007 were included. Based on a structured review of the medical records, patients were classified according to the 1987 American College of Rheumatology criteria, and the year of RA diagnosis was noted. The incidence of major joint arthroplasty was estimated based on linkage of this cohort with the Swedish

National Hip Arthroplasty (through December 2006) and the Swedish Knee Arthroplasty Register (through October 2007). During the study period, indications for joint replacement in Sweden were based on objective clinical and radiographic findings and were relatively stable across different clinics, although minor changes over time can not be excluded. Patients with a registered hip or knee arthroplasty before 1997 or before RA diagnosis were excluded. The incidence rate for the period at and just after the time of the introduction of TNF inhibitors (1998-2001) was compared to the period when biologics were part of the established treatment for severe RA (2002-2006 for hip replacements and 2002-2007 for knee replacements).

Results: There were 2164 patients in the cohort (1545 women, 619 men; mean age at diagnosis 51 years). During the study period, a primary hip arthroplasty was registered for 115 patients and a primary knee arthroplasty for 85 patients. The incidence of primary hip arthroplasties decreased from the period 1998-2001 [12.6/1000 person-years(pyr)] to 2002-2006 (6.6/1000 pyr) [rate ratio (RR) 0.52; 95% confidence interval (CI) 0.35-0.76 for 2002-2006 vs. 1998-2001] There was a trend towards an increase of the incidence of primary knee arthroplasty (4.8/1000 pyr 1998-2001 vs. 6.8/1000 pyr 2002-2007 – RR 1.43; 95% CI 0.89-2.31).

Conclusion: Our investigation shows a significant decrease in hip replacement surgery in patients with RA after 2001. Possible explanations include an effect on joint damage from more aggressive treatment with DMARDs and biologics. The trend towards an increase of knee arthroplasty may be due to changing indications for surgery. Alternatively, destruction of hip and knee joints in RA may be partly due to distinct mechanisms.

Reproductive Issues in Systemic Lupus Erythematosus

Monday, October 19, 2009, 4:30 PM - 6:00 PM

1250

Importance of Cutaneous Manifestations of Neonatal Lupus as a Risk Factor for Subsequent Congenital Heart Block. Peter M. Izmirly, Carolina Llanos and Jill P. Buyon, New York University School of Medicine, New York, NY

Purpose: The cutaneous manifestations associated with placental transport of maternal anti-Ro/La antibodies are generally transient and inconsequential. However, the impact of this manifestation of neonatal lupus on the risk of cardiac disease in a future pregnancy is critical for family counseling and powering of preventive trials.

Methods: Of the 380 families enrolled in the Research Registry for Neonatal Lupus (RRNL) 57 met the following inclusion criteria: a) maternal anti-Ro or La antibodies, b) a child with classic annular or elliptical lesions on the face, scalp, trunk, or extremities which was verified by medical records and/or photographs, c) information on pregnancies subsequent to the child with rash. Maternal risk factors evaluated for recurrence of rash or emergence of cardiac manifestations included: age, race/ethnicity, antibody status, diagnosis, and use of non-fluorinated steroids during pregnancy. The following risk factors were also evaluated: gender of the child, season of birth, latitude of the city at birth, and breast feeding.

Results: The majority (77%) of the 57 mothers were Caucasian. Of the 76 pregnancies following a child with rash, the overall recurrence rate for any manifestation of neonatal lupus was 50%. Specifically 14 (18%) were complicated by congenital heart block (CHB) (all 2nd/3rd degree, 9 accompanied by a rash and 2 with associated liver/hematological abnormalities), a nearly tenfold risk over the 2% rate reported without a previously affected child. Twenty-three (30%) of the subsequent children had a rash (3 accompanied by hematological and/or liver abnormalities). One child (1%) had isolated liver/hematological abnormalities and one neonate (1%) died of unknown reasons. Thirty-seven (49%) were healthy. In an attempt to limit potential referral bias of families with multiple affected children, a subset analysis was restricted to the 45 children who were born prospectively after the initial child was enrolled in the RRNL. In this analysis, the overall recurrence rate for neonatal lupus was 36%. Specifically, 5 (11%) developed CHB (a 6-fold higher risk for CHB), 10 (22%) developed a rash and one child (2%) developed isolated liver/hematological abnormalities. There were no significant differences in the following maternal risk factors for a having a subsequent child with either CHB or rash: age, race/ethnicity, anti-La status, diagnosis or use of non-fluorinated steroids during

pregnancy. Fetal gender of the subsequent child did not influence the development of CHB or rash. Specifically with regard to the development of rash in a subsequent child, breast feeding, season of birth, or latitude of the city at birth did not affect risk.

Conclusion: Based on data from this large cohort, the identification of cutaneous disease in an anti-Ro exposed infant is particularly important since it predicts increased risk for a subsequent child with CHB.

1251

Preventive IVIG Therapy for Congenital Heart Block (PITCH). Deborah M. Friedman[1], Carolina Llanos[2], Peter M. Izmirly[2], Mimi Y. Kim[3] and Jill P. Buyon[2], [1]New York Medical College, Valhalla, NY, [2]NYU School of Medicine, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY

Background: The recurrence rate of anti-SSA/Ro associated congenital heart block (CHB) is 17%. Reversal of 3rd degree block has never been achieved. Prophylactic IVIG was considered based on two presumed mechanisms of efficacy, a) saturation of FcRn to accelerate maternal IgG catabolism and decrease placental transport b) elevation of macrophage FcγRIIB expression to attenuate inflammatory fetal responses.

Purpose: To evaluate IVIG efficacy and safety as a preventive therapy for CHB.

Methods: A multicenter open-label study based on Simon's 2-stage optimal design was initiated. Enrollment criteria included: maternal anti-SSA/Ro antibody, a previous child with CHB/rash,nd or 3 rd degree CHB in three fetuses.

Results: Twenty mothers were enrolled. Sixteen children had normal PR intervals throughout the study and no manifestations of neonatal lupus. One child developed a transient rash consistent with neonatal lupus and had normal PR intervals during pregnancy and normal EKG at birth. However, the pre-determined stopping rule was reached. CHB was detected in three fetuses, at 19, 20 and 25 weeks; none followed an abnormal PR interval. One of these mothers had two previous children with CHB. Antibody titers assessed before every IVIG infusion, and at 28 wks, 34 wks and delivery were compared with values obtained at baseline. No significant changes in maternal antibody titers to SSA/Ro, SSB/La, or Ro52 were detected over the course of therapy or at delivery ($P>0.05$ for all comparisons). There were no changes in maternal blood pressure, severe headaches, rashes, fever or any other adverse effects related to the infusions. Neonatal weight, height, and head circumference were derived from gestational age -specific growth curves to correct for prematurity when necessary. Four (21%) of the newborns, two with CHB and two healthy, were small for gestational age (<10th centile) and 3 healthy babies (16%) were born prematurely (<37 weeks of gestation).

Conclusion: IVIG at doses consistent with replacement does not prevent the recurrence of CHB or reduce maternal antibody titers. Having established safety with this protocol and feasibility of patient enrollment, subsequent studies should address the efficacy of IVIG at higher doses to exploit an anti-inflammatory effect.

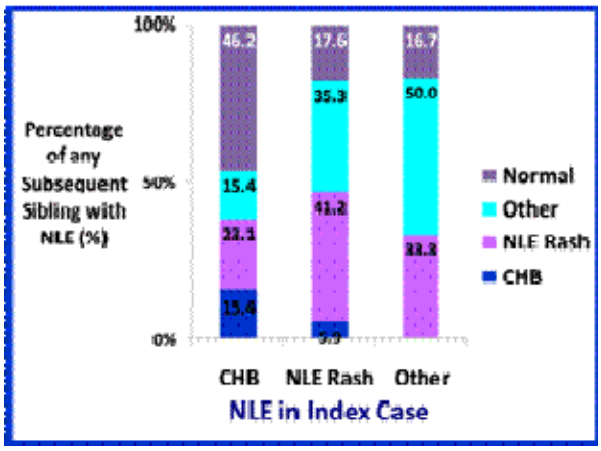
1252

Recurrence of Neonatal Lupus Erythematosus in Siblings. KC Danayan[1], E. Jaeggi[1], PN Tyrrell[2], A. Rogers[1] and ED. Silverman[3], [1]Hospital for Sick Children, Toronto, ON, [2]Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, [3]Hospital for Sick Children and University of Toronto, Toronto, ON

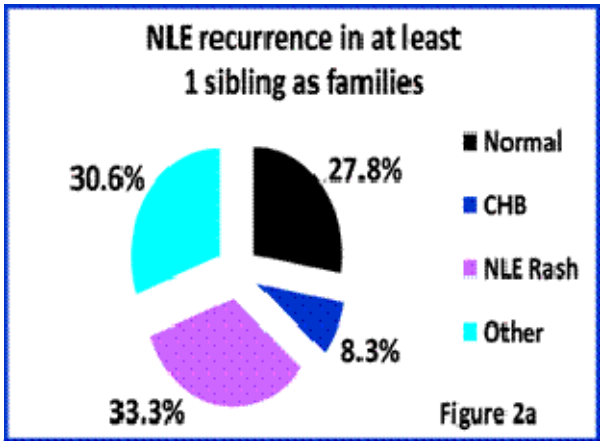
Purpose: Neonatal lupus erythematosus (NLE) is a model of passively acquired autoimmunity due to in utero exposure to maternal anti-Ro and/or anti-La antibodies. Manifestations of NLE include: congenital heart block (CHB), rash, hepatic or haematologic abnormalities, and macrocephaly. Much of the research to date has focused on the cardiac manifestations of NLE with little information on the risk of recurrence of NLE in subsequent pregnancies. The literature suggests a 15% recurrence risk of CHB developing in the subsequent sibling



following the delivery of a child with CHB related to NLE. However, this recurrence rate is based on very few studies and none examined the risk of recurrence of any NLE manifestation following an index case with NLE. Our study was designed to address this clinical question.

Method: A retrospective cohort study of 36 patients with confirmed NLE (index cases) and all 42 of their subsequent siblings followed at a tertiary paediatric hospital from March 1984 to April 2009. Detailed patient and maternal medical information was extracted from a rheumatology database and validated by chart review. The study cohort consisted of 42 consecutive children born to 36 anti-Ro and/or anti-La positive women. The women were identified following the delivery of a first-born child with confirmed NLE and all subsequent pregnancies were followed prospectively for the presence of fetal or neonatal manifestations of NLE. Patients were excluded if the NLE diagnosis was made retrospectively, essential patient information was missing, or the index NLE case was not seen initially at our institution.

Results: Recurrence of NLE in a subsequent sibling after an index case of confirmed NLE occurred in 72.2% of families (26 out of 36 families) and 64.3% of subsequent siblings (27 out of 42 siblings). The outcome of NLE manifestations in index cases compared to any subsequent sibling is illustrated below. The rate of occurrence of CHB was 8.3% in families and 7.1% of all subsequent siblings after an index case of NLE, but 15.4% if the index case had CHB and 0% if the index case did not have CHB or rash as their NLE manifestation.



Conclusion: NLE recurred in at least one subsequent sibling in over two-thirds of families and the majority of subsequent siblings following an index case of NLE - however, it mainly presented as benign and transient non-cardiac features. Interestingly, when an index case had CHB, the risk of CHB in any subsequent sibling was higher (15.4%) compared to families where an index case presented with non-cardiac manifestations of NLE, similar to previously published recurrence rates. Further studies are needed to identify predictors of NLE recurrence of congenital heart block in order to help guide prospective monitoring of future pregnancies and siblings.

High Prevalence of Thyroid Disease in Pregnant Women with Systemic Lupus Erythematosus. Ehtisham Akhter[1], Alex Stagnaro-Green[2], Chang Yim[3], Terry F. Davies[3] and Michelle Petri[4], [1]Johns Hopkins University, Baltimore, MD, [2]Touro University College of Medicine, Hackensack, NJ, [3]Mount Sinai School of Medicine, New York, NY, [4]Johns Hopkins Univ, Baltimore, MD

Purpose: Postpartum thyroiditis (PPT) occurs in 5-10% of all women. Individuals with systemic lupus erythematosus (SLE), a systemic autoimmune disorder, have an increased incidence of autoimmune thyroid disease. The goal of the present study is to determine the incidence of thyroid disease during pregnancy and postpartum in women with SLE.

Method: Sixty-three women who participated in the Hopkins Lupus Cohort and who had sera frozen during pregnancy and/or the first year postpartum were included in the study. All samples were assayed for TSH, thyroid peroxidase and thyroglobulin antibodies. Demographic and laboratory data were available for analysis.

Results: Twenty-four percent of the 63 women were positive for thyroid antibodies. Eight of the 63 women (13%) were on levothyroxine prior to pregnancy. Six of the remaining 55 women (11%) were hypothyroid based on their first pregnancy sample. Six of the remaining 49 women had a serum sample available only during pregnancy, leaving 43 women who were evaluated for PPT. On average, each woman had 2 postpartum samples available for analysis. The incidence of PPT was 14% (6/43). Only one of the women who developed PPT was thyroid antibody positive. Analysis of demographic and laboratory data revealed no correlation with the presence of thyroid disease.

Conclusion: The percentage of women with SLE who either had levothyroxine treated thyroid disease prior to pregnancy, who were diagnosed with hypothyroidism during pregnancy, or who developed PPT was 38%. Women with SLE have a marked increased incidence of autoimmune thyroid disease. Antithyroid antibodies did not predict postpartum thyroiditis. It is recommended that all women with SLE should have a TSH and thyroid antibodies performed prior to pregnancy, as this study showed that the clinical diagnosis was frequently missed, with implications in terms of fetal growth and development and pregnancy outcomes

Cervical Neoplasia and HPV Genetics in Systemic Lupus Erythematosus. J. P Dhar[1], L. Gregoire[1], W. Lancaster[1], A. Stark[2], A. Schwartz[1], D. Schultz[3], L. Essenmacher[1], J. Ager[1], L. Chiodo[1], M. Husain[4] and R. J. Sokol[1], [1]Wayne State University School of Medicine, Detroit, MI, [2]Geisenger Health Systems, Danville, PA, [3]Henry Ford Health Systems, Detroit, MI, [4]Detroit Medical Center, Detroit, MI

Purpose: To determine the frequency of high risk human papilloma virus (HPV), transcription activity, and viral genome integration in neoplastic cervical tissue of women with systemic lupus erythematosus (SLE), an immunosuppressed population with increased risk for cervical neoplasia.

Methods: The presence of high risk HPV types 16 and 18 were assayed in archived cervical biopsies obtained from 124 SLE patients with an abnormal pap smear from two large urban medical centers. DNA was extracted from paraffin blocks for polymerase chain reaction (PCR) All samples were positive for GAPDH amplification and amplified using primers specific for HPV 16 and HPV 18. RNA was extracted from formalin fixed tissues, reverse transcribed, and evaluated by real-time PCR using primers specific for HPV 16 and 18 open reading frames E7, E5, and E2. The presence of viral RNA indicated active transcription of the viral genome. Integration of viral DNA into host genome was determined by reduction of E5 and/or E2 relative to E7. Clinical data were abstracted from medical records; histologic diagnoses were confirmed for this study.

Results: Of the 124 SLE patients 77% were African American, 19% Caucasian, 4% other; mean age=48.1 yrs, mean age at time of biopsy=38.5 yrs. The results are summarized below in TABLE 1. HPV 16 was present in 16.9% (21/124) of biopsies; 7% (9/124) had HPV 18; 0.8% (1/124) had both HPV 16 and 18. Active transcription of the viral genome was present in only 14.3% of low grade lesions indicating most lesions had transcriptionally inactive HPV DNA (latent infection). RNA transcription was seen in the majority of high grade lesions indicating an active infection. However, integration of the viral genome into the host genome was infrequent.

TABLE I: CIN* histology vs. HPV DNA, RNA, integration

Histology	N	HPV 16 DNA	HPV 18 DNA	HPV 16 RNA #active/total present	HPV 18 RNA #active/total present	Integration 16	Integration 18
CIN I	63	7 (11.1%)	4 (6.3%)	1/7 (14.3%)	2/4 (50.0%)	1	0
CIN II	31	7 (22.6%)	2(6.5%)	6/7 (85.6%)	0/2 (0.0%)	2	0
CIN III	21	5 (23.8%)	2 (9.5%)	3/5 (60.0%)	2/2 (100%)	0	1
CIS*	3	1 (33.3%)	0 (0.0%)	1/1 (100%)	0/0 (0.0%)	0	0
Invasive	1	0 (0.0%)	0 (0.0%)	0/0 (0.0%)	0/0 (0.0%)	0	0
Ad.sq.ca*	2	0 (0.0%)	1 (50.0%)	0/0 (0.0%)	1/1 (100%)	0	1
Abnormal - Unclassified	3	0 (0.0%)	0 (0.0%)	0/3 (0.0%)	0/3 (0.0%)	0	0
TOTAL	124	21 (16.9%)	9 (7.3%)	11/21(52.4%)	5/9 (55.5%)	3	2

*CIN:cervical intraepithelial neoplasia, CIS:carcinoma in situ, Ad. sq. ca: adenosquamous carcinoma

Conclusion: This is the first series of SLE patients with data on integration and active transcription of HPV in dysplastic/neoplastic cervical tissue. The presence of high risk HPV types 16 and 18 reported in this study may explain the increased rate of cervical dysplasia seen in lupus. In most low grade lesions, the viral genome was transcriptionally inactive indicating a latent form of HPV. Transcription was lower than the expected overall as was integration in high grade lesions. This data suggests that immunosuppression affects HPV persistence and viral integration in women with SLE.

Risk Factors for Squamous Intraepithelial Lesions in Systemic Lupus Erythematosus- A Prospective Cohort Study. Lai-Shan Tam[1], Paul K. Chan[2], Suzanne C. Ho[2], May M. Yu[1], So-Fan Yim[1], Tak-Hong Cheung[1], Martin C. Wong[1] and Edmund K. Li[1], [1]The Chinese University of Hong Kong, Hong Kong, China, [2]The Stanley Ho Centre for Emerging Infectious Diseases, Hong Kong, China

Purpose: In patients with systemic lupus erythematosus (SLE), association between cervical diseases and cyclophosphamide (CY) was controversial. SLE patients with a high human papillomavirus (HPV)-16 viral load more frequently had squamous intraepithelial lesions (SIL). However, the role of other high risk HPV types has not been addressed. We undertook a prospective cohort study to ascertain the risk factors for the development of SIL in patients with SLE.

Method: One hundred and thirty-seven SLE patients with normal pap smear at baseline were evaluated at six-month intervals for up to three years. At each visit, a Pap test, a test for HPV DNA and clinical assessment were performed. HPV DNA detection was performed using the PGMY PCR targeting the consensus region of the HPV L1 gene. HPV typing was done using the Linear Array HPV Genotyping Test that can detect 37 HPV types. Baseline risk factors for development of SIL included sociodemographic, lifestyle, reproductive and gynecologic variables, disease related variables, the use of immunosuppressants and HPV status.

Results: The mean age was 41 +/- 9 years and 55 (36.7%) were postmenopausal. The mean disease duration was 8.6 (4.6-14.4) years. The total follow up duration was 4,066 patient months. Eleven out of 137 (8.0%) patients developed at least one episode of SIL. Amongst the 30 patients with HPV infection detectable by DNA testing at baseline or during follow-up, 9/30 (30%) developed SIL. Univariate analysis showed that the development of incident SIL was associated with the use of azathioprine and cyclophosphamide (CY) (oral, intravenous (IV) or combined) ever, current use of IVCY; HPV infection (pre-existing, incident and ever), multiple HPV infection (pre-existing, during first incident infection and ever), high risk HPV infection (baseline and ever), any persistent HPV infection (since baseline or ever) and persistent

high risk HPV infection (ever); previous treatment of cervical lesions, age at first sexual intercourse </=22. Other demographic and clinical parameters, and the use of immunosuppressants were not associated with the development of SIL. All these variables were analyzed using regression analysis. The independent risk factor for the incident SIL in this group of SLE patients included the use of CY ever (p=0.021, OR 3.5, 95% CI 12.2-10.2), persistent high risk HPV infection (p=0.007, OR 12.9, 95% CI 2.0-80.9), and previous treatment of cervical lesions (p=0.028, OR 10.0, 95% CI 1.3-77.9).

Conclusion: Persistent high risk HPV infection, previous treatment of cervical lesions and the use of CY were independent risk factors associated with the development of SIL in SLE patients.

Infliximab Plus Methotrexate Significantly Improves Rates of Remission for Methotrexate Naïve Psoriatic Arthritis (PsA) Patients Compared to Methotrexate Alone: The RESPOND† Trial. H. Raffayova[1], N. Kungurov[2], A. Kubanova[3], A. Baranauskaite[4], A. Venalis[5], L. Helmle[6], S. Srinivasan[7] and E. Nasonov[8], [1]National Institute for Rheumatology Diseases, Piestany, Slovak Republic, [2]Urals Dermato-venerology Inst., Yekaterinburg, Russia, [3]Central DermatoVenerology Inst., Moscow, Russia, [4]Kaunas Medical Univ. Hospital, Kaunas, Lithuania, [5]Vilnius Univ. Hospital, Vilnius, Lithuania, [6]Schering-Plough Corp., Budapest, Hungary, [7]Kenilworth, NJ, [8]Institute of Rheumatology, Moscow, Russia

Purpose: To assess the effect of infliximab (IFX) + methotrexate (MTX) vs MTX alone on the rate of remission (DAS28 < 2.6) in MTX naïve patients with active, polyarticular PsA. This study is the first to assess anti-TNF + MTX vs MTX alone in early, MTX-naïve active polyarticular PsA.

Method: Patients ≥18 years of age with active PsA (≥5 swollen and tender joints, + one of the following; ESR≥28 mm/hr, CRP≥15 mg/L, morning stiffness≥45 min) were included in this randomized, prospective, open-label, multi-center, multi-national study. Patients were naïve to MTX, anti-TNF agents, and could not be on DMARDs. Patients were randomized (1:1) to IFX (5 mg/kg) intravenous at week 0, 2, 6, and 14 + MTX (15 mg/week) or MTX (15 mg/week) alone. Study visits were at week 0, 2, 6, 14, and 16. The primary assessment was the proportion of ACR20 improvement at week 16. The study complied with Good Clinical Practices.

Results: 57 patients were randomized in the IFX + MTX group (48.2% male, mean age 40.1 years, mean disease duration 2.8 years)‡ and 58 in the MTX group (61.1% male, mean age 42.3 years, mean disease duration 3.7 years) ‡. Baseline conditions indicated severe disease: mean swollen and tender joint counts of > 14 and 20 respectively, mean CRP > 25 mg/dL, and mean PASI scores > 8 with more then 2/3 patients having a baseline PASI of at least 2.5. Rates of DAS28 remission by visit are summarized in the table. Also, 57% and 25% of patients had 0 swollen joints, 31% and 8% had 0 tender joints, 78% and 38% had a normal CRP level, and 71% and 29% had a PASI90 response at week 16 in the IFX+MTX and MTX groups respectively.

Visit	IFX + MTX (n=56)	MTX (n=54)	*p*-value
Week 2	12/56 (21%)	1/54 (2%)	0.0015
Week 6	24/52 (46%)	7/49 (14%)	0.0005
Week 14	29/50 (58%)	12/46 (26%)	0.0016

Week 16	35/51 (69%)	14/48 (29%)	<0.0001
Last Visit	37/56 (66%)	14/54 (26%)	<0.0001

The most commonly reported adverse event was increased levels of alanine aminotransferase (~10% in both groups). There were 2 serious adverse events in the IFX+MTX group, 1 infusion reaction with dyspnoea and erythema and 1 latent tuberculosis reactivation.

Conclusion: Early MTX naïve PsA patients with active disease achieved significantly greater remission rates when treated with IFX + MTX compared to MTX alone at every time point in the study. †(**RE**micade **S**tudy in **P**sA patients **O**f methotrexate-**N**aive **D**isease) ‡ITT analysis set.

Resolution of Inflammation Following Treatment of Ankylosing Spondylitis with Anti-TNF Agents Is Associated with New Bone Formation. Praveena Chiowchanwisawakit[1], Susanne J. Pedersen[2], Robert GW Lambert[3], Mikkel Ostergaard[2] and Walter P. Maksymowych[3], [1]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Copenhagen University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark, [3]University of Alberta, Edmonton, AB

Purpose: A previous study of patients with ankylosing spondylitis (AS) receiving anti-TNF agents in clinical trials showed that new bone formation was more likely to occur at those vertebral corners (VC) where inflammation had resolved following institution of anti-TNF therapy. A "release of TNF brake" hypothesis has been proposed whereby decreased TNF downregulates Dickkopf-1 allowing new bone formation through signalling by Wnt and other bone growth factors. However, data supporting the association between development of a new syndesmophyte and resolution of a vertebral corner inflammatory lesion (CIL) remain scarce. We aimed to test the hypothesis that a CIL visible on MRI that resolves following treatment is more likely to develop into a *de novo* syndesmophyte visible on plain x-ray than a vertebral corner with no prior CIL visible on MRI.

Method: We studied 51 AS patients (28 on standard and 23 on Anti-TNF treatment) followed prospectively who had MRI at baseline and at follow up (mean of 17.9 months), and radiography of the cervical and lumbar spine at baseline and 2 years. A persistent CIL was defined as being present on both MRI scans whilst a resolved CIL was defined as present at baseline MRI and completely disappeared at follow up MRI. The anterior vertebral corners on anonymised MRI were assessed independently and blinded to patient, treatment, and radiography by 2 readers. We conducted the following comparisons:1. proportion of new syndesmophytes developing at each anterior VC from a *resolved* inflammatory lesion at the corresponding VC; 2. the proportion of new syndesmophytes developing at each anterior VC from a *persistent* inflammatory lesion at the corresponding VC; 3. proportion of new syndesmophytes developing at each anterior VC where there is *no prior* inflammatory lesion. Proportions were compared by the Pearson chi-square analysis of the reader concordant data and discordant data was not included in this analysis.

Results: For patients receiving anti-TNF therapy, new syndesmophytes developed significantly more frequently in those vertebral corners with inflammation on MRI at baseline (10.3%) as compared to those that were normal on MRI (1.4%) ($p = 0.001$). For patients receiving standard treatment, new syndesmophytes developed in 12.5% of vertebral corners with inflammation at baseline as compared to 2.9% of those without ($p = 0.01$). New syndesmophytes developed in an even higher percentage of CIL that resolved following anti-TNF therapy (27.3%).

New syndesmophyte	Treatment	Resolved CIL	Persistent CIL	Normal VC	P value
Yes	Anti-TNF	3 (27.3)	0	5 (1.7)	<0.0001
No		8 (72.7)	3	282 (98.3)	
Yes	Standard	1 (16.7)	0	16 (3.3)	NS
No		5 (83.3)	10	463 (96.7)	

Conclusion: This study of AS spines documents that MRI findings predict subsequent damage on X-ray. Further, the demonstration of an increased likelihood of developing new bone following resolution of inflammation offers strong support for the "TNF brake hypothesis".

Apremilast Is Active in the Treatment of Psoriatic Arthritis (PsA). Georg Schett[1], J. Wollenhaupt[2], Kim Papp[3], Rik Joos[4], Kurt L. De Vlam[5], Jude F. Rodrigues[6], Adele Vessey[7], Angela Hu[7], Wei Zhu[7] and Victor S. Sloan[7], [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Klinikum Eilbek, Hamburg, Germany, [3]Probity Medical Research, Waterloo, ON, [4]ZNA Rheumatology Department, Merksen, Belgium, [5]University Hospitals Leuven, Leuven, Belgium, [6]Clinical Research and Arthritis Centre, Windsor, ON, [7]Celgene Corporation, Summit, NJ

Purpose: Apremilast (APL) is a novel oral phosphodiesterase-4 inhibitor that suppresses multiple pro-inflammatory mediators and cytokines implicated in the pathogenesis of PsA.

Method: This was a phase II randomized, double-blind, placebo (PBO) controlled, multicenter study conducted in North America and Europe. Subjects with joint involvement of ≥6 months' duration, and with PsA satisfying Moll & Wright criteria with ≥3 tender joints (TJ) and swollen joints (SJ) were randomized to APL 20mg BID, APL 40mg QD, or PBO for 12 weeks' treatment. Stable doses of NSAIDs, corticosteroids (≤10 mg/day prednisone or equivalent), and methotrexate were allowed. A total of 126 subjects were then treated in an active-drug extension for 12 weeks (24 weeks total) including 40 PBO subjects who received the two dose regimens of APL in a 1:1 ratio.

Results: Two hundred four subjects were enrolled [53% M, 47% F; mean age 51 (21-81)]. Mean duration of PsA was 7.8 years; mean TJ count of 22, mean SJ count of 10 at baseline. Baseline characteristics were well-balanced between treatment groups. One hundred sixty eight subjects completed the 12 week treatment phase. Primary endpoint, ACR20 at 12 weeks, was met by APL 20 mg BID and 40 mg QD. Efficacy results are given in the table below. In evaluable subjects, response was maintained at 24 weeks (ACR20 40% and 39.1% for 20 mg BID and 40 mg QD, respectively). PBO subjects switched to APL in the extension achieved similar responses at 24 weeks to subjects originally allocated to APL (ACR20 35% and 40% for PBO to 20 mg BID and PBO to 40 mg QD, respectively).

Treatment Group	**(N)**	**Placebo**	**APL 20mg BID**	**APL 40mg QD**
		(68)	**(69)**	**(67)**
ACR20 (%)		11.8	43.5*	35.8**
ACR50 (%)		2.9	17.4***	13.4
ACR70 (%)		1.5	5.8	7.5

* $p<0.0001$ ** $p = 0.002$ *** $p=0.012$

The 5 most common adverse events (AEs) were nausea, diarrhea, headache, nasopharyngitis, and fatigue. Discontinuations due to AEs were 9% and 6% of APL subjects (20 mg BID, 40 mg QD, respectively), vs 3% in PBO group. Discontinuations due to lack of efficacy were 7 and 0% of APL subjects (20 mg BID, 40 mg QD, respectively), vs 15% in the PBO group. Eight subjects reported a serious AE (SAE) during the 12 week study period (4 in 20 mg BID, 0 in 40 mg QD, 4 in PBO); 7 subjects reported an SAE in the extension. There was no obvious difference in infections between APL and PBO groups and there were no deaths.

Conclusion: APL significantly improved signs and symptoms of PsA in this study. The majority of the AEs were mild to moderate and did not lead to discontinuation. Larger, longer-term studies are needed to characterize the optimum dose, efficacy and safety of APL for treatment of PsA.

Golimumab, a New, Human, TNF-α antibody Administered Subcutaneously Every 4 Weeks, in Ankylosing Spondylitis (AS): 104-Week Efficacy and Safety Results of the Randomized, Placebo-Controlled GO-RAISE Study. J. Braun[1], Désirée M.F.M. van der Heijde[2], Atul A. Deodhar[3], L. Diekman[4], J. Sieper[5], S.I. Kim[6], A. Beutler[7], M. Mack[7], S. Xu[7], J. Zrubek[7], B. Hsu[7] and R. D. Inman[8], [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Oregon Health & Science University, Portland, OR, [4]University of Texas Medical School, Houston, TX, [5]Charite Hospital, Berlin, Germany, [6]Pusan National University Hospital, Busan, South Korea, [7]Centocor R&D, Inc, Malvern, PA, [8]University of Toronto, Toronto, ON

Purpose: To assess golimumab (GLM) efficacy/safety in pts with active ankylosing spondylitis (AS).

Methods: 356 pts were randomized (1.8:1.8:1 ratio) to SC GLM 50 or 100mg or PBO q4wks. Eligible pts had definite AS (modified NY criteria), BASDAI ≥4, and a back pain score of ≥4. At wk16, PBO or GLM 50 mg pts with <20% improvement in total back pain and morning stiffness entered early escape (EE) to GLM 50 and 100mg q4wks, resp (double-blind). At wk24, pts still receiving PBO crossed over to blinded GLM 50mg SC injections q4wks; others continued regimen through wk100, with evaluation 4 wks later. Key data summaries are based on randomized treatment groups with no statistical comparisons; other summaries show observed data only by regimen followed.

Results: As reported previously, the primary endpoint (proportion of pts with ASAS20 at wk14), was achieved. Benefit seen at wks 14&24 was maintained through wk104 (Table). BASMI linear scores improved from baseline to wk52; improvements were also maintained through wk104, as were improvements in SF-36 MCS & PCS scores. Pts not responsive to GLM 50mg who increased to 100mg had lower rates of ASAS response and less improvement in other parameters vs other GLM-treated pts (Table). AEs through wk104 were reported for 94% of GLM pts (little variation across GLM doses). Through wk104, 11% of GLM pts had a serious AE; the rate of GLM injection-site reactions was 1.4% (106/7705 inj) through wk104. There were no deaths.

Table:

	Placebo	GLM50mg	GLM100mg
Pts randomized	78**	138	140
ASAS 20[+]	30 (38.5%)	83 (60.1%)	100 (75.6%)
ASAS 40[+]	30 (38.5%)	77 (55.8%)	76 (54.3%)
ASAS partial remission[+]	17 (21.8%)	44 (31.9%)	43 (30.7%)
BASDAI[++]	6.02 (1.36,7.79)	2.65 (0.84, 6.08)	2.73 (1.08,5.34)
BASFI[++]	4.93 (0.98, 7.07)	2.22 (0.52,5.80)	1.77 (0.49, 4.79)

Table footnotes:

*Intent-to-treat analysis

+n in response, (%)

++median, (interquartile range)

**Includes 35 pts who did not meet EE criteria at wk16 and 41 pts who did

Conclusion: Clinical improvements in AS pts previously seen at wk24 were maintained through wk104, with no major differences in efficacy/safety between GLM doses. GLM was generally well tolerated through 2yrs of this 5yr study.

Abatacept in Psoriatic Arthritis: Results of a Phase II Study. P. Mease[1], M. Genovese[2], C. Ritchlin[3], J. Wollenhaupt[4], Paul P. Tak[5], A. Kivitz[6], G. Gladstein[7], O. Bahary[8], S. Kelly[8], J. Teng[8], J.-C. Becker[8] and D. Gladman[9], [1]Swedish Medical Ctr/Univ. of Washington, Seattle, WA, [2]Stanford Univ., Palo Alto, CA, [3]Univ. of Rochester, Rochester, NY, [4]Klinikum Eilbek, Hamburg, Germany, [5]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [6]Altoona Center for Clinical Research, Duncansville, PA, [7]New England Research Assoc, Trumbull, CT, [8]Bristol-Myers Squibb, Princeton, NJ, [9]Univ. of Toronto, Toronto, ON

Purpose: Abatacept (ABA) is a selective co-stimulation modulator approved for the treatment of RA and juvenile idiopathic arthritis. Here we assess the efficacy of ABA in patients (pts) with psoriatic arthritis (PsA) previously exposed to DMARDs in a phase II study.

Method: In this double-blind study, PsA pts with a target lesion (TL) ≥ 2 cm were randomized (1:1:1:1) to placebo (PBO) and ABA at 3, 10, and 30/10 (30 x 2 followed by 10) mg/kg (mpk). Treatments were administered on Days 1, 15, 29, and then once every 28 days. The primary endpoint was ACR20 at Day 169. Secondary endpoints were Health Assessment Questionnaire (HAQ), Short Form-36 (SF-36), investigator global assessment (IGA), TL score at Day 169, and safety. Psoriasis area and severity index (PASI) and magnetic resonance imaging (MRI) score of the joints at Day 169 were exploratory.

Results: Baseline characteristics were similar among groups except for more pts being previously exposed to anti-TNF therapies in the 30/10 mpk arm (51%) than other arms (29-36%). Of 170 pts treated, 147 completed first 6 months of treatment; 23 pts discontinued (7 for AEs and 10 for lack of efficacy). Significant number of pts achieved ACR20 with ABA (10 and 30/10 mpk) compared to PBO (**table**). Improvements in HAQ, physical component summary (PCS) and MRI score were also seen with ABA compared to PBO. The skin response in terms of TL and PASI showed a separation between PBO and ABA arms, with the 3 mpk dose showing the most separation; an improved IGA response was seen only with 3 mpk. Improvements in ACR20 and TL were greater in anti-TNF-naive pts than in pts pre-exposed to anti-TNF therapies. The safety profiles were similar among arms.

Response	ABA			PBO

Golimumab Administered Subcutaneously Every 4 Weeks in Psoriatic Arthritis Patients: 52-Week Health-Related Quality of Life, Physical Function and Health Economic Results of the Randomized, Placebo-Controlled GO-REVEAL Study. A. Kavanaugh[1], D. Gladman[2], P. Mease[3], Iain B. McInnes[4], A. Beutler[5], J. Zrubek[5], J. Buchanan[6], S. Parasuraman[6], M. Mack[5] and G.G. Krueger[7], [1]U of Calif San Diego, San Diego, CA, [2]Toronto Western Hosp, Toronto, ON, [3]Seattle Rheum Assoc, Seattle, WA, [4]University of Glasgow, Glasgow, United Kingdom, [5]Centocor R&D, Inc, Malvern, PA, [6]J&J Pharm Services, Malvern, PA, [7]U of Utah Hlth Sciences Ctr, Salt Lake City, UT

Purpose: The impact of GLM on physical function, self-reported productivity, health-related quality of life (HRQoL), healthcare resource utilization, employability and time lost from work were assessed.

Methods: Adult PsA pts (n=405) with ≥3 SJC & ≥3 TJC were randomized to SC PBO or GLM (50 or 100 mg) q4wks. At wk16, pts with inadequate arthritis response entered early escape (EE). All pts on PBO received GLM50mg from wk24. Wk24 comparisons were between GLM and PBO groups using ANOVA on van der Waerden normal scores for continuous outcomes. At wk52, response was determined using observed data.

Results: Mean age was 46-48yrs, median SJC/TJCs were 12-14/22-24, HAQ scores were 1.0-1.1, and PASI scores were 8.4-11.1. GLM was significantly better than PBO in improving physical function, HRQoL, self-reported productivity and reducing time lost from work for caregivers at wk24 ($p<0.05$, for all endpoints). Through wk24 there were no statistically significant effects on healthcare resource utilization, employability, or pt time lost from work. Improvements in HRQoL, physical function and self-reported productivity continued through wk 52. GLM-treated pts showed improvements in resource utilization, employability, and in caregiver and pt time lost from work at wk 52.

Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis of the skin and internal organs that leads to profound disability and premature death. Accumulating evidence point to a strong genetic component that is underlying the susceptibility of SSc. Here we aimed to identify the genetic factors that underly SSc.

Method & Results: To identify the genetic traits for SSc, we performed a genome-wide association study comparing 842 European Caucasian SSc cases with 1711 European Caucasian controls exploiting the Illumina human BeadChip. Using a replication cohort comprising 1640 European Caucasian SSc cases and 1700 controls matched for country of origin we aimed to replicate the 11 most strongly non-MHC associated SNPs in the GWAS and replicated the association of STAT4 (P = 4.03E-10). After stratification for SSc phenotype, significant association (P<5.0E-08) was reached for ten SNPs in 3 loci (STAT4 in limited disease, MHC region in diffuse disease and CXCR4 region in female subjects). These results replicate the previous published associations to the MHC region and the STAT4 gene with SSc [1-3]. In addition, SNPs in three loci were found to be associated in both our study and the independent US screen (Gorlova et al.) These regions included the MHC, the STAT4, and the TNPO3 genes that when combined reach genome wide significance respectively (P<5.0E-08), further confirming these loci as risk factors for SSc. Finally, one SNP in the CD3Z gene showed association in both the US and EU cohorts (P=1.4E-07)

Conclusion: To date this is the first GWAS performed in SSc in a European population. Apart from the MHC region, two non-MHC loci, STAT4, TNPO3 were confirmed as susceptibility factors for SSc. The identification of these loci underscore a strong role for immune deregulation in the pathogenesis of SSc.

Tyrosine Kinase Inhibitors (TKI) Are Promising Therapeutic Agents for the Proliferative Vasculopathy in SSc. Britta Maurer[1], Nicole Busch[2], Astrid Jüngel[1], Renate E. Gay[1], Georg Schett[3], Beat A. Michel[1], Steffen Gay[1], Jörg HW Distler[2] and Oliver Distler[1], [1]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [2]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: Proliferative vasculopathy such as pulmonary arterial hypertension (PAH) and fibrosis are the leading causes of death in SSc patients. Herein, we analyzed the effects of TKI on the proliferative vasculopathy in the novel vascular SSc model of Fra-2 tg mice, and examined the activation of TKI targets in the skin of SSc patients and fibrotic animal models of SSc.

Method: Fra-2 tg mice (n=12; Bl6), wt littermates (n=3) and bleomycin treated mice (n=3; C3H/HeJ) were analyzed. Subgroups of Fra-2 tg mice (n=6) were treated with the TKI nilotinib at 2 x 35mg/d p. o. from 8 weeks of age. In addition, skin sections from SSc patients (n=5) were examined.

Results: Untreated Fra-2 tg mice developed a strong proliferative vasculopathy in the lungs resembling PAH. Vascular remodelling of small arteries was characterized by proliferation (PCNA staining) of vascular smooth muscle cells (SM22α, double staining) and myofibroblasts/pericytes (α-SMA and Thy). The expression of the phosphorylated and thus activated TKI targets p(phospho)-c-abl and p-PDGFRβ was significantly increased in the pulmonary vessels of untreated Fra-2 tg mice. Accordingly, nilotinib improved the proliferative vasculopathy in the lungs of treated (vessel wall diameter, mean ± SEM 30.6 ± 1.3 μm) compared to the untreated Fra-2 tg mice (43.3 ± 1.4 μm, $p<0.05$) and significantly decreased the numbers of proliferating vascular cells. Interstitial lung fibroblasts did not express activated TKI targets, and thus, perivascular pulmonary fibrosis was not reduced. However, in the skin, the expression of p-PDGFRβ was prominent both in vascular structures and fibroblast-like cells (4.9 ± 0.7 cells/HPF). In accordance, nilotinib prevented the development of skin fibrosis in treated compared to untreated Fra-2 tg mice (skin thickness 290 ± 10 μm vs. 324 ± 10.4 μm ; $p<0.05$). Next, we analyzed the expression of activated TKI targets in the skin of the bleomycin model. P-c-abl (5.9 ± 0.08 cells/HPF) and p-PDGFRβ (6.4 ± 1.5 cells/HPF) were abundantly expressed in all cells including fibroblasts, consistent with the strong antifibrotic effects for TKI seen in this model. Most interestingly, in skin sections of SSc patients, the expression of p-c-abl (1.5 ± 0.8 cells/HPF) and p-PDGFRβ (3.0 ± 1.1 cells/HPF) was largely limited to vascular structures.

Conclusion: Our study suggests that differences in the expression pattern and activation status of TKI targets between animal models and SSc may account for the relatively minor anti-fibrotic effects in humans. However, based on the vascular predominance of TKI targets in human SSc and the effects on vascular remodelling in the vascular Fra-2 tg model, our data suggest TKI as novel promising drugs to treat proliferative vasculopathies such as SSc-PAH. This is supported by preliminary data from human phase II studies with imatinib in PAH.

Hedgehog Signaling Plays a Crucial Role for Fibroblast Activation and Tissue Fibrosis in Systemic Sclerosis. Angelika Horn[1], Clara Dees[1], Alfiya Akhmetshina[1], Nicole Busch[1], Jürgen Beer[1], Oliver Distler[2], Georg Schett[3] and Jörg HW Distler[1], [1]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [2]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [3]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: The Hedgehog (Hh) pathway plays important roles in embryonic tissue development, in the pathogenesis of various tumors and in hepatic fibrosis. The ligand Sonic Hedgehog (Shh) binds to the transmembrane receptor Patched (Ptch), which releases the membrane protein Smoothened (Smo) from its repression. As a result, Smo activates the transcription factor Gli-2 for further activation of several target genes. The aim of the present study was to investigate the role of Hh in SSc.

Method: The expression of Shh, Smo and Gli-2 was analyzed by immunohistochemistry. Hedgehog signaling was activated by recombinant Shh or adenoviral expression of Shh. Two different animal models of SSc, bleomycin-induced dermal fibrosis and tight-skin (tsk-1) mice were used to assess the role of Hh signaling in experimental fibrosis and evaluate the anti-fibrotic potential of the selective Hh inhibitor LDE223.

Results: The expression of Shh and its downstream target Gli-2 was significantly elevated in skin sections of SSc patients compared to healthy controls. Hh signaling was also activated in different models of experimental fibrosis. Stimulation of healthy dermal fibroblasts with recombinant Shh induced an SSc-like phenotype and stimulated the release of collagen dose-dependently by up to 4.4 ± 0.2 fold. This effect was mediated by higher mRNA stability. Adenoviral overexpression of Shh induced dermal fibrosis in mice with dermal thickening, increased accumulation of collagen and myofibroblast differentiation. In addition, mice lacking one allele of the inhibitory receptor Ptch were more sensitive to experimental fibrosis. Next, we evaluated the therapeutic potential of the Hh inhibitor LDE223. Dermal thickening was reduced by 72 ± 2 % in the mouse model of bleomycin-induced fibrosis upon treatment with LDE223. Consistent with the reduced dermal thickening, LDE223 treated mice showed significantly decreased myofibroblast counts and the amount of collagen in the lesional skin was reduced by 67 ± 17 %. LDE223 was also effective in the tight skin 1 mouse model, a non-inflammatory model of SSc. Treatment of tight skin 1 mice with LDE223 reduced hypodermal thickening by up to 78 ± 5 % and completely prevented myofibroblast differentiation.

Conclusion: The Hh pathway is activated in experimental fibrosis and in SSc patients. We demonstrate that activation of Hh activates cultured fibroblasts in vitro and induces fibrosis in vivo. Inhibition of Hedgehog signaling by selective inhibition of Smo exerts potent anti-fibrotic effects in different models of experimental fibrosis. Thus, the hedgehog pathway could be an interesting novel target for the treatment of SSc.

1265

Tgfß Stimulates Promoter Hypermethylation and Subsequent Silencing of the Anti-Fibrotic Gene Socs-3. Clara Dees[1], Alfiya Akhmetshina[1], Nicole Busch[1], Angelika Horn[2], Johannes Gusinde[1], Astrid Jüngel[3], Steffen Gay[3], Oliver Distler[3], Georg Schett[4] and Jörg HW Distler[1], [1]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [2]Dept Int Med 3, Univ Erlangen, Germany, Erlangen, Germany, [3]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [4]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: Tissue fibrosis caused by a pathological activation of SSc fibroblasts is a major hallmark of systemic sclerosis (SSc). TGFβ is a major mediator of fibrosis and has been identified as key-player in the pathogenesis of SSc. Alterations in DNA methylation and subsequent changes in gene transcription have been implicated in the pathogenesis of SSc. The aim of the present study was to investigate whether TGFβ induces DNA methylation.

Method: The methylation status of suppressor of cytokine signaling 3 (socs-3) in fibroblasts was evaluated by methylation-specific PCR. The expression of socs-3 was analyzed by real-time PCR and immunohistochemistry. The expression of socs-3 was specifically targeted by siRNA. The anti-fibrotic potential of 5-aza, a potent inhibitor of DNA methyltransferases, for prevention and treatment of established fibrosis was analyzed in the mouse model of bleomycin-induced skin fibrosis.

Results: Socs-3 potently regulated the release of collagen in fibroblasts. Knockdown of socs-3 by siRNA in healthy fibroblasts increased mRNA and protein levels of col 1a1 and col 1a2 by up to 85 ± 36 % ($p < 0.05$). The expression of socs-3 was strongly reduced in SSc fibroblasts and in the skin of SSc patients. The promoter of socs-3 was heavily hypermethylated in SSc fibroblasts. Incubation with 5-aza reactivated the expression of socs-3 in SSc fibroblasts, but had no effects in control fibroblasts. The hypermethylation of socs-3 in SSc might be mediated by TGFβ. TGFβ induced hypermethylation of the promoter of socs-3 in healthy fibroblasts similar to SSc fibroblasts and reduced the expression of socs-3 by 69 ± 8 % ($p < 0.05$). The increased DNA methylation was mediated by TGFβ dependent induction of the DNA methyltransferase 3a. Coincubation with 5-aza prevented not only the inhibitory effects of TGFβ on the expression of socs-3, but also reduced the TGFβ induced stimulation of the collagen synthesis by 68 ± 6 % ($p < 0.05$). 5-aza also exerted anti-fibrotic effects in vivo. 5-aza reduced dermal thickening upon challenge with bleomycin by 89 ± 9 % ($p < 0.05$). In addition, 5-aza induced regression of pre-established fibrosis with a decrease in dermal thickening of 44 ± 3 % below pre-treatment levels ($p < 0.05$).

Conclusion: We demonstrate that TGFβ induces silencing of the anti-fibrotic gene socs-3 via DNA methyltransferase 3a dependent promoter hypermethylation. Inhibition of the TGFβ induced silencing of socs-3 by 5-aza reduced the stimulatory effects of TGFβ on the collagen synthesis in vitro and exerted potent anti-fibrotic effects in vivo. Thus, we identify inhibitors of DNA methyltransferases as novel anti-fibrotic drugs and provide a novel mechanism for the pro-fibrotic effects of TGFβ.

The Role of GATA-6 in Pulmonary Arterial Hypertension in Scleroderma Patients. Angela V. Ghatnekar, Lukasz Stawski, Elaine Wirrig, Malgorzata Markiewicz, Yoshihide Asano, Russel Harley and Maria Trojanowska, Medical University of South Carolina, Charleston, SC

Purpose: Pulmonary arterial hypertension (PAH) is an increase in blood pressure in the pulmonary artery or lung vasculature and in severe cases can lead to right ventricular heart failure and death. PAH can be idiopathic (cause unknown), familial (genetic), or associated with a variety of other conditions, such as connective tissue diseases like systemic sclerosis (SSc). The key features of this disease are vasoconstriction, followed by intimal proliferation and fibrosis, in-situ thrombosis, and plexogenic changes. Several factors are known to be perturbed in endothelial cells (ECs) during PAH: TGF-β/Bone Morphogenetic Protein (BMP) components, nitric oxide (NO), and endothelin-1 (ET-1). GATA-6 is a zinc finger transcription factor that is indispensable for embryogenesis and subsequent tissue-specific gene regulation. Recent studies have demonstrated that GATA-6 is downregulated in both intramyocardial arteries from spontaneously hypertensive rats and rat carotid arteries following balloon-mediated injury. The goal of this work was to evaluate the potential role of GATA-6 as a novel regulator of gene programs altered in PAH.

Method: The protein levels of GATA-6 were assessed by immunostaining of lung specimens from 9 patients with SSc-PAH and 4 healthy controls. To identify genes regulated by GATA-6 in microvascular ECs, we performed a microarray analysis after AdsiRNA-mediated GATA-6 knockdown, and subsequently validated putative target genes using commercial siRNA oligos followed qRT-PCR and western blotting. To investigate if GATA-6 is a direct transcriptional regulator of these genes, we performed chromatin immunoprecipitation (ChIP) analysis. The mRNA and protein levels of GATA-6 and its potential targets were also examined in the lungs of the monocrotaline (MCT) rat model of PAH by using qRT-PCR and western blot.

Results: The immunostaining revealed that GATA-6 protein levels are dramatically reduced in ECs (e.g. 15% arterioles stained positive in SSc-PAH versus 85% in controls) within occluded and non-occluded vessels of patients. Genes altered in endothelial cells after suppression of GATA-6 included components of the BMP pathway, endothelial cell markers and matrix remodeling proteins. Silencing of GATA-6 with siRNA oligos in ECs confirmed that GATA-6 might be a negative regulator of MMP1 and MMP10 and a positive regulator of eNOS, VE-cadherin and BAMBI gene expression. ChIP analysis demonstrated that GATA-6 is a direct transcriptional regulator of BAMBI, eNOS, MMP1 and MMP10. We also found significant reductions in GATA-6 expression as well as decreased mRNA levels of its putative targets, BAMBI, eNOS and VE-cadherin at both early and late stages of disease in the MCT rat model.

Conclusion: These findings suggest that GATA-6 reduction occurs before vessel occlusion and may reflect an initial phase of EC activation and/or dysfunction and, therefore, may play a critical role in development of PAH by regulating genes associated with vascular remodeling.

Molecular Profiling of Lung Tissues From Patients with Systemic Sclerosis. Eileen Hsu and Carol A. Feghali-Bostwick, University of Pittsburgh, Pittsburgh, PA

Purpose: Pulmonary involvement in systemic sclerosis (SSc) includes pulmonary fibrosis (PF) and pulmonary arterial hypertension (PAH) and is the leading cause of SSc-related mortality. To gain a better understanding of the pathogenesis of SSc-associated PF and PAH, we used microarray analysis to identify the molecular fingerprints of SSc lung tissues and compared them to those of patients with idiopathic pulmonary fibrosis (IPF) and idiopathic pulmonary arterial hypertension (IPAH).

Methods: Lung tissues were obtained from patients who underwent lung transplantation or from normal donors (n=9) whose lungs were not used for transplant surgery. SSc patients were identified as having severe PF (n=9) or PAH (n=9). All SSc-PF patients had severe restrictive

lung disease with FVC <55% of predicted without evidence of PAH. All SSc-PAH patients had mean PA pressure >25mmHg with mild restriction or normal spirometry. IPF patients (n=10) had CT scan or lung biopsy findings consistent with usual interstitial pneumonia without evidence of connective tissue disease or other known exposures. IPAH (n=6) patients had pulmonary arterial hypertension of unknown etiology. Total RNA was extracted from frozen lung tissues. Microarray analysis was done using Illumina HumanRef-8v3.0 Bead Chips. Consensus efficiency analysis was used to determine optimal method of data processing and differentially expressed genes. Ingenuity Pathway Analysis and Gene Ontology Tree Machine software identified the enriched functional groups. Microarray results were confirmed using real-time PCR.

Results: Efficiency analysis of microarray data of SSc, IPF and IPAH whole lung tissues identified 242 genes that were differentially expressed compared to normal lungs. In SSc-PF and SSc-PAH lungs, 73 and 83 genes, respectively, were differentially expressed compared to normal lungs. In IPF and IPAH lungs, 73 and 85 genes, respectively, were differentially expressed compared to normal lungs. Functional groups that were enriched in SSc-PF and SSc-PAH lungs, but not IPF or IPAH, included leukocyte chemotaxis and pepsin A activity. Enriched functional categories shared by SSc-PF and IPF lungs included insulin-like growth factor signaling, caveolar-mediated endocytosis and hepatic fibrosis. Genes shared by SSc-PAH and IPAH lungs included genes involved in IL-17 signaling, antigen presentation, chemokine activity, and transition metal ion binding.

Conclusion: Lung tissues of patients with SSc-associated lung disease exhibit unique molecular profiles compared to idiopathic forms of lung disease. Furthermore, gene expression profiles of SSc-PF and SSc-PAH lungs are distinct. In summary, using lung tissues, we identified novel genes that may play a role in the pathogenesis of SSc-PF and SSc-PAH. We generated unique molecular signatures that are disease (SSc) and phenotype (PF vs PAH)-specific. The identified differentially expressed genes provide new targets for the development of therapies targ

Antiphospholipid Syndrome: Pathogenesis and Clinical Aspects
Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1268

Vitamin D: An Instrumental Factor in the Anti-Phospholipids Syndrome - Inhibiting Tissue Factor Expression. Nancy Agmon-Levin[1], Maya Glazer[1], Howard Amital[2], Gisele Zandman-Goddard[3], Hedi C. Orbach[3], Shlomo Berliner[4], Pierluigi Meroni[5], Angela Tincani[6], Andrea Doria[7], Ricard Cervera[8], Wolfgang Miesbach[9], Ljudmila Stoyanovich[10], Vivian Barak[11], Bat-Sheva Porat katz[12], Miri Blank[1] and Yehuda Shoenfeld[13], [1]Center for Autoimmune Diseases, Sheba Medical Center, Ramat Gan, Israel, [2]Meir Medical Center, Kfar-Saba, Israel, [3]Wolfson Medical Center, Holon, Israel, [4]Sourasky Medical Center, Tel aviv, Israel, [5]University of Milan, Milan, Italy, [6]University of Brescia, Brescia, Italy, [7]University of Padova, Padova, Italy, [8]Autoimmune Diseases. Hospital Clínic, Barcelona, Spain, [9]Johann Wolfgang Goethe-University, Germany, [10]"Bezhanijska Kosa" University Medical Center, Belgrade, Serbia and Montenegro, [11]Department of Oncology, Hadassah University Hospital, Jerusalem, Israel, [12]Faculty of Agricultural, The Hebrew University, Jerusalem, Israel, [13]Center for Autoimmune Diseases, Sheba Medical Center, Incumbent of the Laura Schwarz-Kip Chair for Research of Autoimmune Diseases, Tel-Aviv University, Israel

Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by recurrent thrombotic events and elevated titers of antiphospholipid antibodies (Abs) including anti- beta 2 glycoprotein-I (β2GPI) Abs. Anti-β2GPI-Abs may induce thrombosis *via* induction of tissue factor (TF) expression, which triggers the coagulation cascade. One of the recently suggested novel roles of Vitamin-D entails immunomodulation and anti-thrombotic mechanisms. Therefore, in a large cohort of APS patients we evaluated vitamin-D levels and its effect in an *in vitro* model of thrombosis utilizing an anti-β2GPI–mediated TF expression system.

Methods: Patients: Serum concentrations of Vitamin-D were measured in 337 European APS patients with clinically diagnosed thrombotic events (i.e. venous or arterial).. We used the Liaison chemiluminescent immunoassay method (DiaSorin - Italy).

Experimental model: We purified anti- β2GPI antibodies from 3 patients with APS and utilized them to activate human endothelial cells (HUVEC) to expresses TF. Vitamin D (1,25-dihydroxyvitamin D, 10nM) was added to starved HUVEC in the presence of anti-β2GPI Abs. TF expression was analyzed by immunoblot utilizing mouse anti-human-TF.

Results: The prevalence of vitamin-D deficiency (≤15ng/ml) was documented in 63% of our APS patients. An increased prevalence of thrombotic events (58% *vs*. 41%) were documented in patients with vitamin-D deficiency compared to those with higher levels of vitamin-D ($P<0.05$).

In our experimental model the addition of vitamin-D to endothelial cells significantly inhibited the expression of TF induced by anti- β2GPI Abs purified from the patients.

Conclusion: Vitamin-D deficiency is common among APS patients and associated with clinically diagnosed thrombotic events. Vitamin-D inhibited anti- β2GPI mediated TF expression in an *in vitro* model. Thus, low levels of Vitamin-D may be associated with decreased inhibition of TF expression and thus increased coagulation in APS.

The Phosphatidylserine-Dependent Monoclonal Antiprothrombin Antibody with Lupus Anticoagulant Activity Induces Platelet Activation with Over-Expression of Surface Antigen. Kenji Oku, Tatsuya Atsumi, Olga Amengual, Yuichiro Fujieda, Kotaro Otomo, Masaru Kato, Hiroshi Kataoka, Tetsuya Horita, Shinsuke Yasuda and Takao Koike, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: We previously showed that monoclonal phosphatidylserine-dependent antiprothrombin antibodies (aPS/PT) induced tissue factor (TF) mRNA expression on procoagulant cells (ACR Abstract 1406 in 2007 and 645 in 2008). Increased thrombin generation in vivo would be due to up-regulation of TF expression, presumably correlated with venous thrombosis. In contrast, platelet activation and aggregation is crucial procedures in the development of arterial thrombosis. There have been, however, only little data available to link arterial events / platelet activation and aPS/PT. In this study, we compared the events of arterial thrombosis and aPS/PT in a large cohort of patients with autoimmune diseases. In addition, to explore the pathogenesis of aPS/PT in the arterial disease, we treated platelets with monoclonal aPS/PT and investigated their behavior in vitro.

Methods and Patients**:** This study comprised 500 patients who visited our autoimmune disease clinic (423 female, age 48(15-89) years; 196 systemic lupus erythematosus, 107 primary antiphospholipid syndrome, 48 rheumatoid arthritis, 28 scleroderma, 149 other autoimmune diseases). The arterial thrombosis was found in 70 patients (14%), all confirmed by at least one of CT scan, MRI or angiography. A monoclonal aPS/PT, 231D, that shared the properties with autoimmune aPS/PT (Arthritis Rheum, in press) was used for the following in vitro experiments. Normal platelets were treated with 231D in the presence of prothrombin(PT). Positive ratio of CD62P(P-selectin), a surface marker of activated platelets, was detected by two-colored flow-cytometry. Conventional ADP or collagen induced platelet aggregation assay was performed using 231D-spiked platelet rich plasma (PRP) by turbidimetric method.

Results: IgG aPS/PT were found in 81 patients (16%), and the prevalence of IgG aPS/PT was significantly higher in patients with arterial events than in those without (OR 8.2 95%CI(4.6-14.3)). Positive rate of CD62P was significantly increased on platelet treated with 231D in the presence of prothrombin (PT+231D vs base line, 231D alone, PT+control IgG:0.91+/-0.07 vs 0.78+/-0.06, 0.81+/-0.03 ;all $p<0.005$). PRP spiked with 231D (5,10,20ug/ml) inhibited primary and secondary aggregation induced by ADP. Collagen induced platelets aggregation was not affected by 231D.

Conclusion: The presence of IgG aPS/PT was a strong risk to have arterial events in patients with autoimmune diseases. Platelets were activated by monoclonal aPS/PT, thus aPS/PT may be involved in the pathogenesis of arterial diseases in such patients. However, ADP induced platelet aggregation was inhibited by 231D, suggesting that the *in vitro* behavior of aPS/PT-treated platelets is complex and paradoxical. Further studies will promise to unveil the enigmatic role of aPS/PT in the development of arterial disease in the affected patients.

1270

Association of Anti-oxLDL/ß2 GP1 Immune Complex and Accelerated Atherosclerosis in Patients with Primary Antiphospholipid Syndrome. Antonio Barrera[1], Claudia Hernandez[2], Gabriela Medina[3], Miguel Saavedra[4] and Luis Javier Jara[3], [1]Hospital de Especialidades Centro Medico La Raza IMSS, Mexico Distrito federal, Mexico, [2]Hospital de Especialidades Centro Medico La Raza IMSS, Mexico, Mexico, [3]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, [4]Hospital Angeles Metropolitano, Mexico DF, Mexico

Purpose: Autoantibodies against oxLDL/ß2 GP1 complexes occur in patients with antiphospholipid syndrome (APS) and significantly correlate with arterial thrombosis, but their exact clinical significance in primary antiphospholipid syndrome (PAPS) and accelerated atherosclerosis remains unclear

Method: We included 40 PAPS patients and 40 controls matched by age and gender. Demographic and clinical data were obtained by direct interview, chart review, and physical examination. Cardiovascular risk factors for atherosclerosis were registered. Blood samples from patients and controls were taken for serum determination of IgG, and IgM anti-oxLDL/b2GP1 antibodies (ELISA test, Immunomex commercial kit, normal values: < 20 IU). Atherosclerosis was defined as a carotid intima-media thickness (IMT) greater than 0.8 mm. measured by high resolution B mode ultrasound.

Results: The mean age of patients and controls was 41 ± 6 years with a female predominance (93%), disease duration was 10 ± 5 years. The principal clinical manifestations of PAPS patients were deep venous thrombosis (50%) and cerebral vascular disease (36%). Traditional cardiovascular risk factors were similar in patients and controls. Patients with PAPS had a significant IMT in comparison with controls (0.75 ± .09 mm vs. 0.64 ± 0.09 mm, $p < 0.001$) and they had higher titers of anti-oxLDL/b2GP1 IgG in comparison with controls (67.62 ± 10.50 vs. 14.97 ± 18.01, $p=0.005$). In the group of patients with PAPS, there was not correlation between IgG anti-oxLDL/b2GP1 titers and IMT ($r=-.182$)

Conclusion: Our study suggests that autoantibodies against oxLDL/b2GP1 complexes ocurr in patients with PAPS. However, there was not correlation between IgG anti-oxLDL/b2GP1 titers and IMT. Further prospective clinical studies are necessary to determine its role on aterosclerosis

1271

Association Between CD36 Single Nucleotide Polymorphism and Antiphospholipid Syndrome. Masaru Kato, Tetsuya Horita, Tatsuya Atsumi, Olga Amengual, Hisako Nakagawa, Yuichiro Fujieda, Kotaro Otomo, Kenji Oku, Hiroshi Kataoka, Shinsuke Yasuda and Takao Koike, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: CD36, known as a scavenger receptor, is a transmembrane glycoprotein expressed on monocytes, macrophages, platelets and capillary endothelial cells. CD36 recognizes multiple ligands, including phosphatidyl serine, and is a mediator of both atherogenesis and thrombosis. Some reports indicated that CD36-null mice were resistant for thrombus formation. Human CD36 deficiency was first described in 1989 as refractory to HLA-matched platelet transfusions, and is found in 4 to 10 % of Asian or African population. There has been, however, no report of the correlation between CD36 gene polymorphism and thrombotic diseases. The purpose of this study is to investigate the association between CD36 gene polymorphisms and antiphospholipid syndrome (APS).

Methods: This study comprised a total of 795 Japanese: 39 patients with primary APS, 69 with systemic lupus erythematosus (SLE) complicated with APS, 265 with SLE in the absence of APS, and 422 healthy subjects. All the APS patients fulfilled the Sydney-revised Sapporo criteria of APS, and all the SLE patients fulfilled the American College of Rheumatology classification criteria of SLE. Two following CD36 gene polymorphisms were investigated in this population using the TaqMan PCR genotyping method, the T for C allele substitution at nt478 for Pro90Ser (rs3765187), a common variation linked to CD36 deficiency, and the A for C substitution on the 5' untranslated region (rs1049654). Statistical analysis was performed by Fisher's exact test.

Results: The allele frequency of rs3765187 in each group is presented in the Table1; The T allele at nt478 was less frequent in APS patients than in healthy subjects. There was no significant difference in the allele frequency of rs1049654 among those groups.

Conclusion: The single nucleotide polymorphism linked to CD 36 deficiency was less frequent in APS patients, suggesting that impaired scavenger receptor function correlates with APS-resistant. This is a first report to show the link between CD36 gene and APS.

Table 1. The allele frequencies of CD36 SNP, nt478C/T for Pro90Ser rs3765187, in healthy subjects and patients with APS and SLE

	nt478 T frequency	p value	OR (95% CI)
Healthy subjects (n = 422)	10.2% (43/422)	-	-
All APS (n = 108)	2.8% (3/108)	0.024	0.25 (0.08 to 0.83)
All SLE (n = 334)	6.9% (23/334)	0.11	0.65 (0.38 to 1.11)
Primary APS (n = 39)	2.6% (1/39)	0.15	0.23 (0.03 to 1.73)
SLE+APS (n = 69)	2.9% (2/69)	0.085	0.26 (0.06 to 1.11)
SLE/non-APS (n = 265)	7.9% (21/265)	0.32	0.76 (0.44 to 1.31)

The p value and OR (95% CI) for each group were obtained by the comparison with healthy subjects.

APS, antiphospholipid syndrome; SLE, systemic lupus erythematosus; OR, odds ratio; SNP, single nucleotide polymorphism

1272

Oxidative Stress and Mitochondrial Membrane Potential in Circulating Leucocytes From Antiphospholipid Syndrome Patients: Key Intracellular Events in Thrombosis Development. Chary Lopez-Pedrera[1], Patricia Ruiz-Limon[1], MA. Aguirre[2], Nuria Barbarroja[1], Mj Luque[1], Antonio Rodriguez-Ariza[1], Eduardo Collantes-Estevez[3], José M. Villalba[4], F. Velasco[1], Munther A. Khamashta[5] and Mj. Cuadrado[5], [1]Reina Sofia Hospital, Cordoba, Spain, [2]Reina Sofia Hospital, Spain, [3]Universidad De Cordoba, Cordoba 14012, [4]Cell Biology Department, University of Cordoba, Spain, [5]The Rayne Institute, St Thomas' Hospital, London, United Kingdom

Purpose: Antiphospholipid antibodies (aPL) are involved in the induction of a procoagulant state; yet, precise intracellular mechanisms are poorly understood.There is evidence for oxidative damage in plasma from antiphospholipid syndrome (APS) patients but oxidative stress markers and mitochondrial integrity of circulating APS leucocytes have not been studied yet.

Objectives: To investigate prooxidant/antioxidant status and mitochondrial membrane potential (MMP) in peripheral leucocytes from APS patients, and their association with a procoagulant state.

Methods: The study was conducted in 20 APS patients and 20 healthy donors. Cell surface tissue factor (TF) expression was analyzed by flow cytometry in monocytes. Oxidative stress biomarkers were analysed in purified white blood cells (WBCs): lymphocytes, monocytes and neutrophils. Peroxides, superoxide, MMP and intracellular GSH were analysed by flow cytometry with 2',7'-dichlorodihydrofluorescein diacetate, dihydroetidium, Rhodamine-123, and 5-chloromethylfluorescein diacetate respectively. Monocytes from normal individuals were treated with APS or control IgG to assess the effect of aPL on the oxidative/antioxidant status. Plasma NO, Nitro tyrosine (N-Tyr) and Total Antioxidant Capacity (TAC) were also measured. Correlations between ROS, MMP and TF expression were tested for statistical significance.

Results: Peroxides and superoxide levels were increased in APS monocytes and neutrophils (P=0.032 and P=0.042, respectively) and intracellular glutathione was significantly decreased (P=0.021). More APS monocytes and neutrophils contained depolarised mitochondria (P=0.004). MMP and peroxide levels showed a significant positive correlation with monocyte TF expression (r=0.814, P=0.094 and r=0.988, P=0.0015, respectively, Pearson analysis). Plasma TAC tended to a more pro-oxidant status in APS patients. A drift towards a reduction in NO and N-Tyr plasma levels was also observed. A marked increase in peroxides and superoxide (P=0.03 and P=0.042, respectively) and a

decrease of MMP and GSH (P=0.04 and P=0.01, respectively) was observed after a 6-h stimulation of monocytes with patientxs but not with control IgG.

Conclusion: A redox-sensitive pathway might play a central role in the elicitation of thrombotic events in APS. Our results further suggest a role for mitochondrial alterations in thrombosis development in APS. Induction of a prooxidant state by APS IgG represents a new pathway potentially contributing to thrombotic complications, which would provide alternative targets for therapeutic interventions. Supported by JA0042/2007-P08CVI04234.

1273

Is It Possible to Differentiate " Natural " Antiphospholipid Antibodies From "Thrombophilic" Ones? - Analysis of the Fine Specificity against the Domains of Beta2glycoprotein I. Angela Tincani[1], Laura Andreoli[1], Cecilia Nalli[1], Mario Motta[1], Gary L. Norman[2], Zakera Shums[2], Walter L. Binder[2], Monica Nuzzo[1], Micol Frassi[1], Andrea Lojacono[1], Tadej Avcin[3] and Pier Luigi Meroni[4], [1]University and Spedali Civili of Brescia, Brescia, Italy, [2]INOVA Diagnostics, Inc., San Diego, CA, [3]University Medical Center Ljubljana, Ljubljana, Slovenia, [4]University of Milan, Milan, Italy

Purpose: Anti-$\beta_2$glycoprotein I antibodies (a-β_2GPI) were demonstrated to be directly involved in the pathogenesis of the Antiphospholipid Syndrome (APS). However, they can be detected in asymptomatic patients, especially those affected by systemic autoimmune diseases (SAD). Healthy children may also display a-β_2GPI as a consequence of infections and nutritional exposure to β_2GPI, but they do not usually develop any thrombotic event. It has been suggested that a-β2GPI against domain 1 (D1) associate with thrombosis, while those recognizing domain 4/5 (D4/5) have been identified in non-thrombotic conditions. Aim of this study was to evaluate the fine specificity of a-β_2GPI in different groups of adults and infants. .

Method: The study included 39 one-year-old healthy children born to mothers with SAD (11 Primary APS, 9 SLE, 9 UCTD, 6 Sjögren, 3 MCTD, 1 RA; 33% out of these mothers were a-β_2GPI positive) and 33 children with Atopic Dermatitis (AD). The children of both groups were found positive at Routine a-β_2GPI. No thrombotic events were recorded in both one-year old and AD children.

As controls, 54 adult patients with APS (47 PAPS, 7 associated with SLE) and 5 children with paediatric APS were considered. All subjects were IgG a-β_2GPI pos at our routinely performed home-made ELISA assay. Sera were studied for IgG a-β_2GPI D1 and D4/5 using research ELISAs containing recombinant β_2GPI domain antigens. Cut-off values were calculated as the 95th percentile on 50 NHD.

Results: One-year-old children and AD children displayed a preferential reactivity for D4/5, whereas patients with APS, both adults and infants, were positive mainly for D1. Percentages are shown in the table.

	D1 + D4/5 -	D1 - D4/5 +	D1+ D4/5+
1-year-old children (n=39)	2.5%	33%	8%
AD (n=33)	15%	30%	3%
Adult APS (n=54)	61%	7.4%	3.7%
Paediatric APS (n=5)	50%	17%	0%

A good correlation was present between a-β_2GPI and anti-D4/5 in one-year-old children and DA ($r=0.85$, $r=0.88$; $p<0.01$), and anti-D1 in adult APS ($r=0.66$; $p<0.01$). This suggests that reactivity against a particular domain truly reflects the main specificity of the whole autoantibody population.

Conclusion: A-β_2GPI detected in healthy infants displayed preferential recognition for D4/5, in contrast to the prevalent specificity for D1 in subjects with APS. This could account for the "innocent" profile of natural antibodies against β_2GPI that may develop during infancy. Our study supports the hypothesis that different subpopulations of a-β_2GPI carry a different pathogenic potential.

1274

Do Clinically Relevant IgA-Anti-B2glycoprotein I (anti-B2GPI) Antibodies Bind to Domain IV/V of β2GPI? Laura Aline Martinez-Martinez[1], Renan Aguilar-Valenzuela[1], Alan M. Seif[1], Elizabeth Papalardo[1], Luis M. Vilá[2], Sabeen Najam[1], Terry A. McNearney[1], Emilio B. Gonzalez[1], Prashanth R. Sunkureddi[1], Walter L. Binder[3], John D. Reveille[4], Gary L. Norman[3], Zakera Shums[3], Graciela S. Alarcon[5] and Silvia S. Pierangeli[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [3]Inova Diagnostics, Inc., San Diego, CA, [4]University of Texas Medical School at Houston, Houston, TX, [5]University of Alabama, Birmingham, AL

Purpose: In vitro and in vivo studies have shown that "pathogenic" IgG anti-β_2GPI mainly recognize epitopes in domain I of the protein. Recently, it has been suggested that IgA anti-β_2GPI antibodies may recognize epitopes in domains IV/V of β_2GPI and these antibodies appear to be associated with certain manifestations of Antiphospholipid Syndrome (APS).

Objectives: a) To determine in patients previously found to be positive for IgA anti-β_2GPI whether: a) these antibodies bind to β_2GPI domain IV/V, and b) whether those antibodies are associated with clinical manifestations of APS.

Method: 80 IgA-anti-β_2GPI positive sera were selected from 588 SLE patients in a multi-ethnic, multi-center cohort (LUMINA); Similarly, 35 IgA anti-β_2GPI positive sera were obtained from 2188 patients that were referred to our reference laboratory (APLS) for APS work-up between Jan-2008 and May-2009 (Table 1). IgA anti-β_2GPI binding of the sera to domain IV/V of β_2GPI were examined by ELISA using prototype kits (INOVA Diagnostics, Inc.) A test was considered positive when values were above kit recommended cut-off points. Table 1.

Patients Characteristics	LUMINA cohort (%) (n=80)	APLS lab cohort (%) (n=35)
Females/Males	89/11	25/10
Mean age	35.3	42.6
SLE diagnosis	100	40
African American	46	29
Caucasian	14	34
Other ethnic groups	40	37

Results:

Group	# of samples positive for DIV/V IgA anti-β_2GPI/ (%)	# of samples positive for DIV/V IgA anti-β_2GPI with APS clinical manifestations/(%)
LUMINA (exclusively IgA	30(64%)	27(90%)

anti-β_2GPI positive) n=47		
LUMINA (IgA anti-β_2GPI and other aPL positive) n= 33	18(55%)	16(89%)
APLS (exclusively IgA anti-β_2GPI positive) n=21	5(24%)	2(40%)
APLS (IgA anti-β2GPI and other aPL positive) n=14	9(64%)	3(40%)
Total N=115	62(54%)	48(77%)

A total of 62 out of 115 IgA (54%) anti-β_2GPI positive samples were positive in domain IV/V assay and 77 % of those had clinical manifestations of APS that included: arterial and venous thromboses, pregnancy losses, other APS-related pregnancy complications, seizures, thrombocytopenia, skin ulcers, pulmonary hypertension, livedo reticularis, cardiac valvular disease, and migraines. Correlation of IgA anti-β_2GPI titers between the two kits was 0.69

Conclusion: IgA anti-β_2GPI antibodies that bind to domain IV/V of β_2GPI may represent an important subgroup of clinically-relevant aPL antibodies.

1275

Isolated Elevated Levels of IgA-Anti-Beta2glycoprotein I Antibodies Are Associated with Clinical Manifestations of the Antiphospholipid Syndrome. Renan Aguilar-Valenzuela[1], Alan M. Seif[1], Graciela S. Alarcon[2], Laura Aline Martinez-Martinez[1], Neha Dang[1], Elizabeth Papalardo[1], Jigna Liu[3], Luis M. Vila[4], Sabeen Najam[5], Terry A. McNearney[6], Emilio B. Gonzalez[7], Walter L. Binder[8], Marius C. Teodorescu[9], John D. Reveille[10] and Silvia S. Pierangeli[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Alabama, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Univ of PuertoRico Schl of Med, San Juan, PR, [5]League City, TX, [6]Univ of Texas Med Branch, Galveston, TX, [7]Univ of Texas Medical Branch, Galveston, TX, [8]Inova Diagnostics Inc, San Diego, CA, [9]TheraTest Laboratories Inc, Lombard, IL, [10]University of Texas Health Science Center Houston, Houston, TX

Purpose: Although IgA anticardiolipoin (aCL) antibodies are more frequently found in Afro-Caribbean populations - usually in association with other IgG and/or IgM aCL antibodies – and have been shown to be pathogenic in animal models, their clinical significance has remained elusive. We recently reported five isolated cases of exclusive IgA anti-β2GPI antibody sero-positivity with concomitant APS clinical manifestations. Objectives: a) to examine the prevalence of exclusive IgA-anti-β_2GPI antibody positivity in a large cohort of patients with SLE and in patients suspected of having APS; b) to correlate IgA anti-β_2GPI positivity with APS-associated clinical manifestations

Method: aPL seropositivity was examined in sera of 588 SLE patients from a multi-ethnic, multi-center cohort (LUMINA) and in 2108 sera from patients that were referred to our laboratory (APLS) for APS work-up between Jan-2008 and May-2009. aCL (IgG, IgM, IgA), aPL IgG and IgM, and IgG, IgM anti-β_2GPI antibodies were evaluated by ELISA [in-house method], and by commercial kits (Louisville APL Diagnostics, and INOVA Diagnostics, respectively). IgA anti-β_2GPI titers were determined in two commercial ELISA [INOVA, kit 1) and [Theratest (kit 2)].

Results:

Ethnic group	Prevalence IgA-anti-β_2GPI LUMINA cohort (%)	Prevalence IgA-anti-β_2GPI APLS cohort (%)
African American	47	36.4
Caucasian	17	27.3
Other	46	36.3

Thirty-six patients' samples from the LUMINA cohort and 23 from the APLS laboratory were positive exclusively for IgA-anti-β_2GPI. All the samples were positive for IgA-anti-β_2GPI antibodies in at least one kit. Correlation of IgA anti-β2 GPI titers between the two kits was 0.93. Sixty-nine % of the LUMINA subjects and 78% in the APLS group had at least one APS-related clinical manifestation that included: arterial and venous thromboses, pregnancy losses, other APS-related pregnancy complications, seizures, thrombocytopenia, skin ulcers, pulmonary hypertension, livedo reticularis, cardiac valvular disease, and migraines. One patient in each group was LAC positive.

Conclusion: This study supports the notion that elevated IgA anti-β_2GPI antibody titers may identify additional patients who have clinical features of APS but who do not meet current diagnostic criteria. It may be therefore recommended to test for IgA anti-β_2GPI antibodies when other aPL tests are negative and APS is suspected.

B2-Glycoprotein-I IgA Antibodies (a-b2GPI IgA Ab) but Not the IgG a-b2 and IgG a-Cardiolipin Listed in Sydney Criteria, Predispose to Vascular Events in Hispanics with SLE. George A. Karpouzas[1], Rosalinda C. Moran[1], Chasity Harris[1] and Bevra H. Hahn[2], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Antiphospholipid antibodies (APLs) have been commonly reported in Hispanic patients (pts) with SLE. Lupus anticoagulant (LA), IgM and IgG anticardiolipin (ACL) >40 MPL and GPL U/ml respectively, and a-b2GPI Ab>99th percentile, testing positive twice 12 weeks apart, have been proposed as laboratory diagnostic criteria of the antiphospholipid syndrome (APLS, Sydney-2006). IgA ACL and b2GPI Ab are not included in this classification, and their pathogenic role is less well defined. We examined the prevalence of different classes of APLs including a-b2GPI IgA in Hispanics with SLE, their association with thrombotic events, and the enrichment of individual APL subclasses in pts with thrombus compared to those without.

Methods: We reviewed the charts of 178 Hispanics with SLE from Mexico and Central America between 1/1997 and 6/2008. All fulfilled ≥4 1996 ACR criteria for SLE and had follow-up in a single center. All pts were tested at least twice 12 weeks apart. LA was tested with both aPTT and DRVVT. ACL and b2GPI Ab IgG, IgM, and IgA were tested using commercial ELISA kits (QUEST). ACL IgA>15 APL U/ml and a-b2GPI-IgA>10 U/ml were considered positive. Associations with clots were assessed using Fisher's exact test.

Results: Pts were predominantly female (87%) with mean age of 41±12 years, and largely indigent (84%). Only 5 pts (2.8%) had two positive APL confirmed twice 12 weeks apart, and 42 (23.6%) had at least one positive APL test (table 1). Clots occurred in 28 pts (15.7%): 17 were venous, 9 arterial and 2 glomerular. The presence of any APL more than once significantly increased the risk of thrombosis. LA was the most prevalent APL class (14%) and was significantly associated with thrombotic events (OR=14.8, CI=5.5-39.2, p<0.0001). Interestingly, anti-b2GPI IgA emerged as the 2nd most prevalent Ab (13.6%), also with significant contribution to clotting (OR=4.5, CI=1.6-12.5, p=0.006). Presence of other APL subclasses were overall low (<3%), with insignificant contribution to thrombus formation, except for ACL-IgM (table 1).

Conclusion: In this cohort of Mexican/Central American Hispanics with SLE in Los Angeles, LA was the most prevalent APL Ab and was significantly associated with thrombotic events. Unexpectedly, anti-b2GPI IgA emerged as a prevalent and significant contributor to thrombotic events. Other subclasses of a-b2 and a-CL were uncommon with overall trivial input. B2-GPI IgA Ab should therefore be routinely tested in Hispanic pts with SLE and the diagnosis of APLS entertained in positive pts with events.

Table 1: Patient Demographics

Detection of IgG/IgM Antibodies That Recognize Epitope Gly40-Arg43 in Domain I of Beta2GPI with An ELISA Assay: A New Perspective in Prediction of Thrombotic Manifestations in Antiphospholipid Syndrome? Valentina De Angelis[1], Gwendolyn Van Os[2], Francesca Pregnolato[3], Claudia Grossi[3], Cecilia B. Chighizola[1], Martina Biggioggero[1], Philip G. de Groot[2], Ron H.W.M. Derksen[2], Pier Luigi Meroni[1] and Rolf T. Urbanus[2], [1]University of Milan, Milano, Italy, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Istituto Auxologico Italiano, Milan, Italy

Purpose: Antiphospholipid antibodies (aPL), serological markers of the antiphospholipid syndrome (APS), are mainly directed against β2-glycoprotein I (b2GPI), a plasma protein with phospholipid binding properties. b2GPI consists of five complement control protein or 'sushi'

domains (designated I to V), that are arranged in an elongated, fish-hook shape. Although the location of epitopes recognized by aPL remains the subject of controversy, several studies suggest pathological aPL are directed against the Gly40-Arg43 epitope in domain I of β2GPI.

With this study we want to determine the specificity of assays that detect antibodies against domain I or domain IV of b2GPI for the diagnosis of APS, as well as their predictive value in the clinical outcome of the disease.

Method: We tested plasma or serum samples of 39 primary APS patients, who fulfilled the Sapporo criteria, 9 patients with APS secondary to autoimmune connective tissue disease, 6 asymptomatic aPL positive patients and 8 asymptomatic patients with autoimmune connective tissue disease. We determined the presence of aPL (lupus anticoagulants, anticardiolipin and anti-b2GPI antibodies), as well as serological markers for autoimmune connective tissue disease. Patients with paraproteinaemia (n=10), hypergammaglobulinaemia (n=10), infectious disease (n=22) such as HIV (n=4) or hepatitis B (n=3) and –C (n=15), and autoimmune diseases without aPL (n=35) were used as controls. IgG- and IgM anti-domain I and domain IV antibodies were detected with a home-made assay. Cut-off values were set at the 99th percentile of 50 healthy subjects.

Results: 52 patients with aPL were positive for IgG - and 31 for IgM- anti-b2GPI antibodies , of which 21 (40%) were positive for anti-DI IgG and 10 (32%) for IgM. Only 9 (17%) were positive for anti-DIV IgG with 10 (32%) positive for anti-DIV IgM. 70 % of the patients with anti-DI antibodies had thrombotic events in their clinical history. Anti-domain I and domain IV antibodies were only detected in patients with anti-β2GPI antibodies. None of the controls had anti-domain I or IV antibodies, but 5 samples were positive for IgM anti-domain IV.

Conclusion: APS samples display reactivity against epitopes in both domain I and domain IV of β2GPI. Anti-DI antibodies correlated with a clinical history of thrombotic manifestations

Moderate Versus High Titer Persistently Anticardiolipin Antibody Positive Patients: Are They Clinically Different? Medha Barbhaiya[1], Doruk Erkan[2], Diane George[3], Lisa R. Sammaritano[2] and Michael D. Lockshin[2], [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Yale School of Medicine, CT

Background: The association between antiphospholipid antibodies (aPL) and clinical events is stronger with higher anticardiolipin antibody (aCL) titers.

Purpose: To determine the clinical characteristics of persistently moderate-titer (40-79U) aCL-positive patients compared to those with persistently high (≥80U) aCL titers.

Method: In this cross sectional study, we compared the demographic, clinical, and aPL characteristics of 58 patients with at least two moderate-titer aCL-positive results to another 85 patients with at least two high-titer aCL results. The highest aCL was used in the analyses; in cases with multiple isotypes with the same titer, IgG isotype was chosen over IgM/A, and IgM was chosen over IgA. Categorical variables were compared using the chi-square test or Fisher's exact test when appropriate.

Results: Table demonstrates the demographic and clinical characteristics. High-titer aCL positive patients were more likely to have primary aPL/APS (relative risk [RR] 1.82, confidence interval [CI] 1.25-2.65, $p<0.01$) and positive LA test (RR 2.06, CI 1.38-3.08, $p<0.01$). Although aPL-related criteria (vascular and pregnancy) events were similar between the two aCL groups, the number of patients with at least one non-criteria aPL event was significantly higher in the high-titer aCL group (RR 1.66, CI 1.20-2.30, p: 0.0005). Magnetic resonance imaging (MRI) white matter changes were statistically more common in the high-titer aCL group (RR 2.03, CI 1.04-3.94, p: 0.02), and there was a trend towards increased prevalence of livedo reticularis, cardiac valve disease, and cognitive dysfunction occurring in the high-titer aCL group.

Conclusion: Our results suggest that patients with high aCL titers, compared to those with moderate titers, are more likely to have a positive LA test and a similar risk of aPL-related vascular and pregnancy events, but a higher prevalence of non-criteria aPL features.

Silent Ischemic Myocardial Disease in Antiphospholipid Syndrome. Karim Sacre, Benoit Brihaye, Fabien Hyafil, Jean-Pierre Laissy, Olivier Lidove and Thomas Papo, Bichat-Claude Bernard Hospital, University Paris-7, Paris, France

Purpose: To study prospectively the prevalence of subclinical ischemic myocardial disease in antiphospholipid syndrome (APS)

Method: Fifty four patients of our APS cohort satisfied the APS criteria proposed by the International Consensus Statement in 2006. Eight patients declined to participate to the study. Seven patients were excluded because of severe renal disease (5/7) or claustrophobia (2/7). On the 39 patients included, 24 have completed the study at the present time. Twenty-one had primary APS and 3 had APS associated with systemic lupus erythematosus. Following data were recorded: gender, ethnicity, hypertension, triglycerides, cholesterol, smoking, diabetes mellitus, body mass index, homocysteine, hormone replacement therapy/oral contraceptives and familial cardiovascular events. Electrocardiogram (EKG), transthoracic echocardiography and cardiac magnetic resonance imaging (MRI) using late gadolinium enhancement imaging were systematically performed the same day in all patients.

Results: Fifteen female and 9 male patients participated. The mean age was 44 years (range 19-78) and the mean duration of APS was 9 years (range 1-34). Cardiac MRI showed localised area of late gadolinium contrast enhancement (LGE) in 9 patients (LGE+). Of the 9 patients, 6/9 had LGE extending from the subendocardial region outward in the defined territory of a coronary artery and 3/9 had patchy LGE in a non-coronary artery distribution pattern. The remaining 15 patients had normal cardiac MRI (LGE-). Trans-thoracic echocardiography and EKG did not show myocardial changes in all cases. LGE+ patients (mean age: 61, range: 34-77) were older than LGE- (mean age: 33, range: 19-78) ($p=0.029$) and men seemed to be at significant risk for LGE (male: 6/9 LGL+ versus 3/15 LGL-, $p=0.029$). Other usual risk factors for atherosclerosis were not associated with LGE. Of the 24 patients, 2/9 LGE+ and 2/15 LGE- had a history of stroke, and 2/9 LGE+ and 1/15 LGE- had suffered peripheral arterial disease. Of the 9 LGE+ patients, 6 had no previous cardiac symptom and 3 had had acute myocardial infarction (AMI) documented on troponin rise and abnormalities on EKG. Interestingly, coronarography was normal in the 3 cases of AMI.

Conclusion: Cardiac MRI may detect silent infarcts in APS patients with normal electrocardiogram and trans-thoracic echocardiography.

1280

The Role of Antiphospholipid Syndrome-Related Features in the Development of Cardiovascular Events in Patients with Sjogren Syndrome. Marta Perez-de-Lis[1], Rafael Belenguer[2], Manuel Ramos-Casals[1], Pilar Brito-Zeron[1], Albert Bove[1], Candido Diaz-Lagares[1], Myriam Gandia[1], Antoni Siso[3] and Antonio Coca[4], [1]IDIBAPS, Hospital Clinic, Barcelona, Spain, [2]Hospital 9 d'Octubre, Valencia, Spain, [3]CAP Les Corts, Barcelona, Spain, [4]ICMiD, Hospital Clinic, Barcelona, Spain

Purpose: To investigate the association of the clinical, analytical and immunological features related to antiphospholipid syndrome (APS) with the development of cardiovascular events (CVE) in a large cohort of patients with primary Sjögren's syndrome (SS).

Method: Five hundred and five consecutive patients diagnosed with primary SS between 1980 and 2008 were evaluated (470 females and 35 males, mean age at diagnosis of 57 years). Outcomes measured were CVE (ischemic heart disease, cerebrovascular disease and peripheral arterial ischemia) and death.

Results: Sixty five (13%) patients developed a total of 78 CVE after a mean time of follow-up of 7.75 years. There were 57 (88%) females and 8 (12%) males, with a mean event age of 66.4 years (range 42-91) and a mean time of 4.7 years after primary SS diagnosis. Forty-five patients had ischemic heart disease, 29 had cerebrovascular disease and 4 peripheral arterial disease. Antiphospholipid antibodies (aPL) were detected in 9/26 (41%) patients with CDVE: lupus anticoagulant –LA- was found in 7 patients and anticardiolipin antibodies –aCL- in 4 patients (IgG in 4 and IgM in one). Three SS-CVE-aPL+ patients fulfilled the current classification criteria for APS and 4 had a probable APS (with thrombosis but with only one positive aPL determination in serial measurements). All patients but two had concomitant traditional cardiovascular risk factors. Six (86%) out of the 7 SS-CVE-LA+ patients had stroke and 4 (57%) myocardial infarction.

Conclusion: Nearly half the patients with primary SS and cardiovascular events tested for aPL had positive results, with a close association between LA and stroke/myocardial infarction. We recommend testing for antiphospholipid antibodies in patients with primary SS and cardiovascular events even if patients have concomitant traditional cardiovascular risk factors.

Disclosure: M. Perez-de-Lis, None; **R. Belenguer**, None; **M. Ramos-Casals**, None; **P. Brito-Zeron**, None; **A. Bove**, None; **C. Diaz-Lagares**, None; **M. Gandia**, None; **A. Siso**, None; **A. Coca**, None.

1281

Cardiovascular and Stroke Risk in Patients with Antiphospholipid Syndrome and Renal Artery Stenosis. Marina Zakalka[1], Shirish.R Sangle[2] and David P. D'Cruz[1], [1]Lupus Research Unit, The Rayne Institute, St Thomas' Hospital, London, United Kingdom, [2]The Lupus Research Unit, The Rayne Institute, St Thomas' Hospital, London, United Kingdom

Purpose: We have demonstrated increased arterial stiffness by carotid-femoral pulse wave velocity (PWV_{CF}), digital volume pulse contour analysis stiffness index (SI_{DVP}) and by ankle brachial pressure index (ABPI) in patients with APS and renal artery stenosis (RAS) (APS+RAS) compared with 3 control groups. Aim of this is to determine 10-yr predicted coronary heart disease (CHD) and stroke risks in patients with APS+RAS and 3 control groups.

Method: We recruited 17 Caucasian patients with APS+RAS, with positive antiphospholipid antibodies on more than two occasions and uni- or bilateral RAS on imaging. All had treated hypertension (defined as BP>140/90). The control groups were: 18 women with PAPS thrombosis; 18 women with SLE, negative for aPL (SLE, aPL-ve) and 15 matched healthy women (HC). After informed consent, cardiovascular risk factors, physical activity, disease-related variables and fasting blood specimens were collected. 10-yr predicted coronary heart disease (CHD) and stroke risk scores were calculated with The Joint Societies' Cardiac Risk Assessor program. Physical activity scores were estimated for all study subjects; in SLE patients, SLEDAI disease activity and SLICC damage index were recorded.

Results: Framingham cardiovascular risk profiles did not differ between groups. 10-yr predicted CHD and stroke risk scores were significantly higher in the APS+RAS group versus PAPS patients ($p<0.001$ and $p=0.004$), versus SLE, aPL-ve patients ($p=0.006$ and $p=0.030$) and HC ($p<0.001$ and $p=0.002$) respectively. In the APS+RAS group $\ln PWV_{CF}$ was significantly increased (10.95±5.7m/s) compared to HC (7.61±1.5m/s) ($p=0.006$) and mean ABPI was significantly lower (1.15±0.18mmHg) compared to HC (1.245±0.13mmHg) ($p=0.031$).

Mean SLEDAI of the 10 SLE, APS+RAS patients was 4.6 (2.8) compared to 2.7 (3.2) in the 18 SLE, aPL-ve patients. Median SLICC damage index of the former group was 2.5(IQR: 1-4) and 0.5(IQR: 0-2) in the latter.

In the disease subjects as a group, 10-yr predicted CHD risk score correlated with PWV_{CF} ($r=0.51$, $p<0.01$) and SI_{DVP} ($r=0.53$, $p<0.01$). 10-yr predicted stroke risk score correlated with PWV_{CF} ($r=0.6$, $p<0.01$) and SI_{DVP} ($r=0.53$, $p<0.01$). PWV_{CF} correlated with SI_{DVP} ($r=0.3$, $p=0.031$). ABPI inversely correlated with SI_{DVP} ($r=-0.3$, $p=0.047$). ABPI and physical activity index score were correlated in APS+RAS patients ($r=0.589$, $p=0.016$), in PAPS patients ($r=0.620$, $p=0.008$) and in SLE, aPL-ve patients ($r=0.495$, $p=0.043$).

PWV_{CF} correlated with the SLICC damage index in the 10 SLE, APS+RAS patients ($r=0.640$, $p=0.046$), ABPI correlated with disease duration in the APS+RAS group ($r=0.0519$, $p=0.033$). ABPI correlated inversely with disease duration in PAPS patients ($r=-0.490$, $p=0.046$).

Conclusion: APS+RAS patients had a worse cardiovascular and stroke risk profile than PAPS and SLE patients implying a role for a vasculopathy. Arterial stiffness may be a valuable tool with traditional cardiovascular risk factors in the assessment of APS patients.

1282

Hematologic Manifestations Among Patients Who Fulfill the Sidney Laboratory Criteria for Antiphospholipid Syndrome: a 6 Year Follow-up. Lucía Comellas-Kirkerup[1], Antonio R. Cabral[1] and Gabriela Hernandez-Molina[2], [1]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico city, Mexico

Purpose: To study patients with thrombocytopenia (TP), hemolytic anemia (HA) or both who meet the antiphospholipid syndrome (APS) Sidney laboratory criteria but do or not fulfill the clinical criteria.

Methods: We reviewed the medical charts of 187 patients with primary APS from our patient's Registry (Jan 1986- Dec 2008) and selected those who met the following criteria: a) 2 or more positive determinations of anti-phospholipid antibodies (aPL) according to the Sidney criteria and b) thrombocytopenia (PLTs <100,000 µl) or HA (Coombs+, corrected reticulocyte count >2%, elevated indirect billirrubin and

LDH) or Evans´ syndrome (ES). Patients with SLE and/or positive anti-dsDNA (ELISA) were excluded. Age at onset, follow-up until last medical appointment (LMA), treatment and clinical APS status were assessed. We defined response to treatment (RT) as PLTs ≥100,000 µl at LMA if basal PLTs were >50,000 µl, or PLTs >50,000 µl at LMA if basal PLTs were ≤50,000 µl; and for HA hemoglobin >10 mg/dl in the absence of hemolysis. Relapse was considered when the RT (any point at follow-up) could not be maintained. We used X^2, Student *t* test or U-Mann Whitney test (SPSS).

Results: Fifty-five patients (44 women) met the inclusion criteria, mean age at disease onset 40 ± 12 years with a median follow-up of 5.8 years (0.12-23). Thirty-five had TP, 14 HA and 6 ES. Twenty-five patients (45%) also met one Sidney clinical criteria: 13 thrombosis and 12 pregnancy morbidity. In 4 patients (16%) the hemocytopenia and the clinical criteria started simultaneously, in 6 (24%) the hemocytopenia preceded the obstetric or thrombotic manifestation (3 years (0.5-12)) whereas in 15 patients (60%) the hematological event presented 4.4 years later (0-34). Thirty patients did not develop thrombosis or pregnancy morbidity during follow-up (16 TP, 8 HA, 1 ES). No significant difference was found in the prevalence of aCL and anti-β-$_2$GPI in patients with or without the clinical criteria for APS. A higher prevalence of lupus anticoagulant (LA) (56% vs. 30%, p=0.02) as well as the combination of aCL+LA was found in patients with the clinical criteria for APS (73% vs. 33%, p=0.01; OR=5.6, 95% CI 1.5- 20.4). There were no differences in age, type of hemocytopenia, use of prednisone (83% vs. 76%), immunosuppressive drugs (56 vs. 66%), aspirin (80%), splenectomy (32% vs. 26%), RT at LMA (96% vs. 86%), relapses (52% vs. 46%), basal PLTs and hemoglobin in patients with and without clinical APS.

Conclusion: Hemocytopenia may antedate or follow the accepted clinical criteria for APS. There seems to be no difference at its presentation and RT regardless of the clinical APS status. LA alone or in combination with aCL associates with clinical APS. We are tempted to suggest that aPL associated with hemocytopenia are pathogenically different from those associated with thrombosis.

1283

Longterm Follow-up of ASA/P Trial Participants: No Evidence of Thrombotic Sequelae 20 Years After Anti-Phospholipid-Associated Recurrent Pregnancy Loss. Christine A. Clark[1], Karen A. Spitzer[1] and Carl A. Laskin[2], [1]University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, [2]Mt. Sinai Hosp, Toronto, ON

Purpose: ASA/P (1988-94) was a double-blind, controlled, randomized therapeutic trial of 202 women with a history of recurrent pregnancy loss (RPL) with or without antiphospholipid antibodies (aPL). The study found no difference in live birth rates between treatment with either aspirin and prednisone (ASA/P) or placebo, between a history of early vs late losses, or between aPL positive or negative patients. Others have reported increased rates of thrombotic events (TE) and development of the antiphospholipid syndrome (APS) in this patient population in longterm followup studies 1-12 years after pregnancy loss accompanied by aPL. We wanted to determine the incidence of subsequent TE and APS in our longterm followup cohort.

Method: All participants in the ASA/P trial were sent questionnaires in 2008-09 that included a series of self-report yes/no questions based upon the clinical classification criteria for SLE/APS. We also requested information regarding subsequent pregnancies, medications currently being taken, and medical specialists currently being seen.

Results: Forty (19.8%) patients were considered lost to followup after their questionnaires were “returned-to-sender” and further attempts to update contact information failed. Fifty-five completed questionnaires were received (34.0% response rate). Median age of respondents: 51 (range 42-57); median years since trial participation: 17 (range 14-20). When comparing respondents to the original trial participants, 52% of respondents had received ASA/P, 67% had a live birth in the trial, and 51% were aPL-positive, not significantly different from the group as a whole. Twenty-three women had 34 subsequent pregnancies resulting in 22 live births, 10 early losses, 1 stillbirth, and 1 ectopic pregnancy (18/23 women had at least 1 live birth in the interval since trial participation). There have been no TE and no one has been diagnosed with APS.

Conclusion: The group of 55 women who responded to our followup questionnaire 14-20 years after participating in the ASA/P trial was representative of the original study cohort. In contrast to other longterm followups of patients with RPL and aPL, none of our respondents reported any TE and none has been diagnosed with APS. These results suggest that RPL, even in the context of aPL, is neither associated with nor predictive of the development of subsequent TE even as long as 20 years after initial presentation.

Efficacy and Safety of Long Term Low Molecular Weight Heparin in Antiphospholipid Patients. Jose Vargas, Shirish.R Sangle, Oier A. Barrutia, David P. D'Cruz and Munther A. Khamashta, Lupus Research Unit, The Rayne Institute, St Thomas' Hospital, London, United Kingdom

Purpose: Main objective of this study was to assess both the efficacy and safety of long term Loe molecular weight heparin (LMWH) in patients with antiphospholipid syndrome (APS) that had not previously responded to and/or tolerated Warfarin.

Method: We retrospectively recruited 23 APS patients (22 women) with confirmed (Sapporo Criteria) diagnosis of APS. Patients with primary and APS associated other autoimmune disorders were included in this study. All patients had one or more thrombotic events. All patients were switched to LMWH on account of bleeding, intolerance and /or no response to warfarin therapy. Cardiovascular risk factors and the reasons for switching to LMWH and duration of LMWH treatment was noted. The main outcome was thrombotic events on LMWH. Adverse events such as heparin induced thrombocytopenia (HITS), osteoporosis and bleeding were recorded.

Results: The median age of patients was 42 (26- 67). Eleven patients (47.8%), had Systemic Lupus Erythematosus (SLE), 1 (4.3%) Sjögren syndrome and 1 had (4.3%). Behçet's disease. Other patients had primary APS. Three patients (13%) had arterial thrombosis, 6 (26%) venous thrombosis, 4 (17.4%) had both. 4 were anticoagulated due to cognitive dysfunction and had high density (ischemic) lesions in the brain on Magnetic Resonance Imaging. Five patients had pregnancy morbidity and thrombotic events (2 arterial). Seventeen (73.9%) did not have any cardiovascular risk factors, 2 (8.7%), hypertension, 2 (8.7%) diabetes mellitus and 2 (8.7%). were active smokers. Four (17.4%) received calcium and vitamin D supplements, 6 (26%) on calcium, vitamin D and bisphosphonates and 13 (56.5%) were not on any bone-protective-drug.. atients were switched to LMWH from warfarin due to - 9 (39.1%) no improvement in neurological manifestations, 6 (26%) major bleeding, 4 (17.4%) skin lesions and 2 (8.7%) preference of the patients. The average duration of the LMWH treatment was 44 months (14 – 216). Sixteen (59%) patients received Enoxaparin, 5 (22%) Dalteparin and Tinzaparin 2 (8.7%). Twenty patients remained without any thrombtic events, 3 (13%). had re-thrombosis with no clinical improvement. Osteoporosis, (confirmed by DEXA scan), was reported in 5 (21.7%) who had received corticosteroid treatment previously.

Conclusion: Long term LMWH may be a safe and efficient alternative to warfarin who could not tolerate and/or reluctant to take warfarin.

Primary Prevention of Thrombosis in Antiphospholipid Antibodies Positive Patients: A Prospective, Multicenter, Randomised, Open Trial Comparing Low Dose Aspirin with Low Dose Aspirin Plus Low Intensity Oral Anticoagulation. Mj. Cuadrado[1], ML. Bertolaccini[1], P. Seed[1], M. Tektonidou[2], A. Aguirre[3], L. Mico[4], C. Gordon[5], G. Ruiz-Irastorza[6], A. Gil[7], G. Espinosa[8], F. Houssiau[9], A. Rahman[10], H. Martin[11], M. Galindo[12], MC Amigo[13] and MA Khamashta[1], [1]St Thomas Hospital, London, United Kingdom, [2]University of Athens, Athens, Greece, [3]Hospital Reina Sofia, Spain, [4]Hospital La Fe, Spain, [5]University of Birmingham, United Kingdom, [6]Universidad del País Vasco, Bizkaia, Spain, [7]Hospital La Paz, Spain, [8]Hospital Clinic, Barcelona, Spain, [9]Universite Catholique Louvain, Brussels, Belgium, [10]University College London, England, [11]Hospital de Alcorcon, Spain, [12]Hospital 12 de Octubre, Madrid, Spain, [13]ABC Medical Center, Mexico City,

Purpose: Antiphospholipid antibodies (aPL) has been closely associated with the development of thrombosis. The optimal treatment to prevent the first thrombosis in these patients is controversial. Our aims were**:** 1) To compare the efficacy and safety of low dose aspirin (75mg) with low-dose aspirin plus low-intensity oral anticoagulation (INR-1.5) in the primary prevention of thrombosis. 2) To investigate the contribution of traditional risk factors to the development of thrombosis.

Methods: It is a multicentre, randomised, open controlled trial. One hundred sixty six patients with aPL were assigned to one of the 2 groups of treatment: low dose aspirin (75mg daily) [LDA] or low dose aspirin + warfarin (INR-1.5) [LDA+W]. Allocation to treatment groups was performed randomly, using a minimisation protocol. The sample size required was 1,000 patients. Inclusion criteria were a) the presence of

aPL (medium/ high titres of aCL and/or LA on at least two occasions) b) Four or more ACR classification criteria for SLE and/or obstetric criteria for the classification of APS. Patients meeting the inclusion criteria who declined randomisation were followed-up in an observational arm. Clinical events, conventional risk factors for thrombosis, serological changes in aPL and medication side effects were collected. Duration of treatment was between 1-5 years. The primary outcome measure was time to thrombosis.

Results: Eighty-two patients were randomised to LDA and 84 to LDA+W. Sixty six patients were included in the observational arm. There were no differences in the number of thrombotic events between patients treated with LDA (4/82) or LDA+W (4/84). The incidence of thrombotic events in the randomised patients was 1.76 events/100 person-years at risk and in the observational arm was 4.9 events/.100 person-years at risk (7/66). There were no demographic, clinical or serological differences between both groups.

None of the clinical or biological markers analysed appeared to predict thrombosis in our study.

Side effects for both drugs were: gastrointestinal symptoms in LDA group (n=4). In the LDA+W group, 11 patients suffered minor episodes of bleeding (1 nasal and 10 menorrhagia).

Conclusion: The sample size required to find statistical differences between the two groups was not achieved. With the number of patients included, there were no differences in the number of thrombotic events between patients treated with LDA vs patients treated with LDA+W. We could not identify predictive markers of thrombosis in this population

Autoimmune Diseases Pregnancy Clinic: A Three Year Experience. Cristina Martinez-Dubois[1], Marcos Lopez-Hoyos Sr.[1], Rafael del Barrio Sr.[1], Lorena Alvarez-Rodriguez[2], Mario Agudo Sr.[2], Javier Rueda Sr.[1], Ricardo Blanco Sr.[1], Vicente Rodriguez-Valverde[1] and Victor M. Martinez-Taboada Sr.[2], [1]Hospital Universitario Marques de Valdecilla-IFIMAV, Santander, Spain, [2]Hospital Universitario Marques de Valdecilla, Santander, Spain

Purpose: Women with systemic autoimmune diseases face significant risks during the pregnancy, but the control of these patients in a multidisciplinary setting can improve outcome for women and their babies. The aim of the present study is to describe the 3 year experience of a multidisciplinary clinic at a university hospital

Method: We collected data from patients referred to our autoimmune diseases pregnancy clinic (ADPC) because of suspicion of an autoimmune disease and pregnancy.

Results: The mean age of the patients was 31.8±5.6 years. Patients were mainly referred from the Obstetrics (49%) and Rheumatology departments (16%). After evaluation, patients were divided in several groups: a) Antiphospholipid syndrome (APS): 43 patients (32%); b) serological positive anti-phospholipid antibodies (APL) without fulfilling APS criteria: 30 patients (22%); c) suggestive clinical picture without APL confirmation in 17 (13%); d) patients with other autoimmune conditions different from APS (including 10% of SLE); e) coagulopathies (6%), and f) no evidence of disease in 42 (32%). Isolated obstetric pathology was observed in 71.2% of the patients, whereas 8.3% had associated thrombotic episodes and 2.3% thrombopenia. The most frequent reason for referral were early pregnancy loss (< 10 weeks) in 52.7% and late pregnancy loss (>10 weeks) in 28%, although in one third of the patients there were more than one manifestation. With regard to APL, isolated anti-cardiolipin antibodies were found in 26.1% of patients, isolated anti-beta 2 glycoprotein I in 13.6%, and isolated lupus anticoagulant in 4%. The combination of the three types of APL at the same time was only found in 7.2% of patients. Overall, 92% of the patients were treated with aspirin, and in 38.1% it was combined with low-weight molecular heparin. Only a minority of the patients received other treatments: antimalarials (9.3%), corticosteroids (5%) or azathioprine (2.8%). During the 3-year period a total of 139 pregnancies (133 patients) were followed and treated in our unit. 85. 6% of these pregnancies ended in a successful delivery. Previously, these patients had a total of 257 pregnancies with a 25.7% of successful deliveries.

Conclusion: The experience of our ADPC supports the utility of dedicated clinics in the management of autoimmune diseases during pregnancy. APS is the most frequent disease attended in this type of unit. In this setting, the frequency of seronegative and serological but not clinical APS is rather high and these subtypes of patients not fulfilling the Sidney criteria must be taken into account.

Biology and pathology of bone and joint

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1287

Activation of the EphB4 Receptor by Its Specific Ligand Ephrin B2 Positively Impacts Human Osteoarthritic Chondrocytes. Steeve Kwan Tat[1], Jean-Pierre Pelletier[1], Nathalie Amiable[1], Christelle Boileau[1], Martin Lavigne[2] and Johanne Martel-Pelletier[1], [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]Department of Orthopaedic Surgery, Maisonneuve-Rosemont Hospital, Montreal, Quebec, Canada

Purpose: We recently showed that treatment of human osteoarthritic (OA) subchondral bone osteoblasts by a member of the ephrin system, ephrin B2, inhibits the abnormal resorptive properties of these cells. Hence, we further investigated the possible implication of this ephrin and activation of its specific receptor EphB4 on the catabolic/anabolic activities of human OA chondrocytes.

Method: Ephrin B2 and EphB4 receptor levels were determined by quantitative PCR and immunohistochemistry, and the effects of ephrin B2 by the expression/production of factors involved in the OA process. siRNA was used to investigate the ephrin B2 activation of EphB4 receptors.

Results: Ephrin B2 and EphB4 receptors are expressed and produced by human normal and OA chondrocytes. Ephrin B2 protein levels were similar in both cartilage types, whereas EphB4 receptor expression ($p<0.0001$) and production ($p<0.01$) levels were significantly increased in OA chondrocytes/cartilage. Ephrin B2 treatment significantly inhibited the IL-1β, IL-6, MMP-1, MMP-9, MMP-13, and PAR-2 expression levels, whereas MMP-2 was unaffected, and significantly increased collagen type II. It also markedly inhibited the IL-1β stimulated protein production of IL-6, MMP-1 and MMP-13. Moreover, data revealed that silencing the EphB4 receptor gene abolished the effects of ephrin B2, confirming that these effects are mediated by EphB4 receptors.

Conclusion: Our study is the first to provide data on the presence and role of ephrin B2/EphB4 receptors in human chondrocytes/cartilage. Activation of the EphB4 receptor by ephrin B2 positively impacts the abnormal metabolism of OA cartilage by inhibiting important catabolic factors involved in this disease while increasing anabolic activity.

Quantification of Cells Expressing Mesenchymal Stem Cell Markers in Synovial Membranes and Osteoarthritic Cartilage Repair. Tamara Hermida-Gomez[1], Isaac Fuentes[2], Silvia Diaz-Prado[2], Mª Carmen Arufe[2], Maria Jose Sanchez-Dopico[1], Francisco Javier de Toro[1] and Francisco Javier Blanco[1], [1]INIBIC - Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [2]INIBIC - University of A Coruña, A Coruña, Spain

Purpose: Mesenchymal stem cells (MSCs) have been identified in human synovial membrane and articular cartilage from patients with osteoarthritis (OA). However, detailed quantification studies of MSCs in synovial membranes were not performed. The purpose of this study was to quantitatively measure the expression of stem cells markers in synovial membranes from human health and OA joints and in OA cartilage repair.

Methods: The co-expression of CD44, CD90, CD105 and CD271 was determined by immunofluorescence in health and OA synovial membranes and spontaneous cartilage repair. Synovial membrane-derived cells were isolated from health and OA joints and characterized by flow cytometry for hematopoietic (CD34 and CD45) and mesenchymal (CD44, CD29, CD73, CD90, CD105, CD117 and CD271) markers,

and for differentiation experiments (chondrogenesis, adipogenesis and osteogenesis). Chondrogenesis was assessed by staining for proteoglycans and type II collagen, adipogenesis by using a stain for lipid drops and osteogenesis by detecting calcium deposits.

Results: The number of cells expressing MSCs markers was higher in OA synovial membranes than in synovia from health joints, corresponding the highest percentage of cellular expression to the co-expression of CD90/CD271 (9.8% vs. 2.6%) (Fig 1). Spontaneous repair tissue contained cells positive for CD44 (12.3%), CD90 (10.4%) and CD271 (9.9%) antigens, but the CD105 antigen was absent (Fig 2). Cells positive for MSC markers were diffusely distributed in OA synovial membranes. In health synovia, these cells were localized in the subintimal zone. More than 90% of OA synovial membrane-derived cells were positive for CD44, CD73, and CD90 and negative for CD34 and CD45. OA synovial membrane-derived cells were also positive for CD29 (85.23%), CD117 (72.35%) and CD105 (45.5%). Micropellet analyses showed that culture of the cells with TGF-beta3 stimulated proteoglycan and type II collagen synthesis. Synovial membrane-derived cells culture developed lipid droplets in adipogenic medium and calcification in osteogenic medium.

Conclusion: These results suggest that during the OA process an increment of cells expressing MSCs markers percentage occur in synovial membrane. Absent expression of the CD105 antigen in the OA cartilage repair indicates that cells expressing this marker may be necessary for effective repair processes in OA cartilage.

This study was supported by grants from Secretaría Xeral de I+D, Xunta de Galicia, FISCP03/00127 and FIS05/2495; Fundación Española de Reumatología.

1289

Molecular and Cellular Characterization of Different Populations of Mesenchymal Stem Cells During Chondrogenesis. Claudia Cicione[1], Silvia Diaz-Prado[2], Emma Muiños[1], Isaac Fuentes[2], Francisco Javier de Toro[1] and Francisco Javier Blanco[1], [1]INIBIC - Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [2]INIBIC - University of A Coruña, A Coruña, Spain

Purpose: Mesenchymal stem cells (MSCs) are considered as a promising candidate for cell-based therapy of damaged or degenerated cartilage. Bone marrow represents the most commonly used tissue source of adult MSCs. Bone marrow MSCs are multipotent cells, which can differentiate into different cell types (osteoblasts, adipocytes and chondrocytes). Understanding the potential of the cells and the molecular mechanisms underlying their differentiation should lead to innovative protocols for clinical applications. The aim of this study was to determine if there was an improvement of the chondrogenic potential, in hypoxic conditions, given by the separation of different populations of bone marrow MSCs.

Method: MSCs were isolated from BM stroma and were expanded in monolayer cultures. The subpopulation CD105+ was separated using a magnetic separator (MACS separation columns, Miltenyi Biotec). The three populations of MSCs (CD105+, CD105- and total BM) were differentiated towards chondrocytes using pellet-culture in hypoxic conditions. Chondrogenesis was studied at different intervals of time (0, 2, 4, 7, 14, 21, and 28 days) and differentiation was confirmed by histochemistry (Hematoxylin-Eosin, Massonxs Thrichome, Alcian Blue, Safranin O), immunohistochemistry (types II and I Collagens, and Aggrecan) and Real Time PCR (Sox2, Nanog, Oct3/4, CDH2, TNC, Sox9, Agg, Col I, Col II, Col X and RunX2).

Results: The gene expression analysis of the three populations highlighted some differences. As shown in the table, at the starting point, the stem cell phenotype markers (Sox2, Nanog and Oct3/4) showed higher expression levels in the CD105+ population. These markers remained expressed until day 28th, both in CD105+ and in CD105- populations, indicating that not all the stem cells were differentiated towards chondrocytes but some of them remained undifferentiated. After 21 days of differentiation, the expression levels of the cartilage specific marker Col II was higher in the total BM than CD105- and CD105+ populations. However, the expression level of Sox9 was higher in the CD105- population followed by the total BM.

Conclusion: In our experimental conditions, isolation of CD105+ and CD105- populations showed no improvement of chondrogenic potential regarding to the total BM population.

	0 day			21 day		
	Total BM	CD105+	CD105-	Total BM	CD105+	CD105-

Oral Treatment with a Brachystemma Calycinum D. Don Plant Extract Reduces Disease Symptoms and the Development of Cartilage Lesions in Experimental Dog Osteoarthritis: Inhibition of Protease Activated Receptor-2 (PAR-2). Christelle Boileau[1], Johanne Martel-Pelletier[1], Judith Caron[1], Frédéric Paré[1], Eric Troncy[2], Maxim Moreau[3] and Jean-Pierre Pelletier[1], [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]GREPAQ – Department of Veterinary Biomedicine, Faculty of Veterinary Medicine, University of Montreal, Saint-Hyacinthe, QC, [3]The Companion Animal Research Group, Department of Clinical Science, Faculty of Veterinary Medicine, University of Montreal, Saint-Hyacinthe, QC

Purpose: The aims of this study were to evaluate the effect of oral treatment with a whole plant extract of Brachystemma calycinum D. don (BCD) on the development of osteoarthritic (OA) lesions and symptoms in the experimental dog anterior cruciate ligament (ACL) transection model and to document its mechanism of action.

Method: OA was induced by sectioning the ACL of the right knee in crossbred dogs. There were two experimental groups (n = 6-7 dogs/group): placebo and BCD extract (200 mg/kg/day) given orally for 8 weeks. Macroscopic and histopathological evaluation of cartilage lesions and immunohistochemical analysis of cartilage to assess levels of iNOS, MMP-13, and protease activated receptor (PAR)-2 were done. A gait analysis of dogs was performed.

Results: Treatment with BCD reduced the severity (depth) ($p=0.04$) and histopathological score ($p<0.02$) of OA cartilage lesions. BCD treatment also significantly reduced the OA chondrocyte level of key inflammatory and catabolic factors (iNOS, $p=0.009$ and MMP-13, $p=0.003$) as well as the level of PAR-2 ($p=0.03$). Dogs treated with BCD showed significant improvement in peak vertical force measured at 8 weeks ($p<0.05$).

Conclusion: Treatment with BCD extract can exert a positive effect on the prevention of cartilage lesions induced by joint instability and improve joint function. This effect was associated with the inhibition of major catabolic and inflammatory mediators. This study is the first to demonstrate that a therapeutic intervention that can inhibit PAR-2 is associated with a disease-modifying OA effect.

Normal Intramembranous Bone Repair of Cortical Bone Defects in Mice with Osteoblast-Targeted Disruption of Glucocorticoid Signalling in Mice. Agnes Weber[1], Gang Li[1], Colin Dunstan[1], Frank Buttgereit[2], Markus Seibel[1] and Hong Zhou[1], [1]Bone Research Program, ANZAC Research Institute, The University of Sydney, Sydney, Australia, [2]Charite University Med-Berlin, Berlin, Germany

Purpose: Mechanisms by which glucocorticoids (GC) exert their effects on bone cells, particularly in the fracture healing process, are poorly understood. While GC at pharmacological doses have been shown to interfere with fracture repair the role of endogenous GC in bone healing has not been fully investigated.

Here we examined whether disruption of endogenous GC signalling in osteoblasts affects intramembranous fracture healing in an *in vivo* model of cortical defect repair.

Method: We employed a transgenic (tg) mouse model in which intracellular GC signalling was disrupted exclusively in mature osteoblasts and osteocytes through tg overexpression of 11ß-hydroxysteroid-dehydrogenase type 2 (11ßHSD2) under the control of a collagen type I promoter (Col2.3-11ßHSD2). Unicortical bone defects (Ø 0.8mm) were created in these tg mice (n= 36) and their wild-type (WT) littermates (n=34) using a drill on the anteromedial aspect of the left tibia. Fracture repair was assessed by microcomputed tomography (micro-CT) and histomorphometry at 1, 2, and 3 weeks post-fracture.

Results: Micro-CT images demonstrated the progression of defect repair. One week post-surgery, mineralized bone was present which increased in volume and density throughout week two. At week three, healing of the defect was nearly complete with the fracture site no longer indistinguishable from the surrounding cortical bone. Micro-CT analyses comparing WT and tg animals revealed similar amounts of newly formed bone (BV/TV) for the analyzable time-points at week one and two post-fracture ($p>0.05$). Moreover, histomorphometric analyses performed for all time-points demonstrated similar newly formed bone volume (BV/TV) in WT and tg animals ($p>0.05$). Accordingly, no statistical differences where found between the two groups of mice for the proportion of bone surface covered by osteoblasts (Ob.S/BS), osteoclast surfaces (Oc.S/BS) and osteoclast numbers (N.Oc./BS) at any post-surgical time point.

Conclusion: Our results suggest that osteoblast-targeted disruption of endogenous glucocorticoid signalling does not affect intramembranous fracture healing in a tibia defect repair model. However, it remains to be shown whether GC play a role in endochondral fracture healing.

Microrna-146 Inhibit Human Osteoclast Differentiation in Vitro. Tomoyuki Nakasa, Hayatoshi Shibuya, Takuya Niimoto, Masakazu Ishikawa and Mitsuo Ochi, Hiroshima University, Hiroshima City, Japan

Purpose: MicroRNAs (miRNAs) are a class of non-coding RNAs that regulate gene expression by translational inhibition and messenger RNAs degradation. Several microRNAs exhibit a tissue-specific or developmental stage–specific expression pattern and have been reported to be associated with human diseases. miRNA (miR)-146 was reported to highly express in rheumatoid arthritis (RA) synovium and peripheral blood mononuclear cells (PBMC), and inhibit the expression of IRAK 1 and TRAF6 by binding to the 3' UTR of their mRNAs. TRAF6 is the one of the important mediator in osteoclstogenesis, therefore, the aim of this study was to confirm whether over expression of miR-146 inhibit osteoclastogenesis in vitro.

Method: Human blood was collected from healthy volunteers, and PBMCs were isolated, and seeded in 96-well culture plates. The following day, double strand (ds) miR-146a was transfected into the cells in various concentrations and cultured for 3 weeks in the presence of macrophage colony stimulating factor (M-CSF) and TNFα. After 3 weeks, TRAP positive and multinuclear cells were counted, and pit formation assay was performed. At 3 days after transfection, the expression of PU-1, c-Jun, NFATc1 and TRAP were evaluated by real time PCR.

Results: The number of TRAP positive large multinucleated cell was significantly decreased by over expression of miR-146 in a dose dependent manner. Bone resorption on dentin slice could not be observed with ds miR-146 of concentration of 50nM (Figure 1). The expression of PU-1, c-Jun, NFATc1 and TRAP was significantly down regulated at 3 days after the transfection of miR-146a (Figure 2).

Conclusion: Our result indicated that miR-146 could inhibit TNFα mediated osteoclastogenesis from human PBMC in vitro, and miR-146 might be a novel therapeutic target for bone destruction of RA.

1293

IL-1 Stimulated Production of Chemokines, Aggrecanases and Tissue Inhibitors of Metalloproteinases Are Modulated by IL-4 in OA Chondrocytes. Elisa Assirelli[1], Paolo Dolzani[1], Eleonora Olivotto[1], Stefania Pagani[1], Lia Pulsatelli[1], Rosa M. Borzì[1], Marco Di Carlo[2], Andrea Facchini[3] and Riccardo Meliconi[3], [1]Istituto Ortopedico Rizzoli, Bologna, Italy, [2]Università di Bologna, Bologna, Italy, [3]Istituto Ortopedico Rizzoli and Università di Bologna, Bologna, Italy

Purpose: In osteoarthritis (OA), the final result of chondrocyte metabolic modification is the enhancement of cartilage matrix catabolism, not adequately counterbalanced by anabolic events. Interleukin-4 (IL-4)/interleukin-4 receptor (IL-4R) system has a pivotal role in chondrocyte anabolic response to mechanical stimulation which in turn is an essential condition to maintain cartilage homeostasis. Previous studies reported a modification of mechanotrasduction response in OA chondrocytes suggesting an impaired efficacy of the IL-4/IL-4R system protective effect and underline the importance of disordered mechanical signalling in cartilage breakdown pathways.

We aim to investigate chondrocyte response induced by IL-4/IL-4R system**,** focusing on modulation of peculiar pathways involved in cartilage breakdown.

Method: Articular cartilage specimens were obtained from OA patients undergoing joint replacement surgery. Chondrocytes were isolated from articular cartilage by sequential enzymatic digestion. Chondrocyte micromass and hyperconfluent cultures were set up with IL-4 alone or with pro-inflammatory (IL-1). RNA were extracted from chondrocytes cultured in described conditions and real time PCR analysis were performed. mRNA expression of chemokines (IL-8/CXCL8, GROalpha/CXCL1, IP-10/CXCL10, RANTES/CCL5, MIP-1alpha/CCL3, MIP-1beta/CCL4), matrix degrading enzymes (metalloprotease-13/MMP-13, aggrecanases ADAMTS-4 and ADAMTS-5) and tissue inhibitors of metalloproteinases (TIMP-1, -3, -4) were investigated. Culture supernatants were analysed for chemokine production, IL-8, GROalpha, RANTES, by enzyme-linked immuno-sorbent assay (ELISA).

Results: Data obtained from mRNA modulation analysis of chemokine production by OA chondrocyte cultures showed that IL-4 presence significantly inhibits RANTES, MIP-1alpha, MIP-1beta and IP-10 mRNA expression induced by IL-1. On the other hand, IL-4 did not affect GROalpha and IL-8 mRNA expression induced by IL-1. ELISA quantification of IL-8, GROalpha and RANTES production showed an overlapping pattern to corresponding mRNA expression. mRNA modulation analysis of matrix degrading enzymes and their inhibitors shows that IL-4 down modulated also MMP-13 (confirmed by ELISA measurement of the protein), ADAMTS-4, -5 and TIMP-3, -4 mRNA expression induced by IL-1. On the contrary, TIMP-1 mRNA expression does not appear to be modulated either by IL-1 or by IL-4.

Conclusion: These data underline the complexity of IL-4/IL-4R activity and suggest the involvement of multiple signal transduction pathways of cellular response.

Inhibition of Osteoclastogenesis by Mesenchymal Stem Cells (MSCs): Potential Role of MSCs for the Treatment of Rheumatoid Arthritis. Koichi Oshita, Kunihiro Yamaoka, Keisuke Maeshima, Shigeru Iwata, Sonosuke Yukawa, Shunsuke Fukuyo, Koshiro Sonomoto and Yoshiya Tanaka, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background: Mesenchymal stem cells (MSCs) are multipotent cells that are able to differentiate into various cell lineages including osteoblasts, chondrocytes, and adipocytes. Recently, MSCs were shown to possess immunosuppressive effects on activated T cells and dendritic cells *in vitro*. In relation with this immunosuppressive capacity, MSCs have been reported to prevent the development of arthritis and the progression of bone destruction in collagen-induced arthritis mice. Based on these notions, we considered the possibility of utilizing MSCs as a new choice of therapy against rheumatoid arthritis (RA).

Purpose: Aim of this study was to elucidate the effects of human MSCs on differentiation and function of osteoclasts.

Method: Human MSCs was purchased from Lonza Walkersville, Inc. Peripheral blood mononuclear cells (PBMCs) from healthy donors were cultured in osteoclast-induction medium (OIM) (M-CSF 50 ng/mL, soluble RANKL 50 ng/mL and $1,25(OH)_2D3$ 100 nmol/L) to obtain osteoclast-like cells. In co-culture experiments, cells were cultured under contact-free condition using Transwell® plate. Multi-nuclear cells positive for TRAP-staining were counted under the microscope as osteoclast-like cells.

Results: When PBMCs were co-cultured with either MSCs or condition medium derived from MSCs for 16 days, number of osteoclast-like cells markedly decreased. Osteoprotegerin (OPG), a decoy receptor for RANKL, was produced by MSCs in a time-dependent manner by co-culture with PBMCs. Accordingly, addition of anti-OPG antibody to co-culture system inhibited osteoclastogenesis. Expression of cathepsin K, a protease necessary for bone resorption, was found to be decreased in co-culture of PBMCs and MSCs. Conditioned medium obtained from MSCs also reduced production of cathepsin K from PBMCs.

Conclusion: We have shown here that OPG can be produced by MSCs and its production can be dramatically enhanced by co-culture with PBMCs in a cell-cell contact free condition, which resulted in a decreased osteoclastogenesis and cathepsin K expression in osteoclast-like cells. Previously, it has been suggested that MSCs can be immunosuppressive. Therefore, we propose here that MSCs has a possibility to open a new category of an anti-rheumatic therapy not only by its immunosuppressive effect but also inhibiting osteoclastogenesis, leading suppression of bone resorption and osteoporosis due to disease activity.

Mitochondrial Respiratory Dysfunction Regulates the Metalloproteinases Expression in Human Normal Chondrocytes in Culture. Berta Cillero-Pastor, Ignacio Rego, Beatriz Lema, María J. López-Armada and Francisco J. Blanco, Osteoarticular and Aging Research Laboratory. INIBIC-Hospital Universitario A Coruña, Coruña, Spain

Purpose: Alteration of the mitochondrial respiratory complexes III and V contribute to the chondrocyte inflammation. In this study, we investigated the relationship between the dysfunction of MRC and the modulation of MMPs in human normal chondrocytes in culture.

Method: Human normal chondrocytes were isolated from cartilage obtained from autopsies without history of joint disease. Rotenone, NPA, antimycin A (AA), azide and oligomycin were employed to inhibit the mitochondrial complexes I, II, III, IV and V, respectively. MMPs -1, -3 and -13 mRNA expression was studied by real time PCR. Intracellular protein expression was evaluated by western blot as well as by inmunohystochemistry. Levels of MMPs and Proteoglican (PGs) in supernatant were analyzed by ELISA and alcian blue studies respectively.

Results: From all tested MRC inhibitors only AA and oligomycin modulated the MMPs expression: Oligomycin 5 µg/ml at 24 hours induced the expression of MMP-1 (68.10±39.9 vs. basal =1) and MMP-3 (60.13±29.7 vs. basal =1). In contrast, mRNA expression of MMP-13 decreased after treatment with AA 20 µg/ml (0.34±0.2) and oligomycin (0.67±0.3) vs. basal=1. Oligomycin 25 µg/ml for 36 h increased in the supernatants the levels of MMP-1 (18.06±10.35) and MMP-3 (8.49±4.32) vs basal=1 (n=5; $p<0.05$). However, MMP-13 levels in the supernatants decreased after treatment of chondrocytes with AA 40 µg/ml (0.63±0.13 vs. basal=1) and oligomycin 25 µg/ml (0.41±0.14 vs. basal=1); (n=5; $p<0.05$). These results were reproduced after the stimulation of tissue explants with oligomycin and AA. Alcian blue stain, showed a loose of PGs in tissues that were incubated with oligomycin.

Conclusion: These results show that the dysfunction of MRC modulates the MMPs expression in human normal chondrocytes.

1296

Adenosine Inhibits RANKL-Induced Osteoclastogenesis in Vitro. Elise Soltner[1], Benoit Le Goff[1], Laurence Duplomb[1], Jean-Marie Berthelot[2] and Dominique Heymann[1], [1]INSERM U957, Nantes, France, [2]University Hospital, Nantes, France

Purpose: Adenosine is an endogenous purine nucleoside that modulates many physiological processes. Cellular signaling occurs through four known adenosine receptor subtypes (A1, A2a, A2b, and A3). Adenosine is believed to be an anti-inflammatory agent, implicated in many pathologies such as asthma or inflammatory joint disease. However, there is very few information in the literature on the role and expression of adenosine receptors in bone cells. We investigated therefore whether osteoclasts express adenosine receptors and how adenosine could regulate osteoclastogenesis.

Method: Human peripheral blood mononuclear cells (PBMCs) were isolated by centrifugation over Ficoll gradient. CD14+ cells were magnetically labelled with CD14+ microbeads and positively selected by MACS technology. CD14+ cells were cultured with human M-CSF (25 ng/ml) and, after 3 days of culture, with or without hRANK-L (100 ng/ml). The formation of TRAP positive cells occurred around the 12th day of culture and was observed by TRAP staining. Expression of adenosine receptors was determined by RT-PCR and micro-array analysis of CD14+ cells and osteoclasts. Activity of the PI3K pathway, a key signaling protein downstream of adenosine receptors, was analysed by western blotting. TRAP staining was used to evaluate the effects of adenosine and 4 specific agonists of the adenosine receptors [CCPA (A1), CGS21680 (A2a), NECA (A2b), IB-MECA (A3)] on osteoclast differentiation.

Results: The mRNA for all four adenosine receptors (A1, A2a, A2b, and A3), was detectable by RT-PCR in both CD14+ cells and osteoclasts. Microarray analysis showed a 2-fold increase in expression of the A3 receptor subtype in osteoclasts compared to CD14+ cells, whereas expression of the 3 other subtypes remained stable during differentiation. Western blot analysis showed a decreased phosphorylation of PI3K in CD14+ cells and osteoclasts stimulated with adenosine. TRAP staining demonstrated that adenosine inhibited RANKL-induced osteoclastogenesis. All four specific agonists of individual receptor subtypes inhibited osteoclastogenesis with comparable efficacies.

Conclusion: Our work shows that osteoclasts and CD14+ cells express all four subtypes of adenosine receptor. Furthermore, phosphorylation of PI3K was decreased following stimulation with adenosine, confirming that these receptors are functional. We also demonstrated that adenosine has a potent inhibitory effect on RANKL-induced osteoclastogenesis *in vitro,* through its 4 receptor subtypes. We hypothesise that adenosine may be a regulator of osteoclastogenesis and contribute to the balance between bone formation and resorption in inflammatory conditions.

Inflammatory Response Is Modulated by Mitochondrial Dysfunction in Cultured Normal Human Chondrocytes. C. Vaamonde-García[1], MN Valcarcel-Ares[1], RR Riveiro-Naveira[1], B. Lema[2], Fj Blanco[2] and Mj López-Armada[1], [1]INIBIC-CHU A Coruña. Inflammation and Aging Unit, A Coruña, Spain, [2]INIBIC-CHU A Coruña. Osteoarticular and Aging Research Laboratory, A Coruña, Spain

Purpose: The molecular inflammation hypothesis of aging implicate the notion that the molecular activation of proinflammatory genes by altered redox-sensitive cellular signal pathway would serve as a bridge between normal aging and age-related diseases, such as Osteoarthritis (OA). In this work, we studied the effect that dysfunction of mitochondrial respiratory chain (MRC), main cellular source of Reactive Oxygen Species (ROS), could induce on inflammatory response in cultured normal human chondrocytes, specifically in IL-8 and COX-2 expression.

Method: Antimycin A (AA; 10 µg/ml) and Oligomycin (Oli; 10 µg/ml) were employed as inhibitors of complex III and V of MRC, respectively. IL-1β or TNF-α were employed as inductors of inflammatory response. Protein and mRNA IL-8 and COX-2 expression were analyzed by cytometry and real time PCR, and PGE_2 levels were assayed by ELISA. To identify underlying mechanisms responsible for inflammatory response, catalase, an antioxidative enzyme, and a chemical and a natural ROS scavenger, N-Acetyl-L-Cysteine (NAC; 40mM), and Resveratrol (RESV; 250uM) respectively, were employed. Finally, the implication of nuclear factor-κB (NF-κB) was studied by the inhibitor BAY-117085 (5µM).

Results: Firstly, we tested if mitochondrial dysfunction induced by AA or Oli could modulate the response induced by IL-1β (5, 1.5 and 0.5 ng/ml) on IL-8 expression. The results showed that the pre-treatment of chondrocytes with AA or Oli for 1h increased significantly the expression of IL-8 induced by IL-1β (table 1). Similar effects were observed with 10 ng/ml TNFα. In addiction, the intensification of inflammatory effects of cytokines by mitochondrial dysfunction was counteracted by the addiction of a chemical and a natural ROS scavenger (10.75±2.97% NAC+AA+IL-1ß or 18.10±5.04% RESV+AA+IL-1ß vs. 100% AA+IL-1ß, n= 3, $p<0.01$) and by catalase. When the role of NF-κB was investigated, the results showed that the pre-incubation of cells for 1h with BAY significantly reduced to 26.53±16.80% the production of IL-8 protein induced by AA + IL-1β (100%). Finally, we studied if mitochondrial dysfunction could modulate COX-2 expression induced by IL-1ß; and we found that both COX-2 mRNA and protein levels (399.96±79.93% Oli+IL-1ß vs. 100% IL-1ß and 90.66±7.97% Oli, n=3, $p< 0.001$) and its product, PGE_2 (13522 ±6845 Oli+IL-1ß vs. 1844±1419 IL-1ß and 6825±3813 pg/250000cells Oli, n=3, $p<0.01$) increased significantly in Oli pretreated chondrocytes induced by IL-1ß.

IL-8	IL-1ß (1.5ng/ml)	AA	Oli	AA+ IL-1ß	Oli+IL-1ß
mRNA (%)	100	0.08±0.01	0.19±0.03	256.33±77.03	342.90±59.28
Protein (%)	100	48.26±7.70	50.47±6.49	214.06±35.22	292.06±49.02

Conclusion: These findings suggest that mitochondrial dysfunction may be one of the factors that sensitize chondrocytes to increase cytokines-mediated inflammatory response in OA and aging.

Autophagy Is a Protective Mechanism in Normal Cartilage and Its Aging-Related Loss Is Linked with Cell Death and Osteoarthritis. Beatriz Caramés[1], Noboru Taniguchi[1], Shuhei Otsuki[1], Francisco J. Blanco[2] and Martin K. Lotz[1], [1]The Scripps Research Institute, La Jolla, CA, [2]INIBIC–Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Purpose: Autophagy is a process for turnover of intracellular organelles and molecules that protects cells during stress responses. This study evaluated the potential role of ULK1, an inducer of autophagy, Beclin1, a regulator of autophagy and LC3, which executes autophagy, in the development of osteoarthritis (OA) and in cartilage cell death.

Method: DNA array studies were performed to analyze differences in the expression of ULK1 in normal and OA human knee cartilage. Protein expression of ULK1, Beclin1 and LC3 was analyzed in human normal and OA chondrocytes and cartilage by western blot and immunohistochemistry (IHC). Autophagy markers were also studied in mouse models of aging-associated and surgically-induced OA. The apoptosis marker poly-ADP(ribose) polymerase (Parp p85) was used to determine the relationship between cell death and autophagy.

Results: In normal human articular cartilage ULK1, Beclin1 and LC3 were constitutively expressed. ULK1 gene expression and ULK1, Beclin1 and LC3 protein expression were reduced in OA chondrocytes and cartilage but these three proteins were expressed in the cell clusters in OA cartilage. In mouse knee joints loss of glycosaminoglycans (GAGs) was observed at 9 months of age and in the surgical OA model 8 weeks after knee destabilization. Expression of ULK1, Beclin1 and LC3 decreased together with loss of GAGs, suggesting decreased autophagy correlates with extracellular matrix changes in OA. The decrease in autophagy in the same human and mouse OA cartilage was associated with an increase in Parp p85.

Conclusion: Autophagy may be a protective or homeostatic mechanism in normal cartilage. By contrast, human OA, spontaneous and surgically-induced OA in mice are associated with a reduction and loss of ULK1, Beclin1 and LC3 expression and a related increase in apoptosis. These results suggest that compromised autophagy represents a novel mechanism in the development of OA.

Soluble Syndecan-3 (ssyn3): An Anionic Serum Protein in Ovariectomised Rats Controlling Osteoblastic (OB) Function. Tassos P. Anastassiades[1] and Karen Rees-Milton[2], [1]Etherington Hall Rm 2050, Kingston, ON, [2]Queen's University, Kingston, ON

Purpose: Studies in bone homeostasis in post-menopausal OP have emphasized primarily osteoclastic rather than osteoblastic (OB) regulation. We have been using a model of post-menopausal OP, the ovariectomised (Ovx) rat, for pre-clinical studies of N-butyryl glucosamine (GlcNBu), as an agent for preventing OP in this model. We found that soluble syndecan-3 (ssyn3) was significantly up-regulated in the livers of the Ovx, untreated rats. Here we report on the inhibitory effect of sera from Ovx rats on OB proliferation and the possible role of ssyn3 as accounting for this effect.

Method: The groups of mature female rats were: (1) Glucose (Glc)-fed, non-OVX (control); (2)GlcNBu-fed, non-OVX; (3) Glc-fed, OVX; (4) GlcNbu-fed, OVX. At 6 months, animals were euthanized and the bones evaluated for bio-mechanical properties and bone mineral densities (BMD). RNA was extracted from the livers and subjected to microarray analysis. The serum from Ovx and control rats was used in cell culture experiments with primary neonatal rat calvarial OB and UMR-106 OB. The levels ssyn3 in the sera were quantitated using immunoassays, utilizing chitosan coated plates, which permit a preliminary isolation of the anionic ssyn3.

Results: Ovariectomy (Ovy) resulted in lower femoral and spinal BMDs. GlcNBu-fed OVX rats (Group 4) demonstrated maintenance of femoral head, total femur and spine BMDs. Orally administered GlcNbu, preserved bone biomechanical properties in the OVX rat. Microarray sub-group analysis revealed a small number of genes with relatively low expression that very significantly regulated ($p<0.001$), which included ssyn3. The proliferation of rat OB *in-vitro* was significantly less ($p<0.01$) in sera from Ovx, untreated compared to non-Ovx or GlcNBu rats. There was a neutralization of serum anti-proliferative activity in OVX sera on calvarial OB and UMR-106 proliferation by different antibodies to ssyn3. The addition of syn-3 antibody to OB had no effect on proliferation. The antiproliferative activity fractionated in the region expected for ssyn3. Further, there was a strong correlation ($r=-0.962$) between increasing antibody dilutions and OB proliferation, suggestive of a role of ssyn-3 in inhibiting OB proliferation. The immunoassays on chitosan coated plates are also applicable human sera and are suitable for immunoassays for other bone-related serum anionic proteins, such as soluble phosphoprotein 24.

Conclusion: 1. Orally administered GlcNBu, preserves BMD and bone biomechanical properties in the OVX rat, an animal model for post-menopausal OP. 2. ssyn3 may be a novel modulator of OB proliferation in this model. 3. The effect of GlcNBu in preventing bone loss may be mediated, in part, by regulation of ssyn-3, acting on OB function.

Supported by the Canadian Arthritis Network and NSERC.

Constitutive Expression of NOX4 in Human Articular Chondrocytes and Its Regulation by Cytokines and Transforming Growth Factor-ß. Sonsoles Piera-Velazquez, Alma Makul and Sergio A. Jimenez, Jefferson Institute of Molecular Medicine, Thomas Jefferson Univ, Philadelphia, PA

Purpose: Reactive oxygen species (ROS) are normal by-products of cellular metabolism but alterations in the type and amount of ROS release can cause pathologic effects. ROS are a major factor in the regulation of the metabolism of articular chondrocytes. ROS production is increased in osteoarthritis (OA) and rheumatoid arthritis (RA). ROS overproduction results in oxidative stress mediated cell damage, therefore oxidative stress may be involved in cartilage degradation. NADPH oxidases play a major role in the production of ROS. NOX4 is a member of the NADPH oxidase family and is expressed by SV40 immortalized human articular chondrocyte cell lines. NOX4 expression is increased by hypoxia and TGF-β in vascular endothelial cells and is reduced by interleukin-1 (IL-1) in vascular smooth muscle cells. However, the NOX4 role in articular cartilage pathology and the regulation of its expression by relevant cytokines and growth factors have not been examined. The objective of this study was to examine the expression of NOX4 and the regulation of its expression by cytokines (IL-1 and TNF-α) and TGF-β in normal and OA chondrocytes.

Method: Normal human articular chondrocytes (hAC) were obtained from the knee joint cartilage from normal organ donors through the Cooperative Human Tissue Network. OA chondrocytes were obtained from knee cartilage from patients undergoing knee joint replacement. Chondrocytes were isolated by enzymatic digestion and frozen until used. Primary human chondrocytes were cultured in monolayer and treated with 10 ng/ml of human recombinant TGF-β1 in complete media for 24 h with or without 2.5 and 5 μM of Rottlerin, an inhibitor of protein kinase Cδ (PKCδ), or with 10 ng/ml of IL-1β or 10 ng/ml of TNF-α or both. RNA and proteins were isolated and PCR for NOX4 and GAPDH performed. Cell extracts were prepared from freshly isolated chondrocytes and from the cultured chondrocytes following cytokine/growth factor treatment and Western blots performed using NOX4 antibody.

Results: Normal and OA human articular chondrocytes constitutively express NOX4 protein. NOX4 protein and mRNA are downregulated by either IL-1β or TNF-α *in vitro* and the combination of both cytokines showed synergistic inhibition. NOX4 protein and mRNA were upregulated by TGF-β *in vitro*. The specific PKCδ inhibitor, rottlerin, decreases NOX4 mRNA expression by primary human articular chondrocytes *in vitro* and abolishes the TGF-β-induced stimulation of its expression.

Conclusion: NOX4 is constitutively expressed by freshly isolated normal and OA human articular chondrocytes and its expression is regulated by IL-1β, TNF-α, and TGF-β *in vitro*. IL-1β and TNF-α cause NOX4 downregulation, whereas TGF-β upregulates NOX4 in primary hAC *in vitro.* The upregulation of NOX4 by TGF-β is mediated by PKCδ. The results suggest an important role of this constitutively expressed NADPH oxidase in OA and in articular cartilage function and pathology.

Biomechanical Stretch Is a Key Initiating Event in the Development of Enthesitis in Murine Spondyloarthritis. Peggy Jacques[1], Stijn Lambrecht[1], Rik J. Lories[2], George Kollias[3], Gust Verbruggen[1] and Dirk Elewaut[1], [1]Laboratory for Molecular Immunology and Inflammation, Ghent, Belgium, [2]Laboratory for Skeletal Development and Joint Disorders - KU Leuven, Leuven, Belgium, [3]Biomedical Sciences Research Center Alexander Fleming, Vari, Greece

Purpose: One of the hallmarks of spondyloarthritis (SpA), is the development of enthesitis, most typically of the Achilles tendon and plantar fascia. However, the precise sites where inflammation originates within joints have been a matter of controversy, as enthesitis, synovitis and even bone marrow inflammation may occur during the course of SpA. In this study, we aimed to investigate the initiating events leading towards enthesitis development. We postulated that biomechanical stress is a principal feature of the early events leading to the inflammatory pathway resulting in enthesitis. To evaluate this, we used $TNF^{\Delta ARE}$ mice, which are characterized by an enhanced TNF mRNA stability, which in turn leads to the development of several features of SpA, including peripheral and axial arthritis (sacroiliitis, spondylitis), and Crohn´s like ileitis. One of the striking features of this model is the early appearance of tendinitis/enthesitis of the Achilles tendon, and the small ligaments of the interphalangeal joints. Inflammation of tendons and ligaments is in fact one of the first signs of disease in this model.

Methods: To study enthesitis development, we subjected $TNF^{\Delta ARE}$ mice which had not yet developed signs of inflammation to a biomechanical unloading procedure. Thus, a tail suspension procedure was conducted for 7-14 days, thereby prohibiting weight loading on hind paws. Western blotting was performed for phosphorylated Erk, one of the mitogen-activated protein kinases (MAPK) on cell lysates from Achilles tendon samples of tail suspended $TNF^{\Delta ARE}$ mice, versus mice that were allowed to walk for 15 minutes after a 7 days period of tail suspension. The effect of small molecular inhibitors of Erk and p38 on enthesitis development was evaluated.

Results: Biomechanical unloading studies indicated that virtually no inflammation of the Achilles tendon occurred in unloaded animals compared to weight bearing controls. By contrast, weight bearing front paws exhibited severe inflammation. As early as 15 minutes after

initiation of weight bearing, phosphorylated Erk, one of the mitogen-activated protein kinases (MAPK), was strongly upregulated compared to continuously unloaded conditions. Furthermore treatment of $TNF^{\Delta ARE}$ mice with small molecular inhibitors of Erk and p38 markedly prevented the onset of Achilles tendon enthesitis.

Conclusion: These findings provide a novel proof that biomechanical stretch and the resulting activation of the MAPK pathway through Erk phosphorylation and downstream transactivation, is required for the induction of pathologic loads of TNF sufficient to develop enthesitis in SpA.

Decreased Levels of Sirt1 in OA Articular Cartilage Are Associated with An Increase in MMP-3, -13 and Apoptosis. Odile H. Gabay, Viktoria Gagarina, Eun Jin Lee, Mona Dvir-Ginzberg, Jun Onodera and David Hall Sr., NIH, Bethesda, MD

Purpose: Osteoarthritis is a multi-factorial disease that results from an imbalance between cartilage anabolism and catabolism, which results from the over-expression of pro-inflammatory mediators. Elevation in chondrocyte apoptosis is also evident in OA cartilage, contributing to a lack of cartilage repair. Since OA is a disease associated with aging, the role of the longevity factor SirT1, a protein deacetylase that can prolong lifespan in a variety of organisms, was examined in a number of critical features of OA. :

Method: Human articular cartilage was obtained from OA patients undergoing total knee arthroplasty while normal samples were obtained from cadeavers. Cartilage was embedded sectioned and processed for immunohistochemistry using antibodies for SirT1, DBC1, PTP1B, MMP-3 and -13. Additionally, chondrocytes isolated from cartilage samples were cultured in vitro and used for analysis of gene expression and for immunoblotting. Human chondrocytes were Amaxa transfected with a SirT1 expression plasmid.

Results: In human chondrocyte cell culture we find that overexpression of SirT1 enhances expression of cartilage specific matrix genes (collagen 2, aggrecan) while it represses the expression of matrix degrading metalloproteinases (MMP3, 8, 13, Lee et al., 2009 submitted). Further, Sirt1 was found to be a potent inhibitor of apoptosis in human chondrocytes through repression of the protein tyrosine phosphatase 1B (PTP1B, Gagarina et al, 2009 submitted), an extremely potent pro-apoptotic protein in chondrocytes. Examination of tissue sections revealed that SirT1 levels were significantly downregulated in OA cartilage compared to normal cartilage, while PTP1B, MMP-3 and -13 levels were elevated in OA tissue. DBC1, a protein known to associate with Sirt1 and repress its enzymatic activity was also examined in chondrocytes and cartilage sections. DBC1 was upregulated in OA. These data are consistent with the finding that SirT1 enzyme activity is significantly decreased in OA chondrocytes.

Conclusion: These data indicate that the longevity protein SirT1 is a powerful regulator of cartilage matrix and MMP gene expression as well as chondrocyte apoptosis in human chondrocytes. The results suggest that SirT1 has features of an anti-osteoarthritic protein, consistent with its ability to reduce the severity of age-associated diseases.

Green Tea Polyphenol EGCG Inhibits Advanced Glycation End Products-Induced Endoplasmic Reticulum Stress Stimulated Expression of COX-2 in Human Chondrocytes. Zafar Rasheed, Nahid Akhtar, Arivarasu N. Anbazhagan, Frank R. Voss and Tariq M. Haqqi, School of Medicine, University of South Carolina, Columbia, SC

Purpose: During aging, an important risk factor for osteoarthritis (OA), nonenzymatic glycation of proteins and other molecules results in the accumulation of Advanced Glycation End Products (AGEs) in articular cartilage. AGEs have been shown to activate chondrocytes resulting in the production of proinflammatory molecules. Here we investigated whether AGEs induce endoplasmic reticulum (ER) stress in human chondrocytes and which of the ER stress-activated pathways induce COX-2 in human chondrocytes.

Method: Human chondrocytes derived from OA cartilage by enzymatic digestion were stimulated with AGE-modified BSA (AGE-BSA) and EGCG. Expression of COX-1, COX-2, and mPGES-1 mRNAs was determined by qRT-PCR and protein expression was determined by Western immunoblotting. PGE_2 released in the culture medium was quantified by EIA. Phosphorylation and activation of MAPKs was

detected by Western immunoblotting and activation of NF-KB was analyzed using Luciferase based reporter constructs. Pharmacological studies to elucidate the involved pathways were executed using specific inhibitors of MAPKs and NF-KB.

Results: Several pathways that maintain cellular homeostasis were activated in human chondrocytes in response to AGE-BSA treatment. AGE-BSA induced the expression of the ER chaperone protein BiD and increased the expression of COX-2 and mPGES-1 with concomitant increase in PGE_2 production. Nuclear translocation and activation of NF-kB and phosphorylation of MAPKs was observed in AGE-BSA-stimulated human chondrocytes. IkBα kinase inhibitor Bay-11-7082 or Parthenolide significantly inhibited the expression of COX-2 and mPGES-1. Treatment with EGCG inhibited the p38-MAPK and JNK phosphorylation and attenuated the NF-kB DNA binding activity and COX-2 and mPGES-1 expression. Similar results were obtained when chondrocytes were treated with p38-MAPK specific inhibitor SB-202190 and 2-aminopurine (an inhibitor of eIF2a). In contrast JNK inhibitor SP600125 had no effect on AGE-BSA-induced expression of COX-2 and mPGES-1 whereas MEK inhibitor PD98059 inhibited PGE_2 release in the culture medium but had no effect on the expression of COX-2 or mPGES-1 in AGE-BSA-stimulated human chondrocytes.

Conclusion: Our results demonstrate that AGE-BSA induce ER stress in human chondrocytes and stimulated the expression of COX-2 and mPGES-1 and production of PGE_2 through the activation of NF-kB and p38-MAPK pathways. EGCG is a potent suppressor of ER stress-induced expression of COX-2 but had no effect on COX-1 expression. Our results also demonstrate that ER stress-induced expression of COX-2 and mPGES-1 was independent of the JNK pathway while ERK plays a role in PGE_2 export from human chondrocytes. Thus, our results provide important insights into the mechanism of AGE-BSA-induced ER stress stimulated production of PGE_2 in human chondrocytes. These results also indicate that use of EGCG or compounds derived from it may be of value in AGEs-induced catabolic activation of human chondrocytes.

Regulation of MMP-13 Expression in Human Chondrocytes by MicroRNA-27b. Nahid Akhtar, Zafar Rasheed, Arivarasu Anbazhagan, Frank R. Voss and Tariq M. Haqqi, School of Medicine, University of South Carolina, Columbia, SC

Purpose: Deregulated posttranscriptional regulation of MMPs by microRNAs (miRNAs) may be an important factor in chronic degenerative diseases such as osteoarthritis (OA). In this study we determined the posttranscriptional regulation of matrix metalloproteinase-13 (MMP-13) expression by microRNA-27b (miR-27b) in human OA and normal chondrocytes.

Method: Chondrocytes were derived from OA cartilage by enzymatic digestion and stimulated with interleukin-1β (IL-1b) *in vitro*. Total RNA was prepared using TRIZOL reagent and MicroRNAs (miRNAs) were purified using the mirVANA system. PCR-based arrays were used to determine the expression profile of 352 human miRNAs. Expression of miRNA of interest was quantified using TaqMan miRNA Expression Assay and miRNA targets were identified using bioinformatics. Transfection with 3'UTR reporter construct and miRNA mimic or inhibitor was employed to verify the suppression of luciferase activity. OA chondrocytes were transfected with miR-27b mimic or inhibitor and amount of MMP-13 protein released in the culture medium was determined by ELISA. Expression of MMP-13, argonuate and Dicer mRNAs was determined by RT-PCR and quantified by TaqMan assays and protein expression was determined by Western immunoblotting. Nuclear translocation of NF-kB, degradation of IkBa and phosphorylation of MAPKs was determined using Western immunoblotting and role of MAPKs and NF-kB in regulating the expression of miR-27b and MMP-13 was evaluated using specific inhibitors.

Results: In OA chondrocytes stimulated with IL-1β for 6 h, 42 miRNAs were downregulated, 2 miRNAs were upregulated and expression of 308 miRNAs remained unchanged. Both normal and OA chondrocytes showed approximately 23 fold down regulation of miR-27b expression after stimulation with IL-1β. *In silico* analysis of targets identified a sequence in the 3'UTR of MMP-13 mRNA complementary to the seed sequence of miR-27b. Expression of MMP-13 correlated with the down regulation of miR-27b in OA and normal chondrocytes. Overexpression of miR-27b suppressed the activity of a reporter construct containing the 3'UTR of human MMP-13 mRNA. Further, transfection with miR-27b mimic resulted in down regulation of MMP-13 production, but not mRNA expression, in IL-1b-stimulated OA or normal chondrocytes. In addition transfection with miR-27b inhibitor reversed the inhibitory effect of miR-27b on MMP-13 expression. Additional studies with BAY-11-7082, SB202190 and SP600125 revealed that expression of miR-27b was negatively regulated by the activation of NF-kB and p38-MAPK and JNK pathways respectively.

Conclusion: Thus, we have identified miR-27b as a post-transcriptional regulator of MMP-13 expression in human chondrocytes. Activation of p38-MAPK, JNK and NF-kB, pathways required for optimum expression of MMP-13, down-regulate the expression of miR-27b. These results indicate that miR-27b plays a role in maintaining cartilage integrity by suppressing posttranscriptionally the expression of MMP-13.

Modulation of Mir-27b Expression and Regulation of MMP-13 Production by EGCG in IL-1b Stimulated Human Osteoarthritic Chondrocytes. Nahid Akhtar[1], Zafar Rasheed[2], Arivarasu N. Anbazhagan[2], Frank R. Voss[2] and Tariq M. Haqqi[2], [1]University of South Carolina, Columbia, SC, [2]School of Medicine, University of South Carolina, Columbia, SC

Purpose: MicroRNAs (miRNAs) are recently discovered 20-40 nucleotides long non-coding RNAs involved in key biological processes via suppression of gene expression at posttranscriptional level. We have previously shown that epigallocatechin-3-gallate (EGCG), a polyphenol abundant in green tea (*Camellia sinensis)* suppress the expression of MMP-13 in human chondrocytes. In this study we determined whether this effect was mediated through the modulation of miRNA-27b expression in human OA chondrocytes.

Method: Human chondrocytes were derived from OA cartilage by enzymatic digestion and at 80% confluence stimulated with IL-1β (5 ng/ml) *in vitro*. Total RNA was prepared using TRIZOL reagent. miRNAs were purified using the mirVANA system and expression of miR-27b and MMP-13 was quantified using TaqMan Assays. Western immunoblotting was used to analyze the MMP-13 production in the culture medium. OA chondrocytes were transfected with miR-27b mimic or inhibitor and amount of MMP-13 protein released in the culture medium was determined by ELISA. Nuclear translocation of NF-kB, degradation of IkBa and phosphorylation of MAPKs was determined using Western immunoblotting and role of MAPKs and NF-kB in regulating the expression of miR-27b and MMP-13 was evaluated using specific inhibitors.

Results: Human OA chondrocytes do not express high levels of MMP-13 and this correlated with the expression level of miR-27b in these cells. IL-1β stimulation of human OA chondrocytes for 24 h suppressed the expression of miR-27b, with concomitant increase in the production of of MMP-13. Pretreatment of human chondrocytes with different concentration of EGCG (10 to 150μM) for 2 h and then stimulation with IL-1β showed 2.8 to 14.8 fold up-regulation of miR-27b expression (Mean 9.375 ± 1.66) in the samples analyzed (n=8). In comparison, chondrocytes stimulated with IL-1β alone showed approximately 18 fold downregulation of miR-27b expression. Pretreatment with EGCG showed concentration dependent inhibition of IL-1β-induced expression of MMP-13 in OA chondrocytes and this correlated with the blockage of inhibitory effect of IL-1b on miR-27b expression. Further, transfection with miR-27b mimic resulted in down regulation of MMP-13 production, but not mRNA expression, in IL-1b-stimulated OA chondrocytes. In addition transfection with miR-27b inhibitor reversed the inhibitory effect of miR-27b on MMP-13 expression. Human OA chondrocytes pretreated with EGCG showed inhibition of NF-kB DNA binding activity and JNK activation with a significant downregulation of MMP-13 protein in the culture medium and this correlated with the enhanced expression of miR-27b in these cells.

Conclusion: EGCG inhibits the IL-1b induced downregulation of miR-27b and expression of MMP-13 protein in human OA chondrocytes. This correlated with the inhibition of NF-kB and MAPKs pathways that are essential for the MMP-13 expression. Thus, modulation of miR-27b by dietary constituents may present a novel therapeutic and preventive approach for OA.

Suppression of Osteoclastogenesis From Human Peripheral Blood Mononuclear Cells Co-Cultured with Rheumatoid Arthritis Synovial Fibroblasts by Over-Expression of MiR-223. Hayatoshi Shibuya, Tomoyuki Nakasa, Takuya Niimoto, Nobuo Adachi, Masataka Deie and Mitsuo Ochi, Hiroshima University, Hiroshima City, Japan

Purpose: MicroRNAs (miRNAs) are a class of non-coding RNAs that control gene expression by translational inhibition and messenger RNAs degradation in plants and animals. Although miRNAs have been implicated in developmental and homeostatic events of vertebrates and invertebrates, the role of miRNAs in bone metabolism has not been explored. In previous study, microRNA-223 (miR-223) is expressed

in RAW264.7 cells, mouse osteoclast precursor cell lines, and plays a critical role in osteoclast differentiation. The aim of this study was to confirm whether over expression of miR-223 inhibit osteoclastogenesis in rheumatoid arthritis (RA) in vitro.

Method: Human blood was collected from healthy volunteers, and peripheral blood mononuclear cells(PBMC) were isolated, and seeded in 96-well culture plates. The following day, co-cultured with fibroblast like synovial cell(FLS) of RA in the presence of macrophage colony stimulating factor (M-CSF) and $1,25(OH)_2D_3$. The day after next, for experimental group, double strand miR-223(ds-miR-223) transfected into the cells and co-cultured for 3 weeks. As controlled group, scramble siRNA was used. After 3 weeks, TRAP positive and multinuclear cells were counted. At 2 weeks after transfection, the expression of PU-1, RANKL, and OPG were evaluated by real time PCR. And we co-cultured PBMC and FLS with same method on dentin slice for 3weeks, we comfirmed co-cultured cells have bone resorption ability by toluidine blue stain. We cultured PBMCs in the presense of Tumor Necrosis factor-alpha (TNF-α) and M-CSF in 96 well culture plates. The following day, ds-miR-223 transfected into the cells and cultured for 3 weeks. And then, TRAP positive and multinuclear cells were counted.

Result s: The average number of TRAP positive multinuclear cell was 844±203 at experimental group. On the other hand, control group was 1531±458. There was significant difference between both groups. The expression of OPG in experimental group was higher than control group. Expression in experimental group of RANKL and PU-1 were lower than control group. On bone resorption assay, Pits on the dentin slices of experimental group was less than that of control group. There is a same trend in the PBMCs cultured with TNF-α at experimental group.

Conclusion: Our result indicated that miR-223 could inhibit osteoclastogenesis of RA in vitro, and miR-223 might be a viable therapeutic target for bone destruction of RA.

Immune Complex Mediated Inhibition of Osteoclastogenesis: Role for the Inhibitory Fcgamma Receptor IIb in Bone Erosion in Antigen Induced Arthritis? Lilyanne C. Grevers[1], Peter L.E.M. van Lent[1], Annet W. Sloetjes[1], Teun J. de Vries[2], Vincent Everts[2] and Wim B. van den Berg[1], [1]Radboud University Nijmegen, Medical Centre, Nijmegen, Netherlands, [2]Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam and VU University Amsterdam, Amsterdam, Amsterdam, Netherlands

Purpose: Rheumatoid arthritis is characterised by osteoclast mediated bone loss. In several studies it was shown that SHIP knockout mice are severely osteoporotic due to increased numbers of hyperreactive osteoclasts. Because SHIP is part of the signalling pathway of the inhibitory Fcg Receptor IIB (FcgRIIB) the aim of this study was to investigate the role of FcgRIIB in osteoclastogenesis and osteoclast function.

Method: Knee joints of arthritic FcgRIIB-/- mice and C57Bl/6 wild type controls were examined for bone erosion and cathepsin K expression. Bone marrow cells, isolated from FcgRIIB-/- mice and C57Bl/6 wild type controls, were cultured with M-CSF and RANKL to induce osteoclast differentiation. During differentiation cells were stimulated with or without heat-aggregated rabbit IgG to study the effect of immune complex (IC) mediated activation of FcgR. Osteoclastogenesis was examined by quantitation of TRACP+ cells containing at least three nuclei and by RT-PCR for osteoclast markers. Bone-resorbing capacity was analysed by pit formation after culturing osteoclasts on bovine cortical bone slices. FcgR expression was studied by FACS analysis.

Results: Bone erosion and cathepsin K staining are clearly enhanced during antigen induced arthritis in mice deficient for the inhibitory FcgRIIB, as compared to wild type mice. FACS analysis of in vitro differentiated osteoclasts showed that expression of FcgRIIB was somewhat lower in osteoclasts as compared to macrophages and negatively correlated with osteoclast size. Osteoclasts of FcgRIIB-/- mice and wild type controls showed no differences in the number of TRACP+ cells and mRNA expression of the osteoclast markers cathepsin K, CTR, DC-STAMP, and NFATc1. In line with this no differences were observed in the formation of resorption pits on bone. In the presence of IC differentiation of both FcgRIIB-/- and wild type osteoclasts resulted in significantly reduced numbers of large TRACP+ cells (containing more than 10 nuclei), but not of smaller sized osteoclasts (3 to 10 nuclei). Surprisingly, neither in FcgRIIB-/- nor in wild type mice did the IC-mediated reduction in osteoclast size result in decreased mRNA expression of osteoclast markers or formation of resorption pits on bone, showing that small osteoclasts resorb bone just as well as large osteoclasts.

Conclusion: This study shows that IC inhibit osteoclastogenesis resulting in smaller sized osteoclasts. However, this does not lead to decreased osteoclast function and, using FcgRIIB-/- mice, we demonstrated that the inhibitory effect of IC is not directly mediated by FcgRIIB.

Wnt16 Is a Cartilage-Specific Injury Response Gene Re-Expressed Following Acute and Chronic Cartilage Injury. Noha M. Eltawil, Costantino Pitzalis and Francesco Dell'Accio, EMR, Queen Mary's School of Medicine and Dentistry, London, United Kingdom

Purpose: The outcome of acute joint surface defects varies from healing to osteoarthritis development. The molecular signals regulating repair are largely unknown but their knowledge could be used to support joint surface repair. In an in vitro screening we have identified Wnt16 as a gene upregulated by injury to human articular cartilage. We now validate these finding in vivo, describe Wnt16 expression pattern and dynamics following cartilage injury and induction of osteoarthritis, and describe dynamics of the associated activation of the canonical Wnt signalling.

Method: Full thickness defects were generated in the patellar groove of adult C57BL/6 and DBA/1 mice by microsurgery (Eltawil et al. 2009). Osteoarthritis was induced by destabilization of the medial meniscus (DMM). Control knees were either not operated, or sham operated (arthrotomy and patellar dislocation, no cartilage injury or DMM). Gene expression was assessed by Q-PCR and immunohistochemistry.

Results: Following acute cartilage injury, DBA/1 mice healed consistently, whereas C57BL/6 did not repair. A transient synovial hyperplasia and inflammation was present for 1 week in both injured and sham operated knees. Wnt16 was not detectable in non operated or sham operated joints, but was upregulated at mRNA and protein level 24 hours following injury and DMM. Wnt16 upregulation was associated with downregulation of the secreted WNT inhibitor FRZB, nuclear translocation of β-catenin and up-regulation of the target gene axin2. At later time points, Wnt16 expression subsided, but β catenin accumulation persisted.

Conclusion: Wnt16 is a cartilage-specific early injury response gene (no upregulation took place in sham operated controls which underwent arthrotomy and developed transient synovitis to the same extent as injured knees).

Wnt16 transient expression was associated with the activation of the canonical wnt pathway, and was present in the early phases of osteoarthritis.

In vivo validation of Wnt16 re-activation upon injury and instability-induced osteoarthritis has allowed ongoing functional studies in vivo to investigate whether Wnt16 has a role in outcome determination of cartilage repair and OA in mice.

PGE2 Differentially Regulates Expression of Chondrocyte Markers During Chondrogenesis of Human Bone Marrow Derived MSCs.

Glyn Palmer[1], Hayf Al-Mussawir[1], Mukundan Attur[1] and Steven B. Abramson[2], [1]NYU - Hospital for Joint Diseases, New York, NY, [2]NYU School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Purpose: A necessary step for the successful regeneration of cartilage lesions using stem cell-based therapies is the controlled differentiation of progenitor cells into a stable articular chondrocyte phenotype. Prostaglandin E2 (PGE2) has been shown to have an important role in both fracture healing and chondrocyte maturation during endochondral bone formation. This study investigates the effects of PGE2 on chondrocyte differentiation of adult, human mesenchymal stem cells (MSCs).

Methods: Bone marrow-derived MSCs were isolated from the discarded tissues of patients undergoing hip replacement surgery. Chondrogenesis was induced by seeding MSCs in serum-free aggregate cultures supplemented with dexamethasone (10^{-7} M) and TGF-b1 (10 ng/ml). At various time points, RNA was extracted for gene expression analysis by semi-quantitative RT-PCR. PGE2 levels were determined by RIA.

Results: Gene expression analysis of 4 patient samples revealed an order-of-magnitude increase in chondrogenic markers, col II, col X, MMP-13 and AP. In each case, expression was elevated by day 7 and persisted for the duration of the assay (21 d). To determine the effects of PGE2, aggregates were cocultured in the presence of exogenous PGE2 (10^{-6} M) and expression of chondrocyte markers determined after 14 d. PGE2 increased expression of col II (65%) and decreased expression of hypertrophic markers, col X (20%), MMP-13 (32 %) and AP (55%). Consistent with these observations, histological examination of treated aggregates after 21 d revealed fewer enlarged, hypertrophic chondrocytes following PGE2 treatment compared to control cultures. In aggregate cultures, PGE2 secretion was inhibited by the selective cox-2 inhibitor, celecoxib, approximately 50%, while cox-1 inhibition by treatment with SC-560 had no effect. Accordingly, celecoxib treatment of chondrogenic aggregates for 7 d decreased expression of sox-9 (80%) and col II (97%) compared non-treated controls. Cox-2 inhibition also increased expression of hypertrophic markers. Celecoxib treatment increased col X (95%) and AP (150%), but had no effect on MMP-13 levels. After 21 d, aggregates treated with celecoxib exhibited greater numbers of hypertrophic chondrocytes, and a modest decrease in proteoglycan staining. These findings suggest that cox-2 derived PGE2 has the capacity modulate chondrocyte differentiation of MSCs via differential regulation of chondrocyte marker genes.

Conclusion: PGE2, via upregulation of type II collagen, or inhibition of chondrocyte hypertrophy, has the capacity to regulate chondrocyte phenotype during *in vitro* chondrogenesis of hMSCs. Further characterization should uncover novel PGE2 pathways that can be exploited to modulate chondrocyte phenotype for tissue regeneration therapies.

Novel *NOD2* Mutations Associated with Blau Syndrome and Related Phenotypes. Tammy M. Martin[1], Carine H. Wouters[2], Juan I. Aróstegui[3], Andrew D. Dick[4], C. Stephen Foster[5], Miroslav Harjaček[6], R. Russo[7], Maria D. Perez[8], Athimalaipet V. Ramanan[9], Srilakshmi M. Sharma[10] and Carlos D. Rosé[11], [1]Oregon Health & Science Univ, Portland, OR, [2]University Hospital Leuven, Leuven, [3]Hospital Clınic, Barcelona, Spain, [4]University of Bristol, Bristol, United Kingdom, [5]MERSI, Cambridge, MA, [6]Children's Hospital Zagreb, Zagreb, Croatia, [7]Hospital de Pediatria Juan P Garrahan, Buenos Aires, Argentina, [8]Texas Children's Hospital, Houston, TX, [9]Bristol Royal Hospital for Children, Bristol, United Kingdom, [10]University Hospitals Bristol NHS Foundation, Bristol, United Kingdom, [11]duPont Hospital for Children, Wilmington, DE

Purpose: Pediatric Granulomatous Arthritis (PGA) encompasses Blau Syndrome and Early Onset Sarcoidosis representing respectively familial and sporadic forms of a rare autosomal-dominant disease caused by coding mutations in *NOD2* exon 4, and classically presents as granulomatous arthritis, dermatitis and uveitis. The PGA International registry was created in 2005 to systematically examine rare *NOD2* genotypes and the clinical spectra of disease to better understand these relationships. In 2008 the registry and a national cohort of Spain were combined.

Method: PGA cases were entered into the Registry after review of de-identified clinical data. Presence of giant cell granuloma in tissue biopsy and arthritis were the inclusion criteria. *NOD2* exons were genotyped from genomic DNA by standard techniques. Study activities were approved by human subjects boards at the coordinating centers (duPont Hospital for Children and University Hospital Leuven) and the genetics center (Oregon Health & Science University).

Results: Of 180 subjects (from 58 families), 66 exhibit rare, non-synonymous mutations in *NOD2* exon 4. All with a mutation were affected, except 1 adult and 3 juveniles with incomplete penetrance in a family with classic PGA and 5 juveniles in a family with adult-onset disease involving only uveitis. The majority of affected subjects had substitutions R334Q or R334W. To date, 14 PGA substitutions have been reported. Herein, 5 previously unreported NOD2 substitutions are described: G481D, de novo mutation in 2 unrelated sporadic cases, 1 with expanded disease manifestations ; H520Y, de novo change in a sporadic case; E600K, 2 affected siblings with joint and skin involvement but no uveitis; E600A, large pedigree with inherited, adult-onset, severe uveitis without systemic disease nor joint nor skin involvement; and Q809K, de novo change in a sporadic case. The newly found *NOD2* mutations confirm the association with both complete and incomplete forms of PGA, as well as with expanding clinical manifestations as reported previously (2007 Arthritis Rheum 56:3805 and 2009 Arthritis Rheum 60:1797). E600A is the first example of a NOD2 substitution attributed to isolated severe uveitis without other PGA nor systemic manifestations. Q809K is the first PGA substitution located in the leucine rich repeat functional domain of NOD2 (all others are in/near the NACHT domain), which harbors Crohn's disease-associated NOD2 variants.

Conclusion: These findings significantly contribute both to the genetic (i.e., new mutations) and clinical (i.e., single organ/tissue involvement and new cases of expanded involvement) spectra of *NOD2* associated diseases.

Anti–Tnfα Therapy, but Not Methotrexate (MTX), Affects the Balance Between CD4+CD25+FOXP3+ Regulatory T Cells (Tregs) and Th17 Cells in Children with Juvenile Idiopathic Arthritis (JIA). Biagio Olivito, Gabriele Simonini, Gabriele Rossi, Letizia Betti, Maria Moriondo, Maurizio de Martino, Chiara Azzari and Rolando Cimaz, University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy

Purpose: Anti–TNFα therapy has become a valid and important treatment option for children with JIA although its role in modulating Tregs and Th17 cells has not fully elucidated, particularly in this disease. We therefore investigated the percentage and surface phenotype of Tregs

and Th17 cells from JIA children before and after treatment with two anti-TNFα inhibitors currently available (Adalimumab and Etanercept), comparing them with both healthy children and patients treated with MTX.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from 26 children (16 females and 10 males, median age: 6.2 years) with JIA before and after initiation of anti-TNFα or MTX therapy (median ± S.D.: 13.6 ± 6.6 months and 14.1 ± 4.5 months respectively, both groups n=13). Twenty demographically-matched controls were also included. Expression of FOXP3 was analyzed by flow cytometry and Real Time PCR. The relative expression of RORC2 was investigated on CD3+CD4+ sorted T cells. Surface expression of selectin L (CD62L) by gated CD4+FOXP3+ T cells was also evaluated. IL-17A on gated CD3+CD45RO+ memory T cells was assayed in PBMCs unstimulated and stimulated for 4 hrs with Phorbol Myristate Acetate (PMA) and Ionomycin. The expression of the activation marker CD69 on CD3+CD8+ and CD3+CD8- (representing CD4 T cells) was investigated to exclude the possibility that observed effects may be due to differences in T cell activation.

Results: At baseline, the percentage of Tregs as well as the amount of FOXP3 mRNA were significantly reduced in JIA patients when compared with controls, confirming our previous results. A significant increase in the percentage of CD3+CD45RO+ memory T cells secreting IL-17A was found, upon activation with PMA and Ionomycin, in JIA patients when compared with controls (median % ± S.D. 2.35 ± 0.8% vs 1.45 ± 0.77 %; P=0.0013). Interestingly, both these percentages changed, returning to that seen in controls, only in children who responded to anti-TNFα treatment. In contrast, the percentage of Tregs and Th17 cells remained unchanged in patients treated with MTX or unresponsive to anti-TNFα therapy and the same was true at transcriptional level. Furthermore, treatment with anti-TNFα and MTX did not produce significant changes in the percentage of CD3+CD69+ activated T cells. Of note, contrary to what has been observed in rheumatoid arthritis, no differences in the surface expression of CD62L by gated CD4+FOXP3+ T cells was noted after treatments with anti-TNFα and these levels were comparable to that detected in controls.

Conclusion: This study support an immunomodulatory effect of Etanercept and Adalimumab on Th17 and Treg cells, also suggesting a dominating Th17 responses in JIA children probably as a consequence of their peculiar immunological abnormalities.

Disclosure: B. Olivito, None; **G. Simonini**, None; **G. Rossi**, None; **L. Betti**, None; **M. Moriondo**, None; **M. de Martino**, None; **C. Azzari**, None; **R. Cimaz**, None.

Immature Cell Populations and An Erythropoiesis Gene Expression Signature in Systemic Juvenile Idiopathic Arthritis: Implications for Pathogenesis. Claas H. Hinze[1], Ndate Fall[1], Sherry Thornton[1], Thomas A. Griffin[1], Susan D. Thompson[1], Robert A. Colbert[2], David N. Glass[1], Michael Barnes[1] and Alexei A. Grom[1], [1]Cincinnati Children's Hospital, Cincinnati, OH, [2]NIAMS/NIH, Bethesda, MD

Purpose: Previous observations suggest that active systemic juvenile idiopathic arthritis (sJIA) is associated with a prominent erythropoiesis gene expression signature. The aim of this study was to determine the association of this signature with peripheral blood mononuclear cell (PBMC) subpopulations and its specificity for active sJIA.

Methods: 199 patients with JIA (23 sJIA and 176 non-sJIA) and 88 controls were studied. PBMC were isolated and analyzed for multiple surface antigens by flow cytometry. PBMC RNA was isolated and gene expression profiling was performed using Affymetrix HG U133 Plus 2.0 GeneChips. The proportions of different PBMC subpopulations were compared among sJIA, non-sJIA patients and controls and subsequently correlated with the strength of the erythropoiesis signature. Additional gene expression data from patients with familial hemophagocytic lymphohistiocytosis (FHLH) and from a published sJIA cohort including controls with infectious diseases and other inflammatory conditions were analyzed to determine the presence and predictive strength of the erythropoiesis signature in these cohorts.

Results: Patients with sJIA had significantly increased proportions of immature cell populations, including CD34+ cells (sJIA vs. non-sJIA vs. controls = 0.16% vs. 0.08% vs. 0.09%; $p<0.001$, ANOVA). The proportions of CD34+ PBMC correlated highly with the strength of the erythropoiesis signature ($r=0.54$, $p<0.001$). This expansion was most prominently seen in patients with sJIA and anemia, even in the absence or reticulocytosis. Patients with non-sJIA and anemia did not exhibit the erythropoiesis signature. The erythropoiesis signature was found to be prominent in patients with FHLH and in a published cohort of patients with active sJIA but not in patients with inactive sJIA (receiver-operating characteristic curve area under the curve for active vs. inactive sJIA = 0.92). In addition, some patients with infection also exhibited a prominent erythropoiesis signature.

Conclusion: An erythropoiesis signature in active sJIA is associated with the expansion of CD34+ cells, and is also seen in some patients with FHLH and infection, suggesting a shared pathogenic mechanism among these conditions. The erythropoiesis signature may be an indicator of ineffective erythropoiesis and hemophagocytosis due to hypercytokinemia.

Prevalence of Functionally Active, Senescent T Cells in Juvenile Idiopathic Arthritis. Jeffrey A. Dvergsten, Robert G. Mueller, Sameem Abedin, Bonnie H. Lemster, Allyson Pishko, Joshua Michel, Margalit E. Rosenkranz and Abbe N. Vallejo, Children's Hosp of Pittsburgh, Pittsburgh, PA

Purpose: All somatic cells have a finite proliferative lifespan. T cell activation through a lifetime exposure to antigens or in the setting of chronic immune-mediated disease could result in differentiated cells incapable of mitosis, a cell fate called replicative senescence. Indeed, we have reported that senescent T cells accumulate with normal chronologic aging. And adults with rheumatoid arthritis, disproportionate with age, have large populations of senescent T cells that colonize rheumatoid lesions. To further examine age-independent pathway(s) of T cell senescence, we examined the T cell repertoire of children diagnosed with Juvenile Idiopathic Arthritis (JIA). In JIA, pervasive T cell oligoclonality suggests underlying replicative stress. We hypothesize that T cells of JIA patients are prematurely senescent, abundance of these cells influences clinical disease manifestations.

Method: Children diagnosed with oligo- or poly-articular JIA, and age-matched controls were recruited. Blood and/or synovial fluid samples were collected. T cell phenotypes were examined by flow cytometry. T cell replicative potential was evaluated by telomere fluorescence in-situ hybridization (FISH), by population doubling assays, by rate of production of senescent cells in vitro, and by proliferation assays using CFSE (5- and 6-carboxyfluorescein diacetate succinimidyl ester). Where novel receptor expression on senescent T cells was indicated, receptor cross-linking bioassays were conducted to assess cellular function.

Results: Compared to controls, naïve T cells of children with JIA have significantly lower telomere-FISH fluorescence consistent with premature telomere erosion. In CSFE assays, up to 40% of T cells of JIA patients remained $CFSE^{hi}$ and expressed high levels of CD69 and low levels of CD25 indicating senescence but not quiescence. $CFSE^{hi}$ T cells were mostly $CD4^{+}CD28^{-}CD31^{low/-}$, and $CD8^{+}CD28^{-}CD31^{+}$. Flow cytometry showed over abundance of these cells in blood and synovial fluid. In JIA, $CD8^{+}CD28^{-}CD31^{+}$ T cells co-expressed senescence proteins γ-H2AX and/or pRB, consisting of up to 80% of the T cell repertoire of patients with oligo-JIA. In population doubling and senescence assays, pRB^{+}/γ-$H2AX^{+}$ T cells emerged within 15 days, maximum proliferation at 25 days, and mitotic arrest at 35 days. In receptor cross-linking assays, CD31 ligation, independent of CD3, induced extensive tyrosine phosphorylation and NFkB p65 activation. CD31-driven activation of $CD28^{-}$ T cells resulted in CD25 and CD45RO upregulation.

Conclusion: $CD8^{+}CD28^{-}CD31^{+}pRB^{+}$γ-$H2AX^{+}$ T cells are prematurely senescent T cells in JIA. They are functionally active despite their inability to undergo mitosis. Their prevalence in synovial fluid suggests a role in the pathophysiology of JIA, and are potential targets for therapy.

DEK in the Synovium of JIA Patients: Characterization of DEK Antibodies and Posttranslational Modification of the DEK Autoantigen. Nirit Mor-Vaknin[1], Ferdinand Kappes[1], Amalie E. Dick[1], Maureen Legendre[1], Catalina Damoc[1], Roland Kwok[2], Elisa Ferrando-May[1], David M. Markovitz[1] and Barbara S. Adams[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan

Purpose: DEK is a nuclear phosphoprotein that is an autoantigen in some children with juvenile idiopathic arthritis (JIA). The presence of autoantibodies to DEK in other autoimmune and granulomatous diseases suggests that DEK antibodies are present in a broad spectrum of disorders associated with abnormal immune activation. We have recently demonstrated that 1) activated macrophages secrete DEK, 2) apoptotic T cells release DEK, and 3) DEK is a leukocyte chemoattractant. Heavy post-translational modification of DEK suggests that these modifications may be important regulatory mechanisms that control DEK function. We have also identified DEK in synovial fluids (SF) from JIA patients, leading us to investigate how posttranslational modification of DEK may alter the affinity of DEK antibodies, thereby contributing to the pathogenesis of JIA.

Methods: DEK antibodies, immune complexes, and synovial macrophages were purified from SF from patients with active synovitis. Exosomes were purified from supernatants of cultured synovial macrophages by serial centrifugation and isolation by magnetic beads coated with anti-CD81 beads. Antibodies to DEK were purified from SF of 10 different JIA patients over a Sulfolink-coupled DEK column. Immune complexes were purified by staphylococcal-binding assay analyzed by 2-D gel and Western blot analysis. DEK antibody subclasses were determined by Western blot and ELISA. Recombinant His-DEK was used to study DEK posttranslational modification. DEK posttranslational modifications were analyzed by Western blot and by the Nano-LC-MS/MS sensitive method.

Results: DEK is secreted by synovial macrophages in a free form and also via exosomes; we have also shown for the first time that DEK antibodies and DEK protein are present in SF from JIA patients. Purified DEK antibodies from JIA SF primarily recognize the C-terminal half of the DEK protein. They are predominantly of the IgG_2 subclass, and are thus capable of activating the complement cascade. In addition to showing that DEK protein is present in immune complexes purified from JIA SF, we also demonstrate that DEK antibodies from JIA patients exhibit increased affinity for DEK protein that has been postranslationally modified by acetylation. This is consistent with our Nano-LC-MS/MS analysis of DEK posttranslational modification, which demonstrates that DEK undergoes acetylation on an unprecedented number of lysine residues.

Conclusion: Posttranslational modification of DEK protein by acetylation enhances the affinity of DEK antibodies. This finding suggests a mechanism by which DEK protein and DEK antibodies may contribute directly to joint inflammation by generating immune complexes in the joints of children with arthritis.

Phosphorylated Mitogen-Activated Protein Kinases Are Colocalized with Membrane Attack Complex and Cyclin E in Juvenile Idiopathic Arthritis-Affected Synovial Tissue. Michael J. Ombrello[1], Anil Chauhan[2] and Terry L. Moore[1], [1]Saint Louis University School of Medicine, St Louis, MO, [2]Saint Louis University, St Louis, MO

Purpose: Juvenile idiopathic arthritis (JIA) describes a group of childhood-onset inflammatory arthritic disorders whose causes are unknown. In JIA, disease activity positively correlates with levels of synovial complement activation products and synovial deposition of immune complexes (IC), suggesting a role in JIA pathophysiology. Elevated levels of the complement membrane attack complex (MAC) are present in the synovial fluid of JIA patients, and deposits of MAC have been demonstrated in JIA synovial tissues. Yet, the specific roles of complement and ICs in the pathogenesis of JIA remain to be elucidated. In sublytic doses, MAC demonstrates pleiotropic effects on the cell cycle which are modulated through the mitogen-activated protein kinases (MAPKs). Our previous examination of JIA synovial tissue for cell cycle activation, as indicated by cyclin E (CyE) expression, found that it was almost exclusively confined to areas of MAC deposition. To further investigate the potential relationship between MAC deposition and cell cycle activation in JIA, we used immunohistochemistry (IHC) to examine JIA synovial tissue for MAC, CyE, and the phosphorylated MAPKs, pERK1/2 and pAkt.

Method: Synovial tissue was obtained from an 11-year-old female patient with ANA positive, oligoarticular JIA who underwent surgical synovectomy of the left knee for unremitting synovitis. Standard IHC methods were used to double stain specimens for MAC, CyE, pERK, and pAkt. Images of the specimens were obtained using fluorescent and confocal microscopy.

Results: The patterns of MAC deposition, CyE expression, and MAPK phosphorylation were identical, primarily in the synovial lining layer. CyE was colocalized with MAC deposits, pERK, and pAkt. MAC deposition was colocalized with CyE and pAkt. pAkt was colocalized with MAC deposits and CyE. Collectively, the phosphorylated MAPKs were universally and exclusively present at the sites of MAC deposition and CyE expression.

Conclusion: Cell cycle activation by sublytic MAC is a MAPK-dependent event. Phosphorylation of MAPKs activates the transcription factor, E2F, which in turn activates the G_1/S cell cycle checkpoint. The induction of CyE is a critical event of G_1/S checkpoint activation. Aside from periods of G1/S checkpoint activation, CyE expression is strongly repressed, CyE is rapidly degraded, and CyE protein is absent in most tissues. Based on this knowledge, we interpreted the colocalization of MAC and CyE as evidence of MAC-induced cell cycle activation in the JIA synovium. The current findings of MAPK phosphorylation, colocalized with MAC deposition and CyE expression, provides further support for a role for MAC-induced signaling in the synovial pathophysiology of JIA.

Toll-Like Receptor-2 and -4 Independent Regulation of Cytokine Network in Juvenile Idiopathic Arthritis. Volker N. Umlauf, Martina Kirchner and Wilma Mannhardt-Laakmann, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany

Background: In rheumatic diseases “damage associated molecular patterns” (DAMP) stimulate Toll-like receptors (TLR) to activate macrophages and secondly T cells as major cytokine producers. TLR-2/-4 expression is supposed to play a major role in juvenile idiopathic arthritis (JIA) pathogenesis. Although the cause of JIA, a heterogeneous group of childhood arthritides, remains unknown, it is well known that different cytokines are the main mediators of inflammation in several JIA subgroups.

Purpose: To investigate the pathogenetic association between TLR-2 and -4 expression and cytokine levels in JIA subgroups.

Method: 150 children (29 systemic JIA (SJIA), 38 persistent oligoarthritis (POA), 15 seronegative polyarthritis (SNP), 12 enthesitis related arthritis (ERA), and 32 healthy controls) were included in this study. Cellular expression of TLR-2 and -4 was determinated by staining blood derived monocytes with commercially available monoclonal antibodies for human TLR-2 and TLR-4 followed by flowcytometric analysis. A multiplex fluorescent bead immunoassay was first time used for quantititative detection by flow cytometry of pro- and anti-inflammatory cytokines in JIA blood plasma (proinflammatory cytokines mainly produced by macrophages: IL-1β, TNF-α; by Th1 cells: IL-2, -12p70, IFN-γ; by Th2 cells: IL-6, -8; antiinflammatory cytokines: IL-4, -5 and -10). Data were statistically analysed by Mann-Whitney-U- and Kruskal-Wallis-test and correlated by Spearman-Rho-test.

Results: While TLR-2 expression is decreased in all JIA subgroups, TLR-4 is elevated in certain groups. In SJIA we found a broad spectrum of proinflammatory cytokines (IL-6, IL-12p70, IFN-γ). IL-2 and IL-6 were found to characterize POA, whereas SNP is mainly described through IL-2. TNF-α levels seem to be highest in SNP. ERA is determined by IFN-γ and antiinflammatory IL-10. Interestingly, no correlations between TLR-2/-4 expression and cytokine levels were found. Nevertheless, pro- and antiinflammatory cytokines showed highly positive correlated ($r \geq 0.60$, $p \leq 0.01$) regulatory feedback patterns specific for JIA subgroups (SJIA: IL6 vs. IL-5; POA: IL-6/IL-2 vs. IL-5; SNP: TNF-α vs. IL-4; ERA: IL-6/IL-2 vs. IL-5).

Conclusion: TLR expression in JIA differs from known expression models in rheumatoid arthritis of the adult. The subgroups themselves can be characterized through specific combinations of pro- and antiinflammatory key cytokines which is a useful tool in differential diagnosis. TLR expression and cytokine production seem to be independent events in JIA. Pro- and antiinflammatory cytokines apparently regulate themselves within a disease specific cytokine network. However, the regulatory link between TLRs and inflammatory response in JIA is still under investigation.

Replication of Genetic Associations in Juvenile Idiopathic Arthritis. H.M. Albers[1], T.H.C.M. Reinards[1], D.M.C. Brinkman[1], S.S.M. Kamphuis[2], L.W.A. van Suijlekom-Smit[2], M.A.J. van Rossum[3], E.P.A.H. Hoppenreijs[4], H.J. Girschick[5], C. Wouters[6], R.K. Saurenmann[7], Jeanine J. Houwing-Duistermaat[1], T.W.J. Huizinga[1], R.E.M. Toes[1], R. ten Cate[1] and M.W. Schilham[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]Academic Medical Center, Amsterdam, Netherlands, [4]Radboud University Medical Center, Nijmegen, Netherlands, [5]University of Wuerzburg, Wuerzburg, Germany, [6]University Hospital Gasthuisberg, Leuven, Belgium, [7]University Children's Hospital, Zürich, Switzerland

Purpose: Juvenile Idiopathic Arthritis (JIA) is an autoimmune disease in which both genetic and environmental components are involved. Different genetic variations have been reported as risk factors for JIA, but replication of results in an independent cohort with the same ethnic background remains a difficulty. In this study we have replicated several known genetic associations in a cohort of Caucasian JIA patients.

Method: A case-control association study has been performed in a cohort of 650 Caucasian JIA patients and 870 healthy controls. Patients with oligoarthritis (persistent and extended), polyarthritis (rheumafactor negative and positive) and systemic JIA have been included. Furthermore a transmission disequilibrium test (TDT) has been performed in 440 patient-parent trios. Several polymorphisms have been studied that have previously been described in literature as associated with JIA.

Results: We were able to replicate a genetic association in PTPN22 (in both case-control analysis and TDT), different associations in TNF-alpha and an association in IL6 and systemic JIA. A recent meta-analysis showed that CTLA4 is repeatedly not associated with JIA, as we observe in our data. Neither associations in IL10 and IL1A were observed.

Conclusion: These data show that some genetic associations in JIA are repeatedly found and thereby indicate that these genes might be important in the pathogenesis of (subtypes of) JIA. Moreover, this study underlines the importance of replication of associations in an independent cohort with a similar ethnic background.

Table 1: Association of single nucleotide polymorphisms (SNPs) with (subtypes of) JIA

Gene	SNP	Allelic OR (95%-CI)	p	p of TDT
PTPN22	rs2476601 - A	1.29 (1.03-1.61)	0.027	0.006
CTLA4	rs231775 - G	0.92 (0.79-1.07)	0.277	0.150

Elevated Matrix Metalloproteinase-2 (MMP2) Levels in Cord Blood of Anti-Ro/La Exposed Neonates Associate with the Presence and Severity of Cardiac Manifestations of Neonatal Lupus. Tania L. Rivera, Jill P. Buyon and Robert M. Clancy, NYU School of Medicine, New York, NY

Purpose: Histologic evaluation of autopsies from hearts of neonates dying with cardiac manifestations of neonatal lupus (NL) support fibrosis (replacement of atrioventricular node and endocardial fibroelastosis) as the signature lesion. The role of the MMP2 in tissue remodeling and development of cardiac fibrosis has been studied in adults but never described in newborns. It has been reported that the transforming growth factor beta1 (TGFbeta1) induces secretion of MMP2 by fibroblasts during tissue regeneration. The aims of this study were to investigate the levels of MMP2 in cord bloods of children exposed to anti-Ro//La antibodies, and asses the value of these levels in predicting occurrence and severity of cardiac NL.

Method: One hundred and four cord bloods from children of families enrolled in the U.S. based Research Registry for Neonatal Lupus were evaluated. Criteria for inclusion were: 1) presence of maternal anti-Ro and/or La antibodies 2) substantial medical records regarding health status of the neonate. A neonate was considered to have cardiac NL based on the presence of heart block (1st, 2nd ,3rd, degree) documented by electrocardiogram (if 1st degree), echocardiogram, history of pacemaker, or statement in the medical record; and/or presence of cardiac injury which included autopsy evidence of a mononuclear infiltrate in the endocardium, myocardium and pericardium and/or endocardial fibroelastosis on echocardiogram always associated with cardiac dysfunction. Fifty-four neonates had cardiac NL diagnosed in utero or at birth. Levels of MMP2 were assessed by ELISA.

Results: Of the 104 children evaluated, 50% were females, 80% were Caucasians, and the average age of the mother at the time of birth was 33±0.5 years. Of the mothers, 42% had anti-Ro and anti-La, compared to 58% with anti-Ro alone. There were no differences in gender, race, diagnosis of the mothers, history of previous child with cardiac NL, or titers of maternal anti-Ro/La antibodies in the children with cardiac NL compared to those without cardiac NL. Significantly elevated levels of MMP2 were found in those with cardiac NL compared to those without (median MMP2 438ng/ml±18 vs 338ng/ml±20, p=0.0001).The levels of MMP2 did not predict the degree of advanced block (2^{nd} degree vs 3^{rd} degree 480±44 vs 439±20, p = 0.7). However, there was a trend toward higher levels in children who developed cardiomyopathy (n=6) compared to those who did not (520±42 vs 428±20, p=0.08). There were only 2 deaths in the cardiac NL group (likely underestimating true incidence of death because cord blood was unavailable on those with in uterine demise), and their MMP2 levels were extremely elevated at 574 and 570ng/ml. The heart rate of the children with 2^{nd} or 3^{rd} degree block at the time of diagnosis did not correlate with the levels of MMP2 at birth. There were no differences between MMP2 levels from cardiac NL children who underwent pacemaker implantation compared to those who did not (443±34 vs 434±21, p=0.6).

Conclusion: The increase of MMP2 levels may reflect tissue response to injury and more extensive disease, thus predicting a worse prognosis.

Juvenile Systemic Lupus Erythematosus Frequently Develops in a "Background" of Primary Immunodeficiencies. Adriana A. Jesus[1], Bernadete Liphaus[1], Clovis A. Silva[1], Luis Eduardo C. Andrade[2], Antonio Coutinho[3] and Magda Carneiro-Sampaio[1], [1]Universidade de São Paulo, São Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil, [3]Instituto Gulbenkian de Ciência, Oeiras, Portugal

Purpose: To evaluate the frequency of complement and antibody primary immunodeficiencies (PIDs) in Juvenile Systemic Lupus Erythematosus (JSLE) patients and to compare lupus patients with and without PID regarding demographic data, clinical features, disease activity and damage, treatment and occurrence of severe sepsis.

Method: Seventy-two JSLE (ACR criteria) patients (1 to 16 yrs at diagnosis) were analyzed for early components of the classical complement pathway (C1q, C1r/C1s, C4, C2, C3) and immunoglobulin levels (IgG, IgA, IgM, IgE, and IgG2 subclass). Anti-C1q antibody was detected by ELISA (Inova Diagnostics - QUANTA Lite™ Anti-C1q, San Diego, USA). Statistical analysis was carried out according to Fisher´s exact test, Mann-Whitney test and Backward Stepwise multivariate analysis.

Results: Nineteen patients (26%) had underlying PIDs. Complement deficiencies were detected in 9 JSLE patients: C2 deficiency in 5 cases, C4 deficiency in 2 (all with persistently very low values in the presence of normal levels of other complement components, and SLEDAI < 4) and complete C1q deficiency in 2. All patients had normal C3 levels. Immunoglobulin deficiencies were found in 10 JSLE patients: IgG2 deficiency (<20mg%) in 4, IgA deficiency (<7mg%) in 3, IgM deficiency (<35mg%) in 3. All patients with immunoglobulin deficiencies were identified after 10-years of age and had normal or high total IgG levels. One IgA deficient patient also presented C4 and C2 deficiencies. The frequency of male gender was significantly higher in JSLE patients with PID compared to those without PID (37% vs. 11%, p=0.032). The 2 cases of infantile SLE (age at onset <2 years) were both males (one with C1q deficiency and other with IgM deficiency). A remarkably higher frequency of severe sepsis was observed in the PIDs group (31% vs. 7.5%; p=0.017). Lupus clinical features (cutaneous, mucosal, neuropsychiatric, cardiopulmonary, renal, hematological and articular manifestations and antiphospholipid syndrome) were comparable in patients with and without PID (p>0.05). SLEDAI score and anti-C1q antibody levels were also alike. On the other hand, the median of the cumulative damage (SLICC/ACR-DI) was significantly higher in PIDs group [1(0 - 5) vs 0 (0 - 3); p=0.0075]. Additionally, 44% of JSLE patients (30/68) had high IgE levels (>100UI/ml). Multivariate analysis revealed that male gender (Odds ratio=4.7; CI=1.2 – 19.2; p=0.034) and SLICC/ACR-DI (Odds ratio=2.5; IC=1.13 – 4.8; p=0.007) were the independent risk factors for PID.

Conclusion: An exceedingly high frequency of antibody and complement deficiency was observed amongst JSLE patients, suggesting that these immunologic defects may contribute to the disease development. Our results command that these two groups of PIDs should be systematically investigated particularly in males with disease damage.

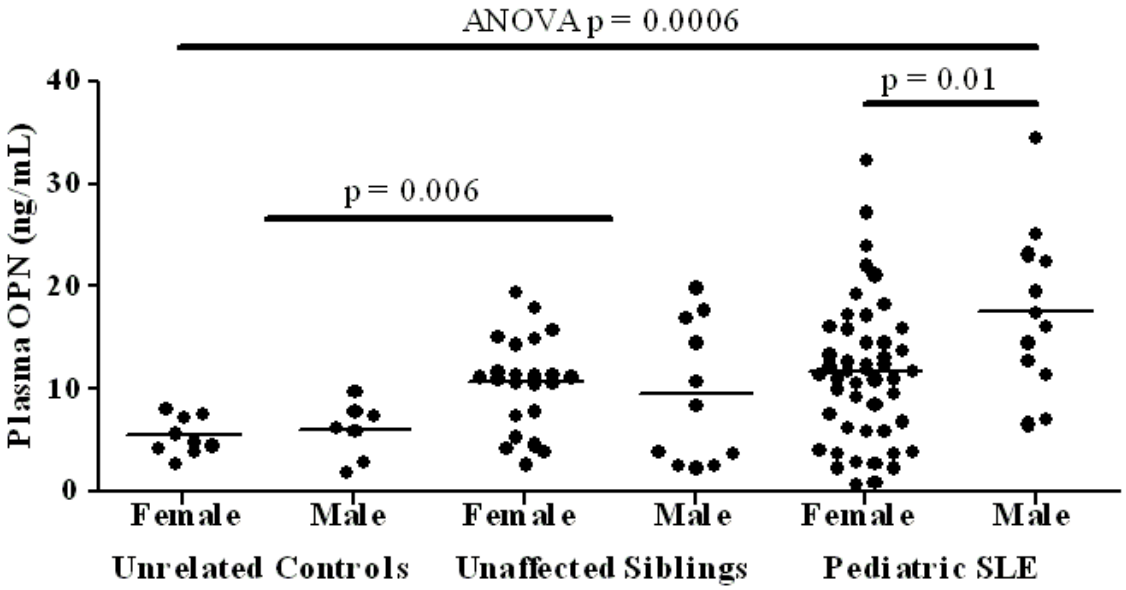
Circulating Osteopontin Levels Are Elevated in Male Pediatric SLE and Their Unaffected Siblings. Ornella J. Rullo[1], J.M.P. Woo[2], Alice DC Hoftman[3], Deborah K. McCurdy[1] and Betty P. Tsao[2], [1]Mattel Children's Hospital UCLA, Los Angeles, CA, [2]Division of Rheumatology, UCLA, Los Angeles, CA, [3]CHOC, Orange, CA

Purpose: Osteopontin (OPN) plays a role in Interferon signaling, an important pathway in SLE pathogenesis. *OPN* gene variants have been associated with SLE, and gender- and age-specific variability in circulating OPN protein levels have also been described. We aim to study OPN in pediatric SLE patients and their unaffected siblings.

Method: Genomic DNA and plasma were collected from 60 (48 female; 12 male) pediatric-onset SLE patients (age of SLE onset <21 years), 35 unaffected healthy siblings (23 female; 12 male), and 16 healthy unrelated pediatric controls (9 female; 7 male). All subjects were < 24 years of age at time of study. Plasma OPN protein levels were measured using ELISA and *OPN* SNP genotyping was performed using Taqman assays. Statistical analysis was performed using Student's t test or nonparametric Mann Whitney U.

Results: Plasma OPN protein levels were higher in unaffected siblings of pediatric SLE patients than in unrelated pediatric controls ($p = 0.006$). Increasing levels of OPN were detected in unrelated controls, unaffected siblings and SLE cases (ANOVA $p = 0.0006$; see figure). OPN levels of the discordant sibling pairs correlated with a Pearson γ value of 0.58 ($p = 0.0009$). Of all the pediatric SLE patients, plasma OPN protein levels were higher in the 12 males compared with the 48 females ($p = 0.01$). No gender difference was observed in plasma OPN protein levels in unaffected siblings of pediatric SLE patients or in unrelated healthy controls ($p = 0.5$ and 0.6, respectively). Male pediatric SLE cases with the known *OPN* rs9138 SLE-risk allele had increased OPN levels compared with females ($p = 0.03$; $n = 9$ and 34, respectively). This increase in OPN levels was not seen based on genotype in the unrelated male controls and unaffected male siblings.



Conclusion: Significant increases in plasma OPN protein levels were seen when comparing pediatric unrelated controls, unaffected siblings, female SLE and male SLE patients, with pediatric male SLE patients having the highest OPN plasma protein concentration. The presence of the *OPN* SLE-risk allele may partially explain the OPN plasma protein gender difference seen in pediatric SLE, but not the difference seen between siblings and controls. The potential role for plasma OPN as a biomarker to help assess autoimmune risk in siblings of pediatric SLE patients needs further study.

Novel Autoantigen for Anti-Endothelial Cell Antibodies (AECA) Identified by Proteomics in Kawasaki Disease. Rie Karasawa[1], Tomohiro Kato[2], Mikiya Fujieda[3] and Kazuo Yudoh[1], [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]St.Marianna University School of Medicine, Kawasaki, Japan, [3]Kochi Medical School, Nankoku, Japan

Purpose: Anti-endothelial cell antibodies (AECA) are thought to be involved in pathophysiology of vasculitis, including Kawasaki disease (KD). However, target molecules of AECA have been poorly identified, which hampers understanding of roles of AECA in detail. We tried to detect and identify target proteins of AECA comprehensively by proteomics. Further, we investigated clinical importance of the identified autoantigens and their related proteins.

Methods: To detect endothelial cell-specific autoantigens for AECA, we separated proteins extracted from human umbilical cord vein endothelial cell (HUVEC) and HeLa cells respectively by 2-dimensional electrophoresis (2DE) and then transferred them onto membranes. By western blotting (WB) using serum samples from patients with vasculitis, we detected autoantigens that were positive only in the HUVEC samples but not in the HeLa cell samples. We next identified the detected proteins by peptide mass finger-printing (PMF) and characterized antigenecity by preparing recombinant autoantigens and antibodies to them.

Results: We have identified 63 proteins out of the 150 HUVEC-specific autoantigens recognized by serum samples from patients with vasculitis by PMF so far. One of the identified proteins was found peroxiredoxin2 (Prx2), an anti-oxidative enzyme. The autoantibodies to Prx2 were detected in 60% of the patients with KD, but not in healthy controls. Interestingly, the autoantibodies to Prx2 were detected in all the tested KD patients with coronary artery lesions. The antigenecity of Prx2 was found different from its related enzymes of Prx1 and Prx4. Indirect immunofluorecence staining revealed existence of Prx2 on the cell surface of HUVEC and WB using cell lysate proved expression of Prx2 not only in HUVEC but also in other endothelial cells (ECs), including human aortic endothelial cells and human coronary artery

endothelial cells (HCAEC) . The anti-Prx2 antibodies also increased various inflammatory cytokine secretion significantly, in particular IL-6. IL-6 and sICAM-1 secretion of ECs stimulated with serum samples of patients with high anti-Prx2 titers was detected. Further, 1DE-WB analysis using HCAEC-extracted proteins as the antigen source detected three bands (53, 44 and 35 kDa) specific for serum samples from KD patients with coronary artery lesions.

Conclusion: The autoantibodies to Prx2, which we found for the first time, would be a useful marker for KD. The anti-Prx2 autoantibodies may have a pathogenic role in Kawasaki disease via inflammatory cytokine production and inhibition of anti-oxidative activity of Prx2 by binding Prx2 on ECs.

Importance of Fcg Rl&lll and CD11b in Susceptibility and Immune Response to CAWS Induced Coronary Angiitis /Aortitis. Ingrid Tomanova-Soltys[1], Joy Whitbred[1], Beverly Dahms[1], Kazuo Suzuki[2], Noriko Miura[3], Naohito Ohno[3], Robert Whitbred[4] and Nora G. Singer[1], [1]University Hospitals/Case Medical Center/Rainbow Babies and Children's Hospital, Cleveland, OH, [2]Graduate School of Medicine, Chiba University, Chiba, Japan, [3]Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan, [4]Cleveland State University, Cleveland, OH

Purpose: To identify critical cell type(s) and receptors involved in the susceptibility and pathogenesis of coronary angiitis and aortitis in a mouse model of human Kawasaki Disease (KD) induced by immunization with *Candida albicans* Water Soluble fraction (CAWS).

Method: 6-12 week old C57Bl/6 (wt) and FcgRI&III knockout (k/o) mice were immunized with a total dose of 4 mg CAWS intraperitoneally (I.P.). Mice were sacrificed on 3-49 days post immunization. Splenocytes were analyzed by flow cytometry. Hearts were dissected and frozen for H&E staining or immunostaining and imaged by confocal microscopy. Statistical analysis was performed using SPSS.

Results: Greater than 75% of wt mice developed coronary angiitis/aortitis 21-28 days post-CAWS immunization. H&E staining demonstrated inflammation of the proximal aorta and/or coronary arteries and appeared to contain a mixed cellular infiltrate of neutrophils and macrophages. Affected mice exhibited splenomegaly consistent with immune activation and increased numbers of splenocytes that expressed CD11b on their surface. Immunoflorescence staining of heart sections analyzed by confocal microscopy demonstrated the presence of CD11b+, CD11c+, and Gr-1+cells within the inflammatory infiltrate along with occasional B220/CD45R+, CD3+ and F4/80+ cells. In contrast to wt mice, mice that lacked FcgRI&III receptors were resistant to CAWS-induced immune activation, as evidenced by absence of splenomegaly, aortitis/angitis, or increased CD11b expression on splenocytes following immunization.

Conclusion: CAWS immunization induces mouse coronary arteritis, aortitis, and splenomegaly and is accompanied by altered immune populations, especially CD11b+ cells, in the spleen. Mice lacking FcgRI and III are resistant to coronary angiitis and lack evidence of CAWS-related immune activation, suggesting that the presence of FcgRI and III are necessary for development of the vasculitis phenotype, and that CD11b+ neutrophils and/or macrophages play a prominent role in the inflammatory process.

Juvenile Dermatomyositis (JDM): Responders and Non-Responders to Medical Therapy Have Differential Genetic Profiles. Nicholas Geraci[1], Lauren M. Pachman[1], Gabrielle Morgan[1] and Yi-wen Chen[2], [1]Children's Memorial Research Center, Chicago, IL, [2]Children's National Medical Center, Washington, DC

Purpose: 1) To identify changes in gene expression profiles of muscle before and after therapy in children with juvenile dermatomyositis (JDM) and, 2) to compare the profiles of those children who responded to medical therapy with those did not.

Method: 8 patients with JDM (mean age at diagnosis (Dx), 6.7 ± 5.5 yrs, 4 females, all with disease duration > 2 months, 5 non-responders) enrolled after informed consent. All patients had an MRI guided open muscle biopsy (Bx) at Dx and a needle Bx after medical therapy (mean 78 ± 1.6months post-Dx). Gene expression profiles of Bx RNA from 4 patient muscle pairs were generated using Affymetrix Human

Genome U133 Plus 2.0 Array with Affymetrix MAS (Version 5.0, Affymetrix, CA). Using Genespring, the JDM samples were normalized to the median of the samples of the responders collected post-treatment. Only probe sets with at least one MAS 5.0 "present calls" across all profiles were retained. Weltch t-test and the Benjamini and Hochberg false discovery rate (5%) were used. Hierarchical clustering was then performed and a branch of genes that differentially responded to treatment was manually selected. The array data was validated by quantitative real-time PCR (qRT-PCR) of 4 additional patient pairs with Qiagen Quantitect primers for 4 genes, and Qiagen Quantifast SYBR Green PCR kits (Valencia, CA). Samples were analyzed on an Applied Biosystems 7500 Fast Real-Time PCR thermal cycling system (Foster City, CA). Expression data were analyzed by Ingenuity Pathway Analysis (IPA, Version 7.5, Redwood City, CA).

Results: Four JDM pairs displayed 182 positively present genes with differential expression in Affymetrix expression arrays. None of the vascular remodeling genes identified in a previous study of JDM disease duration (Chen, *et al.* 2008) displayed differential expression based on treatment response. 20 genes of interest (differentially expressed $\geq$ 2 fold between responders and non-responders at time of diagnosis or at later needle biopsies) were selected for further study based on IPA display. Among those genes were PTPN22 (2.3 to 2.5 fold upregulation before, after treatment in non-responders compared to responders), CPA3 (3.1 to 2.5), LTB (2.6 to 1.7), and CAMK2N1 (1.5 to 3.8). Similar expression patterns were obtained by qRT-PCR, validating microarray results. PTPN22 remained markedly upregulated, 15.4 fold post-treatment in the JDM non-responders compared to responders.

Conclusion: This study of JDM, the responders to conventional JDM therapy display differential gene expression patterns compared to non-responders, both at Dx and at follow-up. Many of those genes are involved in innate immunity. These data suggest that analysis of diagnostic biopsies might identify gene candidates for use as predictors of responsiveness to treatment of JDM, and potentially more effective interventions. Familial Aggregation of Autoimmune Disease in Families of Children with Juvenile Dermatomyositis: Family History of Lupus Is Associated with Increased IFN-α. Timothy B. Niewold[1], Stephanie C. Wu[2], Mariel Smith[2], Gabrielle A. Morgan[2] and Lauren M. Pachman[3], [1]University of Chicago, Chicago, IL, [2]Children's Memorial Research Center, Chicago, IL, [3]Childrens Memorial Research Center, Chicago, IL

Purpose: Familial aggregation of autoimmune diseases likely reflects shared pathogenic factors between different diseases. Familial aggregation of autoimmunity has not yet been examined in juvenile dermatomyositis (JDM). Interferon alpha (IFN-α) is thought to be a pathogenic factor in a number of autoimmune diseases, including systemic lupus erythematosus (SLE) and JDM, and we have previously demonstrated familial aggregation of serum IFN-α.

Methods: Family histories were obtained from 304 families of children with JDM via 3 generation structured interviews upon first visit to the clinic and every 36 months thereafter, by the same person (LMP, IRB #2008-13590). Adopted children were excluded due to lack of biological family history. Rates of autoimmune disease in JDM families as reported by family members are compared with population rates from published epidemiological studies. Serum IFN-α was measured using a functional reporter cell assay in a subset of samples from children with JDM.

Results: Among the 304 families of children with definite/probable JDM, 68.4% were reported to have at least one member affected by an autoimmune disease, and 29.3% of families had three or more individuals affected by autoimmune disease across the three generations ($p=0.0049$ for an increase over population rates). The most common autoimmune diseases found in JDM families included thyroid disease, type I diabetes, rheumatoid arthritis, and systemic lupus erythematosus (SLE). In particular, 11.5% of JDM families had a family member affected by SLE, which is over 5 times the rate which would be expected in the general population (OR=5.86, $p=5x10^{-6}$). Serum IFN-α was measured in a subset of these children with JDM, and untreated subjects with a family history of SLE had higher serum IFN-α than those who did not ($p=0.045$).

Conclusion: We find familial aggregation of autoimmune diseases in JDM families, and in particular SLE is over-represented. Serum IFN-α is higher in children with JDM who have a family history of SLE, suggesting that IFN-α could be a familial pathogenic factor which is common to these two diseases.

1325

Evaluation of Serum Neopterin Level as a Diagnostic Marker of Hemaphagocytic Lymphohistiocytosis Syndrome (HLH). Maria F. Ibarra[1], Marisa Klein-Gitelman[1], Elaine Morgan[1], Maria Proytcheva[1], Christine Sullivan[2], Gabrielle Morgan[2], Lauren M. Pachman[2] and Maurice O'Gorman[1], [1]Children's Memorial Hospital, Chicago, IL, [2]Children's Memorial Research Center, Chicago, IL

Purpose: The diagnosis of HLH is challenging.The presentation in primary and secondary HLH can be atypical and/or all of the clinical and laboratory criteria not present. Neopterin (tetrahydrobiopterin) is synthesized by macrophages and dendritic cells and is a marker of inflammation that has been associated with cell mediated immunity in various diseases. Our hypothesis is that high levels of serum neopterin provide a sensitive and specific diagnostic marker in patients suspected of HLH.

Methods: Demographic, clinical and laboratory characteristics were summarized by retrospective chart review of patients seen at CMH between January 2000 and May 2009 with a diagnosis of HLH (primary or secondary). Serum neopterin levels were measured using a competitive immunoassay with a normal range of <10 nmol/L. Receiver operating characteristic (ROC) analysis was used to examine the tradeoffs in sensitivity and specificity of neopterin as a diagnostic test. In the ROC analysis, we used neopterin levels from the HLH group and from a control group of 50 untreated active juvenile dermatomyositis (JDM) patients (who have neopterin levels measured routinely to assess disease activity) to assess various cutoffs in the tradeoff between sensitivity and specificity. The area under the curve (AUC) from the ROC analysis was also measured to assess the accuracy of neopterin levels as a diagnostic test of HLH. For HLH patients, the association between serum neopterin levels and biochemical data at diagnosis, three and six months was determined by repeated measures modeling.

Results: 17 patients with secondary and 2 patients with primary HLH were identified (mean age: 9.7 years, 53% male, 47% female) and compared with 50 JDM subjects (mean age: 7.5 years, 26% male, 74% female). A cutoff value of 46 nmol/L resulted in a sensitivity of 89% and a specificity of 81% for a diagnosis of HLH. Values above 46 gave lower sensitivity but higher specificity and values below 46 gave higher sensitivity but lower specificity. Area under the curve was 0.92 indicating high accuracy for neopterin as a diagnostic test of HLH. Neopterin levels were associated with ferritin (p=0.0007) and D-dimer levels (p=0.018), and inversely with platelet count (p= 0.034) and fibrinogen (p=0.035).

Cutoff for Neopterin (nmol/L)	**Sensitivity**	**Specificity**
59	61 %	100 %
56	67 %	95 %
51	72 %	86 %
46	89 %	81 %
43	94 %	76 %
37	100 %	64 %

Table 1: ROC results

Conclusion: All of the HLH patients had neopterin levels at least three times higher than the normal range. Compared to patients with active JDM, elevated serum neopterin levels were a very sensitive and specific marker for HLH. Future studies are aimed at confirming serum neopterin level as a new biomarker for the early diagnosis of HLH, and a marker of disease activity and response to therapy.

1326

Characterization of the Inflammatory Skin Lesions in NOMID Before and After Treatment with Anakinra. P. Aubert[1], H. Mitsui[2], M. Suárez-Fariñas[2], L. Johnson-Huang[2], K. Pierson[2], G. Dolan[1], J. Krueger[2], I. Novitskaya[2], I. Coats[2], J. Estes[1], E. Cowen[1], Nicole Plass[3], Raphaela Goldbach-Mansky[3] and MA Lowes[2], [1]NIAMS/NIH, Bethesda, MD, [2]Rockefeller U, New York, NY, [3]NIH | NIAMS, Bethesda, MD

Purpose: Neonatal-onset multisystem inflammatory disease (NOMID) is the most severe phenotype in the spectrum of "autoinflammatory" diseases caused by de novo mutations in the cold-induced autoinflammatory gene, *CIAS1 (also called NLRP2 or NALP3).* This mutation leads to increased assembly of the IL-1β processing NLRP3 or NALP3 inflammasome, which results in IL-1β activation and secretion. Patients with NOMID present with systemic and organ specific autoinflammation of the joints, skin and central nervous system and respond dramatically to treatment with IL-1 blocking agents. This work characterizes the immune pathways downstream of IL-1 in the skin in patients with NOMID treatment.

Method: Paired lesional and non-lesional pre-treatment skin biopsies and post treatment skin samples (n=14) were studied by immunohistochemisty and genomics, and compared to normal skin before and after treatment with anakinra (IL-1RA, Kineret®).

Results: Abundant neutrophils clearly distinguish lesional and nonlesional pretreatment skin, but other skin infiltrating leukocytes, $CD3^+$ T cells, HLA-DR^+ cells, $CD11c^+$ dermal dendritic cells (DCs) and $CD163^+$ macrophages were increased to similar levels in non-lesional and lesional skin compared to normal skin. $CD11c^+$ dermal DCs and $CD163^+$ macrophages expressed activated caspase-1, the enzyme that converts pro-IL-1b into its bioactive form. Gene expression profiling showed that only 64 probe sets were differentially expressed between lesional and non-lesional skin, compared to 2609 probe sets that were different comparing lesional and normal skin. There was marked IL-17 immunostaining in lesional dermis compared to normal skin. Neutrophil attracting chemokine mRNA for CXCL8/IL-8 and CXCL2, as well as CCL20, a chemokine for $CCR6^+$ DCs and T cells, were increased in lesional tissue, compared to non-lesional skin. With successful treatment with the IL-1 receptor antagonist (anakinra, Kineret®), neutrophils disappeared, and $CD11c^+$ DCs reduced, supporting their role as key pathogenic leukocytes.

Conclusion: Tissue macrophages and inflammatory myeloid dermal DCs which are increased in clinically normal looking and "urticarial" NOMID skin are capable of producing bioactive IL-1b likely amplifying the IL-1 response locally. Downstream pathways suggest increased IL-17 production in lesional dermis, which may induce the production of CXCL8/IL-8 and CXCL2, two chemokines known to recruit neutrophils, and CCL20, associated with the recruitment of $CCR6^+$ T cells and DCs. This study describes a stepwise recruitment of inflammatory pathways in NOMID skin and enhances our understanding of the histological and clinical phenotype of skin lesions in NOMID. The characterization of specific inflammatory pathways in the skin in NOMID, a disease with a genetically defined defect in IL-1 production, may help us to understand the organ specific immune responses in other inflammatory skin conditions that are genetically more complex.

1327

Long-Term Follow up of Children with the Low Penetrance R92Q Mutation of TNFRSF1A Gene. Maria Antonietta Pelagatti[1], Antonella Meini[2], Roberta Caorsi[1], Francesca Capra[2], Silvia Federici[1], F. Zulian[3], Alberto Tommasini[4], Alberto Martini[1] and Marco Gattorno[1], [1]UO Pediatria II, Istituto G. Gaslini, Genoa, Italy, [2]Unità di Immunologia e Reumatologia Pediatrica, Spedali Civili e University of Brescia, Brescia, Italy, [3]University of Padova School of Medicine, Padova, Italy, [4]IRCCS Burlo Garofalo, Trieste, Italy

Purpose: To analyze the actual impact of R92Q mutation on *TNFRSF1A* gene in children with periodic fever in comparison with TRAPS patients with structural mutations and periodic fever of unknown origin (PFAPA).

Methods: The extracellular region the *TNFRSF1A* gene was analyzed in 720 consecutive children with periodic fever by means of denaturing high-performance liquid chromatography (DHPLC) and DNA sequencing. The following patients were included in the study: children carrying TNFRSF1A molecularly diagnosed from 2002 to 2009 and routinely followed by centers of Pediatric Rheumatology. Pts were classified in 2 groups according to: 1) the presence of a structural mutations (cysteine or T50M) or 2) the presence of an R92Q substitution. 130 PFAPA patients (genetically negative for MVK, TNFRSF1A, MEFV) were used as disease-controls. Data on the follow-up were collected during routinely control visits or after a phone call to the family. The following variables were analyzed before and at follow-up: n. of episodes of fever/year, duration of the episodes, frequency and intensity of the clinical manifestations. Data from 78 unselected genetically-negative PFAPA patients were also analyzed as disease controls. The Child Health Questionaire (CHQ-PF 50) was used to access the health related quality of life; the results were compared with the ones obtained from an healthy patients control group of 315 healthy children (52.2% female), with a mean (SD) age of 11.2 (3.8) years.

Results: At baseline the TRAPS patients showed a poorer health-related quality of life than healthy children and R92Q patients , with a major impact on physical concepts ($p < 0.001$) in respect to psychosocial concepts. Data on 10 TRAPS patients with structural mutations of *TNFRSF1A* and 20 patients with the R92Q substitution are available. The mean follow-up is 8.7 rears (range 4.4-15.5), 5.6 years (range 2-13) for R92Q patients and 4.9 years (range 1-13 years) for PFAPA patients. At follow-up 32% of R92Q patients and 52% of PFAPA patients displayed a complete resolution of fever episodes. 22% of R92Q patients and 33% of PFAPA patients were improved. Persistence of fever episodes was observed in 20% of both R92Q and PFAPA patients. Conversely, all patients with structural mutations had a stable or worsening disease course and biological tretament (Etanercept or Anakinra) was needed in 5 patients. One R92Q patient developed a chronic disease course (persistent elevation of acute reactants, arthralgia and myalgia), requiring biologic treatment with Anakinra with a complete control of inflammation.

Conclusion: These preliminary data suggest that patients with R92Q mutation of *TNFRSF1A* present a disease course similar to that observed in PFAPA patients. However, a small subgroups of R92Q patients display the persistence of symptoms such as abdominal pain, arthralgia and myalgias, similar to what observed in TRAPS patients with structural mutations.

Genetic Regulation of Serum IFN-α in Juvenile Dermatomyositis. Timothy B. Niewold[1], Silvia N. Kariuki[1], Gabrielle A. Morgan[2], Sheela Shrestha[3] and Lauren M. Pachman[4], [1]University of Chicago, Chicago, IL, [2]Children's Memorial Research Center, Chicago, IL, [3]Children Memorial Research Center, Chicago, IL, [4]Childrens Memorial Research Center, Chicago, IL

Purpose: We have demonstrated that high serum IFN-α is common in children with juvenile dermatomyositis (JDM). In previous work in systemic lupus erythematosus (SLE), serum IFN-α is increased in the setting of particular genetic risk factors. We examined genetic polymorphisms linked to high IFN-α in SLE patients in a cohort of JDM patients to determine whether a similar phenomenon was present in JDM.

Methods: Genomic DNA from 24 children with JDM was genotyped at SNPs in the OPN, IRF5, and PTPN22 genes which have been linked to high serum IFN-α in SLE patients. The cohort consisted of 20 females and 4 males, with a mean age of 5 years old. Data regarding the TNF-α -308 promoter polymorphism were available for these subjects and included in the analysis (21% risk allele carriers). Serum IFN-α was measured using a sensitive reporter cell assay.

Results: The TNF-α -308 allele was independently associated with increased serum IFN-α in the JDM cohort ($p=0.04$). Surprisingly, a SNP in the promoter region of OPN showed evidence for statistical interaction with the TNF-α -308 allele ($p=0.014$), and subjects carrying both of these alleles formed the highest IFN-α subgroup. There was no evidence for association between serum IFN-α and the IRF5 SLE-risk haplotype or the autoimmune disease-associated allele of PTPN22 in our cohort.

Conclusion: In this preliminary study we find evidence for association of the TNF-α -308 allele and increased serum IFN-α in children with JDM. This is interesting as we find that serum IFN-α and TNF-α levels are correlated in simultaneous samples in JDM. The finding of an interaction between SNPs in the promoter regions of OPN and TNF requires further validation, but replicated would suggest a pathogenic synergy between these two loci.

Lymphocyte Subset Analysis and Influenza Specific CD8 Responses in Children with Juvenile Idiopathic Arthritis On Immunosuppressive Medications. James W. Verbsky[1], Gwen Werra[2], Brandon Edwards[2], Jenny Grewal[2], Lance Relland[2], Jack Gorski[3] and Calvin B. Williams[2], [1]Medical College of WI, Milwaukee, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Blood Center of Wisconsin, Milwaukee, WI

Purpose: Infectious pathogens can adversely affect patients with Juvenile Idiopathic Arthritis due to their disease states as well as the immunosuppressive medications they are taking. We have analyzed the peripheral blood lymphocyte profiles of patients with JIA to determine if differences exist from healthy controls. We have also analyzed the ability of these patients to generate antigen specific T cells responses to influenza virus.

Methods: Peripheral blood from 48 HLA-A2 positive patients with JIA (pauciarticular, polyarticular, spondyloarthropathy, and systemic JIA) was longitudinally analyzed by flow cytometry to determine CD4, CD8, NK, T regulatory(Treg) and B cells profiles as well as the expression of the cytotoxic molecules granzyme A(GrzmA), granzyme B(Grzm B), and perforin. The ability to generate antigen specific CD8 cells specific for influenza A was determined by culture of PBMCs with the M1(58-66) peptide.

Results: No differences in CD4, NK, or Treg cells were detected between the different diseases. B cells and CD8 cell percentages were significantly decreased in patients with systemic JRA. There was no difference in the percentage of CD4, CD8, or NK cells expressing the cytotoxic molecules Grzm A, Grzm B, or perforin. When the effect of the immunosuppressant medications was considered, a significant increase in CD4 cells expressing Grzm B was detected in patients taking an anti-metabolite and TNF blockade. Pediatric patients were able to generate antigen specific CD8 cells specific for influenza that was unaffected by treatment with immunosuppressive medication.

Conclusion: Lymphocyte profiles are similar in JIA with the exception of systemic JIA where B and CD8 cells are decreased, likely reflecting the inflammatory state of these patients. Lymphocyte profiles and cytotoxic molecule expression was largely unaffected by immunosuppressive medications with the exception of patients taking combination anti-metabolite and anti-TNF therapies where elevated Grzm B expressing CD4 cells was detected. This could represent a potential biomarker for severe disease. Finally, immunosuppressant treatment of patients with JIA had no effect on the ability to generate influenza specific T cell responses *in vitro*, indicating that the ability to generate immune responses is relatively intact.

ACR/ARHP Poster Session C

Cytokines, Mediators, and Gene Regulation II

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1330

Autoantigen TRIM21/Ro52 Contributes to Suppression of NF-κB-Dependent Cytokine Expression in Fibroblasts. Ryusuke Yoshimi[1], Tsung-Hsien Chang[1], Hongsheng Wang[2], Toru Atsumi[1], Herbert C. Morse III[2] and Keiko Ozato[1], [1]National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD

Purpose: The tripartite motif (TRIM) family member, TRIM21, is an autoantigen known as Ro52/SS-A, which is recognized by antibodies in sera of patients with systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS). Although it has been shown that TRIM21 is an E3 ubiquitin ligase for IRF3 and IRF8 that functions in both innate and acquired immunity, its physiological role *in vivo* has remained unclear. Here we investigated the *in vivo* function of TRIM21 using a gene disruption strategy.

Methods: We generated *Trim21*$^{-/-}$ mice with the *Trim21* gene replaced by an *EGFP* reporter. The populations of leukocyte subsets and detailed expression pattern of TRIM21 were investigated using *Trim21*$^{-/-}$ mice. We stimulated immune cells from *Trim21*$^{+/+}$ and *Trim21*$^{-/-}$ mice and tested cytokine induction, cell proliferation and antibody production. Mice were immunized by specific antigen for *in vivo* Ig production. We also performed promoter analyses using a NF-κB-driven luciferase reporter, ubiquitylation assays for IRF3 and IRF8 and quantitative RT-PCR for gene expression.

Results: *Trim21*$^{-/-}$ mice were born with the expected Mendelian ratio and young adult mice showed no gross abnormality. The populations of leukocyte subsets in thymus, spleen and lymph nodes were also normal in *Trim21*$^{-/-}$ mice. EGFP expression analyses revealed that *Trim21* was widely expressed in many tissues, with the highest levels in immune cells. Studies of *Trim21*$^{-/-}$ embryonic fibroblasts demonstrated that TLR-mediated induction of proinflammatory cytokines, including IL-1β, IL-6, TNFα and CXCL10, was consistently upregulated relative to wild-type cells. Reporter analyses revealed that TLR-mediated NF-κB activation was higher in *Trim21*$^{-/-}$ cells than in wild-type cells, accounting for their enhanced cytokine expression. However, functional analyses of immune cells from *Trim21*$^{-/-}$ mice demonstrated no abnormalities in their composition or function, even though ubiquitylation of IRF3 and IRF8 was impaired. Consistent with possible redundancies in TRIM21-mediated activities, we found that a number of TRIM family members were upregulated in *Trim21*$^{-/-}$ cells.

Conclusion: TRIM21 functions as a negative regulator in NF-κB-dependent proinflammatory cytokine responses in fibroblasts. It may contribute to regulation of inflammation in the pathogenesis of SLE and SS.

Human S100 Proteins Differentially Regulate Pro-Inflammatory Cytokine Release and Cell Migration. Bo Chen[1], Jane Tian[1], Yan Chen[1], Chew-Shun Chang[1], Partha Chowdhury[1], Anthony J. Coyle[1], Ronald Herbst[2] and Gary Sims[1], [1]MedImmune, Gaithersburg, MD, [2]MedImmune, LLC, Gaithersburg, MD

Purpose: The S100 family of calcium-binding proteins regulates a variety of intracellular functions including signaling, trafficking, transcription and homeostasis. S100 proteins released from activated neutrophils and macrophages also play an important role in innate immunity by mediating local inflammation through the induction of pro-inflammatory cytokines and the recruitment of immune cells. S100A12 (EN-RAGE), S100A8, S100A9, and S100B have been implicated in a variety of human diseases including cancer, neurodegenerative disorders, cardiomyopathies, inflammation and autoimmunity. In this study, we have systematically examined S100 proteins for the signaling pathways responsible for pro-inflammatory cytokine induction and cell migration.

Method: Cells were stimulated with human S100 proteins for 16 hrs with or without anti-TLR4 or anti-RAGE Abs. Supernatants were collected and IFN-g, IL-6, IL-1b and TNFapro-inflammatory cytokine levels were measured using Meso Scale Discovery. Cell migration was assessed using a 96-well ChemoTX system. Migration of cells to S100 proteins was enumerated by flow cytometry.

Results: The potency of S100 proteins to induce cell migration and proinflammatory cytokines differed. Antibodies targeting RAGE and TLR4 signaling pathways differentially inhibited S100-mediated pro-inflammatory cytokine induction and cell migration. These data were confirmed using wild-type and knock-out mice.

Conclusion: These results suggest S100 proteins use distinct signaling pathways to induce cell migration and proinflammatory cytokine release. Antagonists targeting RAGE and TLR4 pathways can be used to dissect the relative functions of S100 proteins in models of inflammatory disorders to assess their potential therapeutic benefit.

Urinary TWEAK as a Biomarker of Lupus Nephritis. Noa Schwartz[1], Tamar Rubinstein[1], Linda C. Burkly[2], Christopher E. Collins[3], Lihe Su[2], Bernard S. Hojaili[1], Meggan C. Mackay[4], C. Aranow[5], William Stohl[6], Brad H. Rovin[7], Jennifer S. Michaelson[2] and Chaim Putterman[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Biogen Idec, Cambridge, MA, [3]Washington Hospital Ctr, Washington, DC, [4]The Feinstein Institute for Medical Research, Manhassett, NY, [5]The Feinstein Institute, Manhasset, NY, [6]Univ Southern California, Los Angeles, CA, [7]Ohio State University Medical Center, Columbus, OH

Purpose: TNF-like weak inducer of apoptosis (TWEAK) has been implicated as a mediator of chronic inflammatory processes via prolonged activation of the NF-κB pathway in several tissues, including the kidney. We have recently demonstrated an important role for TWEAK signaling in the pathogenesis of nephritis in an animal model of SLE. Therefore, renal TWEAK production, as reflected by urinary TWEAK (uTWEAK) levels, may serve as an indicator for lupus nephritis (LN) status and activity – providing a tool to non-invasively monitor the progression of LN.

Method: Multicenter cohorts of LN patients and several disease (non-LN SLE, rheumatoid arthritis, osteoarthritis and non-SLE renal disease) and healthy control groups were recruited for cross-sectional and longitudinal analysis of uTWEAK as a potential biomarker of LN. Non-parametric studies were performed to compare uTWEAK levels in the different groups analyzed, as well as for correlating between disease activity and uTWEAK levels. Area-under-the-curve (AUC) calculations of non-parametric receiver operating characteristic (ROC) curves were used to evaluate biomarker capabilities in distinguishing between specific groups of patients. Logistic regression was performed on the cross-sectional data and odds ratio (OR) was derived. Longitudinal data were analyzed using repeated measures ANOVA, followed by Dunn's post-hoc testing for non-parametric data, as well as a linear mixed-effects model examining the relationship between uTWEAK levels and patients' disease activity over time.

Results: uTWEAK levels were significantly higher in LN patients than in non-LN SLE patients and other disease control groups (p=0.039), with neither renal disease nor SLE being lone predictors of high uTWEAK levels. uTWEAK was better at distinguishing between LN and non-LN SLE patients than anti-DNA antibodies and complement levels, with AUC of 0.724 (p<0.001). Furthermore, high uTWEAK levels predicted LN in SLE patients with OR of 7.36. Of note, uTWEAK levels peaked during LN flares, and were significantly higher during the flare than at 4 and 6 months prior and following the flare event. Furthermore, we found a significant association between uTWEAK levels in SLE patients and their renal disease activity over time (p=0.008).

Conclusion: High uTWEAK levels are indicative of LN, as opposed to non-LN SLE and other healthy and disease control populations, and reflect renal disease activity in longitudinal followup. Thus, our study further supports a role for TWEAK in the pathogenesis of LN, and provides strong evidence for uTWEAK as a candidate clinical biomarker for LN.

Nerve Growth Factor Differential Effect On Toll-Like Receptor-Mediated Cytokine Production in Human Monocytes Is Due to Changes in p75-NTR/Trk A Receptor Ratio. Luisa Bracci-Laudiero[1], Giusy Prencipe[2], Raffaele Strippoli[2], Gaetana Minnone[2], Loredana De Pasquale[2], Stefania Petrini[2] and Fabrizio De Benedetti[2], [1]Bambino Gesú Children Hospital and INMM-CNR, Rome, Italy, [2]Bambino Gesú Children Hospital, Rome, Italy

Purpose: Neutralization of the neurotrophin Nerve Growth Factor (NGF) has recently emerged as a potential treatment of pain in humans. In normal condition NGF is ubiquitously present in the organism. However, NGF levels are markedly up-regulated in inflamed tissues, including joints of patients with chronic arthritis. Although immune cells are known to express NGF receptors, TrkA and p75-NTR, it is not clear how NGF levels affect immune cell activity during the inflammatory response. The aim of our study was to investigate NGF effects on cytokine production induced by pathogen-associated molecular patterns in human monocytes.

Method: Using peripheral blood monocytes, purified by Percoll gradient, we investigated the NGF effects on human monocytes after Toll-like receptor (TLR) activation. To mimic the physiological condition in which cells are constantly exposed to NGF, monocytes were pre-incubated overnight with NGF before adding TLR ligands. To mimic the inflammatory condition in which there is an increase in NGF

concentration, monocytes were stimulated with TLR ligands and NGF was added either at same or at later times. The expression of NGF receptors and TLRs, the activation of signalling pathways and the synthesis of IL-6 and IL-1b were evaluated using real-time PCR, western blot, flow cytometry and ELISA.

Results: Pre-incubation with NGF caused an enhanced response to TLR ligands (LPS, LTA, PAM) with a two-fold NGF dose-dependent increase in IL-6 production. NGF alone did not have any effect. The NGF pre-treated cells showed an up-regulation of TLR-2 expression after TLR2 ligand addition. The addition of NGF at the time of or after TLR stimulation induced a two-fold reduction in IL-6 and IL-1b synthesis and a down-regulation of TLR expression.

These dual, apparently opposite, effects of NGF on monocytes appear to be related to a modified ratio of p75-NTR/TrkA receptor expression. After overnight incubation with NGF a marked increase in p75-NTR/TrkA ratio is present. It is known that p75-NTR signals through the NF-kB pathway, and we found a marked increase in nuclear NF-kB translocation in monocytes preincubated with NGF and stimulated with TLR ligands. On the contrary a marked up-regulation of TrkA expression was found following TLR stimulation suggesting that the inhibitory effect of NGF on cytokine production may depend on TrkA signalling.

Conclusion: NGF is part of a physiological mechanism regulating inflammatory response. NGF can amplify or down-regulate monocyte activation via TLRs depending on the differential expression of NGF receptors with subsequent changes in the p75-NTR/TrkA ratio. A better knowledge of the NGF effects, via interaction with the two NGF receptors, on inflammatory response may help to identify proper targets of novel anti-inflammatory analgesic approaches.

Reduced IL-7 Serum Titres in Relation with Symptom Duration Are Associated with Progression towards Rheumatoid Arthritis in Less Than 6 Months Inflammatory Arthritis. Vincent Goëb[1], Rich Cuthbert[1], Elizabeth Horner[1], Sarah Churchman[1], Laura C. Coates[2], Helena Marzo-Ortega[2], Jackie Nam[1], Edith Villeneuve[1], Ed Vital[1], Philip G. Conaghan[3], Patrice Fardellone[4], Xavier Le Loët[5], Paul Emery[6], Olivier Vittecoq[7] and Frédérique Ponchel[1], [1]Leeds University, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]LIMM, Leeds, United Kingdom, [4]CHU d'Amiens, France, [5]CHU Rouen - INSERM U 905, France, [6]Leeds General Infirmary, Leeds, United Kingdom, [7]Rouen, France

Purpose: Early diagnosis of RA is crucial for initiation of therapy in order to obtain sustained remission. IL-7 is a pleiotropic cytokine that play a central role in the development and maintenance of T cells, and has recently been associated with RA. Injection of IL-7 in a collagen induced arthritis model aggravated the disease and the therapeutic value of IL-7 blocking antibodies has also been reported in two separate animal models. We showed that serum circulating levels of IL-7 are reduced in established RA patients. We hypothesised that this reduction may have predictive diagnostic value.

Our objectives are to determine whether IL-7 titres in serum will distinguish patients who will evolve into RA from early inflammatory arthritis (EIA), and whether they are correlated with clinical parameters of disease activity, structural radiographic damage, shared epitope or autoantibody status and titres.

Method: 359 patients with EIA (<6 months duration) were followed up for 2 years and diagnosed according to ACR criteria. 31 were lost to follow up and 77 diagnosed with other forms of musculoskeletal disease (reactive arthritis, osteoarthritis, lupus, connective tissue diseases etc…). 65 controls and 183 patients with established disease were also assessed. IL-7 levels in serum were determined by ELISA.

Results: Patients with EIA were diagnosed as having RA (n=162,), undifferentiated arthritis (UA, n=61), ankylosing spondylitis (AS n=12) or psoriatic arthritis (PsA n=16). IL-7 levels at recruitment were reduced coared to healthy controls (n=67, median 13.8 pg/ml) in RA (median 11.5 $P<0.001$), PsA ($P=0.012$ median 11.1) and UA (median 11.8$P=0.003$) but not in AS or osteoarthritis patients (n=19). We also confirmed reduction in IL-7 levels between healthy controls and established RA (n=106 median 7.9 $p<0.001$), AS (n=56 median 10.1 $p=0.001$) or PsA (n=21 median 7.8 $p=0.001$). There was no correlation between IL-7 titres and disease activity score (DAS), CRP, rheumatoid factor (RF), anti-CCP and *HLA*-SE status at recruitment . The presence of erosions at recruitment was also not associated with IL-7 in early RA. Importantly, IL-7 levels were inversely correlated with symptoms duration at presentation in less than 6 months RA ($R= -0.513$, $P<0.001$), but not in AS or PsA.

Conclusion: Our data demonstrate decrease levels of IL-7 across the inflammatory disease continuum. furthermore, no relationship between IL-7 titres and disease activity, blood inflammation, *HLA*-SE and auto-antibodies in early RA was observed. Further analysis is needed to establish the added value of IL-7 over other parameters in predicting evolution to RA, particularly in CCP negative patients.

Role of the Th17 Phenotypic Differentiation in the Persistence of Early Arthritis. Elena Frati[1], Renato De Stefano[1], Fernando Nargi[1], Caterina Baldi[1], Luana Menza[1], Adriano Spreafico[2], Federico Chellini[2] and Mauro Galeazzi[2], [1]Azienda Ospedaliera Universitaria Senese, Siena, Italy, [2]U,O.C. Reumatologia, Siena, Italy

Purpose: The prevalent phenotypic differentiation toward Th17 instead of the phenotypic differentiation toward the cells Treg may be a possible pathogenetic mechanism for a chronic inflammatory process, otherwise destined to the auto-resolution.

Method: We conducted an investigation on a group of 57 patients with early arthritis to verify if the serum levels of cytokines, able to express a prevailing phenotypic differentiation of naive cells TCD4 + to the line Th17, may constitute potential biomarkers predictive of conversion of an early arthritis in early rheumatoid arthritis. All the patients, under basal conditions, were referred to a drawing of a blood sample stored immediately at -80°C to be subsequently used for determining, through a Bio-Plex Protein System, the serum level of IL-12, INFγ, TGF-ß, IL-17, IL-23, IL-6. After 6 months from the beginning of the arthritic symptoms, all the patients have been submitted to a new clinical, biohumoral and instrumental evaluation and they were inserted in 3 fundamental categories (auto-resolution, persistent idiopathic undifferentiated arthritis or rheumatoid arthritis, persistent differentiated arthritis not rheumatoid).

Results: Serum levels of the various cytokines appear independent from the age of the patients and from the level of the clinical-biohumoral parameters of inflammation, such as VES, number of tender and swollen joints, the DAS28. In the group of patients with a persistent idiopathic undifferentiated arthritis, there is a statistically significant increase of serum levels of the IL-17, IL-6 and IL-23. There is a statistically significant correlation among the serum levels of the IL-17 and the serum levels of the IL-23 ($r = 0.62$, $p = 0.0098$) and among the serum levels of the IL-17 and serum levels IL-6 ($r = 0.51$, $p = 0.039$). In the group of patients with idiopathic persistent undifferentiated arthritis emerge 2 well separate subgroups. One group characterized by serological markers of autoimmunity, rheumatoid factor and anti-CCP, that show a significant increase in the serum levels of the IL-6, but also of the IL-17 and of the IL-23. The second group, seronegative, shows contrarily an increase of the serum levels of the IL-6, an increase of the Il-17 in smaller measure, while the serum levels of IL-23 are similar to those found in the patients with autorisolution of the arthritis.

Conclusion: Results of our study would seem to point out that the prevailing phenotypic differentiation of the lymphocytes T-CD4 + toward the Th17 constitutes a pathogenetic line which is involved in the development of an idiopathic persistent undifferentiated arthritis, at least in those forms associated with the presence of biomarkers of autoimmunity such as rheumatoid factor and anti-CCP. In this group of patients, such phenotypic differentiation appears sustained by the IL-6 but especially by the IL-23.

B and T Lymphocyte Attenuator Regulates TCR Associated Transcription Factors. Brian Greenberg[1], John Sedy[2] and Carl F. Ware[2], [1]UCSD Medical Ctr, La Jolla, CA, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA

Purpose: BTLA (B and T Lymphocyte Attenuator) is a member of the Ig superfamily that interacts with herpesvirus entry mediator (HVEM), a TNF receptor family member. Crosslinking of BTLA by HVEM results in phosphorylation of its cytoplasmic tyrosine residues and association with phosphatases SHP-1 and SHP-2. Cellular effects include attenuated TCR (T cell receptor) induced cell proliferation and cytokine production (Sedy, 2005). Additionally, a SNP (C800T) resulting in an amino acid change (P267L) in the cytoplasmic tail has been described and associated with rheumatoid arthritis (Lin, 2006). In B-cells, BTLA crosslinking attenuates Syk, BLNK and PLC-γ

phosphorylation upon BCR stimulation (Vendel, 2009). The targets of BTLA associated phosphatases in T cells are not known nor is it known whether the targets are proximal or distal in the TCR signaling cascade.

Methods: The T cell line (Jurkat) was used as a model to study BTLA function. BTLA is expressed on Jurkat cells. To enhance BTLA signaling Jurkat cells were transduced by retrovirus or electroporation to over express human BTLA. For IP and western blot experiments, cells were stimulated with anti-CD3-HVEM:Fc coated beads for 5 minutes before lysis. In other experiments, luciferase reporters specific for AP-1, NFκB, NFAT or IL-2 were co-transfected. These cells were stimulated with soluble α-CD3 (5 μg/ml), α-CD28 (5 μg/ml) and either α-BTLA (5 μg/ml) or HVEM:Fc (10 μg/ml) for 6 to 24 hours depending on the specific reporter construct.

Results: TCR activation with HVEM:Fc and α-CD3 coated beads down-regulated tyrosine phosphorylation as detected in whole cell lysates. Under the same stimulation conditions, immunoprecipitation with α-BTLA (clone 6F4) followed by western blot analysis demonstrated SHP-1 and SHP-2 co-precipitation. CD3 stimulation alone did not lead to SHP-1 or SHP-2 recruitment. Incubation with either HVEM:Fc or α-BTLA, in the setting of TCR activation, down-regulated the activity of multiple TCR-related transcription factors. AP-1 activity was reduced by 25% with HVEM:Fc, and NFκB activity was reduced by 53% with α-BTLA and by 66% with HVEM:FC. The IL-2 specific reporter was similarly inhibited showing a 65% reduction with HVEM:Fc and an 80% reduction with α-BTLA. Activity of NFAT was decreased by 30% with BTLA transfection alone. Treatment with HVEM:Fc or α-BTLA further decreased the signal by 30%. In contrast, transfection of BTLA lacking the cytoplasmic domain resulted in increased activation of NFAT by 50%. The function of BTLA with a leucine at residue 267 was also tested. There was no significant difference in IL-2 attenuation in cells transfected with wild-type BTLA compared to those with the SNP or equal quantities of both (heterozygous).

Conclusion: These results support the hypothesis that BTLA recruits phosphatases SHP-1 and SHP-2 when crosslinked and functions to decrease CD3 induced phosphorylation. The ability of BTLA to down-regulate the major TCR related transcription factors argues that its direct target is proximal in the TCR signaling cascade.

Enriching for Sialylated IgG Increases the Inhibition of Interferon-Alpha Production by Human Plasmacytoid Dendritic Cells in Response to TLR7 and TLR9 Activation. Alice E. Wiedeman[1], Deanna M. Santer[1], Mary Bach[1], Fabian Käsermann[2], Sylvia Miescher[2] and Keith B. Elkon[1], [1]University of Washington, Seattle, WA, [2]CSL Behring, Bern, Switzerland

Purpose: IgG in the form of intravenous immunoglobulin (IVIg) has been used as an anti-inflammatory agent in multiple autoimmune diseases. Recent studies reported that it is the small fraction of sialylated IgG in human IVIg preparations that attenuates arthritis or immune thrombocytopenia. However, these studies were performed across species (human IgG injected into mouse models of disease). Our goal was to study the importance of the sialylated subset of IVIg in the inhibition of the inflammatory response by *human* cells stimulated with TLR agonists.

Method: Human IVIg preparations were enriched (SA+, 7- to 10-fold) or depleted (SA-, 2- to 5-fold) of the sialylated subset by lectin affinity chromatography. All preparations had < 0.1EU/mL endotoxin. For cell binding experiments, SA+ and SA- IgG were labeled with biotin. PBMC were isolated from whole blood of healthy individuals, cultured overnight in the presence of TLR7 (Loxoribine, CL097) or TLR9 (CpG) agonists with or without SA+ or SA- IgG at two doses (0.5 and 5 mg/mL). In certain experiments, monocytes were depleted from PBMC using CD14 magnetic beads. Supernatants were collected 20 hours post-treatment and analyzed by ELISA for IFN-α, TNF-α, IL-8, and IL-6. Percent of cytokine inhibition was determined by comparing IFN-α levels from IVIg-treated cultures to those that had not been treated with IVIg.

Results: Both SA+ and SA- IgG bound equally well to monocytes and to B cells as determined by flow cytometry. In response to all TLR7 and TLR9 agonists tested, SA+ IgG was significantly more inhibitory than SA- IgG for IFN-α production ($p<0.05$) **(Figure)** and inhibition by SA+ IgG increased with higher doses ($p<0.05$). Surprisingly, levels of IL-6, IL-8, and TNF-α in response to TLR agonists were not inhibited by SA+ or SA- IgG, and in fact, the production of TNF-α was significantly enhanced in cultures treated with SA+ compared to SA- IgG ($p<0.05$). Preliminary experiments suggest that inhibition of IFN-α by SA+ IgG was decreased in the absence of CD14+ monocytes.

Conclusion: SA+ IgG is more potent at inhibiting IFN-α production in response to TLR agonist stimulation compared to SA- IgG. CD14+ monocytes appear, in part, to mediate this inhibition, and the specific receptor for SA+ IgG is currently under investigation. The greater

potency of SA+ IgG has therapeutic implications because these results suggest that, in some circumstances, a lower dose of IVIg enriched for the active, sialylated subset may be efficacious. Also, identification of the receptor(s) and signaling pathways involved in the SA+ IgG anti-inflammatory effects could reveal targets for immune modulation.

Increased Interferon-Alpha Activity Is Associated with Humoral Autoimmunity and Poor Antigen-Specific Immunity in Systemic Lupus Erythematosus. Lauren R. Cole[1], Sherry R. Crowe[2], Gillian M. Air[1], Linda F. Thompson[2], Timothy B. Niewold[3] and Judith A. James[2], [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]University of Chicago, Chicago, IL

Purpose: Interferon-α (IFNα) has been identified as a key mediator in systemic lupus erythematosus (SLE) pathogenesis. IFNα is a type I IFN that has the ability to disrupt self tolerance by activating antigen-presenting cells containing self-antigen. Elevated IFNα activity is detected in many SLE patient samples, and these elevations have been shown to correlate with disease activity as well as multiple organ involvement. Our goal is to further understand the pathogenic role of IFNα in SLE humoral autoimmunity, as well as to investigate the effect of an antigen-specific challenge in SLE and whether increased IFNα activity in SLE impairs antigen specific responses.

Method: This study enrolled 72 SLE patients who met ACR criteria and matched controls. Detailed clinical and therapeutic information, as well as disease activity measures were obtained at baseline and 2, 6, and 12 weeks after influenza vaccination. Influenza humoral immune responses (native/denatured ELISA responses, relative affinities and hemagglutination inhibition) were measured. Serial samples were tested for interferon activity through a reporter cell assay which measures serum's ability to upregulate three interferon inducible genes, MX1, PKR, and IFIT1. Lupus-associated autoantibodies (aAbs) (Ro, La, Sm, nRNP, ribosomal P, dsDNA, ANAs and phospholipid antibodies) were measured by ELISA and immunofluorescence.

Results: IFNα activity decreased in SLE patients 2 weeks after influenza vaccination compared to baseline levels (baseline mean = 6.4, 2 weeks post-vaccination mean = 3.9, p=0.0195, paired t-test). However, in the subset of patients whose disease activity scores increased after vaccination, this decrease in IFNα activity was not seen. A correlation was seen between elevated baseline IFNα activity and poor humoral immune response to the influenza vaccine (p=0.0126, r^2=0.22). Additionally, a significant association was seen between increased IFNα and total number of lupus-associated autoantibodies (IFNα < 1.0 [n=45], mean aAbs = 2.1, IFNα > 1.0 [n=27], mean aAbs = 3.4, p=0.0003, unpaired t-test). Consistent with previous reports, we also saw a significant association between increased IFNα and disease activity (IFNα < 1.0 [n=45], mean SLEDAI = 7.6, IFNα > 1.0 [n=27], mean SLEDAI = 10.2, p=0.0078, unpaired t-test).

Conclusion: A unique finding in this study was that IFNα decreases in SLE patients post-influenza vaccination. Increased baseline IFNα activity correlated with a poor humoral response to the influenza vaccine. Increased IFNα activity was also associated with an increased number of lupus-associated autoantibodies, as well as with increased disease activity.

Orally Active TNF-Alpha Inhibitor Mediates Anti-Inflammatory Activity by Potentiating Adenosine A2a Receptor Signaling. Ajith A. Welihinda and Edward P. Amento, Theracos, Inc. and Molecular Medicine Research Institute, Sunnyvale, CA

Purpose: Orally active small molecule inhibitors of the pro-inflammatory cytokine TNF-alpha, exemplified by THR-090717 and its analogs, are currently being evaluated for treatment of rheumatoid arthritis and other TNF- alpha -driven inflammatory disorders. In rodent models of arthritis, THR-090717 significantly reduces joint swelling and improves clinical score. The present study examined its mechanism of TNF-alpha inhibition.

Method: Human monocytes were isolated from PBMCs by depleting other cell types. TNF- alpha levels in culture media and intracellular cAMP levels were quantitated by ELISA. Kinase inhibition was evaluated in a TR-FRET assay using recombinant enzymes and peptide substrates. COX and PDE4 assays were performed using commercially available assay kits. PPAR-gamma agonist activity was evaluated using a reporter plasmid. Binding affinity of adenosine A2a receptor was determined using [14C]NECA and cells over-expressing the receptor.

Results: A series of small molecules including THR-090717 and its analogs inhibited TNF- alpha release regulated by multiple distinct signaling pathways with similar efficacy. IC50 values for the inhibition of TNF- alpha by THR-090717 in PMA-stimulated human monocytes, LPS-stimulated human monocytes and IgG-stimulated THP-1 cells were 1.8 + 0.9 uM, 0.9 uM and 1.3 + 0.25 uM respectively. The compound failed to show significant inhibition towards a number of pharmacological targets of inflammation including COX-1, COX-2, p38, JNK1, JNK2, SYK, PDE4D3, PDE4D5 and PPAR-gamma. Of interest, in vivo anti-inflammatory activity was greater than that anticipated by in vitro IC50 values. One possible explanation is our finding that THR-090717 and its analogs enhanced adenosine-mediated cAMP production in PC-12 cells. Synergism between THR-090717 and adenosine was detected at 1 uM of compound ($p < 0.01$). Binding studies demonstrated that the compound increased the affinity of adenosine A2a receptor by 1.5-fold. Moreover, a highly selective adenosine A2a receptor antagonist, ZM241385, blocked THR-090717-mediated inhibition of TNF-alpha production by PMA-stimulated human monocytes.

Conclusion: Our results suggest that THR-090717 and its analogs may potentiate adenosine-mediated cAMP production at the adenosine A2a receptor to inhibit TNF- alpha production and reduce inflammation. These small molecule inhibitors of TNF- alpha production may act by increasing adenosine A2a receptor activity such that endogenously elevated adenosine levels at sites of inflammation effectively concentrate anti-inflammatory activity at disease sites.

The Ang-1/Tie2 Angiogenic Axis Is Selectively Engaged in RA Synovial Tissue Even Before ACR Criteria of RA Are Met. Marleen G.H. van de Sande[1], Daphne deLaunay[1], Gijs P.M. van de Sande[1], Paul P. Tak[2] and Kris A. Reedquist[1], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Angiogenesis contributes to inflammation and joint destruction in rheumatoid arthritis (RA). Angiopoietins (Ang) -1 and -2, which mediate blood vessel remodeling, as well as their receptor Tie2, are expressed in inflamed synovial tissue. We have recently shown that Ang-1 expression relative to Ang-2, and associated Tie2 activation, was significantly higher in RA compared to psoriatic arthritis. It is unknown if these differences in activation of Ang-1 Tie2 axis are also present in the earliest phases of arthritis.

Therefore, we investigated the expression of Ang-1, Ang-2, total Tie2 and phosphorylated active Tie2 in disease-modifying antirheumatic drug (DMARD) naïve early arthritis patients.

Methods: We analyzed synovial tissue biopsies of 55 DMARD naïve early arthritis patients. Patients were prospectively followed and diagnosed after 2 years according to established classification criteria. Quantitative analysis of expression or activation of the angiogenic markers was examined by immunohistochemical analysis combined with computer-assisted digital imaging. Activation status and expression of all markers was compared between different diagnostic groups.

Results: 21 Patients had RA at baseline, 8 patients had undifferentiated arthritis (UA) at baseline and fulfilled ACR criteria for RA after 2 years of follow up, 19 patients had still UA after 2 years of follow up and 7 had spondyloarthritis (SpA) diagnosed at baseline. Expression of Ang-1, Tie2 and pTie2 was comparable between the patients with RA at baseline and the patients who fulfilled ACR criteria over time. Expression of Tie2, pTie and Ang-1 was significantly higher in RA patients compared to the SpA patients (P=0.001, P=0.001, P=0.02 respectively) and UA patients who developed RA compared to SpA patients (P=0.002, P=0.004, P=0.02 respectively). This shows that the Ang-1 Tie-2 axis is specifically activated in RA, even before patients fulfill ACR criteria for RA. On the other hand SpA patients showed a higher expression of Ang-2 compared to the RA patients (P=0.003). UA patients with RA after 2 years of follow up showed increased Tie2 (P=0.001, pTie2 (p=0.006) and Ang-1 (P=0.01) expression compared to patients that remained UA after 2 years of follow up.

Conclusion: Our study extends the results of our previous studies, showing that engagement of the Ang-1/Tie2 axis is specifically active in RA patients, even in the earliest phases of the disease, indicating that this pathway might play an important role in the pathogenesis of RA, whereas Ang-2 plays a more important role in spondyloarthritis .

Regulation of IFN Response Gene Activity During Infliximab Treatment in Rheumatoid Arthritis Is Associated with Clinical Response to Treatment. Lisa G.M. Van Baarsen[1], Carla A. Wijbrandts[2], Francois Rustenburg[1], Tineke Cantaert[2], Tineke C.T.M. van der Pouw Kraan[1], Dominique L. Baeten[2], Ben A.C. Dijkmans[1], Paul P. Tak[3] and Cornelis L. Verweij[1], [1]VU University Medical Center, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Cross-regulation between TNF and type I IFN has been postulated to play an important role in autoimmune diseases. Therefore we determined the effect of TNF-blockade in rheumatoid arthritis (RA) on the type I IFN-response gene activity in relation to clinical response.

Method: Peripheral blood from 33 RA patients was collected in PAXgene tubes before and after the start of infliximab treatment. In a first group of 15 patients the baseline expression of type I IFN-regulated genes was determined using cDNA-microarrays and compared to levels one month after treatment. The remaining 18 patients were used as an independent group for validation using quantitative (q)PCR.

Results: Gene expression analysis revealed that anti-TNF antibody treatment induced a significant increase in type I IFN-response activity in a subset of RA patients, whereas expression levels remained similar or were slightly decreased in others. The findings appear clinically relevant since patients with an anti-TNF induced increased IFN-response gene activity had a poor clinical outcome. This association was confirmed and extended for an IFN-response gene set consisting of OAS1, LGALS3BP, Mx2, OAS2 and SERPING1 in five EULAR good and five EULAR poor responders, by qPCR.

Conclusion: Regulation of IFN-response gene activity upon TNF-blockade in RA is not as consistent as previously described, but varies between patients. The differential changes in IFN-response gene activity appear relevant to the clinical outcome of TNF-blockade in RA.

Th1, Th2 and Th17- Derived Cytokines Levels in Synovial Fluid of RA: Relation with Synovial Lymphoid Neogenesis and Erosive Disease. Juan D. Canete[1], Raquel Celis[2], Miguel Angel Descalzo Sr.[3], Jose L. Pablos[4] and Raimon Sanmarti[5], [1]Hospital Clinic de Barcelona and IDIBAPS, Barcelona, Spain, [2]Arthritis Unit, Barcelona, Spain, [3]Fundacion Española de Reumatologia, Madrid, Spain, [4]Hospital 12 de Octubre, Madrid, Spain, [5]Arthritis Unit, Rheumatology Department, Barcelona, Spain

Background: Synovial lymphoid neogenesis (LN) in rheumatoid arthritis (RA) has been associated with refractory disease but not with the presence of autoantibodies. B cells in LN could also drive antibody-independent Synovial inflammation through the development of T cells responses or enhances cytokine production.

Purpose: To analyze 1) Th1, Th2 and Th17 cytokine levels in Synovial fluid of RA patients regarding the presence or not of Synovial tissue lymphoneogenesis; 2) To determine whether baseline levels of cytokines are associated to erosive disease

Method: Arthroscopic Synovial biopsy specimens from patients with RA were classified as LN+ or LN- by immunohistochemistry for CD3, CD20, T/B cell segregation and peripheral node addressin (PNAd)-positive HEV in relation to the size of lymphoid aggregates. Synovial fluid obtained at the time of the arthroscopy was analyzed by duplicate using the Procarta Cytokine Assay Kit (Panomics, Inc, Freemont, CA) for IFN-gamma, IL-4, IL-7, IL-10, IL12p40, IL-17, IL-23, IL-1beta, TNF-alpha and IL-6. Relevant clinical and biological data of patients were recorded at inclusion and at the end of follow-up. Patients were further classified as having erosive or non erosive RA, as defined by having more than 2 radiographic erosive lesions in at least 2 different joints.

Results: 65 RA patients (68% female, 71% RF+, 51% ACPA+) with matched Synovial tissue and Synovial fluid samples were included with a follow-up, median (p25-p75) of 107 months (83-176). 78% of them had erosive at end of follow-up, 33 (51%) RA patients were LN+ and 32 (49%) LN-, without significant differences in disease duration, RF, ACPA, CRP and DAS28. Also, no significant differences were found in the levels of all cytokines between LN+ and LN- patients.

Chi-square test showed a association between IL-1beta baseline levels and erosive RA (p=0.047). After Multivariable logistic regression adjusted for DAS28 at baseline, DAS28 increase, disease duration, CRP at baseline and anti-TNFa therapy, all of them with a significant association ($p<0.05$) with erosive disease, only IL-23 (p=0.02) and TNFalpha (p= 0.001) levels were associated with erosive RA.

Conclusion: There are no significant differences in the T-cell derived and proinflammatory cytokine levels in synovial fluid of RA with and without Synovial lymphoid neogenesis. This finding suggests that LN does not modifies the pattern of expression of theses cytokines, although analysis of cytokine expression in synovial tissue remains to be explored. On the other hand, Synovial fluid levels of TNFalpha and IL-23, but not IL-17 levels, are associated with erosive disease, highlighting the relevance of theses cyokines in the pathogenesis of RA.

IL-17A Expression Is Upregulated in the Hypoxic Joint and Correlates with IL-6 Production, Inflammatory Cell Infiltrate and Oxidative Damage. Ellen Margaret Moran[1], Chin Teck Ng[1], Jennifer McCormick[1], Rene Heydrich[2], Heiner Appel[2], Ursula Fearon[1] and Douglas Veale[1], [1]Dublin Academic Medical Centre, St.Vincent's University Hospital, Dublin, Ireland, [2]Charite, Campus Benjamin-Franklin, Berlin, Germany

Purpose: IL-17A is overexpressed in the human RA joint and has been implicated in the pathogenesis of RA. The aim of this study was to examine localised expression of IL-17A in the joint and to examine its relationship to inflammatory markers and synovial tissue oxygen tension.

Method: 19 patients with inflammatory arthritis underwent needle arthroscopy. Paired serum/synovial fluid and synovial tissue were obtained. Oxygen levels in synovial tissue (tpO2) were assessed in vivo using a combined oxygen/temperature LICOX probe at the baseline prior to biologic therapy. IL-17A, CD3, CD68 and HNE (lipid peroxidation) expression was assessed by immunohistochemistry in synovial tissue sections. Dual immunofluorescence staining was carried out to co-localise IL-17A to mast cells using mast cell tryptase. IL-17A and

IL-6 levels were measured by ELISA/MSD assay in the paired serum/synovial fluids (SF).Dual immunofluorescence staining was carried out to co-localise IL-17A to mast cells using mast cell tryptase.

Results: Dual immunoflourescent staining demonstrated co-localisation of IL-17A expression to mononuclear cells and mast cells in the sublining. The number of IL-17A producing mononuclear cells correlated with IL-17 serum levels (r2=.545, p<0.05). The number of IL-17-secreting mast cells was found to correlate with sublining CD68 expression (r2=.618) and expression of lipid peroxidation (HNE) staining (r2=.570) (p<0.05). IL-17A SF levels correlated with serum and SF IL-6 expression (p<0.05). SF levels also correlated with CD3 expression in the sublining (r2=.430, p<0.05) and lining layer (r2=.545, p<0.05) of synovial tissue. The median tpO2 level in the synovial tissue was profoundly hypoxic 3.2% (range 0.45-7.7%) and inversely correlated with synovial tissue expression of CD68 and CD3 (r2=-.615, p<0.001 and r2-.611, p<0.01 respectively). When patents were categorized into tp02 <>20mmHg there was no significant difference in tissue or SF levels of IL-17A, however serum levels of both IL-17A and IL-6 were significantly higher in patients with a tp02 <20mmHg (p<0.05) suggesting a systemic effect on these cytokines by hypoxia.

Conclusion: In this study we demonstrate localisation of IL-17A expression to mononuclear cells and mast cells, levels of which correlated with markers of tissue inflammation and damage in the joint. We demonstrated low tpO2 levels in the joint are inversely related to tissue inflammatory markers. Serum IL-17A levels were inversely related to tpO2 levels, however had no association with tissue and SF IL-17A levels, suggesting a divergence in mechanisms regulating IL-17A systemically and locally in the joint.

1344

The Four and a Half LIM Domains Protein 2 (FHL2) Is a Key Regulator of Inflammatory Tissue Damage in Chronic Destructive Arthritis. C. Cromme[1], LH Meyer[1], K. Neugebauer[1], A. Korb[1], C. Wunrau[1], G. Kollias[2], K. Redlich[3], C. Will[1], EM Schnaeker[1], R. Bassel-Duby[4], D. Baeten[5], V. Wixler[1] and T. Pap[1], [1]Univ Hosp, Munster, Germany, [2]A. Fleming BSRC, Vari, Greece, [3]Med Univ, Vienna, Austria, [4]Univ of Texas, TX, [5]AMC, University of Amsterdam, Amsterdam, Netherlands

Purpose: FHL2 is a mediator of protein interactions and involved in cellular processes that are of relevance for the activation of mesenchymal cells. It is interacting with integrins, the focal adhesion- and mitogen-activated kinases, transcription factor AP-1 and is involved in TRAF-6 dependent signalling. Based on these data, we analysed the function of FHL2 in chronic inflammatory arthritis.

Methods: Expression of FHL2 in synovial tissues from RA and OA patients as well as in destructive arthritis of hTNFtg mice was analysed by immunohistochemistry. Fibroblast-like synoviocytes from RA patients (RA-FLS) and from hTNFtg mice and controls were isolated and FHL2 levels were determined by immunoblot after stimulation with cytokines. Knock down of FHL2 was performed by RNAi, and the expression of MMPs was determined by Western blot analysis and ELISA. The invasiveness of FLS was analysed using our established MATRIN-assay. FHL2-mediated signalling pathways (activation of MAP-kinases as well AP-1 and NFkappaB) were also studied. Finally, we crossed hTNFtg with $FHL2^{-/-}$ mice and analysed clinical parameters of arthritis as well as histomorphometric parameters of joint destruction and MMP expression in wt, hTNFtg, $FHL2^{-/-}$ and $FHL2^{+/-}$/hTNFtg animals.

Results: Although there was a significantly higher expression of FHL2 in RA than in OA, only TGFbeta but not TNFalpha induced the expression of FHL2 in RA-FLS. Analysis of FHL2 expression in hTNFtg mice together with further *in vitro* studies confirmed these findings by showing an early TGFbeta dependent induction of FHL2 that was followed by a TNFalpha-mediated suppression of FHL2. However, the TNFalpha mediated suppression of FHL2 in hTNFtg mice was incomplete, as the levels of FHL2 were still significantly higher in hTNFtg mice than in wt controls. *In vitro* analysis revealed a prolonged phosphorylation of p38 MAPK and MAPKAP kinase 2 in murine $FHL2^{-/-}$ cells as well as in siRNA-treated RA-FLS as compared to controls. This was accompanied by significantly elevated MMP levels. We also found an increased invasiveness of RA-FLS after FHL2 knock down. When analysing the offspring of hTNFtg and $FHL2^{-/-}$ mice, we found that the $FHL2^{-/-}$/hTNFtg genotype is lethal before birth and that $FHL2^{+/-}$/hTNFtg mice show increased paw swelling and reduced grip strength as compared to hTNFtg mice. $FHL2^{+/-}$/hTNFtg mice had increased joint destruction with markedly elevated levels of MMPs *in situ*.

Conclusion: Our results suggest that through modulating p38 MAPK activation, FHL2 is involved in the limitation of cytokine-induced MMP expression and as such constitutes an important regulator of inflammatory tissue damage in arthritis. While early tissue damage leads to an up-regulation of FHL2 in affected tissues in frame of a healing attempt, chronic exposure to TNFalpha suppresses FHL2, which ultimately leads to unbalanced and chronically progressing joint destruction.

IL-22 in Inflammatory Arthritis. Bernadette M. Lynch, Jennifer McCormick, Chin Teck Ng, Oliver FitzGerald, Ursula Fearon and Douglas J. Veale, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Purpose: IL-22 is produced by Th17 T cells. It may have both pro- and anti-inflammatory activity. This study examines the role of IL-22 in Rheumatoid arthritis (RA) and Psoriatic Arthritis (PsA) and its relationship to clinical parameters in response to biologic therapy.

Method: Serum was collected from RA (n=59), PsA (n=27) and normal controls (n=11). In a subgroup of patients serum was obtained pre and 3 months post anti-TNF therapy. Anti-CCP titre and smoking history was collected. At arthroscopy RA synovial tissue (ST) was obtained (n=6) to establish *ex-vivo* whole tissue ST explant cultures which closely reflect the joint environment. RA ST was stimulated with IL-22 (100ng/ml). MMP2 and MMP9 were measured by zymography. Mann-Whitney test was performed and results are expressed as median (range).

Results: Serum IL-22 was significantly higher in Inflammatory Arthritis 17.07pg/ml (0-83.5) compared to normal controls 3.38pg/ml (0-11.17) ($p<0.01$). IL-22 was significantly higher in RA 17.46pg/ml (0-83.5) compared to PsA 14.65pg/ml (0-39.54) ($p<0.05$). IL-22 was significantly higher in smokers compared to both non-smokers and ex-smokers. Similarly, IL-22 was significantly higher in anti-CCP positive patients compared to anti-CCP negative patients ($p<0.05$). IL-22 was decreased 3/12 post anti-TNF therapy in 15 of 33 patients from 14.5pg/ml (3.98-69.19) to 9.04pg/ml (0-66.09). IL-22 significantly increased both MMP-2 and MMP-9 ($p<0.05$).

Conclusion: IL-22 is increased in inflammatory arthritis and may regulate the pro-inflammatory response in specific patients. IL-22 expression is associated with smoking and anti-CCP antibody, both risk factors for RA, this further suggests an important role for IL-22 in specific Inflammatory Arthritis patients.

Synovial Fluid and Synovial Tissue Biomarkers of the Response to Intra-Articular TNF-α Blockade in Psoriatic Arthritis. U. Fiocco[1], P. Sfriso[1], F. Oliviero[1], P. Roux-Lombard[2], F. Lunardi[1], F. Calabrese[1], R. Nardacchione[3], E. Scagliori[1], L. Cozzi[1], M. Vezzù[1], B. Molena[1], A. Scanu[1], J. M. Dayer[2] and L. Punzi[1], [1]University of Padova, Padova, Italy, [2]University Hospital of Geneva, Geneva, Switzerland, [3]Abano Terme Hospital, Padova, Italy

Purpose: To identify synovial fluid (SF) and synovial tissue biomarkers of the response to intra-articular (IA) TNF-α blockade.

Methods: SF cytokine/chemokine levels and synovial tissue histology were assessed during a perspective study of repeated IA etanercept injections in the knee joint of 14 patients affected by psoriatic arthritis (PsA) and resistant knee joint synovitis (KJS) (1). SF was aspirated from the knee joint before each IA injection of 0.5 ml of etanercept (E) (12.5mg) once every two weeks, for 12-weeks. IL-1β, IL-1Ra, IL-6, IL-8, IL-17, IL-22, TNF-α, IFN-γ, MCP-1, MIP-1α and MIP-1β were measured on SF samples, obtained at baseline and after the last IA-E injection, by a commercially available multiplex beads immunoassay, based on the Luminex platform (Fluorokine MAP Multiplex Human Cytokine Panel A, R&D Systems, Minneapolis, USA) according to supplier's instructions. Normal values were established in 50 healthy blood donors. Characterization of synovial mononuclear cell infiltrate and synovial vessels was carried out by staining for CD45, CD3, CD68, CD31 and CD105 of serial sections of synovial biopsies obtained from 11 knees before the baseline IA-injection and repeated after the last injection. All parameters were measured by computer-assisted morphometric analysis (Image Pro-plus version 5) and a 2 mm^2 area was evaluated (7 random fields at x 40). The nonparametric Wilcoxon rank test was used to compare SF cytokine levels and synovial tissue infiltrating cells before and after IA-E treatment. For correlation analysis Spearman's rank correlation test was used.

Results: Before IA-E treatment, IL-6 correlated significantly with IL-1Ra, IL-1-β, MIP-1α SF level. Moreover, CD31+ synovial tissue cells were significantly correlated with both IL-1β and IL-6 SF level; CD45+ cells with IL-1β and CD3+ cells with MIP-β SF level, respectively.

IA TNF-α blockade induced a reduction in IL-1β, IL-1Ra, IL-6, IL-22 SF level (Tab I), as well as in CD45+ and CD31+ synovial tissue cells ($p<0.05$). After IA-E, a significant correlation was observed between IL-17 and IL-6 SF level and between IL-1Ra and IL-1β, IL-8, IL-6.

Table I: Comparison of synovial fluid cytokine levels in psoriatic arthritis before and after intra-articular knee joint etanercept treatment

SF-ILs	Pre (M±SD)	Post (M±SD)	p (Wilcoxon rank test)
TNF-α	25±44	27±37	ns
IL-1-β	8±10	4±1	0.014
IL-1Ra	10876±10491	5015±6011	0.004
IL-6	4596±5322	1770±3255	0.016
IL-8	753±1257	622±939	ns
MCP1	413±320	296±168	ns
MIP1- α	99±62	128±151	ns
MIP1- β	80±72	84±135	ns
IL-17	23±73	18±26	ns
IL-22	13±8	5±3	0.039

Conclusion: IA-TNF-α blockade has shown early down-regulation of either IL-1-β and IL-6 in resistant knee joint synovitis, not already reported following systemic anti-TNF-α treatment. The correlations observed after IA-E treatment between IL-1ra and IL-8, as well IL-6 and IL-17, suggest the modulation of the local cytokine balance following TNF-α signal attenuation. IL-22 SF expression in PsA, suggests an underlying role for the Th17 system in both skin and joint involvement.

Glatiramer Acetate (GA), the Immunomodulatory Drug, Inhibits Inflammatory Mediators and Collagen Degradation in OA Cartilage. Mukundan Attur, Mandar Dave, Hayf Al-Mussawir, Jyoti Patel, Glyn Palmer and Steven B. Abramson, NYU - Hospital for Joint Diseases, New York, NY

Purpose: Glatiramer acetate, the generic name for Copaxone, an immunomodulatory agent used in the treatment of multiple sclerosis, has been to shown induce interleukin-1 receptor antagonist (IL-1Ra) production in macrophages and microglial cells. In osteoarthritis, the production of inflammatory mediators, particularly IL-1, by chondrocytes may be important in the pathogenesis and progression of OA. We therefore tested the effects of glatiramer acetate or co-polymer on the catabolic activities of chondrocytes in OA cartilage explants cultures.

Method: Human OA cartilage samples and chondrocytes were isolated from patients undergoing knee replacement surgery as approved by IRB. IL-6, IL-8, proMMP-13 and active MMP-13 ELISA were performed as per manufacturer's recommendations (R&D Systems).

Results: We have previously shown that OA cartilage explant cultures spontaneously release inflammatory mediators such as nitric oxide, Prostaglandin E2 (PGE2), interleukins including IL-1beta, IL-6, IL-8 and matrix metalloproteinase (MMPs). Addition of GA (1mg/ml) inhibited 1) IL-6 (25.19 + 13.27 to 15 + 8.5 ng/ml;$p<0.05$) and IL-8 (30.5 + 9.2 to 15.1 + 6.1 ng/ml;$p<0.01$) production; 2) inhibited spontaneous proMMP-13 production (35.6+ 14 to 18.5 + 5.1ng/ml;$p<0.01$); 3) inhibited MMP-13 activity by more than 30-50% ($p<0.01$); 4) inhibited collagen degradation as assayed by CTX II ELISA (7.4 + 1.7 to 4.5 + 1.9 ng/ml; $p<0.05$). GA also increased significantly ($p<0.001$) IL-1Ra production by OA cartilage explant ex vivo cultures.

Conclusion: Glatiramer acetate is a complex heterogeneous mixture of polypeptides that exhibits "chondroprotective" properties in OA cartilage, inhibiting the production of cytokine/chemokines production as well as MMP-13 expression/activation. The data suggest that these effects may be due to upregulation of IL-1Ra. Based on these studies, we propose that glatiramer acetate may have potential for disease modifying properties in OA and should be evaluated in vivo animal studies.

Cytokine Quantification and Microarray Assessment Differentiate "CIAS1 Mutation Positive and Negative" Patients with Neonatal-Onset Multisystem Inflammatory Disease (NOMID). T.H. Pham[1], N. Plass[1], D. Stone[1], D. Chapelle[1], M. Gadina[1], H.W. Sun[1], W. Fury[2], I. Dozmorov[3] and R. Goldbach-Mansky[1], [1]NIH | NIAMS, Bethesda, MD, [2]Regeneron, Tarrytown, NY, [3]OMRF, Oklahoma City, OK

Purpose: Only about 60% of NOMID patients have mutations in *CIAS1*/ *NLRP3*/ *NALP3*, a gene associated with the activation of IL-1β. Mutation positive (MP) and mutation negative (MN) patients do not differ in their clinical phenotype nor in their response to treatment with anakinra, a recombinant IL-1 blocking agent, indicating that the organ specific pathology is IL-1 cytokine driven. We evaluated cytokine production and compared gene expression profiles in both patient groups.

Methods: Whole blood from mutation positive (MP) (n=13) and negative (MN) (n=7) NOMID patients and controls (n=26) were either spun and plasma collected, cells washed and treated with lipopolysaccharide (LPS) for 3 hours at 37°C or extracted for RNA. For cell treatment experiments, ATP was used as second stimulus, while oxidized ATP (oATP) or caspase-1 blocker (YVAD) was added as inhibitors. Cytokines were quantified using ELISA. Gene expression from microarray analysis using a cDNA profile of 54,000 random genes was assessed.

Results: LPS treated cells from MP patients significantly produced IL-1β (range 53 to 6.9ng/mL), however this is not seen in MN patients and controls ($p<0.001$). When a second stimulus was added to cell cultures only MN patients and controls further secreted IL-1β: LPS treatment alone (range 7 to 0.3ng/mL and 6 to 0.4ng/mL, respectively) to ATP addition (range 26 to 1ng/mL and 69 to 0.6ng/mL, respectively) ($p<0.05$), while IL-1 levels did not change with additional treatment in MP patients' cells. Also, IL-18 was significantly produced in treated cells of MP patients compared to MN patients and controls ($p<0.002$). However, IL-1 and IL-18 secretion were significantly blocked with oATP and YVAD in MP patients ($p<0.05$). MN patients and controls produced increased levels of IL-6 and TNF-α in plasma compared to MP patients ($p\leq0.05$). Of the 54,000 genes that correlated with IL-1 expression, 37 genes correlated well in MP but not MN patients, and 47 genes correlated well in MN vs MP patients. Among the differentially correlated genes, those highly correlated with IL-1 in MN but not MP patients included: ATP-binding cassette ($r=0.94$ for MN and $r=0.07$ for MP), annexin, P2XR, NLRP, while those most correlated with MP but not MN patients were ATPase, ADPRF, TLR1, IRAK, and PDK.

Conclusion: MP NOMID patients are hypersensitive to LPS and maximally produce IL-1β without the need for a second stimulus such as ATP. IL-1 and IL-18 were successfully inhibited in MP patients using YVAD and oATP. Evaluation of protein secretion from cell treatment studies demonstrated differential cytokine production among NOMID patients with and without the *CIAS1* mutation. Microarray analysis in patients demonstrated a set of genes that are differentially expressed in MP and MN patients. This further supports the notion that IL-1 mediated disease in MN NOMID patients may be due to mutation in genes other than *CIAS1*.

IL-27 Inhibits IL-1b and TNF-a, but the Anti-Inflammatory Function of IL-27 Is Abrogated within the Inflammatory Microenvironment. George D. Kalliolias, Rachael Gordon and Lionel B. Ivashkiv, Hospital for Special Surgery, New York, NY

Purpose: TNF-a and IL-1b are implicated in the pathogenesis of Rheumatoid arthritis (RA). Recently it was shown that IL-27, a new member of the IL-6/IL-12 family, is expressed in RA synovium. IL-27 is a pleiotropic cytokine with both anti-inflammatory and pro-inflammatory functions. In Collagen-induced arthritis IL-27 was beneficial by restraining Th17, while in Proteoglycan-induced arthritis and in Adjuvant-induced arthritis it was proven pathogenic by inducing Th1. Whether in human RA IL-27 is pathogenic or protective remains an open question.

Method: CD14+ cells were isolated with positive selection from peripheral blood of healthy donors and synovial fluids (SF) of RA patients. Activation of signaling pathways and gene expression following stimulation with cytokines were measured by immunoblotting and qRT-PCR respectively.

Results: Pretreatment with IL-27 of peripheral blood CD14+ cells derived from healthy donors, inhibited activation of MAPK signaling pathways (ERK and p38) downstream to IL-1b and TNF-a. IL-27 inhibited the induction of IL-1b- target genes (including IL-8, IL-1 and IL-6), suppressed the expression of IL-1RI and induced IL-1Ra in these cells. Surprisingly, we observed that, in stark contrast to CD14+ cells derived from healthy donors peripheral blood, SF CD14+ cells from RA patients were not responsive to IL-27 (there was no activation of Jak-STAT signaling pathway and no induction of target genes). Interestingly, we found that overnight pre-incubation of healthy donors peripheral blood CD14+ with TNF-a or IL-1b inhibited IL-27 signaling and this inhibition was abrogated by etanercept and anakinra. We also found that IL-1b, but not TNF-a, downregulated the cell surface expression of the gp130 subunit of the IL-27 receptor. In the presence of a p38 inhibitor, the inhibitory effect of TNF-a on IL-27 function was abrogated.

Conclusion: In human monocytes, IL-27 exerts anti-inflammatory effects by inhibiting both IL-1b and TNF-a. IL-27 inhibits IL-1b potentially by downregulating IL-1RI and inducing IL-1Ra. On the other hand, IL-1b suppresses the anti-inflammatory function of IL-27 by downregulating gp130. TNF-a also inhibits IL-27 functions in a p38-dependent manner. Our results indicate that in the inflammatory microenviroment the anti-inflammatory function of IL-27 is abrogated.

IL-27 Inhibits Human Osteoclastogenesis. George D. Kalliolias[1], Baohong Zhao[2], Antigoni Triantafyllopoulou[3], Kyung-Hyun Park-Min[1], Rachael Gordon[1] and Lionel B. Ivashkiv[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Hospital for Speical Surgery, New York, NY

Purpose: IL-27 has both stimulatory and regulatory immune functions and is expressed in rheumatoid arthritis synovium. We investigated the effects of IL-27 on human osteoclastogenesis to determine whether IL-27 can stimulate or attenuate osteoclast-mediated bone resorption that is a hallmark of rheumatoid arthritis.

Method: Osteoclasts were generated by culturing blood-derived human CD14+ cells in the presence of MCSF and RANKL. The effects of IL-27 on osteoclast formation were evaluated by counting the number of TRAP+ multinucleated cells and measuring expression of osteoclast-related genes using real time RT-PCR. The induction of NFATc1 and the activation of signaling pathways downstream of RANK were measured by immunoblotting. The expression of key molecules implicated in osteoclastogenesis (including NFATc1, RANK, costimulatory receptors and ITAM-harboring adaptors) was measured by real time RT-PCR. Murine osteoclast precursors were obtained from bone marrow and a similar approach was followed.

Results: IL-27 inhibited human osteoclastogenesis, suppressed the induction of NFATc1, downregulated expression of RANK and TREM-2, and inhibited RANKL-mediated activation of ERK, p38 and NF-κB in osteoclast precursors. In contrast to human cells, IL-27 only minimally suppressed murine osteoclastogenesis, likely due to low expression of the IL-27 receptor subunit WSX-1 on murine osteoclast precursors.

Conclusion: IL-27 inhibits human osteoclastogenesis by a direct mechanism that suppresses responses of osteoclast precursors to RANKL. Our findings suggest that in addition to its well-known anti-inflammatory effects, IL-27 plays a homeostatic role in restraining inflammatory bone erosion.

The Role of the Atypical Chemokine Receptor D6 in Collagen-Induced Arthritis. Chris Hansell, Lindsay MacLellan, Iain B. McInnes, Robert J.B. Nibbs and Carl S. Goodyear, University of Glasgow, Glasgow, United Kingdom

Purpose: Chemokines direct leukocyte migration into inflamed tissue. The chemokine receptor D6 is expressed by a subset of leukocytes in the inflamed human synovium. D6 can bind at least 10 inflammatory CC chemokines but appears not to transduce signals. Instead it acts as a chemokine scavenger and progressively internalizes large quantities of it ligands, which it targets for destruction. As a result D6-deficient mice show a marked predisposition to exaggerated inflammation in a wide variety of experimental in vivo systems. In addition it appears that D6 facilitates the migration of DCs from the inflamed tissue to draining lymph nodes for optimal T cell priming. This underpins the decreased susceptibility of D6-deficient mice to experimental autoimmune encephalomyelitis. The aim of this study was to investigate the role of D6 in the murine models of rheumatoid arthritis (RA).

Methods: D6-deficient mice were back-crossed to DBA/1 mice for 12 generations and then intercrossed to obtain D6+/+ and D6-/- mice. In all experiments, age-matched male littermates at 8-10 weeks age were used. Collagen-induced arthritis (CIA) was induced by immunizing with collagen type-II (CII)/CFA at the base of the tail on day 0 and boosting on day 21 i.p. with CII/PBS. Collagen antibody-induced arthritis (CAIA) was induced by injecting 2 mg of the CII specific monoclonal antibody cocktail i.v. on day 0, and 50µg of LPS i.p. 72h later. Mice were scored for clinical arthritis severity based on joint inflammation and ankle thickness, using standard methods. On day 35, serum, lymph nodes, patella and legs were harvested for determination of anti-Collagen antibodies, recall responses, joint cytokine and chemokine secretion and histology respectively.

Results: D6-/- mice had a small but significant increase in disease severity in CIA. This was associated with an increase in total lymphocyte numbers in the draining lymph nodes, and increased proliferation and secretion of IL-17 in response to antigen. However, no difference was observed in the CAIA studies.

Conclusion: Contrary to expectations, T cell priming in the D6-deficient mice was sufficient to induce clinical disease. In fact, the small increase in antigen-specific proliferation and IL-17 production by LN cells may account for the slight exacerbation of the clinical scores. The results also suggest that, unlike in other tissues, D6 does not play a major role in suppressing inflammation in the joint.

A Rheumatology Curriculum That Is Successful in Preparing Internal Medicine Residents for the Rheumatology Portion of the Internal Medicine in-Service Examination and the American Board of Internal Medicine Certification Examination. Alan R. Erickson[1], Amy C. Cannella[2], Gerald F. Moore[3], T. R. Mikuls[4], Lynell W. Klassen[5] and James R. O'Dell[4], [1]UNMC Physicians - Brentwood, LaVista, NE, [2]University of Nebraska Med Ctr, Omaha, NE, [3]Univ Nebraska Med Ctr, Omaha, NE, [4]U Nebraska, Omaha, NE, [5]Univ of Nebraska Med Ctr, Omaha, NE

Purpose: Teaching internal medicine residents is an important responsibility of academic rheumatologists. At the University of Nebraska Medical Center (UNMC) there is a long-standing and well-developed curriculum for all residents who rotate through rheumatology. In addition to regular teaching rounds, this curriculum includes a didactic lecture series, a computer based x-ray and photographic case series, and 2 distinct and separate 200 question closed book pre- and post-tests. The pre-test answers with explanations are given after the testing to use as a study guide. Using the results of the Internal Medicine(IM) in-training examination and the American Board of Internal Medicine (ABIM) certification examination as a surrogate marker for educational success, our hypothesis is that a well developed rheumatology

curriculum prepares third year internal medicine residents and graduating internal medicine residents for the rheumatology portion of these examinations.

Method: Subjects include 84 third year internal medicine residents at UNMC from July 2003 through June 2009 that completed the IM in-training examination and all graduating internal medicine residents from 1999-2008. Composite results of the in-training examination completed by third year internal medicine residents and ABIM certification examination results of graduating internal medicine residents were reviewed for each year. A manual count was competed of the number of UNMC third year internal medicine residents who had completed our rheumatology rotation prior to the in-service examination. All internal medicine residents complete our rheumatology rotation prior to graduation and thus prior to the ABIM certification examination. For the IM in-service examination we looked at our national percentile rank. For the ABIM certification examination we looked at our percentile ranking for first time takers.

Results: The majority of third year internal medicine residents (65%) completed our rheumatology rotation prior to completing the third year in-training examination. Compared to all program's third year IM in-training examination scores, our program ranked in the top 10th percentile for each year from 2003 to 2008. From 1999-2008, 99% of our residents released their ABIM certification scores to our internal medicine program director. On average, our internal medicine residents' scores ranked among the top 30% of first time test takers in the rheumatology subsection (average decile 7.4).

Conclusion: These results suggest that a well developed curriculum prepares internal medicine residents for the IM in-training examination and the ABIM certification examination. Limitations in this study include the lack of comparative data on other rheumatology curricula and difficulty in generalizing ABIM internal medicine certification board results.

Creation of a Bedside Teaching Atlas. Lori J. Albert[1], Kelsey Mills[2] and Nancy Roper[3], [1]The Toronto Western Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Patient Partners in Arthritis, Toronto, ON

Purpose: Recognition of key physical findings is an essential component of diagnosing rheumatic diseases. Students and residents often have very limited opportunities to learn physical examination on patients having rheumatic diseases. Frequently, these patients have achieved good disease control on medication, and may not show any characteristic changes on examination. Thus, a significant proportion of trainees do not understand what they are looking for on physical exam. We describe the development of a Bedside Teaching Atlas of physical findings in the rheumatology examination. The purpose of this Atlas is to demonstrate the appearance of characteristic or diagnostic changes at the time that physical examination is taught, even when the patient's examination is normal.

Method: Photographs were obtained of key physical findings that can be observed in the rheumatic diseases such as joint effusions, joint deformities, nailfold changes and skin findings. Pages were spiral bound for "flip chart" style use. Descriptive information for each photo was placed on the back of the preceding page to face the instructor. This was done to encourage thoughtful "inspection" of the photo by the student, while permitting non-expert teachers to have information regarding the picture. The number of photos was limited to ensure portability and ease of use. A pilot version of the Atlas was circulated to rheumatologist clinician teachers as well as non-specialist teachers and non-physician teachers (such as Patient Partners in Arthritis®) . Trainees were given a questionnaire following sessions where the Atlas was used. Feedback was also obtained from the teachers using the Atlas.

Results: Qualitative surveys indicated a high level of trainee satisfaction with use of the Atlas during teaching sessions. The Atlas was rated highly for the variety of photos available and for the fact that many of the findings shown had not been seen before, or were not seen in the patient being examined. Importantly, the majority of trainees agreed that the Atlas helped them to recognize changes of early arthritis. Almost all trainees surveyed felt that the Atlas enhanced the learning experience. Free-text comments reflected enthusiasm over observing and understanding rheumatologic findings "for the first time". Many students commented that using the Atlas would promote more careful and informed examination of their own patients in future.

Conclusion: It is predicted that demonstration of key physical findings using the Bedside Teaching Atlas, in the context of teaching rheumatology physical exam, will enhance recognition of these findings in clinical situations and improve the diagnostic acumen of trainees. It is also predicted that use of the Atlas will enhance the effectiveness of physical exam teaching by physicians as well as non-physician teachers.

Integrating the Teaching and Learning of Compassionate Care Into a Rheumatology Outpatient Clinical Skills Exercise. Robert A. Kalish[1] and MA Blanco[2], [1]Tufts Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA

Purpose: Medical education recognizes the need to balance trainees' competency in clinical knowledge and skills with the principles and practice of humanistic care. This study examined the outcomes of a videotaped medical student-patient partner exercise aimed at promoting the teaching and learning of both clinical skills and compassionate care in an outpatient rheumatology clinic setting.

Method: Twenty-two third-year medical students rotating at a tertiary care academic medical center during their internal medicine clerkship participated. Each student performed a complete medical history, which was videotaped, and a complete joint examination on a volunteer rheumatology outpatient who was presented as an unknown diagnosis; the student's task was to determine the rheumatologic diagnosis. The student repeated the joint examination with the preceptor present, received feedback from both preceptor and patient, and requested laboratory and radiographic data.

Subsequently, students viewed their videotape, tagged segments to identify strengths and weaknesses in their rheumatologic history taking and compassionate care skills, and completed a Compassionate Care Interactions and Rheumatologic History-taking Skills Rating Form. The preceptor reviewed the videotape and the student's tags, provided tagged feedback, and independently completed the same rating form. Sixteen patients completed a questionnaire rating the student's interpersonal and compassionate care skills. Within the week, preceptor and student met to discuss differential diagnosis and reinforce physical examination skills through preceptor observation of designated joint examination maneuvers. Students evaluated the exercise through an online questionnaire. Quantitative and qualitative methods of data analysis were employed.

Results: Self-assessment and preceptor assessment through the videotape allowed students to identify weaknesses in history taking skills, including temporal sequencing, symptom details, and question clustering. Students gained confidence in examining joints in subsequent patients during the clerkship. The exercise also increased students' recognition of opportunities to demonstrate compassionate care. No statistically significant differences between student and preceptor ratings of history taking or compassionate care skills were found though a trend to higher preceptor scores for compassionate care skills was noted. Patients unanimously agreed that students demonstrated compassionate care. Five students indicated the experience increased the likelihood they would consider a career in rheumatology.

Conclusion: This educational initiative successfully and efficiently combined the teaching and learning of humanistic and clinical skills in an outpatient rheumatology patient-partner exercise. Videotaping the student-patient encounter was an effective tool for promoting students' self-assessment and reflection, and enhancing the preceptor's feedback.

Elective Rheumatology Program with a Primary Health Care Focus. E. L. M. Bezerra, M. J. Vilar and G. D. Azevedo, Federal University of Rio Grande do Norte (UFRN), Natal, Brazil

Purpose: Rheumatic conditions are very common in primary care. However most general doctors do not have the required expertise to deal with the rheumatic diseases they are likely to encounter in clinical practice. This fact reflects the poor undergraduate Rheumatology curriculum in the majority of medical schools, where its teaching is developed mainly in hospital settings (terciary care) by using traditional methods. Student-selected component (SSC), an innovative teaching method, is an optional program within the medical curriculum first used in UK. Its specific aims include the development of students' skills in self-directed learning, the ability to study areas outside the core curriculum in depth and development of confidence in their own skills and abilities. Thus, the objective of this pilot study was the implementation of SSC in a traditional curriculum to develop Rheumatology skills related to primary care.

Method: Twelve medical students in the clerkship (5^{th} and 6^{th} year) voluntarily participated in this program. They already had applied for a mandatory Rheumatology discipline, with 60 hours of time available, at the 4^{th} year of UFRN regular curriculum.

The SSC program consisted of ten 3-hour weekly sessions, from April to June 2009. The activities developed were the following (S = Session):

S 1- Introduction to module and setting of goals. Use web-based scientific material to highlight the importance of rheumatological primary care.

S 2- Students interviewed general practitioners from the "Family Health Program" (primary care level) on more prevalent rheumatic diseases in the community and access to diagnostic and therapeutic methods.

S 3- Small groups of clinical cases discussions on osteoarthritis and rheumatoid arthritis.

S 4- Small groups of clinical cases discussions on low back pain and shoulder pain.

Note: Pre-class review of the topics were required, both for S 3 and 4.

S 5- A physiotherapist and a psychologist discussed their roles in dealing with patients with long-term chronic pain and debilitating conditions.

S 6 and 7- Primary care of rheumatic patients by students, with supervision of rheumatologists.

S 8- Written assessment (short-answer questions).

S 9- Practical assessment (OSCE with standardized patients).

S 10- Feedback session and program evaluation (semi-structured interview).

Results: All of the students achieved good performance on assessments (grade 8 or above, in a scale ranging from 0 to 10). After completing the program, students surveyed (12/12) stated their confidence for diagnosing and treating rheumatic disease had improved either greatly (90%) or somewhat (10%). Students unanimously indicated that active formats were preferred over lectures and that practical training in Rheumatology primary care was a very rich experience.

Conclusion: This study showed that SSC was an effective learning strategy for development of Rheumatology skills and abilities in undergraduate medical students. These observations deserve further study with a larger number of participants and the results comparison with a control group of clerkship students.

Team-Based Learning in Rheumatology Education of Internal Medicine Residents. Karina D. Torralba[1], Ron Ben-Ari[1], Francisco P. Quismorio Jr.[1] and Beatrice A. Boateng[2], [1]Keck School of Medicine, University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [2]University of Arkansas for Medical Sciences, Little Rock, AR

Purpose: Team-based learning (TBL), a structured approach to classroom instruction has gained acceptance in health professions. It leads to improved student attendance, interest in subject matter and work performance. We studied the effectiveness and outcomes of using TBL in Rheumatology core curriculum learning sessions (CCLS) for Internal Medicine (IM) residents over an initial period of 12 months.

Methods: A needs assessment conducted among PGY1-PGY3 residents in May 2008 determined improvements in scope of topics, and teaching methods. Reorganization for 2008-2009 led to TBL-formatted CCLSs on Evaluation of Joint Pain, Back Pain, Rheumatologic Emergencies, Inflammatory Myopathies, Spondyloarthropathies, Rheumatoid Arthritis and Osteoarthritis. To assess receptiveness to TBL format, a 5-point Likert scale survey was anonymously filled out by residents at end of each session. To evaluate perception of collaborative learning, a Value of Teams Survey (VOTS) was filled out at the end of the CCLS series. As an independent outcomes measure, we compared in-training exam (ITE) scores of TBL vs non TBL participants. An independent t-test was conducted to determine differences in ITE scores between groups.TBL was modified to include 1) accessible learning materials pre-CCLS, 2) individual followed by group in-class readiness assurance testing with an Immediate Feedback Assessment Tool, and 3) team case application exercises. Answers were discussed within and between teams with faculty instructor.

Results: Although TBL participation is voluntary, more residents participated in the TBL sessions (68 vs 53). Across 7 CCLSs, majority (60-100%) agreed-strongly agreed that TBL was conducive for use during CCLSs based on time allocation, organization of activities, quality of learning and interaction between teammates and with instructor. For VOTS, 81% (n=44) agreed cooperation with peers is necessary for success; 87% agreed working with peers is a valuable skill, an effective way to learn, and is needed for better decision-making. Although the average ITE score for TBL participants and all PGY levels (m = 54.4, sd = 12.91) was higher than non-TBL participants (m = 50.7 and sd=11.84) within the study period, differences were not significant (t(119)=1.633, p=1.10). ITE scores by PGY level showed a significant difference in PGY 1 resident scores (t(55)=2.157, p=0.03). No significant differences were found in PGY2 and 3.

Conclusion: IM residents are receptive to the use of TBL for CCLS, and have favorable perceptions of collaborative learning. Additionally, results provide information on potential impact of TBL on available assessments such as the ITE. Evaluating its impact begins the process of determining the place of TBL in Rheumatology education.

Workshop Using Simulators to Teach Medical Students Large Joint Injections. Aasim Rehman, Vanessa C. Osting, Ashley G. Sterrett, John D. Carter, Priya Reddy, Louis Ricca, Joanne Valeriano-Marcet and Helen E. Bateman, University of South Florida, Tampa, FL

Purpose: To teach medical students the proper technique of large joint injections and assess the effect of such a workshop on their comfort levels when performing these procedures.

Method: All 4th year medical students attend the joint injection workshop at the beginning of their rheumatology rotation. The workshop consists of a teaching didactic session followed by the joint simulator injection session. The simulators are pre-wired anatomical models of the knee and shoulder. A pre and post workshop self assessment survey is given regarding student's comfort level with examination and injection of knee and shoulder joints, on a scale of 1 to 5 (1= not comfortable to 5= fully comfortable).

Results: A total of 68 4th year medical students completed the workshop. 23 students had performed knee injections, 6 had performed shoulder injection and 10 students had performed other musculoskeletal injections prior to attending the workshop. Results are shown in table 1.

Table 1: Pre and post workshop comfort levels. (N=68)

	Pre-Workshop Mean Comfort Level (+/- SD)	Post-Workshop Mean Comfort Level (+/- SD)	p-value*
Knee Palpation	2.81 (+/- 0.90)	3.93 (+/- 0.74)	<0.0001
Detecting Knee Effusion	2.75 (+/- 0.90)	3.51 (+/- 0.91)	<0.0001
Knee Injection	1.87 (+/- 1.02)	3.66 (+/- 0.84)	<0.0001
Shoulder Palpation (sub-acromial)	2.59 (+/- 0.85)	3.88 (+/- 0.86)	<0.0001
Shoulder Injection	1.44 (+/- 0.63)	3.59 (+/- 0.83)	<0.0001
Selection of Corticosteroid Preparation	1.55 (+/- 0.68)	3.15 (+/- 1.10)	<0.0001

* Paired t-test of post-workshop comfort level compared with pre-workshop comfort level.

Conclusion: Our joint injection workshop using simulators increases the comfort level of 4th year medical students when performing large joint injections.

1358

Teaching Residents Arthrocentesis and Soft-Tissue Injection Procedures: Practice Outcomes for Internal Medicine Residents in Outpatient and Hospitalist Careers. Catherine J. Bakewell[1] and Gregory C. Gardner[2], [1]Univ of Washington, Seattle, WA, [2]University of Washington, Seattle, WA

Purpose: In 1994 the University of Washington designed a half-day arthrocentesis course for internal medicine residents, followed by a month-long musculoskeletal rotation for primary care residents in 2002. Purpose of this study was to evaluate the impact of the course and rotation on primary care internist graduates of the program and to utilize the data to improve our procedure curriculum.

Method: Surveys were mailed to 2002 – 2006 internal medicine graduates who went into primary care or hospitalist careers. The surveys were designed to provide feedback on resident education in musculoskeletal procedures as well as characterize current clinical application of these procedures. This data was added to a previously collected survey of residents pre-and post arthrocentesis course from 2002.

Results: There were 52 responses from 82 surveys mailed to recent primary care graduates (64% response rate). Thirty-two respondents were practicing outpatient medicine (OPM). Twenty respondents worked only in an inpatient setting (IPM). The most common procedures performed were the knee followed by subacromial bursa, then trochanteric bursa. OPM graduates did 1054 procedures at 11 different sites per year. IPM graduates performed 44 procedures at 9 sites.

Physicians practicing OPM were more comfortable than IPM with procedures. IPM graduates had an average comfort level with knee arthrocentesis of 3.1 (1 = not comfortable, 5 = very comfortable), and performed an average of 1.5 procedures per year, compared to an average comfort level of 4.3 for those practicing OPM, who averaged of 9.9 knee arthrocenteses per year ($p < .05$ for both).

There was non-significant trend favoring increased comfort and number of procedures done for those respondents who took either the R1 arthrocentesis and injection course or the musculoskeletal month as an R2 over those who did not. OPM graduates felt training in residency is necessary in a wide variety of procedures while IPM graduates suggestions were more restricted. Even with training provided in residency and general comfort level of those practicing OPM, almost half of the respondents who practice OPM referred 6 or more musculoskeletal procedures per year to another clinician.

Conclusion: Our 2002 survey found that a focused arthrocentesis course had a significant impact on resident comfort level for up to 6 months. Once an individual enters the job force, their practice environment seems to be the single largest determinant in the practitioner's comfort level and number of procedures performed. Based our results we suggest:

1) Medicine R1s should receive training in aspiration/injection of the knee, subacromial bursa, and trochanteric bursa, as these comprise > 75% of all injections performed in clinical practice.

2) Once an internal medicine resident identifies a career path in primary care, we recommend more comprehensive training in arthrocentesis and soft tissue injection techniques tailored to their future career.

Disclosure: C. J. Bakewell, None; **G. C. Gardner**, None.

The Development of An Interactive Web-Based Rheumatology Teaching Module. Michelle Batthish[1], Ereny Bassilious[2], Nicholas Blanchette[2], Gordon Soon[2], Nadia Luca[2], Rosanne St Bernard, Teddy Cameron[3], Tamara Bahr[3], Avi Hyman[3], Gordon Tait[3], Brian Feldman[1], Rayfel Schneider[1] and Shirley ML Tse[2], [1]The Hospital for Sick Children, Toronto, ON, [2]Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, [3]Academic Computing, University of Toronto, Toronto, ON

Purpose: We previously demonstrated that an interactive web-based rheumatology teaching module would be both accessible and well utilized by paediatric residents. Our objective is to develop an interactive web-based teaching module to improve resident learning and problem solving about rheumatology ("POINTER": Paediatric Online Interactive Teaching in Rheumatology).

Method: We developed interactive case scenarios and patient simulators around commonly encountered rheumatologic topics. This will enable residents to work through modules at their convenience and receive consistent and timely feedback.

Results: POINTER was created on the University of Toronto Portal website with a unique login and password for each user. POINTER consists of two parts. Part I Interactive case-based scenarios: this is a dynamic module that starts with a common clinical stem but based on a random assignment feature the computer generates pathways to different diagnoses, hence promoting its multiple use. Throughout, learners are presented with multi-media and clinical "pearls" of information. Part II Patient simulator: Learners work through a case with total autonomy, selecting relevant history, physical exam maneuvers, and investigations and are ultimately provided with a final diagnosis. The simulator tracks and assigns a time and cost expenditure to the user's interventions. No feedback on performance is provided until a final diagnosis is submitted at which time the learner receives feedback on diagnostic accuracy, time and cost expenditure.

Conclusion: Following development of POINTER, we will evaluate the feasibility, effectiveness and satisfaction of this module by randomizing a group of residents to using the POINTER website or reviewing pre-selected articles. Each group will complete an information based pre and post multiple choice test and a teaching modality satisfaction questionnaire. In addition, we will track POINTER usage, including frequency of use, length of time spent online and time of day POINTER is most accessed.

The Carolinas Fellows Collaborative (CFC): An Educational Model for Rheumatology Training Programs. Beth L. Jonas[1], Lisa G. Criscione-Schreiber[2], Marcy B. Bolster[3] and Kenneth S. O'Rourke[4], [1]Univ of North Carolina, Chapel Hill, NC, [2]Duke University Med Ctr, Durham, NC, [3]Medical Univ of South Carolina, Charleston, SC, [4]Wake Forest University School of Medicine, Winston-Salem, NC

Purpose: The ACGME Outcome Project was approved in 1999 and changed the focus of program evaluation from a process oriented assessment to an evaluation of outcomes assessment. Over the last decade there has been an exponential increase in the requirements for training programs and training program directors in all the specialties of Medicine and Surgery in response to the ACGME Outcome Project. Development and implementation of the continually evolving requirements presents a particular challenge to small programs with limited financial and administrative support.

Method: Previously, each of our programs presented a summer core lecture series for the new rheumatology fellows. Beginning in 2004, the program directors from the four programs in our region combined resources and faculties to provide a July weekend retreat for rheumatology fellows in which the summer core lecture series was covered in three days. This conference was extremely well-received and led the following year to the addition of a winter conference program. This series of biannual retreats rotates among institutions and takes advantage of the particular expertise at each institution. The program directors meet at least twice annually to develop curricula, goals and objectives, evaluation tools, educational research projects, and to discuss issues important to training rheumatology fellows.

Results: In a collaborative fashion, the program directors have successfully developed the curriculum and hosted 5 summer and 4 winter rheumatology fellows' conferences. The July program includes a cadaver lab on joint aspiration and injection techniques. For each of the 4 winter conferences, we have developed and implemented a Rheumatology Objective Structured Clinical Examination. Since its inception, the CFC has worked to develop competency based goals and objectives for all the rheumatology learning activities, and competency- based assessment tools in accordance with the ACGME Outcome Project. In addition, the program directors serve each other as peer mentors who share successful educational tools, collaborate on educational research, help address program problems and together develop strategies to address them. Moreover, fellow interaction at the twice yearly conferences has led to inter-institutional clinical research and publication.

Conclusion: Regional collaboration of rheumatology training program directors serves to combine limited resources for education of rheumatology fellows in the environment of increasing regulation and requirements. Other important advantages of this collaboration include exposure of the fellows to a wider faculty with unique expertise, development of collegial and research relationships among the fellows at different institutions, and opportunities for peer mentoring among the training program directors.

1361

Competency Based Goals, Objectives, and Evaluations for Rheumatology Training Programs: A Standardized Template of Learning Activities From the Carolinas Fellows Collaboration (CFC). Lisa G. Criscione-Schreiber[1], Marcy B. Bolster[2], Beth L. Jonas[3] and Kenneth S. O'Rourke[4], [1]Duke University, Durham, NC, [2]MUSC, Charleston, SC, [3]Univ of North Carolina, Chapel Hill, NC, [4]Wake Forest University School of Medicine, Winston-Salem, NC

Purpose: Each ACGME accredited Rheumatology training program must have written goals and objectives (G&O) for each learning activity (LA). Evaluation of each LA should measure whether rotation objectives are met. Rheumatology training programs nationally will benefit from access to pre-written goals and objectives.

Method: In three working meetings we composed G&O and evaluations for each LA of rheumatology training programs, anticipating that individual programs could modify documents as necessary. G&O were written collaboratively, and objectives feature appropriate verbs based on Bloom's taxonomy. Draft documents were peer reviewed by faculty at the four institutions and by members of the ACR Clinician Scholar Educator Group. Evaluations for each LA were adapted from these competency-based objectives. By consensus, we limited evaluation scores to: superior performance, meets objective, or does not meet objective.

Results: We completed competency-based G&O for 7 core rotations, 8 elective rotations and 7 conferences. LA goals detail progressive fellow performance improvement by educational level. G&O documents include teaching methods and list how progress toward meeting objectives is evaluated. Specific objectives in each competency are mirrored in the evaluations (Figure).

Figure. Sample Evaluation of Medical Knowledge Objectives for the Outpatient Continuity Clinic

Check (1) the appropriate overall assessment, and (2) specific objectives for improvement

MEDICAL KNOWLEDGE	Does not meet expectations	Meets Expectations	Superior Performance	Insufficient Observation

- o Describe pathogenesis & clinical expression of the rheumatic diseases encountered
- o Summarize an approach to evaluation of multi-organ inflammatory disorders
- o Discuss mechanisms of action, uses, and side effects of pharmacologic agents used
- o Identify therapy-related complications
- o Distinguish non-rheumatic disorders from rheumatic diseases
- o Interpret diagnostic tests
- o Critically appraise and cite literature pertinent to the evaluation of outpatients
- o Describes the structure and function of musculoskeletal tissues and joints
- o Discuss the roles of physical and occupational therapy
- o Specify the role of orthopedic surgery in the care of patients with musculoskeletal conditions

Conclusion: We produced detailed competency-based G&O for each potential LA of a rheumatology training program. We propose adoption of these G&O by the ACR, with access available to all US training programs. Evaluation forms that mirror stated objectives ensure that trainees are assessed using standardized measures and are aware of the learning expectations. These documents are now used by the four CFC training programs and are easily modifiable for use by all US rheumatology programs.

1362

Joint Simulator Workshop as a Teaching Tool for Joint Injections: Do Rheumatology Subspecialty Residents Benefit? Vanessa C. Osting, Aasim Rehman, Ashley G. Sterrett, Christopher Koltz, Priya Reddy, Helen E. Bateman, Louis Ricca, John D. Carter and Joanne Valeriano, University of South Florida, Tampa, FL

Purpose: To assess the effect of a joint injection workshop on the comfort levels of rheumatology subspecialty residents in identifying joint anatomy and performing intraarticular injections.

Method: A joint injection workshop consisting of both didactic teaching and interactive joint models was offered to rheumatology subspecialty residents to enhance their knowledge and comfort with the anatomy and injection of the knee, shoulder (sub-acromial), wrist, elbow and ankle joints. A self-assessment survey was administered before and after the workshop to assess comfort levels on a scale (1-5: 1 = not comfortable; 5 = fully comfortable) in performing 3 tasks for each joint: palpating bony structures, selecting a corticosteroid preparation and performing joint injections.

Results: 15 rheumatology subspecialty residents from various institutions participated in the workshop. None of the rheumatology subspecialty residents had prior formal joint injection workshop training. Results are shown in Table 1.

Table 1: Pre and post workshop comfort levels (N=15)

	Pre-Workshop Mean Comfort Level (+/- SD)	Post-Workshop Mean Comfort Level (+/- SD)	p-value*
Knee Anatomy	3.87 (+/- 0.92)	4.67 (+/- 0.49)	0.0004
Knee Effusion	3.60 (+/- 1.12)	4.20 (+/- 0.77)	0.0140
Corticosteroid Preparation for Knee	4.00 (+/- 1.00)	4.73 (+/- 0.46)	0.0032
Knee Injection	4.00 (+/- 1.00)	4.60 (+/- 0.63)	0.0070
Shoulder Anatomy	3.07 (+/- 0.70)	4.13 (+/- 0.92)	0.0013
Corticosteroid Preparation for Shoulder	3.27 (+/- 0.80)	4.20 (+/- 0.68)	0.0005
Shoulder Injection (sub-acromial)	3.27 (+/- 1.03)	4.07 (+/- 0.80)	0.0004

Rheumatology Practice Profiles in Teaching and Community Settings: Implications to Fellowship Training. Amarie M. Negrón, Leyda M. Díaz-Correa, Angel M. Mayor, Salvador Vilá and Luis M. Vilá, University of Puerto Rico Medical Sciences Campus, San Juan, PR

Purpose: Specialty and subspecialty medical training programs must provide trainees a wide and balanced exposure to clinical entities. Although university-based programs usually allow residents to learn the evaluation and management of unusual and difficult cases, they do not always provide the required experience to manage common and less complicated medical conditions which are usually seen at community-based medical facilities. Few studies have addressed these concerns. The aim of this study was to compare the rheumatology practice profiles of a university setting and two community-based rheumatology practices.

Methods: Claim forms submitted from rheumatology practices to healthcare insurance companies in 2007 were evaluated. The university and community settings were located in the same geographic region of a United States city. The university setting has an accredited Rheumatology Training Program by the Accreditation Council for Graduate Medical Education and fellows had clinical exposure to all rheumatology services provided by the institution. Demographic parameters, primary diagnoses (per International Classification of Diseases, Ninth Revision), type of patient visit and rheumatologic procedures (per Current Procedural Terminology-4) were examined. Variables were analyzed by chi-square and Student's *t* tests.

Results: A total of 8,153 claim forms were evaluated; 1,893 from the university setting and 6,260 from the community practices. The demographic features, type of patient visit, rheumatologic procedures and primary diagnoses are shown in the table below.

Feature	**University (n = 1,893)**	**Community (n = 6,260)**	**p value**
Age, mean years (SD)	45.4 (15.3)	55.7 (16.2)	<0.001
Gender, % women	88.3	88.5	0.002
Office visit, %	89.9	99.7	<0.001
Emergency room visits, %	0.5	0.0	<0.001
Hospital visits, %	9.2	0.2	<0.001
Joint injections, %	3.0	10.4	<0.001
Soft tissue injections, %	1.7	5.3	<0.001
Rheumatoid arthritis, %	17.2	11.4	<0.001
Systemic lupus erythematosus, %	39.6	14.0	<0.001
Scleroderma, %	3.4	0.6	<0.001
Sjögren's syndrome, %	0.4	2.2	<0.001
Inflammatory muscle disease, %	2.4	0.4	<0.001
Polymyalgia rheumatica, %	0.3	1.2	<0.001
Unspecified connective tissue disease, %	3.0	8.1	<0.001

Vasculitic syndromes, %	2.6	0.8	<0.001
Spondyloarthropathies, %	1.4	0.9	0.047
Osteoarthritis, %	10.1	19.3	<0.001
Gout, %	1.4	0.2	<0.001
Fibromyalgia syndrome, %	2.0	7.0	<0.001
Regional rheumatic pain disorders, %	1.5	8.0	<0.001
Low back pain, %	0.4	5.8	<0.001

Conclusion: Several differences were found in the rheumatology practice profile among patients seen at the university and community settings. This study suggests that efforts should be undertaken to provide a more rounded and diversified patients' exposure to rheumatology fellows at this institution.

Rheumatology Telemedicine in Rural Australia. Simon Burnet[1], Tim Kelly[2], Alison Marrinan[3], Peter Donohoe[3] and Tori Wade[4], [1]Adelaide, Australia, [2]Crystal Brook Hospital, [3]Adelaide to Outback GP Training Programme, [4]University of Adelaide

Purpose: This pilot study examines the feasibility of interns on rural placements facilitating specialist services to rural areas via an innovative e-health approach. The project was designed to enhance educational opportunities for junior doctor training, as well as increase rural access to specialist services, while providing optimal patient care.

Method: The study involved interns at a rural general practice performing follow-up rheumatology consultations in collaboration with a metropolitan based specialist via videophone broadband link-up. The process replaces the rheumatologist's usual follow-up consultations.

Results: Three telemedicine clinics were evaluated from the patient, intern and Rheumatologist's perspective. We found multiple benefits from this novel approach including;Interns gaining improved rheumatology clinical skills and communication skills;Enhanced understanding between general practice and other specialties;Interns and consultants working together in this way provides a high level of service otherwise not possible; and Reduced travel time and cost savings for both patients and consultants.

Conclusion: Experience in this pilot study indicates potentially unlimited applications for dynamic broadband video link-up to enhance junior doctor training with specialists in general practice. One limitation is Rheumatologist's inability to formally examine patients. It showcases junior doctors gaining valuable high-level learning via technology appropriate to Y-generation learning styles. It offers a solution to overcome rural geographic isolation from specialist care.

Disclosure: S. Burnet, None; **T. Kelly**, None; **A. Marrinan**, None; **P. Donohoe**, None; **T. Wade**, None.

PANLAR Recommendations and Guidelines for Musculoskeletal Ultrasound Training in the Americas. Carlos Pineda and The PANLAR Ultrasound Study Group, Instituto Nacional de Rehabilitacion, Mexico City, Mexico

Purpose: To develop guidelines for Musculoskeletal Ultrasound (MSUS) training in the Americas for Pan American League of Associations for Rheumatology (PANLAR) courses.

Method: Twenty-six Rheumatologists from 19 countries of the American Continent participated in a consensus-based interactive process using two consecutive electronic questionnaires. The first questionnaire included the following: the relevance of organizing courses to teach

MSUS to Rheumatologists; determination of the most effective educational course model; trainee levels; educational objectives; requirements for passing the course(s); course venues; number of course participants per instructor, and percentage of time spent in hands-on sessions. The second questionnaire consisted of questions that did not achieve consensus (> 65%) in the first questionnaire, topics, and pathologies to be covered at each course level. In addition, two meetings were held, to present and discussed the results from the two questionnaires and the questions that did not achieve consensus, to review and approved the final recommendations and guidelines for MSUS training courses in the Americas.

Results: Ninety six percent of the participants answered the first and 100% the second questionnaire. The group agreed that MSUS is an essential diagnostic and procedural tool for the practicing clinical rheumatologist. General consensus was obtained for the courses to be divided into three educational levels: basic; intermediate, and advanced. These courses should be taught using a theoretical-didactic and hands-on model. In addition, the group established the minimum requirements for attending and passing each MSUS course level, the ideal number of course participants per instructor (four participants/instructor), and the specific topics and musculoskeletal pathologies to be covered. In the same manner, the group concluded that 60–70% of course time should be focused on hands-on sessions.

Conclusion: A multinational group using a consensus-based questionnaire established PANLAR recommendations and guidelines for MSUS course training in the Americas. The PANLAR Ultrasound Study Group urges that these recommendations be adopted in the future by both national and regional institutions involved in the training of Rheumatologists for the performance of MSUS.

Peer to Peer Mentoring: Facilitating Individuals with Early Inflammatory Arthritis to Manage Their Arthritis. M. Bell[1], Paula Veinot[2], Gaya Embuldeniya[3], Romy Cho[3], Phedias Diamandis[3], Lopamudra Das[3] and Chris Tran[3], [1]Univ of Toronto, Toronto, ON, [2]U of T, Toronto, ON, [3]U of T, ON

Purpose: Inflammatory arthritis (IA) is a major cause of long-term disability. Peer support has been used in various chronic conditions and may assist individuals with early IA (EIA) to make informed decisions and better manage their disease. Existing peer support programs may not meet the needs of persons newly diagnosed with IA. The purpose of this study is to identify educational preferences as well as informational, emotional and appraisal support needs of individuals with EIA from the perspectives of patients, family and friends, and health care providers (HCPs).

Methods: Semi-structured, one-on-one interviews with individuals were performed with a purposive sample. Themes were identified through constant comparative analysis.

Results: Interviews were conducted with patients with EIA (n=11), family and friends (n=6), and HCPs (n=9). *Individuals with EIA* reported using a variety of information sources (books, Internet, physicians) with informational needs evolving over time. Peer support was thought to be a viable option for support. Disease stage, personal qualities and one-on-one vs. group format were important considerations.

Data from *family and friends* suggested that the general public lacks awareness of EIA. HCPs, the Internet and colleagues who are HCPs were important informational sources. A network of emotional support was reported to be valuable to cope with and learn about EIA. Peer support was a much-lauded approach for informational and emotional support.

From the *HCP* perspective, findings support an arthritis care model that begins with a focus on “therapy initiation” through improved education from HCPs and a later transition to “medication adherence” aided through peer support. Peers were thought to play an important role in helping new patients make lifestyle modification choices and to cope once therapy had begun.

Across the three categories of participants, there was a desire for peer support (learning preferences, delivery method) to be context-driven (e.g., importance of sharing similar socioeconomic status, disease status), and for having choice as to whether or not to participate. Interviews are ongoing to examine whether culture may have an impact on learning needs.

Conclusion: Peers may be considered an instrumental part of decision support and stress management and an adjunct to clinical care for persons with EIA.

Are Fewer Workshop Sessions as Effective as the Classic ASMP? Jean Goeppinger[1], Kate R. Lorig[2], Ziya Gizlice[1], Philip Ritter[2] and Teresa J. .Brady[3], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Stanford University, Palo Alto, CA, [3]Centers for Disease Control and Prevention, Atlanta, GA

Purpose: To determine the effectiveness of a shorter version of the classic six-week Arthritis Self Help Course/Arthritis Self-Management Program (ASHC/ASMP) workshop. We asked if a shorter workshop would have the same positive outcomes as the six-week workshop while – potentially – increasing enrollment and decreasing the financial and personnel barriers experienced by disseminating organizations.

Method: Based on the findings of a needs assessment of persons with arthritis, clinicians, and program providers, we developed a two-week, six hour, lay-led workshop that included the content deemed most important: principles of self-management and pain management, goal-setting/action planning, problem-solving steps and feedback, exercise/fitness, difficult emotions, medication usage, and community resources. Workshop Leaders were trained to facilitate activities focusing on each of these areas. Program participants were recruited at Stanford (N=378) and UNC-Chapel Hill (N=357) and randomized individually (Stanford) and by cluster (UNC-Chapel Hill) to immediately receive (1) the High Resource Intervention: a two-week/six hour workshop with supplementary materials including The Arthritis Helpbook, a self-test, exercise and relaxation CDs, and a "Community Resource" Tip Sheet, (2) the Low Resource Intervention: a two week/six hour workshop with only a supplementary booklet of Tip Sheets, and (3) a four month wait list control group. At the end of four months controls were offered a workshop. All participants were followed in a longitudinal study for 12 months. Self-administered measures included health status, health behavior, arthritis self-efficacy, medical care utilization, and demographic variables. Analyses, including Analysis of Covariance controlling for randomization method, were conducted for participants at both sites.

Results: At four months, comparing all intervention subjects with randomized wait list controls, there were few and inconsistent improvements in health status, health behavior, arthritis self-efficacy, and medical care utilization outcomes at either Stanford or UNC. One out of 16 outcome variables showed statistically significant improvements at Stanford, while two out of 16 showed statistically significant improvements at UNC. There were also few differences between participants in high and low exposure interventions at either site. The twelve month longitudinal study findings were even weaker than those at four months.

Conclusion: The results of this attempt to develop a less time and resource intensive version of the ASHC/ASMP must be considered negative. The improvements subsequent to the two-week interventions were minimal, particularly when comparing the results of the randomized study to six-week small-group, Mailed Tool Kit, and internet interventions.

Osteoporosis Care in a Community-Based Cohort of Patients with Systemic Lupus Erythematosus. Gabriela Schmajuk[1], E.H. Yelin[2], E.F. Chakravarty[3] and J. Yazdany[2], [1]Stanford University, San Francisco, CA, [2]UCSF, SF, CA, [3]Stanford Health Services/Blake Wilbur Clinic, Palo Alto, CA

Purpose: Osteoporosis and fragility fractures are associated with significant morbidity for patients with systemic lupus erythematosus (SLE). Quality indicators (QI) published in 2009 advise the use of calcium, vitamin D, and bone mineral density testing (BMD) among SLE

patients using ≥ 7.5 mg of prednisone daily for ≥ 3 months. Our objective was to evaluate the quality of osteoporosis prevention and care in a community-based cohort of patients with SLE.

Methods: Data were derived from an ongoing longitudinal study of patients with confirmed SLE. Respondents participate in an annual telephone survey and are queried regarding demographic, clinical, and other healthcare-related variables. In 2008, questions regarding bone health (calcium, vitamin D, and BMD use) were posed to 779 subjects. Patients with incomplete data for predictors or outcomes of interest were excluded (n=35). Multiple logistic regression was used to adjust for demographic and healthcare-related covariates.

Results: 744 subjects were analyzed: 92% were female, with mean (standard deviation) age 50.7 (12.6) years and Systemic Lupus Activity Questionnaire score 11.7 (7.8). 76.1% had seen a rheumatologist within the past year. In addition to the full cohort, we examined 2 subgroups: (1) all current steroid users (n=427), (2) current steroid users who met eligibility criteria for the QI (n=127). Proportions of patients reporting calcium, vitamin D, and BMD use are described in Table 1. In all groups, fewer than 50% of patients reported receiving all 3 outcomes. In multivariate analyses, older age, female sex, and seeing a rheumatologist predicted the receipt of appropriate osteoporosis care in the full cohort and among all steroid users. Similar findings were observed among the smaller subgroup of steroid users who met criteria for the QI, although the findings did not reach statistical significance.\

Conclusion: Osteoporosis care in this community-based cohort of SLE patients is suboptimal. Even among patients at highest risk (≥ 7.5 mg of prednisone daily for ≥ 3 months), the proportion of patients fulfilling the SLE osteoporosis QIs is low. Quality-improvement efforts should address osteoporosis prevention and care among all SLE patients, especially those taking moderate-dose, prolonged steroids.

Table 1.

	All patients	**All steroid users**	**QI steroid users***
Outcome	**n=744**	**n=427**	**n=127**
Calcium use	466 (62.6)	293 (68.6)	92 (72.4)
Vitamin D use	411 (55.2)	263 (61.6)	79 (62.2)
BMD within 3 years	428 (57.5)	282 (66.0)	83 (65.4)
All outcomes	270 (36.3)	180 (42.2)	52 (40.9)

* QI steroid users: patients using ≥ 7.5 mg of prednisone daily for ≥ 3 months within the past year

Disclosure: G. Schmajuk, None; **E. H. Yelin**, None; **E. F. Chakravarty**, None; **J. Yazdany**, None.

Disparities in Outcomes Among Persons with Rheumatoid Arthritis From University-Affiliated Clinics. E.H. Yelin[1], J. Barton[2], Laura Trupin[1], L. J. Julian[1], J. Yazdany[1], Mary E. Margaretten[2], Vladimir Chernitskiy[3], Jonathan Graf[2] and John Imboden[2], [1]UCSF, SF, CA, [2]UCSF, San Francisco, CA, [3]University of California, San Francisco, CA

Purpose: This project assesses disparities in outcomes by race/ethnicity, immigrant status, and socioeconomic status among persons with rheumatoid arthritis (RA) sampled from the rheumatology clinics at a public hospital and tertiary-care facility that were designed to serve diverse populations in an urban environment.

Methods: Data are derived from the Rheumatoid Arthritis Cohort Study (RACS). RACS enrolls the universe of persons with RA presenting to rheumatology clinics at an urban county hospital and a tertiary care facility both affiliated with a university. Once enrolled, all data from clinical encounters, including laboratory tests, are entered into a database. RACS also includes an annual structured telephone survey about demographic characteristics, health care utilization, and standardized measures of patient-reported outcomes conducted in English, Spanish, or Cantonese/Mandarin.

Results: Derive from the initial 176 RACS participants with completed interviews for whom encounter data are also available. Outcome measures assessed include Disease Activity Score 28 (DAS 28) and the Health Assessment Questionnaire (HAQ), a measure of functional status, from clinical encounters, and pain rating (0-100) and global RA status (0-100) from the telephone survey. Disparities are assessed by race/ethnicity (Asian/Pacific Islander [API], Hispanic [HISP], African-American [AA], and Non-Hispanic White [WHT); education level (less than high school [<HS], high school or some college [HS/SC], and college graduate or beyond [BA]); and whether individual is an immigrant. We used ordinary least squares to regress the outcome measures on age, gender, duration of RA, a composite measure based on rheumatoid factor positivity, anti-CCP positivity, or the presence of erosions, and, separately, race/ethnicity, education level, and immigrant status.

RACS participants average 55 years of age (range 19-81). 82% are female, 35% WHT, 36% HISP, 23% API, and 6% AA. 54% are immigrants. 44% speak languages other than English at home, of these only 16% can speak English fluently. 31% have <HS-, 36% have HS/SC-, and 33% have BA-level educations. Average duration of RA is 11 years (range 0-53). The table below shows significant disparities in all outcome measures by race/ethnicity, education level, and immigrant status.

Conclusion: Even in medical settings with a history of serving diverse populations, pronounced disparities by race/ethnicity, education level, and immigrant status are observed in all outcomes.

		DAS-28	Pain Rating	RA Global	HAQ
		Adjusted mean (95% CI)			
Race	API	3.7 (3.2,4.2)	45 (36,55)	50 (40,60)	1.1 (0.9,1.4)
	HISP	4.0 (3.7,4.4)	48 (41,56)	47 (39,55)	1.5 (1.4,1.8)
	AA	3.2 (2.4,4.1)	29 (18,47)	48 (29,66)	1.2 (0.7,1.8)
	WHT	2.8 (2.4,3.2)	28 (20,36)	30 (21,38)	0.9 (0.7,1.1)
Educ	<HS	4.3 (3.9,4.6)	53 (45,61)	54 (46,62)	1.5 (1.3,1.8)
	HS/SC	3.5 (3.2,3.9)	35 (27,42)	41 (34,49)	1.2 (1.0,1.4)
	BA	2.6 (2.3,3.0)	30 (22,38)	29 (22,37)	0.9 (0.7,1.1)
Immigrant	No	2.9 (2.5,3.2)	29 (22,36)	33 (27,40)	1.0 (0.8,1.2)
	Yes	3.9 (3.6,4.2)	46 (40,52)	47 (41,53)	1.4 (1.2,1.6)
All variables significant at p<.05

1370

Mortality Impact of Extra-Articular Manifestations of Rheumatoid Arthritis: Observations From a Population-Based Patient Cohort. Elena Myasoedova[1], Cynthia S. Crowson[1], Carl Turesson[2], Sherine E. Gabriel[1] and Eric L. Matteson[1], [1]Mayo Clinic, Rochester, MN, [2]Malmö, Sweden

Purpose: To compare the trends in mortality and examine impact of development of a second extra-articular manifestation of rheumatoid arthritis (ExRA) during the period 1995-2007 to the previous decade, and to examine the possible risk factors for these outcomes.

Method: We conducted a retrospective medical record review of incident ExRA features from an incident population based cohort of patients with RA (1987 ACR criteria first met between 1/1/1995 and 1/1/2008). Patients were followed from 1/1/1995 until 1/1/2009 or death. The date of ExRA incidence was recorded and ExRA were classified according to the predefined criteria (Ann Rheum Dis 62:722-727, 2003). Cox proportional hazards models were used to assess the association of ExRA with mortality and with the development of a second ExRA. Time-dependent covariates were used to model ExRA and risk factors, which developed over time. Patients with ExRA prior

to incidence date were excluded from each analysis. Mortality rates were compared to those reported for the previous decade (incident RA cases between 1/1 1985 and 12/31/1994 from the same population base, followed through 12/31/2000 (J Rheumatol 29:62-67, 2002).

Results: The study population included 463 RA patients with incident RA (mean age 55.6, 69% female) followed up for a median of 5.8 years, during which 53 patients died. Rheumatoid factor (RF) was present in 306 (66%) patients. During the follow-up period, 159 patients developed an incident ExRA (22 with severe ExRA) and 37 developed a second ExRA. There were significantly fewer second ExRA in the 1995-2007 cohort than in the 1985-1994 cohort (hazard ratio [HR] 0.5; 95% confidence interval [CI] 0.3, 0.9). Potential predictors of second ExRA (age, sex, calendar year, smoking, RF positivity, joint erosions/destructive changes, subcutaneous nodules as the first ExRA and exposure to antirheumatic drugs) failed to reveal any significant associations. ExRA was a significant predictor of premature mortality (HR 2.0, 95% CI 1.1, 3.6) after adjusting for age, sex and calendar year. In contrast with previous findings, severe ExRA did not confer a greater mortality risk than overall occurrence of ExRA (HR 2.1, 95% CI 0.8, 6.0, vs no severe EXRA). Similarly, development of a second ExRA did not further increase mortality risk (p=0.33). While not reaching statistical significance, the mortality rates compared to the 1985-1994 decade after occurrence of ExRA (HR 0.7, 95% CI 0.4, 1.4) and after severe ExRA (HR 0.6, 95% CI 0.2, 2.1), suggested improved survivorship in these patients compared to the 1985-1994 decade.

Conclusion: ExRA was significantly associated with decreased survivorship in RA. Patients diagnosed with RA during the 1995-2007 period were half as likely to have a second ExRA compared to RA patients in the previous decade, and a second ExRA was not associated with higher mortality. Survival following ExRA may be improving compared to the previous decade.

1371

Hyperuricemia Is Associated with Subclinical Coronary Atherosclerosis. E. Krishnan[1], M. Bennett[1], L. Chung[1], M. Lyon[1], B. J. Pandya[2] and O. Dabbous[2], [1]Stanford University School of Medicine, Palo Alto, CA, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL

Purpose: To test the hypothesis that asymptomatic hyperuricemia (serum uric acid [sUA] >7.0 mg/dL) is a risk for subclinical coronary atherosclerosis, independent of other known risk factors.

Method: Subjects (n=2,997) without cardiovascular disease participated in a 15-year prospective observational study (the Coronary Artery Risk Development in Young Adults Study, CARDIA) that included 1,374 men (mean age 40.2 years) and 1,623 women (mean age 40.3 years). All subjects underwent clinical and laboratory tests for cardiovascular risk assessment at baseline and year 15. Presence of coronary artery calcification (CAC), defined as an Agatston score >0, was the indicator of subclinical atherosclerosis. Statistical analysis examining the relationship between presence/absence of CAC and sUA concentrations was performed using logistic regression models where the potential confounding effects of age, gender, race, body mass index, low- and high-density lipoproteins, triglyceride, hypertension, diabetes, smoking, alcohol use, and renal disease as measured by serum creatinine and albuminuria were addressed.

Results: Overall, 9.6% (15% men and 5% women) had developed CAC at year 15. Among men and women, the prevalence of CAC approximately doubled among those with the highest quartile of sUA at year 15 compared with those in the lowest quartile (Figure; $P<0.001$). In multivariate analyses adjusting for the risk factors significant in bivariate regressions, sUA >7.0 mg/dL at year 15 was associated with an odds ratio (95% confidence interval [CI]) of 1.67 (1.13-2.48) compared with sUA ≤7.0. When the 15-year change in sUA was the metric of interest, each unit increase in sUA was associated with an odds ratio (95% CI) of 1.18 (1.06-1.32) overall. These results did not change in the subanalyses that excluded individuals with metabolic syndrome.

Conclusion: The risk of subclinical atherosclerosis appears to rise with increasing sUA concentration in young adults in the general community. This trend remains even after controlling for important confounders including the presence of metabolic syndrome. The concept that asymptomatic hyperuricemia is a benign condition deserves to be revisited.

Self-Reported Arthritis Increases Fracture Risk: Results From the Women's Health Initiative. Nicole C. Wright[1], Jeffrey R. Lisse[1], Charles B. Eaton[2], Brian T. Walitt[3] and Zhao Chen[1], [1]University of Arizona, Tucson, AZ, [2]Alpert Medical School of Brown University, Pawtucket, RI, [3]Washington Hospital Center, Washington, DC

Purpose: To study the association between arthritis, a leading cause of disability in the US, and fracture, a major public health concern in elderly populations.

Methods: The relationship between arthritis and fracture was examined in the Women's Health Initiative (WHI), a nationwide multi-ethnic cohort of postmenopausal women. Using self-reported baseline medical questionnaire data, women were classified into three arthritis categories: no arthritis, osteoarthritis (OA), and rheumatoid arthritis (RA). Only those RA cases with report of one of the RA therapeutic agents at baseline were included. Incident fractures were captured through periodic medical update. Trained WHI physicians adjudicated all fractures reported by women participating in the clinical trials component and all reported hip fractures. Age-adjusted fracture rates by arthritis category were generated, and Cox proportional hazards model was used to test the association between arthritis and fracture. Models were adjusted for study assignment and potential confounders such as age, lifestyle characteristics, and medications known to alter bone metabolism.

Results: Of the 161,809 enrolled in the WHI, 52% did not report an arthritic condition and 39.9% reported OA. Medication use could only be verified on 874(11%) of the initial self-reported RA cases. As of March 2008, the women were followed for a mean of 7.83 years. During this time, 26,940 fractures were reported including 2,898 (10.8%) spinal fractures and 1,921 (7.1%) hip fractures. Age-adjusted fracture rates were highest in the RA group and lowest in the non-arthritic group for each fracture type. Based on the adjusted Cox models,

report of arthritis is associated with an increased risk for fracture, with the RA group having the highest risk. For example, compared to the non-arthritis group, the OA and RA groups had 14% and almost 3-fold increase risk of hip fracture (T able).

Conclusion: Report of arthritis is associated with increases in fracture risk. The significant fracture risk increase seen in the OA group suggests that there is an association between bone quality and OA. This study confirmed the association between RA and fracture, consistent with the hypothesis that systemic inflammation may have an adverse effect on bone quality.

Table 1: Adjusted* Hazard Ratio (95% CI) of Fractures by Arthritis Status

	No Arthritis (n=84,168)	**OA (n=64,551)**	**RA (n=874)**
Total (n=26,940)	Ref.	1.10 (1.06, 1.14)	1.53 (1.29, 1.82)
Spine (n=2,898)	Ref.	1.17 (1.06, 1.29)	1.99 (1.31, 3.03)
Hip (n=1,921)	Ref.	1.14 (1.01, 1.29)	2.89 (1.86, 4.50)

* Adjusted for age; race; height; weight; physical activity; assignment in the HT trial, DM trial, and CaD trial; hospitalizations; falls; smoking ; hormone use; parental fracture >age 40; calcium & vitamin D intake; depression score; years since menopause; diabetic treatments; calcium regulating drugs; general health score; and fracture >55

Physician Visits for SLE: Impact of Individual, Neighborhood, and Healthcare Delivery System Characteristics. Chris Tonner[1], Laura Trupin[2], J. Yazdany[2], L. J. Julian[2], Patricia Katz[2], Lindsey A. Criswell[3] and E.H. Yelin[2], [1]University of Califorina, San Francisco, CA, [2]UCSF, SF, CA, [3]University of California, San Francisco

Purpose: To assess the impact of overall health status, sociodemographics, nature of health insurance, characteristics of local community, and variation among local health care markets for hospital services (HSAs) on utilization of physician services among persons with SLE (MDSLE).

Methods: Data are derived from the Lupus Outcomes Study (LOS), a U.S. cohort of 755 persons with confirmed SLE diagnoses, recruited from clinical and non-clinical sources. Principal data collection is from an annual structured telephone interview covering demographics, SLE symptoms and activity, overall health status, and health care utilization. Present analysis includes 2926 person-years of observation from the 2003-2007 interviews. Using geocoded addresses, contextual data were appended for neighborhood socioeconomic characteristics (source: 2000 Census), subspecialists per capita in the county (source: Area Resource File), and HSAs (source: Dartmouth Health Care Atlas). We used a linear mixed model to estimate the impact of fixed effects for education, health care access, and living in a neighborhood with a high proportion of persons below poverty and random effects for the HSA on MDSLE, after adjusting for other sociodemographic characteristics and SLE severity and overall health status.

Results: LOS respondents reported a mean of 11.2 (95% CI 10.3-12.1) MDSLE. Persons with SLE with a high school education or less, living in areas of concentrated poverty and receiving care from HMOs and generalist physicians had significantly fewer MDSLE (Table). Those with a combination of ≤ high school education and who lived in poverty areas had only 74% as many MDSLE as the remainder; those with a combination of HMO and generalist MDs had only 63% as many as the remainder (both results were statistically significant). In addition, there was a statistically significant impact of HSAs on MDSLE, indicating that healthcare markets have an effect on utilization beyond individual and neighborhood characteristics.

Conclusion: Personal, health care system, and community characteristics each contribute independently to MDSLE. Low levels of education, living in areas of concentrated poverty, receiving care from a generalist and being in an HMO reduce MDSLE. The healthcare market also affects MDSLE.

Adjusted Number of MD Visits for SLE in Year Prior to Interview, by Education, Poverty Area, HMO Status, and Specialty of Main SLE MD

Population-Based Association of Sickle Cell Disease with Gout. Allan C. Gelber, Sophie Lanzkron, Janet Maynard and Carlton Haywood Jr., Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Gout is a leading cause of inflammatory arthritis. Hematologic disorders comprise a subset of the secondary causes of gout, including myeloproliferative (e.g. polycythemia) and lymphoproliferative (e.g. tumor lysis) disorders. Inherited hemoglobinopathies, including sickle cell disease [SCD], may contribute to hyperuricemia and gout, via increased nucleic acid production, accelerated hemolysis and impaired renal function. In the 1960s, the association of SCD with gout was described in several case series. A large scale examination, at the population level, has not occurred. If confirmed, identification of SCD as a risk factor for gout would contribute meaningfully to the care of patients with SCD with moderate-severe joint pain.

Method: We examined the 2004 Nationwide Inpatient Sample. For each hospital stay, one primary and 14 secondary ICD-9 diagnoses were recorded, as well as age, gender, race, socioeconomic status (SES) measures of health insurance and median household income. Hospital size and teaching status were recorded. We ascertained all hospital stays with a primary or secondary diagnosis of SCD or gout. A co-morbidity profile of coexistent obesity, renal insufficiency or hypertension was identified. Our analyses were restricted to 26 states with race as a demographic code, to hospital stays among African Americans, and to age 18-59, the adult age range when SCD-related admissions are most prevalent. Using logistic regression, we examined the independent association of SCD with gout.

Results: A total of 463,318 hospital stays met inclusion criteria. There were 12,070 (2.6%) hospitalizations in which SCD and 3,785 (0.8%) in which gout was recorded. Overall, the study population was 63% female, 37% receiving Medicaid, 54% with household income <$36,000, 8% obesity, 34% hypertension, and 3% with renal failure. These admissions were comprised of 60% urban teaching hospitals; 54% in the South, 26% in Northeast. Mean (±SD) age among SCD was 31.7 ± 9.9 years, and 49.9±7.5 in those with gout. The risk of gout among those with SCD, is as follows:

Model	Odds Ratio (95% Confidence Interval)
Age, gender-adjusted	2.4 (1.8 – 3.3)
Age, gender, SES-adjusted	2.2 (1.6 – 2.9)
Age, gender, SES, Co-morbidity-adjusted	3.1 (2.3 – 4.2)
Age, gender, SES, Co-morbidity, Hospital profile-adjusted	3.1 (2.3 – 4.2)

Conclusion: In a broadly representative 2004 sample of US hospitalizations, SCD was associated with a greater than three-fold increase in risk of coexistent gout. Clinicians evaluating hospitalized patients with SCD who manifest joint pain, in young and mid-adult life, ought to consider coexistent gout, in addition to sickle crisis and septic arthritis in the evaluation and management of these acutely ill patients.

1375

Markers of Disease Severity Predict New-Onset Heart Failure in Rheumatoid Arthritis. Soko Setoguchi[1], J. Greenberg[2], Jeffrey R. Curtis[3], Marc C. Hochberg[4], George Reed[5], Peter Tsao[1], Michael E. Farkouh[6], Joel M. Kremer[7] and Daniel H. Solomon[1], [1]Brigham & Women's Hospital, Boston, MA, [2]NYU, New York, NY, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Maryland School of Medicine, Baltimore, MD, [5]University of Massachusetts, Worcester, MA, [6]Mount Sinai Medical Center, New York, NY, [7]Albany Medical College, Albany, NY

Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of heart failure (HF) that may not be explained by traditional cardiovascular (CV) risk factors. However, the independent contribution of markers of RA severity to HF, especially in the presence of the RA treatments has not been well understood.

Method: We conducted a cohort study using a multicenter prospective longitudinal registry of RA from the US. The outcome of interest was subjectsreports of new onset HF confirmed by treating rheumatologists. When records were available, HF was positively adjudicated in 75% of HF cases. We assessed potential predictors of HF at baseline including demographic, life style, CV risk factors, RA treatment, and markers of RA severity (Table). We used Cox proportional hazard regression to conduct multivariate analyses. The discriminatory power of the Cox models including various factors was assessed by calculating the concordance probability (CP) (analogous to c-statistics in logistic regression models).

Results: Among 8,483 RA patients with no previous HF with mean age of 59, 75% women, and 93% white, we observed 33 cases of HF during a median follow-up of 23 months. The incidence rate of HF was 19 (95% CI 13– 26) per 10,000 patient-years. After adjusting for demographic, life style, CV risk factors, and treatment for RA, the risk of HF increased significantly by 180% with 1 unit increase in modified Health Assessment Questionnaire. There was a marginally significant increase in HF (10%) with 5 year increase in the duration of RA. We observed 5 fold increase in the risk of HF with NSAID use and 4 fold increase with oral steroid use >7.5mg (Table). Adding markers of RA severity and RA treatment to the model with demographic and life style factors improved the CP by 0.03 (0.79 to 0.82). The CP improved by another 0.02 by adding CV risk factors (0.82 to 0.84).

Conclusion: In the large sample of RA patients, markers of RA severity were strongly associated with the risk of new onset HF even after controlling for RA treatment and CV risk factors. More functional limitations, moderate dose steroids, and NSAIDs all elevated the risk for new onset HF in patients with RA. Increased HF surveillance may be considered in patients at elevated risk of HF.

Serum 25(OH) Vitamin D Level and Rheumatoid Arthritis-Related Autoantibody: Analysis in a Population-Based U.S. Sample.

Mitsuyo Kinjo[1], Soko Setoguchi[2] and Daniel H. Solomon[3], [1]Okinawa Chubu Hospital, Uruma, Japan, [2]Brigham & Womens Hospital, Boston, MA, [3]Brigham & Women's Hospital, Boston, MA

Purpose: Rheumatoid arthritis (RA)-related autoantibody such as rheumatoid factor (RF) precedes to RA development. Immunomodulatory effect of vitamin D may play an important role in the presence of RA-related autoantibody. To assess the relationship between serum vitamin D levels and RA susceptibility, we compared 25(OH) vitamin D levels between unaffected RF+ subjects and RF- controls in a representative U.S. population-based sample from the Third National Health and Nutrition Examination Survey (NHANES III: 1988-1994).

Method: We identified subjects aged 60 and older who did not meet the criteria for RA (previously described) or did not take DMARDs. Serum 25(OH) vitamin D levels were compared among non-RA subjects with RF+ and RF-. We used multivariable linear regression models to compare 25(OH) vitamin D levels adjusting for relevant covariates (age, gender, body mass index, race, season of blood draw, resion of residence, tobacco use, alcohol, daily calcium and vitamin D intake, serum creatinine, and serum calcium level). Categorical 25(OH) vitamin D levels (<25 nmol/L, 25-50 nmol/L, >50 nmol/L) were also examined in multivariable ordinal logistic regression model. **Results:** Among 4,463 non-RA subjects with mean age of 71.8 years old, 49.9% female, 58.6% Caucasian, we identified 262 (5.9%) RF+ subjects and 4,201 (94.1%) RF- controls. Mean age, gender, and race were similar between RF+ subjects and RF- controls. We found no significant difference in the mean body mass index, % current smoker, daily vitamin D intake, season of measurement, and resion of residence between subjects with RF+ and RF- (Table). In multivariable linear regression, the serum 25(OH) vitamin D levels were not significantly different between RF+ subjects and RF- controls after adjusting for predictors of vitamin D level and RF (Table). Analysis using categorical vitamin D levels revealed similar results.

Conclusion: In this US representative sample aged 60 and older, non-RA subjects with RF+ did not reveal significantly different serum 25(OH) vitamin D levels compared to RF- controls. Our findings failed to show a link between vitamin D levels and RA susceptibility.

Characteristic	RF negative (n=4,201)	RF positive (n=262)
Body mass index (kg/m2), mean (SD)	26.9 (5.0)	26.2 (4.6)
Current smoker, % (N)	15.3 (643)	16.8 (44)
Season of blood draw (winter), % (N)	28.2 (1,183)	24.4 (64)
Resion of residence (northeast), % (N)	15.4 (648)	14.1 (37)
Daily vitamin D intake (IU), mean (SD)	191.9 (2.7)	187.5 (22.0)
Serum 25(OH) vitamin D level (nmol/L)		
Unadjusted	65.5 (65.1, 65.9)	63.0 (61.4, 64.6)
Fully adjusted*	65.6 (65.2, 66.0)	63.9 (62.5, 65.3)

*age, gender, body mass index, race, season of blood draw, resion of residence, tobacco use, alcohol, daily calcium and vitamin D intake, serum creatinine, and serum calcium level

A Low Physical Education Grade Predicts Middle Age Musculoskeletal Disease in Women but Not in Men. Simon Timpka[1], Ingemar F. Petersson[1] and Martin Englund[2], [1]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences, Lund University, Lund, Sweden, [2]Lund University, Lund, Sweden

Purpose: Musculoskeletal disorders are common in the general population and chronic pain is one of the most prevalent complaints, especially in women. Directed primary prevention is possible if high risk groups are identified at an early stage. One goal of Physical Education (PE) is to serve as the foundation for a future healthy lifestyle. However, very little is known about the association between PE grade and musculoskeletal disease later in life.

In this study, we focused on “Disorders of the musculoskeletal system and connective tissue” (ICD-10 chapter XIII, code M) and the subgroup “Other soft tissue disorders, not elsewhere classified” (M79), which contains pain diagnoses such as Unspecified Rheumatism (M79.0) and Fibromyalgia (M79.7).

Method: For a historical cohort study, we identified all the 2298 subjects (48.6% women), born in 1957–1962, who in 1974–1976 graduated from secondary school in a municipality in Southern Sweden. The PE grade and the subjects' 10-digit personal identification number were retrieved from municipal records. We ensured via the Population Register that subjects were still resident in the county in the period 2003–2007, and linked our data to the Skåne Health Care Register (SHCR), a regional register covering both in-and outpatient heath care of the population of the southernmost county of Sweden. Data on occupation and education were collected from Statistics Sweden. All clinic visits with a main diagnosis of our focus in 2003-2007 were identified. For the analysis, we used a logistic regression model adjusted for level of

education and having an occupation associated with high prevalence of musculoskeletal disorders. An average PE grade was used as reference group.

Results: 530 individuals did not reside in the county during the whole study period while 56 did not receive a PE grade and were therefore excluded, 1712 (74.5%) remained eligible (48.8% women). In women, a low PE grade was associated with a higher Odds Ratio (OR) for both "Disorders of the musculoskeletal system and connective tissue" and "Other soft tissue disorders, not elsewhere classified". In men, no association between PE grade and future disease was found.

Odds Ratio (OR) for Musculoskeletal Disorders in the Middle Age by Physical Education (PE) Grade Compared to an Average Grade Adjusted for Occupation and Education

	PE Grade	Disorders of the musculoskeletal system and connective tissue (M)			Other soft tissue disorders, not elsewhere classified (M79)		
		c/n	OR	95 % CI	c/n	OR	95 % CI
Women	Low	81/186	**1.49**	(1.01-2.19)	34/186	**2.14**	(1.23-3.72)
	Average	103/333	1		27/333	1	
	High	107/316	1.24	(0.88-1.74)	33/316	1.47	(0.86-2.53)
Men	Low	69/252	0.76	(0.52-1.11)	17/252	0.71	(0.37-1.37)
	Average	98/321	1		25/321	1	
	High	83/304	0.87	(0.61-1.24)	22/304	0.95	(0.52-1.74)

c/n= Number of cases/Total number of individuals with grade
Code of diagnosis according to WHO's ICD-10.

Conclusion: In women, a low PE grade in adolescence predicts musculoskeletal pain disorders three decades later. No such association was found in men.

1378

Predictors of SF36 Scores in a New Lupus Cohort in Southern California. Janina Cervera[1], Mariko L. Ishimori[1], Dilrukshie Cooray[2], Meenakshi Jolly[3], Emmanuel Katsaros[4], Ioana Moldovan[4], Shuntaro Shinada[5], Karina D. Torralba[5], Daniel J. Wallace[1], Joel A. Block[3], Michael H. Weisman[1] and Perry Nicassio[6], [1]Cedars-Sinai Med Ctr, LA, CA, [2]Harbor UCLA Med Ctr, Torrance, CA, [3]Rush University Med Ctr, Chicago, IL, [4]Loma Linda Univ Med Ctr, Loma Linda, CA, [5]USC LAC Med Ctr, LA, CA, [6]UCLA, LA, CA

Purpose: To evaluate the contributions of demographics, disease and psychosocial factors to patient reported health outcomes in a new cohort of Hispanic and Caucasian systemic lupus erythematosus (SLE) patients in Southern California.

Methods: SLE patients age ≥18, meeting revised ACR criteria, self-identified as Caucasian/fluent in English or Hispanic/fluent in Spanish were recruited from 4 academic medical centers in the PATROL (Patient-reported Outcomes in Lupus) study. Subjects were evaluated by SLE disease activity index (SLEDAI) and self-administered questionnaires. Patient reported health outcomes were measured by Short Form 36 (SF-36). Depression, helplessness and internality were assessed by Patient Health Questionnaire-9 (PHQ9) and Rheumatology Attitudes Index (RAI) respectively. Hierarchical multiple regression analysis was performed for the dependent variables of SF36 Physical Functioning and Mental Health domains to evaluate the stepwise contribution of the following independent variables: ethnicity, age, education and income in step 1, SLEDAI and systemic lupus activity questionnaire (SLAQ) in step 2, and depression (PHQ9), helplessness and internality (RAI) in step 3.

Results: 58 Hispanic and 45 Caucasian SLE subjects were enrolled. In step 1, only age had a statistically significant effect on Physical Functioning. After adjusting for age, the second step of the model showed an association only between lower self reported SLAQ scores (β-0.37, p=0.001) with higher Physical Functioning. In the last step, less helplessness and higher internality on RAI were associated with less Physical Functioning (β=-0.38, p=.001 and β=0.22, ,p=0.046), but PHQ-9 scores did not have a significant effect. The model accounts for 43.5% of the variance in Physical Functioning. For Mental Health scores, only age was a significant factor. After adjusting for age, step 2 of the analysis showed that only lower SLAQ score was highly predictive of greater Mental Health (β =-0.50, , p=0.000). In the last step

depression was inversely associated with Mental Health (β=-0.47,I p=.000); RAI scores did not contribute. The model accounts for 36.6% of the variance in Mental Health.

Conclusion: Ethnicity was not found to be a significant predictor of SF 36 Physical Functioning or Mental Health in our cohort. There was a significant correlation between lower self-reported disease activity but not physician-assessed SLEDAI score, and better Physical Functioning and Mental Health. Less helplessness and higher internality contributed to better Physical Function; less depression to better Mental Health. These findings suggest that successful treatment of SLE patients may need to address not only physical manifestations of disease, but also psychosocial factors that contribute to patients' perception of their disease.

1379

Non-Melanoma and Melanoma Skin Cancer Risk in a National Cohort of Veterans with Rheumatoid Arthritis. Wassila Amari[1], Angelique L. Zeringue[2], Jay R. McDonald[2], Liron Caplan[3], Fran Cunningham[4], Seth A. Eisen[2] and Prabha Ranganathan[1], [1]Washington University, St Louis, MO, [2]St. Louis Veterans Affairs Medical Center, St. Louis, MO, [3]Univ of CO Denver School of Med, Aurora, CO, [4]VA Pharmacy Benefits Management, Hines, IL

Purpose: Although previous studies have examined the risk of malignancy, including skin cancer, in patients with rheumatoid arthritis (RA), only one prior study has looked primarily at skin cancer risk. Our aim was to determine the incidence and risk factors for non-melanoma (NMSC) and melanoma skin cancer (MM) in a national cohort of veterans with RA treated with non-biologic versus tumor necrosis factor (TNF) antagonist DMARDs.

Methods: We examined a retrospective cohort of 16,829 patients with an International Classification of Disease, Version 9, (ICD-9) diagnosis of RA from the Department of Veterans' Affairs (VA) national administrative databases enrolled between October 1, 1998 and September 30, 2006. The cohort was divided into 2 medication groups: patients treated with non-biologic and those treated with anti-TNF DMARDs. Skin cancer was defined as the first occurrence of an ICD-9 code for NMSC and MM after initiation of a DMARD. Outcome risk was described using hazard ratios with Cox proportional hazards regression for time-to-event analysis and logistic regression. Chart review was performed to validate the diagnosis of both cancer types.

Results: Of the 16,829 RA patients, 3,096 were on anti-TNF treatment. The incidence of NMSC was 25.9 per 1000 patient-years in patients on TNF antagonists and 19.6 per 1000 patient-years in those on non-biologic DMARDs. Patients on anti-TNF agents had a higher risk of developing NMSC than those on non-biologic DMARDs with a hazard ratio of 1.34 (95% CI 1.15-1.58; $p<0.0001$). Factors that increased the risk of NMSC included older age, male gender, glucocorticoid use, a history of prior malignancies, and duration of anti-TNF therapy. The incidence of MM was 3.7 per 1000 patient-years in patients on TNF antagonists and 2.6 per 1000 patient-years in those on non-biologic DMARDs. Patients on anti-TNF agents had a higher risk of MM with a hazard ratio of 1.5 (95% CI 1.01-2.24; $p<0.05$). Risk factors for MM included a history of previous malignancies. The increased risk of both NMSC and MM was a drug class effect and not associated with individual TNF antagonists. There was substantial agreement between diagnosis by ICD-9 codes and chart review for NMSC ($\kappa=0.61$) but only moderate agreement for MM ($\kappa=0.45$).

Conclusion: Anti-TNF therapy in veterans with RA is associated with an increased risk of NMSC. Although our data suggest an association with MM, the modest agreement between the ICD-9 codes for MM and chart validation precludes a firm conclusion. Other risk factors for NMSC in RA include older age, male gender, a history of prior malignancies, glucocorticoid use and duration of anti-TNF therapy. These results should prompt rheumatologists to carefully evaluate the use of TNF antagonists in RA patients with such risk factors who may be more prone to develop skin cancer.

Frequency of Lipid Testing in Patients with Rheumatoid Arthritis: A Retrospective Database Analysis. J. R. Curtis[1], A. John[2] and O. Baser[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Roche, Nutley, NJ, [3]University of Michigan Health Systems, Ann Arbor, MI

Purpose: Cardiovascular disease is associated with systemic inflammation and dyslipidemia and contributes to excess mortality among patients with rheumatoid arthritis (RA). The objective of this study was to determine the proportion of pts with RA that received any lab testing for dyslipidemia and to assess whether they were less likely to be tested than pts with osteoarthritis (OA).

Method: A retrospective analysis was conducted using medical and pharmacy claims from a national commercial administrative claims database. Adult pts had at least 2 physician diagnoses of RA or OA at least 2 months apart from April 2005 to March 2008, had continuous medical and pharmacy benefits for at least 18 months, and did not have any other inflammatory disease at baseline. Baseline was defined as 6 months before RA/OA diagnosis. Propensity score matching and multivariate regression analysis were used to control for baseline differences between groups. After matching, we evaluated the risk-adjusted differences in the proportion of RA and OA pts receiving any dyslipidemia testing, and also compared the mean number of total cholesterol (TC), high-density lipoprotein (HDL), low-density lipoprotein (LDL), and triglyceride (TG) tests performed.

Results: There were significant baseline differences between eligible RA and OA pts (RA, N=30,586; OA, N=107,534). Pts in the RA (vs OA) group were younger (50 vs 56 mean years), and more were women (74.1% vs 58.3%; $p<0.0001$, both comparisons). Pts in the RA (vs OA) group had a higher mean Charlson Comorbidity Index (1.07 vs 0.94) and lower rates of diagnosed diabetes (6.2% vs. 9.7%), obesity (2.2% vs 4.1%), and hypertension (23.1% vs 38.4%; $p < 0.0001$, all comparisons). Fewer pts in the RA (vs OA) group used lipid-lowering therapy at baseline (11.7% vs 25.0%; $p<0.0001$). Over a median observation period of 2.3 years, significantly fewer pts in the RA (vs OA) group had at least 1 lipid test ordered (Table). Given that a pt was tested (and after adjusting for baseline factors), the average number of TC tests was 2.0 for the RA group and 2.9 for the OA group ($p<0.0001$). Similarly, pts in the RA group underwent an average of 1.8 HDL, 1.9 LDL, and 2.0 TG tests, and pts in the OA group underwent an average of 2.7 HDL, 2.9 LDL, and 2.9 TG tests ($p<0.0001$, all comparisons).

Conclusion: This real-world analysis indicates that pts with RA receive suboptimal rates of testing for dyslipidemia and also receive testing less often than pts with OA. In light of the increasingly recognized cardiovascular burden associated with RA, physicians should monitor and manage dyslipidemia and other cardiovascular risk factors in RA pts and educate them about the risk associated with the disease.

Table. Proportion of RA and OA Patients for Whom Lipid Tests Were Performed

At Least Once (Median Observation Period of 2.3 Years)

	RA Group N=30,586 %	OA Group N=107,534 %	*p*
Total cholesterol	59.8	69.0	<0.0001
High-density lipoprotein	57.2	66.4	<0.0001
Low-density lipoprotein	58.6	68.4	<0.0001
Triglycerides	59.1	68.4	<0.0001

Quality Adjusted Life Expectancies in Patients with Rheumatoid Arthritis – A Comparison of the EQ-5D, SF-6D and 15D. Louise Linde[1], Jan Sørensen[2], Mikkel Østergaard[3] and Merete L. Hetland[4], [1]Department of Rheumatology, Hvidovre Hospital, Hvidovre, Denmark, [2]University of Southern Denmark, Odense, Denmark, [3]Department of Rheumatology, Copenhagen University Hospital at Gentofte and Hvidovre, Denmark, [4]DANBIO, Hvidovre Hospital, Hvidovre, Denmark

Purpose: Cost-effectiveness analyses of health interventions may be based on outcomes derived from patient-reported utility-based health status measures, such as the EQ-5D, SF-6D and 15D instruments. It is unclear to which degree the outcomes vary depending on the instrument used. We explored differences in index scores and quality-adjusted life expectancies (QALexp) obtained by the above-mentioned three instruments in patients with rheumatoid arthritis (RA).

Method: Health status (EQ-5D, SF-6D, 15D), disease activity score based on 28 joint count and C-reactive protein (DAS28) and Health Assessment Questionnaire (HAQ) regarding patients with RA in routine care were collected cross-sectionally. Individuals with complete health status data were included in the analysis. Danish population based survival data were aggregated into five-year age groups and the expected survival from age 20 to 79 was calculated. The QALexp were estimated as the product of the mean index score and the expected population based survival in each age interval. Data were stratified to compare the QALexp in subgroups according to gender, DAS28 and HAQ assuming that these factors did not impact the mortality.

Results: 1689 patients were available for analysis (73% women, 76% IgM rheumatoid factor positive, mean (SD) DAS28: 3.06 (1.21), HAQ: 0.67 (0.63)). The mean index scores were: EQ-5D: 0.732, SF-6D: 0.709 and 15D: 0.874 ($p<0.01$ for pairwise comparisons (paired t-test)), see Figure. The differences in index scores were reflected in the estimated QALexp, see Table. The EQ-5D and SF-6D index scores and estimated QALexp were largely similar, while the 15D values were consistently higher. For all three instruments, the QALexp differed according to gender, DAS28 and HAQ subgroups. However, the magnitude of the differences varied according to the instrument used: The EQ-5D yielded the largest QALexp differences: men vs women: 2.1; DAS28<3.2 vs DAS28≥3.2: 7.8; HAQ<1 vs HAQ=1-2: 7.3; HAQ=1-2 vs HAQ>2: 6.3, while the 15D yielded the smallest differences.

Conclusion: We have identified methodological challenges in the interpretation of cost effectiveness analyses in RA studies. In this large study of 1689 patients investigated with both the EQ-5D, SF-6D and 15D, substantial variation in the index scores and quality-adjusted life expectancies was observed depending on the instrument used. Comparison of cost-effectiveness analyses should only be performed between studies that have applied the same instruments.

Figure.

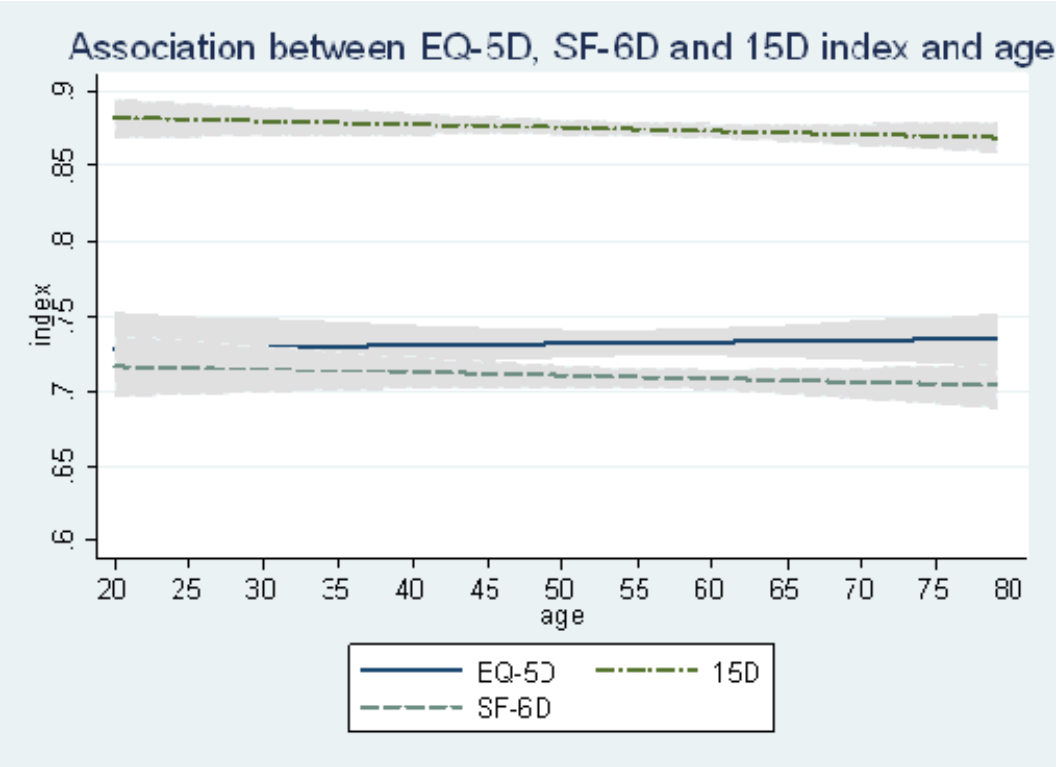

Table. Quality adjusted life expectancies for a 20 year old until 79 years for the EQ-5D, SF-6D and 15D assuming mortality as for the general population.

	n	EQ-5D	SF-6D	15D
Whole sample	1689	40.2	39.0	48.0
Women	1240	39.8	38.6	47.9
Men	449	41.9	39.5	48.3
DAS28 <3.2	704	44.9	42.7	50.2
DAS28 ≥3.2	985	37.1	36.6	46.6
HAQ <1	965	40.9	39.2	48.2
HAQ = 1-2	327	33.6	33.4	44.6
HAQ >2	72	27.3	30.4	41.6

Remission of Rheumatoid Arthritis (RA): Benefits From Socioeconomic and Quality of Life Perspectives. Helga Radner[1], Josef S. Smolen[2] and D. Aletaha[1], [1]Medical University Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria

Background: RA is a disease with a considerable socio-economic burden. This burden is mediated through impairment of physical function, which in turn is mostly dependent on the level of RA disease activity. While the ultimate therapeutic target is achievement of disease remission, it is unclear to what extent the socioeconomic burden of RA is reduced as patients improve in the activity of their disease.

Purpose: To understand the punctual relationship of disease activity states with the socioeconomic burden of RA.

Methods: In 350 consecutive RA patients seen in routine clinical care we obtained data on work productivity using the Work Productivity and Activity Impairment Questionnaire (WPAI), on quality of life using the Short Form-36 (SF-36), and on health states (utility) using the Euroqol-5D (EQ-5D). Patients were then divided into four groups according to their disease activity state by the Clinical Disease Activity Index (CDAI): remission (REM), low, moderate, and high disease activity (LDA, MDA, and HDA). The socioeconomic data were then compared across the four disease activity groups.

Results: The physical component summary measure (PCS) of the SF-36, the EQ-5D, and the work productivity (by the WPAI) were significantly worse if higher levels of disease activity were present ($p<0.01$ by ANOVA, **Table**). Subsequent pairwise comparisons indicated for all measures that the achievement of REM was superior to achievement of LDA ($p<0.01$, Student's t-test).

Table. Quality of life, utility and work productivity (mean values ± SD) at different levels of disease activity defined by Clinical Disease Activity Index (CDAI)

	Total	**REM**	**LDA**	**MDA + HDA**	**p-value (ANOVA)**	**p-value (t-test REM vs. LDA)**
N	350	89	148	113		
SF-36 MCS (range 0-59.1)*	48±12	48.9±11.8	49.4±12	45±12	p=0.021	p=0.75
SF-36 PCS (range 0-70.4)*	37.7±11.2	46±8.8	38.3±10.3	30±8.7	p<0.0001	p<0.0001
EQ-5D (range -0.13-1)*	0.77±0.19	0.89±0.12	0.79±0.15	0.65±0.21	p<0.0001	p<0.0001
WPAI % impairment while working**	27.8±26.9	9±17.6	28.1±23	47.9±29.5	p<0.0001	p=0.001
WPAI % overall activity impairment**	35.3±26.4	18±20.5	33.1±22.8	53.2±24.6	p<0.0001	p<0.0001

Abbreviation: SF-36 MCS /PCS (Short Form 36 mental component summary measure / physical component summary measure); EQ-5D (Euro-Qol 5D); WPAI (Work Productivity and Activity Impairment Questionnaire; REM (remission; CDAI ≤ 2.8); LDA (low disease activity; 2.8<CDAI≤10); MDA+HDA (moderate to high disease activity; CDAI>10); * higher values better; ** higher values worse

Conclusion: While more impairment of work productivity, quality of life, and health states were seen with higher levels of disease activity, even in LDA these measures were significantly worse when compared to REM. This suggests that even in patients with LDA therapeutic adaptations to attain remission are worthwhile and warranted.

Utility Differences in RA and Knee OA Patients. L. M. Manheim, D. D. Dunlop and R. W. Chang, Northwestern University, Chicago, IL

Purpose: Cost Effectiveness analysis relies on utility measurement, a community based assessment of health, to evaluate the relative effectiveness of many arthritis interventions. We examine health utility in persons with rheumatoid arthritis (RA) and Knee Osteoarthritis (KOA) to address the following questions: how does overall health-related utility differ for persons with RA and KOA; are factors related to utility the same for OA and RA patients; and what factors that have potential for interventions significantly associated with utility?

Methods: This study uses baseline data from 107 RA and 91 KOA subjects enrolled in the Increasing Motivation for Physical Activity in Arthritis Clinical Trial (IMPAACT) study, a randomized controlled trial to evaluate an individually tailored physical activity intervention. Prior to randomization each person completed a set of baseline questionnaires including the SF-36 used to derive the SF6-D utility measure, (the outcome) and explanatory factors: physical activity assessed by accelerometer, demographics, BMI, disability, and comorbidity based on prescription drug use. The outcome measure SF6-D utility is a weighted (by community preferences) average of six SF-36 dimensional scores reflecting: physical functioning, role, social, pain, mental health, and vitality. Utility is normally distributed around its mean and predicted values do not exceed 1 or show ceiling effects. Multiple regression was used to examine whether any of these factors explained differences in utility between RA and KOA patients.

Results: Mean SF6-D utility is greater for KOA than for RA (0.752 vs. 0.697, $p<.001$). This utility difference between RA and KOA is approximately the same at the 25^{th}, 50^{th}, and 75^{th} percentiles, suggesting a simple shift of the curve with RA lower by .05 points at all points along the curve. Each of the subcomponents of the utility index is lower for RA than for KOA. Interestingly the largest (and only statistically significant) differences among subscales was in mental health (RA subscore 51% less than KOA:-.033 vs. -.022, $p<.01$) and social role (RA subscore 33% less for RA: -.035 vs. -.017, $p<.01$) subscales, while physical functioning (6.5% less for RA) and pain (9.4% less for RA) show the least differences. Older age, being male, greater physical activity, not being overweight, lack of disability, and fewer comorbidities are all significantly related to better utility. The only significant interactions with disease indicated that greater comorbidity and age impact more negatively on utility for RA than for KOA subjects.

Conclusion: Persons with RA have significantly lower utility levels than persons with KOA. While lower scores for RA are apparent across all global health-related dimensions making up the utility score, they are most pronounced for psycho-social rather than pain and functioning dimensions. Levels of physical activity and being overweight or obese show independent significant effects on utility suggesting areas for intervention to improve health-related quality of life.

Serum Urate and Its Relationship with Alcoholic Beverage Intake in Men and Women: Findings From the Coronary Artery Risk Development in Young Adults (CARDIA) Cohort. Angelo L. Gaffo[1], Jeffrey M. Roseman[2], David R. Jacobs Jr.[3], C. Lewis[4], James M. Shikany[2], T. R. Mikuls[5], Pauline E. Jolly[2] and Kenneth G. Saag[2], [1]Birmingham VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Minnesota, Minneapolis, MN, [4]UAB, Birmingham, AL, [5]U Nebraska, Omaha, NE

Purpose: Choi and colleagues have previously reported differential effects of beer, liquor and wine on serum urate (SU) concentrations in older adults. We examined these relationships in a bi-racial cohort of young men and women enrolled in the CARDIA study.

Method: Data from 3123 participants at baseline (recruited in 1985-6) and follow-up at 20 years were utilized, with balanced proportions of Caucasians and African Americans. The relationships of SU with categories of beer, liquor, wine, and total alcohol intake referent to no intake were examined in sex-stratified cross-sectional and multivariable-adjusted longitudinal regression analyses.

Results: Mean age at entry was 25.1 years. On multivariable analyses and referent to non-drinkers, a significant positive association between SU concentration and beer intake was observed among men and women, being more pronounced and consistent in the latter. A positive association between liquor intake and SU concentration was observed only for men at the year 20 evaluation. Wine intake was not associated with SU changes in either sex at either time point (Figure). Total alcohol intake was positively associated with SU concentrations in both men and women. The magnitude of the associations between alcoholic beverage intake and serum urate was modest (less or equal than 0.03 mg/dL per serving, effect size < 0.11).

Conclusion: Following previous findings in older adults, an association between higher SU concentrations and greater beer intake was found among young women and men, being stronger in the former. No associations were found with wine intake. Small increases in SU associated with alcohol intake in young adults could have clinical implications on gout and cardiovascular disease that deserve further study.

Figure. Multivariable adjusted SU difference (in mg/dL) by categories of alcoholic beverage intake and compared with non-drinkers (referent group). Numbers above the error bars represent the exact SU difference, numbers in parentheses represent the median alcoholic beverage intake for each category in servings per week Significantly different from non-drinkers (P<0.05).

Predicting Absence or Work Stoppage Among Patients with Early Rheumatoid Arthritis. Wei Zhang[1], Huiying Sun[1], Reiko Sato[2], Amitabh Singh[2], Bruce Freundlich[2], Paul Emery[3], Chung-Tei Chou[4] and Aslam H. Anis[5], [1]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, [2]Wyeth Pharmaceuticals, Collegeville, PA, [3]University of Leeds, Leeds, United Kingdom, [4]Taipei Veterans General Hospital, Taipei 112, Taiwan, [5]Univ of British Columbia, Vancouver, BC

Purpose: To assess the association between baseline clinical and patient-reported outcomes parameters and work absence or stoppage during the12 weeks immediately following baseline among employed people with early rheumatoid arthritis (RA).

Method: Data from the COmbination of Methotrexate and ETanercept trial, a double-blind randomized clinical trial, was used. Patients working full-time or part-time at baseline were included in the analysis. The outcomes were work stoppage and work absence that occurred during the first 12 weeks period. Stepwise logistic regression was used to assess the association, including age, gender and treatment variable (etanercept and methotrexate vs. methotrexate alone) for all analyses. Model selection was first conducted within 4 blocks of independent variables: I. demographics, II. medication and medical history, III. baseline clinical variables (pain, fatigue, Disease Activity Score, total swollen joints, total tender joints (TTJ), patient global assessment, physician global assessment, Health Assessment Questionnaire, morning stiffness, disease duration), and IV. baseline quality of life measures (EuroQol [EQ-5D] utility, EQ-5D VAS, SF-36 Mental component summary and Physical Component Summary [PCS]). The clinical and quality-of-life measures were categorized into poor, moderate, and good based on tertiles. The final multivariate model selection was constructed only among the variables selected in each block at the first step using entry criterion p=0.1 and stay criterion p=0.2.

Results: Among the 205 included in the analysis, 69% were females, the mean age was 45 years and the mean RA duration was 8.7 months. 8.5% stopped working and 18.5% missed work between baseline and week 12. First, as per selection criteria, previous NSAID use, neurologic, cardiovascular and psychiatric history in block II, fatigue and TTJ in block III, and EQ-5D VAS in block IV were selected for work stoppage. Caucasian in block I, neurologic history in block II, TTJ in block III, and SF-36 PCS in block IV were selected for work absence. Neurologic (odds ratio [95% confidence interval]: 7.6 [1.6-35.5])history, psychiatric history (4.4 [0.9-21.5]), and fatigue (8.0 [1.5-42.8] for poor vs. good status) were retained in the final multivariate logistic regression for work stoppage, while Caucasian (3.2 [0.8-12.6]), neurologic history (5.4 [1.6-18.8]) and TTJ (5.1 [1.9-13.9] for poor vs. good status) were retained for work absence.

Conclusion: Our results suggest that baseline comorbidities, fatigue, and tender joint counts could predict work stoppage and absence over the subsequent 12 week period in early RA. Measures associated with near-term work stoppage and absence can differ and may suggest that separate factors contribute to distinct work outcomes.

The Increased Risk of Incident Gout in Obese Patients Enrolled in a Community-Based Cohort: Campaign against Cancer and Heart Disease (CLUE II). Mara A. McAdams[1], Janet W. Maynard[2], Alan N. Baer[2], Anna Kottgen[1], Sandy Clipp[1], Allan C. Gelber[2] and Josef Coresh[1], [1]Johns Hopkins School of Public Health, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Community-based cohorts are useful for epidemiologic studies to identify risk factors for chronic diseases. Previous studies have primarily focused on anthropometric risk factors for gout in men. We evaluated the risk of incident gout in men and women by obesity status using the community-based cohort, Campaign Against Cancer and Heart Disease (CLUE II).

Method: The CLUE II cohort contains 26,147 individuals, aged 13 to 87 years, who resided within or surrounding Washington County, Maryland in 1989. The mean age was 47.4 years in 1989), and 99% self-reported white race. At baseline (1989), participants were asked to self-report sex, race, age, height, weight, weight at age 21, education, treatments for high cholesterol and blood pressure, hormone use, and menopausal status. Follow-up questionnaires through 2007 included a question about ever having received a gout diagnosis by a healthcare professional. This study included over 12,000 CLUE II participants who returned at least one follow-up questionnaire after 2000. Incident gout cases were restricted to the participants who self-reported the onset of gout after 1989 based on self-reported age or year of gout onset. We assessed the eighteen-year risk of incident gout in obese participants (BMI >30 kg/m2 at baseline) with cumulative incidence rate ratios (RR) from Poisson regression. We modeled the RR of incident gout using female-specific risk factors in models restricted to female participants.

Results: Of the study population (12,391 participants), 416 had incident gout. The prevalence of obesity at baseline was 16% of the study population. Gout patients were more likely to be male, older age, and treated for high cholesterol and blood pressure at baseline. The 18-year risk of developing gout was increased for every five-unit increase in BMI. The risk of gout was higher in obese participants compared to non-obese participants and this risk was also seen for participants who were obese at age 21. The categorical risk of incident gout was similar in participants whose baseline BMI was 30-35 and those with a BMI greater than 35.

	Model 1: **Adjusted RR of gout***		**Model 2:** **Adjusted RR of gout****	
	RR	CI	RR	CI
Five unit (kg/m^2)	1.55	1.44, 1.66	1.45	1.37, 1.56
Categorical BMI				
<25	1		1	
25-30	2.08	1.61, 2.67	1.94	1.51, 2.50
30-35	3.70	2.81, 4.89	3.18	2.39, 4.24
35+	3.46	2.29, 5.23	2.73	1.78, 4.17
Obesity at baseline	2.38	1.94, 2.91	2.05	1.65, 2.54
Obesity at age 21	2.01	1.31, 3.08	1.68	1.09, 2.60

* Adjusted for baseline age, race and sex

** Additionally, adjusted for baseline treated blood pressure and cholesterol

Conclusion: In a community-based cohort we found that obesity was associated with an increased risk of gout over 18 years of follow-up. Obesity appears to be a strong risk factor for gout. Gout should be considered in the differential diagnosis of acute joint pain in obese patients.

Disclosure: M. A. McAdams, None; **J. W. Maynard**, None; **A. N. Baer**, None; **A. Kottgen**, None; **S. Clipp**, None; **A. C. Gelber**, None; **J. Coresh**, None.

1387

Past Fractures Increase Risk for Subsequent Fractures at Multiple Sites: Global Longitudinal Study of Osteoporosis in Women (GLOW). Kenneth G. Saag[1], Andrea LaCroix[2], Stuart L. Silverman[3], Steven Boonen[4], Juliet Compston[5], J. Coen Netelenbos[6], Johannes Pfeilschifter[7], Philip Sambrook[8], Nelson B. Watts[9], Gordon FitzGerald[10] and Silvano Adami[11], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Fred Hutchinson, Seattle, WA, [3]Cedars Sinai/UCLA, Beverly Hills, CA, [4]University of Leuven, Leuven, Belgium, [5]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [6]VU University Medical Center, Amsterdam, Netherlands, [7]Alfried Krupp Krankenhaus, Essen, Germany, [8]University of Sydney-Royal North Shore Hospital, Sydney, Australia, [9]University of Cincinnati, Cincinnati, OH, [10]UMass Medical School, Worcester, MA, [11]University of Verona, Verona, Italy

Purpose: The ability of a past fracture to predict subsequent fractures is an important criterion in defining a fracture as attributable to osteoporosis. Although some data from large cohorts suggest that fractures at most anatomic sites are associated with future fractures, the specific types of fractures that predispose to future fracture are controversial. We examined the risk of incident fracture based on initial fracture site in a large international study.

Method: The Global Longitudinal Study of Osteoporosis in Women (GLOW) is an observational, longitudinal study of women 55+ recruited by 615 primary physician practices (17 sites, 10 countries). Self-administered questionnaires were mailed at baseline and at 12 months (2:1 over-sampling of women ≥65). Self-reports of fractures at 10 anatomic locations after age 45 were collected at both baseline and follow-up. The odds of any incident fracture at 1 year were determined based on site of past fracture and after multivariable adjustment for age and other fracture sites (in women with multiple fractures).

Results: Among the 47,939 women for whom 1-year data were available (79% of baseline cohort), 1167 (2.4%) had fractures. For women with no previous fracture the incidence was 1.8% (661/36,846) vs 4.6% (506/11,093) for those with a prior fracture ($p<0.001$). The unadjusted odds ratios were significantly elevated for all 10 sites (range 1.8-3.3). After adjustment for age and other fracture locations, the risk of incident fractures was attenuated but remained significant for the rib, hip, wrist, spine, upper arm and ankle (Table).

Table. Incidence of any fracture at 1 year given previous fracture and adjusted odds ratio for any fracture at 1 year vs women without prior fracture

Fracture site	Previous fracture prevalence n (% of overall fractures)	Any incident fracture*, given initial fracture site n (%)	Adjusted OR (95% CI)
Rib	1991 (18)	139 (7.0)	2.4 (2.0-2.9)
Hip	806 (7.3)	56 (7.0)	1.7 (1.3-2.3)
Wrist	4101 (37)	204 (5.0)	1.7 (1.4-2.0)
Spine	1057 (9.5)	66 (6.2)	1.6 (1.4-3.0)
Upper arm	1344 (12)	70 (5.2)	1.4 (1.1-1.9)
Ankle	2923 (26)	119 (4.1)	1.3 (1.1-1.6)
Lower leg	1186 (11)	56 (4.7)	1.3 (1.0-1.7)
Upper leg	419 (3.8)	26 (6.2)	1.3 (0.8-2.0)
Clavicle	626 (5.6)	32 (5.1)	1.2 (0.8-1.7)
Pelvis	479 (4.3)	27 (5.6)	1.0 (0.6-1.5)

*Any incident fracture consists of the 10 categories in the 1st column

Conclusion: In a large practice-based international cohort, the risk of incident fracture at 1 year varied by site of past fracture and was significantly associated with 6 of 10 previous fracture locations. These findings help to define fractures that may be most strongly attributed to osteoporosis.

Long Term Mortality Is Increased in Male as Patients. Gunnstein Bakland[1], Jan Tore Gran Sr.[2] and Hans Nossent[3], [1]University Hospital Northern Norway, Tromsø, Norway, [2]Oslo University Hospital, Rikshospitalet, Oslo, Norway, [3]Tromsø, Norway

Purpose: To report very long term gender specific mortality rates in a population of AS patients compared to a control population. Although increased standardized mortality rates (SMR) have been described in AS patients, no significant increase in mortality was seen in an AS inception cohort in northern Norway during the first twenty years of disease (2). Earlier radiation therapy has been considered an important contributor to early death in AS (1).With increased periods of observation and closer and expanded matching to a control population, we now report the updated estimates of mortality as well as predictors and causes of death in AS.

Method: We identified all AS patients fulfilling the modified New York criteria who had been registered in our hospitals records after 1978. Each case was assigned three controls matched for gender, age and area of residency. The onset of low back pain was defined as the point of debut of AS. All data were entered to and analyzed in SPSS v 16.0. Overall mortality was analyzed using a Log Rank-test (Mantel-Cox). Causes of death were determined through record review where available.

Results: A total of 677 patients were included in the analysis and matched to 2031 controls. As expected the male-to-female ratio was about 3:1. Mean age at symptom debut was 23.7 years (median 22.2) and mean diagnostic delay was 9.0 years (median 7.0). At the time of last follow-up, the crude mortality rate in the patient group was 14.5 % (n=98) as compared to 7.2 % in the control group (OR 2.18 [1.66-2.87]). Overall comparison adjusted for gender (Mantel-Cox) showed a highly significant increased mortality in the patient group ($\chi 2$=48.75, p<0.0009). Standardized mortality rate (SMR) [95% confidence interval] in the patient group was 1.61 [1.29-1.93]. In gender specific analyses, male AS patients had significantly increased mortality (SMR =1.63 [1.29-1.97]), while SMR was not increased for female patients (SMR=1.38 [0.48-2.28]. In time dependent analyses, the increase in mortality among male patients became only apparent more than 15 years after diagnosis, whereas mortality increased slightly though not significantly among female patients after 35 years. Cause of death was established in only 29 of 89 cases, and malignancy was the most prevalent cause (10) followed by infections (5).

Conclusion: The long term risk of mortality is increased in male AS patients with an estimated SMR 1.63. The increased risk become manifest about 15 years after diagnosis in male patients. A non-significant trend towards increased mortality risk in female patients appeared about 35 years after diagnosis.

Scaling Properties of the OAKHQOL Questionnaire for Hip and Knee Osteoarthritis: A Rasch Analysis. Christophe Goetz[1], Emmanuel Ecosse[2], Anne-Christine Rat[3], Jacques Pouchot[4], Joël Coste[2] and Francis Guillemin[1], [1]Nancy-University, Paris Descartes, Metz P Verlaine; Department of clinical epidemiology and evaluation, Nancy University Hospital, Nancy, France, [2]Nancy-University, Paris Descartes, Metz P Verlaine; Biostatistics and epidemiology unit, Hôpital Cochin, AP-HP, Paris, France, [3]Nancy-University, Paris Descartes, Metz P Verlaine; Department of clinical epidemiology and evaluation, Nancy University Hospital; Department of rheumatology, Nancy University Hospital, Nancy, France, [4]Nancy-University, Paris Descartes, Metz P Verlaine; Department of internal medicine, Georges Pompidou European Hospital, AP-HP, Paris, France

Purpose: The self-administered OAKHQOL questionnaire has been developed to assess health-related quality of life in lower limb osteoarthritis (OA). We used a Rasch analysis to further document its validity.

Method: The questionnaire contains 40 items divided in 5 domains: physical activities (PA), mental health (MH), pain (P) social support (SS) and social functioning (SF), and 3 independent items, with a scoring using numerical rating scales ranging from 0 to 10. Patients with knee or hip OA of various stages of severity completed it. For each of the 5 domains, responses to the items were analyzed using a partial credit model. Fit of data to model expectations and thresholds ordering were examined. The invariance of the scales was assessed by looking for differential item functioning (DIF) across gender, age and involved joint. Analyses were run using RUMM2020 software.

Results: Responses of 544 knee (n=237) and hip (n=307) OA patients were analyzed; 297 were treated in rheumatology and 247 were waiting for arthroplasty. Fit of data to initial models was low for all domains except for pain. Internal consistency was good to excellent (Person Separation Index ranging from 0.80 to 0.94). The thresholds of two items in PA and two in MH were not ordered and were rescored from 11 to 3 answering modalities. One item in SS with disordered thresholds was kept unchanged because this item showed misfit when rescored. Five items of PA domain demonstrated a DIF between knee and hip OA (Going down stairs, Climbing stairs, Dressing, Cutting toe-nails and Getting in and out a car), and one item a DIF for gender (Need help). Two items of MH domain showed a DIF for gender (Been afraid of being dependent on others and Feel aggressive and irritable) and one a DIF for age (Feel older than my years). After rescoring items with disordered modalities and splitting items with DIF, fit of data improved. Significant misfit was found in only one item in PA and one in MH. Removing items showing DIF or misfit did not significantly modified the person estimates (less than 0.02 logit), meaning there was no significant bias at the domain level.

Conclusion: The OAKHQOL questionnaire demonstrates satisfying scale properties for each of the five domains in patients with hip and knee OA under medical treatment or awaiting for surgery. Out of 40 items, 9 present DIF and 2 show misfit to the model, but the resulting bias is trivial at the domain level.

Better Patient-Reported Physical Functioning Outcomes in Early Rheumatoid Arthritis Treatment with Adalimumab Plus Methotrexate Than Methotrexate Alone. Edward C. Keystone[1], Sanjoy Roy[2], Naijun Chen[2], Saeed Rasty[2], Benoît Guerette[3], Mary Cifaldi[2] and Robert Landewe[4], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Abbott Laboratories, Abbott Park, IL, [3]Abbott Laboratories, Rungis, France, [4]Maastricht University Medical Center, Maastricht, Netherlands

Purpose: Rheumatoid arthritis (RA) is a chronic, debilitating disease that impairs physical functioning. Global physical functioning in RA is commonly measured by the overall score on the patient-reported Health Assessment Questionnaire (HAQ). Analysis of the individual HAQ items may provide insight about how patients perceive various aspects of their own physical functioning, especially during RA treatment. This study evaluates patient-relevant aspects of physical functioning during treatment with a combination of adalimumab (ADA) and methotrexate (MTX) vs. MTX alone.

Methods: Study data were derived from PREMIER, a 2-year, multicenter, Phase III, randomized, double-blind, comparator-controlled trial of ADA for the treatment of MTX-naïve patients with early RA (<3 years). HAQ data at baseline, Week 52, and Week 104 were analyzed for patients randomized to receive ADA+MTX combination therapy or MTX monotherapy. On the HAQ, patients rated their ability to perform a variety of tasks on this scale: 0=without any difficulty, 1=with some difficulty, 2= with much difficulty, and 3=unable to do. Due to the ordered, categorical nature of the HAQ item responses, ordered logistic regression (OLR) techniques were adopted to estimate the effects of treatment on individual item responses in a proportional-odds model at baseline, Week 52, and Week 104 of the study. A similar

model was also used to estimate the effect of radiographic damage (using modified total Sharp scores [mTSS]) on individual HAQ item responses.

Results: A total of 525 patients (ADA+MTX=268; MTX=257) were included in this analysis. The treatment groups did not differ at baseline in their distributions of HAQ item responses. At both Week 52 and Week 104, the ADA+MTX group had lesser numeric responses (indicating better physical functioning) than the MTX group for 15 of 20 HAQ items (odds ratios: 1.77 to 2.78 at Week 52; 1.62 to 2.77 at Week 104; $p<0.05$ for each comparison). Patients in the ADA+MTX group were approximately 3 times more likely than patients in the MTX group to find it easier to open car doors and to cut their meat and approximately 2 times as likely to have better ability to do most of the remaining activities assessed by the HAQ. The effect of mTSS on HAQ was significant for 4 items at Week 52 and for 6 items at Week 104 (all comparisons $p<0.05$). Only 2 items (walking outdoors on flat ground; bathing) were affected by mTSS at both time points (both $p<0.05$).

Conclusion: For most aspects of physical functioning measured by the HAQ, patients with early RA treated with ADA+MTX had better self-reported outcomes than patients treated with MTX alone. The greatest benefits were experienced in activities involving the hands. Radiographic damage affected several aspects of physical functioning, with greater impact over time.

A Comparison of Traditional Gout Risk Factors Between Men and Women in the Atherosclerosis Risk in Communities (ARIC) Study. Janet W. Maynard[1], Mara A. McAdams[2], Alan N. Baer[1], Anna Kottgen[2], Allan C. Gelber[1] and Josef Coresh[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins School of Public Health, Baltimore, MD

Purpose: Gout is a major form of inflammatory arthritis in both men and women; yet, little is known about whether clinical risk factors for gout vary by gender. In the Atherosclerosis Risk in Communities (ARIC) Study, we evaluated the association of traditional risk factors for gout in women as compared to men.

Methods: ARIC is a population-based cohort study of 15,792 individuals (55% women) recruited in 1987-1989. Our study population consisted of African-American and Caucasian men and women with and without gout. A participant was considered to have gout if 1 or more of the following criteria were met: a) gout was self-reported, b) surveillance of hospital discharge summaries revealed an ICD-9 code for gout (274.0, 274.1, 274.8, or 274.9), or c) use of a medication taken primarily to treat gout at any study visit. We stratified by gender and used multivariable logistic regression to model the risk of prevalent gout. The multivariable models included baseline age, race, obesity, organ meat, animal protein, shellfish, and alcohol intake, diuretic use, hypertension, renal function, and diabetes. Obesity was classified as BMI >30. We generated models using interaction terms to see if gender modifies the relationship between traditional risk factors and gout.

Results: 399 women (4.8%) and 703 men (9.9%) have gout in the ARIC cohort. In women and men, African-American race, obesity, high alcohol intake, hypertension, and decreased kidney function were associated with an increased risk of gout. In women, but not in men, age and organ meat intake were associated with an increased risk of gout. In men, but not in women, diabetes was associated with an increased risk of gout. Gender modified the relationship between gout and three traditional risk factors: race, protein intake, and organ meat intake.

	Women OR (95% CI)	Men OR (95% CI)	P-value for interaction of gender
Age (per 1 year)	**1.04 (1.02, 1.07)**	1.01 (0.99, 1.03)	0.07
Race			
Caucasian (reference)	1	1	
African-American	**1.87 (1.46, 2.40)**	**1.47 (1.20, 1.80)**	**0.05**
Obesity	**2.43 (1.93, 3.06)**	**1.98 (1.66, 2.37)**	0.07

Protein (per 15gm)	1.05 (0.98, 1.13)	0.94 (0.89, 0.99)	**0.005**
Shellfish	0.99 (0.79, 1.25)	1.05 (0.89, 1.25)	0.96
Organ Meat	**1.28 (1.02, 1.61)**	0.85 (0.72, 1.02)	**0.002**
Alcohol			
No drinks/day (reference)	1	1	
1-2 drinks/day	0.98 (0.74, 1.32)	**1.24 (1.03, 1.50)**	0.36
>2 drinks/day	**2.01 (1.08, 3.72)**	**2.30 (1.82, 2.89)**	0.86
Diuretic use	**1.60 (1.22, 2.10)**	**1.44 (1.14, 1.80)**	0.87
Hypertension	**1.71 (1.29, 2.27)**	**2.34 (1.91, 2.86)**	0.44
Kidney function (per 10 mls/min/1.73m^2)	**0.84 (0.77, 0.92)**	**0.77 (0.72, 0.83)**	0.08
Diabetes	1.21 (0.92, 1.59)	**1.33 (1.06, 1.67)**	0.86

Key: OR=odds ratio; CI=confidence interval

Conclusion: Traditional risk factors, including African-American race, obesity, high alcohol intake, diuretic use, decreased kidney function and hypertension are associated with an increased risk of gout in both women and men. The relationship between certain risk factors, such as African-American race, protein intake, and organ meat intake varies by gender. Understanding how gender modifies traditional risk factors may allow for more targeted patient counseling and treatment strategies.

The Significance of Self-Rated Health and Mental Well-Being in Predicting Outcomes Following TJR Surgery for OA. Anthony V. Perruccio[1], Elizabeth M. Badley[2], Sheilah Hogg-Johnson[3] and Aileen Davis[4], [1]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [2]Univ of Toronto, Toronto, ON, [3]Institute for Work and Health, Toronto, ON, [4]Toronto Western Research Institute, Toronto, ON

Purpose: Total joint replacement (TJR) is a frequently performed procedure for hip and knee OA. Studies of the determinants of TJR patient-reported outcomes and the scope of outcomes examined have typically been limited to aspects of physical health, in particular pain and physical function. What has been neglected is the concomitant consideration of patient-reported mental and social health status. Moreover, a number of studies have documented the predictive significance of self-rated health (SRH) for a number of health outcomes. However, SRH has not been fully considered in TJR patient-reported outcomes. The purpose of this study was to examine the predictive significance of physical, mental and social health and SRH for future health status in a cohort of individuals within 6 months of undergoing TJR surgery for hip or knee osteoarthritis (OA) and to simultaneously investigate the predictive significance of these health dimensions for SRH.

Method: Participants (hip: n=215; knee: n=234) completed measures pre-surgery and at 3 and 6 months post-surgery associated with physical: HOOS/KOOS (pain, physical function, sport/rec); mental: POMS (fatigue), HADS (anxiety and depression); and social health: LLFDI (disability limitation), passive/active recreation, community access. Using structural equation modeling, confirmatory factor analyses was used to investigate 3 latent health dimensions characterized as physical, mental and social health. These dimensions were regressed on prior health status and on prior SRH. As well, SRH was regressed on each of these dimensions both within and across time points. Measures of overall model fit were assessed.

Results: Hip group: age range from 31-86 years (mean=62) with 57% female; Knee group: age range from 35-88 years (mean=64) with 63% female. 90% of the sample completed the baseline questionnaire within 3 weeks prior to surgery. Significant improvements in health dimension scores were observed over time. Prior dimension status strongly predicted future status. And, with simultaneous adjustment for prior health dimension scores, comorbidity and sociodemographic characteristics, SRH significantly predicted future health status for all three of the health dimensions. Worse prior SRH predicted less improvement both at 3 and 6 months post-surgery. Mental well-being was the only health dimension to significantly predict SRH, both within and across time points. The effects of physical and social health on SRH were fully mediated through mental well-being.

Conclusion: As a significant predictor of future health status following TJR surgery, improving a patient's SRH appears to be critical for improving the rate of recovery. As the most proximal determinant of SRH, mental well-being should be incorporated as an essential constituent of any care, treatment and management strategy.

Disclosure: A. V. Perruccio, None; **E. M. Badley**, None; **S. Hogg-Johnson**, None; **A. Davis**, None.

1393

Influence of Industry Funding On the Outcome and Quality of Randomized Controlled Trials of Drug Therapy for Rheumatoid Arthritis. Nasim A. Khan[1], Juan I. Lombeida[1], Horace J. Spencer[1] and Karina D. Torralba[2], [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [2]University of Southern California, Los Angeles, CA

Purpose: To assess impact of industry funding on the outcome and quality of randomized controlled trials (RCTs) of drug therapy for rheumatoid arthritis (RA).

Method: MEDLINE and Cochrane Central Register of Controlled Trials databases were searched using terms *Rheumatoid Arthritis* or *Arthritis, Rheumatoid* with a limitation to C*linical Trials, English* and years *2002-3 & 2006-7*. Eligible studies were identified by screening the title and abstract for original, parallel-design, drug trials with clinical primary outcome(s) that randomly allocated patients to different treatment groups. Two reviewers independently assessed each RCT for source of funding [industry, non-profit or mixed/both), outcome type [positive (statistically significant result favoring experimental intervention for the primary outcome), or not positive], and reporting of aspects of methodology whose inadequate performance has been empirically shown to bias the assessment of treatment effect. RCTs with industry funding were compared with those without any industry funding using chi square test.

Results: A total of 107 RCTs were identified. Regarding funding, 61 (57%) RCTs were industry, 20 (18.7%) were non-profit source(s), and 6 (5.6%) were mixed source funded. No funding source was reported in 20 (18.7%) RCTs. Eighty-eight (82.2%) RCTs could be assessed for outcome. Trials excluded from analysis included those that had safety as the primary outcome (10), and those where interventions tested were treatment strategies with no a priori strategy declared as experimental (9). Industry-funded RCTs were not found have higher rates of positive outcomes [industry sponsored (38/51, 74%), non- profit (12/16, 75%), mixed (2/5, 40%), and unspecified source (13/16, 81%); p Value = 0.33]. Industry funded RCTs reported significantly more frequent performance of several quality measures such as double-blinding, adequate descriptions of withdrawals and dropouts during the study, and intention-to-treat analysis (Table).

Conclusion: Industry funded drug RCTs of RA did not differ in frequency of reporting positive outcome from non-industry funded RCTs and had better reporting of some key methodological aspects of RCTs.

	Industry funded (N=60), n (%)	Non-industry funded (N = 47), n (%)	p Value
Positive outcome*	40/56 (71.4)	25/32 (78.1)	0.33
Random sequence generation	23 (34.3)	14 (35)	0.55
Allocation concealment	21 (31.3)	11 (27.5)	0.42
Double-blinding	58 (86.6)	19 (47.5)	< 0.001
Description of withdrawal/dropouts	56 (83.6)	27 (67.5)	0.047
Intention-to-treat analysis**	47/58 (81)	21/39 (53.8)	0.004

*Excluding RCTs safety as primary outcome + strategy trials with no a priori designated "experimental" study group.

** Excluding RCTs safety as primary outcome.

Disclosure: N. A. Khan, None; **J. I. Lombeida**, None; **H. J. Spencer**, None; **K. D. Torralba**, None.

1394

Causes of Hospitalization in Patients Treated with Anti-Tumor Necrosis Factor á Agents. Devy Zisman[1], Amir Haddad[1], Sharbel Hashoul[1], Arie Laor[2], Haim Bitterman[2], Itzhak Rosner[3], Alexandra Balabir-Gurman[4], Reuven Mader[5] and Uzi Milman[6], [1]Carmel Medical Center, Haifa, Israel, [2]Carmel Medical Center / Faculty of Medicine, Technion, Haifa, Israel, [3]Bnai Zion Medical Center / Faculty of Medicine, Technion, Haifa, Israel, [4]Rambam Medical Center / Faculty of Medicine, Technion, [5]Ha'Emek Medical Center / Faculty of Medicine, Technion, Afula, Israel, [6]Clalit Health Services

Purpose: To ascertain causes of hospitalization in patients with rheumatoid arthritis (RA), psoriatic arthritis (PSA), and ankylosing spondylitis (AS) treated with anti-tumor necrosis factor α (anti-TNF) agents compared to patients treated with traditional disease-modifying antirheumatic drugs (DMARDs).

Method: A retrospective cohort study of patients with RA, AS & PSA insured by Clalit Health Services in northern Israel between April 2002 and December 2007 was conducted. 354 treated with DMARDs only (group A) were compared to 322 anti-TNF-treated patients. The latter were assessed during their anti-TNF treatment period (group B) and compared to an equivalent period before anti-TNF initiation (group C). All hospitalization charts were reviewed and diagnoses, co-morbidities, concomitant medications and clinical course analyzed. Statistical analysis was performed using SAS 9.2 software.

Results: In the study period there were 142 hospitalizations in group A, 265 in group B, and 420 in group C with 61 infections requiring hospitalization during anti-TNF treatment compared to 39 before treatment and16 in the DMARDs group. The common relative risk (RR) controlled for age and gender between groups B and C was 4.5 (95% confidence interval 1.57-12.91). Mycobacterial infections (2 cases), multiple sclerosis like syndrome (3 cases), and hematological malignancies (4 cases) occurred exclusively during anti TNF treatment. In contrast, a major significant decrease was noted in hospitalizations due to disease flares and orthopedic admissions during anti-TNF treatment compared to the same patients before treatment (99, 255 and 15, 20, respectively). The common RR controlled for age and gender was 0.31 and 0.14 (95% confidence interval 0.18-0.51 and 0.05-0.4, respectively). No significant differences among the groups in hospitalization due to congestive heart failure or chronic lung disease exacerbations, cerebrovascular accidents nor surgical admissions were noted. One death occurred in group B due to a hematological malignancy

Conclusion: Rheumatic patients treated with anti-TNF agents had an increased risk of hospitalization due to infections compared with DMARD treated patients but the rate of hospitalization due to disease exacerbation and orthopedic admissions declined remarkably after anti-TNF treatment.

Disclosure: D. Zisman, None; **A. Haddad**, None; **S. Hashoul**, None; **A. Laor**, None; **H. Bitterman**, None; **I. Rosner**, None; **A. Balabir-Gurman**, None; **R. Mader**, None; **U. Milman**, None.

1395

Norms-Based Assessment of Patient-Reported Outcomes Associated with Adalimumab Monotherapy in Patients with Ankylosing Spondylitis. Miriam Kimel[1], Chris Thompson[1], Katherine Gooch[2], Dennis Fryback[3], David Feeny[4] and Dennis Revicki[1], [1]United BioSource Corporation, Bethesda, MD, [2]Abbott Laboratories, Abbott Park, IL, [3]University of Wisconsin School of Medicine and Public Health, Madison, WI, [4]Kaiser Permanente Center for Health Research, Portland, OR

Purpose: Adalimumab monotherapy has been shown to improve signs and symptoms, physical function, and general health-related quality of life (HRQOL) for ankylosing spondylitis (AS) patients (pts). The interpretation of the HRQOL score change is not well established. We compared the HRQOL impact of AS with general United States (US) norms and the impact of adalimumab treatment on initial and sustained improvement in HRQOL for pts with active AS compared with general US norms and minimum clinically important differences (MCID) for each HRQOL measure.

Methods: Of 315 pts enrolled in the initial 24-week period of the ATLAS trial, 208 were randomized to adalimumab 40 mg SC every other week and 107 to placebo. HRQOL was assessed using the Short Form 36 (SF-36) Health Survey and the Health Utilities Index Mark 3 (HUI3). The HRQOL burden of AS was assessed by comparing baseline SF-36 (PCS, MCS, and SF-6D) and HUI3 scores with general US norms using National Health Measurement Study (NHMS) data. The impact of adalimumab treatment on HRQOL was assessed by comparing SF-36 and HUI3 scores at Weeks 12 and 24 with NHMS norms.

Results: At baseline, adalimumab and placebo group pts had comparable HRQOL scores for all measures (PCS, MCS, SF-6D, and HUI3); scores for both groups were significantly more impaired compared with the general US population (all $p<0.0001$). Compared with the general population, mean scores for trial pts were approximately 20, 10, 0.25, and 0.33 points less for PCS, MCS, SF-6D, and HUI3, respectively. At Week 12, adalimumab and placebo group scores were significantly worse than for the general population. Mean improvements in PCS (+6.5) and SF-6D (+0.08) scores from baseline to Week 12 were clinically relevant for adalimumab pts (based on MCIDs of 5 points for PCS and 0.03 points for SF-6D). Clinically meaningful differences in PCS and SF-6D scores were observed for adalimumab vs. placebo pts (improvements of 5.4 vs. 0.04 points). Similar within-group improvements and between-group differences in PCS and SF-6D scores were also observed at Week 24. In addition, based on an MCID of 0.03 points, clinically relevant within-group improvements (0.13 points) and between-group differences (0.08 points) were seen for HUI3 scores favoring adalimumab. Previous analyses of 3-year outcomes from ATLAS indicated that mean PCS scores increased from baseline to 43 and 44 points at 1 and 3 years, respectively. The NHMS US population norm for the PCS is 46 points.

Conclusion: After 6 months of therapy, AS pts receiving adalimumab had significantly improved health status. However, a longer duration of therapy may be required to improve health status to levels comparable to general population norms.

1396

Costs Associated with Administration of Intravenous Infusion Therapy for Rheumatoid Arthritis. G.B. Kruse[1], Sanjoy Roy[2], Mary Cifaldi[2], D.C. Skonieczny[3] and B. Wong[1], [1]Bruce Wong & Associates Inc., Philadelphia, PA, [2]Abbott Laboratories, Abbott Park, IL, [3]Medical Present Value Inc., Austin, TX

Purpose: Biologic agents for the treatment of rheumatoid arthritis (RA) are administered either as subcutaneous injections or intravenous infusions. Whereas patients can self-inject subcutaneous drugs, infusion therapy requires drug administration by a health care provider. Although many factors influence the choice of the route of administration for biologic agents, the cost of administering these drugs has not been studied sufficiently. This study assessed the costs of administering infliximab, abatacept, and rituximab based on physician reimbursements for such services.

Methods: Provider claims data were analyzed from Medical Present Value (MPV), a large, longitudinal, national, provider contract-management database. Patients with an RA diagnosis and any claim including an infusion of a biologic agent between January 1, 2003, and December 31, 2008, were identified. Health Care Common Procedure Coding System (HCPCS) and Current Procedural Terminology (CPT) codes were used to identify infused drugs and administration costs.

Results: A total of 4,556 patients with RA receiving at least 1 infusion of infliximab, abatacept, or rituximab were identified. Of 33,354 infusion administration claims, 80% were for infliximab, 15% were for abatacept, and 5% were for rituximab. Mean (SD) total provider cost per infusion (in US $), including the drug, was $2,874 ($1,515) overall and $2,827 ($1,282) for infliximab, $1,827 ($622) for abatacept, and $6,057 ($1,689) for rituximab. The cost of administration was $226 (7.9% of total cost) overall and $224 (7.9) for infliximab, $171 (9.3) for abatacept, and $390 (6.4%) for rituximab.

In a subgroup of patients within the MPV database who received 12 doses of infliximab, the average infused dose increased from 389.7 mg to 428 mg from the first to the twelfth recorded dose. Similarly, the average cost of administering the drug increased from $214 to $241 in these patients.

Conclusion: Although drug cost is the single largest component of infusion therapy in RA, service costs of infusion administration add a significant amount to the total cost. These costs are frequently unrecognized when considering the drug cost effectiveness. Payors should

examine related financial implications when evaluating available options for providing optimal therapy for RA. This evidence is the first to show that the "dose creep" associated with infliximab increases the cost of infusion, potentially due to increased duration of infusion with greater doses. This is likely to be a major unrecognized cost because infliximab represents the largest share of biologic therapy in RA in this study database and has the longest history of use, which may exacerbate the effects of dose creep and related infusion costs.

Methods to Improve the Triage Accuracy of Referrals for Possible Inflammatory Polyarthritis. Glen S. Hazlewood, Liam Martin and Susan G. Barr, University of Calgary, Calgary, AB

Purpose: The accurate triage of referrals for possible inflammatory polyarthritis is critical, particularly to avoid misclassification of non-inflammatory disorders and delays in appropriate therapy. We studied the accuracy of our triage process and the ability of clinical and lab markers of inflammation to correctly identify patients with inflammatory disorders.

Method: Data is collected prospectively on all referrals to our Central Referral Office. All referrals from Jan 2007- Dec 2008 with possible inflammatory polyarthritis, including patients with polyarthralgia, were analyzed. The working diagnosis based on referral data was compared to the final diagnosis after consultation with a rheumatologist. A convenience sample of 200 sequential referrals was reviewed for completeness of several key data elements, including joint distribution, duration of symptoms, morning stiffness (AMS), swelling, past medical history and medications, CBC, RF and either an ESR or CRP. The impact of a rheumatology specific referral form on completeness of information was assessed. The utility of joint swelling, AMS>30min, ESR>20, CRP>8 and RF>20 for identifying inflammatory disorders was determined by calculating likelihood ratios for positive (LR+) and negative (LR-) results. Low cutpoints were chosen to maximize sensitivity and minimize misclassification of patients as non-inflammatory.

Results: A working diagnosis was available for 8284/9182 (90%) of referrals. Polyarthritis was questioned in 3706 (45%). Of these, the working diagnosis was inflammatory arthritis (IA) in 49%, indeterminate (IND) in 21%, osteoarthritis (OA) in 19%, and fibromyalgia (FM) in 12%. A final diagnosis was available for 1832/3706 (49%). Of those with a working diagnosis of FM, 98% (179/182) had a final diagnosis of a non-inflammatory disorder, including 66% with confirmed FM. Referrals triaged as OA were non-inflammatory in 327/369 (89%), possible-IA in 23 (6.2%) and IA in 19 (5.1%). Referrals triaged as IND were diagnosed with IA/possible-IA in 157/432 (36.3%). Patients triaged as IA were confirmed to have IA in 525/849 (61.8%). Reported joint swelling, AMS >30 min. and RF were not able to distinguish inflammatory vs non-inflammatory disorders. An ESR>20 (LR+1.5[95% CI: 1.1-2.1], LR- 0.7[0.5-0.9]), or CRP>8 (LR+1.7[1.0-2.8], LR-0.8(0.7-0.96)] had minimal utility in isolation. However, a normal ESR, CRP and RF in combination, had a moderate LR- of 0.4 [0.3-0.8]. For OA, this would lower the probability of IA/possible-IA from 11% to 5%. The referral form improved the completeness of referral information from 49% to 69% ($p<0.001$). Of the 200 referrals reviewed, 62 (31%) were inadequate and additional data was requested to enable triage. Of these, 19 (31%) had abnormal labs (CBC, ESR, CRP, RF) or x-rays, and 8/19 (42%) were ultimately diagnosed as IA.

Conclusion: Inflammatory arthritis can be reliably excluded for referrals with a working diagnosis of FM. For other consults, a normal ESR, CRP and RF are helpful in lowering the probability of IA, while joint swelling and AMS are not. A referral form can help improve the reporting of key triage information.

Utilization of VA Pharmacy Benefits Management Data and the VA Rheumatoid Arthritis Database to Demonstrate Reduced Disease Activity in Rheumatoid Arthritis Patients Adherent with Methotrexate. G. W. Cannon[1], BC Sauer[1], CL Hayden[1], A.M. Reimold[2], R.S. Hooker[3], G.S. Kerr[4], J.S. Richards[4], L. Caplan[5], D.S. Johnson[6] and T. R. Mikuls[7], [1]VA and University of Utah, Salt Lake City, UT, [2]VA and UTSouthwestern Medical Center, Dallas, TX, [3]VA, Dallas, TX, [4]VA and Georgetown University, Washington, DC, [5]VA and University of Colorado, Aurora, CO, [6]VA and University of Mississippi, Jackson, MS, [7]U Nebraska, Omaha, NE

Purpose: The linkage of pharmacy databases with objective clinical outcome measures provides an opportunity to evaluate rheumatoid arthritis (RA) therapies in real world clinical settings. This work merges information from the Veterans Affairs Rheumatoid Arthritis (VARA) registry initiated in 2003 and the VA Pharmacy Benefits Management (PBM) database with data from 1998 to determine if adherence with prescribed methotrexate (MTX) for the treatment of RA is associated with a reduction in RA disease activity.

Methods: VARA routinely collects 28 joint disease activity score (DAS28) on RA patients as part of this prospective multicenter observation cohort study. PBM data on these subjects were obtained during this observation period. For each MTX prescription, the estimated duration of the prescription, total dose of MTX dispensed, and anticipated date for refill of medication was recorded. The time gap between anticipated refill and actual refill of the next MTX prescription was calculated. MTX treatment course duration was defined as the time from the initial MTX prescription until the expected refill date for the last MTX prescription before a 90 day gap or discontinuation. The medication possession ratio (MPR), a measure of adherence, was calculated as the proportion of treatment time that the patient had drug available. Adherence was defined as an MPR $\geq$ 0.80. For each patient the average DAS28 over the course of therapy, prescribed MTX dose, and observed MTX dose were calculated. Patients included in this analysis were RA subjects who had at least one DAS28 score measured during their initial course of MTX therapy that was greater than 12 weeks in duration.

Results: Compared to non-adherent (MPR < 0.80) patients (n = 61), MTX adherent patients (n=329) had lower mean DAS28 score and ESR despite similar prescribed dose of MTX (Table). Other clinical chacteristics for these two groups were similar.

	Age	Disease Duration (yr)	RF (+)	aCCP (+)	Prescribed MTX dose (mg/wk)	Observed MTX dose (mg/wk)	DAS 28	ESR
MPR<80% (n=61)	65±11	9±10	82%	70%	16±4	11±3	4.1±1.4	30±25
MPR≥80% (n=329)	67±12	10±11	84%	74%	16±4	15±4	3.6±1.2	23±17
p-value	N.S.	N.S.	N.S.	N.S.	N.S.	<0.001	<0.02	<0.01

The impact of adherence on DAS28 was more pronounced after adjusting for weekly observed MTX dose. The results were unchanged after adjustment for age, disease duration, prescribed duration, and prescribed MTX dose.

Conclusion: RA patients in the VARA registry who were adherent with MTX therapy had significantly lower disease activity over follow-up in comparison to similar patients who were not adherent with therapy. This analysis demonstrates the potential for the use of data from these databases to evaluate clinical effectiveness of RA therapies in real world practice.

Lipoprotein Components Are Not Associated with Myocardial Infarction or Stroke in RA. Anne Grete Semb[1], G. Walldius[2], A. Aastveit[3], I. Jungner[4], T.K. Kvien[1] and I. Holme[5], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Karolinska Institute, Stockholm, Sweden, [3]Norwegian University of Life Sciences, Aas, Norway, [4]CALAB research, Stockholm, Sweden, [5]Ullevaal University Hospital, Oslo, Norway

Purpose: The striking contradiction concerning the high incidence of cardiovascular disease (CVD) in rheumatoid arthritis (RA) is low levels of lipids and at the same time there is an accelerated deposition of LDL-c, which is not explained by the traditional CV risk factors as hyperlipidaemia, smoking, diabetes, hypertension, and BMI. We aimed to describe the importance of lipids, apolipoproteins, and their ratios to predict future myocardial infarction (MI) or ischemic stroke (IS) in RA

Methods: In the AMORIS population 480 406 persons were followed for an average of 11.8 (7-17)(range) years. Of these 1 779 patients developed RA. A subgroup (n=150 443, of these were 505 persons with RA) volunteered blood samples, which were analyzed for total cholesterol (TC), triglycerides (TG), Apolipoprotein B (ApoB), apolipoprotein A1(ApoA-1). High and low density lipoprotein cholesterol (HDL-c, LDL-c) were calculated. Those who had any kind of cardiovascular disease at blood sampling were excluded. Cox regression models were used for statistical analyses.

Results: RA patients had lower lipids, apolipoproteins, and ratios than non RA. Despite this, the rate of AMI pr 1000 patient years was 3 fold higher in RA patients compared to the non RA persons in the total AMORIS population[1] ($p<0.001$). Similarly, The rate of IS was 3 times higher in RA patients compared to the non RA persons in the total AMORIS population[2] ($p<0.001$). Furthermore, females with RA were more prone to IS compared to male RA patients ($p<0.0001$). Hazard ratio of time from RA to first AMI or IS by 1 SD increase in lipoprotein components adjusted for age at RA disease onset , gender, hospital recorded diabetes and hypertension, showed that none of the lipid components or their ratios was significantly predictive for AMI or IS. At the same time, though, none of them was significantly different from the relationships found in the non-RA population.

Conclusion: Despite low levels of lipids and apolipoproteins, patients with RA have a higher rate of both AMI and IS compared a non-RA population. Lipoprotein components or their ratios are not predictive risk factors for MI or IS in RA.

Delay in Referral in Early Arthritis and Its Effect On Disease Outcome. Michael van der Linden[1], Saskia le Cessie[1], Karim Raza[2], Diane van der Woude[1], Tom W.J. Huizinga[1] and Annette H.M. van der Helm-van Mil[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom

Purpose: In Rheumatoid Arthritis (RA), rapid initiation of disease modifying drugs (DMARDs) is associated with a better disease outcome. Since DMARDs are rarely started before patients see rheumatologists, this suggests that delays in assessment by rheumatologists will affect outcome. We have assessed the relationship between delay in rheumatology assessment and [1] the rate of joint destruction as well as [2] the chance of achieving DMARD-free remission in RA. In addition, patient characteristics associated with patient-related and general practitioner (GP)-related delay in the entire early arthritis cohort were assessed.

Method: 1935 early arthritis patients from the Leiden Early Arthritis Clinic were studied and patient-related delay in presentation and GP-related delay in referral assessed. In 599 patients that fulfilled the 1987 ACR the criteria for RA during the first year after inclusion the association between the total delay and rate of joint destruction (median followup 4 years, max. 9 years) and achievement of DMARD-free remission were determined.

Results: In all early arthritis the median patient-related, GP-related and total delay were 2.7, 8.3 and 13.9 weeks. In the subgroup of RA-patients these delays were 3.4, 11.8 and 18.3 weeks respectively. Female gender, gradual symptom-onset, involvement of small joints and presence of autoantibodies associated with a longer total delay. Early arthritis patients that were diagnosed with RA had the longest delay in referral compared to all other diagnoses. Within RA-patients, a delay of <12 weeks associated with a significantly lower rate of joint destruction and more achievement of DMARD-free remission.

Conclusion: In RA, the time to referral is correlated with the chance of DMARD-free remission and the rate of joint destruction. Despite this correlation, among all early arthritis patients, those diagnosed with RA had the longest delay in referral. This implies that efforts to diminish the delay in visiting a rheumatologist may improve the disease outcome of RA-patients.

Assessing HRQoL Burden of Disease and Comparison to the U.S. Population in Psoriatic Arthritis Patients Treated with Golimumab: Results From the GO-REVEAL Trial. A. Raju[1], G. Hammond[2], S. Parasuraman, J. Buchanan and T. Gathany[3], [1]Lincoln, RI, [2]Qualitymetric Inc., Lincoln, RI, [3]Johnson and Johnson Pharmaceutical Services, LLC, Malvern, PA

Purpose: Assess the burden of active psoriatic arthritis (PsA) on health-related quality of life (HRQOL) as measured by SF-36. Contrast proportions of individuals meeting or exceeding the age and gender adjusted pop norms.

Methods: Adult patients (n=405) were randomized to golimumab (GLM) 50 mg (tx 1), GLM 100 mg (tx 2), or placebo (tx 3). Inclusion criteria: diagnosis with PsA (for min. of 6 months), exhibition of at least 3 swollen and tender joints. A *t*-test was used to assess equivalence in continuous SF-36 scores between wk 24 trial and norm, disease means. Separate χ^2 tests were used to compare proportions of individuals meeting and exceeding pop norms at wk 24.

Results: At baseline and wk 24, despite improvement, GO-REVEAL means were significantly lower than age and gender-adjusted US population (pop) norms for all SF-36 domain scores, indicating marked health impairment (Table). At baseline, both disease specific norms means were significantly higher than trial means on 3 SF-36 physical scale scores (PF, RP, BP) and PCS summary scores (all *p*s<.05). Trial means were significantly higher than the depression specific norms on mental health scale and summary measures (VT, SF, RE, MH, and MCS) at wk 24, but were comparable on 3 of the physical health scales (RP, BP, GH) (Table). At wk 24, trial means were comparable to rheumatoid arthritis norms on all SF-36 domain scores (Table). At wk 24, 30.2% (tx 1) and 28.5% (tx 2) of individuals exceeded the pop. norms for PCS, relative to 7.6% for tx 3 (χ^2: 16.7 and 18.7, GLM 100, 50, vs. placebo, *p*s<.01). No difference was observed in the proportion of individuals meeting/exceeding the pop norms for MCS across treatments (χ^2: 2.6 and 2.5, GLM 100, 50, vs. placebo, *p*s>.10), although all mental health scales showed significant differences (VT, SF, RE, and MH, all *p*s<.05).

Conclusion: Trial means improved relative to the US pop norms, but all domain scores were still significantly below pop. norms at wk 24. SF-36 domain scores were comparable to those of the RA specific norms. Both GLM doses showed significant and meaningful improvement in both PCS and all 4 mental scales relative to placebo at wk 24, indicating an improvement in both mental and physical health scores.

ACR/ARHP Poster Session C

Fibromyalgia and Soft Tissue Disorders

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1402

What Pain Related Behaviour Tells the MD about a Patient with Fibromyalgia. MA Fitzcharles[1], Marta Ceko[2], Ann Gamsa[2], Mark Ware[2] and Yoram Shir[2], [1]MGH, Montreal, QC, [2]McGill University, Montreal, QC

Purpose: The entire clinical assessment of patients with fibromyalgia (FM) is subjective and depends upon patient report and interpretation of this report by the physician. There has been debate regarding the validity and reliability of the complaint of symptoms by patients with FM, who frequently report important functional impairment. Pain related behaviour (PRB) may be defined as overt demonstrations by an individual indicating the presence of important pain. These behaviours may be perceived by the health care professional as compatible with, or as an exaggerated response to the underlying condition. Some have even suggested that the presence of these behaviours may reflect a conscious effort by the patient to emphasise the severity of symptoms. We examined the frequency and associations of PRB in FM patients attending a specialized multidisciplinary FM clinic in a tertiary care centre.

Method: We evaluated 136 consecutively attending FM patients for the presence of PRB. These was defined as behaviours that occurred during the physician interview and examination, appeared out of proportion to that expected for the symptom complaint, and which conveyed the subjective impression of exaggeration of pain and discomfort. Associations with demographic variables, pain and mood measurements and functional status were explored using the following: McGill Pain Questionnaire (MPQ), Pain Catastrophizing Scale (PCS), Pain disability Index (PDI), the Arthritis Impact Measurement Scale (AIMS) and the Fibromyalgia Impact Questionnaire (FIQ),

Results: PRB was present in 28 (21%) vs. no PRB in 108 (79%). There were no differences between groups for age, gender, duration of symptoms or current employment status. Patients with PRB vs. no PRB scored higher on all pain assessments including MPQ vs. 39, (P=0.03), Affective component of MPQ 7.2 vs. 5.5 (p=0.04), pain VAS 7.2 vs. 6.2 (P=0.04), PDI 42 vs. 35 (P=0.03) and tended to be receiving disability compensation, 50% vs. 31% (P=0.06). There were no differences for pain catastrophizing (PCS), severity of depression and anxiety, presence of allodynia or FIQ.

Conclusion: PRB was observed in one in five of FM patients. All measurement of pain associated with the presence of these behaviours, but there was no association with mood disorders or functional impairment. Contrary to expectations, pain catastrophizing was not more prevalent in those with these overt behaviours. PRB may reflect a truly severe pain experience in FM, rather than a manifestation of attention seeking and histrionic behaviour.

Anxiety and Depression Subselects Fibromyalgia Patients: A Cluster Analysis with Treatment Implications. Juliana Barcellos de Souza[1], Serge Marchand[2], Mark A. Ware[3], Yoram Shir[3] and MA Fitzcharles[4], [1]University of Sherbrooke, QC, [2]Univ, QC, [3]McGill University, Montreal, QC, [4]MGH, Montreal, QC

Purpose: Successful management of fibromyalgia (FM) remains a challenge. Identification of parameters that could direct treatment approaches would be advantageous. We have previously identified 2 patient subgroups, without or with comorbid depression and anxiety, by hierarchical cluster analysis using the fibromyalgia impact questionnaire (FIQ), a well validated quality of life (QOL) assessment for FM. In the present study we report the validation of these subgroupings on a large population of FM patients in a tertiary care setting.

Method: The FIQs for 132 FM patients attending a tertiary care multidisciplinary pain clinic were analysed as follows: (A) patients were assigned to the respective cluster, FM-Type I (without depression and anxiety) and FM-Type II (with depression and anxiety), using the classification coefficient previously published (Souza et al., Rheum. Int. 2008) and; (B) the cluster analysis was reapplied with this new sample. To confirm the number of clusters with this new cluster analysis (B), we analysed progressive changes in the agglomeration coefficient. Positive and negative predictive values for clustering according to mood disorder, as well as specificity and sensitivity for both

models were calculated (A and B). Additional measures of pain and QOL included the McGill Pain Questionnaire (MPQ), Health Assessment Questionnaire (HAQ), Pain Catastrophizing Scale (PCS) and Pain Disability Index (PDI)

Results: Tertiary care FM patients were grouped into Type-I (n=28) and Type-II (n=104) groups with Type-II patients demonstrating higher values for pain, fatigue, stiffness, morning tiredness, anxiety, depression on the FIQ. Repeat analysis (B), identified 2 clusters dependent on mood. The inter-model analysis showed a sensitivity of 0.96, and specificity of 0.71; with positive predictive value of 0.41 and negative predictive value of 0.99. Type-I vs Type-II did not differ regarding duration of pain ($p=0.90$) or tender point count ($p=0.11$), but Type II were younger (47 vs 53 yrs $p<0.01$), and reported higher values for MPQ, HAQ, PCS and PDI (all $p<0.01$).

Conclusion: We have shown that the clustering of FM patients remained valid in a tertiary care setting, often considered to represent patients with more severe symptoms. There is therefore little doubt that different FM profiles exist, and may be identified by a single, comprehensive instrument, the FIQ. These clusters groups have implications regarding treatment approaches. Future studies should take these different patient groups into consideration in order to focus treatment interventions applicable to distinct patient groups.

Relevance of PROMIS Item Banks to Individuals with Fibromyalgia. David A. Williams[1], Stephen Schilling[1], Katrina N. Shibata[2], Lynn Zwinck[1], Lynne Matallana[2] and Lesley M. Arnold[3], [1]U. Michigan, Ann Arbor, MI, [2]National Fibromyalgia Association, Anaheim, CA, [3]U. Cincinnati College of Medicine, Cincinnati, OH

Purpose: In 2004, the NIH Roadmap initiative "Patient-Reported Outcomes Measurment Information System" (PROMIS) began its mission to develop the next generation of patient-reported outcomes measures (PROs) for chronic illnesses facilitated by the methods of item response theory (IRT) and computer adaptive testing (CAT). In practice, large banks of well-calibrated items can be drawn upon to measure a given outcome domain (e.g. function). While these item banks were developed to be applied with chronic illnesses generally, the current study sought to assess whether the items within the item banks were relevant to individuals with Fibromyalgia (FM).

Method: 80 females satisfying ACR criteria for FM (mean age=55.1 (sd=11.6)) were recruited from three sites (the Universities of Michigan and Cincinnati and the National Fibromyalgia Association (NFA). Groups of 20 participants were asked to review all items within one of four item banks: (1) Pain impact, (2) Fatigue, (3) Physical functioning, and (4) Emotional Distress (depression, anxiety, anger). Participants completed each item for themselves and then provided a relevancy rating on a 5-point Likert scale ranging from 1- "not at all relevant to FM" to 5-"very relevant to FM" for all items. Participants also completed open-ended questions soliciting suggestions for potential new items with relevance to FM.

Results: On average, the items contained within the Pain Interference and Fatigue banks were rated as being at least "Somewhat relevant" or better (i.e., ratings of 3,4,or 5) 87% of the time – the modal response for each of these banks was "very" relevant. The items within the physical functioning banks were rated as being at least 'Somewhat relevant" or better 64% of the time. For the negative mood banks, "Somewhat" relevant or better ratings were given to 73% of the depressive items, 67% of the anxiety items, and 55% of the anger items.

Conclusion: These data suggest that the majority of the pain and fatigue items already contained within the PROMIS item banks possess relevance for individuals with FM. The relevance of the items contained within the physical functioning and negative mood banks was more limited. In order to optimize PROMIS as a PRO measurement tool in FM, these item banks may require supplementary work.

Fluctuations in Baseline Clinical Pain Intensity Predict Therapeutic Response to Milnacipran in Patients with Fibromyalgia. Steven E. Harte[1], Lynn J. Zwinck[1], R. Michael Gendreau[2], David A. Williams[1], Daniel Clauw[3] and Richard E. Harris[1], [1]U. Michigan, Ann Arbor, MI, [2]Cypress Bioscience, Inc., San Diego, CA, [3]University of Michigan, Ann Arbor, MI

Purpose: Clinical experience and research indicate that the intensity of chronic pain fluctuates over time. Measures of pain variability that characterize these fluctuations may be useful in predicting treatment outcomes in clinical trials (Harris et al., Arthritis & Rheumatism 52, 2005). Patient electronic diaries (PEDs) that capture momentary pain ratings in real-time are a sensitive method of assessing pain variability. In this study, we used PED data to assess the relationship between pain variability and responsiveness to milnacipran treatment in fibromyalgia (FM) patients.

Method: Following a two week baseline (observational) period, FM patients were randomized to receive placebo (n = 223) or milnacipran (n = 665; 100 or 200 mg/day) for 6 months. Subjects carried Palm-based PEDs that prompted them at random intervals between 8 AM-10 PM to enter their current level of pain on a digital 0-100 numerical rating scale. Baseline pain variability was assessed for each participant as the standard deviation of all pain entries during the two week baseline period (pain variability index, PVI). Patient responsiveness to milnacipran was evaluated at 3 and 6 months using the Patient Global Impression of Change (PGIC) scale coded as a binary outcome measure: responder (very improved/improved) vs. non-responder (no change/worsing symptoms). Logistic regression analysis, adjusted for age and sex, was performed to assess the relationship between pain variability and treatment response. A logarithmic transformation was performed to better fit PVI to a normal distribution.

Results: The observed spread in baseline lnPVI values (mean ± SD 2.32 ± 0.48 [range -1.05 – 3.47]) indicates considerable variation in pain intensity across patients. Individuals with greater pain variability (higher lnPVI values) were more likely to be classified as responders to milnacipran when assessed after either 3 or 6 months of treatment (odds ratios ≥ 1.48, all $p < 0.05$). Participants randomized to placebo showed no significant relationships with lnPVI and responder status (all $p > 0.23$).

Conclusion: PEDs revealed that individuals with FM exhibit considerable fluctuations in pain intensity over time. Moreover, patients with greater baseline pain variability were more likely to respond to milnacipran than placebo. These data suggest that pain variability is predictive of treatment efficacy in chronic pain and should be considered in the design of clinical trials.

Tai Chi Is Effective in Treating Fibromyalgia: A Randomized Controlled Trial. Chenchen Wang[1], C. Schmid[1], R. Kalish[1], J. Yinh[1], Don L. Goldenberg[2], R. Rones[1] and T. McAlindon[1], [1]Tufts Medical Center, Boston, MA, [2]Newton-Wellesley Hosp, Newton, MA

Purpose: Fibromyalgia (FM) is a complex disorder best managed with multidisciplinary therapies. It is characterized by widespread musculoskeletal pain, sleep disturbances, functional limitation and poor quality of life. Tai Chi (TC) is an ancient Chinese exercise with an integrated mind-body approach to enhance both physical and mental health, and may be especially suited to the therapy of FM.

Methods: We conducted a 12-week, single-blind, randomized trial of TC (classical Yang style) vs. attention control (stretching and wellness education) for FM (ACR 1990 criteria). The 60-minute group sessions occurred twice-weekly. The primary endpoint was change in the FM Impact Questionnaire (FIQ) score at 12 weeks. Secondary endpoints included tender point count, patient and physician global assessments, sleep quality (PSQI), timed chair stand, 6-minute walk, grip strength, depression, self-efficacy and quality of life. We repeated these measures at 24 weeks to test durability of response. The TC and control groups were compared using an intent-to-treat analysis.

Results: The mean of the age of 66 subjects was 50y (SD 11), disease duration 11y (SD 7), BMI 33 kg/m^2 (SD 8), 85% were female, and 56% were white. There were no significant differences at baseline characteristics. Participants' baseline expectations of benefit from an exercise intervention were similar [TC=3.7 (SD 0.8), controls=3.9 (SD 0.7)]. At 12 weeks, patients assigned to TC exhibited significantly greater improvement in FIQ score [between-group change -17.9, 95% CI [-27.0 to -8.8]; P= 0.0006), patient global assessment, sleep quality, physical function, depression, and health status **(Table)**. The reduction in VAS pain intensity met the definition of a clinically-meaningful

improvement. At week 24, patients who continued TC exhibited durable benefits in FIQ score, sleep quality and quality of life. The two groups did not differ in medication usage. No adverse events were observed.

Conclusion: TC appears highly efficacious for treatment of both physical and psychological components of FM. TC may be a useful adjunctive treatment in the multidisciplinary management of this difficult disorder.

Table. Changes in Primary and Secondary Outcomes

Baseline Characteristics of Fibromyalgia Patients in 4 Clinical Trials of Milnacipran. Robert H. Palmer[1], Daniel Clauw[2], Yves Mainguy[3], Yong Wang[1] and R. Michael Gendreau[4], [1]Forest Research Institute, Jersey City, NJ, [2]University of Michigan, Ann Arbor, MI, [3]Institut de Recherche Pierre Fabre, Labège, France, [4]Cypress Bioscience, Inc., San Diego, CA

Purpose: Milnacipran is approved in the US for the treatment of fibromyalgia (FM) and has shown efficacy for improving pain, patient global status, functioning, and fatigue in clinical trials. This analysis compares the key baseline demographic and disease characteristics of FM patients enrolled in 3 US and 1 European (EU) trials.

Method: These studies were randomized, double-blind, placebo-controlled trials of 3- or 6-month duration. Patient demographics, medical history, and baseline efficacy variables were recorded during a 2-week assessment period prior to randomization. Baseline efficacy variables included measures of pain (current and recall [24-hour, weekly], using a patient experience diary [PED]; visual analog scale [VAS] recorded on paper or wireless Tablet); function (Fibromyalgia Impact Questionnaire [FIQ]; Short Form-36 Health Survey [SF-36]); fatigue (Multidimensional Fatigue Inventory [MFI]); and cognition (Multiple Ability Self-Report Questionnaire [MASQ]).

Results: A total of 3985 FM patients were included in these trials. Most of the patients (>90%) were female and white. Mean ages were similar among all studies (range, 48.8 to 50.2 years). Duration of FM symptoms (mean years) was lowest in 1 US study (5.6) compared with the other 2 US (9.7, 10.8) and EU (9.5) studies. Weight and BMI differed markedly between the EU and US trials. Weight (mean lb) was lower in EU patients (158.0) compared with US (range, 180.8 to 183.0). EU patients were overweight (25≤mean BMI<30), whereas US were obese (mean BMI≥30). Although baseline efficacy values varied among the 4 trials, the EU and US populations were generally similar in terms of scores on pain (PED 24-hour recall: EU 65.3, US 63.7 to 68.9; PED weekly recall: EU 66.3, US 66.1 to 70.7); multidimensional functioning (FIQ: EU 56.9, US 57.3 to 64.6); physical functioning (SF-36 Physical Component Summary: EU 33.6, US 32.2 to 32.9); mental and cognitive functioning (SF-36 Mental Component Summary: EU 46.7, US 41.7 to 46.7; MASQ: EU 86.6, US 89.0 to 92.7); and fatigue (MFI: EU 66.6, US 67.5 to 69.1).

Conclusion: Baseline demographic and disease characteristics of FM patients were generally similar among 4 randomized, placebo-controlled trials of milnacipran. With the exception of body weight, there were no remarkable baseline differences between the US and EU study populations.

Milnacipran 100 Mg/Day in the Treatment of Fibromyalgia: A Randomized, Double-Blind, Placebo-Controlled Trial. Lesley M. Arnold[1], R. Michael Gendreau[2], Allan Spera[3], Judy Gendreau[2] and Yong Wang[3], [1]University of Cincinnati, Cincinnati, OH, [2]Cypress Bioscience, Inc., San Diego, CA, [3]Forest Research Institute, Jersey City, NJ

Purpose: Milnacipran, a dual norepinephrine and serotonin reuptake inhibitor, is approved in the US for the management of fibromyalgia (FM). Previous clinical trials have demonstrated efficacy of milnacipran in FM with doses up to 200 mg/day. This new Phase 3 trial evaluates the efficacy and tolerability of milnacipran 100 mg/day for the management of FM.

Method: This was a double-blind, placebo-controlled trial of 1025 FM patients randomized to milnacipran 100 mg/day (n=516) or placebo (n=509). Patients underwent 4 to 6 weeks of flexible dose escalation followed by 12 weeks of stable-dose treatment and a 2-week randomized, double-blind discontinuation phase. Primary outcomes included 2 composite responder analyses. A 2-measure composite responder was defined as an individual achieving ≥30% improvement from baseline in pain (VAS 24-h morning recall, collected on a patient experience diary [PED]) and a rating of "very much improved" or "much improved" on the Patient Global Impression of Change (PGIC) scale. A 3-measure composite responder met the above criteria for improvements in pain and PGIC as well as a ≥6-point improvement from baseline in physical function (SF-36 Physical Component Summary [PCS] score). Additional efficacy measures included change from baseline in fatigue (Multidimensional Fatigue Inventory [MFI]), pain (Brief Pain Inventory [BPI]), and function (Fibromyalgia Impact Questionnaire [FIQ]).

Results: Completion rates at the end of the stable dose period were 69.2% for milnacipran 100 mg/day and 70.5% for placebo. At 3 months, a significantly greater proportion of patients treated with milnacipran 100 mg/day relative to placebo met 2-measure composite responder criteria ($P<.001$, BOCF) and 3-measure composite responder criteria ($P<.001$, BOCF). Milnacipran-treated patients demonstrated significantly greater improvements from baseline vs placebo on a number of additional endpoint scores (LOCF), including PED 24-h recall pain, PGIC, SF-36 physical component summary and mental component summary, BPI average pain severity, FIQ total (all measures, $P<.001$), and MFI total ($P=.036$). Significant improvements in mean pain scores were observed after 1 week of double-blind treatment and were sustained throughout the stable-dose period ($P<.001$ vs placebo, all visits after 1 week). Milnacipran was well tolerated by the majority of patients; nausea was the most common adverse event (20.8%, placebo; 36.6%, milnacipran).

Conclusion: Treatment with milnacipran 100 mg/day improved FM patients' pain, global status, physical and mental functioning, and symptoms of fatigue. The safety profile was consistent with that observed in previous FM trials of milnacipran.

Milnacipan Improves Physical Function in Patients with Fibromyalgia: Pooled Results From 3 Phase III Trials. Philippe A. Saxe[1], Robert H. Palmer[2], Yong Wang[2] and R. Michael Gendreau[3], [1]Arthritis Associates of S. Florida, Delray Beach, FL, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego, CA

Purpose: Patients with fibromyalgia (FM) suffer from multiple symptoms, including chronic pain, fatigue, sleep disturbances, stiffness, and dyscognition. Health status studies indicate that FM patients have reduced physical, mental, and social functioning compared with the general population and patients with other pain conditions. Milnacipran, which is approved for the management of FM, has been shown in clinical studies to improve the pain and other symptoms of FM for up to 1 year. In this analysis, data from 3 randomized, double-blind, placebo-controlled trials were pooled to further examine the effects of milnacipran on clinically meaningful improvements in physical functioning. Patients in these trials reported their physical function status by using the Medical Outcomes Study Short Form-36 (SF-36), a self-report health status instrument that has been found to be a reliable measure of function in musculoskeletal disorders.

Method: Three-month data were pooled from 3 phase III pivotal studies ranging from 3 to 6 months in duration. Patients were randomized to receive placebo (n=1133), milnacipran 100 mg/day (n=1139), or milnacipran 200 mg/day (n=837). Physical function was measured by using the SF-36 Physical Component Summary (PCS) and the 4 individual physical health domains included in the SF-36: physical functioning, role limitation due to physical health, bodily pain, and general health. SF-36 domain responders were defined as patients with clinically meaningful improvements from baseline (≥5 points) in each physical domain. For SF-36 PCS responders, a more stringent definition for clinically meaningful improvement was used (≥6-point improvement from baseline score). Responder analyses were conducted by using a generalized linear mixed model (GLMM) approach.

Results: Compared with placebo, treatment with either dose of milnacipran was associated with a significantly higher proportion of SF-36 responders. At the 3-month endpoint, SF-36 PCS responder rates were 30% (placebo), 44% (100 mg/day, *P*<.0001), and 40% (200 mg/day, *P*=.009). Significantly more patients receiving milnacipran vs placebo were also responders for SF-36 physical functioning (27%, placebo; 35%, 100 mg/day, *P*=.017; 35%, 200 mg/day, *P*=.024), role limitation (40%, placebo; 50%, 100 mg/day, *P*=.006; 49%, 200 mg/day, *P*=.020), bodily pain (35%, placebo; 49%, 100 mg/day, *P*<.0001; 55%, 200 mg/day, *P*<.0001), and general health (21%, placebo; 29%, 100 mg/day, *P*=.006; 28%, 200 mg/day, *P*=.029).

Conclusion: Pooled results from 3 pivotal studies indicate that compared with placebo, treatment with milnacipran 100 mg/day or 200 mg/day resulted in a significantly greater proportion of patients with clinically meaningful improvements in physical functioning domains in patients with FM.

Disclosure: P. A. Saxe, Forest Laboratories, 2 ; **R. H. Palmer**, Forest Research Institute, 1, Forest Research Institute, 3 ; **Y. Wang**, Forest Research Institute, 3 ; **R. M. Gendreau**, Cypress Bioscience, Inc., 3 .

1410

Effect of Sodium Oxybate On Pain, PGIc, & Composite Scores in Fibromyalgia – Results From a Phase 3 Controlled Trial. I. Jon Russell[1], Sarah Alvarez-Horine[2], Yanping Zheng[2], Diane R. Guinta[2], Andrew J. Holman[3] and Todd J. Swick[4], [1]U TX Hlth Sci Ctr, San Antonio, TX, [2]Jazz Pharmaceuticals, Inc., Palo Alto, CA, [3]Pacific Rheumatology Assoc, Renton, WA, [4]Houston Sleep Center, UT Houston School of Medicine, Houston, TX

Background/Purpose: Fibromyalgia (FM) is characterized by widespread pain, but is often complicated by unrefreshing sleep, chronic fatigue, and psychologic distress. Small studies have demonstrated that sodium oxybate (SXB), a treatment with a novel mechanism of action, has potential for benefit in FM. This 14-week, double-blind, placebo-controlled trial is the largest study to date examining the treatment effects of SXB in FM.

Methods: 548 subjects with FM (per American College of Rheumatology criteria) were randomized to parallel therapy with SXB 4.5g/night (SXB4.5g), 6g/night (SXB6g), or placebo (PBO) in a 1:1:1 ratio. Treatments were administered in equal, divided doses at bedtime and 2.5-4h later. The primary outcome measure was the percent of patients reporting clinically relevant, >=30% reduction in Pain Visual Analog Scale (PVAS). Other measures included the percent of patients reporting >=50% reduction in PVAS, clinically relevant pain responders defined by >=30% reduction in PVAS *plus* “much better” or “very much better” on the patient global impression of change (PGIc), and FM syndrome composite responders defined by pain responders *plus* >=30% reduction in FM Impact Questionnaire (FIQ). Analysis: LOCF.

Results: Treatment with SXB4.5g and SXB6g resulted in significantly more patients reporting clinically relevant >=30% improvement in PVAS versus PBO (54.2% and 58.5%, respectively, vs 35.2%; both p<0.001). This was also true for >=50% improvement in PVAS (44.7% and 43.3%, respectively, vs 22.7%; both p<0.001). Significant reductions in mean PVAS scores were noted in SXB 4.5g and SXB6g compared with PBO at all weekly time points starting as early as week 1 (p<=0.002 for all). Both SXB4.5g and SXB6g resulted in a higher proportion of pain composite responders (42.9% and 49.6% vs 27.6%; p=0.008 and p<0.001, respectively) and FM syndrome composite responders (40.1% and 48.9% vs 26.1%; p=0.013 and p<0.001, respectively). Both SXB4.5g and SXB6g, vs PBO, showed significant improvement for each of 3 individual FM composite endpoints (PVAS, FIQ, PGIc; p-values all <0.01). Strong Pearson correlations for changes in pain were seen with PGIc and FIQ (0.70 and 0.79, respectively, p<0.001). The most common adverse events (AEs) on SXB treatment with incidences greater than 5% and twice the placebo rate were headache, nausea, dizziness, vomiting, diarrhea, anxiety, and sinusitis. The most commonly reported AE was headache (23.1%, SXB 6g).

Conclusion: This Phase 3 trial confirms earlier work (Russell IJ et al, *Arthr Rheum* 2009; 60:299-309) and demonstrated that sodium oxybate was well tolerated and improved pain in FM patients as early as one week after initiation of treatment. In addition, clinically meaningful improvements were noted in composite measures of pain and FM syndrome.

Patterns of Pain-Related Pharmacotherapy and Healthcare Resource Use Among Elderly Patients with Fibromyalgia Prescribed Pregabalin. Mugdha Gore[1], Alesia Sadosky[2], Gergana Zlateva[2] and Daniel Clauw[3], [1]Avalon Health Solutions, Inc., Philadelphia, PA, [2]Pfizer Inc., New York, NY, [3]University of Michigan, Ann Arbor, MI

Purpose: To characterize patterns of pain-related pharmacotherapy and use of healthcare resources among elderly patients (≥65 years old) with fibromyalgia (FM) prescribed pregabalin in clinical practice.

Method: Using the PharMetrics® Patient-Centric Database, elderly patients with FM (ICD-9-CM diagnosis code 729.1X) who were newly prescribed pregabalin (n=98; mean age 72.4±6.4 years; 82% female) on or after July 1, 2007 were identified. Patterns of pain-related pharmacotherapy and healthcare resource use and costs (pharmacy, outpatient, inpatient and total) were examined in these patients during the 6-month periods preceding (pre-treatment) and following (follow-up) the date of the first pregabalin prescription.

Results: On average patients received 3.3 (±2.3) pregabalin prescriptions; the average days of therapy were 121 (±88.9) days. Although patients had a high medication burden in both the pre-treatment and follow-up periods, except for the use of SSRIs which decreased significantly from pre-treatment to follow-up (24.5% vs. 19.4%, p=0.0253), there were no statistically significant changes in use of any of the other medications including NSAIDs (36.7% vs. 32.7%), opioids (54.1% vs. 59.2%), tramadol (17.4% vs. 24.5%), muscle relaxants (18.4% vs. 21.4%), tricyclic antidepressants (21.4% vs. 18.4%), SNRIs (10.2% vs. 12.2%), and anticonvulsants (17.4% vs. 21.4%). There were decreases in the number of physician office visits and total outpatient visits (both p-values <0.01) and in the proportions of patients with visits to physical therapists (21.4% vs. 12.2%, p=0.0201); however there were no changes in healthcare costs (pharmacy, outpatient, inpatient or total) from the pre-treatment to the follow-up period.

Conclusion: Elderly patients with FM in this study were characterized by a high medication burden. Although it is not possible to establish cause-effect relationships in claims database studies, it is interesting to note the decreases in outpatient resource use after initiation of treatment with pregabalin and also that the addition of pregabalin was cost-neutral.

1412

Sodium Oxybate Improves Fatigue, Sleep Disturbance, and PGIc in Fibromyalgia – Results From a Phase 3, 14-Week, Controlled Trial. Philip J. Mease[1], Todd J. Swick[2], Sarah Alvarez-Horine[3], Neil Inhaber[3], Diane R. Guinta[3], Andrew J. Holman[4] and Ij Russell[5], [1]Seattle Rheumatology, Seattle, WA, [2]Houston Sleep Center, UT Houston School of Medicine, Houston, TX, [3]Jazz Pharmaceuticals Inc, Palo Alto, CA, [4]Pacific Rheumatology Assoc, Renton, WA, [5]U TX Hlth Sci Ctr, San Antonio, TX

Purpose: In addition to the hallmark symptom of widespread pain, fatigue and disturbed, unrefreshing sleep are frequent complaints in patients with fibromyalgia (FM) and can lead to significant impairment in daytime function. This Phase III, 14-week, double-blind, placebo-controlled trial examined the effects of sodium oxybate (SXB) on FM symptoms, including fatigue, sleep disturbance, and global status as measured by patient global impression of change (PGIc).

Method: Subjects with FM (548 meeting American College of Rheumatology criteria) were randomized to parallel therapy with SXB 4.5g/night (SXB4.5g), SXB 6g/night (SXB6g), and placebo (PBO) in a 1:1:1 ratio. Treatments were administered as two equal, divided doses at bedtime and 2.5-4 h later. The primary outcome measure was the percent of subjects reporting a clinically relevant, ≥30% reduction on the Pain Visual Analog Scale (VAS) from baseline to week 14. Secondary measures included Fatigue VAS, Jenkins Sleep Scale (JSS; a 4-item, self-report questionnaire for sleep disturbance, range 5-20), and PGIc at week 14. Analysis: LOCF.

Results: Significant reductions in mean Fatigue VAS scores were seen in SXB4.5g and SXB6g vs PBO at week 14 (-27.94 and -30.02, respectively, vs -17.57; both p<0.001) and at all weekly time points as early as week 1 (p<0.01 for all). These improvements paralleled improvements in pain ≥30% reduction in Pain VAS at week 14 (both active doses vs PBO, p<0.001). Compared with PBO, treatment with SXB4.5g and SXB6g resulted in significantly greater reductions in mean JSS scores at week 14 (-6.1 and -6.2, respectively, vs -2.9; both p<0.001) and at all other time points beginning at the first measurement, week 4 (p<0.001 for all). In addition, a significantly greater percentage of subjects receiving SXB4.5g or SXB6g reported clinically meaningful improvement in global status, evidenced by PGIc scores of "much better" or "very much better" vs PBO (48.3% and 45.4%, respectively, vs 27.2%; both p<0.001). Strong Pearson correlations for

changes in pain were seen with Fatigue VAS and JSS (0.89 and 0.51, respectively, p<0.001). The most common adverse events (AEs) on SXB treatment with incidences greater than 5% and twice the placebo rate were headache, nausea, dizziness, vomiting, diarrhea, anxiety, and sinusitis. The most commonly reported AE was headache (23.1%, SXB6g).

Conclusion: In addition to its effect on the hallmark symptom of pain, SXB resulted in clinically meaningful improvement in patient global status as well as measures of fatigue and sleep disturbance, two important symptoms commonly seen in FM. Sodium oxybate was well tolerated, safe, and efficacious in this Phase III trial.

The Effects of Milnacipran On Self-Reported Complaints of Decreased Cognitive Functioning in Fibromyalgia Patients. Alan Manevitz[1], Robert H. Palmer[2], Wei Chen[2] and R. Michael Gendreau[3], [1]Weill Medical College of Cornell University, New York, NY, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego, CA

Purpose: Fibromyalgia (FM) patients report a number of symptoms in addition to chronic widespread pain, including a heterogeneous collection of problems relating to cognitive dysfunction (commonly termed “fibrofog”). Objective measures of cognitive functioning have shown that FM patients show decrements in terms of their attention, susceptibility to distraction, as well as their working and episodic memory (eg, Glass 2008). Irrespective of documented cognitive decrements, many FM patients report experiencing problems with fibrofog. These analyses evaluate the effect of milnacipran on self-reported problems with cognition in patients with FM.

Method: This study was a pooled analysis of data from 3 phase III pivotal studies in FM patients randomized to receive placebo (n=1133), milnacipran 100 mg/day (n=1139), or milnacipran 200 mg/day (n=837). All 3 studies had similar design: following a dose escalation phase, patients underwent 12 weeks of stable dose treatment that included 4 study visits (Visits 1 to 4). Data from 12 weeks of the stable dose phases were pooled and analyzed by visit. Self-reported problems with cognition were measured by using the 38-item Multiple Ability Self-report Questionnaire (MASQ) total and subscale scores. Mean changes from baseline at individual study visits and the 3-month endpoint were analyzed by using a mixed model repeated measures (MMRM) approach.

Results: Patients treated with milnacipran 200 mg/day demonstrated significantly greater improvement than placebo-treated patients at all visits in MASQ total scores (P<.01). Improvements from baseline in MASQ Verbal Memory and Attention subscale scores were significantly greater in patients treated with milnacipran 200 mg/day than placebo at all visits (Verbal Memory, P=.02; Attention, P=.002). Significant improvements were observed with milnacipran 100 mg/day over placebo on the MASQ total score from Visit 1 to Visit 3 (P<.05).

Conclusion: Milnacipran 200 mg/day resulted in significant improvements in self-reported measures of cognitive complaints in patients with FM.

Long Term Therapeutic Response to Milnacipran Treatment for Fibromyalgia. A European 1-Year Extension Study Following a 3-Month Study. Jaime C. Branco[1], Patrick Cherin[2], Michael Späth[3] and Yves Mainguy[4], [1]Hospital Egas Moniz, Lisbon, Portugal, [2]Hopital Pitié Salpêtrière, Paris, France, [3]Facharzt für Innere Medizin, Grafelfing, Germany, [4]Institut de Recherche Pierre Fabre, Labège, France

Purpose: A dose-blinded, 1-year extension study of milnacipran in the treatment of fibromyalgia (FM) was performed in completers of a 3-month European lead-in phase III study of milnacipran 200 mg/day versus placebo.The objectives were to assess the long-term efficacy and safety of milnacipran 100, 150, and 200 mg/day (BID regimen) used for treating FM.

Methods: 468 FM patients completing the lead-in study were enrolled 1 week later, in the extension study. 198 patients were maintained on milnacipran 200 mg/day and patients receiving placebo in the lead-in study were re-randomised to milnacipran 100 (n=91), 150 (n=92) or 200 mg/day (n=87) for an additional 12 months (including a 4-week dose-escalation period). The efficacy endpoint was a 2-measure composite responder rate (using the lead-in study baseline) requiring a reduction by 30% of the weekly-recall pain score on a paper 100-mm visual analogue scale (VAS) and a much or very much improved scoring of Patient Global Impression of Change (PGIC) .The loss of therapeutic response after 3 months was established if seen at 2 further consecutive visits. Other efficacy assessments consisted of pain, quality of life (QoL), fatigue and sleep scores.

Results: All milnacipran doses showed a long-term beneficial effect with endpoint composite responder rates of 27.5%, 31.5% and 32.2% respectively in the 100 mg/day, 150 mg/day and 200 mg/day groups of re-randomised patients, and 35.9% in the milnacipran 200 mg/day throughout group. The greatest increase in the composite responder rate from extension study baseline occurred with milnacipran 200 mg/day, regardless of the lead-in study treatment. The durability of composite response was also the highest in the 200 mg/day groups with 44.1% (throughout group) and 45.2% (re-randomised group) of early responders maintaining their response throughout the treatment period compared with the lower dose groups: 39% (150 mg/day) and 35.3% (100 mg/day). At endpoint, an improvement from lead-in or extension study baseline was shown in all groups on all measures of pain, QoL-physical, fatigue and sleep measures. These improvements were similar in all groups, except a greater effect with 150 and 200 mg/day on mean changes from lead-in study baseline in weekly-recall pain VAS score (-26.5 to -27.9 mm versus

-20.9 mm with 100 mg/day) and in all fatigue and sleep scores.

Over 1 year, all doses of milnacipran were as well tolerated as in the previous 3-month study. The most common drug-related adverse events were hyperhidrosis (22%) and nausea (20%).

Conclusion: Over 1 year, milnacipran 100, 150 and 200 mg/day exhibited sustained efficacy on the multidimensional symptoms of FM, with a safety profile similar to the lead-in study

Treatment Response to Pregabalin in Fibromyalgia: Effect of Patient Baseline Characteristics. T. Kevin Murphy[1], Danielle Lauren Petersel[1], Ed Whalen[1], Birol Emir[1] and Alison Gagnon[2], [1]Pfizer Global Research and Development, New York, NY, [2]UBC Scientific Solutions, Southport, CT

Purpose: Pregabalin has been shown to reduce pain associated with fibromyalgia. The objective of this study was to evaluate the effect of age, depression and anxiety symptoms, duration of disease, and pain at baseline on the magnitude of treatment response to pregabalin in patients with fibromyalgia.

Methods: Data from 4 randomized, multicenter, placebo-controlled clinical studies of pregabalin in patients with fibromyalgia were used for the analysis. Approved doses (300 and 450 mg/d) were pooled to enhance the sensitivity of the interaction tests. Pain was assessed on an 11-point numeric rating scale (0 [no pain]; 10 [worst possible pain]). Treatment response was evaluated using pain change at last observation carried forward. A centered covariate interaction model was used to assess the treatment effects, but a non-centered model was used for estimated mean pain changes and least square means across different levels of baseline covariates. The interaction was considered significant if $P<0.10$. The covariates of mean pain score at baseline, Hamilton Anxiety Scale (HADS-A), and Hamilton Depression Scale (HADS-D), age in years, and duration of fibromyalgia in months were used for analysis.

Results: Among fibromyalgia patients at baseline, the median pain score was 7.0 (range, 1–10; n=2060), median HADS-A total score was 9.0 (range, 0–21; n=2048), median HADS-D total score was 8.0 (range, 0–21; n=2048), median age was 49 years (range, 18–82 y; n=2061), and median duration of fibromyalgia was 83 months (range, 2–656 mo; n=2060). A significant effect on pain was observed for pregabalin versus placebo in patients with fibromyalgia ($P<0.0001$). No significant interaction was observed between treatment and anxiety (HADS-A;

interaction test, *P*=0.654), depression (HADS-D; interaction test, *P*=0.689), or duration of fibromyalgia symptoms (interaction test, *P*=0.100). Significant treatment by baseline mean pain (interaction test, *P*=0.037) and treatment by age (interaction test, *P*=0.051) interactions were observed. For these combined studies, the pregabalin versus placebo differences in pain changes were –0.91 (baseline pain=9) and –0.33 (baseline pain=5). For age, the differences were –0.45 for age=40 and –0.94 for age=70. As a sensitivity analysis, we excluded a European study and found the interaction effects greatly diminished.

Conclusion: In patients with fibromyalgia, the treatment response to pregabalin may not depend on anxiety and depression symptoms or duration of fibromyalgia at baseline. The magnitude of response to pregabalin in terms of changes in pain may depend on age and pain levels at baseline in patients with fibromyalgia. The magnitude of these effects can be substantial; however, results are sensitive to which studies are included in the analyses.

Women Are More Susceptible to Increased Symptoms of Pain, Fatigue, Negative Mood, and Cognitive Dysfunction After Exercise and Sleep Restriction. Jennifer M. Glass[1], Jacob N. Ablin[2], Angela K. Lyden[1], Kirsten Ambrose[3], David A. Williams[1], Daniel Clauw[4] and Cathryn Byrne-Dugan[1], [1]U. Michigan, Ann Arbor, MI, [2]Rheumatology Institute, Tel Aviv, Tel Aviv, Israel, [3]Algynomics, Inc, Chapel Hill, NC, [4]University of Michigan, Ann Arbor, MI

Purpose: Chronic pain disorders such as fibromyalgia sometimes follow a stressful event that disrupts normal sleep and exercise, and nearly all chronic pain disorders are more common in women. We hypothesize that good sleep and routine exercise are necessary to avoid somatic symptoms such as pain, fatigue, and cognitive problems, as well as depressed mood, and that different subsets of healthy individuals have variable effects of lack of sleep and exercise. Previously, we reported such increases after sleep and exercise restriction. Here we present our findings on sex differences in the expression of these symptoms.

Method: Eighty-seven (45 male) healthy adults ages 18-41 years were included who ran at least five times per week and slept 7-9 hours per night. Subjects were randomly assigned to one of four groups: control (normal activity and sleep), exercise deprivation, sleep restriction (6 contiguous hours in bed per night), or both exercise and sleep restriction. The deprivation period lasted 10 days. We assessed symptom development in 5 domains: pain (McGill VAS), mood (CES-D, POMS, STPI-anxiety), fatigue (Multiple Fatigue Index), somatic symptoms (Modified Somatic Perceptions Questionnaire) and cognition (Multiple Ability Self-Report Questionnaire) at baseline and between days 7-8 of the deprivation period. For initial analyses, a Total Symptom change variable was calculated. Effects of sex, sleep, and exercise were entered into examined via ANOVA. Subsequently, similar analyses were carried out for each symptom domain.

Results: Significant effects of sleep restriction ($p = .001$) and sex ($p = .007$) were found for the Total Symptom variable. Sleep restriction resulted in more symptoms, and women were more likely to report increased symptoms. Exercise restriction did not affect Total Symptoms. Examining individual symptom domains, sleep restriction significantly increased all symptom domains ($p = .008$). Exercise deprivation significantly increased symptoms of fatigue ($p = .021$). Women reported more symptoms of negative mood ($p = .016$), cognition ($p = .031$), and somatic complaints ($p = .052$). Women reported increased fatigue after either exercise or sleep restriction; men reported increases only in the combined group ($p = .044$). A similar, but marginally significant pattern was observed for negative mood ($p = .090$).

Conclusion: Significant increases in somatic symptoms and mood were observed after a period of relatively mild sleep restriction. Exercise deprivation was not as potent a stressor in this study. There was a high correlation between symptom domains, suggesting that when symptoms increased in one domain, they increased in all domains. Strikingly, women appear much more susceptible than men to experience these increased symptoms, particularly in the domains of mood, cognition and somatic symptoms.

Cognitive Dysfunction in Fibromyalgia Assessed by the Multiple Abilities Self-Report Questionnaire. David A. Williams[1], Jennifer M. Glass[1], Paloma Barjola[2], Lynn Zwinck[1] and Daniel Clauw[3], [1]U. Michigan, Ann Arbor, MI, [2]Rey Juan Carlos University, Madrid, Spain, [3]University of Michigan, Ann Arbor, MI

Purpose: Individuals with fibromyalgia (FM) often report cognitive difficulties (a.k.a., "fibro-fog"). Studying fibro-fog has been difficult due to several factors: (a) incongruence between objective (i.e., neuropsychological) assessment and self-report, and (b) the inconsistent manifestation of cognitive difficulties across individuals with FM. The current study sought to (a) assess multiple cognitive difficulties within individuals, (b) compare cognitive difficulties in FM with healthy controls (HC)'s, and (c) identify clinical correlates for the various types of cognitive problems. To date, fibro-fog has been hypothesized to be associated with a wide variety of clinical problems (e.g. pain, sleep loss, fatigue, mood etc.).

Method: 101 individuals meeting American College of Rheumatology criteria for FM were compared to 63 HC's. All participants completed the Multiple Abilities Self-report Questionnaire (MASQ), a measure of perceived cognitive difficulties with language, Visual-perception, verbal memory, visual-spatial memory, and attention/concentration. Multiple Analysis Of Variance (MANOVA) was used to compare the MASQ scales between FM and HC. The following clinical correlates of fibro-fog were assessed: age, pain severity (Brief Pain Inventory, (BPI)), fatigue (physical and mental scales of the Multidimensional Fatigue Inventory, (MFI)), sleep problems (MOS sleep index 1), stress (Perceived Stress Scale, (PSS)), trait anxiety and depression (State-Trait Personality Inventory, (STPI). For individuals with FM, correlations were obtained for the MASQ scales and each clinical variable. Clinical variables having significant first order correlations with the MASQ scales were then used in stepwise regression models so as to identify significant and unique clinical contributors to each of the MASQ scales.

Results: MANOVA revealed significant differences between FM and HC on all MASQ scales (Wilk's Lambda=.070, $p<.0001$.). Language problems were significantly associated with physical and mental fatigue, stress, and trait depression. The strongest predictor of language problems was mental fatigue accounting for 16% of the variance. Problems with visual perception were only significantly correlated with stress accounting for 8% of the variance. Verbal memory difficulties were associated with mental fatigue, stress, and trait anxiety. Together, mental fatigue and stress accounted for 45% of the variance. Visual-spatial memory was associated with age, trait depression, and stress. Stress accounted for greatest amount of variance (12%). Attention/concentration was associated with physical and mental fatigue and trait depression; all three made unique and significant contributions accounting for 24% of the variance.

Conclusion: The MASQ is an assessment tool that can capture multiple dimensions of fibrofog which appear to be related to differing constellations of underlying clinical factors.

1418

Improving Internal Locus of Pain Control in Fibromyalgia. David A. Williams[1], Kirsten Ambrose[2], Linda Skalski[3], Jordana Muroff[4], Lynn Zwinck[1] and Daniel Clauw[5], [1]U. Michigan, Ann Arbor, MI, [2]Algynomics, Inc., Chapel Hill, NC, [3]Duke University, Durham, NC, [4]Boston University, Boston, MA, [5]University of Michigan, Ann Arbor, MI

Purpose: Interventions for pain typically target sensory (e.g. nociceptive) or affective aspects of pain with little to no emphasis on altering cognitive aspects of pain. One cognitive factor, "a perceived ability to control pain" holds clinical relevance across many pain conditions. An internal locus of pain control (I-loc) refers to a belief in pain being an experience that can be modified through personal effort. Actual life experiences may support such beliefs (e.g., success in using behavioral coping skills for pain). An external locus of control such as believing that powerful doctors (PD-loc) or chance events (C-loc) control the experience of pain are more common among individuals with pain. For many diseases including chronic pain, possession of a strong (I-loc) is associated with better outcomes. This study sought to improve (I-loc) in a sample of individuals with FM.

Method: 72 females satisfying ACR criteria for FM (mean age=45.5, (SD=9.9)) were randomly assigned to one of three treatment arms: Exercise (exc), Relaxation (rlx), or standard care (std). Manualized exercise or relaxation sessions consisted of 1 face-to-face session with a therapist who followed patients by scheduled telephone contact over 8 weeks. Baseline and 12-week endpoint evaluations included the following: the Beliefs in Pain Control Questionnaire (BPCQ), the Brief Pain Inventory, and the SF-36. Within subject and between group

comparisons were made using ANCOVA with the baseline value of the dependent variable serving as the covariate. Responders to treatment were defined as individuals demonstrating a minimal clinically important difference on I-loc (i.e., improving >=0.5 SD).

Results: While no differences existed between groups at baseline, ANCOVA revealed significant group differences in (I-loc) at post treatment $F_{(2,68)}$=3.14, p<.05. I-loc was significantly more improved for the exercise arm than for std care but not different from the relaxation arm. Responders were identified in each arm at differing rates: std: 17%; exc: 42%; rlx: 33%. In comparisons of responders with non-responders from any treatment, ANCOVAs revealed that even though pain severity was not different, I-loc responders had significant reductions in the number of painful body regions ($F_{(1,69)}$=4.53, p<.05) at post treatment.. Responders also demonstrated significant improvements in physical functional status as assessed by the SF-36 PCS score ($F_{(1,69)}$=6.55, p<.01). Improvement in I-loc was not associated with change on any of the indices of affect.

Conclusion: I-loc, a belief in personal pain control, is modifiable through brief non-pharmacological approaches such as exercise and relaxation. Bolstering the belief in I-loc appears to influence pain by influencing perceptions of illness impact rather than symptom severity in individuals with FM.

1419

Neurobiological Correlates of Spontaneous Chronic Pain Variability. Richard Harris[1], Daniel Clauw[2], Eric Ichesco[1], Michael Geisser[1] and David A. Williams[1], [1]U. Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

Purpose: Spontaneous large fluctuations in pain intensity are commonly seen in some individuals with fibromyalgia (FM), whereas others have more stable pain over time (Harris et al. Arthritis and Rheumatism 2005). Variability in chronic pain intensity has features of a trait in that it is fairly stable over long periods. However little is known about either the psychological correlates or the underling neuronal mechanisms of this characteristic. Here we couple functional magnetic resonance imaging (fMRI) and "real-time" assessment of chronic pain in individuals with FM to examine neurobiological factors associated with pain variability.

Methods: 20 individuals with FM who were receiving standard medical care participated in the study. Pain intensity levels were captured in real-time over 60 days by participants using electronic Palm-based diaries. Variability in pain was determined as being the standard deviation of pain entries over time (Pain Variability Index:PVI). Participants also underwent a single fMRI session wherein multiple pressures were applied to the thumbnail bed in pseudo-random order. Images were pre-processed with SPM2 and resulting contrast images ($2kg/cm^2$ pressure vs. no touch) were analyzed. Catastrophising and beliefs in personal pain control were also incorporated as predictors of PVI in a regression model using SPSS v.17.

Results: After controlling for age and pain severity, greater PVI was associated with more catastrophising (beta: 2.28, p=0.04) and lower internal locus of control (beta: -0.41, p=0.057). Higher PVI was also associated with reduced pain activation within the periaqeductal grey (PAG: r=-0.53, p=0.01), amygdala (r=-0.56, p=0.005), dorsal anterior cingulate (r=-0.51, p=0.01), and the primary somatosensory cortex (r=-0.61, p=0.002). Within the PAG region, greater pain evoked neural activity was associated with greater internal locus of control (r=0.34, p=0.03) and lower external locus of control (chance: r=-0.36, p=0.02; powerful doctors: r=-0.39; p=0.01).

Conclusion: These data suggest that individuals with FM who have highly variable pain differ from those who do not in that they have: 1) higher levels of catastrophising and lower internal locus of pain control, and 2) different neuronal activation patterns on fMRI, especially in regions such as the PAG which modulate descending analgesic pathways. Future studies are needed to replicate these findings.

A Randomized, Double-Blind, Placebo-Controlled Trial of Dolasetron, a 5-HT(3) Receptor Antagonist, in Patients with Fibromyalgia. Pascale Vergne-Salle[1], Philippe Bertin[1], Carine Dufauret-Lombard[1], Christine Bonnet[1] and Richard Treves[2], [1]University Hospital, Limoges, France, [2]Chu Dupuytren, Limoges Cedex, France

Purpose: the purpose of the study was to evaluate the efficacy and safety of dolasetron for symptomatic relief of pain associated with fibromyalgia (FM) meeting the American College of Rheumatology criteria.

Method: This prospective, double-blind, placebo-controlled trial randomly assigned 60 patients with FM to receive placebo (n=31) or dolasetron (n=29) at the dose of 12.5 mg/d to intravenous route for 4 days in a intermittent way at month 0 (M0), one month (M1), two months (M2) and three months (M3) with a follow-up until 12 months. The primary outcome variable was the reduction of pain intensity measured by visual analog scale (VAS) between M0 and M3. The secondary outcome variables were reduction of pain intensity between M0 and the follow-up visits at M4, M6 and M12, the patient global impression of change (PGIC), the fibromyalgia impact questionnaire, assessments of quality of life (SF-36), the hospital anxiety and depression scale, the manual tender point count and the functional symptoms associated with FM.

Results: reduction in pain intensity at M3 was significantly greater in dolasetron-treated patients (p=0.04, -21.3 on a 0-100 scale) compared with placebo-treated patients (-5.9). More patients in the dolasetron group had ≥30% and ≥50% improvement in pain (42.5% and 28% respectively in the dolasetron group versus 25% and 16% in the placebo group). The pain intensity measured by VAS more decreased in the follow-up visits M4, M6 and M12 in the dolasetron group compared with placebo. The PGIC was significantly greater in the dolasetron group at M3 (p=0.02). The other secondary outcomes failed to reach statistical significance. The most common adverse events were constipation, nausea, dizziness and headache without difference between the two groups.

Conclusion: dolasetron to intermittent intravenous route was safe and efficacious for the treatment of pain associated with FM at three months with persistence of beneficial effects after treatment.

1421

A Randomized, Double-Blind, Placebo-Controlled Clinical Trial of Milnacipran 100 Mg/Day for the Management of Fibromyalgia: Results From a 2-Week Discontinuation Phase. Philippe A. Saxe[1], Lesley M. Arnold[2], R. Michael Gendreau[3], Allan Spera[4], Judy Gendreau[3] and Yong Wang[4], [1]Arthritis Associates of S. Florida, Delray Beach, FL, [2]University of Cincinnati, Cincinnati, OH, [3]Cypress Bioscience, Inc., San Diego, CA, [4]Forest Research Institute, Jersey City, NJ

Purpose: A randomized controlled trial in fibromyalgia (FM) patients demonstrated significant improvements with milnacipran (MLN) 100 mg/d vs placebo (PBO) in measures of pain, global status, and physical function. Patients completing 12 weeks of stable-dose treatment were rerandomized to a 2-week, double-blind, placebo-controlled discontinuation phase to assess durability of efficacy and possible withdrawal effects of MLN 100 mg/d.

Method: Patients completing the stable-dose phase were assigned to a discontinuation phase where patients initially assigned to PBO remained on PBO (n=359) and patients treated with MLN 100 mg/d were rerandomized and switched to PBO (n=178) or maintained on MLN 100 mg/d (n=178). Efficacy assessments included changes during the discontinuation phase in 24-h recall pain (e-diary), Patient Global Impression of Change (PGIC), SF-36 Physical Component Summary (PCS), Fibromyalgia Impact Questionnaire (FIQ), Brief Pain Inventory (BPI), Multidimensional Fatigue Inventory (MFI), and Multiple Ability Self-Report Questionnaire (MASQ).

Results: 715 patients entered the discontinuation phase; 5 patients discontinued before the final study visit (2 PBO; 2 MLN rerandomized to PBO; 1 continuing on MLN). Two weeks after removal of active drug, the proportion of 3-measure composite responders (≥30% improvement in 24-h recall pain; PGIC ≤2; and ≥6-point improvement in SF-36 PCS) was significantly reduced in patients rerandomized from MLN to PBO compared with patients maintained on MLN ($P<.05$). Patients rerandomized from MLN to PBO had an 11.4% increase in 24-h recall pain scores during the discontinuation phase compared with 5.2% and 3.2% increases for patients remaining on MLN or PBO, respectively. Patients rerandomized to PBO also had at least a 2-fold worse change in BPI average pain, PGIC, FIQ, SF-36 PCS, MFI, and MASQ scores than patients remaining on PBO or MLN. In patients discontinuing MLN and rerandomized to PBO, supine systolic blood pressure returned to prestudy baseline values, diastolic blood pressure returned to within 1 mm Hg, and pulse returned to within 4 bpm; values for patients continuing with MLN treatment remained unchanged. Incidences of newly-emergent adverse events (NEAE) were lower in patients discontinuing MLN (16.3%) than in patients remaining on MLN (18.0%) or PBO (19.2%). On abrupt discontinuation of MLN, no NEAE occurred in ≥2% of patients.

Conclusion: Patients discontinuing milnacipran experienced a loss of therapeutic effect in multiple efficacy parameters, including the proportion of 3-measure composite responders compared with patients maintained on milnacipran. Abrupt withdrawal of milnacipran did not appear to result in new safety concerns in this study.

Milnacipran's Effect On Body Weight by Baseline BMI: Results Across 3 Randomized, Double-Blind, Placebo-Controlled Fibromyalgia Trials. Lesley M. Arnold[1], Robert H. Palmer[2], Michael R. Hufford[3] and Wei Chen[2], [1]University of Cincinnati, Cincinnati, OH, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego

Purpose: Fibromyalgia (FM) is a chronic disorder characterized by widespread pain and other symptoms which impair physical function and adversely impact quality of life. Obesity is a common comorbid condition in FM. Weight gain in overweight or obese patient populations can exacerbate negative health effects and adversely affect patients' willingness to continue therapy. Using data from 3 randomized, double-blind, placebo (PBO)-controlled trials, this analysis evaluated the effects of milnacipran (MLN), an FDA-approved medication, on body weight in FM patients stratified by baseline body mass index (BMI).

Method: Baseline BMI and between-group comparisons of 3-month weight change data were analyzed individually from 3 FM studies (Study 1, N=888; Study 2, N=1196; Study 3, N=1025). In Studies 1 and 2, patients were randomized to PBO, MLN 100 mg/d, or MLN 200 mg/d; in Study 3, patients were randomized to PBO or MLN 100 mg/d. Least squares (LS) mean changes in weight (observed cases) were analyzed over 3 months. LS mean weight change at 3 months was also analyzed after pooling the 3 studies and stratifying weight change by baseline BMI subpopulations (ie, underweight to normal weight [BMI<25], overweight [25≤BMI<30], and obese [BMI≥30]).

Results: In all 3 studies, FM patients' mean baseline BMI exceeded the threshold for obesity (baseline BMI: 30.5, Study 1; 30.6, Study 2; 30.9, Study 3). MLN treatment was associated with statistically significant LS mean weight loss relative to PBO at 3 months in all 3 studies (Study 1: +0.9 lb, PBO; -2.4 lb, MLN 100; -2.2 lb, MLN 200; both doses vs PBO, $P<.001$; Study 2: -0.6 lb, PBO; -2.3 lb, MLN 100; -1.8 lb, MLN 200; both doses vs PBO, $P<.05$; Study 3: -0.5 lb, PBO; -2.3 lb, MLN 100; $P<.001$ vs PBO). In each study, nausea rates were consistently lower in MLN-treated patients who lost weight compared with those who did not lose weight, although differences were not significant (all studies, $P>.09$). In the pooled analysis at 3 months, MLN-treated patients who were in the overweight or obese BMI categories at baseline lost statistically significant amounts of weight compared with PBO (Overweight: -0.1 lb, PBO; -2.5 lb, MLN 100; -1.8 lb, MLN 200; both doses, $P<.05$ vs PBO; Obese: -0.5 lb, PBO; -3.0 lb, MLN 100; -2.4 lb, MLN 200; both doses, $P<.01$ vs PBO). MLN-treated patients who were in the underweight to normal BMI categories did not lose a statistically significant amount of weight compared with PBO (0.0 lb, PBO; -0.8 lb, MLN 100; -1.0 lb, MLN 200; both doses, $P>.12$ vs PBO).

Conclusion: Baseline BMI exceeded the threshold for obesity in each of the 3 studies. MLN treatment for 3 months resulted in weight loss across all 3 studies, with MLN-treated patients who were overweight or obese at baseline showing modest, but statistically significant amounts of weight loss compared with patients on PBO.

Milnacipran Improves Fatigue in Fibromyalgia: Pooled Analyses From 3 Randomized, Placebo-Controlled Clinical Trials. Philip Mease[1], Robert H. Palmer[2], Yong Wang[2] and R. Michael Gendreau[3], [1]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego, CA

Purpose: Fibromyalgia (FM) is a chronic disorder that includes symptoms beyond widespread musculoskeletal pain. Fatigue is one of the most common complaints in FM patients. Milnacipran, a dual reuptake inhibitor of serotonin and norepinephrine, is approved by the US FDA for the management of FM. This current analysis further evaluates the effect of milnacipran on fatigue in patients with FM.

Method: Fatigue data were pooled from 3 phase III pivotal studies (3 to 6 months) in FM patients randomized to receive placebo (n=1133), milnacipran 100 mg/day (n=1139), or milnacipran 200 mg/day (n=837). All studies had similar design: following a dose escalation phase, patients underwent 12 weeks of stable dose treatment that included 4 study visits (Visits 1 to 4). Data from 12 weeks of the stable dose phases were pooled and analyzed by visit. Fatigue was measured by using the Multidimensional Fatigue Inventory (MFI) total score and subscale scores (general fatigue, mental fatigue, physical fatigue, reduced activity, reduced motivation) and the Fibromyalgia Impact Questionnaire (FIQ) fatigue items (6 and 7). Mean changes from baseline were analyzed by using a mixed model repeated measures (MMRM) approach.

Results: Patients treated with milnacipran 100 and 200 mg/day demonstrated significant improvements at all visits in MFI total score compared with placebo ($P<.01$). Additionally, all MFI subscale scores were significantly improved at endpoint (Visit 4) in patients treated with milnacipran 200 mg/day compared with placebo (general fatigue, $P=.005$; mental fatigue, $P<.001$; physical fatigue, $P=.001$; reduced activity, $P=.03$; reduced motivation, $P<.001$). Milnacipran 100 mg/day was associated with significant improvements vs placebo in general fatigue ($P=.04$), physical fatigue ($P=.002$), and reduced motivation ($P=.002$) scores. FIQ fatigue scores (items 6 and 7) were significantly improved at all visits in patients treated with milnacipran 100 mg/day compared with placebo ($P<.01$); milnacipran 200 mg/day significantly improved FIQ fatigue over placebo (item 6) at Visit 2 and Visit 4 ($P<.01$), and FIQ fatigue (item 7) from Visit 2 through Visit 4 ($P<.01$).

Conclusion: Among patients with FM, 3 months of milnacipran treatment resulted in significant improvements relative to placebo in multiple dimensions of their fatigue. Milnacipran may be effective in treating symptoms of fibromyalgia beyond pain, including fatigue.

Towards Development of Fibromyalgia Responder Index: Identifying Responders Using Patients Global Assessment. Lesley M. Arnold[1], Gergana Zlateva[2], Alesia Sadosky[2], Birol Emir[2], Ed Whalen[2] and Gayle Scott[3], [1]University of Cincinnati, Cincinnati, OH, [2]Pfizer Inc, New York, NY, [3]UBC Scientific Solutions, Southport, CT

Purpose: The Fibromyalgia (FM) Working Group of OMERACT is developing an FM responder index. Towards that objective, we conducted an analysis of pooled data from pregabalin fibromyalgia trials to determine what FM domains drive patients' perception of improvement.

Method: Data from 3 double-blind, placebo-controlled trials of pregabalin monotherapy (13-14 weeks) in FM conducted in North and South America, Europe, and Asia were pooled for this analysis. We analyzed changes in independent variables, including the Short-Form 36 (SF-36) health survey scale, Medical Outcomes Study (MOS) sleep scale, sleep quality score from the daily sleep diary, pain score from the daily pain diary, Fibromyalgia Impact Questionnaire (FIQ), and Multidimensional Assessment of Fatigue (MAF) as predictors of outcome on the dependent variable PGIC. Correlation analysis was used to assess the strength and direction of relationship between the independent variables and PGIC. Cluster analysis was conducted using Hoeffding's D similarity measure to identify dependencies or clustering among variables. Finally, a LASSO (least absolute shrinkage and selection operator) technique was used to derive rank order among the independent variables most highly related to changes in PGIC.

Results: 1664 patients were included in the intention-to-treat population of these pooled analyses. More than 90% were white women, and mean age was 49 years. In each of the treatment groups (pregabalin 300 mg/day, 450 mg/day, and placebo), improvement in PGIC at endpoint showed highest correlation with improvement in pain, fatigue, sleep, and work and physical function ($0.4< r <0.6$). Mood, emotional and social functioning generally had smaller correlation with PGIC ($0.3 < r <0.4$). When pooled, the combined treatment groups showed similarly moderate correlation between PGIC and pain, fatigue, sleep, and function. Cluster analysis identified 5 main clusters of symptoms in FM patients at endpoint: emotion, function, tiredness, pain, and sleep. LASSO analysis ranked 3 pain variables (pain diary score, FIQ Pain, and SF-36 Bodily Pain) as the most important variables explaining variability in PGIC, followed by MAF Global Fatigue

Index, MOS Sleep Disturbance, FIQ Feel Good, SF-36 Vitality and FIQ Rested domains. LASSO results were similar by dose and across the pooled analysis.

Conclusion: Patients' response to FM treatment was driven by improvement of multiple domains. Pain, fatigue and sleep associate most strongly with improvement in PGIC. Physical and work-related function also correlate with patients overall assessment of improvement. These domains and their respective outcome measures can be used in the development of a responder index.

Assessment of Pregabalin Utilization in Patients with Fibromyalgia at a University-Based Rheumatology Clinic. William Lai[1], Sean Barnes[1], Yingxue Zhang[1], Kevin V. Hackshaw[1] and Thomas Wolfe[2], [1]The Ohio State University Medical Center, Columbus, OH, [2]Pfizer US Medical Affairs and The Ohio State University College of Pharmacy, OH

Purpose: To describe the utilization of Pregabalin in the management of FMS and whether the use of FMS approved medications improves patient care as assessed by changes in concomitant medications, opiate use, and fibromyalgia impact scores.

Method: A retrospective cohort study of adult patients with a diagnosis of FMS on one or more encounters and treated with Pregabalin. Changes in concomitant medications over time were assessed from the Pregabalin Index Date to present or to the discontinuation of Pregabalin. Changes in concomitant medications were assessed for patients with more than 1 office visit (89).

Results: A total of 185 patient records (89% female) were reviewed. Most patients had diagnosis of FMS for more than one year (78%). Pregabalin mean daily dose increased from baseline to follow-up, 82.3 ± 61.3 vs. 197 ± 141 ($p<0.001$), with 68% of patients experiencing a dose increase. A majority of patients were taking multiple medications (74%). Utilization of concomitant therapies increased from baseline to follow-up (0.94 ± 0.97 vs 1.64 ± 1.04, respectively, $p<0.001$). Current therapy in all patients consisted of 2.4 ± 1.2 (0-5) medications per patient. Concomitant medication changes occurred in 95 patients (51.4%). Of the patients currently on Pregabalin, fewer patients had discontinuation of concomitant medications vs. initiation of new medications (48 vs. 76, respectively). SNRI and muscle relaxants were the most common medications added. Concomitant opiate use was more common in patients on high dose (≥ 300 mg/day) Pregabalin compared to low dose (47.8% vs. 21.2%, $p=0.014$). The number of concomitant medications was numerically higher in the high dose Pregabalin group (1.96 vs. 1.53, $p=0.093$). Patients initiated on Pregabalin at the Rheumatology clinic were more likely to be on low dose compared to patients on Pregabalin prior to clinic visit (72.9% vs. 41.7%, $p=0.003$). The number of concomitant medications (1.66 vs 1.92, $p=0.267$) and concomitant opiate use (27.1% vs 25%, $p=0.833$) was not different between those initiated on Pregabalin at the Rheumatology clinic compared to those on prior. Ninety-seven patients (83%) had documentation of symptom relief with Pregabalin. FIQ information was available in 85 patients (physical function score 1.29 ± 0.76 (0-3)). For patients with multiple FIQ scores, mean scores were not statistically different between time periods (68 ± 15.6 vs. 64.6 ± 10.6 $p=0.198$).

Conclusion: Concomitant medication use was common with increased utilization overall from baseline despite taking pregabalin. Discontinuation of concomitant medication is not common. The total number of concomitant medications was not significantly different regardless of where pregabalin was initiated. Relatively low doses of Pregabalin were used. Concomitant use of SNRI and muscle relaxants appeared to increase the most. Patients not on pregabalin when they visited Rheumatology clinic were likely to be on an opiate already.

Pregabalin-Long-Term Follow-up in Treatment of Fibromyalgia Syndrome (FMS). Micha Abeles[1] and Aryeh M. Abeles[2], [1]University Connecticut Health Ctr, Farmington, CT, [2]University of Connecticut Health Center, Farmington, CT

Purpose: Long-term studies regarding the usefulness of pharmacological therapy in FMS are lacking. We compared pregabalin to conventional treatment in fibromyalgia patients and found that although response rate was somewhat better with pregabalin, when accounting for patient dropout due to side effects, there appeared to be no advantage to pregabalin over a 12 week period. The purpose of this study was to monitor the responders to treatment in the original study over an extended period of time to evaluate for persistence of response.

Method: Randomization in the original cohort was done by placing every other patient who presented with FMS on pregabalin or routine therapy (defined as medication chosen by treating physician preference). Evaluation was done utilizing the Fibromyalgia Impact Questionnaire (FIQ), Hospital Anxiety and Depression Scale, and visual analogue scale (VAS). The primary endpoint was a comparison of the FIQ global score and the VAS. In the long- term follow-up, the FIQ global score and VAS were the primary endpoints. Response was considered to be clinically meaningful if there was a 30% or greater improvement from baseline. This was a prospective non-blinded and unfunded study.

Results: 18 of the original 68 pregabalin responders patients and 16 of 66 of the original comparator responders patients entered the long term observational phase of the study. All patients were female. Other characteristics of the subgroup included average age of 53 in the pregabalin and 51 in the comparator groups, average fibromyalgia duration of 6 and 7.2 years duration respectively and predominance of white (80%) and the remainder Hispanic (20%). Therapy in the comparator group included duloxetene (3), gabapentin (2), tricyclics (nortriptyline or amitriptyline), (5) tramadol (5), and hydrocodone (2). At the end of one year, 16 of 18 pregabalin but only 6 of 16 comparator patients were still on the same medication.

Conclusion: Although pregabalin appeared to be equivalent to standard of care therapy in a short-term observational study, when responders are followed for a prolonged period of greater than one year, pregabalin's efficacy appears to persist whereas there is loss of efficacy in standard treatment therapy. Despite this is being an observational uncontrolled and unblinded study, our observations suggest that pregabalin may offer an advantage over standard therapy when prolonged use is indicated; further study comparing the long-term efficacy of individual drugs (or combinations of drugs) in a blinded fashion is warranted.

Inadequately Managed Depression in Fibromyalgia Drives Referral to Specialists. MA Fitzcharles[1], Marta Ceko[2], Ann Gamsa[2], Mark A. Ware[2] and Yoram Shir[2], [1]MGH, Montreal, QC, [2]McGill University, Montreal, QC

Purpose: Although the cornerstone for diagnosis of FM is pain, mood disorders are reported to occur frequently in these patients. Recognition and appropriate management of mood may impact on suffering and quality of life in FM patients, and may be a factor contributing to poor response to standard treatments. We have evaluated the frequency of depression and treatments thereof, in FM patients newly referred to a tertiary care centre.

Method: Demographic, disease related variables and measurements for functional status (fibromyalgia impact questionnaire, FIQ), mood (arthritis impact measurement scale, AIMS), and pain catastrophizing (pain catastrophizing scale, PCS) were recorded for FM patients newly referred. Depression was defined on the AIMS depression scale as 4 or greater. Using this cut-off, comparisons were made between depressed (D) and non-depressed (ND) subjects with respect to selected variables. Univariate comparisons of continuous variables were made using Student's t-tests, and for categorical variables using chi-squared tests. Logistic regression was used to model the association between age, gender, pain duration, catastrophizing, disability and pain intensity.

Results: 137 consecutively attending FM patients referred to a multidisciplinary clinic were evaluated. Depression (D) vs. no depression (ND) was present in 110 (80%) vs 27 (20%). No differences between groups (D vs ND) were noted for age (48 vs. 46 yrs), employment status (32 vs.42%), disability status (35 vs 37%) or pain intensity VAS (6.6 vs 6.0). D vs ND had longer disease duration, 12.2 vs 7.3 years (P=0.03), scored higher for pain catastrophizing, 30 vs. 21.5% (P=0.002), anxiety 6.6. vs 5.5% (P=0.05), and total FIQ 65 vs. 57% (P=0.048). After adjusting for other covariates, duration of pain was the only factor associated with depression in multivariate analysis, adjusted OR 1.11, 95% CI 1.03, 1.19). Use of any antidepressant for D vs ND was 48% vs. 63% (p=0.2), with tricyclic antidepressant (TCA) use in 19 vs 44% (P=0.006) and non-TCA use in 39% vs. 22% (P=0.024).

Conclusion: Important depression was identified in 80% of FM patients. Of greater concern was the lack of any treatment to address depression in more than 50% of depressed patients, with the remainder treated for depression but mostly with inadequate effect. TCA use in the ND reflects treatment patterns for FM pain and sleep, rather than use for mood effect. Prolonged pain duration was independently associated with depression. Poorly controlled depression may be an important factor driving referral of FM patients for specialist consultation.

Sex Differences in Predictors of Increased Symptoms After Exercise and Sleep Restriction. Jennifer M. Glass[1], Jacob N. Ablin[2], Angela Lyden[1], Kirsten Ambrose[3], David A. Williams[1], Richard Gracely[4] and Daniel Clauw[5], [1]U. Michigan, Ann Arbor, MI, [2]Rheumatology Institute, Tel Aviv, Tel Aviv, Israel, [3]Algynomics, Inc, Chapel Hill, NC, [4]U. North Carolina, Chapel Hill, NC, [5]University of Michigan, Ann Arbor, MI

Purpose: Chronic pain disorders such as fibromyalgia are often precipitated by an event that prevents normal sleep and exercise. We hypothesize that sleep restriction and exercise deprivation can act as stressors, and that neurobiological factors can predict if an otherwise healthy individuals will respond to such stress with an acute increase in symptoms of pain, fatigue, cognitive problems and negative mood. Previously, we reported preliminary results where heart rate variability (HRV) measures were significantly correlated with symptoms after sleep and exercise restriction. Here, we report our findings on sex differences in the relationship between HRV and increased symptoms.

Method: Eighty-seven (45 male) healthy adults ages 18-41 years were included who ran at least five times per week and slept 7-9 hours per night. Subjects were randomly assigned to one of four groups: control (normal activity and sleep), exercise deprivation, sleep restriction (6 contiguous hours in bed per night), or both exercise and sleep restriction. The deprivation period lasted 10 days. At baseline, HRV was measured via 24 hour holter readings. We assessed symptom development in 5 domains: pain (McGill VAS), mood (CES-D, POMS, STPI-anxiety), fatigue (Multiple Fatigue Index), somatic symptoms (Modified Somatic Perceptions Questionnaire) and cognition (Multiple Ability Self-Report Questionnaire) at baseline and between days 7-8 of the deprivation period. For initial analyses, a Total Symptom change variable was calculated. Pearson product moment correlations were calculated to assess the association between baseline HRV and changes in symptoms.

Results: Sleep restriction led to increased symptoms across domains (reported separately). However, not all subjects reported increased symptoms. Total Symptom change ranged from -12 to +11. Women were more likely (65%) to report increased symptoms than men (40%). Among men, strong negative correlations were observed between Total Symptom Change and 24-hr total power (TP; $r = -.579$) as well as 24-hr ultra low frequency (ULF; $r = -.628$). Among women, there were no significant correlations between Total Symptom Change and any HRV measure (r values $< -.180$). Among men, all 5 individual symptom domains were significantly correlated with both TP and ULF (r values between -.388 and -.599).

Conclusion: We have shown that sleep restriction leads to increased symptoms of pain, fatigue, mood, cognition, and somatic complaints, especially among women. Somewhat paradoxically, neurobiological measures of autonomic nervous system function were only correlated with increased symptoms in men. However, our results are consistent with previous research on heart rate reactivity and variability to painful stimuli that suggest dramatically different sympathetic regulation of pain in men and women.

The Effects of Nabilone On Insomnia in Fibromyalgia: Results of a Randomized Controlled Trial. MA Fitzcharles[1], Yoram Shir[2], Lawrence Joseph[3] and Mark A. Ware[2], [1]MGH, Montreal, QC, [2]McGill University, Montreal, QC, [3]MUHC, Montreal, QC

Purpose: Fibromyalgia (FM) is a chronic pain syndrome with generalized tender points. Insomnia affects over 75% of patients with FM, and tricyclic antidepressants are the mainstay of treatment. Cannabis has been used by patients with FM to help sleep. We evaluated nabilone, a synthetic cannabinoid, for insomnia in FM.

Method: We conducted a randomized double-blind active control equivalency crossover trial to compare nabilone (0.5-1.0mg qHS) to amitriptyline (10-20mg qHS) in FM patients with chronic insomnia. Subjects received each drug for two weeks with a two-week washout. The primary outcome was sleep quality using the Insomnia Severity Index (ISI) and the Leeds Sleep Evaluation Questionnaire (LSEQ); secondary outcomes included pain, mood, quality of life and adverse events (AEs).

Results: Thirty-one subjects were enrolled and 29 completed the trial (26 female, mean age 49.5y). While sleep was improved by both nabilone and amitriptyline, nabilone was superior to amitriptyline (ISI difference=3.2, 95%CI 1.2-5.3). Nabilone was marginally better on the restfulness LSEQ sleep quality scale (difference=0.5 (0.0-1.0) but not on wakefulness (difference=0.3 (-0.2, 0.8)). Adverse events were all mild-moderate and were more frequent with nabilone (102) than amitriptyline (53). Most common AEs for nabilone were dizziness (10), nausea (9) and dry mouth (7).

Conclusion: Nabilone is effective in improving sleep in patients with FM and is well tolerated. Low dose nabilone given once daily at night may be considered as an alternative to amitriptyline. Longer trials are needed to determine the duration of effect and to characterize long-term safety.

Pregabalin Efficacy in Treatment of Refractory Pain in Fibromyalgia. Brett R. Stacey[1], T. Kevin Murphy[2], Birol Emir[2], Suzanne Giordano[2] and Vardit Dror[3], [1]Oregon Health & Science University, Portland, OR, [2]Pfizer Global Research and Development, New York, NY, [3]UBC Scientific Solutions, Southport, CT

Purpose: Fibromyalgia (FM) is a chronic musculoskeletal pain disorder. Pain associated with FM can be intractable and may not respond to commonly-used treatments, such as tricyclic antidepressants (TCAs) and opioids. This is an analysis of a long-term, open-label study evaluating pregabalin response in the subset of patients with FM whose pain had been judged refractory to other treatments.

Method: Patients had previously participated in a double-blind, placebo-controlled, randomized trial of pregabalin[1] and had moderate to severe pain despite treatment with gabapentin, a TCA, and a third medication (e.g., other anticonvulsants, opioid, SSRI, tramadol). Patients were allowed to take other pain medications during the study. Flexible-dose pregabalin 150-600 mg/day was added for 3-month treatment cycles, each followed by 3- to 28-day pregabalin "drug holiday" that lasted until a relapse occurred. Once the patient completed 4 relapse visits, no additional drug holidays were required. Pain intensity was measured using the visual analogue scale of the Short-Form McGill Pain Questionnaire (SF-MPQ pain VAS) completed at baseline, the end of each 3-month treatment period and at the relapse visit.

Results: In total, 25 patients (76% female; mean age, 64 y; mean duration of FMS, 11 y) were included in this analysis. At baseline, 88% were receiving ≥1 pain medication (24% TCAs, 28% gabapentin, 72% others) other than pregabalin. Pregabalin 150-600 mg/day was associated with clinically meaningful and sustained pain reduction during each treatment cycle. Mean SF-MPQ pain VAS level decreased from 73.6 mm at baseline to 51.7 mm across the treatment cycles (P<0.005). All patients met relapse criteria during each of the drug holidays. The median duration (range from 2-4 days) and mean pain scores (71-79 mm) across the 4 pregabalin drug holidays indicated pain quickly returned to baseline levels, but was reduced again when pregabalin was reinstated. At baseline, 71% of patients experienced severe pain ≥70 mm on SF-MPQ pain VAS compared to only 38% of patients after 15 months of treatment.

Conclusion: These results suggest that pregabalin may be beneficial in patients with fibromyalgia who have had an unsatisfactory response to treatment with other medications.

Genetics, Etiology, and Pathogenesis of Spondyloarthritis

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1431

DKK-1 Levels Are Decreased in Patients with Ankylosing Spondylitis and not Influenced by Anti-TNF Therapy. Seong-Ryul Kwon[1], Won Park[1], Mie-Jin Lim[1], Chang-Hee Suh[2], Hyoun-Ah Kim[2], Yeon-Sik Hong[3] and Bo-Young Yoon[4], [1]IN-HA University Hospital, Choong-Gu Incheon, South Korea, [2]Ajou University School of Med, Suwon, South Korea, [3]Incheon St. Mary's Hospital, Incheon, South Korea, [4]Inje Iniversity Ilsan Paik Hospital, Goyang, South Korea

Background: Signaling through the Wnt pathway leads to new bone formation, whilst DKK-1 is a Wnt antagonist. Preliminary data in patients with ankylosing spondylitis (AS) shows that levels of DKK-1 are low in patients with AS than in healthy controls suggesting that this might account for the propensity to new bone formation in AS.

Purpose: 1. To compare DKK-1 levels and other bone biomarkers in patients with AS compared to controls. 2. To examine the effects of anti-tumor necrosis factor (TNF) therapy for 3 months on DKK-1 levels and other bone biomarkers in AS.

Method: We studied 56 patients with AS (47 males, age 35.1 ± 9.6 years, disease duration 6.9 ± 4.8 years, BASDAI 7.7 ± 1.9, CRP 1.7 ± 2.0 mg/dl, mean ± SD), and 40 controls (31 male, age 43.5 ± 8.6 years). We also assessed DKK-1 in 49 AS patients and 39 healthy controls at baseline and 3 months after initiating anti-TNF therapy in AS patients (etanercept = 6, infliximab = 22, adalimumab = 21). DKK-1 was assayed by ELISA. We evaluated biomarkers of bone formation (osteocalcin, osteoprotegerin) and resorption (C-terminal telopeptide of type I collagen, CTX-1) by ELISA.

Results: Serum DKK-1 (12320.6 ± 6136.8 pg/ml) levels were significantly lower in AS than in controls (20811.1 ± 6136.8 pg/ml) ($p<0.0001$). Serum osteocalcin (14.5 ± 5.6 ng/ml), osteoprotegerin (3.5 ± 1.1 pmol/L) levels were significantly higher in AS than in controls (osteocalcin 8.9 ± 3.4 ng/ml, osteoprotegerin 2.03 ± 1.04 pmol/L, $p<0.0001$ respectively). Mean serum CTX-1 levels were not significantly different between AS and controls. Serum DKK-1 and CTX-1 levels were not changed 3 months after treatment with anti-TNF. But, serum osteocalcin levels increased significantly after treatment with anti-TNF for 3 months (14.5 ± 5.6 to 17.6 ± 4.5 ng/ml, $p<0.0001$). Serum osteoprotegerin levels decreased significantly 3 months after treatment with anti-TNF (3.5 ± 1.1 to 3.1 ± 1.2 pmol/L, $p=0.025$).

Conclusion: In accordance with a previous report, we show decreased DKK-1 in AS than healthy controls. DKK-1 levels are not influenced by anti-TNF therapy for 3 months. Our data does support a role for DKK-1 and Wnt interaction in the pathogenesis of new bone formation in AS.

Heightened HLA Molecules Upregulation and Decreased CD4+ T Cells Stimulation in Monocytes-Derived Dendritic Cells (DCs) From Ankylosing Spondylitis (AS) Patients. Nelly Bonilla[1], Maxime Breban[2] and Gilles Chiocchia[1], [1]Institut Cochin, INSERM U567, Paris, France, [2]Ambroise Paré Hospital, Boulogne-Billancourt, France

Purpose: In lines of rats transgenic for HLA-B27 and human β2-microglobulin, the spontaneous development of an inflammatory disease resembling human AS correlates with high levels of B27 expression. Furthermore, DCs from B27 transgenic rats have a diminished ability to interact with CD4+ T cells and to stimulate a proliferative response, as compared to control DCs. Such results raised the hypothesis that an altered interaction between antigen-presenting cells and CD4+ T lymphocytes might be critical in AS pathogenesis. Thus, it is of first importance to analyse the expression of HLA molecules and to evaluate the function of DCs in AS patients.

Objectives: To study HLA and accessory molecules expression in PBMC and in monocytes-derived DCs, and to examine the functional capacity of monocytes-derived DCs from AS patients and normal controls.

Method: Twenty two AS patients (21 HLA-B27+; mean age 44±12 years; BASDAI = 38±22; BASFI = 19±21) and 17 healthy controls were studied. We used multi-colours FACS analysis of PBMC and *in vitro* monocyte-derived DCs to compare the expression levels of HLA-DR, pan-class I, B27, and a full set of cell markers: CD4, CD8, CD11c, CD14, CD40, CD80, CD83, CD86, and CD123. *In vitro* derived DCs were obtained from purified CD14+ cells cultured for 7 days in the presence of IL-4 and GM-CSF. The cells were activated with LPS and FACS analysis was performed. The capacity of the DCs to stimulate proliferative responses of highly purified CD4+ T cells was evaluated.

Results: Expression levels of total HLA class I molecules were significantly higher on circulating lymphocytes and monocytes in patients than in controls ($p=0.01$, and $p=0.0004$, respectively). The levels of HLA-DR molecules were also significantly increased on lymphocytes from AS patients ($p<0.03$). None of the other markers showed a differential level of expression on PBMCs. The expression level of HLA-DR molecules was higher in AS patients than in controls on monocyte-derived DCs obtained after 7 days of culture. LPS-activation of DCs induced both class I and DR molecules up-regulation and exacerbated the differential level of DR expression between patients and controls ($p=0.009$). Finally, monocytes-derived DCs from AS patients exhibited a weaker stimulatory efficiency of CD4+ T cells than DCs from controls both on autologous and heterologous conditions.

Conclusion: Our findings reveal consistent differences in HLA molecules expression on PBMCs and DCs from AS patients, as compared to healthy controls. We bring evidence that DC from SpA patients have a lower ability to stimulate CD4+ T cell proliferation, as compared to control DC. We propose that this hypostimulatory ability of DCs could play an important role in initiating/maintaining the systemic inflammatory response in AS.

High-Resolution Association Mapping in the MHC Region Identifies Multiple Independent Loci for Psoriatic Arthritis. Proton Rahman[1], Nicole M. Roslin[2], Fawnda Pellett[3], Andrew Paterson[2], Joseph Beyene[4], Mathieu Lemire[5], Lynette Peddle[1], Angela Pope[1], Mohammed Uddin[1], Celia Greenwood[2] and Dafna D. Gladman[3], [1]Memorial University of Newfoundland, St Johns, NF, [2]The Hospital for Sick Children Research Institute, The Center for Applied Genomics, Toronto, ON, [3]Toronto Western Hospital, Toronto, ON, [4]The Hospital for Sick Children Resarch Institute, Child Health Evaluative Sciences, Toronto, ON, [5]Ontario Institute for Cancer Research, Toronto, ON

Purpose: The greatest genetic effect in PsA resides within the MHC region with various HLA alleles demonstrating consistent association. However, HLA alleles by themselves cannot account for the entire genetic contribution of this region. Thus we set out to identify SNPs independent of known HLA alleles within the MHC region that are associated with PsA using a high density SNP map.

Method: In total, 422 PsA cases and 487 controls were analyzed. PsA patients and controls were from two well established PsA cohorts (Toronto and Newfoundland). All PsA patients satisfied the CASPAR criteria. The MHC region was genotyped with 2269 SNPs in a 5 Mb region on chromosome 6 using Illumina's MHC Panel Set. HLA-B, HLA-Cw, and HLA-DRB1 were genotyped to two digit accuracy using sequence -specific oligonucleotide probes (SSOP) or PCR sequence-specific primers (PCR-SSP). A stratified case/control analysis was conducted on each SNP separately to test for allelic association with PsA. Due to extensive LD across the MHC region, a conditioning analysis approach was performed. This approach tests whether a SNP is associated with PsA conditional on known HLA risk alleles: B13, B27, B38, B39, B57, Cw6, and DR7. This analysis was performed using the program UNPHASED 3.1.3.

Results: The high density SNP analysis revealed 17 SNPs from 13 regions that were associated with PsA (p-values $< 10^{-5}$). Conditional tests were performed to find additional risk factors which are not confounded by the background HLA haplotypes. Five SNPs were significant at $< 10^{-4}$, with SNP rs1150735 demonstrating the strongest association. Haplotype analysis was then performed. OR of haplotypes that included SNP rs1150735 and any non-risk allele at all three HLA loci was 2.19, 95% CI: 1.43-3.36, $p=0.00052$. SNP rs1150735 resides 1.5 kb upstream from ring finger protein 39 (RNF39). In humans, SNPs in RFN39 have been associated with disease progression in GWAS in AIDS defined by CD4+ T cell depletion (Fellay J et al. Science, Aug 2007).

Conclusion: Fine mapping of the MHC identified SNP rs 1150735 which resides 1.5 kb upstream RFN39. This SNP association is independent of known HLA alleles.

The Voltage-Gated Potassium Channel Kv1.3 in Psoriasis and Psoriatic Arthritis: A Therapeutic Target for T Cell-Mediated Autoimmune Diseases. Siba P. Raychaudhuri[1], Smriti K. Raychaudhuri[2] and Heike Wulff[3], [1]UC Davis/ VA Sacramento, Davis, CA, [2]VA Sacramento Medical Center, Davis, CA, [3]University of California, Davis, Davis, CA

Purpose: Engagement of the T cell receptor triggers a Ca^{2+}-influx through voltage-independent Ca^{2+} channels, which results in the increase in cytosolic Ca^{2+} concentration necessary for the translocation of NFAT to the nucleus and the initiation of new transcription ultimately resulting in cytokine secretion and T cell proliferation. However, this crucial Ca^{2+}-influx is only possible if the T cell can keep its membrane potential negative by a counterbalancing K^+ efflux through Kv1.3 and/or KCa3.1. Both channels are therefore regarded as attractive new targets for immunotherapy: KCa3.1 for acute immune reactions mediated by naïve T cells and Kv1.3 for chronic immune reactions carried by memory T cells. Here we investigated the functional significance of Kv1.3 in psoriatic disease and rheumatoid arthritis.

Method: Using a combination of immunohistochemistry, flow cytometry and electrophysiology we have studied skin tissue, synovial tissue, lymphomononuclear cells (LMNC) from blood and synovial fluid from patients with psoriasis, psoriatic arthritis and rheumatoid arthritis. In these autoimmune conditions we have identified $Kv1.3^{high}$ T cells and determined their phenotypic and functional features in.

Results: We have found that psoriasis plaques (n=12) and psoriatic arthritis synovial tissues (n=6) are enriched with $Kv1.3^+$ T cells and that $Kv1.3^+$ T cells are retained in the psoriasis SCID mouse model. The numbers of $Kv1.3^+$ T cells in per square millimeter were significantly increased in psoriatic dermis (92 ±18) compared to the non-lesional psoriatic skin (6±4) ($P<0.01$). $Kv1.3^+$ infiltrating T cells in per square millimeter were also significantly higher in psoriatic arthritis synovial tissue (86 ±24) compared to synovial tissues of OA (4 ±2) patients. We have observed a significant enrichment of $Kv1.3^+$ T cells within the synovial fluid of psoriatic arthritis and rheumatoid arthritis as compared to the peripheral blood of PsA/RA patients and synovial fluid of OA patients. We have further seen that the majority of these $Kv1.3^+$ T cells were $CCR7^-$ effector memory T cells.

Conclusion: These results suggest that effector T lymphocytes at the site of inflammation in autoimmune inflammatory diseases like in psoriasis, PsA and RA are of activated memory phenotype and have marked expression of Kv1.3. To demonstrate the functional dependence of "psoriasis" T cells on Kv1.3 and to develop a novel therapeutic approach for T cell-mediated autoimmune diseases we are investigating the therapeutic efficacy of a selective Kv1.3 blocker (PAP-1) in the SCID mouse model of psoriasis. The availability of highly specific Kv1.3 inhibitors and the critical patho-physiologic role of the channel in effector memory T cells make Kv1.3 an important therapeutic target in autoimmune diseases.

1435

Nerve Growth Factor in Psoriatic Arthritis: A New Dimension in the Pathogenesis and a Novel Target Molecule for Therapy. Siba P. Raychaudhuri[1] and Smriti K. Raychaudhuri[2], [1]UC Davis/ VA Sacramento, Davis, CA, [2]VA Sacramento Medical Center, Davis, CA

Purpose: The effect of NGF/ NGF-R in inflammatory and rheumatologic diseases is a novel and an active research field. Major evidences for a role of NGF and its receptor system [NGF-R] in inflammatory disease have come from studies on psoriasis. Here we are reporting the role of NGF and its receptor system in inflammatory arthritis such as in psoriatic and rheumatoid arthritis

Method: We examined, blood, synovial fluid (SF) and synovial tissues from psoriatic arthritis (PsA, n=12), Rheumatoid (RA, n=15). Osteiarthritis (OA=10) was used as control. We have identified levels of NGF in SF and determined the functional significance of NGF/NGF-R on proliferation of fibroblast like synovial cells (FLS) and activation of T cells.

Results: Total NGF level was highest in the PsA group (365.5 pg/ml ±85.2 [mean±SD]). In RA group level of NGF was 120 pg/ml ± 35, whereas in OA patients level of NGF was 35 pg/ml ± 6. PsA derived FLS expressed significantly higher levels of TrkA and produced increased amount of NGF compared to FLS from healthy subjects, RA and OA. Effect of NGF (100ng/ml) on proliferation was determined in FLS derived from PsA (n=4), OA (n=4) and RA (n=4) synovial tissues. Third passage FLS (5000 cells/200ul DMEM complete medium)

in 96 well plates were cultured for 5 days. NGF demonstrated marked mitogenic effect on FLS derived from PsA compared to RA and OA. We have observed that synovial fluid of PsA has significantly higher percentage of activated CD3+T cells expressing TrkA (18±6.2). In RA synovial fluid TrkA+CD3+ T cells were also high (4.5±1.3) whereas OA synovial fluid did not show any detectable TrkA+CD3+ T cells. Further we have demonstrated that NGF activates T lymphocytes and influences the expressions of Th-1 type cytokines/chemokines. This is a plaussible mechanism of the neuroimmunologic interactions of NGF in inflammatory responses

Conclusion: These observations indicate Nerve Growth Factor (NGF) and its receptor system play a critical role in the pathogenesis of psoriatic arthritis by regulating the local pathologic events such as proliferation of target tissues (FLS) and activation of T lymphocytes. A new discipline is emerging in clinical pharmacology focusing on the development of drugs targeting the neuropeptides, NGF, and TrkA. Regulatory role of NGF in inflammatory and proliferative cascades of psoriatic arthritis opens new vistas to develop NGF/NGF-R targeted therapies.

HLA-B27 Expression Affects RANKL and TNF-α Induced Osteoclast Development in Transgenic Rats. Gerlinde Layh-Schmitt[1], Shuzhen Bai[2] and Robert A. Colbert[1], [1]NIAMS, NIH, Bethesda, MD, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Purpose: Susceptibility to spondyloarthritides is strongly linked to HLA-B27. The pathogenesis of these diseases involves inflammation mediated in part by TNF-α, as well as an imbalance in bone formation. The discovery that HLA-B27 misfolding can generate ER stress and activate the unfolded protein response (UPR), suggests that it may have additional immunobiologic effects in cells not principally involved in antigen presentation. Therefore, we examined whether HLA-B27 expression has an effect on osteoclast differentiation in a rat model of spondyloarthritis.

Methods: Bone marrow cells were isolated from HLA-B27 transgenic (B27 Tg) (prior to the development of inflammatory disease) and wild type (WT) rats and cultured with M-CSF (20 ng/ml) for 2 days to obtain CD11b+ myeloid cells/osteoclast precursors. Adherent and non-adherent cells (> 90% CD11b+) were then separated and treated with M-CSF and either RANKL (100 ng/ml) or TNF-α (30 ng/ml) for 5 days to promote osteoclast differentiation. Osteoclast formation was quantified by counting multi-nucleated (>3 nuclei) cells and measuring TRAP (tartrate resistant acid phosphatase) activity. HLA-B27 expression was visualized by immunoblotting.

Results: In the population derived from the non-adherent cells, HLA-B27 expression results in a 2-3-fold inhibition of osteoclast formation as measured by cell number or TRAP staining, with either RANKL or TNF-α stimulation ($p<0.05$). However, in the adherent cell population, HLA-B27 expression leads to a slight (~1.5-fold) increase in osteoclast numbers and TRAP activity when treated with RANKL or TNF-α ($p<0.05$). In fact, only HLA-B27 expressing populations formed mature osteoclasts (>3 nuclei) in response to TNF-α. HLA-B27 upregulation and accumulation of misfolded heavy chains was documented in mature osteoclasts.

Conclusion: Our results indicate that HLA-B27 expression in transgenic rats can lead to differences in osteoclast formation in response to RANKL and TNF-α, with the effect dependent upon the precursor cell population. These results are of interest given that bone loss and bone formation occur simultaneously in spondyloarthritis. The mechanisms involved in differential osteoclast development, and whether HLA-B27 misfolding plays a role, are currently being investigated.

Association of BEND2 with Ankylosing Spondylitis. Mohammed Uddin[1], Proton Rahman[1], Walter P. Maksymowych[2], Dafna Gladman[3], Angela Pope[1] and Robert D. Inman[4], [1]Memorial University of Newfoundland, St Johns, NF, [2]University of Alberta, Edmonton, AB, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]Toronto Western Hospital, Toronto, ON

Purpose: Ankylosing Spondylitis (AS) is a complex rheumatic disease with a clear genetic predisposition. Pleiotropic genes have been associated with AS including IL-23R and IL-1. As a result we examined the genetic association of 13 nonsynonymous SNPs (nsSNPS) in AS that were identified after a pooled analysis from GWAS of related autoimmune diseases.

Method: In order to generate candidate markers, 1,428 nsSNPs that were common to 5 autoimmune diseases (ankylosing spondylitis, rheumatoid arthritis, type 1 diabetes, autoimmune thyroid disease, and multiple sclerosis) that underwent GWAS by the Welcome Trust Case Control Consortium (WTCCC) were selected. The genotypes were retrieved from the European Genome-Phenome Archive. A pooled analysis involving 6812 UK patients with autoimmune disease and 2952 UK controls was performed. 26 nsSNPs showed a significance of $p < 10^{-3}$, of which 13 nsSNPs were prioritized for genotyping a cohort of Canadian AS patients. 889 AS cases of Caucasian European ancestry from Canada and 987 controls were genotyped. The patients came from 2 well established AS cohorts: 510 AS cases 502 controls from Alberta and 379 cases and 485 controls from Toronto. The genotyping was done using the Sequenom platform. The Cochran-Amirtage test for trend was performed using the program PLINK.

Results: All samples satisfied the Hardy-Weinberg equilibrium and all SNPs had at least a 92% call rate. In the combined analysis of the Canadian samples nsSNP rs17274127 located on exon 4 of BEN containing domain 2 (BEND2) gene on chromosome Xp22.13 and rs1063588 is located on exon 3 of GCS1 gene at chromosome 2p13.1 achieved statistical significance. For nsSNP rs17274127 of the BEND2 gene the minor allele frequency for the combined population in the cases was 0.170 and in controls was 0.118 (OR 1.56 (1.14-2.04, p=0.0038). BEND2 is a novel domain in chromatin and DNA viral proteins and mediates protein-DNA and protein-protein interactions during chromatin organization and transcription. For nsSNP rs1063588 of GCS1 gene, the MAF for allele A was 0.183 in the AS cases and 0.153 in the controls (OR 1.24 (1.04-1.48, p=0.016). GCS1 encodes a GTPase activating protein (GAP) for ADP ribosylation factors that regulate the formation of coated vesicles in intracellular trafficking.

Population	Gene	rsSNP	Minor Allele	MAF Case	MAF Control	p-value
Combined	BEND2	17274127	C	0.170	0.118	0.0038
Toronto	BEND2	17274127	C	0.200	0.122	0.0077
Alberta	BEND2	17274127	C	0.152	0.115	0.1168

Conclusion: A nsSNP within gene BEND2 appears to be associated with AS in the Canadian cohort. Further replication studies are warranted to replicate these findings.

Microarray Analyses of Peripheral Blood Cells Identifies Gene Expression Profile That Differentiates Psoriatic Arthritis (PsA) Form Psoriasis and Controls. D. Gladman, Remy Pollock, Carl Virtanen, Fawnda Pellett, Sutharshini Shanmugarajah, Cheryl Rosen and Vinod Chandran, University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Peripheral blood gene expression profiles may help distinguish PsA from psoriasis alone. Our purpose was to identify genes that are differentially expressed in the peripheral blood cells of patients with PsA by comparing the expression profiles of patients with PsA, patients with psoriasis alone, and healthy controls.

Methods: 20 patients with PsA and 20 patients with psoriasis without arthritis were recruited for the study from university hospital-based PsA and psoriasis clinics, respectively. 20 healthy controls were recruited from hospital personnel. Psoriasis in all patients was confirmed by a dermatologist. All patients with PsA satisfied CASPAR classification criteria. Patients with psoriasis alone were evaluated by a rheumatologist and PsA was excluded. All subject groups were matched for age and sex. Patients with PsA and psoriasis were matched for psoriasis duration. None were treated with biologic agents. Peripheral blood was collected at the time of assessment in PAXgene tubes for RNA extraction and stored at -80°C. Total RNA was extracted using PAXgene Blood RNA Kit and RNA quantified. cDNA/cRNA synthesis and labeling were performed and cRNA was hybridized to a 2-colour Agilent 44K Whole Human Genome Oligo Microarray. Appropriate quality control measures were undertaken. Gene expression values (intensities) for each gene were obtained. The expression values of the

differentially expressed genes were log transformed, and compared between groups (Psoriatic disease vs. controls, PsA vs. psoriasis and PsA vs. psoriasis vs. controls using t-test or one-way ANOVA) and genes with >1 fold change and $p<0.05$ corrected for multiple testing (false discovery rate) were used in unsupervised hierarchical clustering to generate heat maps for each comparison. Gene ontologies were examined to determine type of genes over or under represented.

Results: Patients with PsA (10 male, mean age 48.1 years, disease duration 15.5 years, psoriasis duration, 23.2 years) had an actively inflamed joint count of 10.8, swollen joint count of 5.4 and PASI score 5. Patients with psoriasis (mean age 44 years, psoriasis duration 19.8 years) had PASI score of 5.4, and controls had a mean age of 43.5 years. Between the 3 groups there were 1547 differentially expressed genes. 112 genes were differentially expressed between psoriatic disease and controls, and 711 between PsA and psoriasis alone. Between Psoriatic disease and controls, 35 (31%) genes were downregulated, and 77 (69%) were upregulated. Genes downregulated included MPL, MYST3, CREBBP, EP300 and NRLP2; CROP was upregulated. Between PsA and psoriasis 495 genes (70%) were downregulated and 216 (30%) were upregulated. Genes upregulated included CLEC4d, CLEC2b, CSTA, LY96 and P2RY5.

Conclusion: Results indicate that genes of inflammation pathways, innate immunity and epidermal development are differentially expressed in the peripheral blood cells of patients with psoriasis and PsA.

Interferon-γ Production Is Impaired in Patients with Ankylosing Spondylitis. Dorothea Zauner, Eva-Maria Kober, Winfried Graninger and Josef Hermann, Medizinische Universitätsklinik, Graz, Austria

Purpose: In patients with ankylosing spondylitis (AS) impaired IFNγ production has been reported in stimulated peripheral blood mononuclear cells (PBMCs) using flow cytometry and ELISA techniques. We used ELISpot assays to detect cytokines produced spontaneously ex vivo in AS patients. This highly sensitive method allows for the assessment of the number of cytokine producing cells and the amount of cytokine produced per cell.

Method: Blood samples were obtained from 16 patients with AS according to the modified New York criteria (12 male, 4 female; median age 41 years (range 30-66)), median disease duration 9.5 years (range 2-41) and 24 healthy controls (10 male, 14 female; median age 38.5 (range 23-75)). Median BASDAI was 3.2 (range 0.1-7.1), median CRP was 3.6 mg/l (range 1.0-14.8)) and median ESR was 14 mm/h (range 4-63). None of the patients were on corticosteroid or TNF-blocker therapy. PBMCs were isolated from freshly drawn blood samples immediately after acquisition, plated on 96-well microtiter plates pre-coated with IL-17- or IFNγ-antibodies, and incubated overnight at 37°C without prior antigen stimulation. Detection antibodies were added and spot colour reactions developed according to the manufacturer's protocol (ELISpot Kits by R&D Systems, Minneapolis). Microtiter plates were scanned and spots were analyzed for the production of IL-17 and IFNγ using the ImmunoSpot® Image Analyzer (Cellular Technology, Cleveland OH) and ImmunoSpot® Software. Spot sizes were compared between groups using Student's t-test and spot numbers were compared using the non-parametric Wilcoxon rank sum test.

Results: Unstimulated PBMCs of patients with AS produced significantly smaller IFNγ spots compared to healthy controls (mean(SD) spot sizes 6.8(0.5) μm^2 vs. 8.8(0.4) μm^2; $p=0.003$), whereas IFNγ spot numbers did not differ significantly between groups (mean(SD) 76.5(54.2) spots per 10^6 cells vs. 65.2(55.1) spots per 10^6 cells). In addition, we found no significant differences between patients and healthy controls concerning IL-17 spot numbers (mean (SD) 24.7(23.6) spots per 10^6 cells vs. 26.5(26.6) spots per 10^6 cells, respectively) and IL-17 spot sizes (mean(SD) 12.5(3.3) μm^2 vs. 12.3(3.0) μm^2, respectively). IL-17 and IFNγ spot numbers and sizes did not correlate with disease activity measured either by the BASDAI or by serum CRP/ESR levels.

Conclusion: Our data suggest that in patients with AS in vivo IFNγ production of peripheral blood mononuclear cells might be decreased, whereas IL-17 production and frequencies of IL-17 producing T-cells seem to be unaltered.

Is Bone Formation Observed in Patients with Ankylosing Spondylitis Related to Clinical Signs and Symptoms? A Subanalysis of ATLAS. Désirée M.F.M. van der Heijde[1], Paul Emery[2], Kaushik Patra[3], Jesse Hall[3] and Frederic Lavie[4], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leeds Teaching Hospital, Leeds, United Kingdom, [3]Abbott Laboratories, Abbott Park, IL, [4]Abbott Laboratories, Rungis, France

Purpose: In all clinical trials conducted with TNF antagonists in patients with ankylosing spondylitis (AS), patients experienced radiographic progression characterized by bone formation as assessed by the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) at a similar rate and frequency as patients from a historical cohort of AS patients without treatment with TNF antagonists.[1–3] We determined whether there is a link between the level of signs and symptoms in the patients during follow-up visits and the radiographic outcome.

Methods: ATLAS was a Phase III, randomized, placebo-controlled trial of adalimumab in patients with AS. After the 24-week double-blind period, placebo-treated patients switched to adalimumab and enter an open-label extension phase and receive up to 4 years of follow up. Patients were categorized by the degree of radiographic progression (□mSASSS >2 over 2 years). Patients were also evaluated by clinical response measures between baseline and Week 208, including the ASAS20, 40, 5/6, and 70 responses, ASAS partial remission (ASAS PR), BASDAI, ASDAS, ASQOL, and CRP concentrations. All data are observed, and the baseline value for each measure was the last observation before the first dose of adalimumab.

Results: Of the 307 patients analyzed from the ATLAS trial, 257 had no progression in mSASSS (no progression, NP) at 2 years, and 50 had a □mSASSS >2 at 2 years (progression, P). Clinical responses and disease activity levels were similar between the 2 groups at baseline and at each time point for all assessed criteria. ASAS20, ASAS PR, BASDAI, ASQOL, and CRP concentrations observed from baseline to Week 208 are presented in the table.

104	75.7	81.6	43.1	34.7	2.3 (2.2)	2.2 (2.1)	4.7 (4.6)	5.3 (5.2)	0.4 (0.7)	0.5 (1.1)
128	78.8	73.3	42.5	37.8	2.3 (2.2)	2.5 (2.4)	4.5 (4.8)	5.1 (5.6)	0.3 (0.6)	0.8 (2.4)
156	75.4	77.3	41.9	43.2	2.4 (3.3)	2.2 (2.2)	4.4 (4.5)	5.4 (5.2)	0.4 (1.0)	0.4 (0.6)
180	79.4	81.8	41.7	38.6	2.1 (1.9)	2.3 (1.9)	4.2 (4.6)	4.8 (4.6)	0.4 (0.7)	0.3 (0.4)
208	81.6	82.1	43.4	43.6	2.1 (2.0)	2.3 (2.2)	4.2 (4.2)	5.5 (5.5)	0.4 (1.2)	0.5 (1.3)

NA=not applicable; NP=no progression; P=progression.

Conclusion: These results reinforce the hypothesis that mSASSS progression is not related to the level of clinical signs and symptoms. Different mechanisms of action that may explain bone formation in patients with AS should be further explored.

Disturbance in Differentiation Status of B Lymphocytes in Ankylosing Spondylitis. MO Ying-qian, Dai Lie, Zheng Dong-hui, LI Ting and Zhang Bai-yu, 2nd Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Purpose: Disturbance in humoral immunoregulation was found in patients with ankylosing spondylitis (AS), and B lymphocytes could be detected in synovium from inflamed jonits of AS patients. We aimed to detect the differentiation status of B lymphocytes in peripheral blood and synovium from AS patients.

Method: (1) Peripheral blood mononuclear cells from 52 AS patients were measured by flow cytometry with 4-color fluorescence-activated cell sorting analysis, which distinguished three different CD19+ B lymphocyte subpopulations including naïve (CD19+ CD27- CD38- CD69-), activated (CD19+ CD69+) and memory cells (CD19+ CD27+), and CD19- CD38+ plasmocytes. 62 patients with rheumatoid arthritis (RA) and 30 healthy volunteers were chosen as control. (2) Synovium from inflamed knees of 8 AS patients were collected by closed needle synovial biopsies and serial sections were analyzed by HE staining and immunostaining for CD20 (mature B lymphocytes), CD38 (plasmocytes) and CD 79a (all B lymphocytes and plasmocytes)

Results: (1) Ratio of B lymphocytes to total lymphocytes in AS patients was higher than that in healthy volunteers (17.0% vs 11.8%, P=0.007), but there was no significant differences between AS and RA patients. (2) Among CD19+ B lymphocytes, percentage of naïve or activated B cells in AS patients was higher than that in healthy volunteers (naïve B cells: 80.1% vs 72.8%, P=0.01; activated B cells: 18.4% vs 0.62%, P<0.001), and percentage of memory cells in AS was lower than that in RA (19.5% vs 25.4%, P=0.032) and in healthy volunteers (19.5% vs 27.6%, P=0.003). (3) Percentage and count of activated B cells in AS patients with peripheral arthritis were higher than in those without peripheral arthritis (P<0.001). (4)Percentage and count of naïve or activated B cells in AS patients with extra-articular involvement like iritis were higher than in those without extra-articular involvement (P=0.045, 0.031, P<0.001, P<0.001). (5) The counts of CD20+, CD38+ and CD79a+ cells in AS synovium were lower than that in RA synovium (seen in Table 1).

Conclusion: Our results show disturbance in differentiation status of B lymphocytes in AS patients with elevation of activated and naïve cells and reduction of memory cells, especially in patients with peripheral arthritis or extra-articular involvement. Less synovial B lymphocytes in AS might indicate different pathogenesis of B lymphocytes from RA.

Table 1 B lymphocytes and plasmocytes in synovium from AS, RA and orthopedic arthropathies ($\chi \pm s$, /mm^2)

Group	N	CD20	CD38	CD79a
AS	8	148.8±39.2 #	96.6±27.67 #	280±41.0 #
RA	48	420.5±76.1	415.5±96.8	975.3±131.0

ZSTK474, a Phosphatidylinositol 3-Kinase Inhibitor, Ameliorates Ankylosing Enthesitis in DBA/1 Mice. Shigeyuki Mori[1], Fumitaka Kamachi[1], Asako Sasaki[1], Kazuhiko Haruta[1] and Shigeto Kobayashi[2], [1]Central Research Laboratory of Zenyaku Kogyo Co., Ltd., Tokyo, Japan, [2]Juntendo University Koshigaya Hospital, Saitama, Japan

Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disorder that affects the axial skeleton, sacroiliac joints, entheses and peripheral joints, resulting in new bone formation and fusion of the joints. Nonsteroidal anti-inflammatory drugs (NSAIDs) and disease-modifying anti-rheumatic drugs (DMARDs) are often used to treat AS, but there remain unsolved problems such as adverse events or limited effects on the symptoms of AS. However, it was demonstrated that PI3-kinase signaling cascade was crucial for bone formation by osteoblasts. Moreover, we previously reported that ZSTK474, an orally active PI3K inhibitor suppressed the proliferation and activation of lymphocytes. These reports led us to hypothesize that ZSTK474 might have a therapeutic potential for AS. In this study, we attempted to evaluate the efficacy of ZSTK474 on spontaneous ankylosing enthesitis in DBA/1 mice, a model of AS.

Method: First, 26 week-old male DBA/1 mice were divided into two groups according to the presence (semi-therapeutic group) or absence (prophylactic group) of arthritis. Then the animals were orally administered ZSTK474 (50 or 100 mg/kg/day) once a day for 4-5 weeks. Each hind paw was scored every day for clinical signs of arthritis as follow: 0, no symptom; 0.5, instep swelling; 1, redness and swelling in one toe; 2, redness and swelling in more than one toe; 3, toe stiffness; 4, deformity or ankle involvement. After the dosing period, bone formation markers (osteocalcin, alkaline phosphatase) in serum were assessed. Histologically, frozen sections of calcaneus bones in the hind paws were stained with toluidine blue.

Results: Prophylactic treatment with ZSTK474 significantly reduced the mean clinical score and incidence (% score ≥2) of arthritis compared with those in vehicle-treated controls on Day 34 (50 mg/kg [$p<0.05$] and 100 mg/kg [$p<0.01$]). Semi-therapeutic treatment with ZSTK474 also inhibited the mean clinical score and incidence on Day 27 (50 mg/kg [$p<0.001$] and 100 mg/kg [$p<0.001$]). Histological examination revealed that increased bone formation, which was observed in the calcaneal epiphysis from vehicle-treated mice, was decreased in ZSTK474-treated mice (50 mg/kg and 100 mg/kg). Furthermore, ZSTK474 reduced the levels of osteocalcin and alkaline phosphatase in serum.

Conclusion: ZSTK474 ameliorates ankylosing enthesitis in DBA/1 mice by suppressing osteogenesis, suggesting that ZSTK474 is promising candidates for treatment of AS.

1443

Peripheral and Axial New Bone Formation Is Different According to Gender in Ankylosing Spondylitis. Sibel Zehra Aydin, Gokhan Keser, Vedat Inal, Veli Yazisiz, Omer Karadag, Merih Birlik, Pamir Atagunduz, Eren Erken, Haner Direskeneli and Salih Pay, Turkish Ultrasonography Study Group, Istanbul, Turkey

Purpose: To investigate the prevalence of Achilles enthesophytes in ankylosing spondylitis (AS) patients according to gender and to explore the relationship between new bone formation of the spine and presence or severity of peripheral enthesophytes, using US and conventional radiographics.

Method: We conducted a multicenter, case control, prospective study of 170 consecutive AS patients and 86 age and body mass index (BMI) matched healthy controls (HC) in six rheumatology units. All patients were assessed for disease characteristics, activity and enthesitis. Radiographics of the spine were evaluated for mSASSS, presence and number of syndesmophytes. For US data, the same US machine ((E-Saote MyLab70, Genoa, Italy) and US probe (6-18 MHz, lineer) were used in each center. Three images were stored for each Achilles tendon. A semi-quantitative scoring, between 0-3 was performed at the end of the study by one investigator, by mixing all the US images anonymously. The inadequate US images were excluded. The relationship between axial findings and peripheral US findings were compared by separating the data according to genders.

Results: US images and axial imaging was found eligible in 153 AS patients and 84 HC. Male AS patients had significantly higher enthesophyte scores than HC (2.3±1.6 vs 1.3±1.5; p<0.001), whereas differences in females were not significant (2.3±1.5 vs 1.9±1.7; p=0.2). The number of syndesmophytes (r=0.29; p=0.003), mSASSS (r=0.28; p=0.005) and the presence of syndesmophytes (r=0.37; p<0.001) were observed to correlate significantly with peripheral enthesophytes in males. For females, none of the axial findings correlated with US

findings. In multiple regression analysis of a model including age, BMI and enthesophyte scores, the presence of a syndesmophyte was related to age ($p<0.001$) and BMI ($p=0.003$) in males and only to age ($p<0.001$) in females, but not to US scores in both groups.

Conclusion: Age seems to be an independent factor for developing enthesophytes and syndesmophytes in AS patients. Male AS patients have more severe enthesophytes associated with syndesmophyte presence suggesting a gender-associated difference of peripheral and axial new bone formation.

The TH17 Related Cytokines IL-21 and IL-23 in Patients with Spondylarthropathy. Thomas Andersen[1], Tue A. K. Rasmussen[1], Malene Hvid[1], Karen Berenth Madsen[2], AG Jurik[2], Berit Schiøttz-Christensen[3] and Bent Deleuran[1], [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Aarhus Clinic for Rheumatic Diseases, Aarhus, Denmark

Background: The TH17 subprofile of CD4+ T cells has been strongly associated with the pathogenesis of spondyloarthropathy (SpA).

Purpose: The purpose of this study was to investigate the role of the TH17 associated cytokines IL-21 and IL-23 in SpA by analyzing the levels of these cytokines in plasma. Furthermore we investigated, whether levels of these cytokines correlated to clinical findings and MRI-score.

Method: Patients with SpA (n = 80) were clinically examined and characterized in regard to BASMI 0 (0 – 0), BASFI 1.1 (0.2 – 2.8), BASDAI 2.1 (0.9 – 4.4), Global VAS 24 (8 – 51), as well as CRP 20 nmol/l (12 nmol/l – 37 nmol/l). Plasma samples were collected and MRI of the spine and sacroiliac joints was performed using T1-weighted sequence with regard to erosion and fatty marrow degeneration to define chronic changes and STIR to detect activity. Plasma samples from normal healthy volunteers (NHV) (n=37) were used as controls. Plasma levels of IL-21 and IL-23 were measured by ELISA.

Results: IL-21 plasma levels above the detection limit (16 pg/ml) were observed in 46 of the 80 (58%) SpA patients and in 22 of the 37 (58%) NHV. IL-21 was significantly increased in SpA plasma compared to the NHV ($p < 0.05$). Similarly IL-23 levels above the detection limit (2,5 pg/ml) were observed in 25 of the 80 (31%) SpA patients and in 3 of the 37 (8%) NHV. A statistically significant increase of IL-23 was seen in the SpA patients compared to the NHV ($p < 0.001$). When comparing the different subgroups of SpA patients (Psoriatic Arthritis, Ankylosing Spondylitis, Reactive Arthritis, Enteropathic Arthritis and Unspecified Arthritis) regarding IL-21 and IL-23 levels, no difference was observed. However, a significant correlation was observed between individual levels of IL-21 and IL-23 ($r = 0.7$ $p < 0.001$). In contrast, the levels of IL-21 and IL-23 was not correlated to the MRI changes nor to any of the examined clinical parameters, including CRP.

Conclusion: The TH17 related cytokines IL-21 and IL-23 are increased in SpA patients, reflecting the increased T cell and dendritic activity in SpA, but without correlation to MRI or clinical parameters.

ERAP1 R528 Variants Influence the Radiological Progression in Ankylosing Spondylitis. Nigil Haroon[1], Finbar (Barry) D. O'Shea[1], Proton Rahman[2], F.W.L. Tsui[1] and R.D. Inman[1], [1]Toronto Western Research Institute, Toronto, ON, [2]Memorial University of Newfoundland, St Johns, NF

Purpose: The pathogenesis of ankylosing spondylitis (AS) is not well understood. Polymorphisms in the endoplasmic reticulum aminopeptidase 1 (ERAP1) gene are associated with AS. The possible explanations for this association are the involvement of ERAP1 in cytokine receptor shedding or peptide processing. There is no evidence so far that ERAP1 influences radiological progression in AS.

Method: Caucasian AS patients (modified New York criteria) were recruited from the spondylitis clinic and followed prospectively. At the baseline visit the BASDAI, BASFI and BASMI were noted and cervical and lumbar x-rays taken. The x-rays were repeated every 2 years while the clinical data was updated annually. DNA was isolated from peripheral blood and genotyped for the *rs30187, rs27044* and *rs10050860* SNP of ERAP1 gene by allelic discrimination. X-rays were read independently by two readers and mSASSS scores were calculated. The change in mSASSS scores were noted between the first and last visit and divided by the duration between the x-rays to get the rate of change in mSASSS scores per year. The rate of change in mSASSS scores were compared between the different genotypic groups using the Kruskal-Wallis test. Logistic regression was used for identifying baseline predictors of mSASSS progression.

Results: Radiographs were available in 52 patients (7 female) on at least 2 occasions with mean (±SD) gap of 2.6 ± 1.01 years between them. The mean age of the patients was 35.1 ± 13.1 years and had mean disease duration of 14.3 ± 8.7 years. The mean BASDAI, BASFI and BASMI scores were 4.7 ± 2.7, 4.1 ± 2.9 and 2.3 ± 1.9 respectively at baseline visit and 3.6 ± 2.4, 3.3 ± 2.7 and 2.5 ± 2.2 respectively at the last visit. Thirty four patients were on anti-TNF medications for a mean duration of 15.7 ± 2.2 months. The mean baseline and follow up mSASSS scores were 16.0 ± 22.1 and 17.9 ± 22.5 respectively with a mean change of 1.9 ±2.8 units ($p<0.0001$, paired T test) and mean rate of change of 0.9 ± 1.7 units per year. The frequency of ERAP1 genotypes were 13/27/9 (*rs30187*), 19/28/4 (*rs27044)* and 40/10/1 (*rs10050860*) respectively. The age, disease duration, baseline mSASSS scores and the patients as well as the mean duration of anti-TNF intake were comparable between the genotypic groups. There was significant difference in the rate of change in mSASSS between the genotypic groups of the *rs30187* SNP of ERAP1 ($H=8.8$, $df=2$; $p=0.01$). The median (interquartile range) change in mSASS scores were 1.0 (0.4, 1.8), 0 (0, 2) and 0 (0, 1) respectively for the CC/TC and TT genotypes of *rs30187*. There was no significant difference in the rate of change in mSASSS with the *rs27044* and *rs10050860* SNP. Logistic regression showed that the rs30187 genotype predicted patients who had any degree of radiological progression.

Conclusion: This is the first report to suggest a phenotypic influence of ERAP1 polymorphisms in patients with AS. Our novel finding suggests that the K528R ERAP1 polymorphisms can affect the radiological severity in AS.

1446

Interleukin 23 Expression in Inflammatory Arthritis. Axel J. Hueber, Darren L. Asquith, Neal L. Millar, Roger D. Sturrock and Iain B. McInnes, University of Glasgow, Glasgow, United Kingdom

Purpose: A novel subset of IL-17 producing T cells (Th17 cells) has been suggested to be crucial in the pathogenesis of arthritis and psoriasis. The necessity of IL-23 for the polarisation of Th17 cells has been demonstrated using mice deficient for the IL-23 receptor (IL-23R) which exhibit impaired expansion and function of Th17 cell population. Furthermore, deletion of IL-23(p19) in a murine model of arthritis ameliorated disease suggesting a pro-inflammatory effect of IL-23 in inflammation and antibodies against IL-23p40 have yielded beneficial effects in psoriasis. Additionally, psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are strongly associated with IL-23R polymorphisms. These studies support a pathological role of IL-23, potentially by positively regulating the expansion of Th17 cells.

Method: RNA extracted from peripheral blood mononuclear cells (PBMCs) from rheumatoid arthritis (RA, n=48), psoriatic arthritis (PsA, n=22) and ankylosing spondylitis (AS, n=19) patients relative to healthy controls (HC, n=38) was analysed for IL-23 transcripts. For detection of IL-23 in synovial fluid ELISA was performed. IL-23 was stained by immunohistochemistry in synovial tissue (RA n=5, PsA n=3 and OA n=4). Utilising an *in vitro* model of synovitis healthy human $CD3^+$ T cells were activated in the presence of IL-2, IL-6 and TNF-α for 6 days and were added in co-culture to syngeneic MCSF matured $CD14^+$ macrophages. Supernatants were measured by ELISA.

Results: The level of IL-23 transcript was significantly increased in PBMCs from PsA patients ($P = 0.0244$), but was not altered in RA patients and was only detectable in 4 out of 19 AS patients. In synovial fluid, bioactive IL-23 was only detectable in 3 out of 15 patients with PsA and was not detectable in the RA (in contradiction to previous reports) and OA group. Study of IL-23 expression within synovitis revealed cytoplasmic staining for IL-23 in both RA and PsA synovial tissue. However, staining for IL-23 was absent under non-inflammatory conditions in synovial tissue from OA patients suggesting that IL-23 is only expressed under inflammatory conditions within the synovium. To address a potential mechanism by which IL-23 is secreted we sought to determine which cytokines were secreted upon the interactions of T cells and macrophages. Co-culture experiments resulted in the secretion of IL-1β, IL-6 and IL-23 suggesting that macrophage/ T cell interactions within the synovium may provide an environment that would favour Th17 polarisation and expansion.

Conclusion: In summary, we demonstrate an increase in the expression of IL-23 in PsA and by utilising an *in vitro* model of synovitis we demonstrate that the secretion of the cytokines IL-23, IL-1β and IL-6, which support the polarisation and expansion of Th17 cells, is mediated through the interactions of cytokine activated T cells and macrophages.

Identification of Specific Phenotypic Markers for HUMAN Polarized Macrophages. Carmen A. Ambarus[1], Sarah Krausz[1], Marco van Eijk[1], Jorg Hamann[1], Paul P. Tak[2] and D. Baeten[3], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [3]AMC, University of Amsterdam, Amsterdam, Netherlands

Purpose: The concept of macrophage polarization describes the heterogeneity of activated macrophages under specific microenvironmental conditions. Based on their pro- or anti-inflammatory functions in mice, two major types of macrophages (M1 and M2) have been described. According to this paradigm, we aim to assess type 2 inflammation in spondyloarthritis (SpA) versus type 1 inflammation in rheumatoid arthritis (RA). Here, we investigated the expression of cell surface molecules on in vitro differentiated human macrophages in order to identify reliable markers for characterization of polarized human macrophages in vivo.

Method: Monocytes were isolated from peripheral blood of healthy donors and differentiated in vitro for 4 days in the presence of GM-CSF, IFN-γ, LPS, TNF-α, M-CSF, IL-4, or IL-10. Expression of CD14, CD16, CD32, CD64, CD80, CD86, TLR2, TLR4, CD 163, CD200R and CD206 was analyzed by flow cytometry.

Results: M1 macrophages are prototypically induced by IFN-γ (M1a) or by TNF-α or bacterial components like LPS (M1b). In our analysis, IFN-γ induced selective up-regulation of CD64 and CD80,, while LPS strongly up-regulated CD14. M2 cells develop in the presence of IL-4 or IL-13 (M2a), immune complexes (M2b), or IL-10, TGF-β, or glucocorticoids (M2c). IL-4 up-regulated CD200R expression whereas IL-10 strongly up-regulated the expression of CD163 and, to a lesser extent, CD16. In contrast to mouse macrophages, CD206 was not a specific marker for IL-4 polarized macrophages in humans. Additionally, CD86 was not only up-regulated by IFN-γ but also by Il-4. TLR2 and TLR4 did not display a specific expression profile. The expression of specific phenotypic markers by polarized cells was similar for monocytes in healthy controls, RA, and SpA. However, the phenotype defined here upon polarization of fresh peripheral blood monocytes only partially holds through when polarizing already matured macrophages. Especially LPS induced up-regulation of different M1 and M2 markers.

Conclusion: Our data indicate that CD64 and CD80 are specific surface markers for in vitro-polarized M1a macrophages and CD14 for the M1b phenotype. CD200R specifically characterizes the M2a and CD163 and CD16 the M2c macrophages. These phenotypic markers now allow to classify polarized human macrophages in inflamed tissue and to assess the function and signalling pathways of specific macrophage subsets.

1448

ERAP1 Q730E Variants Affect the HLA B27 Free Chain Expression On Monocytes of Patients with Ankylosing Spondylitis. Nigil Haroon[1], F.W.L. Tsui[2], Basil Chiu[1], H.W. Tsui[3], Finbar (Barry) D. O'Shea[1] and R.D. Inman[1], [1]Toronto Western Hospital, Toronto, ON, [2]Toronto Western Research Institute. University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON

Purpose: Polymorphisms in the Endoplasmic Reticulum Aminopeptidase 1 (ERAP1) gene were recently reported to be associated with ankylosing spondylitis (AS). ERAP1 is known to be involved in peptide processing for MHC-I presentation. The surface MHC-I expression level is a surrogate marker for endogenous peptide processing within the ER. To date there is no definite evidence of an interaction between ERAP1 and HLA B27 in the pathogenesis of AS. We studied the surface expression of HLA B27 and free heavy chains on PBMC of patients with AS in the context of their ERAP1 genotype.

Methods: Caucasian HLAB27 positive patients satisfying the modified New York criteria for AS and not on any biologic treatment were recruited from the spondylitis clinic. The BASDAI, BASFI, BASMI, CBC, ESR and CRP were noted. DNA was isolated from peripheral blood and genotyped for the *rs30187* and *rs27044* SNPs of the ERAP1 gene by allelic discrimination. PBMC were isolated by Ficoll

layering and stained with ME1 (Native HLA B27), HC10 (free class I heavy chains), APC tagged anti-CD14 (monocytes) and PE tagged anti-C19 (B cells) antibodies to identify their respective surface molecules. 1 x 10^4 PBMCs were acquired by FACSCalibur and the mean fluorescence intensities (MFI) of ME1 and HC10 on whole PBMC, monocytes and B cells were analyzed using FlowJo. The MFI were compared between the genotypic groups using the dominant and recessive models with relevant statistical tests.

Results: Twenty nine patients (5 females) with a median (interquartile range –IQR) age of 37 (24, 47) years and median (IQR) disease duration of 15.3 (9.5, 24) years, were included in the study. The median (IQR) values for BASDAI, BASFI and BASMI were 3.5 (2.8, 6), 2.3 (1.3, 4.5) and 1.5 (1, 4) respectively. The frequency of patients with the different genotypes of *rs30187* was 3, 13, 13 (TT, CT, CC) and for *rs27044* was 4, 13, 12 (CC, CG, GG). There was no significant difference in the age, disease duration, BASDAI, BASFI, BASMI, ESR or CRP between the genotypic groups. The MFI for HC10 staining was significantly different across the genotypic groups by Kruskal-Wallis test (H=6.28, df=2; p=0.04). In the dominant model, there was significantly higher HC10 staining (Z=-2.4, p=0.01) as well as a lower ME1 to HC10 ratio on the monocytes of patients who had the *rs27044* minor allele G compared to those with only the major allele C. There was no significant difference in the ME1 staining in any cell population nor the HC10 staining in the whole PBMC or B cells in both models.

Conclusion: This is the first study to show a functional consequence of the ERAP1 Q730E variant and to implicate ERAP1 in the pathogenesis of AS, . This is further support for the free chain theory HLA B27 involvement in the pathogenesis of AS.

1449

Analysis of HLA B27 Effect On Macrophage Function Using Transgenic Mice. R. D. Inman and F. Zhu, University of Toronto, Toronto, ON

Purpose: The association of HLA-B27 with spondyloarthritis remains the strongest genetic association in rheumatic diseases, but the mechanistic role of B27 in disease pathogenesis remains unresolved. Hypotheses of B27 mechanisms have implicated distinct features of cell physiology (such as an unfolded protein response) which would predict distinct functional features. The present study addressed this question in mice transgenic for class I MHC alleles.

Method: Mice transgenic for HLA alleles B27, B7, and A2 were crossed with MHC class I-deficient mice (double knock-out, or DKO) so that the human HLA allele was the only class I MHC molecule expressed on the cell surface of the respective mice. Peritoneal macrophages were harvested after thioglycollate injection, and were coincubated with Salmonella typhimurium (1:10 cells/bacteria), IFN-γ (100 units/ml), or LPS (10 mg/ml). Readouts included (i) phagocytosis of bacteria (ii) intracellular killing of bacteria (iii) nitrite generation (iv) TNF-α production (v) IL-10 production.

Results: There was no significant difference in phagocytosis of S. typhimurium by macrophages of the respective mice at 1hr and 4hr time points. Intracellular killing of S. typhimurium was also comparable across the groups. There was no difference between the respective cells in nitrite generation after coincubation with S. typhimurium. In contrast, following exposure to S. typhimurium, B27+ macrophages produced less TNF-α (420.6- pg/ml +/- 16.6) than B7+ macrophages (630.4 pg/ml +/- 5.3) (p=0.002) but more than A2+ macrophages (302.5 pg/ml. +/- 20.5) (p=0.001). These B27-specific differences in TNF-α production were still observed when exogenous IFN-γ was added to the cells concurrent with the bacteria. There was no HLA-related difference in TNF-α production after incubation with LPS. After incubation with Salmonella, B27+ macrophages produced more IL-10 (199.4 pg/ml +/- 7.1) than B7+ macrophages (123.6 pg/ml +/- 7.4) (p=0.003) or A2+ macrophages (98.4 pg/ml +/- 7.1) (p=0.002).

Conclusion: Murine macrophages expressing HLA-B27 generate less TNF-α and more IL-10 than HLA-B7-positive macrophages after *in vitro* exposure to an arthritogenic pathogen. Diminished TNF-α production has previously been associated with defective host clearance of pathogens *in vivo*, suggesting that B27-related alterations in cytokine production may play a role in disease pathogenesis.

Imaging - Ultrasound

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1450

Inter-and Intra-Reliability of Ultrasonographic Joint Scoring in RA Patients with US Atlas as a Reference. Hilde Berner Hammer[1], Pernille Bolton-King[1], Vivi Bakkeheim[2], Torill Helene Berg[1], Elisabeth Sundt[1] and Espen A. Haavardsholm[1], [1]Department of Rheumatology, Oslo, Norway, [2]Department of Rheumatology, Trondheim, Norway

Ultrasonography (US) detects synovitis (BM) and vascularization (power Doppler,PD). Reliable measurements are necessary to assess disease activity. The OMERACT US group has described a scoring system for BM and PD; 0 = Normal, 1= Minor, 2=Moderate, 3=Major. A local US atlas was made using this scoring system, including several examples of each joint for each of the scorings in 32 joints.

Purpose: By use of the US atlas as background to assess the intra-and inter-rater reliability of US scoring (BM and PD) in 32 joints from RA patients.

Method: Five rheumatologists (with 3-8 years of US experience) examined 10 patients with RA (median (range) 63 (34-75) years old, disease duration 13 (3-24) years), with a printed US atlas available. An agreement had been made in advance on the scoring system. Each patient was in a room with a table for hand examination, a bench and an US machine with a fixed settings of BM and PD (Siemens Antares Acuson or Sonoline). Each sonographer was given maximum 20 min for scoring BM and PD of 32 joints (bilateral MCP 1-5, wrist (radiocarpal, intercarpal, radioulnar), elbow, knee, talocrural and MTP 1-5). The patients were assessed in a random order, with as long as possible interval before reassessing the same patient. A study nurse (with six years of experience with joint counting) performed the assessment of tender and swollen joints. CRP and ESR were analyzed. The intra-reliability of the US examinations was assessed by use of kappa values and percentage exact and close agreement, and the inter-reliability was analyzed by use of intraclass correlation coefficients (ICC).

Results: The patients had median (range) 3 (0-19) tender joints and 6 (1-17) swollen joints (of 28), CRP 15 (1-96) mg/l, ESR 27 (10-107) mm/h and DAS28 4.4 (2.9-8.2). Pathological BM (score ≥1) was found in 169 of 320 examined joints. The US examinations were performed on median (range) 16 (9-20) minutes. The intra-reliability results are shown in table 1, and the ICCs for BM and PD are shown in table 2 and 3.

Table 1

Rater 4	0.96	0.95	0.97	**0.94**	0.95
Rater 5	0.98	0.96	0.94	0.93	**0.93**

Intra- and inter-rater reliability BM score (ICCs for sum scores)

Table 3

	Rater 1	**Rater 2**	**Rater 3**	**Rater 4**	**Rater 5**
Rater 1	**0.96**	0.95	0.96	0.95	0.97
Rater 2	0.97	**0.99**	0.99	1.00	0.96
Rater 3	0.96	0.99	**0.97**	0.99	0.96
Rater 4	0.99	0.97	0.97	**0.95**	0.96
Rater 5	0.97	0.96	0.94	0.95	**0.98**

Intra and inter-rater reliability PD score (ICCs for sum scores)

Conclusion: High intra-and inter-rater reliability were found for BM and PD scoring of 32 RA joints in spite of a short examination time. The rheumatologists performing the US examinations had in advance agreed on a scoring system based on the US atlas, and use of an atlas may be important if US scoring should be used in longitudinal follow-up studies.

1451

Utility of Ultrasonographic Measures of Synovitis in Early Phase Clinical Trial Design. M. Seymour[1], F. Pétavy[2], F. Chiesa[2], H. Pocock[2], P. Lukey[3], M. Binks[3], C. McClinton[1], K. Dolan[1] and P. Taylor[1], [1]Imperial College London, London, United Kingdom, [2]GlaxoSmithKline, Middlesex, United Kingdom, [3]GlaxoSmithKline, Stevenage, United Kingdom

Purpose: Current practice in developing new therapeutics for rheumatoid arthritis (RA) involves clinical assessment of response by means of endpoints that include composite measures of disease activity, such as the Disease Activity Score (DAS28). However, many of the component measurements are subjective, imprecise and insensitive to change therefore necessitating lengthy clinical trials using large cohorts of patients. In this study we test the sensitivity of ultrasonographic endpoints to change in the context of an early phase clinical trial in patients with active RA.

Method: The study was a double-blind, placebo and comparator controlled, two-centre study to investigate the effect on synovial thickness and vascularity of 28 days repeat daily oral dosing of 60 mg of the oral iNOS inhibitor GW274150 or 7.5 mg prednisolone in RA subjects. All patients had disease activity defined as DAS28≥4.0 and at least one metacarpophalangeal joint (MCPJ) with either detectable vascularity or synovial thickening. 50 subjects were randomized into 3 treatment arms of 17, 19 and 14 (on placebo, GW274150 and prednisolone respectively). Synovial thickness and vascularity of all 10 MCPJs were assessed at 3 time points (pre-dose on Day 1, Day 15 and Day 28) using the Esaote Technos Plus with a 13MHz transducer. Images were ranked by semi-quantitative scale. Vascularity was also measured by quantitative determination of the power Doppler area (PDA).

Results: At Day 28 GW274150 showed a trend towards reduction in synovial thickness compared with placebo, with an adjusted mean decrease of 33% (p=0.072). Prednisolone 7.5 mg showed a statistically significant decrease of 44% (p=0.011) [Fig.1A]. GW274150 decreased synovial vascularity by 42% compared with placebo but the reduction was not statistically significant (p=0.075). However, prednisolone 7.5 mg resulted in a statistically significant decrease of 55% (p=0.012) [Fig.1B]. There was a 55% decrease in PDA for

GW274150, compared with placebo although the result was not statistically significant (p=0.375). Prednisolone 7.5 mg resulted in a highly statistically significant decrease of 95% (p=0.003) [Fig.1C]. There was a 0.42 decrease in the DAS28 score in the GW274150 group compared with placebo, however this was not statistically significant (p=0.290). Prednisolone showed a statistically significant adjusted mean decrease of 0.98 (p=0.018).

Conclusion: This study confirms the utility of ultrasonographic measures of metacarpophalangeal joint synovitis as a primary endpoint in early phase studies assessing the therapeutic potential of new compounds in small patient cohorts over a 28 day test period.

Ultrasound Quantification of Tendon and Hypodermal Abnormalities in Patients with Systemic Sclerosis. Paul R. Sweeney, R. Simms, Elliot Sternthal, Michael R. York, Hyon K. Choi and Eugene Y. Kissin, Boston University School of Medicine, Boston, MA

Purpose: Systemic sclerosis (SSc) can cause disabling hand contractures, and tendon friction rubs associated with disease severity. Abnormal dermal thickness in SSc has been quantified, but there has been no quantification of tendon involvement. Ultrasound has been used to shown tendon sheath enlargement in diabetic cheirarthropathy (DMc). We aim to define tendon, hypodermal, and skin alteration in SSc with ultrasound by comparing these structures in patients with SSc to those in patients with fibromyalgia (FM), and with DMc.

Methods: Consecutive patients on routine clinic visits with the established diagnosis of FM, DMc, or SSc were recruited. GE Logiq e Ultrasound System with 8-12 MHz linear array transducer, and electronic calipers was used to measure cross sectional areas of the 2nd flexor tendon at the MCP joint and the abductor pollicus longus at the distal radius. The skin and hypodermal thickness were measured at the midpoint of the dorsal forearm, at the interface of the common extensors and extensor carpi radialis. Hand function was assessed by Hand Mobility in Scleroderma (HAMIS) testing.

Results: 10 FM, 10 DMc , 17 limited SSc (lSSc), 14 diffuse SSc (dSSc) patients consented. There was no relationship between BMI, age, or height with any recorded measurements (demographics in Table). Student's T-Test was used to compare means. Diffuse SSc patients had greater mean forearm skin thickness and smaller cross sectional area of the 2nd flexor tendon than FM controls. Abductor pollicus longus cross sectional area was also smaller in patients with either lSSc or dSSc than in FM controls. Mean flexor tendon sheath thickness was greater in both dSSc and in DMc patients compared to FM controls. HAMIS functional testing showed significant impairment in patients with DMc, lSSc, and dSSc in comparison to FM.

Conclusion: This is the first quantification of chronic tendonopathy (tendon sheath thickening), and connective tissue wasting (tendon and hypodermal thinning) occurring in SSc. These changes are associated with SSc hand dysfunction, and are distinct from the changes that occur in DMc, a condition with a similar clinical appearance in the hand.

Ultrasonography Shows Persistent Hyperemia of Synovial Tissues in Rheumatoid Arthritis Despite Apparent Serological Remission.

Ralf G. Thiele, Allen P. Anandarajah and Darren Tabechian, University of Rochester, Rochester, NY

Purpose: The goal of treatment in rheumatoid arthritis is remission. The cardinal features of rheumatoid arthritis are synovitis and tenosynovitis, which subsequently lead to erosive disease and joint deformity. Synovitis can be assessed directly through biopsies, MRI assessment or ultrasound assessment. Often, only indirect measures are used to assess synovitis, including history and physical examination (assessment of painful and swollen joints). More indirectly yet, ESR and CRP are used as a measure of disease activity. However, despite widespread use, such clinical scores correlate only modestly with biopsy results and direct visualizion of inflamed tissues. This study aims at assessing the proportion of patients with active inflammation seen sonographically in patients whose ESR or CRP readings have remained within normal limits.

Method: Patient characteristics: All patients ("all comers") followed for rheumatoid arthritis (fulfilling ACR criteria and had a positive RF and/or CCP antibody) whose acute phase reactants (ESR and CRP) had remained within normal limits within a time frame from 5 days before to 5 days after the visit were included in this analysis to avoid selection bias (n = 233). Patient were seen and examined sonographically by one provider (R.T.) within a period of 3 months. Half of these patients (n=112) underwent an ultrasound examination of MCP joints 2-5, radiocarpal and midcarpal joints. Synovial tissue was defined as hypoechoic, poorly compressible and non-displaceable tissue within the hyperechoic joint capsule. Color and power Doppler examination were performed in all sonographically examined patients. Hyperemia of synovial tissue was defined as a color or power Doppler signal seen within the hyperechoic joint capsule, projecting over synovial tissue and displaying pulsation synchronous with the patient's pulse. Studies were performed on a Toshiba Xario XG machine using a 18 mHz linear probe or on a SonoSite M-Turbo using a 14 mHz linear transducer. At the time of the examination, patients were on no therapy or NSAIDs alone (n=23); on prednisone alone (n=11); on conventional DMARDs alone (n=89) or on biologic agents with or without additional DMARDs (n=111).

Results: Of all comers with RA and normal ESR and CRP, 19.3 % (45/233) were found to have active inflammation by Doppler ultrasound criteria. Of all patients that were examined sonographically, 40.1 % (45/112) had active inflammation. A higher percentage of patients in apparent remission treated with conventional DMARDs showed sonographic inflammation (21/89 or 23.5% of all comers; 21/45 or 46.6% of sonographically examined patients on DMARDs) than patients treated with biologics (9/111 or 8.1 % of all comers; 9/55 or 16% of all sonographically examined patients).

Conclusion: Ultrasound finds active inflammation in a substantial proportion of patients who are in apparent remission based on ESR and CRP normalization. In RA patients with normal CRP and ESR, hyperemic, proliferative synovial tissue is found more often in patients treated with conventional DMARDs than in patients treated with biologics.

Standardized Ultrasound Examination of the Hand in Patients with Rheumatoid Arthritis-a Multicentre Learning Experience: Education in Ultrasound of Rheumatoid Arthritis-EURA. K. Ellegaard[1], S. Torp-Pedersen[2], R. Christensen[3], M. Stoltenberg[4], Annette Hansen[5], T. Lorenzen[6], D. Jensen[7], Hanne Lindegaard[8], L. Juul[9], H. Røgind[10], P. Bülow[11], S. Chrysidis[12], M. Kowalski[13], Bente Danneskiold-Samsoe[14] and H. Bliddal[15], [1]KE, Copenhagen, Denmark, [2]STP, Copenhagen, Denmark, [3]RC, Copenhagen, Denmark, [4]MS, Køge, Denmark, [5]Gentofte, Gentofte, [6]TL, Denmark, [7]DVJ, Hørsholm, Denmark, [8]Odense University Hospital, Odense, Denmark, [9]LJ, Openhagen, Denmark, [10]HR, Openhagen, Denmark, [11]PB, Copenhagen, Denmark, [12]SC, Esbjerg, Denmark, [13]MK, Aalborg, Denmark, [14]Copenhagen, Denmark, [15]Parker Institute, Frederiksberg, Denmark

Purpose: There is a lack of standardized US examination procedures in the rheumatological area and such standardized procedures are needed. Standardized examination procedures are important in order to improve the validity of the US measurements and to make it possible to compare US studies from different institutions.

The purpose of this study was to investigate the learning progress for rheumatologists trained in a standardized US examination of the hand in patients with rheumatoid arthritis (RA).

Method: Ten rheumatologists from Denmark having varying experience in US were trained for two days in a standardized US examination of the wrist and MCP joints in pateints with RA . The examination contained both grey-scale and Doppler assessment. The tutors were two persons with intensive experience in US. After training, the rheumatologists performed the examination in their own clinics. All examinations were sent to the tutors for quality evaluation. The tutors evaluated the examinations according to a scoring sheet containing 16 positions (four in the wrist and 12 in MCP II-V). In each position nine items were scored.

Both the general examination technique and the Doppler examination technique were assessed. A high quality of the Doppler images is essential to obtain a valid measure of hyperaemia. Thus the general examination was accepted if >80% of the scores were correct, but the Doppler part was only accepted if >90% were correct.

Results: Ninety-six patients were scanned in a total of 378 examinations. High level of scores was obtained very fast, however some persisting mistakes were made throughout the study despite the intensive evaluation and feed-back. 97% of the examinations scored >80% in the general examination and 47% scored > 90% in the Doppler examination. No correlation was seen between earlier US experience and scores obtained. Some participants had decreasing scores in the study period, which might be due to carelessness.

Conclusion: Skills in a standardized US examination can be achieved relatively fast making US suitable for clinical practice and both single and multi centre trials. However, to ensure high validity, the investigators must continue performing systematic US examination. This is of particular importance in the Doppler examination.

Is Ultrasonography A Useful, Reproducible and Relevant Tool to Assess Erosion Progression in Rheumatoid Arthritis? Ghislaine Gill[1], Isabelle Chary-Valckenaere[1], Jean-Philippe Sommier[1], Anne-Christine Rat[1], Alain Blum[2] and Damien Loeuille[1], [1]Rheumatology, Nancy, France, [2]Radiology, Nancy, France

Purpose: The aim of this study is to evaluate the reproducibility of a new US erosions score in patients with Rheumatoid Arthritis (RA) and to define a threshold of US structural progression.

Method: 35 patients fulfilling ACR revised criteria for RA were included in a one year long prospective study (age: 51.4±13.7, female: 60%, anti-CCP: 78%, RF: 81%, disease duration: 53±46 months, DAS28: 3.88±1.18, DMARD: 91%, biological agents: 26%). X-rays and US were performed at baseline and at 1-year follow-up. US (Philips HD11 and ESAOTE MPX, linear probe: 5-12 MHz) examinations were performed by two experimented rheumatologists. Erosions at MCP2,3,5 and MTP2,3,5 joints were explored on dorsal, ventral and lateral facets (for MCP2,5 and MTP5 joints) and graded from 0 (absence) to 3 (erosion>3 mm or multiples erosions). ScUSSe (Scoring by US Structural erosions: 0-90) is the sum of grades of the 30 facets studied. US intra and inter-examiner reproducibility was assessed on 11 patients and modified van der Heijde Sharp Score (SHS) intra-observer reproducibility on 30 patients. To define a threshold of US structural progression, the Smallest Detectable Difference (SDD) and the Minimal Detectable Change (MDC) by Bland and Altman's formula have been calculated.

Results: Inter-examiner reproducibility of ScUSSe is excellent (ICC= 0.97 [0.92-0.99]). Inter and intra-examiner reproducibility, SDD and MDC for both imaging techniques are reported in the table. According to the SDD of the ScUSSe, 9/35 (26%) patients showed a structural progression (ΔScUSSe≥5). Among them, only 6 showed a structural progression on X-rays. The US progression observed was the occurrence of new erosion in 83% of cases and the worsening of pre-existent erosions in only 17% of cases. In US, the mainly affected joints were MCP2,5 and MTP5 (87%). Only 6/35 (17%) patients increased significantly their X-rays score (ΔSHS≥8). Spearman's correlation between ScUSSe and SHS at baseline is good (R= 0.61 [0.39-0.92]).

Conclusion: In RA, ScUSSe is a reproducible semi-quantitative score to grade erosions on 12 targeted joints. This US score permits to identify structural progression, defined by ΔScUSSe≥5. ScUSSe permits to identify more patients with a structural progression (50%) than X-rays.

	US ScUSSe (0-90)		**X-Ray** SHS (0-448)
Reproducibility study	**INTRA**	**INTER**	**INTRA**
SDD	4.15	4.06	7.29
MDC (%)	4.6	4.5	1.63

Table: Values of SDD and MDC for US intra-examiner, US inter-examiner and X-ray intra-examiner studies

SDD: smallest detectable difference= 1.96 σ ($exam_1$-$exam_2$)

MDC: minimal detectable change= SDD/ (maximal extreme for the score considered).

Metric Properties of Ultrasound Synovitis in Rheumatoid Arthritis (RA- Systematic Analysis of the Literature. C. Gaujoux-Viala[1], A. Baillet[2], G. Mouterde[3], P. Claudepierre[4], Xavier Le Loët[5], B. Fautrel[1] and Jf Maillefert[6], [1]Rheumatology, Paris VI University, Paris, France, [2]Rheumatology, Grenoble, France, [3]Rheumatology, Montpellier, France, [4]Rheumatology, Créteil Paris XII University, Créteil, France, [5]CHU Rouen, 76031 Rouen Cedex, France, [6]Rheumatology, Dijon, France

Purpose: To assess the metric properties of the ultrasound's synovitis examination in RA.

Method: A systematic review of the literature using PUBMED, EMBASE,Cochrane library and hand searches was performed until March 2009. The outcomes were reproducibility, criterion validity, construct validity, discriminant validity, predictive validity and sensitivity to change.

Results: Of 377 articles, 167 studies with data concerning US synovitis were analyzed.

The intra-observer reliability was evaluated in 19 studies: good (Kappa= 0.59 to 0.90) in 17 (14 with Power doppler assessment) and fair (k= 0.25) in the 2 others (1 with Power doppler). The inter-observer reliability, evaluated in 28 studies, was good in 26 (k= 0.59 to 0.98) (17 with Power doppler) and fair in the 2 others (1 with Power doppler). However half of the studies assessed static images reading rather than real-time acquisition reliability.

The criterion validity was achieved in 7 studies by comparison with histology and in 3 by comparison with macroscopic appearance. The concordance between US and magnetic resonance imaging was evaluated 24 times with a high level of agreement (62 to 100 %, mode B; 52 to 100 %, Power doppler) in 21 studies. The concordance was low in the 3 remaining works, all concerning the shoulder joint. Using MRI as a gold-standard, US was superior to physical examination to detect synovitis (12 studies).

The discriminant validity was excellent in cross-sectional studies evaluating RA patients and healthy controls, but low in the 3 studies comparing RA and other arthritides. The positive predictive value for the diagnosis of RA is unknown. The negative predictive value of US synovitis could be high: 80% if lacking any US synovitis and erosion and 95% in patients with negative antiCCP determination.

The predictive validity for the prediction of further structural progression was evaluated by 6 studies, which suggested that US synovitis is correlated to the 1-year follow-up structural changes (r = 0.59 to 0.78), even in patients clinically considered to be in remission.

The responsiveness was evaluated in 37 studies. 35 demonstrated a reduction in US markers of synovial inflammation following treatment with various agents. This reduction was correlated with similar changes in clinical and laboratory measures of disease activity.

Conclusion: Although further studies are needed to better assess the discriminant and predictive validity, the present results suggest that US examination is a reliable, valid and responsive tool for the assessment of synovitis in RA and more sensitive for assessing signs of disease activity than clinical measures. Further works are needed, particularly therapeutic strategy trials including US synovitis as a surrogate marker for the treatment management.

Does Sonographic Needle Guidance Affect the Outcome of Intraarticular Injections? Kye S. Park[1], Suzanne Delea[1], Natalia Chavez[1], Randy R. Sibbitt[2], Philip A. Band[3], Wilmer L. Sibbitt Jr.[1] and Arthur D. Bankhurst[4], [1]University of New Mexico, Albuquerque, NM, [2]Helena Pain Center, Helena, MT, [3]New York University Medical Center, New York, NY, New York, NY, [4]University of NM Med Ctr, Albuquerque, NM

Purpose: The present randomized controlled study addressed whether sonographic needle guidance affected clinical outcomes of intraarticular joint injections.

Method: 148 painful joints were randomized (NCT 00651625) to intraarticular triamcinolone acetonide injection by conventional palpation-guided anatomic injection or sonographic image-guided injection enhanced with a one-handed control syringe (the reciprocating procedure device). A one needle, two syringe technique was used where the first syringe was used to introduce the needle, aspirate any effusion, and anesthetize and dilate the intraarticular space. After intraarticular placement and synovial space dilation were confirmed, a syringe exchange was performed, and corticosteroid was injected with the second syringe through the indwelling intraarticular needle. Baseline pain, procedural pain, pain at outcome (2 weeks and 6 months), and changes in pain scores were measured with the 0-10 cm Visual Analogue Pain Scale (VAS).

Results: Relative to conventional palpation-guided methods, sonographic guidance resulted in 43.0% reduction in procedural pain ($p<0.001$), a 58.5% and 22.6% further reduction in absolute pain scores at the 2 week and 6 months outcome respectively ($p<0.01$), a 75% reduction in significant pain (VAS pain score ≥ 5 cm) ($p<0.001$), ($p<0.01$), 62.0% reduction in the non-responder rate (reduction in VAS score < 50% from baseline) ($p <0.01$), and an increase in duration of therapeutic effect by 22.1% ($p <0.01$). Sonography also increased detection of effusion by 200% and volume of aspirated fluid by 337%.

Conclusion: Sonographic needle guidance significantly improves the performance and outcomes of outpatient intraarticular injections in a clinically significant manner.

Baseline PASI Is Associated with Sonographic Enthesitis in Psoriatic Arthritis. Sibel Zehra Aydin[1], Pamir Atagunduz[1], Dilek Seckin[2], Tulin Ergun[2], Emilio Filippucci[3] and Haner Direskeneli[1], [1]Marmara University Faculty of Medicine, Rheumatology, Istanbul, Turkey, [2]Marmara University Faculty of Medicine, Dermatology, Istanbul, Turkey, [3]Università Politecnica delle Marche, Ancona, Italy

Purpose: Ultrasound (US) has shown to be a sensitive tool for revealing enthesitis, a predominant feature of spondylarthropathies. We aimed to investigate lower limbs entheses with US in patients with psoriasis, to compare US findings according to the presence of psoriatic arthritis (PsA) and to assess their change within time.

Methods: Sixty-six psoriasis patients (M/F: 31/35 mean (SD) age: 46.6(14.4)) and 20 body mass index (BMI)-age matched healthy controls (HC) were investigated. PASI (Psoriasis Area and Severity Index) was determined by a dermatologist and CASPAR criteria for PsA by a rheumatologist. US was performed using a MyLab70 US system (Esaote Biomedica, Genoa – Italy). The entheses of the lower extremities described in Glasgow Ultrasound Enthesitis Scoring System (GUESS) were scanned with power Doppler (PD) assessment. All US pathologic findings were graded semi-quantitatively from 0-2 as previously indicated (1). A grey-scale (GS) score, PD score, damage score (DS) and a total US score (TS) was determined. Twenty-nine (19 with PsA and 10 without PsA) patients were re-evaluated after a mean duration of 9 months.

Results: HC had significantly lower GS and TS compared to psoriasis patients. Fifty-nine percent (39/ 66) of psoriasis patients had PsA. GS, PD scores and DS were found similar in patients with or without PsA (table 1). In multiple regression analysis, GS score of PsAs significantly correlated to age and initial PASI ($r=0.58$, $p=0.001$), whereas the GS score of PsA(-)s only correlated to BMI ($r=0.36$, $p=0.019$) and not to age or baseline PASI. Similarly, DS of PsAs also significantly correlated to baseline PASI ($r=0.29$, $p=0,017$), whereas PsA(-)'s only correlated to BMI ($r=0.51$, $p=0.002$). Follow-up PASI scores were unrelated to US scores. The change in both GS and PD findings of 29 patients were not significant within time, regardless of PsA diagnosis.

Conclusion: US findings of enthesitis in psoriasis seem unrelated to the presence of arthritis. GS scores and DS correlated with the extent of skin involvement in PsA. The correlation between US findings indicating of enthesitis and the initial PASI scores only in patients with PsA suggests that there may be common mechanisms of inflammation at both skin and entheseal level in PsA.

Table 1: Comparison of US findings according to PsA.

	Baseline (n=66)		**Follow-up (n=29)**	
US findings	PsA (+) (n=39)	PsA (-) (n=27)	PsA (+) (n=19)	PsA (-)(n=10)
GS score (range)	7 (0-24)	6.5 (0-28	10 (0-24)	7 (2-11)
PD score (range)	0 (0-5)	0 (0-5	0 (0-6)	0 (0-1)
DS score (range)	6 (0-23)	5.5 (0-21	7 (0-20)	4.5 (0-17)

TS score (range)	13 (0-49)	12.5 (4-50)	19 (2-40)	12 (4-28)

Lower, Gender-Specific Cut-off Values for US Measurement of Achilles Enthesis Thickness May Better Identify Enthesitis in Spondyloarthropathies. Sibel Zehra Aydin[1], Emilio Filippucci[2], Sule Yavuz[1], Pamir Atagunduz[1] and Haner Direskeneli[1], [1]Marmara University Faculty of Medicine, Rheumatology, Istanbul, Turkey, [2]Università Politecnica delle Marche, Ancona, Italy

Purpose: To define the best cut-off value for identifying Achilles enthesis thickening using ultrasound (US) in patients with spondyloarthropathies (SpA) and to assess its diagnostic utility in comparison with different cut-off values used in the literature (1-3).

Method: Fifty-five SpA patients and 46 age and BMI-matched healthy controls (HC)) were investigated. US was performed using a MyLab70 US system (Esaote Biomedica, Genoa – Italy) with a linear probe 6-18 MHz. Three images per Achilles enthesis were stored and antero-posterior thickness of the enthesis was measured at the level of the Achilles tendon deeper margin insertion into the calcaneal bone on longitudinal median scan. The best cut-off value for each gender was determined by ROC curve analysis. The other cut-off values were 5.29 mm for both genders, according to *Balint et al* (2), and 5.5 mm for females and 6.2 mm for males, according to *Schmidt et al* (3). The number of measurements exceeding the cut-off values as well as specificity (SP), sensitivity (SE), positive (PPV) and negative (NPV) predictive values were calculated.

Results: A significant difference was found for Achilles enthesis thickness between genders (mean ±SD: 4.6±0.7 mm in males vs 4.0±0.8 mm in females, $p<0.00$) and between SpA patients and HC (mean ±SD: 4.4±0.8 mm in SpA patients vs 4.0±0.8 mm in HC, $p<0.001$). The ROC curve analysis revealed the best cut-off value as 3.9 mm for females and 4.8 mm for males (SE: 46-58%, SP: 71-79%, PPV: 69-74%, NPV: 53-59%) (Table 1). Cut-off values for Balint et al. and Schmidt et al. were found to have high SP (91-98%) but with very low SE (2-11%).

Table 1: Diagnostic value of different cut off levels for entheseal thickness

	Sensitivity	Specificity	PPV	NPV	accuracy
Balint et al	10	96	73	47	54
females	11	98	88	49	57
males	11	91	63	44	49
Schmidt et al	4	99	80	46	48
females	5	98	75	48	50
males	2	97	50	43	44
Current study	53	74	70	57	62
females	58	71	69	59	63
males	46	79	74	53	62

Conclusion: Achilles tendon thickness differs between genders, thus it is crucial to refer to normal values specific for gender (*Aydin et al, ACR Meeting 2008; 804*). High cut-off values, previously suggested, showed very low SE in the current study. When Achilles enthesis

thickening is used for the purpose of screening enthesitis in SpA patients, a lower cut-off value has a higher SE with slightly worse SP, PPV and NPV.

Musculoskeletal Ultrasound Assessment of Carpal Tunnel Syndrome in Rheumatoid Arthritis. Michelle M. Ryan[1] and Jonathan Samuels[2], [1]NYU-HJD, New York, NY, [2]NYU - Hospital for Joint Diseases, New York, NY

Purpose: Wrist pain in rheumatoid arthritis (RA) is often complicated by carpal tunnel syndrome (CTS) secondary to active synovitis. In such cases it can be difficult to determine whether to inject the joint or the carpal tunnel – or treat systemically. Recent literature suggests that musculoskeletal ultrasound can diagnose CTS by identifying a median nerve cross sectional area of >10mm^2 at the inlet, or by using a wrist to forearm ratio of >1.4 (from inlet to 12 cm proximally) to correct for patients with confounding diagnoses that may cause larger nerves at baseline (Hobson-Webb 2008). In this pilot study, we aim to assess how well ultrasound can identify median nerve entrapment noninvasively *specifically in RA patients with active wrist pain*.

Methods: We enrolled 19 consecutive patients with RA and active wrist pain in at least one wrist (total of 28 wrists) and assessed them for CTS by history and physical. Using gray scale ultrasound imaging at 12 MHz, we identified the median nerve at the level of the inlet (volar wrist between the scaphoid and pisiform) and 12 cm proximally to calculate the "wrist-to-forearm" ratio. More than a month after capture, we blindly evaluated median nerve cross-sectional area with a tracing function on the machine and calculated the ratio from wrist to forearm. We averaged the scores from two readings (one each by MMR and JS) for each patient.

Results: In our pilot population of painful RA wrists, irrespective of CTS signs or symptoms, the overall average median nerve size at the inlet was 10.9 (range 5.5 to 26, SD of 3.9), while the overall average wrist-to-forearm ratio was 1.9 (range 1.32 to 2.80, SD of 0.47) Separating those with (n=12) and without (n=16) CTS signs and symptoms, the average median nerve areas at the inlet were 13 mm^2 and 9.42 mm^2 respectively (p=0.0097). The corresponding wrist to forearm ratios for patients with and without CTS signs and symptoms averaged 2.19 and 1.68 (p=.0032). Of the patients with CTS signs and symptoms, 92 % (11of 12) had an inlet nerve size >10 mm^2 and 100 % (all 16) had a wrist-to-forearm ratio greater than the published 1.4 cutoff for CTS. Only 25% (4 of 16) of those without CTS signs and symptoms measured an inlet of >10 mm^2, but 75 % (12 of 16) of these asymptomatic patients had a wrist-to-forearm ratio >1.4.

Conclusion: This pilot data suggests that ultrasound evaluation of the median nerve by assessing cross sectional area at the wrist inlet is a sensitive and specific test in RA patients with active wrist pain, as it is in the general population. Conversely, the wrist-to-forearm ratio, introduced to compensate for size variability in healthy median nerves, may reveal false positive results for carpal tunnel syndrome in patients with RA and wrist pain. Measurements of the median nerve at the inlet can help distinguish RA synovitis of the joint from median nerve compression -- and thus spare patients from painful nerve conduction studies.

US Examination of Wrists and Hands: A Comparison Between Rheumatoid Arthritis and Psoriatic Arthritis. A. Delle Sedie[1], N. Possemato[1], E. Sardano[2], Stefano Bombardieri[3] and L. Riente[1], [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Immunology Unit, University of Pisa, Pisa, Italy, [3]University of Pisa, Pisa, Italy

Purpose: Very little is known about the possible differences in the involvement of joints and periarticular structures in rheumatoid or psoriatic arthritis (PsA). The main pathological features detected by US in rheumatoid arthritis (RA) are synovitis and bone erosion while, in spondyloarthropathies, entheseal inflammation is the common feature. Tendon involvement is particularly frequent and dactylitis is a typical PsA manifestation.

Aim of the study was to investigate the features of wrist and hand involvement in PsA and RA.

Method: Bilateral ultrasound (US) examination of the wrist and hand was performed, by the same physician, in a group of subjects affected by RA (n=25; F:M=20:5; disease duration: 12.5±11 years) and PsA (n=25; F:M=8:17; disease duration: 8.5±7 years), using a Logiq 9 (General Electrics Medical Systems, Milwaukee, WI) with a linear probe operating at 14 MHz. We examined radiocarpal, intercarpal, metacarpophalangeal, proximal interphalangeal and distal interphalangeal (DIP) joints and flexor and extensor tendons (both in wrist and hand). The patients were recruited on a time-criteria (the last 25 patients for each diagnosis who camed for an outpatient control) from the whole number of subjects referring to the US unit of our Clinic.

Results: US examination showed joint wrist synovitis in 10/25 (40%) and 12/25 (48%) patients (in PsA and RA respectively), hand synovitis in 14/25 (56%) and in 16/25 (64%) RA and PsA patients respectively. We found DIP joint involvement in only 1 PsA patient, as it was for dactylitis (in a different PsA patient). Bone erosions were present in 10/25 (40%) patients, both in RA and PsA group. Tendon involvement was present in the 7/25 (28%) and 5/25 (20%) in the wrist and 7/25 (28%) and 10/25 (40%) in the hand respectively.

Conclusion: We did not observed significant differences in wrist or hand involvement (both in joint and tendon structures) between RA and PsA patients, except for a more frequent involvement of PIP joints and a slightly higher hand's tenosynovitis in PsA group.

Assessment of Calcific Tendonitis of Rotator Cuff by Ultrasonography: Comparison Between Symptomatic and Asymptomatic Shoulders. Benoit Le Goff[1], Jean-Marie Berthelot Jr.[2], Pascale Guillot[2], Joelle Glemarec[2] and Yves Maugars[2], [1]University hospital, Nantes, France, [2]University Hospital, Nantes, France

Purpose: Calcific tendonitis of rotator cuff is observed on plain radiographs in 10% of adults, but remains asymptomatic in half these cases. Whereas US is widely used for the diagnosis of rotator cuff tears and tendonitis, few studies evaluated this technique in the management of calcific tendonitis. We looked for differences on ultrasound (US) and power Doppler findings between symptomatic and asymptomatic cases of shoulder calcific tendonitis to search for US features associated with pain.

Method: Sixty-two patients (81 shoulders) with symptomatic (N = 57) or asymptomatic (N = 24) calcific tendonitis were included. From each patient, we recorded: demographic data, onset and duration of symptoms, intensity of the pain and nocturnal pain. Ultrasonography of the shoulders was performed using a multifrequential linear transducer (5 to 12 Mhz). Calcific plaque morphology, power Doppler signaling, and widening of the subacromial-subdeltoid bursa (SSB) were recorded. US-guided steroid injection into the SSB (N = 21) or needle puncture of calcific deposits (N = 29) was performed at the end of US evaluation in 50 of the 57 patients with symptomatic shoulders, and a questionnaire was sent to each patient after 11 +/-6 months. For statistic analysis,Wilcoxon' signed rank test and Fisher's exact test were used. The *p* value less than 0.05 was considered statistically significant.

Results: The distal supraspinatus tendon was the most common site of calcification deposit (89%). The mean longitudinal ($p<0.0001$) and transverse ($p=0.0015$) measurements of the plaques were significantly higher in symptomatic than in asymptomatic shoulders. Fragmented calcifications were also associated with pain ($p=0.01$). A power Doppler signal was identified in 21 of the 57 symptomatic calcification (36%), but in none of the cases of asymptomatic calcification ($p<0.005$). It was associated with the existence of nocturnal pain ($p=0,03$) and the longitudinal size of the calcification ($p=0,03$). A widening of the SSB was found in 17 of the 57 symptomatic calcification (30%) but in none of the asymptomatic calcification ($p<0.005$). At least, Doppler signal or widening of the SSB was present in 31 of the 57 (54%) symptomatic shoulders ($p<0.001$). Long term outcome was favourable for 60% of our patients after steroid injection. However, no correlation was found between the evolution of the pain and the US characteristics at the first evaluation.

Conclusion: We found that ultrasonographic findings associated with symptomatic calcific tendonitis are a larger size and a fragmented aspect of the calcification. Positive power Doppler signal within the calcific deposit and SSB widening are also US features strongly associated with pain with a high specificity. US can help physicians to confirm that calcification is responsible for shoulder pain.

Baseline Ultrasonographic Shoulder Assessment Can Predict the Functional Status in PMR Patients After Steroid Treatment. Pierluigi Macchioni, Mariagrazia Catanoso, Luigi Boiardi, Irene Modesto and Carlo Salvarani, Arcispedale S.Maria Nuova, Reggio Emilia, Italy

Purpose: To evaluate the relationship between US shoulder examination and the functional status in PMR patients before and after corticosteroid treatment.

Method: 80 PMR (according to Healey criteria) consecutive outpatients were prospectively evaluated in a single secondary center for clinical and laboratory parameters at diagnosis and during CS treatment for a median follow-up of 6 months (range 4-12 m). All the patients had shoulder US examination by standardized method at the same times. The clinical assessments included the core set parameters considered in EULAR response criteria and the Health Assessment Questionnaire (HAQ). Leeb's desease activity score were calculated at each visit. HAQ value of 42 PMR age matched patients during disease remission were used as controls. Chi square test was used to calculate differences between groups.

Results: 79 patients (F60pts/M19pts, mean age 75±7y, mean disease duration15±27wks) completed the study. Pretreatment mean values were : ESR 55±22.5mm/1st h, CRP 4.2±3.25 mg/dl, pain VAS 73±18mm, patient VAS 70±7mm, physician VAS 66±8, HAQ 1.79±0.47, morning stiffness 172±118min, Leeb's DAS 36.5±14.6. Baseline US examination showed bilateral bursal distension in 57% of the pts, bilateral involvement of long head biceps tendon in 71%, bilateral gleno-humeral distension in 15%.

After CS treatment HAQ score and US signs of shoulder inflammation were significantly reduced (p=0.021 and p=0.001 respectively). Patients with HAQ values below the median value of controls (0.25) were considered as HAQ responders. Comparing HAQ responders vs HAQ non-responders we found that female sex (OR 6.65, 95%CI 1.96-22.5), presence of peripheral joint involvement (OR 3.1, 95%CI 1-9.64), US presence at baseline of bilateral bursal and glenohumeral distension (OR 2.76, 95%CI 1.1-6.96 and 4.36, 95%CI 0.97-21.7 respectively) and presence of sopraspinatus tendon lesion (OR 3.46, 95%CI 1-12) were correlated with reduced functionality at 6 month examination. At the time of the second US examination there was a significant correlation between the number inflammed shoulder structure at US and the HAQ value (Spearman=0.419,p<0.001).

Conclusion: US examination is a useful tool to recognize PMR patients with reduced functionality after CS treatment.

1464

Predicting Radiographic Progression in Rheumatoid Arthritis with Ultrasound and Biomarkers. G. Cavet[1], Y. Shen[1], S. Abraham[2], D. Chernoff[1], M. Centola[3] and P. Taylor[2], [1]Crescendo Bioscience, Inc., South San Francisco, CA, [2]Imperial College London, London, United Kingdom, [3]OMRF, Oklahoma City, OK

Purpose: The ability to predict progressive joint damage has the potential to improve disease management decisions and outcomes for patients with rheumatoid arthritis (RA). Ultrasonographic B mode imaging (US) can be used to evaluate accumulated joint damage and when used together with power Doppler imaging can also be used for assessment of synovial inflammation and associated vascularity. Studies suggest that expert examination by ultrasound is more sensitive to bone erosions and joint inflammation than X-rays or clinical examination. However, such examination is not available or practical in some clinical settings. Blood-based biomarkers that report on the current rate of joint destructive processes could present a powerful complementary approach to identify patients at risk of accelerated bone and cartilage damage.

Method: We examined samples and data from 24 patients followed in a 2-year blinded study comparing methotrexate+infliximab with methotrexate alone in aggressive early RA. Patients were evaluated with US at 0, 18, 54 and 110 weeks and scored for synovial thickening (ST) and for vascularity by power Doppler area (PDA). Radiographic examination with van der Heijde modified Sharp scores was carried out at 0, 30, 54 and 110 weeks. 93 serum proteins associated with biological processes underlying joint damage were measured in serum samples from 0, 6, 18, 54 and 110 weeks. Associations were examined by Spearman correlation. Multivariate analysis used longitudinal hierarchical linear models, evaluated using leave-one-out cross validation.

Results: Patients all had erosions at baseline and experienced a wide range of changes in total Sharp scores (TSS; median change 6.25, inter-quartile range 4-14.5). Detailed clinical outcomes are reported elsewhere. Ultrasonographic scores from early in the study were predictive of radiographic progression. Predicted rates of change in TSS from 0-110 weeks based on ST or PDA at 18 weeks (with time and treatment)

were correlated to actual changes (r=0.59 and r=0.77 respectively in leave-one-out cross validation). Candidate serum biomarkers were also correlated with change in TSS, with the fewest significant correlations observed in baseline samples and the most in 6 week samples. 34 proteins were correlated with change in TSS using combined biomarker time points (FDR<0.05), representing diverse biological processes including inflammatory regulation, ECM degradation and collagen metabolism. Predicted rates of change in TSS from a multivariate model based on biomarkers at 6 weeks (with time and treatment) correlated strongly with observed changes (r=0.79 in leave-one-out cross validation).

Conclusion: Both ultrasonographic imaging and quantitative serum protein biomarkers can be used to estimate rates of progression and predict joint damage in RA. Serum proteins associated with change in TSS represent multiple biological pathways. Predictive models using US and biomarkers have the potential to improve patient outcomes.

Ultrasonographic and Physical Examination of the Inflamed Knee: Intra and Inter Rater Reliability of the Sonographers and Clinical Examiners. Feride Gogus[1], Gulen Hatemi[2], Koray Tascilar[3], Melike Melikoglu[2], Sebahattin Yurdakul[2], Hasan Kilic[2], Serkan Yalim[2], Mine Batumlu[2] and Hasan Yazici[2], [1]Gazi University, Faculty of Medicine, Ankara, Turkey, [2]Istanbul University, Cerrahpasa Faculty of Medicine, Istanbul, Turkey, [3]Numune Research and Teaching Hospital, Ankara, Turkey

Background: We had previously shown in a pilot study that there was considerable inter observer variation in physical examination of the knee. The correlation with ultrasonographic (US) examination was also wanting (1).

Purpose: i) To test intra and inter observer variability of the clinical examination of the knee among clinicians with different levels of rheumatology expertise. ii) To test the intra and inter observer variability of the ultrasonographic examination. iii) to investigate the concordance between the ultrasonographic and clinical examination of the knee.

Patients and Methods: Twenty healthy volunteers and 21 patients with inflammatory arthritis of the knee were included in the study. A rheumatology nurse directed the clinical and ultrasonographic examination sequence in order to maintain blindness. Patients were asked to lie under sheets to conceal their identity and expose the knee joint areas only. 4 examiners (2 rheumatology attendings, 1 rheumatology fellow and 1 resident in internal medicine) examined 82 knee joints twice on the same day. Each examiner visually evaluated the presence of joint swelling, then performed clinical examination with a patellar tap and a sweep test. Two rheumatologists experienced in US and blinded to the clinical examination results did US examinations twice. Presence of effusion and synovial hypertrophy were checked at the suprapatellar, medial and lateral joint regions in standard longitudinal and transverse planes. A semiquantitative 0-3 scale was used for US evaluation for joint effusion and synovial hypertrophy. Data analysis was made by Kendall's coefficient of concordance and Kappa statistics for agreement.

Results: Intra observer agreement between the rheumatology attendings was better than that of the rheumatology fellow and the medicine resident (κ=0.57-1.00 and κ= 0.25-0.77 respectively). On the other hand, the inter observer agreement among the four clinicians was poor in any of the two-way comparisons. Ultrasonographic inter observer agreement (κ) varied between 0.73 and 0.91 in detecting synovial effusion and hypertrophy respectively. Intra observer agreement (κ) at 6 US examination planes differed between 0.39-1.00.

Conclusion: The inter observer variation in physical examination of the knee is considerably more than in US examination**.** The concordance of the physical examination findings is better among more experienced physicians.

The CUSP Study: Comparison of Ultrasound and Physical Findings in Inflammatory Arthritis. BM Lynch[1], J. Kitchen[2], U. Fearon[1], G. Renard[1], O. FitzGerald[1], D. Kane[2] and DJ Veale[1], [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Adelaide and Meath Hospital, Dublin, Ireland

Purpose: High-resolution gray-scale ultrasonography allows detection of erosions, synovitis and effusions in synovial joints in inflammatory disease. Power Doppler (PD) imaging allows functional depiction and assessment of inflamed joints and soft tissues. This study aimed to correlate clinical and ultrasound (US) findings and investigate if power Doppler imaging correlates with vascular endothelial growth factor (VEGF) in inflammatory arthritis.

Method: Patients with Rheumatoid (n=16) and Psoriatic arthritis (n=4) commencing biologic therapy underwent assessment at baseline, 6 and 12 weeks. Patient global and 28 joint counts were performed by an independent clinical assessor. C-reactive protein (CRP) was measured by nephelometry assay and DAS28(CRP) was calculated. US examination of seven joints (wrist, metacarpophalangeal joints 2 and 3, proximal interphalangeal joints 2 and 3, metatarsophalangeal joints 2 and 5) on the dominant hand was performed using standardised presets on a GE Logiq 9 machine with a high frequency (15MHz) linear array transducer by two trained investigators. Gray-scale (GS) and PD synovitis were graded semi-quantitatively. Serum VEGF was measured by ELISA. The results are expressed as mean ± SEM.

Results: GS and PD synovitis scores significantly correlated with DAS28(CRP) both alone and in combination ($p<0.05$). DAS28(CRP) decreased from 4.58 ± 0.27 at baseline to 3.47 ± 0.26 and 3.53 ± 0.27 at 6 and 12 weeks respectively. Similarly, PD scores decreased from 0.76 ± 0.11 at baseline to 0.71 ± 0.13 and 0.72 ± 0.12 at 6 and 12 weeks respectively. Inter-observer variability was very good ($r=0.94$). At baseline, VEGF was 719.28 ± 82.96pg/ml , and at 6 and 12 weeks post biologic therapy was 609.47 ± 75.94pg/ml and 658.82 ± 69.43pg/ml respectively. VEGF did not significantly correlate with power Doppler at any time point in ACR responders and non-responders.

Conclusion: The simplified 7 joint US score used, significantly correlated with DAS28(CRP) validating it as a useful score for assessing synovitis in inflammatory arthritis. VEGF is released in inflammatory arthritis in response to TNF-α, and has been implicated in increasing endothelial permeability and swelling and stimulating angiogenesis. Although VEGF decreased at 6 and 12 weeks post biologic therapy compared to baseline, this did not correlate with PD which is in agreement with observations made by Strunk et al[1]. This suggests dissociation between VEGF secretion and PD or a delayed effect which may become apparent at a later time point.

1467

Evaluation of the 7-Joint Ultrasound Score (US7) by One Year Follow-up Data with Regard to Disease Duration. Sarah Ohrndorf[1], Lydia Naumann[2], Ekkehart Dietz[3], Herbert L. Kellner[4], Johannes Strunk[5], Tina Backhaus[1], Wolfgang Hartung[6], Horst Sattler[7], Gerd R. Burmester[2], Wolfgang A. Schmidt[8] and Marina Backhaus[2], [1]Charité-University Medicine Berlin, Berlin, Germany, [2]Charite University Hospital, Berlin, Germany, [3]Berlin, Germany, [4]Munchen, Germany, [5]Cologne, Germany, [6]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, Bad Abbach, Germany, [7]Bad Dürkheim, Germany, [8]Med Ctr Rheumatol Berlin Buch, Berlin, Germany

Purpose: To further examine US7 of the clinically dominant hand and foot in daily rheumatologic practice by one year follow-up data with regard to disease duration.

Methods: US7 examines clinically dominant wrist, MCP and PIP II and III, MTP II, and V joints for synovitis, tenosynovitis/paratenonitis and erosions by grey scale (GS) and power Doppler (PD) ultrasound (US).

Patients both with early (< 2 years) and long-standing (≥ 2 years) rheumatoid arthritis (RA) and psoriatic arthritis (PsA) were examined at baseline and at 3, 6 and 12 months after start or change of DMARD and/or TNF-inhibitor therapy.

CRP, ESR, DAS28 and US7 were performed.

Results: N=64 patients with disease duration (dd) < 2 years (yrs) and n=137 patients (77% women) with dd ≥ 2 yrs of RA (95%) and PsA (5%) were evaluated.

Both patient groups had an initial moderate disease activity of DAS28=4.9 (dd < 2 yrs) or DAS28=4.8 (dd > 2 yrs).

The initial mean GS and PD synovitis scores of patients with dd < 2 yrs were 7.0 and 3.3, and they had a mean level of ESR=30 mm/h and CRP=19.8 mg/l.

Patients with dd ≥ 2 years had initial higher mean GS and PD synovitis scores of 8.5 and 4.3; their mean ESR was 28 mm/h and mean CRP was 13.5 mg/l.

With DMARD (53%) or TNF inhibitor+/-DMARDs (47%), all evaluated parameters significantly decreased, except for PD tenosynovitis/paratenonitis score as well as erosion score in patients with dd < 2 yrs (see tables 1 and 2).

Conclusion: US7 is a more sensitive tool for examining arthritic patients as it is able to identify disease activity in GS- and PD-US, although patients might seem to be in similar clinical status. By that, US7 is a tool which could influence therapeutic decisions in daily rheumatologic practice. It significantly reflects the therapeutic response.

Laboratory, disease activity and US data of patients with dd < 2 yrs

	Baseline	After 3 months	After 6 months	After 12 months
Mean ESR	30.0	19.2*	19.2*	18.2*
Mean CRP	19.8	7.7*	6.3*	5.5*
Mean DAS 28	4.9	3.5*	3.4*	3.1*
Mean GS synovitis score	7.0	4.7*	4.6*	4.3*
Mean PD synovitis score	3.3	1.8*	1.5*	1.3*
Mean GS tenosynovitis / paratenonitis score	1.2	0.8*	0.7*	0.4*
Mean PD tenosynovitis / paratenonitis score	0.6	0.4	0.4	0.2
Mean erosion score	0.9	1.2	1.0	1.2

**p-value < 0.05 to baseline examination by 2-sided exact Wilcoxon test*

Table 1

Colour Duplex Ultrasonography in the Diagnosis and Management of Giant Cell Arteritis. Giovanni Ciancio[1], Matteo Colina[1], Renato La Corte[1], Francesco De Leonardis[1], Stefania Volpinari[1], Maria Fotinidi[1], Alessandra Bortoluzzi[1], Savino Occhionorelli[2], Antonietta Vanini[3], Marcello Govoni[1] and Francesco Trotta[4], [1]Rheumatology Section, Ferrara, Italy, [2]General Surgery-University of Ferrara, Ferrara, Italy, [3]Non Invasive Vascular Diagnostic Service-S.Anna Hospital, Ferrara, Italy, [4]Rheumatology Section, Ferrara

Purpose: Though several studies have emphasized the diagnostic potentialities of color duplex sonography (CDS) in giant cell arteritis (GCA) biopsy remains the gold standard for the diagnosis. Recently it has been suggested that the dark hypoechogenic halo is strongly related to the acute phase of the disease so CDS of the temporal artery may be a useful tool in monitoring and assisting glucocorticoid tapering in patients with GCA. To date, acute phase reactants are generally used for this purpose but they are not absolute indicators of disease activity. The aim of our study was to evaluate the role of color duplex ultrasonography in diagnosis and follow-up in patients with GCA

Methods: Thirteen consecutive outpatients aged more than 50 years who presented in the last 18 months with suspected GCA were prospectively studied. All patients satisfied the American College of Rheumatology (ACR) classification criteria for GCA. Bilateral CDS examination to check for halo's thickness, ESR and CRP were performed at baseline, 2, 4 and 6 weeks after initiation of corticosteroid treatment. Temporal artery biopsy was performed in all the 13 patients and it was directed to a particular arterial segment in the cases with evidence of halo.

Results: A dark halo of variable size (0.7–2.0 mm) around the vessel lumen was evident at baseline in 10 patients (bilaterally in 7,unilaterally in 3). No CDS alterations were found in 3 patients. Biopsy did prove positive for GCA in all the 10 patients with halo and negative in the 3 patients without CDS changes. During follow-up, halo's thickness decreased progressively and returned to normal earlier than ESR and CRP. Patients without CDS changes and biopsy negative were finally diagnosed as polymyalgia rheumatica (two) and crowned dens syndrome (one).

Conclusion: According to other studies, our data confirm that CDS may be considered a very useful tool in the diagnostic assessment of GCA and follow-up. It may be useful in guiding the site for biopsy . Since it has demonstrated to be more sensitive than VES and PCR it may allow a better monitoring and tapering glucocorticoid therapy.

Synovial Hypertrophy of Metatarsophangeal Joints Is Not Specific of Inflammatory Rheumatism. Frédérique Gandjbakhch[1], Violaine Foltz[1], Sylvie Rozenberg[1], Pierre Bourgeois[2] and Bruno Fautrel[3], [1]MD, Paris, France, [2]Rheumatology, Pierre et Marie Curie University-Paris VI, Paris, France, [3]MD, PhD, Paris, France

Purpose: Ultrasonography practice has considerably increased in the past few years to manage inflammatory rheumatism. Only few data concerns the impact of metatarsophlangeal joints examination for diagnosis of inflammatory rheumatism.

Method: We underwent a case control study performed on 14 rheumatoid arthritis (RA) patients and 13 runners. Exclusion criteria of the runners consisted in history of tender or swollen joint of the feet and hands and history of inflammatory rheumatism. Ultrasonography (US) examination of metatarsophalangeal (MTP) joints was realized by the same rheumatologist with 4 years experience in RA ultrasonography practice. MTP 1 to 5 were examined bilaterally with a My Lab70 ESAOTE equipment in grey scale and in Power Doppler (PD) mode and scored in a semiquantitative score (0-3) according to OMERACT recommandations. Synovial hyperthrophy thickness was measured in dorsal plane perpendicularly to cortical bone at the maximum synovial thickness point. Statistics analysis was performed on a SAS 9.1 software.

Results: 85% of RA patients were female, mean age was 43+/-12 years old, mean disease duration was 6+/-6 years, 78% were positive for FR, 71% were erosive on Xrays. They were all treated by DMARD and one of them were treated by Adalimumab. 50% of them had corticosteroid treatment with a mean posology of 3 mg/day. Runners were female in 46% and mean age was 37+/- 9 years. MTP B- mode Synovitis was not specific of inflammatory arthritis and was detected in most of the runners (table 1). The location of synovitis differed between RA patients and runners. Synovitis appeared mostly in MTP 1 to 3 in runners, while it affected all MTP joints in RA patients, especially MTP5. There was a statistical significant difference concerning the number of synovitis between RA patients and runners in B mode (p=0.0012) and in Doppler mode (p=0.0008). There was also a significant difference between the 2 groups concerning the total score in Bmode (p=0.0121) and in Dopler mode (p=0.0008) and concerning the synovial thickness (p=0.0024). Roc curves were undertaken to determine a cut-off for synovial thickness and total score of B-mode synovitis discrimating between RA and runners. A cut-off were respectively 16 mm for synovial thickness and 10 for Bmode score.

Percentage of patients with at least one synovitis on MTP1 to5

		S Mtp1	S Mtp2	S Mtp3	S Mtp4	S Mtp5
B mode	RA	100	100	100	78	56
	runners	100	92	84	53	8
PD mode	RA	29	23	42	35	35
	runners	7,69	0	0	0	0

Conclusion: MTP Synovitis were not specific of inflammatory rheumatism and could be detected in runners. Yet, runners MTP synovitis and RA MTP synovitis differed in thickness and B-mode score. A cut-off has been determined to distinguish them. Doppler signal was nearly insignificant in runners. This data should be taken into account to help RA diagnosis.

Is Familial Mediterranean Fever (FMF) Associated with Non-Alcoholic Fatty Liver Disease (NAFLD) ? Doron Rimar[1], Itzhak Rosner[1], Michael Rozenbaum[1] and Eli Zuckerman[2], [1]Bnai Zion Medical Center, Faculty of Medicine, Technion, Haifa, Israel, [2]Carmel Medical Center, Faculty of Medicine, Technion, Haifa, Israel

Purpose: FMF is a periodic febrile disease. Liver disease is not considered a part of the spectrum of clinical manifestations of FMF and only rarely such an association has been described. The purpose of this study is to describe and characterize the chronic liver disease which may be associated with FMF.

Method: 26 patients (mean age 48±4.1 years, F:M 16:10) with FMF who were referred to the Liver Unit in Carmel Medical Center for assessment of chronically abnormal liver tests were studied. Data regarding FMF and liver disease were obtained from patient medical files. Liver biopsy was performed in 19 of 26 patients, avoided in 5 (cirrhotic coagulopathy) and was not done in two patients who refused).

Results: Most patients had definite FMF (23) with mean Tel Hashomer severity score of 1.7. Age of onset of FMF was 18 ±8.2.The mean daily dose of colchicine was 1.4±0.3 mg over a mean duration of 22 years ± 8. In 15 of 23 patients there was evidence of NAFLD: 4 with "simple" steatosis, 4 with NASH (one with HBsAg+) and 7 with NASH-cirrhosis. Additional 5 patients had "cryptogenic" cirrhosis (2 with HBcAb+), 4 had chronic "cryptogenic" hepatitis and one had normal liver tissue. Only 5 patients had metabolic syndrome (4 had NASH-cirrhosis) and the mean BMI was 26 ±4.1. Congo red staining for amyloid was negative in all liver biopsies. Seven of 11 patients who underwent mutation analysis for FMF were homozygous for M694V.

Conclusion: 76% of our FMF patients with chronic abnormal liver tests had NAFLD (biopsy proven in most of them) (58%) or "cryptogenic" cirrhosis (19%), which in many patients represents the end result of unrecognized NASH. The extremely high proportion of NAFLD and cryptogenic cirrhosis in our cohort of FMF patients without overt metabolic syndrome may indicate an unappreciated novel association between FMF and NAFLD, which may be related to inflammation induced by IL-1, prolonged colchicine treatment or genetic predisposition.

1471

Serum Cartilage Oligometric Matrix Protein (COMP) Level Is a Marker of Disease Activity in Relapsing Polychondritis. Fernando Kemta Lekpa[1], Jean -Charles Piette[2], Sylvie Bastuji-Garin[1], VB Kraus[3], T. Stabler[4], A. Robin Poole[5], André Marini-Portugal[1] and Xavier Chevalier[6], [1]Hopital Henri Mondor, Creteil, France, [2]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [3]Duke University Medical Center, Durham, NC, [4]Duke University Medical Center, Durham, [5]McGill University, Lancaster, [6]Hopital Henri Mondor, Créteil, France

Purpose: Relapsing polychondritis (RP) is a rare and severe disease which may lead to destruction of elastic cartilages. Until now, no reliable biomarker of disease activity in RP has been available. This study was designed to measure serum levels of cartilage biomarkers during both active and inactive phases of the disease.

Method: Serum levels of cartilage oligomeric matrix protein (COMP), chondroitin sulfate 846 epitope (CS846) of proteoglycan aggrecan and collagen type II collagenase cleavage neoepitope (C2C) were measured retrospectively in 21 subjects with RP. The Wilcoxon matched-pairs signed-rank test was used for statistical comparisons of biomarker levels in active and inactive phases of RP.

Results: Table 1 shows serum biomarker levels in the active and inactive phases of RP. Only the serum level of COMP was significantly increased during disease flares (*p = 0.05*). Steroids did not alter the serum cartilage-related biomarker levels. However, during the active phase, C2C levels were significantly higher in steroid treated patients compared with non-steroid treated patients (66.7 [44.6-81.4] vs 109 [92.6-135.9], *p*=0.011).

Table 1. Serum biomarker levels in the active and inactive phases of relapsing polychondritis.

	Phase of Disease		*p value**
Biomarkers	Active phase (n=21)	Inactive phase (n=21)	Active phase vs. Inactive phase
COMP ng/ml	694.8 [446.4-754.6]	335.7 [241.8-479.3]	0.05
CS846 epitope µg/ml	0.227 [0.147-0.266]	0.189 [0.131-0.227]	0.51
C2C pmol/ml	82.5 [56.5-121.7]	95.6 [68.8-107.2]	0.49

Concentrations are expressed as median [interquartile range]

* *p values* of the Wilcoxon matched-pairs signed-rank test.

Conclusion: This study suggests that serum COMP level may be useful for monitoring disease activity of RP. Further prospective studies are required to confirm this result.

Immunosuppressant Related Neurological Involvement in Behçet's Disease. Akiko Suda[1], Haruko Ideguchi[2], Mitsuhiro Takeno[1], Shigeru Ohno[2] and Yoshiaki Ishigatsubo[1], [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama City University Medical Center, Yokohama, Japan

Purpose: Immunosuppressants such as cyclosporin A (CsA) are efficient for ocular lesions in Behçet's disease (BD), though the agents often cause neurological involvement, which is hardly distinguishable from neuro- Behçet's disease in a natural history.

Methods: Based on clinical charts, clinical features, therapeutic agents, outcomes and other backgrounds were retrospectively reviewed in a total of 412 BD patients who were under care at two Yokohama City University Hospitals from 1991 to 2007.

Results: Fifty-four (13.1%, 21 female, 33 male) of 412 patients had neurological symptoms. Of them, 24 patients had received CsA (20 patients) or Tac (4 patients) before onset of neurological manifestations. While the frequency of neurological symptoms was 26% (24 patients) in 93 patients who had previous medication with CsA or Tac, 9% (30 patients) of 319 patients had never received the immunosuppressive agents ($p<0.001$). No association was found between blood CsA levels and neurological manifestations. Although most of the patients receiving the immunosuppressive agents had uveitis, the incidence of neurological involvement was no different than in the other patients with ocular lesions. There was no association of development of the immunosuppressant related neurological with other

clinical backgrounds such as age, gender, disease duration and HLA-B typing. While 20 of 24 patients had meningitis and/or brainstem encephalitis, which were categorized as the acute type, three patients had a chronic progressive course. Discontinuation of the agents led to remission in 4 patients, and additional corticosteroid therapy resulted in remission in another 9 patients.Re-administration of CsA caused another neurological attack in one patient, whereas 6 patients relapsed acute type episode without these agents.

Conclusion: Our study revealed that treatment with CsA and Tac significantly increased the frequency of neurological manifestations in BD, though the immunosuppressants rarely cause CNS complication in other diseases. Latent CNS lesions may be responsible for the drug related neurological involvement in BD.

1473

Subgroup Analyses Demonstrate Consistent Response to Rilonacept (IL-1 Trap) in Patients with Cryopyrin-Associated Periodic Syndromes (CAPS). Hal M. Hoffman[1], Kristen M. Scheble[2], Douglas Nadler[3] and Steven P. Weinstein[4], [1]University of California at San Deigo, La Jolla, CA, [2]Regeneron Pharmaceuticals, Tarrytown,, NY, [3]Regeneron Pharmaceuticals, Tarrytown,, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Purpose: The IL-1 inhibitor rilonacept (IL-1 Trap) 160 mg/week effectively controlled symptoms in 47 patients with CAPS (44 with familial cold auto-inflammatory syndrome [FCAS] and 3 with Muckle-Wells syndrome [MWS]) in a randomized, double-blind, placebo-controlled trial. An analysis of correlations between baseline patient/disease characteristics and treatment response was undertaken to determine whether any factor influenced response to rilonacept in this study.

Method: Forty-seven CAPS patients were randomized to 6 weeks of treatment with rilonacept 160 mg/week SC (after a loading dose of 320 mg) or placebo. Primary end point was change in key symptom score (KSS), a mean of patient-reported severity score for the 5 key CAPS symptoms (rash, fever/chills, eye redness/pain, joint pain, fatigue), between baseline and week 6, assessed using the Daily Health Assessment Form (DHAF). For the current analysis, change in KSS was compared in different subgroups of patients receiving rilonacept or placebo. Linear regression analysis was used to evaluate the impact of continuous baseline variables (age, weight, height, C-reactive protein [CRP] or serum amyloid A [SAA] level at baseline) on baseline KSS and change in KSS at week 6. Generalized linear modeling was used to undertake correlation analysis for categorical variables: region of residence, gender, presence of high CRP (>20 mg/L) or SAA (>100 mg/L) level at baseline or L353P mutation.

Results: Response to rilonacept was consistent and significant vs placebo in all patient subgroups (Table) analyzed by age, gender, CAPS diagnosis (FCAS or MWS) or baseline disease severity. No correlation was found between mean KSS at baseline and region of residence, age, weight, height, gender, CRP or SAA level at baseline, presence of high CRP (>20 mg/dL) or SAA (>100 mg/dL) level or L353P mutation (P>0.2 for all), nor was there any correlation between any baseline factor and the response to treatment at week 6 in the whole cohort (n=47) or rilonacept-treated patients (n=23) [all non-significant]. The response in patients with MWS (n=3) was similar to that in patients with FCAS.

Conclusion: In a representative population of US CAPS patients, response to rilonacept was consistent in all patients and not influenced by baseline disease or patient characteristics.

Subgroups	**Placebo**		**Rilonacept**		**P-value**
	N	**Change from baseline in KSS**	**N**	**Change from baseline in KSS**	
All patients	24	–0.3	23	–2.6	<0.0001

1474

The IFN-Inducible Gene Signature Is Elevated in SCLE and DLE and Correlates with CLASI Score. Inbal Braunstein, Rachel Klein, Misha Rosenbach, Joyce Okawa and Victoria P. Werth, University of Pennsylvania, Philadelphia, PA

Purpose: To study a set of five interferon (IFN)-inducible genes (LYGE, OAS1, OASL, MX1 and ISG15) in the blood of patients with different subsets of cutaneous lupus erythematosus (CLE) and to correlate expression levels with clinical activity and levels of IFN-inducible chemokines in the skin. Prior studies in SLE show a nonsignificant increase in IFN-inducible gene expression in patients with a history of malar or discoid rash (Feng et al, A&R 2006).

Method: Peripheral blood was obtained from 10 healthy controls and 33 patients with CLE (12 SCLE, 14 DLE, 4 TLE, 3 ACLE). Three subjects (1 SCLE, 2 DLE) were enrolled in a clinical study of lenalidomide for CLE. Total RNA was extracted and reverse transcribed into complimentary DNA. Gene expression levels were measured by real time PCR and normalized to GAPDH. An IFN-score was calculated using published methods. Disease activity was assessed with the Cutaneous Lupus Area and Severity Index (CLASI). Indirect immunohistochemical staining was performed on formalin-fixed, paraffin-embedded skin biopsy samples using anti-human CXCL10 polyclonal antibody. Staining was quantified on 6 high power images (200x) using ImagePro software.

Results: SCLE and DLE patients had significantly elevated IFN-scores as compared to healthy controls ($p<0.05$). The IFN-score correlated with CLASI scores when all 33 patients were analyzed (Spearman $r = 0.5553$, $p = 0.0008$). SCLE subjects who were actively smoking had higher IFN-scores (Spearmans $r = 0.8193$, $p = 0.0011$). The IFN-score did not correlate with expression of CXCL10 in the skin. Three subjects in an ongoing clinical study of lenalidomide for CLE exhibited a dramatic decrease in the IFN-score after two weeks of therapy. (Average baseline IFN score ± SEM: 29.53±1.39, average week two IFN score ± SEM:7.32 ± 2.42). Two of these subjects had concomitant clinical improvement. Levels of CXCL10 staining also decreased from baseline to week 6 in the study subjects, however one subject who did not have clinical improvement with treatment had a robust increase in CXCL10 expression at week 2.

Conclusion: The 5 IFN- inducible genes that are highly expressed in patients with SLE are also highly elevated in patients with DLE and SCLE as compared to healthy controls. These findings point towards a shared pathogenesis between SLE and some subtypes of CLE. In addition this gene signature correlates with CLASI scores, suggesting a potential biomarker of disease activity. We did not find a correlation between IFN-score and IFN-inducible chemokine expression in the skin. This may reflect the variability in the expression of CXCL10 in the skin, and/or suggest a complex relationship between levels of IFN-inducible genes and levels of IFN-inducible chemokines in the skin. Further study is needed to understand the role of elevated IFN-inducible gene expression in CLE.

1475

Correlates of Clinical Response in the Circulating Leukocyte Profile of Subjects On Lenalidomide for Cutaneous Lupus Erythematosus. Inbal Braunstein[1], Noah G. Goodman[2], Misha Rosenbach[1], Joyce Okawa[1], Eline T. Luning Prak[2] and Victoria P. Werth[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia

Purpose: Lenalidomide has been shown to be a potential alternative or adjunctive treatment for patients with severe generalized DLE that is refractory to standard therapies (Shah et al, 2009). Lenalidomide is a thalidomide analogue with potentially fewer side effects than thalidomide. Here we investigated the use of lenalidomide in a larger group of patients with different subtypes of treatment refractory CLE (DLE, SCLE and TLE).

Method: Five subjects with refractory CLE were treated with lenalidomide in an off-label trial using 5 or 10 mg of lenalidomide daily. Immunophenotyping was performed on fresh whole blood samples at baseline and at weeks 2 and 6 of treatment. Antibodies directed against cell surface markers of Dendritic Cells, T-cells, B-cells, regulatory T-cells (Tregs), Cutaneous Lymphocyte Antigen, Natural Killer cells, and T-cell activation markers were used.

Results: Four of the five subjects demonstrated skin improvement. One subject with skin improvement developed worsening arthralgias and new-onset proteinuria and was withdrawn from the study. Here we report trends in the circulating leukocyte subsets in four subjects with skin improvement and unique features of the leukocyte profile in the subject who developed arthralgias and proteinuria. In the subjects showing skin improvement the following trends were observed: decreased percentage of plasmacytoid dendritic cells (pDCs) (mean±SEM: -74% ± 7%) and a mean 4-fold increase in Treg percentage (mean±SEM: 4.1-fold increase ± 1.8-fold increase). Results for the non-responding subject did not follow these trends. Four subjects with available data showed an increase in CD4+ CD25+ HLA-DR+ percentage. This increase was more marked in the three who had responded clinically (mean±SEM: 3-fold increase ± 0.5-fold increase in three responders vs. 0.9-fold increase in the nonresponder). The subject who developed arthralgias and new-onset proteinuria had elevated numbers of resting memory B cells at baseline (~14%), and a robust and unique increase in activated pDCs at week 6.

Conclusion: Here we see evidence that increases in circulating Tregs and T-cell activation markers, and decreases in circulating pDCs may serve as biomarkers of clinical response to lenalidomide in some patients with CLE. Furthermore, these preliminary data suggest that lenalidomide activates T-cells and may activate pDCs, potentially triggering systemic disease in a subset of susceptible CLE patients.

Anti-Inflammatory Effect of Alpha-2 Adrenergic Agonists On Endothelial Cells. Ada Herrera-García[1], María-Jesús Domínguez-Luis[1], Ana Díaz-Martín[1], Maria Teresa Arce-Franco[1], Manuel Feria-Rodríguez Sr.[2] and Federico Diaz-Gonzalez[1], [1]Hospital Universitario de Canarias, Tenerife, Spain, [2]Faculty of Medicine, Tenerife, Spain

Purpose: Two stress pathways, the hypothalamic-pituitary-adrenal axis and the sympathetic nervous system regulate the immune response through the release of corticosteroids and norepinephrine, respectively. Norepinephrine recognizes adrenergic receptors (alpha and beta1) expressed in the surface of cells involved in the inflammatory response. Our group has observed that alpha 2 adrenergic agonists are able to modulate the inflammatory response in animal models of inflammation. However, the mechanism through which these compounds reduce the inflammatory response has not been clarified. OBJECTIVES: To study the potential anti-inflammatory effect of alpha$_2$ adrenergic agonists in human neutrophils and endothelial cells.

Method: Human neutrophils were isolated from peripheral blood of normal donors and incubated at 37ºC for 20´ in medium alone or in the presence of the alpha 2 agonists, xylazine or UK14.304 and/or the alpha2 antagonist, RX821002. Human umbilical venous endothelial cells (HUVEC) isolated from donors were activated with TNF- alpha (20ng/ml) for 6-12h in medium alone, in the presence of one of the alpha2 agonists and/or RX821002. The effect of xylazine and UK14.304 on the basal expression of VCAM-1, ICAM-1 in HUVEC, was assessed by flow cytometry analysis. The strength of endothelial intercellular junctions was analyzed by VE-Cadherin staining and confocal microscopy. Neutrophil migration capability through activated endothelium was assessed by transwell assay (5µm) where IL-8 was the chemotactic factor. Variation in the L-Selectin and CD11b expression in neutrophis activated with TNF-alpha (20ng/ml, 20min) in basal conditions, in presence and absence of Xilazine and UK14.304 were assessed by flow cytometry. Wilcoxon test ($p<0.05$) was used to evaluate the statistical significance.

Results: Both alpha$_2$ adrenergic agonists prevent the variations in L-selectin and CD11b basal expression in a doses-dependent manner in human neutrophils activated with TNF- alpha. In activated HUVEC, the presence of xylazine significantly reduced the up-regulation of ICAM-1 in a doses-dependent manner, with a maximum of 0.8 microM ($p<0.01$). The basal migration of human neutrophils through activated HUVEC was decreased up to 40±8% in presence of UK14.304. This effect was reverted by RX821002. The endothelial intercellular surface positive for VE-Cadherin staining was increased in a 50% by UK14.308 respect to the basal.

Conclusion: The alpha$_2$ adrenergic agonists are able to modulate the inflammatory response at endothelium level. These compounds cause a reduction in the neutrophil movement across the endothelial barrier. This finding supports the endothelium as a therapeutic target for developing new anti-inflammatory agents potentially useful for rheumatic diseases.

Evaluation of Lasting High Levels of CRP Among the Patients with Metabolic Syndrome. Osamu Saiki[1], Makihiko Kuhara[1] and Hiroshi Uda[2], [1]Osaka Prefecture University, Habikino, Japan, [2]Sakai Onshinkai Hospital, Sakai, Japan

Purpose: "Low grade" systemic inflammation is very common findings in patients with metabolic syndrome (MetS). The elevation of CRP levels in these patients is one of causes of several cardiac and metabolic diseases. However, the elevation of CRP is limited (usually less than 10mg/L). Among these patients, we found several patients who presented high levels of CRP without significant clinical symptom of inflammatory diseases for a long time.

The main focus of present study is to determine whether the lasting high levels of CRP is due to MetS or to the other inflammatory diseases, and also to determine whether the treatment for the elevated CRP levels is necessary in these patients.

Method: The patients who met the Japanese criteria for MetS (n = 256) were assessed. Determination of CRP level was mainly based on a high sensitivity enzyme-linked immunosorbent assay. Carotid plaques were evaluated by ultrasound of cervical artery. The abdominal fat distribution was assessed by computed tomography and the scan was performed at the abdominal level. Some patients with high levels of CRP were treated with anti-inflammatory drugs including methotrexate (MTX).

Results: Among 256 patients with MetS, we found eight patients who showed high levels of CRP (40~10mg/L) for more than 5 years. In these patients, the levels of CRP have not changed significantly and are between 40 and 10 mg/L throughout the observation. The levels of serum amyloid A, fibrinogen, and CH50 were also elevated. In the rest of the patients, the levels of CRP were less than 10 mg/L as reported elsewhere. These eight patients have not shown subfever, cough, or other clinical symptoms characteristics for inflammatory diseases. Indeed, no patients have swollen joint or radiographic bone change, but three out of eight patients complained moderate arthralgia of large joint such as knee, shoulder or hip. The levels of rheumatoid factor and anti-CCP antibody were within normal limits and these patients have not satisfied any criteria of inflammatory diseases such as rheumatoid arthritis or collagen disease. Five patients received MTX for more than 1 year but the levels of CRP or the clinical symptom did not improved. In all eight patients, the area of visceral fat was more than 200cm^2. However, the other patients of visceral fat over 200cm^2 presented low levels of CRP. The eight patients showed insulin resistance as was seen in other patients. Ultrasound study of carotid plaques showed no differences between patients of high CRP levels and those of low CRP levels.

Conclusion: There are a series of patients who show high levels of CRP for a long time without clinical symptoms of inflammatory diseases. High levels of CRP merely cannot explain by visceral fat area, insulin resistance, or carotid plaques. MTX treatment was not effective for those patients and it is necessary to clarify the mechanism of elevation of CRP levels and how we take care of these patients.

The Genetics and Clinical Presentation of a Novel TRAPS Mutation. Rachel Glaser, Anna Simon, John G. Ryan, Richard M. Siegel and Daniel L. Kastner, National Institutes of Health, Bethesda, MD

Background: The TNF receptor associated periodic syndrome (TRAPS) is an autoinflammatory disorder characterized by recurrent febrile episodes caused by autosomal dominant mutations of *TNFRSF1A*. TRAPS attacks are distinguished from other periodic fever syndromes by their prolonged duration of attacks, and association with abdominal pain, pleuritis, arthritis, and a centrifugally migrating myalgia and rash.

Purpose: To investigate the genetics, protein expression, and clinical phenotype of a novel mutation in *TNFRSF1A*.

Methods: The index patient was identified as having suspected TRAPS based on his clinical presentation. Data including demographics, flare characteristics, laboratory findings, and treatment were obtained from family members with symptoms consistent with TRAPS. Sequencing of *TNFRSF1A* was performed. Western blot analysis of whole cell lysates from peripheral blood mononuclear cells (PBMCs) of two of the patients was performed.

Results: We identified six affected family members in three generations (see Figure 1). Western blot analysis demonstrated intracellular accumulation of the TNFR1 protein, similar to that seen in other known *TNFRSF1A* mutations. Genetic analysis of the *TNFRSF1A* gene confirmed the presence of a C52G mutation in the 3 symptomatic family members tested. An asymptomatic first degree relative did not carry the mutation. This mutation has not been previously described. The clinical phenotype of the C52G mutation includes fever of 1-4 weeks duration, abdominal pain, diarrhea, and myalgia. .Rash was present in a single patient. Ocular symptoms, oral ulcers, sore throat, pleurisy, and arthralgia were absent. Frequency and intensity of attacks were most severe in the index patient. Inflammatory markers and acute phase reactants were elevated during times of flare with subsequent normalization during periods of remission in the patient for whom data was available.

Conclusion: The novel C52G mutation in *TNFRSF1A* is associated with a phenotype typical of TRAPS and behaves similarly to other cysteine mutations at the protein level, suggesting a trafficking defect with accumulation of the mutant protein in the endoplasmic reticulum. The observed differences in severity of attacks amongst the identified patients may indicate a variable penetrance of this mutation. Western blot analysis of PBMCs is consistent with the accumulation of TNFR1 seen in patients with other severe structural mutations. Exploration of the specificity of Western blot for diagnosis may be of clinical interest.

Are Azathioprine, Cyclophosphamide and Chlorambucil Effective for the Treatment of NON Infectious Autoimmune Uveitis? A Systematic Literature Review. Esperanza Pato[1], Ana M. Ortiz[2], Miguel Abad[3], Loreto Carmona[4], Estibaliz Loza[4], Jesús Maese[4], Santiago Muñoz-Fernández[5] and Felix Francisco[6], [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Hospital de la Princesa, Madrid, Spain, [3]Caceres, Spain, [4]Fundación Española de Reumatología, Madrid, Spain, [5]Madrid, Spain, [6]Rheumatology Section, Hospital Doctor Negrin, Las Palmas de Gran Canaria, Spain

Non infectious autoinmune uveitis (NIAU) might develop a severe course with poor visual prognosis if an adequate control of the disease is not achieved. The treatment of autoimmune uveitis are corticosteroids and immunossupressive agents (IS). Azathioprine (AZA), cylophospamide (CY) and chlorambucil (CB), are IS used for the treatment of these uveitis.

Purpose: To systematically review the published evidence regarding the efficacy of AZA, CY and CB in NIAU.

Method: Systematic review of studies retrieved by a sensitive search strategy in Medline, Embase and Cochrane Library, up to October 2007. Randomized controlled trials, observational studies and case series were included. Selection criteria: population: patients with NIAU (intermediate, posterior and panuveitis); intervention: studies had to test cyclosporine A, tacrolimus, sirolimus, methotrexate, mycophenolate

mofetil, AZA CY and CB; outcomes: visual acuity, Tyndall, vitreous haze, retinal vasculitis, macular edema, pars planitis and adverse events. Three reviewers screened the titles and abstracts of the retrieved articles for selection criteria independently and collected the data by using *ad hoc* standard forms. One of them also graded the quality of the selected studies using a modification of the Oxford Centre for Evidence-based Medicine Levels of Evidence in its May 2001 update.

Results: A total of 128 articles were studied in detail, of which 39 were studies of NIAU with AZA, CY or CB. 13 studies were excluded (literature review, combined treatment), and 26 were included (2 randomized controlled trials, 1 clinical trial, 5 prospective studies,18 retrospective case series). A total of 443 patients with NIAU were analyzed (associated with Beçhet disease, Vogt-Koyanagi-Harada, serpiginous choroiditis, sympathetic ophthalmia and other diagnosis). in spite of the great variability regarding the study design, study samples, treatment duration and outcomes, most patients on AZA, CY or CB showed an stabilization or improvement in the visual outcomes. Minor adverse events were reported.

Conclusion: Treatment with AZA is effective and safe in the treatment of patients with Behçet associated uveitis (level of evidence 1A, grade of recommendation A), and is effective and safe for the treatment of NIAU (level of evidence 4, grade of recommendation C).

Treatment with CY and CB are effective and safe in the treatment of NIAU (level of evidence 4, grade of recommendation C).

Effect of Infliximab On the Treatment of Refractory Posterior Uveitis After Withdrawal of Infusions Due to Remission. Mª Victoria Hernández[1], Juan José Molina[2], Gerard Espinosa[3], Virginia Ruíz-Esquide[1], José A. Gómez-Puerta[1], Josefa Martin[1], Alfredo Adán[2], Ricard Cervera[3], Juan D. Cañete[1] and Raimon Sanmartí[1], [1]Arthritis Unit. Rheumatology Department. Hospital Clínic, Barcelona, Spain, [2]Ophthalmology Department. Hospital Clínic, Barcelona, Spain, [3]Autoimmune Diseases Department. Hospital Clinic, Barcelona, Spain

Purpose: Although efficacy of infliximab (INF) therapy has been demonstrated in some cases of refractory posterior uveitis, it is not established how long treatment should be administered once remission has been achieved and when it should be discontinued. Our objective was to determine the efficacy of INF treatment and outcomes in patients with refractory posterior uveitis after withdrawal of infusions

Method: : 17 patients with posterior uveitis refractory to immunosuppressive drugs (IMS) and/or oral glucocorticoids (GC) were treated with INF (at a dose of 5 mg/kg/iv at 0, 2, 6 and every 8 weeks thereafter), for a minimum of 12 months, until complete remission was achieved. In those patients that showed a good response to INF, therapy with IMS and GC was progressively discontinued. When remission was achieved and maintained during at least six months, INF was discontinued and patients were subsequently evaluated monthly. The main outcome measures were: intraocular inflammation (assessed using the binocular indirect ophthalmoscopy score), best corrected visual acuity (BCVA), and foveal thickness measured by optic coherence tomography (OCT)

Results: Seven out of 17 patients achieve remission and therapy with IMS, GC and INF were discontinued in a progressive form. Of the seven patients, four were female; mean age was 31 ± 5.4 years (range 25-38) and the mean follow-up after INF discontinuation was 8.7 ± 5.2 months (range 4-18). Four patients had posterior uveitis associated with Behçet disease, 2 diffuse subretinal fibrosis syndrome and 1 idiopathic posterior uveitis. Mean INF treatment was 13 infusions (range 9-18). Four out of 7 patients (57.2%) remained in complete remission with no relapses during the follow-up, and are currently without therapy. BCVA was stable in 10 eyes and deteriorated in three. The OCT showed worsening in the macular edema in the three patients with reactivation.

Conclusion: INF is an efficient long-term treatment of refractory posterior uveitis. Repeated infusions are required to maintain long-term remission, which may be sustained, leading to drug discontinuation in a significant percentage of patients.

Dysfunctional Chemotaxis in Familial Mediterranean Fever. Nona T. Colburn[1], Jae Jin Chae[2], Kristina Zaal[2], James Balow Jr.[2], John McManigle[3], Ivona Aksentijevich[2], Hong-Wei Sun[4], Beverly K. Barham[2] and Daniel L. Kastner[2], [1]National Institutes of Health, Bethesda, MD, [2]NIAMS/NIH, Bethesda, MD, [3]Durham, NC, [4]NIH | NIAMS, Bethesda, MD

Purpose: Familial Mediterranean fever (FMF) is a heritable autoinflammatory disease characterized by substantial neutrophil influx at sites of serosal and synovial involvement. Inflammatory attacks are usually prevented by prophylaxis with colchicine, a microtubule inhibitor. Pyrin, the FMF protein, colocalizes with microtubules and may impact leukocyte cytoskeletal functions such as adhesion and migration. We therefore sought to further investigate leukocyte migration in FMF.

Method: Peripheral blood samples were obtained from 25 treated patients, 10 untreated patients, and 16 controls. Subsets of patients were studied in several assays. Mononuclear cells were stimulated for 24 hours with TLR ligands 2, 4, 5, 7, and 9. Chemokines produced from cultured supernatants and from serum samples were evaluated with the Luminex immunoassay. Analysis of gene expression sequences with the Affymetrix system was utilized in 8-paired patient samples who underwent colchicine withdrawal. Chemotaxis assays included a transwell system and a live imaging protocol with both patient granulocytes and the neutrophil-like PLB cell line transfected with V726A, M680I, and M694V pyrin mutations, stimulated to various chemoattractants, including MIP-1 alpha, IL-8 and fMLP.

Results: Microarray analysis revealed a “chemotactic signature” induced by colchicine withdrawal with upregulation of major chemotactic genes including CRK and Integrin beta-1, and downregulation of genes involving chemokine receptors and cell adhesion molecules such as CCR 7 and CXCR3. Moreover, neutrophil activation was increased, as seen with the downregulation of the L-selectin marker, CD 62L. Asymptomatic FMF patients on colchicine showed elevated serum levels of the chemokines, MIP-1 alpha and beta, as compared to controls. In addition, mononuclear cells from treated patients stimulated ex-vivo, suggest a role for TLR4, 5, and 9 in the modulation of chemokines, specifically MIP-1 alpha and beta. Patients off colchicine demonstrated significant hyperresponsive cell movement compared with treated patients and controls, although such movement was found to be random (chemokinetic) and less directed (chemotactic) when visualized. By transwell analysis of the transfected neutrophil-like PLB cell line hypermobility was more apparent with the V726A mutation.

Conclusion: A cascade of intracellular events involving chemokine signaling can impact leukocyte migration in FMF. This study has focused on determining the extent to which these effects represent the underlying pathophysiology of FMF, independent of colchicine.

Improved Health-Related Quality of Life in Patients with Cryopyrin-Associated Periodic Fever Syndrome (CAPS) After Treatment with Canakinumab (Ilaris) – A Fully Human Anti-IL-1beta Monoclonal Antibody. H.J. Lachmann[1], I. Koné-Paut[2], J. Kuemmerle-Deschner[3], K. Leslie[4], E. Hachulla[5], P. Quartier[6], A. Ferreira[7], N. Patel[8], K. Lheritier[7], R. Preiss[8] and P.N. Hawkins[1], [1]National Amyloidosis Centre, UCL Medical School, London, United Kingdom, [2]Hopital, Kremlin Bicetre, Le Kremlin Bicetre, France, [3]Pediatric Rheumatology, Universitätsklinik, Tübingen, Germany, [4]UCSF, School of Medicine, San Francisco, CA, [5]Hopital Claude Huriez, Lille Cedex, France, [6]Unité d'Immunologie, Hopital Necker-Enfants Malades, Paris, France, [7]Novartis, Basel, Switzerland, [8]Novartis, East Hanover, NJ

Background: The direct impact of CAPS on patients' well-being is often underestimated due to limited available data on patients' perception of the disease. In the 48 weeks pivotal Phase III study with canakinumab in CAPS, health reported quality of life (HRQoL) was assessed as an exploratory endpoint at baseline and during treatment using a variety of patient reported outcomes to evaluate the direct impact of the disease on patients' well-being and the improvements observed following treatment with canakinumab.

Purpose: To evaluate the improvement in HRQoL in CAPS patients during treatment with canakinumab.

Methods: In this 3-part study patients received canakinumab 150 mg s.c. or 2 mg/kg s.c. (body weight ≤40 kg) every 8 weeks. HRQoL was assessed in adults using the following domains: general mental and physical health (SF-36®), fatigue (FACIT-Fatigue®) and functional disability (HAQ-DI®).

Results: Baseline scores for general mental and physical health (SF-36®) and fatigue (FACIT-Fatigue®) were considerably lower than those expected in the general population and demonstrates the significant impact that CAPS has on patients' well-being (Table). Following the first canakinumab dose, SF-36 and FACIT-Fatigue® scores improved to the levels expected in the general population. An improvement in functional disability was observed as shown by HAQ-DI scores. HRQoL scores at the end of this 1 year study (48 weeks) were comparable

to those observed following the first injection, and suggest that patient's well-being is improved to levels seen in the general population without chronic disease.

Conclusion: CAPS has a significant impact in patient's well being due to the physical effects of systemic inflammation mediated by direct neurotrophic effects of IL-1beta leading to the deleterious effects on patients physical and mental health. Canakinumab every 8 weeks provides improvement in quality of life, to that of the general population, across a variety of standardized measurement tools addressing physical and emotional well-being as well as fatigue.

Table: Comparison of HRQoL scores of CAPS patients treated with canakinumab

Component	General US population Mean (SD)	n	Baseline Mean (SD)	End of study (48 weeks) Mean (SD)	Change from baseline Mean (SD)
SF-36 (0-100)					
Physical Component	50.0 (10.0)[1]	22	40.4 (9.3)	48.5 (12.6)	8.2 (9.4)
Mental Component	50.0 (10.0)[1]	22	42.6 (12.4)	48.9 (12.4)	6.3 (12.4)
- Physical Functioning	84.2 (23.3)[1]	23	74.1 (28.8)	82.6 (25.7)	8.5 (23.0)
- Role-Physical	80.9 (34.0)[1]	26	50.0 (48.0)	76.0 (40.3)	26.0 (47.7)
- Bodily Pain	75.2 (23.7)[1]	25	48.0 (23.0)	76.5 (30.2)	28.6 (31.8)
- General Health	71.9 (20.3)[1]	25	46.4 (17.2)	60.8 (23.2)	14.4 (17.6)
- Vitality	60.9 (20.9)[1]	26	42.5 (22.2)	60.0 (28.5)	17.5 (30.5)
- Social Functioning	83.3 (22.7)[1]	25	67.5 (29.1)	77.5 (33.5)	10.0 (36.3)

Effect of Canakinumab (Ilaris, a Fully Human Anti-IL-1 beta Monoclonal Antibody) On the Health-Related Quality of Life (HRQoL) in Cryopyrin-Associated Periodic Syndrome (CAPS) Patients. J.B. Kuemmerle-Deschner[1], J. Hoyer[2], E. Hachulla[3], R. Chaturvedi[4], N. Blank[5], F. Hiepe[6], A. Ferreira[7], S. D. Felix[7], A.M. Wright[7], T. Jung[7] and C. Rordorf[7], [1]Universitätsklinikum Tübingen, Klinik fuer Kinder- und Jugendmedizin, Tübingen, Germany, [2]Univ.-Klinikum Gießen und Marburg, Marburg, Germany, [3]Hôpital Claude Huriez CHRU, Lille, France, [4]Pushpawati Singhania Research Institute, New Delhi, India, [5]Medizinische Klinik 5, Universitätsklinikum Heidelberg, Heidelberg, Germany, [6]Charité- Universitätsmedizin Berlin, Berlin, Germany, [7]Novartis, Basel, Switzerland

Purpose: Patient's QoL is markedly affected by the persistent disease features of CAPS. Canakinumab treats the underlying causes of CAPS by potent, rapid, and selective blockade of IL-1β. This Phase II, open-label study evaluated the improvement in the HRQoL following canakinumab treatment in CAPS patients.

Method: The study was conducted in CAPS patients with confirmed NLRP3 mutation. Patients received a single dose of canakinumab 150 mg or 2 mg/kg s.c. (patients ≤16 yrs) with redosing upon each relapse. HRQoL of adult patients were assessed at baseline and during treatment by patient reported outcomes for fatigue (FACIT-Fatigue©), general mental and physical health (SF-36©), and functional disability (HAQ-DI©). Increases from baseline FACIT-Fatigue and SF-36 scores, and decrease from baseline HAQ-DI scores indicate improvement in HRQoL.

Results: The mean baseline scores for FACIT-Fatigue (31.22) and SF-36 mental (43.02) and physical (37.98) component scores were significantly lower than scores expected in the general population (*i.e.*, 43.6 for FACIT-Fatigue and 50 for both SF-36 component scores, respectively)[1,2], confirming the detrimental impact CAPS has on patient's quality of life. HAQ-DI baseline mean score was 0.42 on a scale of 0 (no disability) to 3 (maximum disability). Ten out of 18 patients had functional disability as assessed by HAQ-DI (range 0.13 to 2.5). Canakinumab patients improved their HRQoL scores following a single injection (See Table). Improvements were seen as early as one day after the first single dose and maintained for 5 weeks. FACIT-Fatigue (45.6) as well as SF-36 mental (54.84) and physical component scores (49.52) reached levels comparable to average scores of the general population. Similarly, HAQ-DI improved by 0.2 units 5 weeks after canakinumab administration. HRQoL decreased again prior to canakinumab re-dosing when patients started experiencing a disease flare.

Conclusion: Canakinumab improved the HRQoL in CAPS patients assessed by FACIT- Fatigue, SF-36 mental and physical scores to a level of average scores of the general population and improved functional disability index.

Table. Summary of FACIT-Fatigue, SF-36 and HAQ-DI summary scores by time following a single dose of canakinumab (1st period)

Dose regimen	Time-point		FACIT-Fatigue 0-52		SF-36 (MCS) 0-100		SF-36 (PCS) 0-100		HAQ-DI 0-3	
		Average general population score[1,2] (SD)	43.6 (9.4)		50* (10)		50* (10)		NA	
			n	Mean (SD)	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)
Canakinumab 150mg sc	Baseline		18	31.22 (13.41)	18	43.02 (10.39)	18	37.98 (11.14)	18	0.42 (0.79)
	1 day post-dose		19	35.63 (15.31)	15	41.02 (11.22)	15	41.20 (12.69)	19	0.36 (0.72)
	1 week post-dose		19	45.05 (11.01)	18	47.75 (8.46)	18	45.86 (9.49)	19	0.19 (0.53)
	5 weeks post-dose		15	45.60 (9.50)	14	54.84 (7.25)	14	49.52 (8.36)	15	0.23 (0.58)
	Prior re-dose		17	36.68 (12.56)	17	48.40 (9.43)	17	41.74 (13.48)	17	0.34 (0.62)

MCS, Mental component; PCS, Physical component; NA, Not available; *Scores were normalized so that a score of 50 represented an average US person with no chronic disease; The 1st period includes data from inclusion when patient was flaring to the first relapse ; Prior re-dose= assessment when patient experienced next flare

MRI Imaging Findings in Neuro- Behçet's Disease. Akiko Suda[1], Haruko Ideguchi[2], Mitsuhiro Takeno[1], Shigeru Ohno[2], Atsushi Ihata[1], Atsuhisa Ueda[1] and Yoshiaki Ishigatsubo[1], [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama City University Medical Center, Yokohama, Japan

Purpose: Neurological involvement is one of the most serious manifestations Behçet's disease (BD). The incidence is ranged from 5 to 10 % of BD patients. The clinical symptoms and lesions are diverse from patient to patient. We here assessed the MRI imaging and clinical manifestations in BD patients with central nervous involvement.

Methods: Brain MRI imaging were conducted in 27 NBD patients (16 male, 11 female) under care in Yokohama City University Hospital from 1991 to 2007. The imaging conditions included T1 WI, T2WI, and FLAIR images. We analyzed abnormal signals in individual imaging conditions, the anatomical localization, and morphological abnormalities of the parenchymal brain system including atrophy. Neurological symptoms and signs were also reviewed based on clinical charts when the MRI was taken.

Results: A total of 77 abnormal signals were identified by any imaging conditions in the 27 patients. The lesions were most frequently detected in the cerebrum (77.8%), followed by the brain stem (59.3%), the basal ganglia (37.0%) and the cerebellum (22.2%). The most common abnormality was T2 high intensity in the cerebral subcortex. Cerebellar and cerebral brain atrophy was found in 8 (38.1%) and 3 patients (14.2%) of 27 patients, respectively. Of neurological clinical features, cranial nerve involvement was more common in patients with the brainstem lesions than the others ($p=0.027$). Cerebellar and/or cerebral brain atrophy was associated with personality changes ($p=0.005$) and speech disorder ($p=0.018$). The other symptoms such as headache and meningeal signs were not related with any abnormal MRI findings. There was no significant association of abnormal MRI findings with gender, age and HLA-B phenotype.

Conclusion: : MRI is useful to detect the brainstem lesions, which are responsible for cranial nerve injury, and he parenchymal brain atrophy, which causes personality changes and speech disorder in patients with BD.

Late Improvement in Processing Functions in Patients with Neonatal-Onset Multisystem Inflammatory Disease (NOMID) Treated with the Recombinant IL-1 Receptor Antagonist Anakinra. SM Paul[1], J. Snow, H. Hildenbrand[1], M. Jain[1], C. O'Shea, M. Smith[1], E. Wiggs, C. Henderson[2], L. Comis[1], T.H. Pham[2], N. Plass[2], D. Chapelle[2], D. Stone[2], R. Wesley[2] and R. Goldbach-Mansky[2], [1]CC/NIH Bethesda,MD, [2]NIH | NIAMS, Bethesda, MD

Purpose: To determine the cognitive outcomes after 3 years of treatment with the recombinant interleukin-1 receptor antagonist anakinra of patients with NOMID, an auto-inflammatory syndrome caused by mutations in *CIAS1*, a gene associated with up-regulation of IL-1β production.

Methods: These results come from an ongoing open label prospective treatment trial of 23 subjects between 4 to 28 years with NOMID. Subjects received daily subcutaneous injection of anakinra starting between 2.5mg/kg/day, increasing to 5 mg/kg/day if symptoms persisted. Functional outcome measures included the Assessment of Motor and Process Skills (AMPS), the Pediatric Evaluation of Disability Inventory (PEDI), and standard IQ testing obtained at baseline then 12, 24 and 36 months. Only patients with paired data were included in the analysis.

Results: An early and significant improvement in motor function was already seen within 6-12 months of treatment, however only a trend in the improvement was seen in assessments that required higher cerebral functions. However after 3 years of therapy with anakinra, the mean z-scores for the AMPS processing which were below age expected norm values at baseline, processing score increased from a score of 1.3 (SE 0.1) at baseline to 1.46 (SE 0.1) ($p<0.001$). Mean PEDI scaled scores were below normal at baseline and improved not only in the mobility domain from 73.4 (SE 5.1) to 101.7 (SE 6.1) ($p<0.001$) at 36 months but also the PEDI self care and social functions significantly improved in patients at 36 months ($p<0.001$ respectively). However, the mean IQ which was in the low normal range at baseline remained stable at 85 (SE, 4.1) at baseline and 87.5 (SE, 4.1) at 3 years ($p=0.3$).

Conclusion: Improvement in the functional performance and reduction in disability were rapid effects shortly after the initiation of treatment with anakinra. Interestingly, an improvement in the AMPS process z-score, the PEDI social and self-care scaled scores, were only observed at 3years but had not significantly changed at 12 months. Our data suggest that, the recovery of some CNS function may take adaptive behavioral steps to translate into an improvement of measurable functional improvement in areas where higher cognitive functions are involved including improved processing in performing activities of daily living.

1486

Infliximab Therapy Significantly Suppresses Ocular Inflammation in Behçet's Disease. Takeaki Uehara[1], Mitsuhiro Takeno[2], Sei Samukawa[3], Maasa Hama[2], Kenji Ohmura[4], Akiko Suda[2], Atsushi Ihata[5], Atsuhisa Ueda[4] and Yoshiaki Ishigatsubo[2], [1]Senior resident, Yokohama, Japan, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]Graduate student, Yokohama, Japan, [4]not Trainee, Yokohama, Japan, [5]Yokohama City University Med, Yokohama

Purpose: There is accumulating evidence that infliximab (IFX) is effective on uveitis in Behçet's disease (BD). We evaluated clinical efficacy and safety issues in IFX therapy for BD patients.

Method: IFX therapy was conducted in 13 BD patients (female 2, male 11, age 37+15 yo) who met he International Study Group criteria for diagnosis of Behçet's disease and refractory uveitis to conventional therapies. After screening latent tuberculosis by chest CT scan and tuberculin skin test (TST), 5 mg/kg of IFX was given at 0, 2, 6, weeks and thereafter every 8 weeks. Patients who had suggestive tuberculosis lesions and/or positive TST received anti-tuberculosis chemophylaxis during the first 9 months of IFX therapy. We assessed frequency of ocular attacks and visual acuity before and after infliximab therapy. Surgical operation and adverse events were also noted during infliximab therapy.

Results: Mean duration was 7.4+6.0 years from the disease onset to initiation of infliximab therapy. Before the infiliximab therapy, all patients had received colchicines, 7 patients had cyclosporine A, and 3 patients had prednisolone. The oral agents were discontinued except colchicines in 6 patients and prednisolone in one. Either of isoniazide or refampicin was given to 6 of 13 patients as anti-tuberculosis chemophylaxis because of positive TST. Frequency of ocular attacks was reduced from 2.4 + 0.6/6 month before the IFX therapy to 0.8 + 0.8/6 months after the therapy. Most of ocular attacks, which were commonly accompanied by extraocular symptoms such as oral aphthosis, folliculitis and eryhema nodosum, were found after 6 weeks form the last infusion. Therefore, the infusion intervals were shortened from 8 to 6 weeks in 4 patients. Visual acuity were improved in 12 eyes, unchanged in 11 eyes, and deteriorated in 3 eyes. Especially, early introduction of IFX therapy led to good visual prognosis. Surgical ocular operations were performed in 3 eyes for cataract and glaucoma, respectively, without operation-related ocular attacks. Serious adverse events including tuberculosis were not observed except for cytomegalovirus infection in a patient.

Conclusion: IFX therapy significantly suppresses ocular attacks, leading to improved visual acuity in BD patients with uveitis. Particularly, early introduction of IFX therapy is encouraged in BD patients with serious uveitis.

Rilonacept Treatment of Refractory Adult Onset Still's Disease. Petros Efthimiou[1] and Olga Petryna[2], [1]Weill Cornell Medical College/Lincoln Med & Mental Hlth Ctr, New York, NY, [2]Lincoln Med & Mental Hlth Ctr, New York, NY

Purpose: Adult onset Still's disease (AOSD) is a rare systemic inflammatory disorder characterized for spiking fever, rash, and arthritis. While glucocorticoids remain the cornerstone for treatment, refractory cases abound and have been treated with biologics with varying success. We are reporting successful use of a novel Interleukin (IL)-1 inhibitor, rilonacept, in 2 patients with AOSD after failure of treatment with glucocorticoids, immunosuppressors and biologics, including anakinra.

Methods: We identified through chart review 2 patients with refractory AOSD that were treated with rilonacept. The retrospective study was approved by the institutional review board (IRB)

Results: *Patient 1*: A 36 y/o hispanic female with daily spiking fevers, arthritis of knees, wrists, and MCPs, maculopapular rash and elevated serum ferritin (4253 ng/ml) failed treatment with glucocorticoids, methotrexate and responded partialy to anakinra 100 mg SQ twice daily. Anakinra was switched to rilonacept (220mg SQ loading and 160mg sq weekly maintenance) with dissapearance of rash and arthritis. Prednisone was tapered to 10mg daily and ferritin values normalized (67.3ng/ml).

Patient 2: A 44 y/o hispanic female with daily fever, arthritis and erythematous rash of upper chest and lower extremities was treated with oral prednisone, methotrexate, daily anakinra and abatacept with inadequate response. Rilonacept (220mg SQ loading and 160mg sq weekly maintenance) was added to oral prednisone and methotrexate with amelioration of rash and arthritis that allowed for a significant tapering of the prednisone dose, normalization of acute phase reactants and facilitated weight loss.

Conclusion: Rilonacept, through its long acting IL-1 inhibition, may be an effective treatment of refractory AOSD, even in anakinra treatment failures. To our knowledge this is the first published report of the use of rilonacept in AOSD. Controlled trials, through international collaboration, are warranted.

Healthcare Costs After Closed Fracture in Commercially Insured and Medicare Advantage Populations From a National Health Plan. Laura L. Christensen[1], Sheikh Usman Iqbal[2], Ying Fan[3] and David Macarios[2], [1]i3 Innovus, Ann Arbor, MI, [2]Amgen, Thousand Oaks, CA, [3]i3 Innovus, Eden Prairie, MN

Purpose: To determine annual total health care costs following hip, vertebral and non-hip/non-vertebral (NHNV) fractures (fx) among commercial (COM) and Medicare Advantage Plan (MAP) enrollees

Method: Administrative claims from a large, national health plan were analyzed. Men and women 45 or older with at least one medical claim for a new closed fracture (identified through primary ICD-9-CM diagnosis indicating closed hip, vertebral, or NHNV fracture) at a single site between June 30, 2002 and June 30, 2006, were continuously enrolled with the plan for 12 months before and after the fracture, and had at least two fracture-related outpatient visits during the follow-up period were included. Those with hip, femur, tibia and humerus fractures were required to have inpatient care associated with the first fracture claim. COM and MAP members were analyzed separately. Costs were calculated and stratified for hip, vertebral, and NHNV fx as paid amounts and were adjusted to 2006 dollars. Costs were considered fracture-related if there was a primary fx diagnosis code or a procedure code related to fx.

Results: The study identified 46,681 (COM 36,521; MAP 10,160) closed fragility fx during the study period. Mean post-fracture annual healthcare cost greatly exceeded the cost incurred prior to fracture, increasing 64% from $10,983 to $18,010 in COM patients and 112% from $8,979 to $19,077 in MAP patients.

The sample comprised mostly women (64% COM, 77% MAP) and mean age was 58 yrs and 76 yrs for COM and MAP, respectively. Compared to COM (relatively younger) patients, MAP patients had higher proportions of hip fractures (17% vs 5%) and vertebral fractures (26% vs 16%) and lower proportions of NHNV fractures (58% vs 79%).

In both populations, mean healthcare cost per fracture was highest for hip fractures, followed by vertebral fx (table). Inpatient cost comprised the major portion of total cost for hip and vertebral fx. Average total health care costs per fracture were higher for COM than for MAP patients (14% higher for hip, 40% higher for vertebral). Vertebral fx had the highest mean outpatient and pharmacy costs (table). Mean fx-related medical cost comprised 45-75% of the total medical cost.

Conclusion: Total and fracture-related healthcare costs pose a substantial burden to patients and the healthcare system.

	Hip		Vertebral		NHNV	
	COM	MAP	COM	MAP	COM	MAP

Mean follow-up costs						
Inpatient	23,837	22,827	11,286	9,806	4,921	6,571
Outpatient	7,097	3,578	10,001	5,543	6,619	4,497

Radiocarpal and First Metatarso-Phalangeal Arthrocentesis Site Confirmation with Fluoroscopy. Augustine M. Manadan, Saulat Mushtaq and Joel A. Block, Rush University Medical Center, Chicago, IL

Purpose: Rheumatologists routinely perform arthrocentesis. We attempted to determine the accuracy of routine arthrocentesis of the radiocarpal (RC) and first metatarso-phalangeal joint (MTP).

Method: All board certified attending rheumatology physicians with privileges at John H. Stroger Jr. Hospital of Cook County were asked to complete a voluntary short survey with the following questions:

(1) Have you ever obtained synovial fluid from a wrist joint aspiration?

(2) Which joint in the wrist do you usually aspirate?

(a) RC joint

(b) Intercarpal joint

(c) Carpo-metarcapal joint

(3) What is your estimated success rate during wrist aspiration?

(4) Have you obtained synovial fluid from the first MTP joint?

(5) What is your estimated success rate during first MTP joint aspiration or injection?

Subsequently, they were asked to mark their usual site of arthrocentesis on the skin overlying the right RC and right first MTP joints of the two primary investigators. The actual joint lines had been previously identified fluoroscopically, and had been marked using ink invisible to normal light but visible under ultraviolet illumination (LDP, Inc., www.maxmax.com).

Results: All 10 eligible rheumatologists agreed to participate; they had a mean of 17.9 (range 3-32) years of clinical rheumatology experience and originated from 7 fellowship programs. All reported having obtained synovial fluid during wrist aspiration and 90% reported having obtained synovial fluid during MTP aspiration. In the wrist, 8/10 (80%) preferred to aspirate at the RC joint and 2/10 (20%) preferred the intercarpal joint. The self reported success rates for wrist and MTP arthrocentesis were 61% (range 25-90%) and 37% (range 0-80%), respectively. Each rheumatologist marked the site of preferred aspiration on two wrists and two MTPs. Data from a total of 18 RC markings and 20 MTP markings were obtained. Two physicians reporting intercarpal joint aspiration as their preferred technique were excluded from wrist marking analysis. The sites marked by the rheumatologists were a mean of 0.85 cm (range 0-1.6) from the fluoroscopically identified radiocarpal joint and 0.33 cm (range 0-1.3) from the fluoroscopically identified MTP joint. Review of the data indicated that 7/8 (88%) of physicians had marked the wrist intercarpal joint when they had intended to mark the RC joint.

Conclusion: Blind joint aspiration may be inaccurate, even in superficial joints that are thought to be easily accessible. Fluoroscopic guidance has the potential to improve accuracy of arthrocentesis. Nonetheless, generalizability may be limited because during actual arthrocentesis, the needle angle is frequently adjusted *in situ* to accommodate inaccurate site selection. Moreover, many articular capsules are sufficiently large that it is often not necessary to aspirate directly at the joint margin in order to obtain synovial fluid. Nonetheless, experienced rheumatologists often mistake the wrist intercarpal joints for the RC joint, and misidentify the MTP joint line.

Ultrasound-Guided Percutaneous Injection, Hydrodissection, and Fenestration for Carpal Tunnel Syndrome. Daniel G. Malone[1], Thomas B. Clark[2] and Nathan Wei[3], [1]University of Wisconsin, Madison, WI, [2]MSKUS, Vista, CA, [3]Arthritis & Osteo Ctr of MD, Frederick, MD

Purpose: Carpal tunnel syndrome, caused by compression of the median nerve deep to the flexor retinaculum, is the most common entrapment neuropathy. Most patients are initially treated with conservative measures such as splinting. When conservative measures fail, interventional techniques are considered the next step. Many studies have appeared comparing open surgical flexor retinaculum release to blind injections of corticosteroids into the carpal tunnel, but neither technique has proven superior to the other. Advantages of injection are: lower level of invasiveness, faster recovery, and ease of the technique. Occasional failures and complications occur with all techniques.

Method: We have been using an ultrasound-guided procedure of percutaneous hydrodissection of the median nerve away from the deep surface of the flexor retinaculum, followed by fenestration of the flexor retinaculum along a path parallel to the long axis of the arm, starting from the level of the distal palmar crease and progressing proximally to the level of the radio-lunate joint, the intent being to lower the pressure exerted by the flexor retinaculum on the nerve (panel 1). We have treated a series of 39 wrists in 29 patients with electrically-proven carpal tunnel syndrome, using this technique of hydrodissection and fenestration, performed using standard injection equipment and a GE LogiQ e ultrasound system with a 12 MHz linear array probe. All patients had typical carpal tunnel syndrome symptoms and presented to us for interventional treatment, conservative measures having failed. No patient had had previous surgery, and 2 had had blind carpal tunnel steroid injections, without hydrodissection or fenestration. Outcomes were defined as:

Excellent-all symptoms resolved,

Fair-some residual symptoms, or return of symptoms, but improved compared to prior to procedure,

Failure-required open surgical release.

Follow-up periods after procedure ranged from 5-64 weeks, averaging 38 weeks (as of late June 09). Patients were contacted by telephone, or seen in follow-up in clinic, to determine outcomes.

Results: Excellent—31 wrists; Fair—5 wrists; Failure—3 wrists; No complications were encountered.

Conclusion: Ultrasound-guided hydrodissection and fenestration is a viable, easy, relatively non-invasive therapy for carpal tunnel syndrome that can result in prolonged symptom relief, and may be a way to postpone, or even obviate the need for, open release.

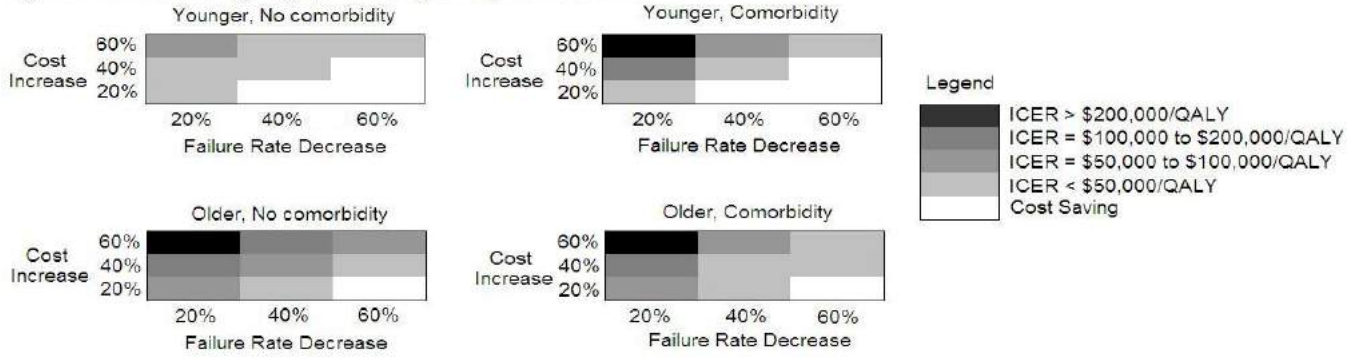
The Cost-Effectiveness of Innovative Implants in Total Knee Replacement. L.G. Suter[1], H. Gerlovin[2], J.N. Katz[3], I. Golovaty[2], N.N. Niu[2], H.L. Holt[2], L. Fraenkel[1], L. Weis[4], D.H. Solomon[2], T.S. Thornhill[2], A.D. Paltiel[5] and E. Losina[6], [1]Yale University and Veterans Affairs Healthcare System, New Haven, CT, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Veterans Affairs Health Care System, West Haven, CT, [5]Yale University, New Haven, CT, [6]Brigham and Women's Hospital, BU School of Public Health and Harvard Medical School, Boston, MA

Purpose: Total knee replacement (TKR) is a cost-effective but increasingly common and expensive treatment for end-stage knee osteoarthritis (OA). Newer, costlier implants promising reduced rates of long term prosthesis failure are under continual development. Our objective was to specify the cost, performance, and target population scenarios under which innovative implants might be cost-effective.

Methods: Using a Markov state-transition computer simulation model of knee OA, we projected failure-free survival, costs and quality adjusted life expectancy (QALE) in patients undergoing TKR using implants with varying failure rates and costs. We considered four populations: 1) younger (50-59 years) and no comorbidities; 2) younger with comorbidity (e.g., obesity and cardiovascular disease); 3) older (70-79 years) and no comorbidities; and 4) older with comorbidity. We considered prosthesis failure rate reductions ranging from 20-60% based upon laboratory data. Outcomes of standard (i.e., using currently available implants) TKR were derived from a national cohort of Medicare beneficiaries undergoing TKR. Using published literature, we derived the current cost of the implant (about 25% of total TKR cost) and considered cost increases ranging from 20-60% based upon published data. We estimated average per person lifetime medical costs (2008 USD) and QALE from a societal perspective with 3% discounting.

Results: Standard TKR resulted in average per person lifetime medical costs of $44,184 with QALE of 16.27 years in healthy 50-59 year olds and $39,782 with QALE of 7.24 years in comorbid 70-79 year olds. A 60% decrease in failure rate increased the proportion of failure-free individuals alive 20 years after TKR from 59.4% to 69.5% for healthy 50-59 year olds and from 9.6% to 11.2% for older individuals with comorbidities. The impact of decreasing TKR failure rates while simultaneously increasing implant cost on the incremental cost-effectiveness ratio (ICER) of innovative versus standard TKR is shown in Figure 1. Implants with high cost increases were less likely to be cost-effective (upper left corners), while those conferring the greatest reductions in failure rate were universally cost-effective or cost-saving (lower right corners).

Figure 1. ICERs according to age, comorbidity and implant characteristics



Conclusion: Age-specific mortality in older populations may limit long term benefits from innovative TKRs. Despite this, newer, costlier implants are likely to be cost-effective at currently acceptable thresholds if they reduce the true long-term TKR failure rate by 40% or more and cost no more than 60% over current implants.

1492

Effect of CYP2C9 and VKORC1 Genotypes On Early-Phase Warfarin Dosing of Rheumatoid Arthritis Patients with Elective Joint Surgery in Japanese. Asami Tokita, Taku Suzuki, So Tsukahara, Katsunori Ikari and Shigeki Momohara, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Elective joint surgery in rheumatoid arthritis (RA) is used to relieve severe pain and improve function of severely deformed joints that do not respond to medication. To prevent pulmonary embolism associated with deep venous thrombosis (DVT) following elective joint surgery, the optimized prophylaxis including warfarin therapy is absolutely essential. The two key enzymes in the metabolism of warfarin are cytochrome P450 (CYP) 2C9 (CYP2C9 gene) and the C1 subunit of the vitamin K 2,3 epoxide reductase complex (VKORC1 gene). These two genes contribute significantly to the variability among patients in dose requirements for warfarin. Recently, the International Warfarin Pharmacogenetics Consortium showed that the pharmacogenetic algorithm with CYP2C9 and VKORC1 genes were useful for estimation of the appropriate warfarin dose. The aim of this study was to investigate whether these genes were associated with the amount of required warfarin and the time to reach the target PT-INR of rheumatoid arthritis patients with elective joint surgery in Japanese.

Method: The study was approved by the Tokyo Women's Medical University Genome Ethics Committee. Written informed consent was obtained from all patients prior to enrollment in the study. The diagnosis of RA is based on the American College of Rheumatology 1987 revised criteria. Acute DVT was diagnosed according to color flow duplex ultrasonography. The initial warfarin treatment was started with a 1-day loading of a dose of 3.0 mg for acute DVT following surgery. The PT-INR measurement was repeatedly monitored with intervals of 3–4 days and then the dose was adjusted. Once it reached a stable dose, the time to reach the target PT-INR was estimated. The therapeutic target INR range of the patients was from 1.5 to 2.5. DNA samples were available from 31 patients treated with warfarin following total hip and knee arthroplasty. Genotyping of CYP2C9*1, CYP2C9*3, and VKORC1 1173C>T were performed using TaqMan SNP genotyping assay (Applied Biosystems, Tokyo, Japan).

Results: All patients were homozygous CYP2C9*1/*1 genotype. Of these, 8 patients were heterozygous VKORC1 C/T and 23 patients were homozygous T/T genotype. The daily warfarin doses were significantly different between VKORC1 C/T and T/T genotype (P=0.009, Table 1).

Conclusion: Patients with VKORC1 T/T genotypes need a lower maintenance dose of warfarin than patients with VKORC1 C/T genotype. Genetic variability helps predict the ideal therapeutic dose of warfarin in Japanese rheumatoid arthritis patients.

Table 1. Characteristics of 31 patients of rheumatoid arthritis in Japanese

Genotype	VKORC1 C/T (N=8)	VKORC1 T/T (N=23)	P
Daily warfarin dose (mg/day)	3 (3-3.6)	2 (1.75-3)	0.009
Days from initial dose (days)	11 (9.25-12.5)	15 (9.5-21)	0.13
Target INR	1.88 (1.7-2.2)	1.91 (1.7-2.1)	0.73

Values are given as median (interquartile range).

Low Back Pain Patients Experience Lower Pain Intensity After Extensive Physical Testing. Thomas Maribo[1], Elena Iversen[2], Lone D. Jensen[1], Kristian Stengaard-Pedersen[3] and Berit Schiøttz-Christensen[2], [1]Aarhus University Hospital, Aarhus, Denmark, [2]Aarhus Clinic for Rheumatic Diseases, Aarhus, Denmark, [3]Rheumatology Universityhospital, Aarhus

Low back pain (LBP) is the most common and costly musculoskeletal complaint with a lifetime prevalence of 70-80 %.

Pain in LBP patients is influenced by many factors, including physical activity, core muscle endurance and physical fitness.

Endurance of core muscles is known to be reduced in LBP patients compared to healthy controls. With regards to physical fitness the results are less clear. No studies have analysed how LBP patients tolerate physical testing.

Purpose: To evaluate intensity of pain before and after physical testing in patients with recurrent LBP.

Method: The study population was 223 LBP patients of both gender and 18-63 years of age that were admitted to the Department of Rheumatology at Aarhus University Hospital. The patients were active on the labour marked and were advised to exercise after physical examination. The physical test battery included postural balance, core muscle endurance, and physical fitness. Postural balance was tested using one leg stand test and sway measures on a force platform. Core muscle endurance was tested using modified Sorensen test and supine isometric chest raise test as described by Ito. Physical fitness was tested using Astrand bicycle test. Every test session lasted 45 minutes.

Pain was recorded just before and 10 minutes after completion of the test battery using a 0-10 numeric rating scale (NRS).

The Mann-Whitney test was used to test for significant changes in pain before and after testing.

Results: Pain was recorded before and after physical testing on all 223 patients.

Patients rated mean initial pain as 2.23 (CI95 1.99; 2.48) and after the test pain was reduced to 1.76 (CI95 1.50; 2.02), the difference was statistically significant ($p<0.001$). Of all the patients 100 (44.8 %) reported decreased pain, 88 patients (39.5 %) reported unchanged pain and 35 patients (15.7 %) reported increased pain.

One hundred seventy six patients (74.8 %) reported none or mild initial pain (NRS ≤ 3) before the test this group rated mean pain as 1.37 (CI95 1.19; 1.54) and after test this was reduced to 1.00 (CI95 0.81; 1.19) this reduction was significant ($p<0.001$).

Fifty five patients (24.6 %) reported moderate initial pain (NRS ≥ 4), before the test this group rated mean pain as 4.82 (CI95 4.54; 5.10) and after test this was reduced to 4.04 (CI95 3.50; 4.58) this reduction was significant ($p=0.001$).

The presence of patients with severe initial pain (NRS ≥ 8) was negligible.

Conclusion: Physical testing for both postural balance, core muscle endurance, and physical fitness was safe in patients with recurrent LBP. Most patients reported the same or less pain after the 45 minutes of physical testing. Only 15.7 % reported an increase in pain.

Dose Stability of Tapentadol ER for the Relief of Chronic Low Back Pain: Results of a Randomized, Active- and Placebo-Controlled Study. Robert Buynak[1], Mila Etropolski[2], Bernd Lange[3], Douglas Y. Shapiro[2], Akiko Okamoto[2], Achim Steup[3], Ilse Van Hove[4] and Christine Rauschkolb[5], [1]Northwest Indiana Center for Clinical Research, Valparaiso, IN, [2]Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan, NJ, [3]Grünenthal GmbH, Aachen, Germany, [4]Johnson & Johnson Pharmaceutical Research & Development, Division of Janssen Pharmaceutica, N.V., Beerse, Belgium, [5]Johnson & Johnson Pharmaceutical Research and Development, L.L.C., Raritan, NJ

Purpose: Tapentadol is a new centrally acting analgesic with μ-opioid receptor agonist and norepinephrine reuptake inhibitor activity. The efficacy, safety, and dose stability of tapentadol extended release (ER) in patients with moderate to severe chronic low back pain were evaluated.

Method: Patients were titrated over 3 weeks to an effective and tolerable bid dose of tapentadol ER (100-250 mg), oxycodone HCl controlled release (CR; 20-50 mg), or placebo, then maintained at that dose for 12 weeks; additional dose adjustments were allowed as needed under the supervision of the patients' physician to maintain an optimal balance of efficacy and tolerability. Efficacy was measured as change in mean pain intensity (0-10 NRS) from baseline to Week 12 of maintenance; in the event of early patient discontinuation, missing values were imputed using last observation carried forward. Dose stability was evaluated as the percentage of days patients took their modal (most frequently used) dose.

Results: The intent to treat population included 958 patients. Improvements in average pain intensity scores from baseline to Week 12 of maintenance were significant versus placebo in the tapentadol ER (least squares mean difference vs placebo, −0.8, P <0.001) and oxycodone CR (−0.9, P <0.001) groups. A total of 235 patients in the tapentadol ER group and 199 patients in the oxycodone CR group entered the maintenance period and were evaluated for dosing. During the maintenance period, median modal TDDs were 400 mg tapentadol ER and 80 mg oxycodone HCl CR. The median percentage of time on the modal dose was ≥93% for both active treatments, indicating that patients were on a stable dose for the majority of the maintenance period. The median number of the most consecutive days that patients took the modal dose was 49.0 days for tapentadol ER and 47.0 days for oxycodone HCl CR. The range of mean TDDs (tapentadol ER, 384.6-393.2 mg; oxycodone HCl CR, 72.3-74.5 mg) and mean pain scores (tapentadol ER, 4.4-4.2; oxycodone CR, 4.6-4.5) were relatively stable from Week 3 of maintenance to the end of the study. A higher percentage of patients completed treatment with tapentadol ER (54.1%) than with oxycodone CR (43.3%), mainly because of the lower rate of discontinuation due to adverse events (AEs) in the tapentadol ER group (16.7%) than in the oxycodone CR group (32.3%).

Conclusion: Tapentadol ER (100-250 mg bid) relieved moderate to severe chronic low back pain more effectively than placebo, with fewer AE-related discontinuations than oxycodone HCl CR (20-50 mg bid). Most patients maintained a stable TDD and a stable level of effective pain relief on tapentadol ER.

1495

Long-Term Safety and Gastrointestinal Tolerability of Tapentadol Extended Release or Oxycodone Controlled Release in Patients with Chronic Low Back or Osteoarthritis Pain. Stefan Grond[1], Brigitte Kuperwasser[2], Bettyanne McCann[2], Robert Lange[3], Bernd Lange[3], Akiko Okamoto[2], Jane Gilbert[4], Achim Steup[3], Thomas Häufel[3] and Mila Etropolski[2], [1]Clinical Center Detmold-Lippe, Detmold, Germany, [2]Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan, NJ, [3]Grünenthal GmbH, Aachen, Germany, [4]Johnson & Johnson Pharmaceutical Research & Development, Division of Janssen-Cilag Ltd., High Wycombe, United Kingdom

Purpose: This phase 3, open-label study evaluated the safety and efficacy of tapentadol extended release (ER), a new, centrally acting analgesic with μ-opioid receptor agonist and norepinephrine reuptake inhibitor activities, and oxycodone controlled release (CR) for up to 1 year in patients with moderate to severe chronic low back or osteoarthritis hip or knee pain.

Method: Patients were randomized 4:1 to receive controlled, adjustable, oral bid doses of tapentadol ER 100-250 mg or oxycodone HCl CR 20-50 mg. Dose titration was performed in steps of 50 mg bid for tapentadol ER or 10 mg bid for oxycodone HCl CR to a dose providing an optimal balance of efficacy and tolerability. Efficacy was assessed as the average pain intensity score over the preceding 24 h; at each visit, patients indicated their pain score using on an 11-point numerical rating scale. Odds ratios (ORs) for specific gastrointestinal (GI) treatment-emergent adverse events (TEAEs) were estimated using a logistic regression model.

Results: Of 1,117 patients who received ≥1 dose of study drug and were analyzed for safety, 46.2% (413/894) and 35.0% (78/223) completed 52 weeks of treatment with tapentadol ER and oxycodone CR, respectively. Mean (SD) treatment duration was numerically longer with tapentadol ER (211 [157.4] days) than with oxycodone CR (161 [163.1] days). Mean (SD) daily doses were 326.7 (120.2) mg tapentadol ER and 51.5 (26.9) mg oxycodone HCl CR. Mean (SD) values of average pain scores decreased from 7.58 (1.54) with tapentadol ER and 7.61 (1.63) with oxycodone CR at baseline to 4.37 (2.57) and 4.52 (2.23), respectively, at study endpoint. Tapentadol ER was associated with significantly better GI tolerability than oxycodone CR based on estimated ORs for the incidence of all assessed GI TEAEs (52.0% vs 64.1%, respectively; OR [95% CI], 0.606 [0.45-0.82]; P = 0.001) and for specific GI TEAEs of constipation (22.6% vs 38.6%, respectively; 0.469 [0.34-0.64]; P <0.001), nausea (18.1% vs 33.2%, respectively; 0.447 [0.32-0.62]; P <0.001), vomiting (7.0% vs 13.5%, respectively; 0.490 [0.31-0.78]; P = 0.002), and the composite of nausea and/or vomiting (20.7% vs 37.2%, respectively; 0.441 [0.32-0.61]; P <0.001).

Conclusion: Tapentadol ER provided sustained long-term relief of chronic low back or osteoarthritis pain. Tapentadol ER 100-250 mg bid was associated with significantly lower ORs for the assessed GI TEAEs compared with oxycodone HCl CR 20-50 mg bid.

A 12-Month Randomized Controlled Trial of Balance Training in Elderly Women with Osteoporosis: Improvement of Quality of Life and Reduction of Falls. Melisa M. Madureira and Rosa M.R. Pereira, Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil

Purpose: Physical and also psychological incapacity, including fear of falling was strongly related to self-reported decreased satisfaction with life in osteoporosis. The impact of a balance exercise prevention programs in improving quality of life is not well established. We therefore have investigated the effect of 12-month Balance Training Program in quality of life and falls in elderly women with osteoporosis.

Method: Sixty consecutive women with senile osteoporosis (age:65 to 85 years) were recruited from the Osteometabolic Disease Outpatient Clinic and randomized into two groups: Balance Training Group (BT) with 30 patients and Control Group (CG) with 30 patients. The Balance Training Program was focused mainly on techniques to improve balance, coordination and mobility and consisted of one-hour exercise session/week supervised by a physiotherapist for 12-months and oriented exercises to be performed at home 3 days/week. Both groups were sedentary before inclusion in the study and all patients were taking their prescribed medication for osteoporosis. The quality of life, in both groups, was evaluated before and at the end of the trial using the Osteoporosis Assessment Questionnaire (OPAQ). The quality of life scores are standardized into identical units ranging between 1 (good health status) and 10 (poor health status). Falls in the preceding year were noted and compared to the period of study.

Results: The groups BT and CG were similar in all basal scores domains of OPAQ, except for Social Interaction that was lower in BT compared to CG (2.69±1.42 vs. 3.49±1.47, p=0.013). The comparison of OPAQ domains variations (basal values – mean final values) revealed a significant improvement of quality of life in all parameters for BT group compared to CG: well being (1.61± 1.44 vs. -1.46 ± 1.32, p<0,001), physical function (1.30±1.33 vs. –0.36±0.82, p<0.001), psychological status (1.58±1.36 vs. –1.02±0.83, p<0.001), symptoms (2.76±1.96 vs. –0.63±0.87, p<0.001), social interaction (1.01±1.51 vs. 0.35±1.08, p<0.001). A significant progress was also observed regarding psychological status, fear of falls (3.78±3.15 vs. -0.72±1.89, p=0.001) and independence (-0.28±0.77 vs. -2.11±2.80, p=0.004) in BT group compare to CG. Of note, this overall improvement was paralleled by a reduction of falls in 50% of patients in BT group compared to 26.6% for the CG (OR: 7.50, p<0.025).

Conclusion: Our longitudinal prospective study demonstrated that 12-month Balance Training Intervention improve the quality of life and prevent falls in elderly people.

Acupuncture for Acute Non-Specific Low Back Pain: A Randomized, Controlled, Placebo Trial. Tatiana Molinas Hasegawa, Andreia Salvador Baptista, Marcelo Cardoso de Souza, Alexandre Massao Yoshizumi and Jamil Natour, Federal University of Sao Paulo, Sao Paulo, Brazil

Purpose: Acute non-specific low back pain (LBP) is defined as an episode of low back pain, not attributed to a recognizable or known specific disease, persisting for less than 6 weeks. Evaluate the effectiveness of Yamamoto's method of acupuncture on pain, functional status and quality of life using on patients with acute non-specific LBP.

Method: 80 patients with acute non-specific LBP were invited to participate in a randomized and blinded controlled clinical trial. The patients were randomized to an intervention-group (submitted to five real acupuncture sessions) or a control-group (placebo-submitted to five non-penetrating acupuncture sessions). The patients were evaluated by a blinded examiner in the beginning (T0), 3 (T3), 7 (T7), 14 (T14), 21(T21) and 28 (T28) days after intervention, using the following outcomes: visual analogue scale (VAS) for pain before (last week) and after intervention, Roland-Morris questionnaire (RM), SF-36, patient improvement by visual scale (LIKERT) and number of anti-inflammatory taken. The number of visits to the doctor was considered as co-interventions. Following treatment, patients were asked whether they thought they had undergone real acupuncture or the placebo treatment. The primary outcome was to detect a 2-point reduction in pain

VAS; the minimal clinically important difference (MCID) for the RM scale was a reduction of 2.5 points. Statistical analysis was performed using the Student's t-test to compare the baseline characteristics and analysis of variance (ANOVA) with repeated measurements to assess inter/intra-group changes.

Results: The groups were homogeneous at baseline. 80 patients completed the study and intention-to-treat analysis was performed. Until day 14, the only difference found between groups (p=0.03) was on VAS for pain before and after intervention what we call of immediate improvement; or all the other outcomes both groups improved and there was no significant difference between them. After 14 days the intervention group showed a significant improvement (p<0.05) in last week pain-VAS; RM; bodily pain and vitality domains of SF-36. Physical function domain of SF-36 revealed a meaningful difference after 21days, in the intervention-group (p<0.001). There was also a reduction in anti-inflammatory tables intake in the intervention-group (p=0.002). There was no meaningful differences between the groups concerning the variables LIKERT (p=0.67) and number of visits to the doctor (p=0.33). Thirty-six (90%) patients in the placebo group believed they had received real acupuncture, thereby supporting the credibility of non-penetrating placebo used in this study.

Conclusion: Acupuncture was more effective than placebo regarding decreasing pain and anti-inflammatory intake and improving functional status, bodily pain, vitality and physical function domains of SF-36. Acupuncture was ineffective regarding the others domains of SF-36, Likert scale and number of visits to the doctor.

1498

The Effectiveness of a Weak Opioid Medication Versus a COX-2 Selective NSAID in Treating Flare-up of Chronic Low Back Pain: Results From a Randomized, Double-Blind, 6-Week Study. John B. O'Donnell[1], Evan F. Ekman[2], William M. Spalding[3], Pritha Bhadra[3], Dorothy McCabe[3], Manuela F. Berger[3] and Leigh Prevost[4], [1]Union Memorial Hospital, Baltimore, MD, [2]Southern Orthopaedic Sports Medicine, Columbia, SC, [3]Pfizer Inc., New York, NY, [4]Parexel, Worthing, United Kingdom

Purpose: To compare the analgesic efficacy, safety, and tolerability of nonsteroidal anti-inflammatory drugs (NSAIDs) and opioids for the treatment of chronic low back pain (CLBP).

Method: In this parallel-group, double-blind, active comparator study, 802 subjects aged ≥18 years with a diagnosis of CLBP (lower back pain ≥12 weeks duration) who required regular use of analgesics (≥4 days/wk) and had a baseline score of ≥4 on an 11-point numeric rating scale (NRS-Pain; where 0 = no pain and 10 = worst possible pain), were randomized to receive either celecoxib 200 mg bid or tramadol HCl 50 mg qid for 6 weeks. This treatment duration represents standard clinical care for patients with short-duration flare-ups. No rescue medication was allowed. Successful responders (primary end point) were defined as subjects completing 6 weeks' treatment and having ≥30% improvement from baseline to week 6 on the NRS-Pain scale. A 2-stage analysis was used to test for noninferiority (evaluable population) and superiority of celecoxib (intent-to-treat [ITT] population). Safety and tolerability were carefully assessed for both treatment strategies.

Results: Of the 802 randomized subjects, 792 subjects were treated and included in the ITT and safety populations. A significantly greater percentage of celecoxib subjects responded successfully to treatment than tramadol HCl subjects (64.1% and 55.1%, respectively; $P < 0.001$). Significantly fewer celecoxib subjects discontinued treatment due to lack of tolerability (specific adverse events [AEs] of gastrointestinal or central nervous system origin) than tramadol HCl subjects (1.0% vs 10.6%, respectively; $P < 0.0001$) (Table). Fewer AEs and serious AEs were also reported in the celecoxib group, and fewer celecoxib subjects discontinued due to any treatment-related events (3.8% vs 13.4%, respectively). Overall, a significantly higher percentage of subjects withdrew due to lack of tolerability in the tramadol HCl group (10.6%) than in the celecoxib group (1.0%; $P < 0.0001$) (Table).

Permanent Withdrawals Due to Lack of Tolerability (All Causality) (ITT)

Adverse Event	Celecoxib 200 mg bid (n = 396), n (%)	Tramadol HCl 50 mg qid (n = 396), n (%)	*P Value*[a]
Abdominal pain	0 (0.0)	0 (0.0)	-
Dyspepsia	1 (0.3)	0 (0.0)	-
Nausea	1 (0.3)	25 (6.3)	-
Vomiting	0 (0)	14 (3.5)	-
Somnolence	2 (0.5)	7 (1.8)	-
Dizziness	2 (0.5)	20 (5.1)	-
Vertigo	0 (0.0)	1 (0.3)	-
Total	4 (1.0)	42 (10.6)	<0.0001

a Based on Cochran-Mantel-Haenszel test (general association), stratified by center.

Conclusion: Celecoxib 200 mg bid was more effective than tramadol HCl 50 mg qid in the treatment of CLBP, with fewer AEs reported. However, further studies are required to evaluate the longer-term effects of treatment for this chronic medical condition.

Risk Factors for Renal Lithiasis During the Treatment with Uricosuric Drugs. Fernando Perez-Ruiz, Hospital De Cruces, Barakaldo, Spain

Purpose: This study intends to find factors at baseline, prior to starting ULT with uricosurics, and during follow up that could be associated with an increased hazard risk of developing renal lithiasis.

Method: Patients with gout and no previous history of renal lithiasis or severe renal function impairment were included in a prospective cohort follow-up study when treated with uricosurics. They were encouraged to drink fluids but no alkali was prescribed. Clearance of creatinine (Ccr) and urate (Cur), and 24-hour urinary uric acid (24-h Uua) were calculated using urine 24-h collection urine samples urinary pH, along with pH,density, and abnormals. Undissociated urinary uric acid concentration (UUua) and also 24-hour undissociated urinary uric acid excretion (24-hUUuua) were calculated in each urine sample using a nomogram. Cox proportional hazard regression analysis using a forward stepwise model was used to identify those variables independently associated with lithiasis as outcome. The rate of lithiasis was compared to that of patients on allopurinol and no previous history of renal stones.

Results: 216 patients, mean age of 59±13 years (range 24-92) and 784 patient-year exposure. 206 patients with renal underexcretion of uric acid (Cur<6 ml/min) and 10 were treated with uricsurics despite normal excretion (overproducers) of uric acid due to intolerance to allopurinol. There were 21 events, 7 oxalate, and 14 uric acid or mixed uric acid-oxalate stones. When all patients were included in multivariant regression analysis, two variables showed increased risk hazard for developing lithiasis: clearance of uric acid at baseline (Risk Hazard 1.52 per ml/min increase, 95%CI 1.13-2.05) and UUua during follow-up (Risk Hazard 1.11 per mg/dL increase, 95% CI 1.06-1.15). When patients showing overproduction were excluded from analysis, only UUua during follow-up remained to be statistically significant (Risk Hazard 1.12 per mg/dL increase, 95% CI 1.08-1.16). There was an exponential increase in the cumulated incidence of lithasis when patients were stratified on UUua (Table 1). For comparison, data 330 patients on allopurinol with no previous history of lithiasis and 985 patient-yr follow up were analyzed. Patients on uricosurics who showed UUua<20 mg/dl did not show an increase in the rate of lithiasis or events per 100-pt-yr compared to that of patients on allopurinol (Table 1).

Table 1. Events (lithiasis) depending on UUua strata and patients treated with allopurinol.

	UUua < 10 mg/dL	UUua 10-19 mg/dL	UUua 20-29 mg/dL	UUua ≥30 mg/dL	UUua < 20 mg/dL	Allopurinol
Events	1/90	6/84	8/32	6/10	7/174	10/330
%	1.11	7.14	25.00	60.00	4.02	3.03
Events per 100 pt-yr	0.30	1.89	7.41	17.14	1.08	1.01

Conclusion: Clearance of uric acid at baseline may be useful to exclude patients with normal renal handling of uric who could be exposed to a higher risk of developing lithiasis during the treatment with uricosuric drugs. The concentration of UUua was found to be the only variable independently associated with an increased risk of lithiasis during follow-up.

Risk of Recurrent Gout After Acute Infection and Vaccination: The Online Case-Crossover Gout Study. Yq. Zhang[1], C. Chen[1], T. Neogi[1], C. Chaisson[1], Hyon K. Choi[2] and David J. Hunter[3], [1]BUSM, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]New England Baptist Hospital, Boston, MA

Purpose: Acute infection induces a systematic inflammatory response, which may act as a precipitant of pro-inflammatory stimuli to trigger recurrent gout attacks. Similarly, vaccination could trigger pro-inflammatory stimuli and increase the risk of recurrent gout. Furthermore, acute infection and vaccination could lead to fever and dehydration, which may also trigger recurrent gout. We evaluated the risk of recurrent gout after acute infection and vaccination in the Online Case-Crossover Gout Study.

Methods: The Online Case-Crossover Gout Study is a self-controlled prospective study to assess a set of putative risk factors triggering recurrent gout attacks. Subjects who had experienced a gout attack within the past year were recruited online and were asked to provide access to medical records for verification of gout diagnosis. Subjects were asked to log onto the study website when they experienced a gout

attack. Risk factors, including acute infection and vaccination occurring each day over the two-day period prior to an acute gout attack (case-period) were assessed using an online questionnaire. The same questionnaire was used over each of the two days during an intercritical period (control-period). We examined the relation of acute infection and vaccination over the 2-day period to the risk of recurrent gout attacks using conditional logistic regression adjusting for alcohol consumption, purine intake, and diuretic use.

Results: Include in this analysis were 535 subjects who experienced recurrent gout attacks during the study period. Participants were predominantly white (89%) and male (78%), and 58% had a college education. Of the 517 medical records obtained to date, 76% fulfilled ACR criteria for a gout diagnosis. The median time between the onset of gout attack and logging on to the website was 2 days. The proportions of acute infection and vaccination were 6.4% and 1.0%, respectively, over the control-periods. The corresponding proportions were 10.1% and 2.6% over the case-periods. Acute infection and vaccination were associated with an increased risk of recurrent gout attacks, with adjusted odds ratios of 1.7 (95% CI: 1.2-2.4) and 5.3 (95% CI: 1.4-19.6), respectively

Conclusion: Acute infection and vaccination increase the risk of recurrent gout attacks among gout patients. Our findings provide support for the concept that acute infection and immunization act as precipitants of pro-inflammatory stimuli or dehydration to trigger recurrent gout attacks.

Documentation of Fewer Gout Flares After Long-Term Urate-Lowering Treatment. M. A. Becker[1], H. R. Schumacher Jr.[2], S. Chohan[1], P. MacDonald[3], B. Hunt[3] and R. L. Jackson[3], [1]University of Chicago, Chicago, IL, [2]U Penn & VA Med Ctr, Philadelphia, PA, [3]Takeda Global Research & Development Center, Inc., Deerfield, IL

Purpose: Compare efficacy, gout flare rates, and safety of 6-month treatment with febuxostat (FEB) or allopurinol (ALLO) between subjects whose gout and hyperuricemia had been successfully treated in prior clinical trials with either FEB or ALLO for 3-5 yrs vs subjects not previously so treated.

Methods: In the 6-month CONFIRMS trial, 2269 subjects with gout and hyperuricemia were randomized to receive daily FEB 40 or 80 mg or ALLO (300 or 200 mg based on creatinine clearance). A subset of 276 subjects had previously participated in the FOCUS (5 yrs) or EXCEL (3 yrs) trials, maintaining sUA <6 mg/dL for up to 5 yrs while receiving FEB 40, 80, or 120 mg, or ALLO 300 mg. Randomization was stratified by renal function and by participation or lack thereof in the prior long-term urate lowering therapy (ULT) studies. All subjects who had previous ULT washed out for 30 days and had baseline serum urate level (sUA) ≥8 mg/dL before participating in CONFIRMS. Subjects received gout flare prophylaxis with colchicine or naproxen throughout the study. Subjects received gout flare prophylaxis with colchicine or naproxen throughout the study.

Results: The demographic and co-morbid features of subjects in the prior treatment subset did not differ from those of the entire group. The proportion of subjects with prior participation who achieved sUA <6 mg/dL at the final visit in the FEB 40 mg, FEB 80 mg, and ALLO groups was 57%, 77%, and 52%, respectively vs 43%, 66%, and 41%, respectively, among subjects without prior participation ($p \leq 0.05$ for comparison of subjects with and without prior participation for each treatment group). The **figure** shows the proportion of subjects in each treatment group requiring gout flare treatment. Overall, subjects with prior participation in each treatment group had lower rates of flares

(p≤0.001) vs those without prior participation. Rates of AEs were similar among subjects with and without prior participation, with the most frequent being URIs, abnormal LFTs, musculoskeletal pain, and diarrhea.

Conclusion: The subset of subjects who had previously received 3-5 yrs of ULT achieved sUA <6 mg/dL more often and had substantially fewer reported gout flares vs subjects who had not. This demonstrates the clinical benefit of maintaining sUA <6 mg/dL over time in reducing the incidence of subsequent gout flares and supports the likelihood of long-term urate pool depletion during successful ULT.

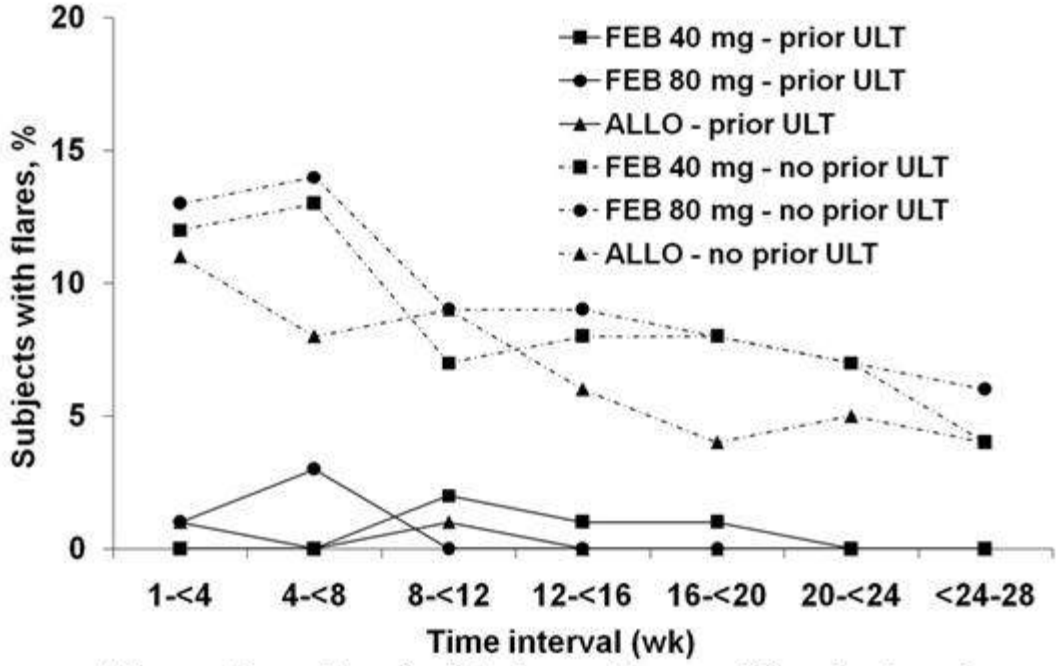

Figure. Proportion of subjects receiving gout flare treatment.

Relationship Between Serum Urate and Plasma Oxypurinol - Is There a Target Plasma Oxypurinol Concentration to Achieve Serum Urate ≤6mg/Dl. Lisa Stamp[1], J.L. O'Donnell[2], M. Zhang[3], C. Frampton[4], PT Chapman[3] and M. Barclay[3], [1]University of Otago, Dunedin, New Zealand, [2]Canterbury Health Laboratories, Christchurch, [3]Christchurch Hospital, Christchurch, New Zealand, [4]University of Otago, Christchurch, New Zealand

Purpose: Allopurinol is the most commonly used urate lowering therapy. The most feared adverse effect of allopurinol is the allopurinol hypersensitivity syndrome (AHS) which can be fatal. It has been suggested that impaired renal function, concomitant diuretic therapy and plasma oxypurinol >100µmol/L are associated with AHS. A therapeutic range of plasma oxypurinol 30-100µmol/L 6-9 hours post dose has been suggested. We wished to determine the relationship between plasma oxypurinol and serum urate (SUA) and the accuracy of the postulated therapeutic oxypurinol range.

Method: Patients with gout on stable dose allopurinol for at least one month were recruited. Allopurinol dose was gradually increased to obtain the target SUA ≤6mg/dL. Patients were seen monthly until SUA was ≤6mg/dL for 3 consecutive months. Then patients were seen 3 monthly until at least 12 months after study entry. Plasma oxypurinol at 6-9 hours post dose was determined at each visit using HPLC.

Results: 45 patients were enrolled, mean age 59.3 years (27-83), 93.3% male. Mean CrCl was 61.9ml/min (19-132) and mean SUA 7.4 mg/dL (6-10.8mg/dL). The mean allopurinol dose at baseline was 221.1mg/d (100-400mg/d) and mean plasma oxypurinol 92.3µmol/L (42.5-266.7µmol/L). 31/36 (85%) patients achieved the target SUA <6mg/dL at the 12month endpoint, mean SUA 5mg/dL (3.9-5.9mg/dL), mean plasma oxypurinol 141.8µmol/L (71.6 – 359.8µmol/L) and mean allopurinol dose 359.7 mg/d (150-600mg/d). Using mixed-effect linear modelling, allowing for individual patient effects, there was a significant relationship between allopurinol dose and plasma oxypurinol concentration ($p<0.001$). An increase of allopurinol dose by 100mg resulted in a mean increase in plasma oxypurinol of 46.8µmol/L. Additionally, mixed-effect linear modelling allowing for individual patient effects revealed a significant inverse relationship between SUA and plasma oxypurinol ($p<0.001$). A mean increase in plasma oxypurinol of 47µmol/L resulted in a 0.1mmol/L reduction in SUA. For those patients who achieved a SUA <6mg/dL, plasma oxypurinol was on average 136.8µmol/L at the first point when SUA reached the target. In comparison, plasma oxypurinol was on average 100.8µmol/L when SUA was >6mg/dL. There were no serious adverse events despite the higher plasma oxypurinol concentrations.

Conclusion: Increasing allopurinol dose results in an increase in plasma oxypurinol and a reduction in SUA. In general plasma oxypurinol, concentrations above the proposed therapeutic range were required to achieve SUA <6mg/dL. Larger studies will be required to determine the role of dose adjustment based on plasma oxypurinol concentrations.

Proinflammatory Effects of Octacalcium Phosphate (OCP) Crystals Are Mediated by IL-1b through NALP3 Inflammasome Activation. Borbala Pazar[1], Nathalie Busso[1], Laeticia Kolly[1], Sharmal Narayan[1], Veronique Chobaz[1], Nathalie Bagnoud[1], Hang-Korng Ea[2], Jurg Tschopp[3], Frédéric Lioté[2] and Alexander K. So[1], [1]Department of Rheumatology, CHUV, Lausanne, Switzerland, [2]INSERM UMR-S 606, Lariboisière Hospital, Paris Diderot University, Paris, France, [3]University of Lausanne, Lausanne, Switzerland

Purpose: OCP is a member of the family of basic calcium phosphate (BCP) crystals that are capable of eliciting joint and periarticular inflammation. BCP crystals have also been associated with cartilage destruction and osteoarthritis but the underlying mechanisms remain unclear. We investigated the pro-inflammatory effects of OCP in vitro and in vivo, with particular emphasis on the role of the NALP3 inflammasome.

Method: We tested the effects of OCP crystals in vitro on THP1 cells and mouse bone marrow derived macrophages (BMDM). To determine the role of the NALP3 inflammasome in OCP induced IL-1β production, BMDM from mice deficient in caspase-1, ASC and NALP3 were studied. IL-1β production was measured in the supernatants. In vivo, we tested the proinflammatory properties of OCP crystals in the mouse peritonitis model. The role of IL-1 in OCP-induced inflammation was assessed by the administration of IL1RA (anakinra) at the same time as crystal injection. Total neutrophil counts and IL-1β were measured in the peritoneal fluid.

Results: In vitro, THP1 cells stimulated with different concentrations of OCP crystals produced IL-1β in a dose-dependent manner. Release of IL-1β was maximal at 500 µg/ml (IL1 β = 2302.6 ± 46.9 pg/ml at 6h). Similarly, BMDM from wild type (WT) mice produced high concentrations of IL-1β (1123.9 ± 224.1 pg/ml) after stimulation with 500 µg/ml OCP crystals. Mouse BMDM deficient for NALP3, ASC and Caspase-1 did not produce any IL-1β after OCP crystal stimulation. In the mouse peritonitis model, injection of 1 mg of OCP crystals significantly increased total neutrophil counts (control mice: 2.6 x 104 cells, injected mice: 4.6 x 106 cells) and peritoneal exudate IL-1β levels (control mice: 2.6 ± 0.4 pg/ml, injected mice: 9.5 ± 3.2 pg/ml). The IL1 receptor antagonist, anakinra (200 µg/mouse) significantly reduced peritoneal neutrophil influx (OCP: 4.6 x 106 cells, OCP + anakinra: 1.6 x 106 cells, MSU: 4 x 106 cells, MSU + anakinra: 1.76 x 106 cells).

Conclusion: OCP crystals strongly induced IL-1β production in vitro via the NALP3 inflammasome. This was confirmed in vivo in the peritoneal inflammation model, as anakinra significantly inhibited neutrophil influx. IL-1β blockade represents an interesting and novel strategy to inhibit OCP-induced inflammation in human disease

Musculoskeletal Complications of Hereditary Hemochromatosis: A Case-Control Study. P. Richette, Sébastien Ottaviani, Eric Vicaut, Philippe Orcel and Thomas Bardin, Hopital Lariboisière, Paris, France

Purpose: Osteoporosis (OP) and an arthropathy that mimics osteoarthritis (OA) are considered as classical complications of hereditary hemochromatosis (HH), but have never been investigated in a cross-sectional study. The aim of this work was to determine whether HH is associated with an increased prevalence of OA and OP.

Method: A questionnaire designed for self-completion was obtained from 303 patients with HH and 306 age- and sex-matched unaffected controls.

Results: Mean age of patients was 60.1 ± 11.3 years and 47.4% were female. Mean ferritin level at diagnosis was 1556 ± 1623 µg/l. More HH patients than controls had been given a diagnosis of OA: 50.5% vs. 28.9% (aOR=2.52 [95% CI 1.7-3.5]). Compared with the control group, we found that HH patients had a higher crude and adjusted risks of knee and hip replacement prosthesis (aOR=4.9 [95% CI 1.0-23.1] and aOR=5.1 [95% CI 2.2-11.9], respectively). Prevalence of self-reported back pain and sciatica were also higher in HH patients (OR=3.5 [95% CI 2.5-5.0] and aOR=2.0 [95% CI 1.4-2.8], respectively).

In the crude analysis, we found that more patients than controls had been diagnosed with OP: 23.3% vs. 4.6% (P=<0.0001, OR=6.2 [95% CI 3.4-11.4]). This was associated with an increased crude risk of wrist fracture (OR=1.73 [95% CI 1.0-2.9]. The difference in OP prevalence between groups persisted after adjustment for confounding factors (aOR=4.82; 95%CI [3.35-9.91]). In the adjusted model, a non significant trend of increased prevalence of wrist or vertebral fractures was found in HH patients (aOR=1.6; 95%CI [0.9-2.9] and aOR=1.6; 95%CI [0.7-3.6], respectively). The severity of iron overload, defined by a ferritin level at diagnosis 1000 µg/l, was associated with OA (P=<0.0001) and the presence of hip prosthesis (P=0.01). OP was more frequent in HH patients with a severe iron overload (P=0.004) as were wrist (P=0.03) and vertebral fractures (P=0.04), respectively. The mean delay between the start of the joint complaints and the diagnosis of HH was 8.6 ± 8 years. One-third of patients stated that their pain worsened following phlebotomy. Joint pain was the symptom reported to prominently affect the quality of life of HH patients (57% of responders), following by asthenia (33%).

Conclusion: This first case-control study demonstrates a significant association between HH and OA, low back pain and OP. Joint involvement in patients with HH can be severe, especially when serum ferritin levels at diagnosis are increased to 1000 mg/L or more. Physicians should be better aware of HH, to achieve an earlier diagnosis.

How Successful Are Joint Aspirations in Patients with Suspected Gout? Soumya G. Rao[1], Gilda M. Clayburne[2], Janet E. Dinnella[1] and H. Ralph Schumacher Jr.[1], [1]U Penn & VA Med Ctr, Philadelphia, PA, [2]VA Medical Center, Philadelphia, PA

Purpose: Crystal proof is accepted as the gold standard for the diagnosis of gout. Synovial fluid (SF) aspiration may be difficult from some joints such as shoulders, wrists, fingers, ankles and feet. There are few reports evaluating success of joint aspirations in patients suspected of acute gout.

Method: All SF aspiration attempts by faculty or fellows at this center are recorded in detail in the electronic system. We retrospectively collected data for 1 year (Jan 2008 - Dec 2008) on any patient who underwent arthrocentesis with gout as a diagnostic consideration. If the amount of SF collected was determined to be sufficient to perform a crystal search, the arthrocentesis was considered successful. 139 patients with a clinical diagnosis of suspected acute gout were considered for this study. SF aspiration was attempted from 156 joints for analysis with compensated polarized light microscopy. Of the 139 patients, 87 had a history of gout (38 had prior positive crystal proof) and 47 patients had an initial swollen joint.

Results: Table:

	Total	Knee	MTP	Ankle	Wrist	Olecranon	MCP	Shoulder
Total attempts	156	78	25	13	11	20	8	1
Unsuccesful Aspiration	15	0	5	3	3	1	2	1
Succesful Aspiration	141	78	20	10	8	19	6	0
MSU	114	60	19	6	8	15	6	0
Other Diagnosis	28							
Septic Joint	5	3	1			1		
Rheumatoid Arthritis	1					1		
Traumatic	4	2				2		
Osteoarthritis	7	6		1				
CPPD	8	8*						
Undetermined	3			3				

*1 patient had both MSU and CPPD

90% of aspiration attempts were successful. Monosodium urate (MSU) crystals were identified in 73% of samples. Knee aspirations were most common (50%) followed by MTPs (16%). We had 100% success in knee aspirations. MTP aspirations were successful in 80% and they resulted in identification of MSU crystals in 95%. Other diagnoses were made or supported in 18% of the attempts. Interestingly 2 of the patients without crystals found were re-aspirated and were found to have positive MSU crystals in an adjacent joint. Unresolved issues were most common in the ankle joint. Some patients with previous MSU at some joint had no MSU crystals and other causes for the arthritis were found.

Conclusion: Joint aspirations even of the more difficult joints have a good chance of confirming suspected gout or supporting some important alternative diagnosis. Further evaluation of techniques for and experience with aspiration of some joints may improve results.

A Strong Role for the ABC-Binding Cassette G2 (ABCG2) Gene in Susceptibility to Gout in New Zealand Western Polynesian, but Not Eastern Polynesian (Mäori), Cases and Controls. Tony R. Merriman[1], Nicola Dalbeth[2], Amanda Phipps-Green[1], Marilyn Merriman[1], Ruth Topless, Peter Gow[3], Andrew Harrison[1], John Highton[1], Peter B. B. Jones[2], Lisa Stamp[1] and Jade Hollis-Moffatt[1], [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Counties Manukau District Health Board, Auckland, New Zealand

Purpose: New Zealand (NZ) Māori and Pacific Island men have the highest reported rates of gout. Genetic variation in ABC efflux transporter G2 (*ABCG2*), a renal urate transporter, is convincingly associated with gout in Caucasian, with the non-synonymous single nucleotide polymorphism (SNP) Q141K (*rs2231142*) the likely etiological variant. The aim of this study was to examine a role for *ABCG2* in susceptibility to gout in three NZ cohorts (of Māori, Pacific Island and Caucasian ancestry).

Methods: Patients that satisfied the ACR classification criteria for gout (n=55, 102 and 171, for Māori, Pacific Island and Caucasian respectively) were recruited from rheumatology outpatient clinics. The control samples were comprised of 89, 41 and 555 individuals, respectively, without arthritis. SNP *rs2231142* was genotyped using Taqman. Population stratification in the Māori and Pacific Island analyses was accounted for using genomic control markers together with STRUCTURE and STRAT software.

Results: Strong association of the minor allele of *rs2231142* with gout was observed in the Pacific Island samples (OR = 4.13, $P = 9.8 \times 10^{-6}$) but not in the Māori samples (OR = 1.59, $P = 0.25$). Similar results were evident after accounting for population structure ($P_{Maori} = 0.15$; $P_{Pacific} < 0.001$). Within the Pacific Island case samples there was a region-specific effect; 93 % of the risk allele positive individuals were Western Polynesian (Samoa, Tonga, Niue, Tokelau), compared to 58% of the risk allele negative individuals, with the remainder Eastern Polynesian (Cook Islands); $P = 2 \times 10^{-5}$. The genotype distribution in the Cook Island Māori cases (1,1 = 74%; 1,2 = 26%; 2,2 = 0%) was similar to that observed in the NZ Māori cases. Association with gout was also seen in the Caucasian samples (OR = 2.00, $P = 9.7 \times 10^{-6}$).

Cohort	Genotype (n, freq)			Minor allele (n, freq)	OR [95% CI]	$P_{allelic}$	P_{strat}
	1/1	1/2	2/2				
Māori							
Case	35 (0.686)	16 (0.314)	0 (0.000)	16 (0.157)	1.59 [0.76-3.31]	0.25	0.15
Control	64 (0.790)	17 (0.210)	0 (0.000)	17 (0.105)			
Pacific Island							
Case	33 (0.327)	43 (0.426)	25 (0.248)	93 (0.460)	4.13 [2.14-8.00]	9.8×10^{-6}	< 0.001
Control	25 (0.658)	13 (0.342)	0 (0.000)	13 (0.171)			
Caucasian							
Case	101 (0.601)	59 (0.351)	8 (0.048)	75 (0.223)	2.00 [1.47-2.73]	9.7×10^{-6}	-
Control	429 (0.763)	125 (0.222)	8 (0.014)	141 (0.125)			

Conclusion: Our data confirm a role for *ABCG2* in gout susceptibility in NZ Pacific Island and Caucasian sample sets. Unlike the situation at *SLC2A9* where the Caucasian-associated variants are considerably stronger risk factors for gout in both Māori and Pacific Island people than in Caucasian, the ABCG2 Q141K variant has a stronger effect only in Pacific Island people. The reason for this could be genetic difference between Western and Eastern Polynesian populations.

Low Glycosaminoglycan Levels in Osteoarthritic Articular Cartilage Vesicles. Kathryn Kiehn, Claudia Gohr and Ann K. Rosenthal, Medical College of Wisconsin, Milwaukee, WI

Purpose: Calcium containing crystals are commonly found in osteoarthritic joints and correlate with increased severity of cartilage degeneration. Articular cartilage vesicles (ACV) are chondrocyte derived extracellular organelles active in calcium crystal formation. Quantification of calcium uptake by ACVs is a standard model of pathologic cartilage mineralization. Paradoxically, ACVs isolated from osteoarthritic cartilage form fewer crystals than those from normal cartilage. The extracellular matrix, comprised largely of collagen and proteoglycans, dramatically affects ACV mineralization behavior in vitro. We recently showed that human ACVs contain higher levels of type II collagen than porcine ACVs, and this correlated with a reduced capacity for mineralization. Little is known about proteoglycans and their component glycosaminoglycans (GAGs) in ACV preparations. This study characterizes the GAG and proteoglycan composition of ACVs and compares ACVs derived from normal human, normal porcine and osteoarthritic human articular cartilage.

Method: Porcine cartilage from adult knee joints (n=5), human osteoarthritic cartilage from knee replacement surgery for osteoarthritis (n=5) and age matched normal human cartilage from NDRI (n=2) was obtained. ACVs were isolated by sequential enzymatic digestion followed by differential centrifugation. GAG analysis was performed using the dye binding Blyscan assay. Keratan sulfate was estimated by measuring chondroitinase ABC resistant GAGs. Western blotting was performed with antibodies against protein cores of biglycan, fibromodulin, aggrecan, and decorin.

Results:

	Normal	**Osteoarthritic**	**Porcine**
Total GAGs (ng/mg protein)	227.6 ± 29.3	108.5 ± 19.6	157.07 ± 23.8
% Keratin Sulfate	35 ± 8	74 ± 11	64 ± 4

1. All ACV fractions contain GAGs, despite enzymatic exposure to hyaluronidase and trypsin.
2. Osteoarthritic ACVs contain less sulfated GAGs ($p \leq 0.001$) and a higher percentage of keratan sulfate ($p \leq 0.02$) than normal human ACVs
3.Porcine ACVs have a GAG composition intermediate between normal and osteoarthritic human ACVs.
4. Non-quantitative Western blotting revealed similar types of proteoglycans on ACVs from osteoarthritic, normal human and porcine ACVs

Conclusion: GAGs are present in ACV preparations. Differences in quantities and types of GAGs in ACV preparations derived from osteoarthritic and normal human cartilage reflect matrix changes seen in aging and osteoarthritis. However, unlike type II collagen levels, the lower levels of GAGs on osteoarthritic ACVs are unlikely to explain their reduced capacity to mineralize in vitro. Knowledge of the residual matrix components in ACVs is crucial to understanding their mineralization behavior, as matrix components may dramatically affect crystal formation. Further characterization of ACVs will allow for new insights into the pathogenesis of cartilage mineralization and osteoarthritis.

Developing American College of Rheumatology and European League against Rheumatism Criteria for Definition of a Flare in Patients with Gout. Angelo L. Gaffo[1], H. R. Schumacher Jr.[2], Kenneth G. Saag[3], William J. Taylor[4], Jeroan Allison[3], Lang Chen[3], Janet E. Dinnella[2], Ryan C. Outman[3] and Jasvinder A. Singh[5], [1]Birmingham VA Medical Center, Birmingham, AL, [2]U Penn & VA Med Ctr, Philadelphia, PA, [3]UAB, Birmingham, AL, [4]University of Otago Wellington, Wellington, New Zealand, [5]VA Medical Center, Minneapolis, MN

Purpose: Various non-validated flare criteria have been used in published gout studies. Our objective is to develop criteria for definition of acute flare in patients with known gout.

Method: Following Delphi panels and cognitive mapping, possible flare criteria were identified, including report of swollen, tender, or warm joints, pain & global assessment, Health Assessment Questionnaire (HAQ), and acute phase marker levels. For greatest relevance to clinical trials utilization, we also focused on patient self-reported items and added patient self-report of a flare. Data were then cross-sectionally collected on 212 consecutive crystal-proven gout patients from 8 international clinic sites. We evaluated potential gout criteria against a gold standard of presence of a gout flare defined by an experienced investigator who examined each patient. Possible gout flare criteria rules were initially selected using multivariate logistic regression. Subsequently, an approach using the number of independent criteria and a classification tree were utilized to define the diagnostic rules.

Results: The mean age (SD) of the study sample was 56.3 (15) years, 210 (98%) were men, and gout duration was 13 ± 11 years. Fifty-four (26%) patients were having physician-diagnosed flares. Using multivariable logistic regression the presence of any warm joint [OR 3.3, 95% CI 1.1-10.4], pain at rest > 3 (scale from 0 to 10) [OR 11.7 95% CI 2.5-55.6], patient self-defined flare [OR 25.6 95% CI 5.8-113.0], and presence of any swollen joint [OR 22.2 95% CI 1.1-434.0] were more significantly associated with presence of an acute gout flare. Using the number of criteria format the greatest discriminating power was seen with ≥ 3 criteria (sensitivity 90.7%; specificity 82.1%) (Table). A classification tree identified pain at rest > 3 followed by patient self-defined flare as the rule most strongly associated with a flare (sensitivity 83.3%; specificity 90.4%). The areas under the curve for the number of criteria model and the classification tree were 0.931 and 0.873, respectively.

Conclusion: We propose criteria for a gout flare based on patient self-report items. Patient self-reported flare, overall pain at rest, warm joints, and swollen joints were the items most consistently predictive of flares. Final validation of the criteria will examine its performance among patients participating in clinical trials.

# of gout criteria required*	Sensitivity (%)	Specificity (%)	PPV	NPV	Accuracy
0	100	0	25.7	NA	25.7
1 or more	100	26.3	32.0	100	45.2
2 or more	98.2	60.3	46.1	99.0	70.0
3 or more	90.7	82.1	63.6	96.2	84.3
4 or more	72.2	95.5	84.8	90.9	89.5

*Criteria examined: positive gout flare according to patient, presence of any swollen joint, presence of any warm joint, and overall pain at rest greater than 3.
PPV - Postive Predictive Value
NPV - Negative Predictive Value

The Independent Impact of Gout On Risk for Coronary Heart Disease Among Elderly Women: A Population-Based Study. Mary De Vera, M. Mushfiqur Rahman, Vidula Bhole, James Rankin, Jacek Kopec and Hyon K. Choi, Arthritis Research Centre of Canada / University of British Columbia, Vancouver, BC

Purpose: Despite the substantial prevalence of gout among aging women, little is known about associated cardiovascular risks. While it has been shown that men with gout have an increased risk of coronary heart disease, no corresponding data are available for women. Our objective was to evaluate the independent association between gout and acute myocardial infarction (AMI) requiring hospitalization among elderly women, aged ≥65 years.

Method: Using population-based administrative health data from a musculoskeletal cohort and a cohort study design, we compared incidence rates of AMI in 9,642 newly diagnosed gout patients and 48,210 controls, with no history of ischemic heart disease, matched (1:5 ratio) on age, gender, and length of medical record. Definitions of gout exposure were based on ICD-9 codes in physician claims and hospitals databases. AMI outcomes were ascertained from hospitalization data; discharge information was used to determine fatal and non-fatal outcomes. We performed Cox proportional hazards models stratified by gender to estimate the relative risk (RR) for AMI, adjusting for baseline characteristics (age, history of diabetes, hypertension, hyperlipidemia, and chronic obstructive pulmonary disease [COPD]) and time-dependent prescription medication use (non-steroidal anti-inflammatory drugs, glucocorticoids, anticoagulants, diuretics, statins, and hormone replacement therapy).

Results: The mean age for the cohort was 73.9 years and for women, 75 years. The proportion of individuals with hypertension, COPD, diabetes, and hyperlipidemia were 45%, 21%, 14%, and 11%, respectively; and for women, 50%, 21%, 13%, and 12%, respectively. Over a mean 6-year study follow-up, we identified 3,268 (778 fatal, 2,490 non-fatal) incident AMI cases, 996 among women. Women with newly diagnosed gout had 39% increased risk of AMI (95% CI, 1.20 to 1.61) and 41% of non-fatal AMI (95% CI, 1.19 to 1.67) compared with women without gout **(Table)**. These RRs were significantly larger than those among men (p values for interaction, 0.003 and 0.005, respectively).

	Women			**Men**			**Multivariate p-value for interaction by**
	N	**Crude**	**Multivariate**	**N**	**Crude**	**Multivariate**	

		RR	RR		RR	RR	gender
All AMI	996	1.67 (1.45, 1.93)	1.39 (1.20, 1.61)	2,272	1.19 (1.07, 1.32)	1.11 (0.99, 1.23)	0.003
Non-fatal AMI	735	1.71 (1.44, 2.02)	1.41 (1.19, 1.67)	1,755	1.18 (1.05, 1.33)	1.11 (0.98, 1.25)	0.005

Conclusion: These population-based data indicate that women with gout are at an increased risk for AMI, and the magnitude of excess risk is higher than men. Potential mechanisms behind these observations include gender differences in serum uric acid levels, uric acid metabolism, and female hormonal influence. These findings provide extended support for aggressive management of cardiovascular risk factors in all gout patients, and particularly among elderly women.

Chronic Fructose Ingestion Stimulates Hepatic Purine Release and Promotes the Development of Fatty Liver. Zhongsheng Peng[1], Tuere Wilder[1], Adrienne Williams[1] and Bruce N. Cronstein[2], [1]NYU School of Medicine, New York, NY, [2]New York Univ Med Ctr, New York, NY

Purpose: Recent studies indicate that increased fructose ingestion is a risk factor for development of hyperuricemia and gout. Hyperuricemia is also more common in obese individuals and often accompanies the metabolic syndrome and non-alcoholic fatty liver disease (NAFLD). It has long been known that fructose induces ATP hydrolysis in the liver and the hydrolyzed ATP is further metabolized to uric acid in the intracellular and extracellular space (by ecto-5'nucleotidase, CD73). An intermediate in ATP hydrolysis to uric acid, adenosine, acts at one or more of four receptors (A1, A2A, A2B and A3) to effect a variety of physiologic and pharmacologic effects. Because we have recently demonstrated that A1 and A2B adenosine receptors play a critical role in the development of fatty liver due to ethanol ingestion, another risk factor for hyperuricemia (Peng, Z. J Clin Invest, 2009), we therefore determined whether adenosine and its receptors play a role in fructose-induced NAFL as well.

Method: Fatty liver was induced by feeding a high-fructose diet (protein 20%, fat 13%, fructose 60%, and complex carbohydrates 7% of total kcal) for six weeks. Mice (all on C57Bl6 background) were treated with either the selective A1 receptor antagonist DPCPX or the selective A2B receptor antagonist enprofylline for the final four weeks of the experiment. Hepatic steatosis was graded semiquantitatively and hepatic triglyceride was measured photometrically. Adenosine concentration in the supernatant of cultured hepatic slices was measured by HPLC.

Results: Livers from fructose-fed mice released significantly more adenosine than chow-fed mice (643±53 vs 91±2nM, n=6, $p<0.01$) and this increase depended, in part, on the presence of ecto-5'nucleotidase since the increase was blunted in livers of CD73KO mice (384±18 vs 26±3 nM, n=6, $p<0.01$). WT and A3KO mice developed severe hepatic steatosis after chronic fructose ingestion with obvious lipid droplets present in nearly 100% of hepatocytes in both periportal and pericentral areas, but A1KO mice and DPCPX-treated WT mice suffered only minimal fatty change (Steatosis grades: WT 3.9±0.6 or A3KO 3.7±0.4 vs A1KO 2.7±0.5 or DPCPX: 2.8±0.5, $p<0.01$, respectively). Similarly hepatic triglyceride levels increased following fructose ingestion in WT and A3KO mice (WT: from 30±3 to 131±11mg/g; A3KO from 32±2 to 138±11mg/g, n=6, $p<0.01$, respectively) but not so much in A1KO mice or mice treated with DPCPX (A1KO: from 29±3 to 76±6mg/g; DPCPX: 74±11mg/g vs untreated, n=6, $p<0.01$, respectively). Mice treated with enprofylline were similarly protected from developing hepatic steatosis as reflected by steatosis grade (2.5±0.3, n=6, $p<0.01$, vs untreated) and hepatic triglyceride content (72±8mg/g, n=6, $p<0.01$, vs untreated).

Conclusion: These results indicate that chronic fructose ingestion leads to increased release of adenine nucleotides resulting in higher uric acid levels and fatty liver.

A Diagnostic Rule for Gout Arthritis in Primary Care without Joint Fluid Analysis. Hein Janssens[1], Jaap Fransen[2], Eloy Van de Lisdonk[1], Piet L.C.M. van Riel[2], Chris van Weel[1] and Matthijs Janssen[3], [1]Radboud University Nijmegen, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Ziekenhuis Rijnstate, Arnhem, Netherlands

Purpose: Gout is a common medical problem, with a world-wide prevalence of 1-2%. Most cases are managed and diagnosed by primary care physicians, and in a large number of patients without joint fluid analysis.We performed a study to estimate the validity of signs and symptoms for gout arthritis in primary care, and to develop a diagnostic rule for gout without the need of synovial fluid analysis.

Methods: Patients with a mono-arthritis were recruited from an open population of 330,000 Dutch inhabitants. Patients with a gout diagnosis according to family physicians (FPs) were enrolled in a diagnostic study (March 2004 through July 2007). Clinical variables, including the presence of monosodium urate (MSU) crystals in the synovial fluid of the affected joint, were collected within 24 hours of presentation to the FP. Statistical significant variables selected after univariate regression, and variables predefined by external knowledge and availability in primary care, were entered in multivariate logistic regression models to predict the presence of MSU-crystals in the synovial fluid. The diagnostic performance of the models was tested. The most appropriate model was transformed to a clinically useful diagnostic rule.

Results: There were 328 patients included. The most appropriate model contained the predefined variables ‘male gender’, ‘acute (mono-)arthritis before’, ‘onset within one day’, ‘joint redness’, ‘MTP1 involved’, ‘hypertension, or one or more cardiovascular diseases’, and ‘serum uric acid>0.35mmol/l’. This model had a ROC-area of 0.85 (95%CI 0.81-0.90). The performance did not change after transforming the regression coefficients to easy-to-use scores and was nearly equal to the statistical optimal model (ROC-area 0.87; 95%CI 0.83-0.91).The final prediction rule after transforming the shrunken regression coefficients resulted in the following clinical scores:Male gender:2,One or more previous attacks:2,Onset within one day:0.5, joint redness:1, Joint location MTP-1:2.5,Hypertension,or one or more CV diseases;1.5,Serum uric acid>0,35mmol/l:3,5.The prevalence of gout at 3 cut-off points were:≤4 points,2%;>4 and <8 points,31% and ≥8 points 80%.

Conclusion: In this study a diagnostic rule for gout was developed, that can be used validly by primary care physicians without joint fluid analysis.In addition it can be used for research purposis

Ultrasonography Shows Active Inflammation in Clinically Unaffected Joints in Chronic Tophaceous Gout. Ralf G. Thiele[1] and Naomi Schlesinger[2], [1]University of Rochester, Rochester, NY, [2]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Purpose: To examine whether persistent low-level inflammation is present in asymptomatic, chronic tophaceous gout. It is unclear whether there is ongoing inflammation in chronic tophaceous gout in between attacks, if joints appear unaffected, and serological markers of inflammation remain within normal limits. It is further unclear how erosions develop in gout. In contrast to rheumatoid arthritis, synovial proliferation is only moderate in gout, and bony erosions occur outside of synovial joints as well. In vitro, gouty tophi are surrounded by a corona of foreign body giant cells and an associated inflammatory response of mononuclear cells. Sonographically they are surrounded by an anechoic halo. Persistent inflammation has not been demonstrated yet in vivo.

Method: 45 ultrasound (US) studies of 34 consecutive patients (female = 13, male = 21) were included in this study. Inclusion criteria: 1. History of chronic tophaceous gout, monosodium urate crystal proven. 2. Absence of signs or symptoms of active gout (pain, redness or warmth) during visit. 3. CRP and ESR within normal limits within one week of visit. A total of 1154 images and video clips were reviewed. Examined joints included MTP (n=76); MCP (n=62); ankle (n=16); wrist (n=8); DIP (n=3); PIP (n=5); IP (n=2); knee (n=10); elbow (n=2).

All US studies were performed according to published guidelines, by a rheumatologist certified in musculoskeletal US, with >15 years of US experience (RT). MCP joints were examined from dorsal in long and short axis, first MTP joints from a dorsal, medial and plantar aspect. Tophi were defined as hypo- to hyperechoic, inhomogeneous aggregates with a “wet clumps of sugar” sonographic appearance. Synovial tissue was defined as poorly compressible hypoechoic tissue within the hyperechoic joint capsule or hyperechoic tendon sheath. Gray scale and Doppler studies were performed in all patients. Inflamed tissues were defined as displaying a pulse synchronous power Doppler or color Doppler signal. Studies were performed using 14-18 mHz linear transducers.

Results: Pulse synchronous Doppler signals associated with tophi were seen in 19/34 patients. Inflammatory changes were seen in 24/76 MTP joints; 12/62 MCP joints; 2/10 knee joints; 2/16 ankle joints; 4/8 wrist joints; 2/2 IP joints; 1/5 PIP joints; 1/2 elbow joints. Doppler signals were more often seen over the anechoic corona surrounding tophi or invading tophi than over tissue that emanates from the synovial lining of the joints. Erosions were associated with tophaceous material and not with synovial tissue. Doppler signal could occasionally be seen surrounding tophi as they invade the bone.

Conclusion: Persistent inflammatory changes were seen in more than half of asymptomatic gout patients. ESR and CRP seem to be unreliable markers of subclinical inflammatory gout. Our study suggests that tophi and their surrounding anechoic corona are associated with erosion formation in gout. In contrast to rheumatoid arthritis, synovial proliferation was limited, and invading pannus was not appreciated. Gout is frequently a chronic inflammatory arthropathy.

Heart Failure and Gout: An Intimate Relationship? Patricia Ninaber[1], Margareth Rolfes[1], Frank Willems[1], Lian Roovers[1], Richard Westra[1] and Matthijs Janssen[2], [1]Rijnstate Hospital, Arnhem, Netherlands, [2]Ziekenhuis Rijnstate, Arnhem, Netherlands

Purpose: Heart failure is strongly associated with gout. Known risk factors for gout are the use of diuretics, renal impairment, overweight and obesity. We analysed in an observational cross-sectional study the prevalence of gout with regard to the severity of heart failure as expressed in levels of NT-ProBNP, left ventricle ejection fraction(LVEF), and functional class.

Methods: We collected by standard questionnaires the clinical characteristics of heart failure patients, the functional class based upon the New York Heart Association (NYHA class) and related risk factors for gout. LVEF was determined using 2D echocardiography. In addition renal function, uric acid and NT-pro BNP(n<15pmol/l) were determined. NT-ProBNP samples were collected in a stable phase of heart failure.

Results: In total 157 patients(98 men, 59.women), mean age 67.9 yrs, (range 36 to 92.yrs), mean disease duration 3.7yrs (range 0.25.to 24 yrs) were included. Gout was diagnosed in 36 patients(28 men ,8 women). All except for two patients were treated with loop diuretics (98,7%) and 84.6.% had elevated serum uric acid levels. In respectively 17 out of 83 patients with NYHA class I and II (20,3%) and 21 out of 57 patients with NYHA class III and IV (36,8%) gout was diagnosed (p=0,06). In patients with gout mean NT-ProBNP was 578 pmol/l (median 548 pmol/l) compared to a mean of 300 pmol/l (median 371 pmol/l) in the group without gout (p<0,0001). Mean LVEF in patients with gout was 26% (22%-30%) compared to 30%(28%-33%) for patients without gout(p=0,11) .

Conclusion: Although almost all patients were treated with diuretics the severity of heart failure as expressed in levels of NT-ProBNP was strongly related to the presence of gout. This applies also for LVEF and functional class although not significantly. This study gives evidence that gout is associated with severe forms of heart failure

Biomarkers of Juvenile Dermatomyositis (JDM) Aid in Assessing Disease Activity Over Enzymes Alone. L. Rider[1], L. Li[1], J. Chipman[1], R. Costello[2], T. O'Hanlon[1], T. Fleisher[2], G. Csako[2] and F. Miller[1], [1]NIEHS, NIH, Bethesda, MD, [2]Laboratory Medicine, Clinical Center, Bethesda, MD

Purpose: To evaluate the utility of acute phase reactants, serum muscle enzymes, lymphocyte flow cytometry and von Willebrand Factor VIII related antigen (vWF) as correlates of disease activity in juvenile dermatomyositis (JDM).

Method: Serum or plasma was measured for acute phase reactants, and muscle enzymes using commercial assays (BN-II immunoturbidimetry [Siemens], Hitachi 736 [Roche] and Synchron LX-20 [Beckman Coulter]) in 33 JDM patients (median age 11.5 yrs) and 37 age, gender and race-matched controls, after holding morning medications. Flow cytometry assessed for T, B and NK cell subsets. vWF antigen was quantified by agglutination (STA-R, Roche/Stago). Disease activity measures were assessed by physicians blinded to laboratory results.

Results: Serum levels of muscle enzymes (CK, LDH, AST, ALT, and CK-MB/CK ratio [$P < 0.004$ for all]), acute phase reactants (albumin, alpha-1-acid glycoprotein [AAG], serum amyloid A [SAA], ferritin, haptoglobin, erythrocyte sedimentation rate [ESR]), and vWF lets were increased in JDM patients compared to controls. Lymphocyte subsets (CD3% and CD8% were also increased but NK% was decreased in JDM patients ($P = 0.0001$- 0.045). Many measures correlated moderately with each other ($r_s = 0.25–0.68$, $P = 0.0001–0.046$) and only two were redundant (AST with ALT, $r_s = 0.74$). vWF, CK-MB/CK ratio, albumin, LDH, AAG, AST, ALT, ESR, hematocrit (Hct), and NK% all correlated with MD global activity ($r_s = 0.39–0.60$, $P = 0.001–0.046$). Many of these also correlated with muscle strength by manual muscle testing (MMT) as well as C reactive protein (hsCRP), CD8%, and complement components C3c and C4 ($r_s = 0.39 – 0.62$, $P = 0.001 – 0.048$). Extramuscular activity (ExMA) by the Myositis Disease Activity Assessment Tool correlated with several of these markers, but also with SAA, ferritin, C3c, hsCRP, cystatin C and IgA ($r_s = 0.41– 0.67$, $P = 0.001$- 0.049). Multivariable linear regression modeling using backwards elimination yielded a model that best predicted MD global activity and included vWF, CK-MB/CK, ALT, AST, ESR, Hct and AAG ($R^2 = 0.69$, $P = 0.004$). This was improved from a model that included only muscle enzymes (CK-MB/CK alone, $R^2 = 0.30$, $P = 0.01$). Predictors of strength included CK-MB/CK, CD8%, and albumin ($R^2 = 0.75$, $P < 0.001$), which was also improved over a model consisting of only enzymes (CK-MB/CK alone, $R^2 = 0.19$, $P = 0.042$). ExMA was highly predicted by the combination of vWF, CK-MB/CK, hsCRP, and AAG ($R^2 = 0.85$, $P < 0.001$) and not predicted by muscle enzymes in isolation ($R^2 = 0.0$).

Conclusion: An endothelial activation marker vWF, as well acute phase reactants, peripheral blood lymphocyte subsets, and muscle enzymes are good biomarkers of disease activity for JDM. In various combinations, these predict global activity, strength, and are most helpful in assessing ExMA. The addition of these biomarkers appears to improve upon the assessment of disease activity over muscle enzymes measured in isolation.

1515

Clinical Indicators of Disease Are Not Indicative of Aspiration Risk in Newly-Diagnosed Patients with Juvenile Dermatomyositis.

Julie Fuller[1], Richard Adams[2] and Marilynn G. Punaro[2], [1]UT Southwestern Medical School, Dallas, TX, [2]Texas Scottish Rite Hospital for Children, Dallas, TX

Purpose: To evaluate in newly-diagnosed patients with juvenile dermatomyositis (JDM) the incidence and severity of dysphagia as assessed by videofluoroscopic swallow study (VFSS) and to correlate this objective data with symptoms reported, physical exam findings and Childhood Myositis Assessment Scores (CMAS).

Methods: This study is a retrospective chart review on all patients with newly-diagnosed JDM at our institution between January 1, 2000 and March 10, 2009 for whom VFSS were available for analysis. VFSS is performed routinely at our institution on all newly-diagnosed patients with JDM by a speech-language pathologist. Patients are seated in an upright position and offered a selection of foods of various textures and liquids of varying consistencies that are treated with barium liquid or paste. Videofluoroscopy during feeding is recorded and reviewed by a speech language pathologist for various swallow abnormalities, including laryngeal penetration and aspiration.

Results: 70 patients met inclusion criteria and had undergone VFSS at the time of diagnosis. The female to male ratio was 3.67:1 (55 F/15 M). 64% of the patients were white, 20% Hispanic, 14% black and 1% Indian. The median age at symptom onset was 5.5 years (range 0.5-17.6 yrs) and the median age at diagnosis was 6.0 years (range 1.7-17.8 yrs). The median age at VFSS was also 6.0 years (range 1.7-17.7 yrs).

Swallow Abnormality	**Yes**	**%**
Abnormal Oral Phase	35	50
Abnormal Pharyngeal Phase		

Delayed swallow	60	86
Pooling/stasis	51	73
Residue	66	94
Laryngeal penetration	47	67
Aspiration	22	31
Any abnormality	70	100

Aspiration rate when	**Present**	**Absent**	**p-value**
Dysphagia + dysphonia	2/3(67%)	20/67(30%)	0.2307
Dysphagia only	10/21(48%)	12/49(24%)	0.0904
Dysphonia only	2/3(67%)	20/67(30%)	0.2307
CMAS score ≤8	4/5(80%)	18/65(28%)	0.0312
Female	21/55(38%)	1/15(7%)	0.0264
Vasculitis	1/13(8%)	20/56(36%)	0.0904

Conclusion: All patients had some abnormality on VFSS; nearly a third of patients had aspiration. Clinical indicators of disease alone did not predict aspiration, which may be asymptomatic.

Disclosure: J. Fuller, None; **R. Adams**, None; **M. G. Punaro**, None.

99mTechnetium-Labeled Methylene Diphosphonate Bone Scintigraphy in the Initial Assessment of Chronic Non-Bacterial Osteomyelitis of Childhood and Adolescents. H. Morbach, T. Schwarz, C. Beck, M. Stenzel, C. Dueren, M. Beer, P. Schneider and H.J. Girschick, University of Wuerzburg, Wuerzburg, Germany

Purpose: Chronic non-bacterial osteomyelitis (CNO) is an inflammatory, non-infectious disorder of the skeletal system with unknown aetiology mainly affecting the metaphyseal regions of long bones in children and adolescents. Radiological methods covering the whole body are an important tool in the diagnostic approach of CNO. Therefore we wanted to analyse the sensitivity of ^{99m}Technetium-labeled methylene diphosphonate (Tc-99m MDP) bone scintigraphy in comparison to whole-body magnetic resonance imaging (MRI) in detecting the extent of inflammatory lesions in CNO at the time of diagnosis.

Methods: Tc-99m MDP bone scintigraphy and MRI has been performed in the initial assessment of 32 patients diagnosed with CNO. Both methods were compared with regard to sensitivity by two independent radiologists.

Results: A total of 54 clinically affected body sites could be found by clinical examination in the patient group. Whereas inflammatory lesions could be detected in 53 out of 54 sites by MRI (98.1 %), Tc-99m MDP only revealed inflammatory foci in 40 out of 54 body sites (74.1 %). In 2 of the 32 patients bone scintigraphy did not reveal any suspicious lesion, whereas MRI revealed multiple lesions in these patients. In particular, the sensitivity of bone scintigraphy was inferior in the detection of symmetrical and/or metaphyseal lesions.

Conclusion: Tc-99m bone scintigraphy was less sensitive in detecting multifocal inflammatory lesions in childhood CNO, potentially due to the symmetrical and/or metaphyseal localization of inflammatory lesions in this disease. Therefore, whole body MRI techniques can be considered as the gold standard in the diagnosis of children and adolescents with CNO.

Disclosure: H. Morbach, None; **T. Schwarz**, None; **C. Beck**, None; **M. Stenzel**, None; **C. Dueren**, None; **M. Beer**, None; **P. Schneider**, None; **H. J. Girschick**, None.

1517

Vitamin D Levels in Children with Rheumatologic Diseases. Christina F. Pelajo, Jorge Lopez-Benitez and Laurie C. Miller, Floating Hospital for Children at Tufts Medical Center, Boston, MA

Purpose: Vitamin D deficiency has been linked to development of autoimmune diseases such as inflammatory bowel disease, type 1 diabetes, multiple sclerosis, rheumatoid arthritis, and systemic lupus erythematosus (SLE). However, literature about this subject in children is sparse. The aim of this study was to evaluate the prevalence of vitamin D deficiency among children with autoimmune diseases versus non-autoimmune conditions attending a pediatric rheumatology specialty clinic.

Method: Chart and laboratory review of all consecutive visits at a pediatric rheumatology clinic between September 2008 and May 2009 (N=184; F:M 128:56).

Results: Of these patients, 125 had autoimmune rheumatologic diseases (SLE, juvenile idiopathic arthritis [JIA], dermatomyositis, scleroderma, vasculitis) and 59 had non-autoimmune conditions (Lyme, patello-femoral syndrome, hypermobility, etc). Mean age was 12.5 years (range 1-19 years).

	Vitamin D deficiency < 20 ng/ml	Vitamin D insufficiency 20-29 ng/ml	Combined deficiency & insufficiency
Autoimmune rheumatologic diseases N =125	35 (28%)	46 (37%)	81 (65%)
Non-autoimmune conditions N N=59	11 (19%)	25 (42%)	36 (61%)

Vitamin D deficiency was found in 50% of SLE patients, 50% of dermatomyositis patients and 22% of JIA patients. Children with autoimmune diseases taking prednisone had lower levels of vitamin D than those who were not on this medication (21.5 ± 2.4 vs 26.9 ± 1.0, p=0.04). Ethnicity, body mass index and age were also risk factors for vitamin D deficiency. African-Americans and Hispanics were more likely to be vitamin D deficient than Caucasians (p<0.0001). Overweight children had lower levels of vitamin D than those with normal body mass index (p=0.01). Age correlated inversely with vitamin D levels (r=0.18, p=0.01). Notably, 59% of children taking vitamin D supplements had levels <30ng/ml. Of the 88 patients with active autoimmune disease, 24 (27%) had deficient and 30 (34%) had insufficient levels of vitamin D. However, disease activity did not correlate with vitamin D levels.

Conclusion: About 2/3 of children attending a pediatric rheumatology specialty clinic were vitamin D deficient or insufficient. Factors contributing to low vitamin D levels included age, body mass index, prednisone intake, and ethnicity. Autoimmune disease did not appear to be a specific risk factor for vitamin D deficiency.

Prevalent Vertebral Fractures Among Children with Rheumatic Disorders at the Time of Initiation of Glucocorticoid Therapy: Results of the Canadian STeroid-Associated Osteoporosis in the Pediatric Population (STOPP) Research Program. A. Huber[1], D. Cabral[2], B. Lang[1], A. Ni[3], P. Dent[4], J. Ellsworth[5], K. Houghton[2], C. LeBlanc[5], P. Miettunen[6], Kiem G. Oen[7], J. Roth[3], C. Saint-Cyr[8], R. Scuccimarri[9], S. Atkinson[10], J. Hay[11], B. Lentle[12], M. Matzinger[3], N. Shenouda[3], K. Siminoski[13], Leanne M. Ward[3] and Canadian STOPP Consortium, [1]IWK Health Centre, Halifax, NS, [2]BC Children's Hospital, Vancouver, BC, [3]Children's Hospital of Eastern Ontario, Ottawa, ON, [4]Hamilton Hlth Sci McMaster Div, Hamilton, ON, [5]Stollery Children's Hospital, Edmonton, AB, [6]Alberta Childrens Hospital, Calgary, AB, [7]University of Manitoba, Winnipeg, MB, [8]CHU Sainte-Justine, Montreal, QC, [9]Montreal Childrens Hospital, Montreal, QC, [10]McMaster University, Hamilton, ON, [11]Brock University, St. Catharine's, ON, [12]Vancouver Hospital and Health Sciences Centre, Vancouver, BC, [13]University of Alberta, Edmonton, AB

Purpose: Vertebral fractures have emerged as an important but under-recognized problem in children with chronic inflammatory disorders. The timing of vertebral fracture onset in relation to disease onset and glucocorticoid (GC) administration remains unknown. The aim of this study was to evaluate spine health among 134 children (89 girls) with rheumatic conditions (median age 10 years; 25th, 75th inter-quartile range 6.0 to 14.0) who were enrolled in a national bone health research program within 30 days of initiating GC therapy.

Method: Children were divided into 3 sub-groups: 1) juvenile dermatomyositis (JDM, N=30); 2) juvenile idiopathic arthritis (JIA), excluding systemic JIA (N=28); and 3) other diagnoses (systemic lupus erythematosus, systemic vasculitides, systemic JIA and other rheumatic diseases; N=76). Thoracolumbar spine radiograph and lumbar spine areal bone mineral density (LS BMD) were performed within 30 days of GC initiation. Genant semi-quantitative grading was used to assess vertebral morphometry. Clinical variables were analyzed for association with vertebral fracture and LS BMD Z-score.

Results: Thirteen vertebral fractures were noted in 9 children (7% of the cohort; 3 JDM patients, 6 with Other Diagnoses). Six patients had a single vertebral fracture and 3 patients had between 2 and 5 fractures. Fractures were clustered in the mid-thoracic (69%) and upper lumbar regions. Three vertebral fractures (23%) were moderate (Grade 2); the others were mild (Grade 1). For the entire cohort, mean (±SD) LS BMD Z-score was low (-0.6±1.22, $p<0.001$) despite a mean height Z-score that was similar to the healthy average (0.02±1.0, $p=0.8$). LS BMD was not significantly associated with vertebral fractures. Back pain was highly associated with increased odds for fracture (OR 10.6, 95% CI 2.0-54).

Conclusion: In children with rheumatic conditions, vertebral fractures are present in a significant percentage of patients prior to prolonged GC exposure. LS BMD within 30 days of GC initiation did not predict development of vertebral fractures; however, back pain was highly associated with fractures.

Spinal Epidural Lipomatosis in Pediatric Patients with Chronic Autoimmune Disorders. Jana Möller, Juliane Hamel, Gabriele Hahn and Frank Pessler, Technical University Dresden Children's Hospital, 01307 Dresden, Germany

Purpose: Spinal epidural lipomatosis (SEL) is a pathological accumulation of fat in the spinal epidural space that may arise as a rare complication of corticosteroid therapy. The natural history of this entity in pediatric patients is inadequately understood. We analyzed the available cases of corticosteroid-associated SEL in pediatric patients with autoimmune disorders.

Method: Case series and literature review. Inclusion criteria: autoimmune disorder with chronic corticosteroid treatment; onset of SEL before age 16 years.

Results: Two new cases were identified, plus 11 cases published in the international literature. Patient 1 is a 14-year-old Caucasian girl with SLE who was treated with mycophenolate mofetil, hydroxychloroquine, methyl-prednisolone pulses, and oral prednisolone (2 mg/kg tapered to 0.2 mg/Kg over 6 months). At the end of the taper, she was admitted to the hospital because of vomiting, paresthesias, back pain, and incontinence to urine and stool. The anal wink reflex was absent. Spinal MRI showed no abnormalities in the spinal cord but extensive SEL abutting the entire length of the spinal cord. Patient 2 is a 10-year-old African American girl with Sjoegren syndrome involving the central nervous system. She had been treated with cyclophosphamide and high-dose corticosteroids for 6 months when she developed radicular pain

and paresthesias. MRI showed extensive SEL compressing several dorsal nerve roots. In order to minimize corticosteroid-related untoward effects, treatment with rituximab was initiated in both patients, deflazacort was given instead of prednisolone and subsequently tapered successfully, while lipomatosis-related symptoms improved. Review of all 13 cases (mean age, 11 +/- 3.3 years; table 1) showed that steroid-related spinal epidural lipomatosis occurred after a mean duration of corticosteroid treatment of 1.3 years (median, 0.7 years), but as early as after 3 months. Two patients (17 %) required surgical decompression, whereas the others responded adequately to reduction in corticosteroids.

Conclusion: SEL should be considered in pediatric patients on chronic corticosteroid therapy, who develop spinal neurological symptoms or radicular pain, even in the first months of therapy. Corticosteroid-sparing therapies and, in severe cases, surgical decompression are warranted to prevent long-term complications resulting from spinal cord compression.

Table. Characteristics of patients.

Pt.	Age (y)	Sex	Diagnosis	Duration of steroid treatment (y)	Treatment
1	6	m	JIA	1	surgical
2	16	m	Renal transplant	3	steroid reduction
3	11	m	Nephrotic syndrome	0.8	surgical
4	14	f	Nephrotic syndrome	0.4	steroid reduction
5	14	m	Nephrotic syndrome	0.8	steroid reduction
6	10	m	HSP nephritis	0.3	steroid reduction
7	8	f	IBD	6.5	steroid reduction
8	10	f	Nephrotic syndrome	0.4	steroid reduction
9	5	f	Nephrotic syndrome	1.4	steroid reduction
10	14	m	SLE	0.17	not available
11	10	m	Nephrotic syndrome	0.7	steroid reduction
12	11	f	Sjögren Syndrome	0.6	steroid reduction
13	14	f	SLE	0.5	steroid reduction

Assessment for Early Cardiovascular Risk in Pediatric Rheumatic Disease. Pascal N. Tyrrell, Timothy J. Bradley, Lawrence Ng, Cameron Slorach, Sunita Sidhu, Khosrow Adeli, Joseph Beyene, Rayfel Schneider, Brian M. Feldman and Earl D. Silverman, The Hospital for Sick Children and University of Toronto, Toronto, ON

Purpose: Adults with systemic lupus erythematosus (SLE) and rheumatoid arthritis are at increased risk of premature atherosclerosis irrespective of the presence of traditional cardiovascular risk factors. The aims of this study were to determine the prevalence of early vascular markers of atherosclerosis and the role of treatment and disease activity related factors in children with SLE, systemic juvenile idiopathic arthritis (SJIA) and juvenile dermatomyositis (JDM).

Method: Subjects were enrolled into a prospective longitudinal study and assessed following the first visit. Drug therapy and disease activity were recorded. Fasting lipid and glycemic profiles were performed. Vascular assessment included carotid intima-media thickness (CIMT), flow-mediated dilatation (FMD), pulse wave velocity (PWV). These indices were converted to z-scores using normal population data from the same center. Between group comparisons were made using parametric methods.

Results: Of the 137 children tested, SLE patients were older and more predominantly female (n=88, mean age: 15.4 ±2.5, 83% female) than JDM (n=28, 13.9 ±2.3, 50% female) and SJIA patients (n=21, 13.9 ±2.4, 57% female). Most children had a relatively healthy BMI (mean 22.4 ±4.6) and normal lipid profile of total cholesterol, LDL and HDL cholesterol, and triglyceride levels except for JDM patients who had elevated triglyceride (mean z-score: 1.8 ±2.9) and total cholesterol levels (mean z-score: 1.2 ±2.4). At the time of testing, subjects had been followed for a mean of 3.1 ±3.0 years and 91% were treated with corticosteroids (mean cumulative dose/kg: 0.2 ±0.3g). The following inflammatory markers were found to differ significantly for SLE compared to JDM and SJIA: higher ESR, lower complement levels C3 and C4, and lower albumin levels. CRP was found to be significantly higher in SJIA than SLE. Vascular function measures compared with controls: CIMT was lower in SJIA only (p=0.020); FMD was no different; and PWV was higher in SLE and JDM (both p<0.001). No difference between the three disease groups was found for CIMT, FMD or PWV when adjusting for sex, age, BMI, disease duration or cumulative corticosteroid dose.

Conclusion: Vascular markers of early atherosclerosis were found in children with rheumatic diseases but differed from controls according to the underlying disease. We found different disease-specific inflammatory factors in these patients which are likely to be important in determining risk of atherosclerosis and warrant further investigation.

Varicella Vaccine in Children and Adolescents with Systemic Lupus Erythematosus (SLE) – Immunogenicity and Safety. Cassia M. P. Barbosa[1], Maria T. Terreri[1], Claudio A. Len[2], Maria Isabel Moraes-Pinto[2], Paula Rosario[2] and Maria O. Hilário[2], [1]Universidade Federal de Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo,, Brazil

Purpose: To determine the immunogenitiy and the safety of the varicella vaccine in children and adolescents with SLE.

Methods: In a prospective, randomized and controlled study we included two groups of SLE patients (55 patients) who were randomized to be vaccinated or not and a group of healthy controls (28 individuals). The patients were excluded if they had received gammaglobulin, cyclophosphamide or metilprednisolone in the last 3 months. Other immunossupressors and corticosteroids under 20 mg/day were allowed. Leucocytes number below 700 and platelets number below 100 000 were also exclusion criteria. Each patient received single dose of the varicella vaccine (Biken® Aventis Pasteur). All patients and controls were evaluated pre vaccination and at 30-45, 180 and 360 days afterwords. At first visit they were submitted to a questionnaire, physical examination and laboratory tests, including serum antibody titres for VZV antigen (ELISA) and specific varicella zoster interferon gamma (IFN**)** production by CD4 and CD8 T cells. At days 30-45, 180 and 360, we analyzed the vaccinated groups' serological responses and the percentage of specific IFN positive CD4 and CD8 T cells. Repeated measure ANOVA was used for analysis of data evaluated more than once in time, with multiple comparisons performed by Tukey test. Level of significance was set at p<0.05.

Results: The study comprised of 28 SLE vaccinated patients (21F/7M, mean age 15.3±2.5 years; mean disease duration 4.4±2.6 years), 27 unvaccinated SLE patients (22F/5M, mean age 14.1±3.1 years; mean disease duration 4.7±2.7 years) and 28 healthy controls (21F/7M, mean age 15.0±2.5 years). The vaccinated groups (SLE and controls) showed no difference in the frequency of adverse events (p=0.797), all were mild. The serum antibody titres to VZV antigen increased in both vaccinated groups with no difference between them (p=0.227). The production of INF specific to VZV was lower in the SLE group compared to healthy controls (p= 0.001). The frequency of flares was the same in both groups of patients (4 in each group). The SLEDAI (SLE Activity Index) was similar in both groups of patients (p=0.797) in all assessments. In the follow-up period of two years there were 4 herpes zoster in the SLE unvaccinated group and zero in the vaccinated group.

Conclusion: In this controlled group, without or with low activity of SLE, the varicella vaccine was shown to be safe, without severe adverse events and with no association with disease flares. The varicella vaccine immunogenicity measured by serum antibody titres was appropriate. Immunizing SLE patients with the varicella vaccine may be a possibility to prevent herpes zoster.

1522

Malignancy in Pediatric-Onset SLE. S. Bernatsky[1], Rosalind Ramsey-Goldman[2], K. G. Oen[3], A. Rosenberg[4], C. Gordon[5], Susan Manzi[6], Dafna Gladman[7], E. M. Ginzler[8], M. A. Petri[9], S.C. Bae[10], Murray Urowitz[7], M. A. Dooley[11], S. Edworthy[12], O. Nived[13], G. S. Alarcon[14], J. G. Hanly[15], C. Aranow[16], K. Steinsson[17], M. Zummer[12], J-L. Senecal[12], J. Pope[12], P. R. Fortin[7], A. E. Clarke[1] and SLICC, [1]MUHC, Montreal, QC, [2]Northwestern Univ., Chicago, IL, [3]Univ. Manitoba, Winnipeg, MB, [4]Royal Univ Hosp, Saskatoon, [5]Univ. Birmingham, Birmingham, United Kingdom, [6]Univ. Pittsburgh, Pittsburgh, PA, [7]TWH, Toronto, ON, [8]SUNY-Downstate, Brooklyn, NY, [9]JHU, Baltimore, MD, [10]Hosp. Rheumatic Dis., Seoul, South Korea, [11]UNC, Chapel Hill, NC, [12]CaNIOS Investigator, [13]Univ. Hospital, Lund, [14]Univ. Alabama, Birmingham, AL, [15]Dalhousie, Halifax, NS, [16]Feinstein Inst., Manhasset, NY, [17]Univ. Hospital

Purpose: Recent data have confirmed an increased cancer risk in adult-onset systemic lupus erythematosus (SLE), particularly for lymphoma. However, to date there have been no assessments specifically in pediatric-onset SLE. We examined cancer incidence in subjects with pediatric-onset SLE, comparing this to expected risk based on general population cancer rates.

Methods: We examined cancer occurrence in 2 cohorts of patients diagnosed as having pediatric-onset SLE. Cohort 1 was comprised of patients followed at 2 pediatric centres. Cohort 2 (which contained no subjects from cohort 1) was comprised of individuals with the onset of lupus before age 16, who had been followed since adulthood at non-pediatric centres. All patients were linked to regional tumor registries to determine cancer occurrence over the observation interval. The person-years of follow-up for each subject were calculated from the date first seen at the respective clinic, & the first of 3 possible events: death, invasive cancer, or end of study interval. Standardized incidence ratios (SIRs) were calculated as the ratio of observed to expected cancers. Cancers expected were determined by multiplying person-years in the cohort by the geographically matched age, sex, & calendar year-specific cancer rates, summing over all person-years.

Results: There were 77 patients in Cohort 1(81.8% female) & 488 patients in Cohort 2 (89.7% female). The average age at SLE diagnosis was similar in Cohort 1 (12.1 years, standard deviation, SD, 3.5) compared with Cohort 2 (12.9 years, SD 2.8). Cohort 1 subjects were followed from an average age of 12.1 years & contributed a total of 925 patient-years of follow-up (average 12.0 years of follow-up time, SD 8.7). Cohort 2 subjects were followed from an average age of 20.2 years (SD 8.3, median 18) and contributed a total of 4,260 patient years (average 8.7 years, SD 7.2). Within the observation interval, no invasive cancers occurred in Cohort 1 (expected number of cancer, 0.4, SIR 0.0), and 2 cancers (upper aerodigestive tract and renal adenocarcinoma) occurred in Cohort 2 (expected number of cancers 4.4, SIR 0.45). Combining both cohorts, the over-all SIR was 0.42 (95% CI 0.05, 1.50).

Conclusion: This is the first-ever report of malignancy occurrence focussed on pediatric-onset SLE. Previous literature, based primarily on adult-onset SLE, has suggested a moderate increased risk of cancers over-all, with a 3 to 4 fold increased risk of lymphoma. We were unable to demonstrate this increased risk in pediatric-onset disease. However, a larger study of longer-term cancer outcomes in this population, following all patients from the time of diagnosis onward, is in progress.

Ten-Year Follow up of Children Systematically Treated with Cyclophosphamide for SLE. Risa Alperin[1], Anusha Ramanathan[1], Emma J. MacDermott[1], Alexa B. Adams[1] and Thomas J. A. Lehman[2], [1]Hospital for Special Surgery, New York, NY, [2]Hosp for Special Surgery, New York, NY

Purpose: To assess the 5- and 10-year outcomes of a cohort of children systematically treated with 36 months of bolus IV cyclophosphamide (IVCY) for SLE.

Method: The records of all childhood-onset SLE patients who were treated with systematic IVCY were reviewed. Laboratory parameters were compared using the Wilcoxon matched-pairs signed-ranks test pre-IVCY and at 5 and 10 years after completion of treatment (8- and 13-years follow-up). Prednisone dose and laboratory parameters were recorded at each clinic visit and BILAG and SLEDAI scores were calculated.

Results: Sixteen patients children with SLE were systematically treated with IVCY for 36 months as previously described (1). The average age at diagnosis was 12.7 years old and female:male ratio was 3:1. Mean follow up was 9.94 years (5-16 years). Mean SLEDAI pre-IVCY was 10.125 +/- 5.018, at 5-years post-completion 4.875 **+/-** 3.096 ($p<0.0061$), at 10-year post-completion 4.667 +/- 3.464 ($p<0.1094$). BILAG pre-IVCY was 9.688 +/- 6.041, at 5-year 3.063 +/- 2.932 ($p<0.0001$), at 10-year 4.000 +/- 2.872 ($p<0.0117$). Mean initial prednisone dose pre-IVCY was 42.317 +/- 42.454, at 5-year 11.614 +/- 9.486 ($p<0.0003$), at 10-year 9.444 +/- 7.156 ($p<0.0273$).

Urine protein pre-IVCY was 1.875+ +/- 1.310, at 5-year 0.8750+ +/- 1.025 ($p<0.0574$), at 10-year 0.5714+ +/- 0.7868 ($p<0.0313$). Hemoglobin pre-IVCY was 11.569 +/- 1.638, at 5-year 13.381 +/- 1.454 ($p< 0.0001$), at 10-year 13.722 +/- 1.615 ($p< 0.0078$). ESR pre-IVCY was 47.438 +/- 25.193, at 5-year 22.625 +/- 30.024 ($p< 0.0052$), at 10-year 23.444 +/- 35.200 ($p<0.0391$). C3 pre-IVCY was 69.027 +/- 26.079, at 5-year 94.394 +/- 27.386 ($p<0.0413$), at 10-year 103.22 +/- 30.462 ($p<0.1953$). CreatInine pre-IVCY was within normal range at mean 0.8063 +/- 0.1843, at 5-year 0.8267 +/- 0.2789 ($p<0.9460$), at 10-year 0.9189 +/- 0.1788 ($p<0.1563$).

Conclusion: The drug was well tolerated without major infection in patients who completed follow up. There was one death secondary to end-stage renal disease and sepsis in a patient who had been lost to follow-up and discontinued all medications for 2 years. One patient had persistent fungal skin infection. One patient contracted hepatitis A and C in association with IV drug abuse. Less than 50% of patients had minor infections with multiple infections occurring in a small number of patients. There were no malignancies reported. There were no reported instances of infertility. There were three desired pregnancies and one adoption.

These data demonstrate that consistent 36-month IVCY was associated with significant improvement of both laboratory and qualitative-outcome measures as seen in our cohort of sixteen patients. Side-effect profile was excellent with infection being the most significant occurrence. There was a dramatic decrease in corticosteroid doses and the associated side effects.

1. Intermittent intravenous cyclophosphamide therapy for lupus nephritis. Lehman et al. J Pediatrics 1989 Jun:114(6):1055-60

The Biologic Rationale for Recurrent Intravenous Methylprednisolone Pulsing for Induction of Pediatric Systemic Lupus Erythematosus. Tracey Wright[1], Marilynn G. Punaro[2], Jeanine Baisch[3], Zhaohui Xu[3] and M. Virginia Pascual[3], [1]Univ of TX Southwestern, Dallas, TX, [2]Texas Scottish Rite Hospital for Children, Dallas, TX, [3]Baylor Institute for Immunology Research, Dallas, TX

Purpose: Intravenous methylprednisolone (IVMP) is commonly used to induce remission and treat moderate to severe flares of systemic lupus erythematosus (SLE). The frequency of IVMP use varies by center according to physician preference and is not standardized. The objectives of this study were to 1) characterize an IVMP induction protocol, and 2) examine the flow cytometry and gene expression analysis that provide the justification for this therapy.

Method: Medical chart review was used to determine the clinical characteristics of 60 children and adolescents with SLE who received recurrent IVMP during the first 6 months following diagnosis. Gene expression analysis was also performed on 7 subjects who were initially IVMP naïve using the following methods. At each clinic visit, three milliliters of whole blood were collected in Tempus tubes for RNA extraction and hybridization. Microarray analyses were performed using the Illumina platform. In addition, RNA was also analyzed using NanoString technology, a novel method based on direct multiplexed measurement of gene expression.

Results: The majority of the cohort (85%) was female and 62% were Hispanic. Nephritis (83%), cytopenias (77%), arthritis (74%), and mucocutaneous manifestations (59%) were common clinical features. The median SLEDAI score was 8 (0-37). The median number of IVMP doses administered during the first 6 months of disease was 12 (1-33) with most subjects receiving 3 consecutive doses for 3 consecutive weeks. Using flow cytometry and gene expression technologies, IVMP was found to significantly decrease the plasmacytoid dendritic cells (pDC) which produce IFN α and to erase the IFN α gene signature. The IFN α gene signature was abrogated for 7-10 days and then returned. Daily oral corticosteroids did not extinguish the IFN α gene signature. IVMP also effectively spared subjects from high dose daily oral corticosteroids. By 3 and 6 months after diagnosis, 65% and 73% of subjects were on daily maintenance corticosteroids of 10 mg or less. Three cases of significant infection occurred after the first course of IVMP.

Conclusion: Frequent use of IVMP is an effective method of corticosteroid administration during induction therapy in SLE. It reduces the need for high dose daily oral corticosteroids during the lead time of steroid-sparing immunosuppressive agents and is generally well tolerated. IVMP effectively extinguished the IFN α signature which characterizes pediatric SLE and is often correlated with disease activity. The pDCs which make IFN α were also reduced. Until more targeted therapies are developed, frequent IVMP may be the best therapy during induction. Future longitudinal analysis will clarify the optimal regimen of recurrent IVMP pulsing.

Variability of Mycophenolic Acid (MPA) Pharmacokinetics (PK) in Childhood-Onset Systemic Lupus Erythematosus (cSLE) May Be Partly Explained by UGT Genotype. A. Carmela Sagcal-Gironella[1], Tsuyoshi Fukuda[2], Kristina Wiers[1], Shareen Cox[2], Shannen Nelson[1], Marisa Klein-Gitelman[3], Alexander A. Vinks[2] and Hermine Brunner[1], [1]Cincinnati Children's Hospital Medical Center (CCHMC) Division of Rheumatology, Cincinnati, OH, [2]CCHMC Division of Clinical Pharmacology and Pediatric Pharmacology Research Unit, Cincinnati, OH, [3]Children's Memorial Hospital, Chicago, IL

Purpose: Mycophenolate mofetil (MMF) is a prodrug that is pre-systemically hydrolyzed by esterases to the biologically active moiety, mycophenolic acid (MPA). MPA is mainly metabolized by UDP-glucuronosyltransferases (UGTs) in the liver, intestine, and kidney into the inactive 7-O-glucuronide (MPAG) metabolite. Since genetic variants in UGT1A8, 1A9, and 2B7 have been proposed to explain the large variability of MPA exposure (PK) in transplant patients, the utility of pharmacogenetic (PG) testing is currently being investigated for individualizing MMF therapy. The relevance of these UGT polymorphisms to MPA PK in cSLE has not been addressed, but may be helpful in better understanding the MPA exposure-effect relationship in cSLE. In our ongoing pharmacokinetic-pharmacodynamic study, the contribution of UGT genotype in relation to MPA PK in cSLE was investigated in an exploratory fashion.

Methods: Full 9-hour pharmacokinetic profiles were obtained from cSLE patients (n=18; F:M=17:1; age 10-30 years, 43% Caucasian, 57% African-American, 81% non-Hispanic) who were on stable MMF treatment. The MPA PK parameters dose-normalized area under the curve from 0 to 9 hours ($AUC_{0\text{-}9h}$), peak concentration (Cmax), time to peak concentration (Tmax), and oral clearance (CL/F) were assessed and analyzed by non-compartmental analysis. Genomic DNA was extracted using standard procedures and genotyped for *UGT1A8*3 (830G>A)*, *UGT1A9*3 (98T>C)*, *1A9-2152T>C*, *1A9-440C>T*, *1A9-331T>C*, *1A9-275T>A* and *UGT2B7-900A>G* by TaqMan assay and direct sequencing.

Results: Large inter-patient variability in $AUC_{0\text{-}9h}$ (mean ± S.D.: 38.7 ± 19.8 mg*hr/L/gMPA, range: 14.9 - 95.4) and oral clearance (CL/F) of MPA (mean ± S.D.: 27. 9 ± 13.7 L/hr, range: 8.3 - 59.3) was observed. Patients with *UGT1A9 -440T (-331C)* or *UGT2B7 -900G* appeared to have a trend toward lower CL/F and higher MPA exposure (AUC) than the wild-type of all evaluated single nucleotide polymorphisms (SNPs). Patients with *UGT1A9 -275A* showed relatively high CL/F over a wide range. No patients with the *UGT1A9*3* genotype were found. In an exploratory fashion, wild-type and *-275A*-carriers were analyzed and showed significantly higher CL/F compared to the rest of the carriers of SNPs *1A9 -440T (-331C)* or *2B7-900G* ($p<0.05$, Mann-Whitney's U test).

Conclusion: Our preliminary data suggest that UGT1A9 and UGT2B7 polymorphisms may explain in part inter-individual differences in MPA exposure in patients with cSLE. Further studies in larger cohorts are needed to confirm the observed trends.

Efficacy of Mycophenolate Mofetil in the Prevention and Treatment of Lupus Nephritis in Pediatric Lupus Patients. Lenore M. Buckley[1] and Krista Edelman[2], [1]Virginia Commonwealth University School of Medicine, Richmond, VA, [2]Virginia Commonwealth University School of Medicine, Riichmond, VA

Purpose: To assess the experience with mycophenolate mofetil (MMF) and hydroxychloroquine (HCQ) in the prevention and treatment of nephritis in pediatric lupus patients at one center.

Methods: Observational study of the results of treatment with MMF and HCQ in pediatric patients who presented with lupus nephritis and those who did not have nephritis at presentation but were considered to be high risk.

Results: 49 patients with childhood onset SLE (average age 14 yrs at presentation) have been followed for a mean of 6 yrs. 22 (45%) were treated for nephritis, 16 (35%) had nephritis at presentation and 6 (10%) after a mean follow up of 2 yrs . Two children were in renal failure and on dialysis when treatment was begun – one with nephritis at presentation and one who developed nephritis during follow up. Of the 16 patients who presented with nephritis, the mean serum creatinine was 1.78 mg/dl at presentation and 0.77 mg/dl at last visit. 4 children (25%) presented with an elevated creatinine (1.2-5 mg/dl, one on dialysis). All 16 were treated with MMF and HCQ and all responded to treatment with improvement in proteinurea, serum albumin, and normalization of serum creatinine. After years of good control of renal disease, 2 (13%) developed worsening renal function after a prolonged period of noncompliance. Both were subsequently treated with IV cyclophosphamide and have stable renal function but significant damage by renal biopsy (creatinine 1.8 mg/dl and 1.7 mg/dl).

Of the 33 children (67%) without nephritis at presentation, 18 (55%) were considered high risk for the development of nephritis as defined by: onset of SLE < 18 yrs, positive anti DSDNA antibody, and one other risk factor (non white race, anti RNP antibodies, age of onset of SLE< 10, or low complement levels). All received treatment with MMF and HCQ due to other SLE manifestations. Nephritis developed in 1 of the 15 (7%) and 5 of 18 (28%) of the low risk and high risk patients, respectively. Of the 5 high risk patients who developed nephritis, 5 (100%) had anti DSDNA antibodies, 5 (100%) had anti RNP antibodies, and 5 (100%) had low complement levels at presentation. All 6 patients who developed nephritis had onset of renal disease after a prolonged period of noncompliance. In this group, the initial and last creatinine was 0.58 mg/dl mg and 0.79 mg/dl respectively. Two patients have persistently elevated creatinine of 1.2 mg/dl. Fair to good compliance with treatment was seen in 0% and 50% of the high risk patients who did and did not develop nephritis, respectively.

Conclusion: MF and HCQ were effective therapies for treating nephritis and for preventing renal disease in high risk patients. All children with nephritis at presentation responded to treatment and only those high risk patients who were noncompliance with MMF and HCQ treatment developed nephritis. Progression to renal damage occurred only in those with significant nephritis risk factors and significant noncompliance. Noncompliance with oral medications is a major limitation in the successful treatment of pediatric lupus.

Disclosure: L. M. Buckley, None; **K. Edelman**, None.

Urinary Biomarkers May Differentiate Between Children with ISN/RPS Class IV Versus Class V of Lupus Nephritis (LN). Lena Das[1], Michiko Suzuki[1], Michael Bennett[1], Kathleen A. Haines[2], Marisa Klein-Gitelman[3], Judyann C. Olson[4], Karen Onel[5], Kathleen O`Neil[6], ED. Silverman[7], Nora G. Singer[8], Lori B. Tucker[9], Michael Wyder[10], Kenneth Greis[10], Prasad Devarajan[1] and Hermine Brunner[1], [1]Cincinnati Children`s Hospital Medical Center, Cincinnati, OH, [2]Hackensack Univ Med Ctr, Hackensack, NJ, [3]Children's Memorial Hospital, Chicago, IL, [4]Med Coll of Wisconsin, Milwaukee, WI, [5]Univ of Chicago, Chicago, IL, [6]Oklahoma University Health Science Ctr, Oklahoma City, OK, [7]Hospital for Sick Children and University of Toronto, Toronto, ON, [8]University Hospitals/Case Medical Center/Rainbow Babies and Children's Hospital, Cleveland, OH, [9]BC Childrens Hospital, Vancouver, BC, [10]University of Cincinnati, Cincinnati, OH

Purpose: Biopsy-proven LN occurs in up to 75% of all children with SLE. ISN/RPS classes of LN differ in major histological features, clinical manifestations and prognosis. Our aim was to identify urinary biomarkers that can differentiate between ISN/RPS class IV and class V in children with LN.

Method: In this ongoing study, urine samples from children with LN ISN/RPS class IV (n=6) and pure class V (n=7) collected within 60 days of a kidney biopsy and those of controls with focal segmental glomerulosclerosis (n=4) were tested. Two proteomic methods were employed that reliably measure large and mid-molecular weight proteins, i.e. 2-dimensional gel electrophoresis (2-DGE) and surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF-MS), respectively. Candidate biomarker proteins were

selected if levels differed significantly when comparing class IV vs. V, class IV vs. controls, or class V vs. controls. The identity of relevant protein spots seen on 2-DGE was obtained by MALDI-TOF-MS/MS.

Results: Using 2-DGE and MALDI-TOF-MS/MS, we found human serum albumin fragments (25kDa) and α1-B glycoprotein (60kDa) significantly over-expressed in class IV vs. class V LN. For SELDI-TOF-MS/MS four different chromatographic surfaces were tested; spectra were analyzed with ProteinChip Data Manager 3.07. The resulting urinary signature of mid-molecular weight proteins that differed between groups of samples based on robust and reproducible peaks is shown in the ***Table***, with areas under the receiver operating characteristic curves > 0.7 (all $p < 0.05$).

Conclusion: We have identified two proteins and a urinary biomarker signature that appear to be significantly different between LN ISN/RPS class IV and class V. Further studies in larger patient groups, including adults with SLE, are needed to confirm our findings and to assess the diagnostic accuracy of these candidate biomarkers.

Class V Nephritis in Pediatric SLE: Treatment and Long-Term Outcome. Boris Hugle[1], Earl D. Silverman[2], Pascal N. Tyrrell[1], Elizabeth Harvey[3], Diane Hebert[1] and Susanne M. Benseler[1], [1]The Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children and University of Toronto, Toronto, ON, [3]Hospital for Sick Children, Toronto, ON

Purpose: To evaluate presenting features, treatment regimens and long-term outcome of pure membranous lupus nephritis in pediatric systemic lupus erythematosus (pSLE).

Method: A single-center cohort study of consecutive patients diagnosed with pSLE at age < 18 years between January 1990 and July 2008 was performed. Data collection: demographics including ethnicity, clinical features, laboratory test results, medications and SLE disease activity (SLEDAI). Outcomes: 1) survival, 2) renal survival, 3) renal flares and time to flare, 4) proteinuria as measured by total urine protein/24 hours at last follow up and urine protein:creatinine ratio (uP:Cr) at 1 year and last follow up, 5) serum creatinine at last follow-up and 6) damage (SLICC-DI plus renal and treatment-related domains).

Results: A total of 32 of 457 consecutive pSLE patients (7.0%) had membranous lesions on first renal biopsy. Of these, 25 patients had biopsy-confirmed class V nephritis, alone or in combination with mesangial hypercellularity (WHO class Va/Vb). These were 4 boys and 21 girls with a median age at first renal biopsy of 13.8 years (4.2-18.4), mean nephritis follow-up 3.8 years (0.7-14.8). Ethnicity: Asian (52%), Black (24%), Caucasian (16%) and mixed (8%); mean SLEDAI at presentation 9.1 (0-19); proteinuria: mean urine protein at diagnosis 2.7 ± 4.6 g/24h (21/25); mean UP:CR 327.4 g/mol (21.0-2020.8 g/mol, 19/24), mean serum creatinine 54.1 µmol/l, Treatment: prednisone in 24/25 (96%), azathioprine in 8 (36%), cyclosporine in 7 (28%), ACE inhibitors in 11/25 (44%). Outcome: 1) overall survival: 100%, 2) renal survival: 100%, 3) flares: 11 renal flares in 8/25 patients (32%) (mean time to 1st flare: 18.6 months), 4) proteinuria: mean urine protein excretion 0.4 ± 0.7 g/24h (0.03-2.8 g/l, 23/24) at last follow-up and mean uP:Cr 23.5 ± 31.6 (18/25) at 1 year follow-up and 27.2 ± 33.1 (23/25) at last follow up, 5) serum creatinine 58.5 ± 13.4 µmol/l at last follow-up and 6) mean SLICC-DI 0.52 at last follow-up (0-4), 0/25 (0%) with damage as defined by the renal domains, 4/25 (16%) cataract, 2/25 (8%) diabetes, 2/25 (8%) osteoporosis.

Conclusion: The long-term outcome of pediatric patients with pure membranous lupus nephritis is excellent. No patient had persistent renal damage at last follow-up. The study suggests that the need for aggressive immunosuppression in pediatric patients with pure Class V nephritis may need to be questioned.

Development of a Predictive Rule for Nephritis in Pediatric Lupus Patients. Lenore M. Buckley[1] and Krista Edelman[2], [1]Virginia Commonwealth University School of Medicine, Richmond, VA, [2]Virginia Commonwealth University School of Medicine, Riichmond, VA

Purpose: Approximately 20% of patients with lupus have onset in childhood and childhood onset is a risk factor for more severe disease. Children with lupus are more likely to develop renal disease, receive more immunosuppressive treatments, have higher SDI scores over time, and are more likely to receive glucocorticoid treatment and to develop associated damage such as cataracts, AVN, and psychosocial morbidity. In addition, the cost of care for lupus patients with nephritis is significantly greater than for those without nephritis. The ability to prospectively identify pediatric lupus patients with a high likelihood of developing nephritis would allow clinicians to implement early treatment to prevent progression to renal disease and the associated glucocorticoid use, hospitalizations, declines in quality of life, and time missed from school and work. Predictive rules have been used to develop estimates of the likelihood of an event over time (i.e. FRAX for 5 and 10 year risk of fracture using risk factors) which can aid clinical decision making.

Methods: We analyzed data on risk factors in an inception cohort of 49 children with SLE (mean FU 6 yrs) to develop a predictive rule for the development of nephritis.

Results: Of this cohort, 73% were African American, 14% Caucasian, and 12% of other ethnicity. 22 children (45%) had nephritis - 16 (73%) at presentation and 6 (27%) during follow up. Children with nephritis were less likely to be Caucasian (5% vs 21%) or to have good medication compliance (9% vs 33%), and more likely to have anti DSDNA antibodies (95% vs 35%), anti RNP antibodies (11% vs 3%), both anti DSDNA and anti RNP antibodies (64% vs 42%), or low complement levels (60% vs 42%) at presentation. Using combinations of risk factors (age, race, serologies, complement level, compliance, insurance, and medications), 2 pilot predictive rules were developed with different sensitivity, specificity, and positive predictive value to estimate the likelihood of nephritis in this cohort (details and statistics to be presented at the meeting).

Conclusion: Predictive rules for nephritis in pediatric lupus patients can be developed using a combination of demographic, clinical, and laboratory based risk factors. The next step is to test these models in larger and ethnically varied cohorts of children with lupus to develop a validated predictive rule. Identification of children with lupus at high risk of developing nephritis will aid in clinical decision making about early implementation of immunosuppression and other preventive modalities as well as in risk-benefit and cost-effectiveness analyses.

Refractory Juvenile-Onset Lupus Nephritis Treated with Rituximab. Carlos Olmos[1] and Clara Malagón[2], [1]Fundación Cardioinfantil IC, Bogotá, DC, Colombia, [2]Asociación Colombiana de Reumatología, Bogotá, DC, Colombia

Purpose: Juvenile-onset SLE is usually aggressive and associated to severe renal involvement. About 30% of patients fail the standard treatment being considered refractory, which is also frequently associated to severe side effects. Rituximab has a very good safety and efficacy profile in adults; however, its use in children with juvenile-onset SLE and renal involvement is limited and without long-term experience. Our objective is to describe the clinical response and safety of Rituximab in a group of Colombian patients with refractory juvenile lupus nephritis.

Method: This is an observational study of 12 patients, 10 female and 2 male with a mean age of 13 years with refractory juvenile lupus nephritis. Eleven patients had lupus nephritis type 4 and 1 patient type 5. Rituximab was used in 2 intravenous infusion of 1 gram each fifteen days apart. The patients have been followed for an average of 24 months.

Results: B cell depletion has occurred in all patients; clinical disease activity index measured by SLEDAI, 24-hour proteinuria, C3, C4 and anti-DNA autoantibodies improved more than 97% in 11 out of 12. Seven out of 10 patients are out of prednisone. Only 2 patients required oral antibiotics and hospital admission for sinus and pneumonic infections, respectively. Two patients have required additional courses of rituximab due to relapse. The patient with type 5 lupus nephritis did not respond besides being B cell depleted. We did no see any serious adverse events.

Conclusion: This experience supports the use of rituximab as an excellent option of treatment for patients with refractory juvenile-onset lupus nephritis, especially in type 4 nephritis. B-cell depletion was demonstrated in this group of Colombian patients.

Defining and Measuring Global Flares of Juvenile Systemic Lupus Erythematosus (JSLE). Rina Mina[1], B. Anne Eberhard[2], Emily von Scheven[3], Gloria C. Higgins[4], Sivia Lapidus[5], Jamie Eaton[1], Laura E. Schanberg[6], Karen Onel[7], Marilynn G. Punaro[8], Judyann C. Olson[9], Jun Ying[10], Marisa Klein-Gitelman[11] and Hermine Brunner[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Schneider Children's Hospital, New Hyde Park, NY, [3]Univ of Calif San Francisco, San Francisco, CA, [4]Nationwide Childrens Hosp, Columbus, OH, [5]AI duPont hospital for Children, Wilmington, DE, [6]Duke University Medical Center, Durham, NC, [7]Univ of Chicago, Chicago, IL, [8]Texas Scottish Rite Hospital for Children, Dallas, TX, [9]Med Coll of Wisconsin, Milwaukee, WI, [10]University of Cincinnati, Cincinnati, OH, [11]Children's Memorial Hospital, Chicago, IL

Purpose: To define global disease flares of jSLE and use a data-driven approach to derive high-quality candidate criteria for measuring jSLE flares.

Methods: Pediatric rheumatologists answered 2 Delphi questionnaires to achieve consensus on a jSLE flare definition and identify variables for its operationalization. Candidate flare criteria were generated with these variables and tested for diagnostic accuracy using prospective data from jSLE patients (n=98) who were followed every 3 months for up to 7 visits (623 visits total). Physician-rated changes in jSLE disease course (jSLE worsening yes/no) at each visit served as criterion standard.

Results: The 1st Delphi survey was sent to 299 pediatric rheumatology members of CARRA, PANLAR and PRES (53% response rate), and the 2nd one had a response rate of 84%. There was 96% consensus that "*a flare of disease is a measurable worsening of jSLE disease activity in at least one organ system, involving new or worse signs of disease that may be accompanied by new or worse SLE symptoms. Depending on the severity of the flare, more intensive therapy may be required*". Variables suggested for use in jSLE flare criteria were: physician-rated disease activity (V_1), patient well-being (V_2), protein/creatinine ratio (V_3), disease activity index score (V_4), Child Health Questionnaire physical score (V_5), anti-dsDNA antibodies (V_6), ESR, and complement levels. There were 89 episodes of clinically relevant worsening of jSLE. Candidate flare definitions based on percent change of some or all of the jSLE variables were at most 53% sensitive, despite having a high specificity (78 – 97%) with areas under the receiver operating characteristic curves (AUC) all < 0.67. The SELENA Flare Tool had a sensitivity and specificity of 56% and 81%, respectively. Using multiple logistic regression modeling, we derived several candidate flare definitions with all AUC > 0.88. The best performing was (Δ = absolute change in variable): $-2 + [\Delta V_1 - \Delta V_4 - \Delta V_6]/5 + 1.8x\Delta V_2 + [2*\Delta V_3 - \Delta V_5]/25$ where score of > 15 identifies a patient with flare with 83% sensitivity and 86% specificity.

Conclusion: Consensus has been reached on a common definition of global disease flare in jSLE and promising candidate flare criteria have been developed. Further assessment of ease-of-use and accuracy in a prospective study is needed.

1532

Suicidal Ideation Common in Childhood-Onset Systemic Lupus Erythematosus (cSLE); Genetic Expression and Depressive Symptoms in cSLE.

Lorien A. Nassi[1], Marilynn G. Punaro[1], Anne Morton[1], Corinne Fribley[2], Jeanine Baisch[3], Zhaohui Xu[3] and M. Virginia Pascual[3], [1]Texas Scottish Rite Hospital for Children, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]Baylor Institute for Immunology Research, Dallas, TX

Purpose: Interferon (IFN) alpha plays an important pathogenic role in cSLE. People receiving alpha interferon (for hepatitis C, e.g.) have been noted to have depression. The purpose of this study is to determine the frequency of depressive symptoms in cSLE, and its relationship to IFN alpha signature.

Method: 40 unselected consecutive cSLE subjects (ages 13-18) were recruited for this study at our institution. Subjects completed the Children's Depression Inventory (CDI) at routine clinic visits, minimally 3 months apart, for three consecutive visits. Blood samples for gene expression studies were obtained at each visit, total RNA was isolated, and samples were analyzed using Illumina Human Ref8 BeadChips.

Results: 34 subjects have completed 3 study visits. 86% were female, mean age was 15.3 years, mean duration of SLE was 3.7 years, and 64% were Hispanic, 19% were African American, 11% were Caucasian, and 5% were Asian. Average SLEDAI score was 6.1, 64% were taking corticosteroids, 25% were receiving high-dose "pulse" corticosteroids, 94% had renal disease, 11% had been diagnosed with a mood disorder, and an additional 5.6% had other CNS disease.

Average CDI score for first time point was 4.6 (general adolescent population = 9). 19% admitted to some degree of suicidal ideation over the previous 2 wks, while 22% had a CDI score of 12 or greater (1 std above mean). 33% were evaluated by psychology/psychiatry. Not all subjects with suicidal ideation had elevated CDI scores.

A weak correlation between CDI and SLEDAI scores was found ($R^2 = 0.12$, $p = 0.03$). No significant correlation between interferon alpha-inducible gene expression and CDI scores was found (M1.2 r = -0.04, p = 0.84, M3.4 r = -0.04, p = 0.81, M5.12 r = -0.06, p = -0.76.) Microarray analysis did identify 9 groups of transcriptionally co-regulated transcripts (modules) with unknown biological function that

correlated with CDI scores (M7.26 r = 0.35, p = 0.04, M8.10 r = 0.40, p = 0.02, M8.14 r = 0.36, p = 0.04, M8.29 r = 0.42, p = 0.01, M8.88 r = 0.36, p = 0.04, M8.97 r = 0.40, p = 0.02, M9.1 r = 0.39, p = 0.02, M9.42 r = 0.44, p = 0.01, M9.46 r = 0.43, p = 0.01.)

Conclusion: A significant fraction (19%) of children with SLE had some degree of suicidal ideation in the 2 weeks previous to our evaluation. 33% admitted symptoms prompting psychiatric evaluation. Genomic studies showed that although there was no correlation between CDI scores and individual interferon alpha signatures, expression of a series of co-regulated transcripts of unknown biological function did correlate with these scores. This study suggests that screening for depressive symptoms and suicidal ideation should be performed in children with SLE. Although preliminary, our data suggests that blood gene expression signatures might be used to monitor depression symptoms in patients with SLE.

Further Validation of the Pediatric Automated Neuropsychological Assessment Metrics for Adolescents with Lupus. Eyal Muscal[1], Stephen L. Holliday[2], Douglas R. Bloom[1], Barry L. Myones[1] and Robin L. Brey[3], [1]Baylor College of Medicine, Houston, TX, [2]US Department of Veterans Affairs, San Antonio, TX, [3]UTHSCSA, San Antonio, TX

Purpose: To validate the computerized Pediatric-Automated Neuropsychological Assessment Metrics (Ped-ANAM) against a traditional neuropsychological battery (TNPB) in adolescents with SLE.

Method: TNPB and Ped-ANAM were administered on the same day to 22 adolescents with SLE by a tech blinded to clinical status. Z-scores were computed for each test score in TNPB (raw test scores) and Ped-ANAM (raw Throughput – correct responses/minute) based on Ms/SDs from this patient sample. These Z-scores were then averaged to produce a single summary Z score for each battery. Pearson Correlation Coefficients ($p<.05$) were computed between the two summary scores and individual test raw scores. The summary scores were also correlated with demographic/clinical variables potentially related to cognitive performance to examine differential sensitivity of Ped-ANAM and TNPB.

Results: 22 adolescents (age range 13-18; 90.9% female, 40.9% Hispanic, 31.8% African-American) without current neuropsychiatric manifestations were evaluated during a 1-year period. Summary scores for Ped-ANAM and TNPB were moderately correlated ($r=.36$, $p<.05$). Summary scores were negatively associated with a history of antihypertensive medication use for both Ped-ANAM ($r=-.43$, $p<.03$) and TNPB ($r=-.44$, $p<.03$). The Ped-ANAM summary score but not TNPB was negatively associated with blinded ratings of cerebral volume loss on MRI ($r=-.51$, $p<.01$), current prednisone dose ($r=-.60$, $p<.01$), and BMI ($r=-.37$, $p<.05$). The TNPB summary score but not Ped-ANAM was positively associated with age ($r=.76$, $p<.01$), anti-phospholipid positive history ($r=.44$, $p<.03$), and anti-ribosomal P positive history ($r=.37$, $p<.05$). Surprisingly, patients with a positive history for these two antibodies performed better on the TNPB. Neither battery summary score was significantly related to depression, cumulative prednisone dose, disease activity/damage, flares in the past year, lupus anticoagulant positivity, or anti-neuronal antibody positivity. Six of 15 (40%) TNPB raw test scores significantly correlated with the Ped-ANAM summary measure ($r=.41$-$.65$, $p<.03$-$.01$) and four of 11 (36%) Ped-ANAM raw scores correlated with the TNPB summary score ($r=.41$-$.52$, $p<.03$-$.01$).

Conclusion: Ped-ANAM and TNPB summary raw scores are moderately correlated but appear to be differentially sensitive to selected demographic and clinical measures that may modify cognitive performance in SLE. Results from this multi-ethnic cohort generally support similar conclusions from a study published by Brunner in 2007. This suggests that Ped-ANAM, which takes less time to administer and is less susceptible to practice effects than TNPB, is a promising technique for assessing cognitive performance in SLE. Replication with larger samples and normative control groups for Ped-ANAM is needed.

1534

Preliminary Findings of Functional Magnetic Resonance Imaging (fMRI) Assessments of Visuoconstructional Ability in Childhood-Onset Systemic Lupus Erythematosus (cSLE) Patients and Best-Friend Controls. A. Carmela Sagcal-Gironella[1], Marisa Klein-Gitelman[2], Aimee Baker[1], April German[1], Eric Anderson[3], Tresa Roebuck-Spencer[4], Dean Beebe[1], Frank Zelko[2], Darren Gitelman[5], Scott Holland[3], Mark DiFrancesco[3] and Hermine Brunner[1], [1]Cincinnati Children's Hospital Medical Center (CCHMC), Cincinnati, OH, [2]Children's Memorial Hospital, Chicago, IL, [3]CCHMC Imaging Research Center, Cincinnati, OH, [4]National Rehabilitation Hospital, Washington, DC, [5]Northwestern University, Chicago, IL

Purpose: 1) To use fMRI to identify cognitive neuronal networks involved in visuoconstructional ability (VCA) which is often impaired in cSLE. 2) To characterize both cognitive and neural differences in VCA between cSLE patients and matched best-friend controls using fMRI, the Pediatric Automated Neurological Assessment Metrics (Ped-ANAM), and formal neuropsychological (NP) testing.

Methods: 10 subjects (F:M=8:2, 40% African-American, 60% Caucasian), 5 with cSLE and 5 controls matched for age, sex, and race performed the square completion task to probe VCA during fMRI. Imaging was done on a 3T scanner with a 12-channel head coil. Functional data consisted of T2*-weighted echo-planar images acquired at TR=3 seconds with a resolution of 4x4x3 mm. A high resolution T1-weighted anatomic reference image was acquired for each subject. Group average responses were calculated ($p<0.001$ uncorrected). Other VCA assessments were: throughput scores of the matching grid, matching to sample, and spatial processing subtests of the Ped-ANAM and the Wechsler Abbreviated Scales of Intelligence block design subtest and Kaufman Assessment Battery for Children II block counting and Gestalt closure subtests in formal NP testing.

Results: Activation was seen in both dorsal ("where") and ventral ("what") visual pathways as expected for a task probing VCA. Figure 1 shows the group results for cSLE patients and controls. Both groups show activations in the two pathways, but cSLE patients appeared to activate more weakly in the dorsal pathway and more strongly in the ventral pathway compared to the controls. A negative correlation between performance on the Ped-ANAM matching grid subtest and fMRI activation in dorsal ($R^2=0.66$, $p<0.05$) and ventral ($R^2=0.63$, $p<0.05$) pathways were found across all subjects. Performance on other VCA assessments did not significantly correlate with activation patterns on fMRI, though the trend was the same.

Conclusion: In this ongoing study, cSLE patients differed in their VCA-related fMRI activation patterns from controls. Activation strength correlated with some VCA assessments across subjects. A more complete characterization of cSLE-specific fMRI activation patterns is expected as this cohort of subjects is augmented.

Figure 1: Composite activation maps for controls and cSLE subjects performing the square completion task. Color key: Red/orange= activation, Blue/green= deactivation. Black ovals indicate activation in the dorsal visual stream while the white ovals indicate activity in the ventral stream. L/R indicate the left/right orientation of the images.

1535

Diffusion Tensor Imaging (DTI) and Cognition in Children with SLE. Eyal Muscal[1], Elisabeth A. Wilde[1], Pavani Adapa[1], Ragini Yallampalli[1], Douglas R. Bloom[1], Barry L. Myones[1], Zili Chu[1], Robin L. Brey[2] and Jill V. Hunter[1], [1]Baylor College of Medicine, Houston, TX, [2]UTHSCSA, San Antonio, TX

Neurocognitive impairment is a prevalent feature of SLE. Disease-related white matter damage may be a mediator of these cognitive deficits.

Purpose: To assess neurocognitive functioning and white matter integrity in adolescents with SLE. We hypothesized that neurocognitive test scores would be associated with markers of tissue integrity and axonal damage on diffusion tensor imaging (DTI, an MRI tool that assesses white matter microstructure).

Method: Adolescents with SLE underwent DTI and completed neurocognitive testing. Researchers blinded to clinical status measured fractional anisotropy (FA, higher values indicate white matter tract integrity) and apparent diffusivity coefficient (ADC, higher values suggest axonal damage) metrics from DTI. Neuropsychologists blinded to clinical status assessed executive, visuo-spatial, psychomotor speed, and inter-hemispheric transfer task performance.

Results: 24 adolescents were evaluated during a 1-year period. The cohort had a female predominance (95.8%) and multi-ethnic composition (45.8% Hispanic, 33.3% African-American). Mean age at testing was 15.7 ± 1.6 years (range 13-18) and disease duration was 40.0 ± 23.0 months. Four children (16.6%) had previous severe NPSLE. Twelve subjects (50%) met a criterion of impairment (> 1.5 SD below the mean on at least 2 tests). Lowest group mean scores were on visual motor integration (VMI), verbal fluency, visual memory/spatial organization (Rey Complex Figure Test, RCFT), and inter-hemispheric transfer tests. Higher disease activity scores and number of flares within 1 year correlated significantly with lower FA and higher ADC values in corpus callosum areas, frontal white matter, and left arcuate fasciculus (range of r=0.42 to 0.71, p=<0.001-<0.05). Significant correlations between lower FA and higher ADC values in these regions and lower RCFT recall subscale scores were observed (r=0.41 to 0.52, p=0.009-0.04). Higher ADC values in right temporal and internal capsule regions were associated with lower VMI scores (r=-0.44 to -0.53, p=0.007-0.04). Lower FA and higher ADC values in posterior internal capsule and cingulate regions were associated with lower inter-hemispheric transfer subscale scores (r=0.44 to 0.59,

p=0.003-0.03). Children with prior severe NPSLE had lower median FA and higher ADC values in these regions. DTI values and neurocognitive test score differences were not significant when comparing by LAC status, history of nephritis or cumulative corticosteroid dosing.

Conclusion: We observed modest associations between white matter integrity and complex organizational task performance. This was seen even in children without prior neurological events and suggests that white matter may be an early disease target. Larger, prospective controlled studies are needed to confirm these associations and determine their value as risk predictors in children with lupus.

1536

Use of Cellular Text Messaging to Improve Visit Adherence in Adolescents with Childhood-Onset Systemic Lupus Erythematosus (cSLE). Tracy V. Ting[1], Deepa P. Kudalkar[2], Shannen Nelson[1], Jamie Eaton[1], Jennifer Rammel[1], Jennifer L. Huggins[1], Dennis Drotar[1] and Hermine Brunner[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH

Purpose: Adherence is a critical component to achieving successful outcomes in chronic illnesses like cSLE. Previous studies have indicated worse outcomes among non-adherent patients. Poor adherence to routine clinic visits is a significant problem in the management of SLE. Regular clinic appointments provide ideal opportunities for early intervention to avoid disease flares and maximize therapeutic regimens. Our aim was to improve visit adherence using cellular text messaging reminders (CTMR) and assess its impact on disease outcomes in cSLE.

Methods: An individualized CTMR was sent 7, 3, and 1 day(s) prior to each scheduled clinic appointment. Scheduling of subsequent follow-up clinic visits was also aided by CTMR as needed. Overall visit adherence was monitored prospectively over 8 months and compared to the historic visit attendance for each participant over the preceding 30 months (following standard of care [SOC]). Acceptable visit adherence was defined as attendance of ≥80% of the recommended visits as per the managing physician. Disease outcomes (SLEDAI-SLE Disease Activity Index and number of unplanned emergency room visits and hospitalizations) during the 8-month CTMR intervention period were compared to each subject's previous information during the SOC time period prior to the use of CTMR.

Results: 70 cSLE subjects (ages 13-28 years old, 93% female, 51% African American) agreed to participate by providing cell phone numbers and cellular service providers. Of the 66 participants with complete data, 64% (42/66) had poor visit adherence (<80%) during the SOC time period. Overall, the proportion of subjects with good attendance improved from 36% to 56% (p=0.04). With CTMR, 52% (22/42) of non-adherent subjects had newly acceptable visit attendance (≥ 80%). In addition to positive attendance trends, rates of visit no-shows significantly decreased (p=0.004), while self-requested visit cancellations increased (p=0.0001). No important changes in disease outcomes were observed.

Conclusion: Advances in communication technology are widely utilized by teens and young adults with cSLE. CTMR can be used as a means of improving clinic visit adherence. Important changes in disease outcomes may require longer-term CTMR intervention periods. Further studies of CTMR for both visit and medication adherence may prove highly effective and ultimately translate into improved health care utilization and better disease control in cSLE.

Von Willebrand Factor Antigen - A Novel Biomarker of Disease Activity in Childhood CNS Vasculitis. Tania Cellucci[1], Eleanor Pullenayegum[2], Pascal N. Tyrrell[1] and Susanne M. Benseler[1], [1]The Hospital for Sick Children, Toronto, ON, [2]McMaster University, Hamilton, ON

Purpose: To characterize the presenting clinical, laboratory and imaging features of children with distinct subtypes of central nervous system (CNS) vasculitis, to determine disease activity trajectories and associated inflammatory markers, and to explore the role of the novel biomarker von Willebrand Factor antigen (vWF) levels as a marker of disease activity.

Method: A single centre cohort study of consecutive children diagnosed with primary angiitis of the CNS (cPACNS) or secondary CNS vasculitis between June 1989 and October 2008 was performed. All patients were less than 18 years of age and had to have serial vWF levels measured. Demographic, clinical, laboratory, imaging and histological data were collected. The primary outcome was disease activity as measured by physician global assessment visual analogue scale (PGA) at 3, 6, 12, 18 and 24 months. Analysis included descriptive statistics and linear mixed effects models.

Results: A total of 114 CNS vasculitis patients were identified: 102 (89%) had cPACNS, including 78 (76%) with large vessel disease (68 non-progressive, 10 progressive) and 24 (24%) with small vessel disease, and 12 (11%) had secondary CNS vasculitis. The study inception cohort consisted of 23 children: 12 (52%) were female, median age at diagnosis was 10 years (3.3, 17.8 yrs), 14 (61%) had small vessel cPACNS, 8 (35%) had large vessel cPACNS (5 progressive, 3 non-progressive) and 1 (4%) had secondary CNS vasculitis. At diagnosis: elevated CRP was seen in 26%, increased ESR in 57%, leukocytosis in 52%, high opening pressure on lumbar puncture in 85%, elevated cerebrospinal fluid (CSF) protein in 58%, CSF leukocytosis in 79%, abnormal MRI in 91%, abnormal cerebral angiogram in 33%, and vasculitis on brain biopsy in 75% patients. Disease activity decreased significantly over time (mean PGA at 3 months 4.81 (±2.52), 12 months 1.36 (±1.59) and 24 months 1.18 (±2.59); $p<0.001$) and differed significantly between cPACNS subtypes with small vessel cPACNS having persistently higher disease activity ($p=0.01$). vWF levels mirrored the course of disease activity and were significantly associated with prednisone dose ($p=0.007$) and CRP ($p=0.004$). Change in vWF levels did not predict disease activity scores over time. Linear mixed effects modeling demonstrated a trend for an association between vWF and disease activity.

Conclusion: Subtypes of childhood CNS vasculitis are distinguished by their presenting features and follow distinct disease activity trajectories. Disease activity improved significantly in all subtypes during the 24 month follow-up period. Small vessel cPACNS patient had consistently higher disease activity over time. vWF levels mirrored disease activity and therefore may be a promising novel biomarker of disease activity in childhood CNS vasculitis.

ROLE of FGF23 IN Kawasaki Disease (KD): A Possible Predictor of Subclinical Atherosclerosis. F. Falcini[1], L. Masi[2], G. Leoncini[2], F. Franceschelli[2], A. Vitale[3], S. Capannini[1], F. La Torre[3], G. Calcagno[3], M. Matucci Cerinic[4] and ML Brandi[2], [1]Department of BioMedicine, Division of Rheumatology, Transition Unit, University of Florence, Firenze, Italy, [2]Department of Internal Medicine, Metabolic Bone Disease Unit, University of Florence, Firenze, Italy, [3]Department of Paediatrics, Rheumatology Unit, University of Messina, Messina, Italy, [4]University, Firenze, Italy

Purpose: Vascular endothelial damage is a key event in KD, a systemic necrotizing vasculitis complicated by widespread long term arterial dysfunction. Endothelial damage is crucial in the process of atherogenesis as intimal lesions can become atherosclerotic plaques. KD pts seem to be at risk of early subclinical atherosclerosis. The relationship between inflammation and calcification provides evidence that inflammation is a potent initiator of vascular damage in atherosclerosis. Phosphatonins are new hormones involved in phosphate homeostasis and bone mineralization. FGF23, the master phosphatonin, acts through FGF receptor 1 present in several tissues including vasculature and heart. The *fgf23* knockout mice develop ectopic calcification, vascular and heart damage.

Aims: 1.To evaluate the serum level of intact FGF23 in KD pts. 2. To screen all patients for mutation in *FGF23* gene.

Method: 70 pts (47 M, 23 F, mean age 38.6 ± 26.65 mths) with history of KD were enrolled in the study. 14/70 had CAA. At study entry, lipid profile (total cholesterol, HDL, LDL, triglycerides) was evaluated. Forty age and sex matched healthy children acted as controls.

The serum intact FGF23 concentration was measured, using an ELISA assay (Immunotopics Inc. San Clemente, CA, USA). Genomic DNA was extracted from peripheral blood and the three *FGF23* exons, including the intron-exon boundary regions, were PCR-amplified. Purification products were analyzed on ABI Prism 100 Genetic Analyzer (Applied Biosystems, Foster City, CA, USA). The obtained sequences were compared to wild type reference sequence of the *FGF23* gene published on Genbank Database (NT_009759).

Results: FGF23 serum levels were higher in KD pts than in controls **(**23± 4.14 *vs*10.3±3 pg/ml; p=0.004). DNA analysis showed new intronic C insertion between -36 and -37 nucleotides close exon2, and polymorphism C>T in exon3. Interestingly, all CAA pts had FGF23 serum levels significantly higher than those without coronary disease (Mann-Whitney U test: DF: 2.5 p=0.6); 10/14 had the new C insertion and 4/14 polymorphism C>T. Conversely, C insertion was detected only in 4/56 pts without CAA and none had polymorphism C>T. CAA pts had higher cholesterol level, in particular significant LDL in comparison to those without.

Conclusion: This is the first study of serum FGF23 levels and *FGF23* gene polymorphism in pts with history of KD. Our preliminary results point to circulating FGF23 values and *FGF23* gene polymorphism as two potential predictors of early atherosclerosis in KD pts. The high amount of serum FGF23 may be in part responsible of the pathogenesis of vascular and heart damage and its complications in KD.

1539

Perinatal Exposures and Kawasaki Disease in Washington State: a Population Based, Case-Control Study. Kristen N. Hayward[1], Beth A. Mueller[2], Carol A. Wallace[3] and Thomas D. Koepsell[4], [1]University of Washington & SCH, Seattle, WA, [2]Fred Hutchison Cancer Research Center, Seattle, WA, [3]Seattle Children's Hospital, Seattle, WA, [4]University of Washington, Seattle, WA

Purpose: Kawasaki Disease (KD) is an acute systemic vasculitis of childhood. It is currently the leading cause of acquired heart disease in adolescents and young adults in the United States. The etiology of KD remains unknown, but is thought to involve environmental triggers and genetic factors leading to an aberrant autoimmune-autoinflammatory response. The young age of onset of KD suggests that events in the perinatal period may be of etiologic interest. The goal of the study was to test for associations between maternal and infant perinatal exposures and KD. We hypothesized that certain perinatal infectious exposures alter infant immune development and predisposition to KD. Additionally, prenatal conditions such as preeclampsia, diabetes or maternal autoimmune disease may induce differential programming of fetal vascular responses and influence infant susceptibility to KD.

Method: A retrospective, population based, case-control, record-linkage study was performed. KD cases <10 years old occurring between 1987-2007 (N=995) were identified through Washington State Comprehensive Hospital Abstract Reporting System (CHARS) and Washington State Death Certificates via ICD9 or ICD10 codes. Cases were linked to birth certificates and birth hospitalization records. Controls were randomly selected from remaining birth records and were frequency matched to cases in a 4:1 ratio based on birth year and infant sex. Exposure information was abstracted from maternal and infant birth and hospital discharge records. Unconditional logistic regression was used to obtain adjusted odds ratio (OR) estimates and 95% confidence intervals (CI).

Results: After adjusting for infant race, sex, and year of birth, the following exposures were significantly associated with KD: maternal age ≥ 35y (OR 1.65 [1.20-2.27], p = 0.002); mother of foreign birth (OR 1.36 [1.06-1.75], p = 0.02); maternal Group B streptococcal colonization (OR 0.51 [0.26- 0.97], p=0.04); and infant hospitalization within the first 6 months of life (OR 1.42 [1.04-1.93], p = 0.03). In particular, early infancy hospitalization for bacterial illness was associated with 2.8-fold increased risk of KD in later childhood (OR 2.84 [1.6-5.1]; p < 0.0001). There was weak evidence to suggest that infant gender modifies the association between early hospitalization and KD with excess risk in males.

Conclusion: This study provides preliminary evidence of association between certain perinatal Infections and subsequent KD. The association between bacterial illness in the first 6 months of life and KD deserves additional study.

Temporal Association in Hospitalized Cases of Influenza or Streptococcus Infection and Incident Hospitalized Cases of Henoch Schönlein Purpura. Pamela F. Weiss, Andrew J. Klink, Xianqun Luan and Chris Feudtner, Children's Hospital of Philadelphia, Philadelphia, PA

Purpose: Prior epidemiologic studies have postulated that infectious agents play a role in the pathogenesis of Henoch Schönlein purpura (HSP), as evidenced by the seasonal nature of the disease.

Methods: We conducted a retrospective cohort study of children with new onset HSP between 1 January 2002 and 31 December 2008 using administrative data from over 30 children's hospitals to determine if specific infectious exposures are associated with hospital admission. We examined the association of standardized counts of group A ß-hemolytic *Streptococcus, Staphylococcus aureus,* influenza, parainfluenza, and adenovirus with standardized counts of HSP hospital admissions using autoregressive moving average process to account for temporal autocorrelation and clustering by hospital.

Results: Among the 2,303 admissions for new-onset HSP observed over the 7-year study period, hospital admissions were most frequent September through April, but with wide variability between hospitals for each month (Figure, in which each hospital's rates are standardized as a z-score for that specific hospital). Accounting for these month-by-month differences within each hospital for rates of hospitalization due to the 5 infections and rates of HSP admissions, the rate of HSP admission in a given month increased significantly as the standardized rates of group A ß-hemolytic *Streptococcus* (estimate=0.05, 95% CI: 0.01, 0.09; p-value=0.03) or influenza (estimate=0.05, 95% CI: 0.00, 0.10; p-value=0.05) increased.

Conclusion: This is the first large multi-center cohort study to examine the association of specific infectious agents and HSP hospital admissions. Influenza and group A ß-hemolytic *Streptococcus* were both significantly associated with HSP admissions and warrant further investigation.

Figure: Monthly z-scores for admissions for influenza, *Streptococcus*, and HSP.

Clinical Features of Childhood Scleroderma in An Incidence Cohort. Ariane L. Herrick[1], Holly Ennis[1], Alan J. Silman[2] and Eileen Baildam[3], [1]University of Manchester, Manchester, United Kingdom, [2]Arthritis Research Campaign, Chesterfield, [3]Royal Liverpool Children's Hospital, Liverpool, United Kingdom

Purpose: Most studies of childhood scleroderma have concentrated on well-established disease. Our aim was to describe clinical features and pattern of care in those children presenting to secondary care during a 25 month incidence study.

Method: 94 cases of childhood scleroderma (87 localised scleroderma, 7 systemic sclerosis [SSc]) were identified. Referring clinicians were asked to complete questionnaires at the time of notification and 12 months later, documenting (i) clinical features (including the site[s] of skin thickening and any extracutaneous features) (ii) serum autoantibodies (iii) current treatment and (iv) outcome at 12 months

Results: *Localised scleroderma.* The mean age when first seen was 10.4 years (± 3.7). 55 (63%) were female. 58 (67%) had linear scleroderma, 25 (29%) had non-linear morphoea and 4 (4%) had a mixed (combined) pattern. Of the 58 patients with linear scleroderma, 29 (50%) presented with lesions of the trunk and/or limbs only, 26 (45%) with face-head localisation only, and 3 (5%) with both face-head and limb involvement. Of the 87 patients with localised scleroderma, 14 (16%) had extracutaneous features, including arthritis, central nervous system, and eye involvement. Antinuclear antibody (ANA) testing was performed in 37 (43%) of patients at diagnosis and was positive in 16 (43%). Fewer than half of patients (45%) had received any treatment prior to notification, but at 12 months over half (59%) were on methotrexate. Of the 78 patients for whom 12 month follow-up data were available, 51 (65%) were improved/resolved, 14 (18%) were unchanged and 13 (17%) had deteriorated.

SSc. The mean age when first seen was 12.1 years (± 2.2). All were female. 6 (86%) had limited cutaneous SSc, 2 of whom had a dermatomyositis overlap. 6 (86%) were ANA positive. Of those tested for SSc-specific autoantibodies, 2 of 6 were anti-topiosomerase positive and 1 of 2 anticentromere positive. 6 (86%) of patients had received treatment prior to notification (5 methotrexate). 12 month outcome data were available for 6 patients: 4 were improved, 1 was unchanged and 1 deteriorated.

Conclusion: Key findings included the high prevalence (50%) of face-head involvement in those with linear disease and the high prevalence of extracutaneous disease (16%) and of ANA positivity (43%) across all localised disease. Although numbers with SSc were very small, most had limited cutaneous SSc, in contrast with larger studies in well-established disease. Over a 12 month follow-up period most patients with localised disease improved according to clinican's opinion.

Assessing the Impact of Childhood Scleroderma On Physical Function and Quality of Life. EM Baildam[1], Holly Ennis[2], Ariane L. Herrick[3] and Helen L. Richards[4], [1]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]University of Manchester, Manchester, UK, United Kingdom, [4]Mercy University Hospital, Cork, Ireland

Purpose: There have been few studies of quality of life (QOL) and physical function in childhood scleroderma and these have focused predominantly on self-perception and the impact of skin lesions. Yet QOL issues are likely to be used in the future as part of a composite assessment to measure disease activity and estimate disease impact. This cross-sectional study aimed to describe QOL and physical function in childhood scleroderma in relation to their clinical and demographic profiles.

Method: Children with either localised scleroderma or systemic sclerosis (SSc) attending paediatric rheumatology clinics, together with their parents or guardians, were asked to complete a set of three validated measures: the Child Health Questionnaire (CHAQ), Child Dermatology Life Quality Index (CDLQI) and Child Health Questionnaire (CHQ-PF50). Clinical and demographic data were provided by consultant paediatric rheumatologists.

Results: 28 children and their parents/guardians participated in the study. Of the 28 children, 24 (86%) had localised scleroderma and 4 (14%) had SSc. 68% were female and the median age was 13 years (range 5-17). Median CHAQ physical function score (0-3 scale) was 0.1, indicating only moderate impairment, although 4 (14%) reported scores ≥1 (2 with localised trunk or limb lesions and 2 with SSc). Median pain VAS score (0-100 scale) was 15 indicating moderate pain with 5 (17%) reporting pain ≥ 15 (4 in children with localised trunk or limb lesions and 1 with SSc). There was a positive relationship between CHAQ scores and pain VAS scores (ρ=0.69, $p<0.00$). Median CDLQI score was 5, indicating moderate impairment in self-perception. Parental assessments on the CHQ-PF50 indicated that children with localised scleroderma had greater impairment in psychosocial domains than in physical domains, while the opposite was true for children with SSc. Lower self-esteem assessments were significantly associated with higher CHAQ function and pain scores ($p=0.04$ and $p=0.03$ respectively). Family activity was also impaired by scleroderma, with a median score of 83 (0-100, with 0 indicating greater impairment) and 13 children (46%) scoring ≤ 80.

Conclusion: Scleroderma had only a moderate impact on QOL and physical function as measured by the three validated instruments used. This is encouraging, given its potential disfiguring and debilitating nature, although a small number of children reported a greater degree of impairment.

Localised scleroderma had a more detrimental impact on psychosocial than on physical wellbeing, highlighting the importance of measuring both affective and physical outcomes.

A reduction in physical function was associated with impaired self-esteem.

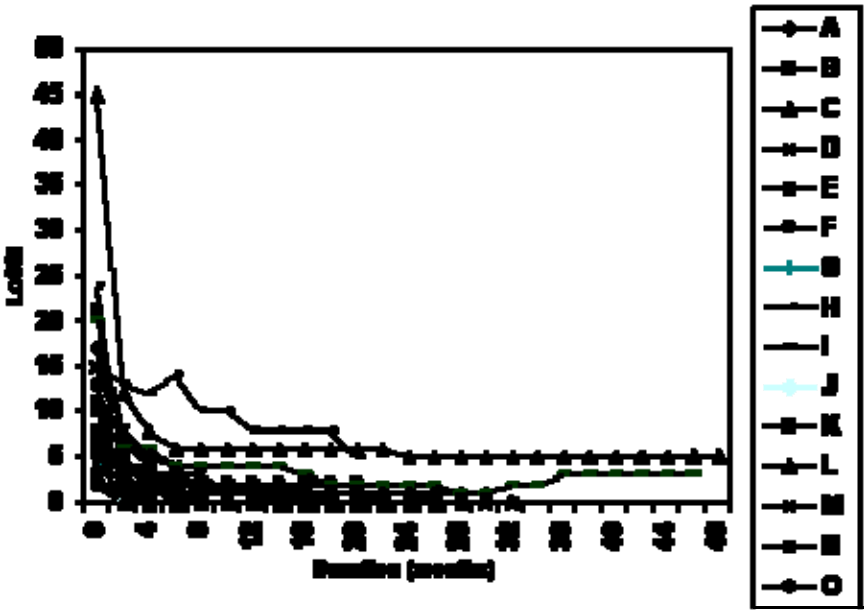
Localized Scleroderma Therapy: Do Different Regimens Matter? Amanda G. Brown[1], Kathryn S. Torok[2] and Thaschawee Arkachaisri[3], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]KK Women's and Children's Hospital, Singapore, Singapore

Background: Localized Scleroderma (LS) is the most common form of juvenile scleroderma. Its long-term physical and psychological impact continues to cause significant disability. Certain treatment regimens have been found to be effective in LS; however, they include small patient numbers and limited follow-up. Currently, no single treatment regimen has been established as standard of care.

Purpose: We report preliminary prospective data on the effectiveness of a single center treatment protocol in a pediatric LS cohort.

Methods: LS patients were recruited from the Scleroderma Clinic at the Children's Hospital of Pittsburgh. Patients with active disease, defined as those with erythematous lesions, and/or new lesions, or expansion of existing lesions, were started on oral prednisone 2mg/kg/day (max 60mg/day) and SC methotrexate (MTX) at 1 mg/kg/week (Max 30 mg/week). Prednisone was weaned to reach 1 mg/kg/day by the end of 6-8 weeks, and then further weaned to 0.25 mg/kg/day to complete 12 months of steroid therapy. MTX was continued for a full 24 months of SC therapy with subsequent oral therapy for 12 more months. Disease parameters evaluated were LS Skin Severity Index (LoSSI), which incorporates the following: degree of erythema, skin thickness, enlargement of existing lesions and new lesions, and physician global assessment of disease activity (PGA).

Results: 27 LS patients had serial outcome measures available to analyze. 19 were female with mean age at onset of 8.1 ± 4.1 years, mean age at first visit of 9.1 ± 3.8 years. Ten patients had linear scleroderma, 3 had *en coup de sabre*, 2 had subcutaneous morphea, 3 each had generalized or plaque morphea and 6 had mixed LS. Mean duration of follow-up was 21.6 ± 11.4 months. The change in LoSSI overtime during treatment and follow-up is demonstrated in the figure below:



All patients demonstrated a significant improvement as evidenced by a dramatic drop in the LoSSI within the first 1-2 months after therapy. PGA followed the same trend. There was no significant adverse reaction from the therapy. No patients experienced a flare during the follow-up period.

Conclusion: This single center LS treatment protocol was effective and well tolerated. Clinical outcome in LS is affected by dose and route of administration of immunosuppressive regimens. We uniformly use continuous and weaning dose of oral corticosteroids, instead of intermittent administration, along with parenteral MTX treating our LS patients without significant adverse reaction. This regimen successfully controls the acute inflammation and effectively prevents recurrence. Longer follow-up time is still needed. This regimen should be included as one of the therapy regimens for LS clinical trials.

Disclosure: A. G. Brown, None; **K. S. Torok**, None; **T. Arkachaisri**, None.

The Efficacy of Imiquimod 5% Cream in Children and Adolescents with Plaque Morphea. Ronald M. Laxer[1], Paul Babyn[2], Andrea Doria[2] and Elena Pope[2], [1]The Hospital for Sick Children, Toronto, ON, [2]ON

Purpose: Therapeutic options for pediatric patients with localized plaque morphea are limited. A previous small case series suggested that Imiquimod may be useful in the infiltrative stage of morphea due to a dose dependent inhibition of human fibroblast collagen production by INF alpha and gamma, resulting in a decrease in the production of both collagen and glycosaminoglycans. Pediatric data are currently unavailable.

Objectives: 1) To evaluate the efficacy of Imiquimod in pediatric patients with localized plaque morphea, 2) To evaluate to usefulness of high frequency ultrasound in evaluation and monitoring of plaque morphea lesions.

Methods: This is an open labeled, cohort, double baseline (each 1 month in length) study, using Imiquimod 5% cream for 48 weeks, in patients of 6-18 years, with plaques of morphea less than 100 cm^2, followed in the Specialized Morphea Clinic, SickKids Hospital, Toronto. The outcome measures included 2 clinical measures: 1) an investigator and parent visual analog scale (VAS), a 100 mm scale where 0 represented no thickening and 100, “wooden-like” thickening of the skin and each 10 mm represented 10% thickening; 2) DIET (D-dyspigmentation, I-induration, E-erythema and T-telangiectasia) score, where each item can take a value of 0- none to 3-severe (maximum score of 12); and one ultrasonography score (ranging from 0-9).

Results: 9 patients participated in the study, 89% females. Their mean age was 7.83 (SD=3.79) years at onset and 8.72 (SD=3.99) years at diagnosis. Baseline data revealed a mean size of the morphea plaques of 38.87 (SD=34.44) cm^2, a mean VAS of 48.08 (SD=18.85)% and a mean DIET score of 4.38 (SD=1.2). At 48 weeks the mean VAS decreased to 20.96 (SD=10.96)%, $p<0.0001$, and the mean DIET score decreased to 2.94 (SD=1.43), $p=0.006$. The major change in the DIET score was due to changes in the induration (I), which decreased from 1.94 (SD=0.57) at baseline to 1 (SD=0.61) at 48 weeks. The ultrasonographic data is pending. The cream was well tolerated; one patient experienced ulceration that required discontinuation of the medication for 2 weeks.

Conclusion: Imiquimod 5% cream is effective in pediatric patients with plaque morphea. The benefit is more significant in the induration/infiltration. Larger prospective studies in both active and static lesions are needed.

Is the Outcome of Childhood Growing Pains Associated with Changes in the Pain Threshold? Gil Chapnick[1], Philip J. Hashkes[2], Lutfi Jaber[3], Dan Nemet[1] and Yosef Uziel[1], [1]Meir Medical center, Kfar Saba, Israel, [2]Cleveland Clinic, Cleveland, OH, [3]Child Health Center, Taibe, Israel

Purpose: We found previously that the pain threshold in growing pains (GP) is significantly lower compared to healthy controls. We examined the long-term outcome of our GP cohort and tested whether it correlates with changes in the pain threshold.

Method: We studied 35 (20 male, 15 female, mean age 13.4 ± 2.7 years) from 44 subjects in the original cohort, 5.0 ± 0.2 years after the original measurement, compared to 38 similar gender and age pain-free controls (20 males, 18 females, mean age 13.6 ± 2.7). Current GP status was assessed by parental questionnaires. Pain thresholds were measured with a Fisher-type dolorimeter applied to tender points associated with fibromyalgia.

Results: Seventeen (49%) subjects still reported pain compatible with GP. In fourteen (83%) the pain was milder and less frequent. No subjects developed other pain syndromes, including fibromyalgia. Pain thresholds of the tender points were similar in the GP group and the healthy controls (4.7 ± 1.1 kg/cm^2 in GP vs. 4.9 ± 1.1 in controls). The 17 patients with continued GP had significantly lower pain thresholds than both the control group (4.23 ± 0.72 Vs. 4.9 ± 1.1 $p<.01$) and the patients whose GP resolved (4.23 ± 0.72 Vs 5.09±1.25 $p<.01$).

Conclusion: In most subjects GP has resolved or improved after 5 years. Pain threshold remained low only in patients still suffering from GP. This finding reconfirms our hypothesis that GP may represent a variant of a noninflammatory pain syndrome in young children.

Ask Me Where It Hurts?- Developing a Standardized Approach to the Assessment of Pain in Children and Youth Presenting to Pediatric Rheumatology Providers. Jennifer N. Stinson[1], Mark Connelly[2], Elizabeth J. Chalom[3], Peter Chira[4], Laura E. Schanberg[5], Michael A. Rapoff[2], Gary Walco[6], Shirley ML. Tse[1] and Lynn R. Spiegel[1], [1]The Hospital for Sick Children, Toronto, ON, [2]University of Kansas Medical Center, Kansas City, KS, [3]St Barnabas Med Center-ACC, Livingston, NJ, [4]Stanford SOM, LPCH, Stanford, CA, [5]Duke University Medical Center, Durham, NC, [6]Seattle Children's Hospital, Seattle, WA

Purpose: To develop a Standardized Universal Pain Evaluation by Rheumatology providers for children (SUPER-KIDZ) for use at Childhood Arthritis and Rheumatology Research Alliance (CARRA) sites in North America.

Method: A 2-stage Delphi technique followed by a 2 day consensus conference (to resolve areas of disagreement and finalize items/response options) was conducted to develop consensus among CARRA members and pediatric pain experts regarding variables that should comprise pain assessment in children with rheumatic conditions. Delphi survey respondents rated importance of pain assessment domains from Ped-IMMPACT group for use in pediatric chronic pain trials (McGrath et al., 2008) in two iterative surveys.

Results: Of the 251 CARRA members, 115 (46%) and 157(63%) completed the 1st and 2nd surveys respectively. All Ped-IMMPACT domains except one (economic factors) were retained. In survey 2, poor agreement on two additional domains (lifestyle and family factors) led to their proposed exclusion. Consensus conference discussion yielded general agreement on the following domains and items for both

child self-report and parent proxy measures: Pain characteristics (current pain, average pain intensity over past 2 weeks, pain episode duration, pain frequency, pain location), associated symptoms (fatigue frequency), cognitive and emotional factors (catastrophizing, positive affect, sadness, anger, worry, stressors), and functioning (physical, social, and role). Areas agreed to be omitted from the pain assessment included: pain sensory descriptors, pain aggravating/alleviating factors, pain unpleasantness, comfort goal, global pain treatment satisfaction rating, appetite, pain self-efficacy, recent peer group changes or conflicts, and level of independence. During the consensus conference, lack of agreement over the specific questions and metrics to use for quantifying items (except for pain intensity) resulted in the assignment of workgroups to conduct further reviews of existent measures and provide recommendations thereafter.

Conclusion: A standardized approach to assessing pain that is feasible and easy to implement in clinical settings may improve pain outcomes and quality of life in children with rheumatic conditions.

Distal Limb Pain as Onset of Fabry Disease. Ilaria Pagnini[1], Anna Frullini[2], Franco Cecchi[2], Walter Borsini[2] and Rolando Cimaz[3], [1]Meyer Children's Hospital, Florence, Italy, [2]AOU Careggi, Florence, Italy, [3]University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy

Purpose: Fabry disease is an X-linked lysosomal storage disorder caused by α-Gal A deficiency. The onset of disease is often in childhood, and acroparesthesia (distal limb pain) are frequent early findings. These patients may not be diagnosed correctly for years.

Method: We have reviewed medical charts of 64 patients (32 M, 32 F) with Fabry disease followed in our Units, with the aim of evaluating the prevalence, characteristics, and age of onset of acroparesthesia, as well as associated signs and symptoms during the disease course. Relevant demographic and clinical data were entered into a customized database. In addition to the retrospective data analysis, we also have sent more detailed questionnaires to families in order to collect informations on acroparesthesia onset and characteristics.

Results: According to chart review, almost half of patients (30/64) presented acroparesthesia during the disease course. Acroparesthesia were more prevalent in males than in females (20M, 10F), and initially occurred in childhood or adolescence in all cases except four. Fever was present in most cases. The disease progressed involving subsequently skin (42.6%), central nervous system (49.2%), kidneys (52.4%), heart (60.6%) and gastrointestinal tract (19.7%). Mean age at diagnosis ranged from 5 to 81 years (males, 40.8; females, 47.5 years) and was only slightly earlier in patients with acroparesthesia (36.9 years, range 5-60). Diagnosis was always confirmed by low or absent α-galactosidase activity in plasma.

More detailed informations have been collected from questionnaires, up to now we received from 29/49 eligible patients (15 either deceased or refused to partecipate). Of those (18 M; 11 F), the majority (20/29, 68.9%) did present acroparesthesia during the disease course. Acroparesthesia onset occurred frequently during childhood or adolescence (median 14 years) and were severe in intensity, sometimes needing analgesic treatment. Acroparesthesia were presenting signs in more than half of the cases (15 M, 5 F), and subsequent signs occurred even years after onset (1-5 years in n=4; 5-10 years in n= 7; >10 years in n=6). In six patients acroparesthesia remained the only disease feature. Misdiagnoses before Fabry disease were: juvenile idiopathic arthritis in two cases, connective tissue disease in one, growing pains in seven, pain related to fever in one, gout in one, and anxiety disorder in one. At follow-up acroparesthesia are still present in 14/20, and their intensity is mostly mild.

Conclusion: The age of presentation of Fabry disease in our cohort was variable, but the clinical manifestations can begin in pediatric age with episodes of acroparesthesia, even isolated. Diagnostic delay is common and can be very long. Since pain is most intense in hands and feet, and is frequently associated with fever, misdiagnoses of rheumatologic conditions are common. Pediatric rheumatologists should be aware of this disorder in the differential diagnosis of limb pain.

ACR/ARHP Poster Session C

Systemic Lupus Erythematosus Outcomes-Cardiac, Cognitive, and other Outcomes

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1548

Disease Activity and Levels of Anti-Apolipoprotein A1, Anti-HDL and Anti-Oxidised LDL in Patients with Systemic Lupus Erythematosus – a Prospective Study. Bethan Goulden, Ian P. Giles, Anastasia Lambrianides, Sean O'Neill, Eva Papadimitraki, David A. Isenberg and Anisur Rahman, University College London, London, England

Purpose: Patients with SLE have an increased risk of developing cardiovascular disease (CVD). Traditional risk factors do not account for all of this increased risk and inflammatory disease activity may also play a role. Inflammation may cause endothelial injury via the action of autoantibodies that interact with apoliporotein A1 (apoA1), high density lipoprotein (HDL) or oxidized low density lipoprotein (oxLDL). In a previous retrospective study we found significantly higher levels of anti-apoA1 and anti-HDL in patients with persistently active SLE disease activity than those with persistently quiescent disease. This abstract presents results of a prospective study of the same antibodies with the addition of anti-oxLDL measurements.

Method: 104 serum samples were collected from 90 different patients with SLE attending the lupus clinic at University College London Hospital. The patients were classified according to disease activity using the following definitions based on the British Isles Lupus Assessment Group Index.

Active disease - BILAG A or B score in at least one organ/system on day of sample.

Inactive disease – No BILAG A or B in any system

Persistently active disease - BILAG A or B on at least three occasions affecting at least two systems in the previous two years.

Persistently inactive disease – No BILAG A or B in any system for two years

Intemediate activity – Those who were neither persistently active nor persistently inactive by these definitions

The samples were tested by ELISA for levels of total IgG, IgG anti-apoA1, IgG anti-HDL and IgG anti-oxLDL. Values for anti-apoA1 and anti-HDL were expressed in comparison to a standard positive control used on each plate (control binding = 100AU). Values for anti-oxLDL were expressed as optical density (OD) at 405nm.

Results: The mean age of the patients was 41.1 (SD13.5) years with 93% female, 60% Caucasian and 24% Black. Of the 104 samples, 49 were from active and 55 from inactive patients. The numbers in the persistently active, intermediate activity and persistently inactive groups were 58, 24 and 20 respectively. Median anti-apoA1 was higher in active versus inactive patients (20AU vs 12AU p=0.006) and the same was true for anti-HDL (15AU vs 10AU p=0.05) but not anti-oxLDL (OD=0.12 in both groups). There was no correlation between level of any antibody and total IgG. Results for the persistently active, persistently inactive and intermediate groups are shown in the table below.

	Persistently active	Intermediate	Persistently inactive	P (Kruskall-Wallis)
Median anti-apoA1 (AU)	18	12.5	12	0.061
Median anti-HDL (AU)	12.5	15.5	8	0.062
Median anti-oxLDL (OD)	0.11	0.26	0.07	0.08

Conclusion: Raised anti-apoA1 levels were most clearly associated with both current and persistent disease activity. This agrees with our previous retrospective study and is of interest because there is a known correlation of anti-apoA1 with ischaemic heart disease in non-lupus patients. Anti-oxLDL showed no association with disease activity in this study

Effects of Hydroxy-Choloroquine On Lipid Profile in Systemic Lupus Erythematosus. Rohit Aggarwal, Rachel Mikolaitis, Winston Sequeira, Joel A. Block and Meenakshi Jolly, Rush University Medical Center, Chicago, IL

Purpose: To determine the effects of Hydroxy-choloroquine (HCQ) on fasting lipid profile in patients with systemic lupus erythematosus (SLE).

Method: Data were extracted from an ongoing prospective study of quality of life in SLE. Consecutive consenting adult SLE patients were enrolled from September 2006 to April 2008. All patients were assessed prospectively using a standard protocol including demographic, clinical, and treatment variables as well as SLE Disease Activity (SLEDAI) and SLICC damage indices. These variables associated with dyslipidemia were evaluated: diabetes, hypertension, smoking, alcohol, weight, renal function, albumin and proteinuria. Fasting lipid profiles including total cholesterol (TC), High density lipid-cholesterol (HDL-C) and triglycerides (TG) were measured using standard coupled enzyme assays. Low density lipoprotein (LDL-C) was calculated using the formula LDL-C = TC – HDL – (TG/5). Abnormal values were defined as LDL-C ≥ 130 mg/dl, TC ≥ 200 mg/dl, HDL-C ≤ 40 mg/dl for men & ≤ 50 mg/dl for women; and TG ≥ 150 mg/dl. Dyslipidemia was present if at least one of the 4 components was abnormal. The background characteristics and lipid profiles of patients with and without HCQ were compared using t-tests or Mann-Whitney test for continuous variables and chi-squared tests for categorical variables.

Results: Fasting lipid profiles were available in 150 patients. Mean (± S.D) age was 44.8 (± 12.9) years and 92.8 % were females. Seventy five percent of subjects were on HCQ and 59.4 % had dyslipidemia. There were no differences between patients with or without HCQ for the following baseline variables: age, gender, ethnicity, diabetes, hypertension, smoking, alcohol, prednisone, ACE-inhibitor, protienuria, serum creatinine, SLEDAI and SLICC. In comparison to patients who were not taking HCQ, those who were treated with HCQ had a greater BMI (182.3 ± 56.2 vs. 160.7 ± 38.3, p=0.03), lower frequency of dyslipidemia (56/103, 54.3%, vs. 26/35, 74.3%, p= 0.03), fewer with abnormal TG (21/98, 21.4% vs. 15/34, 44.1 %, p =0.01), and fewer abnormal HDL-C (18/100, 18% vs. 12/32, 37.5%, p = 0.02). There were no group differences in LDL-C or TC. TG serum levels (mean ± SD) were lower in patients treated with HCQ (120.6 ±72.2) than in patients not treated (152.3 ± 75.8), p = 0.02. However, no differences were observed in serum levels of HDL-C, LDL-C or TC.

Among patients treated with prednisone, dyslipidemia (57.8 % vs. 83.3%, P = 0.039) and abnormal TG (27.7 % vs. 52.2 %, P =0.04) were less common in the HCQ group. Serum TG were highest in patients taking prednisone but not HCQ (167.2± 79.5) and lowest in patients taking HCQ but not prednisone (111.2 ± 54.2), P<0.01. Patients who were treated with both prednisone and HCQ had intermediate serum TG (128.2 ± 83.7) and were not different than patients who were only taking HCQ.

Conclusion: HCQ alone or added to prednisone therapy has beneficial effects on dyslipidemia in SLE, particularly by decreasing TG.

Relative Importance of Remote, Recent and Cumulative Exposure to Risk Factors for Atherosclerotic Coronary Events in SLE. Mandana Nikpour, Dominique Ibañez, Dafna D. Gladman, Paula Harvey and Murray B. Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: SLE is strongly associated with premature coronary artery disease. Traditional risk factors as defined in the Framingham model only partly account for the increased risk of coronary events in SLE. Furthermore, many of these risk factors take a dynamic course in SLE, fluctuating over time due to changes in disease activity or treatment.

Objective: To compare ‘summary measures' of cumulative exposure with first available (‘remote') and recent values for each of total cholesterol (TC), systolic (SBP) and diastolic (DBP) blood pressure in terms of ability to estimate hazard of subsequent coronary events in SLE.

Method: Using a single centre SLE database, patients with two or more measurements of TC and BP taken before a coronary event (or last clinic visit) were included. For each patient, for each of TC, SBP and DBP, arithmetic *mean*, ‘time-adjusted' mean (*AM*) and area-under-the-

curve (*AUC*) was calculated for all serial measurements up to and including the visit before outcome. Cox and time-dependent proportional hazards regression models were used to compare summary measures with most recent and first available ('remote') measurements of each of TC, SBP and DBP in terms of ability to estimate risk of coronary event. Demographic, disease and treatment related variables were included as covariates in the models.

Results: There were over 950 patients with a mean±SD of 20±20 serial measurements of TC and BP per patient, and a mean±SD time interval between measurements of 4.2±2.3 months. Over a mean±SD follow-up of 7.0±6.7 years, among patient in the TC and BP analyses, there were 86 (71 angina, 22 MI, 2 sudden cardiac death; SCD) and 94 (75 angina, 28 MI, 2 SCD) 'first' coronary events respectively. While first available TC was not significantly predictive of coronary event, *mean* and *AM* TC were more strongly predictive (HR 2.07, p=0.003 for both mean and AM) than most recent TC (HR 1.86, p=0.001). *Mean* (HR 1.03, p=0.04) and *AM* (HR 1.03, p=0.03) DBP were significantly predictive of coronary events while first available and most recent DBP were not. Results were similar for SBP. AUC was not predictive of coronary event for either TC or BP. Other covariates in the models that were significantly predictive of coronary events were older age (HR in TC models: 1.12; HR in BP models 1.05, p<0.0001), male sex (HR 1.86, p=0.04), higher recent disease activity score (HR 1.1, p<0.0001) and recent treatment with corticosteroids (in TC models only; HR 1.87, p=0.01).

Conclusion: In contrast to the population-based Framingham model, first available ('remote') measurement of TC and BP is not significantly predictive of subsequent coronary events among patients with SLE. In SLE, summary measures of cholesterol and BP, reflecting cumulative exposure over time are better able to estimate risk of future coronary events.

Prediction of Cardiovascular Event in Systemic Lupus Erythematosus - A 7-Year Follow up Study. Christin Bengtsson[1], Bozena Möller[2], Torgny Smedby[3], Johan Back[4] and Solbritt Rantapää Dahlqvist[5], [1]Inst of Clinical sciences, Lund, Sweden, [2]Sunderby Hospital, Luleå, Sweden, [3]Östersund Hospital, Östersund, Sweden, [4]Sundsvall sjukhus, Sundsvall, Sweden, [5]Umeå University, Umeå, Sweden

Purpose: SLE is an inflammatory multi-organ disease with the main mortality problem in atherosclerotic associated diseases. It has been shown that the mortality due to cardiovascular disease (CVD) is up to 50 times greater than in the population overall. Candidate genes and genetical loci had been revealed associated to systemic lupus erythematosus (SLE) and specific SLE manifestations.

The aim of this study was to follow up CVD event in SLE patients in the northern region of Sweden. We also wanted to study genetical, SLE specific and traditional risk factors predictive value for CVD.

Method: During one year 277 patients with SLE (≥ 4 ACR criteria) were identified and assessed using SLEDAI, SLICC/ACR, laboratory parameters, medication, smoking status and history of CVD were registered. The patients were recruited from the Departments of Rheumotology, Internal medicine, and Dermatology and all GPs in northern Sweden. The mean (±SD) age was 51.2±14.9 yrs and mean disease duration 12.5±9.7 yrs. SLEDAI was 3.5 and SLICC/ACR index was 2.4±1.3, 48.5% were ever smokers, 10.4% had angina pectoris and/or coronary artery bypass (AP/CAB), 5.9% previous myocardial infarction (MI) and 10.4% venous thrombosis (VT). The patients and 2 matched controls for each were followed up 7 years later by cross-linkage with other national health- and census-registers and the frequencies of events (CVE) e.g. AP/CAB, MI, VT/pulmonary embolism and stroke were compared with matched controls. Genetic polymorphisms of STAT1, STAT4, TRAF6, Il-10, IRF5 and TYK2 in relation to the CVE was also analysed using minisequencing.

Results: CVEs (35 vs. 20) altogether were more frequent among SLE patients compared to controls (OR= 3.97; 95%CI2.14-7.37, p<0.0001). Among the events MI (p=0.001) and VT (p=0.017) per se was significantly more common among patients compared to controls. History of previous AP, AMI, age, higher values of ACR criteria, higher SLICC and SLEDAI and presence of aCL IgG and anti-Sm antibodies at inclusion predicted significantly CVE after adjustments. Hypertension, diabetes, smoking habits, disease duration, inflammatory activity, high doses of steroids, or any of the other events did not predict subsequent CVD event. There were no association between the analyzed genetic loci and CVEs among the SLE patients.

Conclusion: Disease related factors besides some of the traditional risk factors were associated with development of CVE in SLE patients, but not treatment or any of the analysed gene polymorphisms.

1552

Racial Disparities in Age of CVD in SLE. Lisabeth V. Scalzi, Christopher S. Hollenbeak and Li Wang, Pennsylvania State University, Hershey, PA

Purpose: To identify if inter-racial age differences exist for cardiovascular (CVD) events and CVD mortality in systemic lupus erythematosus (SLE) patients.

Methods: Using data from the Health Care Utilization Project (HCUP) for 2003-2005, 17.6 million hospital admissions were analyzed to examine racial disparities of mean ages for in-hospital CVD events and CVD mortality in SLE patients vs non-SLE patients. HCUP is a sample of nearly 1,000 hospitals from 37 states. SLE and CVD were identified by the ICD-9 code from hospital discharge diagnoses. Mean ages for Non-SLE and SLE patients in each racial group were computed and used to calculate the difference between SLE and non-SLE (Age Δ Non SLE vs SLE) and the diference between White SLE patients and each minority SLE group (Age Δ White SLE vs minority).

Results: There were 11,099 admissions identified for CVD and 1,746 CVD mortalities in SLE. The mean ages and racial breakdown for SLE CVD events was; White, 64.5 years (yrs) (66%), Black 53.2 yrs (22%), Hispanic 55.4 yrs (8.4%), Asian 56.5 yrs (1.6%), and Other 58.1 yrs (2.1%). The mean ages and racial breakdown for in-hospital SLE CVD mortality was; White 67.4 yrs (69.8%), Black 55.5 yrs (18.9%), Hispanic 61.7 yrs (6.3%), Asian 62.7 yrs (3.4%), and Other 65.8 yrs (1.6%). SLE patients were all younger than non-SLE patients and White SLE patients were older than all minority groups for both outcomes.

The greatest age difference between SLE and non-SLE patients with CVD was in the Asian group (14.3 yrs), followed by a 13 yrs for Hispanics, 12.4 yrs for Blacks, 9.6 yrs for Others, and a 7.5 yrs for Whites (See **Table 1**). This changed when examining age differences for CVD mortality. Black SLE patients were 16.7 yrs younger, Asian SLE patients 14.1 yrs , Hispanics 12.8 yrs , Whites 11 yrs , and the Other group was 9.2 yrs younger than the race-matched non-SLE groups for CVD mortality.

Table 1: Mean Age Differences in SLE with CVD and CVD Mortality

	Whites	Blacks	Hispanics	Asians	Other
CVD					
Number of SLE Patients	7,340	2,407	936	181	235
Age Δ Non SLE vs SLE (yrs)	7.5	12.4	13	14.3	9.6
Age Δ White SLE vs minority (yrs)		11.3	9.1	8.0	6.4
CVD Mortality					
Number of SLE Patients	1004	471	171	47	53
Age Δ Non SLE vs SLE (yrs)	11	16.7	12.8	14.1	9.2
Age Δ White SLE vs minority (yrs)		14.8	12.1	11.6	13.7

We also examined the age differences between White patients and minority populations (See **Table 1**). The greatest age difference between White SLE patients and any of the minority groups was with the Black SLE patients. There was 11.7 year difference between Whites and Blacks with CVD admissions, and a 14.8 year difference for CVD mortality.

Conclusion: Age at CVD admission and CVD mortality differs between racial groups in SLE patients. The greatest age difference between SLE and non-SLE patients for CVD admission was in the Asian group (14.3 years younger than Asians without SLE) and was in the Black group for CVD mortality (16.7 years younger than Blacks without SLE). The greatest age difference between White SLE patients and a minority group was with Black patients. In the SLE population, Black patients were 11.3 years younger than Whites with CVD admissions and 14.8 years younger with CVD mortality. More detailed data analysis is warranted to examine if identifiable group characteristics may be related to these racial disparities.

Higher Frequency of Valvular Heart Disease in Patients with Systemic Lupus Erythematosus and Jaccoud's Arthropathy.
Mittermayer Santiago[1], Stella Dourado[2], Natália Silva[3], Marina Motta[4], Lara Grimaldi[4], Vinicius Rios[5] and Verena Galvão[6], [1]Adjunct Professor at Escola Bahiana de Medicina e Saúde Pública, Salvador, Brazil, [2]Salvador, Brazil, [3]Medical Student, Salvador, Brazil, [4]Medical student, Salvador, Brazil, [5]Cardiologist at HSI, Brazil, [6]Physiotherapist, Brazil

Purpose: Jaccoud's Arthropathy (JA) was initially described as a secondary complication to rheumatic fever (RF). However, most recently described cases are associated to systemic lupus erythematosus (SLE). At least in RF, this articular complication has been observed to occur in association with valvular heart disease. The aim of this work is to investigate the presence of valvulopathy in patients with SLE and JA, when compared to lupus patients without such complication.

Methods: Patients with diagnosis of SLE based on the American College of Rheumatology criteria were enrolled in the study and divided into two groups: with or without JA and evaluated by transthoracic echocardiography.

Results: A total of 113 patients with SLE (25 with JA and 88 without JA) were assessed, of which 108 were females and five were males. Echocardiographic changes were found in 24 patients (21.2%) out of the entire population, including valvulopathy in 17 cases (15%), pulmonary hypertension in 7 cases (6.2%) and pericardial effusion in 2 cases (1.8%). In general, echocardiographic changes were more frequently seen in the JA group in comparison with the control group ($p=0.04$). Additionally, in the JA group, valvulopathy was found in 9 cases (36%) against 8 cases (9%) in the control group ($p=0.001$).

Conclusion: This study reveals for the first time the association between the presence of valvular heart disease and JA in SLE patients, suggesting that the presence of JA may be a marker of such complication. Additional studies are required for clarification of the mechanisms involved in both complications.

Non-Calcified Coronary Plaque (NCP) in Systemic Lupus Erythematosus (SLE). Adnan Kiani[1], Jens Vogel-Claussen[1], Margaret Yew[1], Laurence Magder[2] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]University of MD, Baltimore, MD, [3]Johns Hopkins Univ, Baltimore, MD

Purpose: Coronary calcium (CC) is increased in SLE. Although an excellent measure of atherosclerotic burden, CC is considered to be stable. New technology can measure non-calcified plaque (NCP). We report on the first study of quantified non-calcified coronary plaque in SLE.

Method: 64 slice coronary multidetector computed tomography (MDCT) was performed in 56 patients with SLE. The MDCT scans were evaluated quantitatively by a radiologist, using dedicated software. To quantify the non-calcified plaque at each vessel

examined, we multiplied a plaque severity score (which took the values of 0-3) by a measure of the percentage of that plaque which was non-calcified. The overall non-calcified plaque score was computed as the average score from seven vessels examined.

Results: The 56 SLE pts were 88% female, 59% Caucasian, 34% African-American, 7% other; mean age 53±10 yrs. Table 1: Mean NCP score, by different variables

	Group	Mean Calcium Score	P-value	Age-adjusted p-value
Age	<45	0.15	0.30	
	45-55	0.12		
	55	0.21		
Gender	Female	0.16	0.68	0.66
	Male	0.13		
Weight	<150 lbs	0.12	0.44	0.40
	150-199	0.17		
	200+	0.20		
Body Mass Index (BMI)	<25 (n=19)	0.09	.0066	.0088
	25-29 (n=18)	0.13		
	30+ (n=19)	0.25		
Anti-ds DNA	No	0.15	0.61	0.17
	Yes	0.17		
Low C3	No	0.16	0.83	0.65
	Yes	0.15		
Low C4	No	0.17	0.72	0.96
	Yes	0.15		
Lupus anticoagulant	No	0.17	0.32	0.60
	Yes	0.13		
Prednisone	No	0.07	0.15	0.055
	Yes	0.17		
Plaquenil	No	0.14	0.88	0.91
	Yes	0.16		
Hormone Replacement	No	0.11	0.0029	0.021
	Yes	0.25		
NSAIDs	No	0.10	0.20	0.22
	Yes	0.17		

Table 2: Multivariable regression model to assess the joint association of Prednisone, HRT with NCP, controlling for age, sex, and BMI

Variable	Effect on mean NCP score (95%	P-value

	confidence Interval)	
Age (per 10 years)	.03 (-.01, .07)	.18
Male vs. Female	.02 (-.10, .15)	.70
Prednisone use	.08 (-.05, .21)	.21
Hormone Replacement	.10 (.01, .20)	.032
BMI (per 5 unit change)	.05 (.01, .08)	.0096

Conclusion: This is the first study of quantified noncalcified coronary plaque in SLE. NCP burden was more common with age > 55 and with prednisone use. Most importantly it was strongly associated with hormone replacement therapy, even after age, sex and BMI adjustment. This study strongly suggests that hormone therapy increases noncalcified plaque in SLE, and should be avoided.

Cardiovascular Risk May Not Be Increased in Women with Mild Lupus. Maria J. Santos[1], Luis M. Pedro[2], Filipe Vinagre[3], Helena Canhao[4], Victor Gil[5], J. Canas da Silva[3] and Joao E. Fonseca[6], [1]Rheumatology Research Unit and Hospital Garcia de Orta, Almada, Portugal, [2]Instituto Cardiovascular de Lisboa, Lisboa, Portugal, [3]Hospital Garcia de Orta, Almada, Portugal, [4]Rheumatology Reseach Unit and Hospital Santa Maria, Lisboa, Portugal, [5]Hospital Fernando Fonseca, Amadora, [6]Rheumatology Research Unit and Hospital Santa Maria, Lisboa, Portugal

Purpose: Cardiovascular morbidity and mortality is increased in patients with Systemic Lupus Erythematosus (SLE) and accelerated atherosclerosis emerges as a major contributor. Both traditional and disease-related risk factors have been shown to contribute to premature atherosclerosis. However, it remains unclear to what extent low disease activity and the control of traditional cardiovascular (CV) risk factors might prevent cardiovascular complications. The aim of this study was to address whether women with mild lupus and well controlled CV risk factors have increased subclinical atherosclerosis.

Method: Women fulfilling criteria for SLE, with normal renal function and no previous CV events were evaluated in comparison with age-matched healthy women from the same ethnic background. Disease characteristics, presence of traditional CV risk factors, and medication were determined. An overnight fast blood sample was drawn to measure blood glucose, lipid profile, creatinine, uric acid, CRP, anti-DNA antibodies and complement levels. Bilateral ultrasound of carotid and femoral arteries assessed intima-media thickness (IMT) and the presence of atherosclerotic plaques.

Results: Twenty eight lupus women (aged 46.3 ± 12 years, 46% postmenopausal, mean disease duration 7.7±4.7 years, 35% positive for antiphospholipid antibodies, median SLEDAI 2[IQR 0-4]; median SLICC damage index 0[IQR 0-2], 46% receiving steroids (average daily dose 5.9 mg) and 78.6% receiving antimalarials) and 20 healthy women with comparable demographic characteristics were assessed. Both groups had a median of 1 [IQR 0-2] traditional CV risk factor. Patients with diabetes (7%), hypertension (32%) or hyperlipidemia (25%) were all receiving medication with a satisfactory control (Table). Atherosclerotic plaques were found in 2 patients and 2 controls. Carotid and femoral mean IMT was similar in both groups (0.7±0.2 and 0.7±0.2 mm respectively in SLE; 0.8±0.1 and 0.9±0.3 mm respectively in controls). Carotid IMT significantly increased with age (OR 1,08 per year of age; 95% CI 1,014-1,154).

	Smoker	BMI Kg/m^2	Systolic BP mmHg	Diastolic BP mmHg	Glycemia mg/dl	Cholesterol mg/dl	HDL mg/dl	LDL mg/dl
SLE (n=28)	7%	28.5 (4.8)	127 (22)	76 (10)	85 (18)	196 (43)	58 (12)	117 (41)
Control (n=20)	10%	28 (4.8)	124 (17)	70 (11)	86 (8)	217 (31)	65 (13)	137 (27)

Conclusion: The prevalence of subclinical atherosclerosis was not increased in this group of patients with mild lupus. Low disease activity as well as a good control of traditional CV risk factors might have contributed to prevent accelerated arterial disease.

The Impact of Systemic Lupus Erythematosus On Diastolic Function:A Tissue Doppler Imaging Study in Patients without Traditional Risk Factors for Coronary Disease. Orlando Escárcega[1], Mario García Carrasco[2], Ruben Sánchez Pérez[3], Mario Jiménez Hernández[2], Claudia Mendoza Pinto[2], Pamela Munguia[2], Bernardo Briones Aguirre[2], Manuel Sandoval[2], Renan Sanchez Porras[2], Margarita Muñoz Guarneros[2], Leticia Zamudio[2] and Aurelio Lopez Colombo[4], [1]Internal Medicine: Temple University Hospital Philadelphia, PA, Philadelphia, PA, [2]Systemic Autoimmune Diseases Research Unit, HGR 36, CMN Manuel Avila Camacho, Instituto Mexicano del Seguro Social, Puebla, Mexico, [3]Fundacion de Cuore. Cardiovascular Unit, Puebla, Mexico, [4]State Research Department Instituto Mexicano del Seguro Social, Puebla, México, Puebla, Mexico

Purpose: The aim of our study was to analyze the impact of systemic lupus erythematosus on diastolic function in patients without traditional risk factors for coronary disease.

Methods: A case-control analysis was conducted. 46 women with the diagnosis of Systemic Lupus erythematosus and no previous history of smoking, hypercholesterolemia, hypertension, diabetes mellitus were included. Conventional echocardiography and tissue doppler echocardiography were performed in these patients as well as in 40 age- and sex- matched controls.

Results: 46 patients included were all female, with a mean age of 39 ± 11 years vs the control group with a mean age of 38 ± 11 years (P= 0.870). Mean age at diagnosis was 30.3 ± 9.39 years (range, 19-47). Mean time from diagnosis was 3.9 years ± 3.3 (range, 0-10). LV diastolic and systolic volumes were 53.2 vs 45.21 p=0.008 and 24.96 vs. 17.54 p=0.005 respectively, Mitral valve inflow velocities were E 66.94 vs 72.31 p=0.152, A 66.14 vs. 53.14 p = 0.012, E/A 1.01 vs. 1.36 p= 0.093. Myocardial tissue doppler velocities were e' septal at mitral annulus 8.7 vs 9.9 p=0.030, a' septal at mitral annulus 10 vs 9.8 p=0.690, e' lateral mitral annulus 9.12 vs. 11.8 p=0.001, a' lateral mitral annulus 9.9 vs 9.6 p=0.5. RV tissue doppler showed e' 9.22 vs 11.77 p=0.001, a' 10.36 vs 10.75 p=0.190.

Conclusion: Patients with systemic lupus erythematosus without traditional risk factors for coronary artery disease showed increased LV volumes and decreased velocities in tissue doppler which accounts for early diastolic dysfunction likely related to the disease itself.

1557

Systemic Reactive Intermediate Measures as Biomarkers of Atherosclerosis in Systemic Lupus Erythematosus. Roneka L. Ravenell[1], J. David Spence[2] and Jim C. Oates[1], [1]Medical University of South Carolina, Charleston, SC, [2]Robarts Research Institute, London, ON

Purpose: Systemic lupus erythematosus (SLE) patients have a greater incidence of cardiovascular disease (CVD) and major cardiovascular events (MCE) than the general population. Traditional risk factors for CVD are not as predictive of MCE in the SLE population. Emerging reports indicate that increased reactive intermediate (RI) production in proximity to apolipoproteins is associated with CVD in the general population. This study was designed to determine if novel serum biomarkers of RI production indicate the extent of atherosclerosis in patients with SLE.

Methods: In a pilot study, 41 subjects (93% female, 98% African-American, ages 21-65) with at least 4 ACR SLE criteria and no history of MCE were enrolled. Framingham risk factors, SLE disease activity (SLEDAI) and damage (ACR/SLICC Damage Index) scores and estimated total prednisone dose (pred) were determined. Lipid levels and SLEDAI activity markers were determined. Novel biomarkers of systemic RI production (serum protein nitrotyrosine (NTyr), ortho-Tyr (oTyr), meta-Tyr (mTyr) and chloro-Tyr (ClTyr)) were determined by high performance liquid chromatography with electrochemical detection after precipitation of serum proteins and digestion to amino

acids. These post-translational modifications of proteins (PTM) are stable indicators of reactive oxygen and reactive nitrogen stress. Carotid ultrasound measurements were performed to determine total plaque area (TPA) in both carotids. This measure is predictive of stroke, myocardial infarction, or death at five years. Univariate regressions were performed between traditional risk factors, SLEDAI, SLICC, PTM and TPA. Elevated TPA was defined as above age-adjusted values for a Canadian stroke population. These data were used to create multiple variable linear regression models. Backward regression was used to eliminate variables that did not contribute to the model. Chi square testing was performed for association between TPA and quartiles of PTM levels and Framingham risk factors. Only p values <0.05 were reported as significant.

Results: Significant associations were observed between mTyr and systolic blood pressure, SLEDAI scores, and anti-double stranded DNA antibody levels (r=0.44, 0.36, and 0.43), oTyr and waist-hip ratio (r=0.35), ClTyr and pred (r=0.36), and Ntyr and SLICC (r=0.59). TPA was associated significantly with age (r=0.44, p=0.004) in univariate models. Linear models improved upon the univariate age model by adding VLDL (r=0.46, p=0.01) and VLDL+NTyr (r=0.52, p=0.01) as independent variables with age. In chi square analysis, oTyr quartiles (but not Framingham risk factors) were associated with TPA (p=0.053).

Conclusion: This study demonstrates associations between PTM and SLE activity/damage and traditional atherosclerosis risk factors in SLE patients. PTM markers improve models with TPA as the dependent variable, and oTyr associates with increased TPA. These data suggest that interactions between lipoproteins and RI may increase the risk for CVD in SLE and are consistent with reports that RI can negatively impact cholesterol flux.

Cardiac Magnetic Resonance Imaging Abnormalities in Patients with Systemic Lupus Erythematosus: A Preliminary Report. Hitomi Kobayashi[1], Jon T. Giles[2], Yoshiyuki Arinuma[3], Isamu Yokoe[4], Masaharu Hirano[5] and Yasuyuki Kobayashi[6], [1]Itabashi Chuo Medical Center, Itabashi-ku, Tokyo, Japan, [2]Johns Hopkins University, School of Medicine, Baltimore, MD, [3]Teikyo University, School of Medicine, Tokyo, Japan, [4]Itabashi Chuo Medical Center, Japan, [5]Tokyo Medical University, Tokyo, Japan, [6]St. Marianna University, Kanagawa, Japan

Purpose: Heart disease, including myocardial dysfunction, is a major cause of morbidity and mortality in Systemic Lupus Erythematosus (SLE). The aim of this study was to assess and compare cardiac MRI (cMRI) findings in asymptomatic patients with SLE and explore the association of these outcomes with SLE disease characteristics.

Methods: Patients with SLE and no history and/or clinical findings of arterial hypertension, pulmonary hypertension, coronary artery disease, severe valvular heart disease, atrial fibrillation, diabetes mellitus, or echocardiographic abnormalities underwent a detailed history and physical examination, including disease activity scoring with the Systemic Lupus Disease Activity Index (SLEDAI). They underwent contrast-enhanced cMRI on a 1.5T MRI. Adenosine was used for stress perfusion to assess perfusion defects due to micro or macrovascular impairment, and delayed enhancement images were obtained for the assessment of myocardial inflammation and/or fibrosis. We evaluated the associations of cMR abnormalities with SLE disease activity and severity measures.

Results: Sixteen patients (75% female) were studied (mean age 38.7 years). The mean SLEDAI for the cohort was 4.88, with 10 participants (62.5%) falling into the low disease activity category (SLEDAI<7) and 6 participants (37.5%) falling into the high disease activity category (SLEDAI>7). Eight patients (50.0%) demonstrated a myocardial abnormality. Stress perfusion defects were seen in seven patients (43.8%),indicating microvascular impairment or myocardial ischemia. Five patients (31.2%) were found to have delayed enhancement, indicating myocardial inflammation, necrosis or fibrosis, four of whom also demonstrated a perfusion defects. Median SLEDAI was significantly higher in the group with delayed enhancement compared to the group without (4 vs. 7 units, respectively; p=0.041) and in the group with perfusion defects compared to the group without (3 vs. 8 units, respectively; p=0.001). Myocardial abnormalities were observed in all 5 patients with dsDNA antibodies vs. in 3 (27%) of those without dsDNA (p=0.026). Other SLE characteristics were not significantly associated with myocardial abnormalities.

Conclusion: Myocardial involvement, as detected by cMR, was frequent in SLE patients without known cardiac disease. Microvascular impairment and myocardial inflammation/fibrosis were both observed and, combined with their associations with SLEDAI score and dsDNA, suggest a mechanistic link between SLE activity, autoimmunity, and subclinical myocardial pathology.

1559

Plasma Microparticles in SLE. Michelle Petri[1], Cristina Lanata[2], Adnan Kiani[2], Jayesh Jani[3] and Thomas S. Kickler[2], [1]Johns Hopkins Univ, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Hospital, Baltimore, MD

Purpose: Plasma microparticles (PMPs) are circulating phospholipid rich particles released from cellular membranes, including platelets, endothelial cells and white cells. These microparticles promote the generation of thrombin, which may be associated with clotting. Elevated levels have been associated with vascular dysfunction, thrombosis and inflammation.

Method: PMPs were measured in 536 SLE patients (91% female, 43% African-American, 57% Caucasian, mean age 44.8 years). 60% of SLE patients had elevated PMPs. Clinical manifestations were recorded in a cohort database. Organ damage was assessed using the SLICC/ACR Damage Index.

Results:

Factor	PMP Pos (N=319)	PMP Neg (N=203)	P-value	OR (95% CI)
African-American	48%	36%	0.0106	1.68 (1.13, 2.48)
High School Education	89%	95%	0.0273	0.44 (0.22, 0.89)
Private Insurance	78%	85%	0.0684	0.64 (0.40, 1.02)
Livedo ever	24%	35%	0.0052	0.57 (0.39, 0.84)
Arthralgia ever	96%	91%	0.0412	2.12 (1.03, 4.36)
Renal Failure	6%	2%	0.0455	2.97 (0.99, 6.90)
Leukopenia ever	46%	55%	0.0591	0.70 (0.49, 1.00)
Cholesterol ever high	47%	57%	0.0245	0.66 (0.46, 0.94)
Triglycerides ever high	15%	22%	0.0684	0.64 (0.40, 1.02)
Plaquenil use ever	91%	84%	0.0368	1.81 (1.06, 3.07)
NSAID use currently	29%	42%	0.0032	0.57 (0.39, 0.82)
Cognitive Impairment	9%	5%	0.0562	2.17 (1.00, 4.68)
Cranial Neuropathy damage	8%	15%	0.0202	0.51 (0.29, 0.90)
Proteinuria damage	7%	2%	0.0052	4.97 (1.47, 16.8)
Arthritis damage	5%	11%	0.0238	0.45 (0.23, 0.88)
Scarring Alopecia damage	6%	2%	0.0463	3.15 (1.06, 9.40)
Dermatologic Damage Score	0.05 + 0.30	0.11 + 0.33	0.0391	
Myocardial Infarction	3%	3%	0.7908	1.30 (0.44, 3.85)
Stroke	8%	6%	0.3755	1.49 (0.72, 3.10)
Hypertension	49%	50%	0.7204	0.94 (0.66, 1.33)

Deep venous thrombosis	15%	11%	0.2932	1.36 (0.80, 2.31)
Obesity	45%	39%	0.2044	1.27 (0.88, 1.81)
Smoking	38%	36%	0.7113	1.08 (0.75, 1.55)
Diabetes mellitus	6%	9%	0.2933	0.69 (0.35, 1.37)

Conclusion: PMPs are extremely frequent in SLE and more common in African-Americans. Vascular risk factors (hypertension, lipids, obesity, smoking) and thrombosis were NOT associated with PMPs. Surprisingly, since they are associated with cardiovascular risk, NSAID use may be protective against PMPs. Prospective studies are needed to determine if PMP elevation is associated with future cardiovascular disease or arterial thrombosis.

Ability of Nonfasting and Fasting Triglycerides to Predict Coronary Artery Disease in Lupus Patients. Zahi Touma[1], Murray Urowitz[2], Dominique Ibañez[1] and Dafna Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Hypertriglyceridemia is a metabolic disorder associated with atherosclerosis. We have previously shown that there is no clinically significant difference in individual lupus patients in the levels of fasting triglycerides (FTG) and nonfasting triglycerides (NTG). We aimed to determine whether nonfasting triglycerides predict coronary artery disease (CAD) in lupus patients.

Method: Patients are followed at regular intervals (at 2-6 months) according to a standard protocol which includes: complete history and physical exam, SLE Activity Index (SLEDAI-2K), and Systemic Lupus International Collaborative Clinics Damage Index (SDI). Fasting lipid profile was measured once yearly and nonfasting was determined at all other visits. We included the entire patient cohort and all the values of TG available in our data. Time-dependent covariate survival analysis was conducted to determine the predictive ability of TG for CAD – whether fasting and nonfasting. Variables considered were: sex, age at diagnosis, age, SDI , SLEDAI-2K, smoker, glucocorticoid, antimalarial, immunosuppressive drugs, cholesterol. Variables retained for multivariate analysis were selected through the variable reduction strategy (Harell) – selecting variables which alter the parameter estimate of TG by ±10% when include in the model. Using this variable selection, age, SDI, and immunosuppressive drugs were selected to be included in the models.

Results: We identified 1289 patients since the date of the first TG available. Eighty eight percent of the patients were female. Five hundred forty one patients had elevated cholesterol level and the length of follow-up from the 1st TG to CAD/last visit was 8.82±8.19 (table 1).

Tabel1. Patients' demographics

Number of patients	1289
Number of CAD events	108 (8.1%)
Mean number of visits with TG available prior to CAD / last visit	18.8 ± 19.8
Sex F	1143 (88.7%)
Age at diagnosis (years)	30.7 ± 13.7
Age * (years)	34.9 ± 13.5
Disease Duration * (years)	4.2 ± 5.8
SDI *	0.33 ± 0.82
SLEDAI-2K *	8.81 ± 7.21

Smoker *	249 (19.7%)
Steroids *	834 (64.9%)
Antimalarial *	516 (40.2%)
Immunosuppressive *	296 (23.0%)
Elevated Cholesterol *	541 (42.1%)
Length of FU from 1st TG to CAD / last visit (years)	8.82 ± 8.19

* as of date of 1st TG available

One hundred eight patients (8.1%) developed CAD. We identified 89 events of CAD in 1137 patients in the nonfasting model and 35 events of CAD in 707 patients in the fasting model (table 2). Both nonfasting and fasting model showed ability of the variables to predict CAD; triglycerides, age and SDI while immunosuppressive drug use predicted CAD only in the nonfasting model.

Table 2. Hazard ratio for CAD in both group of analysis

	Non-fasting Model			Fasting Model		
	HR	95% CI	p	HR	95% CI	p
TG	1.80	1.10, 2.93	0.02	2.76	1.07, 7.10	0.04
Age	1.06	1.04, 1.08	<0.0001	1.06	1.03, 1.09	<0.0001
SDI	1.11	1.00, 1.23	0.06	1.18	1.00, 1.37	0.04
Immunosuppressive	2.20	1.41, 3.44	0.0005	1.27	0.61, 2.65	0.52

Conclusion: Both fasting and nonfasting TG predicted CAD in lupus patients. Nonfasting TG levels can be used in clinic to detect CAD event in lupus patients.

Systemic Lupus and Cardiac Risk Factors: A Study of Patient Record Documentation and Compliance. Christin Bengtsson[1], Anders A. Bengtsson[1], Sol-Britt Rantapää-Dahlqvist[2], Gunnar Sturfelt[1], Andreas Jönsen[1] and Ola Nived[1], [1]Inst of Clinical sciences, Lund, Sweden, [2]University Hospital, Umeå, Sweden

Purpose: Knowing that SLE patients are at greater risk for developing cardiovascular disease (CVD) and that traditional cardiac risk factors (CR) are associated with this comorbidity, we found it of importance to study patients knowledge of CR. We also wanted to analyze how we in every day clinic document information and advice about CR. Finally we were interested in compliance to received instructions about medication and improved lifestyle according to CR.

Method: This study was performed at four hospitals. All patients that fulfilled ≥4 ACR criteria, were asked to participate and fill in a cardiovascular health questionnaire (CHQ). The CHQ was blinded to the investigator that read the medical record and noted the documented CR. After this the results of the questionnaires were recorded into the same database. The CHQ is adapted from the National Health and Nutrition Examination Survey I Epidemiological Follow up Study and reveals the patients opinion of possible CR impact on developing CVD. The CHQ also asks about the patients knowledge of CR, if a physician has advised lifestyle or medication changes and if the patient has followed this advice. Compliance was based on subject´s responses, if they had followed their physicians advice.

(By permission of Dr Karen Costenbader). Kappa statistics was used to compare patients record with CHQ and to evaluate compliance.

Results: Altogether 210 out of 291 (72%) SLE patients completed the CHQ. The mean age of the patients were 55 years. High cholesterol, smoking and hypertension were known by the patients as very important risk factors and nobody considered hypertension, smoking and overweight as not important for developing CVD. The agreement between documentation and patients report was moderate for hypertension, overweight and hypercholesterolemia (kappa 0.60-0.42), for diabetes substantial (kappa 0.66) but for physical inactivity and smoking below fair (kappa 0.02, 0.05).

Patients compliance to information that they had received regarding medication and dietary changes (the latter in patients with hypercholesterolemia and diabetes) was substantial (kappa 0.58-1.0). For lifestyle changes, though, in patients with hypertension and overweight the compliance was fair to moderate (kappa 0.13-0.47).

Conclusion: All three CR fields investigated in this CHQ study (awareness, documentation and compliance), could be improved. This opens up for discussions of the best ways to accomplish this in every day clinic.

Association of Soluble E-Selectin and Adiponectin with Carotid Plaque, Independent of Clinical Activity, in Patients with Systemic Lupus Erythematosus. Peter M. Izmirly[1], Harmony R. Reynolds[1], Tania L. Rivera[1], Mimi Y. Kim[2], PA Tunick[1], Jill P. Buyon[1] and Robert M. Clancy[1], [1]NYU School of Medicine, New York, NY, [2]AECOM, Bronx, NY

Purpose: The mechanisms underlying premature atherosclerosis in SLE are not understood. The endothelium merits focus since it provides the physiologic boundary which limits extravasation and diapedesis of inflammatory cells.

Methods: One hundred and nineteen patients with SLE, predominantly non-Caucasian, and 71 healthy controls matched for age, sex and race, underwent carotid ultrasonography and donated blood for evaluation of circulating endothelial cells (CEC), soluble endothelial protein C receptor (sEPCR) and gene polymorphism at A6936G, soluble E-selectin, and adiponectin.

Results: Carotid plaque was more prevalent among patients than controls (43% vs 17%, p=0.0002). Mean CCA IMT was greater in patients compared to controls (0.59mm±0.19 vs 0.54mm±0.11, p=0.03). Levels of CEC (19 vs 3 CECs/mL,p<0.0001) and sE-selectin (64 vs 36 ng/ml, p<0.0001) were significantly elevated in patients compared to controls. Unexpectedly, adiponectin was also significantly higher in patients compared to controls (16 ug/mL versus 11 ug/mL, p=0.0001) but no differences were seen in the levels of sEPCR or the distribution of genotype. Independent predictors of plaque status using logistic regression models included: age (p<0.0001; OR=2.1 per 10 year increase; 95% CI: 1.5-3.0), SLE status (p=0.015; OR=3.4 for SLE vs control; 95% CI: 1.3-9.1), sE-selectin (p=0.016; OR=1.2 per 10 unit increase; 95% CI: 1.0-1.4) and adiponectin (p=0.050; OR=1.5 per 10 unit increase; 95% CI: 1.0-2.4). Comparing SLE patients with and without plaque, there were no differences in cardiac CRP, complement, anti-dsDNA ab, CEC, sEPCR levels and EPCR SNP. However, sE-selectin and adiponectin levels were significantly higher in SLE with plaque compared to those without (sE-selectin 78 vs 52 ng/ml; p=0.006; adiponectin 18 vs 14 ug/ml; p=0.033). The estimated odds ratios for plaque in the final logistic regression model were: $OR_{selectin}$= 1.3 per 10 ng/ml increase (95% CI: 1.1-1.5) and $OR_{adiponectin}$=1.8 per 10 ug/ml increase (95% CI: 1.1-3.0). SELENA-SLEDAI scores were similar between groups, and the proportion of patients with SLEDAI≤ 4 did not segregate with the absence of plaque. Neither past nor current medications significantly associated with plaque. In the stable subjects (SLEDAI ≤4), age (p=0.007), sE-selectin (p=0.02) and adiponectin (p=0.02) remained associated with plaque. The prevalence of plaque was greatest in the stable patients with high sE-selectin plus high adiponectin (55%; p =0.0009) confirming the multivariable analyses. Sixty-two patients donated blood at a second visit. High sE-selectin and adiponectin were sustained in plaque patients compared to non-plaque patients (p=0.0009 and p=0.0011 respectively).

Conclusion: These results confirm that SLE patients, irrespective of race, are at increased risk for premature atherosclerosis and support the hypothesis that endothelial perturbation is contributory even in the absence of clinically measurable disease activity.

Variability Over Time and Correlates of Total Cholesterol, Systolic and Diastolic Blood Pressure in SLE. Mandana Nikpour, Dafna D. Gladman, Dominique Ibañez, Paula Harvey and Murray B. Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Hypercholesterolemia and hypertension, two known risk factors for coronary events, are likely to take a dynamic course over time in patients with SLE, fluctuating due to changes in disease activity and treatment.

Objective: To describe and quantify variability over time of total cholesterol (TC) and blood pressure (BP) among patients with SLE and to determine their correlates.

Method: Using a single centre SLE Database, patients with two or more serial measurements of TC, systolic and diastolic blood pressure (SBP and DBP), taken simultaneously, were included in the analysis. Variability over time was described in terms of the proportion of patients whose TC and BP profile fluctuated between normal and 'elevated' (TC >5.2 mmol/L; SBP>140 mmHg *or* DBP>90 mmHg), and also in terms of within- and between-patient variance quantified using analysis of variance modelling. Generalized estimating equations (GEE) were used to determine independent correlates of each of TC, SBP and DBP, treated as continuous outcome variables.

Results: In total 1,260 patients, comprising 26,267 measurements of each of TC, SBP and DBP were included. Mean±SD number of measurements per patient was 20.8±20. The mean±SD time interval between measurements was 5.4±9.7 months. The mean±SD time interval from the start to the end of the study was 9.3±8.5 years. Over time, 64.7% of patients varied between having normal and elevated cholesterol levels, while the status of 46.4% of patients varied between normotensive and hypertensive. Using ANOVA, the between-patient percentage of total variance for each of TC, SBP and DBP was 51.8%, 48.8% and 36.1% respectively, while the *within-patient* percentage of total variance for each of TC, SBP and DBP was 48.2%, 51.2% and 63.9% respectively. Using GEE, in addition to statins and antihypertensives, independent correlates of TC & BP included age ($p=0.0005$), disease activity ($p<0.0001$) and corticosteroids ($p<0.0001$). In women, other correlates of TC and BP included disease duration ($p=0.0008$), hormone replacement therapy ($p<0.0001$) and smoking ($p=0.017$). Antimalarial use was negatively correlated with TC ($p<0.0001$). There was a strong and independent association between hypertension and hypercholesterolemia.

Conclusion: TC and BP vary markedly over time in patients with SLE, with half to two-thirds of variance over time seen *within* individuals. This variability is due not only to lipid-lowering and antihypertensive medications, but also due to disease and treatment-related factors such as disease activity, corticosteroids and antimalarials. The dynamic nature of TC and BP in SLE makes a compelling case for deriving summary measures that better capture cumulative exposure to these risk factors.

1564

Effects of Ezetimibe Plus Pravastatin On Endothelial Dysfunction in Patients with Systemic Lupus Erythematosus (pilot study). Olga L. Vera-Lastra[1], Silvia Mendez[1] and Luis J. Jara[2], [1]MD, Mexico City, Mexico, [2]MD, Mexico

Background: Patients with systemic lupus erythematosus (SLE) have a higher risk for cardiovascular disease (CVD) not explained for the conventional risk factors. These patients have endothelial dysfunction (ED) as an early process of atherosclerosis. Treatment with statins plus ezetimibe may have a beneficial effect similar to the one seen in other groups of patients.

Purpose: To measure the effect of ezetimibe plus pravastatin after 12 months of treatment in patients with SLE on the endothelial function.

Method: An open study, before and after, which assessed the efficacy of treatment, was performed. Twenty two patients (21 women and 1 man) with diagnosis of SLE were studied, the mean age 40+/- x years. A flow-mediated vasodilatation (FMV) with doppler echocardiography of the brachial artery for the ED, basal and after 12 months of treatment with pravastatin 40 mg/day plus ezetimibe 10 mg/day was performed. In addition, a lipid profile: total cholesterol (TC), cholesterol HDL (C-HDL), cholesterol LDL (C-LDL) and serum reactive c-protein (RCP) were done.

Results: After 12 months of treatment with pravastatin and ezetimibe we found the following: improvement on the average of FMV of 10.64% IC 95% (7.58-13.58) $p<0.001$. TC decreased from 201.3+/- 58.9 mg/dl to 158.06+/-50.13 mg/dl ($p<0.01$); C-LDL from 125.78+/- 44.4 mg/dl to 78.8 +/- 32.9 mg/dL ($p<0.001$); C-HDL increased from 49.0+/- 16.8 mg/dl to 52.2+/-13.8 mg/dl ($p= 0.077$). The concentration of RCP decreased in and average of 2.11 mg/dl IC 95% (0.908-3.32) $p= 0.002$. Medications were well tolerated.

Conclusion: FMV improved significantly with treatment of ezetimibe plus pravastatin in patients with SLE, therefore decreasing ED as an initial manifestation of atherosclerosis as well as the lipid profile.

A Brachial-Ankle Pulse Wave Velocity Is Affected by the Level of Serum Amyloid A in Patients with Systemic Lupus Erythematosus. Masato Moriguchi, Yurika Kamiya, Tadashi Sakurai and Chihiro Terai, Jichi Medical University, Saitama Medical Center, Saitama, Japan

Purpose: Systemic lupus erythematosus (SLE) is associated with increased premature cardiovascular (CV) morbidity and mortality. For estimating CV risk, several techniques, such as electron beam CT scanning, myocardial perfusion imaging, and cervical ultrasonography were developed. However, these modalities are expensive and time-consuming methods. Pulse wave velocity (PWV) is a gold-standard measure of arterial stiffness closely associating with CV risk. Brachial-ankle PWV (baPWV) measure can be performed more easily and repeatedly and is more suitable for screening in general out-patients clinics. Using baPWV measure, we analyzed arterial stiffness of SLE patients and determined the clinical variables affecting CV risk of SLE.

Method: Seventy-six female SLE patients fulfilled ACR criteria and 54 age-matched healthy female controls were enrolled in this cross-sectional observation study. Written informed consent was obtained from every patient and control. Using form PWV/ABI, baPWV were measured in all subjects and were compared between SLE group and control. In SLE group, clinical features (age, BMI, blood pressure, duration of SLE, smoking history and SLEDAI), laboratory data (C-reactive protein, serum amyloid A, lipid profile, HbA1c, C3, C4 and serum creatinine) and treatments (dose of corticosteroid and use of immunosuppressants) were assessed simultaneously. Stepwise multiple regression analysis was performed to determine the variables affecting baPWV in SLE patients.

Results: Mean baPWV of SLE patients was significantly higher than that of healthy controls (1353±275 versus 1214±154cm/sec, $p<0.0005$). Stepwise multiple regression analysis showed that systolic blood pressure, level of serum amyloid A (SAA), and use of immunosuppressants significantly affected baPWV in patients with SLE ($\beta=0.66$; t-value=8.74; $P<0.0001$, $\beta=0.20$; t-value=2.68; $P=0.0125$, and $\beta=0.17$; t-value=2.54; $P=0.0136$, respectively). Also the multiple linear regression analysis showed that SAA levels in SLE were significantly influenced from SLEDAI score ($\beta=0.57$, t-value=5.08, $P<0.0001$).

Conclusion: This study indicated that arterial stiffness of SLE correlated with both classic CV risk factor, especially hypertension, and inflammation due to SLE per se. Not C-reactive protein but SAA may reflect active status of SLE.

Coronary Angiogram-Defined CAD in Systemic Lupus Erythematosus (SLE): Risk Factors and Outcomes. Mala S. Kaul[1], Emily Honeycutt[2], Linda Shaw[2], Stacy P. Ardoin[3], Sunil Rao[1] and E. William St. Clair[1], [1]Duke University Medical Center, Durham, NC, [2]Duke Clinical Research Institute, Durham, NC, [3]Ohio State University Medical Center, Columbus, OH

Purpose: Relatively little is known about the severity of coronary artery disease (CAD) on coronary angiography in patients with SLE. The objective of this study was to compare number of diseased vessels on coronary angiogram, risk factors, and outcomes between SLE patients and non-SLE controls undergoing cardiac catheterization for suspected ischemic heart disease (IHD).

Method: SLE patients (N=86) and matched controls (N=258) were identified from the Duke Databank for Cardiovascular Disease undergoing cardiac catheterization between January 1986 and October 2008 for evaluation of suspected IHD (including recent myocardial infarction, abnormal functional study, or angina). SLE diagnosis was confirmed by chart review. Controls were matched by gender and year of catheterization. Multivariable logistic regression was used to determine if SLE was associated with significant CAD (defined as >70% stenosis in at least one major vessel). Risk adjusted survival differences between the two groups were also assessed using Cox proportional hazards modeling.

Results: SLE patients (85% female) were younger than non-SLE patients (median age 49 years vs. 70 years, p<0.001), had less diabetes (14% vs. 35%, p<0.001) and hyperlipidemia (30% vs. 50%, p=0.001). Both SLE and non-SLE patients had similar rates of hypertension (70% vs.71%, p=0.892) and number of diseased vessels (Table 1). However, after adjustment for risk factors, SLE was found to significantly predict the presence of CAD (OR 2.24, 95% CI: 1.08, 4.67) (Table 2). There was a significant interaction between diabetes and SLE on the outcome of CAD such that diabetes was associated with CAD in non-SLE patients but not in SLE patients. With median follow-up duration of 4.3 years (IQR 1.9 to 8.0), after adjusting for risk factors, SLE was not significantly associated with CVD mortality (HR 1.585, 95% CI: 0.804, 3.122 p=0.184) or all-cause mortality (HR 1.683, 95% CI: 0.979, 2.892, p=0.06). However, the relationship between SLE and all-cause mortality approached statistical significance.

Conclusion: SLE is confirmed to be a significant, independent predictor of CAD identified by coronary angiography, the gold standard for assessing flow-limiting lesions in this disease. Patients with SLE have an equal severity of CAD and similar mortality rates as non-SLE controls, despite having less than half the rate of diabetes and being 20 years younger compared with controls. Diabetes was not associated with an increased risk of CAD among SLE patients.

Table 1. Number of Diseased Vessels

Diseased Vessels	SLE(%)	Control (%)
0	48	38
1	23	23
2	12	16
3	17	23

Overall p-value 0.0813

Table 2. Multivariable Logistic Regression Model for significant CAD

	p-value	Odds Ratio	95% Confidence Interval	
History of Myocardial Infarction	<0.001	7.77	4.11	14.67

Low Physical Activity Is Associated with Proinflammatory High-Density Lipoprotein and Increased Subclinical Atherosclerosis in Women with Systemic Lupus Erythematosus. Elizabeth R. Volkmann[1], Jm Grossman[2], Lori J. Sahakian[1], Brian J. Skaggs[1], John D. FitzGerald[3], Nagesh Ragavendra[3], Christina Charles-Schoeman[3], Weiling Chen[4], Alan H. Gorn[3], George A. Karpouzas[5], Michael H. Weisman[3], Daniel J. Wallace[3], Bevra H. Hahn[3] and Maureen A. McMahon[3], [1]Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]UCLA, LA, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA, [4]UCLA, Los Angeles, CA, [5]Harbor-UCLA Medical Center, Torrance, CA

Purpose: Discovering ways to decrease cardiovascular disease in patients with Systemic Lupus Erythematosus (SLE) remains a substantial challenge in clinical practice. The present study investigates the impact of physical activity on subclinical atherosclerosis and on dysfunctional, proinflammatory high-density lipoprotein (piHDL), which may increase risk for atherosclerosis in SLE.

Method: Patients (242 women) fulfilling the ACR 1997 criteria for SLE participated in this cross-sectional study. Carotid plaque and intima-media thickness (IMT), antioxidant function of HDL, and traditional cardiac risk factors were measured. Disease activity and organ damage were assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the Systemic Lupus International Collaborating Clinics/ACR Damage Index (SLICC/ACR), respectively. Physical activity was evaluated from self-reports by calculating the metabolic equivalent-minutes (METs) per week and by the physical function component of the Medical Outcomes Study Short Form-36 (SF-36). Data were analyzed using bivariate and multivariate regression analyses.

Results: Number of METs per week spent performing strenuous exercise was negatively correlated with IMT (r = -.30, P = 0.002) and number of plaques (r = -.30, P = 0.0001). Physical function as assessed by the SF-36 was also negatively correlated with IMT (r = .14, P = 0.03) and number of plaques (r = -.14, P = 0.04). In multivariate analyses, number of strenuous exercise METs was significantly associated with IMT (t = -2.2, P = 0.028) and number of plaques (t = -2.5, P = 0.014) when controlling for markers of SLE disease activity and damage, but not after controlling for traditional cardiac risk factors. Low physical activity, defined as < 225 total METs per week, was associated with presence of piHDL in multivariate analysis, controlling for both traditional cardiac risk factors and markers of SLE disease activity and damage, (*OR* 2.0, P = 0.03). Neither total METs per week, nor SF-36 physical function correlated with SLEDAI score, cumulative or current prednisone dose, or use of hydroxychloroquine.

Conclusion: Low physical activity is associated with increased subclinical atherosclerosis and with piHDL in patients with SLE. Increased strenuous exercise may potentially reduce the risk of atherosclerosis in SLE.

1568

Pro-Inflammatory High Density Lipoprotein (PiHDL) in Systemic Lupus Erythematosus. Adnan Kiani[1], Maureen A. McMahon[2], Lori J. Sahakian[2], Laurence Magder[3], B H. Hahn[2] and Michelle Petri[4], [1]Johns Hopkins University, Baltimore, MD, [2]Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]University of MD, Baltimore, MD, [4]JHU, Baltimore, MD

Purpose: HDL has long been considered to be protective against coronary artery disease (CAD), due to inhibition of oxidation of LDL and promotion of cholesterol efflux. However, abnormalities in HDL composition are now recognized. Acute and chronic inflammation lead to a transformation of anti-inflammatory HDL to a pro-inflammatory form (PiHDL) which has multiple structural differences, including less apolipoprotein B and more serum amyloid A. In half of SLE patients with CAD and normal lipid profiles, PiHDL may be one of the mechanisms leading to abnormal lipid function and atherosclerosis. We looked at the association of PiHDL with subclinical measures of atherosclerosis as well as traditional and non-traditional cardiovascular risk factors.

Method: PiHDL was measured on stored sera of fifty six SLE patients at baseline and after 2 years in the Lupus Atherosclerosis Prevention Study, a clinical trial of atorvastatin vs. placebo.

Results: The patients were 89% female, 57% Caucasian, 36% African-American and 7% other ethnicity with mean age 43±10 years. Atorvastatin failed to decrease PiHDL during the 2 year trial period (Table 1).

Table 1: Change in PiHDL over the two year study based on 41 patients with both baseline and follow-up PiHDL

Baseline PiHDL	Follow-up PiHDL (mean ± SD)	Mean (±SD) change	p-value	Number (%) with increase in PiHDL	Number (%) with a decrease in PiHDL
1.66 ± 0.71	1.61 ± 0.55	-0.05 ± 0.57	0.56	22 (54%)	19 (46%)

Mean PiHDL was higher in men vs. women (2.04 vs 1.51; p=0.08), African-American vs. Caucasian (1.61 vs 1.54; p=NS), <35 years of age vs. 35-49 or 50+ (1.81 vs 1.64 vs 1.25; p=0.06 for negative trend with age), BMI>30 vs. <25 or 25-29 (1.71 vs 1.44 vs 1.54; p=NS).

Table 2 shows how subgroups defined by PiHDL correlates with measures of subclinical atherosclerosis and other risk factors for atherosclerosis.

	Low PiHDL (<1), (n=15)	Medium PiHDL (1-2), (n=26)	High PiHDL (>=2), (n=15)	P-value
Proportion (%) with coronary calcium	3/15 (20%)	12/26 (46%)	7/15 (47%)	0.20
Mean (SD) log-transformed coronary calcium score	0.53 (1.19)	1.73 (2.48)	0.83 (1.18)	0.12
Mean carotid IMT	0.60 (0.13)	0.56 (0.08)	0.54 (0.07)	0.26
Mean carotid Plaque Score	1.53 (0.83)	2.31 (2.13)	1.20 (0.77)	0.08

The proportion with coronary calcium was higher in those with medium or high PiHDL, but not statistically significant.

Conclusion: Atorvastatin failed to reduce PiHDL levels during the 2 year trial period. In contrast to previous studies, PiHDL was not associated with measures of subclinical atherosclerosis, but CAC was higher in those with moderate to high PiHDL. However, this study was limited by the use of stored samples which may have lost PiHDL activity.

Genetically Determined Mannose-Binding Lectin Deficiency Is Associated with Subclinical Atherosclerosis in Patients with Pediatric-Onset Systemic Lupus Erythematosus. Jing-Long Huang, Chang Gung Memorial Hospital, Kueishan, Tayoyuan, Taiwan

Purpose: Mannose-binding lectin (MBL) is an innate immune protein. The aim of this study was to determine whether genetically determined MBL deficiency is associated with subclinical atherosclerosis in pediatric-onset systemic lupus erythematosus (SLE).

Methods: Between 2002 and 2009, forty-five patients with pediatric-onset SLE and 38 normal controls were recruited. In patients with SLE, prospectively longitudinal carotid ultrasonography was performed to assess subclinical atherosclerosis. MBL2 gene mutations were determined by polymerase chain reaction method and sequence analysis to identify genotypes of MBL. Functional MBL plasma concentrations were detected using enzyme-linked immunosorbent assay. Subclinical atherosclerosis was defined as intima-media thickness (IMT) of carotid artery greater than +1 standard deviation of normal controls. Associations between clinical and laboratory variables and MBL genotypes were determined by simple regression analysis, Mann-Whitney and chi-square tests.

Results: The high, medium and low MBL expression genotype groups were associated with MBL plasma concentrations (3610±6396 ng/ml vs. 580±474 ng/ml vs. undetectable, $P < 0.01$). The patients with subclinical atherosclerosis and thickening of IMT had lower MBL plasma concentrations on diagnosis of SLE than others (983±808 ng/ml vs. 3560±6716 ng/ml , $P = 0.034$ and 936±958 ng/ml vs. 2504±4834 ng/ml, $P = 0.03$, respectively). The high MBL expression genotype was associated with less subclinical atherosclerosis compared to the medium MBL expression genotype (30.8% vs. 62.5%, $P = 0.04$).

Conclusion: High MBL expression genotype was a protective factor to subclinical progression of atherosclerosis in patients with pediatric-onset SLE. Low MBL level at diagnosis of SLE was a risk factor to the subclincal atherosclerosis.

Disclosure: J. L. Huang, None.

1570

Evidence for Antimalarial Beneficial Effect in Cardiac Arrhythmic Events in a Large Systemic Lupus Erythematosus (SLE) Cohort. Ricardo A. Teixeira[1], Eduardo F. Borba[2], Eloisa Bonfa[2], Anísio Pedrosa[1], Silvana Nishioka[1] and Martino Martinelli Filho[1], [1]Incor, Faculdade de Medicina da USP, São Paulo, Brazil, [2]Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil

Purpose: There are no prevalence studies of arrhythmias and conduction disturbances in a large SLE population determining the influence of disease factors and long-term antimalarial use.

Method: Three-hundred seventeen consecutive SLE patients (ACR criteria) age>18 y were evaluated by resting-ECG and 24-hour *Holter* monitoring (n=142, randomly selected) for arrhythmia, conduction disturbances, heart rate variability, and repolarization parameters. Data were obtained in an ongoing electronic database protocol which consists of an extensive clinical/ laboratorial/treatment evaluation.

Results: The majority was female (91%) with medians of age and disease duration of 40.25 years and 11.36 years, respectively. Renal involvement was observed in 26.2% and hypertension in 18.9%. Antimalarial therapy (minimum of 6 months) was observed in 69% with a mean duration of 8.47 ± 6.74 years. Resting-ECG abnormalities were detected in 66 patients (20.8%): long QT in 14.2%; RightBBB in 1.9%; LeftBBB in 0.6%; 1st degree AV-block in 1.6%; sinus bradycardia in 1.3%; sinus tachycardia in 1.3%, and supraventricular tachycardia in 0.3%. Prolonged PR interval was associated with less chloroquine use (p=0.01), shorter chloroquine treatment duration (1.00±2.45 vs. 6.10±6.88 years, p=0.018) and older age (54.17±7.33 vs. 42.26±13.25 years, p=0.029). Holter monitoring events were observed in 121 patients (85.2%): HR<50bpm in 31.6%; pauses>2.0s in 2.8%; atrial tachyarrhythmia in 18.3%; atrial isolated ectopies in 63.4%, ventricular ectopies in 45.7%, and ventricular tachycardia in 2.8%. Tachyarrhythmias were associated with shorter chloroquine treatment duration (7.05±7.99 vs. 3.63±5.02 years, p=0.043) with a trend to less use of chloroquine (p=0.054), and older age (40.19±11.54 vs. 52.50±12.02 years, p<0.001). Clinical and laboratorial variables such as renal and cardiac insufficiency, hypertension, and anti-La/SS-B were not associated with conduction abnormalities (p>0.05), except for anti-Ro/SS-A with an association with supraventricular arrhythmia (p=0.042). Logistic regression model revealed that predictors for supraventricular tachyarrhythmia (AT/AF) were age (p<0.001; OR=1.100; IC95%=1.050-1.154) and shorter antimalarial use (p=0.035; OR=0.921; IC95%=0.853-0.994).

Conclusion: Antimalarials seem to have a protective role in the unexpected high rate of cardiac arrhythmias and conduction disturbances observed in SLE. Further studies are necessary to determine if this anti-arrythmogenic effect is due to the disease control or a direct effect of the drug.

Smokers, Suffering by SLE, Have Higher Platelet Agregability Than the Non-Smokers. Low-Dose Aspirin Therapy Abrogates This Difference. Petr Bradna[1], Jaroslav Maly[1], Tomas Soukup[1], Miroslav Pecka[1], Vaclav Blaha[2], Jan Toms[1] and Zbynek Hrncir[1], [1]University Hospital and Charles University Faculty of Medicine, Hradec Kralove, Czech Republic, [2]University of Defence, Faculty of Medicine, Hradec Kralove, Czech Republic

Purpose: Both systemic lupus erythematosus (SLE) and smoking are prothrombotic situations with increased risk of atherogenesis. Aim of study was to elucidate, if smoking affects aggregation of blood platelets

Method: Study group consists of 63 patients, fulfilling ACR criteria of SLE. 46 were non-smokers, current smokers were 17 patients. 55 percents of the group were treated by low dose (100 mg QD) aspirin. We examined presence of antiphospholipid antibodies, morphological parameters of platelets, aggregation capability by aggregometry after epinephrine and ADP and by PFA-100 equipment.

Statistical analysis was performed by T-test and two-way ANOVA.test.

Results: Smoking SLE patients, not treated by aspirin, had significantly higher agregability of platelets than non-smokers (p=0, 02). Aspirin (100 mg QD) aligned the differences between smokers and non-smokers. Effect of aspirin was more displayed in patients with larger platelets (p<0, 01).

Patients with antiphospholipid antibodies demonstrated improved effect of aspirin on PFA-100 closing time. .

Conclusion: Smoking SLE patients displayed higher promptness to platelet aggregation than non-smokers.This feature with prothrombotic and proatherogenic potential could be antagonized by aspirin therapy. SLE patients, smokers, which are not able to stop smoking, should be treated by low-dose aspirin.

1572

Acute Transverse Myelitis and Antiphospholipid Antibodies in Lupus-No Evidence for Anticoagulation. Christina G. Katsiari[1], Irene Giavri[1], Dimos D. Mitsikostas[2], Konstantina G. Yiannopoulou[3] and Peter P. Sfikakis[1], [1]First Department of Propaedeutic and Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]Department of Neurology, Athens Naval and Veterans Hospital, Athens, Greece, [3]Neurology Service Laikon Hospital, Athens, Greece

Purpose: Current views suggest that the prothrombotic properties of antiphospholipid antibodies (aPL) have a role in the development of acute transverse myelitis (ATM) in patients with systemic lupus erythematosus (SLE). Although, trials assessing the role of aPL in SLE-associated ATM have not been possible to conduct due to the rarity of this condition, empiric anticoagulation is included in these patients' treatment. We performed a systemic review of the literature to explore, 1) the clinical and prognostic value of the presence of aPL antibodies in patients with lupus myelitis and 2) the effectiveness of anticoagulation.

Method: We systematically searched Medline using the terms: myelitis, myelopathy and lupus. Publications presenting cases of lupus myelitis that provided data on aPL antibodies were obtained. Selection of myelitis cases was based on the proposed diagnostic criteria of acute transverse myelitis: we included only cases where magnetic resonance imaging was performed 1) to exclude other pathologies and 2) to confirm myelitis. In cases where MRI was normal, we searched for other evidence of spinal cord inflammation as confirmed by pleocytosis and abnormal IgG index in cerebrospinal fluid (CSF). Demographic data as well as data on presentation, treatment and outcome were extracted from the literature. Neurological impairment was measured using the Expanded Disability Status Scale (EDSS, score range: 0 – 10). Statistical analysis was performed using the Mann-Whitney and the Fisher's exact tests.

Results: We report on a total of 67 patients (age range:15-58 years, 89% women, 66% with continuous involvement of ≥3 spinal segments, referred also as longitudinal ATM). Thirty-six patients (54%) were aPL-positive and did not differ in respect to demographic characteristics, clinical and laboratory SLE manifestations from aPL-negative patients. The presence of aPL did not predict the involvement of the thoracic part of the spine, which has been postulated to reflect a predominantly thrombosis-induced injury. The presence of aPL antibodies did not correlate with relapsing ATM, additional lupus CNS manifestations or worse clinical outcome. An unfavourable outcome could be predicted by paralysis and abnormal CSF findings at presentation (p=0.04 and 0.02, respectively), irrespective of the presence of aPL. While all patients received major immunosuppressive regiments, severe neurological impairment (EDSS score >7) was found primarily in aPL-negative patients (p=0.03). Anticoagulation was more frequently applied in aPL-positive patients (p=0.04), but any additional therapeutic effect was not evident.

Conclusion: Detection of circulating aPL appears unreliable to suggest a thrombotic cause and inadequate to support the therapeutic use of anticoagulation. Creation of a registry for ATM in SLE patients is needed to obtain more definite answers on the role of aPL in this condition.

1573

Cognitive Dysfunction in Patients with SLE: A Controlled Study. Marc A. Antonchak[1], Mahnaz Saoudian[1], Amber Khan[1], Tara Adhikari[1], Hermine Brunner[2] and Michael E. Luggen[1], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cincinnati Children's Hosp, Cincinnati, OH

Purpose: Cognitive dysfunction (CD) has been reported to occur frequently in SLE. But, almost all estimates of prevalence have utilized normal healthy individuals as controls. Chronic rheumatic diseases cause pain, fatigue, and depression which may all affect cognitive function. In order to determine the extent to which CD in SLE is caused by SLE per se, we have performed a case-control study of a community based population of patients with SLE and compared them to patients with rheumatoid arthritis.

Methods: A random subsample of SLE patients referred by community-based primary care physicians was examined. Controls consisted of RA patients who were matched for age, sex, and race. Cognitive function was assessed by the Automated Neuropsychological Assessment Metrics (ANAM), a validated, computerized, cognitive testing battery. Baseline demographic information, disease activity and damage, and treatment variables were ascertained. The primary outcome measure was the total throughput score (total number of correct responses/time).

Descriptive statistics and their distributions were determined. Final results were compared using Wilcoxon rank-sum test and Fischer's exact test. Correlates of CD were ascertained and independent factors identified by multiple linear regression.

Results: In this ongoing study, 96 lupus patients were randomly selected and 31 of them have been evaluated to date. Patients with SLE were significantly more depressed (Beck Depression Index score:16 vs. 8, $p<0.0001$), had lower quality of life (SF-36 mental component score [MCS]): 43.6 vs. 50.4, $p=0.009$), and had lower family incomes ($p=0.0154$) than the RA patients. Education, family income, fatigue, depression, pain, and SF36 physical component score and MCS were all found to correlate moderately with the ANAM performance as measured by the mean total throughput score. Independent risk factors of poorer performance included: low MCS, low educational level, and high pain scores. The total throughput scores of SLE patients were not statistically significantly different (with a power of 80% to detect a 20% difference) from those of patients with RA, even when adjustments were made for the above covariates.

Conclusion: Surprisingly, our results demonstrate no significant differences in cognitive function between community-based patients with SLE and their well matched RA controls. This would suggest that the CD observed in some patients with SLE may be due more to the effects of chronic disease than SLE per se.

1574

Assessment of Cognitive Function in Systemic Lupus Erythematosus, Rheumatoid Arthritis and Multiple Sclerosis Using Computerized Neuropsychological Tests. J. G. Hanly, Antonina Omisade, Li Su, Vernon Farewell, Tina Linehan and John D. Fisk, Division of Rheumatology, Capital Health and Dalhousie University, Halifax, NS

Purpose: Computerized neuropsychological testing may facilitate screening by non-experts for cognitive impairment in SLE. The Automated Neuropsychological Assessment Metrics (ANAM) is a computerized test battery that takes 45 minutes to administer. We used ANAM to evaluate the cognitive performance of SLE patients compared to patients with rheumatoid arthritis (RA), multiple sclerosis (MS) and healthy controls.

Methods: Ambulatory patients with SLE (68), RA (33), and MS (20), with mild to moderate disease activity and severity, were compared to 29 healthy controls matched to SLE and MS patients for gender, age (±5 years) and education (±3 years). ANAM measures reaction time and accuracy in Simple Reaction Time (SRT), learning and recall using code substitution subtests (CDS and CDD), working memory using the Mathematical Processing (MTH) and the Sternberg Memory Scanning (ST6) subtests, sustained attention using a Continuous Performance subtest (CPT), visual-spatial processing using the Matching Grids (MSG) subtest, and short-term visual memory using the Match to Sample subtest (MSP). Efficiency of performance on each subtest was examined by "throughput"(TP) (number of correct responses per minute) and "inverse efficiency" (IE) (response speed/proportion of correct responses). Group differences were determined using O'Brien's generalized least squares test and all results were adjusted for age and education.

Results: Overall group differences were found for both IE ($p=0.01$) and TP ($p<0.01$). Control subjects were the most efficient while MS patients were least efficient. MS patients also demonstrated less efficient performance in comparison to both SLE ($p=0.01$) and RA ($p<0.01$) patients who did not differ from each other. To examine for differences in the frequency of overall "impairment", patients' IE scores on each subtest as well as the SRT subtest scores were converted to Z scores, based on the normal subjects' performances on each ANAM subtest. $Z \geq -1.5$ was considered to represent "impairment" in IE on any given subtest. Sixty-one percent of RA patients and 50% of SLE patients were impaired on at least one ANAM subtest compared to 75% of MS patients. Only 9% of RA patients and 11% of SLE patients were impaired in $\geq 4/7$ ANAM subtests, whereas 20% of MS patients were impaired to this extent. Performance on specific ANAM subtests indicated that MS patients were most often impaired on SRT, CDD and MTH subtests; SLE patients were most often impaired on SRT, CDS and CDD subtests; RA patients were most often impaired on SRT, CDS, MTH and ST6 subtests.

Conclusion: ANAM is sensitive to cognitive impairment in patients with neurologic disease, such as MS. Patients with SLE and RA had comparable performance on ANAM subtests. Slowing on SRT was common for all patient groups. While computerized testing may be sensitive to cognitive impairment in SLE, our results emphasize the lack of specificity of such deficits in many SLE patients and the role of chronic disease in the etiology.

Prevalence and Types of Cognitive Impairment in Young Women with Systemic Lupus Erythematosus (SLE). Simone Appenzeller[1], Bruce Pike[2], Gabriel Leonard[2], Martin Veilleux[2] and A. E. Clarke[3], [1]State University of Campinas, Campinas, Brazil, [2]McGill University, Montreal, QC, [3]MUHC, Montreal, QC

Purpose: To determine prevalence and types of cognitive impairment in young women with SLE.

Method: We screened consecutive female SLE patients followed in a longitudinal cohort between 2007/2008. We excluded patients with any clinical factors associated with cerebral atrophy or vasculopathy [i.e., age ≥ 50 years, hypertension (BP >140/90 on 2 occasions or 1 occasion with concomitant antihypertensive medications), renal insufficiency (creatinine > 200mmol/dl on 1 occasion), transient ischemic attack or stroke, scleroderma features, diabetes, drug abuse or malignancy, or not educated primarily in English or French]. Healthy age matched women were selected as controls. SLE patients were assessed for disease activity [SLE Disease Activity Index (SLEDAI)] and damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)]. All subjects underwent a standardized neuropsychological evaluation to screen for possible impairment in the following cognitive domains: simple attention, complex attention, memory, visuospatial processing, language, reasoning/problem solving, psychomotor speed and executive functions. The individual test results were converted into standard scores, which were compared to the normative data of the controls. Subjects with a total score in any of the 8 domains ≤2 SD below the normative value were considered impaired. Cognitive dysfunction was considered mild if there were deficits in <3 domains, moderate if deficits in 3-4 domains, and severe if deficits in ≥5 domains.

Results: One hundred and twenty seven patients < 50 years were screened, 52 fulfilled the inclusion criteria, and data are currently available on 27 (mean age 34.08, SD 8.85). Ten controls (mean age 33, SD 8.3) matched for years of education participated. Mean SLE duration was 8.1 years (SD 7.0), with a mean SLEDAI of 4.8 (SD 4.5) and mean non central nervous system SDI of 0.9 (SD 1.2). Cognitive impairment was identified in 21 (77.8%) SLE patients, mild in 8, moderate in 9, and severe in 4. Memory was impaired in 14 of 21 patients, executive functions and psychomotor speed in 11, simple attention in 9, complex attention in 6, language in 5, reasoning/problem solving in 3, and visuospatial processing in 3. Spontaneous complaints of cognitive impairment were mentioned by only 2 patients. None of the controls had any cognitive impairment. SLE patients with cognitive impairment had similar age distribution (mean difference 0.24; 95%CI of difference -4.83, 5.32), disease duration (mean difference 1.26; 95%CI -5.17, 7.70), disease activity (mean difference in SLEDAI 1.4; 95%CI -0.56, 1.31) and non central nervous system SDI scores (mean difference SDI=0.37; 95%CI -1.88,4.69) as SLE patients without cognitive impairment.

Conclusion: Cognitive impairment was frequently observed in young SLE patients and most patients did not have spontaneous complaints. The most frequently impaired domains were memory, executive functions and psychomotor speed. This study suggests that SLE patients should be routinely screened for cognitive dysfunction.

1576

Cognitive Dysfunction in Patients with SLE: A Prospective Study. Marc A. Antonchak[1], Mahnaz Saoudian[1], Amber Khan[1], Tara Adhikari[1], Hermine Brunner[2] and Michael E. Luggen[1], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cincinnati Child Hospital Medical Center (CCHMC) Division of Rheumatology, Cincinnati, OH

Purpose: Cognitive dysfunction (CD) has been reported to occur frequently in SLE. It is unclear, however, it this CD is transient, persistent, or progressive. Published reports have estimated persistence or progression in anywhere from 17% to 93% of patients. These widely divergent results may be due in part to the definition of CD employed and the lack of assessment of pre-morbid cognitive function. The later can result in misclassification with both false positive (pts with low native intelligence who score low) and false negative determinations (pts with high native intelligence who now fall within the “normal” range). Chronic rheumatic diseases cause pain, fatigue, and depression which may affect cognitive function. All studies to date have employed normal healthy individuals as controls. Definitions of CD relative to this

population will identify some pts whose major problems are depression, pain, or fatigue, which may improve, and some who have structural CNS disease, which may not.

Methods: A random subsample of SLE patients referred by community-based primary care physicians was examined at baseline and after 6 months. Cognitive function was assessed by the ANAM (Automated Neuropyschologic Assessment Metrics), a validated, computerized, cognitive testing battery, utilizing as the primary outcome measure the total throughput score (TTS=total number of correct responses/time). Disease activity, damage, and treatment variables were ascertained at baseline and at 6 mos. Premorbid intelligence was estimated by the Peabody Picture Vocabulary Test (PPVT) which correlates with other measures of native intelligence and is minimally affected by moderate CNS disease. Abnormality was defined as having scores 2 SD below the mean of an age and sex matched RA control population. The results were compared using paired t-tests or Wilcoxon sign rank test

Results: Ninety-six SLE patients were randomly selected. Twenty-nine have been evaluated to date on at least two occasions. Comparisons of baseline scores with scores at 6 months showed no significant differences in 6 of the 10 ANAM subtests but statistically significant improvement in 4 subtests and in the TTS (by ~8%, P=0.0007). The median PPVT standardized score was 99.0 (IQR: 93.5, 111.0). The PPVT did not appear to be correlated with TTS at baseline or 6 mos. At baseline, 5/29 (17.2%) patients had abnormal TTS. Three of the 5 pts remained impaired at 6 mos and 2 improved.

Conclusion: Using RA controls, 17.2% of a community based SLE cohort had CD. Most of these had persistent deficits. However, most SLE pts had normal cognitive function which remained stable or improved over 6 mos. Adjustment for premorbid intelligence did not appear to influence results in this sample. This study suggests that, in a community based population, significant CD is uncommon.

Benign Intracranial Hypertension Is a Significant Cause of Intractable Headache in Lupus Patients with Normal Cerebrospinal Fluid Composition. Ji-Min Kim, Chang-Hun Lee, Su-Jin Moon, Ho-Sung Yoon, Kwi-Young Kang, Seung-Ki Kwok, Ji-Hyeon Ju, Kyung-Su Park, Sung-Hwan Park and Ho-Youn Kim, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea

Purpose: Headache is a common symptom described by patients with systemic lupus erythematosus (SLE). Headache can be a neuropsychiatric manifestation of SLE as well as a symptom of central nervous system infections such as septic meningitis. We evaluated the etiologies of intractable headache in lupus patients who underwent cerebrospinal fluid (CSF) study.

Method: We conducted a retrospective medical record review of 1034 patients who were diagnosed of SLE in the rheumatology department of Seoul St. Mary’s Hospital between June 1996 and May 2009. We identified 24 (2.3%, mean age 27.6±9.2 years) patients who underwent CSF studies because of their intractable headache. The clinical characteristics, laboratory data, findings of brain imaging, and prognosis of these patients were analyzed.

Results: Of the 24 patients, septic meningitis was identified in 7 (29.2%) patients, aseptic meningitis in 8 (33.3%), and normal CSF composition in 9 (37.5%). Of the 9 patients with normal biochemical and cytological CSF findings, 4 (44.4%) patients were identified to have benign intracranial hypertension. The other 5 patients with normal CSF composition and normal CSF opening pressure included 2 with migraine, 2 with acute confusional state, and 1 with seizure disorder. Patients were divided into 4 groups; those with septic meningitis, aseptic meningitis, benign intracranial hypertension, and normal CSF composition and pressure. Although there were no significant differences in clinical manifestations, findings of brain imaging, and prognosis among the 4 groups, patients with benign intracranial hypertension had significantly high SLE disease activity index (SLEDAI) score compared to other groups ($p<0.001$). Serum albumin level was significantly lower in the benign intracranial hypertension group than the septic meningitis group ($p<0.005$) and the aseptic meningitis group ($p<0.05$). Serum levels of C3 were also lower in the benign intracranial hypertension group than the septic meningitis group ($p<0.05$) and the aseptic meningitis group ($p<0.05$).

Conclusion: Although benign intracranial hypertension has been reported to be a rare cause of headache in patients with SLE, our data suggest that it does account for a significant portion of headache in lupus patients with normal CSF composition. Measurement of CSF opening pressure in addition to serum levels of albumin and C3 and SLEDAI score is thought to be useful in evaluating intractable headache in lupus patients and lowering CSF opening pressure and controlling SLE disease activity seems to be helpful in those patients.

Thalamic Volumes Predict Cognitive Impairment Evaluated by Speed Processing Tasks in Systemic Lupus Erythematosus. Simone Appenzeller[1], Bruce Pike[2], Leticia Rittner[1], Gabriel Leonard[2], Martin Veilleux[2] and A. E. Clarke[3], [1]State University of Campinas, Campinas, Brazil, [2]McGill University, Montreal, QC, [3]MUHC, Montreal, QC

Purpose: To evaluate the relationship between thalamic volumes and speed processing tasks in systemic lupus erythematosus (SLE).

Method: We screened consecutive female SLE patients followed in a longitudinal cohort between 2007/2008. We excluded patients with any clinical factors associated with cerebral atrophy or vasculopathy [i.e., age ≥ 50 years, hypertension (BP >140/90 on 2 occasions or 1 occasion with concomitant antihypertensive medications), renal insufficiency (creatinine > 200mmol/dl on 1 occasion), transient ischemic attack or stroke, scleroderma features, diabetes, drug abuse, or malignancy] or not educated primarily in English or French. Healthy age-matched women were selected as controls. Speed information processing was assessed with the stroop, trail making, finger tapping, and digital symbol tests and raw data and z-scores were used for analysis. Magnetic resonance imaging (MRI) was performed on a Siemens 3 Tessla scanner and volumetric T1 1mm thick slices were used for automatic segmentation of the thalamus. Atrophy of the thalamus was defined as a volume smaller than 2 SD of the control mean. The thalamic volumes and cognitive testing were compared between groups using the t-test. The pearson correlation was used to determine the correlation between individual cognitive tests and thalamic volumes.

Results: One hundred and twenty seven patients < 50 years were screened, 52 fulfilled the inclusion criteria, and data are currently available on 27 (mean age 34.08, SD 8.85). Ten controls (mean age 33, SD 8.3) participated. We observed significantly smaller right (mean volume 6413.48mm3; SD 664.78) and left (mean volume 6380.85mm3; SD 680.99) thalamic volumes in SLE patients when compared to controls [mean right volume 7006.82mm3; SD 523.00 (mean difference -593.33; 95% CI -118.85, -1067.83) and mean left volume 7019.42mm3; SD 495.37 (mean difference -638.56; 95%CI -158.76, -1118.37)]. Bilateral thalamic atrophy was identified in 6 patients and unilateral left in 2 patients. Speed information processing was similar between groups, except for finger tapping, in which SLE patients had significantly poorer results (mean difference -38.02; 95%CI -32.45; -43.56). Right thalamic volumes correlated directly with the stroop test (pearson correlation (PR) 0.55; p 0.0001), trail making test (PR 0.487; p 0.02), digital symbol test (PR 0.35; p 0.044), and finger tapping test (PR 0.44; p 0.006). Left thalamic volumes correlated directly with the stroop test (PR 0.56; p 0.001), trail making test (PR 0.55; p 0.005), and finger tapping test (PR 0.460; p 0.04).

Conclusion: We observed significantly smaller thalamic volumes in SLE patients when compared to healthy age and sex matched controls; speed information processing was similar with the exception of finger tapping which was poorer in SLE patients. Performance of speed processing tasks correlated directly with thalamic volumes. Correlation between structural volumes and specific cognitive testing can help identify underlying structural central nervous system pathology and explain cognitive impairment in visually normal appearing MRIs.

1579

Diagnostic Reliability of Magnetic Resonance Imaging for Central Nervous System Syndromes in Systemic Lupus Erythematosus: A Prospective Cohort Study. Yasuhiro Katsumata[1], Masayoshi Harigai[2], Yasushi Kawaguchi[1], Makoto Soejima[1], Kae Takagi[1], Takahisa Gono[1], Yuko Ota[1], Katsuji Nishimura[1], Hisashi Yamanaka[1] and Masako Hara[1], [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan

Purpose: Magnetic resonance imaging (MRI) is often used in the diagnosis of central nervous system (CNS) syndrome in systemic lupus erythematosus (SLE). However, previous studies of MRI as a diagnostic tool for CNS syndromes in SLE contained several limitations such as study design, number of enrolled patients, and definition of CNS syndromes. We overcame these problems and statistically evaluated the diagnostic values of abnormal MRI signals and their chronological changes in CNS syndromes of SLE.

Method: We prospectively studied 191 patients with SLE, comparing those with (n = 57) and without (n = 134) CNS syndrome. CNS syndromes were characterized using the American College of Rheumatology case definitions.

Results: Any abnormal MRI signals were more frequently observed in subjects in the CNS group (n = 25) than in the non-CNS group (n = 32) [relative risk (RR), 1.7; 95% confidence interval (CI), 1.1-2.7; $p = 0.016$] and the positive and negative predictive values for the diagnosis of CNS syndrome were 42% and 76%, respectively. Significant differences were also found when the CNS group with neurologic disorders (n = 17; RR, 2.3; CI, 1.3-4.1; $p = 0.007$) and the CNS group with psychiatric disorders (n = 16; RR, 1.9; CI, 1.1-3.4; $p = 0.038$) were separately compared with the non-CNS group. Large abnormal MRI signals ($ø \geq 10$ mm) were seen only in the CNS group (n = 7; RR, 3.7; CI, 2.9-4.7; $p = 0.0002$), whereas small abnormal MRI signals ($ø < 10$ mm) were seen in both groups with no statistical difference. Large signals always decreased in size or resolved completely in the subjects where CNS syndromes were ameliorated by treatment, but were unchanged in the subjects where CNS syndromes did not improve; this difference was statistically significant ($p = 0.029$). Chronological changes in small signals did not correspond with clinical outcome ($p = 1.000$).

Conclusion: MRI alone does not have sufficient predictive value for a diagnosis of CNS lupus, although abnormal MRI signals showed statistical associations with CNS syndrome. A large MRI signal is, however, useful as a diagnostic and surrogate marker for CNS lupus, although it is less common.

1580

The Prevalence of Neuropsychiatric Syndromes in SLE: A Meta-Analysis. Avraham Unterman[1], Johannes ES Nolte[1], Mona Boaz[2], Maya Abady[3], Yehuda Shoenfeld[1] and Gisele Zandman-Goddard[2], [1]Sheba Medical Center, Ramat Gan, Israel, [2]Wolfson Medical Center, Holon, Israel, [3]Edgecliff Physiotherapy Sports & Spinal Centre, Sydney, Australia

Purpose: To assess the prevalence of the 19 neuropsychiatric (NP) syndromes in systemic lupus erythematosus (SLE) patients, as defined by the 1999 Ad Hoc committee of the American College of Rheumatology (ACR), by performing a meta-analysis of relevant publications.

Methods: A literature search from April 1999 to May 2008 was performed to identify studies investigating NP syndromes in patients with definite SLE, applying the 1999 ACR case definitions and having a sample size of at least 30 patients. Excluded were studies that did not relate to all 19 NPSLE syndromes, presented duplicate data, or were irrelevant.

Results: Seventeen of 112 identified studies matched the inclusion criteria, reporting on a total of 5057 SLE patients, including 1439 NPSLE patients, with 2709 NPSLE syndromes. In a sub-analysis of the 10 higher quality prospective and elicited studies (2049 patients) using the random-effects model, NPSLE prevalence was found to be 56.3%, and the most frequent NP syndromes were headache (28.3%), mood disorders (20.7%), cognitive dysfunction (19.7%), seizures (9.9%), and cerebrovascular disease (8.0%), though significant between-study heterogeneity was present ($p<0.05$). Autonomic disorder and Guillain-Barré syndrome carried a prevalence of less than 0.1%. No case of plexopathy was reported.

Conclusion: Neuropsychiatric syndromes were found to exist in more than half of SLE patients. The most prevalent manifestations were headache, mood disorders, cognitive dysfunction, seizures and cerebrovascular disease. Some NP syndromes were found to be rare and their association with SLE is questionable, necessitating reconsideration of their inclusion in the ACR criteria.

Cardiovascular Disease, Cognitive Functioning, and Depression in SLE: A Study Using Diffusion Tensor Brain Imaging. L. J. Julian, P.P. Katz, L. Trupin, L.A. Criswell, E.H. Yelin, D. Wofsy and R. Henry, UCSF, San Francisco, CA

Purpose: Cognitive dysfunction and depression are common in SLE; yet the causal mechanisms of these neuropsychiatric syndromes are unclear. The purpose of this study is to evaluate the associations of depression, cognitive function and white matter integrity. To study white matter abnormalities we used an improved neuroimaging technique, diffusion tensor imaging (DTI) which identifies microstructural changes in normal appearing white matter (NAWM). Additionally, the relationships among DTI, cognitive function, and depression were evaluated with a particular focus on cardiovascular (CV) disease as a potential risk factor for WM brain abnormalities.

Methods: Participants included 41 patients with diagnostically confirmed SLE and no history of other neurological syndrome who underwent a neuropsychological and psychiatric evaluation, and brain MRI. Cognitive measures included tests of learning and memory, executive functioning, and motor speed. MRI procedures were conducted on 3Tesla MRI (GE Medical Systems Milwaukee, WI). The primary DTI index in this study is fractional anisotropy (FA) of whole brain WM with lower values indicative of poorer WM structural integrity. Patients were also categorized as having high cardiovascular risk if they had ≥ 2 traditional CV risk factors including: history of CV event, hypertension, hypercholesterolemia, family history, current or past smoking, obesity, or diabetes. Pearson or Spearman correlation coefficients were calculated to estimate associations among variables. Group comparisons were conducted using t-tests.

Results: Mean age of participants was 48±9 years, 70% had at least a high school education, and they were well represented across racial/ethnic groups. Average disease duration was 15.5±7.2 years. Reduced FA (reduced white matter integrity) was associated with increased CV risk ($r=-.46$, $p<.01$), and with reduced cognitive performance on measures of simple and complex sequencing, episodic memory, and working memory among patients with and without increased risk for cardiovascular disease (all $p<.05$). Depression was strongly associated with reduced FA among participants with increased CV risk (See Figure 1).

Conclusion: Alterations in WM structural integrity are associated with increased CV risk, depression, and poorer performance on measures of cognitive functioning. DTI can identify microstructural alterations in WM and may be a useful technique to study brain changes in SLE. The relationships with traditional CV risk factors provide some preliminary evidence in support of a vascular etiology for cognitive impairment and depression in SLE.

Figure 1. Depression and WM integrity among SLE patients stratified by CV risk

Decreased Live Births in Women with SLE. E. Vinet[1], A. E. Clarke[1], C. Gordon[2], M.B. Urowitz[3], C. A. Pineau[1], D. A. Isenberg[4], A. Rahman[4], D. J. Wallace[5], G. S. Alarcon[6], I. N. Bruce[7], M. A. Petri[8], M. A. Dooley[9], C. Aranow[10], Ronald F. van Vollenhoven[11], SLICC and S. Bernatsky[1], [1]MUHC, Montreal, QC, [2]Medical School, Birmingham, United Kingdom, [3]TWH, Toronto, ON, [4]U College of London, London, United Kingdom, [5]Cedars-Sinai Medical Center/UCLA, West Hollywood, CA, [6]U of Alabama, Birmingham, AL, [7]Manchester Royal Infirmary, Manchester, [8]JHU, Baltimore, MD, [9]U of NC at Chapel Hill, Chapel Hill, NC, [10]The Feinstein Institute, Manhasset, NY, [11]Karolinska Univ Hosp, Stockholm, Sweden

Purpose: Multiple disease-related factors may limit the number of children borne to women with SLE. Though well-designed studies are lacking, there is a general notion that live births are not decreased in SLE, compared to healthy women. We calculated live births in women with SLE, and compared this with general population rates.

Methods: We studied women with SLE from a subset of centers participating in the SLICC Registry for Atherosclerosis inception cohort study. Women diagnosed with SLE before age 50 were included. We determined the number of children borne as of the last follow-up visit, and summed the years from the age of 15 up to the age of 50, or oldest age attained if the subject was aged < 49. We applied age- and country-specific general population birth rates, as well as relevant calendar-period rates, to these years to determine the expected number of live births for the period. We then calculated the standardized incidence ratio (SIR) of observed to expected live births. We also performed a multivariate analysis with the SIR as the dependent variable to explore potential predictors of live births, such as marital status, drugs(immunomodulators, prednisone, ASA, anticoagulants), antiphospholipid antibodies, disease activity & damage.

Results: 339 women with SLE were studied. Mean age at diagnosis was 35.3 years (standard deviation, SD, 13.3) & mean disease duration at the last visit was 2.7 years (SD 2.0). Most (43%) women were from the US, 27% from Canada, 27% from the UK, and 3% from Sweden. The majority of women (61%) were white, 19% were black, 10% were Asian and 5% were Hispanic. Most (42%) were currently married or living common-law.

Overall, the number of live births over the interval (313) was substantially below that which would be expected (479) (SIR 0.65; 95% CI 0.58, 0.73). In sensitivity analyses, we used race-specific general population birth rates, with similar results (SIR 0.65; 95% CI 0.58, 0.72). In multivariate analyses, being married or living common-law (SIR 2.07; 95% CI 1.58, 2.69) and current use of aspirin (SIR 1.36; 95% CI 1.02, 1.80) were associated with increased live births. There were trends for fewer live births in women exposed to cyclophosphamide (SIR 0.82; 95% CI 0.53, 1.27) and in those with high disease activity (SLEDAI $\geq$ 5) (SIR 0.76; 95% CI 0.54, 1.07). We did not definitively establish a decrease in live births independently attributable to positive antiphospholipid antibodies (SIR 0.98: 95% CI 0.73, 1.32) or disease damage (SLICC score $\geq$ 2) (SIR 1.02: 95% CI 0.70, 1.48), when drug exposures & clinical characteristics were adjusted for.

Conclusion: Women with SLE have fewer live births compared with the general population. Marital status & current ASA use were the most important predictors of live births (relative to the general population) in our sample.

1583

Lupus Activity Does Not Correlate with Estradiol During Pregnancy. Megan E. B. Clowse and Martin Tochacek, Duke University, Durham, NC

Purpose: Estradiol is considered a strong promoter of systemic lupus erythematosis (SLE) disease activity based on animal and epidemiologic studies. Estradiol levels rise 100-fold during pregnancy, suggesting that lupus activity might increase during this period. We investigated in women with SLE the association between estradiol, disease activity, and inflammatory markers during pregnancy.

Method: Consecutive pregnant women with rheumatologic disease were enrolled in the Duke Autoimmunity in Pregnancy Registry. Women were seen as soon as pregnancy was diagnosed, at mid-pregnancy between 22 and 26 weeks gestation, and post-partum. At most visits, we measured serum levels of estradiol, C reactive protein (CRP), C3, C4, and anti-dsDNA antibodies, and the erythrocyte sedimentation rate (ESR) as well as determined the SLE Pregnancy Disease Activity Index (SLEPDAI) and physician's global assessment (PGA). We correlated levels of estradiol and SLE activity at 3 separate time points to diminish the confounding effect of gestational age: 1st trimester, mid-pregnancy between 22-26weeks gestation, and post-partum. No pregnant women had multiple visits within the pre-specified time frames.

Results: The study included 29 pregnancies with a total of 91 visits. As expected, estradiol increased over the course of pregnancy and fell dramatically postpartum (correlation 0.8, $p<0.001$). There was marked inter-patient variability in estradiol levels at the mid-pregnancy visit. SLE activity did not correlate with estradiol level at any of the 3 time points (see table). In addition, mean levels of disease activity were similar at each of the time points. Levels of C3 and C4, anti-dsDNA antibody, and CRP did not correlate with estradiol levels. The ESR

was higher during pregnancy than post-partum (mid-pregnancy mean 48 vs post-pregnancy mean 17, p=0.01), but it did not correlate with estradiol at any time point.

Figure: distribution of estradiol levels by gestational age.

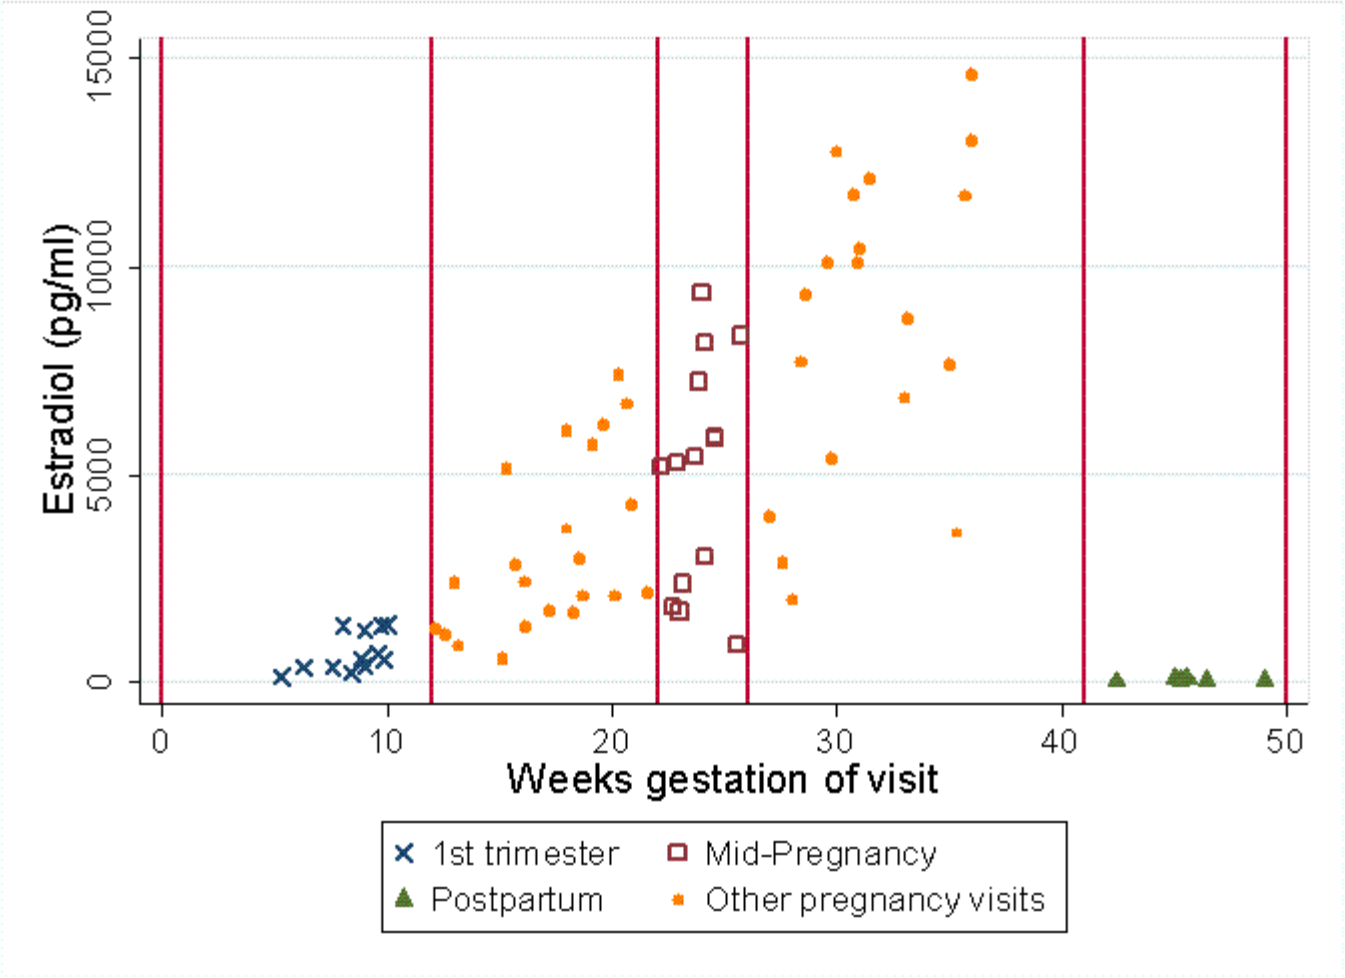

Table: SLE activity correlated with estradiol at 3 time points during and following pregnancy.

		1st trimester N=12	Mid-pregnancy N=14	Postpartum N=6
Estradiol	*Mean pg/ml (range)*	726 pg/ml (139-1389)	5056 pg/ml (906-9385)	41 pg/ml (10-81)

SLEPDAI *Mean (range)* Correlation with estradiol *(p-value)*	3.0 (0-10) 0.2 (p=0.6)	3.9 (0-10) -0.4 (p=0.2)	3.0 (0-5) 0.4 (p=0.4)
PGA *Mean (range)* Correlation with estradiol *(p-value)*	0.4 (0-1) 0.4 (p=0.2)	0.4 (0-1) -0.005 (p=0.9)	0.4 (0-1) 0.7 (p=0.1)

Conclusion: Although estradiol induces SLE activity in some murine models, it was not associated with disease activity in this cohort of pregnant women. The results of this study do not support the hypothesis that increasing levels of estradiol during pregnancy trigger SLE flares.

Disclosure: M. E. B. Clowse, None; **M. Tochacek**, None.

Standardized Follow up of 54 Pregnancies IN 42 PATIENTS with Systemic Lupus Erythematosus. A. Theulin[1], M. Ardizzone[2], Jf Kleinmann[1], Christelle Sordet[1], Jacques-Eric Gottenberg[1] and J. Sibilia[1], [1]University Hospital of Strasbourg, Strasbourg, France, [2]Centre Hospitalier de Mulhouse, Mulhouse, France

Purpose: The prognosis of lupus pregnancies is not well known. We therefore investigated this issue in one of the national reference centers for auto-immune diseases.

Method: We performed a monocenter retrospective study of lupus pregnancies followed in a tertiary reference center between 1998 and 2008. All our patients had SLE according to the ACR criteria. Each patient was followed up using a standardized follow up, including clinical, biologic and fetal echocardiography procedure when needed (patients with anti-SSA/SSB antibody).

Results: Among the 425 patients with SLE followed in this reference center, 54 pregnancies occurred in 42 mothers. Twenty four patients had anti-Ro/SS-A, and 6 had anti-SSA and anti-SSB antibodies.

- Demographical data of mothers : Mothers age was 29.7 +/- 4.9 years, the mean SLE duration was 3.4 +/- 2.6 years and the mean number of immunosuppressor was 1.3 +/- 0.7. Ten pregnancies occurred in 7 women followed for lupus nephropathy.

At onset of pregnancy, patients were treated with low dose of corticosteroids (41 patients, 75%), mean dose was 11 +/- 8.8 mg per day, hydroxychloroquine (27 patients, 49%), azathioprine (3 patients, 5%), aspirin (37 cases, 67%). Combined treatment with aspirin and heparin was given in 4 patients with APS.

- Follow up of lupus flares during pregnancies : twenty four (44%) lupus flares were observed, 15 (27%) during pregnancy and 9 (16%) during post-partum. These flares were mild, mainly represented by arthralgia or arthritis (19 patients), and cutaneous involvement (8 patients). Among the patients with lupus nephropathy, an increasing proteinuria and transient alteration of renal function were observed in 3 patients (30%). No death and no APS-related thrombotic events occurred.

- Fetal outcome : Two (3,6%) fetal loss occurred in a patient with APS and another associated with a congenital heart block in a patient with anti-Ro/SSA auto-antibody. Thirteen (24%) preterm deliveries, and 9 (16 %) neonates with low birth weight were observed. No case of fetal deformity was observed, especially under hydroxychloroquine.

Conclusion: These data of 54 lupus pregnancies confirm that the maternal and fetal risk deserves a protocolized follow-up of these pregnancies, which allows a quite good maternal and fetal prognosis.

Sex Hormones and Gender Influences the Function of Regulatory T Cells in SLE Patients. Ram P. Singh, Ravi Dinesh, Antonio La Cava and B H. Hahn, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: The goal of the present study was to determine the effect of gender and sex hormones on the quantity and function of regulatory T cells.

Method: Immunophenotyping was performed by flow cytometry and mRNA gene expression studies were performed by real time PCR. Protein expression was analyzed by intracellular staining and Western blot analysis. The *in vitro* effect of sex hormones b-estradiol (60pg/ml), b-estradiol inhibitor (10-20ng/ml), and androgen (10-50ng/ml) were studied by culturing cells for 72 hours followed by FACS/Western blot analyses. Apoptosis was measured by Annexin V and 7AAD staining.

Results: 1- The numbers of $CD4^+$ and $CD8^+$ regulatory T cells are decreased in healthy females compared to healthy males.

2- Both $CD4+CD25^{hi}$ and $CD8+CD25^{hi}$ subsets of healthy males had 3-4-fold higher Foxp3 mRNA compared to healthy females.

3- Foxp3 expression was higher in healthy male PBMCs than in healthy females PBMCs with and without stimulation with recombinant TGFb.

4- Stimulation of PBMCs with b-estradiol (30pg/ml) decreases Foxp3 expression in healthy females but not in age matched healthy males. At higher doses (60, 150pg/ml) estrogen has little effect on PBMCs from either sex.

5- Immunophenotyping of PBMCs from SLE patients (n~40) indicated significantly

reduced numbers of $CD4^+CD25^{hi}$ $Foxp3^+$ T cells and $CD8^+Foxp3^+$ T cells when compared to healthy matched controls (n ~20) and autoimmune disease control RA patients (n~30).

6- The in vitro proliferative potential of $CD4^+$ and $CD8^+$ T regulatory cells were defective in SLE patients compared to healthy controls ($p<0.001$).

7- Estrogen decreases Foxp3 mRNA and protein expression in $CD4^+CD25^-$ T cells from both female and male SLE patients ($p<0.05$).

8- An inhibitor of b-estradiol (ERa) increased apoptosis in male SLE patients only.

Conclusion: These data suggest that the numbers of regulatory T cells are decreased in healthy females compared to healthy males. Women may be more susceptible to SLE than men due to estrogen deregulation of the T regulatory compartment. These findings may have possible implications in understanding the regulation of disease in relation to gender bias in SLE patients.

1586

Longitudinal Evaluation of Idiotypic and Anti-Idiotypic Response to the Major Epitope of La/SSB Autoantigen in Mothers Enrolled in the PITCH (Preventive IVIG Therapy for Congenital Heart Block) Study. Jg. Routsias[1], Nikolaos Kyriakidis[1], Carolina Llanos[2], Robert M. Clancy[2], Jill Buyon[2] and Athanasios G. Tzioufas[1], [1]School of Medicine, National University of Athens, Athens, Greece, [2]NYU School of Medicine, New York, NY

Neonatal lupus (NL) affects children of mothers with anti-Ro/SSA and anti-La/SSB autoantibodies. NL can cause permanent and life-threatening damage to the fetal heart, most commonly congenital heart block (CHB). Previous studies have shown that anti-idiotypic antibodies to autoantibodies against La/SSB are found in sera of mothers with healthy children, suggesting that anti-idiotypic antibodies may protect the fetus by blocking the pathogenic maternal autoantibodies.

Purpose: To investigate the effect of IVIg on the idiotype (id)-antiidiotype (anti-id) network in pregnant women with anti-Ro/SSA and anti-La/SSB antibodies who had a previous history of a child with CHB (high risk pregnancies).

Method: The interaction of IVIg with the synthetic peptides was investigated by direct ELISA assays as well as inhibition experiments. Ten mothers who previously gave birth to a child with CHB were treated during a subsequent pregnancy with IVIG using a protocol in the Preventive IVIG Therapy for Congenital Heart Block (PITCH) Study. All individuals exhibited ELISA reactivity against epitope 349-364 of La/SSB in their initial samples. Sequential sera were drawn from all mothers during pregnancy (before each IVIg infusion at 12, 15, 18, 21, 25 and 28, 34, delivery), and evaluated for antibodies against the epitope 349-364 (pep) of La/SSB (idiotypic), as well as its complementary

epitope (cpep) and anti-349-364 Fab_2 fragments (both anti-idiotypic). Anti-349-364 reactivity was also evaluated after removal of anti-Id antibodies.

Results: IVIg contains low affinity antibodies, most probably polyreactive antibodies, binding to both pep and cpep. The reactivity of anti-cpep (anti-id) antibodies appeared to be higher, compared to anti-pep antibodies. A partial inhibition of idiotype-antiidiotype binding (30%), was observed after IVIg treatment of purified antibodies. Following dosing of IVIg the maternal antibody titres to the major epitope of La/SSB decreased by 20% to 50% in four patients, remained stable in five and increased in one by 30%. In contrast, there was a substantial increase of anti-Id reactivity in all patients, ranging from 20% to 250%. After removal of anti-Id antibodies the Id reactivity was increased (up to 300%) in all patients. None of the children developed any conduction abnormality.

Conclusion: This study supports the novel finding that IVIg administration decreases autoantibody titres and enhances the anti-idiotypic antibody response in pregnant women with anti-Ro/SSA and anti-La/SSB antibodies.

Fetal and Maternal Outcomes with Mycophenolate Mofetil (MMF) Exposure During First Trimester of Pregnancy in Patients with Systemic Lupus Erythematosus. Elizabeth C. Ortiz, Karina D. Torralba, Christine M. Evelyn and Francisco P. Quismorio Jr., University of Southern California-Los Angeles County Medical Center, Los Angeles, CA

Purpose: The US Food and Drug Administration has recently changed the pregnancy category of mycophenolate mofetil (MMF) to Category D (positive evidence of fetal risk) based on postmarketing data. MMF use during the first trimester may increase the risk of pregnancy loss and congenital malformations. The objective of the study is to establish the outcomes of SLE patients exposed to MMF during their first trimester of pregnancy.

Methods: Retrospective chart review of 700 SLE patients followed during 2006-2009 was done to identify patients who were on MMF during their first trimester of pregnancy. The patient population was primarily Hispanic, low income and without private health insurance. Obstetric and drug histories were noted, focusing on cumulative MMF dose at the time of conception, gestational age at the time of discovery, contraceptive use and outcome of pregnancy.

Results: Five SLE patients were exposed to MMF during their first trimester. The mean duration of disease was 6.2 years (3-10yrs). MMF was prescribed for nephritis (3 cases), hemolytic anemia (1) and thrombocytopenia (1). Three patients had anticardiolipin antibodies. At the time of discovery of the pregnancy, mean SLEDAI score was 2.4 (0-10); mean age of gestation was 28 days (21-37 days). Mean cumulative dose from conception to birth/fetal loss was 49g (28-103g); mean daily dose was 1.5g; maximum MMF dose from time of start of medication was 4,000g. Other medications used at the time of conception were hydroxychloroquine (4 patients), prednisone (5), alendronate (3) and benazepril (1). Three patients used barrier methods for contraception while two patients were not using contraception of any kind. All had received physician counseling regarding use of contraception prior to and while on MMF. Three patients delivered healthy babies; 2 reached full-term, 1 required emergent caesarian section for pre-eclampsia at 32 weeks. One patient who elected to terminate the pregnancy experienced fetal demise at 6.5 weeks and subsequently had passage of products with misoprostol. One patient had spontaneous abortion at 22 weeks; this patient had ongoing nephritis. There were no reported fetal malformations. No changes in SLEDAI were noted during duration of all pregnancies.

Conclusion: MMF exposure during first trimester of pregnancy in our cohort of SLE patients was associated with pregnancy loss in 40% of patients which is similar to that reported in the National Transplantation Pregnancy Registry (45%). No fetal malformations were observed, however number of live births was small. Our study emphasizes the need for better patient education and counseling, and closer monitoring for use of effective contraception while on MMF and other teratogenic medications.

Pregnancy Outcome in SLE Patients Before and After Diagnosis. Regina Fare, Esther Rodriguez-Almaraz, Patricia E. Carreira, Isabel Mateo and María Galindo, Hospital 12 de Octubre, Madrid, Spain

Purpose: To analyze predictive factors for pregnancy outcome in a large group of SLE patients.

Methods: Ever pregnant SLE patients followed in the rheumatology department of a University Hospital between 1977-2008 were included. Demographic (age, time from onset and diagnosis, cardiovascular risk factors, follow up and death), clinical (SLE activity, obstetric history), treatment and pregnancies outcome data were obtained from previous databases, obstetric charts or phone questionnaires. Outcome complications included: pregnancy loss, preterm delivery, intrauterine growth retardation (IUGR), preeclampsia/eclampsia, or fetal death. Chi-square test was used to analyze associations between categorical variables and univariate and multivariate logistic regression to analyze risk factors for pregnancy outcome.

Results: We included 177 SLE patients who presented 406 pregnancies, 280 and 126 previous and after SLE diagnosis, respectively. Mean age at SLE diagnosis was 32 years (range 6-69) and mean age at pregnancy was 28 years (range 16-45). From 406 pregnancies, 307 (76%) were alive newborns, 9 (2%) IUGR and 83 (21%) preterm delivery. There were only 3 cases of neonatal lupus (3 skin and 2 hematological involvement) all in mothers with anti-Ro antibodies. There were 3 perinatal deaths but none related to SLE. Among pregnancies developing after SLE diagnosis, 52,4% presented at least one complication (30,2% miscarriage); 22,7% ended in caesarea, and 28% and 22% developed SLE flares during pregnancy and postpartum, respectively. Most of these SLE flares were mild (skin and joints). Outcome complications were more frequent in pregnancies occurring after than before SLE diagnosis: pregnancy losses (p=0,04), IUGR (p=0,003), hypertension (p=0,002), and caesarea (p=0,001). In univariate analysis, risk factors for poor outcome were previous renal involvement (p=0.04), and pregnancy less 6 months after SLE flare (p=0.02). Factors associated with good outcome were antimalarials treatment (p=0.05) and carefull monitoring in high risk pregnacy clinic (p=0.01). Previous proliferative nephritis was a risk factor for preclampsia (p=0.003). Haemolytic anemia was a risk factor for preterm delivery (p=0.003), and for preeclampsia (p=0.01). Raynaud phenomenon was a risk factor for preterm delivery (p=0.02). APS diagnosis was a risk factor for miscarriages (p=0,03), specially in 2nd trimester (p=0.01), IUGR (p=0.05) and preclampsia (p=0.03). Becoming pregnant less than 6 months after the last SLE flare was a risk factor for preclampsia (p=0.05). Treatment with steroids did not exert any protective or worsening effect for pregnancy outcome. In the multivariate analysis, renal involvement (p=0.001), and previous SLE flare (p=0.004) persisted as risk factors for poor outcome, and careful monitoring as a good prognosis factor (p=0.03).

Conclusion: Pregnancy in SLE patients should not be considered as an unacceptable high risk condition for mother and newborns. Nevertheless, the existence of previous renal involvement, haemolytic anemia or APS confer a higher risk for pregnancy complications. Pregnancy must be planned at least 6 months after last SLE flare and must be careful monitored in specialized high risk pregnancy clinics.

1589

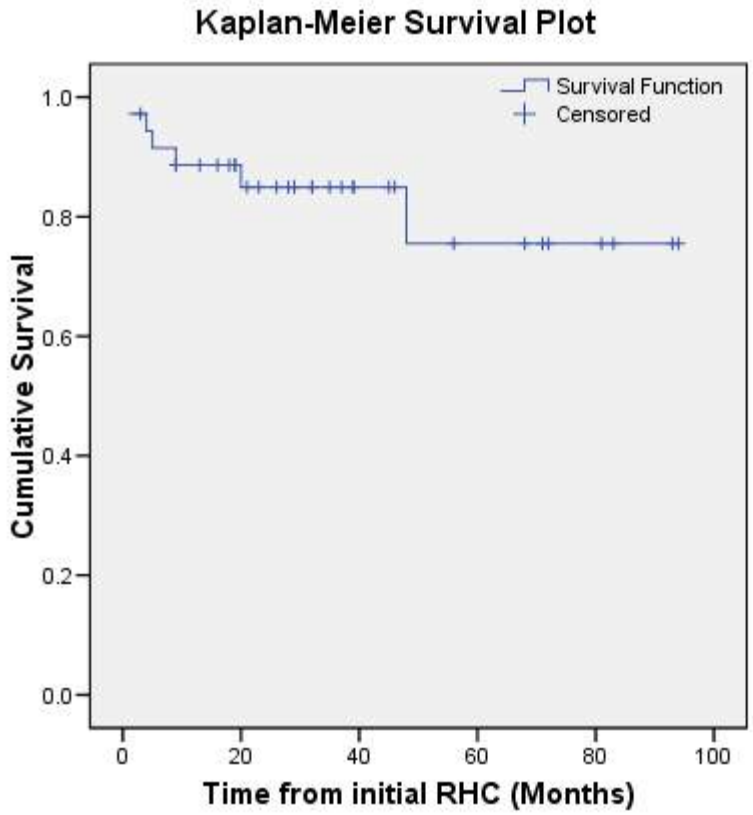
Pulmonary Hypertension in Systemic Lupus Erythematosus – A Retrospective Analysis. Rhodri Martin[1], Richard W. Lee[2], John G. Coghlan[3] and David P. D'Cruz[4], [1]Lupus Research Unit, Rayne Institute, St Thomas' Hospital, London, United Kingdom, [2]Lupus Research Unit, St Thomas' Hospital, London, United Kingdom, [3]Royal Free Hospital, London, United Kingdom, [4]St Thomas Hosptial, London

Purpose: Pulmonary hypertension (PH) is less well described in systemic lupus erythematosus (SLE) than in other connective tissue disorders such as scleroderma. National Pulmonary Hypertension Service (NPHS) guidelines state that patients should be assessed in a NPHS centre with right heart catheterisation (RHC) as the gold standard investigation.

We define burden and severity of PH in a cohort of patients with SLE referred to the NPHS.

Methods: RHC Pulmonary arterial pressures (PAP) and key clinical features were audited.

Results: RHC data was obtained for 47 patients with SLE referred between 2001 and 2008. Ten patients had lupus overlap syndromes (e.g. with scleroderma) or mixed connective tissue disease. Forty-three patients (91%) were Female with mean age 49 years (24 to 80 years). PH (PAP >25mmHg) was confirmed in 32 patients. Five others were labelled as "post-capillary" PH. Mean RHC data included (mmHg): Mean-PAP 39 (22-66); systolic-PAP 63 (32-115); diastolic-PAP 24 (11-40); wedge pressure 11 (1-25). Mean mixed venous oxygen saturations were 64% (42-82%). Eleven (23%) patients had pulmonary fibrosis. NYHA grades were: I (1); II (5); III (21); IV (8). Six deaths (16%) were recorded over 34 months mean follow up.



Conclusion: Although PH is rare in SLE, our cohort of patients suffered considerable morbidity with grade III or IV disease in 83%. Mortality rates compared favourably to those reported for Scleroderma.

Alveolar Hemorrhage in Systemic Lupus Erythematosus: Demographic, Serologic and Clinical Associations. Aikaterini Thanou-Stavraki, Joanne Tesiram, John B. Harley and Judith A. James, Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: Alveolar hemorrhage (AH) is an uncommon but oftentimes deadly severe manifestation of systemic lupus erythematosus (SLE). However, serologic and clinical predictors of SLE patients at increased risk of developing AH are not clear. Limited data from small case series suggest a link between AH and renal disease. This study uses a well-characterized, large, multi-ethnic, cross-sectional SLE cohort (n=2,448) to examine demographic, clinical and serologic associations with AH.

Method: De-identified, electronic records of the SLE database were searched for patients with AH. Each case was matched with 4 SLE affected controls for age, sex, ethnicity and race, as well as compared to the entire remaining collection. Demographic, serologic and clinical characteristics were gathered from among 1,900 datapoints for each AH positive and AH negative SLE patient. Chi-square, McNemar's test and paired t-test were used for data analysis.

Results: Among 2,448 SLE patients screened, 13 cases of well-documented AH were identified (10 females and 3 males). African race was more prevalent in AH patients than controls (23% vs. 8%, p=0.035). Patients with AH were younger at SLE diagnosis compared to controls [mean age at diagnosis 29.9 vs. 33.7 years (mean age difference 3.8 years, 95% CI 0.98-6.67, p=0.009)]. Of the ACR classification criteria for SLE, lupus nephritis as defined by presence of cellular casts was associated with AH (OR 4.75, 95% CI 1.58-19.19, p=0.003); however, no association of AH with proteinuria was found (p=0.4). Even in this small cohort, AH was significantly associated with the presence of

vasculitis at other sites (OR 3.25, 95% CI 1.00-13.68, p=0.05). Although no significant relation with clinically manifest antiphospholipid (aPL) syndrome was shown (p=0.55), aPL antibodies were more common in patients with AH (OR 3.17 with 95% CI 1.22-9.69, p=0.016). On the contrary, anti-Sm was significantly more prevalent in patients without AH in this cohort (OR <0.01 with 95% CI 0.00-0.69, p=0.023). The prevalence of other auto-antibodies, including anti-dsDNA, anti-Ro, anti-La and anti-nRNP, did not differ significantly in patients with and without AH.

Conclusion: Clinical association of AH with vasculitis at other sites, as well as with the presence of cellular casts, suggests a possible common autoimmune pathway that leads to multicentric, microvascular involvement in the lung, glomerulus and other organs. Association of AH with aPL antibodies supports a presumed pathogenic mechanism that leads to AH through formation of miscovascular thrombi, with or without pulmonary capillaritis. Replication and expansion of these findings in additional longitudinal cohorts of SLE patients is warranted, as well as expanded evaluation of potential serologic predictors of this oftentimes severe clinical manifestation.

Disclosure: A. Thanou-Stavraki, None; **J. Tesiram**, None; **J. B. Harley**, None; **J. A. James**, None.

1591

Pleurisy in a Large SLE Cohort. Roshan Dhawale[1] and Michelle A. Petri[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]Johns Hopkins University, Baltimore, MD

Background: Pleurisy is one of the ACR criteria for systemic lupus erythematosus (SLE) and one of the more frequent manifestations of the disease. Little is known however, about the serological status, associated clinical features and damage accrual in patients with pleurisy.

Purpose: To compare demographics, serologies and clinical features in patients with and without pleurisy.

Methods: A well-defined cohort of 1708 SLE patients was followed longitudinally for 20 years. Patients were included if they met 1997 ACR criteria for definite SLE. Clinical features, serologic data and damage accrual (SLICC/ACR) were recorded at the time of entry into the cohort and were updated at subsequent visits. Using SELENA-SLEDAI, pleurisy was diagnosed when any of the following were present: typical pleuritic chest pain; pleural rub; and clinical/radiological evidence of pleural effusion. Analyses were performed using student t-test.

Results: SLE patients with pleurisy were found to have a younger age of onset (27.4 vs 29.6 years) and were more likely to have had fever [(OR) 1.72 (95% CI 1.35, 2.22)], lymphadenopathy [OR 1.48 (1.15, 1.94)], pericarditis [OR 3.66 (2.81, 4.77)], arthralgias [OR 3.66 (2.81, 4.77)] and arthritis [OR 1.97 (1.33, 2.91)]. They were associated with presence of anti-Smith [OR 1.52 (1.11, 2.08)], anti-dsDNA [OR 1.53 (1.18, 1.98)] and aCL [OR1.67 (1.3, 2.15)], which was highly significant. Patients with pleurisy were also more likely to develop pulmonary fibrosis (p<0.0001) and pulmonary hypertension (p=0.0013).

Table 1: Comparison of patients with and without pleurisy

Factor	**Pleurisy (n=305)**	**No Pleurisy (n = 1403)**	**P-value**	**Odds Ratio OR (95% CI)**
Demographics:				
Female Gender	96%	92%	0.0213	1.95 (1.08, 3.51)
Age at onset	27.4 +/- 11.7	29.6 +/- 12.7	0.0056	
Age at diagnosis	30.4 +/- 12.1	33.0 +/- 12.9	0.0015	
Clinical features:				
Fever	51%	38%	<0.0001	1.73 (1.35, 2.22)
Lymphadenopathy	37%	28%	0.0029	1.49 (1.15, 1.94)
Raynauds	60%	49%	0.0006	1.56 (1.21, 2.01)
Vasculitis	21%	14%	0.0052	1.58 (1.15, 2.16)

Arthralgias	98%	92%	0.0002	3.66 (1.69, 7.93)
Arthritis	84%	73%	<0.0001	1.97 (1.41, 2.74)
Myositis	13%	7%	0.0011	1.97 (1.33, 2.91)
Pericarditis	44%	17%	<0.0001	3.66 (2.81, 4.77)
Cardiac Murmur	59%	45%	<0.0001	1.74 (1.36, 2.24)
Serologies :				
Lupus anticoagulant	31%	25%	0.0425	1.33 (1.01, 1.75)
Anticardiolipin Ab	58%	45%	<0.0001	1.67 (1.30, 2.15)
Low C3	62%	53%	0.0023	1.49 (1.15, 1.92)
Low C4	57%	46%	0.0006	1.56 (1.21, 2.00)
Anti-dsDNA	66%	56%	0.0014	1.53 (1.18, 1.98)
Anti-Smith	21%	15%	0.0114	1.52 (1.11, 2.08)
Anti-RNP	33%	24%	0.0016	1.57 (1.19, 2.06)
Damage:				
Pulmonary Fibrosis	14%	6%	<0.0001	2.72 (1.84, 4.04)
Pulmonary Hypertension	12%	7%	0.0013	1.98 (1.33, 2.95)

Conclusion: Pleurisy is a common, but important, manifestation of SLE. Pleurisy is associated with the presence of anti-Smith and anti-dsDNA. These patients are more likely to develop pulmonary fibrosis and pulmonary artery hypertension. Pleurisy can serve as an important predictor of pulmonary damage and these patients should be monitored periodically over time to assess for complications.

Medication Use in Systemic Lupus(SLE). S. Bernatsky[1], C. Peschken[2], Murray Urowitz[3], Dafna D. Gladman[3], A. E. Clarke[1], J. Pope[4], P. R. Fortin[3], C. A. Pineau[1], M. Zummer[5], C.D. Smith[5], H. Arbillaga[5], M. Hudson[6] and Canadian Network for Improved Outcomes in Systemic Lupus, [1]MUHC, Montreal, QC, [2]University of Manitoba, Winnipeg, [3]Toronto Western Hospital, Toronto, ON, [4]St Joseph Health Care, London, ON, [5]CaNIOS, [6]McGill University, Montreal, QC

Purpose: To evaluate factors affecting therapeutic approaches used in clinical practice for the management of SLE, in a multi-centre cohort. A priori, factors of potential interest include patient age, race/ethnicity, disease duration, lupus activity, and accumulated damage.

Methods: We combined data from 10 clinical adult SLE cohort registries in Canada. We used multivariate generalized estimating equation methods to model dichotomized outcomes, running separate regressions where the outcome was current exposure of the patient to specific medications. Potential predictors of medication use included demographic (age at baseline, sex, residence, race/ethnicity) and clinical factors (disease-duration, time-dependent damage index scores and adjusted mean SLE Disease Activity Index (2K) scores. The models also adjusted for clustering of subjects by centre.

Results: Higher disease activity and damage scores were each independent predictors of exposure to non-steroid immunosuppressive agents, and for exposure to prednisone. This was not definitely demonstrated for anti-malarial agents. Older age at diagnosis was independently and inversely associated with exposure to any of the agents studied (immunosuppressive agents, prednisone, and anti-malarial agents). An

additional independent predictor of prednisone exposure was black race/ethnicity (adjusted rate ratio, RR 1.46, 95% confidence interval, CI 1.18, 1.81). For immunosuppressive exposure, an additional independent predictor was race/ethnicity, with greater exposure among Asians (RR 1.39, 95% CI 1.02, 1.89) and persons identifying themselves as First Nations/Inuit (2.09, 95% CI 1.43, 3.04), compared to whites. All of these findings were reproduced when adjustment for disease activity was limited to renal involvement.

Conclusion: Ours is the first portrayal of determinants of clinical practice patterns in SLE, and offers interesting real-world insights. Further work, including efforts to elucidate how differing clinical approaches may influence outcome, is ongoing.

ACR/ARHP Poster Session C

Rheumatoid Arthritis - Human Etiology And Pathogenesis II

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1633

DNA Microarray Analysis Revealed Abnormal Networks of Immune Response Molecules in Bone Marrow Cells From Patients with Rheumatoid Arthritis. Hooi-Ming Lee[1], Hidehiko Sugino[1], Yasuo Adachi[2], Takahiro Ochi[3] and Norihiro Nishimoto[2], [1]Osaka University, Osaka, Japan, [2]Wakayama Medical University, Osaka, Japan, [3]Osaka Police Hospital, Osaka, Japan

Purpose: To investigate the abnormal functional networks of differentially expressed genes in bone marrow (BM) cells compared between rheumatoid arthritis (RA) and osteoarthritis (OA).

Method: Gene expression profiles (GEPs) in BM cells from 9 RA patients and 10 OA patients were obtained by using DNA microarray. Up- and down-regulated genes were identified by comparing between the GEPs of RA and those of OA. Bioinformatics analysis was performed using Expression Analysis Systemic Explorer (EASE) 2.0 based on gene ontology (GO) followed by network pathway analysis with Ingenuity Pathways Analysis (IPA) 7.5.

Results: 764 up-regulated and 1910 down-regulated genes were identified in RA compared to OA. GO term of "Biological Process" in EASE analysis revealed that up-regulated genes were most significantly classified into "Response to Biotic Stimulus" category (61 genes), which included functional category of "Immune Response" (57 genes). Abnormalities in "Cell Organization and Biogenesis", and "Signal Transduction" were also identified; down-regulated genes were dominantly classified into "Cell Proliferation" (139 genes), "Regulation of Cell Cycle" (64 genes), and "DNA Replication and Chromosome Cycle" (52 genes). Most of the genes in these 3 functional categories were overlapped with each other. Relationships among the 61 up-regulated genes in "Response to Biotic Stimulus" and the 139 down-regulated genes in "Cell Proliferation" were further analyzed by using IPA. There were 4 networks represented by the 61 up-regulated genes. The first network that with interferon (IFN) alpha, IFN beta, and MHC class I (family) *etc.* at the center included 5 IFN-inducible molecules, a cluster of human leukocyte antigen (HLA), i.e. HLA-E, HLA-F, HLA-G, and tapasin (TAP) *etc*. This network was relevant to antigen presentation, cell-mediated immune response, and humoral immune response. The remaining 3 networks were also related to cell-mediated immune response. Meanwhile, there were 7 networks constructed by the 139 down-regulated genes. The functions of the top 3 networks were related to cell cycle and DNA replication, recombination, and repair. E2F transcription factors, several cyclins and cyclin-dependent kinase played central roles in these networks. Down-regulation of these molecules was considered due to Methotrexate (MTX) effect as this repression was not significant in the patients without MTX treatment.

Conclusion: Abnormal functional networks of "Immune Response" were identified in BM cells of RA compared to OA. Overexpression of the genes that take part in antigen presentation pathway and IFN signaling was suggested contributed to pathogenesis of RA. Our results also suggested that the main therapeutic effect of MTX is demonstrated by repressing cell cycle and DNA replication genes in BM cells.

Expansion of Immature Plasmacytoid and Myeloid Dendritic Cells within CD34+ Cells of the Bone Marrow in Rheumatoid Arthritis. Shunsei Hirohata[1], Tetsuya Tomita[2] and Hideki Yoshikawa[2], [1]Kitasato Univ School of Med, Kanagawa, Japan, [2]Osaka University Graduate School of Medicine, Suita Osaka, Japan

Purpose: We previously showed that bone marrow CD34+ cells from rheumatoid arthritis (RA) patients have abnormal capacities to respond to tumor necrosis factor-alpha (TNF-α) and to differentiate into fibroblast-like cells producing MMP-1, resembling type B synoviocyte. In addition, we have recently demonstrated that bone marrow plasmacytoid dendritic cells (pDC) from RA patients as well as those from osteoarthritis (OA) patients have prominent capacities to differentiate into type B synoviocyte-like cells under the influences of TNF-α. Since depletion of BDCA2-positive cells from bome marrow CD34+ cells diminished their capacities to differentiate into type B synoviocyte-like cells, it is possible that CD34+ cells expressing BDCA2 might be expanded in RA bone marrow compared with OA bone marrow. The current studies were therefore undertaken to explore in detail the phenotypic characteristics of bone marrow CD34+ cells from RA patients and OA patients.

Method: Bone marrow samples were obtained from 25 patients with RA (1 male and 24 females: mean age 60.8 years), who satisfied the ACR 1987 revised criteria for RA and gave informed consent, during joint operation via aspiration from the iliac crest. As a control, bone marrow samples were similarly obtained from 22 patients with osteoarthritis (OA) (4 males and 18 females: mean age 70.7 years). The capacity of pDC and mDC purified from bone marrow mononuclear cells by positive selection with magnetic beads to produce MMP-1 upon stimulation with TNF-α was evaluated by ELISA. The expression of BDCA2 (pDC marker), and BDCA3 (mDC marker) by CD34+ cells were examined by 2-color analysis on flow cytometry.

Results: Both bone marrow pDC and mDC from RA patients differentiated into type B synoviocyte-like cells producing MMP-1 upon stimulation with TNF-α as effectively as those from OA patients. There were no significant differences in percentages of CD34+ cells within bone marrow mononuclear cells between RA and OA. However, RA bone marrow mononuclear cells contained higher percentages of BDCA2+ CD34+ cells and BDCA3+ CD34+ cells than OA bone marrow mononuclear cells. Accordingly, percentages of cells expressing BDCA2 or BDCA3 within RA bone marrow CD34+ cells were significantly higher than those within OA bone marrow CD34+ cells. The numbers of BDCA2+ CD34+ cells were significantly correlated with those of BDCA3+ CD34+ cells in RA bone marrow, but not in OA bone marrow.

Conclusion: These results indicate that the enhanced capacity of RA bone marrow CD34+ cells to differentiate into type B synoviocyte-like cells is accounted for the expansion of cells expressing DC markers BDCA2 and BDCA3. Moreover, the data suggest that enhanced differentiation of pDC and mDC from bone marrow CD34+ cells might be involved in the pathogenesis of RA through providing precursors of type B synoviocytes.

Histone Deacetylase Inhibitors SAHA and MS-275 Induced Growth Arrest, Suppressed NF-κB Activation, Down-Regulated the Secretions of Nitric Oxide, IL-6, IL-18, VEGF and MMPs in Rheumatoid Arthritis Synovial Fibroblast-Like Cells. Qiu-Yi Choo[1], Paul C. Ho[1], Yoshiya Tanaka[2] and Hai-Shu Lin[1], [1]National University of Singapore, Singapore, Singapore, [2]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Purpose: Histone deacetylase inhibitors SAHA and MS-275 exhibited potent anti-rheumatic efficacy in rodent models for rheumatoid arthritis (RA). However, their mechanisms of actions remain elusive. This study aimed to investigate their anti-rheumatic mechanisms.

Method: The anti-rheumatic mechanisms of SAHA and MS-275 were studied in E11 cells, a cell line established from rheumatoid arthritis synovial fibroblasts (RASFs).

Results: MS-275 and SAHA inhibited E11 proliferation at low nM levels (IC_{50}s<100 nM). Such anti-proliferative activities were independent of cytotoxicity but associated with cell cycle arrest at G_0/G_1 phase and the induction of cyclin dependent kinase inhibitor p21. MS-275 and SAHA also suppressed LPS-induced NF-kB p65 nuclear translocation. As a probable consequence, the secretions of nitric oxide (NO), IL-6, IL-18, VEGF, MMP-2 and MMP-9 from E11 cells were down-regulated.

Conclusion: Histone deacetylase inhibitors MS-275 and SAHA displayed therapeutic potential for RA. Anti-rheumatic mechanisms include RASFs proliferation blockade, pro-inflammatory cytokine and NO secretion suppression as well as angiogenesis and matrix metalloproteinase production down-regulation. These activities might be mediated through p21 induction and the inactivation of NF-kB.

Table 1. IC_{50} values (nM) of MS-275 and SAHA in E11 cells

Inhibition	MS-275	SAHA
Cell proliferation	65	44
NF-kB activation	<100	<100
NO production	<1	<1
IL-6 secretion	121	5311
IL-18 secretion	<1	<1
VEGF secretion	5	62

Expression and Function of Novel Phosphoinositide 3-Kinases (PI3K) Isoform in Fibroblast-Like Synoviocytes. Beatrix Bartok[1], David L. Boyle[1], Christian Rommel[2], Sanna Rosengren[1] and Gary S. Firestein[1], [1]UCSD School of Medicine, La Jolla, CA, [2]Intellikine, La Jolla, CA

Purpose: Class I phosphoinositide 3-kinases (PI3K) regulate diverse cellular functions such as cell survival, proliferation, migration and glucose metabolism. Of the four PI3K isoforms (α, β, γ, δ), α and β are ubiquitously expressed. γ and δ, however, are mainly expressed in leukocytes and therefore could be important targets for inflammatory disease. This hypothesis is supported by the observation that genetic deletion or selective inhibition of PI3K γ or δ decrease inflammation in several pre-clinical models. To explore the biology of these two kinases in rheumatoid arthritis (RA), we assessed their expression, regulation and function in cultured fibroblast-like synoviocytes (FLS).

Method: Quantitative real-time PCR (qPCR) was used to determine relative expression of the PI3K isoforms in cultured FLS after IL-1 (2ng/ml), TNF (50 ng/ml) or LPS (1ng/ml) stimulation. PDGF (1ng/ml) induced Akt phosphorylation was detected using Western blot analysis. To evaluate PI3Kδ–mediated Akt phosphorylation in RA FLS in response to PDGF we used a novel, selective PI3K δ inhibitor INK007 with 30 fold selectivity over γ (IC50= 0.2 nM for δ; 6 nM for γ, and > 5000nM for α and β). FLS proliferation in response to PDGF was measured using the MTT assay on day 0, 2, and 4.

Results: RNA transcripts for PI3K α, β, δ were constitutively expressed in cultured FLS cell. Relative PI3K δ mRNA expression was increased 4-6 fold in response to IL-1, TNF or LPS stimulation, peaked after 24 hr (n= 3, $p< 0.05$) and decreased to baseline by 48 hr. There was no effect of PDGF or TGFβ on PI3K δ expression. PI3K α and β mRNA levels were only marginally increased by the TNF or IL-1 (1-2 fold increase). Western blot analysis showed that PI3K δ protein was also increased by pro-inflammatory cytokines. Of interest, PI3Kγ mRNA was not detected in resting FLS or after exposure to cytokines or LPS. Akt activation, especially after PDGF exposure, is responsible for many PI3K effects on cellular function. Akt phosphorylation in FLS was already detected within 5 min of stimulation with PDGF. To determine if PI3K δ contributes to Akt activation, FLS were preincubation with the selective PI3K δ inhibitor INK007 and then stimulated with PDGF. INK007 decreased P-Akt levels by 70% compared with PDGF alone. To evaluate the functional relevance of PI3K δ-mediated Akt activation, we assessed the effect of PI3K δ inhibition on FLS proliferation in vitro. INK007 decreased FLS proliferation in response to PDGF. The concentration dependent inhibitory effect was evident within 2 days in culture. By day 4, PDGF-stimulated cell growth was decreased 20% by 0.3 μM and 50% by 3 μM (n=2 separate experiments).

Conclusion: This is the first demonstration that PI3K δ is expressed and inducible in fibroblasts. Because it regulates Akt phosphorylation and cell growth, PI3K δ could contribute to synoviocyte hyperplasia in RA. In contrast, the γ isoform was not expressed in FLS. Selective inhibition of this PI3K δ could be useful in RA by suppressing synoviocyte function.

SPACIA1, A Novel Gene Involved in Proliferation of Synoviocytes in Arthritis. Tomoo Sato[1], Ryoji Fujii[1], Koji Konomi[2], Naoko Yagishita[1], Hiroyuki Aono[2], Yoshihisa Yamano[1], Moroe Beppu[1], Kusuki Nishioka[3] and Toshihiro Nakajima[4], [1]St. Marianna University School of Medicine, Kanagawa, Japan, [2]Santen Pharmaceutical Co. Ltd., Nara, Japan, [3]St Marianna University, Kawasaki Kanagawa, [4]Choju Medical Institute, Fukushimura Hospital, Misato Marine Hospital, St. Marianna University, Kanagawa

Purpose: Synovial proliferation is an important aspect of Rheumatoid arthritis (RA), however its mechanism is still unclear and no effective target for synovial proliferation has been isolated. Here we show a novel gene involved in proliferation of synoviocytes in arthritis

Methods: To find the molecules related synovial proliferation, we perform transcriptome analysis using model mice of collagen-induced arthritis (CIA). The effects of candidate molecules on proliferation of synovial fibroblasts were confirmed by using siRNA. In regard to one of the candidate molecules, synoviocytes-proliferation associated in CIA 1 (SPACIA1), we analyzed expression in RA and osteoarthritis synoviocytes with or without synovitis. The effects of SPACIA1 overexpression on CIA were assessed by using its transgenic mice.

Results: We identified a novel gene involved in the proliferation of synoviocytes in arthritis from the candidate molecules and named SPACIA1. SPACIA1 knock down by its siRNA reduced proliferation in RA synovial fibroblasts. SPACIA1 was up-regulated in multilayered synovial lining cells in RA and OA. SPACIA1 transgenic mice showed fast onset and exacerbated of collagen-induced arthritis, compared with wild type mice.

Conclusion: SPACIA1 could be associate synovial proliferation and might be related synovitis. Overexpression of SPACIA1 led to exacerbation of collagen-induced arthritis. These findings indicate the importance of SPACIA1 in synovial proliferation in RA. SPACIA1 might be a potential therapeutic target for synovial proliferation in RA.

Secretory Phospholipase A_2 Group IIA Binds to Integrin αvβ3 and Induces Proinflammatory Signaling. Jun Saegusa[1], Masaaki Fujita[1], Shino Tanaka[1], Akio Morinobu[1], Seiji Kawano[1], Yoshikazu Takada[2] and Shunichi Kumagai[1], [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]University of California, Davis, Sacramento, CA

Purpose: Secretory phospholipase A_2 group IIA (sPLA$_2$-IIA) was first isolated and purified from synovial fluid from patients with rheumatoid arthritis (RA). Increased levels of sPLA$_2$-IIA are detected in the serum and synovial fluid of patients with RA. In addition to being an acute phase reactant, sPLA$_2$-IIA is considered to play an important role in the pathogenesis of inflammatory diseases by activating immune cells. It has been demonstrated that intraarticular administration of sPLA$_2$-IIA in the rabbit led to the development of arthritis. Notably some biological effects associated with sPLA$_2$-IIA are independent of its catalytic function. Therefore It has been proposed that sPLA$_2$-IIA action is mediated through interaction with specific receptors. However sPLA$_2$-IIA receptors in human have not been established. Integrins are a family of cell adhesion receptors that recognize extra cellular matrix ligands and cell surface ligands. Integrins transduce signals to the cell upon ligand binding. In this study, we investigated whether sPLA$_2$-IIA binds to integrins and transduces proinflammatory signals.

Method: The binding of sPLA$_2$-IIA to integrins was studied by ELISA-type binding assays, adhesion assays, flow cytometry and surface plasmon resonance. Amino acid residues in sPLA$_2$-IIA that are critical for integrin binding were investigated by docking simulation and mutagenesis. Several mutations were introduced within the predicted interface of sPLA$_2$-IIA with integrin, and integrin-binding defective sPLA$_2$-IIA mutants were generated. Catalytically inactive mutant of sPLA$_2$-IIA were also generated by mutating His-47 to Gln (H47Q) as a control.

Results: sPLA$_2$-IIA specifically bound to integrin αvβ3 at a high affinity ($K_D = 2\times10^{-7}$ M). We identified amino acid residues in sPLA$_2$-IIA (Arg-74 and Arg-100) that are critical for integrin binding. The R74E and R100E mutations in sPLA$_2$-IIA significantly reduced the binding to integrin αvβ3, while the H47Q mutation did not. Interestingly, wild-type and the catalytically inactive H47Q mutant of sPLA$_2$-IIA induced

cell proliferation and MAPK activation in monocytic cells in a dose-dependent manner, but the integrin binding-defective mutants did not. This indicates that integrin binding is required, but catalytic activity is not required, for $sPLA_2$-IIA-induced proliferative signaling.

Conclusion: Integrin αvβ3 may serve as a receptor for $sPLA_2$-IIA and mediate pro-inflammatory action of $sPLA_2$-IIA in a manner independent of its catalytic activity. Integrin-$sPLA_2$-IIA interaction may be a novel therapeutic target for RA and other inflammatory disorders.

Expression of Synoviolin in the Synovium of Patients with Rheumatoid Arthritis, Psoriatic Arthritis and Osteoarthritis in Relationship to the Response to TNF Blockade. Ruth Klaasen, Desiree Pots, Carla A. Wijbrandts, Danielle M. Gerlag and Paul P. Tak, Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: The E3 ubiquitin ligase synoviolin functions as an anti-apoptotic factor and its expression is associated with the development of arthritis in mice (1). It has been suggested that increased levels of synoviolin in peripheral blood are related to non-response to infliximab treatment in patients with rheumatoid arthritis (RA) (2). We investigated the expression of synoviolin in the synovium of patients with active RA compared to psoriatic arthritis (PsA) and osteoarthritis (OA), and its relationship to response to tumor necrosis factor (TNF) blockade in RA and PsA.

Methods: Synovial tissue samples were obtained from 54 active RA and 21 active PsA patients on stable methotrexate therapy before start of TNF blockade (infliximab and adalimumab, respectively); 11 inflammatory OA patients served as disease controls. In 5 of these RA patients serial synovial tissue samples were obtained 28 days after start of anti-TNF treatment. Synoviolin expression was detected by immunohistochemistry and evaluated by digital image analysis. Double immunofluorescence was performed to detect co-expression of synoviolin with CD3, CD55 and CD68. Clinical response was defined as a decrease in DAS28 $\geq$ 1.2 after 16 weeks of therapy.

Results: Expression of synoviolin was higher in RA patients compared to PsA (median and interquartile range, IQR), respectively 89187 (23066-170625) integrated optical density (IOD)/mm^2 and 37740 (7325-101802) IOD/mm^2 (P = 0.039). The expression in the OA group tended to be lower compared to both groups (median 27809, IQR 3956-267125 IOD/mm^2 (N.S.). In the intimal lining layer synoviolin was expressed by both CD68+ intimal macrophages (50-60%) and CD55+ fibroblast-like synoviocytes (40-50%). In the synovial sublining synoviolin was mainly expressed by CD68+ macrophages (80%), but also by CD3+ T cells (<10%). Clinical response to anti-TNF therapy was observed in 29/54 (54%) RA and in 14/21 (67%) PsA patients. Of interest, there was not relationship between synoviolin expression at baseline and the clinical response to TNF blockade in either group. Twenty-eight days after infliximab therapy there was persistent synoviolin overexpression in 4 of the 5 patients.

Conclusion: Synoviolin is overexpressed in the synovium of RA patients, and is expressed by macrophages, fibroblast-like synoviocytes and T cells. Synoviolin expression at baseline is not related to the clinical response to anti-TNF therapy. Persistent synoviolin expression after anti-TNF therapy may contribute to autonomous disease progression and could represent an additional therapeutic target.

Effect of FTY720 On Bone Remodeling in Rheumatoid Arthritis. Chieri Kanda[1], Tsuyoshi Iwasaki[2], Sachi Tsunemi[1], Sachie Kitano[1], Harunori Takeshita[2] and Hajime Sano[1], [1]Hyogo College of Medicine, Nishinomiya, Japan, [2]Hyogo University of Health Sciences, Kobe, Japan

Purpose: Bone remodeling is controlled by bone formation by osteoblasts and bone resorption by osteoclasts. The pathogenesis of bone destructive disorders such as rheumatoid arthritis (RA) and osteoporosis is caused by an uncoupling of bone remodeling. Sphingosine 1-phosphate (S1P) is one of the cell-derived lysophospholipid growth factors that signal diverse cellular functions such as proliferation, angiogenesis, and inflammation. We previously demonstrated that S1P signaling induced proliferation and prostaglandin productions by synovial cells from RA patients (Arthritis Rheum 54;2006). The present study we investigated the role of S1P signaling for bone remodeling using murine myoid cell line which differentiate into osteoblasts, human $CD4^+$ T cells, and B cells.

Method: Bone morphogenetic protein (BMP)-induced osteoblastogenesis was examined using murine myoid cell line C2C12. Osteoblast generations were examined by the expression of alkaline phosphatase (ALP) in the cells and productions of osteocalucin by the cells. RANKL expressions on C2C12 cells and human B cells were examined by RT-PCR analysis.

Results: Both S1P and S1P antagonist, FTY720, enhanced BMP-induced expression of ALP in C2C12 cells and osteocalucin production by these cells. These enhancing effects were stronger in the FTY720 treatment than in the S1P treatment. RANKL expressions on C2C12 cells were increased by the S1P treatment but were not increased by the FTY720 treatment. RANKL expressions on human B cells were also increased by either the S1P or the FTY720 treatment. These augmenting effects were stronger in the S1P treatment than in the FTY720 treatment.

Conclusion: These results indicate that although S1P signaling induces osteogenesis by the enhancement of BMP-induced osteoblast generation, it may also have an adverse effect on bone remodeling by the enhancement of RANKL expression on osteoblasts and B cells in synivial tissues. In contrast to S1P, FTY720 may enhance osteogenesis without affecting RANKL expressions on osteoblasts and B cells in synovial tissues. FTY720 may therefore be able to control bone remodeling in RA.

The Role of Sphingosine 1-Phosphate/S1P1 Signaling in the Osteoclastogenesis of Rheumatoid Arthritis. Masayasu Kitano[1], Harunori Takeshita[2], Sachi Tsunemi[1], Chieri Kanda[1], Masahiro Sekiguchi[1], Naoto Azuma[1], Tsuyoshi Iwasaki[2] and Hajime Sano[1], [1]Hyogo College of Medicine, Nishinomiya, Japan, [2]Hyogo University of Health Sciences, Kobe, Japan

Purpose: Sphingosine 1-phosphate (S1P) via the S1P receptor signaling elicits diverse cellular responses such as cell proliferation, differentiation and migration. Furthermore S1P is involved in various pathologic conditions and has been implicated as an important mediator of angiogenesis, inflammation and osteoclastogenesis. We previously reported S1P/S1P receptor 1 ($S1P_1$) signaling played an important role of synoviocyte proliferation and cyclooxygenase-2-induced prostaglandin E_2 production by RA synoviocytes (A&R 2006;54:742-53). In the pathogenesis of RA, receptor activator of nuclear factor-κB ligand (RANKL) plays an essential role in the osteoclastogenesis. Recently, it is reported that S1P regulates the osteoclast differentiation and osteoclast-osteoblast coupling. In the present study we have investigated the role of S1P/S1P1 signaling in RANKL expression of RA synoviocytes and human $CD4^+$ T cells.

Method: To investigate the expression of $S1P_1$ and RANKL mRNA and protein in human RA synoviocyte cell line (MH7A cells) and human $CD4^+$ T cells, we performed the reverse transcriptase-polymerase chain reaction (RT-PCR) and western blot analysis for $S1P_1$ and RANKL mRNA and protein expression, respectively. Next, we determined the effects of S1P for RANKL mRNA expression in MH7A cells and $CD4^+$ T cells. These cells were incubated with various concentrations (0-0.1μM) of S1P. After 6 to 24 hours incubation, RANKL mRNA in these cells was examined by RT-PCR. Moreover, MH7A cells were incubated with S1P alone or in combination with 100ng/ml of TNFα. After 24 hours incubation, RANKL mRNA in MH7A cells was similarly examined by RT-PCR. Finally, we examined whether these effects of S1P were sensitive or insensitive for pertussis toxin (PTX), the specific G_i/G_o inhibitor.

Results: $S1P_1$ mRNA and protein were detected in MH7A cells and $CD4^+$ T cells as well as RANKL mRNA and protein. S1P induced RANKL expression of MH7A cells and human CD4+ T cells in a dose dependent manner, and enhanced TNFα-induced RANKL expression in MH7A cells. In addition, these effects of S1P were inhibited by pretreatment of PTX.

Conclusion: These results indicate that $S1P/S1P_1$ signaling may play an important role of osteoclastogenesis via the RANKL expression of synoviocytes and $CD4^+$ T cells. $S1P/S1P_1$ signaling of RA synoviocytes is closely connected with synovial hyperplasia, inflammation, angiogenesis and osteoclastogenesis. Thus, the regulation of $S1P/S1P_1$ signaling may become a novel therapeutic target in RA.

The Selective Adhesion of α5β1^{high} Memory T Cells by βig-h3 in Rheumatoid Arthritis. Young Mo Kang, Jin Hee Kang, Kheum Hee Sa, Hyun Jung Cho, Eun Joo Song, Eon Jeong Nam and In San Kim, Kyungpook National University School of Medicine, Daegu, South Korea

Purpose: During the early stage of transendothelial migration, T cells come in contact with extracellular matrix proteins, including βig-h3 which is over-expressed within the rheumatoid synovium. βig-h3 has been shown to mediate the adhesion of α5β1^{high} T cells that are expressing activation markers. The aim of this study was to investigate whether βig-h3 is involved in the selective recruitment of subsets of T cells into the rheumatoid synovium.

Method: T cells were isolated using negative selection kit with MACS, following separation of mononuclear cells with Ficoll gradient centrifugation from peripheral blood (PB) and synovial fluid (SF) of rheumatoid arthritis (RA) and controls. Cell surface markers were evaluated using flow cytometry. T cell subsets were isolated with antibodies against CD4, CD45RO, and α5 integrin using FACS Aria^{TM}. Adhesion of T cell subsets was investigated on microtitre plate coated with wild-type βig-h3 and inhibition assay was performed by the preincubation of T cells with function blocking antibodies against integrins.

Results: T cells isolated from SF of RA were expressing higher level while most of those from PB of controls were expressing lower level of α5β1 integrin. Enhanced adhesion of SF T cells on the coated βig-h3 compared with normal or RA PB T cells was efficiently inhibited by the function blocking antibody against α5β1 integrin. RGD peptide, which binds to αvβ5 integrin, did not block βig-h3-mediated adhesion of T cells, while dhfas-1, a fragment of the 4th fas-1 domain of βig-h3, blocked the adhesion in a dose-dependent manner. The proportion of CD45RO^{+} cells among T cells was increased in the PB of RA compared to PB of controls, and was highest in the SF of RA. Most of the CD45RO^{+} T cells were α5β1^{high} population, while almost all the CD45RO^{-} T cells were α5β1^{low} population. βig-h3-mediated adhesion were higher in the CD4^{+}CD45RO^{+}α5^{high} T cells compared with CD4^{+}CD45RO^{+}α5^{low} and CD4^{+}CD45RO^{-}α5^{low} T cells (0.40 ± 0.03 vs 0.19 ± 0.03 and 0.22 ± 0.02, $p<0.01$). Among CD8^{+} T cells, CD45RO^{-}α5^{high} subpopulation, which was not observed in the CD4^{+} T cells of normal PB, consisted of CD28^{Null} cells.

Conclusion: The present data indicate that βig-h3 may play a critical role in the regulation of inflammation by the selective recruitment of memory T cells into the synovial tissues of RA through the interaction with α5β1 integrin.

1643

Serum Amyloid A Protein Stimulates Th17-Related Cytokines Production in Rheumatoid Synoviocytes. Tomohiro Koga[1], Kiyoshi Migita[2], Satoshi Yamasaki[1], Mami Tamai[1], Shin-ya Kawashiri[1], Naoki Iwamoto[1], Hideki Nakamura[1], Tomoki Origuchi[1], Hiroaki Ida[1], Atsushi Kawakami[1] and Katsumi Eguchi[1], [1]Nagasaki University, Nagasaki, Japan, [2]NHO National Nagasaki Medical Center, Nagasaki, Japan

Purpose: Rheumatoid arthritis (RA) is characterized by a systemic inflammatory response that exhibits elevated levels of pro-inflammatory cytokines and acute-phase reactants, such as serum amyloid A protein (SAA). High levels of SAA and its receptor formyl peptide receptor-like 1 (FPRL1) have been demonstrated in the rheumatoid synovium and a relationship between SAA and rheumatoid inflammation has been suggested. Th17 cells are a defined subset of proinflammatory T cells that contribute to the rheumatoid synovitis. Although the in vitro requirements for human Th17 development are well established, it is less clear their requirements in rheumatoid synovium. To study the contribution of acute phase reactants to the induction of Th17 cells in rheumatoid synovium, we investigated the effects of SAA on Th17-related cytokine production.

Method: Synoviocytes isolated from rheumatoid arthritis (RA) patients were stimulated with recombinant SAA. The cellular supernatants were analysed by a RayBio Human Cytokine Antibody Array V (Ray Biotech, Inc. Norcross, GA) and IL-6, CCL20-specific ELISA. IL-1b, IL-6, IL-23p19, IL-12p40, CCL-20 mRNA expression was analysed by real-time polymerase chain reaction (PCR). Assays for chemotaxis of peripheral blood mononuclear cells were performed using 5 μm pore polycarbonate filters in a transwell chamber (Costar, Cambridge, MA) with SAA-stimulated or control RA synoviocyte-conditioned media.

Results: SAA is a most potent inducer of IL-6, CCL20, IL-23p19 production in RA synoviocytes compared to other inflammatory cytokines (IL-1, TNF-a, IL-17A). SAA stimulation induced IL-1b, IL-6, IL-23p19, IL-12p40, CCL-20 mRNA expression in RA synoviocytes, which was not affected by polymyxin B pretreatment. SAA-induced CCL20 production was down-regulated by NF- kB inhibition and partially by JNK inhibition. SAA-induced IL-6, CCL20 production was also suppressed by dexamethasone or FK506.

Conclusion: These findings suggest that SAA may promote the generation and recruitment of CCR6-expressing Th17 cells, in RA synovium by up-regulating Th17-related cytokine production by synoviocytes.

Fas-Associated Death Domain Protein Expression Regulation by Secretion in Rheumatoid Arthritis. Lea Tourneur[1], Sylvie Mistou[2] and Gilles Chiocchia[3], [1]Inserm U567, Paris, France, [2]INSERM; CNRS; Paris Descartes University, Paris, France, [3]Institut Cochin, INSERM U567, Paris, France

Fas-Associated Death Domain Protein Expression Regulation by Secretion in Rheumatoid Arthritis

Background: Although Fas-associated death domain (FADD) is the key adaptor transmitting the apoptotic signal mediated by death receptors, it is also implicated in numerous non apoptotic functions. In particular, FADD can regulate inflammatory processes. In rheumatoid arthritis (RA), FADD can act as an anti-inflammatory molecule by inhibiting the NF-kB inflammatory signal mediated by IL-1β and TLR4 ligands, which are expressed in the joint of patients. Thus, an absence of FADD expression in synoviocytes could contribute to TLR4- and IL-1R1-mediated chronic inflammation. FADD protein can localize both in the cytoplasm and nucleus of most cells. Recently, we demonstrated the existence of a new localization of FADD in microvesicles and a new regulatory mechanism of the protein by secretion. Moreover, we identified adenosine receptors (AR) as regulators of this FADD secretion process.

Purpose: Since we have demonstrated the existence of an AR-dependent FADD protein expression regulation by secretion, and since adenosine is present at high concentration in the synovial fluid (SF) from RA patients, we tested whether FADD protein could be released in the SF from RA patients, as compared to osteoarthritis (OA, non inflammatory disease) suffering patients.

Methods: FADD protein expression in SF (50 µl) from two independent cohort of patients was assessed by sandwich-ELISA. Results are expressed in arbitrary units. Statistical analyses were performed by using the Student's t test. P-values of <0.05 were considered to indicate statistical significance.

Results: We found that FADD protein was detected at high level in the SF from 65% of RA patients (17/26), whereas it was detected significantly in the SF from only 17% of OA patients (6/36). In two independent cohorts of patients, mean secreted FADD in SF from RA and OA patients was 0.098 +/- 0.025 vs 0.014 +/- 0.005 (P=0.002) and 0.252 +/- 0.052 vs 0.022 +/- 0.012 (P=0.001), respectively.

Moreover, we are presently looking for secreted FADD in more than 800 sera of untreated recently diagnosed arthritis suffering patients including 545 RA affected patients (ESPOIR consortium cohort), using FADD-specific quantitative ELISA.

Conclusion: This is the first demonstration that human FADD protein could be secreted specifically during the course of an inflammatory disease, and it suggests that secreted FADD could be a new inflammatory marker. Moreover, these results confirmed that absence of FADD in joints through a release of the protein in SF could contribute to the development of RA.

Expression of Human TIM-3 and Its Correlation with Disease Activity in Rheumatoid Arthritis. Jaejoon Lee[1], Ji-Min Oh[1], Joong Kyong Ahn[1], Eun-Kyung Bae[1], Ji Young Chai[2], Chan-Hong Jeon[3], Jinseok Kim Kim[4], Eun-Mi Koh[1] and Hoon-Suk Cha[1], [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Jesang Hospital, Seongnam, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea, [4]Cheju National University College of Medicine, Cheju, South Korea

Purpose: T cell immunoglobulin-and mucin-domain-containing molecules (TIMs) are a novel family of transmembrane proteins that are involved in the regulation of Th1- and Th-2 cell-mediated immunity. TIM-3 is preferentially expressed on terminally differentiated Th1 cells and negatively regulates Th1 responses. Recently, Galectin-9, a ligand to TIM-3, has been shown to induce apoptosis of TIM-3 expressing cells in vitro and in vivo. The role of TIM-3 and its interaction with Galectin-9 in Rheumatoid Arthritis (RA), an autoimmune disease traditionally thought of as Th-1 mediated process, has not been fully understood. Thus, this study was undertaken to investigate the expression of TIM-3 in synovial tissue and peripheral blood mononuclear cells (PBMCs) in RA patients using quantitative real-time PCR and its correlation with RA disease activity measured by DAS28. We also investigated Galectin-9 mRNA expression in PBMCs and its correlation with FoxP3 mRNA level.

Method: Synovial tissues were available from 5 RA and 5 OA patients for immunohistochemistry and real time PCR. Blood samples were collected from 39 RA patients and 31 healthy controls. DAS28 was obtained at the time of venipuncture.

Results: TIM-3 mRNA expression was significantly higher in the synovial tissue in RA patients compared to those in OA patients (p=0.03). Immunohistochemistry showed that TIM-3 was expressed in the synovial sublining area in RA patients. No significant difference in TIM-3 mRNA level was found between PBMCs from RA patients and those from healthy controls. However, we observed a negative correlation between TIM-3 mRNA expression in PBMCs with DAS28 (r_s= -0.379, P=0.039). Furthermore, Galectin-9 mRNA was overexpressed in PBMCs in RA patients compared to the healthy controls (p=0.01), and was significantly higher in RA patients with low disease activity (DAS28 <3.2) compared to those with moderate to high disease activity (DAS28 ≥3.2, p=0.034). We also found that Galectin-9 mRNA expression in PBMCs in RA patients was positively correlated with FoxP3 mRNA expression (r_s=0.544, P=0.0004). The plasma level of interferon-gamma was significantly correlated with DAS28 (r_s=0.472, P=0.015) in RA patients, whereas no such correlation was observed between plasma interleukin-17 level and DAS28.

Conclusion: Our data suggest that TIM-3 and its interaction with Galectin-9 are closely associated with RA disease activity and may represent a potential therapeutic target in RA. In addition to the negative regulatory effect of Galectin-9 on Th-1 cells mediated through TIM-3, Gal-9 may exert its suppressive effect on RA disease activity by upregulating FoxP3, thereby inducing regulatory T-cells.

Inhibition of Bid Cleavage by High Akt Activity Protects Rheumatoid Synovial Fibroblasts From Fas-Induced Apoptosis. Carmen Conde, Samuel Garcia and Juan J. Gomez-Reino, Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain

Purpose: Synovial hyperplasia is a main feature of RA pathology that leads to cartilage and bone damage in the inflammed joints. There are several pieces of evidence suggesting that impaired apoptosis of resident synoviocytes is pivotal in this process. Apoptosis resistance involves defects in the extrinsic and intrinsic apoptotic pathways. Therefore, we aimed to investigate the connection between the two pathways and the role of PI3Kinase/Akt in the resistance to Fas-mediated apoptosis of FLS from rheumatoid athritis (RA) patients.

Method: FLS from RA patients were treated with two PI3 Kinase inhibitors, Wortmannine (Wort) and LY294002 (LY) before anti-Fas stimulation. Apoptosis was determined by two methods, quantification of nucleosomal release by ELISA and Hoechst staining. Bid expression was suppressed in RA FLS by small interfering RNA (siRNA) transfection. It was overexpressed by transfection with the pDsRed2-Bid vector. Western blot was used to determine phosphorilated Akt, caspase-9 and Bid expression.

Results: Apoptosis of RA FLS induced by anti-Fas stimulation was highly increased after treatment with PI3 Kinase inhibitors (p=0.008). Surprisingly, this change was accompanied by an increase in Bid cleavage. To check if the two findings are related, we suppressed Bid expression with siRNA. Absence of Bid made RA FLS completely resistant to Fas-induced apoptosis even in presence of Akt inhibition. On the contrary, Bid overexpression leads to significantly higher apoptosis (p=0.008). To further confirm that the mitochondrial pathway is involved in Fas-induced apoptosis in RA FLS, we pretreated with the caspase-9 inhibitor, LEHD before Fas stimulation. This treatment almost completely blocked apoptosis induced even in cells overexpressing Bid and treated with Wort.

Conclusion: These results show that the high typical phosphorilation of Akt protects RA FLS against apoptosis induced by Fas through inhibition of Bid cleavage, which is the bridge between the extrinsic and intrinsic apoptotic pathways. Therefore, PI3Kinase is a potential RA therapeutic target.

Altered Expression of MiR-155 and MiR-181a in Periphery Blood Mononuclear Cells of Rheumatoid Arthritis. Li Long[1], Jinxia Shi[1], Ru Li[1] and Zhanguo Li[2], [1]Bejing Univ People's Hosp, Beijing, China, [2]Peking University People's Hospital, Beijing, China

Purpose: 1. To Screen for the miRNAs differently expressed in Periphery Blood Mononuclear Cells (PBMCs) of RA by microarray experiments. 2. To further evaluate the expression of miR-155 and miR-181a in PBMCs of RA. 3. To determine the relevance between the expression of miR-155/miR181a and clinical as well as laboratory features. 4. To test whether inflammatory mediators can induce miR-155 and miR-181a in PBMCs of RA.

Method: 1. Total RNA was isolated from peripheral blood mononuclear cells obtained from 5 patients of RA and 5 normal controls. Expression profiling of miRNAs was performed in a microarray analysis. 2. MiR-155 and miR-181a were identified for further study by stem-loop real-time RT-PCR based on SYBR-Green. PBMC from 26 patients of RA and 23 normal controls were collected. 3. Associations between miR-155/miR-181a and the clinical and laboratory features of RA were evaluated. 4. Induction of miR-155 following stimulation with TNF-α , IFN-γand LPS of cultures of RA PBMCs was examined by real-time RT-PCR.

Results: 1. Expression profiling of miRNAs revealed significant differential expression of 46 miRNAs. MiR-155 was up-regulated in PBMC of RA than in normal controls, and miR-181a was down-regulated in RA group. 2. The expression level of miR-155 had a positive correlation with serum CRP level. 3. Expression of miR-155 was markedly up-regulated in PBMCs of RA after stimulation with TNF-α, IFN-γ and LPS, especially with TNF-α. 4. Similar up-regulated expression of miR-155 upon stimuli was observed in healthy controls, however, RA PBMCs exhibit much higher expression of miR-155 in response to stimuli.

Conclusion: MiRNA-155 may be a positive regulator in RA pathogenesis, while miRNA-181a may be a negative one. The expression of miR-155 is induced by stimulation with TNF-α , IFN-γ and LPS. Further studies are required to elucidate the function of miR-155 and miR-181a.

Human Six-Transmembrane Epithelial Antigen of Prostate 4 Is Induced by TNFα and Regulates IL-6 Secretion in Rheumatoid Synovium. Yoko Tanaka-Watanabe, Isao Matsumoto, Asuka Inoue, Reiko Minami, Taichi Hayashi, Daisuke Goto, Satoshi Ito and Takayuki Sumida, University of Tsukuba, Tsukuba, Japan

Purpose: Human six-transmembrane epitherial antigen of prostate 4 (STEAP4) is one of STEAP family as a homolog of mouse tumor necrosis factor-α-induced adipose-related protein (TIARP). The TIARP gene expression was remarkably increased in murine spleen and joints of glucose-6-phosphate isomerase (GPI)-induced arthritis in the effector phase, suggesting pivotal association to arthritis. TIARP mRNA and protein expression was known to be upregulated by TNFα in a dose-dependent manner by using adipocyte cell line, however a role of STEAP4 in rheumatoid arthritis (RA) is still unclear. We examined the expression of STEAP4 in PBMCs and joints from RA patients, and explored the relationship between STEAP4 and TNFα /IL-6.

Method: Complementary DNA was prepared from PBMC (20 RA, 16 healthy controls (HC)) and joint synovium (39 RA, 18 osteoarthritis (OA)).

1) The expression of STEAP4 gene was quantified by real time PCR.

2) The localization of STEAP4, EEA1 (known to be a lysosome marker) or CD68 was examined by fluorescence immunohistochemistry (IF).

3) Fibroblast like synoviocytes (FLS) obtained from RA synovium were treated with TNFα (2ng/ml), and the fluctuation of STEAP4 was evaluated by real time PCR, Western blot analysis or IF.

4) STEAP4 mRNA from primary synovial cell lines obtained from RA was knockdown by specific siRNA, and then cultured for 24 h. IL-6 mRNA was quantified by real time PCR.

5) STEAP4-GFP was transfected to FLS, then cultured for 24 h with TNFα. IL-6 secretion was detected by ELISA.

Results: 1) The expression of STEAP4 gene in RA synovium was not significantly different from OA (3.11±3.37 vs 4.16±3.61). The STEAP4 expression in PBMC from RA was not different from that in HC (0.57±0.54 vs 1.49±2.14). 2) STEAP4 was co-localized with CD68 in the FLS obtained from RA patients. STEAP4, EEA1 and CD68 were clearly co-localized in cytoplasm (lysosome) of the synovium. 3) In vitro analysis, the expressions of STEAP4 gene and protein in FLS were up regulated by TNFα-stimulation confirmed by real time PCR ($p<0.05$) and by Western blot analysis. 4) The expression of IL-6 mRNA was up regulated by STEAP4 siRNA ($p<0.05$). 5) The amount of IL-6 secretion was down regulated by over expression of STEAP4 ($p<0.05$).

Conclusion: STEAP4 expression was observed in human joints, clearly up regulated by TNFα stimulation, and controlled IL-6 secretion in FLS. Therefore, STEAP4 might play a potential role in the pathogenesis of TNFα- induced arthritis.

Adiponectin Affects Gene Expression of Rheumatoid Arthritis Effector Cells Including Synovial Fibroblasts, Lymphocytes, Endothelial Cells and Chondrocytes. Klaus W. Frommer[1], Birgit Zimmermann[1], Dirk Schröder[1], Andreas Schäffler[2], Christa Büchler[2], Fabia Brentano[3], Steffen Gay[4], Ulf Müller-Ladner[5] and Elena Neumann[6], [1]Justus-Liebig-University of Giessen and Kerckhoff-Clinic, Bad Nauheim, Germany, [2]University Hospital Regensburg, Regensburg, Germany, [3]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [4]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [5]Justus-Liebig-University of Giessen, Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim, Germany, [6]Justus-Liebig-University of Giessen and Kerckhoff-Clinic, 61231 Bad Nauheim, Germany

Purpose: Rheumatoid arthritis (RA) is associated with increased production of adipokines. Elevated levels of these cytokine-like mediators are found both in synovial tissue and synovial fluid of RA patients. RA effector cells may be affected by these adipokines. We therefore investigated the effect of the adipokine adiponectin on human synovial fibroblasts (SF), lymphocytes, endothelial cells and chondrocytes. We focused on the expression of proinflammatory and matrix-degrading mediators induced by adiponectin. We also analyzed the signaling pathways of adiponectin in RASF.

Method: Human RASF, lymphocytes, endothelial cells and chondrocytes were stimulated in vitro with adiponectin. Affymetrix microarrays and protein arrays were used to screen for changes in gene expression. Real-time PCR and immunoassays were used to quantify mRNA and protein levels, respectively. Signaling analysis was performed using intracellular chemical inhibitors.

Results: Adiponectin stimulation of RASF induced the expression and secretion of chemokines (protein: e.g. ENA-78, 22.5-fold), proinflammatory cytokines (mRNA: e.g. IL-11, 24.3-fold), other inflammatory molecules (mRNA: e.g. PGE synthase, 3.4-fold), growth factors (mRNA: e.g. fibroblast growth factor 10, 5.0 fold), genes involved in bone metabolism (mRNA: e.g. stanniocalcin-1, 19.8-fold) and matrix remodeling proteins (mRNA: e.g. MMP3 62.5 fold; protein: e.g. pro-MMP1 15.4-fold). Increased chemokine and cytokine secretion (e.g. IL-8, IL-6) was a common response to adiponectin stimulation found in all cell types studied, while chondrocytes additionally secreted increased levels of MMPs. Adiponectin-induced secretion of IL-6, MCP-1 and MMP10 by RASF was decreased using inhibitors against p38 MAPK and PKC but not by inhibitors against PKA and NFkB.

Conclusion: Adiponectin promotes the progression of RA primarily by inducing the secretion of proinflammatory molecules, chemokines and matrix-degrading enzymes in cell types involved in RA pathophysiology. While proinflammatory molecules such as IL-6 and PGES promote inflammation directly, chemokines attract and activate inflammatory cells further increasing inflammation. Additionally, elevated levels of MMPs lead to degradation of extracellular matrix and cartilage. According to our results, adiponectin-induced signaling in RASF is not only mediated by p38 MAPK but also by PKC, whereas PKA and NFkB appear not to be involved. Our data further elucidate the complex molecular mechanisms of RA.

The Noxa/Mcl-1 Axis in Rheumatoid Arthritis Synovial Fibroblasts. Arthur M. Mandelin II and Richard M. Pope, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Apoptosis is critical for the resolution of inflammation, but despite an environment which should favor it, little apoptosis is seen in rheumatoid arthritis (RA) joint tissues. This implicates a failure of apoptosis in RA. The Noxa/Mcl-1 axis is a cell fate decision pathway involved in the mitochondrial control of apoptosis. We previously showed that anti-apoptotic Mcl-1 is more abundant in RA synovial fibroblasts (SF) and macrophages, and that forced reduction of Mcl-1 promotes their apoptosis. However, the contribution of Mcl-1's inhibitory partner Noxa has not been studied. Since SF are crucial in RA pathology, we sought to characterize the Noxa/Mcl-1 axis in SF in order to determine its suitability as a therapeutic target.

Method: Synovial tissue was taken from RA and osteoarthritis (OA) patients at joint replacement, or from undiseased autopsy specimens, and SF were isolated and cultured. Cell lysates were analyzed for Noxa and Mcl-1 by Western blotting. Since the investigational drug obatoclax is considered a Noxa mimetic, we sought to determine whether it alters cell viability in SF by exposing cultured SF to media containing obatoclax or diluent and then examining mitochondrial integrity by the colorimetric MTT metabolism assay.

Results: Western blot data reveal the ratio of Noxa to Mcl-1 in normal SF and OA SF is in approximate balance at 0.91±0.09 (SEM) and 0.86±0.20, respectively. In contrast, Noxa is relatively less abundant than Mcl-1 in RA SF at a ratio of 0.64±0.08 ($p=0.020$ vs. normal, $n=8$). MTT assay data (see table) show a dose-response effect of obatoclax on the viability of all types of SF, and further suggest that RA SF are more sensitive to the drug than normal SF ($p < 0.02$ at 1.25 μM drug). Attempts to amplify the effect in RA SF by co-administration of the kinase inhibitors roscovitine or stauroporine, which reduce Mcl-1 levels, did not result in a significant synergistic effect (data not shown). Obatoclax had no effect on human *in-vitro* differentiated macrophages (not shown), arguing against nonspecific toxicity.

Cell Viability (%)

	Obatoclax concentration (μM)						
SF type	0	0.25	0.5	1	1.25	2.5	5
Normal	100±3.0	81.4±7.9	73.2±8.6	70.8±10.3	69.4±4.8*	66.2±2.7*	60.1±3.6*
OA	100±2.0	74.0±6.5*	67.0±5.5*	66.3±4.8*	58.2±2.4*	59.4±5.3	53.0±4.6
RA	100±3.4	66.7±9.8	60.6±9.2	54.2±9.1*	52.6±4.0*	44.6±6.7*	44.2±6.7*
Macroph.	100±3.2	110.0±1.3	107.0±2.1	111.4±1.1	96.3±3.1	94.1±4.5	93.6±3.1

* for each cell type indicates $p \leq 0.03$ vs. no drug

Conclusion: Our data suggest that the Noxa:Mcl-1 ratio is decreased in RA compared to osteoarthritis (OA) and non-diseased SF. Based on these data, we conclude that a relative lack of Noxa permits the sustained action of Mcl-1 in RA SF, and is responsible for their pathologic resistance to apoptosis. We further conclude that obatoclax is an effective pro-apoptotic agent in SF, and that differential sensitivity to this agent between RA and normal SF indicates that it merits further study in the context of this disease.

Atorvastatin and Simvastatin Inhibit Osteoclastogenesis by Decreasing the Expression of Receptor Activator of Nuclear Factor κ B Ligand (RANKL) in Rheumatoid Arthritis Fibroblast-Like Synoviocyte. Jeong Yeon Kim, Eun Young Lee, Eun Bong Lee, Yun Jong Lee, Yoo Jin Hong, Ji Ah Park, Hyun Jung Yoo and Yeong Wook Song, Seoul National University College of Medicine, Seoul, South Korea

Purpose: To determine the effects and their mechanism of simvastatin and atorvastatin on the expression of osteoprotegerin (OPG) and receptor activator of nuclear factor κ B ligand (RANKL) in RA fibroblast-like synoviocyte (FLS) and whether they inhibit osteoclastogenesis.

Methods: FLS was isolated from 3 RA patients and cultured in the presence of 20 ng/ml of TNF-α with or without atorvastatin or simvastatin for 24 hours. RANKL expression was assayed by Western blotting and reverse transcription-polymerase chain reaction (RT-PCR). OPG expression was measured by enzyme-linked immunosorbent assay and RT-PCR. Mevalonate was added to reverse the effect of atorvastatin and simvastatin on RA FLS. Phosphorylation of mitogen-activated protein kinases (MAPKs) [p38, Jun N-terminal kinase (JNK), extracellular signal-regulated kinase (ERKs)] and Akt was detected by Western blotting. Peripheral blood mononuclear cells (PBMC) and RA FLS were cocultured in the presence of macrophage colony stimulating factor, 1,25-dihydroxyvitamin D_3, and various concentrations of atorvastatin. Osteoclast formation was assayed by counting cells after staining for tartrate-resistant acid phosphatase.

Results: Both atorvastain and simvastatin inhibited the expression of RANKL in RA FLS in a dose dependent manner, and the suppression of RANKL was reversed by mevalonate. Atorvastatin and simvastatin did not affect the OPG expression in RA FLS. Atorvastatin suppressed TNF-α induced p38 phosphorylation in RA FLS and also significantly decreased TRAP-positive multinucleated osteoclast formation in the coculture of PBMC and RA FLS.

Conclusion: Both atorvastatin and simvastatin suppressed RANKL expression in RA FLS. Atorvastatin inhibited osteoclast formation in the coculture of PBMC and RA FLS. These results suggest that atorvastatin and simvastatin may inhibit osteoclastogenesis and bone destruction in RA patients.

ENO1 Enhances TNF-α, IL-1α/β, IFN-γand PGE2 Production in PBMC and Synovial Fluid Cells From Rheumatoid Arthritis Patients. Jae Seung Kang[1], Seyeon Bae[1], Jinhyun Kim[2], Churl Hyun Im[2], Ji Ah Park[2], Eun Bong Lee[2], Eun Young Lee[2], Wang Jae Lee[1] and Yeong Wook Song[2], [1]Seoul National University College of Medicine, Seoul, South Korea, [2]Seoul National Universitiy College of Medicine, Seoul, South Korea

Purpose: a-Enolase1 (ENO1) is 60-70 kDa of protein expressed ubiquitously. Recently, we found that the production of prostaglandin E_2 (PGE_2) from Burkitt's lymphoma cell line and activated PBMC is increased upon ENO1 stimulation via the activation of nuclear factor kappa B (NF-kB). Therefore, we investigate the roles of ENO1 on the regulation of inflammation and chronic inflammatory disease, rheumatoid arthritis (RA).

Methods: Human peripheral blood mononuclear cells were purified from healthy donors, RA and osteoarthritis (OA) patients and synovial fluids mononuclear cells in knee joint were purified from of RA patients by Ficoll-density gradient. The expression of ENO1 on PBMC and synovial fluids mononuclear cells were analyzed by flow cytometry. The production of inflammatory cytokines and PGE_2 by ENO1 stimulation were measured by ELISA. ChIP assay and immunoblotting were performed to examine signaling mediators for inflammatory cytokines and PGE_2 by ENO1 stimulation.

Results: ENO1 is highly expressed on PBMC and synovial fluids mononuclear cells from RA patients, but not from OA patients. TNF-a, IL-1a/b, IFN-g and PGE_2 production were markedly increased from concanavalin A (Con A)-activated PBMCs by ligation of ENO1. In addition, We also observed that those of inflammatory mediators are increased from PBMCs and synovial fluid mononuclear cells of RA patients upon ENO1 stimulation. The increased production of TNF-a and IL-1b were completely suppressed by pre-treatment of inhibitors for p38 MAPK (SB203580) and NF-kB (Bay11-7082) before ENO1 stimulation. The phosphorylation of p38 MAPK were increased in Con A-activated PBMC and PBMC and synovial fluids mononuclear cells from RA patients in a time dependent manner after ENO1 stimulation. In addition, the binding of NF-kB after ENO1 stimulation on promoter of TNF-a and IL-1b was also confirmed by ChIP assay.

Conclusion: Our results strongly suggest that ENO1 plays a critical role on the disease progression of RA via the induction of disease-related pro-inflammatory cytokines and PGE_2 production. Therefore, ENO1 can be used for effective therapeutic target of RA.

Notch Plays a Critical Role in Synovial Angiogenesis in Response to Hypoxia. Wei Gao, Aisling Kennedy, Chin Teck Ng, Catherine Sweeney, Douglas J. Veale and Ursula Fearon, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Purpose: Angiogenesis is a critical step in the progression of inflammatory arthritis, supporting cell recruitment and aberrant synovial proliferation. This process depends on endothelial cell (EC) survival mechanisms to preserve synovial blood vessels integrity. The Notch signaling pathway is critical for EC survival, however the upstream mechanisms involved in inducing these pathways in the inflamed joint remains to be elucidated.

Aim: To examine the expression and regulation of the Notch signaling pathways in the inflamed joint.

Method: Synovial whole tissue explants and primary synovial fibroblasts (RASFC) were established from synovial biopsies obtained at arthroscopy, along with microvascular endothelial cell cultures (HDEC). Hypoxia was measured *in vivo* in the synovial membrane using a LICOX probe. Notch 1IC, 3IC, 4IC an HIF-1a expression and distribution in synovial tissue, primary synovial fibroblasts and HDECs was assessed by immunohistology/immunofluorescence and/or western blot. The expression of Notch signaling components in response to growth factors VEGF and Angiopoietin-2 and potential upstream triggers of inflammation and hypoxia were assessed in RA synovial explants cultures and HDEC. siRNA or DAPT (a specific inhibitor of Notch) was utilized to directly block Notch expression.

Results: Notch 1IC, 3IC and 4IC and their downstream signaling components Hrt1, 2 and 3 and Hes were localized to perivascular and lining layer regions. We demonstrated strong expression of Notch 1IC, 3IC and 4IC by Western blot in RA and PsA synovial tissue lysates with minimal expression in OA. VEGF and Ang2 alone regulated Notch1-IC, 3IC and 4IC in RA synovial explants cultures and HDEC, however the combination of VEGF and Ang2 only had a synergistic effect on Notch 1IC expression compared to either alone. VEGF induced Notch 1IC was completely blocked in the presence of siRNA or DAPT, demonstrating a direct effect, which was reflected at a functional level by inhibition of MMP-2 and 9 expression and HDEC tube formation. We demonstrated profound hypoxia in synovial tissue (median [range] 3.2% [0.48-7%]). To mimic these conditions *in vitro* we exposed HDEC and RASFC to normoxic and hypoxic conditions of 3% (reflecting *in vivo* joint measurements) and demonstrated increased HIF-1a and Notch1-IC expression in response to 3% hypoxia.

Conclusion: These data demonstrate expression of Notch signaling pathways in the RA synovial joint. Notch 1IC is synergistically induced in response to VEGF +/- Ang2, which play a critical role in promoting angiogenesis and EC survival a process that maybe initiated upstream by hypoxia.

IL-17 Induces Production of Human Cartilage Glycoprotein-39 in Human Fibroblast Like Synoviocytes From Rheumatoid Arthritis Patients. Alison Gizinski, Judith Endres, Steven K. Lundy and David A. Fox, Univ of Michigan, Ann Arbor, MI

Purpose: We have previously shown that RA fibroblast-like synoviocytes (FLS) can function as antigen presenting cells (APC) and can present peptides derived from the human cartilage glycoprotein of 39 kD molecular mass (HC gp-39), a protein found within joint tissues, to activated T cells *in vitro*. Moreover, RA FLS can extract and present HC gp-39 from synovial fluid. It is also known that HC gp-39, a candidate autoantigen in RA, can be produced by FLS. These studies were undertaken to determine the influence of pro-inflammatory cytokines on the production of HC gp-39 in RA FLS, to further define the potential role of FLS in contributing to autoreactive immune responses in inflamed synovial tissues.

Methods: FLS were obtained by collagenase digestion of human

synovial tissue obtained at arthroplasty or synovectomy from RA and OA patients, and were used at passage >4 from primary cultures. Cells were maintained in CMRL medium supplemented with 20% fetal calf serum, 2 m*M* glutamine, 50 units/ml penicillin and 50 mg/ml

streptomycin. FLS were cultured in 6 well plates at 200,000/well and were allowed to adhere for 48 hrs prior to addition of cytokines. Supernatants were collected 120 hrs after exposure to cytokines for ELISA. mRNA was isolated 16 hrs after exposure to cytokines. ELISA for HC gp-39 protein was performed using a YKL-40 ELISA Kit (Quidel, San Diego, CA) according to manufacturer's protocol. Quantitative real time polymerase chain reaction (qRT-PCR) was used to provide quantitative measurements of gene transcription of HC gp-39 in human FLS that had been exposed to varying concentrations of IL-17, TNF-a and IFNg in cell culture.

Results: Exposure of FLS from RA patients to increasing concentrations of IL-17 resulted in significantly higher concentrations of HC gp-39 protein in cell supernatants as measured by ELISA compared to controls. Exposure to increasing concentrations of TNF-a and IFNg resulted in significantly decreased amounts of HC gp-39 protein that could be detected in the supernatants of FLS from RA patients compared to controls. Exposure to varying concentrations of IL-15, IL-1b and IL-6 had no discernable effect on HC gp-39 protein concentration in cell supernatants. After exposure to IL-17 at varying concentrations for 16 hrs, no change in mRNA for HC gp-39 was measured by qRT- PCR compared to controls. Likewise, after exposure to TNF-a for 16 hours, no change in mRNA for HC gp-39 was measured by qRT-PCR compared to controls. However, when human FLS from RA patients were exposed to increasing concentrations of IL-17 and TNF-a simultaneously for 16 hrs, there was a significant four fold increase in mRNA for HC gp-39 compared to GAPDH and appropriate controls.

Conclusion: RA and OA FLS can not only function as APCs for the human autoantigen HC gp-39, but also express high levels of this protein. The effects of pro-inflammatory cytokines on expression of HC gp39 mRNA and secretion of HC gp39 protein are distinct, and our results indicate a primary role for IL-17 in upregulation of this arthritogenic autoantigen. These findings suggest the possibility of a positive feedback loop within the RA joint, involving T cell activation by an autoantigen that is in turn upregulated by the T cell cytokine IL-17.

Rheumatoid Arthritis Clinical Aspects: Treatment Response - Biologics

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1593

Safety Profiles of Disease-Modifying Anti-Rheumatic Drugs and Biologics in Patients with Rheumatoid Arthritis: Observations From the RADIUS Registry. Allan Gibofsky[1], W. Palmer[2], Edward C. Keystone[3], Michael H. Schiff[4], JingYuen Feng[5], Scott Baumgartner[5] and Joseph A. Markenson[6], [1]Hospital for Special Surgery, New York, NY, [2]Westroads Medical group, Omaha, NE, [3]Professor of Medicine/University of Toronto, Toronto, ON, [4]University of Colorado, Greenwood Village, CO, [5]Amgen Inc., Thousand Oaks, CA, [6]Hosp for Special Surgery, New York, NY

Purpose: To assess the safety profiles of traditional DMARDs and biologic agents in patients (pts) with RA being treated at rheumatology clinics in North America.

Methods: Rheumatoid Arthritis DMARD Intervention and Utilization Study (RADIUS) comprises 2 prospective, 5-year, multicenter observational registries of over 10000 pts with RA. RADIUS registries were designed to gain a better understanding of the safety of different treatment patterns prescribed by rheumatologists. Pts with RA who required a new DMARD or biologic (either addition or switch) were eligible for enrollment. In RADIUS 1 (R1), pts initiated any new DMARD at entry; in RADIUS 2 (R2), pts initiated etanercept (ETN) at entry. Pts in both registries could switch to any other approved RA therapy at the discretion of their rheumatologist. Safety events analyzed include serious adverse events (SAEs); serious infectious episodes (SIEs) and other infections; and events of medical interest. Exposure-adjusted event rates represent the number of events per 100 pt-yrs of exposure. Safety events were coded using MedDRA terminology.

Results: Safety data from R1 (4968 pts enrolled) and R2 (5103 pts enrolled) reported in these analyses were collected through December 2008. Of pts who had received ETN at entry, 71% of pts in R1 and 63% in R2 were still receiving ETN at month 12. Exposure-adjusted incidence rates of SAEs and events of interest are shown (Table). All 95% confidence intervals for relative risk (RR) compared to methotrexate crossed 1 (P = not significant). The most common SAE recorded in both registries was pneumonia. Of all enrolled pts, 181 pts

in R1 and 131 pts in R2 have died, for adjusted rates of 1.23 and 0.84 events/100 pt-yrs and standardized mortality ratios (observed vs expected deaths) of 0.89 and 0.83, respectively.

Conclusion: In this large group of pts with extended follow-up, no unexpected safety signals and no trends of concern have been noted. Across multiple therapies, the rates for SAEs, SIEs, and events of interest in this pt population are comparable to the rates observed with methotrexate treatment. Results from this registry and others are important in validating data reported in pharmaceutical long-term extension safety studies and thereby provide information for use in rheumatology practice.

Do Men and Women with Rheumatoid Arthritis Respond Differently to Treatment? Damini Jawaheer[1], JingYuan Feng[2], James Louie[1] and Harold Paulus[1], [1]UCLA, Los Angeles, CA, [2]Amgen Inc., Thousand Oaks, CA

Purpose: To examine gender differences in treatment responses in rheumatoid arthritis (RA) patients.

Method: We examined gender differences in RA in two unique, real-world prospective observational cohorts, each with patients from approximately 350 rheumatology practices across the US, as part of the RA DMARD Intervention and Utilization Study (RADIUS). Patients requiring a new disease-modifying anti-rheumatic drug (DMARD) were enrolled in RADIUS 1 (n=4359), and patients initiating etanercept (ETN) were enrolled in RADIUS 2 (n=4623). We investigated gender differences a) in disease manifestations, and b) in proportions of patients who achieved a modified ACR20 (mACR20) [1] response 6 months after start of treatment, using Chi-square tests for categorical variables, and the Wilcoxon-Mann-Whitney test and t-test for continuous variables.

Results: Overall, a higher proportion of women had been treated with DMARDs than men prior to study entry (RADIUS 1: 74.8% vs. 68.7%, p=0.0001; RADIUS 2: 92.4% vs. 90.6%, p=0.059). At study entry, all patients had active disease, as assessed by the Clinical Disease Activity Index (CDAI) (mean±SD:35.6±16.7 RADIUS 1; 36.2±15.9 RADIUS 2). Men had significantly later mean age at onset than women and shorter disease duration, whereas women had worse function (HAQ), increased arthritis-related pain (pain visual analog scale, VAS), and higher physician global scores (table 1). Interestingly, no consistent gender differences were observed in seropositivity for rheumatoid factor, tender and swollen joint counts and disease activity (CDAI). Among patients with moderate/severe RA (CDAI>10), there was a non-significant trend for higher proportions of men achieving a mACR20 response at 6 months follow-up, for all treatment regimens (table 1). Similar results were observed when we restricted our analyses to patients with early RA (< 1 year duration).

Conclusion: These results demonstrate that, in RA, significant differences in disease manifestations relating to function and pain are observed between men and women. It is uncertain whether the observed trend toward differences in treatment response between men and women, at 6 months, is influenced by gender, disease state, or both.

Rheumatoid Arthritis: Insights, Strategies and Expectations—Global Results of the RAISE Patient Needs Survey. Iain B. McInnes[1], B. Combe[2] and Gerd R. Burmester[3], [1]University of Glasgow, Glasgow, United Kingdom, [2]Immuno-Rheumatology, Montpellier, France, [3]Charite University Hospital, Berlin, Germany

Purpose: Understanding the perceptions of patients who live with rheumatoid arthritis (RA) and their views on its treatment can provide a valuable perspective to the rheumatologist and may help to shape our management strategies. The RAISE survey was designed to reveal the perceptions of RA patients on their disease and therapy.

Method: A questionnaire was developed with input from 53 rheumatologists from 8 European countries and Canada. Questions included, but were not limited to, the following topics: diagnosis, disease information sources, daily living with RA, quality of life (QoL) and views on current therapy and treatment options. Surveyed patients were either on biologic therapy or biologic naïve but eligible for biologic treatment based on broad criteria of a DAS28 >3.2 or an acute phase response, plus erosive disease and moderate-to-severe active RA.

Results: A total of 586 patients, approximately 30 biologic naïve and 35 on anti-TNF therapy from each of 9 countries, were interviewed. Mean age at onset of RA symptoms was 41 years. Patients reported that most physician-patient communication centered on symptoms and treatment; less frequently discussed was the impact of RA on QoL. While all patients reported improvement on their current versus previous treatment, biologic users had significantly more ‘good’ days per month than biologic-naïve patients (71% vs 61%, respectively). The survey revealed a large percentage of patients (22%) reporting high levels of pain. For most patients, biologic therapy improved their symptoms and overall QoL compared with their previous non-biologic therapy. Biologic-experienced patients were significantly more satisfied with their treatment than biologic-naïve patients. Patients (41%) use the internet as a resource for information about RA. Approximately 20% of biologic users require help (emotional and/or physical) in preparing and/or administering subcutaneous injections and have concerns around injection site pain or irritation. Despite being eligible for biologic therapy by a broad definition of criteria, 62% of biologic-naïve patients were not aware of biologic therapies and the majority (88%) were never recommended a biologic treatment. Factors influencing

willingness to try a new medication included symptom control, stopping disease progression and improving the overall experience of living with RA. Patients were most interested in a product that worked consistently (76%), was simple to use (69%) and had a less frequent dosing schedule (75%).

Conclusion: This large patient survey provides key insights into how RA patients live with their disease and how therapy has impacted them. The data reveal that biologic therapy has had significant impact on improving patients' lives. However, all patients reported some level of continuing symptoms and current pain indicating unmet clinical need.

The Comparative Effectiveness of Biologic Therapies Versus Traditional DMARDs for Fatigue in Rheumatoid Arthritis - A Systematic Review of Clinical Trials. Richard CJ Campbell, Gabrielle H. Kingsley and D. L. Scott, King's College London, London, United Kingdom

Purpose: The OMERACT initiative have considered the appropriateness of fatigue as an outcome measure in RA and recently concluded was that, where relevant, fatigue should be measured in RA clinical trials. Recent studies, largely investigating effectiveness of newer biologic therapies, have been including fatigue as an outcome. Here, the comparative effectiveness of biological therapies versus traditional DMARDs is compared across clinical trials.

Method: Original clinical trials limited to English language were retrieved using MEDLINE, EMBASE and The Cochrane Library through the OVID gateway and analysis of retrieved bibliographies. The 'population' was RA patients. The 'intervention' was anti-rheumatic drugs exploded to include therapies used in routine clinical practise. These were combined with terms fatigue, tiredness and lassitude. Other search terms included were FACIT-F and SF-36.

A quality checklist was employed to check studies against 6 specific quality criteria. Studies were ranked according to this checklist and size of study.

All identified studies were analysed for therapeutic approaches, type of fatigue data collected, length of intervention and mean change in fatigue. Data were presented narratively and also graphically, where possible, for each fatigue scale. Mean differences for FACIT-F, SF36 and Fatigue VAS weighted for number of study participants were calculated for the RCTs only (extension studies were excluded from this analysis).

Results: 16 clinical trials were identified (9 RCTs, 3 extension studies and 3 observational studies). All RCTs were considered to be of high quality. Of 6 quality criteria, 7 studies fulfilled all and 2 fulfilled all but one criterion. 6 different types of outcomes for fatigue were used altogether. FACIT-F was the most common. Intervention periods ranged from 8 weeks to 52 weeks (3 years for the longest extension study).

All 9 RCTs compared fatigue between biologic therapies and standard DMARD therapies. All of the 12 primary trials except one found that mean fatigue reduced most in the biological treatment arm. Mean differences in mean change in fatigue (weighted for number of study participants) between biological and control arms for FACIT F was 3.41, SF36 was 4.14 and fatigue VAS 15.8mm (all in favour of biological treatment arms).

Conclusion: This study suggests that biological therapies reduce RA fatigue more than traditional DMARDs in clinical trials. The one study that does not is cross sectional in design, where treatment followed clinical practise rather than pre- determined protocol. Many of the studies are for relatively short intervention periods (although the few extension studies suggest maintenance of this superiority). Some studies compared newly introduced biologic treatments against established DMARD regimes which, when presenting results regarding change, may be misleading since they do not account for rate of change between these newly introduced and established regimes.

1597

Physician Preference Motivates Use of Anti-TNF Therapy Independent of Clinical Disease Activity. Jeffrey R. Curtis[1], Lang Chen[1], Leslie R. Harrold[2], Pongthorn Narongroeknawin[1], George Reed[3] and Daniel H. Solomon[4], [1]UAB, Birmingham, AL, [2]UMass Medical Schl, Worcester, MA, [3]University of Massachusetts Medical School, Worcester, MA, [4]Brigham & Womens Hospital, Boston, MA

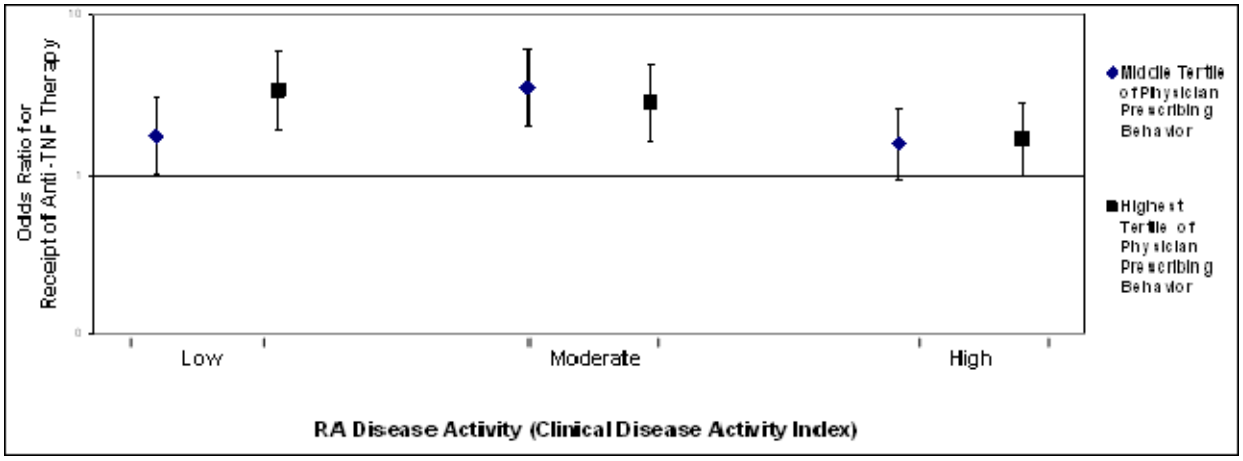
Purpose: Physician preference has been previously shown to be an important determinant of prescription patterns, independent of patient-specific factors. We evaluated whether physician preference was important in the decision to select anti-TNF therapy rather than non-biologic disease modifying anti-rheumatic drugs (DMARDS) among rheumatoid arthritis (RA) patients initiating a new RA medication.

Method: Using data from the Consortium of Rheumatology Researchers of North America (CORRONA), we identified biologic-naïve RA patients initiating either anti-TNF therapy or a DMARD in 2001-2008. Physician preference for use of anti-TNF agents was calculated using data from the preceding calendar year for each physician's other RA patients. Multivariable logistic regression with generalized estimated equations accounted for clustering of patients within physician practice and evaluated the relationship between physician preference and receipt of anti-TNF therapy, controlling for patient-related factors and disease activity using the Clinical Disease Activity Index (CDAI).

Results: We identified 1,532 RA patients initiating anti-TNF therapy or a DMARD. In models adjusting for tender and swollen joint counts and global disease activity, physician preference for use of anti-TNF therapy was an independent predictor of receipt of these agents. Patients of physicians in the highest and middle tertiles of physician preference had a 2.76 (95% CI 2.02 – 3.77) and 1.79 (1.33 – 2.40) greater likelihood to receive anti-TNF medications, respectively. As shown in the Figure, physician preference for use of anti-TNF therapy had a somewhat greater influence on prescribing decisions for RA patients with low or moderate disease activity (CDAI) than for patients with high disease activity.

Conclusion: Physician preference is an important determinant of patients' receipt of anti-TNF therapy and may be useful to examine in future studies of RA treatment patterns, costs, and medication safety.

Figure: Adjusted Relationship Between Physician Preference For Use of Anti-TNF Therapy (calculated using data from his/her other RA patients) and the Initiation of Anti-TNF Therapy (vs. non-biologic DMARDs) for the next RA patient, by Disease Activity*



Note: the lowest tertile of physician preference for Anti-TNF therapy is referent and corresponds to an Odds Ratio of 1.0

* RA disease activity quantified using the Clinical Disease Activity Index (CDAI) and categorized as low (CDAI <= 10), moderate (CDAI > 10 to <= 22), or high (> 22)

1598

Physician's Perception of (in)Acceptable Disease Activity in Rheumatoid Arthritis: Some Clues From a 7 Year Follow-up Study of Patients Treated with Infliximab. Bert Vander Cruyssen[1], Patrick Durez[2], Rene Westhovens[3] and Filip De Keyser[4], [1]University Hospital Ghent, Ghent, Belgium, [2]Univ Catholique de Louvain, Brussels, Belgium, [3]University Hosp KU Leuven, Leuven, [4]Ghent University Hospital, Ghent, Belgium

Purpose: The definition of (in)acceptable disease activity state in rheumatoid arthritis (RA) is important not only for standardization of care in daily practice; in some countries social security instances are seeking to implement such definitions as reimbursement criteria for expensive biological treatments. This study is based on the results from a Belgian expanded access program in which 511 patients with active refractory and erosive RA were treated with intravenous infusions of infliximab (IFX) in combination with methotrexate (MTX). Patients were followed over 7 years.

Method: Between 2000 and 2001, 511 patients were enrolled in this nationwide program. Patients had a median disease duration of 10 years and had failed an average of 3.9 disease modifying anti-rheumatic drugs (DMARDs), including MTX. Patients were treated with IFX at week 0, 2, 6 and every 8 weeks thereafter with a standard dose of 3 mg/kg. From week 30 on, patients could receive a dose increase, which was decided at week 22. This decision to give or not to give a dose increase is the first proxy of “physician’s perception of acceptable/inacceptable disease activity state”. A second proxy of this perception is given by the DAS28 measured at the moment to stop IFX treatment due to inefficacy

Results: ROC analysis at week 22 (decision to give a dose increase; data collected between 2000 and 2002) provides a clue to define cut-offs of "acceptable/inacceptable disease activity”. A DAS28 score of 3.2 corresponded with 90% sensitivity; DAS28 score of 5.2 corresponded with 90% specificity. As such, a cut-off can be proposed in function of the desired sensitivity and specificity (table 1). Mean DAS28 at the moment of stopping the treatment due to inefficacy evolved over years from 5.6 in 2001 to 4.8 in 2008. Regression analysis confirmed this trend of a decline of cut-off for acceptable/inacceptable disease activity with 0.17 units of DAS28 per year.

Conclusion: This analysis provides some clues to define DAS28 cut-offs for (in)acceptable disease activity in RA. Over years, in parallel with the increase in the number of treatment options becoming available, less remaining disease activity seemed to be acceptable.

Table 1: ROC-analysis for the association of DAS28 and the decision to give a dose increase (data collected between 2000 and 2002)

DAS-cut-off	Sensitiviy	Specificity
2.0	0.99	0.13
2.5	0.99	0.22
3.0	0.98	0.38

1599

Risk Factors Associated with Depletion of Endothelial Progenitor Cells in Rheumatoid Arthritis Patients and Effect of Anti-TNF Therapy On EPCs Restoration. Yun-Jung Park[1], Ki-Jo Kim[2], Ji-Young Kim[3], Jin-Jung Choi[4], Wan-Uk Kim[5] and Chul-Soo Cho[6], [1]Catholic University of Korea, South Korea, [2]Catholic University of Korea, St. Mary's Hospital, Seoul, South Korea, [3]Catholic univeristy of Korea, Seoul, South Korea, [4]Bundang CHA General Hospital, CHA University, Bundang, South Korea, [5]St. Vincent Hospital, Suwon, South Korea, [6]St. Mary's Hospital, Seoul, South Korea

Purpose: It has been shown that circulating endothelial progenitor cells (EPC) decreased in rheumatoid arthritis (RA) patients, but the precise factors linked to reduction of EPC remain elusive. In this study, we determined the circulating EPC number in RA patients and variables associated with its depletion, and compared the effects of anti-TNF therapy and disease modifying anti-rheumatic drugs (DMARD) on the restoration of EPC.

Method: 164 RA patients and 67 age-gender matched control subjects were included. Circulating EPC was quantified by flow cytometry based on expression of CD34 and KDR. 85 RA patients were randomly assigned in 24-week comparator-controlled study to receive anti-TNF therapy (n=59) and DMARD alone (n=26). Endothelial function assessed by flow-mediated dilatation (FMD) was measured before and after the completion of study.

Results: The median EPC number was significantly reduced in RA patients than control subjects (44 vs 71 cells/ml, $P<0.01$). EPC number was significantly lower in RA patients with rheumatoid factor, anti-CCP antibody and bony erosion ($p=0.04$, $p=0.01$, and 0.03, respectively). The EPC number was inversely correlated with disease duration and cumulative C-reactive protein levels ($p<0.01$ for both). In multiple regression analysis, longer disease duration, cumulative CRP levels, and ESR were associated with EPC depletion. Compared to DMARD treatment, anti-TNF therapy led to further increase the EPC number and FMD change ($p<0.05$ for both). In parallel, patients in the highest tertile of EPC showed significantly higher FMD than the others at 24 weeks ($p<0.05$).

Conclusion: Circulating EPC was reduced in RA patients. Longer disease duration, inflammatory burden were associated with reduction of EPC. Anti-TNF therapy has beneficial effect on restoration of EPC depletion but also improving endothelial dysfunction.

Quantification of Dyslipidemia Among Patients with Rheumatoid Arthritis and Changes Associated with Initiation of Anti-TNF Therapy: A Retrospective Database Analysis. J. R. Curtis[1], A. John[2] and O. Baser[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Roche, Nutley, NJ, [3]University of Michigan Health Systems, Ann Arbor, MI

Purpose: Previous research suggests that onset of rheumatoid arthritis (RA) results in decreased lipid levels. Several small studies have shown that tumor necrosis factor-α inhibitor (TNFi) treatment in RA patients (pts) generally leads to increases in total cholesterol (TC), high-density lipoprotein (HDL), and triglyceride (TG) levels (Choy, 2009). This analysis compared lipid levels in pts with RA and osteoarthritis (OA) [objective 1] and determined lipid level changes in RA patients after initiation of TNFi treatment [objective 2].

Method: We used medical and pharmacy claims and laboratory results from a national commercial administrative claims database. Adults had diagnoses of either RA or OA between April 2005 and March 2008; test results for TC, low-density lipoprotein (LDL), HDL, or TG; and

no other inflammatory diseases. For objective 1, baseline was defined as 6 months before lipid test results. For objective 2, pts had at least1 lipid test before and 1 at least 6 weeks after TNFi initiation; baseline was defined as 6 months before TNFi initiation. Results were stratified by whether patients were already taking lipid-lowering medication (LLM) at the time of TNFi initiation. Propensity score matching [objective 1] and multivariate regression [objectives 1, 2] were used to control for baseline differences between RA and OA pts.

Results: We identified 12,319 RA pts and 29,621 OA pts who met eligibility criteria. The proportion of pts with diagnosed hyperlipidemia was significantly lower for RA than OA (49% vs 57%, $p<0.0001$). RA (vs OA) pts were younger (54 vs 59 mean years) and had higher mean Charlson Comorbidity Index (1.2 vs 0.5) and Chronic Disease Score (4.5 vs 3.1). Use of baseline LLM was lower in RA pts (27% vs 30%; $p<0.0001$). After controlling for baseline differences, pts with RA (vs OA) had significantly lower TC and LDL levels (Table); RA (vs OA) pts had lower adjusted mean TC (196 mg/dL vs 201 mg/dL, $p<0.0001$) and LDL (113 mg/dL vs 117 mg/dL, $p<0.0001$) values. Among the subgroup of RA pts not taking LLM, we observed small but significant increases after initiation of TNFi in TC (5 mg/dL; $p<0.0001$), LDL (4 mg/dL; $p=0.004$), and HDL (1 mg/dL; $p=0.02$). These changes associated with TNFi initiation were not observed in the subgroup of RA pts already taking LLM.

Conclusion: Results of this real-world analysis indicate that RA pts have lower average lipid levels compared with OA pts. In RA pts, initiation of TNFi therapy reversed this effect and modestly increased lipid levels except in pts already taking LLM. Aggressive management of dyslipidemia and decreasing systemic inflammation with biologic agents may reduce excess cardiovascular disease associated with RA.

Table. Proportion of RA and OA pts in each ATP-III lipid category after propensity score matching

Lipid level, mg/dL	RA n=11,053 % of pts	OA n=11,053 % of pts	*p*
Total cholesterol			
Desirable, <200	58.1	52.4	<0.0001
Borderline high, 200-239	30.5	33.0	0.0001
High, ≥240	11.4	14.6	<0.0001
Low-density lipoprotein			
Optimal, <100	36.6	31.6	<0.0001

Women with Rheumatoid Arthritis Have Better Responses to Anti-TNF Therapy in the First Year, but Men Respond Significantly Better in the Long-Term – Results From the Danish DANBIO Registry. Damini Jawaheer[1], Jorn Olsen[1] and Merete L. Hetland[2], [1]UCLA, Los Angeles, CA, [2]DANBIO, Copenhagen Univ. Hospital, Copenhagen, Denmark

Purpose: To investigate gender differences in anti-TNF treatment outcomes over time in rheumatoid arthritis (RA) patients.

Method: We investigated treatment outcomes over 54 months in men and women with RA who initiated anti-TNF therapy between January 2003 and June 2008 in Denmark. Demographic and clinical data collected every 6 months by trained rheumatologists from hospitals* nationwide were documented in the DANBIO Registry. Gender differences in disease features at baseline were examined using Chi-square tests for categorical variables, and the Mann-Whitney and t-tests for continuous variables. Using a generalized estimating equations (GEE)

model for repeated measures, we also examined changes in disease outcomes in men and women over time, including ACR20 and EULAR responses, adjusting for baseline values of the disease activity score (DAS28CRP4), disease duration and anti-TNF treatment.

Results: At initiation of anti-TNF therapy (baseline), men (n=656) and women (n=1,852) had equally active disease (mean±SD DAS28CRP4: 5.1±1.3). Men had significantly later age at diagnosis, shorter disease duration, and higher C-reactive protein (CRP) (table 1). Women had worse disability (HAQ-DI), pain visual analogue scale (VAS), patient global scores, and fatigue VAS, and more tender joints. There were no differences in physician global scores, swollen joint counts and in proportions of men and women with erosions (73%). The GEE models revealed that, although women showed better responses during the first 12 months of treatment, in the longitudinal setting, men were more likely to achieve an ACR20 treatment response as well as a EULAR "good" response; these differences were statistically significant, and of clinical relevance, from 3 years onwards (ACR20: p=0.037, EULAR: p=0.035) (fig 1). Loss to follow up was similar in both genders and hence did not account for differences in response. No significant gender differences were observed in DAS28CRP4 scores, HAQ-DI, pain VAS, patient global scores and fatigue VAS over time, although women consistently had higher mean scores.

Conclusion: In this RA cohort, women had a better response to anti-TNF therapy for the first year of treatment. However, in the long-term, men responded better, with a significantly better response after 3 years of treatment.

Validation of An Algorithm Using Genome-Wide SNP Analysis for Prediction of Responders and Non-Responders, and Adverse Events of Infliximab- or Etanercept-Treated RA Patients by Using Two Population Samples From Multiple Medical Cohorts.

Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], Sayumi Toriyama[3], Kunihiko Nakahara[3], Takafumi Hagiwara[1], Takako Miura[1], Kosuke Okuda[1], Akira Sagawa[4], Takeo Sakurai[5], Hiroaki Matsuno[6], Tomomaro Izumihara[7] and Eisuke Shono[8], [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]HuBit genomix, Inc., Tokyo, Japan, [4]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [5]Inoue Hospital, Takasaki, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [8]Shono Rheumatology Clinic, Fukuoka, Japan

Purpose: Infliximab (IFX) and etanercept (ETN) are efficient biologic agents for inflammatory diseases such as RA. However, there is no method for prediction of responders or non-responders, and which patients are prone to adverse events. We established and validated an SNP algorithm for prediction of responders or non-responders, and adverse events among IFX- or ETN-treated RA patients by using multiple medical cohorts.

Methods and Patients**:** The first population samples included 187 RA patients and the second population samples included 206 patients, total 393 patients from 6 hospitals in different regions of Japan. Efficacy was determined by DAS28(CRP) within 24-30 weeks after the initial treatment with the biologics according to EULAR criteria (good and moderate response group- 'responders', poor response group- 'nonresponders'), and adverse events such as fever, skin manifestations, and GI tract symptoms were documented. Genome-wide SNP genotyping was performed by HumanHap300K chip. Case-control analyses between 285,548 SNPs and efficacy or adverse events were examined by chi-square tests. We selected 10 SNPs associated with IFX- or ETN- responsiveness, or adverse events which are common in both analyses of the first and second populations ($p < 0.02$).

Results: For IFX responsiveness, accuracy ((true positive+true negative)/total) of the algorithm of the first, second and total populations were 85.1%, 80.4% and 82.8%. For IFX adverse events, accuracy of the algorithm of the first, second and total populations were 86.3%,

88.0% and 87.3%. In responsiveness of ETN, accuracy of the algorithm of the first, second and total populations were 95.5%, 96.3% and 95.9%. The accuracy of the algorithm of ETN adverse events in the first, second and total populations were 78.3%, 88.8% and 83.4%. An endocrine hormone-acting gene was revealed in the associated genes, linking association of TNF with the endocrine hormone.

Conclusion: The highly accurate algorithm using SNP analysis may prove useful in the prediction of responsiveness or determining those patients prone to adverse events before treatment of IFX or ETN, and may facilitate future tailor-made treatment of anti-TNF biologic agents.

Anti Tumour Necrosis Factor Alpha Therapy Improves Insulin Resistance in Normal-Weight but Not in Obese Patients with Rheumatoid Arthritis. Antonios Stavropoulos-Kalinoglou[1], Giorgos S. Metsios[1], Vasileios F. Panoulas[2], Yiannis Koutedakis[1] and George D. Kitas[2], [1]University of Wolverhampton, Walsall, United Kingdom, [2]Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom

Purpose: Insulin resistance (IR) associates with obesity and is a predisposing factor for cardiovascular disease (CVD) and type-II diabetes. In Rheumatoid Arthritis (RA), IR is common and is a potential contributor to the increased CVD risk of these patients. Anti tumour necrosis factor alpha (anti-TNFa) therapies are suggested to reduce CVD risk in RA; they have also been suggested to improve insulin kinetics. However, obesity – a potent contributor to IR – might influence the way anti-TNFa therapy affects insulin kinetics in RA. The aim of this longitudinal study was to compare the effects of anti-TNFa therapy on insulin kinetics between normal weight and obese individuals with and without IR.

Method: Patients embarking on anti-TNFa treatment, who were of normal-weight but had IR (N+IR), or were obese and had IR (O+IR), were invited to participate. Assessments included body mass index (BMI), CVD risk factors and RA disease characteristics before and following six months of anti-TNFa treatment. The results of the N+IR and O+IR patients were compared to age-, gender-, BMI-, disease duration- and smoking status-matched normal-weight patients without IR (N-IR) and obese patients without IR (N-IR) respectively. IR was defined as a HOMA (Homeostasis Model of Assessment) ≥ 2.5, or a QUICKI (quantitative insulin-sensitivity check index) ≤ 0.333. Patients with diabetes mellitus, or using anti-diabetic medication were excluded from the study. A total of 20 patients (16 women, age range 45-69), 5 in each of the groups, were assessed for this study.

Results: One-way Analysis of Variance (ANOVA) found no differences in BMI in any of the groups following six months of treatment ($p>0.05$). Inflammation and disease activity were significantly reduced in all groups ($p<0.05$) but to a similar extend (p for differences between groups >0.05 in all cases). Repeated measures ANOVA showed that the treatment resulted in greater (beneficial) changes in HOMA ($p=0.031$), QUICKI ($p=0.025$), systolic BP ($p=0.048$) and triglycerides ($p=0.034$) in N+IR patients compared to N-IR. In the obese groups, there was only a non-significant trend of improvement in IR [O+IR ($p=0.075$); O-IR ($p=0.082$)]. There were no differences in the magnitude of improvements between these two groups in HOMA, QUICKI, or any other CVD risk factors.

Conclusion: Anti-TNFa therapy improves insulin kinetics in normal weight but not in obese RA patients with IR. This suggests that in normal weight RA patients, IR associates mostly with active inflammation and is largely reversible, while in obese RA patients IR associates mostly with obesity and does not reverse with potent anti-inflammatory therapy, such as the anti-TNFs. This has obvious implications for CVD prevention strategies in RA.

Is the Response to Infliximab Influenced by Body Mass Index in Rheumatoid Arthritis Patients? Ruth Klaasen, Carla A. Wijbrandts, Danielle M. Gerlag and Paul P. Tak, Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: The influence of body mass index (BMI) on rheumatoid arthritis (RA) is unclear. Obesity is characterised by low-grade inflammation and could potentially aggravate disease activity and severity. On the other hand, an association has been suggested between high BMI and less erosive disease (1). Therefore, we investigated prospectively the influence of the BMI on the response to infliximab therapy in RA patients. Infliximab was chosen, as it is dosed per body weight.

Methods: In 91 patients with active RA (DAS28≥3.2) in spite of stable methotrexate treatment, we calculated the BMI before initiation of infliximab treatment (3 mg/kg according to the standard dosing regimen). At week 16 the clinical response was defined by a decrease in DAS28 ≥ 1.2 (twice the measurement error of the DAS28 over time, representing a clinically significant improvement).

Results: Mean BMI was 26.11 (SD ± 4.88) and BMI varied between 17.40 and 42.19. BMI was <20 in 8.8%, between 20 and 30 in 73.6% and >30 in 17.6% of the RA patients. At baseline there was a positive correlation between BMI and DAS28 (r = 0.340; P = 0.001). Anti-citrullinated peptide antibody (ACPA, measured by the anti-CCP test) positive patients had a higher BMI than ACPA negative patients (28.9 SD ± 6.1 versus 25.3 SD ± 4.2, respectively, P = 0.003). Of 91 patients 61 (67%) responded to treatment. An inverse correlation was found between the decrease in DAS28 after 16 weeks of therapy and BMI (r = -0.214; P = 0.055). Because DAS28 at baseline was positively correlated to BMI, and BMI was higher in ACPA negative patients, we performed a stepwise backward linear multi-regression analysis. When DAS28, BMI and ACPA were put into this model as dependent variables, BMI at baseline (P = 0.001) and DAS28 at baseline (P < 0.001) predicted the decrease in DAS28 after 16 weeks (R^2 = 0.205). BMI tended to be higher in non-responders compared to responders (26.8 SD ± 4.4 versus 25.5 SD ± 4.7). When we performed stepwise backward binary logistic regression and included BMI, DAS28 and ACPA into the model, DAS28 (P = 0.010) and BMI (P = 0.038) predicted clinical response to infliximab treatment (Nagelkerke R^2 = 0.139).

Conclusion: Although infliximab dosage is based on body weight, RA patients with a high BMI responded less well to infliximab, also when controlled for ACPA status. These results support the notion that fat tissue may be involved in the disease process.

Perioperative Complications in Patients with RA Receiving Tumor Necrosis Factor Inhibitor. Kosei Kawakami, Katsunori Ikari, Takuji Iwamoto, So Tsukahara and Shigeki Momohara, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Tumor necrosis factor inhibitors are established as therapeutic agents for active rheumatoid arthritis (RA) resistant to conventional drug treatment. However, these agents have been associated with risks for surgical site infections (SSI) and other complications due to systemic blockade of tumor necrosis factor. Furthermore, while deep vein thrombosis (DVT) is considered to be one of the most significant complications after major orthopedic surgery of the lower limbs, risk for DVT in RA patients receiving tumor necrosis factor inhibitor remain unclear. Our objective is to analyze the risk of infectious complications, and to clarify the risk for developing postoperative deep vein thrombosis in RA patients receiving tumor necrosis factor inhibitor treatment after major orthopedic surgery of the lower limbs.

Method: We evaluated 45 operations (33 total knee arthroplasties, 8 total hip arthroplasties, 1 total ankle arthroplasty, 1 femoral head replacement, 1 ankle arthrodesis and 1 fracture) in 34 RA patients receiving tumor necrosis factor inhibitor treatment (infliximab [n=23] and etanercept [n=22]) performed at our hospital between May 2004 and March 2009. There were 34 women and 11 men with a mean age of 56.8 years (range, 30-73 years). Forty-five operations in 44 RA patients without receiving tumor necrosis factor inhibitor who were matched for sex and the type of operation were enrolled as controls. SSI was diagnosed according to the criteria of the Centers for Disease Control. The diagnosis of DVT was based on ultrasonography. Multivariate logistic regression analysis was performed to test the association of SSI or DVT with the putative risk factors (sex, age, body mass index, disease duration, preoperative CRP, the use of biological agent, methotrexate, sulfasalazine [for analyzing SSI], NSAID, prednisone dosage, antiplatelet [for analyzing DVT], past DVT [for analyzing DVT]).

Results: We identified biological agents use as a risk for SSI (P=0.03, OR=2.31) and developing DVT (P=0.03, OR=2.83) after major orthopedic surgery. Eighteen percent of the patients receiving biological agents had SSI (8/45), while 2 percent of the patients without

receiving biological agents had SSI (1/45). Fifty-one percent of the patients receiving biological agents were DVT positive (23/45), while only 26 percent of the patients without receiving biological agents were DVT positive (12/45).

Conclusion: Biological agents use is a risk for SSI and developing DVT in RA patients after major orthopedic surgery.

1606

Improvement of Thyroid Function During Six Months Adalimumab. Hennie G. Raterman[1], Anna Jamnitski[2], W.F. Lems[1], Alexandre E. Voskuyl[1], Ben A.C. Dijkmans[3], W.H. Bos[2], Suat Simsek[4], Paul Lips[1], Rob v.d. Stadt[2], Margret de Koning[2] and Michael T. Nurmohamed[2], [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Institute, Amsterdam, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands, [4]Medical Center Alkmaar, Alkmaar, Netherlands

Purpose: Rheumatoid arthritis (RA) is an inflammatory disease characterized by high levels of cytokines as tumor necrosis factor (TNF). TNF appears to have an etiologic role in thyroid dysfunction and, interestingly, thyroid dysfunction is a common comorbidity in RA. Therefore, thyroid dysfunction in RA patients might be beneficially influenced by TNF blocking agents.

Method: At baseline and after 6 months thyroid function (thyroid stimulating hormone [TSH], free thyroxine [fT4] and antibodies against thyroid peroxidase [TPOabs]) were assessed in an observational cohort of consecutive adalimumab treated RA patients (n = 180). Patients were categorized in 3 groups:euthyroid, hypothyroid (TSH > 4.0 or a known verified diagnosis) and hyperthyroid (TSH < 0.3 or fT4 > 24 or a known verified diagnosis). In these groups changes in thyroid status were determined.

Results: At baseline (see table), 21 (12%) and 9 (5%) RA patients were hypothyroid and hyperthyroid, respectively. At baseline 23 (13%) RA patients were positive for TPOabs (levels > 34 IU/ml) and after six months median TPOab levels decreased from 267 IU/ml to 201 IU/ml (p = 0.026) in TPOab positive patients. After 6 months treatment fT4 decreased from 24 (20 – 25) to 21 (18 – 24) pmol/l (p = 0.086) in hyperthyroid patients and TSH decreased from 4.0 (1.8 – 5.1) to 3.5 (1.6 – 6.0) mU/l (p = 0.085) in hypothyroid patients. In hyperthyroid patients without thyroid hormone substitution TSH levels increased from 0.5 (0.3 – 0.8) to 0.7 (0.4 – 1.5) (p = 0.075) and fT4 decreased significantly from 24 (19 – 25) to 20 (18 – 24) pmol/l. In hypothyroid patients without thyroid hormone substitution a trend (p = 0.071) for declining levels of TSH was found. Interestingly, in TPOab positive hypothyroid patients without thyroid hormone replacement TSH levels improved significantly from 12.5 (6.7 – 18.4) to 7.1 (4.9 – 13.8) mU/l (p = 0.043).

Conclusion: Anti-TNF treatment improves thyroid function in patients with thyroid dysfunction, providing further evidence that cytokines as TNF play an important role in thyroid disturbances.

	hypothyroid (n = 21)	euthyroid (n = 150)	hyperthyroid (n = 9)
TSH, mU/l	4.0 (1.8 - 5.1)	1.4 (1.0 - 2.1)	0.5 (0.23 - 0.86)
fT4, pmol/l	17 (13 - 21)	17 (16 - 19)	24 (20 - 25)
TPOab positive, n (%)	11 (52)	10 (7)	2 (22)
TPOab levels, IU/ml	98 (9 - 339)	8 (7 - 11)	12 (8 - 50)
Use of L-thyroxine, n (%)	9 (43)	0 (0)	1 (11)

1607

How Early Can We Predict Remission at 1 Year in Early Rheumatoid Arthritis? - A Subanalysis of PREMIER. Maxime Dougados[1], Edward C. Keystone[2], Benoît Guerette[3], Kaushik Patra[4] and Frédéric Lavie[3], [1]University of Paris V, Cochin Hospital, Paris, France, [2]Professor of Medicine/University of Toronto, Toronto, ON, [3]Abbott Laboratories, Rungis, France, [4]Abbott Laboratories, Abbott Park, IL

Purpose: Previous analyses of PREMIER, a 2-year trial in patients (pts) with early rheumatoid arthritis (RA), demonstrated that adalimumab (ADA)+methotrexate (MTX) was superior to MTX monotherapy in preventing nearly all radiographic progression, regardless of clinical response to therapy.[1] Current recommendations from international societies define remission as the treatment goal in early RA. In pts with persistent active disease, therapy adjustment is recommended at least every 3 months. However, data suggest that the efficacy of currently available therapies increases overtime, at least during the first year. Using the PREMIER database, we aimed to answer the following questions: (1) After initiating a therapy because of active disease, how long should we wait before considering this treatment ineffective and deciding to change it?; (2) Is the time to reach this decision the same regardless of the treatment used?

Methods: Data from intent-to-treat pts in PREMIER were analyzed. Clinical outcomes were Disease Activity Score 28 (DAS28) at Weeks 4, 8, 12, and 26 and change (Δ) from baseline in DAS28. Predicted probability plots of remission at 1 year were obtained, depending on DAS28 or ΔDAS28 at Weeks 4, 8, 12, 26. At each time point, probability of remission was also evaluated for 4 categories of DAS28 (<2.6, 2.6–<3.2, 3.2–<5.1, and ≥5.1) and 2 categories of ΔDAS28 (improvement of ≤0.6 or >0.6) for both treatment groups (MTX and ADA+MTX).

Results: Probability of remission at 1 year was greater for pts treated with ADA+MTX vs. MTX alone for each level of DAS28 or ΔDAS28 at all time points ($p<0.05$). The table shows the predicted probabilities to reach remission at 1 year for each level of DAS or ΔDAS28. A probability of <15% to reach remission at 1 year was found as early as Week 8 for MTX-treated pts with an improvement of <0.6 in their DAS28. In ADA+MTX-treated pts with the same level of response, a <15% probability of remission was not observed before Week 26.

Predicted Probabilities for Each Level of DAS28 or DDAS28 at Each Time Point

Variable		**MTX***				**ADA+MTX***			
		Week 4 N=183	Week 8 N=183	Week 12 N=184	Week 26 N=186	Week 4 N=207	Week 8 N=210	Week 12 N=213	Week 26 N=209
Absolute DAS28	<2.6	59	55	73	71	76	74	86	83
	2.6–<3.2	50	57	46	41	69	76	66	59
	3.2–<5.1	40	28	25	11	59	46	42	21
	≥5.1	19	17	11	3	34	32	21	7
Improvement in DAS28	≤0.6	21	11	11	5	41	25	26	13
	>0.6	32	32	31	30	56	56	55	30
*Each number=% of pts achieving DAS28 remission at 1 year.									

Conclusion: These data suggest that the time to the decision to change treatment in pts with early RA may vary, depending on the treatment and the pt's response category. Some pts treated with MTX and presenting nonsignificant improvement of their DAS28 at Week 8, or a DAS28 ≥5.1 at Week 12, or a DAS28 ≥3.2 at Week 26 could be considered good candidates for treatment adjustment. In patients treated with ADA+MTX, clinicians should consider waiting ≥6 months before adjusting therapy.

1608

Impact of Disease Duration On the Outcome of RA Patients Treated with Infliximab (The RemiTRAC Study). Denis Choquette[1], William G. Bensen[2], Hayssam Khalil[3] and John S. Sampalis[4], [1]University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]McMaster University, Hamilton, ON, [3]Schering Plough Canada, Kirkland, QC, [4]JSS Medical Research, Westmount, QC

Purpose: In recent years, the efficacy of anti-tumor necrosis factor (TNF-alpha) agents in the treatment of rheumatoid arthritis (RA) has been demonstrated in controlled clinical trials. The time to initiation of treatment may impact effectiveness of treatment.

Method: RemiTRAC is a Canadian registry providing real – life data on patients treated with infliximab that was initiated in 2002 at more than 70 rheumatology offices. Patients enter the cohort at the time of initiation of treatment and are followed prospectively indefinitely. The current analysis assesses the impact of disease duration on the real–life effectiveness of infliximab in the treatment of RA.

Results: A total of 679 RA patients were enrolled by December 31, 2008 of which 112 completed 36 months of treatment and are included in this report. Disease duration was ≤ 3 years (as per ERA population, ASPIRE trial) for 26 patients and > 3 years for 86 patients. Mean age of the two groups was 56 and 57 years respectively. The table describes laboratory and clinical parameters of the cohort during the first 36 months of treatment. The results show that although both groups experienced significant improvement in all clinical parameters patients with ≤ 3 years of disease duration at treatment onset had significantly more improvement in the Health Assessment Questionnaire (HAQ), swollen joint count (SJC) and higher proportion with ACR70 endpoint.

Parameter	**≤ 3 years (N = 26)**			**> 3 years (N = 86)**			**P – Value**
Mean (SD)	**Baseline**	**Change at 36 months**	**P – Value**	**Baseline**	**Change at 36 months**	**P – value**

ACR20: N (%)	19 (73.1)			57 (66.3)			0.515
ACR50: N (%)	19 (73.1)			50 (58.1)			0.170
ACR70: N (%)	18 (69.2)			37 (43.0)			0.019

HAQ = Health Assessment Questionnaire. PGA = Physician Global Assessment of Disease Activity. SGA= Patient Global Assessment of Disease Activity. TJC=Tender Joint Count. SJC=Swollen Joint Count.

Conclusion: The results of this observational study have shown that infliximab is effective in managing RA, however, earlier initiation of treatment may increase the beneficial effect.

Anti-Tnfα Therapy: Cardiac Safety in Rheumatoid Arthritis and Ankylosing Spondylitis with Subclinical Diastolic Dysfunction.
Julio C. B. Moraes, Alessandro C. Lianza, Ana C. M. Ribeiro, Carla Gonçalves, Jozelio F. Carvalho, Rosa M. R. Pereira, Lissiane K. N. Guedes and Eloisa Bonfa, Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Purpose: Recent studies have suggested that N-terminal pro-brain natriuretic peptide (NT-proBNP), a sensitive marker used for diagnosis of heart failure (HF), is elevated in rheumatoid arthritis (RA) without an association with clinical cardiac dysfunction. We therefore have prospectively evaluated this biochemical parameter concomitantly with a new highly sensitive non-invasive tissue Doppler imaging (TDI) in RA and Ankylosing Spondylitis (AS) patients pre- and post- anti-TNFα therapy in order to accurately define the presence of subclinical myocardial injury.

Methods: Twenty-five patients, 11 RA (ACR criteria) and 14 AS (NY criteria) were prospectively enrolled. Exclusion criteria were history of HF, coronary disease, renal insufficiency and severe hypertension. Patients were evaluated at baseline (BL) and 6 months (6M) after anti-TNFα therapy for demographic, clinical and laboratory data. Myocardial function was determined by NT-proBNP (electrochemiluminescence immunoassay) and echocardiogram [M- mode, TDI and conventional Doppler techniques] using GE Vingmed Vivid-3 Expert.

Results: BL evaluation revealed for RA and AS, respectively: mean age 49.4±11.9 and 35.5±10.6 yrs old; female gender 100 and 28.6%; white race 63.6 and 78.6%; current smoker 27.3 and 16.7%; hypertension 27.3 and 7.1%; body mass index 24±2.9 and 24.3±3,3kg/m^2 and prednisone current dose 8±4.6 and 2.7±4.4mg/d. Initial measurements demonstrated diastolic ventricular dysfunction (DVD) in 9/11 (81.8%) RA and 4/14 (28.6%) AS, p=0.015. None of these 9 RA worsened and 3 recovered after 6M with a tendency of improvement in right ventricle lateral wall velocities (LWV) [S wave (p=0.05), A wave (p=0.07)] in the TDI, whereas no change was observed in left ventricle LWV and interventricular septum (p>0.05). All other parameters (fraction of ejection, E mitral wave, A mitral wave, desaceleration time and isovolumetric relaxed time (p>0.05) remained stable. With regard to echocardiographic finding in AS, 2(50%) improved and the other 2 had no change. NT-proBNP, in RA, was initially elevated in 5 (45.6%), all with DVD, contrasting with normal levels in AS. Mean NT-proBNP RA levels reduced significantly at 6M (145±146 vs. 79.±73pg/mL, p=0.046). Disease activity parameters comparing BL and 6M were for RA [DAS 28 (5.7± 0.9 vs. 3.9±1.4, p= 0.0019), CRP (11.1±13.1 vs. 5.5±7.1mg/L, p=0.06) and ESR (29±19.8 vs. 16.6±12.5mm, p=0.06)], and for AS [BASDAI 4.3±2.2 vs. 1.9±2.6 p=0.019), CRP (28.5±28 vs. 5.5±9.2mg/L, p=0.0013) and ESR (24.1±22.3 vs. 5.1±5.6mm, p=0.026].

Conclusion: Our data supports the cardiac safety of anti-TNFα therapy for RA and AS patients in spite of the remarkable high frequency of subclinical diastolic dysfunction in severe RA patients determined by TDI. This finding is further emphasized by the longitudinal reduction of NT-pro-BNP

1610

Characteristics of Rheumatoid Arthritis (RA) Patients Starting Abatacept and Rituximab.
Susan J. Lee[1], George Reed[2], Joel Kremer[3] and Arthur Kavanaugh[4], [1]San Diego VA and UCSD, San Diego, CA, [2]University of Massachusetts Medical School, Worcester, MA, [3]Albany Medical College, Albany, NY, [4]UCSD, San Diego, CA

Purpose: Studies have shown that both abatacept and rituximab are effective in RA patients. Currently, it remains unclear which biological agents should be used among those patients who have already failed tumor necrosis factor inhibitors (TNF-I). Understanding current treatment prescribing pattern can provide insight and guidance for future use of biological agents. We sought to determine the rates of use and factors affecting the prescription pattern of abatacept and rituximab among RA patients.

Method: 20,455 RA patients with 114,659 visits enrolled in the CORRONA database were evaluated. The primary outcome was the rate of abatacept and rituximab use as a factor of several demographic and disease specific characteristics. Odds ratio (OR) for using abatacept or rituximab was evaluated using multivariate logistic regression analysis.

Results: Since 3/06, 849 RA patients initiated abatacept (71%) or rituximab (29%). Majority were Caucasians (85%), seropositive for rheumatoid factor (RF, 73%) with mean disease duration of 14 years. Rituximab users were younger (56.3 vs 59.6, p=0.001) with a higher prevalence of cancer (16.5% vs 7.6%), especially lymphoma (8.6% vs 0.2%). Approximately 75% were on at least 1 concomitant DMARD. Both groups had comparable level of disease activity (rituximab vs abatacept: mHAQ 0.63 vs 0.61, DAS28 4.5 vs 4.7) at initiation of these drugs. Abatacept initiators had higher estimated patient global assessment of arthritis (VAS 46.3 vs 42.9, p=0.094) than rituximab initiators. While the majority had previously failed TNF-I, 12.4% of abatacept and 14.6% of rituximab users were TNF-I naive. TNF-I naive abatacept users were older (66.0 vs 58.6, p<0.001) with shorter disease duration (10.3 vs 14.6, p=0.001) and less disease activity (mHAQ 0.44 vs 0.66, MD and patient VAS global 22.0 vs 30.9 and 33.3 vs 48.1 respectively; p< 0.001) than TNF-I exposed users. TNF-I naive rituximab users had lower patient derived measures of disease activity and swollen joint count (4 vs 6, p=0.048) than TNF-I exposed. Patients who are younger (OR 0.97) with history of lymphoma (OR 62.1) were more likely to receive rituximab than abatacept (p<0.001). The type of practice (academic, private) was not significantly associated with receiving abatacept vs rituximab.

Conclusion: The overall prevalence of abatacept and rituximab use was 6% overall and 14% of prevalent biologic users. 13% were TNF-I naive. While age, disease activity, and history of cancer affected prescription pattern of abatacept and rituximab, RF and clinic type did not influence the rate of overall use.

1611

The Effect of Tocilizumab On the Risk Factors for Atherosclerosis Development. Kentaro Susaki[1], Hiroaki Dobashi[1], Tomohiro Kameda[1], Katsuharu Kittaka[1], Ikuko Ohnishi[2], Masayuki Inoo[2], Michiaki Tokuda[3] and Toshihiko Ishida[1], [1]Faculity of Medicine, Kagawa University, Kagawa, Japan, [2]Utazu-hama clinic, Utazu-cho, Japan, [3]Sanuki Municipal Hospital, Kagawa

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease induced by several inflammatory cytokines including TNF-alpha and interleukin-6 (IL-6). TNF-alpha and IL-6 are considered as the most important cytokine in the pathogenesis of RA. On the other hand, TNF-alpha is one of the adipocytokines known as the substances of physiological activity secreted by adipose cells. TNF-alpha interferes the phosphorylation of intra-cellular domain in the insulin receptor on target organs, such as skeletal muscle and liver, which results in enhancement of insulin resistance. Recently, it is reported that the insulin resistance of skeletal muscle in model rat can be decreased by treatment with soluble TNF-alpha receptor to neutralize serum TNF-alpha. The insulin resistance in RA is induced by administration of corticosteroid treatment or TNF-alpha released from arthritic joint. In this study, we examined the effect of two anti-TNF therapy agents, infliximab (IFX) or etanercept (ETA) and anti-IL-6 receptor antibody (Tocilizumab; Toc) on insulin resistance, adipocytokine expression, serum lipids and visceral fat of RA patients.

Methods: Ninety-four subjects diagnosed with RA according to the criteria of the American College of Rheumatology were included in this study. They (IFX; 46, ETA; 33, Toc; 13 cases) were given IFX at weeks 0, 2, 6, following every 8 weeks or given twice a month injections of ETA and treated with Toc for every 4 weeks. Blood samples were collected at 0, 54 weeks. Weinvestigated the insulin resistance of each RA patient using the Homeostasis Model Assessment Insulin Resistance (HOMA-IR). Insulin secretion ability was analyzed with Homeostasis Model Assessment Insulin Secretion (HOMA-beta). Serum lipids and adipocytokines (adiponectin, resistin and leptin) were measured by commercial available Enzyme-Linked Immunosorbent Assay.

Results: The disease activity of RA was decreased in all patients. HOMA-IR decreased more dominantly in patients treated with ETA than IFX and Toc. All biologics enhanced the expression of adiponectin at 54 weeks. There was no significant difference of the modulatory effect on adipocyokine expression between IFX and ETA. LDL-cholesterol and atherosclerosis index were tended to decrease in patients treated with ETA. All cases treated with biologics were decreased HbA1c level.

Conclusion: Anti-TNF and anti-IL-6 R antibody therapy could improve insulin resistance and disorders of lipid metabolism in RA patients. It suggested that ETA had an advantage effect on glucose metabolism and atherosclerosis development compared with IFX.

The Measure of Disease Activity, but Not Reduction of the Acute Phase Response (APR), Determines Attainment of Disease Activity States by Tocilizumab. Josef S. Smolen, Farideh Alasti and Daniel Aletaha, Medical University of Vienna, Vienna, Austria

Purpose: The APR is a major component of disease activity measures. In the DAS28, it is ESR which is strongly weighted (Bakker et al, ARD 2007). In the Simplified Disease Activity (DA) Index (SDAI), it is CRP with a low weight. The Clinical DAI (CDAI) is the SDAI without CRP, thus purely clinical. The APR is activated by IL-6 in the liver, and tocilizumab (TCZ), which inhibits IL-6 receptor signalling, could contribute to improvement of APR beyond clinical effects. We determined the effects of TCZ on DA, including attainment of remission (REM), using measures of DA that do and do not comprise APR, to learn on the contribution of effects on APR in the response in clinical trials.

Method: We were provided an 80% sample of patient level data from 3 TCZ trials of patients with active disease despite MTX/DMARDs (LITHE, OPTION, TOWARD) and pooled the 8mg/kg arms (n=899). DAS28, SDAI and CDAI were calculated and disease activity states defined according to the criteria for these indices.

Results: In the TCZ group, with similar baseline values (not shown), changes in DAS28, SDAI and CDAI were significantly higher when compared with placebo (3.2±1.5 vs 1.3±1.3; 26.0±15.8 vs 15.6±15.0; 23.7±15.1 vs 15.1±14.5, resp., all p<0-0001). However, TCZ-REM rates were much higher with DAS28 than SDAI or CDAI (30%, 7.9%, 6.6%, resp). Among patients with DAS28-REM, 26% had SDAI-REM and 20.7% CDAI-REM. The others were in low or moderate disease activity states by SDAI or CDAI. Individual variables in patients with DAS28-REM/CDAI-non-REM were significantly higher for all core set variables except APR (Table).

Table. Relative change from baseline to 6 months (mean %±SD) of individual core set variables in patients with DAS28-REM at 6 months who did, or did not achieve CDAI or SDAI REM upon TCZ+MTX/DMARD therapy (SJC, TJC: swollen/tender joint count; EGA/PGA: evaluator/patient global assessment)

Change in variable	DAS28-REM/CDAI-REM	DAS28-REM/CDAI-nonREM	DAS28-REM/SDAI-REM	DAS28-REM/SDAI-nonREM
SJC	98.1±6.4	49.5±58.3*	97.1±7.5	48.9±58.5*
TJC	96.9±13.4	56.7±55.5*	95.6±13.8	56.3±55.7*
EGA	91.0±9.8	53.9±38.5*	89.8±10.6	53.5±38.6*
PGA	86.2±20.7	35.7±74.7*	85.7±19.3	35.0±75.0*
HAQ	66.6±33.0	30.5±51.1*	66.4±31.8	82.8±42.8*
ESR	76.2±32.3	72.1±66.1**	79.8±29.3	71.7±66.6**
CRP	89.4±22.5	83.1±42.4**	91.8±15.7	82.8±42.8**

*p<0.0001; **p=ns

Conclusion: Disease activity is reduced by TCZ irrespective of the type of composite measure. Patients in DAS28-REM but not CDAI- or SDAI-REM had significantly larger changes of joint counts, HAQ and global assessments, but not APR than those in CDAI- or SDAI-REM. Thus, a major determinant of remission rates is not improvement in APR, but rather the selection of composite measure.

Gastrointestinal Safety in Patients with Rheumatoid Arthritis Treated with Tocilizumab: Data From Roche Clinical Trials. Ronald F. van Vollenhoven[1], Edward C. Keystone[2], R. Furie[3], A. Blesch[4], C. Wang[4] and J. R. Curtis[5], [1]Karolinska Univ Hosp, Stockholm, Sweden, [2]Professor of Medicine/University of Toronto, Toronto, ON, [3]NS-LIJHS, Lake Success, NY, [4]Roche, Nutley, NJ, [5]University of Alabama at Birmingham, Birmingham, AL

Purpose: To characterize upper and lower gastrointestinal (GI) perforation events in the tocilizumab (TCZ) worldwide rheumatoid arthritis (RA) Roche clinical trials database and to compare with GI perforation event rates among RA patients enrolled in a managed care database.

Method: Cases of GI perforations have been systematically identified on a quarterly basis since 1Q2006 using the TCZ worldwide RA clinical trials database. Cumulative safety data through February 6, 2009, for adverse events were integrated for patients with RA from the Roche clinical trials database. Rates of GI perforations that occurred in patients with RA in clinical practice were analyzed using administrative claims data from the United Health Care database.

Results: In worldwide Roche clinical trials, 4009 patients with RA have received at least one dose of TCZ (4 mg/kg or 8 mg/kg), with a total cumulative exposure of 9414.3 patient-years (PY). There were 26 cases of GI perforations reported for patients with RA from Roche TCZ clinical trials and long-term extension studies. The rate for lower GI perforation was 1.9 per 1000 PY (Table). The mean age of the 26 individuals experiencing a perforation was 63 years at the initiation of the trials. The majority of patients who perforated were taking chronic corticosteroids (up to 10 mg/day prednisone), one or more NSAIDs, and methotrexate. Three deaths were secondary to GI perforations or associated complications, one of which was an iatrogenic esophageal perforation. Sixteen of the 18 (89%) patients with colonic perforations had diverticulitis. The majority were recognized only after the perforation had occurred. The GI perforation rate in patients with RA who were exposed to corticosteroids in the United Health Care database was 3.9 per 1000 PY (95% CI, 3.1-4.8), and in those exposed to anti-TNFs, it was 1.3 per 1000 PY (95% CI, 0.8-1.9).

Conclusion: Most patients receiving TCZ who experienced GI perforation were also receiving corticosteroids, NSAIDS, and methotrexate. The rate of GI perforations in patients treated with TCZ in the Roche clinical trials was within the range of the rates observed in populations of RA patients treated with corticosteroid and/or anti-TNF therapy in the United Health Care database.

Anatomic Distribution of GI Perforation Cases in RA Patients Exposed to TCZ in Clinical Trials or Open Label Extensions

Anatomic Location	Number	Rate per 1000 Patient-Years[a]
Upper GI		
Esophagus	1	
Stomach and duodenum	1	
Jejunum and ileum	3	
Appendix	2	
Abdominal abscess	1	
Lower GI		
Colon	18	1.9
Diverticular (including abscess, fistula)	**16**[b]	**1.7**
Total	**26**	**2.8**

[a] Total exposure = 9414.3 patient-years.

[b] One patient had a diverticular perforation in the jejunum and was not included as a colon diverticular perforation case.

A Clinical Study to Assess the Effect of Tocilizumab at a Therapeutic Dose & a Supra-Therapeutic Dose of Tocilizumab On QT/QTc Interval After a Single Dose in Healthy Subjects. Susan Grange[1], Christophe Schmitt[1], Angela Georgy[2], Banken Ludger[1], Barbara Kuhn[1] and Xiaoping Zhang[2], [1]Roche, Basel, Switzerland, [2]Roche, Nutley, NJ

Purpose: Tocilizumab (TCZ) is a humanized IL-6 receptor inhibitor that has demonstrated significant improvements in the signs and symptoms of moderate-to-severe rheumatoid arthritis (RA). This study was designed to evaluate the threshold pharmacological effect on cardiac repolarization, as detected by changes in the QT/QTc interval on 12-lead ECGs in healthy volunteers.

Method: This was a multi-center, double-blind, placebo- and active-controlled, parallel group study. A total of 121 healthy male & female subjects received either an intravenous infusion of TCZ 10 mg/kg (N=30) or 20 mg/kg (N=31), oral moxifloxacin 400 mg (MOX, N=31), or placebo (N=29). Triplicate ECGs were obtained at predose and 2 hr post dose on Day 1 and Days 8, 15 and 29 to cover entire TCZ serum concentration-time profile. Time-matched ECGs were taken on Day -1 for baseline corrections. All ECGs were centrally read by a blinded cardiologist. Study-specific corrected QT (QTcS) was derived from linear regression of individual mean QT on individual mean RR interval data obtained at baseline (Day -1). The change from time-matched baseline in QTcS was determined at each time point. An analysis of variance with the fixed factors treatment and day and their interaction and the random factor subject was applied to time-matched change from baseline in QTcS to estimate the placebo-corrected mean change from baseline together with one-sided upper 95% confidence intervals (CI). Blood samples for pharmacokinetic analyses were collected at predose and up to 28 days post dose.

Results: Of 121 subjects dosed, 67 were female and 54 male. Mean age varied from 29 to 37 years with an age range of 18 to 64 across groups. The majority of subjects were white. For TCZ at both 10 and 20 mg/kg doses, the estimated placebo-corrected mean change from time-matched baseline was negative at all time points and ranged from -5.4 msec to -1.0 msec. The associated upper one-sided 95% confidence limit was below 10 msec. Similar results were obtained for QTcF (Fridericia correction). The estimated placebo-corrected mean change from time-matched baseline for MOX was around 6.8 msec (95% CI: 0.8 to 12.7 msec). The upper bound of the 2-sided 95% CI is comparable to the literature reported value for MOX, establishing study assay sensitivity. There were no clinically significant abnormalities for other ECG parameters (QRS, PR, heart rate, RR, T-wave and U-wave morphology). There were no ECG abnormalities that constituted an adverse event. Following 10 and 20 mg/kg TCZ dosing, the time to reach maximum serum concentration was 2 hours post dose and the mean half-life was 9.3 days for 10 mg/kg and 12 days for 20 mg/kg. Both doses of TCZ were well tolerated and no unexpected safety findings were observed.

Conclusion: Analysis of the 12-lead ECG data obtained from this study indicates that there is no QT prolonging effect of clinical concern by TCZ at both the low (10mg/kg) & high (20mg/kg) dose.

Serious Infections in Patients with Rheumatoid Arthritis (RA) Treated with Anakinra (ANA): Experience From the BSR Biologics Register (BSRBR). J. B. Galloway[1], W. G. Dixon[2], L. K. Mercer[3], K. D. Watson[3], M. Lunt[4], K. L. Hyrich[3], D. P. Symmons[1] and On behalf of the BSRBR[3], [1]University of Manchester, Manchester, United Kingdom, [2]The University of Manchester, Manchester, [3]The University of Manchester, Manchester, United Kingdom, [4]arc Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Purpose: A recent Cochrane review of trials of ANA (an interleukin-1 receptor antagonist) in RA identified no significant difference in serious infection (SI) rates compared to placebo. Our aim was to explore the influence of ANA on SI rate using data from the BSRBR, a prospective cohort study set up in 2001 to monitor the safety of biologic therapies in the UK.

Method: Consecutive RA patients treated with ANA were recruited between October 2001 and May 2008 by the BSRBR and were followed 6 monthly via consultant and patient questionnaires until December 2008, end of follow up or death. A comparison cohort with active RA on disease modifying anti-rheumatic drugs (DMARD) was recruited and followed up in the same way. SI was defined as an infection requiring

hospitalisation or intravenous antibiotics or resulting in death. Incident cases of SI were identified from follow-up questionnaires and verified via medical records. SI was attributed to ANA if it was diagnosed while on drug or within 30 days of the last dose. Event rates in the ANA and DMARD cohorts were compared using Cox proportional hazard ratio estimates adjusted for age, gender, disease severity, prior joint replacement, co-morbidity, year of entry into the study and steroid use.

Results: 111 patients received ANA as their initial biologic. Patients prescribed ANA were younger, had more severe disease, longer disease duration, and higher exposure to steroids than the comparison cohort (Table). Drug survival on ANA was short (median survival on drug 5 months (IQR 3 – 12)) and 84% of patients switched biologic agent during follow up. In total 15 SI occurred in 10 patients on ANA, with the most common sites being respiratory and skin / soft tissue. 3 ANA treated patients died from SI. The crude rate of first SI was 92/1000 pyrs (95% CI 44, 170) in the ANA cohort compared to 34/1000 pyrs (30, 38) in the DMARD cohort. The unadjusted hazard ratio (HR) for first SI was 2.8 (1.5, 5.3) in the ANA cohort. After adjusting for confounding factors the HR was 2.5 (1.0, 6.4)

Conclusion: The rate of SI in the ANA cohort appears higher than in the DMARD cohort; however the number of events in the ANA cohort were small and there may be residual confounding.

Table:

No of patients ever received the drug	**Control cohort** **n=3515**	**Anakinra cohort** **n=111**
Number	3515	111

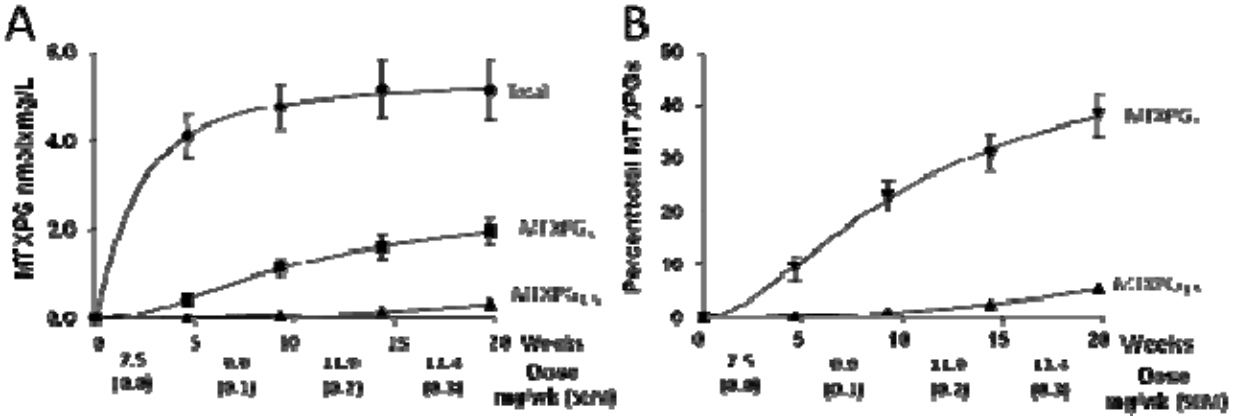
Intracellular Methotrexate Pharmacokinetics in Rheumatoid Arthritis: Selective Emergence of Methotrexate Polyglutamates as a Function of Time and Dose Intensity. Thierry Dervieux[1], Rong Zablocki[1] and Joel M. Kremer[2], [1]Cypress Bioscience, San Diego, CA, [2]Albany Medical College, Albany, NY

Purpose: Methotrexate (MTX) is a prodrug producing antiarthritic effects through a Folylpolyglutamate Synthase (FPGS) mediated activation to active MTX polyglutamates (MTXPGs). We sought to evaluate the intracellular pharmacokinetics of MTXPGs during a dosage escalation of oral MTX in rheumatoid arthritis (RA).

Method: A total of 47 adult patients with RA were enrolled in a longitudinal study. Oral MTX was initiated at 7.5mg weekly and increased by 2.5mg every 4-6 weeks to reduce disease activity. Intracellular MTXPG concentrations ($MTXPG_{1-5}$) were measured in erythrocytes using liquid chromatography. Pharmacokinetics analyses consisted of non linear mixed models. Because dosing was increased with time, the change in MTXPG concentrations was analyzed after normalization with dose (i.e. MTXPG/dose expressed in nmolxmg/L). Covariates included in the pharmacokinetic models consisted of glomerular filtration rate (GFR), age and dose as appropriate.

Results: The figure (A) highlights the buildup of dose normalized $MTXPG_s$ in the erythrocytic compartment from initiation of therapy to the fourth study visit corresponding to 19.8±0.5 weeks MTX therapy at a final dosage of 13.4±0.3 mg/week. The accumulation of $MTXPG_{1-5}$ (total) followed a Michaelis-Menten kinetics (V_{max}=5.7±0.3; K_m=1.7±0.5, average±SEM) with V_{max} as the maximum level and K_m as the time needed to achieve half-maximum. After 7 weeks of therapy, 80% of the V_{max} (steady state) was reached. Older age and decreased GFR were both associated with increased V_{max} and decreased K_m ($p<0.001$). A total of 93% of the intra-patient variability was explained by this model. The change in dose normalized long-chains $MTXPG_3$ and very long-chains $MTXPG_{4-5}$ were best modeled using allosteric sigmoidal kinetics with a total of 91% and 83% of the intrapatient variance explained, respectively. After 4 weeks MTX therapy the vast majority of MTXPGs in the erythrocytic compartment consisted of short-chains $MTXPG_{1-2}$ (90%±1.2; average±SEM), while additional exposure and further MTX dosage escalation produced a selective redistribution toward longer chain MTXPGs (Figure B). Higher percentage $MTXPG_3$ in RBCs was associated with higher MTX dosage administered (estimate= 1.3±0.5%; p=0.019) thereby indicating that the selective emergence of these active metabolites was a function of dose intensity.



Conclusion: The data indicate that steady state $MTXPG_{1-5}$ concentrations are achieved after 7 weeks therapy in patients treated with weekly oral MTX. However, increasing time of exposure and dose escalation contribute to a selective redistribution of $MTXPG_{1-5}$ toward longer chain derivatives that are known to produce enhanced de novo purine biosynthesis inhibition compared to shorter chains MTXPGs. This data are consistent with an activation of FPGS during MTX therapy as previously described (Blood. 1994 84:564-9) and support the notion that the effects of this prodrug increase over time.

Adverse Events and Factors Associated with Toxicity in Patients with Early Rheumatoid Arthritis Treated with Methotrexate (the CAMERA study). S.M.M. Verstappen[1], M.F. Bakker[2], A.H.M. Heurkens[2], M.J. van der Veen[2], A.A. Kruize[2], M. Geurts[2], J.W.G. Jacobs[2], J.W.J. Bijlsma[2] and Utrecht Arthritis Cohort study group, [1]arc Epidemiology Unit, the University of Manchester, Manchester, United Kingdom, [2]Utrecht Arthritis Cohort study group, Utrecht, Netherlands

Purpose: In the CAMERA study (Computer Assisted Management in Early Rheumatoid Arthritis) we found that more patients with rheumatoid arthritis (RA) in the intensive methotrexate (MTX) strategy group compared to the conventional MTX strategy group achieved at least one period of remission. However, to compare the value of the two strategies, both beneficial effects and adverse events (AE) are important to weigh. Therefore, the objective of this study was to evaluate toxicity profiles in patients with early RA treated either according to an intensive or a conventional treatment strategy approach with MTX and to study factors associated with MTX related toxicity.

Method: Data were used from the CAMERA study in which AEs were recorded at each visit using a predefined form. Data on AEs were compared between the intensive strategy group (n=149) and conventional strategy group (n=140). Logistic regression analyses were used to identify possible associations between factors assessed at baseline, including demographic variables, clinical factors and laboratory values, and withdrawal due to MTX related AEs (adjusted for treatment group and NSAID use at baseline) in the total study population and for liver toxicity at follow-up (adjusted for NSAID use at baseline) for the two strategy groups separately. We present Odds ratios (OR) with 95% confidence intervals (95%CI).

Results: Although significantly more patients in the intensive strategy group (95%) experienced MTX related AEs compared to the conventional strategy group (90%), all recorded AEs were relatively mild and often reversible. The percentages of patients with an event were respectively: GI symptoms (66% vs 54%, p=0.030); mucocutaneous (54% vs 40%, p=0.025); CNS (59% vs 39%, p=0.001); hepatic (55% vs 35%, p=0.001); renal (39% vs 44%, p=0.403); haematological (26% vs 11%, p=0.001); and general AE (27% vs 15%, p=0.015). None of the baseline variables was associated with withdrawal due to MTX related AEs in the univariate regression analyses, but a higher BMI was significantly associated with withdrawal due to MTX related adverse events in the multiple regression analyses (OR 1.21, 95%CI 1.02 to 1.44). There was a trend towards an association between diminished creatinine clearance and MTX withdrawal (OR 0.97, 95%CI 0.94 to 1.00). For liver toxicity, increased serum transaminase and creatinine levels at baseline were associated with liver toxicity during follow-up.

Conclusion: Although the occurrence of AEs was higher in the intensive strategy group than in the conventional strategy group, the previously observed clinical efficacy of an intensive treatment strategy seems to outweigh the observed toxicity profiles. When starting MTX, attention should be given to patients with a high BMI and those with increased transaminase levels and decreased renal function.

Tight Control Aiming at a DAS28 Remission Is More Effective in Reaching High Remission Rates Than Usual Care in Rheumatoid Arthritis. Lydia G. Schipper[1], Marloes Vermeer[2], Ina H. Kuper[2], Monique Hoekstra[3], Cees J. Haagsma[4], Alfons A. Den Broeder[5], Piet L.C.M. van Riel[1], Jaap Fransen[1] and Martin A.F.J. van de Laar[2], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands, [3]Isala Klinieken, Zwolle, Netherlands, [4]Ziekenhuisgroep Twente, Almelo, Netherlands, [5]Sint Maartenskliniek, Nijmegen, Netherlands

Purpose: The ultimate treatment goal in Rheumatoid Arthritis (RA) is to achieve and sustain clinical remission as early as possible. In clinical trials, tight control was shown to be very effective in achieving this goal. However, the question is in how far these promising results can be transferred into daily clinical practice. Therefore, the aim of this study was to investigate whether a tight control treatment strategy is more effective than treatment according to usual care in reaching remission after 1 year of follow-up in patients with early RA.

Methods: Two early RA inception cohorts from two different regions including patients who fulfilled the ACR criteria for RA and disease duration <1 year were studied. In both cohorts, DAS28 was evaluated every 3 months. Patients in the tight control cohort (n=126) were treated between 2006-2008 according to a DAS28-driven step-up treatment strategy starting with MTX, addition of SSZ, exchange of SSZ

by anti-TNF. Patients in the usual care cohort (n=126) were treated between 2004-2008 and were mainly treated with MTX or SSZ monotherapy at discretion of the rheumatologist, thus without DAS28 guided treatment decisions. Primary outcome was the percentage of patients in remission (DAS28<2.6) after 1 year. Secondary outcome measure was the mean change in the DAS28 from baseline to 1 year.

Results: At baseline, the tight control and usual care cohorts were comparable: age 56 vs 59 years, 63% vs 74% rheumatoid factor positive, baseline DAS28 was 5.0 vs 4.8 and baseline HAQ 1.2 vs 0.9, except for female gender (62% vs 48%). After 12 months, 55% of patients in the tight control cohort had a DAS28<2.6, versus 30% of usual care patients (P<0.0001, OR 3.1 (95% CI 1.8-5.2), adjusted for baseline DAS28). The median time to first remission was 19 weeks for tight control and 26 weeks for usual care (P<0.0001). The DAS28 was decreased with -2.5 in the tight control cohort and -1.5 in the usual care cohort, the between-group difference adjusted for baseline DAS28 was 0.85 (95% CI 0.58 - 1.12, P<0.0001) (Fig. 1).

Conclusion: In daily clinical practice, a tight controlled treatment strategy aiming for remission leads to more rapid and higher percentages of DAS28 remission after 1 year than treatment according to usual care.

Figure 1: Mean decrease of DAS28 in tight control and usual care groups.

Preliminary Estimates and Significance of Red Blood Cell Methotrexate Polyglutamate Measurements IN the Rheumatology Practice Setting. Thierry Dervieux, Mariko Matsutani, Debbie Stimson, Mary Barry and Curtis McGuyer, Cypress Bioscience, San Diego, CA

Purpose: Large interpatient variability in Methotrexate (MTX) absorption, excretion and activation to MTX Polyglutamates (MTXPGs) contributes to a wide spectrum of therapeutic responses in patients with rheumatoid arthritis (RA). We previously reported that red blood cell (RBC) MTXPG concentrations were associated with MTX efficacy in RA (Arthritis Rheum. 2004 50:2766-74). As the blood test was recently made available, our clinical and scientific impetus was to compare RBC MTXPG levels observed in our clinical study cohort to those observed in routine clinical practice setting.

Method: In 256 patients enrolled in a previous clinical study, lack of good response and poor response were associated with low RBC MTXPG levels, high weekly MTX dosage and low RBC MTXPGs per mg MTX administered (polyglutamation rate). Among RBC MTXPG levels recently requested in the course of clinical care by practicing rheumatologists a total of 1045 measurements were available along with MTX dosing information. RBC MTXPGs levels were measured in our accredited clinical laboratory using liquid chromatography. Concentrations were reported as nmol/L RBCs. To maintain patient privacy, all specimens were de-identified prior to the analysis. Differences between groups were assessed using non parametric tests or $\chi 2$ as appropriate. Data are presented as average±SD.

Results: The Table indicates that RBC MTXPG levels from our laboratory specimens were lower than those observed in good responders ($p<0.001$) but similar to those lacking good response ($p=0.90$). The proportion of laboratory test results was over-represented in the low level category (<20 nmol/L) but underrepresented in the high level category (>60 nmol/L) when compared to good responders ($p<0.01$). A 33% lower polyglutamation rate was observed between the clinical laboratory test results and good responders to MTX ($p<0.001$). On a population basis, estimates indicated that an average dose of 20 mg/week MTX may increase RBC MTXPG levels from 35 nmol/L to 44 nmol/L, the average observed in good responders (44 nmol/L/2.2 nmolxmg/L =20 mg).

	Clinical study: Good response	Clinical study: Lack of good response	Clinical Laboratory: test results
Weekly MTX dose (mg)	13.7±4.1	14.4±4.8	16.9±5.2
RBC MTXPGs (nmol/L)	44±25	35±20	35±22
RBC MTXPG per mg MTX (nmolxmg/L)	3.3±1.9	2.6±1.5	2.2±1.6
Low MTXPG: <20 nmol/L (%)	16.2%	28.0%	28.0%
High MTXPG: >60 nmol/L (%)	28.7%	8.5%	14.0%

Among patients who received a weekly MTX dose ≥15mg, RBC MTXPG concentrations were below the quantification limit (<5 nmol/L) in 6.3% of clinical laboratory specimens compared to 2.8% who presented with a poor response and 0% in patients without a poor response ($p=0.02$). Poor compliance and/or rapid excretion of un-metabolized MTX may explain these results.

Conclusion: These observations are consistent with our recommendation to assess MTX exposure in the context of poor MTX efficacy. These measurements may help rheumatologists to optimize MTX dosing and exposure in RA.

Disease Activity, Joint Damage and Functional Disability and the Effect of Methotrexate Treatment in Patients with Undifferentiated Arthritis with or without Anti-Citrullinated Protein Antibodies. Karen Visser[1], J. van Aken[1], H. van Dongen[1], L.R. Lard[1], H.K. Ronday[2], I. Speyer[3], A.J. Peeters[4], R.E.M. Toes[5], Désirée M.F.M. van der Heijde[5], C. Allaart[1] and T.W.J. Huizinga[1], [1]LUMC, Leiden, Netherlands, [2]HAGA hospital, The Hague, Netherlands, [3]Bronovo hospital, The Hague, Netherlands, [4]GDGG, Delft, Netherlands, [5]Leiden University Medical Center, Leiden, Netherlands

Background: In rheumatoid arthritis (RA) treatment is aimed at minimal disease activity as this is associated with less radiographic progression and better functional ability. For undifferentiated arthritis (UA) these relationships are yet unclear.

Purpose: To investigate the relationships between disease activity, radiographic progression and functional disability, and the effect of treatment with methotrexate (MTX), in UA patients with or without anti-citrullinated protein antibodies (ACPA).

Methods: In the PROMPT study, 110 UA patients (ACR 1958 probable RA criteria, symptoms <2 years) were randomized to one year MTX or placebo therapy. Every three months, the disease activity scores (DAS), health assessment questionnaires (HAQ) and patient-reported symptoms on a VAS were measured. Radiographic progression, scored on 6-monthly radiographs of hands and feet using the Sharp-van der Heijde score (SHS) was defined as an increase of >=3. The longitudinal relationships between DAS-HAQ, SHS-HAQ and DAS-SHS, and the effect of MTX treatment on all outcomes were analyzed via longitudinal regression analysis with generalized estimating equations (GEE) or logistic regression analysis. Differential associations for ACPA positive and ACPA negative patients were explored via interaction terms. All analyses were corrected for age, gender, ACPA, treatment group, and baseline values of the studied variables.

Results: The DAS (beta=0.14, p=0.001), the baseline erosion score (beta=0.04, p=0.045), but not the momentary SHS, were longitudinally associated with the HAQ across time. A higher DAS in the initial 6 months was associated with radiographic progression after 12 months in logistic regression (OR=4.1, 96%CI 1.0-16.5, p=0.050). The above relationships were not different for ACPA positive or negative patients (interaction terms not significant). MTX treatment was associated with a lower DAS across time (beta=-1.0, p<0.001), including ESR, swollen (SJC) and painful (RAI) joints, lower patient's VAS for pain (beta=-10.8, p=0.039) and for disease activity (beta=-12.4, p=0.015) and less damage progression after 12 months (OR=0.2, 95%CI 0.04-0.8, p=0.027) in ACPA-positive, but not in ACPA-negative patients. The HAQ decreased significantly in the ACPA positive patients (beta=-0.027, p=0.002), but not in the ACPA negative patients (beta=-0.003, p=0.515).

Conclusion: Similar to RA, in UA, disease activity is related to functional disability and future radiographic progression, irrespective of ACPA status, providing prove of concept and a rationale for early intensive treatment of UA. MTX, however, is only beneficial for ACPA positive UA, thus effective therapy for ACPA negative UA needs yet to be found.

Meta-Analysis of Tight Control Strategies in Rheumatoid Arthritis: Protocolized Treatment Has Additional Value with Respect to the Clinical Outcome. Lydia G. Schipper, Laura T.C. van Hulst, Marlies E.J.L. Hulscher, Piet L.C.M. van Riel and Jaap Fransen, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Purpose: Randomized controlled trials show that tight control in Rheumatoid Arthritis (RA) is effective. Several ways for tight control have been studied, varying from ‘monitoring with using a treatment protocol' to ‘monitoring without applying a treatment protocol'. Whether these approaches differ in terms of clinical efficacy is not clear yet. Therefore, the efficacy of monitoring with protocolized treatment adjustments was compared to the efficacy of monitoring without protocolized treatment adjustments.

Methods: A systematic literature search was performed to identify clinical trials evaluating the effect of tight control compared to usual care. PubMed was used to find clinical trials from 1995 up to August 2008. The efficacy of both types of tight control interventions was determined by calculating the difference between usual care and the intervention in Disease Activity Score (DAS28) decrease from baseline to end of trial. If DAS values were calculated instead of the DAS28 the translation formula was used to calculate a DAS28. These differences were used in a meta-analysis to compare the effect of monitoring in combination with protocolized treatment adjustments versus monitoring without protocolized treatment adjustments. Outcomes were reported as weighted mean differences (WMD), obtained by pooling the mean changes. Differences were tested using the Z-statistic.

Results: Six tight-control studies were included in the meta-analysis: three studies used tight control with a treatment protocol and three applied tight control without a treatment protocol. All studies showed that tight control leads to a higher decrease in disease activity after one year of treatment compared to usual care (WMD=0.47, 95% 0.33-0.62). Treatment protocol-driven tight control was far more effective than usual care (WMD=0.66, 95% CI 0.46-0.86), if no treatment protocol was used tight control was only slightly more effective than usual care

(WMD=0.25, 95% 0.03-0.46) (Figure 1). This resulted into a significant difference in change of disease activity after one year (0.41, P<0.0001) between protocol-driven and no protocol-driven tight control.

Conclusion: In the treatment of RA, a tight control approach is more effective if monitoring is combined with protocolized treatment adjustments compared to tight control consisting of monitoring alone. Therefore, in tight control of RA, monitoring should be followed by protocolized treatment adjustments to accomplish the largest difference.

Figure 1: Mean difference in change of DAS28 between usual care and tight control.

Knowledge of Methotrexate in a Multiethnic Cohort of Adults with Rheumatoid Arthritis. J. Barton[1], John Imboden[1], Jonathan Graf[1], Vladimir Chernitskiy[2], Laura Trupin[3], E.H. Yelin[3] and Dean Schillinger[4], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, CA, [3]UCSF, SF, CA, [4]University of California, San Francisco, San Francisco, CA

Purpose: Methotrexate (MTX) is a recommended first line treatment for rheumatoid arthritis (RA) but adverse events are reported in over 70% of patients. Poor understanding of side effects and toxicity may limit use of MTX and cause unnecessary harm. We sought to determine RA patients' understanding of MTX among a diverse cohort of adults and assess whether knowledge varied by age, English language proficiency, or education.

Methods: Data were derived from a cohort of adults with confirmed RA seen at public hospital- and university hospital-based clinics. Subjects completed an annual structured telephone survey in English, Spanish, or Chinese, that included 11 questions on MTX (based on previously validated items). English language proficiency was assessed using the U.S. Census question “How well do you speak English?”

Those who reported “very well” were considered proficient [EP] and those who reported “well,” “not well” or “not at all” were considered to have limited English-proficiency [LEP]. Education level was dichotomized as less than high school [<HS] or high school graduate and beyond [HS/BA]. We compared frequencies of correct answers among patients with LEP and EP, <HS and HS/BA education, age < 55 and ≥ 55 using chi-square and t-tests. Multivariate linear regression was also performed.

Results: Ninety-four of 176 subjects reported taking MTX; 75% were female, 35% Hispanic, 31% non-Hispanic White, 25% Asian, 6% African American and 3% Other. Mean age was 55 ± 15 years; mean RA disease duration 8 years. Forty-four subjects had LEP, 57% were non-U.S. born, 30% had < HS education. Mean MTX knowledge score was 5.7 ± 2.7 (out of 11); scores did not differ by LEP/EP or education, but did by age (table). The table shows frequencies of correct responses by age <55 and age ≥ 55. Overall, 84% correctly identified weekly dosing and need for regular monitoring; 78% of women of childbearing age identified MTX as teratogenic. Knowledge of potential side effects was poor. In multivariate linear regression, age ≥ 55 was associated with decrease in score of 2.2 compared to subjects < 55 (adjusting for LEP, education and disease duration). LEP and education were not significant predictors in multivariate analyses.

Conclusion: Among ethnically diverse subjects with RA, knowledge of MTX weekly dosing, regular monitoring, and teratogenicity (among women of child-bearing age) was high. However, scores on a similar test of MTX knowledge in the Midwest were higher. Knowledge of potential side effects, and teratogenicity among males, was poor and may be due to lack of provider education. Interventions to increase knowledge of MTX and its side effects should be targeted to all patients, specifically to those ≥ 55, regardless of language proficiency or education.

Table. Methotrexate knowledge questionnaire results

Test (correct answers)	% correct N=94	Age < 55 N=46	Age ≥ 55 N=48	p-value
Drug safety				
MTX frequency (weekly)	84%	96%	83%	1.00
Alcohol intake (none)	64%	83%	48%	0.10
Frequency of blood tests (2-3 months)	84%	98%	77%	0.17
birth defects (yes)				
If female	89%	79%	29%	<0.001
If male	21%	60%	6%	0.07
Potential side effects				
Nausea (yes)	39%	49%	29%	0.02
low blood counts (yes)	24%	36%	16%	0.03

Etoricoxib Improves Pain and Function in Rheumatoid Arthritis Patients On Background Biological Therapies. M. Greenwald[1], P. Peloso[2], A. Mehta[2], H. Wang[2], F. Hasler[3] and A. Gammaitoni[2], [1]Desert Medical Advances, Palm Desert, CA, [2]Merck & Co., Inc., Rahway, NJ, [3]Private Practice, Neue Bungertrechti, Switzerland

Purpose: Biologic therapy (i.e. TNF-α, IL-1 inhibitors) has altered the management of synovitis and long term outcomes in RA. Patients may still experience pain and impaired function; however, little is known about the efficacy of COX inhibitors in conjunction with biologics. We conducted this post-hoc analysis to explore the efficacy of etoricoxib, a COX-2 selective NSAID, in RA patients with or without biologic therapy.

Methods: RA patients were randomized to etoricoxib 10, 30, 60 or 90 mg or placebo in a double-blind 12-week study. Using the time-weighted change from baseline over 12 weeks, we evaluated: Patient global assessment of pain (Pain; 0- 100mm VAS); Swollen Joint Count (SJC; Out of 66 Joints); Tender Joint Count (TJC; Out of 68 Joints) and Health Assessment Questionnaire (HAQ; 0-3 Likert Scale). Three treatment groups were evaluated: placebo; pooled etoricoxib 10/30/60 mg; and etoricoxib 90mg. The following biologics were considered: etanercept; anakinra; adalimumab, natalizumab, infliximab, and abatacept. Least-square means were estimated from ANCOVA models with terms for baseline parameter, treatment, biologic usage and its interaction with study therapy.

Results: Of 761 patients randomized, 178 (23.4%) were on concomitant biologic therapy. Baseline values for those on/ not on biologicals, for each endpoint were similar, although patients on biologics demonstrated slightly lower pain, but higher TJC and SJC. For placebo, etoricoxib 10/30/60 mg, and etoricoxib 90 mg, baseline values for pain [no biologic (with biologic)] were 73.3 (70.8), 71.1 (70.0), and 71.1 (70.5); baseline values for SJC [no biologic (with biologic)] were 15.9 (16.8), 16.0 (19.8), and 15.5 (18.8); baseline values for TJC [no biologic (with biologic)] were 26.4 (29.4), 26.5 (31.2), and 25.8 (28.4); baseline values for HAQ [no biologic (with biologic)] were 1.3 (1.4), 1.3 (1.4), and 1.2 (1.5). LS mean changes vs. placebo for each group for patients on biologics and those not on biologics are in the table.

Conclusion: The biologics subgroup had significant pain and functional impairment at baseline. Etoricoxib 90 mg provided improvements in pain and function with and without concomitant biologic therapy, with greater improvements in TJC and SJC noted for those not on biologics. Etoricoxib is effective in RA patients who are taking concomitant biologicals and 90 mg is the most effective dose. Table

Prevalence of Alcohol Consumption Among Rheumatoid Arthritis (RA) Patients On Methotrexate (MTX) and Impact On Liver Function Tests. C. Iannaccone, M. Frits, J. Cui, M. E. Weinblatt and N. Shadick, Brigham & Women's Hospital, Boston, MA

Purpose: There is little data on the prevalence of alcohol consumption among RA patients, especially those taking MTX. The American College of Rheumatology (ACR) guidelines state that patients on MTX should limit alcohol intake to 2 drinks or less per month because it can significantly increase the risk of liver damage. This study looks at the prevalence and quantity of alcohol use in RA patients on MTX and evaluates whether alcohol consumption results in elevated liver function tests (LFTs), mainly aspartate transminase (AST) and alanine transminase (ALT).

Method: Eligible subjects are RA patients enrolled in a prospective observational cohort (BRASS). Data on patients' medication use was obtained from physicians and alcohol use was self-reported in an interview. A general linear model analysis was used to determine the differences between patients who reported drinking more than the ACR recommendations while on MTX (drinkers) versus those who followed the ACR guidelines (abstainers). A mixed model was used to compare the LFTs of patients on MTX who were drinkers versus abstainers evaluating multiple time points for the cohort adjusting for potential confounders.

Results: We examined 738 patients (563 on MTX). Six percent of the MTX users had a diagnosis of diabetes and 23% were obese (BMI>30). Alcohol use was reported by 56% of the patients on MTX (Mn=8 drinks/month) compared to 66% (Mn=17 drinks/month) of patients not on MTX (p=.0004). Of the MTX drinkers, 38% were drinking more than the recommended amount. After adjusting for gender and age, a general linear model showed MTX drinkers tended to have lower BMIs, a shorter disease duration, less pain and better physical function than those who abstained (see table).

Of the patients on MTX, we found no difference in the percentage of drinkers (34%) and abstainers (34%) having at least one abnormal LFT result. Also, the mixed model analysis adjusting for age and gender showed no difference in AST or ALT levels between MTX drinkers compared to abstainers (p=0.5, p=0.3) over time. Furthermore, in a subgroup analysis of those with diabetes and obesity, there was still no difference in AST or ALT levels among MTX drinkers compared to abstainers (p=0.5, p=0.9).

Conclusion: Despite warnings of the dangers of drinking alcohol while taking MTX, many patients continue to drink. However, we could find no further evidence that MTX drinkers had higher LFTs overall compared with abstainers. While MTX drinkers tended to report less pain and better physical function further study is necessary to determine the clinical impact of this level of alcohol use among MTX users.

MTX Drinkers vs. Abstainers	≥ 2 drinks/month (±SE)	< 2 drinks/month (±SE)	P-Value

Tacrolimus-Induced Pulmonary Injury in Patients with Rheumatoid Arthritis. Ryuji Koike[1], Michi Tanaka[1], Yukiko Komano[1], Fumikazu Sakai[2], Haruhito Sugiyama[3], Toshihiro Nanki[1], Nobuyuki Miyasaka[1], Masayoshi Harigai[1] and Study Group for Tacrolimus-induced Pulmonary Injury[4], [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]International Medical Center, Saitama Medical University, Hidaka-shi, Japan, [3]International Medical Center of Japan, Tokyo, Japan, [4]Tokyo, Japan

Purpose: Tacrolimus has been approved for rheumatoid arthritis (RA) with inadequate response to other disease modifying anti-rheumatic drugs (DMARDs) in Japan since 2005. Post-marketing surveillance (PMS) of the drug and spontaneous reports to Astellas Pharma Inc. identified twenty-seven cases of exacerbation or new development of interstitial pneumonia (IP) among the 3,638 patients with RA by May 2007. The objective of this study was to identify patients with high likelihood for tacrolimus-induced pulmonary injury (TIPI) and describe clinical and radiological characteristics of TIPI.

Method: We sent a letter to the attending physicians who reported IP as an adverse event in the PMS or the spontaneous reports to the pharmaceutical company and collected eleven cases from eleven hospitals. Clinical, radiological and laboratory data of these cases were provided from the physicians. Each case was evaluated by the Study Group for Tacrolimus-induced Pulmonary Injury including a radiologist (F.S.) and a pulmonologist (H.S.). Cases were classified into four categories according to the clinical likelihood for TIPI: presumptive TIPI, probable TIPI, possible TIPI, non-TIPI. Presumptive TIPI indicates TIPI is clinically more likely than other pulmonary diseases including rheumatoid lung and pulmonary infections. Probable TIPI indicates both TIPI and other pulmonary diseases are likely to the same degree. Possible TIPI indicates other pulmonary diseases are more likely than TIPI. Non-TIPI indicates TIPI is unlikely.

Results: Ten out of the eleven cases were analyzed because of lack of radiological data other than chest X-ray in one case. Baseline data of the ten patients were as follows: mean age, 69.7 y/o; sex, female 70%; mean disease duration of RA, 9.4 years; mean CRP level, 3.67 mg/dl (n=9); pulmonary comorbidity, 90%. Six and four cases were classified as the presumptive and probable TIPI, respectively. Among the patients with the presumptive TIPI, TIPI developed 88.4 days after the initiation (n=5) or 5 days after reinstitution (n=1) of tacrolimus. Four and two cases were exacerbation of pre-existed IP and newly developed pulmonary injuries, respectively. Main radiological patterns of the patients in the presumptive TIPI were DAD- (n=2), NSIP- (n=1), COP- (n=1) and UIP-pattern (n=2). All patients with the presumptive TIPI received high dosage of corticosteroids and two received immunosuppressants. Four out of the six patients survived.

Conclusion: Rheumatologist should be aware of this rare, but possibly life-threatening adverse drug reaction of tacrolimus in patients with RA.

Early Effects of High Dose Glucocorticoids On Blood Pressure and Weight in Early Rheumatoid Arthritis. Debby den Uyl[1], Hennie G. Raterman[2], Michael T. Nurmohamed[3], Ben A.C. Dijkmans[4], Alexandre E. Voskuyl[2], Dirkjan van Schaardenburg[3], Pit J.S.M. Kerstens[3] and Willem F. Lems[1], [1]VU University medical center, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Jan van Breemen Institute, Amsterdam, Netherlands, [4]VU Medical Centre, Amsterdam, Netherlands

Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular morbidity and mortality, partly due to a higher prevalence of traditional cardiovascular risk factors as hypertension (HP) and a higher body mass index (BMI). Treatment with glucocorticoids (GC's) might result in a higher cardiovascular risk due to the induction of HP and weight gain. On the other hand, GC's might reduce cardiovascular risk in RA patients due to favourable effects on the disease activity.

Purpose: To evaluate the short term effects of high dose glucocorticoids on blood pressure and weight in patients with early rheumatoid arthritis.

Method: In this ongoing study, patients were randomised for treatment with COBRA (including 60mg prednisone, tapered in 6 weeks to 7,5mg/day) or COBRA-light (including 30mg prednisone, tapered in 9 weeks to 7,5 mg/day). At baseline, 2 weeks, 4 weeks and 8 weeks of treatment, blood pressure (BP), body weight and body mass index (BMI) were determined. HP was defined as a systolic BP≥140 and/or diastolic BP≥90. BP and weight at week 2, week 4 and week 8 were compared with baseline measurements by Wilcoxon tests **Results:** 40 patients had complete 8 weeks follow-up available for analyses. There were no differences in baseline characteristics between patients treated with COBRA and COBRA-light. Median systolic blood pressure (IQR) was 130 mmHg (120-140), median diastolic blood pressure (IQR) was 80 mmHg (75-86) and 36% had prevalent high blood pressure. Median weight (IQR) was 72 kg (64-81) and median BMI (IQR) was 25 (22,6-26,3). BP did not change significantly during treatment, while after 8 weeks weight increased significantly compared with baseline. (table)

Table Systolic blood pressure, diastolic blood pressure, weight and BMI during 2, 4 and 8 weeks treatment

	2 weeks	4 weeks	8 weeks
Delta Median Systolic BP, mmHg (IQR)	0,0 (-10 - 7)	-1,0 (-10 – 9,5)	0,0 (-10 – 6,8)
Delta Median Diastolic BP, mmHg (IQR)	-1,0 (-7 - 5)	0,0 (-5 – 2)	0,0 (-9,8 - 5)
Delta Median Weight, kg (IQR)	0,5 (-1,6 – 1,5)	0,4 (-1,0 – 2,0)	1,0 (-0,4 – 2,0)*
Delta Median BMI (IQR)	0,3 (-0,6 – 0,6)	0,0 (-0,4 – 0,7)	0,4 (-3 – 1,6)

*$p<0.05$ compared with baseline

Conclusion: In our preliminary analyses, short term treatment with high dose corticosteroids in patients with early RA does not significantly influence blood pressure and increases weight minimally.

Documenting Adequate Versus Incomplete Responses to Methotrexate (MTX) at Initiation of Biologic Agents in Routine Clinical Care, According to ESR, RAPID3, and Component Patient-Reported Scores for Physical Function, Pain and Global Estimate. Theodore Pincus[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: To analyze adequate responses to methotrexate (MTX) in patients who were not subsequently treated with biologic agents, compared to incomplete responses in patients who subsequently were treated with biologic agents in usual care of patients with rheumatoid arthritis (RA), according to five measures: erythrocyte sedimentation rate (ESR), multidimensional health assessment questionnaire (MDHAQ) scores for physical function (MDHAQ-FN), pain (PN), patient global estimate (PTGL), and RAPID3 (routine assessment of patient index data), an index of the 3 patient-reported RA Core Data Set measures.

Methods: Patients seen from 1990-2006 had scores for MDHAQ-FN, PN, and ESR available from each visit; PTGL and the capacity to score RAPID3 was introduced in 1996. Adequate responders were defined as having no treatment with a biologic agent, while incomplete

responders were defined as having treatment with a biologic agent months to years after initiation of MTX. The mean interval from MTX initiation to a biologic agent was 2.6 years, 5.4 years before 1999, and 1.6 years after 1999. Mean and median measures at MTX initiation were compared to values at initiation of a biologic agent in incomplete responders, and to values 2.6 years after initiation of MTX in adequate responders who never were treated with a biologic agent. The proportion of patients with normal or abnormal values was also computed, defined as: ESR □28 mm/h; MDHAQ-FN >2 (after conversion to 0-10 scale from 0-3); PN and PTGL >2 (0-10 scale), and RAPID3 >6 (0-30 scale). A "RAPID3-estimate" without PTGL (correlated with RAPID3 at r □0.9) was used to assess patients seen prior to 1996. RAPID3 severity categories are high >12, moderate 6.1-12, low 3.1-6, and remission □3.

Results: Median baseline values in 63 patients who had adequate responses to MTX and never took a biologic agent were: 25 mm/h for ESR, 2.3 for MDHAQ-FN, 4.1 for PN, 4.2 for PTGL, and 10.6 (moderate/high severity) for RAPID3 (0-30 scale). Overall, 46%, 53%, 73%, 75% and 76% had "abnormal" values for these 5 measures, respectively, at initiation of MTX. At follow-up of these patients, improvement was seen with values of 16 mm/h for ESR, 1.0 for MDHAQ-FN, 1.4 for PN, 0.9 for PTGL, and 3.6 for RAPID3 (indicating low severity/remission). Improvement in each measure was 33%, 56%, 66%, 79% and 66%, respectively, over the mean of 2.6 years since initiation of MTX. In 30 incomplete responders, mean baseline values were somewhat higher than in those who ultimately were adequate responders to MTX, including ESR of 28 mm/h, MDHAQ-FN 3.2, PN 5.2, PTGL 5.5 and RAPID3 score of 14.9 (high severity). However, at initiation of a biologic agent at a mean 2.6 years later, mean values were improved only for ESR, by 36%, with poorer status MDHAQ-FN of -3%, PN of -31%, PTGL unchanged, and RAPID3 of -9%, with a median of 14.9, indicating high severity.

63 patients MTX-only: Adequate responses – no biological agents					
	MTX start		Follow-up mean 2.6 years later		
	Median	% abnormal	Median	% abnormal	% improvement
ESR (mm/h)	24	46%	16	22%	33%
MDHAQ-FN (0-10)	2.3	53%	1.0	40%	56%
Pain (0-10)	4.1	73%	1.4	44%	66%
PTGL (0-10)	4.2	75%	0.9	35%	79%
RAPID3 (0-30)	10.6	76%	3.6	39%	66%
30 patients biologic agents: Incomplete response to MTX with addition of biologic					
	MTX start		Biologic start mean 2.6 years later		
	Median	% abnormal	Median	% abnormal	% improvement
ESR (mm/h)	28	50%	18	40%	36%
MDHAQ-FN (0-10)	3.2	63%	3.3	77%	-3%
Pain (0-10)	5.2	90%	6.8	83%	-31%
PTGL (0-10)	5.5	96%	5.5	87%	0
RAPID3 (0-30)	14.9	88%	16.2	87%	-9%

Conclusion: Adequate or incomplete responses to MTX can be documented effectively with quantitative RAPID3 collected in routine clinical care. MDHAQ-FN, pain, PTGL and RAPID3 are more likely to document adequate vs incomplete responses than ESR.

Hydroxychloroquine Use: Significant Improvement of Lipid Profile in Rheumatoid Arthritis Patients. Stephanie Morris[1], Jennifer Sartorius[2], Lester Kirchner[2], Eric D. Newman[1], M. C. Wasko[3] and Androniki Bili[1], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Medical Center, Danville, [3]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Purpose: Cardiovascular disease (CVD) is the leading cause of mortality in patients with rheumatoid arthritis (RA). Both traditional and nontraditional risk factors contribute to atherogenesis. Disease modifying-therapies that also improve metabolic risk factors for CVD, such as type 2 diabetes mellitus (T2DM) and dyslipidemia are desired. In a recent study, hydroxychloroquine (HCQ) use was associated with

reduction in T2DM risk. This study used an electronic health record (EHR) to determine if HCQ use was associated with an improvement in lipid levels in a large population-based cohort of RA patients.

Method: Patients diagnosed with RA from September 2000-February 2008 (ICD-9 code 714.0 at ≥2 office visits with a rheumatologist) were identified through the EHR (n= 2093). 1,078 patients did not have available lipid profiles after RA diagnosis and were excluded. Information on demographics, medical history, body mass index (BMI; kg/m^2), lab measures, and medications were collected at office visits. 1,015 patients had repeated post-RA lipid measurements, resulting in 4,408 lipid-level results. Each patient's post-RA diagnosis HCQ usage status was evaluated at each lipid measurement. Potential risk and protective factors for dyslipidemia were controlled for in the time-varying, random effects regression models for the following lipids: low density lipoprotein (LDL), high density lipoprotein (HDL), total cholesterol, and triglycerides. The time in years from each patient's RA diagnosis date to each lipid result date was calculated and included in all models. Nonlinear time trends and interactions between HCQ and time were checked for all models.

Results: Patients were 70% female, 98% Caucasian, with median age of 65 y and body mass index (BMI) 29.5 kg/m^2. Rheumatoid factor (RF) (22% known) and anti-cyclic citrullinated peptide (anti-CCP) (17% known) antibodies were positive in 66% and 42%, respectively. Of the 1,015 patients that were included in the analysis, 236 (23%) were ever on HCQ. The median levels of individual lipids according to years post-RA diagnosis by HCQ use are shown in Table 1. In the regression models, after adjusting for demographic features, BMI, sedimentation rate, RF, anti-CCP, T2DM, hypertension, use of steroids, NSAIDs, anti-TNF agents, methotrexate, and lipid-lowering medications, HCQ use was associated with the following average changes in lipids over time: LDL – decrease of 8.40 mg/dl ($p<0.001$), total cholesterol – decrease of 8.49 mg/dl ($p<0.001$), triglycerides – decrease of 11.49 mg/dl ($p=0.023$), and HDL – increase of 1.97 mg/dl ($p=0.005$). These effects were found to be constant over time.

Conclusion: Use of HCQ in this RA cohort was independently associated with a significantly improved lipid profile over time with significant average decreases in total cholesterol, LDL, triglycerides, and increase in HDL. Considering these results, its safety profile, and low cost, HCQ remains a valuable initial or adjunct therapy in this high CVD risk patient population.

Table 1. Lipid Results over Time since RA Diagnosis by HCQ Medication Status (n=4,406)

Lipid	HCQ Status	Years since RA diagnosis to lipid result		
		0-3 (n=2389)	>3-6 (n=1779)	>6 (n=230)
LDL (mg/dl)	No (n=3501)	106 (83-132)	102 (80-126)	98 (72-123)
	Yes (n=661)	102 (79-126)	90 (72-111)	72 (57-93)
HDL (mg/dl)	No (n=3296)	52 (43-63)	50 (41-62)	46 (39-56)
	Yes (n=616)	59 (44-64)	57 (48-68)	60 (54-70)
Total Cholesterol (mg/dl)	No (n=3359)	192 (165-223)	187 (162-214)	183 (150-213)
	Yes (n=636)	188 (162-212)	176 (158-210)	158 (132-190)
Triglyceride (mg/dl)	No (n=3288)	146 (108-211)	145 (107-207)	148 (93-214)
	Yes (n=599)	140 (101-192)	113 (84-163)	84 (56-122)

Decrease in the Ratio of Small Dense LDL to LDL in the RA Patients Treated with Anti-TNF-α Agents. Sachiko Onishi[1], Taku Yoshio[1], Takao Nagashima[1], Shoji Yamazaki[2], Masahiro Iwamoto[1] and Seiji Minota[1], [1]Jichi Medical University, Shimotsuke, Japan, [2]Jichi Medical University Hospital, Shimotsuke, Japan

Purpose: The mortality among patients with rheumatoid arthritis (RA) is higher than that among the healthy population. This increased mortality is largely associated with the complication of cardiovascular disease (CVD). Recently, small dense LDLs (sdLDLs) were reported to contribute to the risk for CVD, even when the total plasma LDL levels are not elevated. RA patients are also reported to have significantly increased sdLDL levels. Anti-TNF-α agents may improve the survival of RA patients; therefore, we examined the lipid profiles including sdLDL levels in RA patients who were treated with anti-TNF-α agents.

Method: 24 and 26 RA patients treated with infliximab and etanercept, respectively, were incluced in this study.Plasma samples were collected at the baseline (before drug initiation at week 0) and at 2 and 6 months and 1 year. The response to these agents was evaluated on the basis of the changes in the C-reactive protein (CRP) levels and the DAS28-CRP score. Serum lipid profiles were assessed using a high-sensitivity lipoprotein-profiling system with high-performance liquid chromatography.

Results: Both agents significantly decreased the DAS28 score, number of tender and swollen joints, global health scores, and CRP levels. The plasma levels of total cholesterol (TC), LDL-cholesterol, and HDL-cholesterol (HDL-C) significantly increased, but the atherogenic index, which was calculated as (TC – HDL-C)/HDL-C, did not change. Although the plasma sdLDL levels significantly increased, the ratio of sdLDL to LDL decreased from 35.3% to 27.6% (p=0.0006).

Conclusion: Anti-TNF-α agents may have beneficial effects by decreasing the sdLDL-to-LDL ratio, and may contribute to the improved mortality of RA patients.

Plasma Myeloperoxidase Activity Is Increased in Patients with RA Compared to Healthy Controls and Is Associated with Abnormal Anti-Inflammatory Function of High Density Lipoprotein. Christina Charles-Schoeman[1], Yuen Yin Lee[1], Sogol Amjadi[1], Maureen A. McMahon[2], Harold E. Paulus[1] and Srinivasa T. Reddy[1], [1]David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: We have previously shown that abnormal anti-inflammatory function of high density lipoprotein (HDL) in RA patients is associated with high levels of systemic inflammation and an altered HDL-associated protein cargo. Myeloperoxidase (MPO) is a heme peroxidase abundant in activated neutrophils which has been shown to inhibit HDL function by oxidatively modifying apolipoprotein A-1 (apoA-1). Systemic MPO levels predict the presence and extent of coronary artery disease in the general population. The current work investigates whether plasma MPO activity is increased in RA patients compared to healthy controls, and whether higher MPO activity is associated with worse anti-inflammatory function of HDL in patients with RA.

Methods: 40 patients with RA were compared with 40 age and sex matched healthy controls. Plasma MPO activity was assessed by a commercially available colorimetric assay which uses a polyclonal antibody specific for human MPO. HDL's anti-inflammatory function was assessed by a previously published cell free assay which assesses the ability of patient HDL to inhibit oxidation of a stock LDL. Plasma levels of ApoA1 were assessed by standard ELISA and paraoxanase-1 (PON-1) activity was measured by a previously described arylesterase assay.

Results: Patient characteristics are described in the table below. Plasma MPO activity was higher in RA patients compared to healthy controls and was significantly correlated with HDL function in patients with RA (r = 0.41/p=0.009); higher plasma MPO activity was associated with worse HDL anti-inflammatory function as measured by the HDL inflammatory index (HII). Both MPO activity and HDL function were significantly correlated with RA disease activity measured by the DAS28 (r = 0.45 and 0.42 respectively, p values<0.008). Higher RA disease activity was associated with higher MPO activity and worse HDL function. The activity of PON-1, an anti-oxidant enzyme associated with HDL, was lower in RA patients compared to healthy controls (p=0.03). There were no significant differences in quantitative HDL, LDL, or ApoA-1 levels between the two groups.

Group	HII	Age (yrs)	F (%)	HSCRP (mg/L)	ESR (mm/h)	HDL (mg/dL)	LDL (mg/dL)	ApoA-1 (ug/ml)	MPO (ng/ml)	PON (mOD/min)

								77		

F=Female; HII=HDL Inflammatory Index; *p value < 0.05 compared to controls.

Conclusion: Plasma MPO activity is increased in RA patients compared to healthy controls and is associated with abnormal HDL anti-inflammatory function and increased disease activity. Oxidative modification of HDL by MPO may provide another mechanism by which active RA increases cardiovascular morbidity and mortality.

Short Term Treatment of High Dose Glucocorticoids Improves the Lipid Profile in Early Rheumatoid Arthritis. Debby den Uyl[1], Hennie G. Raterman[2], Willem F. Lems[1], Ben A.C. Dijkmans[3], Alexandre E. Voskuyl[2], Dirkjan van Schaardenburg[4], Pit J.S.M. Kerstens[4] and Michael T. Nurmohamed[4], [1]VU University medical center, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands, [4]Jan van Breemen Institute, Amsterdam, Netherlands

Early rheumatoid arthritis (RA) is associated with an unfavourable lipid profile, i.e. a lower total cholesterol (TC) and an even more depressed high density lipoprotein (HDL)-cholesterol, resulting in a higher atherogenic index. Treatment with low-dose glucocorticoids might have favourable effects on the lipid profile.

Purpose: To compare the early changes of medium and high dose prednisone on lipid profile in patients with early rheumatoid arthritis.

Method: In this ongoing study, patients were randomised for treatment with COBRA (incl. 60mg prednisone, tapered in 6 weeks to 7,5 mg/day) or COBRA-light (incl. 30mg prednisone, tapered in 9 weeks to 7,5 mg/day). At baseline and after 2, 4 and 8 weeks of treatment, fasting blood samples were collected and C-reactive protein (CRP), TC, HDL-cholesterol, LDL-cholesterol and triglycerides were determined. The atherogenic index (AI) was assessed (TC/HDL). General estimation equations (GEEs) was used to analyse the time course of lipid levels and to investigate the influence of disease activity (i.e. CRP).

Results: 49 patients had complete 8 week follow-up data available for analysis. There were no differences in baseline characteristics between patients treated with COBRA and COBRA-light. During treatment CRP decreased rapidly. After 8 weeks an increase in lipids was seen; median TC by 15%, median HDL by 29%, median LDL by 10%, median triglycerides by 18%, while the median AI decreased by 12%. GEE analyses revealed that TC, HDL, LDL, triglycerides and the AI changed significantly over time, which remained significant after adjusting for age, gender and CRP. Table lipide profile during treatment

	Baseline	2 weeks	4 weeks	8 weeks
Median CRP, mg/l (IQR)	16 (6,5-44,5)	2,00 (1,0-4,25)*	2,75 (1,25-7,75)*	3,00 (2,0-11,5)*
Median total cholesterol, mmol/l (IQR)	4,7 (4-5,75)	5,2 (4,65-6,25)*	5,6 (5,0-6,4)*	5,5 (5,05-6,45)#
Median HDL-cholesterol, mmol/l (IQR)	1,29 (1,05-1,56)	1,79 (1,36-2,04)*	1,88 (1,46-2,36)*	1,69 (1,39-1,96)*
Median LDL-cholesterol, mmol/l (IQR)	2,89 (2,05-3,59)	2,92 (3,36-3,72)	3,01 (2,6-3,7)#	3,29 (2,63-4,04)*
Median Triglycerides, mmol/l (IQR)	1,14 (0,9-1,42)	1,27 (1,11-1,67)#	1,25 (1,0-1,71)#	1,39 (0,99-1,75)#
Median atherogenic index (IQR)	3,57 (2,82-4,82)	3,13 (2,54-3,88)*	2,90 (2,36-3,59)*	3,29 (2,65-4,14)*

*p<0.001 compared with baseline, # p<0,05 compared with baseline (Wilxocon test)

Conclusion: In our preliminary analyses, aggressive treatment with high dose corticosteroids in early RA rapidly increases total cholesterol and HDL-cholesterol and decreases the atherogenic index. Whether or not this results this favourable effect on the cardiovascular risk is ultimately offset by other side effects of corticosteroid use remains to be established.

The ApoB/ApoA1 Ratio Predicts Future Cardiovascular Events in Patients with Rheumatoid Arthritis. Solveig Wållberg-Jonsson, Maria Öhman and Solbritt Rantapää-Dahlqvist, Norrland University Hospital, Umeå, Sweden

Purpose: Patients with rheumatoid arthritis (RA) have increased mortality and morbidity due to cardiovascular disease (CVD). The reasons are not fully understood. A high apolipoproteinB (apoB)/apolipoproteinA1(apoA1) ratio has been shown to predict CV event in the general population. ApoA1 has, besides anti-atherogenic effects, been suggested to have anti-inflammatory properties (1). In a previous study we found a relationship between apoB and IL-1RA in RA (2). In the present study, we evaluated the importance of apoA1, apoB and the apoB/apoA1 ratio in addition to lipids, hemostatic variables and measures of disease activity, for the development of CVE during 18 years, in patients with RA.

Method: 74 patients (61 f/13 m, mean age 63.6 years, disease duration 22.1 years) with seropositive, inflammatory active RA (mean ESR 47.9±2.4mm/h) were investigated in a previous study (3) consecutively regarding apolipoproteins (apoA1, apoB), hemostatic factors (von Willebrand factor (vWF), tissue plasminogen activator (tPA) and its inhibitor (PAI-1), lipid levels (cholesterol, triglycerides (TG)), lipoprotein(a) and markers of inflammation (ESR, CRP, haptoglobin). A survey of all hospital records was made after 18 years with registrations of: First CVE during follow-up (myocardial infarction, stroke/TIA, deep vein thrombosis/pulmonary embolism, CABG), traditional CV risk factors (hypertension, smoking, diabetes mellitus, previous CVD) extraarticular disease and pharmacological treatment (DMARDs, corticosteroids).

Results: In all 33 patients had a new CVE during the follow-up. These patients had significantly higher apoB/apoA1 ratio (0.96 vs 0.81, $p<0.05$), significantly higher levels of TG (1.5 vs 1.2 mmol/l, $p<0.05$) and ESR (54.3 vs 42.6, $p<0.05$) and of vWF (212.6 vs 143.9%, $p<0.001$) than patients without development of CVE. No correlation was found between the apoB/apoA1 ratio and inflammatory variables. ApoA1 corrrelated weakly and inversely with haptoglobin ($p=0.056$). In multiple cox regression, the apoB/apoA1 ratio could predict a new CVE significantly besides vWF, ESR and previous CVD.

Conclusion: The apoB/apoA1 ratio was associated with the development of CVE during 18 years follow up in patients with active RA. There was no obvious association between apolipoproteins and inflammation. References: (1)Breshnihan B et al. Arthritis Res Ther 2004, (2) Ljung et al. 1655

Seven Year Follow-up of Infliximab (IFX) in Rheumatoid Arthritis (RA) Patients : Attrrition, Safety and Efficacy. Bert Vander Cruyssen[1], Patrick Durez[2], Rene Westhovens[3] and Filip De Keyser[4], [1]University Hospital Ghent, Ghent, Belgium, [2]Univ Catholique de Louvain, Brussels, Belgium, [3]University Hosp KU Leuven, Leuven, [4]Ghent University Hospital, Gent, Belgium

Purpose: This study is based on the results from a Belgian expanded access program in which patients with active refractory and erosive rheumatoid arthritis (RA) were treated with intravenous infusions of infliximab (IFX) in combination with methotrexate (MTX). The objective of this study was to evaluate the continuation rate of IFX and its clinical effect over a 7 year period.

Method: Between 2000 and 2001, 511 patients were enrolled in the program (ref). Patients had a median disease duration of 10 years and had failed an average of 3.9 disease modifying anti-rheumatic drugs (DMARDs), including MTX. Patients were treated with IFX at week 0, 2, 6 and every 8 weeks thereafter with a standard dose of 3 mg/kg, although dose increases with 1 extra vial (100 mg) were possible. After 7

years, apart from routine clinical follow-up, treating rheumatologists were asked to complete a questionnaire designed specifically for the present study to evaluate the current therapy with IFX, the level of disease activity (DAS28) and functional disability (HAQ) and to document the reasons for IFX discontinuation

Results: After 7 years, available data were obtained from 441 of 511 patients: 4 patients did not initiate treatment, 17 patients died and 49 patients were lost to follow-up. Of the remaining 441 patients, 160 were still on IFX-treatment at year 7. The major reasons for IFX discontinuation included lack of efficacy (104 patients), adverse events (107 patients) and elective change of therapy (70 patients).

50% of treatment discontinuation for safety reasons occurred during the first two years. There were no unexpected long-term safety issues. In contrast, discontinuation due to inefficacy, showed a more constant discontinuation rate over the 7 years. Mean DAS of patients still under treatment with IFX decreased from 5.7 (SE = 0.1) at baseline to 3.0 (SE= 0.12) at year 4 and remained that low till year 7. Mean HAQ was 1.07 (SE=0.06) at year 7. Low disease activity (defined as DAS28 < 3.2) was present in 60.9% of patients and 45.5% achieved remission (DAS28<2.6).

Conclusion: This study describes the 7 year follow-up of a cohort of 511 RA patients with longstanding, refractory disease who were treated with IFX in combination with MTX. After 7 years patients who continue to receive IFX experience sustained clinical benefit, as reflected by the maintenance of low DAS and HAQ scores. Long term treatment with IFX appears to be safe : safety issues occurred in a higher frequency during the first 2 years of IFX treatment.

Sustainability of Clinical Remission with Etanercept and Methotrexate, in Combination or as Monotherapy, in Early Active Rheumatoid Arthritis. Paul Emery[1], Patrick Durez[2], T.K. Kvien[3], Nicholas Manolios[4], Ronald Pedersen[5], Debbie H. Robertson[6], Joanne Foehl[5], Andrew S. Koenig[5] and Bruce Freundlich[5], [1]Leeds General Infirmary, Leeds, United Kingdom, [2]Univ Catholique de Louvain, Brussels, Belgium, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Westmead Hospital, Westmead, Australia, [5]Wyeth Research, Collegeville, PA, [6]Wyeth Pharmaceuticals, Collegeville, PA

Purpose: This subanalysis was done to identify those subjects with active early RA from the COMET trial who sustained remission from Week 24 to Week 104 while receiving etanercept (ETN) + methotrexate (MTX), ETN monotherapy, or MTX monotherapy.

Method: This double-blind, randomized study consists of two 12-month periods. In Year 1, subjects received either combination therapy or MTX monotherapy. In Year 2, a subset of the combination group dropped MTX and a subset of the MTX monotherapy group added ETN. Eligible subjects had disease duration ≤2 years, were MTX-naïve, and had active RA (DAS28 ≥3.2) with either elevated ESR (≥28 mm/hr) or CRP levels (≥20 mg/L). MTX was titrated from Wk 4 to a maximum of 20 mg/wk at Wk 8. An observed analysis of remission (DAS28 <2.6) was performed at Wk 24; from these responders; sustained remission was assessed by completers' analysis at Wks 52 and 104. Additionally, for subjects who completed Wk 24, evaluation of sustained remission at Wk 52 and again at Wk 104 was performed using nonresponder imputation (NRI).

Results: Of 542 subjects enrolled, 446 subjects were evaluated for remission at Wk 24; 348 of these completed 104 wks of study. 165/446 (37%) fulfilled the remission criteria at Wk 24; 112/165 (68%) of the Wk 24 responders sustained remission to Wk 52, and 90/165 (55%) sustained remission to Wk 104. The numbers of completers were less in groups MTX/ETN+MTX and MTX/MTX due to the larger dropout rate in the MTX monotherapy group *v* combination therapy group over 2 years. Remission by treatment arm is given in the Table. Results of the NRI analysis at Wks 52 and 104 were similar to those of the observed analysis.

Conclusion: In this population of early, active RA subjects, sustained remission from 24 to 52 to 104 wks was achieved in a greater percentage of subjects who were treated with combination therapy for at least 1 yr compared with those who received MTX monotherapy throughout the entire 2-yr study. Sustained remission in early RA subjects who achieve remission at 24 wks appears to be an attainable goal, based on both completers' and NRI analysis in this study. Further research on sustained radiographic nonprogression and normal function in this subset of Wk 24 responders is indicated.

N (%) of Subjects by Treatment Group, Completers' Analysis of Sustained Remission to Wk 104 Based on Wk 24 Responders

	ETN+MTX/ETN+MTX	ETN+MTX/ETN	MTX/ETN+MTX	MTX/MTX
Week 24	52/113 (46%)	54/122 (44%)	29/107 (27%)	30/104 (29%)
Week 52	37/48 (77%)	41/48 (85%)	20/26 (77%)	14/27 (52%)
Week 104	32/46 (70%)	32/41 (78%)	17/22 (77%)	9/23 (39%)

Disease Remission, Radiographic Non-Progression and Normalization of Function Achieved at Year 1 Are Sustained Long-Term in a Majority of Patients: 5-Year Outcomes with Abatacept in Biologic-Naïve Patients. R. Westhovens[1], M. Dougados[2], S. Hall[3], D. Moniz Reed[4], J. C. Becker[4], J. Teng[4] and J. M. Kremer[5], [1]UZ Gasthuisberg, KU Leuven, Leuven, Belgium, [2]Hospital Cochin, Descartes Univ, Paris, France, [3]Cabrini Medical Center, Malvern, Victoria, Australia, [4]Bristol-Myers Squibb, Princeton, NJ, [5]Albany Medical College, Albany, NY

Purpose: EULAR/ACR recommendations stress the importance of reporting the sustainability of treatment outcomes[1]. In the AIM (Abatacept in Inadequate responders to MTX) trial at the group level, improvements in signs/symptoms were sustained or further improved in the majority of abatacept patients (pts) over 5 yrs[2]. Here, we present pt-level analyses examining sustained reduction of disease activity, inhibition of X-ray progression, and improvements in physical function and health-related quality of life (HRQoL) with abatacept from Yr 1 up to Yr 5.

Methods: These as-observed analyses were based on pts randomized to abatacept who entered the long-term extension (LTE). For Low Disease Activity State (LDAS; DAS28 □3.2), DAS28 (CRP)-defined remission (DAS28 <2.6), X-ray non-progression (change in Genant-modified Sharp total score □0), Health Assessment Questionnaire-Disability Index (HAQ-DI) normalization (≤0.5) and Short Form-36 mental and physical component scores (PCS and MCS, respectively [≥50]), the proportions of patients sustaining responses from Yr 1 to Yrs 2, 3, 4 and 5 were assessed.

Results: Overall, 378 pts randomized to abatacept entered the LTE and were eligible for analysis; 46, 21, 22 and 23 pts discontinued in Yrs 2, 3, 4 and 5, respectively (in the LTE, 22 [5.8%] due to lack of efficacy and 37 [9.8%] due to adverse events). Disease activity was >5.1 at baseline (mean DAS28: 6.4 and mean HAQ-DI: 1.7). Sustainability of LDAS, DAS28-defined remission, normalization of HAQ-DI, X-ray non-progression, and PCS and MCS □50 are presented (Table).

Conclusion: In approximately 2/3 of pts randomized to abatacept in AIM, clinical remission, radiographic non-progression, and normalization of physical function and HRQoL were maintained over 5 yrs of abatacept treatment. These data suggest that abatacept can provide sustained disease modification and restore normal physical function in patients with RA.

Safety of Infliximab in the Patients with Rheumatoid Arthritis and History of Hepatitis B Virus Infection. Xuewu Zhang, Xia Liu, Yuan An, Xu Liu and Zhanguo Li, Bejing Univ People's Hosp, Beijing, China

Purpose: The biological agents such as infliximab are becoming more and more important in treating autoimmune diseases (eg. RA). There was also evidence to prove the significant efficacy of these drugs in inhibiting disease progression and bone destruction. However, the risk of inducing or exacerbating infections by these agents has also been increasingly recognized. Furthermore, there were existing debates over whether to use these agents in patients with chronic HBV infection history. To evaluate the safety of treatment with tumor necrosis factor α (TNF-α) monoclonal antibody (Infliximab) in patients with rheumatoid arthritis(RA) who had the normal liver function and pre-existent HBV infection.

Method: In this multicenter study, all 41 cases met the ACR 1987 revised criteria for RA, including 7 men and 34 women, with average age of 46.2±2.72 years old and average disease course of 11.40±5.72 years. In patients were assessed for serological status(anti-HBC, anti-HbsAb, anti-HBeAb). Four of them were only anti-HBC (+); fifteen were anti-HBsAb (+), anti-HBeAb (+) and anti-HBc (+); six were anti-HBsAb (+) and anti-HBeAb (+); forteen were anti-HBsAb(+) and anti-HBc(+), two were anti-HBeAb (+) and anti-HBc (+); but normal for both alanine aminotransferase(ALT) and aspartate aminotransferase (AST), except one patient with positive anti-HBc showed elevated ALT before administration of infliximab (60U/L). All patients received intravenous Infliximab therapy with doses of 3 mg/kg at weeks 0, 2, 6, 14 and 22 respectively after testing liver function, Creatinine, T-bilirubin, leukocyte and platelet. All the above parameters were reexamined at week 26.

Results: 40 out of 41 patients, the ALT, AST, T-bilirubin, Creatinine, leukocyte and platelet were in the normal range, with no significant differences between HBV positive and HBV negative groups. As for the patients with elevated ALT and AST levels after the infusion, there was no statistically significant difference between the HBV patients and the non-HBV patients.

Conclusion: In RA patients with preexisting HBV infections, liver function abnormality were not observed during the Infliximab administration, as long as HBsAg was negative with normal liver function at baseline.

1659

An Increasing Proportion of Patients Achieve a Low Disease Activity State or Remission When Switched From Infliximab to Abatacept Regardless of Initial Infliximab Treatment Response: Results From the ATTEST Trial. M. Schiff[1], M. W. Keiserman[2], D. Moniz Reed[3], M. Le Bars[4], J.-C. Becker[3], C. Zhao[3] and M. Dougados[5], [1]Univ of Colorado School of Medicine, Denver, CO, [2]Pontificial Catholic Univ, Porto Alegre, Brazil, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Bristol-Myers Squibb, Rueil-Malmaison, France, [5]Hospital Cochin, Descartes Univ, Paris, France

Purpose: Clinical trials of patients (pts) who switch between biologic therapies generally assess pts after failure of a prior biologic. At Yr 1 of ATTEST[1] (Abatacept or infliximab vs placebo, a Trial for Tolerability, Efficacy and Safety in Treating RA) all pts received abatacept regardless of clinical response or original treatment group. Uniquely, this trial design allowed the assessment of pts who switched from infliximab to abatacept after 1 yr, with various degrees of prior response to infliximab.

Methods: Biologic-naïve pts with RA were randomized to abatacept (~10 mg/kg every 4 weeks), placebo or infliximab (3 mg/kg every 8 weeks), plus MTX. At Mth 6 and Yr 1, placebo- and infliximab-treated pts, respectively, were switched to abatacept. Disease activity was assessed by DAS28 (CRP). High, Moderate and Low Disease Activity States (HDAS, MDAS and LDAS, respectively), and remission were defined as >5.1, >3.2–5.1, □2.6–3.2 and <2.6, respectively. These as-observed *post-hoc* analyses include pts originally randomized to infliximab who entered the long-term extension and had data available at Yr 1 and Yr 2. Data from the original abatacept group are not presented here.

Results: In total, 136 infliximab-treated pts entered the LTE and were eligible for inclusion in these analyses. After switching from infliximab to abatacept at Yr 1, 81.5% (22/27) of pts who were in HDAS improved their disease state by Yr 2. The majority of pts in MDAS and LDAS after 1 yr of infliximab treatment improved their disease state after receiving abatacept for 1 yr (at Yr 2, 60.7 [34/56] and 64.3% [9/14] had improved, respectively). Of the pts who had achieved remission after 1 yr of infliximab treatment, 71.4% maintained their disease state at Yr 2 after switching to abatacept.

Disease status at Yr 1		**Shift in DAS28 status from Yr 1 to Yr 2 after switching from infliximab to abatacept, %**			
	Total, % (n)	**HDAS**	**MDAS***	**LDAS†**	**Remission**
HDAS	21.6 (27)	18.5	55.6	7.4	18.5
MDAS*	44.8 (56)	5.4	33.9	33.9	26.8
LDAS†	11.2 (14)	0	21.4	14.3	64.3
Remission	22.4 (28)	3.6	14.3	10.7	71.4

*But not LDAS/remission; †But not remission

Conclusion: In these *post-hoc* analyses, despite 1 yr of infliximab treatment, the majority of patients improved/maintained their disease status after switching to abatacept regardless of their initial infliximab treatment response. In total, an additional 30% of patients achieved remission after switching to abatacept.

1660

An Open-Label, Prospective Study (SUNDIAL) of the Safety of Rituximab in Combination with Disease-Modifying Anti-Rheumatic Drugs in Patients with Active Rheumatoid Arthritis (SUNDIAL). James Loveless[1], E. Olech[2], Charles H. Pritchard[3], A. Chai[4], Ariella Kelman[4] and Micki Klearman[4], [1]Intermountain Orthopedics, Boise, ID, [2]OK Med Research Foundation, Oklahoma City, OK, [3]Willow Grove, PA, [4]Genentech, South San Francisco, CA

Purpose: Rituximab (RTX) in combination with methotrexate (MTX) is an effective and well-tolerated therapy in patients with rheumatoid arthritis (RA). The primary objective is to characterize the safety of RTX when used in combination with DMARDs other than MTX alone in patients with RA.

Method: SUNDIAL is an open-label study of patients with RA who have had an inadequate response to ≥1 DMARD. Patients aged 18-80 years who received a DMARD regimen for ≥12 weeks received RTX (1000 mg IV x 2) plus their current DMARD therapy. Combinations included MTX (7.5–25 mg/wk), leflunomide (10–20 mg/day), sulfasalazine (1000–3000 mg/day), azathioprine (50-200 mg/day), and/or hydroxychloroquine (200–400 mg/day). Other than MTX alone or in combination with LEF, all other DMARDs (or combinations thereof) were permitted. The primary endpoint was the proportion of patients developing a serious adverse event (SAE) within 24 weeks after receiving one course of RTX.

Results: Of 401 patients, the mean (SD) age was 53.3 (11.3) years with 75% Caucasian and 75% female. The mean (SD) RA disease duration was 10.0 (9.3) years and 54% had previously used biologics. Mean (SD) baseline disease activity (DAS28) was 6.2 (1.1). A total of 27 (6.7%) withdrew before/at Week 24, with 3 (0.7%) due to AE. Patients received 15 different DMARD combinations; 54% were on a MTX-containing regimen; 59% were on 2 or more DMARDs. Overall, 26 SAEs in 24 (6.0%) patients were observed for an event rate (95% CI) of 14.39 events/100 pt-yr (9.9, 21.1) (Table). The most common SAEs included chest pain (n=3), pneumonia (n=2), and cellulitis (n=2). One patient died from malignant lung neoplasm considered unrelated to RTX treatment. Seven (1.7%) patients experienced 7 serious infections for a rate (95% CI) of 3.8 events/100 pt-yr (1.8, 8.1). Infusion reactions occurred in 59 (14.7%) patients after the 1st infusion and in 25 (6.2%) patients after the 2nd infusion. One serious infusion reaction (chest pain) occurred with the 1st infusion and none after the 2nd infusion. At Week 24, 15 (3.7%) patients were HACA+. HACA positivity was not related to choice of concomitant DMARD.

Conclusion: The overall safety of a single course of rituximab in combination with multiple non-biologic DMARDs did not reveal any new or unexpected safety concerns. Safety data was consistent with that previously reported for RTX + MTX (Cohen et al; A&R, 2006,54:2793-806, Emery et al; A&R, 2006, 54:1390-400). Further follow-up is ongoing.

Table Safety summary

	No. (%) Patients (N=401)	**No. of Events**	**Event Rate / 100 Patient-years (95% CI) (Total Patient Years =180.6)**
Any SAE	24 (6.0%)	26	14.39 (9.9-21.1)
Any Infection	164 (40.9%)	269	148.9 (132.1-167.8)
Serious Infections*	7 (1.7%)	7	3.8 (1.8-8.1)

*SAE or any infection that was treated with an IV antibiotic

Decreased Expression of the Endothelial Cell Activation Marker HLA-DQ in Skeletal Muscle After Three Months of Adalimumab Treatment in Patients with Rheumatoid Arthritis. Ulf Bergström[1], Cecilia Grundtman[2], Ingrid E. Lundberg[2], Lennart Jacobsson[1], Käth Nilsson[1] and Carl Turesson[1], [1]Malmö University Hospital, Malmö, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

Purpose: Treatment with tumor necrosis factor (TNF) inhibitors for severe rheumatoid arthritis (RA) has been associated with a decreased risk of cardiovascular (CV) disease in observational studies. Previous findings indicate that systemic endothelial expression of HLA-DQ and interleukin-1α (IL-1α) is increased in patients with severe extra-articular RA, indicating that they may be markers of systemic inflammation and increased CV risk. The aim of this study was to investigate these markers in muscle biopsies from patients treated with adalimumab.

Methods: 14 patients with active RA [11 females, 3 males; mean age 63.7 years; median (M) disease duration 9.0 years, interquartile range (IQR) 2.6-11.6; 11 (78 %) RF positive] were started on treatment with adalimumab 40 mg subcutaneously every two weeks. The patients had not been treated with adalimumab previously and had not received other TNF inhibitors within the last three months or glucocorticoids (> 20 mg prednisolon/day) within the last two weeks. 8 patients were on methotrexate (mean dose 18.75 mg/week, range 10-25). None of the patients had clinical signs of myopathy. A structured clinical evaluation was performed and muscle biopsies were taken from the tibial anterior muscle at inclusion and after 3 months treatment. Signs of inflammation and muscle fiber degeneration were evaluated in hematoxylin-eosin stained sections. IL-1α, HLA-DQ, and CD31 expression was investigated by immunohistochemistry. Quantification was based on the total tissue area and performed using blinded digital computerized image analysis.

Results: Disease activity decreased (DAS28 mean 5.6 vs 4.1; p=0.007) from baseline to the 3 month evaluation. A good or moderate EULAR response was seen in 8/14 patients. Muscle biopsies from 11 patients (6 responders/5 non-responders) were available for evaluation. There were no major inflammatory infiltrates within the skeletal muscle. HLA-DQ was mainly expressed in endothelial cells in capillaries, whereas IL-1α was mainly seen in larger vessels. Staining for HLA-DQ decreased significantly after treatment (M 0.073 %, IQR 0.027-0.121 vs M 0.023%, IQR 0.009-0.040; p=0.041). There was a similar trend for IL-1α (mean difference 0.049 %; 95 % confidence interval -0.069-0.168). Capillary density, measured as the proportion of CD31 positive area, also tended to be reduced after adalimumab treatment. Decreased expression of IL-1α was seen in EULAR good/moderate responders, but not in non-responders (mean difference 0.114% vs -0.028%). HLA-DQ expression decreased in both groups (median difference 0.046 % vs 0.036 %).

Conclusion: Treatment with adalimumab was associated with decreased expression of endothelial markers previously associated with severe systemic inflammation in RA. Our findings could indicate reduced systemic endothelial activation in patients treated with anti-TNF drugs, which may contribute to a lower risk of CV co-morbidity.

Reduced Incidence of Infusion Reactions to Infliximab in Patients Pre-Medicated with Acetaminophen. D. Choquette[1], William G. Bensen[2] and Francois Nantel[3], [1]Montreal, QC, [2]McMaster University, Hamilton, ON, [3]Kirkland, QC, QC

Purpose: Patients treated with infliximab (IFX) sometimes receive premedication in order to reduce the risk of infusion reactions (IR). These pre-medications including anti-histamines, intravenous steroids or acetaminophen either alone or in combination, are sometimes used by physicians in order to prevent the development of allergic reactions.

Methods: RemiTRAC Infusion is an observational registry among 12 Canadian sites where patients receiving IFX are followed prospectively to document pre-medication use, adverse events, infusion reactions and the management of IRs. Seven hundred and fourteen subjects have been enrolled since the registry inception in 2005. A total of 7598 infusions were recorded with a mean of 10.6 ± 7.3 infusions per patient representing 935 years of exposure. The majority of patients (n=366 or 51%) had rheumatoid arthritis whereas 17% (n=120) had ankylosing spondylitis and 6% (n=42) had psoriatic arthritis. The remaining patients were treated for gastroenterological or dermatological diseases.

Results: Among all infusions recorded (n=7598), 161 infusions resulted in an IR (2.1%) and almost all IRs were mild to moderate in severity (151/161 or 94%). Anti-histamines were used in 1591 infusions (21%) compared to steroids and acetaminophen which were used in 1488 (20%) and 1694 (22%) of infusions, respectively. The table below shows the effect of pre-medication on the incidence of IRs.

Premedication	Number of IRs (IR/# of infusions)	Incidence of IRs (%)	p value (vs None group)
None	87/4532	1.9 %	-
Any	74/3066	2.4 %	<0.05
Anti-histamines (AH)	57/1591	3.6%	<0.0001
Steroids (Ster)	45/1488	3.0 %	<0.001
Acetaminophen (Acet)	17/1694	1.0 %	<0.0001
AH alone	19/468	4.0 %	<0.01
Ster alone	10/503	2.0 %	n.s.
Acet alone	4/676	0.6 %	<0.0001
AH + Ster	24/292	8.2 %	<0.0001
Ster + Acet	1/211	0.5 %	<0.05
AH + Acet	4/337	1.2 %	n.s.
AH + Ster + Acet	5/416	1.2 %	n.s.

There was a significantly higher incidence of IRs in infusions that were pre-medicated compared to infusions that had no pre-medication (2.4 % vs 1.9%, $p<0.05$). Most of this increase could be accounted to anti-histamine pre-medication, either alone or in combination with steroids. This elevation in IRs under anti-histamine or steroid pre-medication may result from a selection bias since patients who experienced an IR were more likely to receive pre-medication and to have a subsequent IR. Surprisingly though, infusions in patients receiving acetaminophen, either alone or in combination with steroids, had a significantly reduced incidence of IR.

Conclusion: In a "real-life setting" registry, acetaminophen appears to be a premedication that significantly reduces the incidence of infusion reactions to IFX. The mechanism is unknown but suggests that most infusion reactions might be non-immunogenic in nature.

Serum Markers Associated with Clinical Response in Methotrexate Naïve Rheumatoid Arthritis Patients Treated with Golimumab, A Human Anti-TNF α Monoclonal Antibody. C. Wagner[1], M. U. Rahman[2], E. C. Hsia[2], P. Emery[3], R.M. Fleischmann[4], M. Mack[1], M. Elashoff[5] and S. Visvanathan[1], [1]Centocor R&D, Inc, Malvern, PA, [2]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [3]University of Leeds, Leeds, United Kingdom, [4]Metroplex Clinical Research Center, Dallas, TX, [5]Elashoff Consulting, Redwood City, CA

Purpose: To identify serum markers that are associated with clinical response in MTX naïve rheumatoid arthritis (RA) patients treated with golimumab (GLM) with and without MTX.

Methods: In the GO-BEFORE study, 637 patients were randomly assigned in a 1:1:1:1 ratio to receive Placebo (PBO) + Methotrexate (MTX): GLM 100 mg+ PBO: GLM 50 mg + MTX:GLM 100 mg + MTX. Sera were collected at wks 0, 4 and 24 from all patients for testing CRP and a subset of 100 - 150 patients for testing select markers of inflammation and bone/cartilage metabolism and protein profiling using multi-analyte profiles. The % change from baseline in markers was compared between the PBO+MTX and combined GLM+MTX group (50 mg + 100 mg) and the GLM+PBO group using ANOVA on the van der Waerden normal scores and t tests. For CRP analyses all GLM groups combined were compared with PBO+MTX. Logistic regression models were used to test for the association of serum markers with clinical endpoints.

Results: Select acute phase (CRP, serum amyloid P) and inflammatory (ICAM-1, MIP1b, MMP-3, ENRAGE and IL-16) markers were significantly decreased at wk 4 and /or wk 24 after treatment with GLM + MTX as compared to PBO + MTX ($p<0.01$). Similar markers

were modulated by GLM + PBO treatment. Further, in the GLM + MTX group, baseline levels of CD40L and osteocalcin were associated (OR 2.04, 2.39, p<0.02) with ACR 50 response at wk 24 and baseline deoxypyridinoline and α1anti-trypsin levels were associated with ACR 20 response (OR 8.74, 0.226, p <0.05) at wk 24. Decreases in MIP1α and ICAM-1 levels at wk 4 were associated with ACR 20 (OR 0.226, 0.113; p<0.05) and DAS 28 (OR 0.231, 0.037; p<0.05) responses at wk 24 in GLM + MTX treated patients. Significant changes in select markers were observed in ACR 20/ACR 50/DAS28 responders as compared to non-responders at wk 24 – including MMP-3, von Willebrand factor, haptoglobin, fibrinogen, ICAM-1, IL-16, serum amyloid P, VEGF, CRP, ENRAGE, IL-6 and bone alkaline phosphatase. A 50% decrease from baseline in CRP level at week 4 was associated with ACR 20 response in patients receiving GLM+/-MTX (OR=1.82; p<0.0026,) but not in patients receiving PBO+MTX (OR=1.42; p=0.367).

Conclusion: Baseline levels and changes at wk 4 in levels of select markers were associated with clinical response to GLM + MTX or GLM + PBO treatment at wk 24 in MTX naïve RA patients. Select markers were significantly changed in clinical responders as compared with non-responders. A 50% decrease from baseline in CRP level 4 wks after first dose of GLM were associated with clinical response at wk 24.

1664

Golimumab Is Efficacious in Anti-TNF Agent Experienced Patients with Active RA Regardless of Type of Agent or Reason for Discontinuation of Prior Anti-TNF Agent: Results From the GO-AFTER Study. J. S. Smolen[1], M. K. Doyle[2], Jonathan Kay[3], E. L. Matteson[4], R. Landewé[5], E. C. Hsia[2], Y. Zhou[6] and M. U. Rahman[2], [1]Medical Univ Vienna, Vienna, Austria, [2]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [3]University of Massachusetts Memorial Medical Center, Worcester, MA, [4]Mayo Clinic, Rochester, MN, [5]U Hosp Maastricht, Maastricht, Netherlands, [6]Centocor R&D, Inc, Malvern, PA

Purpose: To assess efficacy and tolerance of GLM by type, number, or reasons for d/c of prior anti-TNF agent(s).

Method: Pts could have received 1 or more anti-TNF agent(s) and may have d/c'd for any reason(s). Concomitant use of DMARDs, methotrexate, sulfasalazine and hydroxychloroquine was allowed. Subgroup analyses were performed for ACR20 response at wk14 across DMARD use, number of prior anti-TNFs and reason for d/c of prior TNF inhibitor, such that odds ratios and 95% confidence intervals were calculated comparing the proportions of ACR20 responders at wk14 in the combined GLM vs PBO groups. We also examined the subset of pts receiving a single prior anti-TNF agent to assess the impact of the type of TNF inhibitor (P75 receptor-fusion protein vs mAb) on GLM response. Overall incidences of AEs were determined for pt subgroups defined by type and number of prior anti-TNF agents.

Results: Assessed by the proportion of pts achieving an ACR20 at wk14, GLM was effective vs PBO in RA pts previously receiving anti-TNF therapy irrespective of DMARD use (ACR20 40% vs 18%, p<0.001) or the reason for d/c of prior anti-TNF (due to efficacy: 39% vs 18%, p<0.001; all other: 34% vs 20%, p=0.027). This was not the case for pts not receiving DMARDs at baseline (29% vs 19%, p=0.184). A consistent treatment benefit of GLM vs PBO was observed for prior use of 1 (39% vs 20%, p=0.002) or 2 (38% vs 16%, p=0.014) anti-TNF agents; too few pts received 3 prior agents for a meaningful comparison. GLM was also effective regardless of a P75 receptor-fusion protein vs mAb agent. 80% of these subgroup pts received prior anti-TNF therapy for ≥12wks, and 49% received anti-TNF therapy for ≥48wks. The occurrence of AEs through wk24 was similar among pts previously receiving only adalimumab (76.3%), etanercept (70.4%), and infliximab (78.1%), as well as among pts who received 1, 2, & 3 prior anti-TNF agents in both PBO- (74.4%, 77.3%, 71.4%, resp) and GLM- (74.6%, 70.4%, 77.3%, resp.) treated pts. **Table. GLM efficacy among pts who received only 1 prior anti-TNF and discontinued anti-TNF therapy for any reason, by prior anti-TNF agent**

	Adalimumab only	**Etanercept only**	**Infliximab only**
No. of pts	59	81	73
Week 14			
ACR20	19 (32.2%)	33 (40.7%)	30 (41.1%)
ACR50	10 (16.9%)	13 (16.0%)	16 (21.9%)

DAS-CRP responder	33 (55.9%)	45 (55.6%)	49 (67.1%)
DAS-ESR responder	26 (44.1%)	44 (54.3%)	49 (67.1%)
DAS-CRP remission	11 (18.6%)	13 (16.0%)	16 (21.9%)
DAS-ESR remission	5 (8.5%)	9 (11.1%)	8 (11.0%)
Week 24			
ACR20	20 (33.9%)	36 (44.4%)	35 (47.9%)
ACR50	10 (16.9%)	18 (22.2%)	15 (20.5%)
DAS-CRP responder	26 (44.1%)	47 (58.0%)	50 (68.5%)
DAS-ESR responder	25 (42.4%)	46 (56.8%)	48 (65.8%)
DAS-CRP remission	12 (20.3%)	13 (16.0%)	17 (23.3%)
DAS-ESR remission	8 (13.6%)	10 (12.3%)	14 (19.2%)

Conclusion: These data suggest that pts previously treated with adalimumab, etanercept or infliximab responded to, and tolerated GLM regardless of the type, number (although too few pts received 3 prior anti-TNF agents to provide conclusive results) or reason for d/c of prior anti-TNF therapy.

1665

Rituximab Improved Physical Function and Quality of Life in Patients with Early Rheumatoid Arthritis Who Were Naive to Methotrexate (IMAGE study). W. Rigby[1], G. Ferraccioli[2], M. Greenwald[3], B. Zazueta-Montiel[4], R. Fleischmann[5], S. Wassenberg[6], A. Jahreis[7], L. Burke[8], C. Mela[9] and A. Chen[7], [1]Dartmouth, Lebanon, NH, [2]Catholic Univ of the Sacred Heart, Rome, Italy, [3]Desert Medical Advances, Palm Desert, CA, [4]Inst, Mexico City, Mexico, [5]Univ of Texas, Dallas, TX, [6]Evangelisches Fachkrankenhaus, Ratingen, Germany, [7]Genentech, South San Francisco, CA, [8]Roche, Welwyn Garden City, United Kingdom, [9]Roche, United Kingdom

Purpose: To assess the effect of rituximab (RTX) with methotrexate (MTX) compared to MTX alone on patient (pt) reported outcomes (PRO) of physical function and health-related quality of life (HRQoL) in pts with early active rheumatoid arthritis (RA) who had not previously been treated with MTX.

Methods: Inclusion criteria included no prior exposure to MTX, disease duration ≥8 weeks and ≤4 yrs, swollen and tender joint count ≥8; C-reactive protein ≥1.0 mg/dL, and positive RF or erosive damage. Pts were randomized to placebo + MTX, RTX (2 x 500mg) + MTX, or RTX (2 x 1000 mg) + MTX. MTX in all groups was initiated at 7.5mg/wk and titrated to 20 mg/wk by Wk 8. RTX was given by IV infusion on Days 1 and 15. At Wk 24, pts with DAS28-ESR≥2.6 received a second RTX course. Those with DAS28-ESR<2.6 were retreated if their DAS28-ESR increased to ≥2.6. Physical function was assessed using the Heath Assessment Questionnaire Disability Index (HAQ-DI), and HRQoL with the SF-36, with assessments taken at regular intervals up to 52 wks (primary analysis time point). Minimally clinically important differences (MCID) for HAQ-DI, SF-36 physical component summary (PCS), and mental component summary (MCS) were defined as ≥0.22, >5.42, and >6.33 respectively. Additional PRO endpoints included fatigue (FACIT score), patient global score of disease, and pain (determined using 100mm visual analogue scales).

Results: 748 randomized pts received study drug (intent-to-treat population). Pt characteristics were balanced at baseline with mean RA duration of 0.9 yrs and high disease activity (DAS28 >7). At Wk 52, both RTX groups showed significant changes in HAQ-DI ($p<0.0001$) and also higher proportions of pts achieving MCID compared to MTX alone. Mean change in SF-36 PCS was significant for both dose

groups but only RTX (2 x 1000mg) had higher proportions of pts achieving MCID. Change in SF-36 MCS did not achieve significance for either dose group, however higher proportions of pts receiving RTX (2 x 1000mg) achieved the MCID. Fatigue, pain, and pts global disease score were significantly reduced in RTX groups compared to MTX alone.

Conclusion: RTX at either 2 x 500mg or 2 x 1000mg with MTX was associated with significant improvement in physical function and QoL outcomes compared to MTX alone; however, only RTX 2x1000mg had higher proportions of pts achieving the MCID for SF-36 MCS and PCS.

The Efficacy of Certolizumab Pegol Added to Methotrexate Is Sustained Over 2 Years in the Treatment of Rheumatoid Arthritis.

Edward C. Keystone[1], Roy Fleischmann[2], J. S. Smolen[3], V. Strand[4], Robert Landewé[5], Bernard Combe[6], Philip J. Mease[7], Zainab Ansari[8], Niti Goel[9] and Désirée M.F.M. van der Heijde[10], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]University of Texas Southwest Medical Center at Dallas, Dallas, TX, [3]Medical University of Vienna, Vienna, Austria, [4]Stanford University, Palo Alto, CA, [5]University Hospital Maastricht, Maastricht, Netherlands, [6]Lapeyronie hospital, Montpellier, [7]Seattle Rheumatology, Seattle, WA, [8]UCB, Slough, United Kingdom, [9]Smyrna, GA, [10]Leiden University Medical Center, Leiden, Netherlands

Purpose: Certolizumab pegol (CZP) 200 or 400 mg Q2W + MTX was found to be significantly more effective than placebo + MTX in the treatment of rheumatoid arthritis (RA) over 1 year (RAPID 1 trial).(1) Here we present the efficacy of CZP + MTX over 2 years.

Methods: Patients who completed 52 wks of double-blind treatment in RAPID 1 (completers) or who withdrew at Wk 16 due to lack of ACR20 response (at Wks 12 and 14; withdrawers) were eligible to enter open-label (OL) treatment with CZP 400 mg Q2W + MTX. This analysis focuses on CZP completers who entered the OL study (n=243 for CZP 200 mg + MTX and n=265 for CZP 400 mg + MTX) and had 100 wks (2 years) of CZP exposure from BL. Efficacy analyses included degree of radiographic progression (assessed in hands, wrists, and feet using change from BL in modified total Sharp score [mTSS; linear extrapolation]), ACR20/50/70 responses (nonresponder imputation), ACR core component scores, and DAS28(ESR) (LOCF). Treatment-emergent AEs (AEs after first study drug administration) were assessed in all patients at each visit.

Results: Of all RAPID 1 CZP completers, 95.8% reconsented and received OL CZP. Of these, 91.1% were in the OL study through at least 100 wks. Inhibition of radiographic joint damage progression was maintained throughout 2 years in this patient population (Figure). At 2 years, 72.4% and 77.3% of completers originally in the CZP 200 mg and 400 mg groups were classified as non-progressors (mTSS change ≤0.5 units from BL). ACR20/50/70 responses were also sustained throughout 2 years in CZP completers, as were improvements in ACR core component scores and DAS28 (not shown). Comparable benefits were observed in patients who received CZP 200 or 400 mg through Year 1 based on their original randomization. There were no new safety signals in the OL study.

Conclusion: CZP + MTX provided sustained, long-term inhibition of the progression of radiographic joint damage and improvements in RA signs and symptoms, with no new safety signals, over 2 years.

Golimumab in Rheumatoid Arthritis: GO-FORWARD Week 52 Results. Edward C. Keystone[1], M.C. Genovese[2], L. Klareskog[3], E. C. Hsia[4], S. Hall[5], P.C. Miranda[6], J. Pazdur[7], S.C. Bae[8], W. Palmer[9], S. Xu[10] and M. U. Rahman[4], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Stanford U, Palo Alto, CA, [3]Karolinska Institutet, Stockholm, Sweden, [4]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [5]Cabrini Medical Center, Malvern, Victoria, Australia, [6]U of Chile/Hosp San Juan de Dios, Santiago, Chile, [7]Instytut Reumatologii, Warszawa, Poland, [8]Hanyang University Hospital, Seoul, South Korea, [9]Westroads Medical group, Omaha, NE, [10]Centocor R&D, Inc, Malvern, PA

Purpose: To assess efficacy and safety of golimumab (GLM) + MTX vs MTX alone in pts with active RA despite MTX.

Methods: Pts were randomized to PBO + MTX (Grp 1), GLM 100mg + PBO (Grp 2), GLM 50mg + MTX (Grp 3), and GLM 100mg + MTX (Grp 4). At wk16, pts in Grps 1, 2, and 3 who had < 20% improvement in tender and swollen joints entered early escape (EE). At wk 24, pts in Grp 1 crossed over to 50mg + MTX.

Results: Through wk52, 4%, 10%, 12%, and 16% had a sustained clinical response (ACR70 at 6 consecutive monthly visits) in Grps 1 to 4, respectively; sustained remission (DAS 28 remission at 6 consecutive monthly visits), was observed in 15%, 16%, 29%, and 28% of the respective grps. SAEs were reported in 11%, 17%, 14%, and 18% of pts in Grps 1 through 4, respectively & 2%, 6%, 2%, and 8%, respectively, had serious infections. Between wks 24 and 52, 9 serious infections were reported: 2 in Grp1 EE, 4 in Grp2, 1 in Grp3, & 2 in Grp4. During this period 4 pts had malignancies: squamous and basal cell cancer (Grp1), basal cell cancer (Grp4), breast cancer (Grp 3 and Grp 4).

Conclusion: GLM efficacy was sustained through 1 yr with many pts achieving sustained remission and sustained clinical response. More pts in grps receiving GLM 100 mg had SAEs and serious infections.

Table: Wk 52 Efficacy*

Assessment	Group 1: PBO + MTX (wk 0-20) and GLM 50 mg + MTX (wk 24-52)	Group 2: GLM 100 mg + PBO	Group 3: GLM 50 mg+MTX	Group 4: GLM 100 mg+MTX
Pts randomized	133	133	89	89
ACR 20	58(43.6%) [81(62.3%)]	60(45.1%) [75(59.1%)]	57(64.0%) [63(70.8%)]	52(58.4%) [51(58.0%)]
ACR 50	37(27.8%) [49(37.7%)]	38(28.6%) [45(35.2%)]	39(43.8%) [41(46.1%)]	40(44.9%) [39(44.3%)]
ACR 70	20(15.0%) [27(20.8%)]	23(17.3%) [27(21.1%)]	22(24.7%) [22(24.7%)]	30(33.7%) [29(33.0%)]
DAS28 (CRP) Good and Mod responders	72(54.1%) [95(73.1%)]	81(60.9%) [101(78.9%)]	65(73.0%) [76(86.4%)]	70(78.7%) [68(78.2%)]
DAS28 (CRP) remission (< 2.6)	42(31.6%) [52(40.0%)]	38(28.6%) [50(39.1%)]	43(48.3%) [47(53.4%)]	41(46.1%) [41(47.1%)]
Proportion of pts achieving HAQ improvement >0.25	58(43.6%) [69(53.1%)]	57(42.9%) [67(52.3%)]	50(56.2%) [55(61.8%)]	60(67.4%) [59(67.0%)]

* Intent-To-Treat (ITT) analysis [observed analysis] for pts achieving the respective endpoint. ITT analyses considered pts entering EE as non-responders (NR) for categorical endpoints and used LOCF for continuous endpoints. Observed analyses (for Grps 1-3) included all the rules of the ITT analysis except pts entering EE were not considered NR automatically and the observed data at wk 52 were used. Pts

entering EE at wk16 received: Grp 1 (42 pts) GLM 50mg +MTX, Grp 2 (36 pts) GLM 100 mg+MTX, & Grp 3 (15 pts) GLM 100mg+MTX. No EE for Grp4.

Incremental Benefit of Open-Label Certolizumab Pegol + MTX in Rheumatoid Arthritis (RA) Patients Following Double-Blind Placebo + MTX Treatment out to 2 Years. Bernard Combe[1], Sergio Schwartzman[2], Elena Massarotti[3], Edward C. Keystone[4], Kristel Luijtens[5] and Désirée M.F.M. van der Heijde[6], [1]Immuno-Rheumatologie, Hospital Lapeyronie, Montpellier, France, [2]Hosp for Special Surgery, New York, NY, [3]Brigham & Women's Hosp, Boston, MA, [4]Professor of Medicine/University of Toronto, Toronto, ON, [5]UCB, Brussels, Belgium, [6]Leiden University Medical Center, Leiden, Netherlands

Purpose: Certolizumab pegol (CZP) 200 or 400 mg Q2W + MTX significantly reduced the signs and symptoms of RA when compared with placebo (PBO) + MTX (RAPID 1 trial).(1) Subjects treated with either PBO + MTX or CZP + MTX who completed the 1-year study were allowed to enter open-label (OL) treatment with CZP 400 mg Q2W + MTX. Data is presented on efficacy outcomes in subjects who completed 1 year of PBO + MTX followed by 1 year of OL CZP + MTX for a total of 2 years' treatment.

Methods: Analyses included ACR20/50/70 response rates (nonresponder imputation), changes from BL in DAS28(ESR) and HAQ-DI scores (LOCF), and assessment of the inhibition of joint damage progression (assessed in hands, wrists, and feet using change in the modified total Sharp score [mTSS; linear extrapolation] from RAPID 1 BL) over 2 years.

Results: 95.3% of the PBO + MTX RAPID 1 completers reconsented and received OL CZP + MTX. Of these, 92.7% completed a total of 100 wks of observation (52 wks PBO + MTX /48 wks OL + MTX). This patient population experienced reductions in RA signs and symptoms at Wk 52 (ACR20/50/70 responder rates were 63.4%; 39.0%; and 17.1%) that were sustained through to at least Wk 100. The change in mTSS for subjects treated with PBO + MTX was 2.5 U at Wk 52 compared with 2.8 U for subjects completing Wk 100, indicating marked inhibition of radiographic progression (change of only 0.3 from Wk 52 to Wk 100). This difference is demonstrated by the differences in the cumulative probability curves of change in mTSS during double-blind (Wks 0-52) and OL (Wks 52-100) treatment (Figure). Patients also experienced marked improvement in DAS28 and HAQ-DI scores upon switching from PBO + MTX to CZP + MTX that were sustained throughout year 2; changes from BL at Wk 100 were -3.3 and -0.73 for DAS28 and HAQ-DI, respectively.

Conclusion: Radiographic disease progression slowed upon initiation of OL CZP + MTX in subjects who completed 52 wks of double-blind treatment with PBO + MTX. These subjects also experienced sustained improvements in the signs and symptoms of RA throughout 2 years, including marked improvements in DAS28 and HAQ-DI scores upon switching to OL CZP treatment.

1669

Golimumab in Rheumatoid Arthritis Patients Previously Treated with Anti-TNFα Agents (GO-AFTER Study): Week 52 Results. J. S. Smolen[1], Jonathan Kay[2], M. K. Doyle[3], R. Landewé[4], E. L. Matteson[5], J. Wollenhaupt[6], N. B. Gaylis[7], F. T. Murphy[8], J. Neal[9], Y. Zhou[10], S. Visvanathan[10], E. C. Hsia[3] and M. U. Rahman[3], [1]Medical Univ Vienna/Hietzing Hosp, Vienna, Austria, [2]U of Mass Med School, Worcester, MA, [3]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [4]University Hospital Maastricht, Maastricht, Netherlands, [5]Mayo Clinic, Rochester, MN, [6]Klinikum Eilbek, Hamburg, Germany, [7]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [8]Altoona Ctr for Clin Research, Duncansville, PA, [9]Arthritis Center of Lexington, Lexington, KY, [10]Centocor R&D, Inc, Malvern, PA

Purpose: To evaluate the efficacy and safety of golimumab (GLM) in patients (pts) with active rheumatoid arthritis (RA) previously treated with anti-TNFα agent(s).

Methods: Patients in the GO-AFTER study were randomized (1:1:1) to subcutaneous injections of PBO, GLM 50 mg or 100 mg q4wks. Pts could have received ≥1 anti-TNFα agent(s) and discontinued for any reason(s). Pts with <20% improvement in tender and swollen joint counts at wk 16 entered early escape (EE) in a double-blinded fashion: PBO group → GLM 50 mg q4wks, GLM 50 mg → GLM 100 mg q4wks, GLM 100 mg group remained on 100 mg q4wks. At wk 24, PBO pts crossed over to GLM 50 mg and the study was unblinded after the last pt completed the wk 24 visit, and pts on GLM 50 mg could escalate to 100 mg at physician discretion. Wk 24 data presented previously, data through wk 52 are now presented.

Results: The significant improvement in signs and symptoms of RA and physical function observed with GLM at wk 24, as assessed by American College of Rheumatology (ACR) response criteria, Disease Activity Score (DAS) response criteria, and the Health Assessment

Questionnaire (HAQ), was maintained through and at wk 52. In the table below, the 50 → 100 mg column includes pts from the GLM 50 mg group who met EE criteria at wk16 and pts from both PBO and GLM 50 mg groups who were receiving GLM 50 mg q4wks after wk 16 and dose escalated to GLM 100 mg q4wks at the discretion of the investigator after wk 24. These patients may have more refractory disease, but they also had a fairly good response after adjusting their dose of GLM.

Assessment	PBO→50 mg	50 mg only	50→100 mg	100 mg
No. patients	72	64	96	121
Week 52				
ACR 20	52.1%	62.5%	52.6%	60.5%
ACR 50	33.8%	40.6%	18.8%	31.7%
DAS28 responders*	.	.	.	.
CRP	72.1%	81.0%	68.1%	79.1%
ESR	70.4%	79.0%	63.0%	73.0%
HAQ (median improvement from baseline)	0.25	0.25	0.25	0.31
% improvement from baseline in:	.	.	.	.
No. swollen joints	70.0%	61.3%	55.6%	75.0%
No. tender joints	65.9%	81.3%	52.4%	66.7%

* DAS28 Responders (EULAR Moderate-Good)

Through wk 52, 75.6% and 76.4% of pts receiving GLM 50 and 100 mg, respectively, had ≥1 adverse event and 12.9% and 7.7%, respectively, had ≥1 serious adverse event. Serious infections were reported in 3.9% and 3.1%, and injection-site reactions were reported in 1.2% and 2.3%, of pts receiving GLM 50 and 100 mg, respectively.

Conclusion: The efficacy (signs/symptoms/physical function) of GLM was maintained through wk 52 in this population. The GLM safety profile was similar to that reported for other anti-TNFα agents.

Impact of Golimumab On Physical Function, Health-Related Quality of Life, Productivity and Employment in Rheumatoid Arthritis Patients: Week 52 Results From GO-FORWARD. M.C. Genovese[1], Edward C. Keystone[2], E. C. Hsia[3], J. Buchanan[4], L. Klareskog[5], F. T. Murphy[6], Z. Wu[7], S. Parasuraman[4] and M. U. Rahman[3], [1]Stanford U, Palo Alto, CA, [2]Professor of Medicine/University of Toronto, Toronto, ON, [3]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [4]Johnson and Johnson Pharmaceutical Services, Malvern, PA, [5]Karolinska Inst & Karolinska Hosp, Stockholm, Sweden, [6]Altoona Ctr for Clin Research, Duncansville, PA, [7]Centocor R&D, Inc, Malvern

Purpose: To evaluate impact of SC golimumab (GLM) on physical function, HRQoL and fatigue.

Methods: 444 pts with active RA (□ 4 TJC and □4 SJC) despite MTX were randomized to PBO+MTX, GLM 100 mg+PBO, GLM 50 mg+MTX, or GLM 100 mg+MTX q4 wks through wk48. At wk16, any pt with <20% improvement from baseline in SJC & TJC entered early escape (EE) in a double-blinded fashion such that PBO+MTX received GLM 50mg+MTX, MTX was added for GLM 100 mg+PBO,

and GLM 50 mg+MTX received GLM 100 mg+MTX; dosing for GLM 100 mg+MTX was unchanged. PBO+MTX crossed over to GLM 50 mg+MTX at wk24. Physical function was assessed using HAQ disability index and SF-36 PCS score. HRQoL was assessed using the PCS and MCS scores of the SF-36. Productivity was assessed on a 10-cm VAS. An ANOVA on van der Waerden normal scores was performed for between-group comparisons at wk24. At wk52, observed efficacy was summarized; no treatment grp comparisons were performed.

Results: Mean baseline HAQ scores indicated moderate functional impairment; PCS scores were lower than US population norm (50±10). GLM+MTX was significantly better than PBO+MTX in improving physical function, HRQoL, productivity, and time lost from work by pt (50 mg only) at wk24 ($p<0.05$). Through wk24, there were no statistically significant improvements in employability, time lost from work by caregiver or healthcare resource consumption. Improvements in HAQ, PCS, MCS, and productivity observed at wk24 were sustained/enhanced through wk52. By wk52, approx 75% of pts receiving GLM 50 or 100 mg+MTX achieved improvement in baseline HAQ ≥ 0.25 and mean changes in productivity ranged from -2.4 to -2.7 across GLM grps. Time lost from work by pts and caregivers decreased from wks24-52.

Conclusion: In pts with active RA despite MTX, GLM 50 mg or 100 mg q4wks + MTX improved physical function, HRQoL, and productivity.

Data are mean±SD or n(%)

	PBO + MTX	GLM 100 mg + PBO	GLM 50 mg + MTX	GLM 100 mg + MTX

Six-Month Results From the Collaborative European REgistries for Rituximab in Rheumatoid Arthritis (CERERRA). Efficacy of Rituximab Is Highest in RF-Positive Patients and in Those Who Failed at Most One Prior Anti-TNF. Ronald F. van Vollenhoven[1], K. Chatzidionysiou[1], E. Nasonov[2], G. Lukina[2], M. L. Hetland[3], U. Tarp[3], C. Gabay[4], P. L.C.M. van Riel[5], D. C. Nordström[6], J. J. Gomez-Reino[7], K. Pavelka[8], M. Tomsic[9], E. Lie[10] and T. K. Kvien[10], [1]Karolinska Univ Hosp, Stockholm, Sweden, [2]Institute of Rheumatology, Moscow, Russia, [3]DANBIO, University Hospital, Copenhagen, Denmark, [4]University of Geneva, Geneva, Switzerland, [5]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [6]ROB-FIN Helsinki University Central Hospital, Helsinki, Finland, [7]H. Clinico Universitario de Santiago, Santiago de Compostela, Spain, [8]Charles University, Prague, Czech Republic, [9]University Medical Centre Ljubljana, Ljubljana, Slovenia, [10]Diakonhjemmet Hospital, Oslo, Norway

Purpose: Rituximab is increasingly used in the treatment of RA. Longitudinal cohorts may provide important information on outcomes in clinical practice and predictors of efficacy. The purpose of this study was to analyse the efficacy after 6 months of the first RTX course for RA, based on data from ten large European registries, and to find possible predictors of response.

Method: Ten European registries submitted anonymized datasets with baseline, 3- and 6-month data for patients who had started RTX. These datasets were pooled and analysed. A small number of patients were re-treated before 6 months (6.7%) and were not included in this analysis. Heterogeneity between countries was analysed by ANOVA. Predictors of response and remission were analysed by logistic regression.

Results: 1372 patients were included. The mean (SD) disease duration was 12.3 (8.4) years. 80.4% of patients were female and 85.6% RF positive. They had failed an average of 2.7 DMARDs (range: 0-10). 33% of patients had failed ≥2 anti-TNF agents, 30% had failed one, and 37% of patients were given RTX as their first biologic agent. Significant heterogeneities ($p<0.0001$) were noted between countries for several baseline characteristics including the number of prior biologics. DAS28 decreased from 5.9±1.4 at baseline to 4.1±1.4 at 6 months ($p<0.0001$). These improvements were achieved already at 3 months and remained stable at 6 months. The subset of patients with 0-1 prior anti-TNF had higher baseline DAS28 compared to the group of patients with >1 prior biologics and significantly better responses after 3 and 6 months (table 1). Lower number of prior DMARDs and biologics were found to be prognostic factors for response to treatment ($p<0.0001$ and $p=0.0013$ respectively), as well as positive RF (OR 1.5, 95% CI 0.96-2.0). At the end of 3 and 6 months, 64.4% and 66.2% of patients had achieved EULAR good/moderate response.

Conclusion: In this large observational cohort, RF positivity is a predictor of good response to RTX. Efficacy results were best when RTX was used as first biologic or in patient who failed one anti-TNF.

Table 1. DAS28 at baseline, 3 and 6 months for patients with differentnumbers of prior biologics.

	DAS28 at baseline	DAS28 at 3 m	DAS28 at 6 m
No prior anti-TNF	6.2±1.2	4.2±1.1	4.1±1.3
One prior anti-TNF	6.1±1.3	4.1±1.4	4.1±1.4
>1 prior anti-TNF	5.6±1.4	4.4±1.4	4.3±1.6

Rapid Prediction of Low Disease Activity at 1 Year Among RA Patients Treated with Certolizumab Pegol. Jeffrey R. Curtis[1] and Kristel Luijtens[2], [1]UAB, Birmingham, AL, [2]UCB, Brussels, Belgium

Purpose: Rapidly predicting which RA pts will respond to biologics may optimize outcomes.The objective of our analysis was to determine the prognostic significance of data collected early after starting certolizumab pegol (CZP) to predict low disease activity (LDA) at 1 year.

Methods: Wks 4 and 12 data from CZP-treated pts in RAPID 1 were used as variables to predict LDA (DAS28 (ESR) ≤3.2) at Wk 52. Classification and Regression Tree (CART) software (Salford Systems) identified variables, built a prediction model, and tested its performance using a split sample (ie, separate training/testing datasets). The ability of this model (Model 1) to discriminate between pts who did/did not achieve LDA at Wk 52 was assessed using area under the receiver-operator curve (AUC). For pts for whom the prediction of LDA at Wk52 using Wk 4/12 data was suboptimal, Wk 28 data were added. A second prediction model (Model 2) was constructed in which more complex variables (ie, DAS) were replaced with ones more easily measured in clinical practice (ie, Clinical Disease Activity Index).

Results: Of 783 pts randomized to CZP (RAPID 1 ITT pop), 703 were included in this analysis (80 pts who withdrew for safety were excluded); 83% female, mean age 51.7 yrs, disease duration 6.1 yrs, concomitant MTX 13.6 mg/wk, baseline DAS28 6.9. Using Wk 4/12 data, LDA at Wk 52 was predicted with ~71-87% accuracy for 80% of pts. For the remaining 20% of pts, adding Wk 28 data resulted in similar accuracy (Figure below). Model 2 had comparable discrimination and accuracy. Overall results from the testing dataset are shown below; results from the training dataset were somewhat better (not shown).

Figure. Model 1, any variable, Weeks 4 and 12

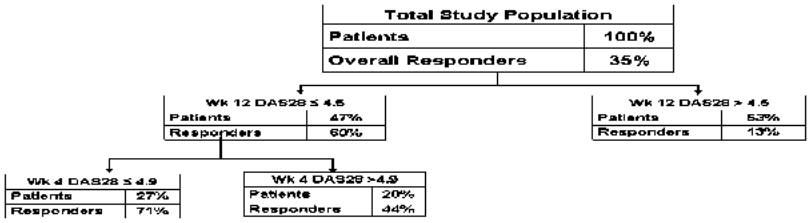

Table: Model discrimination and calibration

Data used from these Wks	AUC	% Correctly Classified
Model 1, Wks 4/12	0.76	74%
Model 1, Wks 4/12/28	0.83	84%
Model 2, Wks 4/12	0.71	76%
Model 2, Wks 4/12/28	0.81	82%

Conclusion: Using CART, we accurately classified ~75% of RA pts as early responders/non-responders within 12 wks of initiating CZP. Wk 28 data improved predictability by an additional 10%. Classification trees may be useful to prospectively guide the management of individual RA pts treated with CZP and perhaps other biologic therapies.

Beneficial Effect of One Year Etanercept Treatment On Lipid Profile in Patients with Rheumatoid Arthritis: ETRA Study. Anna Jamnitski[1], Ingrid M. Visman[1], Mike J.L. Peters[2], Ben A.C. Dijkmans[2], Alexandre E. Voskuyl[2] and Michael T. Nurmohamed[1], [1]Jan van Breemen Institute, Amsterdam, Netherlands, [2]VU Medical Centre, Amsterdam, Netherlands

Purpose: Patients with active rheumatoid arthritis (RA) have an unfavorable lipid profile i.e. a higher TC/HDL cholesterol ratio and Apo B/Apo A-I ratio. Effective anti-inflammatory treatment with TNF blocking agents may improve the lipid profile by increasing HDL cholesterol and Apo A-I levels. Hence, we investigated the influence of long-term etanercept treatment on the lipid profile in RA patients.

Method: Between 2004 and 2008, 292 consecutive patients with active RA (DAS28 > 3.2) and a new etanercept prescription were included in an observational cohort. Disease activity and clinical response variables were assessed at baseline and every three months thereafter. Non fasting lipid samples were collected at baseline (n=149), 16 (n=115) and 52 (n=112) weeks. A paired t-test or the Wilcoxon signed ranks test was used to determine significant changes from baseline, missing values were excluded listwise.

Results: DAS28 score improved significantly (5.2 versus 3.1) reflected by 84% good or moderate responders according to the EULAR response criteria after 1 year of treatment. Changes in the lipid profile are shown in table 1. Apo A-I increased significantly after 1 year of treatment leading to a significant decrease of apo B/apo A-I ratio. When stratified for EULAR response atherogenic index increased significantly (p= 0.027) in non-responders, and did not change in EULAR responders (p = 0.595). Apo A-I levels increased (p= 0.001) and Apo B/Apo A-I ratio decreased further in EULAR responders (p= 0.000) and remained unchanged in EULAR non-responders (p= 0.850).

Conclusion: Treatment with etanercept induced a significant improvement of the Apo B/Apo A-I ratio. Ultimately this may have a beneficial effect on the cardiovascular risk, as we have also demonstrated that etanercept treatment restores the anti-inflammatory properties of HDL-cholesterol (van Eijk IC, et.al. Artrhitis Rheum 2009;60(5))

Table 1. Lipid profile during the one year treatment.

	baseline	16 weeks	P-value	52 weeks	P-value
DAS28	5.21 ± 1.3	3.54 ± 1.5	0.000	3.11 ± 1.3	0.000
ESR	23 (12 - 40)	14 (6 - 26)	0.000	13 (6 - 26)	0.000
CRP	8 (3 - 21)	3 (1 - 8)	0.000	3 (1 - 7)	0.000
Total cholesterol	5.22 ± 1	5.24 ± 1.0	0.492	5.22 ± 0.9	0.777
Triglycerides	1.20 (0.9 - 1.7)	1.27 (0.9 - 1.9)	0.177	1.26 (0.9 - 1.9)	0.000
HDL-cholesterol	1.57 ± 0.5	1.56 ± 0.4	0.137	1.49 ± 0.4	0.166
Totaal chol - HDL chol	3.66 ± 1.0	3.66 ± 0.9	0.135	3.73 ± 0.9	0.294
LDL-cholesterol	3.06 ± 0.9	2.99 ± 0.8	0.178	3.03 ± 0.8	0.889
Atherogenic index	3.65 ± 1.2	3.56 ± 1.1	0.245	3.72 ± 1.1	0.174

Association of Serum Markers with Clinical Response Measures in Rheumatoid Arthritis Patients Treated with Golimumab, a Human Anti-TNFα Monoclonal Antibody. C. Wagner[1], M. U. Rahman[2], M.C. Genovese[3], E. L. Matteson[4], Jonathan Kay[5], Edward C. Keystone[6], E. C. Hsia[2], M. K. Doyle[2], M. Elashoff[7] and S. Visvanathan[1], [1]Centocor R&D, Inc, Malvern, PA, [2]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [3]Stanford U, Palo Alto, CA, [4]Mayo Clinic, Rochester, MN, [5]University of Massachusetts Memorial Medical Center, Worcester, MA, [6]Professor of Medicine/University of Toronto, Toronto, ON, [7]Elashoff Consulting, Redwood City, CA

Purpose: To examine changes in markers associated with clinical response in 1) active rheumatoid arthritis (RA) patients despite methotrexate (MTX) treated with golimumab (GLM), and 2) RA patients previously treated with TNFα inhibitors.

Methods: Sera were collected at wks 0, 4 and 14 from a subset of the GO-FORWARD (active RA patients despite MTX) and GO-AFTER (active RA patients previously treated with TNF inhibitors) studies. Samples were tested for select markers. The change from baseline in markers was compared between GLM ± MTX and PBO + MTX using ANOVA on the van der Waerden normal scores and t-tests. Logistic regression models were used to test for marker associations with clinical endpoints.

Results: Select inflammatory markers were decreased at wks 4 and 14 after treatment with GLM±MTX as compared to PBO+MTX ($p<0.05$). In a regression analysis including data from both studies, baseline levels of CRP, IL-6, MMP-3, ENRAGE, α2 macroglobulin, insulin, vWF, leptin, apolipoprotein CIII, and bone alkaline phosphatase were associated (OR from 0.59 to 1.19,$p<0.05$) with ACR 20 and ACR 50 response at wk 14 in the GLM ±MTX group. Changes from baseline to wk4 in CRP, IL-6, MMP-3, and ENRAGE plus ICAM-1,VEGF, TIMP-1, TNFRII, IL-1Rα, α1anti trypsin, apolipoprotein C III, serum amyloid P, IL-16, hyaluronic acid and haptoglobin were associated with the same clinical measures at wk14. In GLM ± MTX patients, baseline levels of α2 macroglobulin, apolipoprotein CIII, CRP and MMP-3 were significantly different between ACR 20 and ACR 50 responders and non-responders at wk14($p<0.05$).

Conclusion: GLM impacts multiple proteins associated with the TNFα pathway and RA disease processes. The measurement of select markers in patients with active RA despite MTX and those previously treated with anti-TNF therapy could be used to predict response to GLM.

Microsomal Prostalglandin E Synthase and Related Enzymes in Rheumatoid Arthritis B Cells and Effects of B Cell Depleting Therapy On Enzyme Expression. Karina R. Gheorghe[1], Rogier M. Thurlings[2], Marie Westman[1], Marina Korotkova[1], Vivianne Malmström[1], Christina Trollmo[1], Per-Johan Jakobsson[1] and Paul P. Tak[3], [1]Karolinska Institute, Stockholm, Sweden, [2]Academic Medical Center/Univ. of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Microsomal prostaglandin E2 synthase 1 (mPGES1) catalyzes the formation of PGE2, which has important contributions to the rheumatoid arthritis (RA) inflammatory process. B cells are essential in promoting immune activation in the rheumatoid synovium. Previously it was reported that activated B lymphocytes form PGE2 through upregulation of cyclooxygenase (COX) 2 enzyme. In this study we aimed to investigate the expression of PGE2 pathway enzymes in RA B cells and to evaluate the effects of B cell depleting therapy on their expression in rheumatoid synovial tissue.

Method: In a first group, synovial fluid and peripheral blood were collected from 9 RA patients and mononuclear cells (MC) were isolated and stimulated overnight with *Stafilococcus aureus* Cowan strain I (SAC) and pokeweed mitogen (PWM). Unstimulated cells were used as controls. Expression of mPGES1, COX1 and COX2 was analyzed by flow cytometry and double immunofluorescense staining identified mPGES1 positive B cells. In a second group, synovial biopsies were obtained from 12 RA patients before starting Rituximab treatment, 4

weeks later and 16 weeks after initiation of therapy. Immunohistochemical analysis of mPGES1, COX1 and COX2 in biopsy sections was performed and the enzyme expression was quantified using computer image analysis.

Results: Unstimulated MC from either rheumatoid arthritis SF or PB did not express mPGES1 or COX2 enzymes, but their expression was significantly upregulated upon stimulation with SAC and PWM ($p < 0.01$). Also, mPGES1 positive B cells were detected after *in vitro* stimulation of SF mononuclear cells using double immunofluorescence, confirming thus the flow cytometry data. Expression of COX1 was not different between control and stimulated cells. In synovial biopsy sections, regardless of the patients' response to treatment as assessed by the change in the 28-joint Disease Activity Score (DAS28), Rituximab therapy resulted in no influence on mPGES1, COX1 or COX2 expression at 4 weeks or 16 weeks after therapy start.

Conclusion: These data demonstrate that RA B lymphocytes are capable of upregulating mPGES1 and COX2 expression in response to activating stimuli. In addition, therapy with B cell depleting agents, although efficient in achieving good clinical response, leaves essentially unaffected the PGE2 pathway in the rheumatoid synovium.

The Type I IFN Signature Is a Negative Predictor of the Clinical Response to Rituximab Treatment in RA. Rogier M. Thurlings[1], Maartje J. H. Boumans[1], Janneke Tekstra[2], Johannes W.J. Bijlsma[2], Lisa G.M. Van Baarsen[1], Koen Vos[1], Carina Bos[3], K. A. Kirou[4], Mary K. Crow[4], Cornelis L. Verweij[3] and Paul P. Tak[5], [1]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]University Medical Centre Utrecht, Utrecht, Netherlands, [3]VU University Medical Centre, Amsterdam, Netherlands, [4]Hospital for Special Surgery, New York, NY, [5]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Background: In several autoimmune conditions a subset of patients displays type I interferon (IFN) signalling in their peripheral blood; most of these conditions are characterized by auto-antibodies. Type I IFNs may enhance B cell survival.

Purpose: To test whether type I IFN signalling is associated with decreased clinical efficacy of rituximab treatment in RA.

Methods: Twenty RA patients were treated with rituximab (cohort 1). The clinical response was defined as the decrease in DAS28 at week 24 and according to the EULAR response criteria. In peripheral blood mononuclear cells from baseline the presence of an IFN signature was analyzed using polymerase chain reaction on 3 interferon regulated genes. After comparison with healthy controls, patients were qualified as IFN high or IFN low. The data were confirmed in a second independent cohort (n = 30). In this cohort also type I serum IFN bioactivity was analyzed using a reporter assay. The relationship with the clinical response (at week 24) was analyzed using regression analysis.

Results: In cohort 1, the decrease in DAS28 tended to be lower in the IFN high group (n=6) compared to the IFN low group (n=14; -0.67 (±0.9) compared to -1.7 (±1.6); $P = 0.06$). A similar trend was found when analyzing response according to the EULAR criteria in this cohort. In the second, validation cohort IFN high patients (n = 18) experienced a significantly lower decrease in DAS28 at week 24 compared to IFN low patients (n = 13; mean (±SD) -0.98 (±1.6) compared to -2.3 (±1.3); $P = 0.022$). Less patients obtained a EULAR response in the IFN high compared to the IFN low group ($P = 0.05$). Serum type I IFN bioactivity at baseline negatively predicted the decrease in DAS28 at week 24 ($R^2 = 0.13$, $P = 0.046$). The pooled data of the 2 cohorts also showed a significant lower decrease in DAS28 in the IFN high patients (n=24) at week 24 compared to the IFN low group (n=27; mean (±SD) -0.90 (±1.5) compared to -2.0 (±1.4); $P = 0.012$) and less patients obtained a EULAR response in the IFN high compared to the IFN low group when the data are pooled ($P = 0.032$).

Conclusion: The type I IFN signature negatively predicts the clinical response to rituximab treatment in RA. These data support the notion that type I IFN signalling plays a role in RA immunopathology.

Radiographic Progression of Cervical Lesions in Patients with Rheumatoid Arthritis Receiving Infliximab Treatment. Yasuhide Kanayama, Toshihisa Kojima, Tomone Shioura, Masatoshi Hayashi, Koji Funahashi and Naoki Ishiguro, Nagoya Univeristy GraduateSchool & Faculty of Medicine, Showa, Nagoya, Japan

Purpose: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with Anti-TNFα agents are more clinically effective than the disease-modifying antirheumatic drugs (DMARDs) that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasized. However, most clinical studies on the efficacy of biological agents in suppressing joint destruction in the hands and feet, and no studies have been carried out on efficacy against cervical lesions. Therefore, we carried out the present study, which was a prospective investigation in patients receiving infliximab, in order to elucidate the efficacy of infliximab for inhibiting the radiographic progression of RA cervical lesions .

Method: This study was carried out with 47 patients with active RA who received continuous infliximab treatment for at least 1 year. Infliximab treatment was initiated between November 2003 and December 2007. The infliximab dose was 3 mg/kg. The first three doses were administered at Week 0, 2 and 6, and the fourth and later doses were administered every 8 weeks up to Week 54. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at baseline and Week 54.

Results: When progression was defined as a change of 1 mm or more in one of the radiographic cervical lesion parameters for a period of 1 year, the numbers of patients, of a total of 47, who showed progression in ADI, SAC and Ranewat value were 16 (34%), 15 (32%), and 10 (21%), respectively, and the number who showed progression in at least one of these three parameters was 20 (43%).With respect to MMP3, the non-progressive group showed marked and significant alleviation in 1 year, from 423.6 ± 389.4 to 165.5 ± 150.8 ng/ml ($p < 0.001$), whereas the change in the progressive group was from 305.2 ± 222.7 to 224.4 ± 109.5 ng/ml ($p = 0.136$), which was not significant. At Week 54, the responses to infliximab on the basis of the EULAR response criteria were good and moderate in 23 patients (49%) and 24 patients (51%), respectively. Whereas cervical lesion progression was suppressed in 19 of 23 good-response patients (83%), progression occurred in 16 of 24 moderate-response patients (67%), and this difference was shown to be significant by the Fisher's exact test ($p = 0.002$). In the good-response patients ($n = 23$) and moderate-response patients ($n = 24$), the respective changes in cervical lesion parameters in 1 year were as follows: ADI: 0.17 ± 0.49 and 0.54 ± 0.58 mm ($p = 0.013$); SAC: −0.17 ± 0.49 and −0.54 ± 0.59 mm ($p = 0.025$); and Ranawat value: −0.09 ± 0.29 and −0.42 ± 0.65 mm ($p = 0.032$).

Conclusion: Infliximab treatment can be used to suppress the progression of RA cervical lesions, as well as hand and foot joints lesions. It is possible that response to infliximab and MMP3 improvement could be used to predict the progression of RA cervical lesions.

BLyS Promoter Polymorphism and Response to Rituximab in Rheumatoid Arthritis (RA) Patients Positive or Negative for the Rheumatoid Factor. Martina Fabris[1], Luca Quartuccio[1], Marta Saracco[2], Raffaele Pellerito[2], Fabiola Atzeni[3], Piercarlo Sarzi-Puttini[4], Marco A. Cimmino[5], Maurizio Benucci[6], Cinzia Fabro[1], Pia Morassi[7], Martina Bolzan[1], Fabio Fischetti[7], Elio Tonutti[8] and Salvatore De Vita[9], [1]University of Udine, Udine, Italy, [2]Ospedale Mauriziano, Torino, Italy, [3]L.Sacco University Hospital, Milano, Italy, [4]L. Sacco University Hospital, Milano, Italy, [5]University of Genova, Genova, Italy, [6]Ospedale San Giovanni di Dio, Firenze, Italy, [7]Ospedali Riuniti of Trieste, Trieste, Italy, [8]Azienda Ospedaliero-Universitaria of Udine, Udine, Italy, [9]University of Udine, Italy

Purpose: To analyse the relationship between the -871C/T BLyS promoter polymorphism and the response to therapy in a large series of RA patients treated with rituximab (RTX), distinguishing also rheumatoid factor (RF)-positive and negative cases.

Method: One hundred and twenty (120) consecutive RA patients (mean age 61.6±12.8 yrs; mean disease duration 14.4±10.8 yrs) from 6 different Rheumatologic Centres of Italy were enrolled in the study. Patients fulfilled the ACR criteria for the classification of RA and were 82.5% RF-positive. The patients previously failed several DMARDs (3.4±1.5) and/or anti-TNF agents (1.2±0.9) and presented a high disease activity at baseline (DAS28 6.3±0.9). RTX therapy was administered at the standard dose regimen, and the ACR criteria were used to assess the response 6 months after RTX first infusion (mo. +6). BLyS promoter polymorphism was analysed by PCR-RFLP following previously reported methods (Novak et al, J Clin Oncol 2006). BLyS serum levels were analysed in all the available serum samples by ELISA using commercial kits (R&D Systems).

Results: At mo. +6 we found 15.8% non responders (NR) and 17.5% ACR20, 46.7% ACR50 and 20% ACR70/90 responder patients. BLyS serum levels at baseline were significantly more elevated in cases carrying the BLyS promoter genotypes CT/TT than in the those carrying the CC genotype, both at baseline (1.33±0.61 ng/ml versus 0.91±0.24 ng/ml; p=0.032), and in the follow-up (4.92±2.06 versus 3.58±1.10 ng/ml; p=0.083, at mo. +6). A response to RTX ≥ACR50 was found in 23/27 (85.2%) of the low BLyS producers CC patients compared to 57/93 (61.3%) of the high BLyS producers CT/TT patients [OR:3.63; CI95%:1.16-11.37; p=0.0215]. No NR patients were found among the CC patients. The presence of the RF, as previously reported (Quartuccio et al, Reumatismo 2008), was significantly associated with a response ≥ACR50 to RTX (OR:3.38; 95%CI:1.28-8.91; p=0.02). Patients carrying the CC genotype presented an elevated degree of response either in RF-positive (19/23, 82.6%) and in RF-negative (4/4, 100%; p=ns) cases. In contrast, CT/TT patients disclosed a significant increase of poor/non responder cases (ACR20/NR) in RF-negative (12/17, 70.6%) compared to RF-positive patients (23/75, 30.7%; OR:5.43, 95%CI:1.71-17.19, p=0.0045).

Conclusion: RF-negative RA patients carrying the CT/TT genotype present the highest risk of unfavourable outcome with RTX therapy. The analysis of the -871C/T BLyS polymorphism, influencing BLyS serum levels, may then deserve further attention to optimize the treatment of RA with RTX.

1679

Long-Term Impact of Adalimumab Plus Methotrexate On Radiographic, Clinical, and Functional Progression of Rheumatoid Arthritis. Edward C. Keystone[1], Arthur Kavanaugh[2], Désirée M.F.M. van der Heijde[3], Sandra Sinisi[4], Jesse Hall[4] and Benoît Guerette[5], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]University of California San Diego, La Jolla, CA, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Abbott Laboratories, Abbott Park, IL, [5]Abbott Laboratories, Rungis, France

Purpose: Assessing long-term efficacy is important when tailoring treatment. We describe the long-term (8-yr) impact of adalimumab (ADA) plus methotrexate (MTX) on radiographic, clinical, and functional parameters in patients (pts) with rheumatoid arthritis (RA).

Methods: In the DE019 study, pts with RA were randomized to double-blind (DB) MTX (n=200), ADA 40 mg every other week (eow) plus MTX (n=207), or ADA 20 mg weekly plus MTX (n=212) for 1 yr.[1] Pts completing DB therapy received open-label ADA 40 mg eow plus MTX for an additional 7 yrs. Observed data analyses were performed using the intention-to treat population (all pts who received ≥1 dose of study drug with data at each visit). American College of Rheumatology (ACR) responses and swollen (SJC66) and tender joint counts (TJC68) were used to assess clinical response. Remission was defined using 28-joint Disease Activity Score (DAS28)<2.6, SJC66=0, and TJC68=0. The Health Assessment Questionnaire (HAQ) was used to assess physical function. Two experts blinded to sequence and order read radiographic films from baseline and Yrs 5, 6, and 8. Radiographic changes were determined using the modified total Sharp score (mTSS); nonprogression was defined as a change in mTSS<0.5.

Results: After 8 yrs, 81%, 62%, 46%, and 19% of ADA+MTX pts (n=185) achieved ACR20, 50, 70, and 90, respectively. Mean SJC decreased from 26 to 4 and mean TJC decreased from 20 to 4. DAS28<2.6, SJC=0, and TJC=0 were achieved by 60%, 42%, and 40% of pts, respectively. Mean HAQ decreased from 1.33 to 0.65 (n=186). Radiographic nonprogression occurred in 55% of pts (table).

Mean Changes in Radiographic Endpoints From Baseline to 8 Yrs

Original Treatment Group	□mTSS	□JES	□JSN	□mTSS<0.5, %
MTX (n=65)	5.12	1.74	3.38	37
ADA 20 mg weekly+MTX (n=90)	1.85	0.53	1.32	45
ADA 40 mg eow+MTX (n=96)	0.57	–0.21	0.78	55

JES=joint-erosion score; JSN=joint-space narrowing.

Conclusion: After 8 yrs of therapy, ADA+MTX provided sustained improvements in clinical efficacy; remission occurred in 60% of pts. Radiographic nonprogression was achieved by 55% of pts. Pts treated with MTX, for whom ADA 40 mg eow therapy was delayed 1 yr, experienced a 29% relative increase in the percentage of pts with radiographic progression. Overall, 8 yrs of ADA 40 mg eow+MTX prevented radiographic progression and provided the best outcomes.

Identification of Biomarkers for Enhanced Benefit to Rituximab in Rheumatoid Arthritis: Role of Autoantibodies and Inflammatory Markers. G. J. Silverman[1], Sergio Schwartzman[2], M. Townsend[3], Z. Su[3], C. Holweg[3], S. Read[4], D. Yocum[3] and P. Lal[3], [1]UCSD, La Jolla, CA, [2]Hosp for Special Surgery, New York, NY, [3]Genentech, South San Francisco, CA, [4]Roche, United Kingdom

Purpose: Rituximab has been shown to significantly improve the signs and symptoms of rheumatoid arthritis (RA) as well as slow the progression of joint damage. The purpose of this analysis was to examine serologic markers in randomized clinical trials (RCT) and identify biomarkers that best distinguish patient subsets with high hurdle clinical responses (ACR 50 at 24 weeks) to rituximab therapy.

Methods: With baseline samples from the REFLEX trial of 517 RA patients with previous inadequate response to TNF inhibitors, a threshold sensitivity method was used to identify candidate biomarkers that enriched for placebo corrected ACR50 response at 24 weeks, and which represented at least 20% of subjects. Of 19 serological markers and 9 clinical features examined, we identified the best four biomarkers, which included levels of IgA isotype of rheumatoid factor (RF), sCD25, and IgG anti-CCP3 antibodies, as determined by ELISA, and of C-reactive protein (CRP), as determined by nephelometry. These biomarkers and five of their two-biomarker combinations as well as levels of IgM and IgG isotypes of RF were then further investigated following a pre-specified diagnostic plan using data from the SERENE RCT of 501 RA patients with an inadequate response to methotrexate. We then also calculated odds ratios for achieving an ACR50 response at 24 weeks compared to placebo, as well as additional summary statistics for biomarker positive/negative subgroups (Table1).

Results: In discovery studies we found that, compared to seronegative patients, seropositivity for any isotypes of RF or IgG anti-CCP antibodies was associated with a higher rate of placebo controlled ACR50 responses at 24 weeks. Patients with elevated levels of CRP also demonstrated more frequent clinical benefit. These findings were independently reiterated in the SERENE patient populations. The greatest enhancement was seen in patients with both elevated baseline CRP (>2.9 mg/dL) and positivity for RF of any isotypes or IgG anti-CCP. These patients had better clinical responses across a spectrum of clinical outcome measures (ACR responses, delta DAS, and EULAR response).

Conclusion: In the REFLEX and SERENE RCT, the presence of autoantibodies and elevated CRP identified a subgroup of RA patients with an enhanced benefit to rituximab. However, these findings need to be verified in large independent data sets.

Table Efficacy difference (95% CI) between Rituximab and placebo treated patients at Week 24 in the SERENE trial.

	□ **ACR50***	**ACR50 O.R.**	□ **ACR20**	□ **EULAR good/moderate**	□ **mean DAS change from baseline**
Biomarker(+) CRP>2.9 mg/dL & RF IgA**>25 U/ml 22% population	34% (20%, 48%)	10.4 (2.9, 37.2)	44% (28%, 60%)	55% (39%, 71%)	-1.54 (-2.00 , -1.08)

Biomarker(-) 78% population	13% (6%, 20%)	2.7 (1.4, 5.2)	26% (16%, 36%)	25% (15%, 35%)	-0.82 (-1.11, -0.53)

*□ is between active and placebo. Permutation p-value=0.02, unadjusted for the number of biomarkers considered.

**Similar enhanced benefit to rituximab in the biomarker (+) group was observed when any other isotype of RF or Total RF was substituted for RF IgA.

Three-Year Effectiveness of Adalimumab in Patients with Rheumatoid Arthritis with and without History of Other Tumor Necrosis Factor Antagonist Therapies. G. Burmester[1], Sonja Kary[2], Kristina Unnebrink[2], Benoît Guerette[3], Uemit Oezer[2] and Hartmut Kupper[2], [1]Charité-University Medicine, Berlin, Germany, [2]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [3]Abbott Laboratories, Rungis, France

Purpose: For treatment of patients (pts) with rheumatoid arthritis (RA), switching to another tumor necrosis factor (TNF) antagonist is effective after failure with or intolerance of a prior anti-TNF therapy.[1] However, data on the maintenance of effectiveness are rare. We compared the effectiveness of adalimumab (ADA) for pts with and without history of anti-TNF therapy who continued ADA in an ongoing, 5-yr observational study (ReAlise) after completion of a multinational, uncontrolled, Phase IIIb study (ReAct), during which pts received ADA therapy for ≥12 weeks.

Methods: Data were analyzed from the first 3 years (yrs) after the first ADA injection in ReAct. Treatment effectiveness was measured by 28-joint Disease Activity Score (DAS28), Health Assessment Questionnaire (HAQ) score, and American College of Rheumatology (ACR) responses (ACR20 and ACR50). Scores for pts with and without prior anti-TNF treatment were compared. Outcomes for pts with prior anti-TNF therapy were analyzed by reason for anti-TNF therapy discontinuation.

Results: Data were available for 3,433 ReAlise pts, including 408 (12%) with prior anti-TNF therapy. At ReAct baseline, mean DAS28 and HAQ scores were greater for pts with vs. without prior anti-TNF therapy (table). After 3 months (M), treatment responses were marked in all pt groups and were sustained after 1 and 3 yrs of therapy. Pts with prior anti-TNF therapy achieved quite similar improvement.

Golimumab and Cardiovascular Disease in Inflammatory Arthritides. J. Bathon[1], M. C. Wasko[2], E. C. Hsia[3], B. Kirkham[4], Roy Fleischmann[5], M.C. Genovese[6], E. L. Matteson[7], H. Liu[8] and M. U. Rahman[3], [1]Johns Hopkins Univ Sch of Med, Baltimore, MD, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [4]Guy's and St. Thomas' Hosp, London, England, [5]Metroplex Clinical Research Center, Dallas, TX, [6]Stanford U, Palo Alto, CA, [7]Mayo Clinic, Rochester, MN, [8]Centocor R&D, Inc, Malvern, PA

Purpose: To assess the effect of golimumab (GLM) +/- MTX on serum lipid profile and inflammatory markers associated with cardiovascular disease (CVD), and on cardiovascular (CV) events.

Methods: Serum lipids and inflammatory CV markers (eg. hsCRP, VEGF, ICAM-1 SAA, fibrinogen, IL-6) were assessed in 2 phase 3 GLM trials in pts with rheumatoid (RA): MTX-naïve (GO-BEFORE); MTX inadequate responders (IR) (GO-FORWARD). Changes from baseline (BL) to wk14 or 24 were compared between PBO+MTX (N=293) and combined GLM 50 and 100 mg + MTX (N=496) groups (grps). CV events (not adjudicated) from these & another phase 3 trial in anti-TNF experienced RA pts (GO-AFTER; N=461) were summarized.

Results: The changes in lipid profile & a CV inflammatory marker are shown in the table. In the GO-FORWARD study, total cholesterol (TC), HDL and LDL levels all increased in the GLM+MTX compared to PBO+MTX grp whereas atherogenic ratios (TC/HDL, LDL/HDL, ApoB1/A1) were not substantially changed. Favorable changes in the LDL subfraction (increase in large and decrease in small LDL) were seen in GLM groups. In the GO-BEFORE study (with MTX-naïve pts), similar changes were seen in both the MTX and GLM groups. Most inflammatory CV markers improved significantly with GLM+MTX compared to PBO+MTX in both studies (1 shown in Table as representative data). During the PBO-controlled period, 7 of 449 pts (1.6%) in the PBO+/-MTX & 10 of 1088 pts (1%) (p=0.275) in the GLM+/-MTX grps had CV events. Through June 2, 2008 (all pts had completed ≥1 yr), CV events per 100 pt-yrs (95% CI) were 2.72 (1.09, 5.6) for PBO+/-MTX & 0.8 (0.45, 1.32) for GLM+/-MTX grps (p=0.35).

Conclusion: This is the first demonstration of favorable changes in LDL sub-fractions in response to anti-TNF therapy. Despite increase in TC & LDL, the atherogenic indices remained stable and CV-related inflammatory markers improved. A suggestion of lower incidence of CV events (not adjudicated) was noted in GLM+MTX treated pts.

Table: Data are median value or median % change.

Multiple Courses of Rituximab (RTX) Produce Sustained Efficacy in Patients (pts) with Rheumatoid Arthritis (RA) with An Inadequate Response (IR) to One or More TNF Inhibitors. Edward C. Keystone[1], Roy Fleischmann[2], Paul Emery[3], Maxime Dougados[4], Andrew R. Baldassare[5], Gillian K. Armstrong[6], Matthew D. Linnik[7], Mark Reynard[6] and Helen Tyrrell[6], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]University of Texas Southwest Medical Center at Dallas, Dallas, TX, [3]Leeds General Infirmary, Leeds, United Kingdom, [4]Hôpital Cochin, Paris, France, [5]St Louis University, St Louis, MO, [6]Roche Products Ltd, Welwyn Garden City, United Kingdom, [7]Biogen Idec, San Diego, CA

Purpose: To assess the effect of repeat courses of RTX in pts with a prior inadequate response to TNF inhibitors (TNF-IR).

Methods: RA pts recruited into Phase II or III studies with RTX and who had previously had an IR to a TNF inhibitor were permitted to receive further courses of RTX in open-label extensions. Eligibility for retreatment included a response to the initial course (at least 20% reduction in swollen and tender joint counts [SJC/TJC]) with courses no more frequently than every 4 months. Criteria for retreatment included active disease defined as either ≥8 SJC and TJC or DAS28≥2.6 (depending on the study). Each course (C) consisted of 2 x 1000mg given as IV infusions 2 weeks (wks) apart. Efficacy was determined 24 wks following each course of RTX with outcomes assessed relative to the pts pre-RTX treatment baseline. Analyses were performed using observed data on all pts, and on all pts with efficacy data at 24 wks following each of their first 4 courses of RTX, the within pt, within visit (WW) population.

Results: 500 RA TNF-IR pts had been exposed to at least 1 course of RTX and had efficacy data at Week 24, with 146 evaluable at 24 wks following each course (WW population). Observed efficacy in all pts show higher responses for C2 onwards compared with C1. However, retreatment criteria cause this analysis to become enriched for RTX responders as pts were required to achieve a response to C1. The same maintained or improved responses were seen in the WW population (Table). From C1 to C4, the proportion of pts in the WW population achieving DAS28 low disease activity (LDA) or remission doubled. Safety over repeat courses did not show any unexpected findings with rates of infection, including serious infection unchanged.

Table:

	All patients				**Within pt, within visit**			
	C1	**C2**	**C3**	**C4**	**C1**	**C2**	**C3**	**C4**
ACR responses (n)	500	355	264	178	146	146	146	146

The Relationship Between Synovial Lymphocyte Aggregates and the Clinical Response to Infliximab in Rheumatoid Arthritis: a Prospective Study. Ruth Klaasen, Rogier M. Thurlings, Carla A. Wijbrandts, Arno W.R. van Kuijk, Dominique L. Baeten, Danielle M. Gerlag and Paul P. Tak, Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: The extent and pattern of lymphocyte infiltration in the inflamed synovial tissue is widely variable among rheumatoid arthritis (RA) patients. In some tissues a diffuse or scarce infiltration of T cells is present while in others B, T, and plasma cells are organized in aggregates exhibiting germinal center-like features. Our previous work has suggested that the clinical response to anti tumour necrosis factor (TNF) antibody treatment is related to pre-treatment synovial tissue inflammation (1) and that the presence of synovial lymphocyte aggregates is a secondary phenomenon due to chronic inflammation (2). Therefore, we hypothesized that the presence of synovial lymphocyte aggregates at baseline could in part predict clinical response to TNF blockade and that their presence is reversible after anti-TNF treatment.

Methods: Synovial tissue biopsies were obtained from 97 patients with active RA before initiation of infliximab treatment. Aggregates were counted and graded according to size (0-3). Grade 2 and 3 aggregates were termed ‘large' lymphocyte aggregates and grade 1 aggregates ‘small' lymphocyte aggregates. We determined the responder status by the reduction in disease activity score (DAS28) of at least 1.2 after 16 weeks of therapy. Serial synovial biopsies were obtained before and 28 days after initiation of TNF blockade to evaluate the effects of TNF blockade on lymphocyte aggregates in 15 RA and 9 psoriatic arthritis (PsA) patients.

Results: Good treatment response was found in 75% of patients. Of 97 patients 43% had diffuse synovial inflammation, 25% had only small lymphocyte aggregates and 32% had large and small lymphocyte aggregates. At baseline lymphocyte aggregates were found in 67% of clinical responders compared to 38% of non-responders and their presence was a highly significant predictor of the clinical response to anti-TNF treatment ($R^2 = 0.08$, $P = 0.007$). Separate analysis of large aggregates suggested a relationship with response (NS). Positivity for lymphocyte aggregates increased the prediction of clinical response to $R^2 = 0.29$ in a model including DAS28, anti-CCP positivity and synovial TNFa expression. There was reduction of lymphocyte aggregates after anti-TNF antibody therapy in both RA and PsA.

Conclusion: RA patients with synovial lymphocyte aggregates have on average a better response to infliximab treatment than those with only diffuse leukocyte infiltration. Moreover the presence of lymphocyte aggregates is reversible after TNF antibody treatment.

Body Surface Area, Erythrocyte Sedimentation Rate, Methotrexate and Antibodies to Infliximab Influence the Pharmacokinetics of Infliximab in Rheumatoid Arthritis. Emilie Ducourau[1], David Ternant[1], Anca Corondan[2], Benoit Legoff[3], Aleth Perdriger[4], Valérie Devauchelle[5], Elisabeth Solau-Gervais[6], Philippe Goupille[1], Gilles Paintaud[1] and Denis Mulleman[1], [1]Université François Rabelais de Tours; CNRS, UMR 6239; CHRU de Tours, Tours, France, [2]CHR d'Orléans, Orléans, France, [3]CHU de Nantes, Nantes, France, [4]CHU de Rennes, Rennes, France, [5]CHU Brest, Brest, France, [6]University Hospital of Poitiers, Poitiers, France

Purpose: Infliximab, a chimeric monoclonal antibody targeting tumor necrosis factor alpha**,** is used in rheumatoid arthritis (RA) but around 1/3 of patients are non responders. Serum trough concentrations are variable between individuals and are related to clinical response (1). To date, no detailed analysis of infliximab pharmacokinetic (PK) has been reported in RA. Our objective was to describe infliximab PK in RA and to quantify the influence of its sources of interindividual variability.

Method: Forty-three RA patients treated with infliximab for at least 14 weeks were studied. They had a stable dose of infliximab, prednisone and methotrexate (MTX) since the last infusion. Infliximab concentrations were measured by enzyme-linked immunosorbent assay (2) before the infusion, 2 hours, 1 week, 4 weeks after the infusion and immediately before the next infusion. Infliximab PK was studied using a population approach. Influences of sex, body surface area (BSA), age, cotreatment, disease activity score on 28 joints (DAS 28), erythrocyte sedimentation rate (ESR), and presence of antibodies toward infliximab (ATI), on pharmacokinetic parameters were studied.

Results: A two-compartment model with first-order distribution and elimination constants allowed a satisfactory description of infliximab PK. Population estimates were obtained from the final covariate model as follow: clearance = 0.01 L/h, volume of the central compartment = 2.1 L, intercompartment clearance = 0.02 L/h, and volume of the peripheral compartment = 1.7 L. Volume of distribution of the central compartment increased with BSA. Clearance was lower in presence of MTX and higher in the presence of ATI and increased with ESR. Mean elimination half-life was 9 days without MTX, 12 days with MTX and 2.6 days with MTX and ATI.

Conclusion: This detailed description of infliximab PK in RA allowed to quantify influence of individual sources of variability. For a given dose, infliximab concentrations were higher during MTX cotreatment and lower in the presence of ATI. Exposure to infliximab decreased when BSA and ESR increased.

1686

Early Changes in Serum Levels of Cytokines and Chemokines Are Predictive of the Response to Rituximab Treatment in Rheumatoid Arthritis. Rogier M. Thurlings[1], Maartje J. H. Boumans[1], Koen Vos[1], Wilco de Jager[2], B. Prakken[3], Danielle M. Gerlag[1] and Paul P. Tak[4], [1]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]University Medical Center, Utrecht, Netherlands, [4]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Background: Rituximab induces a rapid decrease in B cells in peripheral blood, but the mechanism by which B cell depletion leads to clinical improvement is not completely understood.

Purpose: We used a multiplex assay to analyze the early changes in mediators of inflammation in serial serum samples after initiation of rituximab treatment in rheumatoid arthritis (RA) patients and aimed to identify soluble biomarkers of response.

Method: Twenty-eight rheumatoid factor positive and/or ACPA positive RA patients were treated with rituximab. Methylprednisolone pre-medication was omitted to study the specific effects of rituximab. Clinical response was assessed at baseline and monthly after initiation of treatment using the DAS28. A clinical response was defined as the decrease in DAS28 at week 24 and according to the EULAR response criteria. Serum cytokines, chemokines, soluble adhesion molecules and growth factors were measured using multiplex analysis before, 4 and 16 weeks after treatment. Changes were analyzed using the Wilcoxon's signed rank test.

Results: The DAS28 decreased significantly from 8 weeks after treatment ($P < 0.001$). At week 4, before any change in the DAS28, we found a decrease in serum levels of IL-22 ($P = 0.002$), IL-23 ($P = 0.03$) and CCL19 ($P = 0.04$). In the clinical responders (defined at week 24), there was also a statistically significant decrease in serum levels of IL-6, IL-15, IFNγ, TNFα, CXCL3, CCL22 and OPG at week 4. Thus, the changes in several cytokines and chemokines at week 4 were predictive of the clinical response at week 24. At week 16 most cytokines and chemokines were decreased.

Conclusion: We identified several mediators of inflammation (including those associated with the Th1 and Th17 adaptive immune response) that appear predictive of the response to rituximab treatment in RA. Rituximab-induced B cell depletion may cause a decrease in the activation state of T cell subsets, contributing to clinical improvement.

Effectiveness of Rituximab (RTX) + Methotrexate (MTX) in Patients (pts) with Early Active Rheumatoid Arthritis (RA) and Disease Characteristics Associated with Poor Outcomes. Xavier Mariette[1], Alan Kivitz[2], John D. Isaacs[3], William Stohl[4], Paul P. Tak[5], Richard E. Jones[6], Angelika Jahreis[7], Gillian K. Armstrong[8] and Tim M. Shaw[8], [1]Hospital Bicêtre, Kremlin-Bicêtre, France, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Newcastle University, Newcastle Upon Tyne, United Kingdom, [4]Univ Southern California, Los Angeles, CA, [5]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [6]Clinic for Rheumatic Diseases, Tuscaloosa, AL, [7]Genentech, South San Francisco, CA, [8]Roche Products Ltd, Welwyn Garden City, United Kingdom

Purpose: To determine if RTX plus MTX is effective in pts with early RA in reducing the rate of joint damage and achieving clinical responses in subgroups known to be associated with poor prognoses.

Methods: IMAGE is a randomized active controlled study of RTX plus MTX compared with MTX + placebo (Plc) in MTX-naive pts with RA [1]. Pts were randomized to either Plc + MTX, RTX (2 x 500 mg) + MTX, or RTX (2 x 1000 mg) + MTX. MTX in all groups was initiated at 7.5 mg/wk and titrated to 20 mg/wk by Week 8 as tolerated. RTX was given by IV infusion with a 24-week repeat treatment schedule based on DAS28 >2.6 [1]. Radiographic (Genant modified Sharp score [mTSS]) and clinical outcomes were assessed at Week 52 and explored by baseline subgroups including pts with high DAS28 (7.5-8.3), high CRP (4th quartile) and autoantibody presence (seropositive [sero+ve] for rheumatoid factor [RF] or anti-cyclic citrullinated peptide antibodies [aCCP] or seronegative [sero–ve] for both).

Results: At Week 52 only RTX (2 x 1000mg) + MTX significantly reduced the rate of joint damage [1]; consequently data are only presented for this dose. In patients with high DAS or high CRP receiving RTX + MTX, superior clinical outcomes were observed compared with matched pts treated with Plc + MTX. In sero+ve pts receiving RTX + MTX, superior outcomes were observed compared with sero+ve pts treated with Plc + MTX (Table). Although limited by low numbers and lower radiographic progression compared with sero+ve pts, outcomes in sero–ve patients receiving RTX + MTX or Plc + MTX were similar.

Conclusion: Efficacy was demonstrated in RTX + MTX-treated MTX-naïve pts with baseline characteristics associated with poor prognosis. The presence of RF and/or aCCP may indicate a subset of MTX-naïve RA patients with more aggressive disease more likely to benefit from treatment with RTX + MTX compared with MTX alone.

Patients with Early RA Treated with Abatacept Plus MTX Have a Higher Likelihood of Increasing or Maintaining Initial Improvements in Signs and Symptoms and Physical Function Over Time Than Those Treated with MTX Alone. Y. Yazici[1], D. Moniz Reed[2], A. Covucci[2], J. C. Becker[2] and R. Westhovens[3], [1]NYU Hospital for Joint Diseases, New York, NY, [2]Bristol-Myers Squibb, Princeton, NJ, [3]UZ Gasthuisberg, KU Leuven, Leuven, Belgium

Purpose: EULAR/ACR recommendations stress the importance of reporting the sustainability of treatment responses in patients (pts) with RA[1]. Here we assess the likelihood of maintaining/improving initial improvements in the signs/symptoms of RA and physical function with abatacept over 1 year (yr), in MTX-naive pts with early RA and poor prognostic factors.

Methods: In the 12-month (mth) double-blind period of AGREE (Abatacept study to Gauge Remission and joint damage progression in MTX-naïve pts with Early Erosive RA)[2], pts with RA ≤2 yrs received abatacept (~10 mg/kg) + MTX or MTX alone. In these *post-hoc* analyses, shifts in ACR response and Health Assessment Questionnaire-Disability Index (HAQ-DI) status from Mth 3 to 12 were evaluated in pts who completed the DB period (as-observed). Discrete ACR categories were defined as ACR non-responders (NR; those not achieving ACR 20), ACR 20, 50 and 70 responders; and HAQ-DI status categories as >1.5 (high), >0.8–1.5 (moderate), >0.5–0.8 (low) and ≤0.5 (normalized function)[3].

Results: In total, 232 and 227 pts were eligible for these analyses in the abatacept + MTX and MTX alone groups; baseline characteristics were comparable[2]. Shifts in ACR responses are shown (Table); between Mths 3 and 12, ACR responses deteriorated in 33.3% of MTX alone pts, compared with only 17.7% of abatacept + MTX pts. For abatacept + MTX pts with high HAQ-DI and moderate HAQ-DI at Mth 3, 50.0 and 41.3%, respectively, improved their status by Mth 12. Of the abatacept + MTX pts with low HAQ-DI at Mth 3, 65.5% achieved normalized HAQ-DI at Mth 12. For those abatacept + MTX pts who achieved normalized HAQ at Mth 3, 89.6% retained their status at Mth 12. Similar patterns of maintenance were seen for the MTX alone active comparator group; 76.9% of MTX alone pts achieved normalized HAQ-DI at Mth 3 and retained their status at Mth 12.

Proportion with ACR response at Mth 3	**Shift in ACR response from Mth 3 to 12 (%)**			
	ACR 20 NR	**ACR 20**	**ACR 50**	**ACR 70**
Abatacept + MTX				
ACR 20 NR, 35.9%	46.7	27.2	12.0	14.1
ACR 20, 24.2%	21.0	22.6	27.4	29.0

ACR 50, 21.1%	7.4	14.8	14.8	63.0
ACR 70, 18.8 %	2.1	2.1	4.2	91.7
MTX alone				
ACR 20 NR, 46.6%	49.2	20.3	13.6	16.9
ACR 20, 30.8%	33.3	28.2	19.2	19.2
ACR 50, 12.6%	15.6	3.1	12.5	68.8
ACR 70, 9.9%	28.0	12.0	12.0	48.0

Conclusion: At Yr 1, the majority of abatacept-treated pts with early RA demonstrated improvement/maintenance in signs/symptoms and physical function. Pts treated with abatacept + MTX had a higher likelihood of maintaining or improving ACR responses over time than those treated with MTX alone. These data demonstrate the sustained efficacy of abatacept in early RA.

Abatacept Demonstrates Consistent Safety and Sustained Improvements in Efficacy through 4 Years of Open-Label Treatment in Patients with An Inadequate Response to Anti-TNF Therapy. M. C. Genovese[1], M. Schiff[2], M. E. Luggen[3], M. Le Bars[4], J. C. Becker[5], R. Aranda[5], A. Elegbe[5], R. Cohen[5] and M. Dougados[6], [1]Stanford University, Palo Alto, CA, [2]Univ of Colorado, Denver, CO, [3]University of Cincinnati Medical Center, Cincinnati, OH, [4]Bristol-Myers Squibb, Rueil-Malmaison, France, [5]Bristol-Myers Squibb, Princeton, NJ, [6]Hospital Cochin, Descartes Univ, Paris, France

Purpose: Abatacept has demonstrated sustained efficacy and consistent safety over 3 years in patients with RA and an inadequate response to anti-TNF therapy in the ATTAIN (Abatacept Trial in Treatment of Anti-TNF INadequate responders) trial[1]. Here we evaluate the long-term safety and efficacy of abatacept over 4 years of the open-label (OL) long-term extension (LTE) of this trial.

Methods: Patients completing the 6-month double-blind (DB) period were eligible for the LTE (abatacept ~10 mg/kg, every 4 wks plus DMARDs). Here we present interim as-observed analyses of long-term safety and efficacy. Safety was assessed monthly for all patients who received ≥1 dose of abatacept during the LTE.

Clinical efficacy (ACR 20, 50 and 70 responders), disease activity status (DAS28 [CRP]-defined remission [DAS28<2.6] and Low Disease Activity State [LDAS; DAS28 ≤3.2]) were evaluated quarterly to Year 3, and biannually thereafter, for patients originally randomized to abatacept.

Results: In total, 258 and 133 patients were randomized and treated with abatacept or placebo in the DB period; 218 and 99 entered the LTE, respectively. At the time of reporting, 6 months of DB and 4 years of LTE efficacy data were available, while safety analyses were reported up to Nov 2008 (mean abatacept exposure during the DB period plus LTE=42.2 months [range=3.7–65.5]). Up to Nov 2008, 165 (52.1%) patients discontinued from the LTE. In the DB period vs the LTE, incidence rates for serious adverse events were 25.98 vs 19.55/100 patient–years (pt–yrs), and for serious infections were 5.28 vs 3.40/100 pt–yrs. There were no cases of TB or opportunistic infections in the LTE. Rates of malignancies were 3.51 vs 2.17/100 pt–yrs in the DB vs LTE period. Rates of autoimmune events were 1.75 vs 1.53/100 pt–yrs in the DB vs LTE period. There was a sustained improvement over 4 years of OL abatacept treatment in ACR 20 responders (Month 6=60.1% [95% CI: 53.6, 66.6] vs Year 4.5=80.9% [75.7, 86.1]). A similar pattern was observed for ACR 50 and 70 responders (Month

6=23.9% [18.2, 29.6] and 11.8% [7.5, 16.1] vs Year 4.5=45.0% [38.4, 51.7] and 23.2% [17.6, 28.8]), and for patients achieving LDAS and DAS28-defined remission (Figure).

	Year 0.5 (n)	Year 1.0 (n)	Year 1.5 (n)	Year 2.0 (n)	Year 2.5 (n)	Year 3.0 (n)	Year 3.5 (n)	Year 4.0 (n)	Year 4.5 (n)
LDAS/remission	208	194	164	153	133	133	126	115	105

Conclusion: In this trial of patients with RA and an inadequate response to anti-TNF therapy, the safety of abatacept over 4 years of the LTE was consistent with the DB period. Sustained clinical efficacy was observed in patients initially randomized to abatacept, supporting long-term use of abatacept in this patient population with refractory disease.

Abatacept Reduces Osteitis and Inhibits Bone Erosion in Anti-CCP2 Positive Patients with Synovitis at High Risk of Developing RA.

C. Peterfy[1], P. Durez[2], J. DiCarlo[1], J. C. Becker[3], G. Vratsanos[3], S. Overfield[3], K. Qi[3], P. Mitra[3], H. K. Genant[4] and P. Emery[5], [1]SYNARC, Inc, San Francisco, CA, [2]Cliniques Universitaires Saint-Luc, UCL, Brussels, Belgium, [3]Bristol-Myers Squibb, Princeton, NJ, [4]University of California, San Francisco, [5]University of Leeds, Leeds, United Kingdom

Purpose: Osteitis on magnetic resonance imaging (MRI) is a strong predictor of radiographic progression in patients with RA[1]. Here, for the first time, we assess the impact of T-cell co-stimulation modulation with abatacept on MRI osteitis score in very early arthritis in patients with synovitis and anti-CCP antibodies, who are at a high risk of developing RA.

Methods: ADJUST (Abatacept study to Determine the effectiveness in preventing the development of RA in patients with Undifferentiated inflammatory arthritis and to evaluate Safety and Tolerability) was a randomized, double-blind, Phase II, placebo-controlled exploratory study of patients with undifferentiated arthritis, symptomatic clinical synovitis of ≥2 joints and anti-CCP2 positivity; the primary endpoint was proportion of patients who developed RA by ACR criteria. A total of 56 patients with mean symptom duration of 7.9 months were randomized 1:1 to abatacept (~10 mg/kg) or placebo for up to 6 months, after which treatment was stopped. Patients who developed RA were discontinued. In this substudy, 21 patients had gadolinium-enhanced MRI of one hand/wrist within 2 weeks prior to initiating study drug and repeated at Month 6 and Year 1. MRI images were scored using the OMERACT 6 method[2].

Results: At Month 6, osteitis scores had improved from baseline with abatacept, but increased with placebo (Table). For patients who completed Year 1, 6 months after stopping therapy there was little progression in osteitis in the abatacept group but worsening in the placebo group (Table). MRI erosion and synovitis scores showed a similar trend; at Month 6, mean changes from baseline were 0.45 and 0.27, respectively, in the abatacept group and 1.20 and 1.60 in the placebo group. By Year 1, mean change from baseline in erosion and synovitis scores were 0 and 0.22, respectively, in the abatacept group versus 5.00 and 2.33 in the placebo group.

Osteitis scores	**Abatacept**	**Placebo**
Month 6	**n=11**	**n=10**
Baseline (SD)	2.36 (5.28)	3.40 (8.42)
Month 6 (SD)	0.73 (1.10)	4.80 (7.84)
Change (95% CI)	–1.64 (–4.94, 1.67)	1.40 (–2.19, 4.99)
Month 12	**n=9**	**n=6**
Baseline (SD)	0.56 (1.01)	0.67 (1.63)
Year 1 (SD)	0.78 (1.30)	7.33 (11.52)
Change (95% CI)	0.22 (–0.92, 1.36)	6.67 (–4.19, 17.53)
SD=standard deviation; CI=confidence interval		

Conclusion: This small substudy in anti-CCP2 positive patients with early arthritis suggests that administration of abatacept reduces osteitis and synovitis, and inhibits bone erosion on MRI. This inhibition was maintained to Year 1, demonstrating a sustained benefit that persisted after therapy cessation.

1691

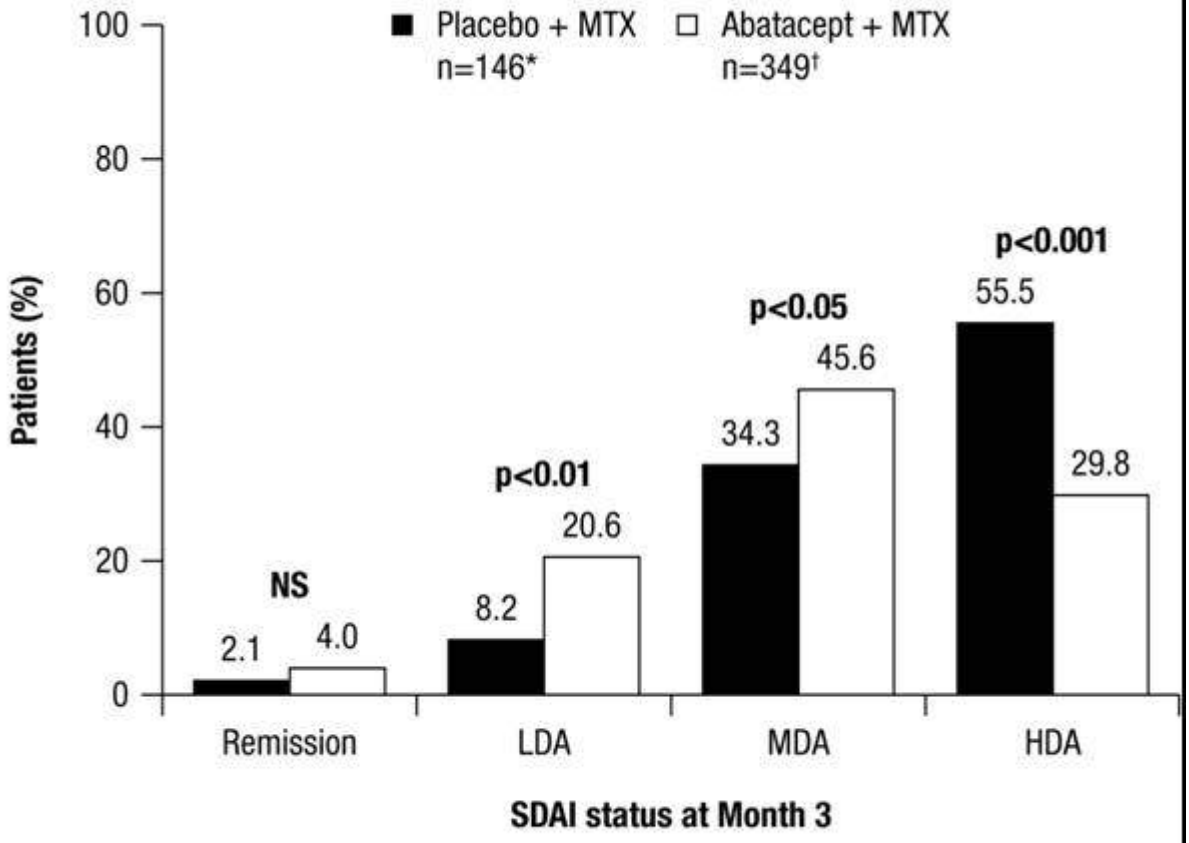
A Significant Proportion of Patients with RA Achieve Simplified Disease Activity Index (SDAI)-Defined Low Disease Activity or Remission with Abatacept Vs Placebo, and SDAI Remission Is Associated with Reduced Radiographic Progression. J. S. Smolen[1], D. Aletaha[1], M. Le Bars[2], C. Poncet[3], M. Schiff[4], J. M. Kremer[5], Y. Yazici[6], P. Emery[7], R. Westhovens[8] and M. Dougados[9], [1]Medical Univ Vienna, Vienna, Austria, [2]Bristol-Myers Squibb, Rueil-Malmaison, France, [3]Docs International, Issy-les-Moulineaux, France, [4]Univ of Colorado, Denver, CO, [5]Albany Medical College, Albany, NY, [6]NYU Hospital for Joint Diseases, New York, NY, [7]Univ Leeds, Leeds, United Kingdom, [8]UZ Gasthuisberg, KU Leuven, Leuven, Belgium, [9]Hospital Cochin, Descartes Univ, Paris, France

Purpose: The SDAI composite disease activity index is a stringent measure of remission[1], and good correlation between SDAI states and changes in radiographic progression have been reported[2]. Analyses were performed to assess SDAI disease activity status and to determine the correlation between SDAI status and radiographic progression in patients (pts) with RA and an inadequate response to MTX.

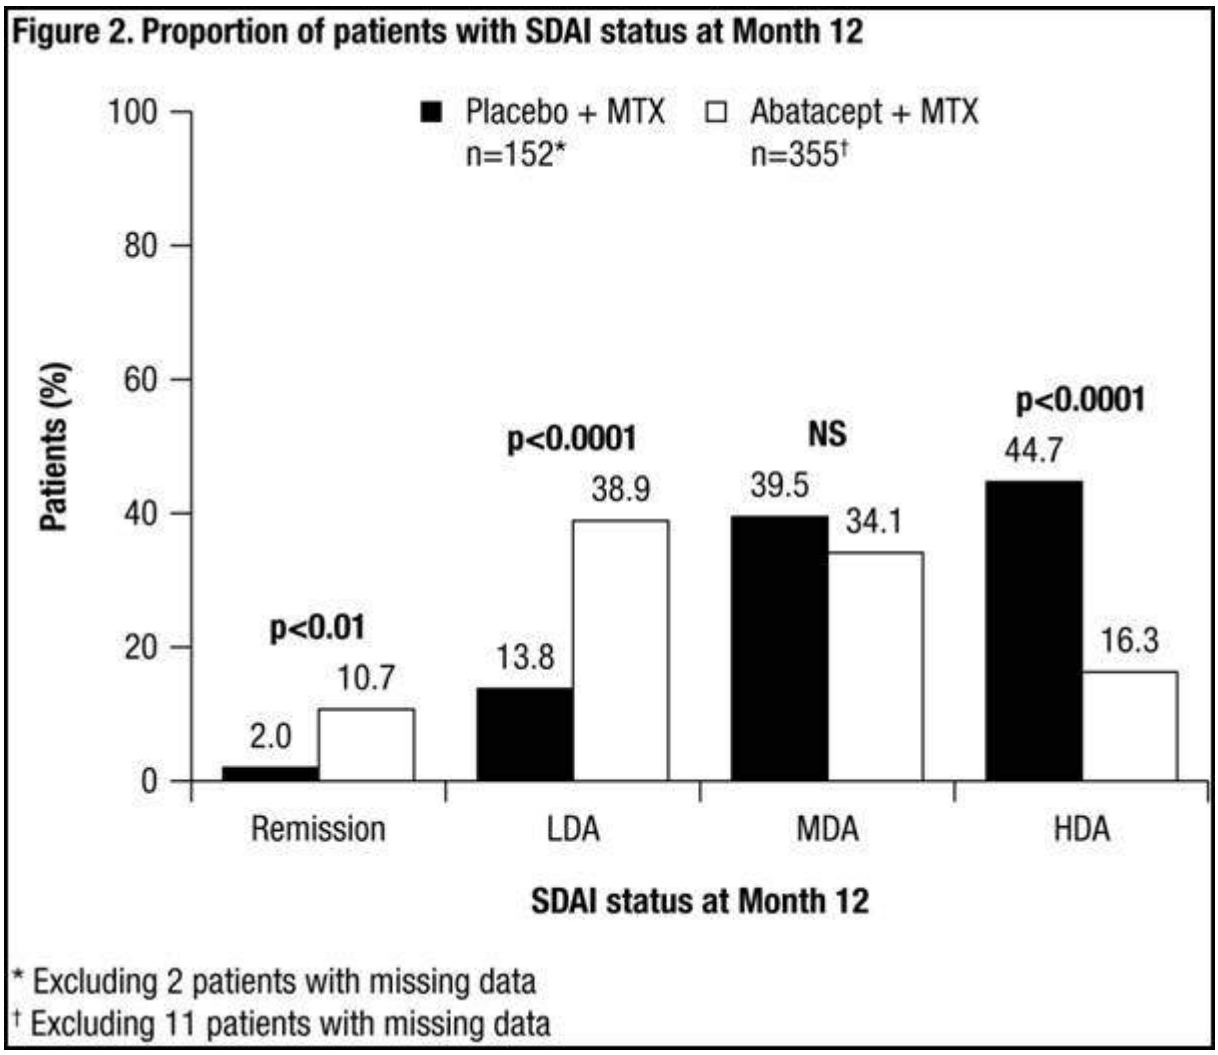
Methods: Pts who completed the 1-yr, randomized, double-blind period of the AIM (Abatacept in Inadequate Responders to MTX) trial (abatacept ~10 mg/kg or placebo, plus MTX)[3] and had radiographs at baseline and Yr 1 were eligible for analysis (*post hoc*, as observed). SDAI states were assessed at Mths 3 and 12, defined as High Disease Activity (HDA; >26), Moderate Disease Activity (MDA; >11–26), Low Disease Activity (LDA; >3.3–11) or remission (≤3.3). Changes from baseline to Mth 12 in Genant-modifed Sharp total score (TS) were analysed by SDAI status attained at Mth 3.

Results: 366 abatacept and 154 placebo pts were eligible for analysis. Baseline demographics were comparable between treatment groups[3]. At Mth 3, significantly more abatacept than placebo pts had achieved LDA; at Mth 12, the proportions of abatacept pts in LDA and remission had increased ~twofold and differences between treatment groups were statistically significant for both measures (Figs). The proportion of abatacept pts in HDA was reduced by ~45% from Mth 3 to 12; levels were significantly lower vs placebo at both time points (Figs). In the radiographic analysis, the smallest change in TS from baseline to Mth 12 was observed in abatacept pts who achieved remission at Mth 3 (change in TS: –0.2 [n=14]); mean changes in TS were 0.63 (72), 1.1 (159) and 1.97 (104) for LDA, MDA and HDA, respectively. For placebo pts mean changes in TS were 0.73 (3), 2.75 (12), 2.26 (50) and 2.9 (81) for remission, LDA, MDA and HDA, respectively. Changes in TS, especially in the remission and LDA groups, were numerically smaller in abatacept vs placebo pts.

Figure 1. Proportion of patients with SDAI status at Month 3



* Excluding 17 patients with missing data
† Excluding 8 patients with missing data



Conclusion: A significant proportion of abatacept pts achieved LDA or remission vs placebo over 1 yr according to the stringent SDAI criteria. SDAI remission and LDA at Mth 3 were associated with low levels of radiographic progression at Mth 12, in particular with abatacept compared with placebo, suggesting that these states are predictive of a reduction in radiographic progression, as observed with other biologics[4].

1692

Immunogenicity Is Not Increased with Subcutaneous Administration of Abatacept with and without Methotrexate in Patients with Rheumatoid Arthritis: Results From a Phase III Study. P. Nash[1], S. Nayiager[2], M. Genovese[3], A. Kivitz[4], K. Oelke[5], C. Ludivico[6], W. Palmer[7], C. Rodriguez[8], I. Dalaet[8], S. Overfield[8], A. Elegbe[8] and M. Corbo[8], [1]University of Queensland, Brisbane, Australia, [2]St Augustine's Hospital, Durban, South Africa, [3]Stanford University, Palo Alto, CA, [4]Altoona Center for Clinical Research, Duncansville, PA, [5]Rheumatic Disease Center, Glendale, WI, [6]East Penn Rheumatology Associates, Bethlehem, PA, [7]Westroads Medical group, Omaha, NE, [8]Bristol-Myers Squibb, Princeton, NJ

Purpose: Abatacept (ABA), a selective co-stimulation modulator, is approved for IV use in rheumatoid arthritis (RA). Subcutaneous (SC) administration may provide further dosing flexibility. The use of some biologics requires background methotrexate (MTX) to suppress immunogenicity[1]. We present data from a phase III study in RA patients (pts) examining the immunogenicity and safety of SC ABA with or without background MTX in the absence of an initial IV loading dose of ABA.

Method: In this multi-center, 4-month, parallel-cohort, open-label trial, RA pts were stratified to SC ABA + MTX or SC ABA only. SC ABA was self-administered once weekly at a fixed dose of 125 mg in a ready-to-use prefilled syringe. The primary endpoint was the proportion of pts seropositive by ELISA for anti-ABA or anti-CTLA4 antibodies at Day 113. Antibodies were also assessed by electrochemiluminescence meso-scale discovery (MSD) method. Safety was monitored throughout. Clinical efficacy and pharmacokinetics were secondary endpoints.

Results: One hundred pts (mean age, 54.0 yrs; mean weight, 83.1 kg; mean disease duration, 10.1 yrs) were treated with SC ABA + MTX (n = 51) or SC ABA only (n = 49). ELISA detected no antibody response to ABA or CTLA-4 at Day 113, giving an immunogenicity rate of 0%. Prior to Day 85, 2 pts (1, anti-ABA; 1, anti-CTLA4) in the SC ABA + MTX group (3.9%) and 1 pt (anti-CTLA4) in the SC ABA only group (2.0%) developed antibodies. MSD method confirmed the low immunogenicity rate observed with ELISA. No neutralizing antibodies were detected. Treatment-related AE rates were similar between SC ABA + MTX (27.5%) and SC ABA only (24.5%) with 1 serious AE considered drug-related in each group. Injection site reactions were mostly mild and similar between SC ABA + MTX (5.9%) and SC ABA only (8.2%). No malignancies, autoimmune disorders or deaths were reported. Improvements in Disease Activity Score (DAS) 28 from baseline to Day 113 were seen in both arms. Immunogenicity was transient; it did not affect efficacy or serum ABA Cmin, nor did it increase injection site reactions.

Conclusion: Weekly SC ABA resulted in low immunogenicity after repeat dosing regardless of the presence or absence of background MTX or an initial IV loading dose of ABA. SC ABA was well tolerated with no new safety signals observed. These results are consistent with previous experience with IV ABA[2] and support the continued development of SC ABA with and without background MTX.

A Safety Analysis of Oral Prednisone as a Pre-Treatment for Rituximab in Rheumatoid Arthritis. John D. Carter[1], Anthony I. Sebba[2], Nancy L. Albritton[1], Angie H. Osorio[1], Ginger L. Pfeiffer[2], Joanne Valeriano[1] and Frank B. Vasey[1], [1]University of South Florida, Tampa, FL, [2]Palm Harbor, FL

Purpose: The administration of 100mg of methylprednisolone intravenously (IV) ½ hour prior to rituximab decreases the incidence and severity of acute infusion reactions (AIRs). However, the recommended pretreatment with IV methylprednisolone adds considerable time to the medication administration protocol; it also conveys potential risk. We present preliminary results of an assessment of oral prednisone as a pretreatment to rituximab.

Methods: This is a 6-month open-label assessment of 40mg of oral prednisone given ½ hour prior to rituximab as a prophylaxis against acute infusion reactions in patients with rheumatoid arthritis (RA). Subjects are ages 18-80 and are either methotrexate (MTX) or TNF-antagonist inadequate responders. All subjects have to be on concomitant methotrexate. Standard safety and laboratory exclusions applied. All subjects were treated with 40mg of oral prednisone ½ hour prior to their rituximab infusions. Rituximab was administered as per the standard RA protocol; i.e. 1000mg IV twice at days #1 and #15. The primary endpoint is AIRs in the first 24 hours after the initiation of their day #1 infusion. The severity, timing, and treatment (including rituximab dose modifications) of any AIRs are also recorded. Secondary endpoints include AIRs during the 24 hours following the day #15 infusion and any adverse events experienced during the 6 month study; efficacy measures (DAS-28 and HAQ-DI) were also followed as secondary endpoints.

Results: 32 subjects have been screened and 27 subjects qualified. Baseline demographics include 25 females and 2 males, with 22/27 (81%) Caucasians, 4 (15%) Hispanics, and 1 other. The subjects mean age was 52.9 years (range 29-80) and disease duration was 10.7 years (range 1-40). The average MTX dose is 15.1mg weekly and 16/27 (59%) have failed previous anti-TNF therapy (average number of TNF-antagonists used was 1.5). 12/27 (44%) subjects were on glucocorticoids at baseline with an average dose of 6.3mg prednisone daily; 18/27 (67%) subjects were seropositive. The mean DAS28 at screening was 5.48 and their HAQ-DI was 1.38. Regarding the primary endpoint, 7/27 (26%) of the subjects had AIRs within 24 hours of their day #1 infusion; 6 were mild in severity and 1 was moderate. There were only 3 (11%) AIRs within 24 hours of their day #15 infusion; all were mild. None of the AIRs required drug discontinuation. Of the 13 subjects who have completed the entire 6 months of the study, 8 (62%) experienced an AE at some point during the trial. There were 2 SAE's (a-fib and asthma) deemed not to be study-drug related. The DAS28 and HAQ-DI all improved significantly at weeks 8, 16, and 26 compared to baseline.

Conclusion: Historical controls demonstrate that 27-33% of RA subjects experience AIRs with their first rituximab infusion. Our data suggest a smaller dose of oral prednisone is an effective alternative to IV methylprednisolone as a pretreatment for rituximab in patients with RA.

Single Infusion of Infliximab Reduced Excessive Bone Resorption in Patients with Rheumatoid Arthritis. Masao Nawata, Kazuyoshi Saito, Kentaro Hanami and Yoshiya Tanaka, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background: Bone disorders associated with rheumatoid arthritis (RA) are classified mainly into joint destruction due to spread of synovitis, abnormal periarticular and systemic bone metabolism. However, a growing body of evidence including ATTRACT study has emphasized suppressive effects of tumor necrosis factor (TNF)-α inhibitor infliximab on joint destruction at one year, precise mechanisms of infliximab for bone metabolism in RA patients remain to be clarified. We here addressed the involvement of TNF-α in bone destruction in RA, by observing how infliximab effects on bone metabolism in RA patients from 2 to 54 weeks.

Purpose: The aim of this study is to investigate the short and long term effect of infliximab on bone metabolism and to elucidate the mechanism of suppressive effect of infliximab on bone destruction by infliximab in RA.

Method: 105 active RA patients were enrolled. Among them, 90 patients were refractory to MTX and were treated with infliximab (3 mg/kg, administered every 8 week) and 15 patients were treated with MTX alone as the control group. Clinical disease activity was determined using DAS28 and bone mineral density (BMD), urinary crosslinked N-terminal telopeptide of type I collagen (u-NTx) and serum bone alkaline phosphate (BAP) were measured at a baseline and week 2, 22 and 54 after the treatment.

Results: The enrolled RA patients showed a high disease activity (DAS28 5.3±0.91) and corresponding levels to the age of BMD (L2-4; 0.89±0.18 g/cm^2, hip; 0.67±0.14 g/cm^2). Serum BAP were within normal levels (26.9±10.5 U/I), whereas u-NTx levels (76.9±74.1 nmol/mmol CRE) were markedly increased at baseline. No significant difference was observed between infliximab and MTX group

regarding background. BMD did not change for 54 weeks in both groups. MTX alone did not change u-NTx and BAP levels during 54 weeks. It is noteworthy that treatment with infliximab significantly decreased u-NTx to 59.5±43.7 ($p<0.05$) with in only 2 weeks and this decrease of u-NTx levels was maintained with 55.4±29.7 ($p<0.05$) and 47.8±26.5 ($p<0.05$) at the week 22, and 54, respectively. The rate of change in u-NTx at 2 week was significantly correlated with the rate of u-NTx at 54 week by the multivariate analysis ($r=0.529$, $p<0.0001$). In contrast, serum BAP levels increased significantly at week 22 (31.6±11.5 ; $p<0.05$) and 54 (31.8±11.6 ; $p<0.05$) but not at week 2 (24.3±7.4; ns) by infliximab.

Conclusion: Although bone resorption was markedly enhanced in RA, single infusion of infliximab significantly reduced excessive the bone resorption within 2 weeks, implying rapid and strong suppression of bone resorption or joint destruction by infliximab. This reduction of bone resorption was maintained for 52 weeks. Thus, the complete inhibition of yearly progression of Total Sharp Score might be due to such a rapid and marked reduction of bone resorption within 2 weeks after infliximab infusion.

Effectiveness of Treatment with Rituximab Depends On Autoantibody Status – Results From 2 Years of Experience in the German Biologics Register RABBIT. Anja Strangfeld[1], Maria Eveslage[1], Joern Kekow[2], Anett Gräßler[3], Jörg Kaufmann[4], Joachim Listing[5] and Angela Zink[1], [1]German Rheumatism Research Center, Berlin, Germany, [2]Univ of Magdeburg, Clinic of Rheumatology, Vogelsang-Gommern, Germany, [3]Rheumatologist in Private Practice, Pirna, Germany, [4]Rheumatologist in Private Pactice, Ludwigsfelde, Germany, [5]DRFZ, Berlin, Germany

Purpose: To investigate the effectiveness of treatment with Rituximab (RTX) over the first six to twelve months in daily rheumatologic care.

Methods: The German biologics register RABBIT is a prospective cohort study observing all licensed biologic agents. Since 2006, patients with a first or repeat treatment cycle of RTX have been enrolled. They will be followed up for at least 5 years. Regular assessments include clinical status as well as therapy.

Results: Of a total of 661 patients enrolled at start of RTX therapy, 424 patients (78% female) were observed for at least six months. Their median disease duration was 11 years. 16.3% of the patients achieved a EULAR good response, 44.7% a moderate response and 39.0% no response after six months. There was no difference in the proportion of moderate or good responses between patients who received RTX for the first time or a repeat cycle or between patients who received RTX in combination with methotrexate and those on RTX monotherapy.

	Treatment RTX		Rheumat. factor		anti-CCP	
	+ MTX	Mono ther.	Neg.	Positive	Neg.	Positive
n	229	120	75	348	82	342
DAS28 month 0	5.5	5.7	5.3	5.6	5.2	5.6
DAS28 month 6	4.5	4.3	4.7	4.3	4.4	4.4
% EULAR response #	56.8	64.2	45.3	64.4	54.9	62.6
OR EULAR response *	Refer.	1.38	Refer.	2.01	Refer.	1.26
CI 95% of OR		[0.86; 2.21]		[1.2; 3.4]		[0.76; 2.07]

* odds ratio adjusted for baseline status of DAS28, # DAS28 good or moderate response

Rheumatoid factor (RF) positive patients had a significantly better response than seronegative ones ($p=0.003$). Taking the baseline status into account this difference corresponds to an adjusted odds ratio of 2.0 (95%CI: 1.2 - 3.4). A similar, albeit insignificant, difference was observed for anti-CCP antibodies. Among 265 patients observed for at least 12 months, 180 (68%) had a second cycle of RTX after a mean duration of 8.7 months. After six months, 9% of the patients had already received their second cycle.

Conclusion: The data show effectiveness of RTX in a majority of unselected real-life RA patients. The higher improvement in rheumatoid factor and/or anti-CCP antibody positive patients might indicate that B-cell depletions is more effective in autoantibody positive patients.

1696

Efficacy of Golimumab, a Human Anti-TNFα Antibody, by Baseline CRP Level in Patients with Rheumatoid Arthritis: Results From Three Phase 3, Randomized, Double-Blind, Placebo-Controlled Studies. P. Emery[1], M.C. Genovese[2], R.M. Fleischmann[3], E. L. Matteson[4], E. C. Hsia[5], S. Xu[6], M. K. Doyle[5] and M. U. Rahman[5], [1]Leeds Gen Infirmary, Leeds, United Kingdom, [2]Stanford University, Palo Alto, CA, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Mayo Clinic, Rochester, MN, [5]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [6]Centocor R&D, Inc, Malvern, PA

Purpose: To assess GLM efficacy by baseline disease severity as measured by CRP level in three Phase 3 RA clinical trials (GO-BEFORE, GO-FORWARD, and GO-AFTER).

Methods: Adult pts with active RA were randomized to placebo (PBO)+/- methotrexate (MTX) or GLM (50 or 100 mg)+/-MTX across the three studies. Study agent was administered subcutaneously q4wks. The studies enrolled pts who were MTX-naive (n=637; GO-BEFORE), responded inadequately to MTX (n=444; GO-FORWARD), and who were previously treated with a biologic anti-TNFalpha agent (n=459; GO-AFTER). ACR20, ACR50 and DAS28-CRP (good or moderate) responses at wk 24 were assessed by baseline disease severity, as determined by baseline CRP quartiles. The baseline CRP quartiles (Q1-Q4) were ≤0.5, >0.5-≤1.3, >1.3-≤3.4, >3.4 mg/dL for GO-BEFORE; ≤0.4, >0.4-≤ 0.9, >0.9-≤ 2.3, >2.3 mg/dL for GO-FORWARD; ≤0.3, >0.3-≤0.8, >0.8-≤2.3, >2.3 mg/dL for GO-AFTER.

Results: GLM +/- MTX demonstrated efficacy in three distinct RA populations in all 4 quartiles of baseline serum CRP levels, although statistical significance vs PBO was not reached for all efficacy parameters in all subgroups (Table). In MTX-naïve pts, GLM was effective, with comparable ACR 20, ACR50 and DAS28-CRP responses at wk 24 across CRP quartiles. In pts with inadequate response to MTX, GLM was effective across CRP quartiles, with pts in the 2nd and 3rd quartiles achieving the highest ACR and DAS-CRP response rates at wk24. In pts with prior biologic anti- TNFalpha agent experience, benefit was observed across all CRP quartiles, including in the highest quartile.

Table:

Summary of Results

Baseline CRP quartile (Q)	**PBO(+/-MTX)**	**GLM 50mg (+/-MTX)**	**GLM 100mg (+/-MTX)**
GO-BEFORE			
1Q, N, ACR20/50/DAS	40, 48%, 15%, 53%	41, 61%, 27%, 76%*	52, 48%, 27%, 62%

1697

Open-Label Certolizumab Pegol Is Effective in Patients Who Withdrew From Double-Blind Treatment Due to Non-Response.

Edward C. Keystone[1], Désirée M.F.M. van der Heijde[2], J. S. Smolen[3], D. E. Furst[4], Michael E. Weinblatt[5], Tore K. Kvien[6], V. Strand[7], Z. Ansari[8], N. Goel[9] and B. Combe[10], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Medical University of Vienna, Vienna, Austria, [4]David Geffen School of Medicine at UCLA, Los Angeles, CA, [5]Brigham & Women's Hosp, Boston, MA, [6]Diakonhjemmet Hospital, Oslo, Norway, [7]Stanford University, Palo Alto, CA, [8]UCB, Slough, United Kingdom, [9]Smyrna, GA, [10]Immuno-Rheumatology, Montpellier, France

Purpose: The RAPID 1 trial demonstrated that double-blind treatment with certolizumab pegol (CZP) 200 or 400 mg Q2W + MTX significantly reduces RA signs and symptoms and inhibits radiograph progression compared with placebo (PBO) + MTX.(1) Here we present the efficacy of open-label (OL) CZP + MTX in patients who withdrew from double-blind treatment with either CZP or PBO.

Methods: Of the 199, 393 and 390 patients treated with PBO, CZP 200 mg and CZP 400 mg, respectively, in RAPID 1, 137, 91, and 74 withdrew at Wk 16 due to ACR20 non-response at Wks 12 and 14 (as per protocol). 287 (95.0%) patients reconsented and were enrolled in the OL study. Efficacy assessments included ACR20/50/70 responder rates (using non-responder imputation based on enrollment in the OL portion of the trial), DAS28(ESR) and HAQ-DI (LOCF).

Results: Of the patients who withdrew at Wk 16 due to ACR20 non-response, 8% of PBO-treated patients and 16% of CZP-treated patients demonstrated ACR20 responses at Wk 8 that were transient (Figure). Upon receiving OL CZP treatment, patients rapidly achieved ACR20 responses, which reached 63% in PBO withdrawers switched to OL CZP and 54% in CZP withdrawers (400 mg) switched to OL CZP, and were comparable to response rates in the double-blind trial. Responses were sustained through to at least Wk 100. Similar trends for both the PBO and CZP withdrawers were observed for ACR50 and 70 response rates, HAQ-DI scores and DAS28 (data not shown). Comparable benefits were observed in patients who received either CZP 200 mg or 400 mg for the first 16 weeks.

Conclusion: A subset of patients with ongoing active disease that failed to respond to CZP or PBO in the double-blind phase rapidly responded to CZP upon receiving OL therapy. These data suggest that response to CZP + MTX, and perhaps other study drugs, may be underestimated in a double-blind trial, and supports the use of an early escape to OL treatment in clinical trials. These results may also

contribute to the understanding as to how both patient and physician perceptions are influenced by the possibility of receiving placebo versus active treatment.

1698

Certolizumab Pegol (CZP) Added to Methotrexate (MTX) Provides Lasting Improvements in Patient-Reported Outcomes (PROs) Over 2 Years. V. Strand[1], R. Fleischmann[2], Tore K. Kvien[3], A. Kavanaugh[4], J. S. Smolen[5], Alvin F. Wells[6], E. Nikaï[7], G. Coteur[7] and B. Combe[8], [1]Stanford University, Palo Alto, CA, [2]Univ of Texas, Dallas, TX, [3]Diakonhjemmet Hospital, Oslo, [4]UCSD, San Diego, CA, [5]Medical Univ Vienna, Vienna, Austria, [6]Rheum & Immunotherapy Center, Oak Creek, WI, [7]UCB, Brussels, Belgium, [8]Immuno-Rheumatology, Montpellier, France

Purpose: CZP 200 or 400 mg Q2W+MTX provided rapid, sustained, and clinically meaningful improvements in physical function and HRQoL, as well as reductions in arthritis pain and fatigue over 1 year (RAPID 1 trial). Here we present the impact of CZP+MTX on these PROs over 2 years.

Methods: This analysis focuses on patients who completed 52 wks of double-blind CZP treatment (completers) and then continued with open-label CZP+MTX; patients had at least 100 wks (2 yrs) of CZP exposure from BL. PROs included physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]), pain (Visual Analog Scale [VAS; 0-100 mm]), fatigue (Fatigue Assessment Scale [FAS, 0-10]), and HRQoL (SF-36). Changes from RAPID 1 BL and % of patients achieving Minimum Clinically Important Differences (MCIDs) were assessed. MCIDs are ≥0.22 for HAQ-DI, ≥10 for pain VAS, ≥1 for FAS, ≥5 points for the 8 SF-36 domains (Physical Functioning, Role Physical, Bodily Pain, General Health, Vitality, Social Functioning, Role Emotional, and Mental Health) and ≥2.5 points for SF-36 physical and mental component summaries [PCS, MCS]).

Results: Clinically-meaningful improvements in physical function and reductions in pain and fatigue were reported at Wk 1 with CZP; HRQoL improvements were reported at Wk 12 (first post-BL assessment). Improvements in all PROs were sustained through at least Wk 100 (Table). At Wk 100, physical function (HAQ-DI) was improved on average by 0.79 points for completers originally treated with CZP 200 mg+MTX; pain relief averaged 39.5 points, and fatigue relief averaged 3.2 points. Patients originally receiving CZP 200 mg+MTX had mean improvements of 10.1 and 7.7 points for the PCS and MCS, respectively (Wk 100). HRQoL levels approached US population norms in the Vitality and Mental Health domains. Comparable benefits were observed in completers who received CZP 400 mg+MTX in RAPID 1.

Table. HAQ-DI, Pain, Fatigue, and HRQoL Change from Baseline and % of Patients Achieving MCID at Wk 100

	CZP Dose in RAPID 1	HAQ-DI	Pain VAS	FAS	SF-36 PCS	SF-36 MCS
Change from baseline	200 mg+MTX	-0.79	-39.5	-3.2	10.1	7.7
	400 mg+MTX	-0.78	-40.6	-3.0	10.5	7.1
%MCID	200 mg+MTX	64.1%	66.7%	63.3%	56.6%	48.4%
	400 mg+MTX	61.8%	67.6%	61.5%	59.0%	42.6%

Conclusion: Over 2 yrs, CZP+MTX provided lasting and clinically meaningful improvements in physical function and HRQoL, as well as relief from pain and fatigue, with improvements maintained at average levels at least 3 times higher than the thresholds for meaningful improvement.

1699

Safety Update On Certolizumab Pegol (CZP) in Patients with Active Rheumatoid Arthritis (RA). Ronald F. van Vollenhoven[1], J. S. Smolen[2], M. Schiff[3], Roy Fleischmann[4], B. Combe[5], N. Goel[6], C. Desai[7], Jeffrey R. Curtis[8] and Edward C. Keystone[9], [1]Karolinska Univ Hosp, Stockholm, Sweden, [2]Medical Univ Vienna, Vienna, Austria, [3]Univ of Colorado School of Medicine, Greenwood Village, CO, [4]Metroplex Clinical Research Center, Dallas, TX, [5]Immuno-Rheumatology, Montpellier, France, [6]Smyrna, GA, [7]UCB, Slough, United Kingdom, [8]Univ of Alabama at Birmingham, Birmingham, AL, [9]Professor of Medicine/University of Toronto, Toronto, ON

Purpose: To update the safety profile of CZP in RA clinical trials and open-label extensions (OLEs).

Methods: Adverse event (AE) data were pooled from Phase 1 and 2 studies as well as the Phase 3 studies RAPID 1, RAPID 2, FAST4WARD and 014 (and their OLEs). Analyses were performed using cut-off dates of Jan 31, 2007 (initial) and Aug 31, 2007 (update). These analyses are presented by incidence (AEs/100 patient-years [pt-yrs]; data were censored per pt at first occurrence of the AE or serious AE [SAE]) and by proportion of pts experiencing each AE. Malignancy data are presented as standardized incidence ratios (SIRs) vs the GLOBOCAN database (excluding non-melanoma skin cancers and cancers within 30 days of first study drug injection).

Results: As of Aug 2007, 2367 CZP-treated RA pts with 4065 pt-yrs of exposure were available for safety analyses. Most AEs were mild/moderate (Table). The most common AEs were infections: 55.5% and 61.2% (70.6 vs 65.8/100 pt-yrs) in Jan and Aug 2007, respectively. The most frequently reported serious infections were respiratory tract infections and tuberculosis (TB). Most TB cases occurred in countries with a high prevalence of latent TB; no cases of TB were reported in the US. Opportunistic infections included 3 fungal esophagitis cases and 1 case each of geotrichosis and *Pneumocystis*. 1 patient had gastrointestinal perforation. In Jan and Aug 2007, the malignancy SIRs were 1.06 (95% CI:0.65-1.61) and 1.22 (95% CI:0.82-1.74), respectively; the lymphoma SIRs were 4.97 (95% CI:1.03-14.54) and 4.10 (95% CI:0.84-11.97). The standardized mortality ratios were 1.02 (95% CI:0.67-1.49) and 0.96 (95% CI:0.65-1.36), respectively. The % of pts with injection site reactions and pain was 7.9% and 1.8%.

Table. AEs (safety population)

	All CZP doses		**All CZP doses**	
	N=2367		N=2367	
Cut-off date	**Jan 31, 2007**		**Aug 31, 2007**	
Exposure (pt-yrs)	3218.0		4065.2	
	Incidence/100 pt-yrs	**%**	**Incidence/100 pt-yrs**	**%**
Any AE	199.5	81.7	183.1	86.1
SAE	17.9	22.1	17.0	26.0
AE leading to death	1.15	1.2	1.27	1.4
AEs leading to withdrawal	7.0	10.0	6.5	12.2
Serious infections	5.4	7.3	5.3	8.9
Lower respiratory tract and lung	1.2	1.6	1.3	2.2
TB	0.7	1.0	0.7	1.3
Cardiac disorders	4.7	6.3	4.3	7.3
Ischemic coronary artery disorders	1.3	1.7	1.1	1.9
Rate and rhythm disorders	1.2	1.7	1.1	1.9

Conclusion: The incidence rate of AEs and SAEs and the overall safety profile of CZP remained similar to previous reports with the addition of 850 pt-yrs of CZP exposure. These data support the favorable benefit/risk balance for CZP in RA.

Infliximab Concentration Monitoring Improves the Control of Disease Activity in Rheumatoid Arthritis. Jean-Camille Méric[1], Denis Mulleman[2], Gilles Paintaud[2], Emilie Ducourau[2], Charlotte Magdelaine-Beuzelin[2], Jean-Pierre Valat[1] and Philippe Goupille[3], [1]CHRU de Tours, Tours, France, [2]Université François Rabelais de Tours; CNRS, UMR 6239; CHRU de Tours, Tours, France, [3]Université François Rabelais de Tours, CNRS, UMR 6239; CHRU de Tours, Tours, France

Purpose: To study if measurement of infliximab serum concentration in RA modifies the therapeutic strategy and improves the control of disease activity.

Method: RA patients routinely treated with infliximab were included in an observational open label study. On visit 1 (V1), according to the patient's disease activity, a preliminary therapeutic decision was selected among four scheduled therapeutic options and a blood sample was collected to measure infliximab trough serum concentration. The final therapeutic decision was chosen and applied on the following infusion (V2), by taking into account both disease activity and infliximab serum concentration assessed on V1. Clinical and biological evaluations were performed on V3 and V4 and compared with those of V1.

Results: Twenty-four patients were studied. No patient had high infliximab concentration, 17 patients (71%) had medium infliximab concentrations and 7 (29%) had low infliximab concentration. The final therapeutic decision differed from the preliminary therapeutic decision for 12 patients (50%). In patients who had an increase of their infliximab dosage on V2, mean DAS28 decreased of about 20% on V3 or V4 as compared with V1 (see *figure1*). Decrease in DAS28 was correlated with increase in infliximab serum concentration ($p < 0.02$).

Conclusion: The measurement of infliximab trough concentration modifies the therapeutic strategy for RA patients and lead to an improved control of disease activity. Pharmacological drug monitoring of infliximab in RA may be useful for individual dosage adjustment to improve the control of disease activity

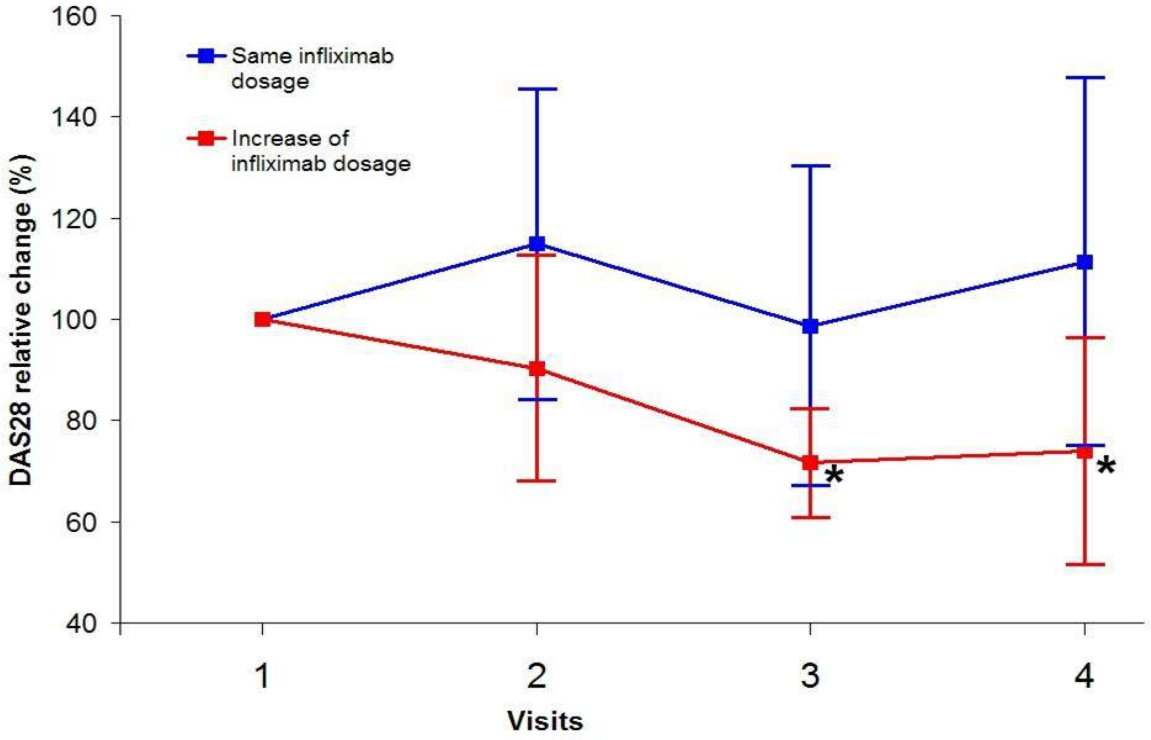

Figure 1: Relative changes in mean DAS28 according to final therapeutic decision.

Reasons for Different Infliximab Survival Time Among Patients with Rheumatoid Arthritis and Spondyloarthritis. Enrique Calvo, Carlos M. Gonzalez, Irene Díez-Merchán, Elena Becerra, Carmen Martínez-Porras, Delia Gerona, Francisco Aramburu, Carolina Marín, María Montoro, Laura Cebrián, Indalecio Monteagudo, Francisco J. López-Longo and Luis Carreño, HGU Gregorio Marañón, Madrid, Spain

Purpose: To know the reasons of the different infliximab survival time observed among patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).

Method: All patients treated with infliximab in our hospital were included in this prospective, observational study. Data concerning patient's demographics and drug efficacy, tolerability, concomitant therapy, adverse events, and drug discontinuation were recorded. Survival was studied with Kaplan-Meier method and variables analyzed using Cox proportional-hazards regression model.

Results: 183 patients with RA and 170 with SpA (63.5% ankylosing spondylitis, 18.2% psoriatic arthritis, 10% undifferentiated spondyloarthritis and 8.2% arthritis associated with inflammatory bowel disease) were included in the study and followed for a total of 874.1 patient-years (p-y). Infliximab was the first anti-TNF used in 335/353 (95%) patients. Infliximab survival time in SpA patients was

significantly higher than in RA patients. Median survival time (months): SpA 26.1; RA: 19.1. The unadjusted hazard ratio (HR) for infliximab discontinuation in SpA compared with RA was 0.45 (95% confidence interval [CI] 0.32-0.63). 138/353 (39.1%) patients discontinued infliximab due to lack of efficacy, infusion reaction or adverse events. Lack of efficacy: 3.64/100 p-y SpA vs 7.80/100 p-y RA; HR 0,46, 95% CI: 0.25-0.83. Infusion reaction: 3.87/100 p-y SpA vs 7.12/100 p-y RA; HR 0.54, 95% CI: 0.30-0.98. Adverse events: 2.05/100 p-y SpA vs 7.12/100 p-y RA; HR: 0.29, 95% CI: 0.14-0.61 (all HR unadjusted). When adverse event discontinuation was adjusted by diagnosis, age at infliximab start, gender and concomitant treatment, the only significant variable was age at the beginning of infliximab treatment: HR 1.07, 95% CI: 1.04-1.1 per year. SpA or RA diagnosis was not significant for adverse event discontinuation. When infusion reaction discontinuation was compared between all SpA patients and RA patients with methotrexate (MTX) as concomitant treatment there was no significant difference between both groups: 3.87/100p-y vs 4.60/100 p-y; NS.

Conclusion: Long term treatment with Infliximab is a good and safe therapeutic option for both RA or SpA patients. Infliximab survival time is better in SpA patients. Adverse event discontinuation is related to age at infliximab star but not to diagnosis. RA patients concomitantly treated with MTX had no significant difference in infusion reaction discontinuation than SpA patients.

1702

Adalimumab Dose Escalation Induces Durable Remissions and Is Safe in Minorities with Moderate to Severe Rheumatoid Arthritis (RA). George A. Karpouzas[1], Alexander Broumand[1], Shirin Bagheri[1], Leila Sayed[1], James S. Louie[2], Daniel E. Furst[2] and Dilrukshie Cooray[1], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]UCLA, Los Angeles, CA

Purpose: Patients (pts) with RA and partial response to disease modifying drugs (DMARDs) are treated with Tumor Necrosis Factor-Alpha inhibitors (TNFi) with good results. Adalimumab (ADA) is a human monoclonal antibody that inhibits TNFa, approved for use in RA at 40mg SQ every other week (QOW) or every week (QW). We investigated whether dose escalation to QW renders additional clinical benefit, whether the responses are sustained, and if this regimen is safe.

Methods: We studied 65 pts fulfilling 1987 criteria for RA and given ADA 40mg QOW. All had follow-up in a single academic center, where ADA is the recommended formulary drug. Subjects were largely minorities, indigent, and part of an assistance program. All had Disease Activity Scores (DAS28-3v-ESR) recorded every 3 months (mo). Good EULAR response (GER) was the primary outcome. Partial responders were given ADA 40mg QW. Flares were defined as: DAS28>3.2 and increase in DAS28>0.6 (from the initial good response) and/ or addition of a new drug. Intra-articular injections and/or 1 dose of intramuscular steroid were allowed. Response and flare data was analyzed with paired t-tests and Fisher's exact tests. Adverse events were reported as n/100-PY.

Results: Twenty two of 65 pts (33.8%) achieved GER in 5.3±3.9 mo and remained on QOW ADA for 23.5±17.8 mo. Forty three pts (66.2%) did not and received ADA 40mg QW for 17.2±12 mo. Twenty four of 43 (56%) achieved new GER within 7.5±5.9 mo, that lasted over 12±9.6 mo. Eleven of 24 (46%) had a flare within 11.7±10.2 mo, and 4/11 (36.4%) resolved without change in regimen over 4.5±3 mo. More flares occurred in the group on QW vs. on QOW ADA (OR=3.6, CI=0.9-13.9, p=0.07). GER persisted in 17/24 (71%) of the QW ADA group to the end of observation. Serious infections were 5.5 /100-PY in the QW group, not different from 4.9/100-PY in the QOW group. No cases of Tuberculosis (TB) or opportunistic infections were noted.

Conclusion: ADA dose escalation to 40 mg QW in partial responders induced new and durable GER. It was well tolerated with serious infections within the expected range for pts with RA.

Predictive Risk Factors of Severe Infections in RA Patients Treated with Rituximab in Real Life: Results From the AIR Registry.

Jacques-Eric Gottenberg[1], Xavier Mariette[2] and For the scientific committee members of AIR registry, [1]University Hospital of Strasbourg, Strasbourg, France, [2]Bicetre Hospital, Paris-Sud University, Le Kremlin Bicetre, France

Purpose: We investigated the rate and predicting factors of severe infections in patients with rheumatoid arthritis treated with rituximab (RTX) in daily practice.

Method: AIR is an independent registry promoted by the French society for Rheumatology.Standardized information are prospectively collected every 6 months during 5 years, by trained clinical nurses in each center. Central reviewing of charts of patients with SAEs is performed by the two coordinators of the study. Only severe infections occurring during the year following last infusion of RTX were analyzed. Statistical models included patients for whom all studied variables were available.

Results: -Baseline characteristics and comorbidities

1681 patients (1690 patients/year) were included in 85 centers. 712 patients had been retreated with RTX (2 cycles: 466; 3 cycles: 176; 4 cycles: 45; ≥5 cycles: 25). 13.7% of patients had a record of cancer, 28.7% a record of severe infection, including 40 previous tuberculosis infections, 11.8% had chronic cardiac or lung disease.

-Rate and description of severe infections

82 severe infections (4.9 severe infections/100 patients/year) were observed, resulting in 4 deaths. Bronchopulmonar, skin/soft tissue, urinary, digestive, osteo-articular, ENT and septicaemia represented 41.5%, 15.9%, 13.4%, 13.4%, 12.2, 2.4 and 1.2% of severe infections, respectively. Only 1 opportunistic infection was observed (a fungal septic arthritis). No tuberculosis reactivation was observed. 56 infections occurred after the 1st cycle, 22 after the 2d cycle, 3 after the 3d cycle, 1 after the 4th cycle. 79% of the severe infections occurred in the 6 months (50.6% before 3 months, 28.4% between 3 and 6 months) following RTX infusion.

998 patients had a follow-up duration longer or equal to 3 months and were included in the analysis of predicting factors of severe infections. On univariate analysis, age, chronic lung or cardiac disease, record of or current smoking, diabetes, a lower number of previous anti-TNF, extraarticular involvement, initial corticosteroid dosage, existence of at least one value of gammaglobulins or IgG below 6g/l since enrollment were associated with a higher risk of severe infections. On multivariate analysis, an older age (OR = 1.43 [1.02 ; 2.01], p=0.0382), chronic lung or cardiac disease(OR = 2.70 [1.17 ; 6.26], p=0.0205), extraarticular involvement (OR = 3.10 [1.45 ; 6.65,], p=0.0035), and occurrence of at least one value of IgG below 6g/l since enrollment (OR = 4.18 [1.42 ; 12.25], p=0.0092 were associated with an increased risk of severe infection (Figure 1).

Conclusion: In AIR registry, the rate of severe infections is similar in unselected patients as that reported in clinical trials. Interestingly, severe infections are time-dependent and occur in the first months following RTX infusion. Predicting factors of severe infections include age, comorbidities, extraarticular involvement, and hypoIgG. This suggests to monitor IgG levels before retreating patients with RTX and discuss the individual benefice/risk balance of RTX in patients with hypoIgG.

Figure 1. Multivariate analysis of the risk of severe infections in patients with RA treated with RTX

ACR/ARHP Poster Session C

Systemic Lupus Erythematosus - Human Etiology and Pathogenesis II

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1743

Genetic Variation at the IRF7/PHRF1 Locus Is Associated with Autoantibody Profile and Serum Interferon Alpha Activity in Lupus Patients. Rafah Salloum[1], Beverly S. Franek[1], Silvia N. Kariuki[1], Lesley Rhee[1], Rachel A. Mikolaitis[2], Meenakshi Jolly[2], Tammy O. Utset[1] and Timothy B. Niewold[1], [1]University of Chicago, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

Purpose: Interferon alpha (IFN-α) is a heritable risk factor for systemic lupus erythematosus (SLE). Studies have implicated genetic variation near interferon regulatory factor 7 (IRF7) in SLE susceptibility. SLE-associated autoantibodies can stimulate IFN-α production through the Toll-like receptor/IRF7 pathway. We hypothesized that variants of IRF7 may cause risk of SLE by increasing IFN-α production, and that autoantibodies may be important to this phenomenon.

Methods: 511 SLE patients were studied: 255 African-American, 162 European-American, and 94 Hispanic-American. Serum IFN-α was measured using a reporter cell assay. The rs4963128, rs12286521, rs702966, and rs2246614 SNPs in the IRF7/PHRF1 locus were genotyped.

Results: In European-American subjects, rs702966C was associated with anti-dsDNA antibodies (OR=1.81, p=0.030). The rs702966C allele was only associated with higher serum IFN-α in European-American and Hispanic-American patients with anti-dsDNA antibodies (p=0.0024 and p=0.0014 respectively). In African-American subjects, anti-Sm antibodies were associated with the rs4963128 SNP downstream of IRF7 (OR=1.92, p=0.0019). African-American patients with anti-Sm antibodies showed a dose-response effect between rs4963128T and higher IFN-α (p=0.0021). In African-American patients lacking anti-Sm antibodies, the anti-dsDNA/rs702966C interaction upon serum IFN-α was observed, similar to the other ancestral backgrounds. In European-American and Hispanic-American patients, an SLE-risk variant of interferon regulatory factor 5 (rs2004640T) showed an additive effect with rs702966C upon IFN-α in patients with anti-dsDNA antibodies.

Conclusion: These data suggest that IRF7/PHRF1 variants cooperate with SLE-associated autoantibodies to result in higher serum IFN-α, providing a biologic relevance for this locus at the protein level in SLE in vivo.

1744

A Polymorphic Microsatellite in the Fli1 Promoter Is Associated with Nephritis and Serositis in the Carolina Lupus (CLU) Cohort.

John L. Svenson, Paul Nietert, GS Gilkeson and Tamara K. Nowling, Medical University of South Carolina, Charleston, SC

Purpose: The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Fli1 levels are elevated in lymphocytes from lupus mouse models and patients. Lowering the levels of Fli1 in two lupus mouse models significantly improved disease and prolonged survival. We identified a polymorphic GA microsatellite in the mouse Fli1 promoter that is shorter in lupus prone mouse strains compared to control mouse strains and demonstrated that the length is inversely proportional to expression in T cells. The microsatellite is conserved between mouse and human. To determine whether microsatellite length is associated with disease or disease characteristics in lupus patients and to analyze the role of the microsatellite in the human gene in T cells.

Methods: The promoter region containing the microsatellite was amplified from over 1100 patients and unaffected controls enrolled in the Carolina Lupus (CLU), SLE in Gullah Health (SLEIGH) and MUSC lupus clinic cohorts and genotyped. Fli1 message levels were measured by real-time RTPCR in 50 lupus patient RNA samples. The length of the microsatellite and message levels were analyzed for correlation/association with disease and disease characteristics. The promoter region of the human gene was cloned from four unaffected controls and role of the microsatellite analyzed by transient transfection in a T cell line.

Results: We identified 23 alleles spanning 13-39 repeats of the GA microsatellite. The length of the microsatellite was inversely correlated with activity of the human promoter in a T cell line. There was significant association of microsatellite length of 22 repeats with disease in the CLU cohort and specifically with nephritis in the CLU patients. A microsatellite length of 26 repeats was associated with serositis in the CLU patients and inversely associated with serositis in the SLEIGH patients. Interestingly, Fli1 message levels were significantly higher in patients with serositis.

Conclusion: Although there is a correlation between length of the Fli1 promoter GA microsatellite and Fli1 expression in a T cell line, a specific microsatellite length of 22 repeats was associated with disease, specifically with nephritis, in the CLU cohort. Additionally, a microsatellite length of 26 repeats was associated with serositis in the CLU patients whereas the same length appears to be protective in the SLEIGH patients and higher Fli1 transcript levels correlated with serositis. Together these results suggest that a specific lengths of the microsatellite may serve as markers for disease, specifically nephritis and serositis. It will be of interest to determine how the microsatellite functions in regulating Fli1 expression and how Fli1 levels specifically impact nephritis and serositis.

1745

Two Single Nucleotide Polymorphisms (SNPS) in the Endothelial Protein C Receptor (EPCR) Gene Are Associated with Lower Soluble EPCR (sEPCR). Low Complement C4 and Thrombotic Risk in Patients with Lupus (SLE). J. T. Merrill[1], Robert M. Clancy[2], Stan Kamp[3], Kenaz Thomas[3], Barry Woodhams[4] and Naomi L. Esmon[3], [1]OMRF, Oklahoma City, OK, [2]NYU School of Medicine, New York, NY, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]92600 Asbueres, France

Purpose: Patients (pts) with SLE develop widespread vascular inflammation and life threatening thrombotic events which are not completely explained by typical antiphospholipid antibodies. Since EPCR is a critical regulator at a crossroads of inflammation and thrombosis, two SNPs were evaluated in 199 active SLE pts to determine if genotype has an impact on circulating sEPCR, autoantibodies to EPCR, and thrombotic risk.

Methods: Genotyping was performed by RTPCR with TaqMan primers for rs6936 A-G (serine to glycine) and rs7014 G-C (3' UTR). Circulating sEPCR was quantified by the ASSERACHROM sEPCR ELISA (Stago). Antibodies to EPCR were measured by a novel ELISA, calibrated against sera from 60 healthy individuals. Medical history and disease activity scores were obtained at the time of sampling.

Results: Mean pt age was 39.1, 89.9% female, 62.3% Caucasian, 25.6% African descent and 12.1% Asian. There was no demographic bias in rs6936 genotypes, but most African descent pts were homozygous for G at rs7014 (40/51 vs 46/148 in others, $p < 0.001$). Lupus activity (by BILAG) was the same between groups with overall mean (SD) score of 6.9 (4.3), suggesting moderate vascular inflammation throughout the population. In pts with the genotype rs6936 AA, median sEPCR was 145 ng/ml vs 317 ng/ml in non-AA ($p < 0.001$). There was also a difference between genotypes at rs7014: 130 ng/ml in CC pts vs 164 in non-CC ($p=0.005$). Median sEPCR of 37 pts who carried both of the low sEPCR genotypes was 130 ng/ml vs 317 ng/ml in the rest of the population ($p<0.001$). Low C4 complement was unevenly distributed in rs7014 genotypes, found in 25% of GG, 41.6% of GC and 33.3% of CC, ($p=0.041$, GG vs GC).

More women with rs6936 AA had a history of pregnancy loss and/or pre-eclampsia (23.6% vs 8% of those with G alleles in that gene, $p=0.054$) and the same for rs7014 (37.8% CC vs 17% with G alleles, $p=0.011$). Overall pts with a history of pregnancy complications, arterial and/or venous thromboses were also increased in rs6396 AA, 32.9% vs 15% in non-AA ($p=0.06$) and rs7014 CC, 37.8% vs 26.7% in non-CC (p=ns). Combining genotypes in assessing thrombotic risk, AA/CC women had a high rate of pregnancy complications (14/35 or 40% vs 3/35 or 8.57% of non-AA/non-CC ($p=0.004$). Pts with any type of thrombotic event included 14/37 (37.8%) of AA/CC vs 6/38 (15.7%) of non-AA or CC ($p=0.039$). 38 pts had autoantibodies to EPCR, more common in rs6936 AA than in pts with the G allele (32/162 vs 6/38 (p=ns) and more common in rs7014 pts with G allele than CC (34/163 vs 4/37) (p=ns). There were no pts with both 6936 AA and a G allele in 7014 even though each genotype represents about 19% of the population.

Conclusion: These data suggest that genetic variants influence sEPCR levels in active lupus and may increase complement consumption, autoantibody formation and thrombotic complications in these patients.

1746

Patients with C1q Deficiency Have Elevated Serum Interferon-Alpha and IP-10 Associated with Defective Suppression of Immune Complex Stimulation of Plasmacytoid Dendritic Cells. Deanna M. Santer[1], Peter D. Arkwright[2] and Keith B. Elkon[1], [1]University of Washington, Seattle, WA, [2]University of Manchester, Manchester, England

Purpose: Patients with Systemic Lupus Erythematosus (SLE) have an 'IFN-signature' which correlates with disease severity. Deficiency of C1q (C1qD) has the highest penetrance for susceptibility to SLE (>90%). Although the mechanism(s) responsible for this strong association is not clear, there is evidence to suggest that defective clearance of apoptotic cells and/or immune complexes (ICs) may, in part, be responsible. We recently demonstrated that normal human serum (NHS) contains potent inhibitors of IFN-α induced by SLE ICs. Since we observed that heat inactivation of NHS almost completely abrogated its inhibitory activity, we asked whether C1q played a critical role in inhibiting IC stimulation of IFN-α by pDC.

Method: NHS selectively depleted of C1q or C2 was obtained commercially. Serum was obtained from a family where there are four C1qD (C1q <10U/ml) and one unaffected (normal C1q levels) sibling. In addition, cerebrospinal fluid (CSF) was available from one C1qD patient who had neuropsychiatric symptoms. IFN-α and IP-10 levels in serum and CSF were quantified by a multiplex protein array. To stimulate IFN-α, SLE ICs were formed by SLE serum and necrotic cell extract and added to normal donor PBMCs in the presence or absence of the

inhibitor being tested. IFN-α was quantified by ELISA in culture supernatants 20 h later. In certain experiments, monocytes were depleted from PBMCs using CD14-magnetic beads (<0.2% remaining) or pDCs were isolated by negative selection (>95% pure).

Results: With respect to IFN-α inhibition, C1q depleted, but not C2 depleted serum was significantly less inhibitory compared to NHS ($p<0.01$). To verify that C1q was an important inhibitor in serum, we tested sera from C1qD affected and unaffected siblings. C1qD patient sera were also unable to inhibit IFN-α induction by SLE ICs such that higher concentrations of IFN-α were induced by IC when C1q was absent. With all C1qD sera tested, add back of purified C1q protein completely restored inhibition of IFN-α to normal levels. 3 of 4 C1qD patients had elevated serum levels of IFN-α, which strongly correlated with levels of the IFN inducible chemokine IP-10 ($r= 0.98$, $p=0.004$). Levels of IFN-α in the CSF from the C1qD patient with neuropsychiatric symptoms were also markedly elevated (79 vs 1 pg/ml control CSF). Addition of purified C1q protein to SLE IC led to a dose dependent inhibition of IFN-α, which further illustrates the role of C1q itself as an inhibitor of IFN-α. Surprisingly, C1q could not directly inhibit purified pDCs and instead required the presence of monocytes for the full inhibitory effect.

Conclusion: *Ex vivo* detection of high serum concentrations of IFN-α and IP-10 in patients with C1q deficiency coupled with the impaired ability of C1qD sera to suppress IFN-α responses to IC, suggest a new mechanism to explain the susceptibility of C1qD individuals to develop SLE.

Angiogenic Factor Imbalance in Pregnant SLE Patients May Explain Increased Risk for Complications. Jane E. Salmon[1], Mimi Y. Kim[2], Sarosh Rana[3], Marta Guerra[1], Michael D. Lockshin[1], D. Ware Branch[4], Carl A. Laskin[5], Michelle Petri[6], Allen D. Sawitzke[4], Joan T. Merrill[7], Jill P. Buyon[8] and S. Ananth Karumanchi[3], [1]Hospital for Special Surgery, New York, NY, [2]Albert Einstein Coll Medicine, Bronx, NY, [3]Beth Israel Deaconess Med Ctr, Boston, MA, [4]Univ of Utah, Salt Lake City, UT, [5]Mt. Sinai Hosp, Toronto, ON, [6]Johns Hopkins Univ, Baltimore, MD, [7]Oklahoma Med Res Found, Oklahoma City, OK, [8]NYU School of Medicine, New York, NY

Purpose: Pregnant women with lupus are at increased risk for complications characterized by insufficient placental vascularization, such as preeclampsia and intrauterine growth restriction. Elevated levels of circulating antiangiogenic factors (sFlt-1 and sEng) and increased rates of increase of these factors through pregnancy predict such complications in healthy women and contribute to disease pathogenesis. Angiogenic imbalance can be triggered by complement activation. We hypothesized that pregnant patients with SLE have altered regulation of anti-angiogenic factors providing a basis for their increased risk for complications.

Methods: We performed a nested case-control study of SLE patients within the PROMISSE Study (Predictors of pRegnancy Outcome: bioMarkers In antiphospholipid antibody Syndrome and Systemic lupus Erythematosus). Poor pregnancy outcome was defined as: fetal death >12 wks; neonatal death; preeclampsia; preterm delivery <36 wks due to placental insufficiency; or intrauterine growth restriction. We studied 23 SLE patients with poor pregnancy outcomes (SLE/outcome) and 100 SLE patients with uncomplicated pregnancies (SLE/no outcome) matched by age, race/ethnicity to 98 pregnant healthy controls (HC). Subjects were evaluated and blood collected monthly beginning at <12 wks gestation. Mean levels of angiogenic factors were compared between groups at each time point using analysis of variance models. In addition, linear mixed effects models were fit to the data to estimate and compare rates of change in these factors over the entire gestational period.

Results: The rates of increase in sFlt-1 and sEng through pregnancy were significantly higher in SLE/no outcome patients than HC ($p=0.01$ and $p=0.03$, respectively). The rates of rise in sFlt-1 and sEng were also higher in SLE/outcome compared to SLE/no outcome and HC ($p < 0.0001$). Levels of sFlt-1 and sEng were significantly increased in SLE/outcome compared to HC as early as 20 and 16 wks gestation, respectively, and these differences persisted through 39 wks.

Conclusion: Angiogenic dysregulation occurs in pregnant SLE patients and may increase their vulnerability to placental insufficiency. Inflammatory mediators associated with SLE, such as complement products and interferon α, create an anti-angiogenic milieu. They may amplify the rates of rise of sFlt-1 and sEng through pregnancy and thereby increase risk for poor placental development and decrease threshold for complications like preeclampsia. We have identified predictors of risk; defining the mediators of angiogenic imbalance will identify targets to treat at-risk patients.

Altered Balance Between the Effector and Regulatory T Cell Pathways in Systemic Lupus Erythematosus and Decreased Regulatory T Cell Levels in Active Lupus Nephritis. Danilo Mesquita[1], Wilson M. Cruvinel[2], Julio A. P. Araujo[1], Esper G. Kallas[3] and Luis Eduardo C. Andrade[1], [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Catolica de Goias, Goiania, Brazil, [3]Universidade de Sao Paulo, Sao Paulo, Brazil

Purpose: Deficiency in $CD4^+CD25^+$ regulatory T cells (TREG) has been related to the pathogenesis of human and experimental autoimmune diseases. Controversy in published data on TREG frequency in systemic lupus erythematosus (SLE) is partially due to heterogeneity in phenotype TREG markers and in patient selection. We aimed to quantify TREG and effector T cells (TEFF) based on the CD25, CD127 and FoxP3 expression in active and inactive systemic lupus erythematosus (A-SLE & I-SLE).

Method: Thirty-one patients with A-SLE (SLEDAI>6) and 32 patients with I-SLE (SLEDAI=0) fulfilling the ACR criteria were sequentially retrieved from the University Hospital outpatient clinic. Kidney involvement was defined according to the ACR criteria. Twenty-six HC were recruited among staff personnel. Peripheral blood mononuclear cells (PBMC) were analyzed by multicolor flow cytometry (FACSCANTO) and data analyzed using FlowJo software.

Results: The frequency of $CD25^{high}$ cells was increased in A-SLE (5.2±5.7%) as compared to I-SLE (3.4±3.4) and HC (1.73±0.8%) (P=0.007). However, this did not represent an increase in TREG subset in A-SLE since the frequency of $CD25^+CD127^{low}$ cells was equivalent in A-SLE (1.4±0.8), I-SLE (1.37±1.0) and HC (1.13±0.59) (P=0.42). In fact the percentage of $FoxP3^+$ cells in the $CD25^{high}$ subset was decreased in A-SLE (24.6±16.4%) as compared to I-SLE (33.7±16) and HC (45±25.1%) (P<0.01). This was possibly due to an increased frequency of TEFF cells ($CD25^{high}CD127^+FoxP3^{neg}$) in A-SLE (10.7±7.3%) as compared to I-SLE (8.5±6.5) and HC (6.1±1.8%) (P=0.02). Interestingly we observed a lower frequency of TREG cells ($CD25^+CD127^{low}FoxP3^+$) in renal A-SLE patients (0.8±0.4) as compared to non-renal A-SLE patients (2.19±1) (p<0.001).

Conclusion: The high degree of T cell activation in SLE hampers the use of CD25 as a marker for TREG since A-SLE samples present increased levels of $CD25^+$ and $CD25^{high}$ effector T cells not related to TREG. There seems to be an altered balance between the effector and regulatory pathways in active SLE patients, especially in those with kidney involvement, and this imbalance may favor high effector T cell activity and thus contribute to the pathophysiology of this disease.

CD4+ T Cells in Systemic Lupus Erythematosus Secrete IL17 After Antigenic Challenge. Sandra Schneider[1], Arne Sattler[1], Tobias Alexander[1], Sarah Meier[2], Udo Schneider[1], Regina Stark[2], Michael Mahler[3], Andreas Radbruch[4], Andreas Thiel[2], Gerd-R. Burmester[1] and Falk Hiepe[1], [1]Charité, Rheumatology and Clinical Immunology, Berlin, Germany, [2]BCRT, Regenerative Immunology and Aging, Berlin, Germany, [3]Dr. Fooke Laboratorien, Neuss, Germany, [4]DRFZ, Berlin, Germany

Background: $CD4^+$ Interleukin (IL)17 secreting cells (Th17 cells) seem to contribute to inflammation in autoimmune disease such as rheumatoid arthritis or Crohn's disease. Also in systemic lupus erythematosus (SLE) there is growing evidence for a pathogenic relevance of IL17.

Purpose: Since viral and bacterial infections have the potential to trigger lupus flares our aim was to further investigate IL17 compared to interferon gamma (IFNg) secretion in $CD4^+$ cells after antigen stimulation ex vivo in SLE patients and healthy controls (HC).

Method: We stimulated full blood samples from 8 SLE patients and 7 HC in the presence of CD28 and brefeldin A for 6 hours with *staphylococcus* enterotoxin B (SEB), with a peptide mixture of the cytomegalo virus (CMV) protein pp65, with a peptide mixture of the hexon protein of adenovirus 5 (AdV5) and with a protein mixture of the RNP/Sm complex (a nuclear target of autoantibodies in lupus). After erythrocyte lysis and permeabilization samples were stained for multicolor FACS analysis with antibodies against CD3 and CD4 to gate on $CD4^+$ T cells and with CD14 and CD19 to gate out B cells and monocytes. Frequencies of activated cytokine producing $CD4^+$ T cells were determined by intracellular staining of IL17 and IFNg together with the activation marker CD40 ligand (CD40L).

Results: After SEB stimulation we found frequencies of IFNg/CD40L double positive cells in $CD4^+$ cells from 1.51 to 4.65% in SLE patients vs. 0.87 to 2.80% in HC and frequencies of IL17/CD40L double positive cells from 0.21 to 1.24% in lupus vs. 0.04 to 0.22% in HC. Whereas for the IFNg production no significant difference in between groups could be seen, Mann Whitney test showed significantly higher IL17 levels ($p = 0.02$) as well as significantly higher IL17/IFNg ratios ($p = 0.04$) in the SLE group. After CMV stimulation the highest detectable frequency for IFNg/CD40L was 1.72% in patients vs. 0.22% in HC, for IL17/CD40L 0.06% in a lupus patient and 0.01% in a HC with no significant differences detectable. In AdV5 stimulated probes only very low frequencies of cytokine producing $CD4^+$ cells could be observed: for IFNg up to 0.10 vs. up to 0.16% in lupus vs. HC and for IL17 up to 0.04 and up to 0.02%, respectively. Towards the autoantigen stimulation with RNP/Sm neither in patients nor in HC any clear IFNg reaction was detectable, but in one of 8 patients we found a weak IL17 reaction with a frequency of 0.06%.

Conclusion: We found a significantly increased frequency of Th17 cells but not of IFNg secreting Th cells after ex vivo stimulation with SEB in SLE patients compared to HC. We also could detect low frequencies of IL17 secreting $CD4^+$ cells after viral and - in one patient - after autoantigenic challenge. Our data provide further affirmation for a disease related role of IL17 in SLE.

Silencing of Endogenous Retrovirus Is Impaired in B Cells From Systemic Lupus Erythematosus. Yves Renaudineau[1], Christelle Le Dantec[1], Sandrine Jousse-Joulin[2], Soizic Garaud[1] and Pierre Youinou[1], [1]Brest University Medical School Hospital, Brest, France, [2]CHU Brest, Brest, France

Purpose: Systemic Lupus Erythematosus (SLE) is a heterogenous autoimmune disease of unknown origin. Both genetic and epigenetic factors have been implicated in its pathogenesis. A defect in DNA methylation has been demonstrated in T cells and more recently in B cells from SLE patients. The aim of the study was to analyse several promoters known to be methylation-sensitive in B cells from SLE patients.

Method: Samples were B cell-enriched from the blood of 7 patients with SLE and 6 healthy controls (HCs). Seven methylation-sensitive promoters were tested (CD21, CD70, Pax5, Syk, HRES-1, CD5-E1A and HERV-CD5) using methylation-specific PCR assays and bisulfite sequencing following or not BCR engagement. B-cells were stimulated in vitro with anti-IgM antibodies, or incubated with DNMTs inhibitors (procainamide, 5-azacytidine and PD98059).

Results: In SLE and HCs, at basal level all promoter tested were hypomethylated. However, in HCs, BCR engagement with an anti-IgM increased DNA methylation in the two endogenous retrovirus derived promoters (HRES-1 and HERV-CD5). In contrast, promoters from anti-IgM stimulated SLE B cells remains demethylated. Demethylation of HERV-CD5 increases CD5-E1B expression in lupus B cells and B cells treated with DNA methyl transferases inhibitors (procainamide, 5-azacytidine, and PD98059). We provide further evidence that production of high IL-6 levels by SLE B cells abrogate the ability of SLE B cells to methylate HRES-1 and HERV-CD5 promoters. This effect is reversed in SLE B cells in the presence of a blocking Ab to IL-6 receptor, and in HCs B cells in the presence of rIL-6.

Conclusion: The study reveals that engagement of the BCR silence endogenous retroviral elements and that this mechanism is impaired in SLE B cells. This derepression could in turn promote the expression of endogenous retrovirus and then promote B cell autoreactivity.

Multiple Pro-Atherogenic Pathways Are Activated in Monocytes After Acute Treatment with Pro-Inflammatory HDL. Brian J. Skaggs, Lori J. Sahakian, Bevra H. Hahn and Maureen A. McMahon, Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Accelerated atherosclerosis is a major co-morbid condition of women with SLE. Data from our group illustrates that the presence of dysfunctional, pro-inflammatory HDL (piHDL) in plasma of SLE patients increases the risk for carotid artery plaque 16-fold. It is unclear if piHDL directly influences monocytes, recognized as the main immune cell involved in both the initiation and progression of atherosclerosis. We hypothesized that piHDL might be directly responsible for altered monocyte gene expression, protein expression, and function.

Methods: HDL and piHDL were isolated from human plasma (a single subject for each, both with SLE) using a magnetic bead reagent. RNA and protein were isolated from the human monocyte cell line THP-1 after short-term (4 hr) and long-term (24 hr) treatment with normal, anti-inflammatory HDL or piHDL at multiple doses and different concentrations of fetal calf serum (FCS). Transcript levels of 84 atherosclerosis-specific genes were examined by real-time PCR-based gene arrays (SA Biosciences). In addition, other transcripts associated with atherosclerosis in SLE (identified by microarray analysis of human subjects) were examined by independent qPCR assays. Altered transcript levels were confirmed by western blot and ELISA. Migration of HDL-treated THP-1 cells was examined with the QCM chemotaxis kit (Millipore).

Results: Short-term piHDL treatment (20 ug/mL) of THP-1 cells in low FCS (1%) led to significant upregulation of multiple pro-inflammatory transcripts when compared to cells treated with normal HDL. The adhesion molecules CD11c (2.03-fold, p=0.001) and tenascin c (2.77-fold, p=0.007), the inflammatory cytokines IL1-alpha (3.31-fold, p=0.001) and IL-5 (4.45-fold, p=0.002), the HDL receptor ABCA1 (2.25-fold, p=0.006), the TNF family member lymphotoxin-beta (2.27-fold, p=0.001), and both PDGFR-beta (2.84-fold, p=0.037) and PDGFA (2.04-fold, p=0.033) were upregulated by sub-endogenous levels of piHDL treatment. Long-term treatment of THP-1 cells required higher FCS levels (3%) and only PDGFR-beta and ABCA1 were upregulated in piHDL-treated cells versus normal HDL. The number of cells migrating towards an exogenous chemoattractant (MCP-1) was 39% higher in THP-1 cells treated with piHDL for 4 hours versus cells treated with normal HDL (p=0.012).

Conclusion: Treatment of a human monocyte cell line with piHDL upregulates multiple pro-inflammatory and pro-atherogenic molecules. In addition, piHDL treatment activates monocytes and stimulates their migration towards an atherogenic chemoattractant. These results suggest that the presence of piHDL in the plasma of SLE patients initiates atherosclerosis in part by directly activating pro-inflammatory and pro-atherogenic pathways in monocytes.

The Presence of Carotid Plaque in SLE Patients Correlates with Upregulated Monocyte TNF Family Genes. Brian J. Skaggs[1], Lori J. Sahakian[1], David Elashoff[2], Jennifer M. Grossman[1], Bevra H. Hahn[1] and Maureen A. McMahon[1], [1]Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Premature atherosclerosis is widely recognized as a significant co-morbid condition of SLE. Although the role of the immune system in the initiation and progression of atherosclerosis is now well appreciated, little is known about the cell types and molecular pathways that contribute to plaque in SLE. Monocytes are the main immune mediator of atherosclerosis, and we hypothesized that alterations in monocyte gene expression could provide clues to the mechanism of premature atherosclerosis in SLE and yield novel therapeutic targets and/or biomarkers.

Methods: Monocytes were isolated from 60 subjects from our UCLA cohort by Ficoll and magnetic bead separation of CD14+ cells. B-mode and Doppler ultrasound scanning of carotid arteries assessed plaque. The 60 subjects were stratified into three groups: 1) healthy controls (n=15), 2) SLE no plaque (n=30), and 3) SLE plaque (n=15). We examined monocyte whole genome transcript levels after RNA isolation using Illumina Ref6 chips. Data was analyzed by Illumina BeadStudio software. We confirmed expression levels by real-time PCR (mRNA) and western blot (protein).

Results: Multiple TNF family ligands and receptors, including lymphotoxin-beta(2.21-fold, p=0.0045), lymphotoxin-alpha (2.34-fold, p=0.0044), TNFRSF4/Ox40 (4.75-fold, p=0.0037), TNFSF4/Ox40 ligand (4.72-fold, p=.0294), and TNFRSF25/DR3 (2.93-fold, p=0.0248) were significantly increased in monocytes from SLE plaque subjects versus SLE no plaque (fold and p-values shown above) as well as healthy control subjects (not shown). Functional annotation analysis (DAVID, NIH) revealed that the immune response gene category was the only significant family increased in the comparison between SLE no plaque and SLE plaque subjects (Benjamini corrected p-value 0.0003). When this category was selected as a subset, it was made up of mostly transmembrane proteins (Benjamini p=2.8e-11), including all of the TNF family members above. There were very few significantly altered monocyte transcripts between healthy controls and SLE no plaque subjects. Real-time PCR experiments validated significantly upregulated transcript levels in all genes mentioned. Protein levels of Ox40 and Ox40L were approximately 1.5-2 fold higher in SLE plaque subjects, suggesting that transcript levels are not fully indicative of translated protein levels.

Conclusion: The TNF family members lymphotoxin-beta, lymphotoxin-alpha, Ox40, Ox40L, and DR3 are all upregulated in SLE patients with plaque versus SLE patients without plaque and healthy controls. All of these genes have been implicated in promoting atherosclerosis in non-SLE patients, although no studies have reported cooperation between these three different TNF family pathways. Our results suggest that upregulation of multiple TNF-related signaling pathways could contribute to premature atherosclerosis in SLE.

LRRC20 Is a Novel Gene Associated with Serum IFN-α in SLE Patients. Silvia N. Kariuki[1], Beverly S. Franek[1], Rachel A. Mikolaitis[2], Joel A. Block[2], Meenakshi Jolly[2], Tammy O. Utset[1], Andrew D. Skol[1] and Timothy B. Niewold[1], [1]University of Chicago, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

Purpose: Interferon alpha (IFN-α) is a heritable risk factor for systemic lupus erythematosus (SLE), although the genetic regulation of this risk factor is complex and not well understood currently. We performed a small scale multi-ancestral background case-case genome-wide study of SLE patients stratified by extremes of phenotype in autoantibodies and serum interferon alpha (IFN-α) to detect novel genes associated with IFN-α in SLE. A SNP in the leucine-rich repeat containing 20 (LRRC20) gene demonstrated an association signal, which is followed up in this study.

Methods: We used a Bayesian algorithm to select candidate genes from the top hits in our GWAS for validation. We chose to follow up a SNP in the 3' UTR region of the LRRC20 gene (rs10762360) in 511 independent cases and 739 matched controls from our multi-ancestral local cohort (cases include 255 African-American, 162 European-American, and 94 Hispanic-American subjects). Genotyping was performed using Taqman genotyping probes, and IFN-α was measured using a sensitive reporter cell assay.

Results: The minor allele of rs10762360 was associated with higher serum IFN-α in our cohort in a dose-response fashion (p=0.0002). This pattern was shared across all of the different ancestral backgrounds included in our study. Additionally, we used logistic regression modeling to detect associations between autoantibodies and this allele in each ancestral background separately. We discovered a strong association between the minor allele of rs10762360 and anti-La antibodies in African-American SLE patients (OR=2.28, p=0.0007), which was not observed in the other ancestral backgrounds. While autoantibodies have been associated with higher serum IFN-α in SLE, this antibody association did not account for the differences we observed in serum IFN-α by genotype. There were no significant differences in allele frequencies between cases and controls in our cohort.

Conclusion: We used a case-case subphenotype strategy to discover a novel gene associated with increased serum IFN-α and autoantibody profile in a multi-ancestral SLE cohort. These data suggest that LRRC20 plays a role in IFN-α signaling in SLE, and will thus mediate disease phenotype and severity.

1754

Serum Interferon Alpha Correlates with Disease Activity, Specific Clinical Manifestations and Circulating Plasma Cells Levels in Systemic Lupus Erythematosus. Alexis Mathian[1], Christophe Parizot[2], Karim Dorgham[3], Makoto Miyara[1], Julien Haroche[1], Patrice Debré[3], Jean -Charles Piette[1], Pierre Lebon[4], Guy Gorochov[3] and Zahir Amoura[1], [1]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [2]Department of Immunology, Pitié-Salpêtrière Hospital, Paris, France, [3]Inserm Umrs-945, Pitié-Salpêtrière Hospital, Paris, France, [4]Department of Virology, Saint-Vincent de Paul Hospital, Paris, France

Purpose: Previous clinical studies in humans and murine models suggest that Interferon alpha (IFNα) is a key-cytokine in Systemic Lupus Erythematosus (SLE). However, little is known about the association between IFNα and clinical manifestations of SLE. Antibody-Secreting Cells (ASC), comprising plasma cells and plasma blasts, are found in excess in active SLE and are strongly implicated in the pathogenesis of SLE. IFNα have been described to exert a variety of effects on the function and development of B cells, enhancing plasma cells and plasma blasts differentiation. The question arises as to whether IFNα might be responsible for the increased frequency of ASC seen in SLE. We measured serum IFNα levels in SLE and studied their relationship with disease activity, clinical manifestations and circulating levels of ASC.

Method: IFNα levels in sera were calculated using an antiviral cytopathic bioassay. The levels of circulating ASC were determined as $CD27^{high}CD19^{dim}$ cells by fluorescence-activated cell sorting (FACS) analysis. SLE activity was measured by the SLE Disease Activity Index (SLEDAI).

Results: Serum IFNα levels were measured in 136 SLE patients. Levels were increased in 65 SLE patients (47.8%) whereas none of the healthy donors had detectable levels of the cytokine in their sera. Patients with active SLE (SLEDAI $\geq$ 4, n = 66) had higher levels of IFNα than patients with inactive SLE (SLEDAI < 4, n = 70) (4 UI/ml (0-300) versus 0 UI/ml (0-30), $p < 0.0001$). IFNα positively correlates with SLEDAI ($p < 0.0001$; $r = 0.56$). IFNα levels were significantly higher in patients with neurologic involvement compared with patients without neurologic involvement [25 UI/ml (extremes: 2-300) versus 2 UI/ml (extremes: 0-100), p corrected = 0.03], in patients with fever compared with patients without fever [35 UI/ml (extremes: 2-300) versus 2 UI/ml (extremes: 0-100), p corrected = 0.006] and in patients with cytopenia (leucopenia or thrombocytopenia) compared with patients without cytopenia [35 UI/ml (extremes: 3-300) versus 2 UI/ml (extremes: 0-200), p corrected = 0.006]. IFNα positively correlates with circulating ASC levels ($p < 0.0001$; $r = 0.48$).

Conclusion: We demonstrate the association between IFNα, disease activity and specific clinical manifestations of SLE: fever, leucopenia, thrombocytopenia and neurologic involvement. These manifestations are frequently encountered after IFNα injections, for example, in hepatitis C viral infection treatment. Thus IFNα may be a direct mediator of these clinical manifestations in SLE. Furthermore the strong correlation between serum IFNα concentrations and circulating ASC levels suggests a pathogenic role of IFNα on B cell differentiation toward ASC in SLE.

Mannose-Binding Lectin Polymorphisms in Brazilian Patients with Systemic Lupus Erythematosus. O.A. Monticielo[1], J.A.B Chies[2], T. Mucenic[1], G.G. Rucatti Sr.[1], J.M. Zimmermann Júnior[1], G.K. Silva Sr.[2], N. Glesse Sr.[2], B. Keiserman[1], Y.M. Badad[1], J.C.T Brenol[1] and Ricardo M. Xavier[3], [1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [2]Universidade Federal de Porto Alegre, Porto Alegre, Brazil, [3]Porto Alegre, Brazil

Purpose: The mannose-binding lectin (MBL) gene has emerged as a candidate for systemic lupus erythematosus (SLE) susceptibility, but studies in Brazilian population has not been achieved. We conducted a case-control study to examine potential associations of the MBL alleles G57E, G54D, IVSnt5, R52C and R52H with susceptibility to and clinical expression of SLE in southern Brazilian patients.

Method: Three hundred and twenty seven consecutive patients with diagnosis of SLE, satisfying the American College of Rheumatology criteria, who were recruited from the outpatient clinic of the Division of Rheumatology of the Hospital de Clínicas de Porto Alegre, and 244 healthy controls from the same geographic area, were genotyped by Restriction Fragment Length Polymorphism-Polimerase Chain Reaction (RFLP-PCR) analysis. Clinical, demographic and laboratory data were collected.

Results: A statistically significant difference in the frequencies of allele R52C was observed in European-derived SLE patients as compared to controls (9.6% vs. 3.3%, P<0.001, odds ratio 3.15, 95% confidence interval 1.761-5.622, P<0.05). The frequencies of alleles G54D and G57E were not different between European-derived SLE patients and controls (allele G54D 15.9% vs. 15.8%, P=0.971 and allele G57E 3.6% vs. 2.9%, P=0.509). There were no differences between clinical and laboratory features in SLE patients according to the presence or absence of MBL allelic variants.

Conclusion: These results support an increased risk of SLE in European-derived individuals carrying the R52C allele. Patients carrying this allele have an approximately 3-fold higher odds ratio of developing SLE when compared with controls. Our data do not support associations between the MBL allelic variants studied and clinical expression of SLE in southern Brazilian population.

Phenotype Characterization of Regulatory T Cells (CD25highCD127low FoxP3+) in Systemic Lupus Erythematosus. Danilo Mesquita[1], Wilson M. Cruvinel[2], Julio A. P. Araujo[1], Esper G. Kallas[3] and Luis Eduardo C. Andrade[1], [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Catolica de Goias, Goiania, Brazil, [3]Universidade de Sao Paulo, Sao Paulo, Brazil

Purpose: $CD4^+CD25^+CD127^{LOW}$ $FoxP3^+$ regulatory T cells (TREG) are specialized in immune response suppression and are apparently involved in the pathogenesis of autoimmune diseases. A variety of TREG surface markers has been described in healthy subjects but not in systemic lupus erythematosus (SLE). This study aimed to characterize the expression of GITR, HLA-DR, PD-1, OX40, CD40L, CD28, CTLA-4 and CD45RO on $CD25^+CD127^{LOW}FoxP3^+$ TREG cells from patients with active SLE (A-SLE), inactive SLE (I-SLE), and healthy controls (HC).

Method: Thirty-one patients with A-SLE and 32 patients with I-SLE were sequentially retrieved from the outpatient clinic at the University Hospital. Twenty-six HC were recruited among staff personnel. SLE patients fulfilled the ACR classification criteria. Disease activity was established as SLEDAI equal or above six and disease quiescence was defined as SLEDAI equal to zero. Peripheral blood mononuclear cells (PBMC) were analyzed by multicolor flow cytometry and obtained data were analyzed using the FlowJo software.

Results: We detected lower frequency of $CTLA\text{-}4^+$ TREG cells in A-SLE as compared to I-SLE and HC (2.4±4.2, 4.4±6.7, 7.8±10.8, respectively; $p<0.05$). The same was true for $CD28^+$ TREG cells (85.8±12.25, 91±9.7, 92.7±7.9, respectively; $p<0.05$). In contrast, the frequency of $CD40L^+$ TREG cells was higher in A-SLE as compared to I-SLE and HC (5.3±5.4, 2.5±3.1, 0.9±1.2, respectively; $p<0.0001$). In addition the frequency of $CD40L^+$ TREG cells correlated with SLEDAI ($r=0.1080$, $p=0.0163$, $n=53$). The ratio between TREG and effector T cells (Teff) was analyzed for T cell subsets presenting each one of the surface markers. TREG/Teff ratio was decreased in A-SLE and I-SLE as compared to HC for $GITR^+$ cells (1.6±1.3, 1.5±0.9, 2.4±1.5, respectively; $p<0.05$), $HLA\text{-}DR^+$ cells (1.1±0.6, 1.2±0.5, 1.5±0.6, respectively; $p<0.05$), $OX40^+$ cells (1±0.7, 1±0.6, 1.5±0.9, respectively; $p<0.05$) and $CD45RO^+$ cells (1.1±0.3, 1.2±0.3, 1.4±0.4, respectively; $p<0.001$). In contrast the TREG/Teff ratio for CD40L+ cells was increased in A-SLE when compared with I-SLE and HC (5±6.3, 2.1±2.1, 1.7±1.8, respectively; $p<0.05$).

Conclusion: TREG phenotype evaluation indicated derangements in the cellular and molecular balance of CTLA-4, CD40L, GITR and OX40 on TREG and effector T cells in SLE and highlights potential therapeutic target for this disease.

Purpose: To analyze the relationship between SLE susceptibility alleles and some clinical features

Method: Genotypes of SLE-associated SNPs in ITGAM, STAT4, C8orf13-BLK, MECP2, BANK1, TYK2, KIAA1542, PXK and 1q25.1 were available for 1579 patients with SLE obtained in 16 European centres. They were correlated with age of disease onset and with ACR classification criteria. Regression analyses were performed according to a genetic additive model. Allelic analyses combined data with the Mantel-Haenszel approach. Consistency of results across recruiting centres and the number of test done were considered for interpretation

Results: A single association was consistent and significant: the rare allele of the SNP in the C8orf13-BLK locus determined increased risk of nephritis (O.R. = 1.35, 95 % C.I. = 1.15-1.60, P = 0.00026). Some other clinical features showed association with genotypes but they were not consistent or not enough significant. Suggestive findings in this category were association of the BANK1 SNP with absence of oral ulcers and of the MECP2 SNP with increased risk of lupus nephritis. We did not replicate the described associations of STAT4 with nephritis or oral ulcers, and only weakly the associations of STAT4 with early age of onset and of BANK1 with immunological criteria and nephritis

Conclusion: Our results together with previous studies indicate that clinical variability of SLE correlate only weakly with the SLE susceptibility alleles. However, it is possible that more complex interactions, between genetic factors or with environmental exposures, play a more significant role in defining the SLE phenotype

Association of MIF with Disease Activity, Damage, and Serum IL17 and IL6 in Systemic Lupus Erythematosus. Eric F. Morand, Melissa Northcott, A. Richard Kitching, Fiona Brown and Alberta Hoi, Monash University, Melbourne, Australia

Purpose: MIF is a broad-spectrum pro-inflammatory protein with actions in T cells, B cells, macrophages and endothelial cells. MIF-deficiency is protective in MRL/lpr mice, and a single nucleotide polymorphism (SNP) at position -173 in the MIF promoter (rs755622) is associated with increased SLE susceptibility. Associations between MIF and disease manifestations in SLE have not been reported. We examined these associations prospectively.

Method: Patients of the Monash Lupus clinic in Melbourne Australia have routine collection of disease activity (SELENA-SLEDAI) and serum at each visit. Damage (SLICC-ACR) is recorded annually. Serum MIF, IL6, and IL17 concentrations were measured by ELISA and genomic DNA was analysed for MIF -173 polymorphisms.

Results: 350 sera were analyzed from 97 subjects satisfying ACR criteria for SLE (mean (±SD) age 42 ± 14, disease duration 10 years ± 7.3, 78 female:17 male), followed over 17 ± 6 months. MIF was detected in all samples (median 3.1 ng/ml, mean (± SEM) 4.3 ± 0.2 ng/mL). SLEDAI varied during study (median (range) 5 (0 – 26)). Correlation between MIF and SLEDAI was not observed in the overall population,

but in SLE patients without active renal disease, (renal SLEDAI = 0), a significant correlation between serum MIF and SLEDAI was observed (r = 0.16, p = 0.024). MIF genotype was analyzed in 81 patients, with the -173*C MIF allele being present in 21 patients (20 heterozygous, 1 homozygous). In patients with a disease duration > 10 years, the MIF -173*C allele was associated with significantly increased SLICC (3.0±0.68 vs 1.4±0.19, p =0.0274). No association between MIF genotype and SLEDAI or steroid exposure was detected. In samples in which IL17 was above assay detection limit (16ng/mL, n = 131), a significant correlation between MIF and IL17 was present (r = 0.36, p <0.0001). Serum MIF and IL-6 were also significantly correlated (r = 0.18, p = 0.0007). Consistent with this, samples in which MIF concentration was >1SD above the mean were characterized by higher mean IL17 (338±135 pg/mL vs 144±21, p=0.0166) and IL6 (180±73 pg/mL vs 62±12, p=0.0088).

Conclusion: Serum MIF correlates with disease activity, and with serum IL17 and IL6, in SLE, and a MIF overexpression polymorphism is associated with increased disease-related damage in longstanding SLE. These results further support the potential role of MIF in the pathogenesis of SLE, and as a biomarker and outcome predictor. Moreover, these findings suggest the ability of MIF to regulate IL-17 and IL6 expression in SLE.

Serum IL17 in Systemic Lupus Erythematosus: Association with Serum IL6, MIF, and CNS Disease. Eric F. Morand, Melissa Northcott, A. Richard Kitching, Fiona Brown and Alberta Hoi, Monash University, Melbourne, Australia

Purpose: IL17 is the prototypic Th17 cytokine, believed to be important in autoimmune disease. Preliminary studies in SLE suggest elevated IL17 levels in patients compared to controls, and a pathogenic role of IL17 in mouse models. A recent report suggests IL17 stimulates B cell activation in SLE. Prospective studies of IL17 associations with disease manifestations in SLE have not been reported.

Method: Patients of the Monash Lupus clinic in Melbourne Australia have routine collection of disease activity (SELENA-SLEDAI) and serum at each visit. Damage (SLICC-ACR) is recorded annually. Serum IL17, IL6, and MIF concentrations were measured by ELISA.

Results: 97 subjects satisfying ACR criteria for SLE (mean (±SD) age 42 ± 14, disease duration 10 years ± 7, 78 female:17 male) were recruited. 350 paired sera and SLEDAI samples were obtained during a mean follow up of 17 ± 6 months.

Serum IL17 was undetectable in a majority of samples and varied widely (median 0, range 0 – 3423, mean ± SEM 146 ± 22 pg/mL). Serum IL17 was above assay detection limit (>16 ng/mL) in 131 samples (mean ± SEM 370 ± 50 pg/mL).

Th17 differentiation is in part dependent on IL6, and T cell IL17 release is regulated by macrophage migration inhibitory factor (MIF). In samples in which serum IL17 was detectable, serum IL17 was very highly correlated with serum IL6 (r = 0.62, p <0.0001), and this relationship persisted when all samples were analysed, as undetectable IL17 and IL6 were strongly associated. A significant correlation between serum IL17 and serum MIF was also observed (r = 0.36, p <0.0001) and samples in which serum IL17 levels were >1 SD above the mean were associated with significantly higher MIF (8.3 ±1.1 vs 3.9±0.2 ng/mL, p<0.0001).

Correlations between IL17 and SLEDAI, the presence or activity of renal disease, or SLICC were not observed. Unexpectedly, there was no correlation of either serum IL17 or IL6 with serum CRP. However, patients with elevated IL17 levels (> 1 SD above the mean) had an increased incidence of CNS involvement (defined as positive CNS ACR criteria, a positive CNS SLEDAI during follow up, positive CNS SLICC score or documented CNS disease on blinded chart review (p=0.0459). Similarly, those patients with a history of CNS involvement had a significantly higher IL17 area under the curve during follow up than those without CNS disease (p<0.05).

Conclusion: These prospective data indicate that IL17 is undetectable in a majority of SLE patients and does not correlate with overall measures of disease activity or damage. IL17 is highly correlated with IL6 and MIF in lupus patients, supporting the regulation of IL17 by these cytokines in SLE. Moreover, the observation of increased CNS disease in a subset of patients with elevated IL17 suggests the existence of a subset of patients with distinct clinical features related to IL17 expression. Anti-IL17 therapy, or strategies directed at IL6 or MIF, may be protective in CNS lupus, and selection of patients for the study of anti-IL17 therapy in SLE may be facilitated by these observations.

The HRES-1/RAB4 Lupus Susceptibility Gene Promotes Nitric Oxide Production in Human T Cells through Direct Interaction with Endothelial Nitric Oxide Synthase Interacting Protein. Tiffany Telarico, Edward Doherty, David Fernandez and Andras Perl, Upstate Medical Univ, Syracuse, NY

Purpose: Polymophic haplotypes of the HRES-1 endogenous retrovirus influence lupus susceptibility. The HRES-1/Rab4 gene product of HRES-1 is overexpressed in lupus T cells which contributes to altered T cell activation via regulating endosomal recycling of surface receptors and adaptor protein involved in signal transduction. Increased production of nitric oxide (NO) has been linked to abnormal activation of lupus T cells and NO production has been localized to the T-cell synapse, we investigated the role of HRES-1/Rab4 in NO production.

Method: Expression of proteins involved in NO production was investigated by microrray analysis of gene expression and follow-up western blot analysis of negatively isolated T cells from 44 Caucasian female lupus patients and 23 age-matched Caucasian female controls. NO production was measured by flow cytometry. The effect of HRES-1/Rab4 on NO production and expression of proteins involved in NO synthesis was investigated by overexpression of a wild-type HRES-1/Rab4 and its dominant-negative form HRES-1/Rab4^{S27N}. Direct interaction of HRES-1/Rab4 with potential binding partners was assessed by pull-down assays.

Results: No production was increased in lupus T cells by 32% (p=0.009) Expression of endothelial NO synthase (eNOS) interacting protein (NOSIP) was reduced by 61% in lupus T cells (p=0.010). Over-expression of HRES-1/Rab4 suppressed NOSIP expression and enhanced eNOS expression, and NO production while dominant-negative HRES-1/Rab4^{S27N} had the opposite effects in human T cells. NOSIP was efficiently pulled down by HRES-1/Rab4-GST but not by GST alone in Jurkat cells and human peripheral blood lymphocytes.

Conclusion: The results indicate that over-expression of HRES-1/Rab4 promotes NO production through a direct interaction with NOSIP, possibly through regulating the intracellular traffic, expression, and activity of eNOS.

TLR8 and STAT4 Expression Is up-Regulated Differentially by Estrogen Stimulation of Peripheral Blood Mononuclear Cells From Patients with Systemic Lupus Erythematosus. Nicholas Young[1], Hayley James[2], Margaret Shupnik[2] and Wael N. Jarjour[1], [1]The Ohio State University Medical Center, Columbus, OH, [2]University of Virginia Health System, Charlottesville, VA

Purpose: Systemic Lupus Erythematosus (SLE) is a multi-organ autoimmune disorder predominately affecting females in the reproductive age range. This gender-bias of female to male is highest in premenopausal women (12:1) and decreases to 4:3 post menopause. Although the precise pathogenesis of SLE remains to be elucidated, the influence of hormonal factors is evident both experimentally and in humans, and it was further investigated in this study.

Method: Here, gene array analysis of peripheral blood mononuclear cells (PBMC) of premenopausal SLE women was compared to that of healthy individuals. All patients and healthy subjects were not receiving birth control or any hormonal medication. The PBMC were also examined after stimulation with a physiologic dose of estrogen in-vitro in order to determine the contribution of this hormone to SLE pathobiology. Each experimental subject served as her own control by subtracting gene expression at baseline from gene expression after stimulation with estrogen. The gene expression was then compared among the healthy subjects and the lupus patients. The resulting expression profile of statistically significant genes represented the estrogen effect observed in SLE samples.

Results: Our findings reveal significantly elevated expression of both signal transducer and activator of transcription 4 (STAT4) and toll-like receptor 8 (TLR8) in premenopausal SLE women when compared to healthy subjects.

Conclusion: These observations establish a possible mechanism by which estrogen may differentially induce the up-regulation of genes that contribute to the pathogenesis of SLE, as both of these genes have been strongly linked to SLE previously. Ongoing work will investigate the impact of co-stimulation on cytokine signaling, particularly interferon-α, and will examine the effects of various estrogen agonists and antagonists on the expression of STAT4 and TLR8.

The Number of C4 Gene Copies Is Associated with Autoantibody Profile in SLE. Elisabet Svenungsson[1], Emeli Lundstrom[1], Iva Gunnarsson[1], Johanna Gustafsson[1], Yee Ling Wu[2], Kerstin Elvin[3], Lars-Olof Hansson[4], Anders Larsson[5], Chack-Yung Yu[2] and Leonid Padyukov[1], [1]Dept. of Medicine, Rheumatology Unit, Karolinska Insitutet, Stockholm, Sweden, [2]Dept. of Molecular Virology, Immunology and Medical Genetics, the Ohio State University, [3]Dept. of Clin. Immunology and Transfusion Medicine, Unit of Clin. Immunology, Karolinska Institutet, Sweden, [4]Dept. of Laboratory Medicine, Karolinska Hospital, Stockholm, Sweden, [5]Dept. of Laboratory Medicine, Akademiska Hospital, Uppsala, Sweden

Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous systemic autoimmune disease characterized by the presence of autoantibodies and complex inheritance. C4A and C4B genes are located on human chromosome 6p21.3, the region with strongest linkage to SLE according to recent whole genome scans. Copy number polymorphism (CNP) is one of many possible sources of phenotypic heterogeneity. We analyzed the associations between C4 CNP and SLE. Among SLE patients we also investigated the association of C4 CNP with plasma levels of complement and autoantibodies.

Method: 283 SLE patients and 180 controls matched for age, sex and region of living participated. C4 CNP was determined with RT-PCR. Plasma levels of C4, C3, and C3d were measured in patients by rate nephelometry and autoantibodies with enzyme linked immuosorbent assay. The Lupus anticoagulant (LAC) test was performed with a Dilute Russel Viper Venom method. Associations were determined with Chi-square and Mann-Whitney tests.

Results: SLE patients more often had < 2 copies of C4A (OR: 2.3, 95% CI: 1.4-3.7) or < 4 copies of 'C4 total' (C4A+C4B) (OR: 2.3, 95% CI: 1.4-3.6) than controls. No association between C4B CNP and SLE was observed. Analyses among SLE patients revealed an association between low copy numbers (<4 copies) and low serum levels of C4 (p = 0.02). No association between C4 CNP and plasma levels of C3 and C3d was observed. A strong association between SLE patients carrying < 2 copies of C4A or < 4 copies of C4tot and presence of SSA/SSB antibodies (OR C4A: 1.8, 95% CI: 1.1-3.1) (OR C4tot: 4.1, 95% CI: 2.4-7.00) was observed. SLE patients carrying < 2 copies of C4A or < 4 copies of C4tot, were less likely to have β2GP1 IgG (OR C4tot: 0.4 95% CI: 0.2-0.7), anticardiolipin (aCL) IgM (OR C4A: 0.5, 95% CI 0.2-0.9) or a positive LAC test (OR C4tot: 0.3, 95% CI: 0.1-0.5). No significant association with aCL IgG, aDNA or aSm antibodies was present.

Conclusion: This study demonstrates a strong association between C4 CNP and autoantibody profile in SLE. Low numbers of C4 gene copies were strongly associated with the presence of SSA and SSB antibodies while SLE patients with high numbers of C4 gene copies were more likely to have antiphospholipid antibodies. Our data corroborate previous findings that a genetic deficiency of C4 is associated with SLE and with low levels of C4 protein in plasma. Further studies related to the complement system are warranted to understand how genetics is related to subgroups of SLE patients with different autoantibody profiles.

1763

The Association of the Defects in ER Stress-Induced Autophagic Reaction and Apoptotic Cell Death of T Lymphocytes in Systemic Lupus Erythematosus. Eun Gyeong Lee[1], Hee Jin Yun[1], Yun Kyung Hong[1], Myung Soo Lee[2], Hyun-Ok Kim[3], Sang-IL Lee[4], Sung Il Kim[5] and Wan-Hee Yoo[1], [1]Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Iksan, South Korea, [3]Gyongsang University, Jinju, South Korea, [4]College of Medicine, Gyeongsang National University, Jinju, South Korea, [5]Pusan National University Mediacal School, Busan, South Korea

Purpose: Autophagic reaction is involved in the control of CD4+ T lymphocytes homeostasis and also is essential for T lymphocyte survival and proliferation. Systemic lupus erythematosus (SLE) is a prototype of autoimmune diseases of unknown etiology and characterized by high-titer autoantibodies against ubiquitous nuclear self-antigens and aberrant T lymphocyte functions. This study was to define the roles of endoplasmic reticulum (ER) stress-induced autophagic reaction of T lymphocytes in patients with SLE.

Methods and Materials: The survival of T lymphocytes was evaluated with CCK-8 reagent and the percentage of apoptotic cells was examined with flow cytometry with propidium iodide and annexin V in the presence or absence of ER stress with thapsigarnin. The expression of beclin 1 and LC3 as markers of autophagic reaction, and Bcl-2 and Bcl-Xl was examined by immunoblotting. To detect

autophagic reaction, T lymphocytes were transfected with plasmid GFP-LC3 and stained with 0.1% Triton X-100 and counterstained with 4',6'-diamidino-2-phenylindole (DAPI) nuclear dyes and observed under fluorscence microscopy.

Results: ER stress-induced autophagic reaction was decreased in T lymphocytes of patients with SLE compared to healthy controls. Decreased ER stress-induced autophagic reaction was associated with reduced expression of antiapoptotic proteins, Bcl-2 and Bcl-Xl after stimulation with thapsigarnin. It also associated with decreased survival and increased apoptosis of lupus T lymphocytes compared with T lymphocytes of healthy controls.

Conclusion: ER stress-induced autophagic reaction was decreased and associated with survival of T lymphocytes in SLE. Thus, we suggest that defects in autophagic reaction of T lymphocytes are involved in the pathogenesis of SLE.

B Cell Signatures as Biomarkers in SLE. Chungwen Wei[1], Arumugam Palanichamy[1], Scott A. Jenks[1], Jennifer Barnard Hossler[1], Alex Rosenberg[1], James Kobie[1], Bo Zheng[1], Eun-Hyung Lee[1], Yu Qian[2], Richard Scheuermann[2], Jennifer H. Anolik[3] and Iñaki Sanz[1], [1]University of Rochester Medical Center, Rochester, NY, [2]UT Southwestern, Dallas, TX, [3]University of Rochester, Rochester, NY

Purpose: B cells play central protective roles against infection and key pathogenic roles in autoimmunity. Whether diverse and opposing functions are played by distinct subsets or result from plasticity of the same subsets remains to be understood. This gap in knowledge is a major impediment to understand the pathogenesis of autoimmunity and to develop safe and effective B cell targeted therapies. Thus, a comprehensive and consistent definition of the phenotypic heterogeneity of human B cells is of the essence. Here, we utilize state-of-the-art 11-color flow cytometry and new analytical algorithms to explore B cell diversity in SLE and define B cell profiles as biomarkers of disease activity and prognosis.

Methods: 11-color flow cytometry (on a LSRII cytometer) was used to simultaneously analyze multiple markers: CD19, IgD, CD27, CD24, CD38 and CD21, mitotracker extrusion (specific for naïve B cells), systemic homing (CXCR3), activation (CD69), and proliferation (Ki67) in the peripheral blood of normal controls (n=10) and SLE patients (n=23). Selected experiments also included staining for markers of lymphoid homing (CD62L). Basic subsets were defined using core markers. In order to objectively identify cell populations, we applied a novel methodology, Flow Cytometry Clustering without K (FLOCK), which uses the fluorescence intensity data from all staining parameters simultaneously to automatically define all unique populations. B cell profiles were initially compared in an unsupervised fashion by cluster analysis. SLE disease activity was assessed by SLEDAI.

Results: Human B cell populations, as revealed by FLOCK methodology, display considerable heterogeneity in normal controls and increased heterogeneity in SLE samples with 12-16 distinct populations identified in peripheral blood. In an analysis of 23 SLE patients several distinct B cell profiles were identified. As a whole, the SLE group had higher transitional B cells (14%+/-11 SLE vs. 7.7%+/-2.8 controls, p=0.04) and CD69+ plasmablasts (10.6%+/-7.5 SLE vs. 4.3%+/-2.9 controls, p=0.01). CD27+ memory predominant SLE patients (defined as 2 SD above the control mean) (observed in 36%) had a relative paucity of transitional and naïve B cells. This phenotype is also associated with an expansion of isotype switched CD27- B cells with an effector phenotype (CXCR3+CD62L-; observed in 46%). Disease flare was associated with a memory predominant B cell profile. In contrast, the normal controls clustered with the SLE patients with low SLEDAI scores requiring minimal immunosuppression. Expanded numbers of patients, detailed clinical correlations, longitudinal analysis, and additional mining tool application are underway.

Conclusion: Human B cell diversity has previously been underappreciated given the limitation of pauci-color flow cytometry strategies. Our results suggest that B cell profiles can be utilized as biomarkers of disease activity in SLE. We hypothesize that autoimmunity reflects a dysregulation in the balance between functionally distinct lymphocyte populations that is reflected in distinct B cell profiles.

1765

Single Anti P-Ribosomal Antibodies Are Not Associated to Lupus Nephritis in Patient with Active Systemic Lupus Erythematosus. Theory of the Nephritogenicity by Clusters. Gerardo Quintana[1], Paola Coral-Alvarado[1], Gustavo Aroca[2], Paul Mendez[1], Philippe Chalem[1], Antonio Iglesias[3] and Ariel Ruiz[3], [1]Unidad de Reumatología, Universidad Nacional de Colombia, Bogota, Colombia, [2]Clinica de la Costa, Colombia, [3]Universidad Nacional de Colombia, Bogota, Colombia

Purpose: In the clinical practice sometimes it is difficult to diagnose a relapse in patients with Systemic Lupus Erythematosus (SLE) and lupus nephritis (LN) with potential complications including renal insufficiency and death. Some immunological markers can help to determine their association with LN and diagnose early this complication. The aim of this study was to evaluate the association between systemic and kidney activity and the anti-P ribosomal antibodies and to determine its coexistence with anti-dsDNA on nephritogenicity's theory in patients with active SLE.

Method: Three-hundred and eighty nine patients were analyzed but only 140 were included (inclusion criteria), 70 in each group in a case-control study in Colombian population with SLE - ACR 1997 -. All of the subjects had some score of activity. The activity was determined by SLEDAI. Those patients with active LN (proteinuria ≥ 0.5 grams/24 hours; urinalysis with cellular cylinders, proteinuria and/or hematuria; and/or an increase ≥ 30% of the basal serum creatinine levels) were considered to be "cases". We use ELISA'S kit and the indirect immunofluorescence method with *Crithidia luciliae* for determining the presence of antibodies anti-P ribosomal and anti-dsDNA, respectively.

Results: No association between anti-P ribosomal and the LN (p=0.2971) was found, but if it was between anti-P ribosomal and SLEDAI > 5 (OR=4.87, IC 95% 1.32-17.98, p=0.008). The coexistence of anti-P ribosomal and anti-dsDNA was associated to LN (OR = 3.52; IC 95% 1.07-13.42, p=0.019). Finally, anti-dsDNA was associated to LN (p=0.001). None histopathologic type of LN was associated to anti-P ribosomal.

Conclusion: There was not association among anti-P ribosomal and LN, but the coexistence of anti-P ribosomal and anti-dsDNA was associated with it, what suggests that the coexistence of two antibodies is more nephritogenic. Anti-P ribosomal is associated with activity score with/without LN. Additional studies are needed to evaluate coexistences of antibodies specific to kidney on SLE to determine the biological nature of the LN.

Sensorineural Hearing Loss in Diffuse Systemic Sclerosis. Tatiana A. Monteiro[1], Romy B. C. Souza[2], Eloisa Bonfa[1], Ricardo F. Bento[1], Elaine S. Novalo[1] and Laura G. E. Vasconcelos[1], [1]Faculdade de Medicina da USP, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao Paulo, Brazil

Purpose: Hearing loss has been reported in 77% patients with limited SSc but there are no systematic evaluation regarding diffuse SSc subtype. Since this later form has distinct clinical manifestation with a more extensive organ involvements we have evaluated auditory dysfunction in 26 consecutive SSc patients with diffuse subtype.

Methods: 26 diffuse SSc patients (ACR criteria) were included in this study. All patients were interviewed with a standard questionnaire regarding otological symptoms. A completed ear/nose/throat physical examination was performed followed by speech/pure tone audiometry and impedance measurements. In those with unilateral or asymmetrical hearing loss a magnetic resonance imaging was performed to exclude retrocochlear etiology. Hearing loss was defined when audiometric tests disclosed pure-tone thresholds equal to or greater than 25 dB HL in 2 frequencies of the audiogram. Individuals with a history of cranial trauma, meningitis, ototoxic drugs use, noise exposure, acoustic trauma, ear malformation, otologic surgery and other connective tissue disease were excluded.

Results: Two patients with other autoimmune diseases were excluded. Among the 24 analyzed, the mean age was 47.0 ± 11.9 years with mean disease duration of 9.4 ± 9.1 years and a clear female predominance (83%). The questionnaire revealed auditory complaining in 50% (25% hearing loss, 20% aural fullness, 20% tinnitus and 20% dizziness). Patients had a uniform normal otoscopy, except for two patients (central neotympani and tympanosclerosis). Audiometric diagnosis of hearing loss occurred in almost half of the patients (45.8%), all of them had a sensorineural component, 8 (72,8%) a descending configuration in the audiogram and recruitment phenomenon occurred in 6 (54,5%), suggesting cochlear involvement. Stapedial reflex was present in 23 (96%) and abnormal tympanogram in 5 (21%). Asymmetrical or unilateral hearing loss occurred in 2 patients and both had a normal MRI.

Conclusion: The finding of predominant sensorineural hearing loss in diffuse SSc suggests that inner ear damage is probably due to the vascular involvement of the disease.

1705

Clinical and Histopathologic Comparison of Generalized Subcutaneous Morphea (GSM) with Eosinophilic Fasciitis (EF). Fazleomar Mahmood[1], Ann J. Impens[1], Elena Schiopu[1], Kristine Phillips[1], Lori Lowe[2], Stephen Olsen[2] and James R. Seibold[1], [1]Scleroderma Program, University of Michigan, Ann Arbor, MI, [2]Division of Dermatopathology, University of Michigan, Ann Arbor, MI

Purpose: GSM (morphea profunda) and EF are both characterized by inflammation and fibrosis involving the lower dermis, subcutaneum, fascia and even superficial muscle. Clinical and laboratory findings overlap as well but these entities have been classified as distinct syndromes. We identified 25 patients investigating clinical and histopathologic distinctions as well as response to therapy and outcomes.

Methods: Retrospective chart review (1998-2008) by ICD9 codes. Cases were selected from the database of outpatient clinical services at the University of Michigan Health Center. Reference area: 3200 patients. Patients with systemic sclerosis and other forms of indurative skin disorders were excluded. Collected data included demographic, clinical and diagnostic variables. Two dermatopathologists have reviewed 8 out of 24 blinded biopsy specimens to date.

Results: 19 patients [10 male, mean age 50.7 y (range 18-83)] diagnosed as GSM and 6 [3 male, mean age 46.3 y (range 27-62] with EF were identified. Important clinical descriptors are represented in the following table.

	GSM n=19		**EF n=6**	
Intense physical activity	3 (n=5)	60 %	1 (n=2)	50%
Skin Induration	19 (n=19)	100 %	6 (n=6)	100%
Peau d' orange	11 (n=11)	100%	4 (n=4)	100%
Venous furrowing	11 (n=13)	84.6%	5 (n=5)	100%
ANA positivity	4 (n=15)	26.7%	2 (n=6)	33.3%
Hypergammaglobulinemia	4 (n=5)	80%	3 (n=4)	50%
Hypereosinophilia	6 (n=17)	35.3%	2 (n=5)	40%
Corticosteroids	18 (n=19)	94.7%	6 (n=6)	100%
Methotrexate	11 (n=19)	57.8%	5 (n=6)	83.3%
Mycophenolate Mofetil	8 (n=19)	88.8%	1 (n=6)	16.6%

Pathology diagnoses of GSM were made in 6/8 cases by one and 5/8 cases by the other blinded reader. The remaining cases were assigned EF.

Important histopathologic descriptors were:

	GSM		EF	
	Pathologist 1	Pathologist 2	Pathologist 1	Pathologist 2
Dermal Inflammation	50% (3/6)	40% (2/5)	0 (0/2)	0 (0/3)
Dermal Sclerosis	100% (6/6)	100%(5/5)	0 (0/2)	33.3%(1/3)
Subcutaneous Inflammation	66.7%(4/6)	60%(3/5)	0 (0/2)	33.3%(1/3)
Fascial Inflammation	66.7%(4/6)	60%(3/5)	100%(2/2)	100%(3/3)

No differences were identified in treatment response and time to remission.

Conclusion: Clinical and laboratory features are indistinguishable between GSM and EF. Based on the 8 out 24 biopsy reviews so far, there are some histopathologic differences between GSM and EF, although these data do not support separate terminology, prognosis or approach to therapy.

Disclosure: F. Mahmood, None; **A. J. Impens**, None; **E. Schiopu**, Actelion Inc, 8 ; **K. Phillips**, None; **L. Lowe**, None; **S. Olsen**, None; **J. R. Seibold**, None.

1706

Correlation Between Submaximal Exercise Testing and Right Heart Catheterization in Patients with Systemic Sclerosis (SSc).

Suparaporn Wangkaew[1], Ann J. Impens[1], Melvyn Rubenfire[2], Vallerie V. McLaughlin[2], Daniel G. Montgomery[2] and James R. Seibold[1], [1]Scleroderma Program, University of Michigan, Ann Arbor, MI, [2]Cardiology, University of Michigan, Ann Arbor, MI

Background: The six-minute walk test (6MWT) has been used as a primary outcome measure in studies of pulmonary arterial hypertension (PAH). Correlations of 6MWT and right heart catheterization (RHC), a gold standard of PAH diagnosis, have not been examined in SSc patients.

Purpose: To determine the correlations between the 6MWT and RHC variables in SSc patients.

Method: 41 SSc patients with 1 test set of RHC, 6MWT and PFT within 12 weeks of the corresponding RHC were retrospectively identified. Data included clinical characteristics; RHC variables: right atrial pressure (RAP), mean pulmonary arterial pressure (mPAP), pulmonary capillary wedge pressure (PCWP), pulmonary vascular resistance (PVR), mixed venous O2 saturation (SvO2), cardiac output (CO); 6MWT variables: 6MW distance, SaO2 (baseline, nadir), Δ SaO2 (SaO2base-nadir), heart rate (HR baseline, peak), HR change (Δ HR: HR peak-base), Borg Dyspnea Index (BDI rest, peak), Borg Fatigue Index (BFI rest, peak); and PFT variables: FVC and DLCO (% predicted). Forehead probe pulse oximeter was used to measure SaO2. PAH was defined as mPAP >25 mmHg at rest and PCWP ≤ 15 mmHg. Interstitial lung disease (ILD) was defined as % FVC < 85. Pearson correlation coefficients were used to determine the correlations between 6MWT and RHC variables.

Results: Mean (SD) age was 55.8 (10.1) yrs and mean disease duration 6.5 (4.9) yrs. 85.4% were female; 82.9% were classified as limited SSc, 58.5% SSc-PAH-ILD, 19.5% SSc-ILD, 17.1% SSc-PAH, 2.4% SSc-PH-LVdys, and 2.4% SSC-none. Mean (SD) values were: RAP 9.3 (6.3) mmHg; mPAP 40.2 (15.7) mmHg; PCWP 10.5 (4.0) mmHg; PVR 7.1 (4.4); SvO2 64.8 (8.2) %; CO 4.6 (1.3) L/min; 6MWD 312.6 (94.6) m; HR baseline 83.7 (15.3) beat/min; HR peak 118.4 (17.9); Δ HR 34.2 (14.8); SaO2 baseline 98.0(1.5); SaO2 nadir 91.8 (4.4); Δ SaO2 6.2 (4.4); BDI rest 0.8 (1.2); BDI peak 4.2 (3.0); BFI rest 0.9 (1.3); BFI peak 3.5 (2.8); % FVC 67.9 (20.5), and % DLco 34.7 (15.8). 6 (14.6%) patients were on current use of beta blockers and 18 (43.9%) who used oxygen supplementation during the 6MWT. Correlations between 6MWT and RHC variables were:

Variable	6MWD	HR base	HR peak	Δ HR	SaO2 base	SaO2 base	ΔSaO2	BDI rest	BDI peak	BFI rest	BFI peak

Total grp. (N=41)											
RAP	-.47** 40	.15 40	-.24 38	-.44** 38	-.42** 40	.12 38	-.25 38	.37* 32	.27 34	.16 30	.40* 30
mPAP	-.48** 41	.06 41	-.30 39	-.42** 39	-.24 41	-.11 39	.03 39	.29 33	.37* 35	.03 31	.33 31
PVR	-.40* 37	.00 37	-.32 35	-.38* 35	-.27 37	-.08 35	-.00 35	.25 29	.21 31	-.00 27	.17 27
SvO2	.39* 35	.05 35	.37* 33	.39* 33	.16 35	-.14 33	.18 33	.01 28	.08 30	.24 26	-.01 26
CO	.36* 41	.13 41	.39* 39	.36* 39	.19 41	-.19 39	.25 39	-.27 33	-.11 35	-.01 31	-.19 31

*p< 0.05, ** p< 0.01

Conclusion: 6MWD and heart rate change show statistically significant low to moderate correlation with the RHC variables. Correlations between RHC variables and HR peak, SaO2 baseline, BDI, and BFI peak, if significant, are low to moderate. HR baseline, SaO2 (nadir, □ SaO2), and BFI rest reveal no significant correlations with RHC variables. Further study is needed to validate HR response as an outcome measure of SSc-PAH.

1707

Relevance of the Heart Rate Recovery After Six-Minute Walk Test (6MWT) in Patients with Systemic Sclerosis (SSc). Suparaporn Wangkaew[1], Ann J. Impens[1], Melvyn Rubenfire[2], Elena Schiopu[1], Vallerie V. McLaughlin[2], Daniel G. Montgomery[2] and James R. Seibold[1], [1]Scleroderma Program, University of Michigan, Ann Arbor, MI, [2]Cardiology, University of Michigan, Ann Arbor, MI

Background: Heart rate recovery (HRR) after 6MWT has been shown to be predictive of mortality in patients with idiopathic pulmonary fibrosis (1), but its role has not been examined in patients with SSc.

Purpose: To examine the correlations of HRR with other non-invasive measures of cardiopulmonary function.

Methods: 147 SSc patients were retrospectively identified as having had at least one test set of 6MWT, PFT, and echocardiogram performed within 12 weeks. Abstracted data included clinical characteristics, 6MW distance (6MWD), Δ oxygen saturation (Δ $SpAO_2$ baseline minus nadir), peak heart rate (HR peak) during 6MWT, HR at 1 min of recovery, FVC and DLco (% predicted), and estimated systolic pulmonary artery pressure (sPA). Heart rate recovery (HRpeak-1min) was recorded as HR peak minus HR-1min. PAH was defined as estimated sPA ≥ 45 mmHg. Interstitial lung disease (ILD) was defined as % predicted of FVC < 85. Student's *t* test was performed to determine mean difference in HRR in subgroups of SSc.

Results: Mean (SD) age was 53.8 (10.9) yrs and mean disease duration 8.0 (8.0) yrs. 86.4% were female and 70.1% were classified as limited SSc. Patients were categorized as 42.9% SSc-ILD, 17.0 % SSc-PAH and ILD, 4.8 % SSc-PAH and 35.4% SSc with neither ILD or PAH. Mean (SD) values were: 6MWD 394.3 (129.0); Δ $SpAO_2$ 3.2 (4.1); HR-1m 20.6 (11.3); % of predicted FVC 77.7 (19.6); % of predicted DLco 54.6 (21.1), and sPA 40.2 mmHg (26.2). 84 (57.1%) patients had 6MWD ≥ 380 m. Echocardiography revealed sPA ≥ 45 mmHg in 32 (21.8%), right ventricular dysfunction (RV dys) in 24 (16.3%) and left ventricular diastolic dysfunction (LVD dys) in 14 (9.5%). 13 (8.8%) of patients were receiving beta-blockers.

Differences in mean HRpeak-1min between subgroups were:

Subgroup			Mean (SD)	Mean (SD)	Mean difference	P
	A	B	A	B	A-B	
Distance (m)	<380	≥380	15.8 (10.5)	24.0 (10.6)	-8.2	<0.01
sPA (mmHg)	<45	≥45	21.8 (10.3)	15.9 (13.6)	5.9	<0.05
RV dys	without	with	22.4 (10.4)	10.5 (10.4)	11.9	<0.01
LVD dys	without	with	21.2 (11.3)	15.2 (7.7)	5.9	NS
Beta-blockers	without	with	21.2 (11.3)	14.5 (8.8)	6.7	<0.05

Conclusion: Mean HRpeak-1min after 6MWT are significantly decreased in SSc patients with poor 6MWD, higher sPA, right ventricular dysfunction, and current use of beta- blockers. Left ventricular dysfunction did not affect HRpeak-1min. HRpeak-1min offers promise as a measure of outcome and response in patients with SSc.

1708

Improvement in Long-Term Prognosis of Pulmonary Arterial Hypertension in Patients with Connective Tissue Diseases, Including Systemic Sclerosis, Mixed Connective Tissue Disease and Systemic Lupus Erythematosus. Sumiaki Tanaka, Tatsuhiko Wada, Reiko Matsushita and Shunsei Hirohata, Kitasato University School of Medicine, Sagamihara, Japan

Purpose: Under current circumstances where a variety of potent drugs for treating pulmonary arterial hypertension (PAH) have become available, sophisticated strategy for treatment of PAH has become more important in patients with connective tissue disease (CTD). We aimed to assess whether our strategy for treating PAH improves long-term prognosis of PAH associated with CTD, including systemic sclerosis (SSc), mixed connective tissue disease (MCTD) and systemic lupus erythematosus (SLE)

Method: We performed a retrospective-cohort study among 96 PAH patients with CTD, including SSc (40 patients), MCTD (20 patients) or SLE (18 patients), who received treatments and were followed up between 1980 and March 2009 in our hospital. Our therapeutic strategy for PAH intended to achieve the following goals: 1) improvement in WHO-functional class after 6 month of treatment and 2) reduction of serum BNP level of less than 73.8 pg/ml, based on our previous study results as well as on the results demonstrated by Hoeper et. al, (Eur Respir J 2005; 26: 858–863). The PAH-specific medications, including bosentan, sildenafil, epoprostenol, and beraprost (an oral prostacyclin analog that is only available in Japan), were switched from drug to drug or adopted in combination so as to achieve these predetermined therapeutic goals. Survival was measured from the date of the diagnosis of PAH, and analyzed using Kaplan-Meier method and Cox's proportional hazard model.

Results: Thirty-seven patients who were treated under this therapeutic strategy were placed in the goal-oriented treatment Group. The PAH-specific medications in this group at the last observation are shown in table 1. Fifty-nine patients including 27 patients who were treated using beraprost without intention for achievement of the therapeutic goals, and 32 patients who had been treated before these PAH-specific medications became available or who had been unavoidably treated with only conventional drugs due to adverse effect, were placed in the control group. Patients in the goal-oriented treatment group showed significant improvement in survival (Figure 1). Multivariate analysis for survival demonstrated that our therapeutic strategy markedly improved long-term prognosis (Table 2). The age and WHO- functional class at the diagnosis of PAH also affected survival, while the type of CTDs did not affect survival.

Conclusion: Our therapeutic strategy for PAH using the PAH-specific medications markedly improved long-term prognosis of CTD patients complicated with PAH. These data clearly indicate that early diagnosis and early intervention to inhibit the progression of WHO-functional class and reduce serum BNP levels are important for CTD patients susceptible to PAH.

Employment Status and Burden in Systemic Sclerosis: A Cross-Sectional Survey. Christelle Nguyen[1], Serge Poiraudeau[1], Caroline Mestre-Stanislas[2], François Rannou[1], Alice Bérezné[2], Agathe Papelard[1], Michel Revel[1], Loïc Guillevin[2] and Luc Mouthon[2], [1]Rehabilitation Department, Cochin Hospital, Paris-Descartes University, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France, [2]Department of Internal Medicine, Cochin Hospital, Referent Center for Necrotizing Vasculitis and Systemic Sclerosis, Paris-Descartes University, AP-HP, Paris, France

Purpose: To assess employment status and burden in systemic sclerosis (SSc).

Method: Eighty-seven SSc patients (72 females), fulfilling the ACR and/or the Leroy and Medsger criteria, were assessed for employment status and burden. Statistical analysis was performed using nonparametric Mann-Whitney and Fisher's exact tests.

Results: Mean age and disease duration were 48.6±8.5 and 8.1±6.4 years, respectively. Seventy percent of SSc patients were on full-time sick leave and 35.6% were disabled. Twenty percent of patients were professionally reoriented after the diagnosis of SSc was made. Myalgias were the only clinical manifestation more frequently encountered in sick leave patients than in others (73.6% vs. 47.1%, p = 0.012). Karnofsky performance status was reduced in SSc patients on sick leave or disabled as compared to others (78.1±8.7 vs. 83.1±11.2, p = 0.016; and 78.5±10.6 vs. 85.8±9.0, p = 0.004, respectively). In addition, greater hand and mouth disabilities and depression were observed in patients on sick leave (Cochin hand function scale 21.7±18.9 vs. 10.7±12.1, p = 0.003; mouth handicap in SSc scale 20.2±10.8 vs. 14.6±10.0, p = 0.021; and depression dimension of the hospital anxiety and depression scale 7.1±3.9 vs. 4.8±3.4, p = 0.003). Lastly, disabled patients reported more frequent income decrease (71% vs. 23.2%, p < 0.001), absence of advancement (71% vs. 28.6%, p < 0.001), and a feeling of discrimination (22.6% vs. 5.4%, p = 0.030).

Conclusion: In SSc patients, perceived health status and disability are associated with sick leave status and represent major factors of the employment burden.

Endothelial Dysfunction Is Associated with Decreased Circulating Endothelial Progenitor Cells in Pateints with Systemic Sclerosis.

Mo Yin Mok[1], Hung Fat Tse[1], Yi Lo[1], Ws Wong[1] and Chak Sing Lau[2], [1]Department of Medicine, The University of Hong Kong, Hong Kong, [2]Department of Medicine, The University of Dundee, United Kingdom

Background: The role of circulating bone marrow derived endothelial progenitor cells (EPCs) for vascular repair in scleroderma (SSc) remains unclear.

Purpose: To examine endothelial dysfunction in SSc patients and to correlate findings with biochemical markers of endothelial injury, circulating EPC count, disease activity and organ involvement.

Methods: Endothelial dependent and independent vasodilation responses were assessed by changes in flow mediated dilation (FMD%) and nitroglycerin challenge (NTG%) in the brachial artery respectively in SSc patients compared to age- and sex- matched controls. Serum levels of vascular endothelial growth factor (VEGF) and soluble vascular cell adhesion molecule (sVCAM)-1 were measured by ELISA. Enumeration of circulating CD133/VEGFR2+ EPCs was performed by flow cytometry.

Results: Median FMD% (4.8% vs. 7.8%, P<0.001) and NTG% (17.0% vs. 21.4%, P=0.002) were found to be significantly lower in SSc patients (n=52) than controls (n=52), especially in patients with limited disease (lSSc). Median circulating EPC count was significantly lower in lSSc patients (23.0/µl) compared to controls (73.0/µl) (P<0.001). This was accompanied by higher level of sVCAM-1 in these patients compared to those with diffuse disease (P=0.01). Lower circulating EPC count was found to be associated with high disease activity (P=0.04), abnormal forced vital capacity (P=0.003), longer disease duration (P=0.04), total skin score>20 (P=0.03) and lSSc subset (P<0.001). Multivariate analysis identified disease duration as the only independent predictor for circulating EPC count (P=0.04).

Conclusion: Endothelial dysfunction was demonstrated in SSc and correlated with biochemical markers of endothelial injury. Lower circulating EPCs might contribute to deficient vascular repair in SSc patients.

1711

An On-Line Screening Tool for Cardiopulmonary Complications of Scleroderma - the Australian Scleroderma Screening Program.

Susanna M. Proudman[1], Jill Byron[2], J. Zochling[3], Peter Youssef[4], P. Nash[5], Kathleen Tymms[6], Madelynn Chan[7], Allan D. Sturgess[8], Leslie Schrieber[9], Catherine Hill[10], David Celermajer[4], Joanne Sahhar[11] and Wendy Stevens[2], [1]Royal Adelaide Hospital, Adelaide, Australia, [2]St Vincent's Hospital, Melbourne, Australia, [3]University of Tasmania, Hobart, Australia, [4]Royal Prince Alfred Hospital, Sydney, Australia, [5]University of Queensland, Brisbane, Australia, [6]Canberra Hospital, Canberra, Australia, [7]Royal Perth Hospital, Perth, Australia, [8]St George Hospital, Sydney, Australia, [9]Royal North Shore Hospital, Sydney, Australia, [10]The Queen Elizabeth Hospital, Adelaide, Australia, [11]Monash Medical Centre, Melbourne, Australia

Purpose: It is recommended that patients with scleroderma (SSc) be screened annually for the serious complication of pulmonary arterial hypertension (PAH), as it is often clinically silent early in the disease and is now treatable. Compliance with evidence-based clinical guidelines (CG) in a real-life setting can be poor.

Method: A nation-wide, multicentre on-line database of patients with SSc was established in 2007, with a computer decision support system (CDSS) for implementing screening CG for PAH. Doppler echocardiograms (ECHO) and pulmonary function tests (PFTs) are performed annually and recommendations for diagnostic tests for PAH including right heart catheter (RHC) are made by the CDSS after risk stratification according to systolic pulmonary artery pressure (sPAP), diffusing capacity (DLCOc) and symptoms. Definitions of risk categories are: high risk: ECHO sPAP > 50 mmHg; moderate risk: sPAP 40-50 mmHg; at risk: unexplained dyspnoea and/or DLCOc < 50% with FVC > 85 % despite sPAP < 40 mmHg. Detailed clinical and laboratory data are collected annually and entered on-line.

Results: By April 2009, 714 patients (66% lSSc; 26% dSSc) had been recruited into the database from 12 centers and screened. Of these, 341 (45%) had had a second visit, 75 (10%), a third. Mean±SD age and disease duration at entry were 57.9±12.5 and 12.5±10.4 years respectively. Clinical characteristics included esophagitis (82% lSSc cf 84% dSSc), fecal incontinence (16% cf 12%), digital ulcers (24% cf 38%), joint contractures (21% cf 65%), pulmonary fibrosis (19% cf 39%), modified Rodnan score (9 cf 21) and renal crisis (1% cf 5%). 28 (4%) had had RHC-defined PAH prior to 2007. 47 (6.7%) of the remaining 686 patients had RHC-defined PAH as a result of screening (9 on

exercise RHC). Of 33 patients at high risk, 22 were found to have PAH. Of 62 patients at moderate risk, 23 with symptoms were referred for RHC and 11 had PAH. Of 32 at risk patients, 10 were diagnosed with PAH (one with unrecordable ECHO sPAP). A further 5 patients had PAH due to left ventricular dysfunction. The most common reason for CG violation in the moderate risk group was underestimation of symptoms.

Conclusion: Not all patients with PAH have an abnormal ECHO and risk stratification which includes PFTs and symptoms, aids detection. This is the first time a CDSS has been used to facilitate compliance with CG for screening for PAH in SSc, allowing comprehensive clinical assessment and early institution of potentially beneficial therapy. This web-based database serves as a model for effective multi-centre collection of data for an uncommon rheumatic disease.

Elevated B-Type Natriuretic Peptide Levels Are Associated with Worse Survival in Systemic Sclerosis Associated Pulmonary Hypertension. Lorinda Chung[1], Miho Bennett[1], Roham T. Zamanian[1], Virginia D. Steen[2] and the PHAROS Investigators, [1]Stanford University, Palo Alto, CA, [2]Georgetown Univ Medical Center, Washington, DC

Purpose: B-type natriuretic peptide (BNP) and N-terminal proBNP (NT-proBNP) are cardiac neurohormones that are released in response to myocardial pressure or volume overload. Elevation of these hormones has been associated with worse outcomes in patients with idiopathic pulmonary arterial hypertension (PAH), and elevated NT-proBNP has been shown to predict mortality in patients with systemic sclerosis (SSc)-associated PAH. We sought to assess the prognostic utility of natriuretic peptide levels in SSc patients at high risk for or with incident pulmonary hypertension (PH).

Methods: PHAROS is a multicenter prospective cohort of patients at high risk for PAH (pre-PAH) or with definite PH diagnosed by right heart catheterization (RHC) within 6 months of enrollment. Criteria for pre-PAH include any one of the following: diffusing capacity (DLCO) <55% predicted, forced vital capacity (FVC)/DLCO ratio >1.6, or pulmonary artery systolic pressure (PASP) on echocardiogram >35 mmHg. Patients with definite PH have a mean pulmonary artery pressure (mPAP) ≥25 mmHg at rest or ≥30 mmHg with exercise on RHC. A pulmonary capillary wedge pressure ≤15 mmHg was used to differentiate Group I (PAH) from Group II (PH related to left heart disease). Those with moderate or severe interstitial lung disease on chest imaging and FVC <60% predicted were included in Group III (PH related to hypoxemia). BNP and NT-proBNP levels were log-transformed when used as continuous variables as their distributions were highly skewed. For Cox regression and survival analyses, elevated natriuretic peptide levels were defined as BNP ≥ 180 or NT-proBNP ≥ 553 pg/mL.

Results: 69 definite PH (51 Group I, 9 each in Groups II and III) and 99 pre-PAH patients had natriuretic peptide levels available. Mean(SD) BNP and NT-proBNP levels were significantly higher in the definite PH compared with the pre-PAH patients (226.6(437.7) vs. 62.7(58.6) pg/mL, p<0.0001 ; 1426.1(2684.7) vs. 201.2(453.6) pg/mL, p=0.005, respectively). Group I tended to have the highest levels (mean BNP 249.6(473.2) pg/mL, mean NT-proBNP 2061.0(3121.9) pg/mL, p=0.09 compared with Groups II and III for both tests). In the definite PH group, NT-proBNP but not BNP correlated with mPAP (r=0.65 vs. 0.36) and pulmonary vascular resistance (r=0.77 vs. 0.17). In the pre-PAH group, NT-proBNP had a moderate correlation with PASP on echocardiogram (r=0.56). In the definite PH group, an elevated BNP or NT-proBNP level was associated with >8-fold increased risk of death, which remained when correcting for creatinine and New York Heart Association functional class, but this did not reach statistical significance (HR 8.6(0.8-92.2), p=0.07). 1- and 2-year survival in those with an elevated BNP or NT-proBNP was 89.4% and 78.2%, respectively, but remained 97.6% through 2 years in those with levels below the designated cut-off values (log-rank p=0.03).

Conclusion: B-type natriuretic peptide levels, and NT-proBNP in particular, may be useful in monitoring and predicting outcomes in patients with SSc-associated PH.

Renal Dosimetry for Patients Treated with Total Body Irradiation (TBI) for Severe Systemic Sclerosis (SSc) On the SCOT (Scleroderma: Cyclophosphamide or Transplantation) Trial. O. Craciunescu, B. Steffey, C. Kelsey, R. Prosnitz, N. Larrier, C. Paarz-Largay and KM Sullivan, Duke University Medical Center, Durham, NC

Purpose: To describe techniques and dosimetry in delivering TBI to patients with severe SSc enrolled on a multicenter stem cell transplant (SCT) protocol.

Methods: The SCOT protocol employs an immunoablative regimen of high-dose CY, ATG and 800 cGy TBI given in 200 cGy fractions twice a day followed by CD34 selected autologous SCT. Due to possible organ impairment from SSc, shielding is used to limit irradiation to kidney and lung to a total of 200 cGy. Since renal shielding has not been previously used during TBI, block thickness and dosimetry were investigated and guidelines developed for safety and technique. Due to concern for worsening of SSc nephropathy, CT-based planning was performed without IV contrast. Data on kidney shape and the shifts from prone to standing position were assessed using diagnostic ultrasound (US). During treatment, we performed *in vivo* dosimetry for each patient using OneDose® (Sicel Technologies) at eleven locations, including the umbilicus, mid mediastinum, lumbar spine, hip, and under the lung/kidney block and calculated the mean dose at each location. Minimum distances between the kidney blocks (dkB) and the dose to the lumbar spine were also determined.

Results: Phantom measurements revealed that a 10 - 20 % dose inhomogeneity in the lumbar spine region could be achieved with a minimum kidney block separation of 4-5 cm (typical width of a vertebral body). Eleven subjects have been treated on the transplant arm of the trial at Duke since 2006. The average lumbar spine dose was 179.6 ± 18.1 cGy, with an average dkB of 5.0 ± 1.0 cm. Block design and placement were accomplished using a combination of CT and US or CT alone. Kidney-localization based on the combination of CT and US yielded more accurate block positioning and reduced superior-inferior block margins. Kidney shape proved similar among the eleven patients imaged, leading to a potential use of standard kidney blocks. The US information revealed a wide range of kidney displacement, both inferior and superior. The mean inferior displacement of the left kidney was 1.2 ± 1.1 cm, and 1.0 ± 1.3 cm for the right kidney. One subject exhibited a superior displacement of 3.5 cm for the right kidney. The average dose measured for the prescription point was 193.4 ± 5.1 cGy, for the mid mediastinum area 196.6 ± 10.6 cGy, for the hip area 206 ± 11.8 cGy, for under the lung blocks 54.7 ± 7.7 cGy, and under the kidney blocks, 50.8 ± 7.1 cGy. With this technique, no deterioration in renal function was observed and the study continues to enroll patients.

Conclusion: Prescribed TBI can be delivered with acceptable homogeneity over the entire body. Attenuation of TBI dosing to the kidneys by 75% can be achieved while maintaining a 10-20% dose inhomogeneity. Localization of the kidneys is more accurate using both CT and US as compared to CT alone. Supported by NIH award AI-05419.

Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS): Two-Year Outcomes for Patients with Pulmonary Hypertension. Lorinda Chung[1], Vivien M. Hsu[2], Marcy B. Bolster[3], ME. Csuka[4], Laura K. Hummers[5], John Varga[6], Ann J. Impens[7], Virginia D. Steen[8] and the PHAROS Investigators, [1]Stanford University, Palo Alto, CA, [2]UMDNJ, New Brunswick, NJ, [3]Med Univ South Carolina, Charleston, SC, [4]Med Coll of Wisconsin, Milwaukee, WI, [5]Johns Hopkins University, Baltimore, MD, [6]Northwestern University Feinberg School of Medicine, Chicago, IL, [7]University of Michigan, Ann Arbor, MI, [8]Georgetown Univ Medical Center, Washington, DC

Purpose: Pulmonary hypertension (PH) is a frequent complication of patients with systemic sclerosis (SSc) and remains a leading cause of death. Pulmonary arterial hypertension (PAH, World Health Organization Group I) is the most common form of PH in SSc, but PH related to left heart disease (Group II) and interstitial lung disease (ILD, Group III) can also occur. The purpose of this analysis was to characterize patients with incident PH from the PHAROS Registry.

Methods: PHAROS is a multicenter prospective, observational study to determine risk factors and outcomes of patients who are at high risk or have PH. Patients with definite PH, defined as mean pulmonary artery pressure (MPAP) ≥25 mmHg at rest or ≥30 mmHg with exercise on right heart catheterization within 6 months of enrollment or newly developed during follow-up, were included in the analysis. A pulmonary capillary wedge pressure ≤15 mmHg differentiated Group I from Group II patients. Those with moderate or severe ILD on chest imaging and forced vital capacity <60% predicted were included in Group III. ANOVA analyses were used to compare baseline features among the groups.

Results: Of the 103 patients with PH, 79 were included in Group I (10 with exercise-induced PAH), and 12 each in Groups II and III. Overall, 85% of the patients were female with a mean(SD) age of 57.8(10.8) years and disease duration from first non-Raynaud's symptom of 9.1(7.8) years. Group III had more African Americans (42% vs. 13% (Group I) and 17% (Group II), p=0.007) and a higher proportion with the SCL-70 antibody (25% vs. 5% (Group I) and 8% (Group II), p=0.02) and a lower proportion with the centromere antibody (8% vs. 28% (Group I) and 25% (Group II), p=0.03), but the groups did not differ by SSc subtype (overall 63% limited). MPAP was similar among the groups with an overall mean of 33.9(11.3) mmHg. Pulmonary vascular resistance was highest in Group I (404(245) dyn·s·cm-5 vs. 210(182) (Group II) and 305(215) (Group III), p=0.03). The groups did not differ with respect to New York Heart Association functional class or percentage using home oxygen. In Group I, initial treatment was with prostacyclins, endothelin receptor antagonists, sildenafil, and combination PH therapies in 13%, 22%, 30%, and 8%, respectively. At last follow-up, the proportion of patients taking these therapies increased to 15%, 38%, 42%, and 19%, respectively. There were 7 deaths in Group I, none in Group II, and 1 in Group III over a mean follow-up time of 22.8(12.2) months. 1- and 2-year survival rates in Group I were 93% and 91%, respectively.

Conclusion: Patients with SSc-associated PH have improved short-term outcomes compared with historical controls. Early diagnosis and treatment of all forms of SSc-associated PH may result in improved short-term outcomes.

Plasma Oxidative Stress in Patients with Diffuse Systemic Sclerosis Versus Control Group. Maria del Pilar Cruz-Dominguez[1], Olga Vera-Lastra[1], Daniel Montes-Cortes[1], Gabriela Medina[2] and Marco Medina[1], [1]MD, Mexico City, Mexico, [2]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico

Purpose: To evaluate plasmatic biomarkers of lipid peroxidation, oxidized proteins and total antioxidant capacity (TAC) in patients with DSS compared with a healthy group

Method: We included 28 patients with DSS according to The American College of Rheumatology. They were grouped according to disease evolution: early DSS (less than five years) and late DSS (longer than to five years). Patients suspended all medications that interfered with plasmatic OS, 72 hours previous to obtaining serum samples. As a control we used thirty-two healthy people with similar age and gender. Patients who had some other conditions that will increase the OS, another systemic illness, pregnancy or acute infection were excluded. Biomarkers of oxidative stress: lipid peroxidation products (malondialdehyde, MDA) and protein oxidation (reduction of nitroblue tetrazolium (NBT) to formazan, protein carbonyl levels and dityrosines) were measured. We also investigated total antioxidant capacity (CAPT). Statistical analysis was performed using the Student's t-test, ANOVA, Tukey's test and Spearman's rank correlation.

Results: We studied 28 patients with DSS (32% early and 68% late) and 32 healthy controls (47.5+/-10 y 48+/-7 years old respectively, p=ns). DSS patients showed higher concentrations of MDA (17.6+/-8.6 versus 6.58+/-3.59 nmol/mg free fatty acids, p<0.01), dityrosines (530.6+/-149.7 versus 132.76+/-48.6 pmol/mg proteína, p<0.01), protein carbonyls (1.75+/-0.39 versus 0.68 +/- 0.47 nmol/mg protein, p<0.01) and formazan (17.2+/-3.46 versus 10.2 +/-2.79 nmol/mg protein, p<0.01) compared to healthy people respectively. Compared with control subjects, DSS patients had lower CAPT (0.64+/- 0.095 U versus -2.7+/-0.96 U, p<0.001). There were no significant differences between early and late DSS or among target organs.

Conclusion: Biomarkers concentrations of oxidative stress to lipids and proteins in plasma were in all cases significantly higher in DSS patients than healthy controls. The treatment with anti-oxidants may be important in these patients

High-Resolution 18 MHz Ultrasonography(US) of Carpal Tunnel Syndrome (CTS) in Systemic Sclerosis (SSc). Francesca Bandinelli[1], Olga Kaloudi[1], Irene Miniati[1], Maria Letizia Conforti[1], Antonio Candelieri[2], Daniela Melchiorre[1] and Marco Matucci-Cerinic[1], [1]University of Florence, Italy, Florence, Italy, [2]University of Calabria, Italy, Italy

Purpose: To evaluate with ultrasound (US) tunnel carpal syndrome (TCS) in Systemic sclerosis (SSc) patients

Method: 64 SSc patients (55 women and 9 men, mean age 57±14 years) were consecutively studied by two observers with US of the carpal tunnel (My Lab 25 XVG US Esaote 18 MHz linear array transducer) and compared with 19 healthy controls. The median nerve cross-sectional area (MNA) and the transverse (MNT) and anteroposterior (MNAP) diameters were measured in the transverse plane at the proximal boundary of the carpal tunnel at the level of the pisiform bone (1). The Italian version of the Boston Carpal Tunnel Questionnaire (I-BCTQ) was used (2). Friction tendon rubs of flexor tendons and Tinel sign were verified clinically and with US. The following was also collected: duration of disease, subset (limited, diffuse), clinical phase (oedematous, fibrotic, atrophic), and modified Rodnan skin score. EMG was performed in 50 patients (distal motor latency and sensory conduction velocity from the third and fourth fingers to the wrist for median nerve).

Results: MNA (11,1±3,6 mm^2, $p<0,001$) and MNT (6,8±1,6 mm $p<0,005$) were significantly higher in SSc, while no difference in MNAP was found. Intraobserver and interobserver agreement was high (interclass correlation coefficient 0,9). MNT correlated positively with BCTQ ($p<0,05$, Pearson coefficient 0,3). No significant difference of median nerve US area and diameters was observed between Tinel test positive and negative patients. There was no correlation between median nerve and subset, clinical phase, and skin score. Only lower MNAP correlated inversely with longer disease duration ($p<0,05$, Spearman coefficient -0,2). 20/50 patients (40%) had EMG positive for STC and all US values were significantly higher in patients with EMG positive for TCS ($P<0,001$). In two cases only friction rubs of the flexor tendons were detected, and only one was positive at EMG.

Conclusion: US is a sensitive tool that identifies detailed investigation of median nerve in all phases of SSc.

1717

Predicting Lung Function Decline in Systemic Sclerosis. Shikha Mittoo[1], Keng Wong[1], David B. Robinson[2], Marie Hudson[3], Csrg and Murray Baron[4], [1]University of Manitoba, Winnipeg, MB, [2]University of Manitoba, Winnipeg, [3]McGill University and Jewish General Hospital, Montreal, QC, [4]Jewish General Hospital, Montreal, QC

Purpose: Lung involvement is a common and lead cause of mortality in systemic sclerosis (SSc), but progression to end-stage restrictive lung disease is variable and predictors of rapidly progressive lung function decline are unknown. As treatment for lung disease carries significant toxicity, there is a pressing need for biomarkers to predict which patients are most likely to suffer a rapid decline. Surfactant-D (SP-D), a glycoprotein expressed in lung airways, indicates early lung damage and correlates with lung function in SSc. It is not known if SP-D levels correlate with the rate of change in lung function and predicts a rapid decline in lung function.

Methods: Baseline serum from SSc patients enrolled in a multi-center cohort who had at least 2 pulmonary function tests (PFTs), separated by a year, was analyzed for SP-D levels by ELISA. Levels were correlated with: (1) the annual rate of change in percent (%) predicted forced vital capacity (FVC) and % predicted carbon monoxide diffusing capacity (DLCO) on PFT and (2) a rapid decline in lung function (rapid progressors), defined as an annual rate of decline in % predicted FVC at a rate two fold faster than the general population (>2%/year). Values reported as mean ± SD.

Results: Of 67 SSc patients with an age of 54.5 ± 12.1 years, disease duration of 8.6 ± 7.3 years, 88% were women, 90% Caucasian, and 36% current smokers. Forty diffuse and 27 limited cutaneous SSc subtype had serial PFTs with a duration between PFTs of 32.7 ± 11.7 months; 18 and 17 had positive anti-centromere and anti-Scl 70 antibodies, respectively. No patient was on cyclophosphamide at baseline. The % predicted FVC and DLCO at baseline was 94.2 ± 26.8 % and 71.8 ± 23.0 %, respectively. The annual rate of change in % predicted FVC and DLCO was -2.9 ± 13.4 %/year and -3.3± 7.7 %/year, respectively; 63% were rapid progressors. SP-D levels among rapid progressors were significantly higher than levels in non-rapid progressors (237.9 ± 176.7 ng/mL and 173.5 ± 95.1ng/mL, respectively,p=0.02).
A significant, inverse correlation between SP-D level with annual rate of change in % predicted FVC (r=-0.27, p=0.03), but not with DLCO, was observed. SP-D significantly predicted rapid progressors (p=0.03). Age, gender, disease duration, anti-Scl 70 antibody status, smoking status, SSc subtype, presence of restrictive lung disease, or radiographic findings of pulmonary fibrosis were not associated with rapid progressors. Adjusting for age, smoking status, disease duration, SP-D, and SSc subtype, SP-D [OR=1.5 per 100 ng/mL, 95% CI of 1.09-1.10, p=0.02] and active smoking [OR=3.7, 95% CI of 1.008-13.4, p=0.05] were significantly associated with rapid progressors.

Conclusion: Baseline SP-D levels significantly correlate with the annual rate of decline in % predicted FVC. SP-D levels and current smoking predicts a rapid decline in lung function. SP-D may be useful to identify a high risk group of SSc patients for close monitoring and therapeutic intervention.

Effectiveness of a Multidisciplinary Treatment Program in Comparison with Usual Care in Patients with Systemic Sclerosis. A.A. Schouffoer[1], M.K. Ninaber[2], F.J. van der Giesen[1], A.J.M. Schuerwegh[3], L.J. Beaart-van de Voorde[1], Z. de Jong[1], J. Stolk[2], A.E Voskuyl[4], J.M. van Laar[5] and T.P.M. Vliet Vlieland[3], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Newcastle University, Newcastle, United Kingdom

Purpose: In many rheumatic conditions the effectiveness of multidisciplinary team care has been established, however in systemic sclerosis (SSc) the evidence is scanty. The aim of this study was to compare a multidisciplinary treatment program with usual outpatient care in patients with SSc.

Methods: Patients with limited or diffuse SSc, stable medication over the past 2 months and no pulmonary or cardiac contra-indications for aerobic exercises were randomly assigned to a multidisciplinary day treatment program (2 days per week, 12 weeks, with individual treatments and group exercises and education) or usual outpatient care. Assessments were done at baseline, 12 and 24 weeks. Primary outcome measures were the 6-minute walk test and the Physical Component Summary Scale of the SF-36 (PCSS). Secondary outcome measures were maximal oxygen consumption during bicycle exercise test (VO2max), SSc-HAQ (Health Assessment Questionnaire), and the Mental Component Summery Scale of the SF-36 (MCSS).

Results: Fifty-three patients were randomised (28 intervention and 25 control). Thirty patients (57%) had diffuse SSc, the mean age was 53.4 yrs (SD 10.6), the mean disease duration was 8.3 yrs (SD 7.5) and the mean Modified Rodnan Skin Score 5.1 (SD 5.1). Drop-out rates were 4 (14%) in the intervention and 3 (12%) in the control groups after 24 weeks. At 12 weeks, the improvements of the 6 minute walk test and HAQ score were significantly greater in the intervention group than in the control group (6 minute walk test mean 42.9 m (95% confidence interval 22.1, 63.6) versus 3.9 (-20.8, 28.5) meter, p=0.015; HAQ -0.18 (-0.36, -0.01) versus +0.13 (-0.02, 0.27), p=0.003). For all other outcome measures, the 12 and 24 weeks change scores did not differ significantly between the two groups.

Conclusion: A multidisciplinary treatment program in SSc improved physical functioning more than usual outpatient care in patients with SSc. This emphasises the importance of rehabilitation in systemic sclerosis.

1719

Clinical Significance of Anti-RNA Polymerase III Antibodies in A Cohort of Patients From the Australian Scleroderma Screening Program (ASSP) Database. Maree E. Micallef[1], Pravin Hissaria[2], Susanna M. Proudman[2], Jillian Byron[1], William Paspaliaris[1], Joanne Sahhar[3], P. Nash[4], Allan D. Sturgess[5] and Wendy Stevens[1], [1]St Vincent's Hospital, Melbourne, Australia, [2]Royal Adelaide Hospital, Adelaide, Australia, [3]Monash Medical Centre, Melbourne, Australia, [4]University of Queensland, Brisbane, Australia, [5]St George Hospital, Sydney, Australia

Purpose: Anti-RNA polymerase III antibodies (anti-RNAP Abs), detectable in up to 25% of patients with systemic sclerosis (SSc), may define a novel subset of patients with severe cutaneous disease and an increased risk of renal hypertensive crisis. This is the first time the clinical associations of this Ab have been examined in an Australian population. We examined the prevalence and clinical variables associated with anti-RNAP Abs in a cohort of patients from the Australian Scleroderma Screening Program (ASSP) Database, a national prospective on-line electronic registry of clinical, laboratory and investigational parameters related to SSc and MCTD.

Method: Review of patients from the ASSP Database tested for anti-RNAP Abs, since 2007. Anti-RNAP was measured using a commercially available ELISA kit (Quanta Lite RNA Pol III-Integrated Sciences) and compared with anti-Scl70 Ab.

Results: Of the 714 patients on the ASSP database, 219 were tested for anti-RNAP Abs and 36 (16%) were positive. These patients were more likely than RNAP negative patients to have diffuse (dcSSc) than limited (lcSSc) cutaneous disease (72% cf 28% $p<0.001$), higher mean Rodnan skin scores (20 cf 10, $p<0.001$), more joint contractures (66% cf 22%, $p<0.001$), more hypertension (56% cf 32%, $p<0.01$), and more suspected or proven renal crisis (18% cf 2%, $p<0.001$). In the subset of patients with dcSS, anti-RNAP Abs were associated with higher mean skin scores (23 cf 18, $p <0.05$), joint contractures (81% cf 48%, $p<0.05$) and hypertension (54% cf 26%, $p<0.05$), suggesting additional risk beyond that seen in patients with dcSSc subtype alone. 215 of the 219 patients were also tested for anti-Scl70 Ab. 44(20%) were positive, 53% had dcSSc and 45% lcSSc. Anti-RNAP Ab positive patients compared to anti-Scl70 Ab positive patients had higher mean Rodnan skin scores (20 cf 14), more joint contractures (67% cf 45%), hypertension (56% cf 34%) and suspected or proven renal crisis (18% cf 2%). Only 1 patient was positive for both anti-RNAP and anti-Scl70 Ab.

Conclusion: The ASSP Database results support findings from previous studies showing an association between RNAP Ab positivity and severe skin and renal disease. Our results suggest the risk is above that seen with diffuse disease subtype or anti-Scl-70 Ab alone. ELISA testing for anti-RNAP Abs may therefore be useful to predict those at risk of severe skin and renal disease.

Lower Extremity Ulcers in Systemic Sclerosis: Features and Response to Therapy. Victoria K. Shanmugam, Christopher E. Attinger and Virginia D. Steen, Georgetown University Medical Center, Washington, DC

Purpose: Lower extremity ulcers are a recognized complication of scleroderma but their prevalence and etiology are unknown. We report the features of a series of 12 scleroderma patients with lower extremity ulcers and estimate the prevalence of this complication.

Methods: The Connective Tissue Disease Leg Ulcer Etiology (CLUE) study is a prospective observational study. Between August 2007 and April 2009, 7 scleroderma patients were evaluated in the CLUE study, and during the same time period, 249 scleroderma patients were seen in the rheumatology clinic, 2 of whom also had leg ulcers. Prior to August 2007, an additional 3 patients with leg ulcers and scleroderma had been evaluated, but have since been lost to follow-up. The clinical and laboratory features of all 12 patients and the outcomes of the 7 patients in the CLUE study are reported.

Results: In a cohort of 249 scleroderma patients evaluated over a 21-month period, 9 had active leg ulcers, giving a prevalence of 3.6%. Of the 12 patients reported, only 3 had diffuse disease; 7 had limited scleroderma, and 2 had scleroderma sine scleroderma. The demographic distribution reflects that seen in our scleroderma population (75% female, 83% Caucasian). Ulcers were bilateral in 91%. The mean age at first ulcer was 59.33 years. The mean disease duration at the time of ulcer development was 16.78 years (range 2-46). However, patients with diffuse scleroderma had shorter disease duration prior to ulcer development (mean 3.33 years +/-0.67) compared to limited scleroderma

(mean 23.50 years +/-4.82, p value 0.02). Anti-centromere antibody was positive in 4 of the 7 patients with clinically limited disease. Biopsy specimens were available in 7 cases, and the most common finding was vasculopathic changes with fibrin plugging.

The prevalence of antiphospholipid antibodies in scleroderma is approximately 19%; however, 5 of the 7 patients reported here had positive antiphospholipid antibodies (71%). Genetic procoagulant work up was completed in 7 patients; 5 had heterozygous MTHFR gene mutation, 3 had heterozygous and 1 homozygous plasminogen activator inhibitor-1 gene mutation. Factor V leiden and prothrombin gene mutations were not seen in any of the patients tested.

Healing was seen within 3 months in 2 patients with high antiphospholipid antibody titers treated with low-dose low-molecular-weight-heparin (enoxaparin 40mg daily); however, 2 other patients with lower antibody titers did not respond. One of these refractory patients was subsequently successfully treated with recombinant erythropoietin. Another patient healed following arterioplasty, and the remaining 2 patients have had continued refractory lesions and have been unable to get insurance approval for either medication.

Conclusion: The prevalence of lower extremity ulcers in scleroderma is 3.6%, and antiphospholipid antibodies may have a role in their pathogenesis. We propose that scleroderma patients who develop leg ulcers should be evaluated for anti-phospholipid antibodies, and if present a trial of low-molecular-weight-heparin is warranted.

High Frequency Ultrasound Measurement of Digital Dermal Thickness in Systemic Sclerosis (SSc). Olga Kaloudi[1], Francesca Bandinelli[1], Emilio Filippucci[2], Maria Letizia Conforti[1], Irene Miniati[1], Serena Guiducci[1], Antonio Candelieri[3], Domenico Conforti[3], Walter Grassi[4] and Marco Matucci Cerinic[1], [1]University of Florence, Italy, Florence, Italy, [2]Università Politecnica delle Marche, Ancona, Italy, [3]University of Calabria, Italy, [4]Rheumatology Department, Jesi, Ancona, Italy

Purpose: In SSc, measurement of dermal thickness is essential to identify the disease subset and the prognosis of the disease and is currently performed by palpation with the modified Rodnan Skin Score (mRSS). The purpose of this study is to verify if high frequency ultrasound (US) may be a reliable and a reproducible method to measure digital dermal thickness.

Method: In 80 SSc patients, skin thickness and echogenicity were evaluated with US by two observers in two different sites (1.5 cm over the dorsal aspect of the proximal phalanx and 1cm over the dorsal aspect of the distal phalanx) of the second digit of the dominant limb to determine the inter-observer variability. Patients and controls were examined twice by the first observer for intra-observer variability. Patients were divided into three subgroups according to (oedematous, fibrotic and atrophic) skin involvement. US measurements of dermal thickness were compared with local and systemic mRSS.

Results: At both examined areas, US showed a significant dermal thickening ($p<0,001$) in all SSc patients. A low intra- and inter-observer variability of US measurements was found (ICC: 0.960 for site 1 and ICC: 0.917 for site 2) and (ICC: 0.969 for site 1 and ICC: 0.924 for site 2) . A highly significant correlation between the global mRSS and the digital dermal thickness at the two examined sites (p:0.032 and p:0.021, respectively) was detected. No correlation was found between US and local digital mRSS. Skin thickness resulted significantly higher in the oedematous than in the fibrotic group ($p<0.001$) and significantly higher in the fibrotic and the oedematous group ($p<0.001$) than in the atrophic group ($p<0.002$), respectively.

Conclusion: US is a reliable and reproducible tool, able to detect digital dermal thickening in SSc. In the future, US may become a reliable outcome measure in clinical trials.

Assessment of Skin Involvement in Systemic Sclerosis (SSc) with Ultrasound Elastography. Annamaria Iagnocco[1], Chiara Perella[1], Valeria Riccieri[1], Olga Kaloudi[2], Francesca Bandinelli[2], Francesco Porta[2], Guido Valesini[1] and Marco Matucci Cerinic[2], [1]Cattedra di Reumatologia, Dip Clinica e Terapia Medica, Sapienza Università di Roma, Roma, Italy, [2]University of Florence, Italy, Florence, Italy

Purpose: Excessive dermal deposition of collagen and changes in the architecture of connective tissue components are hallmarks of SSc that is characterised by reduced dermal elasticity due to tissue thickness and fibrosis. A new tool able to correlate tissue US imaging with tissue structure and/or pathology, namely US elastography (UE), has been used to assess skin elasticity in SSc.

Method: 18 consecutive SSc patients (mean age 58.8 years) and 15 healthy controls (mean age 29.8 years) were studied. Each UE exam was performed separately by two blinded sonographers who repeated each single exam twice and each evaluation was then repeated, after an interval of 4 weeks, up to calculate intra- and inter- observer reliability. Modified Rodnan skin score, physical examination and assessment of organ involvement were performed. UE was performed on the middle forearm and on the fingers. The echo signals captured in real-time during free-hand operations of probe compression and relaxation produced images representative of tissue elasticity, consisting in translucent coloured bands superimposed on the B-mode images. The colour scale varied within a large band-spectrum from red, indicative of a soft and highly elastic tissue, to blue, which denoted a hard and scarcely elastic one.

Results: On the forearm of all patients, UE showed a homogeneous blue area corresponding to the dermis visualized in B-mode image; in controls, a blue pattern was never detected and a predominance of green with sporadic areas of pale blue was observed. At sequential evaluations UE of fingers produced inconstant and changeable coloured areas, this might be due to the reduced presence of tissue and the prevalent bony component within the elastographic field. The overall inter-observer sonographers agreement and the intra-observer reliability, for patients and controls, resulted always of 100%

Conclusion: The imaging pattern observed in the forearm of SSc patients may represent the reduction of strain in the dermis due to loss of elasticity. The finger evaluation instead was not reliable for the measurement of skin elasticity. UE may evaluate skin involvement in SSc in areas where the dermis is highly expressed and where the bone hyperreflection is minimal. Further studies and in particular, correlations with histopathologic findings, are needed to confirm our results and determine the criterion validity of this new imaging modality.

Endothelial-Dependent Flow Mediated Dilation of the Brachial Artery Correlates with Nailfold Microvascular Involvement and Identifies Endothelial Dysfunction in Systemic Sclerosis. Daniela Rollando[1], Alberto Sulli[2], Gian Paolo Bezante[1], Maurizio Cutolo[2], Claudio Brunelli[1], Francesco Indiveri[3] and Massimo Ghio[3], [1]Unit of Cardiology, Genova, Italy, [2]Research Laboratory and Academic Unit of Clinical Rheumatology, Genova, Italy, [3]Unit of Clinical Immunology and Internal Medicine, Genova, Italy

Purpose: Vascular impairment is one of the main features in the pathogenesis of systemic sclerosis (SSc), and it is detectable in the early phase of the disease. Recent evidences show that SSc vascular impairment might be considered as a consequence of the endothelial cell dysfunction, involving both macro- and microvascular systems. The aim of the study was to assess possible correlations between endothelial-dependent flow mediated dilation of the brachial artery (FMD) and nailfold microvascular involvement as evaluated by nailfold videocapillaroscopy (NVC) in SSc patients.

Method: Forty-seven consecutive patients (mean age 51.0±10.8SD years) affected by SSc were studied. Twenty-four patients were suffering from limited cutaneous SSc (lcSSc) and 13 were complaining of diffuse cutaneous SSc (dcSSc). Twenty-seven healthy subjects (mean age 48.0±8.4) were recruited as controls. Ultrasound assessment of FMD, was performed in all subjects in order to evaluate macrovascular function (1). Following the NVC analysis the patients were divided into three different patterns of microvascular damage (“Early”, “Active” and “Late”), and the microangiopathy evolution score (MES) was calculated, as previously reported (2,3). Statistical analysis was carried out by non parametric tests.

Results: FMD was significantly reduced in SSc patients compared to the healthy subjects (median 6% vs 16% respectively, $p<0.0001$). Moreover, FMD was significantly reduced in SSc patients with the Late NVC pattern of microangiopathy (median 3.0%) when compared to Active and Early patterns (median 8.6% and 9.4% respectively) ($p=0.03$ and $p=0.05$, respectively). A negative correlation between FMD and MES was found in SSc patient ($p=0.04$). No statistically significant difference concerning the FMD was observed between patients with lcSSc and dcSSc (median 6.0% and 5.4% respectively).

Conclusion: A correlation between macro- and microvascular dysfunction in SSc patients seems evident, and the endothelial function impairment is suggested as the common pathway.

The Prevalence of Sicca Symptoms and Sjogren's Syndrome of Patients with Systemic Sclerosis. Gercek Can[1], Sulen Sarioglu[2], Merih Birlik[3], Ozgul Soysal[1], Vedat Gerdan[1], Dilek Solmaz[1], Fatos Onen[4], Nurullah Akkoc[5] and Servet Akar[4], [1]Dokuz Eylül University Faculty of Medicine, Izmir, Turkey, [2]Dokuz Eylül University Faculty of Medicine, Pathology Department, Turkey, [3]Dokuz Eylül University Faculty of Medicine, Istanbul, Turkey, [4]Turkish Takayasu's Arteritis Study Group, Istanbul, Turkey, [5]Dokuz Eylül University, Istanbul, Turkey

Purpose: Systemic sclerosis (SSc) is a heterogeneous systemic disorder that is characterized by massive deposition of collagen and other matrix substances in connective tissue.Sicca symptoms are thought to be a frequent complaint associated with SSc although little is known about how often they occur.The aim of this study was to determine the prevalence and contributing factors of sicca symptoms and Sjogren's syndrome (SS) in patients with SSc.

Method: *C*onsecutive *79* SSc patients [71 female(90%), mean age 53,17 ± 10,773)]followed by an outpatient rheumatology clinic at a university hospital in Izmir, a city located in western Turkey were included in the study.All of the patients fulfilled the criteria proposed by the American College of Rheumatology for the classification of SSc.The patients were evaluated for sicca symptoms.The systematic first-line clinical evaluation included a questionnaire specific for the subjective presence of xerophthalmia and xerostomia,based on the revised American–European Consensus Group criteria for SS, together with the Schirmer I test and unstimulated whole salivary flow.If the findings of the first-line clinical evaluation were positive a labial salivary gland biopsy was performed.The presence of focal lymphocytic sialadenitis with a focus score ≥ 1 was necessary for a diagnosis of SS. Glandular fibrosis was also evaluated.Routine blood tests and serologic analysis for antinuclear antibody (ANA) and extractable nuclear antigens (ENA) were performed.

Results: Of 79 patients,64 (83%) had limited SSc(lcSSc),9(%12) diffuse SSc (dcSSc),and 4(5%) had sine scleroderma.The most common type of ANA detected was homogenous pattern (48%).The other antinuclear and ENA types identified included centromeric(38%), nucleolar(3%),scl-70 (42%),SSA alone or combination with another ENA(5.6%).Fifty-seven patients(72,2%) had sicca syndrome(50[63,3%] had xerostomia, and 40[50,6%] had xerophthalmia).Forty-one of the 79 patients (62%) had positive findings on the Schirmer test and 27(34%) patients had positive salivary flow test.A total salivary gland biopsy was indicated in 70 patients according to our study protocol.Three patients refused the procedure therefore biopsy were performed sixty-seven (85%) patients.On histopathologic examination of biopsy samples; fibrotic lesion were observed in 56 out of 67 (84%) and in 30 (45%) focus score was ≥1.Fifteen patients (19%) fulfilled American European Consensus Group criteria for SS.Fourteen patients who diagnosed SS had lcSSc and one of them had sine scleroderma.

Conclusion: Despite fibrosis seems to be main cause of sicca symptoms our study showed one of the highest prevalence of SS in patients with SSc.These results suggest that limited cutaneous subtype of SSc carries a greater risk for SS.

Lymphatic Vessels Are Decreased in Patients with Systemic Sclerosis and Correlate Inversely with Fingertip Ulcers. Alfiya Akhmetshina[1], Jürgen Beer[1], Matthias Englbrecht[2], Karin Polzer[1], Clara Dees[1], Nicole Busch[1], Oliver Distler[3], Georg Schett[4] and Jörg HW Distler[1], [1]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [2]Dep Int Med 3, Univ Erlangen, Erlangen, Germany, [3]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [4]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: Systemic sclerosis (SSc) is a connective tissue disease with progressive vascular manifestations. The irregular architecture and the reduced capillary density are major hallmarks in microvasculature of the blood vascular system. However, the lymphatic vessel (LV) system has not been studied in SSc.

The aim of the present study was to analyze, whether the LV system is affected in SSc patients and whether potential alterations of the LV are associated was dystrophic changes and tissue damage in SSc.

Method: Skin biopsies from SSc patients (n = 27) and from age and sex matched healthy volunteers (n = 20) were analyzed by immunohistochemistry (IHC). Antibodies against podoplanin and prox-1 were used to detect specifically lymphatic endothelial cells and discriminate between LV and blood vessels. CD31 was used as pan-endothelial marker. Statistical analysis was performed using Kruskal-Wallis, Mann-Whitney-U and Spearman's Rank Correlation tests.

Results: The numbers of LV were significantly reduced in SSc. The mean count of podoplanin positive LV in SSc patients was 0.6 ± 0.1 / high power field (HPF) in SSc patients versus 1.9 ± 0.3 / HPF in healthy individuals ($p < 0.001$). Consistent with the findings obtained for podoplanin, the number of prox-1 positive LV was also significantly reduced. Further analysis demonstrated that the reduction of lymphatic precollector vessels was more pronounced than the reduction of lymphatic capillaries (84 ± 17 % and 49 ± 10 %, respectively, compared to healthy individuals). Of note, the number of podoplanin positive precollector LV were significantly lower in SSc patients with fingertip ulcers than in SSc patients without fingertip ulcers ($p = 0.03$). The number of positive LV both podoplanin and prox-1correlated inversely with the number of ulcers at the time of biopsy and the number of ulcers per year ($r = - 0.75/ p < 0.001$ and $r = -0.51/ p = 0.04$, respectively). The inverse correlation between LV counts and the number of fingertip ulcers remained significant after statistical control for blood vessel count, age and mRSS, indicating that lymphangiopathy is an independent risk factor for fingertip ulcers in SSc.

Conclusion: The present study demonstrates for the first time a lymphangiopathy with a severe reduction of lymphatic capillaries and lymphatic precollector vessel in patients with SSc. We show that patients with decreased LV counts are of particular high risk to develop fingertip ulcers. We also present evidence that the lymphangiopathy is an independent risk factor for fingertip ulcers in SSc patients.

Faecal Incontinence in Systemic Sclerosis Is Related to Neuropathy. Nora M. Thoua[1], Alastair Forbes[1], Christopher P. Denton[2] and Anton V. Emmanuel[1], [1]University College London Hospital, London, United Kingdom, [2]UCL Medical School, London, United Kingdom

Purpose: Systemic sclerosis (SSc) is an autoimmune disorder which can affect multiple organs. The gastrointestinal (GI) tract is affected in up to 90% of patients. The pathogenesis of gastrointestinal abnormalities may be both myogenic and neurogenic. While anorectal involvement occurs in up to 50% of patients, studies have not reliably shown correlation between manometric findings and clinical symptoms.

Method: 44 SSc patients referred to a tertiary referral centre were studied: 24 patients (21 female, mean age 58) with faecal incontinence and other lower GI symptoms (Sx), and 20 (20 female, mean age 61) with no or minimal lower GI symptoms (ASx). Mean disease duration in Sx and ASx groups were 12 and 8 years respectively (p=NS). Patients underwent anorectal manometry, endoanal ultrasound (EAUS), rectal mucosal blood flow (RMBF), rectal compliance (barostat) and rectoanal inhibitory reflex assessment.

Results: (Mean and 95% CI)

Wexner incontinence scores (Sx 11 [9-13] vs ASx 2 [1-4]; $p<0.0001$) and constipation scores (Sx 10 [8-12] vs ASx 4 [2-6]; $p=0.0001$) were significantly different between the 2 groups. Anal pressures, RMBF and rectal compliance did not differ between groups. However anal sensation, not rectal sensation, was significantly attenuated in Sx patients (see table). The RAIR was absent in 11/24 Sx patients but only 2/20 ASx. There was a positive correlation between anal sensory thresholds and incontinence ($r=0.59$; $p<0.001$) and constipation scores ($r=0.46$; $p=0.0015$). IAS atrophy was evident in 75% of Sx patients and 40% of ASx patients.

Conclusion: Anorectal symptoms in SSc are mainly related to neuropathy as suggested by absent RAIR and higher anal sensory threshold and less so to sphincter atrophy and rectal fibrosis. This raises the possibility that sacral neuromodulation may be an option for some minimally symptomatic SSc patients with latent neuropathy.

	Sx – mean (95% CI)	**ASx – mean (95% CI)**	**p value**
Resting pressure (cmH20)	51 (41-61)	64 (54-74)	p=0.07
Squeeze pressure (cmH20)	121 (101-142)	105 (81-128)	p=0.26
Rectal compliance (ml/mmHg)	10.6 (8.8-12.5)	10.9 (9.1-12.7)	p=0.82
RMBF (flux units)	150 (124-177)	158 (134-183)	p=0.64
Anal sensation (mA)	10.4 (8.8-12)	6.7 (5.7-7.7)	**p=0.0003**
Rectal sensation (mA)	24.4 (20.4-28.4)	19.7 (15.5-24)	p=0.1

Histologic and Molecular Basis of Improved Skin Scores in Scleroderma Patients Treated with Imatinib Mesylate (Gleevec). Jessica Gordon[1], S. Vukelic[1], C.M. Magro[2], Jamie Mersten[1], H. F. Wildman[2], M. K. Crow[1], K. A. Kirou[1] and R.F. Spiera[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medical College, New York, NY

Purpose: Imatinib mesylate is a tyrosine kinase inhibitor with activity against the profibrotic effects of TGF-β and PDGF in animal models and in vitro human studies. It is under investigation for the treatment of Diffuse Cutaneous Systemic Sclerosis (dcSSc), and preliminary results show improvement in skin thickness as assessed by the Modified Rodnan Skin Score (MRSS). To investigate the histologic and molecular basis of the improved skin scores, we assessed skin samples from dcSSc patients prior to and after imatinib treatment.

Methods: Four consecutive patients in the Gleevec in Systemic Sclerosis clinical trial at our institution were selected for review of dermatopathology. 4-mm punch biopsies of lesional forearm skin were taken before and after treatment with imatinib 400 mg po daily for 12 months. The post-treatment biopsy was taken 1 cm adjacent to the original biopsy site. Histologic analysis included staining with H & E, Masson's trichrome for collagen, anti-α-smooth muscle actin (SMA) for activated myofibroblasts, and anti-procollagen. To quantify procollagen production, real time polymerase chain reaction (RT-PCR) was performed on cDNA prepared from skin specimens.

Results: The patients are described in the table below. All prebiopsy specimens were similar in appearance showing pandermal sclerosis with a paucity of adnexal structures and increased dermal thickness, as is typical for dcSSc. Collagen bundles showed loss of fibrillar architecture without discernible interstitial space. 3 of 4 post-treatment specimens showed improvement in pandermal sclerosis with narrower caliber collagen bundles and increased space between the collagen bundles. The quantity of adnexal structures in the skin increased in 3 of 4 specimens. Skin thickness decreased in 1 specimen, from 2.45 mm to 1.9 mm, and α-SMA staining decreased in 2 of 4 specimens. Procollagen I staining decreased in intensity in 2/3 patients, an observation supported by RT-PCR analysis of collagen 1α2 expression, which decreased by a mean of 45%.

Conclusion: Treatment of dcSSc patients with imatinib for one year was associated with decreased collagen production and histologic improvement in 3 of 4 patients, corresponding to clinical improvement as assessed by MRSS. These results support further characterization of the effects of imatinib on fibrotic skin in dcSSc and suggest that this agent alters the underlying molecular basis of skin fibrosis in this disease.

Patient	Disease Duration - years	MRSS before	MRSS after 12 Months Imatinib	Change on H&E	% decrease col1a2 expression
A	2	19	10	+	- 70

B	5.5	41	29	+	- 59
C	1.5	23	18	-	- 3
D	0.5	24	15	+	- 48

1728

Gastrointestinal Involvement in Systemic Sclerosis Leads to a Wide Range of Symptoms and a Significant Effect On Quality of Life.

Nora M. Thoua[1], Catey Bunce[2], Geraldine Brough[3], Alastair Forbes[1], Anton V. Emmanuel[1] and Christopher P. Denton[3], [1]University College London Hospital, London, United Kingdom, [2]Moorfields Eye Hospital, London, United Kingdom, [3]UCL Medical School, London, United Kingdom

Purpose: The gastrointestinal tract (GIT) is affected in up to 90% of patients with systemic sclerosis (SSc). Although the most commonly affected site is the oesophagus, the extent as well as the severity of GIT involvement may vary. GIT involvement may be associated with significant morbidity and in severe cases mortality. With improved survival from cardiopulmonary and renal involvement, gastrointestinal symptoms are becoming more prominent. The im of this study was to establish the frequency and range of GI symptoms in SSc patients at the Royal Free Hospital, a tertiary referral centre.

Method: We used a 52-item, previously validated (Khanna *et al*), questionnaire to capture SSc-related gut dysfunction. The questionnaire assesses the *frequency* of 5 categories of symptoms (reflux, distension, diarrhoea, constipation, abdominal pain) and their *impact* on social functioning and emotional well-being during the previous week. The questionnaire was given to consecutive patients with SSc attending the rheumatology outpatient department. Incomplete questionnaires were excluded from analysis. Patients' notes were reviewed to establish disease subtype, autoantibody profile and other internal organ involvement.

Results: We collected 402 completed questionnaires (357 females; mean age 55, range 18-82). 69% of patients had lcSSc and 30% dcSSc with mean disease duration of 11 years. Mean questionnaire scores showed that patients have a wide range of GI symptoms. 83% of patients were taking medication for GI symptoms despite which 94% reported upper and 79% lower GI symptoms. Only 3% of patients reported no symptoms, and 10% reported daily symptoms. 28% reported significant adverse effect on emotional well being. There was no association between disease subtype or autoantibody profile and GI symptoms. There was a positive correlation between diarrhoea scores (high scores = best health) and pulmonary fibrosis ($r=0.134$, $p=0.0068$), suggesting that patients with lung fibrosis were less likely to have diarrhoea. No other association between GI symptoms and other internal organ involvement was found.

Conclusion: GI symptoms, both upper and lower, are common in patients with SSc and have a significant effect on quality of life. Patients should be asked specifically about GI symptoms as they may be under-reported and therefore under-treated. GI focused questionnaire is an effective way to assess gut symptoms and adjust treatment.

Joint Involvement and Relationships with Systemic Inflammation in the EULAR Scleroderma Trial and Research Group (EUSTAR) Database of Systemic Sclerosis Patients. Jérôme Avouac[1], Ulrich A. Walker[2], Alan Tyndall[3], A. Kahan[4], Marco Matucci-Cerinic[5] and Yannick Allanore[6], [1]Université Paris Descartes; Hôpital Cochin, Service de Rhumatologie A, Paris, France, [2]Felix Platter Spital, Basel, Switzerland, [3]Department of Rheumatology, Basel, Switzerland, [4]Rheumatology A, Cochin Hospital, Paris Cedex 14, France, [5]University of Florence, Firenze, Italy, [6]Paris Descartes Univ, Paris, France

Background: Articular structures may be involved in systemic sclerosis (SSc), causing functional disability. The precise prevalence of clinical articular manifestations has not been accurately defined in a large population of SSc patients.

Purpose: To determine the prevalence of, and independent factors associated with joint involvement in a large population of patients with SSc.

Methods: We queried the EUSTAR database to extract data regarding global evaluation of SSc patients and presence or not of any clinical articular involvement: synovitis (defined by inflammation of the synovial membrane leading to pain and swelling), joint contractures (resulting from joint destruction turning into ankylosis and fibrotic changes in the skin) and tendon friction rubs (defined by tendonitis characterised by fibrosis of the tendon sheaths). Overall joint involvement was defined by the occurrence of synovitis and/or joint contracture and/or tendon friction rubs. We recruited 7286 SSc patients (86% of whom were women); the mean ± SD age was 56±14 years old, the mean ±SD disease duration was 10±29 years and 4210 (58%) had a limited cutaneous subtype.

Results: The point prevalence of joint involvement was 58%: the frequencies of synovitis, joint contractures and tendon friction rubs were 16%, 31% and 11%, respectively. In multivariate stepwise regression, overall joint involvement was associated with the following items, provided in table 1.

Table 1

	Multivariate analysis (stepwise regression) Odds ratio (95% Confidence Interval, CI)
Diffuse Cutaneous subtype	1.84 (1.62-2.10)
Digital ulcers	1.80 (1.60-2.03)
Elevated acute phase reactants	1.66 (1.46-1.88)
Muscle weakness	1.65 (1.45-1.87)
Elevated systolic pulmonary artery pressure (>40 mmHg)	1.62 (1.42-1.84)
European disease activity score	1.40 (1.23-1.64)
Pulmonary fibrosis	1.14 (1.01-1.28)

Focusing on systemic inflammation, when elevated acute phase reactants were considered as the dependent variable, they were found highly associated with joint symptoms (OR: 2.21, 95% CI 1.77-2.77).

Conclusion: Our results highlight the striking level of articular involvement in SSc, as evaluated by systematic examination in the largest worldwide available cohort of patients. In addition, our data also show that synovitis, joint contracture and tendon friction rubs are associated with a more active and severe disease phenotype. Joint involvement also appeared to strikingly contributes to systemic inflammation. The prospective follow-up of this cohort is ongoing; it will allow to confirm the above associations and to assess articular involvement as a marker and a predictor of disease severity.

1730

An Analysis of Outcomes in Patients with Systemic Sclerosis- and Systemic Lupus Erythematosus-Associated Pulmonary Arterial Hypertension. Lorinda Chung[1], Juliana Liu[1], Lori Parsons[2], Paul M. Hassoun[3], Michael McGoon[4], David Badesch[5], Dave P. Miller[2], Mark R. Nicolls[1] and Roham T. Zamanian[1], [1]Stanford University, Palo Alto, CA, [2]ICON Clinical Research, San Francisco, CA, [3]Johns Hopkins University, Baltimore, MD, [4]Mayo Clinic, Rochester, MN, [5]University of Colorado, Denver, CO

Purpose: Patients with systemic sclerosis associated pulmonary arterial hypertension (SSc-APAH) have extremely poor outcomes with high mortality rates. A previous study indicated that SSc-APAH is associated with poorer survival than systemic lupus erythematosus (SLE)-APAH. To gain insight regarding pathophysiologic mechanisms responsible for differences between these two groups, their presentation and outcomes were compared.

Methods: The Registry to Evaluate Early and Long Term PAH Management (REVEAL) is a prospective registry of >3,000 patients with World Health Organization Class I pulmonary hypertension from 54 US centers. Kaplan-Meier curves were estimated for survival, freedom from hospitalization, and freedom from initiation of parenteral PAH therapy in patients with SSc-APAH vs. SLE-APAH from the time of enrollment. Differences in outcomes between the groups were assessed by the log-rank test. Multivariable Cox proportional hazards models were developed to assess the risk for poorer outcomes in patients with SSc-APAH, controlling for B-type natriuretic peptide (BNP) levels, diffusing capacity of carbon monoxide (DLCO), pulmonary vascular resistance (PVR), and renal insufficiency (investigator clinical judgment).

Results: Patients with SSc (302: 78 diffuse, 224 limited) had higher BNP levels than patients with SLE (105) with mean(SD) values of 471.2(889.5) vs. 288.0(349.4) pg/mL (p=0.03). DLCO was significantly lower in the SSc patients (43.2(16.6) vs. 52.6(19.1) % predicted, p=0.0003). Baseline mean pulmonary artery pressure and PVR were lower in the SSc group, (44.0(11.9) vs. 46.7(9.2) mmHg, p=0.03; 9.3(5.4) vs. 10.8(5.7) Wood units, p=0.01, respectively). Renal insufficiency was more common in the SSc patients, but this did not reach

statistical significance (8.4% vs. 4.8%, p=0.2). 1- and 2-year outcomes were as follows in the SSc vs. SLE groups: survival 85% and 74% vs. 94% and 84% (p=0.05) (Figure); freedom from hospitalization 69% and 59% vs. 77% and 56% (p=0.7); and freedom from parenteral therapy 91% and 90% vs. 96% and 88% (p=0.6). SLE patients were less likely to die than SSc patients (HR=0.57(0.33-1.0), p=0.05), but this difference was not statistically significant after adjusting for other variables (HR=0.77(0.43-1.4), p=0.38).

Conclusion: Analysis of the REVEAL Registry has demonstrated that poorer survival in patients with SSc compared with SLE-APAH can be explained by differences in clinical parameters, including BNP, DLCO, and renal insufficiency. Further research is necessary to investigate the pathophysiologic role of these markers in SSc-APAH.

A Two Year Prospective Study of Changes in Nailfold Capillary Architecture in Primary and Secondary Raynaud's Phenomenon.

Ariane L. Herrick[1], Tonia L. Moore[1], Andrea K. Murray[1], Andy Vail[1] and Christopher J. Taylor[2], [1]University of Manchester, Salford Royal Hospital, Salford, United Kingdom, [2]University of Manchester, United Kingdom

Purpose: Recent advances in nailfold capillaroscopy, including high magnification videocapillaroscopy and the ability to track change over time, allow non-invasive and detailed analysis of the abnormal capillary morphology which is a characteristic feature of systemic sclerosis [SSc]-spectrum disorders. We have developed software to allow automated measurements of microvessel architecture (width, intercapillary distance, tortuosity and derangement). The time period over which SSc-related microvascular derangement evolves is not currently known. The aim of this prospective study was to assess changes in nailfold capillary architecture over 2 years in different subgroups of patients with Raynaud's phenomenon.

Method: 26 healthy controls, 10 patients with primary Raynaud's phenomenon, 13 patients with undifferentiated connective tissue disease, 15 patients with diffuse cutaneous SSc and 80 patients with limited cutaneous SSc were studied at baseline and at 24 months. Their mean age was 53 years, range 20 to 84 years. 119 (83%) were female. Following acclimatisation for 20 minutes at room temperature (23^{o}C), the ring finger of the non-dominant hand was imaged with video microscopy at 300x magnification. Measurements were made using the automated analysis programme to give measures of capillary width, intercapillary distance, tortuosity (curliness) and derangement (variation in dominant direction of capillaries).

Results: Results for the 5 capillary measurements (4 automated) are summarised in the table. The P-value relates to non-parametric before-and-after testing excluding controls.

Measurement (all arbitrary units)	Baseline Median (IQR)	24 months Median (IQR)	p-value
Automated intercapillary distance*	25312 16851 to 46475	30289 18852 to 56666	0.005
Width	13.8 11.5 to 15.7	12.5 10.4 to 15.1	0.0001
Derangement	11.6 8.6 to 16.4	11.0 8.3 to 15.4	0.05
Tortuosity	3.26 3.15 to 3.34	3.23 3.12 to 3.32	0.04
Manual distance*	113 94 to 150	116 95 to 166	0.06

* analysed on log scale

These results show that for all measurements (except manually measured distance, p= 0.06) there was significant change over two years: intercapillary distance increased, whereas width, derangement and tortuosity all fell over 2 years. Non-parametric group comparison of change scores showed no evidence that the size of the change varied between subject subgroups (although subgroups were small).

Conclusion: 1. Capillary morphology changes over 2 years in patients with Raynaud's phenomenon, lending further support for nailfold capillaroscopy as an outcome measure in long-term clinical trials.

2. The increase in intercapillary distance suggests disease progressed across the different subgroups.

3. The fall in width, derangement and tortuosity were not anticipated and these require further assessment as outcome measures.

1732

An Epidemiological Study of the Prevalence of Systemic Sclerosis in South East Norway. Anna-M. Hoffmann-Vold, Oyvind Midtvedt, Torhild Garen and Jan Tore Gran Sr., Oslo University Hospital, Rikshospitalet, Oslo, Norway

Background: SSc is a rare disease and, consequently, it has been difficult to conduct population-based studies revealing its true prevalence. Norway is a relatively small country and its population is homogenous. Potentially noxious environmental factors are rare, with hardly any industry or mines. This could indicate epidemiological differences to other investigated populations.

Purpose: The purpose of the study was to estimate the prevalence of SSc in Norway and to compare this to that of other countries.

Methods: The department of Rheumatology at the Oslo University Hospital (Rikshospitalet) is a highly specialized unit for connective tissue diseases and is a referral unit for South East Norway with a population of 2 672 951 inhabitants. All patients meeting either ACR criteria or the modified Medsger and LeRoy criteria for SSc are recorded in a database which was reviewed. 180 such cases were found.

Results: The median age of SSc patients in Southeast Norway was 57 yr. (19-87 yr.), for women 56 yr., compared to 59 yr. for men. The female: male ratio was 3.6:1, the overall ratio for lSSc: dSSc was 2.8:1 (women 3.5:1, men 1.4:1).

The unadjusted prevalence of SSc was 6.7 per 100.000 (2.9 for male and 10.5 for female). The prevalence by subtype and age group is shown in Table 1 and 2.

Conclusion: The overall prevalence of SSc was estimated to 6.7 per 100.000 which compared to other investigated countries was remarkably low. This can indicate differences due to geographic, climatic and social factors, which strengthens the need for further investigations.

Table 1: Population prevalence per 100.000 for Southeast Norway by SSc subtype

	Male		Female		All	
Type	No.	Prevalence	No.	Prevalence	No.	Prevalence
Limited SSc	23	1.7	110	8.2	133	5.0
Diffuse SSc	16	1.2	31	2.3	47	1.8
Both	39	2.9	141	10.5	180	6.7

Table 2: Prevalence of SSc by age group

Age group	Southeast Norwegian population	Number of SSc per group	Prevalence per 100.000
0-15	529.290	0	0

Late-Age Onset Scleroderma. Rebecca L. Manno, Fredrick M. Wigley and Laura K. Hummers, Johns Hopkins University, Baltimore, MD

Purpose: Peak age for the onset of scleroderma is mid-life between 40 to 50 years. However, late-onset disease does occur and with the population aging it may become more common. We sought to determine unique characteristics of scleroderma associated with late-age of onset focusing on elderly with age of scleroderma onset greater than 65 years.

Methods: Data were retrospectively reviewed from a comprehensive database at a University based Scleroderma Center where data is prospectively collected every 6 months. Patients from this cohort were dichotomized by age of onset. Late-onset disease was defined as first non-Raynaud's phenomenon (RP) symptom of scleroderma that started after age 65 years. All patients with an established date of scleroderma onset were included in this analysis. Comparisons of covariates by age of scleroderma onset were made by Pearson chi-squared and student's t-test.

Results: 2359 patients from the cohort were analyzed. 1797 (77.5%) satisfied American College of Rheumatology criteria for scleroderma. There were 222 patients with age of disease onset greater than 65 years, 114 of whom had disease onset at age 70 or greater. Table 1 summarizes comparisons made between those with scleroderma onset before and after age 65. Patients with late-onset disease had more co-morbid illnesses and a drastically different temporality of malignancy. Older patients were more disabled as assessed by HAQ score. They had less severe Raynaud's but more significant renal, cardiac, and pulmonary disease. Older patients had more anti-centromere antibodies (41.18% vs 26.7%, p=0.001) and less anti-RNP (3% vs 9.35%, p=0.032) with all other autoantibodies being comparable.

Table 1	Age of onset < 65 years	Age of onset ≥ 65 years	p-value
Total # patients	2137	222	
% female	82.83	85.59	0.297
% limited subtype	62.68	68.78	0.074
SSc duration			
Years from RP onset to 1st non-RP SSc symptom	2.56	6.47	<0.001
Years from 1st non-RP SSc symptom to SSc diagnosis by physician	2.30	0.47	<0.001
Years to death from SSc onset	11.60	4.69	<0.001
Mean number of visits to Scleroderma Center	4.63	3.05	<0.001
Co-morbidities			
% with cancer diagnosis	8.11	16.22	<0.001
Years to cancer diagnosis after SSc onset	-5.61	0.914	0.004
Function			

HAQ score	1.10	1.22	0.055
SSc VAS: disease	1.58	1.50	0.746
intestine	0.95	0.79	0.074
breathing	1.00	1.07	0.445
Raynaud's	1.28	0.94	<0.001
digital ulcers	0.96	0.66	0.006
Organ involvement			
Skin score: diffuse	23.17	25.52	0.130
% with history of digital ischemia	56.32	37.38	<0.001
% renal crisis	2.95	4.95	0.103
% any weakness	23.16	32.00	0.009
Mean max Medsger severity score:			
General	1.04	1.13	0.339
GI	1.43	1.21	<0.001
Renal	0.29	0.57	<0.001
Cardiac	0.72	1.16	<0.001
Mean max RVSP	44.34	49.71	0.004
Mean min ejection fraction	56.62	55.55	0.150
Pulmonary	1.88	2.18	0.005
Mean min % predicted FVC	69.33	75.08	<0.001
FEV1/FVC	97.07	98.13	0.217
TLC	78.90	87.29	<0.001
DLCO	61.23	61.54	0.879

Conclusion: Patients with onset of scleroderma after the age 65 have unique characteristics and clinical outcomes compared to younger onset disease. These data suggest that the temporal relationship of malignancy diagnosis, severe Raynaud's, cardiopulmonary complications and poor functional status are distinct features in this older group.

Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS): Utility of Six Minute Walk Test.

Ann J. Impens[1], Monique E. Hinchcliff[2], Laura K. Hummers[3], M. Mayes[4], Chris T. Derk[5], Lee S. Shapiro[6], Robyn T. Domsic[7], Barbara M. Segal[8], Avram Z. Goldberg[9], Firas Alkassab[10], Virginia D. Steen[11] and the PHAROS Investigators, [1]University of Michigan, Ann Arbor, MI, [2]Northwestern University, Chicago, IL, [3]Johns Hopkins University, Baltimore, MD, [4]U.Texas Houston, Houston, TX, [5]Jefferson Medical College, Philadelphia, PA, [6]Albany, NY, [7]University of Pittsburgh, Pittsburgh, PA, [8]Hennepin County Medical Center, Minneapolis, MN, [9]North Shore-LIJ Health System, Lake Success, NY, [10]Univ of Massachusetts Med Schl, Worcester, MA, [11]Georgetown University Medical Center, Washington, DC

Purpose: 6MWT is a standardized measure of submaximal exercise capacity and has served as a major outcome measure in pulmonary arterial hypertension (PAH) clinical trials. This study looks at the effectiveness of serial 6MWTs to evaluate PH in SSc patients.

Methods: PHAROS is a multicenter prospective, observational study to determine risk factors and outcomes of patients who are at high risk for PAH or have PH. We identified patients with multiple 6MWT's in the following PH subgroups: a.Pre-PAH **(PRE)** patients with one of the following entry criteria: DLCO ≤ 55% predicted without significant fibrosis, FVC%/DLCO% ratio > 1.6, or echocardiographic systolic PAP (sPAP) >40 mmHg; b.Definite pulmonary hypertension patients (**PH**) - mean pulmonary artery pressure ≥25 mmHg at rest or ≥30 mmHg with exercise on right heart catheterization , c.New PH patients **(NPH)-** patients in the PRE group who developed PH during follow up. Analyses used included Anova, t-test analyses and Pearson.

Results: 115 patients had multiple 6MWT's. Selected results at different time points are shown in Table. There was a significant difference in 6MWT distance (6MWD) between **PRE** and **PH** groups at all time points. 6MWD was remarkably stable over time, but some trends in change over time were evident. In the **NPH** group the 6MWD decreased by 62m near the time of diagnosis of PH . In the **PH** group, a mean increase of 54m occurred in 30 patients with walks 6 months after starting treatment (p=0.18); and in the **PH** group, patients with 'clinical worsening' decreased their 6MWD by 76m at time of worsening (p=.02) In the **PRE** group, the 6MWD showed significant correlations with FVC%/DLCO%, the sPAP. In **PH** patients significant correlations were found with Echo sPAP, PFTs and patient reported measures at the different points in time.

Conclusion: The 6MWD appropriately differed between the **PRE** and **PH** groups. Although stable over time in **PRE** and **PH** groups, there was data supporting its use to measure change within specific subgroups. In spite of its non specificity to PH, serial 6MWTs may be a valid measure to use in the PH spectrum of SSc patients.

1735

Effectiveness and Safety of Mycophenolate Mofetil in the Treatment of Interstitial Lung Disease in Patients with Systemic Sclerosis. Giovanna Cuomo[1], Giuseppina Abignano[2], Michele Iudici[1], Ambrogio Petrillo[2] and Gabriele Valentini[2], [1]Second University of Naples, Naples, Italy, [2]Second University of Naples, Napoli, Italy

Purpose: Interstitial lung disease (ILD) is a frequent manifestation of systemic sclerosis (SSc). ILD heralds a poor prognosis and is associated with high mortality. Cyclophosphamide (CYC) is commonly used in SSc-ILD and is presently considered the first line therapy for this condition (1). Some recent report have pointed out the efficacy of mycophenolate mofetile (MMF) in SSc both in patients with early diffuse disease and in those with SSc-IDL whatever the disease duration and the subset (MMF) (2-4). Since, in our experience, CYC treatment fails in about 24% of SSc-ILD patients treated, we underwent a prospective observational study in such patients to investigate the effectiveness and the safety of MMF.

Methods: From October 2006 we identified and subsequently enrolled into the study 18 (16 female, 2 male; median age 46: range 18-68; disease duration 7 years; range 1-25) consecutive patients with SSc and active ILD unresponsive [i.e. decrease of either Forced Vital Capacity (FVC) or diffusing lung capacity for CO (DLCO) >10% of the basal value after 10 grams total CYC dosage] to therapy with low dose of CYC i.v. MMF was administered orally at a dosage of 2000mg daily. Treatment duration ranged from 5-24 months. At basal, after 6 and 12 months were evaluated as outcome measures were evaluated: FVC, DLCO. Every three months side effects were registered.

Results: At 6 months, DLCO (n=16) increased from 47.6 (% of the predicted value)±8.8 to 49.7±9.2 ($p<0.05$) No other significant difference was detected. At 12 months (n=10) no significant difference has been pointed out. The following adverse effects occurred: liver toxicity,1; otitis media, 1; bacterial bronco-pneumonitis infection,1; herpes zoster infection, 1; neutropenia, 1; arthritis, 1.

Conclusion: Previous studies have pointed out the effectiveness of MMF in SSc-ILD. Our data suggest that MMF might freeze the deterioration of lung function, but does not seen to reverse the process in most cases

1736

Prevalence and Clinical Associations of Pulmonary Involvement in Systemic Sclerosis – Data From the German Systemic Sclerosis Network Registry (DNSS). M.O. Becker[1], D. Huscher[2], C. Brückner[1], DNSS Centres, Gerd R. Burmester[3] and Gabriela Riemekasten[1], [1]Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Center (DRFZ), Berlin, Germany, [3]Charite University Hospital, Berlin, Germany

Purpose: Systemic sclerosis (SSc) is characterized by abnormal fibrosis of the skin and other organs. Its main cause of death is pulmonary involvement which may be pulmonary arterial hypertension (PAH) or interstitial lung disease (ILD) or both. We analysed data from the German DNSS network registry to evaluate the prevalence and clinical associations of pulmonary involvement in SSc patients.

Method: Data from 2062 SSc patients were analyzed and grouped according to the type of pulmonary involvement. Baseline demographic, clinical and laboratory variables were analyzed to reveal significant statistical associations. In addition, we calculated the estimated Kaplan-Meier survival curves.

Results: Of 2062 patients in the DNSS register, 965 patients (46.8%) had pulmonary involvement and of these 140 had PAH (6.8%), 591 had ILD (28.7%) and 234 patients had both (11.3%). Clinical and laboratory parameters as well as the survival curves revealed significant differences amongst the three groups: PAH was associated with limited SSc, anti-centromere antibodies, a lower median modified Rodnan skin score (mRSS) and heart involvement, whereas ILD had associations with diffuse SSc, anti-Scl70 antibodies, a higher median mRSS and kidney involvement as well as a higher male/female ratio. The third group (PAH and ILD) was similar to the ILD group in its association with diffuse SSc, a higher male/female ratio and higher mRSS and kidney involvement, but had also the highest percentage of heart involvement and dyspnoea as well as the lowest diffusing capacity for carbon monoxide (DLCO). The mean DLCO was highest in patients with PAH (>ILD>PAH and ILD). Vice versa, restrictive defects were most frequent in the PAH and ILD group (>ILD>PAH). A follow-up

of lung function parameters in selected patients revealed no significant differences after 3 consecutive visits. 41 registered SSc patients died and of these, 11 were PAH patients (7.9%), 18 had ILD (3.1%) and 12 had both PAH and ILD (5.1%). The survival curves revealed three distinct groups: patients without pulmonary involvement had the best survival, followed by patients with ILD and patients with both ILD and PAH. Patients with isolated PAH were least likely to survive. Of those patients who died, the ones with PAH and ILD had a tendency to die more quickly than others and there were significant differences to patients still alive for male gender (PAH, PAH and ILD), mRSS (PAH), DLCO (PAH), age (ILD) and organ involvement (ILD, PAH and ILD).

Conclusion: Pulmonary involvement in SSc can be divided into three groups of patients according to the presence of PAH and ILD. Although patients with PAH and ILD share many features with ILD patients, they also share some features with PAH patients. This study emphasizes the need for further investigations into the natural history and subgroups of patients with pulmonary involvement.

Myopathy Independently Predicts Mortality in Scleroderma Patients. Ritu Valiyil, Laura K. Hummers and Fredrick M. Wigley, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Skeletal muscle dysfunction and weakness, or myopathy, is prevalent in systemic sclerosis (SSc) and can be caused by numerous factors including malnutrition, disuse, medications, inflammatory myositis, or muscle fibrosis. We postulated that presence of myopathy of any cause during the course of disease associates with unique clinical features and outcomes.

Method: We searched our cohort database that documents clinical and laboratory information prospectively collected every 6 months of all SSc patients seen at our specialty scleroderma center. Myopathy was defined if muscle weakness graded less than 5/5 by manual muscle strength testing and any one of the following characteristics was present: elevated muscle enzymes (CK or aldolase), abnormal muscle MRI, abnormal electromyography, or abnormal muscle biopsy. For each subject with myopathy, one SSc control without myopathy was selected by closest last visit and matched by age (± 5 yrs) and disease duration (± 3 mo). Demographic, disease activity, laboratory, pulmonary, and echocardiogram data were obtained from the database. Differences between SSc patients with and without myopathy were analyzed by chi-squared analysis or student's t test. Conditional multivariable logistic regression models were used to assess associations.

Results: 178 of 2,359 SSc patients met our criteria for myopathy and were matched to 178 patients without myopathy. Between the myopathy and non-myopathy groups, there were no statistical differences in mean age (55 yrs), disease duration (8.4 yrs), and sex (78% female vs. 85% respectively). When compared to controls, subjects with myopathy were more likely to be the diffuse skin subtype (66 vs. 37%, p<.001) and African-American (34 vs. 17%, p=0.001). Arthralgias were more frequent with myopathy (83 vs. 69%, p=0.003), as were tendon friction rubs (34 vs. 17%, p<.001) and synovitis (24 vs. 11%, p=0.001). SSc patients with myopathy were more likely to have lung disease with a lower mean % predicted FVC (59.3) than SSc patients without myopathy (73), p<.001, as well as cardiac dysfunction with a mean lower ejection fraction (54%) compared to controls (58%), p=0.004. Anti-RNP antibodies were strongly associated with myopathy (OR 5.5, CI 1.22-24.8), while antibodies against centromere and topoisomerase I were negatively associated (OR 0.09, CI 0.02-0.39 and OR 0.29, CI 0.11-0.80 respectively). In adjusted multivariable analysis, a significant association was observed between myopathy and diffuse skin subtype (OR 2.7, CI 1.1-6.5) and % predicted FVC ≤ 60 (OR 3.27, CI 1.8-6.0). There was no association with smoking, cancer, FEV_1/FVC ratio, and maximum RVSP. Increased mortality was associated with myopathy (OR 3.4, CI 1.3-8.9) and % FVC ≤ 60 (OR 14.5, CI 2.5-82). In subjects with % FVC >60, death was more frequent in subjects with myopathy (27 vs. 9%, p<.001).

Conclusion: Myopathy in scleroderma is significantly associated with diffuse skin subtype and lung disease and independently predicts mortality. Early recognition of muscle disease may identify scleroderma patients at high risk for poor outcomes and provide an opportunity for therapeutic intervention.

Aminaftone Enhances Iloprost Beneficial Effects in Patients with Systemic Sclerosis and Recurrent Ulcers. Raffaella Scorza, Monica Caronni, Alessandro Santaniello, Karen Toussoun and Lorenzo Beretta, Fondazione IRCCS Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena and University of Milan, Italy, Milan, Italy

Purpose: Endothelin-1 (ET-1) and adhesion molecules overexpression plays a pivotal role in the pathogenesis of vascular remodelling that characterizes systemic sclerosis (SSc). Indirect observations indicate that ET-1 is relevant in the pathogenesis of digital ulcers (DU) in scleroderma subjects. Treatment of digital ulcers in SSc patients is challenging as in many patients they tend to be chronic and relapse and largely affect the quality of life, in spite of efficacious pharmacological treatment like prostanoids and the dual ET-1 receptor blocker. In this study we investigated whether aminaftone that downregulates in vitro ET-1 (1) production and ex vivo expression of endothelial adhesion molecules (2) should favour ulcers' healing in SSc patients with recurrent and/or refractory ulcers resistant to cyclic iloprost treatment.

Method: Thirteen patients referring to our outpatient clinic (11 females and 2 males) with diagnosis of SSc according to ACR criteria where included in this study. Five patients had a diagnosis of dcSSc, 8 a diagnosis of lcSSc. Mean age ± s.d. was 54 ± 10 years (range 35-69); disease duration (mean ± s.d.) was 9 ± 5 years. All the patients had chronic and/or recurrent digital ulcers (number of active ulcers/patients 2,43 ± 1,02) in spite of the chronic treatment with cyclic iloprost (2ng/kg/min for 8 hrs every 4 weeks). Iloprost treatment duration (mean ± s.d.) was 6 ± 1 years (range 5-9). All the patients had careful information about aminaftone, its usual therapeutical use in capillary disorders and gave informed consent to the treatment with oral aminaftone (75 mg t.i.d.), in addition to cyclic iloprost treatment. The duration of the aminaftone treatment was 12 months. The effect of aminaftone in enhancing Iloprost effect was analyzed by Students' T-test for paired samples.

Results: The addition of aminaftone to cyclic Iloprost treatment in patients with refractory/relapsing digital ulcers favoured the healing (number of ulcers pre- and post-treatment: 2,43 ± 1,02 Vs 1,29 ± 0,61, $p<0.005$).

Conclusion: These results show that aminaftone is able to increase the beneficial effects of iloprost in the management of digital ulcers secondary to SSc, supposedly by its capability to reduce ET-1 production and adhesion molecule expression. Further randomized study are needed to confirm whether this cheap and well tolerated drug is effective in association with conventional therapy to favour the healing of digital ulcers.

The Development of Updated Criteria for Systemic Sclerosis (SSc) Using Delphi Technique and Cluster and Frequency Analyses From a Large SSc Patient Database. Corrine Coulter[1], Canadian Scleroderma Research Group, Scleroderma Clinical Trials Consortium, Marie Hudson[2], Russell Steele[3], Murray Baron[4] and Janet Pope[5], [1]University of Western Ontario/St. Joseph's Health Care, London, ON, [2]McGill University and Jewish General Hospital, Montreal, QC, [3]McGill University, Montreal, QC, [4]Jewish General Hospital, Montreal, QC, [5]St Joseph Health Care, London, ON

Purpose: The ACR classification criteria for Systemic Sclerosis (scleroderma, SSc) fail to identify at least 12% of individuals in the Canadian Scleroderma Research (CSRG) database all of whom have been diagnosed with SSc by a rheumatologist and this finding is concordant in other databases, thus modification of criteria is welcome.

Method: Literature was searched for a list of possible suggested SSc criteria, and a list thorough list of signs, symptoms and tests was composed and sent in random order to 96 SSc experts {from the Scleroderma Clinical Trials Consortium (STCC), CSRG and others} who were also asked to add other criteria that may be missing from the list. A Delphi Consensus exercise of three rounds was conducted. Cluster analysis (using Tetrachoric correlations and Proc VARCLUS) reduced the final consensus list to criteria with a best fit. The CSRG database was used to determine the proportion of patients the criteria classified and the 1000 Faces of Lupus database was used to determine the frequency of some of the criteria that were suggested within that database.

Results: 71 of 96 (71%) completed all 3 rounds (response rate round 1, and 2 were 80% and 74%); where 47 items on the original list of possible criteria were expanded to 76 in the second round (some were combinations of previous criteria or different definitions of criteria such as ILD) and 30 items on round 3 that had at least 50% consensus were included. In round 3, 18 items had >75% agreement to include (a priori cut point), ranging from 75 to 100% agreement. Cluster analysis identified subset criteria into 4 categories: skin involvement, capillary characteristics, auto-antibodies and tissue damage. Frequency analysis of skin involvement that was on fingers and proximal to MCPs (identified 80% of patients) or 1 or more items from at least 2 of 3 categories were able to identify 94% of the CSRG patients including Vascular: dilated capillaries, telangiectasia, Raynaud's phenomenon (RP), auto-antibodies {anti-centromere or anti-topoisomerase (Scl70)}, sclerodactyly, damage (esophogeal dysmotility / dysphagia, fibrosis, digital ulcers). The best fit was skin involvement of the fingers and proximal to the MCPs; or sclerodactyly plus one of: RP, anti-centromere (ACA) or Scl70 which described 98% of the CSRG patients. We studied the frequency of potential SSc criteria in SLE patients (n>600) where 1.1% had a digital ulcer ever, 2% were Scl70+, 0.5% were ACA+ and 0.5% had telangiectasia and sclerodactyly proximal to the MCPs did not occur in lupus without a SSc overlap. Thus, these criteria may also have good specificity.

Conclusion: Updated classification criteria should improve disease identification and case definitions for research purposes, and patient care. This is a first step toward developing new criteria as the sensitivity and specificity have not been determined.

Genetic and Biological Models of Epistasis to Predict Digital Ulcer Occurrence in Italian Systemic Sclerosis Patients. Lorenzo Beretta[1], Alessandro Santaniello[1], Michael Mayo[2], Francesca Cappiello[1], Maurizio Marchini[1] and Raffaella Scorza[1], [1]Fondazione IRCCS Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena and University of Milan, Italy, Milan, Italy, [2]University of Waikato, Hamilton, New Zealand, Hamilton, New Zealand

Purpose: Digital ulcers (DUs) are a frequent complication of systemic sclerosis (SSc) that may occur in up to 50% of patients during their disease history and that constitute a significant cause of discomfort and morbidity. DUs are thought to be the consequence of endothelial injury and small-vessel vasculopathy, which may be sustained by immune system activation and cytokine release.

Method: Twenty-two functional cytokine single nucleotide polymorphisms (SNPs) and 3 HLA-class I and II antigens, -including HLA-B*3501 which may contribute to regulate the endothelin-1 (ET-1) production (1), HLA-DR*11 and HLA-DR*07, previously associated with SSc in Italian subjects (2), were typed at the genomic level by polymerase chain-reaction in 200 Italian SSc patients. Associations with DUs were sought by parametric models and with the Multifactor Dimensionality Reduction (MDR) algorithm to depict the presence of gene-gene or gene-environment interactions. Biological models consistent with MDR results were built by means of Petri nets to better describe the metabolic significance of our findings.

Results: On the exploratory analysis, the dcSSc subset was the only factor associated with DUs (p=0.045, ns after Bonferroni correction). Gene-gene and gene-environmental analysis showed that a 3-factor model comprising the IL-6 C-174G, the IL-2 G-330T SNPs and the HLA-B*3501 allele was associated with DUs (testing accuracy=66.9%, p<0.005 after permutation testing). Petri nets allowed us to build a biological model to explain the non-linear interactions among the abovementioned variables. The main findings that emerge from this model are the following: 1) IL-6 and HLA-B*3501 synergize to eventually determine DUs occurrence; 2) IL-6 may sustain/amplify HLAs responses; 3) IL-6 production is amplified by an autocrine loop where IL-2 acts as a co-enhancing factor.

Conclusion: We provide evidence for a complex genetic susceptibility to DUs in Italian SSc patients. In the model we found, IL-6 appears to be a key-factor in determining DUs occurrence. This model is biologically plausible and may constitute the basis for further translational research.

1741

Associations with Digital Ulcers (DU) in a Large Cohort of Systemic Sclerosis (SSc). Sarit Khimdas[1], Sarah Harding[2], Ash Bonner[3], Brittany Zummer[2], Canadian Scleroderma Research Group, Murray Baron[4] and Janet Pope[5], [1]Schulich School of Medicine & Dentistry, University of Western Ontario, London, ON, [2]University of Western Ontario, London, ON, [3]McMaster University, Hamilton, ON, [4]Jewish General Hospital, Montreal, QC, [5]St Joseph Health Care, London, ON

Purpose: Digital ulcers (DU) are a common disabling complication of systemic sclerosis/scleroderma (SSc) and can be associated with devastating complications such as osteomyelitis and amputation. There is debate as to whether DUs are increased in SSc with pulmonary arterial hypertension (PAH) as the literature is controversial in this area[1, 2]. Although occurring in 30 to 50% of patients, information is lacking on whether DUs are associated with other organ complications and SSc subsets.

Method: Data from the CSRG (Canadian Scleroderma Research Group) are collected annually on an incident and prevalent SSc cohort. Presence, location and number of digital ulcers are collected annually as well as complications and other internal organ involvement, skin score and labs results. Correlation coefficients, Chi squared and logistic regression modeling were done to determine the associations of DUs (and subset of complicated DU) with other factors such as internal organ complications

Results: 938 patients were included. 86% were women, mean age was 56 and disease duration was 14 years. 53% had limited SSc. 15% had a DU currently, 46% had a DU ever and 53% had digital pits. DUs were not associated with PAH (P=0.35). Complicated DUs including gangrenous (P=0.72) and amputated (P=0.93) digits were not associated with PAH. In patients with a disease duration longer than three years, DUs were associated with higher skin scores (P=0.00). Gender (P=0.95) and smoking (0.91) were not associated with DUs. Organ involvement including renal crisis (P= 0.66) and interstitial lung disease (P=0.20) were not associated with DUs. DUs were associated with: a decreased DLCO in diffuse SSc (P=0.01) and both earlier age of Raynaud's (P=0.00) and first non-Raynaud's symptom (P=0.00). DUs were further associated with GERD in diffuse SSc (P=0.00) and esophageal hypomotility as measured by esophageal dilatation (P=0.00). DUs were associated with the presence of topoisomerase 1 (Scl-70) antibodies (P=0.00). Patients with diffuse SSc were almost twice as likely to have had a DU than patients with limited SSc. However, neither patients with gangrenous (P=0.61) nor amputated digits (P=0.46) were associated with a subtype of SSc.

Conclusion: It appears that DUs are not associated with PAH. DUs increase with diffuse SSc, early onset of disease, low DLCO, esophageal involvement and presence of topoisomerase 1 (Scl-70) antibodies. Complicated DUs are not associated with an SSc subtype or specific organ involvement. Some of the associations are confounded as diffuse SSc onsets earlier than limited and thus earlier age of onset increases DU risk. Understanding the associations with digital ulcers in scleroderma may help to risk stratify patients and better treat or prevent this disabling complications. 1. Sunderkotter C. Pilot Study of Intense Pulsed Light (IPL) for the Treatment of Systemic Sclerosis-Related Telangiectases. Andrea K. Murray[1], Tonia L. Moore[1], Helen L. Richards[2], Holly Ennis[3], Christopher Griffiths[1] and Ariane L. Herrick[1], [1]University of Manchester, Salford, United Kingdom, [2]Mercy University Hospital, Cork, Ireland, [3]University of Manchester, Manchester, United Kingdom

Purpose: Cutaneous telangiectases, caused by dilation of microvessels, are a major source of concern and disfigurement in patients with systemic sclerosis (SSc) especially when they occur on the face. Current treatments include camouflage techniques and laser therapy, although the latter is time-consuming, can result in considerable bruising, and not all lesions respond. Our aim was to examine the safety and tolerability of intense pulsed light (IPL) treatment in an open pilot study.

Method: 20 patients (mean [range] age 55[37-70] yrs; 4 male 16 female; 18 limited cutaneous SSc, 2 diffuse cutaneous SSc) with telangiectases of face and/or upper limb were recruited. If the patch test at the screening visit was uneventful, all patients received 3 IPL treatments to a selected area at monthly intervals, unless lesions completely resolved after the first or second treatment, in which case no further treatments were given. Patients were followed for up to 12 months. Outcome measures included the appearance of the telangiectases from clinical photographs [2 observers compared each post treatment image to baseline and judged lesions as – worse, no change, improved,

much improved or resolved], the Hospital Anxiety and Depression Scale (HADS), and the Derriford Appearance Scale (DAS-59) (an assessment of distress and dysfunction in relation to appearance). Telangiectases were imaged at each visit by laser Doppler, but these results are not included in this analysis.

Results: One patient failed the patch test, one patient was subsequently excluded for not fulfilling the study criteria and 1 patient's images were ungradable. Of the remaining 17, all but one had all 3 IPL treatments. Two weeks after the final treatment, patients were categorised as follows: 4 ‘no change', 5 ‘improved' and 8 as ‘much improved'. At the follow-up visits (6 to 12 months) patients were categorised as 5 ‘no change', 8 ‘improved' and 4 ‘much improved'. The median HADS anxiety score pre-treatment was 5 (range 0 to 11) and post-treatment 7 (range 1 to 14) (p=0.4) and the median HADS depression score pre-treatment was 4 (range 1 to 11) and post-treatment 6 (range 1 to 12) (p=0.7). Median DAS-59 pre-treatment was 81 (range 25 to 173) and post-treatment 78 (range 29 to 218) (p=0.9). The treatment was well tolerated in most patients but one patient withdrew after the first treatment following facial swelling, and one had blistering of the dorsum of the hand following the third treatment.

Conclusion: 1. Most patients improved after IPL treatment and the treatment was well tolerated.

2. The degree of improvement was not maintained in all patients at 6-12 months, suggesting that further treatments might be necessary.
3. Improvement was not matched by an improvement in the HADS or DAS-59.
4. This was a small pilot study and longer term studies are now required, comparing IPL to laser treatment.

Cartilage Biomarkers Profile and Correlations with Measures of Disease Activity in Ankylosing Spondylitis Patients. J.L Fernandez-Sueiro[1], J. Pinto[2], Sonia Pertega[3], A. Atanes[1], J.C. Fernandez-Lopez[4], Natividad Oreiro[3], E. Gonzalez-Diaz de Rabago[1], F. Galdo[1] and Francisco J. Blanco[5], [1]Hospital Universitario Juan Canalejo, La Coruña, Spain, [2]Hospital, La Coruña, Spain, [3]INIBIC - Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [4]MD, La Coruña, Spain, [5]Hospital Juan Canalejo, A Coruna

Purpose: To evaluate the biomarkers profile and their correlations with measurements of disease activity in a longitudinal observational cohort of anti-TNF naïve AS patients.

Method: 79 AS patients and 86 healthy controls (HC) were studied. Current ASAS recommendations as well as radiological examination with BASRI were performed in AS anti-TNF naïve patients. Serum determinations of YKL-40, C2C and CPII were performed in AS patients at the entry in the cohort, time 0 (t0), and at 12 months (t1). Determinations in healthy controls were performed at t0. YKL-40, C2C and CPII were determined by ELISA with commercial kits following manufacturer’s instructions results are shown in ng/ml. Comparisons between AS patients and HC were performed using the Mann-Whitney test. Changes in biomarkers between t0 and t1 were assessed by the Wilcoxon’s signed rank test. Correlations were assessed using the Spearman’s rho correlation coefficient.

Results: At t0 there were statistical significant differences between AS patients and HC in the levels of CPII (390.5 vs 271.8) ($p<0.001$) and CPII/C2C (18.5 vs 12.7) ($p<0.001$), but not in the levels of YKL-40 (126.4 vs 128.4) (p=0.989) and C2C (23.6 vs 22.8) (p=0.610). Among AS patients, there were statistical significant differences between t0 and t1 in the three markers: YKL-40 (mean increase: 38.3, $p<0.001$), C2C (mean increase: 3.7, p=0.002), CPII (mean decrease: 84.2, p=0.001) and CPII/C2C (Mean increase: -6.9, $p<0.001$). There was a significant correlation between basal levels of CPII/C2C and changes in disease activity; BASDAI t1-t0 (Rho=0.358, p=0.001), physician global assessment t1-t0 (Rho=0.225, p=0.047). On the other hand there was a correlation between biomarkers variation and changes in disease activity; BASDAI t1-t0 (Rho=-0.227, p=0.047), Physician global assessment (Rho=-0.237, p=0.037).

Conclusion: As the disease progress there seems to be a worsening of cartilage break down products. The increase of YKL-40 and the decrease of CPII/C2C at T1 suggest the persistence of an ongoing inflammation. There was a direct correlation of the basal CPII/C2C ratio with an increase in measurements of activity such as BASDAI and physician global assessment. On the other hand a decreased in the CPII/C2C ratio correlated with a worsening of the disease measured by BASDAI and physician global assessment.

Axial Metrology Measurement and Functional Status in Ankylosing Spondylitis. J. Sieper[1], Amitabh Singh[2], Bruce Freundlich[2], Andrew S. Koenig[2] and Wenzhi Li[3], [1]Rheum/Charite Hosp, Berlin, Germany, [2]Wyeth Research, Collegeville, PA, [3]Wyeth Research, Philadelphia, PA

Purpose: It has been suggested that evaluation of spinal mobility using axial metrology could be used to assess disease modification in ankylosing spondylitis (AS). Although axial metrology has been shown to have a good correlation with radiography, its relationship with functional status has not been systematically evaluated. To assess the relationship between spinal mobility measured using axial metrology and functional status.

Method: In a randomized, 16-week, double-blind, randomized, multicenter, active comparator [sulfasalazine (n=187)] study to assess the efficacy and safety of etanercept (50 mg once weekly (n=379)] in patients with AS, spinal mobility was measured by Bath Ankylosing Spondylitis Metrology Index (BASMI: range 0-10). Functional status was measured with Bath Ankylosing Spondylitis Functional Index (BASFI: range 0-100). We estimated how the end of study (Week 16) changes (δ) in functional status would be related to δ in disease activity, δ in spinal mobility, age, gender and disease duration. The relationships were estimated with a linear regression model with change in BASFI as the dependent variable. Three alternative scoring algorithms have been proposed for BASMI: BASMI 2, BASMI 10 and BASMI Linear. Although the range of score is unaffected, BASMI Linear has been found to be most sensitive to change, followed by BASMI 10 and BASMI 2. Accordingly, three separate regression models were estimated using these different scoring algorithms for BASMI.

Results: The study population was predominantly male (75%) with an average age of 40.7y and disease duration of 7.6y. The baseline BASMI 2, BASMI 10, and BASMI Linear scores were 3.66, 4.08, and 4.10 respectively. The table below presents the standardized beta coefficients for the 3 regression models (I: BASMI 2, II: BASMI 10, III: BASMI Linear)

	Regression Models		
	I (N=519)	**II (N=519)**	**III (N=519)**
δ BASDAI	0.777^{+}	0.761^{+}	0.757^{+}
δ BASMI 2, δ BASMI 10, δ BASMI Linear	-0.089^{+}	-0.115^{+}	-0.128‡
Disease Duration	-0.034	-0.033	-0.033
Age	0.059	0.058	0.058
Gender (Male=1)	0.020	0.021	0.020
Adj R^2	0.64	0.65	0.65
‡P<0.001			

Each of the 3 models was able to explain about 64% of the variation in BASFI. Only δ in disease activity and δ in spinal mobility were significantly associated with BASFI. δ in BASFI was independent of disease duration, gender and age. Apart from disease activity, changes in spinal mobility had the largest impact on functional status.

Conclusion: This study demonstrated that changes in spinal mobility are significantly associated with changes in functional status in patients with AS. Because BASMI has shown good correlations with radiography, the potential for using BASMI as a surrogate for disease modification should be further examined.

The Electronic Version of the Psoriatic Arthritis Screening Questionnaire (EPASQ) Is An Effective Tool in Detecting Patients with Psoriatic Arthritis. Majed M. Khraishi and Jonathan Mong, Nexus Clinical Research, St Johns, NF

Purpose: Psoriatic arthritis (PsA) is a serious inflammatory disease that can cause significant joint damage, disability and co-morbidities. Early PsA detection and effective treatment may prevent these serious problems. We developed the Psoriatic Arthritis Screening Questionnaire (PASQ) as a tool for reliable diagnosis of PsA in patients with skin psoriasis. In a previous communication (Poster presentation EULAR 2008) we reported that the PASQ was highly sensitive and specific in detecting patients with psoriatic arthritis (PsA) fulfiling the CASPAR criteria A natural next step was to provide an easy to perform electronic version that can be widely distributed and eliminate possible inaccuracies of the diagram scoring.

Objectives: To examine the sensitivity and specificity of an electronic version of the PASQ and validate it against the original paper version.

Method: The electronic version of the PASQ (EPASQ) was developed using Adobe Creative Suite 4 software, and was based on the previous paper version of the PASQ. The EPASQ was programmed to provide a maximum of 15 points. The PASQ contained 10 differently weighted questions as well as a diagram where patients marked where they had or have had pain and or swelling. The same questions were included in the EPASQ in addition to a diagram with 68 joints plus the spine. The diagram and the questionnaire can be electronically marked and automatically scored. Validation was conducted using the questionnaires from 42 patients with confirmed PsA (mean disease duration 12 months). Questionnaires from 12 psoriasis patients without PsA were used as a control. Comparison of scores obtained from the manual and the electronic versions were conducted. A receiver operating curve (ROC) was determined for both the paper version as well as the electronic version using MedCalc® software. Descriptive statistics for both were obtained using SPSS.

Results: The original PASQ, data was collected from 87 patients (58 with established PsA meeting the CASPAR criteria and 29 with psoriasis and no evidence of arthritis). Analysis of the PASQ score [AUC = 0.913, 95% C.I.: (0.833, 0.963), p = 0.0001] yielded an optimal cut-off score of 9, with 86.27% sensitivity and 88.89% specificity. A score of 8 would yield a sensitivity of 91.16% and a specificity of 77.78%.

The electronic (EPASQ) Data was collected from a prospective cohort of 42 patients with early PsA (meeting the CASPAR criteria), and from 12 psoriasis patients without PsA. All but two of the PsA patients scored 8 or more in the paper PASQ. Concordance of the paper and electronic scores was very high with only one patient who scored 7 in the paper PASQ and 11 in the EPASQ. The ROC Curve of the entire group yielded an optimal 97.62% sensitivity and 75.00% specificity for a cut-off score of 7. A cut-off point of 8 yielded a sensitivity of 88.10% while still maintaining a specificity of 75.00%.

Conclusion: The electronic version of the PASQ is a simple self-administered and scored program with a high sensitivity and specificity. It can be an effective tool to screen for early and established PsA patients.

Major Clinical Response of Rituximab in Active TNF-Blocker-Naive Patients with Ankylosing Spondylitis but Not in TNF-Blocker-Failure Patients- An Open Label Clinical Trial. In-Ho Song[1], Frank Heldmann[2], Martin Rudwaleit[3], Joachim Listing[4], Heiner Appel[1], J. Braun[5] and J. Sieper[6], [1]Charite, Campus Benjamin-Franklin, Berlin, Germany, [2]Centre of Rheumatology, Herne, Germany, [3]Charité - Campus Benjamin Franklin, Berlin, Germany, [4]DRFZ, Berlin, Germany, [5]Rheumazentrum Ruhrgebiet, Herne, Germany, [6]Rheum/Charite Hosp, Berlin, Germany

Background: Histological studies have shown B-cell clusters in the facette joints of patients with ankylosing spondylitis (AS) [1]. On this background an immunotherapy targeting B cells in AS is of interest.

Purpose: To examine the efficacy and safety of rituximab in NSAID-refractory AS patients with or without previous treatment with TNFalpha-blockers.

Methods: In this open label phase-II-clinical trial rituximab 1000mg was administered intravenously at baseline and week 2 in 20 patients with active AS, 10 TNF-naïve and 10 TNF-refractory patients. Clinical outcome assessments included disease activity (BASDAI, patient global assessment), function (BASFI), assessments of pain, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

Results: Baseline characteristics: out of 20 patients 75% were male; 90% HLA-B27 positive, mean age 39.7 (SD 10.6); mean disease duration 16.8 years (SD 9.5). Patients had active disease and all suffered from axial pain. 85% of the patients reached week 24.

In the TNF-naïve group (n= 10) at week 24 ASAS20 was reached by 50%, ASAS40 by 40% and ASAS remission by 30%; BASDAI20 by 60% and BASDAI50 by 50%. Significantly more patients reached a BASDAI50 response in the TNF-naïve group (50%) compared to the TNF-failure group (0%), p= 0.033. There was nearly no change in the BASDAI values in the TNF-failure AS patients. In the TNF-naive patient there was a significant improvement between screening and week 24 regarding BASDAI (5.7 to 3.7, p= 0.047), patient pain assessment (7.3 to 4.4, p= 0.021) and CRP-values (24.6 mg/L to 19.1 mg/L, p= 0.017).

Overall, rituximab was well-tolerated, 5 serious events (SAEs) occurred during the study. 1 SAE (surgical treatment of hemorrhoids) occured before baseline, so this was definitely not drug-related. The other SAEs were an ulnar fracture, a nephrolithiasis, a skin abscess after colonscopy and a GI-bleeding which was considered to be not related to study drug.

Conclusion: While rituximab does not seem to be effective in TNF-failure AS patients it shows a significant efficacy in TNF-naive patients. Therefore a further application in TNF-naïve AS patients should be explored.

Treatment of DMARD Resistant Knee Monoarthritis with Repeated Intra-Articular Infliximab: Clinical and Ultrasound Outcome. Sarah J. Levy, Oliver Wignall, Christine Heron, James Pilcher and Patrick D. Kiely, St Georges Hospital, London, United Kingdom

Purpose: Intra-articular (IA) injection of steroid and systemic DMARD therapy are often used to treat inflammatory monoarthritis. Therapeutic options are limited in those who fail this regimen. Recent reports suggest that IA Infliximab (IF) may give benefit in refractory knee monoarthritis but little is known about the optimum use of this therapy.

Method: We studied 14 (8 M, 6 F) patients (diagnosis: seronegative monoarthritis (7), psoriatic (3), rheumatoid (3), enteropathic (1)). 8 were on DMARD monotherapy and 6 on combination therapy. Each patient was treated with a maximum of 3 IA injections of 100mg Infliximab. Clinical (Composite Knee Score (CKS), Pain Visual Analogue Score, Function Score), Ultrasound (synovial thickness, appearance and power doppler) and haematological parameters were recorded at baseline and weeks 2, 4, 8, 12, 20, 24, 28, 36, 46 and 52. Primary response criteria was reduction in the CKS by at least 2 points and relapse was defined as return to baseline CKS. Patients were eligible to be retreated

if they had at least 8 weeks benefit from the previous injection. During the latter half of the study patients were pre-treated with IA long acting steroid 1 week prior to the IF injection in an attempt to prolong duration of response to IF.

Results: 14/14 patients responded to the 1st injection with a mean time to response of 3.4 weeks and a mean response of 2.86 CKS points. 3/14 (21%) remained in remission at 1 year and 11/14 (79%) relapsed at a mean 10.54 weeks and were retreated. Of these, 1/11 remained in remission at 1 year, 2 were withdrawn due to short duration of response to the 2nd injection (< 8 weeks) and one moved away. 7 patients were treated with a 3rd injection. Mean duration of response for 2nd and 3rd injections was 8.77 and 10.16 weeks respectively and pre-treatment with IA steroid did not improve duration of response (mean duration with IA steroid 8.95 weeks compared with 9 weeks without). Patients who were in remission at 1 year were more likely to be female (M:F 1:3 compared with 7:3) and to have less severely affected knees at baseline (CKS mean 2:4.1, synovial thickness mean 3.6mm: 4.55mm, mean PD 0.66:0.71). Lack of complete response to initial injection (clinical and US) predicted relapse.

Conclusion: IA IF resulted in clinical and US remission at 1 year in 4/14 (29%) patients. In this study female patients with less severely affected knees at baseline were less likely to relapse. The addition of IA steroid 1 week prior to IF injection did not prolong duration of response.

Ultrasound parameters paralleled clinical changes accurately but did not offer advantage over clinical measures in either measuring response or predicting relapse.

IA IF is safe and easy to administer in the clinical setting and may result in prolonged remission in over a quarter of patients with the majority responding after a single injection.

1771

Effects of 14 Weeks of TNF Alpha Blockade Treatment On Lipid Profile in Ankylosing Spondylitis. Sylvain Mathieu, Christelle Gibert, Jean-Jacques Dubost, Jean-Michel Ristori and Martin Soubrier, Rheumatology. Gabriel Montpied Teaching Hospital, Clermont-Ferrand, France

Purpose: Cardiovascular morbidity and mortality seem to be increased in ankylosing spondylitis, perhaps as the result of biological inflammation and consecutive dyslipidemia. This study aims to investigate the impact of TNF alpha-inhibitors, an effective treatment, on lipid profile.

Method: Thirty-four ankylosing spondylitis (AS) patients with active disease undergoing anti-TNF alpha therapy (infliximab n=20; etanercept n=7; adalimumab n=7) were recruited. Total cholesterol, LDL-cholesterol, HDL-cholesterol and triglyceride levels and, disease activity parameters, Visual Analogical Scale (VAS) pain or VAS disease activity, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Bath Ankylosing Spondylitis Functional Index (BASFI), Erythrocyte Sedimentation Rate and C-Reactive Protein, were assessed at baseline and after 14 weeks of treatment.

Results: After 14 weeks of TNF α blockade treatment, there was a significant increase in levels of total cholesterol (5.08 ± 1.20 vs. 4.73 ± 1.12 mmol/l; p=0.014) and HDL cholesterol (1.61 ± 0.47 vs. 1.47 ± 0.35 mmol/l; p=0.008), but no resulting change in the atherogenic index (3.43 ± 1.13 vs. 3.35 ± 0.93; p=0.879). There was also no change in concentrations of triglycerides (1.33 ± 1.22 vs. 1.27 ± 0.98 mmol/l; p=0.794) and LDL cholesterol (3.15 ± 0.99 vs. 2.91 ± 0.93 mmol/l; p=0.248). TNF alpha inhibitor treatment was followed by a significant improvement in all disease activity parameters: VAS pain or VAS disease activity, BASDAI or BASFI, and systemic inflammation. Sub-group analysis showed that monoclonal antibodies increased total and LDL cholesterol levels but did not change the atherogenic index. Conversely, 14 weeks of etanercept treatment was followed by no change in lipid profile.

Conclusion: TNF alpha inhibitors may be successful in reducing cardiovascular risk in ankylosing spondylitis, as in RA, but not by affecting lipid profile. However, we lack sufficient documented evidence, and long-term investigations are needed to define the possible protective mechanisms of TNF-alpha inhibitor treatment in spondylarthropathies.

Identifying Cases of Psoriatic Arthritis in Electronic Medical Records Using Random Forests and Natural Language Processing.

Thorvardur J. Love[1], Tianxi Cai[2] and Elizabeth W. Karlson[3], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Brigham & Women's Hosp, Boston, MA

Purpose: The objective of the current study was to apply reproducible strategies to identify psoriatic arthritis (PsA) cases in an electronic database, and to determine the value of using natural language processing in addition to coded clinical data to predict case status.

Method: An outpatient and inpatient electronic database including electronic notes, lab reports, and billing codes for >1,350,000 patients was searched and 2318 individuals with at least one ICD-9 or billing code for PsA identified. From these, 550 were randomly selected and their records reviewed for case status using the documented opinion of a rheumatologist as the gold standard. The resulting data set was used to train random forest algorithms and create a prediction rule to apply to the remaining 1768 cases. Thirty-one predictors were extracted electronically for all 2318 patients, 16 from electronic notes using natural language processing (NLP) and 15 from coded clinical data. Three algorithms were trained in the subset of 550 reviewed patients using coded predictors only, NLP predictors only, and all available predictors. The algorithm with the largest area under the receiver operator curve (ROC) was used to generate a prediction rule. A cut-point was selected with the goal of achieving a 90% positive predictive value (PPV) with the highest possible predicted sensitivity based on the 550 reviewed records. The prediction rule based on that cut-point was applied to the remaining 1768 charts, and validated by reviewing a random sample of 300 patients from among those predicted to have PsA.

Results: The PPV of a single PsA code was 57% (95%CI 55%-58%). The area under the ROC curve of the algorithm using combined coded and NLP predictors was the largest of the three algorithms generated (figure 1), and was larger than for coded predictors alone (p=0.0007). The prediction rule based on all coded and NLP predictors had a predicted PPV of 90% (95%CI 86%-93%) and predicted sensitivity of 87% (95%CI 83%-91%) based on the training dataset. Among the remaining 1768 cases, the prediction rule classified 851 as having PsA. A review of 300 cases randomly selected from the predicted PsA group showed a validated PPV of 93% (95%CI 90%-96%) for the final prediction rule.

Conclusion: Random forests can be applied to electronic medical record data to reliably identify cases of psoriatic arthritis. Adding NLP predictor variables to readily available coded information increased the area under the curve for the prediction rule.

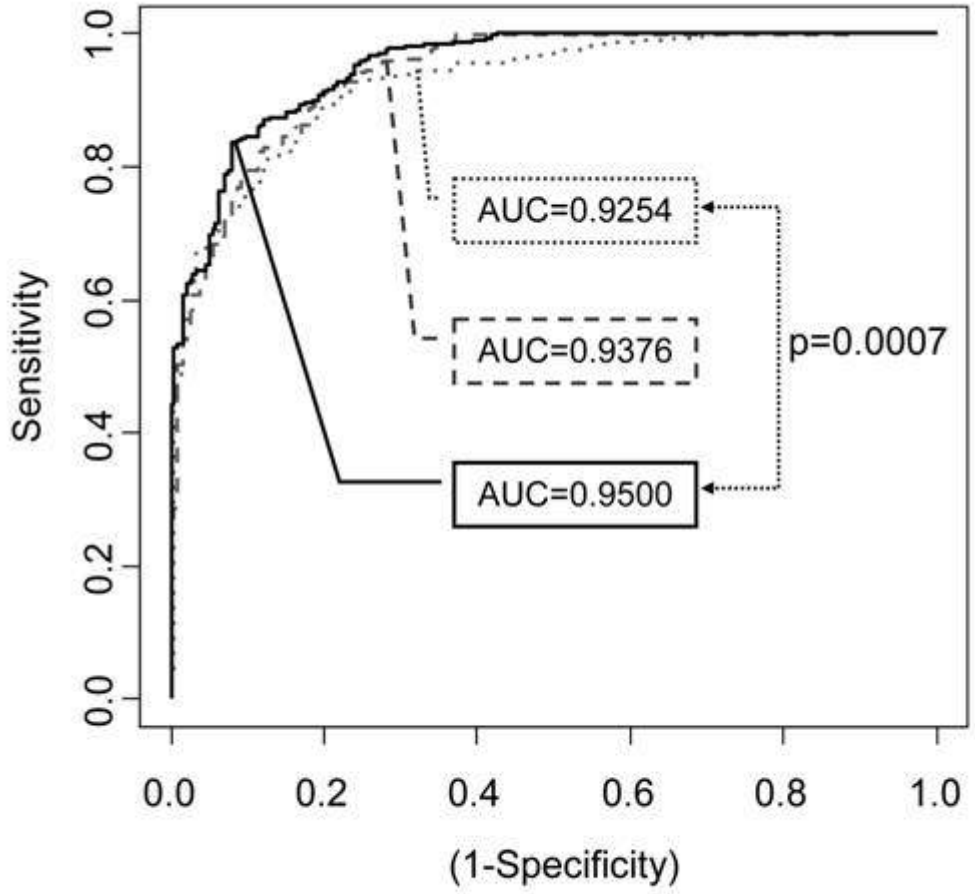

Figure 1 – ROC curves for random forest algorithms based on coded data only (dotted line), NLP data only (dashed) and combined (solid).

Development and Preliminary Validation of A Method for Scoring Bone Proliferation in Ankylosing Spondylitis Using Magnetic Resonance Imaging by the Canada-Denmark MRI Working Group: The Can-Den SAS (Spur and Ankylosis Score). Praveena Chiowchanwisawakit[1], Mikkel Ostergaard[2], Susanne J. Pedersen[2], Robert GW Lambert[3] and Walter P. Maksymowych[3], [1]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Copenhagen University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark, [3]University of Alberta, Edmonton, AB

Purpose: Bone formation in patients with ankylosing spondylitis (AS) is currently assessed on lateral radiographs of the lumbar and cervical spine using the mSASSS scoring method because the thoracic spine is not clearly visualized on radiographs. Further, detection of bone formation by the mSASSS is limited to the anterior margins of the vertebral endplates. MRI may provide superior detection of new bone in the thoracic spine and within intervertebral discs. We aimed to conduct preliminary validation of a new method for scoring bone formation throughout the spine of patients with AS using MRI.

Method: The scoring method is based on assessment of two principal bone lesions observed on sagittal slices using T1-weighted sequences, bone spurs and ankylosis. A bone spur is defined as bright (marrow) signal on T1W extending from the vertebral endplate towards the adjacent vertebra. Ankylosis is defined as bright (marrow) signal on T1W extending from a vertebra and being continuous with the adjacent vertebra. Lesions are scored dichotomously (present/absent). Each lesion is assessed at anterior and posterior vertebral corners on central (i.e. including the spinal canal) sagittal slices. Bone formation at non-vertebral corner locations is assessed on both central and lateral slices (i.e. do not include the spinal canal and the pedicle is continuous between vertebral body and posterior elements). By analogy with the mSASSS a bone spur is assigned a score of 2 while intervertebral ankylosis is assigned a score of 6. The maximal score per discovertebral unit is set at 12. Bone lesions were independently recorded from lower C2 to the upper sacrum of 20 AS patients by 4 readers after a feasibility exercise. Reliability was assessed by intra-class correlation coefficient (ICC).

Results: The mean (SD) (range) score for bone formation per patient was 40.3 (31.5) (6.5-126.5). Overall reliability for the total spine score amongst all 4 readers was excellent (ICC (95%CI) = 0.93 (0.79-0.98)) and was very good (cervical spine ICC = 0.85) to excellent (thoracic and lumbar spine ICC = 0.91 and 0.96, respectively) for spinal segment scores. ICC values for inter-reader pairs was also very good to excellent for thoracic and lumbar segments while good for the cervical spine.

Inter-reader pairs	**C-spine**	**T-spine**	**L-spine**	**Total**
Readers 1 & 2	0.63 (0.03, 0.85)	0.90 (0.76, 0.96)	0.80 (0.48, 0.92)	0.87 (0.68, 0.95)
Readers 1 & 3	0.88 (0.70, 0.95)	0.77 (-0.21, 0.94)	0.97 (0.92, 0.99)	0.88 (0.05, 0.97)
Readers 1 & 4	0.79 (0.43, 0.92)	0.93 (0.83, 0.97)	0.94 (0.85, 0.98)	0.92 (0.76, 0.97)
Readers 2 & 3	0.72(0.30, 0.89)	0.78 (-0.23, 0.94)	0.88 (0.50, 0.96)	0.81 (-0.21, 0.95)
Readers 2 & 4	0.72 (0.31, 0.89)	0.95(0.86, 0.98)	0.92 (0.79, 0.97)	0.95 (0.87, 0.98)
Readers 3 & 4	0.70 (0.04, 0.89)	0.74 (-0.25, 0.93)	0.97 (0.89, 0.99)	0.81 (-0.20, 0.95)
Mean ICC (range)	**0.74 (0.63, 0.88)**	**0.85 (0.74, 0.95)**	**0.91 (0.80, 0.97)**	**0.87 (0.81, 0.95)**

ICC (95% CI) values

Conclusion: The CanDen SAS reliably scores bone proliferation in all regions of the spine in patients with AS.

1774

How Is the New Ankylosing Spondylitis Disease Activity Score (ASDAS) Related to Different Aspects of Health-Related Quality of Life? – A Comparison with SF-36 in a Longitudinal Study of Spondyloarthritis Patients Treated with TNF-α Inhibitors.

Susanne J. Pedersen[1], Inge J. Sørensen[2], Ole R. Madsen[3], Niels Tvede[4], Michael S. Hansen[3], Gorm Thamsborg[5], Lis S. Andersen[6], Ole Majgaard[2], Anne Gitte Loft[7], Jon Erlendsson[8], Karsten Asmussen[9], Annette Hansen[10] and Mikkel Østergaard[11], [1]University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark, [2]Hvidovre, [3]Gentofte, [4]Rigshospitalet, [5]Glostrup, [6]Graasten, [7]Vejle, [8]Horsens, [9]Bispebjerg, [10]Gentofte, Gentofte, [11]Hvidovre and Gentofte, Denmark

Purpose: Recently, ASAS has proposed ASDAS as a new disease activity score for patients with ankylosing spondylitis. We investigated ASDAS in relation to the generic quality of life questionnaire Short-Form Health Survey (SF-36) in patients with spondyloarthritis (SpA) treated with tumor-necrosis-factor-alpha (TNF-α) inhibitors.

Method: ASDAS (0.121 x back pain + 0.058 x duration of morning stiffness + 0.110 x patient´s global assessment + 0.073 x peripheral pain/swelling + 0.579 x Ln(CRP+1) (1)), conventional clinical measures of disease activity and SF-36 were compared in a longitudinal multi-center study of 60 SpA patients (48 men, 12 women, median age 40 years (range 21-62)) treated with TNF-α inhibitors (infliximab (n=41), etanercept (n=13), adalimumab (n=6)).

Results: Patients with high ASDAS disease activity (ASDAS>4.5) (1) at baseline (n=15) had significantly lower scores for Physical Functioning (median 22.5 (range: 13.8-35) v. 65 (40-78)), Bodily Pain (12.0 (0-22) v. 41.0 (22-51)) and Physical Component Scale (22.6 (15.7-26.1) v. 34.4 (26.8-39.2)) (all p<0.001) compared with patients with moderate disease activity (ASDAS≥1.9 but ≤4.5) (n=41). No patients had low ASDAS (<1.90).

Table 1 shows the correlations between SF-36 subscales and summery scales, ASDAS, BASDAI and BASFI. ASDAS, BASDAI and BASFI correlated significantly and to a comparable extent with physical aspects of SF-36, whereas ASDAS was less correlated with mental aspects of SF-36 than BASDAI and BASFI.

	Baseline ASDAS (n=56)	Baseline BASDAI (n=60)	Baseline BASFI (n=60)	Δweek 0-22	ΔASDAS week 0-22 (n=47)	ΔBASDAI week 0-22 (n=53)	ΔBASFI week 0-22 (n=53)
Physical Functioning	-0.58***	-0.67***	-0.75***	ΔPF	-0.58***	-0.60***	-0.70***
Role Physical	-0.20	-0.33*	-0.39**	ΔRF	-0.50**	-0.50***	-0.52***
Bodily Pain	-0.67***	-0.68***	-0.62***	ΔBP	-0.69***	-0.70***	-0.61***
General Health Perception	-0.37**	-0.30*	-0.38*	ΔGHP	-0.41**	-0.34*	-0.51***
Vitality	-0.35**	-0.51***	-0.42**	ΔVI	-0.59***	-0.76***	-0.62***
Social Functioning	-0.26	-0.50***	-0.46***	ΔSF	-0.35*	-0.56***	-0.54***
Role Emotional	-0.13	-0.34*	-0.29*	ΔRE	-0.29	-0.35*	-0.37**
Mental Health	-0.23	-0.34*	-0.29*	ΔMH	-0.52***	-0.47**	-0.60***
Physical Component Scale	**-0.55*** **	**-0.52*** **	**-0.58*** **	**ΔPCS**	**-0.69*** **	**-0.67*** **	**-0.66*** **
Mental Component Scale	**-0.14**	**-0.32***	**-0.23**	**ΔMCS**	**-0.29**	**-0.47*** **	**-0.50*** **

Spearman rank correlation coefficients: p<0.05*; p<0.01**; p<0.001***

Conclusion: ASDAS appears more exclusively related to patient´s perception of physical health compared with BASDAI and BASFI. ASDAS may therefore be a better measure of disease activity, whereas BASDAI and BASFI also reflect aspects of mental health and social functioning.

1775

European Ankylosing Spondylitis Infliximab Cohort (EASIC): Safety of Longterm Therapy with Infliximab in Patients with Ankylosing Spondylitis (AS). Frank Heldmann[1], Jan Brandt[2], Jürgen Braun[1] and EASIC, [1]Centre of Rheumatology, Herne, Germany, [2]Berlin, Germany

Purpose: The knowledge on longterm safety of anti-TNF therapy is rather limited so far. This trial studies the longterm safety of treatment with infliximab in patients who took part in EASIC, a 2-year open label extension trial.

Method: All 149 European AS patients who took part in ASSERT were asked to continue with EASIC 1.3 ± 0.9 years after ASSERT. 103 patients (69%) from 6 European countries were included in the trial, 89 had been treated with infliximab between the two trials (EASIC group 2) and 14 had not (group 1). Patients of group 2 and 9 patients of group 1 continued infliximab during EASIC, 5 patients of group 1b were only followed up. Patients were examined and treated every 4-12 weeks. All adverse events (AE), all serious adverse events (SAE) and all drop-outs were analyzed.

Results: 88 of 103 patients (85.4%) showed AEs during EASIC, 77 patients (87.5%) had more than one AE. There was a total of 545 AEs of whom 47.2% were infections. 76 patients (73.8%) had infections and 55 (53.4%) showed more than one infection. Of the total of 257 infections, 178 (69.3%) were respiratory and ear infections. The other were gastrointestinal, urogenital, skin infections and other infections.

Ten patients (9.7%) had 20 infusion reactions (3.7% of all AEs) during 15 infusions. 16 of these infusion reactions occurred in 7 patients of group 1. Six of 10 patients with infusion reactions dropped out (4 due to these infusion reactions, all after reintroduction, the latest after visit 3).

There were 8 cases of uveitis in 4 patients, of whom 7 were flares and one was a new onset of uveitis. 1 patient of group 1 showed 3 flares, the other 3 patients belonged to group 2. Fourty-one dermatologic AEs occured during EASIC, 2 of these were established cases of psoriasis and 3 cases of herpes zoster. One worsening of Crohn's disease was reported.

We observed 12 SAEs during EASIC, 9 of those were considered to be unrelated to infliximab. The 3 remaining cases were labelled as possibly related to the drug. One of these 3 SAEs was a pneumonia, one a chronic sinusitis that required surgical intervention. The third SAE was a diverticulitis with colon perforation which required partial colon resection and enterostomy, complicated by impaired wound healing. Two patients dropped out due to SAEs, one was this last case of diverticulitis, one an unrelated intraspinal calcification.

A total of 81 patients (78.6%) completed the trial, 22 (21.4%) dropped out. Of these 22 drop-outs 6 were attributable to AEs (4 to infusion reactions) and 4 due to lack of efficacy. The table summarizes the distribution of AEs of interest between the patient groups.

	Total	Group 1	Group 2
Number of AEs	545	70	475
Patients with AEs	88	13	75
Infections	257	27	230
Serious infections	3	0	3
Tuberculosis	0	0	0
Malignancies	0	0	0
Uveitis	8	3	5
Infusion reactions	20	16	4

Conclusion: Infliximab was well tolerated by the patients taking part in EASIC. Infections were the most common adverse events. Less than 10% of the patients (3.4% of patients in group 2) developed infusion reactions. Overall, infliximab was well tolerated and safe for AS patients over about 5 years.

1776

Thalidomide Delays the Rate of Relapse in Ankylosing Spondylitis After Discontinuing Etanercept Treatment. Xiaohu Deng, Feng Huang and Jianglin Zhang, Chinese PLA General Hospital, Beijing, China

Purpose: To determine whether thalidomide can delay relapse after discontinuing the treatment of etanercept in ankylosing spondylitis (AS) and to investigate the predictors of the relapse.

Method: One hundred and twenty male patients with active AS were enrolled to a randomized, double-blind, and placebo-controlled clinical study and treated with etanercept 50mg/wk for 12 weeks. BASDAI, BASFI, BASMI, patient's global assessment (PGA) VAS, nocturnal spinal pain VAS, global spinal pain VAS, morning stiffness, enthesitis indices, total swollen and tender joint counts as well as biochemistry and safety profiles were taken at baseline and at week 12. One hundred and five of them attained an ASAS20 response at week 12. Etanercept was discontinued. These 105 patients were then randomly assigned to an open study to receive either thalidomide 150mg/night, or sulfasalazine (SSZ) 2.0g/day, or non-steroidal anti-inflammatory drugs (NSAIDs) only. All patients were followed monthly for BASDAI, BASFI, PGA and spinal pain VAS. A Kaplan-Meier survival analysis was used to calculate the probability of relapse which is defined by either increase of BASDAI of 2 or more compared to the lowest point, or alternately BASDAI returning to at least of 80% of baseline value before etanercept therapy. Cox proportional hazards regression analysis was used to identify possible predictors of relapse.

Results: One hundred patients completed the follow-up for up to 12 months, with a mean follow-up time 5.1 months. Thirty patients were treated with thalidomide, 33 patients with SSZ and 37 patients with NSAIDs only. At the end of follow-up, 79 patients (79.0%) relapsed. The mean relapse time was 3.2±2.0 months, with the shortest time of relapse 2 weeks. The percentage of patients who relapsed in the thalidomide group was 60.0%, much lower than SSZ group (84.8%) and NSAIDs group 89.2% (P=0.0265 and 0.0053 respectively). No difference was found between the relapse rates of SSZ and NSAIDs only group (P=0.58). In this study, thalidomide was safe and well tolerated. The most frequently reported adverse effects were drowsiness, increased dandruff, constipation and dry mouth. These adverse effects were mild in severity. Multivariate regression analysis revealed that at the point of discontinuing etanercept, the predictors of a early relapse were PGA ≥8 (P=0.0138), higher spine inflammation score (defined as the average of the last 2 VAS scores in the BASDAI concerning morning stiffness intensity and duration) ≥6.4 (P=0.0026) and CRP > 0.8mg/dl (P=0.0425).

Conclusion: Though relapse was common after discontinuing etancercept, thalidomide was more efficacious than SSZ or NSAIDs alone in preventing relapse. High PGA, spine inflammation score and CRP level at baseline predict early disease relapse.

Assessment of Ankylosing Spondylitis Criteria in Chronic Low Back Pain Patients with Vertebral Endplate Modic 1 Signal Changes. Christelle Nguyen[1], Imad Bendeddouche[1], Katherine Sanchez[1], Marylène Jousse[1], Agathe Papelard[1], Antoine Feydy[2], Michel Revel[1], Serge Poiraudeau[1] and François Rannou[1], [1]Rehabilitation Department, Cochin Hospital, Paris-Descartes University, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France, [2]Department of Radiology B, Cochin Hospital, Paris-Descartes University, AP-HP

Purpose: Chronic low back pain (CLBP) patients with vertebral endplate Modic 1 signal changes on lumbar magnetic resonance imaging (MRI) have been reported to display clinical features that could mimic back pain of inflammatory origin, especially back pain related to ankylosing spondylitis (AS). We aimed to assess whether CLBP patients with vertebral endplate Modic 1 signal changes on MRI fulfilled criteria for AS.

Method: Between April and September 2008, all patients (n = 314) referred to a tertiary care physical medicine and rehabilitation department in France were consecutively screened. 185 hospitalized for common CLBP were prospectively assessed. Forty patients (13 males) fulfilling inclusion criteria were consecutively enrolled, and included in 2 groups according to the MRI findings (Modic 1, n = 15 and non-Modic 1, n = 25). MRI were assessed independently by a panel of 2 spine specialists and a radiologist. Human leukocyte antigen (HLA)-B27 antigen status was evaluated in one laboratory. Recording of clinical parameters, fulfilment of Amor (AC) and clinical and radiological modified New York criteria (mNYC) were performed. All assessors were blinded to HLA-B27 antigen status.

Results: Whatever the Modic group, no patient fulfilled the AC and mNYC, and mean total scores were comparable (3 ± 2 [range 0-22; p = 0.977], 1 ± 1 [range 0-3; p = 1.000], and 0 ± 0 [range 0-1; p = 1.000] for AC and clinical and radiological mNYC, respectively). HLA-B27 status was similar in both groups (n = 2 [13%] vs. n = 0 [0%], p = 0.135).

Conclusion: CLBP patients with Modic 1 vertebral endplate signal changes on lumbar MRI do not fulfil widely used and validated criteria sets for AS. CLBP associated with Modic 1 signal changes on lumbar MRI is a clinical entity distinct from AS.

Soluble Biomarkers Predict Response to Anti-Tumour Necrosis Factor (TNF) Therapy in Psoriatic Arthritis (PsA). Vinod Chandran[1], Hua Shen[2], Remy Pollock[1], Fawnda Pellett[1], Catherine T. Schentag[1], Richard J. Cook[2] and Dafna D. Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON

Purpose: Soluble biomarkers for PsA have been identified. Our purpose was to identify biomarkers associated with response to therapy with anti-TNF agents in patients with active PsA.

Method: The study was conducted at a large observational PsA clinic where patients are assessed according to a standard protocol every 6 months and serum samples are collected and stored once a year at the time of clinical assessment. 40 patients with active PsA who had serum samples collected prior to treatment with anti-TNF agent and after at least 3 months of therapy were identified. Patients were classified as anti-TNF responders if actively inflamed joint count (AJC) was <3, swollen joint count (SJC) was 0 and PASI score was <4 at the time when the second sample was collected. Those not achieving this state were classified as partial responders. The following biomarkers were tested using commercially available ELISA kits: Tumour Necrosis Factor Super Family member 14 (TNFSF14 pg/mL), Matrix Metalloproteinase-3 (MMP-3 ng/mL) , Receptor Activator for Nuclear Factor κB Ligand (RANKL pmol/L), Osteoprotegrin (OPG pg/mL), Cartilage oligomeric protein (COMP ng/mL), C-propeptide of type II collagen (CPII ng/mL), collagen fragment neoepitopes Col2-3/4(long mono) (C2C ng/mL) and Col2-3/4(short) (C1-2C ug/mL), Aggrecan 846 epitope (CS-846 ng/mL) and highly sensitive C - reactive protein (hsCRP mg/L). Paired t-test and logistic regression was used to detect changes in biomarker levels with treatment and association with anti-TNF responder status.

Results: The 40 patients (28 males, mean age 44 years, psoriasis duration 17 years, PsA duration 12 years) had mean Actively inflamed Joint Count of 12, Swollen Joint Count of 6, and PASI score of 6.4 pre-treatment. After a mean treatment period of 11 months with anti-TNF agents (Etanercept 28, Adalimumab 6, Golimumab 4, Infliximab 2), 29 were classified as anti-TNF responders and 11 as partial responders. There was a significant decline in the serum levels of hsCRP ($p<0.001$), MMP-3 ($p<0.001$) and the ratio CPII/C2C ($p=0.039$), whereas there was an increase in RANKL ($p=0.002$) and C2C ($p=0.021$). Only reduction in MMP-3 correlated with reduction in hsCRP (correlation coefficient 0.43, $p=0.005$). Multivariate logistic regression showed that baseline level of MMP-3 was associated with attaining responder status [Odds ratio (OR) 1.067 for each one unit increase, 95% CI (1.002,1.138), $p=0.045$]. A reduction in MMP-3 levels increased the odds of achieving response (OR 1.213 for each one unit increase, 95% CI (1.019,1.445), $p=0.030$), whereas a reduction in COMP decreased it (OR 0.587, for each 100 units increase, 95% CI (0.354, 0.973), $p=0.039$).

Conclusion: Baseline as well as reduction in serum MMP-3 levels is associated with response to anti-TNF therapy in patients with PsA. Decline in MMP-3 levels correlate with decline in hsCRP.

1779

Soluble Biomarkers in Psoriatic Disease: Differences Between Psoriasis and Psoriatic Arthritis. Vinod Chandran[1], Jonathan Edwin[1], Hua Shen[2], Fawnda Pellett[1], Sutha Shanmugarajah[1], Catherine T. Schentag[1], Cheryl Rosen[1], Richard J. Cook[2] and Dafna D. Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON

Purpose: There is high prevalence of PsA in patients with psoriasis seen in dermatology clinic. Biomarkers may be helpful in screening psoriasis patients for PsA. Our purpose was to identify serum biomarkers for psoriasis and PsA.

Methods: Fifty-two patients with psoriasis and 26 healthy controls were recruited. Psoriasis was diagnosed by a dermatologist. 26 of these patients had PsA satisfying CASPAR classification criteria, and in the remaining 26 PsA was excluded by a rheumatologist. Patients with psoriasis and PsA were group matched for age, sex and psoriasis duration, while controls were matched for age and sex. Blood samples were drawn at the time of assessment and serum was analyzed for the following: Interleukin (IL)-12, IL-12 p40, IL-17 (all pg/mL), Tumour Necrosis Factor Super Family member 14 (TNFSF14 pg/mL), Matrix Metalloproteinase (MMP)-3 (ng/mL), Receptor Activator for Nuclear Factor κB Ligand (RANKL-pg/L), Osteoprotegrin (OPG-pg/mL), Cartilage oligomeric protein (COMP-ng/mL), C-propeptide of type II collagen (CPII-ng/mL), collagen fragment neoepitopes Col2-3/4(long mono) (C2C-ng/mL) and Col2-3/4(short) (C1-2C ug/mL), and highly sensitive C - reactive protein (hsCRP mg/L). Data were analyzed using logistic regression and Receiver Operating Characteristic curves.

Results: The 52 patients with psoriatic disease had a mean age of 46 years and psoriasis duration of 16.8 years. Compared to controls, increased serum levels of RANKL [Odds ratio per unit increase (OR) 1.004, 95% CI 1.000,1.008], TNFSF14 (OR 1.007, 95% CI 1.000,1.013), MMP-3 (OR 1.156, 95% CI 1.023,1.306) and COMP (OR 1.001 95% CI 1.000,1.002) independently associated with psoriatic disease ($p<0.05$) in a multivariate reduced full. The 26 PsA patients (mean PsA duration 13 years, actively inflamed joint count 16, swollen joint count 5) were then compared to 26 patients who had psoriasis alone, and to controls. hsCRP, OPG, TNFSF14, MMP-3, CPII/C2C were different between the 3 groups. Increased levels of hsCRP (OR 2.057 95% CI 1.127, 3.754), OPG (OR 1.011 95% CI 1.002,1.021), MMP-3 (OR 1.275 95% CI 1.018,1.597) and the ratio CPII/C2C (OR 4.762, 95% CI 1.352,16.767) were independently associated with PsA ($p<0.03$). ROC analysis using this reduced model showed an area under the curve (AUC) of 0.904. The full model had an AUC of 0.941

Conclusion: This pilot study indicates that hsCRP, OPG, MMP-3 and the ratio CPII/C2C are biomarkers for PsA in patients with psoriasis.

Infliximab Plus Methotrexate Significantly Improves Synovitis and Psoriatic Lesions in Methotrexate Naïve Psoriatic Arthritis (PsA) Patients: Results of the RESPOND† Trial. H. Raffayova[1], N. Kungurov[2], A. Kubanova[3], A. Baranauskaite[4], A. Venalis[5], L. Helmle[6], S. Srinivasan[7] and E. Nasonov[8], [1]National Inst. for Rheumatology Diseases, Piestany, Slovak Republic, [2]Urals Dermato-venerology Inst., Yekaterinburg, Russia, [3]Central DermatoVenerology Inst., Moscow, Russia, [4]Kaunas Medical Univ. Hospital, Kaunas, Lithuania, [5]Vilnius Univ. Hospital, Vilnius, Lithuania, [6]Schering-Plough Corp., Budapest, Hungary, [7]Schering-Plough Corp., Kenilworth, NJ, [8]Institute of Rheumatology, Moscow, Russia

Purpose: To assess the efficacy of infliximab (IFX) + methotrexate (MTX) vs MTX alone in MTX naïve patients with active, polyarticular PsA. This study is the first to assess anti-TNF + MTX vs MTX alone in early, MTX-naïve active polyarticular PsA.

Method: Patients ≥18 years of age with active PsA (≥5 swollen and tender joints, + one of the following; ESR≥28 mm/hr, CRP≥15 mg/L, morning stiffness≥45 min.) were included in this randomized, prospective, open-label, multi-center, multi-national study. Patients were naïve to MTX, anti-TNF agents, and could not be on DMARDS. Patients were randomized (1:1) to IFX (5 mg/kg) intravenous at week 0, 2, 6, and 14 + MTX (15 mg/week) or MTX (15 mg/week) alone. Study visits were at week 0, 2, 6, 14, and 16. The primary assessment was the proportion of ACR20 improvement at week 16. The study complied with Good Clinical Practices.

Results: 57 patients were randomized in the IFX + MTX group (48.2% male, mean age 40.1 years, mean disease duration 2.8 years)‡ and 58 in the MTX group (61.1% male, mean age 42.3 years, mean disease duration 3.7 years) ‡. Robust differences in clinical response of the articular and skin component favored the IFX + MTX group (table).

Baseline Characteristics‡ and Response‡	IFX + MTX	MTX
Tender joint count, mean (SD)	21.1 (13.32)	20.1 (11.24)
Swollen joint count, mean (SD)	15.1 (10.07)	14.3 (9.47)

CRP, mean (SD)	29.0 (38.83)	25.3 (26.11)
DAS28, mean (SD)	5.16 (1.074)	5.07 (1.178)
PASI, mean (SD)	8.27 (10.197)	11.62 (12.535)
ACR 20/50/70 (%)	86.3/72.5/49.0	66.7º/39.6¹/18.8¹
Good/Moderate DAS28 Response (%)	82.4/15.7	33.3/39.6²
DAS28 remission (%)	68.6	29.2²
PASI 50%/75%/90% (%)	100.0/97.1/70.6	80.0¹/54.3²/28.6¹

The most commonly reported adverse event was increased levels of alanine aminotransferase (~10% in both groups). There were 2 serious adverse events in the IFX+MTX group, 1 infusion reaction with dyspnoea and erythema and 1 latent tuberculosis reactivation. [Sign. levels for table ºp<0.05, ¹p<0.01, ²p<0.0001]

Conclusion: Early MTX naïve PsA patients with active disease achieved significantly greater ACR20 response rates and ≥75% improvement in PASI scores when treated with IFX + MTX compared to MTX alone. †(**RE**micade **S**tudy in **P**sA patients **O**f methotrexate-**N**aive **D**isease) ‡ITT analysis set.

Sustained Clinical Response in Psoriatic Arthritis Patients Treated with Anti-TNF Agents: A 5-Year Long-Term Study. Ioanna Saougou[1], Theodora E. Markatseli[1], Paraskevi V. Voulgari[2], Charalampos Papagoras[3] and Alexandros A. Drosos[4], [1]Trainee in Rheumatology, Ioannina, Greece, [2]Assistant Professor of Rheumatology, Ioannina, Greece, [3]Fellow in Rheumatology, Ioannina, Greece, [4]Ioannina Medical School, Ioannina, Greece

Purpose: To investigate the efficacy, safety and drug discontinuation in patients with psoriatic arthritis (PsA) treated with anti-tumor necrosis factor (TNF) agents.

Method: Fifty-five patients with PsA were included in this prospective open label study. All patients had active disease which was included: tender or swollen joint count ≥6, Psoriasis Activity Severity Index (PASI) score ≥10 and erythrocyte sedimentation rate ≥28 mmHg/H or C-reactive protein ≥10 mg/l. They were all refractory to at least 2 disease modifying anti-rheumatic drugs. Thirty were treated with infliximab, while 25 with etanercept. Infliximab (5 mg/kg/body weight) was given intravenously at weeks 0, 2, 6 and every 8 weeks thereafter for a period of 5 years, while etanercept was given subcutaneously (25 mg) twice a week for the same period of time. Data concerning anti-TNF therapy efficacy, tolerability, concomitant therapy, adverse events and drug discontinuation were recorded. The percentage of patients who achieved the Psoriatic Arthritis Response Criteria (PsARC) and the improvement of PASI were also recorded as well as the clinical improvement according to the American College of Rheumatology (ACR) criteria and the Disease Activity for 28 joint indices score (DAS-28).

Results: After 5 years of treatment with infliximab, PsARC was achieved by 60% (18/30), PASI70 by 66.7% (20/30), PASI90 by 63.3% (19/30), while ACR50 by 56.7% (17/30) and ACR70 by 33.3% (10/30) of the patients. On the other hand, after 5 years of treatment with etanercept, PsARC was achieved by 64% (16/25), PASI70 and PASI90 by 68% (17/25), while ACR50 by 56% (14/25) and ACR70 by 32% (8/25). A significant improvement was also noted in the DAS-28 score throughout the 5 years of the study in both groups. Five patients were increased the dose of infliximab and 3 of them have shortened the interval infusion. Overall, 13 patients treated with infliximab and 6 treated with etanercept were withdrawn from the study, mostly because of adverse events. At the end of the 5 years of treatment, the survival of infliximab was 56.7% , while the survival rate for the etanercept was 76%.

Conclusion: Both anti-TNF blockers were effective, safe and well-tolerated in patients with PsA. The clinical improvement was maintained through the 5 years of the study with sufficient infliximab and high etanercept survival rate.

Entheses Ultrasound (US) Evaluation in Early Psoriatic Arthritis (ePsA) Patients Is Independent of Psoriasis Extension and Clinics.

Francesca Bandinelli[1], Francesca Bartoli[1], Diletta Bonciani[2], Francesca Prignano[2], Sergio Generini[1], Torello Lotti[2], Antonio Candelieri[3] and Marco Matucci-Cerinic[4], [1]University of Florence, Italy, Florence, Italy, [2]University of Florence, Florence, Italy, [3]University of Calabria, Italy, [4]University of Florence, Firenze, Italy

Purpose: To investigate the presence of lower limb entheseal abnormalities in patients with early psoriatic arthritis.

Method: 92 patients with early PsA (ePsA), defined as inflammatory joint symptoms and signs with a duration < 1 year , with psoriasis (69), past psoriasis (2) and without psoriasis (21), diagnosed according to the Classification Criteria for Psoriatic Arthritis (CASPAR) [1] were consecutively studied with US (My Lab 25 XVG US Esaote 7-18 MHz linear array transducer) of Achilles, quadriceps, patellar entheses and plantar aponeurosis.

Patients (51 female and 41 male, 51±15 years old) were scored according to the 0-36 Glasgow Ultrasound Enthesitis Scoring System (GUESS)[2] and with total Power Doppler signal (calculated with semiquantitative system, score 0-3), with total Psoriasis Area and Severity Index (PASI) and with Maastricht Ankylosing Spondylitis Enthesitis Index (MASES). We studied the correlation between GUESS and Power Doppler with clinical characteristic of patient (PASI, MASES, pain and fatigue visual analogic scale -VAS-, duration of symptoms).

Results: Intraobserver agreement was high (interclass correlation coefficient 0,99). All patients presented almost one alteration on tendons (GUESS >1). Mean GUESS and Power Doppler score were respectively in patients 6,6±3,3 and 0,95±1,5. The GUESS score was not correlated with duration of symptoms, pain and fatigue VAS, morning stiffness (correlation coefficient of Spearman >0,05).

US revealed the presence of enthesophytes, erosions, bursitis, thickness of tendons, in different percentage (table 1).

Major features		
Enthesophytes	85%	
Erosions	6%	
Bursitis	27%	
Thickness of tendon (1)	Quadriceps (>6,1 mm)	40%
	Proximal rotuleus (>0,4 mm)	74%
	Distal rotuleus (>0,4 mm)	60%
	Achilleon (>5,29 mm)	30%
	Plantar fascia (>4,4 mm)	11%

Conclusion: Entheseal abnormalities are present in all patients in ePsA. US is a reliable tool to disclose entheseal involvement and more available than clinical examination and symptoms.

1783

Markers of Bone Formation Are Increased in Psoriatic Arthritis Compared to Rheumatoid Arthritis at Baseline and Increase Further After 3 Years of Anti-TNF-α Therapy. Agnes Szentpetery[1], Chin Teck Ng[1], Barbara F. Murray[2], Jennifer J. Brady[2], Phil Gallagher[1], Susan Van der Kamp[1], Barry Bresnihan[1], Douglas J. Veale[1], Malachi J. McKenna[2] and Oliver FitzGerald[1], [1]St. Vincent's University Hospital, Department of Rheumatology, Dublin, Ireland, [2]St. Vincent's University Hospital, Department of Metabolism, Dublin, Ireland

Purpose: To evaluate changes in clinical responses, bone turnover markers and bone mineral density (BMD) measurements in patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) prior to and 3 years after commencing anti-TNF-α therapy.

Method: RA and PsA patients were recruited following a decision to commence anti-TNF-a therapy. Clinical assessments including DAS28-CRP and HAQ were recorded. EULAR response criteria were applied. Markers of bone formation ((serum osteocalcin (OC1-49) serum procollagen type I Npropeptide (PINP) and serum bone alkaline phosphatase (bone ALP)) and of bone resorption (urine free deoxypyridinoline crosslinks (fDPD) and urine N-terminal crosslinking telopeptide of type I collagen (NTX-I)) were measured at baseline, 1 and 3 years. The results are reported as T-values. Bone density measurements (DXA) were obtained at baseline, 1 year and 3 years (spine and hips).

Results: 51 patients (28 RA, 23 PsA) out of 62 recruited completed 3 years of follow up. At baseline ESR and CRP levels were lower in PsA than RA (median ESR 10 v. 25 p=0.0017; median CRP 8.0 v. 21.5 p=0.004). DAS28 CRP level was lower in PsA at all time points during the study. After 3 years follow up DAS28 CRP and HAQ were lower in both PsA and RA than at baseline (median DAS28CRP PsA 2.85 v. 5.67, RA 3.35 v. 5.925 p<0.0001) (HAQ median PsA 0.5 v. 1.125 p=0.0192, RA 0.5 v. 1.31 p=0.0002). Bone ALP was higher at baseline and at 3 years in PsA compared to RA (median bone ALP at baseline 1.42 v. -0.03 p=0.0117). After 3 years of anti-TNF-αtherapy bone ALP increased in both diseases compared with baseline (median bone ALP PsA 3.1 v. 1.42 p=0.0001, RA 1.855 v. 0.05 p= 0.0002). PINP levels were also higher in PsA good responders (PsAGR) at 3 years compared to baseline (median PINP 0.88 v. -0.59 p=0.0266). There were no significant differences observed between RA and PsA in terms of bone density measurements at the different time points. In RA BMD and T-scores were lower at 3 years compared to baseline measurements (median BMD hip 0.931 v. 0.933 p=0.0436, median T-score hip -0.3 v. -0.1 p=0.0377; median BMD spine 0.97 v. 1.007 p=0.0325, median T score spine -0.9 v. -0.5 p=0.0447). In contrast, BMD and T-scores increased in PsAGR in the lumbar spine (median BMD 1.03 v. 0.96 p=0.0015; median T-score 0 v. -0.5 p=0.0039).

Conclusion: DAS28 CRP scores are higher in RA compared to PsA at all time points but clinical responses to anti-TNF-α therapy were similar in both diseases after 3 years follow up. Bone formation markers, in particular bone ALP is higher in PsA compared to RA at baseline and at 3 years but increases in both treatment groups after 3 years. Following anti-TNF-α therapy bone remodelling balance improves in both diseases with an increase in bone formation and a decrease in bone resorption. In PsA but not in RA axial bone density loss is reversed after 3 years of anti-TNF-α therapy.

The Extended SPARCC MRI Spinal Inflammation Score: Assessment of Inflammation in Posterior Elements of the Spine Substantially Increases Discrimination. Walter P. Maksymowych[1], Sean M. Crowther[2], Suhkvinder S. Dhillon[2] and Robert GW Lambert[2], [1]Department of Medicine, University of Alberta, Edmonton, AB, [2]Department of Radiology, University of Alberta, Edmonton, AB

Purpose: Systematic evaluation has shown a high frequency of inflammatory lesions in the posterior elements of the spine on MRI which are responsive to treatment with anti-TNF. It is unclear whether formal scoring of these lesions enhances the performance of established MRI-based instruments for scoring inflammation in the spine. We aimed to assess the performance of the Spondyloarthritis Research Consortium of Canada (SPARCC) MRI spinal inflammation score when inflammation in posterior elements is additionally quantified.

Method: We scanned 32 patients recruited to randomized placebo-controlled trials of various anti-TNF therapies (12-24 weeks). Inflammatory lesions were detected by systematic review of consecutive sagittal STIR slices of the entire spine imaged in two halves and were recorded dichotomously (present/absent) using a custom-designed online scoring tool depicting the following posterior elements: pedicle, facet joint, processes (transverse and spinous), soft tissues. Two readers independently evaluated pre- and post-treatment films, blinded to diagnosis and time sequence, on a 3-monitor review station that permits simultaneous visualization of all spinal segments. Vertebral body inflammation was also quantified using the SPARCC MRI method for both clinical trials (the 6-DVU score: scoring limited to the 6 most severely affected disco-vertebral units) and observational studies (the 23-DVU score: all 23 DVU are scored) using an online scoring tool. Discrimination was assessed by Guyatt's effect size (ES). Convergent validity with clinical measures of disease activity was assessed using Spearman's correlation.

Results: The median number of spinal levels with inflammation in at least one posterior element per patient was 5.5 (mean (SD) = 6.7(5.3)). The spinous processes were the most commonly affected structure (median per patient = 3, mean (SD) = 3.7(2.9)). Discrimination between anti-TNF therapy and placebo was substantially enhanced when inflammation in posterior elements was scored and added to either the 6-DVU or 23-DVU scores. This was noted irrespective of whether inflammation was scored in each individual posterior element (All-PE score) or when inflammation was recorded as being present in at least one of the posterior elements at a particular spinal level (Any-PE score). Correlation with change in CRP was also superior when either the All-PE or Any-PE score was added to the SPARCC MRI 6-DVU or 23-DVU scores. No significant correlation was noted between change in BASDAI and any MRI score.

	6-DVU	**6-DVU +Any-PE**	**6-DVU + All-PE**	**23-DVU**	**23-DVU + Any-PE**	**23-DVU + All-PE**
Guyatt's ES	2.68	3.39	3.83	3.01	3.77	4.07
Correlation with CRP	0.43	0.51	0.60	0.50	0.51	0.59

Conclusion: The addition of a simple dichotomous method for scoring posterior element inflammation substantially enhances the discrimination provided by the SPARCC MRI spinal inflammation score which quantifies inflammation in the vertebral bodies. This method may be particularly valuable for proof-of-concept studies of new therapeutics in ankylosing spondylitis.

Infliximab Withdrawal in Patients with Spondyloarthritis Who Presented Criteria of Clinical Disease Remission. An Open Study of Clinical Practise (REMINEA). V. Torrente[1], J. Gratacos[2], X. Juanola[3], R. Sanmartí[4], D. Suarez[5], M. Moreno[6] and REMINEA Group, [1]Hospital Sant Pau, Barcelona, Spain, [2]H Parc Taulí, Barcelona, Spain, [3]Hospital Universitari Bellvitge (IDIBELL), Barcelona, Spain, [4]H Clínic i Provincial, Barcelona, Spain, [5]Parc Taulí Hospital, Sabadell, Spain, [6]Parc Tauli Hospital, Sabadell, Spain

Purpose: Anti-TNF therapy (infliximab) has demonstrated good efficacy, especially in early-onset spondyloarthritis patients. However, the consequences of infliximab withdrawal in these patients are not yet determined, particularly in those who reach an excellent response.

Objective: To evaluate the percentage of patients under infliximab treatment who achieve criteria of clinical remission. To assess, after 1 year follow-up, the outcome after infliximab withdrawal in disease remission achieved patients and in the re-treated ones since they had a disease flare.

Methods: 107 patients (70%M) mean age 42 yrs (20-72) with spondylarthitis (82 with ankylosing spondylitis, 25 with undifferentiated spondylarthritis) who met criteria of anti-TNF therapy were included and treated with infliximab (5mg/Kg, 0,2, 6 and every 8 weeks infusions). The mean disease duration before treatment was 11 yrs (0.5-39), 50% of patients included had less than 10 yrs of disease evolution. Infliximab withdrawal was performed in those patients who presented persistent clinical remission (two consecutive visits, after the induction period) defined as both absence of peripheral arthritis/enthesitis and presence of a BADAI≤2 and a CRP≤0.8mg/dl. During the discontinuation treatment period (≈1yr) patients who presented a flare (BASDAI≥4) were re-treated with infliximab (5mg/Kg every 8 weeks.

Results: 36/107 patients (34%) achieved remission criteria. Remission patients compared to non-remission ones were significantly younger (39 vs 43 p=0.05) had a lesser disease evolution (9 vs 14, p=0.04) and more disease activity (CRP 3.4 vs 1.6 mg/dl, p=0.005). Over the treatment discontinuation period 21/36 patients (58%) presented a flare (62% during the first 6 months). After reintroduction of infliximab therapy 11/21 (52%) again reached clinical remission, and only 3/21 (14%) did not achieved a significant response (BASDAI≥4). No other problems associated to re-treatment were observed.

Conclusion: Infliximab as continuous therapy appears to be the best choice in this group of patients with spondylarthritis. However, we observed both high (34%) percentage of complete remission patients during 1yr follow-up, and good efficacy and safety of infliximab re-treatment in reactivated patients. In terms of cost-effectiveness, these findings seem to reinforce the infliximab withdrawal in clinical practise in patients who get persistent clinical remission.

Achievement of a Patient Acceptable Symptom State (PASS) and of a Minimum Clinically Important Improvement (MCII) with Etanercept in Refractory Heel Enthesitis Related to Spondyloarthritis: Results of a Double Blind Placebo Controlled Study (HEEL).

M. Dougados[1], B. Combe[2], J. Braun[3], R. Landewe[4], J. Sibilia[5], Alain Cantagrel[6], V. Leblanc[7] and I. Logeart[7], [1]Hôpital Cochin and University of Paris, Paris, France, [2]Immuno-Rheumatology, Montpellier, France, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Maastricht Univ Medical Ctr, Maastricht, Netherlands, [5]University Hospital of Strasbourg, Strasbourg, France, [6]JE 2510, Purpan University Hospital, Toulouse, France, [7]Wyeth Pharmaceuticals France

Purpose: To investigate the short-term symptomatic efficacy of etanercept in chronic heel enthesitis related to spondyloarthritis (SpA)

Method: Prospective, randomized, 12-week, placebo- controlled trial. *Study treatments*: etanercept 50 mg OW *vs* placebo. *Patients*: Adults, SpA (Amor criteria) with active and refractory heel enthesitis. *Outcome variables*: Apart from the conventional ones (*e.g.* visual pain [VAS scale 0-100], function [WOMAC function sub-scale, normalized unit 0-100]), the PASS concept was evaluated according to the following question: "*If you were to remain in the next several months as you were during the last 48 hours, would this be acceptable for you?*" and the MCII by "*Compared to when you started the study, how have you been during the last 48 hours*?" Such questions were asked at each visit after baseline. *Statistical analysis*: Time to reach a sustained PASS using the Kaplan Meier survival analysis and Log-Rank test; MCII using a GEE model.

Results: Of the 24 enrolled patients (males: 67%, age: 37±12 y, B27 positive: 71%), 12 received etanercept and 12 placebo. Groups were comparable at baseline concerning symptomatic activity of the disease (patient's global: 70±17, heel pain: 68±16, functional impairment: 47±20). Estimated percentage of patients achieving a sustained PASS after 3 months was 50% vs 0% (p=0.0168) in the etanercept and placebo group respectively and such status was achieved as soon as the first 4 weeks of therapy. Statistically significant difference between etanercept and placebo was reported for the MCII at week 12 (75% versus 22.2% patients very or moderately improved, p=0.020).

Conclusion: This study, the first one using a prospective, placebo-controlled design in patients with active and refractory heel enthesitis demonstrated a symptomatic clinically relevant and statistically significant effect of etanercept. In addition it shows the achievement of another treatment goal such as PASS and MCII, addressing "therapeutic success" at patient level

This study was sponsored by Wyeth Pharmaceuticals France.

1787

Health-Related Quality of Life (Physical Component) in Ankylosing Spondylitis Is Independently Determined Both by Disease Activity and by Physical Function. Pedro Machado[1], Robert Landewé[2], Jürgen Braun[3], Kay-Geert Hermann[4], Benjamin Hsu[5], Daniel Baker[5] and Désirée M.F.M. van der Heijde[6], [1]Coimbra University Hospital, Coimbra, Potugal, and Leiden University Medical Center, Leiden, Netherlands, [2]University Hospital Maastricht, Maastricht, Netherlands, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Charité Medical School, Berlin, Germany, [5]Centocor Inc., Malvern, PA, [6]Leiden University Medical Center, Leiden, Netherlands

Purpose: Improvement in patients' quality of life is one of the ultimate goals in health care. In order to achieve that goal it is useful to understand the health concepts driving quality of life in ankylosing spondylitis (AS). Our aim was to investigate which factors determine the level of the physical component summary score of health related quality of life (QLPCS) in patients with AS.

Method: In this investigator-performed sub-analysis of the ASSERT database at baseline, in total 214 patients, representing an 80% random sample, were investigated. The Short Form 36 health survey questionnaire was used to assess QLPCS, physical function was assessed by the BASFI, spinal mobility by the linear definition of the BASMI (BASMI-lin), disease activity by the ASDAS-CRP or by the BASDAI, MRI inflammation by the ASspiMRI-a score and structural damage by the mSASSS. Correlations were performed by use of Spearman correlation analysis. Univariate regression analyses were used to examine for associations and to select the variables to enter in a linear regression analysis. C-reactive protein, disease duration, age, sex, body mass index and HLA-B27 status were also investigated. Non-normally distributed variables underwent a normalization procedure using the van der Waerden technique before entering in the linear regression analysis.

Results: QLPCS correlated moderately well with BASFI (Spearman's rho=-0.55), ASDAS (rho=-0.34) and BASDAI (rho=-0.48) and weakly with BASMI-lin (rho=-0.19) and age (rho=-0.18). In the linear regression analysis only BASFI, disease activity (either ASDAS or BASDAI) and sex remained significantly associated with QLPCS (table I). Results were similar using either ASDAS or BASDAI.

Table I: Best-fit model for QLPCS

	B (95% CI)	**Beta**	**p-value**
BASFI	-1.910 (-2.396, -1.425)	-0.501	<0.001
ASDAS	-1.450 (-2.317, -0.583)	-0.193	0.001
BASMI-lin	0.222 (-0.343, 0.787)	0.048	0.439
Age	-0.072 (-0.154, 0.010)	-0.099	0.085
Sex (male)	2.524 (0.595, 4.453)	0.144	0.011

Conclusion: Quality of life (physical component summary score) in patients with AS is independently determined both by disease activity and by physical function. Function and disease activity should be critical domains in the treatment of AS in order to maximize benefits in quality of life.

1788

Is Adalimumab An Efficacious Treatment for Enthesitis of the Achilles Tendon in Patients with Spondyloarthritis? Christopher Ritchlin[1], Philip Mease[2], Renee Perdok[3], Hartmut Kupper[4] and Frédéric Lavie[5], [1]University of Rochester, Rochester, NY, [2]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [3]Abbott Laboratories, Abbott Park, IL, [4]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [5]Abbott Laboratories, Rungis, France

Purpose: Adalimumab (ADA) significantly improved enthesitis for patients (pts) with ankylosing spondylitis (AS) in the ATLAS trial,[1] but the efficacy of ADA for spondyloarthritis (SpA) pts with enthesitis (including pts with peripheral SpA) has never been evaluated. This *post-hoc* analysis compared the effect of ADA vs. placebo (PBO) for enthesitis of the Achilles tendon in pts with peripheral and/or axial SpA who were enrolled in 1 of 3 different clinical trials.

Methods: ATLAS was a Phase III randomized controlled clinical trial comparing ADA with PBO in pts with AS.[1] ADEPT was a Phase III randomized controlled clinical trial comparing ADA with PBO in pts with psoriatic arthritis (PsA).[2] RHAPSODY was an open-label study assessing the effectiveness of ADA in pts with AS in typical European clinical settings.[3] In both ATLAS and ADEPT, only enthesitis of the Achilles tendon was assessed. Data from pts who had at least 1 Achilles tendon enthesitis in ATLAS and ADEPT were analyzed separately and as pooled data at available time points. Similar data from RHAPSODY were analyzed at baseline and at Weeks 2 and 12.

Results: Data from 309 pts in ATLAS (ADA, N=204; PBO, N=105), 310 pts in ADEPT (ADA, N=149; PBO, N=161), and 1,220 pts in RHAPSODY were analyzed. A greater percentage of pts with PsA in the ADEPT trial had enthesitis of the Achilles tendon than pts with AS in either the ATLAS or RHAPSODY trials (32.0%, 21.7%, and 18.4%, respectively). Results over time are presented in the table.

Patients With Enthesitis of at Least 1 Achilles Tendon at Different Time Points in ADEPT, ATLAS, and RHAPSODY

	Clinical Trial						
	ADEPT		**ATLAS**		**ADEPT+ATLAS**		**RHAPSODY**
Time Point	ADA N=149	PBO N=161	ADA N=204	PBO N=105	ADA N=353	PBO N=266	ADA N=1,220
Week 0	47 (31.5)	52 (32.5)	39 (19.1)	28 (26.7)	86 (24.4)	80 (30.2)	224 (18.4)
Week 2	47 (31.8)	54 (33.5)	NA	NA	NA	NA	98 (11.7)
Week 4	41 (27.5)	47 (30.1)	NA	NA	NA	NA	NA
Week 8	32 (21.9)	48 (31.2)	NA	NA	NA	NA	NA
Week 12	29 (20.4)[a]	52 (33.8)	26 (17.3)	9 (17.6)	55 (18.8)[a]	61 (29.8)	65 (8.1)

Data shown are n (%). [a]$p<0.05$ compared with PBO using Fisher's exact test.

NA=not applicable (enthesitis was not assessed at these time points in ATLAS or RHAPSODY).

Conclusion: These data demonstrate the efficacy of ADA on Achilles tendon enthesitis for pts with axial or peripheral SpA.

Sexual Functioning in Male Ankylosing Spondylitis Patients. Anthony So[1], Finbar (Barry) D. O'Shea[2] and R.D. Inman[2], [1]University of Toronto, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON

Purpose: Ankylosing Spondylitis (AS) is commonly associated with fatigue, pain, and stiffness, resulting in significant disability. Sexual functioning plays an important role as a contributor to quality of life factors. Sexual functioning in AS patients has not been studied extensively. This study assessed the sexual function of male AS patients and its correlation with to various measures of disease activity and severity.

Methods: The International Index of Erectile Function (IIEF) was used as a validated measure of sexual functioning, with a higher score reflecting better sexual function. Nocturnal Back Pain (NBP), Total Back Pain (TBP), Global Disease Activity (GDA), BAS-G (Bath Ankylosing Spondylitis Global score), BASDAI (BAS Disease Activity Index), BASFI (BAS Functional Index), and ASQoL (AS Quality of Life) surveys were self-administered to randomly selected AS patients. Spearman rank correlation was used to assess for correlation. Student t-test was used to compare morbidity measures between groups. P values less than 0.05 were considered significant.

Results: 27 Male AS patients were recruited, of whom 23 patients were on an anti-TNF agent and 4 were on NSAIDs. The mean age of the group was 39.6±12.2 years. 4 patients (all on an anti-TNF agent) reported no sexual activity. According to the Sexual Health Inventory for Men (SHIM), a sensitive marker for erectile dysfunction (ED) constructed from the IIEF, 10 of the 23 patients with sexual activity had ED (mild ED=6, mild-moderate ED=1, moderate ED=2 , and severe ED=1). Of the 23 patients, 3 were taking sildenafil or tadalafil, two were on anti-depressants, and one was on a β-blocker. IIEF scores negatively correlated with NBP (rho=-0.553, p=0.006), TBP (rho=-0.675, p<0.001), GDA (rho=-0.526, p=0.010), BAS-G (rho=-0.718, p<0.001), BASDAI (rho=-0.712, p<0.001), BASFI (rho=-0.612, p=0.002), and ASQoL (rho=-0.437, p=0.037). A subcomponent analysis of the IIEF demonstrated that different subcomponents correlated with different measures of morbidity. Significant differences were found between patients with and without ED in regards to NBP (p=0.01), TBP (p=0.003), GDA (p=0.013), BAS-G (p=0.003), BASDAI (p=0.001), and BASFI (p=0.001), but not ASQoL (p=0.057) nor age (p=0.172). The mean IIEF scores of patients on Biologics *vs* NSAIDs alone were 62.8±9.0 vs 38.5±11.7 respectively (p<0.001).

Conclusion: Sexual dysfunction is common in AS patients and the strongest correlation was with the degree of pain experience by the patient. Patients with ED had worse indicators of back pain severity compared to those without ED. Patients with sexual activity on biological therapy reported significantly higher IIEF scores, reflecting better sexual functioning, than those on non-biological therapy.

1790

Update of the ASAS Recommendations On the Use of TNF-Blockers in Ankylosing Spondylitis. Désirée M.F.M. van der Heijde[1], Joachim Sieper[2], Walter P. Maksymowych[3], Maxime Dougados[4], Ruben Burgos Vargas[5] and Jürgen Braun[6], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Charite - Campus Benjamin Franklin, Berlin, Germany, [3]University of Alberta, Edmonton, AB, [4]Paris Descartes University, Medicine Faculty - Cochin Hospital, Paris, France, [5]Universidad Nacional Autonoma de Mexico, Mexico, Mexico, [6]Rheumazentrum Ruhrgebiet, Herne, Germany

Purpose: ASAS, the Assessment of SpondylArthritis international Society has published recommendation on the use of TNF-blockers (aTNF) in AS in 2003 with an update in 2006. The aim of the current work is to update the recommendations taking into account available literature, a survey among rheumatologistis worldwide and the expert opinion of the ASAS members.

Method: The literature on the management of AS was reviewed since the last review in 2005. A survey asking about the conceptual agreement with the current recommendations and the level of application in practice as well as the barriers in applying the recommendations was completed by 787 practicing rheumatologists in 13 countries in Europe, Asia, Middle-East, S-America and Canada. These data were presented to the ASAS members, a group of experts in the field of AS, in two sessions. Discussion and voting resulted in the following changes.

Results: The recommendation on the diagnosis is expanded to: 'Patients fulfilling the modified New York criteria or the ASAS criteria for axial SpA'. The latter criteria indicate that MRI can be used to define sacroiliitis on imaging. Inadequate response to NSAIDs is considered fulfilled if at least 2 NSAIDs are ineffacious (or not tolerated) over a 4-week period in total. Pretreatment with sulfasalazine in patients with predominantly peripheral symptoms is no longer mandatory. However, patients with predominantly peripheral symptoms 'Should normally have had a therapeutic trial of a DMARD, preferably sulfasalazine'. Patients with pure axial manifestations do not have to take DMARDs

before anti-TNF treatment can be started. The level and assessment of response is unchanged (improvement of >=50% in BASDAI or >=2 units), but the timeperiod to assess response has been extended to 'at least 12 weeks'. The recommendations on monitoring (ASAS core set for clinical practice and BASDAI) remain unchanged. There are no special recommendations with respect to safety for patients with AS as compared to other rheumatic diseases treated with aTNF.

Conclusion: The updated recommendations give the option to include patients at an earlier stage of the disease with sacroiliitis on MRI but without structural damage on radiographs. Moreover, the requests for pretreatment have been loosened both for the duration of treatment with NSAIDs and no longer a mandatory use of sulfasalazine in patients with predeominantly peripheral involvment. This is all in accordance with data from the literature, and the wishes from a large group of practicing rheumatologists worldwide and AS experts.

1791

Validation of the Assessment of Spondyloarthritis International Society (ASAS) Disease Activity Candidate Scores According to MRI Parameters of Axial Inflammation. Walter P. Maksymowych[1], Praveena Chiowchanwisawakit[2] and Robert GW Lambert[1], [1]University of Alberta, Edmonton, AB, [2]Siriraj Hospital, Mahidol University, Bangkok, Thailand

Purpose: Four candidate disease activity indices for AS (ASDAS1-4) have been developed by ASAS based on a Delphi exercise amongst ASAS experts followed by item selection according to the theoretical decision by ASAS members whether to start treatment with anti-TNF agents. Further validation using objective parameters of disease activity is desirable. MRI shows active inflammation in both the sacroiliac joints (SIJ) and spine that correlates with histopathological scores and is responsive to anti-TNF agents. We aimed to validate the candidate ASAS disease activity indices according to MRI parameters of axial inflammation and compare them with current methods for assessing disease activity.

Method: We studied 89 patients with AS by modified New York criteria followed prospectively who received either standard therapy (n = 53) or anti-TNF agents (n = 36). Clinical and lab assessments were collected at baseline, 3 months (for anti-TNF patients), and every 6 months. MRI of the SIJ and spine was conducted at baseline and at 3-12 months. Data on clinical, lab, and MRI was also available at baseline and 12-24 weeks on 30 AS patients recruited to placebo-controlled trials of anti-TNF agents. MRI quantification of axial inflammation was based on the Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ and Spine scoring methods with spinal inflammation being measured in all 23 spinal units. SPARCC SIJ and Spine scores were combined into a SPARCC Total axial inflammation score. Correlations of baseline and change scores between the ASDAS indices and SPARCC scores were assessed by the Pearson correlation coefficient. Discriminatory ability of the ASDAS indices was compared using the standardised mean difference between subgroups of patients with high versus low disease activity defined by the SPARCC scores (<10 and >30 = low and high activity, respectively, for both baseline and change scores).

Results: All the ASDAS change scores correlated significantly and similarly with change scores for MRI in the anti-TNF trial cohort (p = 0.02-0.006) but only change in ASDAS1 and ASDAS3 scores correlated significantly with MRI in the anti-TNF treated observational cohort. For baseline scores the weakest correlation was observed for ASDAS2. Discriminatory ability was also lowest for ASDAS2 according to baseline and change scores for MRI inflammation. None of the ASDAS indices outperformed the CRP.

	Baseline MRI correlation	**Change MRI* correlation**	**Change MRI** correlation**	**Baseline MRI SMD**	**Change in MRI SMD**
ASDAS1	0.32 (0.003)	0.37 (0.03)	0.49 (0.01)	0.76	0.66
ASDAS2	0.24 (0.03)	0.29	0.44 (0.02)	0.54	0.49
ASDAS3	0.32 (0.002)	0.41 (0.02)	0.46 (0.007)	0.71	0.60

ASDAS4	0.30 (0.005)	0.32	0.52 (0.006)	0.72	0.60
BASDAI	0.17	0.31	0.51 (0.002)	0.27	0.52
CRP	0.39 (<0.0001)	0.53 (0.001)	0.40 (0.02)	0.58	0.86
ESR	0.26 (0.005)	0.22	0.44 (0.02)	0.37	0.42
** observational cohort **clinical trial cohort p values provided in brackets*					

Conclusion: This analysis supports the construct validity of the ASDAS indices according to MRI scores for axial inflammation. The ASDAS2 performs less well and none of the indices outperforms the CRP.

Associations with Radiographic Damage in Ankylosing Spondylitis in a Large Cohort. Finbar (Barry) D. O'Shea, Nigil Haroon, Reena Riarh and R.D. Inman, Toronto Western Hospital, Toronto, ON

Purpose: To study the radiographic damage in a large ankylosing spondyltis (AS) in relation to multiple clinical parameters using the modified Stoke AS Spinal Score (mSASSS).

Methods: The patients were drawn from the clinical database of the Spondylitis Clinic in a large teaching hospital. Patients are evaluated according to a standard protocol in which demographic, clinical, radiographic and laboratory variables are recorded at regular intervals. Mean and standard deviation (SD) were calculated for the various clinical variables. The mSASSS was correlated with the grade of sacroiliitis using Pearson correlation coefficients, and the mSASSS was examined in a number of different sub-groups.

Results: Data was available for 319 AS patients who all fulfilled modified New York criteria. 79.9% were male, 80.5% were HLA-B27 positive, and 22.3% had juvenile onset AS (defined as symptom onset ≤ 16 years old). Mean (+/-SD) BASDAI was 4.6 (+/-2.6), mean BASFI was 3.8 (+/-2.8), and mean mSASSS was 18.4 (+/-22.6). Mean age was 40.2 (+/-13.1). Mean ESR was 13.5 (+/-14.5), and mean CRP was 11.9 (+/-15.5). There was a significant difference between the mSASSS scores for males versus female patients, for HLA-B27 positive versus negative patients, and for Adult onset versus Juvenile onset patients – see Table 1. There was a good correlation between the total mSASSS score and the grade of sacroiliitis ($r=0.616$, $p<0.001$). Specifically, male patients ($r= 0.630$, $p<0.001$), and adult-onset patients ($r=0.653$, $p<0.001$), had the strongest correlation between severity of spinal and sacroiliac disease.

Conclusion: Male AS patients who are HLA-B27 +ve, have the highest radiographic scores according to the mSASSS. Radiographic changes in the spine correlate well with the severity of sacroiliitis. Juvenile onset AS patients have less severe radiographic damage in comparison to adult onset AS. These features should assist in the identification of patients at higher risk of radiographic damage.

	Mean mSASSS (+/-SD)	
Total Cohort (N=319)	18.4 (+/-22.6)	
Male	20.9 (+/-23.8)	
Female	8.2 (+/-12.6)	p<0.001
Adult onset	21.1 (+/-23.9)	
Juvenile onset	8.8 (+/-13.5)	p<0.001
B27+ve	18.5 (+/-22.7)	
B27-ve	11.5 (+/-16.2)	p=0.007

Table 1. mean (+/-SD) MSASSS for the different subgroups

The Majority of Peripheral Spondyloarthritis Is 'Undifferentiated' at the Time of Diagnosis – Lessons From the ASAS Study On New Classification Criteria for Peripheral Spondyloarthritis. M. Rudwaleit[1], Désirée M.F.M. van der Heijde[2], R. Landewé[3], N. Akkoc[4], J. Brandt[5], J. Braun[6], CT Chou[7], M. Dougados[8], J. Gu[9], F. Huang[10], H. Mielants[11], I. Olivieri[12], E. Roussou[13], M. Ostergaard[14], S. Scarpato[15], R. Valle-Oñate[16], J. Wei[17] and J. Sieper[1], [1]Charité, Berlin, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Maastricht, Netherlands, [4]Izmir, Turkey, [5]Berlin, Germany, [6]Herne, Germany, [7]Taipei, Taiwan, [8]Paris, France, [9]Guangzhou, China, [10]Beijing, China, [11]Gent, Belgium, [12]Potenza, Italy, [13]London, United Kingdom, [14]Copenhagen, Denmark, [15]Scafati, Italy, [16]Bogota, Colombia, [17]Taichung, Taiwan

Purpose: The Assessment in SpondyloArthritis international Society (ASAS) has recently developed new classification criteria for axial SpA and new criteria for peripheral SpA. In the group of patients with peripheral symptoms only, we were interested to assess the frequencies of SpA subgroups.

Method: In a prospective international study involving expert rheumatologists from ASAS, patients with axial and/or peripheral symptoms, an age at onset <45 years, and no definite diagnosis at the time of referral were included. Among these, 266 patients had peripheral manifestations only. The clinical expert diagnosis (SpA vs no SpA) upon routine diagnostic work-up was taken as reference standard for diagnosis. Patients with peripheral SpA but without concomitant psoriasis, without inflammatory bowel disease (IBD), and without evidence of preceding infection (clinical or laboratory) were classified 'undifferentiated' peripheral SpA. The ASAS classification criteria for peripheral SpA (arthritis or enthesitis or dactylitis PLUS [≥1 of psoriasis, IBD, preceding infection, HLA-B27, uveitis, sacroiliitis by imaging (radiographs or MRI)] or [≥2 of arthritis, enthesitis, dactylitis, IBP, positive family history for SpA]) were compared with the ESSG and Amor criteria.

Results: Of the 266 patients, 86.6% had peripheral arthritis, 45.9% enthesitis, and 14.7% dactylitis (all were clinically assessed). A diagnosis of SpA was made in 176 patients (66.2%) in whom psoriasis was found in 9.1%, IBD in 3.4%, and evidence of preceding infection (i.e. reactive arthritis) in 5.7%. Radiographic sacroiliitis was found in 18.0% and active sacroiliitis on MRI in 12.5% but none of these patients had current back pain and only 1 patient had previous IBP. Thus, peripheral SpA not associated with psoriasis, IBD or preceding infection ('undifferentiated SpA) was diagnosed in 81.8% of all SpA patients. The ASAS classification criteria for peripheral SpA had a sensitivity of 75.0% and specificity of 82.2%. This was a better sens/spec balance than the ESSG criteria (sens. 55.1%, spec. 81.1%), ESSG modified for MRI (sens. 62.5%, 81.1%), Amor criteria (sens. 35.2%, spec. 97.8%), and Amor modified for MRI (sens. 39.8%, spec. 97.8%).

Conclusion: The majority of newly diagnosed peripheral SpA patients is 'undifferentiated' at the time of diagnosis. The new ASAS classification criteria for peripheral SpA performed well in patients with predominant peripheral manifestations, and appeared to be better balanced than the ESSG and Amor criteria.

High Sensitivity C-Reactive Protein Outperforms Standard C-Reactive Protein in Disease Activity Assessment in Patients with Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis. Denis Poddubnyy[1], Martin Rudwaleit[1], Joachim Listing[2], Jürgen Braun[3] and Joachim Sieper[1], [1]Charité - Campus Benjamin Franklin, Berlin, Germany, [2]DRFZ, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany

Purpose: This study was aimed at comparing high sensitivity C-reactive protein (hsCRP) measurement with routine C-reactive protein (CRP) evaluation as disease activity parameters in patients with ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (SpA).

Method: 269 patients (153 with AS and 116 with non-radiographic axial SpA) from the German Spondyloarthritis Inception Cohort (GESPIC) were included. hsCRP levels were measured using particle-enhanced immunoturbidimetric method (Roche) with the lowest detected level of 0.1 mg/l. hsCRP values were compared to results of routine turbidimetric CRP test with the lowest detected level of 6 mg/l.

Results: In the group of patients with AS (n = 153) hsCRP showed better than routine CRP correlation with clinical parameters: general pain level (Spearman's ρ = 0.340 for hsCRP vs 0.253 for routine CRP), spinal pain level (0.247 vs 0.177), night pain level (0.325 vs 0.253), intensity of morning stiffness (0.213, vs 0.168), and BASFI value (0.271 vs 0.238). Only hsCRP demonstrated significant correlation with the level of enthesitis-related discomfort (ρ = 0.173, p = 0.032) and the overall BASDAI value (ρ = 0.173, p = 0.034). In the group of patients with non-radiographic axial SpA (n = 116) neither hsCRP nor routine CRP demonstrated significant correlation with clinical parameters, except the correlation between the hsCRP level and the level of enthesitis-related discomfort in tender areas (ρ = 0.224, p = 0.018).

65 patients with AS (42.5%) and 61 patients with non-radiographic axial SpA (52.6%) had level of routine CRP <6 mg/l. In the group of patients with AS and level of routine CRP <6 mg/l there was a clear trend for an increased level of pain, stiffness, and functional impairment in patients with higher hsCRP concentration (table). Such trend was less pronounced in patients with non-radiographic axial SpA.

Table. Clinical parameters (median and IQR) in relation to a level of hsCRP in patients with the level of routine CRP <6 mg/l

	AS			**Non-radiographic axial SpA**		
	hsCRP, mg/l					
	0-1.9 (n=40)	2.0-3.9 (n=14)	≥4.0 (n=11)	0-1.9 (n=46)	2.0-3.9 (n=12)	≥4.0 (n=3)
Spinal pain, points NRS	3.5 (2.0-6.0)	6.0*(3.8-7.3)	5.0 (4.0-8.0)	5.5 (2.0-7.0)	5.5 (1.5-7.8)	6.0 (6.0-8.0)
Night back pain, points NRS	2.0 (1.0-5.0)	4.5*(3.0-6.3)	7.0*(3.0-7.0)	4.5 (2.0-7.0)	5.0 (0.8-7.8)	8.0 (5.0-10.0)
Morning stiffness, points NRS	3.0 (1.0-5.8)	5.5 (2.8-7.0)	5.0 (2.0-8.0)	4.0 (1.0-7.3)	2.0 (1.0-6.0)	6.0 (5.0-7.0)
BASDAI	2.8 (1.4-5.5)	3.9 (2.8-5.9)	3.6 (1.7-5.7)	3.6 (1.4-5.0)	4.7 (2.0-5.3)	3.6 (1.7-5.7)
BASFI	1.3 (0.2-4.7)	2.5 (1.4-3.7)	3.0 (1.0-5.9)	1.3 (0.3-3.7)	2.7 (1.1-4.3)	4.7 (4.0-5.4)

* p < 0.05 in comparison to the first tertile (hsCRP 0-1.9 mg/l)

Conclusion: High sensitivity CRP correlates better than standard CRP with clinical disease activity parameters in patients with AS and non-radiographic axial SpA. Within the normal range of routine CRP (<6 mg/l) parameters of disease activity tended to be higher with higher hsCRP levels. Therefore, hsCRP could be superior to standard CRP in assessing disease activity in axial SpA.

Early Psoriatic Arthritis "Sine Psoriasis": Clinical Aspects and Sensitivity of the CASPAR Classification Criteria. Giovanni Ciancio, Matteo Colina, Cesare Savini, Valentina Foschi, Marcello Govoni and Francesco Trotta, Rheumatology Section, Ferrara, Italy

Purpose: Psoriatic arthritis (PsA) is a chronic and potentially disabling inflammatory arthritis. Skin psoriasis usually precedes joint disease in 70% of patients with PsA whereas it may occur at the same time in 15%.In about 10-30% of patients arthritis may precedes psoriasis even for many years. In these cases the recognition of the so-called psoriatic arthritis "*sine psoriasis*" represents a diagnostic challenge. Classification criteria for PsA (CASPAR criteria) were recently developed. They give a sensitivity and specificity of 0.914 and 0.987 respectively. Our purposes were to evaluate the clinical spectrum and to verify the sensitivity of the CASPAR criteria in patients with early psoriatic arthritis (PSA) "*sine psoriasis"*.

Methods: All patients with early PsA "sine psoriasis" (disease duration < 12 months) who consecutively attended our centre in the last 2 were recruited for study. The inclusion criteria were: 1) a clinical picture suggestive of PSA; 2) psoriasis in at least one first degree relative; 3) absence of other rheumatic diseases. All patients were evaluated for the presence of spinal involvement (SI) (inflammatory spinal pain and/or radiological sacroiliitis); peripheral arthritis (PA), dactylitis (D), tenosynovitis (T) and peripheral enthesitis (PE), documented by ultrasound and/or MRI. Laboratory evaluation included ESR, CRP, rheumatoid factor and anti-cyclic citrullinated peptide . The proportion of patients meeting CASPAR criteria (i.e., the sensitivity) was determined.

Results: Forty patients with early PsA *"sine psoriasis"* were studied (Tab.1). CASPAR criteria were satisfied by fourteen patients (sensitivity: 35%). Radiologic criteria were satisfied by only 1 patient.

Conclusion: The clinical spectrum of PSA "*sine psoriasis"* appears as wide as that of PSA. However CASPAR criteria have a very low sensitivity when applied to early PsA

"sine psoriasis".

Ankylosing Spondylitis Diasease Activity Score (ASDAS): What Level Corresponds to Low Disease Activity and What Is An Important Improvement? Elisabeth Lie[1], Désirée M.F.M. van der Heijde[2], Till Uhlig[1] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands

Purpose: ASDAS is a newly developed ASAS endorsed disease activity score calculated from BASDAI questions 2, 3 and 6, patient global assessment, and CRP. Cut-points for ASDAS states and changes as well as response criteria based on the ASDAS are not yet established. Our objective was to examine how ASDAS relates to patient acceptable symptom state (PASS), minimal clinical important improvement (MCII) and levels of/changes in physician global assessment (PhGA).

Methods: AS patients were extracted from a multi-center treatment registry where patients (pts) with inflammatory arthropathies starting treatment with DMARDs and biologicals are followed longitudinally. 448 pts (69% male, 89% HLA-B27 pos, biologicals n=340, DMARDs n=66) were included in the baseline analyses while 243 pts had 3-month follow-up data. Patients were at each time point asked if they were in a satisfactory condition (yes/no), i.e. PASS, and pts were from 3 months onward asked if they had experienced a considerable improvement since start of therapy (yes/no), i.e. MCII. ASDAS levels/changes were examined across disease states and level of changes defined by PASS, MCII and PhGA (0-10 cm VAS). We performed receiver operating characteristic (ROC) curve analyses (maximum accuracy and 80% specificity approaches) to find cut-offs for ASDAS.

Results: At treatment start (baseline) mean(SD) ASDAS were 3.51(1.01) and 3.28(0.97) for pts on biologicals and pts on DMARDs, respectively, while mean(SD) 3-month changes were -1.31(1.24) and -0.31(0.97). 28%/58% of pts were in PASS at baseline/3 months, while 65% reported an important improvement on therapy. Among pts reporting/not reporting PASS at baseline and 3 months mean(SD) ASDAS were 2.96(0.95)/3.72(0.97) and 1.84(0.91)/3.00(1.14), respectively. Mean(SD) 3-month ΔASDAS were -1.71(1.07)/-0.20(0.97) in pts

reporting/not reporting significant improvement, and -1.85(1.15)/-0.59(1.06) for pts with ΔPhGA ≤-2/>-2, respectively. The results of the ROC analyses are shown in the table.

ROC analyses – ASDAS cut-points for state and change			
ASDAS state	**80% spec.**	**Max. accuracy**	**AUC (95% CI)**
Baseline PASS yes (vs. no)	2.96	3.15	0.71 (0.65-0.77)
3-month PASS yes (vs. no)	2.01	2.50	0.79 (0.74-0.84)
Baseline PhGA <4 (vs. ≥4)	3.05	3.40	0.70 (0.65-0.75)
3-month PhGA <4 (vs. ≥4)	3.55	3.55	0.92 (0.88-0.96)
ASDAS change			
3-month MCII yes (vs. no)	-0.88	-0.68	0.86 (0.81-0.91)
3-month ΔPhGA ≤-2 (vs. >-2)	-1.40	-1.27	0.79 (0.73-0.85)
3-month ΔPhGA ≤-4 (vs. >-4)	-2.00	-1.53	0.80 (0.73-0.88)

Conclusion: In this study, PASS corresponded to ASDAS levels of 2.01 to 3.15 depending on time for assessment and method. The ASDAS levels corresponding to PASS were considerably lower at baseline than at 3 months. MCII corresponded to ΔASDAS of -0.7 to -0.9 while >2 point improvement of PhGA corresponded to a larger ASDAS change. These data show how ASDAS relates to PASS, MCII and the PhGA, but further work is needed to define cut-points for ASDAS change and states.

A Prediction Model for Future Radiologic Damage in Ankylosing Spondylitis Based On a Prospective Cohort Analysis. Finbar (Barry) D. O'Shea, Nigil Haroon, Reena Riarh and R.D. Inman, Toronto Western Hospital, Toronto, ON

Purpose: Spinal ankylosis is a predominant and disabling feature of ankylosing spondylitis (AS). Identifying baseline predictors of radiological progression of AS can be helpful in prognostication and treatment decisions.

Methods: Patients with AS (modified New York criteria), attending the Spondylitis Clinic were prospectively enrolled in this study. At the baseline visit the BASDAI, BASFI and BASMI were noted and cervical and lumbar x-rays were taken. Patients were reviewed annually and X-rays repeated every 2 years. The x-rays were scored for mSASSS by 2 independent investigators with an ICC of 0.9. X-rays were arranged sequentially and scored for mSASSS after blinding. Partial correlation coefficients were calculated after correcting for disease duration at the baseline visit. Predictors of future radiological damage were identified using a linear regression model with the last mSASSS score as the dependant variable and a regression equation was obtained for prediction. The rate of change in radiologic damage was also calculated by dividing the change in mSASSS by the time interval between the X-rays.

Results: Eighty seven patients (12 female), 76% were HLA-B27 positive, 64% were receiving an anti-TNF agent. Each patient had X-rays repeated at least twice with a minimum interval of 2 years. At baseline, the mean age ± SD of the patients was 36.6 ± 12.9 years and mean ±

SD disease duration was 14.7 ± 9.5 years. The mean ± SD BASDAI, BASFI and BASMI were 4.8 ± 2.6, 4.1 ± 2.9 and 2.4 ± 2.0 respectively. The mean baseline and follow up mSASSS were 16.5 ± 21.8 and 18.5 ± 22.3 respectively in a mean interval of 2.7 ± 0.9 years. The mean change in mSASSS was 1.97 ± 2.9 at rate of 0.88 ± 1.6 units/year.

After correcting for disease duration, the baseline BASMI (R=0.314, p=0.04), ESR (R=0.447, p=0.001), and CRP (R=0.460, p=0.002) correlated with change in mSASSS. Baseline mSASSS, BASDAI, BASFI and age of onset did not significantly correlate with change in mSASSS. Regression analysis determined that the only two significant predictors of the final mSASSS score were baseline mSASSS and CRP. The model with mSASSS alone had and adjusted R^2 of 0.981 ($p < 0.01$) and the addition of CRP improved the model only minimally (R^2 of 0.983; $p < 0.01$). The regression equation for predicting mSASSS was 1.12 + 1.01 (baseline mSASSS) + 0.04 (baseline CRP). There was no difference in the rate of radiographic progression between patients who were or were not treated with anti-TNF agents. However there was a negative correlation between the duration of biologic intake and the rate of change in mSASSS (R=-0.297, p=0.03).

Conclusion: This prospective study demonstrates that baseline radiographic damage is the strongest predictor of future radiographic damage. A longer duration of anti-TNF therapy was associated with a slower rate of radiographic progression. The proposed model could have important clinical utility in defining prognosis in AS patients.

No Progression of Chronic Sacroiliac Changes in Patients with Active, Non-Radiographic Axial Spondyloarthritis Treated with Adalimumab Over 52 Weeks. Hildrun Haibel[1], Valeria Rios[2], Kay-Geert Hermann[3], Christian Althoff[4], Martin Rudwaleit[5], Hartmut Kupper[6], J. Braun[7] and Joachim Sieper[8], [1]Department of Rheumatology, Charité CBF, Berlin, Germany, [2]Department of Rheumatology, Bellvitge University Hospital, Barcelona, Spain, [3]Charité Medical School, Berlin, Germany, [4]Charité–University Medicine Berlin, Berlin, Germany, [5]Charité - Campus Benjamin Franklin, Berlin, Germany, [6]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [7]Rheumazentrum Ruhrgebiet, Herne, Germany, [8]Charite - Campus Benjamin Franklin, Berlin, Germany

Purpose: To evaluate the progression of chronic changes, as observed in T1 sequences on MRI, over 52 weeks in a 12-week, placebo-controlled study of adalimumab with a 40-week, open-label extension in the treatment of patients with active axial spondyloarthritis (SpA) not yet fulfilling the modified New York Criteria who had previously demonstrated good clinical response.[1]

Methods: T1 sequences of MRIs of the sacroiliac joints (SIJ) were obtained at baseline, at Week 12 (placebo phase), and at Week 52 (40 weeks of open-label extension) in patients treated with adalimumab. MRIs were read in 1 batch blinded for both sequence and therapy regimen by 2 assessors employing a recently developed score for chronic changes. Fatty lesions were scored (0–8), sclerosis was read for each joint (0–2), and erosions were counted for each joint (0–24).

Results: Nine pairs each of MRIs for both the placebo and adalimumab groups were available at baseline and Week 12. In addition, 12 pairs of MRIs for the former placebo group and 14 pairs for the adalimumab group were available at baseline and Week 52. No changes were observed after 40 weeks (former placebo group) or 52 weeks of adalimumab treatment regarding fatty lesions, sclerosis, or erosions in the SI joints. Through analysis of the 12-week placebo-controlled data, significant reductions of fatty lesions were found in the adalimumab-treated patients vs. the placebo-treated patients (p=0.042). No significant changes and no differences between the two groups were found for erosions and sclerosis.

Conclusion: This was the first study analysing chronic SI-joint changes by MRI in patients treated with a TNF antagonist. These data indicate that fatty degeneration and erosions might be stopped. These findings need to be confirmed by longer observation periods. Furthermore, it has yet to be determined how and whether this affects also new bone formation.

Mean Scores for Chronic Changes in T1 sequences by MRIs of Sacroiliac Joints

Ten Year Outcome of Spondyloarthritis Related Oligoarthritis Involving the Knee: What Are the Predictors? Alexander.N. Bennett[1], Helena Marzo-Ortega[2], Ai Lyn Tan[2], EM Hensor[2], Mike Green[2], Paul Emery[2] and Dennis McGonagle[2], [1]Defence Medical Rehabilitation Unit, London, United Kingdom, [2]University of Leeds, Leeds, United Kingdom

Purpose: To investigate longterm outcome of Spondyloarthropathy (SpA) related oligoarthritis involving the knee and establish predictors of outcome with a specific hypothesis that HLA-B27 and PsA would be linked to more severe MRI bone marrow oedema (BMO), and these variables would predict a poor longterm outcome.

Method: Patients with seronegative oligoarthritis involving the knee of suspected SpA origin were recruited. Assessment including ESSG SpA criteria, MRI, rheumatoid factor, and HLA-B27 were all performed at baseline, Patients where given standard treatments at the discretion of their treating rheumatologist and followed up at 10yrs. Outcome assessments included joint counts, ESSG SpA criteria, functional and symptomatic questionnaire, CRP, and radiographic assessment for knee OA.

Results: Forty-four patients were recruited, (Mean age 32.3yrs {range 15-59yrs}, 68% male) with a mean disease duration at baseline of 9.75months (1-48months). Twenty-six patients (59%) (mean age 42.6yrs, 61.5% female) returned for followed up after a mean of 10years (range 8.4-12.6yrs). The mean total bone marrow oedema score for the whole knee MRI was 2.86 (range 0-29). The patella was the most severely and frequently affected area by BMO. HLA-B27 and BMO were not predictive of 10yr outcome but PsA was. Ten patients (38%) had persistent clinical synovitis and 31% of affected knees' had secondary radiographic OA. Global outcome was poor or very poor in 69% of cases. PsA patients had significantly worse outcome compared to ReA.

Conclusion: SpA releated oligoarthrits involving the knee has significant long term clinical and radiological morbidity despite standard treatments. HLA-B27 and MRI BMO do not appear to be predictors of poor outcome as they are in axial-SpA. However PsA oligoarthritis has a significantly worse long term outcome than ReA.

ACR/ARHP Poster Session C

Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Pathogenesis, Animal Models and Genetics II

Tuesday, October 20, 2009, 9:00 AM - 6:00 PM

1800

Association of *FAM167A (C8orf13) - BLK* Region with Systemic Sclerosis. Ikue Ito[1], Yasushi Kawaguchi[2], Aya Kawasaki[1], Minoru Hasegawa[3], Jun Ohashi[1], Manabu Kawamoto[2], Manabu Fujimoto[3], Kazuhiko Takehara[3], Shinichi Sato[4], Masako Hara[2] and Naoyuki Tsuchiya[1], [1]University of Tsukuba, Doctoral Program in Life System Medical Sciences, Tsukuba, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]Kanazawa University, Graduate School of Medical Science, Kanazawa City, Japan, [4]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Purpose: Association of single nucleotide polymorphisms (SNPs) in *FAM167A (C8orf13)* - B lymphoid tyrosine kinase (*BLK*) region with systemic lupus erythematosus (SLE) has been demonstrated in the Caucasian and Asian populations. Recent studies showed that many genes including *IRF5*, *STAT4* and *PTPN22* are shared susceptibility genes for multiple autoimmune diseases. This study was performed to examine whether the *FAM167A-BLK* region is also associated with susceptibility to systemic sclerosis (SSc).

Method: A two-tiered case-control association study was performed on 309 Japanese patients with SSc and 769 healthy controls. Tier-1 examined association of 16 tag SNPs encompassing the *FAM167A-BLK* region on 124 patients and 412 controls. Tier-2 analyzed additional 185 patients and 357 controls for a SNP rs13277113, selected based on the results of tier-1.

Results: At tier-1, rs13277113 A allele, previously shown to be associated with SLE, demonstrated significant association after correction for multiple testing (permutated P=0.024). Conditional logistic regression analysis revealed that this SNP could account for association of other SNPs. At tier-2, additional 185 patients and 357 controls were genotyped for rs13277113. When tier-1 and tier-2 samples were combined, rs13277113 A allele was significantly associated with SSc and its clinical subsets (Table 1). This association was not observed in the patients who did not possess any of the three major autoantibodies associated with SSc in Japanese: anti-topoisomerase I (anti-topo I), anti-centromere (ACA) and anti-U1 snRNP (anti-RNP) antibodies, suggesting that the genetic effect may be accounted for by autoantibody production.

Conclusion: The rs13277113 A allele is associated not only with SLE but also with SSc. The association was preferentially observed in autoantibody-positive patients. These findings indicate that the *FAM167A-BLK* region is a common genetic risk factor for SLE and SSc.

Table 1. Association of rs13277113 with SSc and its clinical subsets.

	n	Genotype, n (%)			A allele frequency	Allelic association	
		AA	AG	GG		OR (95% CI)	*P*

HLA-DPB1 and DPB2 Are Genetic Loci for Systemic Sclerosis -Genome-Wide Association Study in Koreans with Replication in North Americans. Xiaodong Zhou[1], Jong Eun Lee[2], Frank C. Arnett[1], Momiao Xiong[3], Min Young Park[2], Yeon Kyeong You[2], Eun Soon Shin[2], John D. Reveille[1], M. Mayes[4], Jin Hyun Kim[5], Ran Song[5], Ji Yong Choi[5], Ji Ah Park[5], Yun Jong Lee[5], Eun Young Lee[5], Yw Song[6] and Eun Bong Lee[5], [1]University of Texas Medical School at Houston, Houston, TX, [2]DNA Link Inc, Seoul, South Korea, [3]University of Texas School of Public Health, Huston, TX, [4]U.Texas Houston, Houston, TX, [5]Seoul National University College of Medicine, Seoul, South Korea, [6]Seoul National Univ, South Korean

Purpose: To investigate the most susceptible genetic loci in systemic sclerosis (SSc) with genome-wide association study (GWAS).

Methods: A genome-wide association study was performed in 137 patients with systemic sclerosis and 564 controls from Korea using the Affymetrix Human SNP Array 5.0. After fine mapping study, the results were replicated in 1,107 SSc patients and 2,747 controls from a US Caucasian population.

Results: The SNPs (rs3128930, rs7763822, rs7764491, rs3117230 and rs3128965) of HLA-DPB1 and –DPB2 on chromosome 6 formed a distinctive peak with log p-values ($p = 8.16 \times 10^{-13}$) for association with SSc susceptibility. Subtyping analysis of HLA-DPB1 showed that DPB1*1301 ($p = 7.61 \times 10^{-8}$) and DPB1*0901 ($p = 2.56 \times 10^{-5}$) were the most susceptible subtypes for SSc in Koreans. In US Caucasians, two pairs of SNPs, rs7763822/rs7764491 and rs3117230/rs3128965, showed strong association with SSc patients who had either circulating anti-DNA topoisomerase I ($p = 7.58 \times 10^{-17}/4.84 \times 10^{-16}$) or anti-centromere autoantibodies ($p = 1.12 \times 10^{-3}/3.2 \times 10^{-5}$), respectively.

Conclusion: Our GWAS in Koreans revealed that the region of HLA-*DPB1* and *–DPB2* contains the most susceptible loci to Korean SSc. The confirmatory studies in US Caucasians indicated that specific SNPs of the HLA-DPB1 and/or –DPB2 were strongly associated with US Caucasian SSc patients who were positive to anti-topoisomerase I or anti-centromere autoantibodies.

1802

BANK1 Is a Genetic Risk Factor for Diffuse Cutaneous Systemic Sclerosis Having Additive Effects with IRF5 and STAT4. Philippe Dieudé[1], Mickael Guedj[2], Julien Wippf[3], Inga Melchers[4], Catherine Boileau[5], Yannick Allanore[3] and GFRS and DNSS co-workers, [1]Bichat Claude-bernard, Universitary Hospital, APHP, Paris, France, [2]Université d'Evry Val d'Essonne, Evry, France, [3]Paris Descartes Univ, Paris, France, [4]University Medical Center, Freiburg, Germany, [5]Hôpital Ambroise Paré, AP-HP, Boulogne, France

Background: Systemic sclerosis (SSc) and systemic lupus erythematosus (SLE) share common genetic risk factors including *IRF5* and *STAT4* variants. Polymorphisms of the B-cell scaffold protein with ankyrin repeats gene, *BANK1*, were recently identified as SLE risk factors.

Purpose: To determine whether the functional *BANK1* rs3733197 and rs10516487 variants are associated with SSc in European Caucasians populations. To investigate the putative gene-gene interaction between *BANK1* and *IRF5* and *STAT4*.

Methods: *BANK1* SNPs were genotyped in 2407 individuals comprising a French set (874 SSc patients and 955 controls, previously genotyped for both *IRF5* rs2004640 and *STAT4* rs7574865) and a German set (421 SSc patients and 182 controls).

Results: The *BANK1* variants were found to be associated with the diffuse cutaneous SSc (dcSSc) in both samples providing an OR of 0.77 for the rs10516487 T rare allele in the combined populations compared to controls (95%CI [0.64-0.93]) and an OR of 0.73 (95%CI [0.61-0.87]) for the rs3733197 A rare allele. *BANK1* haplotype analysis found the A-T haplotype to be protective in dcSSc (P=0.0003, OR 0.70 [95% CI 0.57-0.86]) and the G-C haplotype to be a risk factor (P= 0.008, OR 1.25 [95% CI 1.06-1.47]). Significant differences were also observed when the limited cutaneous subset of SSc was compared to dcSSc both for rare alleles and haplotypes. The *BANK1*, *IRF5* and *STAT4* risk alleles risk alleles displayed a multiplicatively increased 1.43-fold risk of dcSSc (Figure).

Conclusion: Our results establish *BANK1* as a new SSc genetic susceptibility factor and *BANK1*, *IRF5* and *STAT4* act with additive effects.

Figure. Joint effects of risk alleles of *BANK1* (rs10516487 & rs3733197) *STAT4* (rs7574865) and *IRF5 (*rs2004640) on SSc and dcSSc susceptibility

1803

Phenotype-Haplotype Correlation of IRF5 Gene in SSc : Association with Different Fibrotic Sub-Phenotypes and Severe Patterns.

Philippe Dieudé[1], Karen Dawidowicz[1], Mickael Guedj[2], Catherine Boileau[3], Yannick Allanore[4] and GFRS co-workers, [1]Bichat hospital APHP, Paris, France, [2]Université d'Evry Val d'Essonne, Evry, France, [3]Hôpital Ambroise Paré, AP-HP, Boulogne, France, [4]Paris Descartes Univ, Paris, France

Background: Systemic sclerosis (SSc) is a complex multi-organ disease affecting the microvascular network, the immune system and connective tissue. The type 1 interferon (IFN) pathway has been postulated to play a key role in autoimmune diseases. Our original finding of an association between the *IRF5* rs2004640 and SSc have provided additional support for the pivotal role of IRF5 and the type 1 IFN pathway in autoimmune diseases. To date, additional *IRF5* variants have been convincingly identified as autoimmune genetic factor.

Purpose: To test for association with SSc the *IRF5* rs3757385, rs2004640 and rs10954213 variants. To investigate whether *IRF5* haplotypes determined by those 3 single nucleotide polymorphisms (SNPs) would be also involved in SSc and SSc sub-phenotypes genetic background.

Methods: *IRF5* single marker and haplotype analyses were performed in 1625 individuals of French Caucasian origin (743 SSc patients and 882 controls), all the individuals having a full genotyping information for the 3 *IRF5* SNPs investigated.

Results: The *IRF5* variants were found to be associated with SSc samples providing an OR of 1.27 for the rs3757385 C risk allele compared to controls (95%CI [1.10-1.47]), an OR of 1.34 for the rs2004640 T risk allele and an OR of 1.17 (95%CI [1.01-1.34]) for the A risk allele. *IRF5* haplotype analysis found the A-G-G haplotype to be protective in SSc ($P = 8.8x10^{-4}$, OR 0.78 95% CI [0.68-0.90]) and the C-T-A haplotype to be a risk factor ($P = 0.0024$, OR 1.23 95% CI [1.07-1.40]). In this sample, single marker analysis do not provided any significant differences when phenotype-genotype correlation was performed. Interstingly, the *IRF5* C-T-A risk haplotype frequency was strongly associated with the diffuse cutaneous SSc subset when compared to limited cutaneous SSc (50.9% vs 43.8%, $P = 0.008$). The frequency of the *IRF5* A-G-G protective haplotype was found to be significantly decreased in SSc patient with fibrosing alveolitis compared to those without (24.1% vs 29.6%, $P = 0.018$). The risk haplotype aws also found to be associated with a severe phenotype defined by the presence of renal crisis and/or CVF <75% and/or HTAP and/or ulcerations($P = 0.045$)

Conclusion: Our results establish *IRF5* as a new SSc genetic susceptibility factor influencing the SSc fibrotic phenotype and a severe disease.

1804

Genotype-Phenotype Correlation in Systemic Sclerosis: STAT4 rs7574865 Is a Relevant Marker for Interstitial Lung Disease.

Yannick Allanore[1], P. Dieudé[2], M. Guedj[3] and Catherine Boileau[4], [1]Paris Descartes Univ, Paris, France, [2]Bichat Claude-bernard Hospital, Paris, France, [3]Université d'Evry Val d'Essonne, Evry, France, [4]Hôpital Ambroise Paré, AP-HP, Boulogne, France

Purpose: Two recent large studies (Rueda et al, Hum Mol Genet. 2009 and Dieude et al Arthritis Rheum 2009) have showed that rs7574865, a variant allele of *STAT4,* confers an increased risk for systemic sclerosis (SSc). However, genotype-phenotype correlation analyses revealed discrepancies for subphenotype associations.

Objectives: We sought to assess whether combined analyses clarified the contribution of rs7574865 to the phenotypic heterogeneity of SSc.

Method: We pooled the SSc and control populations from the 2 available studies providing an overall sample of 2190 SSc patients and 4104 controls all of European Caucasian origin.

Results: STAT4 being associated with various auto-immune diseases (AID), we stratified SSc patients according to the co-occurrence of another AID in the French sample. However, we could not identify any difference for allele or genotype frequencies between SSc patients with (n=72) or without (n=801) *STAT4* associated AID and thus included the whole French population in the subsequent analyses. The pooled data confirmed the association of *STAT4* rs7574865 T allele with SSc providing an OR of 1.39 ($P = 2.48 \times 10^{-13}$, 95%CI [1.2-1.51]). When subphenotypes related to cutaneous subsets, auto-antibody status or pulmonary involvement were queried, comparisons to controls provided evidence of association of T allele for all of them with the higher values of ORs for lung involvement. When comparisons were performed within SSc patients comparing those with *versus* without the clinical trait, significant findings were observed for lcSSc compared to dcSSC ($P = 0.045$ OR 1.16 95%CI [1.01-1.33]) and more strongly for fibrosing alveolitis compared to lack of lung involvement with an OR of 1.69 (95%CI: 1.07-2.69; p=0.025) for TT genotype

Conclusion: The common rs7574865 polymorphism of *STAT4* is strongly associated with SSc and contributes to its phenotypic heterogeneity. It seems to particularly predispose to interstitial lung disease and may be useful for risk stratification of SSc patients. In addition, STAT4 pathways may offer new therapeutic approaches.

Purpose: To investigate the possible role of the FAS -670A>G functional polymorphism in the genetic predisposition to systemic sclerosis (SSc) susceptibility or clinical phenotype.

Methods: A total of 2900 SSc patients and 3186 healthy controls were included in this study. We analyzed the genotype and allele frequencies of the FAS -670A>G polymorphism in 9 distinct ethnic cohorts. Six case-control sets of European ancestry; a Spanish cohort: 228 SSc patients and 265 controls; a Dutch cohort: 203 SSc patients and 277 controls; a German cohort: 313 SSc patients and 247 controls; an Italian cohort: 323 SSc cases and 89 controls; a British cohort: 269 SSc patients and 182 Swedish patients. In addition, three distinct ethnic cohorts resident in the USA were considered in the FAS -607A genotyping; 1047 US white SSc patients and 692 controls, 159 US Hispanic SSc patients and 137 controls and 176 US African SSc patients and 194 controls. Genotyping was performed using Taqman 5´allelic discrimination assay.

Results: In the British, Italian and American white cohort we observed an association of the FAS -670G allele with lcSSc (respectively p=0.049; OR 1.25; 95%CI; 1.00-1.60 and p=0.045; OR 1.43; 95%CI; 1.00-207 and p=0.036; OR 1.18; 95%CI 1.01-1.39). A meta-analyses comprising all 9 cohorts revealed an association with both the FAS -670G allele and FAS -670GG genotype (both; p=0.036 allele; OR 1.10 95%CI 1.01 to 1.21 and genotype OR 1.13 95%CI 1.01 to 1.27) and the lcSSc phenotype. In a meta-analyses considering only Caucasian individuals we found that both the FAS -670G allele as well as the FAS -670GG genotype were associated with lcSSC (genotype; p= 0.017; OR; 1.16 95%CI 1.03 to 1.31 and allele p= 0.020;OR 1.12; 95%CI 1.02-1.24). In addition, a recessive model of the -670GG genotype revealed a strong association with SSc, lcSSc and ACA+ lcSSc (respectively, p=0.004; OR 1.23; 95%CI 1.07 to 1.41, p=0.0003; OR 1.33; 95%CI 1.14 to 1.56) and p=0.0002; OR 1.45; 95%CI 1.19 to 1.76)

Conclusion: Our data show that the FAS -670A>G polymorphism plays a role in lcSSc susceptibility, a trend observed in other auto-immune diseases as well.

1806

Activin-Smad Pathway Is Activated in Systemic Sclerosis. Kae Takagi, Yasushi Kawaguchi, Yuko Ota, Takahisa Gono, Akiko Tochimoto, Yasuhiro Katsumata, Chikako Fukasawa, Masako Hara and Hisashi Yamanaka, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Systemic sclerosis is a chronic disease of unknown etiology characterized by autoimmunity, vascular damage, and progressive fibrosis of the skin and internal organs. However, it has not been elucidated how the fibrosis is achieved. The pathogenesis of fibrosis is not well understood and then there are not any effective treatments. It has been reported that overproduction of collagen, fibronectin, other many extracellular matrix and cytokines such as transforming growth factor b(TGF-b) and connective tissue growth factor (CTGF) in fibroblast cultured from SSc patients skin. TGF-b is thought to be the most important mediator, which induce fibrosis in SSc patient. Activin is a member of the TGF-b superfamily and initially discovered as inducers of follicle-stimulating hormone release. Recently wide varieties of functions of activins have been reported. Particularly, activin has the important functions to repair a tissue in acute and chronic inflammatory diseases, and to induce fibrosis in liver and renal tissue. Previous report was suggested the activin receptor 1B (ACR1B) also known as ALK4/5 mRNA was highly expressed in SSc patient. Then, we have investigated how activin is involved in the development of fibrosis in SSc.

Method: Serum activin levels were measured by an ELISA assay. The expression of activin was determined by RT-PCR and immunohistochemistry in fibroblasts cultured from skin of SSc patients and healthy controls (HC). The production of procollagen type I was measured by an ELISA assay, and gene expression of COL1a was quantitated using real-time PCR. Ligand induced activation of the Smad signaling pathway was examined by Western blot analysis.

Results: Serum activin levels were significantly higher in SSc patient than HC. Activin expression was also higher in cultured SSc fibroblasts. Activin stimulation induced phosphorylation of Smad2/3 and CTGF expression in SSc fibroblasts. Procollagen production and Col1a mRNA was also increased by activin stimulation. The basal level of Smad2/3 phosphorylation was higher in cultured SSc fibrobrast,

and treatment of ALK4/5 inhibitor SB431542 abrogated phosphorylation of Smad2/3 and CTGF expression. Treatment of ALK4/5 inhibitor also attenuated collagen production induced by activin. The mechanism for activation of activin pathway in SSc fibroblast is speculated using autocrine activin production.

Conclusion: Activin play a critical role in collagen production of SSc fibroblast. Inhibition of activin-smad pathway would be a new approach for treatment of SSc.

1807

The PPAR Gamma Agonist Rosiglitazone Reverses the Persistent Fibrotic Phenotype of Scleroderma Fibroblasts. Xu Shi-wen[1], Andrew Leask[2], Mark Eastwood[3], Liaquat Suleman Verjee[4], Christopher P. Denton[1] and David Abraham[1], [1]UCL Medical School, London, United Kingdom, [2]University of Western Ontario, London, ON, [3]University of Westminster, London, United Kingdom, [4]London, United Kingdom

Purpose: The transcription factor peroxisome proliferator-activated receptor (PPAR)γ plays an important role in controlling cell differentiation. The aim of the present study was to examine whether PPARγ expression was reduced in scleroderma (SSc) fibroblasts and whether PPARγ agonists could suppress the persistent fibrotic phenotype of SSc fibroblasts.

Method: Fibroblasts (n=6) were obtained from control and SSc tissue. The effect of PPARγ agonist rosiglatizone (20 μM) on the phenotype of normal and SSc fibroblasts was assessed using Western blot, cell migration and 3D-collagen matrix contraction analyses. Results were verified using PPARγ knockout dermal fibroblasts and normal dermal fibroblasts transfected with PPARγand control siRNA.

Results: PPARγ protein expression was significantly reduced in SSc fibroblasts compared to normal control ($p<0.05$). Rosiglitazone reduced the characteristic overexpression of α-SMA, Col-1 and CTGF protein and elevated PPARγ expression by lesional SSc fibroblasts ($p<0.05$). Moreover, rosiglitazone alleviated the enhanced ability of SSc fibroblasts to migrate and to contract collagen gel lattices ($p<0.05$). TGFβ-induced Smad3 phosphorylation and CTGF protein expression was impaired in PPARγ knockout fibroblasts and normal fibroblasts treated with specific PPARγ siRNAs ($p<0.05$). Basal fibroblast activity was unaffected by rosiglitazone.

Conclusion: Reduced PPARγ expression by lesional SSc fibroblasts appears to contribute to the persistent fibrotic phenotype of this cell type. The PPARγ agonist rosiglitazone may represent a novel, selective treatment for SSc.

1808

Augmentation of IL-21 Receptor by Endothelin-1 Via Endothelin Receptor B in Skin Fibroblasts From Systemic Sclerosis. Yasushi Kawaguchi, Kae Takagi, Akiko Tochimoto, Yuko Ota, Yasuhiro Katsumata, Takahisa Gono, Masako Hara and Hisashi Yamanaka, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Endothelin (ET)-1 is a vasoconstrictive agent which is involved in endothelial dysfunction in patients with systemic sclerosis (SSc). Recently, it is reported that ET receptor antagonist is a useful treatment for Raynaud's phenomenon and pulmonary arterial hypertension in patients with SSc, and currently we are able to select a selective antagonist for ET receptor A (ETRA) or a dual antagonist for ETRA and ETRB. However, the effects of ET-1 on skin fibroblasts derived from patients with SSc (SSc fibroblasts) remain to be elucidated. In this study, we sought to determine key mediators induced by ET-1 through ETRA and/or ETRB in SSc fibroblasts.

Method: The expression of ETRA and ETRB in skin fibroblasts was estimated by immunohistochemistry using antibodies against a specific for ETRA or ETRB. We comprehensively analyzed ET-1-induced genes by skin fibroblasts from SSc patients and healthy donors using DNA microarray using Affymetrix GeneChip Human U133 Plus 2.0 Array. Recombinant ET-1, BQ123 as selective ETRA antagonist, BQ788 as selective ETRB antagonist, and PD145065 as dual ETRA and ETRB antagonist were purchased in Sigma. A quantitative analysis of mRNA was performed by a real-time RT-PCR method using a specific TaqMan probe. IL-6, TGF-beta and procollagen type I were measured by commercial ELISA kits.

Results: Both ETRA and ETRB were expressed in skin fibroblasts constitutively. In addition of optimal ET-1 and BQ-123 in culture media, IL-21 receptor (IL-21R) mRNA was over-expressed in SSc fibroblasts using DNA microarray. This phenomenon was confirmed by real-time RT-PCR. On the other hand, the stimulation of ET-1 with BQ788 or PD145065 failed to induce IL-21R gene expression in SSc fibroblasts. Those findings strongly suggest that IL-21R expression is dependent upon ET-1 signal transduction through ETRB alone. It was reported that IL-21 induced collagen production in intestinal fibroblasts from inflammatory bowel disease. In the next experiments, we investigated whether exogenous IL-21 could induce the fibrogenic mediators and procollagen production in skin fibroblasts. The addition of recombinant IL-21 increased the production of IL-6, TGF-beta, and procollagen type I in culture media of SSc fibroblasts. These phenomena were augmented by pre-stimulation with optimal ET-1.

Conclusion: ET-1 induced IL-21R through ETRB in SSc skin fibroblasts, and the addition of IL-21 increased the production of IL-6, TGF-beta and procollagen type I, suggesting that blocking ETRB as well as ETRA may play an important role in treatment for systemic sclerosis.

1809

Cytokines Produced by Type I Collagen (CI)-Stimulated PBMC From Patients with Systemic Sclerosis (SSc) but Not Localized Scleroderma (LS) Inhibit Matrix Metalloproteinase (MMP-1) Expression in SSc Dermal Fibroblasts. Monica Brown[1], Arnold E. Postlethwaite[2], Linda K. Myers[3] and Karen Hasty[4], [1]University Tennessee Health Science Center, LeBonheur Children's Medical Center, Memphis, TN, [2]Univ Physicians Found Inc, Memphis, TN, [3]UT Medical Group Inc, Memphis, TN, [4]Supported by the National Institute of Arthritis and Musculoskeletal and Skin Diseases/National Institute of Allergy and Infectious Diseases (contract N01-AR-902242), the NIAMS US Department of Veterans Affairs, TN

Purpose: Patients with SSc in contrast to patients with LS have cellular immunity to a variety of autoantigens, including CI. How immunity to autoantigens contributes to disease pathogenesis is not understood. Fibroblasts grown from explants of lesional skin of patients with SSc but not from non-lesional skin exhibit a transient resistance to TNFa-induced stimulation of MMP-1, the major collagenase of human dermal fibroblasts, that is reversed after multiple population doublings, suggesting this is an acquired phenotype. The purpose of this study is to test the hypothesis that PBMC from SSc patients cultured with CI will synthesize cytokines/factors that will induce fibroblast resistance to expression of MMP-1.

Methods: In preliminary studies, PBMC from ten adult SSc patients were isolated and cultured with bovine CI for 6 days. The supernatants were pooled and added to cultures of SSc dermal fibroblasts and incubated for 21 days with periodic media renewal. The response of the fibroblasts was determined by induction of MMP-1 by TNFa. The pooled supernatant was further assayed for cytokine content using an antibody array. To compare juvenile and adult disease, supernatants from cultures of PBMC, incubated with and without CI, from six juvenile patients with LS or SSc and four adult patients with limited or diffuse cutaneous SSc were also analyzed.

Results: Pooled supernatants from PBMC co-cultured with CI from ten adult SSc patients induced MMP-1 resistance to TNFa stimulation in the fibroblasts similar to cultures of low passage fibroblasts taken from lesional skin of adult SSc patients. Assay of the supernatant showed distinct cytokines were induced by incubation with CI. Supernatants from PBMC, cultured without collagen, from adult and juvenile patients with SSc as well as juvenile patients with LS significantly increased levels of MMP-1 by 2-3 fold over media/collagen controls, with or without TNFa stimulation ($p<0.05$). However, when PBMC from juvenile or adult SSc but not juvenile LS patients were cultured with collagen, the supernatants induced marked resistance to TNFa upregulation of MMP-1 in SSc fibroblasts ($p<0.05$). Array analyses showed CI induced production of a variety of cytokines in PBMC from patients with SSc that were not found in LS CI-stimulated PBMC supernatants.

Conclusion: CI induces production of soluble cytokines/factors by PBMC that inhibit MMP-1 synthesis by dermal fibroblasts. These cytokines/growth factors are specific for adult and juvenile SSc and are not elevated by CI-stimulated PBMC from LS patients. Identification of the involved cytokines and the associated regulatory pathways should provide a better understanding of the pathogenesis of fibrosis in SSc.

Rac Inhibition Reverses the Fibrotic Phenotype of Scleroderma Fibroblasts. Andrew Leask[1], Xu Shi-wen[2], Mark Eastwood[3], Christopher P. Denton[4] and David Abraham[4], [1]University of Western Ontario, London, ON, [2]University College London, London, United Kingdom, [3]University of Westminster, London, United Kingdom, [4]UCL Medical School, London, United Kingdom

Purpose: Rac GTPase plays a key role myofibroblast formation and is required for bleomycin-induced skin fibrogenesis. The aim of the present study was to examine whether rac1 activity was elevated in scleroderma (SSc) fibroblasts and whether rac antagonists could suppress the persistent fibrotic phenotype of SSc fibroblasts.

Method: Fibroblasts (n=6) were obtained from control and SSc tissue. The effect of rac antagonist NSC 23766 (100mM) on the phenotype of normal and SSc fibroblasts was assessed using Western blot, cell migration and 3D-collagen matrix contraction analyses. Results were verified by overexpressing rac1 in normal and rac1 knockout dermal fibroblasts. The mechanism underlying the effects of rac1 on fibroblasts was evaluated using inhibitors of specific signal transduction pathways.

Results: Rac1 activity was significantly elevated in SSc fibroblasts compared to normal controls ($p<0.05$). NSC 23766 reduced the characteristic overexpression of a-SMA, Col-1 and CTGF protein in lesional SSc fibroblasts ($p<0.05$). Moreover, NSC 23766 alleviated the enhanced ability of SSc fibroblasts to contract collagen gel lattices ($p<0.05$). NSC 23766 also reduced elevated Akt phosphorylation in SSc fibroblasts. In an Akt/PI3-kinase-dependent fashion, overexpressing rac1 caused elevation of a-SMA, Col-1 and CTGF expression and matrix contraction in normal and rac1 knockout fibroblasts ($p<0.05$). Basal fibroblast activity was unaffected by NSC 23766.

Conclusion: Elevated rac activity in lesional SSc fibroblasts appears to contribute to the persistent fibrotic phenotype of this cell type, via an Akt-dependent mechanism. Targeting rac/Akt may represent a novel, selective treatment for SSc.

Functional Regulation of Fibrosis in Vitro and In Vivo by CUTL1 Isoforms. Tetsurou Ikeda[1], Maria Fragiadaki[2], Xu Shiwen[3], Markella Ponticos[4], Patricia Garcia[4], Korsa Khan[3], Christopher P. Denton[3], Osamu Hosono[1], Chikao Morimoto[1], David Abraham[4] and George Bou-Gharios[2], [1]Univ of Tokyo/Inst of Med Scie, Tokyo, Japan, [2]Renal medicine, Imperial College of London, United Kingdom, [3]UCL Medical School, London, United Kingdom, [4]Royal Free and University College Medical School, London, United Kingdom

Purpose: Tissue scarring occurs after injury following the release of several mediators including TGF-beta, PDGF, CTGF, Wnt and ET1. These factors stimulate fibroblasts to differentiate into myofibroblasts characterized by the expression of α-smooth muscle actin and the excessive production of extracellular matrix molecules such as type1 collagen (COL1). Prolonged or abnormal production of these cytokines results in irreversible fibroblast stimulation (fibrosis), a major cause of keloid and

Scleroderma (SSc). In SSc patients COL1 is deposited in many organs including the lung, kidney and skin. The data from knock-in mice, overactive TGF-beta signalling show the same fibrogenic pathology as in SSc, supporting a key role for cytokines in the pathogenesis of fibrosis. COL1 expression is controlled in vivo by an enhancer containing 5 DNase Hypersensitive sites encompassing pivotal regulatory sites.

Analysing these sites we found cis-element consensus site for the transcription factor CUTL1. CUTL1 is known as both activator and repressor of gene transcription. But the role of CUTL1 in for the normal regulation COL1 or in fibrosis is unknown.

Methods: NIH 3T3 cell lines having Empty vector (EV) and sh-CUTL1(sh-C) vector were selected by puromycin. Transient transfection of CUTL1 and short CUTL1expression vectors were performed on the NIH3T3 cells and normal human fibroblast cells. Western blots were performed to check protein level of the ET1, CTGF, Wnt and COL1. Reporter assay of human COL1A enhancer+proximal vector or proximal vector only were apply to EV, sh-C cells and transiently transfected with CUTL1 and short CUTL1 over-expression vectors. EMSA(electorophretic mobility shift assay) and ChIP assay were done to verify its binding ability to the promoter of COL1A.Wound

healing assay were performed on sh-CUTL1 cell lines. Bosentan(both ET1 and ET-2 receptors antagonist) were used. SSc lung fibroblasts were used too.

Results: Over-expression of CUTL1 and short CUTL1 increased protein level of ET1,Wnt, beta-catenin, CTGF and COL1. EMSA and ChIP results showed the CUTL1 can bind to 1095 ,1609 of enhancer sites and proximal site. Wound healing assay indicated that sh-CUTL1 reduced the cell mobility ($p<0.05$). Bosentan treatment of sh-CUTL1 reduced the protein level of COL1 compared to control. CUTL1 isoforms expression was increased in the SSc compare to control.

Conclusion: CUTL1 isoforms up-regulated the protein level of ET1,CTGF, Wnt and COL1.Treatment of Bosentan on the sh-CUTL1 showed the synergistic reduction of collagen protein. These results indicated that CUTL1 up-regulates fibrosis related cytokines and COL1. In the SSc fibroblasts, CUTL1 isoforms were increased compare to control. More over, sh-RNA of CUTL1 in SSc showed the reduction of COL1. These results indicated that CUTL1 isoforms are the new pathway via TGF-beta in fibrosis.

Dysregulated Pro- and Antiangiogenic Chemokine Expression in Systemic Sclerosis. Bradley J. Rabquer[1], Yong Hou[1], Pei-Suen Tsou[1], G. Kenneth Haines Haines III[2], Michele L. Gerber[1], James R. Seibold[1] and Alisa E. Koch[3], [1]University of Michigan, Ann Arbor, MI, [2]Yale University, New Haven, CT, [3]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Systemic sclerosis (SSc) is characterized by microvascular abnormalities and leukocyte infiltration. Chemokines are a family of small proteins that have leukocyte activation and chemoattractant properties. Also, some chemokines have angiogenic or antiangiogenic effects. Monokine induced by interferon-γ (IFN-γ) (MIG/CXCL9) and IFN-inducible protein 10 (IP-10/CXCL10) are CXC chemokines that are antiangiogenic. Their effects are mediated by a shared receptor, CXCR3, which is expressed on endothelial cells (ECs). In contrast, CXCL16 is a proangiogenic chemokine with a unique receptor, CXCR6, which is also expressed on ECs. In this study we sought to determine the expression of MIG, IP-10, CXC16, and their receptors in SSc skin and serum.

Methods: Biopsies from proximal (less involved) and distal (more involved) skin and serum were obtained from patients with SSc and normal (NL) volunteers. Immunohistochemistry was performed to determine the expression of MIG, IP-10, CXCL16, CXCR3, and CXCR6 in SSc and NL skin. ELISAs were performed to determine the concentration of MIG, IP-10, and CXCL16 in SSc and NL serum.

Results: MIG is highly expressed in the stratum spinosum of the epidermis of distal SSc skin (52%, n=21 patients), proximal SSc skin (52%, n=21), and normal skin (48%, n=10). Similarly, IP-10 is also highly expressed in the stratum basalis layer of the epidermis of distal SSc skin (100%, n=21 patients), proximal SSc skin (100%, n=21), and normal skin (100%, n=10). The levels of MIG and IP-10 were also significantly increased in SSc serum (876 pg/ml and 495 pg/ml, respectively, n=21 patients) compared to normal serum (126 pg/ml and 263 pg/ml, respectively, n=8, both $p<0.05$). In contrast, the expression of their receptor, CXCR3, is significantly decreased on ECs in distal SSc skin (21%, n=21) and proximal SSc skin (25%, n=21) compared to NL skin (54%, n=10, both $p<0.05$). In addition, the expression of CXCL16 is significantly decreased on the surface of ECs in distal SSc skin (20%, n=21) and proximal SSc skin (18%, n=21) compared to NL skin (45%, n=10, both $p<0.05$), while being significantly increased in SSc serum (4.6 ng/ml, n=21) compared to normal serum (3.3 ng/ml, n=9, $p<0.05$). However, the expression of its receptor CXCR6 is significantly increased on the surface of ECs in distal SSc skin (15%, n=19) and proximal SSc skin (16%, n=19) compared to NL skin (4%, n=8, both $p<0.05$).

Conclusion: Antiangiogenic MIG and IP-10 are highly expressed in SSc skin and serum, whereas the expression of their receptor, CXCR3, is downregulated in SSc skin. In contrast, angiogenic CXCL16 is upregulated systemically in SSc serum, while the expression of its receptor, CXCR6, also is upregulated in SSc skin. These results indicate that despite an abundance of pro- and antiangiogenic chemokines in SSc serum, that chemokine receptor expression in SSc skin is regulated in an effort to promote angiogenesis in the avascular SSc skin.

1813

Specific Histone Deacetylases (HDACs) Modulate Fibrosis and Angiogenesis in Systemic Sclerosis (SSc). Hossein Hemmatazad, Britta Maurer, Hanna Maciejewska Rodrigues, Renate E. Gay, Beat A. Michel, Steffen Gay, Oliver Distler and Astrid Jüngel, Center of Experimental Rheumatology, Zurich Center of Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland

Purpose: Recently, we have shown that Trichostatin A (TSA) does not only inhibit the activity of HDACs but also modulates significantly the transcriptional expression of two isoforms of HDACs, HDAC3 and 7. While the expression of HDAC7 is almost completely down-regulated by TSA, HDAC3 expression is up-regulated. Furthermore, we demonstrated that silencing of HDAC7 has anti-fibrotic effects in skin fibroblasts from patients with SSc. However, there are reports indicating that silencing of HDAC7 affects angiogenesis in human umbilical vein endothelial cells (HUVECs). Since microvascular damage is characteristic for SSc, we investigate here the role of HDAC3 in fibrosis and in angiogenesis in human uterine microvascular endothelial cells (HUMECs).

Method: Over-expression of HDAC3 in SSc skin fibroblasts and HUMECs was achieved by transfecting a HDAC3-expression vector/plasmid into cells using Amaxa nucleotransfection. An empty vector was used as control. Gene expression patterns of collagen types I and III, connective tissue growth factor (CTGF) and intercellular adhesion molecule-1 (ICAM-1) were analyzed by Sybr Green Real-time PCR. To assess the expression on the protein level, antibodies against collagen types I and III, CTGF and ICAM-1 were used for Western blot. Endothelial capillary sprouting was assessed using tube formation assay.

Results: After over-expression of HDAC3 in skin fibroblasts from patients with SSc, the transcription of collagen types I and III was reduced by 38 ± 16 % and 25 ± 20 % (n=6 each, $p<0.05$) respectively. These changes could be confirmed on the protein level by Western blot. In addition, the mRNA expression of other pro-fibrotic molecules such as CTGF remained unchanged in cells over-expressing HDAC3, while the expression of ICAM-1 was significantly reduced (50 ± 20 %, n=4, $p<0.05$). Western blot confirmed the results on the protein level. Over-expression of HDAC3 did not affect the expression levels of HDAC7, suggesting that HDAC3 exerts its anti-fibrotic effects independently of HDAC7. Using the tube formation assay, over-expression of HDAC3 did not inhibit the angiogenesis in HUMECs. However, in HDAC3 over-expressing cells, the accumulative length and number of tubes were increased to 204 ± 46 and 185 ± 52 % ($p<0.05$), after 18h of seeding the cells on Matrigel, compared to cells transfected with the empty vector.

Conclusion: Based on the fact that the altered angiogenesis is a major factor in the pathogenesis of SSc, we could show here that the over-expression of HDAC3 improves angiogenesis and has anti-fibrotic effects in SSc.

1814

Inhibiting B-Cell Activation by Skin Fibroblasts and Pulmonary Epithelial Cells: a New Treatment for Systemic Sclerosis ? Antoine Francois[1], Isabelle Couillin[2], Dominique Wachsmann[3], Jean Sibilia[4] and Jacques-Eric Gottenberg[5], [1]EA 3849 Laboratoire de Physiopathologie des Arthrites, Illkirch Graffenstaden, France, [2]UMR-IEM 6218 Molecular Immunology and Embryology, F-45071 ORLEANS Cedex 2, France, [3]Illkirch - Graffenstaden, France, [4]Hautepierre, Strasbourg, France, [5]University Hospital of Strasbourg, Strasbourg, France

Purpose: B lymphocytes might play a role in the induction of skin and pulmonary fibrosis in systemic sclerosis. BAFF and APRIL, key cytokines for B-cell activation, are increased in serum and skin from patients with systemic sclerosis. Lung fibrosis induced by bleomycin (BLM) is decreased in CD19-/- mice. We therefore investigated whether an increase of these cytokines could be observed in the activated skin fibroblasts isolated from SSc patients and in the bleomycin model of systemic sclerosis.

Method: Quantitative RT-PCR and ELISA were performed to evaluate BAFF mRNA induction and BAFF release by skin fibroblasts isolated from patients with SSc and subsequently stimulated with TLR ligands : BLP for TLR2, poly I:C for TLR3, LPS for TLR4, IFNs I, IFN-γ and TNF-α. BAFF levels were also evaluated in the broncho-alveolar lavages (BAL) and lung lysates from bleomycin-treated mice 1, 7, 10 or 14 days after administration of BLM (15mg/kg) (n=4 mice per group).

Results: Skin fibroblasts isolated from SSc patients synthesized and released BAFF in response to poly I:C (25 fold, 500pg/mL), LPS (10 fold, 200pg/mL) and IFNs I (15 fold, 200pg/mL) stimulation. BLP, IFN-γ and TNF-α had no effect. Interestingly BAFF secretion by skin fibroblasts seemed to be disease specific as this cytokine was not detected in activated normal skin fibroblasts culture supernatants. No

increase of APRIL expression was observed compared to controls skin fibroblasts. We also found a major increase of BAFF expression in BAL and lungs from bleomycin-treated mice (5000 pg/ml in BAL vs 340 pg/mL in controls after 14 days). Interestingly, BAFF increase was higher in BAL than in lungs, which suggests that alveolar epithelial cells are the main contributors to BAFF secretion.

Conclusion: Taken together, these data suggest that resident cells may participate through BAFF release to B cells-induced fibrosis in skin and lung from patients with SSc. BAFF might thus be a relevant therapeutic target in systemic sclerosis.

1815

Measurement of Total Serum Activin A in Patients with Systemic Sclerosis. Vasiliki-Kalliopi K. Bournia[1], Haralampos M. Moutsopoulos[2] and Panayiotis G. Vlachoyiannopoulos[2], [1]School of Medicine,National University of Athens, Greece, [2]School of Medicine, National University of Athens, Athens, Greece

Purpose: Activin A is a member of the transforming growth factor-β superfamily that has been implicated in the pathogenesis of inflammatory diseases and has been shown to enhance hepatic, pulmonary, kidney and pancreatic fibrosis. Recently, evidence of elevated circulating levels of activin A was reported in patients with pulmonary hypertension. Our aim was to assess the levels of total Activin A in sera from patients with Systemic Sclerosis.

Method: Sera were obtained from 40 patients with systemic sclerosis (SSc) and 39 age and gender matched healthy controls (**patients:** mean age 58,6 years, range 23-74 years, mean disease duration 13,15 years, lcSSc=15, dcSSc=25 / **controls:** mean age 58,4 years, range 24-75 years). Female patients and controls were also matched for menstrual cycle phase. All participants provided written informed consent prior to blood sampling. The samples were stored at -80°C until assayed. Levels of total serum Activin A were analyzed using a commercial solid phase sandwich ELISA kit (OXFORD BIO-INNOVATION LTD, product code: MCA1426KZZ). All samples were assayed in duplicate and the mean was calculated.

Results: Total serum activin A levels were higher in the patient group as compared to the control group (median 522.8 pg/ml vs 431.4 pg/ml, Mann-Whitney-U-test, p= 0.0131). The non parametric Kruskal-Wallis test was used to determine significant differences in total serum activin A levels between the subgroups of SSc patients with (n=8, median 567.3 pg/ml) or without pulmonary arterial hypertension (PAH)(n=32, median 499.8 pg/ml) and controls (p= 0,0167). Dunn's multiple comparison test was used to compare serum activin A levels in subgroups. A significantly higher Activin A serum level was shown for patients with PAH compared to controls ($p<0.05$). In addition we compared activin A levels in the subgroup of SSc patients with disease of recent onset (<5 years) (n=8, median= 669,8 pg/ml) to SSc patients with established disease (> 5years) (n=32, median= 511,7 pg/ml) and to controls (Kruskal-Wallis test, p= 0.0057). Significantly higher activin A serum levels were shown for SSc patients with disease duration of less than 5 years compared to controls (Dunn's multiple comparison test $p<0.05$).

Conclusion: Elevated total serum activin A levels in SSc patients with pulmonary involvement and in particular in those with pulmonary arterial hypertension could indicate a possible role of this molecule in the pathogenesis of systemic sclerosis and especially in the initial disease stages.

Activation of Scleroderma-Like Signaling Pathway: Importance of PDGFR-NADPH Oxidase Complex and Receptor Integrity. Tatiana Spadoni[1], Silvia Svegliati[1], Lucia De Gennaro[1], Gianluca Moroncini[1], Enrico Avvedimento[2] and Armando Gabrielli[1], [1]Università politecnica delle Marche, Ancona, Italy, [2]Università "Federico II", Napoli, Italy

Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by widespread vascular changes and progressive fibrosis of the skin and internal organs. We have demonstrated the presence of stimulatory immunoglobulins binding to PDGF receptor in serum of SSc patients. These autoantibodies from SSc patients show functional agonistic activity as demonstrated by induction of tyrosine phosphorylation and production of reactive oxygen species (ROS). Moreover isolated IgG from SSc patients induced myofibroblast conversion and type I collagen expression in normal human fibroblasts. The scope of this study is to elucidate the cellular and molecular changes elicited by the

PDGFR autoantibodies in normal cells and to assess the molecules engaged in the membrane complex recognised by SSc IgG and their role in the generation of PDGFR signalling and ROS.

Method: The interaction between SSc IgG, PDGFR and the subunits of the NADPH oxidase complex was evaluated by immunoprecipitation of extracts from stimulated and unstimulated fibroblasts and HeLa cells, constitutively devoid of PDGFR, stably transfected with different alpha and beta PDGFR recombinant DNA constructs, with purified SSc IgG and monoclonal anti-PDGFR antibodies. Immunocomplexes were characterized by specific immunoblotting with anti PDGFR, Nox-2 and Ha-Ras antibodies. The stably trasfected cell lines were used to determine the regions of PDGFR recognized by the different IgG and the importance of receptor integrity on signalling transduction.

Results: We have found that SSc IgGs from several different patients selectively immunoprecipitate gp91 phox, the NADPH oxidase Nox-2 subunit, in addition to PDGFR. SSc IgG stabilized a membrane-associated complex made of PDGFR and NADPH oxidase with the consequence of lengthening ROS/Ras activation. The recombinant receptors devoid of the cytoplasmatic domain are bound to gp91 but the lack of tyrosine phosphorylation sites impairs the transduction of the signalling.

Conclusion: SSc IgGs interact with the extracellular part of the PDGFR and prolong the formation of a stable PDGFR/NADPH oxidase complex on the cell membrane, leading to a persistent ROS production and appearance of the disease pathological signatures.

1817

The Interplay of Vascular Function, Low Grade Inflammation and Innate Immunity in Raynaud's Phenomenon and Systemic Sclerosis. Marina E. Anderson, Theresa Barnes, Paula Pyrkotsch, Janette Lamb, Emma Naylor, Steven W. Edwards and Robert J. Moots, University of Liverpool, Liverpool, United Kingdom

Purpose: The pathophysiological processes underlying systemic sclerosis (SSc) are incompletely understood, despite considerable morbidity and risk of early mortality in this multi-system disease. However, preliminary work from our department suggests that, in addition to well-described vascular, fibrotic and immunological abnormalities, low-grade inflammation and innate immunity play a role. Our aim was to investigate the link between inflammation, innate immunity and vasculopathy in this disease.

Method: In our cohort of patients with limited and diffuse cutaneous SSc (lcSSc and dcSSc), primary RP (PRP), undifferentiated connective tissue disease (UCTD) and healthy control subjects, we studied three groups of parameters:

1) **NK cells and neutrophils:** peripheral blood

2) **Markers of inflammation and vascular activation:** peripheral blood

3) **Vascular physiology:**

a) Macrovascular function: Applanation tonometry

b) Microvascular morphology: Digital nailfold video capillaroscopy

c) Microvascular function: Digital iontophoresis of acetylcholine (ACh, endothelial-dependent vasodilatation) and nitroprusside (NP, endothelial-independent vasodilatation) measured by laser Doppler imaging.

Spearman's rank correlation coefficient was used to examine the relationship between the three groups of parameters.

Results: Having determined, in 40 subjects (9 controls, 5 PRP, 4 UCTD & 22 SSc), that there are significant differences between the studied subject groups of

1) markers of apoptosis (annexin V), activation (CD16) & adhesion (CD11b & CD18) on isolated **neutrophils**

2) markers **of endothelial activation** (VCAM-1, E-selectin & ET-1) and inflammation (IL-6) in sera , and

3) tests of **vascular function / morphology**,

we correlated our findings to examine the relationship between variables.

Significant correlations between markers of neutrophil / endothelial activation and vascular morphology / function are shown in table 1.

Table 1: Correlations between markers of neutrophil / endothelial activation and vascular morphology / function

	Spearman's rho correlation coefficient (p)	
lcSSc	Annexin V vs ACh iont	-0.929 (<0.001)
	Annexin V vs NP iont	-0.857 (0.007)
	CD11b vs Loops/mm	0.700 (0.036)
All disease groups	Annexin V vs ACh iont	-0.591 (0.016)
	Annexin V vs NP iont	-0.544 (0.029)
	E-selectin vs Loops/mm	-0.419 (0.024)
	ET-1 vs Appl tonometry	0.620 (0.018)
	IL-6 vs ACh iont	-0.388 (0.034)
	IL-6 vs Loops/mm	-0.414 (0.026)

Significant correlations were also seen between IL-6, ET-1 and cellular adhesion molecules in the disease states.

Conclusion: We demonstrated that 1)neutrophil apoptosis and 2)markers of both neutrophil and endothelial adhesion / activation are associated with micro- and macro-vascular function and morphology in RP and SSc, suggesting that low-grade inflammation, innate immunity and the micro-/macro-circulation play an integrated role in the pathogenesis of SSc.

Further work is underway to further characterise the role of both the innate immune system and the vasculature, and the interplay of these two systems in SSc, with the ultimate aim of identifying new markers of disease activity and severity.

1818

Upregulated Versican in Monocytes From Patients with Systemic Sclerosis: Role in Amplification of Monocytes-Chemoatrractant Protein-1 (MCP-1) Activity at Site of Fibrosis. Hidekata Yasuoka[1], Ayako Masuda[1], Yukie Yamaguchi[2], Takashi Satoh[1] and Masataka Kuwana[1], [1]Keio University School of Medicine, Tokyo, Japan, [2]Division of Pulmonary, Allergy, and Critical Care of Medicine, University of Pittsburgh, Pittsburgh, PA

Purpose: Pathologic features of systemic sclerosis (SSc) in early disease phase include infiltration of lymphocytes and monocytes surrounding small vessels, which may contribute to the subsequent fibrotic process. Phenotypic and functional alteration of circulating monocytes have been reported in SSc patients, but their roles in the pathogenesis of SSc are largely unknown. In this study, we identified molecules that preferentially expressed by SSc monocytes using DNA microarray analysis and examined their roles in the fibrotic aspect of SSc.

Methods: Peripheral blood samples were obtained from 36 patients with SSc (22 diffuse and 14 limited) and 32 healthy controls (HC). Circulating monocytes were isolated as CD14+ cells using the MACS™ sorting system. Pooled RNA samples derived from SSc and HC monocytes were applied to Oligo GEArray® system to evaluate expression profiles of 330 genes related to extracellular matrix and adhesion molecules, chemokines, and endothelial cell biology. Candidate genes defined by >1.5 fold increase of the expression level in SSc versus HC monocytes were further subjected to semi-quantitative RT-PCR combined with densitometry and TaqMan™ quantitative RT-PCR for confirmation. Protein expression of genes of interest in monocytes was evaluated by immunoblots or ELISA using culture supernatants of unstimulated monocytes and by 3-color fluorecent immunocytostaining. Chemoattractant activity of MCP-1 was assessed in cultures of monocytes in a TransWell® system in the presence or absence of the condroitin sulfate (CS) chain.

Results: By screening with oligo DNA microarray system, type I collagen, versican, MCP-1, IL-8, MMP-2 and CCR1 were selected as candidate genes preferentially expressed by SSc monocytes. The subsequent analyses by semi-quantitative and quantitative RT-PCR revealed that MCP-1 and versican were upregulated 3.5 and 4.8 times in SSc monocytes compared with HC monocytes, respectively. Protein expression analysis of culture supernatants from 14 SSc and 11 HC monocytes showed upregulated protein expression of versican ($p = 0.03$) and a trend toward increased expression of MCP-1 ($p = 0.2$) in SSc versus HC monocytes. Immunocytostaining analysis on SSc monocytes demonstrated colocalization of MCP-1 and versican in the Golgi apparatus. Since versican functions as a reservoir of various chemokines, through binding to its CS chain, we further examined the role of the CS chain on activity of MCP-1, one of fibrogenic chemokines. Binding of MCP-1 to the CS chains resulted in protection of MCP-1 from protease attack, and enhanced MCP-1-induced monocyte migration in a dose-dependent manner.

Conclusion: Increased expression of versican in complexed with MCP-1 in SSc monocytes may contribute to the pathogenesis of SSc by amplifying fibrogenic activity of MCP-1 in the affected tissues where monocytes are recruited.

Disclosure: H. Yasuoka, None; **A. Masuda**, None; **Y. Yamaguchi**, None; **T. Satoh**, None; **M. Kuwana**, None.

1819

Mesenchymal Stem Celles From Bone Marrow of Patients with Systemic Sclerosis: Properties and Pathogenic Perspectives. N. Del Papa[1], N. Quirici[2], C. Scavullo[2], L. Corti[2], M. Introna[3], W. Maglione[1], D. Comina[1], N. Vaso[1], F. Onida[4] and G. Lambertenghi Deliliers[4], [1]G. Pini Hospital, Milano, Italy, [2]1Università degli Studi di Milano, Milano, Italy, [3]OORRBG, Bergamo, Italy, [4]Fond.Osp. Magg. Policlinico e Università di Milano, Milano, Italy

Purpose: Bone marrow-derived mesenchymal stem cells (MSCs) are currently being studied to evaluate their potential role in the pathogenesis and/or management of autoimmune diseases. Several studies suggest that systemic sclerosis (SSc) may be seen as a stem cell disorder, however it is unclear whether MSCs from SSc patients are defective. Aim of the study was to evaluate the biological properties of bone marrow (BM) derived MSCs in patients with SSc, focusing on their phenotype and functional characteristics.

Method: BM samples were obtained from 28 SSc patients and 17 healthy donors. The MSCs were purified according to their adherence to the plastic (PA) and by positive selection for the expression of the low-affinity nerve growth factor receptor (L-NGFR), the p75 antigen known to be expressed in early MSCs. The stromal compartment was then analyzed in its progenitor number and functional properties by various assays. In addition, the anti-proliferative effects of normal and SSc MSCs were evaluated by co-culture experiments with SSc cutaneous fibroblasts.

Results: Phenotype analysis showed a decrease in the percentage of $NGFR^+$ cells with respect to normal marrows (nBM) (0.53±0.43% *vs* 1.17±0.64%; P=0.001). Furthermore, SSc $NGFR^+$ cells showed increased levels of CD105 surface expression, the TGF-b receptor (25.6±10.3% *vs* 13.8±5.9%; P=0.03). Proliferation ability was always impaired in comparison to healthy subjects both in the whole PA stromal compartment and in $NGFR^+$ cells, with a 1 to 4 log lower cell expansion. The clonogenic efficiency, evaluated by a CFU-F assay, was impaired both in the whole PA fraction (16.1±20.4 colonies/$1x10^6$ cells *vs* 34.2±18.3 in controls; P=0.01) and in the $NGFR^+$ cells (7±12.8 colonies/$1x10^5$ cells *vs* 69±61; P=0.011). Long-term BM culture assays showed that the impaired stromal growth poorly supported hematopoiesis, with a decrease in hematopoietic precursors during culture. Co-culture assays showed a inhibition of fibroblast proliferation, higher when fibroblasts were cultured with nBM MSCs (% of inhibition: 40±6.5% with nBM MSCs *vs* 26.3±8.6% with SSc MSCs; P=0.04).

Conclusion: The analysis of the SSc BM stromal compartment showed that MSCs are impaired in their number and functional properties, with an increased expression of the TGF-b receptor, suggesting that MSCs are involved in the pathogenic mechanisms of SSc. In addition, we show for the first time an anti-proliferative effect of MSCs on SSc cutaneous fibroblasts, even if it was lower in the presence of SSc BM MSCs. Our results arise relevant questions on BM MSCs as a therapeutic tool in Scleroderma. MSCs therapy is already considered for treating severe acute graft versus-host disease, which bears many similarities to SSc. The ability of MSCs to inhibit SSc fibroblast proliferation opens up exciting prospects for their use in anti-fibrotic strategies.

Faecal-Calprotectin as a Biomarker in Systemic Sclerosis. Kristofer Andréasson[1], Agneta Scheja[1], Tore Saxne[1], Bodil Ohlsson[2] and Roger Hesselstrand[1], [1]Dept of Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden, [2]Dept of Clinical Sciences, Section of Gastroenterology and Hepatology, Lund University, Malmö, Sweden

Purpose: In systemic sclerosis (SSc), involvement of the gastrointestinal (GI) tract is frequent and its assessment distal to the oesophagus complicated in clinical practice. Faecal calprotectin (F-calprotectin), also known as S100A9/A8, is a validated biomarker in inflammatory bowel disease. In this study we analysed F-calprotectin to explore the mechanisms of GI involvement in SSc and to test its potential as a biomarker of GI involvement in SSc.

Method: The study comprised 77 consecutive SSc patients (65 female, 12 men). Mean disease duration, defined as years from first non Raynaud manifestation, was 9 (S.D.=7) years. Levels of calprotectin in stool and plasma were measured with ELISA (Bühlmann laboratories AG, Switzerland). F-calprotectin >50 µg/ml was considered pathologically increased. P-calprotectin was compared with the median (0.83 µg/ml) for healthy controls. Patients were subjected to a clinical, radiological and biochemical examination and their medical records studied. Statistical correlations were done with parametric tests using the logarithm of F-calprotectin and P-calprotectin.

Results: A majority of the patients had increased levels of F-calprotectin (median 125; interquartile range (IQR) 45-213 µg/ml). A significant relationship was noted between patients' reported proton pump inhibitor-usage and F-calprotectin ($r=0.50$; $p<0.001$) and the number of medications prescribed for GI dysfunction including malnutrition ($r=0.34$; $p=0.002$). Patients with radiological evidence of oesophageal dysfunction had higher levels of F-calprotectin than those without (mean 141 *vs* 60 µg/ml; $p=0.015$). F-calprotectin correlated with the estimated pulmonary arterial pressure (PAP; $r=0.47$; $p<0.001$), but not with finger arterial pressure or nailfold capillary density. Patients showing signs of diastolic dysfunction had higher F-calprotectin values ($p=0.006$). There was a weak relationship between F-calprotectin and vital capacity ($r=-0.25$; $p=0.027$) but no correlation with modified Rodnan Skin Score, limited or diffuse skin involvement or NSAID-usage. P-calprotectin was higher than previously reported in healthy controls (median 1.5; IQR 0.7-1.9 µg/ml), correlated with other markers of systemic inflammation, e.g. orosomucoid ($r= 0.58$; $p<0.001$), but did not show any significant relationship with F-calprotectin ($r=0.22$; $p=0.061$).

Conclusion: Patients with SSc have increased levels of calprotectin in faeces, which suggests presence of an inflammatory process in the GI tract. F-calprotectin correlates with clinically relevant GI manifestations and may prove to be a useful non-invasive marker of GI involvement in SSc.

1821

Possible Genetic Association of HLA-A*2601 and B39 with Ocular Behçet's Disease in Japan. Toshikatsu Kaburaki[1], Misuko Takamoto[1], Jiro Numaga[1], Hidetoshi Kawashima[1], Makoto Araie[1], Yuka Ohnogi[1], Shinji Harihara[2], Shoji Kuwata[3] and Fujio Takeuchi[1], [1]The University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]The University of Tokyo Graduate School of Science, Tokyo, Japan, [3]Teikyo University Chiba Medical Center, Teikyo University School of Medicine, Chiba, Japan

Purpose: Behçet's disease (BD) is known to be associated with HLA-B*51 in many different ethnic groups. Recently, several HLA-A alleles including HLA-A*2602 have been proposed as a candidate gene for BD susceptibility in several ethnic groups. To confirm the association of the HLA-A*26 allele and the other HLA class I alleles to BD, we studied HLA-A and -B polymorphisms in Japanese ocular BD patients.

Method: Seventy-nine Japanese BD patients who suffered from uveitis and 104 healthy controls were enrolled for analysis of polymorphisms of HLA class I. Statistical analysis was performed with Fisher's exact test and odds ratio (OR) with 95% confidential interval (95%CI). The significance (p value) was corrected by the numbers of alleles compared.

Results: The phenotype frequencies (PF) of HLA-A*2601 were significantly higher in BD patients (36.7%) than in controls (14.4%) (p=0.0110, OR=3.44, 95%CI=1.69-7.02). The PF of HLA-B*5101 was also significantly more frequent in BD patients (45.6%) than in controls (18.3%) (p=0.00240, OR=3.75, 95%CI=1.92-7.29). The PF of the HLA-A*2601 is significantly increased in the group of BD without HLA-B*5101 (53.5% Vs 14.1%, $p=7.50x10^{-5}$, OR=7.00, 95%CI=2.97-16.46), whereas the PF of HLA-A*2601 is not increased in the group of BD with the HLA-B*5101 (16.7% Vs 15.8%). The PF of the BD patients carrying the HLA-A*2601 or HLA-B*5101 is extremely increased comparing to the frequency in the control (74.7% Vs 29.8%, $p=6.64x10^{-8}$,OR=6.95, 95%CI=3.60-13.41). Whereas the association with the HLA-A*2602 in Japanese BD was reported previously, we could not detect the association of HLA-A*2602 in our BD cases (6.3% Vs 3.8%). The PF of the HLA-B39 is significantly increased in the BD-group without HLA-A*2601 and HLA-B*5101 (30.0% Vs 4.1%, p=0.0491, OR=10.00, 95%CI=2.23-44.82). The PF of the HLA-A*2601 is significantly associated with severe ocular disease (p=0.023) and poor visual prognosis corresponding the best corrected-visual acuity of 0.1 or less in the worse eyes (p=0.0113).

Conclusion: Our results indicate that HLA-A*2601 is associated with BD independently from the HLA-B*5101, indicating that HLA-A*2601 is the additional susceptibility gene in the patients of BD in Japan. HLA-A*2601 might be a disease marker for the severity of ocular disease. Moreover, HLA-B39 might be a possibility of another susceptibility gene for ocular BD.

Localized Vasculitis of the Gastrointestinal Tract: A Case Series. Carlo Salvarani[1], Kenneth T. Calamia[2], Cynthia S. Crowson[3], Dylan V. Miller[3], Aaron W. Broadwell[2], Gene G. Hunder[3], Eric L. Matteson[3] and Kenneth J. Warrington[3], [1]Arcispedale S. Maria Nuova, Reggio Emilia, Italy, [2]Mayo Clinic Jacksonville, Jacksonville, FL, [3]Mayo Clinic, Rochester, MN

Purpose: Localized vasculitis of the gastrointestinal tract (LVGT) occurring in isolation is unusual. The objective of this study is to describe the clinical features and outcomes of patients with LVGT.

Method: Medical records of 608 patients diagnosed with vasculitis involving the intraabdominal vasculature and/or abdominal viscera between 1/1996 and 12/2007 were reviewed. Only patients with histopathological confirmation or typical angiographic findings of vasculitis were included; patients with evidence of vasculitis outside the abdomen were excluded.

Results: We identified 18 cases with LVGT over the 12-year study period. The patients were predominantly Caucasian (89%) and female (67%). Mean age at diagnosis: 53.6 (±16.9) years. Most presented with abdominal pain (94%). Other symptoms included nausea (56%), vomiting (44%), diarrhea (44%) and abdominal angina (44%). GI bleeding (17%) was uncommon.

At presentation, mean hemoglobin was 12.7 (±1.6) g/dL, mean ESR was 30.6 mm/hour (±23.6) and mean CRP was 20.2 mg/L (±22; nl <8.0mg/L). ANCA, cryoglobulins and RF were negative in all patients tested. ANA and hepatitis C antibody were positive each in 1. Hepatitis B surface antigen was absent in all tested. Abdominal computed tomography (CT) scan findings included: bowel wall thickening, 3 (25%); bowel infarction, 2 (17%); liver infarcts, 2 (17%); splenic infarcts, 3 (25%). Conventional angiography was performed in 14 (78%) patients, 6 patients (33%) had CT angiography and 6 patients (33%) magnetic resonance (MR) angiography. Findings are listed in the table. Eleven patients (61%) underwent surgical intervention. Histologic confirmation of necrotizing vasculitis was recorded in 5 (28%) of patients, most commonly from gallbladder or small intestine specimens.

Corticosteroid therapy was administered to 10 patients (56%), 4 of whom also received other immunosuppressive agents. Mean follow-up was 12.6 (± 26.6) months. No evidence of vasculitis in other districts was observed during the follow-up. Eight patients (44%) died during the follow-up period (mean survival from diagnosis 6.7 (± 11.6) months) and of these, 3 deaths were related to vasculitis.

Conclusion: This largest series of LVGT reported to date reveals this uncommon form of vasculitis to be associated with significant morbidity and mortality. Laboratory tests are nonspecific; imaging is particularly helpful in assessing patients with suspected LVGT. Optimal treatment remains to be defined.

Table . Angiogram findings

Angiogram findings	No. of patients (%) (N= 15)				
Artery	aneurysm	stenosis	thickening	dilatation	occlusion
Celiac	3 (20)	7 (46.7)	2 (13.3)	2 (13.3)	2 (13.3)
Hepatic	1 (6.7)	5 (33.3)	0	3 (20)	3 (20)
Gastric	1 (6.7)	1 (6.7)	0	0	0
Splenic	2 (13.3)	4 (26.7)	0	0	3 (20)
Superior mesenteric	3 (20)	10 (66.7)	2 (13.3)	6 (40)	2 (13.3)
Inferior mesenteric*	0	5 (35.7)	1 (7.1)	4 (28.6)	1 (7.1)
Right renal	1 (6.7)	4 (26.7)	0	3 (20)	0
Left renal	1 (6.7)	3 (20)	0	1 (6.7)	0

1823

Identification of KIAA1529 as a Novel Susceptibility Gene for Behçet's Disease. Amr H. Sawalha[1], Yiping Fei[2], Ryan Webb[3], Beth L. Cobb[4], Jonathan Wren[5], Haner Direskeneli[6] and Güher Saruhan-Direskeneli[7], [1]University of Oklahoma, Oklahoma Medical Research Foundation, Department of Veterans Affairs Medical Center, Oklahoma City, OK, [2]University of Oklahoma, Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Oklahoma Medical Research Foundation, JK Autoimmunity, Inc., [5]Oklahoma Medical Research Foundation, [6]Marmara University, Istanbul, [7]Department of Physiology, Istanbul Faculty of Medicine, Istanbul University

Purpose: Behçet’s disease is a chronic vasculitis characterized by recurrent oro-genital ulcers, skin lesions, uveitis, recurrent venous thrombosis and arterial aneurysms. The disease also affects the brain, joints, and in some cases the gastrointestinal tract. Behçet’s disease is poorly understood, and treatment options currently available are nonspecific and frequently ineffective. There is clear evidence to suggest a genetic contribution to the pathogenesis of Behçet’s disease. The genetic association with HLA-B51 is the only established and repeatedly confirmed genetic association with this disease. The association in the HLA region, however, accounts for less than 20% of the genetic risk for Behçet’s disease.

Method: We have performed a genome-wide association scan (GWAS) in a cohort of 152 Behçet’s disease patients and 172 ethnically-matched healthy controls using DNA pooling and the Affymetrix 500K arrays, followed by TaqMan® genotyping in individual samples in candidate susceptibility loci.

Results: We identified 5 novel candidate genes for Behçet’s disease (*KIAA1529*, *CPVL*, *LOC100129342*, *UBASH3B*, and *UBAC2*). Cluster analysis of the GWAS data identified 14 SNPs in the *KIAA1529* locus (9q22) that are associated with Behçet’s disease. Among the associated SNPs, the Behçet’s disease risk allele in rs2061634 located within *KIAA1529* leads to the change in the amino acid at position 995 to cysteine (S995C) in the *KIAA1529* protein (odds ratio= 2.04, 95%CI= 1.45-2.88, P value= $4.2X10^{-5}$). By identifying genes specifically and consistently co-expressed with *KIAA1529* over 3,651 human 2-color microarray datasets from NCBI’s GEO, we used an algorithm to

infer function using a "guilt by association" method. The 20 genes most closely matching *KIAA1529*'s expression trends (i.e., up and down-regulated with it) were analyzed for commonalities using a literature mining software (IRIDESCENT). Through these analyses, we predict that the transmembrane protein KIAA1529 is expressed on the nuclear membrane and is involved in nuclear trafficking.

Conclusion: We identified the genetic association between Behçet's disease and *KIAA1529* (Behçet's disease associated gene 1, *BDAG1*). Determining the functional consequences of the identified missense polymorphism might help to better understand the pathogenesis of this debilitating disease.

1824

Efficacy of Infliximab in Patients with Different Types of Refractory Uveitis. Laura Niccoli, Carlotta Nannini, Emanuele Cassarà, Daniela Chindamo, Michele Bertoni, Giampaolo Gini, Ivo Lenzetti and Fabrizio Cantini, Hospital of Prato, Prato, Italy

Purpose: To evaluate the long-term efficacy and safety of infliximab (IFX) in patients with different types of sight threathening uveitis resistant to corticosteroid (CS) with associated immunosuppressants. Primary outcome measure was visual acuity (VA) at the end of follow up. Secondary measures were the proportion of relapse-free subjects through months 12.

Method: Open-label, single-center, 12-month, prospective, follow up study on 20 consecutive patients, 13 with Beh□et's disease (BD), 2 with Vogt-Koyanagi-Harada (VKH) disease and 5 with idiopathic posterior uveitis (IPU), who had failed at least one immunosuppressants in addition to CS. At baseline patients received prednisone 1 mg/Kg/day with rapid tapering, IFX infusions (5 mg/Kg) over a 12-month period. Non-responders after the third infusion withdrew from the study. Patients were evaluated for visual VA, ocular inflammation degree, number of ocular attacks, and incidence of adverse events (AEs).

Results: At 12-month visit, 10/13 (77%) BD patients achieved a complete remission with no relapse. All patients suspended corticosteroids at week 22. Mean VA improved from 0.2±0.6 to 0.5±0.2 ($p<0.001$), and ocular attacks dropped from 40 in the year before therapy to 5 after IFX cessation ($P<0.001$), 2/13 (15%) patients showed no improvement.

Two females with VKH disease, achieved a complete disease remission after the second infusion and CS were suspended with no relapse after the sixth. IFX monotherapy allowed maintaining the remission in both patients with improvement of VA (median VA before IFX 0.45, median VA after IFX 0.85).

Five IPU patients had inactive disease after the fourth infusion, and the remission was maintained over a median follow-up of 12 months. None of the patients required additional treatment with local CS. Median VA (9 eyes) improved from 0.15 at baseline to 0.8 ($p:0.001$) at the end of follow-up. No serious adverse events were recorded.

Conclusion: Infliximab is rapidly effective and safe in a high proportion BD patients, and both in VKH and IPU patients with refractory posterior uveitis, and may be helpful to prevent recurrences.

1825

Catastrophic Primary Central Nervous System Vasculitis. Carlo Salvarani[1], Robert D. Brown Jr.[2], Kenneth T. Calamia[3], Teresa J. H. Christianson[2], John Huston III[2], James F. Meschia[3], Caterina Giannini[2], Dylan V. Miller[2] and Gene G. Hunder[2], [1]Arcispedale S. Maria Nuova, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Jacksonville, FL

Purpose: Primary Central Nervous System Vasculitis (PCNSV) is an uncommon and heterogeneous condition that affects the brain and spinal cord. Recently, we reported 101 patients with PCNSV seen over a 21-year period (1983-2003). Although most patients responded to therapy, an increased mortality was observed. This study was undertaken to identify the subset of patients who appear to have a catastrophic clinical course in the context of the largest cohort of consecutive patients with PCNSV studied to date.

Methods: The present study extends the previous cohort and includes 131 patients with PCNSV seen over the 25 year period of 1983 to 2007. PCNSV diagnosis was based on brain/spinal cord biopsy or angiograms. Intracranial internal carotid artery and proximal anterior, middle, and posterior cerebral arteries were considered large cerebral vessels. The modified Rankin Scale was used to identify catastrophic disease: patients with Rankin 5 (severe disability) or 6 (stroke death) at diagnosis and/or Rankin 5 or 6 at last follow-up (patients with Rankin < 5 at diagnosis must develop a score of 5 or 6 within 6 months after the diagnosis). We compared patients with catastrophic disease to those without.

Results: 11 cases had catastrophic PCNSV. Cerebral angiography was performed in 10 patients and showed bilateral, multiple, large-vessel changes in 9. Three cases had positive CNS biopsy. Compared with the 120 patients without, the 11 patients with catastrophic vasculitis more frequently had paraparesis/quadriparesis at presentation (36.4% vs 2.5%, $p < 0.001$), angiographic presence of bilateral, large-vessel vasculitis (90% vs 52.9%, $p = 0.04$), and MRI evidence of cerebral infarctions (100% vs 51.4%, $p = 0.004$); those infarctions were more frequently multiple and bilateral (77.8% vs 37.6%, $p = 0.03$) and more frequently involved both the cortex and subcortex on initial MRI (66.7% vs 25.7%, $p = 0.02$). Parenchymal and meningeal gadolinium-enhancing lesions occurred less frequently (0% vs 42.2%, $p = 0.01$). Other differences in those with catastrophic PCNSV that were not statistically significant included a higher frequency of persistent neurological deficit or stroke at presentation (63.6% vs 36.7%) and more patients were treated initially with cyclophosphamide or azathioprine (63.6% vs 47.5%). Cerebrospinal fluid abnormalities and the frequency of relapses/recurrences were similar in the two groups. No patients with catastrophic PCNSV showed a lymphocytic histopathological pattern. Survival of the patients with catastrophic PCNSV was significantly reduced ($p < 0.001$).

Conclusion: Catastrophic PCNSV appears to form a clinical subset of PCNSV characterized by bilateral, multiple, large-cerebral vessel lesions and multiple cerebral infarctions.

1826

Defective FOXP3 Expression in Patients with Acute Kawasaki Disease and Restoration by Intravenous Immunoglobulin Therapy.

Biagio Olivito[1], Andrea Taddio[2], Gabriele Simonini[1], Cristina Massai[1], Sara Ciullini[1], Eleonora Gambineri[1], Maurizio de Martino[1], Chiara Azzari[1] and Rolando Cimaz[1], [1]University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy, [2]Institute of Child Health, IRCCS Burlo Garofolo, University of Trieste, Trieste, Italy

Purpose: The acute phase of Kawasaki disease (KD) is characterized by an impaired immunoregulation and a link between CD4+CD25+FOXP3+ regulatory T cells (Tregs) and Intravenous Immunoglobulin (IVIG) has recently been suggested. We therefore investigated FOXP3 expression in patients with KD, comparing the expression pattern during the acute phase and after defervescence. A possible association of the FOXP3 SNP 543 (rs2232367) with KD was also evaluated.

Methods: FOXP3 expression was evaluated on 8 children with KD and 15 healthy children by flow cytometry and Real-Time Taqman polymerase chain reaction. FOXP3 SNP 543 was genotyped by denaturing high-performance liquid chromatography (DHPLC) and sequencing on DNA samples from 58 additional children with KD and 114 healthy donors.

Results: The percentage of Tregs was significantly ($p=0.0002$) lower during the acute phase of KD than in sex-and age-matched healthy donors (median % ± SD: 4.8 ± 1.3 vs 7.7 ± 1.7) and a similar tendency was revealed for FOXP3 mRNA transcripts ($p<0.0001$). FOXP3 expression increased significantly, at both protein and mRNA levels, after intravenous immunoglobulin (IVIG) treatment (at least 48 hrs; median 9.5 days, range 2-30) and achieving complete remission of disease. Of the 58 patients screened, only one female subjects (1.7%) carried the presence of 543 SNP in heterozygosis (C>T; for a total of 1 allele out of 88), with no difference between KD patients and controls (0/203 alleles).

Conclusion: Our data reinforce the notion of an impaired immunoregulation in KD, suggesting also a role of IVIG treatment in modifying the Tregs compartment. FOXP3 SNP 543 do not seem to be involved in susceptibility to KD in Italian children.

1827

Frequency of Fibromyalgia , Depression and Sleep Disorders in Wegener Granulomatosis. Rula Hajj-Ali[1], William S. Wilke[1], Leonard H. Calabrese[2], Gary S. Hoffman[3], Tiffany Clark[1] and C. A. Langford[1], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic, OH

Purpose: Morbidity and mortality for Wegener granulomatosis (WG) has dramatically improved. Nonetheless, patient surveys have revealed that despite remission, patients often complain of diffuse pain and fatigue. We hypothesized that there is an increased frequency of fibromyalgia (FM), depression, and sleep disorders in patients with (WG) that may contribute to the fatigue and pain.

Method: The frequency of FM, depression and sleep disorders in 55 patients with WG was assessed by 3 validated instruments: the London Fibromyalgia Epidemiologic Study Screening Questionnaire (LFESSQ), Epworth Sleepiness Scale (ESS), and the Brief Patient Health Questionnaire (BPHQ-9).Questionnaires were administered prospectively to patients who met the ACR criteria for WG and who have been followed at the Center for Vasculitis Care and Research at Cleveland Clinic for at least 2 visits. Eligibility included age of >18 years and duration of WG for at least 3 months. Pain in all 4 items and on both sides of the LFESSQ was used to identify fibromyalgia. BPHQ-9 score of ≥ 10 were used to indicate moderate depression. An ESS score of ≥10 was used to indicate abnormal sleepiness. Fatigue was captured quantitatively by the visual analogue scale (FVAS) and qualitatively by the LFESSQ fatigue questionnaire. Disease activity and damage were captured by using the Birmingham Vasculitis Activity for WG (BVAS/WG) and the Vasculitis damage index (VDI). Furthermore we assessed the correlation between VDI, BVAS/WG, disease duration, gender and BPHQ9, LFESSQ ESS, FVAS and evaluated correlations between ESS, BPHQ -9 and fatigue (FVAS).

Results: Patients mean age was 52 years, 60 % were males , and mean disease duration was 104 months. Based on the LFESSQ, 23.64 % of patients had fibromyalgia, 21.8 % had moderate depression defined as BPHQ-9 ≥ 10 , and 29 % had sleep abnormalities per ESS scores of ≥ 10. 76.4 % reported fatigue and 47.3% indicated that fatigue significantly limited their activities. There was no correlation between the score of the BPHQ-9, ESS, LFESSQ, FVAS, and VDI, BVAS-WG, or disease duration. There was no difference in BPHQ-9, LFESSQ, and ESS based on gender. Comparison of the WG cohort to the general population, revealed WG patients have a significantly greater frequency of fibromyalgia (LFESSQ 23.6 vs. 13 p=0.02) and depression (21.8 vs. 7.6 p< 0.001). There was a strong correlation between FVAS (fatigue) and BPHQ-9 (depression) [correlation coefficient of 0.73 (95% CI: 0.54, 0.92)].The correlation between FVAS and ESS was significant but not as strong as with the BPHQ 0.36 (95% CI: 0.10, 0.62).

Conclusion: Fibromyalgia and depression occur more often in WG compared to the general population. The association is not related to disease activity, damage or disease duration. Fatigue is very common and significantly limits the normal daily activities. Depression and sleep disorders contribute to fatigue in WG patients. Further studies with larger numbers of patients will be necessary to confirm these observations.

1828

Comprehensive Analyses of Serum Peptides in Microscopic Polyangiitis. Yukiko Takakuwa[1], Manae S. Kurokawa[2], Seido Ooka[1], Kouhei Nagai[2], Mitsumi Arito[2], Kayo Masuko[2], Naoya Suematsu[2], Kazuki Okamoto[2], Shoichi Ozaki[1] and Tomohiro Kato[2], [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]St.Marianna University Graduate School of Medicine, Kawasaki, Japan

Purpose: Microscopic polyangitis (MPA), one of systemic vasculitides, is charactered by necrotising vasculitis of small vessels. We comprehensively analyzed serum peptides from MPA patients by proteomics techniques to find disease-specific peptides that would be a candidate disease marker, or that would be useful for elucidation of the pathogenesis.

Method: Peripheral blood was obtained from 26 patients with MPA before treatment and 1 or 6 weeks after start of the treatment, and from 27 patients with systemic lupus erythematosus (SLE) before treatment. Serum peptides were isolated by using magnetic beads with hydrophobic carriers. Then the peptides were detected comprehensively and quantitatively by mass spectrometer. Peptides increased or decreased significantly by the treatment, and those differently expressed between MPA and SLE before treatment, were selected by using ClinProt software. Amino acid sequences of a part of the increased/decreased peptides were identified by MS/MS analysis and protein data base searching.

Results: We detected peptides with 1523m/z, 1737m/z, 2503m/z, and 7767m/z whose ion intesities were high before the treatment but were low after the treatment. Similarly, peptides with 1625m/z, 2115m/z, and 7160m/z whose ion intesities were low before the treatment but were high after the treatment were detected. Interestingly, the peptides with 1523m/z, 1737m/z, and 2503 m/z were specifically detected in the serum samples from the MPA patients before the treatment, not in those from the SLE patients. The peptide with 1523m/z (p1523) was identified as C-terminal 13 amino acids (AA) of apolipoprotein A-I (ApoA1). Serum concentration of ApoA1 was found to be low in the MPA group before the treatment (5.9 mg/dL on average), which recovered into the normal range (11.9-16.5 mg/dL) 6 weeks after start of the treatment (12.9 mg/dL on average) by ELISA. A chemically synthetic peptide of p1523 was found to increase secretion of IL-6 and IL-8 from microvascular endothelial cell lines.

Conclusion: We made a surveillance of serum peptides in the patient with MPA and found several peptides whose abundance was changed depending on the disease activity. Of the peptides, p1523, the C-terminal 13 AA of ApoA1, was increased in peripheral blood of the patients with active MPA. Our results suggest that the peptide promotes the inflammation and migration of neutrocytes to the inflamed sites, by increasing secretion of IL-6 and IL-8, which leads to exacerbation of the vasculitis.

The Relationship Between Markers of Platelet Activation and Inflammation with Disease Activity in Wegener's Granulomatosis.

Gunnar Tomasson[1], Michael P. LaValley[1], Kahraman Tanriverdi[1], Javier D. Finkielman[2], John C. Davis Jr.[3], Gary S. Hoffman[4], W. Joseph McCune[5], E. William St. Clair[6], Ulrich Specks[2], Robert Spiera[7], John H. Stone[8], Jane E. Freedman[1] and Peter A. Merkel[1], [1]Boston University, Boston, MA, [2]Mayo Clinic, Rochester, MN, [3]Genentech, Inc, South San Francisco, CA, [4]Cleveland Clinic, Cleveland, OH, [5]University of Michigan, Ann Arbor, MI, [6]Duke University Medical Center, Durham, NC, [7]HSS, New York, NY, [8]Massachusetts General Hospital, Boston, MA

Purpose: There is an increased occurrence of venous thromboembolic events (VTEs) in anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV). The objective of this study was to determine if measures of platelet activation or inflammation are associated with disease activity in Wegener's granulomatosis (WG).

Methods: Study subjects were participants in a clinical trial. Soluble CD40 ligand (sCD40L), C-reactive protein (CRP), interleukin (IL) -6, IL-8, monocyte chemoattractant protein 1 (MCP-1), P-selectin, and vascular endothelial growth factor (VEGF) were measured with commercially available ELISA kits. PR3-specific ANCA were measured by capture ELISA. Plasma samples were obtained at baseline (active disease), at remission, and prior to, during, and after first flares. Disease activity was assessed by the Birmingham Vasculitis Activity Score for WG (BVAS/WG). Association of biomarkers with disease activity was determined with conditional logistic and linear regression. To provide a graphical representation of change in marker levels at baseline, remission and at times surrounding flares, a non-parametric smoothing curve was generated for selected markers using the LOESS algorithm (Figure).

Results: 180 subjects underwent 2044 visits over a mean follow-up of 27 months; markers were measured in 563 samples. Longitudinally, all markers, other than IL-6, were associated with disease activity. Strongest associations for active disease at baseline vs. remission were observed for PR3- ANCA (OR= 9.41; 4.03-21.99), sCD40L (OR=4.72; 95%CI: 2.47-9.03), P-selectin (OR=6.26; 95%CI: 2.78-14.10), and inversely for MCP-1 (OR=0.36; 95%CI: 0.22-0.57). BVAS/WG increased 0.80 (95%CI:0.44-1.16), 0.83 (95%CI: 0.42-1.25) and 0.81 (95%CI: 0.48-1.15) per unit increase in PR3-ANCA, sCD40L and P-selectin respectively, and decreased 1.54 (95% CI: 2.12 -0.96) per unit increase in MCP-1.

Conclusion: Selected measures of platelet activation correlate with disease activity in WG. Thrombosis and inflammation in AAV might have related underlying biologic processes. Future studies of this relationship might lead to insights into the pathophysiology of AAV and discovery of clinically useful biomarkers.

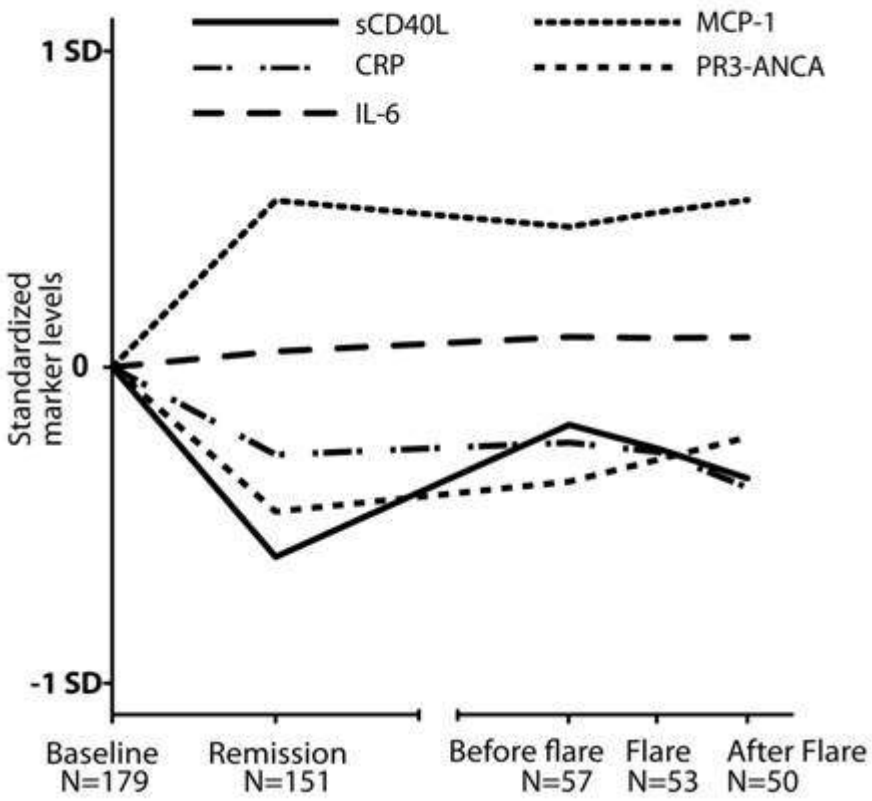

Figure. Non-parametric smoothing of selected marker levels at several time points. The x-axis represents different study visits and the y-axis represents standardized marker levels after subtraction of the baseline value (all baseline values set to zero).

Pulmonary Involvement in Microrcopic Poliangiitis: Focus On Prevalence and Outcome of Pulmonary Fibrosis. Maria A. Kokosi[1], Athanasios G. Tzioufas[2], Sophie P. Toya[2], Kyriaki A. Boki[3], Alexandra Zormpala[1], Haralampos M. Moutsopoulos V[2] and George E. Tzelepis[2], [1]Laikon General Hospital, Athens, Greece, [2]Medical School-Univ of Athens, Athens, Greece, [3]Sismanogleion General Hospital, Athens, Greece

Purpose: We sought to determine the type of pulmonary involvement in microscopic polyangiitis (MPA), focusing primarily on pulmonary fibrosis (PF), its prevalence, temporal relationship with other disease manifestations, and outcome.

Methods: Thirty three patients (16 men) with biopsy proven p-ANCA positive MPA (age 63.5 years) participated in the study. Pulmonary involvement was assessed with standard methods, including radiographic imaging (chest radiographs and high resolution CT), pulmonary function testing, bronchoscopy and bronchoalveolar lavage, and lung biopsy if indicated. All-cause mortality was analysed by the Kaplan-Meier method and was compared between MPA patients with and without PF.

Results: At the time of diagnosis, renal involvement was detected in all patients, with renal biopsies being consistent with segmental necrotizing glomerulonephritis in all patients. The most common respiratory symptom was hemoptysis, found in 9 (27%) of patients. Pulmonary fibrosis was present in 12 (36%) of patients at time of diagnosis, whereas one patient developed PF while on therapy, approximately 10 years from disease diagnosis. In 7 patients with PF, respiratory symptoms related to fibrosis preceded other disease manifestations by a period (median) of 13 months (range 5-120 months). Patients were followed up for a period of 38±30 months (mean±SD). Presence of PF was associated with increased mortality (p=0.02), with 6 deaths occurring in the fibrotic group and 1 in the nonfibrotic group. In the fibrotic group, most deaths were related to PF.

Conclusion: Pulmonary fibrosis occurs frequently in MPA, may precede other disease manifestations by a variable length of time, and has a poor prognosis.

1831

Human Neutrophil Peptide as a Potential Inflammatory Mediator in Behçet's Disease. Joong Kyong Ahn[1], Ji-Min Oh[1], Ji Young Chai[2], Eun-Kyung Bae[1], Jaejoon Lee[1], Chan-Hong Jeon[3], Jinseok Kim[4], Hoon-Suk Cha[1] and Eun-Mi Koh[1], [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Jesang Hospital, Seongnam-Shi Gyeonggi-Doe, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea, [4]Cheju National University College of Medicine, Cheju, South Korea

Purpose: Behçet's disease (BD) is a systemic vasculitis of unknown etiology, characterized by orogenital ulcers, uveitis, and arthritis, which is more prevalent in Korea, China, Japan and Turkey. Neutrophil hyperactivity plays an important role in the pathogenesis of BD. Human neutrophil peptides (HNPs) are released into the extracellular milieu from neutrophils during inflammation, resulting in stimulation of cell adhesion, release of chemokines, induction of reactive oxygen species and T cell chemotaxis. In this study, we examined the expression of HNP-1 in the peripheral blood of BD patients and aim to show that HNP-1 expression level is associated with clinical features of BD.

Method: Our patients fulfilled the diagnostic criteria of the international BD study group. ELISA and real-time PCR were performed to measure HNP-1 protein level in the sera and HNP-1 mRNA level in peripheral blood mononuclear cells in BD patients and healthy control (HC).

Results: There was no significant difference in the serum HNP-1 protein level between BD patients (n=20) and HC (n=19)(2.20 ± 0.45 vs. 2.04 ± 0.42 ng/ml, p=0.796). However, the level of HNP-1 mRNA was significantly higher in BD patients (n=56) compared to HC (n=36)(0.52 ± 0.11 vs. 0.20 ± 0.04, p=0.007). The level of HNP-1 mRNA was significantly higher in BD patients with arthritis than those without arthritis (0.97 ± 0.24 vs. 0.29 ± 0.08, p=0.014). Based on organ involvement, patients were grouped into vascular BD (n=21), Behçet's arthritis (n=20), ocular BD (n=7), intestinal BD (n=5), CNS BD (n=3). The mean HNP-1 mRNA levels of each group were 0.37 (±0.14), 0.74 (±0.21), 0.20 (±0.13), 0.81 (±0.53), and 0.33 (±0.28), respectively. High level of HNP-1 mRNA was observed not only in the patients with arthritis but also in the patients with intestinal involvement. However because of the small patient number, this difference did not reach statistical significance (p=0.157). In BD patients, the HNP-1 mRNA and protein level had a positive correlation with leukocyte counts (r=0.333, p=0.018; r=0.615, p=0.019). No significant correlations were found between HNP-1 mRNA level and ESR or CRP.

Conclusion: The HNP-1 mRNA is overexpressed in the peripheral blood mononuclear cells of BD patients, especially in patients with the clinical manifestations of arthritis and intestinal ulcers. Considering its role in the innate and adaptive immune responses, these findings suggest that HNP-1 may play an important role as a potential inflammatory mediator in BD.

Testicular Vasculitis: Findings Differentiating Isolated From Systemic Disease in 75 Patients. José Hernández-Rodríguez[1], Carmela D. Tan[2], Curry L. Koening[3], Atul A. Khasnis[2], E. René Rodríguez[2] and Gary S. Hoffman[2], [1]Hospital Clínic. IDIBAPS. University of Barcelona, Barcelona, Spain, [2]Cleveland Clinic, Cleveland, OH, [3]University of Utah, Salt Lake City, UT

Purpose: Testicular vasculitis (TV) may be recognized as part of a systemic vasculitis (SV), such as polyarteritis nodosa (PAN) or Wegener's granulomatosis (WG), or exist as single-organ/isolated (testicular) vasculitis (ITV). The current study sought to identify clinical and histologic features that distinguish SV from ITV. The distinction is deemed important because it is already well established that in other forms of single organ vasculitis surgical therapy alone may be curative.

Method: We identified patients with biopsy-proven TV from pathology databases from our institution and from an English language PubMed search. Patients were included if there was data available to confidently determine TV extent. Data recorded included clinical, laboratory and histologic features, treatment and clinical follow-up.

Results: 75 patients with TV (mean age 41 yrs; range 4-78) were included (8 from our institution). 75% of patients presented with painful testicular swelling/mass, 10.5% with a painless swelling/mass and 4% with epididymal swelling/mass or inguinal pain. 10.5% had no testicular complaints and vasculitis was discovered at autopsy or in interventions for incomplete testicular descent or vasectomy repair. Constitutional and/or musculoskeletal (systemic) symptoms were reported in 36% patients. Vasculitis involved the testicle in 81% of cases, the epididymis in 43% and the spermatic cord in 33%. Forty-three (57%) patients had ITV and 32 (43%) had SV. 7/8 (88%) patients from our institution had ITV. No differences between ITV and SV patients were found in regards to age, presenting testicular features, duration of testicular symptoms or time of follow-up. Compared to ITV patients, SV patients presented more often with systemic symptoms (100% vs. 12%; p=0.0001), elevated ESR (94% vs. 24%; p=0.0001) and anemia (53% vs. 3%; p=0.0001). Neoplasm was more frequently suspected in ITV than in SV (68% vs. 25%; p=0.002). Only 2 ITV patients received corticosteroids for a short period of time, whereas 96% of SV patients were treated (p=0.0001) and 65% also received cytotoxic agents. ITV was diagnosed more often by orchiectomy (77% vs. 41%; p=0.002) and less frequently by testicular biopsy (2% vs. 31%; p=0.0006) than SV. Non-granulomatous inflammation affecting medium-sized vessels occurred in most patients with both ITV and SV (>70%). Testicular carcinoma occurred concomitantly in 2 ITV patients. Among SV, PAN was the most frequently diagnosed (66%), followed by WG (16%).

Conclusion: TV occurs as ITV in men usually presenting with a testicular mass in the context of normal laboratory results and the absence of systemic symptoms. In most ITV patients a testicular neoplasm is initially suspected and TV is an unexpected finding. After surgical removal, ITV does not require systemic therapy. PAN is the systemic vasculitis most frequently associated with testicular involvement.

Characteristics of Wegener Granulomatosis (WG) Patients According to ANCA Status: Data From the FVSG Database. Raphaèle Seror[1], Christian Pagnoux[1], Philippe Guilpain[1], Loïc Guillevin[1] and French Vasculitis Study Group, [1]National Referral Center for Necrotizing Vasculitides and Systemic Sclerosis, Hôpital Cochin, Paris, France

Purpose: To study and compare the characteristics of anti-$PR3^+$, anti-MPO^+ and $ANCA^-$ WG patient subgroups.

Methods: Systematic retrospective study of the FVSG-database patients, diagnosed with WG according to the ACR and Chapel Hill Nomenclature classification criteria, and whose ANCA-test results were available. Their characteristics at diagnosis and outcomes were analyzed and compared according to their ANCA status.

Results: Among the 454 WG patients (261 (57.5%) male; mean±SD age = 51.3±16.2 years) of known ANCA status, 402 (88.5%) were $ANCA^+$ by immunofluorescence, with a cytoplasmic (n=315), perinuclear (n=56) or nonspecific (n=31) labeling pattern; enzyme-linked immunosorbent assay-determined specificities were: 280 anti-$PR3^+$, 48 anti-MPO^+ and 4 had both.

Compared to the 52 $ANCA^-$ patients, $ANCA^+$ patients had significantly higher median [IQR] creatinine levels (100 80–190] vs. 77 [67–100] µmol/l; p<0.001) and median [IQR] BVAS (21 [15–28] vs. 14 [11–20]; p<0.001). Multivariate analyses retained rhinitis (p=0.005) and elevated creatinine level ≥140 µmol/l (p=0.004) as being significantly associated with ANCA-positivity. Comparing anti-MPO^+ to anti-$PR3^+$ WG patients, the former were more frequently febrile (62% vs. 45%; p=0.01), and had arthralgias (55.3% vs. 34.0%; p=0.008) and cutaneous involvement (27.5% vs. 12.8%; p=0.03), but lower frequencies of myocardial infarction (1.8% vs. 8.5%; p=0.03) and recent-onset hypertension (6.3% vs. 14.9%; p=0.01).

During a mean±SD follow-up of 4.4±4.4 years, 239 (52.6%) patients relapsed and 12.3% died; relapse (48.1% of ANCA$^-$, 45.8% of anti-MPO$^+$, and 53.8% of anti-PR3$^+$ patients; NS) and mortality rates (13.5% of ANCA$^-$, 12.5% of anti-MPO$^+$, and 8.8% of anti-PR3$^+$ patients; NS) were comparable, regardless of ANCA status.

Conclusion: ANCA$^-$ WG patients were at lower risk of having renal involvement than ANCA$^+$ patients. Anti-MPO$^+$ WG patients were at higher risk of cardiovascular complications than anti-PR3$^+$ patients. However, mortality and relapse rates of our WG patients seemed to be independent of ANCA status.

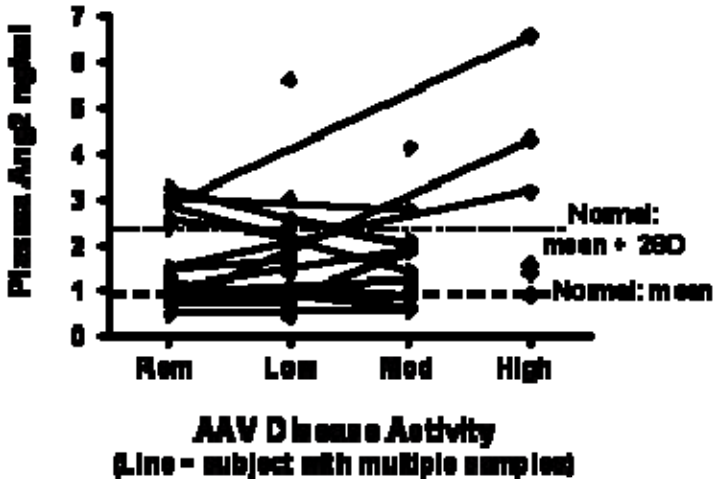
1834

Angiopoietin-2 as a Biomarker in ANCA-Associated Vasculitis. Paul A. Monach[1], Philipp Kumpers[2], David Cuthbertson[3], Simon Carette[4], Gary S. Hoffman[5], Nader A. Khalidi[6], Carol A. Langford[5], Philip Seo[7], U. Specks[8], S.R. Ytterberg[8], Marion Haubitz[2] and Peter A. Merkel[9], [1]BU, Boston, MA, [2]Medical School Hannover, Germany, [3]University of South Florida, FL, [4]Toronto Western Hospital, Toronto, [5]Cleveland Clinic, Cleveland, OH, [6]Hamilton, [7]Johns Hopkins University, Baltimore, MD, [8]Mayo Clinic, Rochester, MN, [9]Boston University, Boston, MA

Purpose: To explore angiopoietin-2 (Ang-2) as a biomarker of active ANCA-associated vasculitis (AAV). Ang-2 is an inducible mediator of endothelial activation and vascular permeability. We have shown that circulating levels of Ang-2 are elevated in AAV prior to treatment and drop to normal levels after treatment. The present study was conducted to i) confirm the association of elevated Ang-2 with AAV at different levels of clinical disease activity and ii) evaluate changes in Ang-2 over time in patients transitioning between clinical remission and mildly-active disease.

Methods: 108 plasma samples from 59 patients with Wegener's granulomatosis or microscopic polyangiitis were selected from a repository linked to comprehensive longitudinal clinical data. Disease activity at each visit was assessed using BVAS, BVAS/WG, and physician global assessment (PGA). Ang-2 was measured by ELISA. Generalized linear models (GLM) were used to study the association of Ang-2 levels with activity measures while controlling for subject-specific effects.



Results: Active AAV, using any index, was associated with higher levels of Ang-2. This association was driven by subjects with highly active disease (Figure): mean Ang-2 levels were 2.99, 1.43, 1.42, and 1.49 ng/ml (normal = 1.0 ± 0.7 ng/ml) in high, moderate, low, or absent (remission) disease activity (p=0.0002). Among subjects with multiple assessments, most of whom transitioned between low activity and remission, Ang-2 levels tended to be stable relative to baseline (Figure).

Conclusion: Ang-2 levels are associated with highly-active AAV but not partially-treated or smoldering AAV. Assessing the value of Ang-2 as a predictor of relapse will require more study of longitudinal cohorts.

1835

Oral Cyclophosphamide Therapy Diminishes Ovarian Reserve in Women with Wegener's Granulomatosis. Megan E. B. Clowse[1], Susannah Copland[1], T.C. Hseih[1], S.C. Chow[1], Gary S. Hoffman[2], Peter A. Merkel[3], Robert Spiera[4], John C. Davis Jr.[5], Steven R. Ytterberg[6], W. Joseph McCune[7], E. William St. Clair[8], U. Specks[6], J. H. Stone[9] and WGET Research Group, [1]Duke University, Durham, NC, [2]Cleveland Clinic, Cleveland, OH, [3]Boston University, Boston, MA, [4]Hospital for Special Surgery, New York, NY, [5]Genentech, Inc, South San Francisco, CA, [6]Mayo Clinic, Rochester, MN, [7]University of Michigan, Ann Arbor, MI, [8]Duke University Medical Center, Durham, NC, [9]MGH, Boston, MA

Purpose: Daily oral cyclophosphamide (CYC) is a standard treatment for severe Wegener's granulomatosis (WG). Monthly IV CYC for lupus leaves a third of women with ovarian failure. We hypothesized that the larger cumulative dose of CYC used to treat WG would result in a higher rate of diminished ovarian reserve.

Method: The Wegener's Granulomatosis Etanercept Trial (WGET) was a 180-patient randomized, placebo-controlled trial of etanercept therapy for this disease. Patients also received either CYC for severe WG or methotrexate for mild WG. All women under age 50 at enrollment were tested at the beginning and end of the study for plasma levels of anti-mullerian hormone (AMH) and follicle stimulating hormone (FSH). Diminished ovarian reserve was defined as a plasma AMH<1.0ng/ml and/or FSH>20mIU/ml. AMH is produced by the ovary and decreases with oocyte decline.

Results: This analysis included 42 women, ranging in age from 14-46 years (mean 32 ± 9). Baseline blood samples were available in 40 subjects. Daily oral CYC was administered during WGET to 28 women with a cumulative dose of 27 ± 23 grams (range 1-107 grams).

Women with exposure to CYC had a high rate of diminished ovarian reserve and a low mean AMH level (see table). For women with normal ovarian function at baseline, 6/8 who received CYC during the trial developed diminished ovarian reserve *vs*. 0/4 without CYC ($p<0.05$). The change in AMH was inversely correlated with cumulate CYC dose (regression coefficient -0.08, $p=0.01$), indicating a 0.8ng/ml decline in AMH for each 10g of CYC received.

Eighteen women, all but 2 under the age of 32, had not had a child prior to enrollment in the trial. Of these, 14 received CYC either before or during the trial and 13 of these had diminished ovarian reserve by the end of the study.

Conclusion: Diminished ovarian reserve occurred in 91% of women with WG treated with daily CYC. Compared to reports of patients with lupus treated with IV CYC, women with WG treated with daily CYC had a dramatically higher rate of ovarian dysfunction.

Table: AMH and diminished ovarian reserve based on CYC exposure.

	N	AMH** Mean ng/ml (SD)	Diminished Ovarian Reserve N (%)
Baseline evaluation (n=40)			
No prior CYC	16	2.5 (2.4)*	8 (50%)*
Prior CYC	24	0.6 (1.2)	20 (83%)

Final Evaluation (n=42)			
No CYC	9	1.9 (2.1)*	5 (56%)*
CYC prior to/during WGET	33	0.3 (0.5)	30 (91%)

* p<0.05 comparing no CYC vs CYC groups

** AMH declines with oocyte loss; AMH<1.0 is associated with decreased fertility.

1836

Prevalence of Monozygotic Twins with Behçet's Syndrome. Seval Masatlioglu[1], F. Gogus[2], E. Seyahi[3], I. Fresko[3], E. Tahir-Turanli[4] and Hasan Yazici[3], [1]Istanbul, Turkey, [2]University of Gazi, Ankara, Turkey, [3]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [4]Istanbul Tecnical of University, Istanbul, Turkey

Background: Case reports about monozygotic twins with Behçet's syndrome (BS) have been very few (1-3). We considered this could have been due to in utero deaths. We are not aware of previous formal, systemic studies on monozygotic twin studies in this disorder.

Purpose: 1. To seek for the frequency of monozygotic twin births in BS and compare it to a healthy population sample from the same geography; 2. To seek for concordance/discordance if such monozygotic twins existed.

Methods: 1705 (1039 M/ 666 F) consecutive patients attending a dedicated BS outpatient clinic were questioned about a monozygotic twin(s). Similarly 7782 (3848 M/ 3913 F) consecutive medical school students were asked about having a monozygotic twin during their initial school registration. Monozygotic twins thus identified among both patients and controls were individually seen at the clinic. In addition, for BS patients, probands and twins were HLA, DNA and blood group typed to further confirm twin ship and being a carrier of HLA B51. All discordant monozygotic twins were contacted 8 years later for new emergence of disease.

Results: There were 6 (4 M/ 2F) (0.35%) patients among the BS and 28 (0.35%) among the controls who had a monozygotic twin. Of the 6 pairs of monozygotic twins 2 were concordant and 4 discordant. This was reconfirmed by DNA, HLA and blood groups analysis. 2 concordant patients and siblings were HLA B51 positive. Of the 4 discordant monozygotic twin pairs 2 pairs were carriers of HLA B51. The other 2 were HLA B51 negative. The syndrome had developed within 12 and 18 months in the 2 concordant twins and the organ systems involved were quite similar in both families. None of the monozygotic twin siblings of the remaining 4 probands developed the syndrome after 8 years of follow up.

Conclusion: The frequency of monozygotic twin births in BS is not different than that in the general population. The persistence of discordance after 8 years of follow up among the monozygotic twins of 4 probands gives some support for environmental factors operative in BS.

Cardiovascular Outcomes in a Cohort of 100 Patients with Wegener`s Granulomatosis. Vidya Nadig, Sriharsha Subramanya, Eamonn S. Molloy, Carol A. Langford and Rula A. Hajj-Ali, Cleveland Clinic, Cleveland, OH

Purpose: There is a growing body of evidence, based on surrogate markers of atherosclerosis, that patients with vasculitides, including Wegener`s Granulomatosis (WG) have an increased risk of cardiovascular disease. However there is little data confirming the link between vasculitis and overt cardiovascular events . The aim of this study was to examine the frequency of cardiovascular outcomes in patients with WG and to assess the relationship between WG disease activity and cardiovascular events.

Method: We examined a cohort of 100 patients with a diagnosis of WG according to the American college of Rheumatology criteria. Data were collected regarding ischemic events- Unstable Angina(UA), Non ST elevation myocardial infarction(NSTEMI), ST elevation MI(STEMI), transient ischemic attacks(TIAs) and ischemic stroke. We also collected data regarding WG disease activity by using the Birmingham Vasculitis activity score(BVAS-WG), a validated outcome measure used to assess disease activity, within one month of the ischemic event, when available.

Results: The male to female ratio was 1.2 :1 and the age of onset of disease ranged from 17-78 years of age. There were a total of 2 STEMI`s, 5 NSTEMI`s, 1 UA, 2 TIA`s, 3 Ischemic strokes. Among these events, BVAS-WG scores were available within 1 month of the cardiovascular event in 8 patients. Of these, 6 patients (75%) had active WG (BVAS-WG >0) . Among these 6 patients, the median interval between occurrence of the ischemic event and the diagnosis of WG flare was 0 days (range -3 to + 7 days).

Conclusion: Our results support the hypothesis that WG is associated with a high frequency of cardiovascular disease. Furthermore, the strong temporal relationship between WG flares and the occurrence of cardiovascular events raise the possibility of an etiologic link, potentially attributable to the pro-inflammatory milieu associated with active WG. These data suggest that it is advisable to proactively address modifiable risk factors in patients with WG and to be cognizant of the potential for ischemic heart disease during a disease flare.

1838

Rituximab- Peg-IFN a /Ribavirin Compared to Peg-IFN a /Ribavirin in Mixed Cryoglobulinemia Vasculitis. David Saadoun[1], Damien Sene[2], Benjamin Terrier[3], Jeremie Sellam[4], Alexandre Karras[5], Laurent Perard[6], François Blanc[7], Pascale Ghillani[8], Michelle Rosenzwacj[9], Zahir Amoura[2] and Patrice P. Cacoub[10], [1]Pitie-Salpetriere Hospital, Paris, France, [2]Pitie salpetriere, Paris, France, [3]Pitie Salpetriere, France, [4]Saint Antoine hospital, Paris, France, [5]George Pompidou European Hospital, Paris, France, [6]Hôpital Edouard Herriot, Lyon, France, [7]Hôpital Lapeyronie, Montpellier, France, [8]Hôpital Pitié-Salpetrière, Paris, France, [9]Pitie Salpetriere, Paris, France, [10]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris

Purpose: To compare Rituximab plus Peg-IFN a /ribavirin to Peg-IFN a/ribavirin in patients with mixed cryoglobulinemia (MC) vasculitis.

Method: The outcome of ninety three consecutive patients with hepatitis C (HCV) associated MC from a single university hospital was analyzed. The efficacy and tolerance of Rituximab (375mg/m² w0, w1, w2 and w3) plus Peg-IFN a/ribavirin (n=38) was compared to Peg-IFN a/ribavirin alone (n=55) in patients with HCV-MC vasculitis.

Results: The mean age was 59.9 ± 11.7 years. Main clinical symptoms of MC vasculitis included arthralgia (38.7%), purpura (66.6%), peripheral neuropathy (72%), glomerulonephritis (33.3%) and central nervous system and gastrointestinal tract involvement (8.6%). Cryoglobulin was of type II in 78 (83.9%) with a mean level of 0.97 ± 1.2 g/l. Overall clinical, immunological and virological response rate were 73.1%, 52.7% and 59.1%, respectively. Compared with antiviral therapy alone, Rituximab plus Peg-IFN a/ribavirin had a shorter time for clinical remission (5.4 ± 4 versus 8.4 ± 4.7 months, p=0.004), a higher efficacy on kidney involvement (i.e membrano-proliferative glomerulonephritis) (80.9% versus 40% of complete response), and a higher efficacy on immunological response (68.4% versus 43.6%, p<0.01). The analysis of B-subpopulation showed that Rituximab specifically targets naive B-cells while antiviral therapy act on memory B cells. Treatment was well tolerated with 10% of discontinuation due to antiviral therapy.

Conclusion: Rituximab combined with antiviral therapy, shorten the time of clinical remission, increase the efficacy on kidney involvement and cryoglobulin clearance and synergizes the immunological effect of antiviral therapy in mixed cryoglobulinemia vasculitis.

Primary Systemic Vasculitis in Patients with Severe Alpha1-Antitrypsin (α1-AT) Deficiency - Report On Five Cases and Incidence Estimates. Mårten Segelmark[1] and Aladdin Mohammad[2], [1]Lund University Hospital,, Lund, Sweden, [2]Lund University Hospital, Lund, Sweden

Purpose: The aetiology of primary systemic vasculitis (PSV) [Wegener's granulomatosis (WG), microscopic polyangiitis (MPA), Churg-Strauss syndrome (CSS), and polyarteritis nodosa (PAN)] is unknown. Environmental and genetic factors are postulated. The association between proteinase-3 ANCA positive small vessel vasculitis and a heterozygote state for the PiZ allele of α_1-AT was established in the beginning of the 1990s. In 1996 we reported nine Swedish patients with the combination of severe α_1-AT deficiency (PiZZ) and systemic vasculitis [1,2]. Since then very little have been published concerning this subject. In this study we describe five new cases with severe α_1-AT deficiency and systemic vasculitis and compare incidence rates with the background population.

Methods: Case records were reviewed for all new patients with the combination of PSV and PiZZ diagnosed at our department between 1996 and 2008. The diagnosis was confirmed by clinical, serology and histopathology data and patients were classified according to an algorithm based on the American College of Rheumatology classification criteria 1990 and the Chapel Hill Consensus Conference definitions 1994. The level of α_1-AT was measured and the α_1-AT phenotype was determined by electrophoretic focusing. The incidence rate among population with homozygote's α_1-AT deficiency was calculated using the estimated number of people living with α_1-AT deficiency in our area.

Results: Table 1 shows demographic and clinical data of the five patients diagnosed with PSV in our area during the study period. All patients responded well to therapy, however, three of them have experienced less severe relapses. The prevalence of the PiZZ phenotype of α_1-AT in Swedish population is 0.06%, corresponding to a total number of 720 individuals in the county of Skåne (population 1.2 million), where four of the patients resided. The annual incidence of PSV in patients with PiZZ phenotype carriers of α_1-AT deficiency was calculated to 42.7 per 100.000 (95% CI 0.9-84.6) which should be compared to the figure 2.1 reported previously by us from this area.

Conclusion: Individuals with the PiZZ phenotype of a_l-AT in this study exhibited a more than 20-fold increased incidence rate compared with the general population. Severe α_1-AT deficiency should be considered as an important genetic risk factor for PSV.

Table 1

Patient	Sex	Age at diagnosis, Yrs	Diagnosis	Clinical presentation	Histopathology	ANCA
1	M	16	PAN	Abdominal pain, diarrhea, weight loss. Acute intestinal perforation	Small Intestine: necrotizing lesion at medium sized arteries	Neg.
2	F	46	WG	Long standing facial pain and pulmonary infiltrate. Later severe pulmonary haemorrhage and acute renal failure	Not done	PR3+
3	F	49	WG	Skin vasculitis, arthralgia, nasal symptoms	Not done	PR3+
4	F	71	WG	Uremic symptoms (s-creatinine >1200µmol/l), minor stroke, arthralgia, otitis.	Kidney: Crescentic GN	PR3+
5	M	66	MPA	Prodromal symptoms of fatigue and arthralgia. High s-creatinine	Kidney: Crescentic GN	MPO+

1840

Decreased Numbers of Circulating Dendritic Cells and Defective Suppressive Function of T Regulatory Cells in ANCA-Associated Vasculitis. Marie Rimbert[1], Mohamed Hamidou[2], Xavier Puéchal[3], Marie Audrain[2], Cecile Braudeau[2], Luis Teixeira[4] and Régis Josien[1], [1]CHU and INSERM U643, Nantes, France, [2]CHU, Nantes, France, [3]Centre Hospitalier Du Mans, Le Mans, France, [4]AP-HP Hôpital Cochin, Paris, France

Purpose: Anti-neutrophil-Cytoplasmic Antibodies (ANCA) associated vasculitis (AAV) are small vessel vasculitis including Wegener's granulomatosis, microscopic polyangiitis and Churg –Strauss syndrome. Even if the role of the ANCA in the inflammatory process is well known, AAV pathogenesis is still unclear. Dendritic cells (DC) play a pivotal role in controlling the immune response in both physiological and pathological conditions. DC also control T regulatory cells (Treg) function which are critically involved in autoimmune diseases. The aim of our study was to assess the frequency and phenotype of peripheral blood DC subsets and the frequency and suppressive function of $CD4^+$ $CD25^+$ $CD127^{low/-}$ T cells (Treg) in patients with AAV either during the acute phase or remission.

Method: Blood samples from 19 untreated patients in acute phase (BVAS>6), 17 patients in remission (with low dose steroids <10mg and without immunosuppressive treatment) rand 18 age-matched healthy controls were analysed. DC and Treg were measured by flow cytometry and DC were characterised for maturation and homing potential with CD86, CCR7 and CD62L. Suppressive function of FACS-sorted Treg was determined by coculture assay.

Results: We observed significant decrease in total DC numbers in acute phase versus healthy control and remission (8 DC/µL vs 20 DC/µL, p<0,0001; 8 DC/µL vs 15 cells/µL p=0.0006). DC numbers were also reduced in patients in remission as compared healthy control (15 cells/µL vs 20 DCs/µL; p= 0.0391). This diminution was observed at the same extent in pDC and mDC. Levels of CD86 and CCR7 were not significantly different between the 3 groups. However, a significant increase in CD62L expression levels was observed on DC from acute phase patients as compared to remissions and controls. Treg numbers were slightly but significantly reduced in AAV patients as compared to healthy controls. In contrast, Treg from acute phase patients exhibited a dramatic decrease of suppressive activity as compared to controls group (8% vs 78%. p<0.001) and remission group (8% vs 36%. p=0.0364). Treg suppressive function from the remission group was also reduced as compared to control group (36% vs 78%. p=0.0004).

Conclusion: We conclude that DC numbers as well as Treg suppressive activity are significantly reduced during AAV in a disease activity-specific manner. The decrease in DC numbers may reflect their recruitment in secondary lymphoid organs as suggested by the increase in CD62L expression on DC. The decrease in Treg suppressive function might be related to changes in DC function and might be an important defective tolerance checkpoint in AAV.

1841

Strictly and Persistently Single-Organ Localized Wegener's Granulomatosis (WG) Is Rare: Study of the 18 Patients From the FVSG Cohort. Muriel Stubbe[1], Christian Pagnoux[2], François Lifermann[3], Patrick Jego[4], Nadine Méaux-Ruault[5], Jean Cabane[6] and Loïc Guillevin[7], [1]UZ Gent, Ghent, Belgium, [2]National Referral Center for Necrotizing Vasculitides and Systemic Sclerosis, Hôpital Cochin, Paris, France, [3]Centre Hospitalier Général de Dax, Dax, France, [4]CHU de Rennes, Rennes, France, [5]CHU de Besançon, Besançon, France, [6]Hôpital Saint Antoine, Paris, France, [7]National Referral Center for Necrotizing Vasculitides and Systemic Sclerosis, Hôpital Cochin, Assistance Publique–Hôpitaux de Paris, Université Paris Descartes, Paris, France

Purpose and Background: It remains unclear whether patients with WG strictly localized to 1 organ have a distinct disease subset or are diagnosed at an early phase. Hence, whether or not they should be treated aggressively remains debated.

Objective: To study patients with single-organ localized WG that did not progress to more generalized forms throughout their entire follow-up.

Methods: Among 545 WG patients entered in the FVSG database, only 18 with such single-organ localized and non-progressing disease were identified: 8 with ENT involvement, 6 with lung nodules and 4 with ocular involvement.

Results: Nine (50%) were female. Mean age at diagnosis was 41.3 yr. Ten (56%) had PR3-ANCA and 4 (22%) had MPO-ANCA. Mean follow-up from diagnosis and start of therapy was 77.6 [12–238] mo. Twelve (67%) achieved sustained (6 partial and 6 complete) remissions with first-line therapy: corticosteroids (CS) and IV cyclophosphamide (CYC) for 9 or oral CYC for 3, co-trimoxazole (CTX) alone for 1 or combined with CS for 3, and CS alone for 2. Azathioprine or methotrexate maintenance therapy was prescribed with no difference in terms of efficacy or safety. Six (33%) patients relapsed (2 once, and 4 had ≥2 relapses) and required different immunosuppressive regimen(s). Relapses occurred in patients treated with CS alone, or combined with oral or IV CYC. Second-line therapies were: IV CYC (n=3), IV immunoglobulins (n=1), mycophenolate mofetil (n=1) and oral CYC (n=1). Rituximab was also prescribed as 3rd- or 4th-line therapy. At the last evaluation, 9 (50%) had complete and 8 had partial remissions (4 grumbling ENT manifestations, 1 persistent exophthalmia, 1 tracheal stenosis, 2 lung nodules); 1 patient had just relapsed; 15 (83%) were still on maintenance therapy.

Conclusion: Strictly and persistently single-organ localized WG is highly unusual. The majority of our patients received aggressive induction therapy. However, CTX alone or combined with CS was effective in a few patients. Identification of the characteristics of these patients with single-organ localized disease at diagnosis and at higher risk of disease progression might help decide their treatment intensity.

1842

Efficacy and Tolerance of Rituximab with or without Peg-Interferon alpha2b-Ribavirin in Severe Hepatitis C Virus-Related Vasculitis: a Long-Term Follow-up Study of 32 Patients. Benjamin Terrier[1], David Saadoun[1], Damien Sène[1], Jeremie Sellam[2], Laurent Perard[3], Brigitte Coppéré[3], Alexandre Karras[4], François Blanc[5], Matthias Buchler[6], Emmanuelle Plaisier[7], Pascale Ghillani[8], Michelle Rosenzwacj[9] and Patrice Cacoub[1], [1]Pitié-Salpétrière, Paris, France, [2]Saint-Antoine, Paris, France, [3]Hôpital Edouard Herriot, Lyon, France, [4]George Pompidou European Hospital, Paris, France, [5]Hôpital Lapeyronie, Montpellier, France, [6]Bretonneau, Tours, France, [7]Tenon, Paris, France, [8]Hôpital Pitié-Salpetrière, Paris, France, [9]Pitie Salpetriere, Paris, France

Purpose: To report on the long-term follow-up of a cohort of patients treated with rituximab (RTX) +/- Peg-interferon (IFN) a2b-ribavirin in hepatitis C virus (HCV)-related vasculitis.

Method: Thirty-two patients HCV RNA+ with HCV-vasculitis were included: antiviral-naïve patients (n=9) and antiviral-resistant or relapser patients (n=11) treated with RTX and Peg-IFNa2b-ribavirin, and antiviral-intolerant patients (n=12) treated with RTX alone.

Results: RTX and Peg-IFNalpha2b-ribavirin induced a clinical complete (CR) and partial (PR) response in 80% and 15% of cases, respectively; an immunological CR and PR in 67% and 33%, respectively; and a sustained virological response in 55%. RTX alone induced a clinical CR and PR in 58% and 9% of patients, and immunological CR and PR in 46% and 36%, respectively. B cell depletion was achieved in 96%, and B cell recovery began after a median delay of 12 months. After a mean follow-up of 23±12 months, 22% experienced a clinical relapse, and 34% an immunological relapse. All relapses were associated with the absence of virological control, and in 78% with an increase in the number of B cells. Six patients were retreated with RTX: 100% were clinical CR, and immunological CR and PR were noted in 50% each. RTX was well-tolerated overall.

Conclusion: RTX is an effective treatment for severe and/or refractory HCV-vasculitis. Relapses were consistently associated with the absence of virological control. RTX seems to have the same clinical and immunologic efficacy after repeated infusions.

1843

A Novel 60 Kda Reactivity in Cyclic Neutropenia: High Titer Classic ANCA Pattern and Negative Anti-Peroxidase-3. Camila E. Rodrigues[1], Eloisa Bonfá[1], Elvira R.P. Velloso[2], Flávia K. Teixeira[1], Vilma S.T, Viana[1], Cleonice Bueno[1], Andréa Kondo[2] and Rosa M.R. Pereira[1], [1]Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil, [2]Hematology Division, Facudade de Medicina da USP, São Paulo, Brazil

Purpose: To evaluate the presence of antineutrophil cytoplasmic antibodies (ANCA) in patients with chronic neutropenia.

Method: Twenty-two patients with hematological disorders under granulocyte-colony stimulating factor treatment for neutropenia (10 with aplastic anemia, 2 cyclic neutropenia, 1 myelodysplastic syndrome, 1 auto immune pancytopenia and 8 chronic myeloid leukemia with imatinib mesylate neutropenia induced) were enrolled in the study. Patient's charts were extensively reviewed for demographic, clinical, laboratorial and therapeutic data. ANCA were detected by indirect immunofluorescence (IIF) using isolated human neutrophils and ELISA (myeloperoxidase and proteinase-3). Characterization of the antigenic specificity of these antibodies was performed by Western blot using crude extract of human neutrophils as source of antigen. Exclusion criteria were drug use that induces neutropenia (except for imatinib) or ANCA.

Results: Among the 22 patients, an evident predominance of female gender (63.6%) and white race (86.3%) was observed. The mean age was 49 (from 17 to 79) years and mean disease duration was 38 months. Of note, ANCA were detected in two (9.1%) patients and both had cyclic neutropenia. These two sera displayed the classic ANCA pattern with high titer reactivity (1/1.260 and $\geq$ 2.520, respectively). The longitudinal evaluation of several frozen sera samples showed a persistent high titer classic ANCA pattern. Sera were uniformly negative for anti-peroxidade-3 and anti-mieloperoxidase antibodies. Western blot analysis revealed that serum from these two patients showed a common reactivity to a protein fraction with molecular weight of 60 kDa. One of these two patients during follow-up of 4 years had an additional diagnosis of large granular lymphocytic proliferation and none developed signs and symptoms compatible with Wegener granulomatosis.

Conclusion: A novel 60 kDa reactivity autoantibody is described in cyclic neutropenia which is characterized by high titer classic ANCA pattern with a uniformly negative anti-peroxidase-3 reactivity. The underlying inducing stimulus of this abnormal humoral response is not associated with granulocyte-colony stimulating factor treatment.

1844

Clinical Spectrum of Type 1 Cryoglobulinemia: Retrospective Analysis of 8 Year Single Center Experience. Cassandra M. Calabrese[1], Manju Gupta[2] and Leonard H. Calabrese[3], [1]Ohio University of Osteopathis Medicine, Athens, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH

Purpose: Cryoglobulins are immunoglobulins that precipitate from serum at temperatures below 37°C and may be symptomatic or associated with wide spread vasculitis. Cryoglobulins are classified into types I, II and III based on immunochemical composition. Type I cryoglobulinemia is the most clinically rare and has been described in few small-series case reports in the past 25 years. This study was intended to describe a large clinical series of patients with type I cryoglobulinemia from the clinical, pathologic and etiologic perspectives and to determine the influence of recently introduced biologic therapeutics on clinical outcomes.

Method: After receiving IRB approval, the laboratory records of the Clinical Pathology Department were reviewed for the 8 year period starting Jan 1, 2000 through Dec 31 2007. All samples with detected monoclonal cryoglobulins (type I) were included in the analysis. Both print and electronic medical records were reviewed and from them extracted standardized information on the etiology, clinical manifestations, immunologic features and outcomes.

Results: Over this 8 year period, more than 16,000 clinical samples were analyzed for cryoglobulins. Approximately 400 of these samples were strongly positive (> 500ugr/cc) and screened for immunochemical composition. From these records a total of 19 patients were found to have type I cryoglobulinemia (freq = 1.11/1,000 samples). Of these patients, 18 had adequate medical records for examination. The most common clinical manifestations were cutaneous involvement and cold-induced symptoms (61% and 31% respectively). Renal, hepatic and articular involvement was also observed (22%, 22% and 17%, respectively). Overall, 83% had hematologic disorders and only 11% were HCV infected, which is consistent with traditional views of the disease. 8 of our patients were treated with the B cell depleting agent rituximab with varying responses, and a single patient treated with thalidomide experienced complete remission of his cryoglobulinemia.

Conclusion:

1. Type I cryoglobulinemia is an extremely rare form of blood disorder.

2. The most common etiology appears to be within the spectrum of hematologic disorders and in contrast to previous reports is uncommonly associated with HCV infection.

3. Patients diagnosed with type I cryoglobulinemia since the year 2000 have frequently been treated with newer biologic therapeutic agents with varying responses. Thalidomide was used to induce a complete clinical and laboratory remission in a single patient and should be further evaluated in clinical trials.

1845

Efficacy and Safety of TNF-Alpha Antagonists in the Management of Behçet's Syndrome: A Systematic Review. Gulen Hatemi, Vedat Hamuryudan, Sebahattin Yurdakul and Hasan Yazici, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

Purpose: There is growing evidence on the efficacy of TNF-alpha antagonists in BS mainly based on open studies or case series. This systematic review aims to analyze the current literature on the efficacy and safety of TNF-alpha antagonists in BS patients.

Methods: We performed a systematic literature search covering articles in PubMed until May 2009 and searched the abstracts from the annual meetings of EULAR, ACR and International Conferences on Behçet's Disease.

Results: The literature search yielded 187 published articles and 31 meeting abstracts. Among these 97 articles and 17 abstracts were included in the analyses. Infliximab was used in 98 of these studies, etanercept in 11 of them and adalimumab in 5. The only RCT was the one comparing etanercept to placebo in 40 patients with mucocutaneous and joint involvement. Etanercept had a medium effect size on oral ulcers and papulopustular lesions (0.59 and 0.51 respectively) and a small effect size on genital ulcers and arthritis (0.33 and 0.24 respectively). In 14 open studies evaluating the efficacy of infliximab for eye involvement, 110/124 patients showed an immediate response and 57/97 patients had a sustained remission. Case series showed a rapid onset of response, improvement in visual acuity, suppression of retinal vasculitis, vitritis, retinitis, cystoid macular edema, decrease in the number of uveitis attacks and corticosteroid use. Relapses were observed when the drug was stopped and long term treatment with either infliximab or other immunosuppressives was required for maintenance. In an open study etanercept showed a significant improvement in visual acuity which tended to decrease after stopping the treatment. The only open study and 4 case reports for neurologic involvement showed a good clinical response and regression in MRI findings. One open study and 11 case reports on the use of infliximab for gastrointestinal involvement showed rapid healing of ulcers, resolution of bloody diarrhea and healing of esophageal perforation and fistulae. The response in gastrointestinal involvement seems to be more sustained compared to other organs. The limited experience with vascular involvement shows that infliximab was beneficial in 2 patients with pulmonary artery aneurysms, but in another case series 2 of the 3 patients with hepatic vein thrombosis had died. Tuberculosis, cryptococcal meningitis, pyomyositis, cytomegalovirus colitis, simple infections, infusion reactions, angioedema, acute heart failure, psoriasiform skin lesions and formation of autoantibodies were the adverse events.

Conclusion: TNF-alpha antagonists seem to be promising agents especially for resistant eye, GI and CNS involvement of BS. Controlled studies are needed since current evidence which relies mostly on open studies and case reports might have caused a false impression of efficacy due to publication bias. Side effects are similar to those reported for TNF-alpha antagonist use in other diseases.

1846

Association of Behçet's Disease with Familial Mediterranean Fever. Fulya Cosan[1], Neslihan Abaci[2], Bahar Artim Esen[1], Aris Cakiris[2], Duran Ustek[2], Orhan Aral[1] and Ahmet Gul[1], [1]Istanbul University, Istanbul, Turkey, [2]Istanbul University, Turkey

Purpose: Behçet's Disease (BD) is a systemic inflammatory disorder, and it has a strong genetic contribution in its pathogenesis. Familial Mediterranean fever (FMF) is an autosomal recessively inherited autoinflammatory disorder caused by mutations in the MEFV gene. There are patients presented with the clinical features of both BD and FMF. However, it is still controversial that whether there is an association between BD and FMF. We herein aimed to analyse the genetic and clinical features of a group of patients with BD+FMF in a cohort of 1235 BD patients.

Method: The main study group consisted with BD+FMF, and we used the findings of 288 patients with BD (170 male, 118 female) and 289 patients with FMF (134 male,155 female). All BD patients fulfilled the ISG criteria, and all FMF patients fulfilled the Tel-Hashomer criteria. We isolated genomic DNA from all subjects, and genotyping for the MEFV gene M694V, V726A, M680I, E148Q mutations was done by PCR-RFLP. Clinical features of patients were recorded using a standard form. Study protocol was approved by local ethics committee, and all subjects provided written informed consent prior to blood collection.

Results: We identified increased frequency of FMF patients (n=21, 8 male, 13 female; 1.7%) in the BD cohort amongst to other accompanying disorders. Genetic analysis of 21 patients with BD+FMF for 4 common MEFV mutations showed that 42.8% of them had two mutations, 28.6% had one mutation, and 28,6 % had no mutation. The frequency of four MEFV mutations was not significantly different from FMF patients (71.4% vs 85.5%), however the frequency of E148Q was significantly higher in BD+FMF group compared to the frequency in FMF patients (31.3% vs 6.2%, P = 0.003). We compared BD-related clinical finding of BD+FMF patients with the findings of BD patients. We found that arthritis was significantly higher (85.7% vs 55.2%, P = 0.006, OR = 4.9, 95% CI 1,4-16,9), and eye involvement was significantly lower (33.3% vs 57.9%, P = 0.028, OR = 0.36, 95% CI 0,14-0,9) in BD+FMF group compared to BD patients. There was no BD+FMF patient with neurological or intestinal involvement. When we grouped the patients according to disease severity, patients with mild disease were significantly higher in BD+FMF group (52.4% vs 22%, P = 0,006, OR = 3.9, 95% CI 1.6-9.7). We did not observe any association between MEFV mutations and BD-related clinical findings including vascular involvement. Also, in the BD patient group with no FMF findings (n=288), BD patients carrying MEFV mutations was found to be significantly higher (27%) compared to the frequency in healthy controls (10%) (P<0.001, OR = 3,35, %95 CI 1,7-6, 8). We observed no association between the MEFV mutations and any of the BD manifestations, nor the disease severity in this BD group.

Conclusion: This study shows that patients presenting with the clinical features of both BD+FMF run less severe disease course with more frequent articular features and less frequent uveitis. We also observed that the frequency of E148Q mutation was higher in BD+FMF patients compared to FMF patients. Further analysis of BD+FMF patients may provide clues to understand the association of BD with FMF and the role of inflammasome in BD pathogenesis.

Renal Transplantation in Wegener's Granulomatosis and Microscopic Polyangiitis. Duvuru Geetha, Mark Haas, Edward S. Kraus, Hamid Rabb and Philip Seo, Johns Hopkins University, Baltimore, MD

Purpose: ANCA-associated vasculitis (AAV) is an important cause of end-stage renal disease. How modern immunosuppressive regimens influence outcomes among patients with Wegener's granulomatosis (WG) and microscopic polyangiitis (MPA) after renal transplant is unclear.

Methods: We conducted a retrospective cohort study of patients who underwent renal transplant at The Johns Hopkins Hospital between 1999 and 2008. Analysis was performed using STATA 9.0 (College Park, TX).

Results: A total of 24 patients with end stage renal disease due to AAV received a kidney transplant at the Johns Hopkins Hospital between 1999 and 2008. Follow-up data are available for 11 patients with WG and 6 patients with MPA who were followed for 799 patients-months of observation. The majority of these patients were Caucasian (82.4%) with an approximately equal numbers of men and women (8:10). 9/11 of the patients with WG were PR3-ANCA positive, while 5/6 of the patients with MPA were MPO-ANCA positive. Two of the patients with MPA also had anti-GBM antibodies.

All but one patient (94.1%) had renal involvement at the time of their vasculitis diagnosis; 5 WG patients (45.5%) and 2 MPA patients (33.3%) presented with end-stage renal disease. Most patients in this cohort received first renal transplants (72.2%) from a living-related donor (70.6%).

At the time of transplant, patients with WG were older (median age 51.5 versus 39 years) and carried a diagnosis of vasculitis for longer (51 months versus 18.5 months) than patients with MPA, although the difference was not statistically significant (P=0.2 for each comparison).

Most patients (10/16) were ANCA-negative at the time of transplant; none of these patients have experienced a vasculitis flare during the observation period. There was one flare per 22 patient-years of observation; all flares occurred in patients who were ANCA-positive: one

patient with WG and one with MPA had recurrent glomerulonephritis affecting the transplanted kidney; one additional WG patient experienced a non-renal vasculitis flare.

All patients received maintenance immunosuppression with a mycophenolate mofetil/tacrolimus-based regimen. There were no episodes of rejection among patients with MPA. Two patients with WG had an episode of rejection; both occurred in patients who were highly sensitized and had received treatment with rituximab, plasmapheresis, and IVIG prior to transplant.

The median serum creatinine following transplant was 1.1 mg/dL. The median serum creatinine at the time of last follow-up was 1.3 mg/dL among patients with WG and 1.0 mg/dL among patients with MPA (P=0.1)

Conclusion: Renal transplantation is effective in patients with WG and MPA. The combination of mycophenolate mofetil and tacrolimus is effective at preventing both disease relapse and rejection for most patients with AAV. Patients who are ANCA-negative have particularly good outcomes; patients who are ANCA-positive may benefit from more aggressive maintenance immunosuppression. Whether patients with MPA may have better outcomes after transplant than patients with WG merits further study.

Cardiac Involvement in Churg-Strauss Syndrome: Impact of Endomyocarditis. Thomas Neumann[1], Bernhard Manger[2], Michael Schmid[2], Claus Kroegel[1], Andreas Hansch[1], Werner A. Kaiser[1], Dirk Reinhardt[3], Gunter Wolf[1], Gert Hein[1], Gerhard Mall[4], Georg Schett[2] and J. Zwerina[5], [1]University-Hospital, Jena, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Evangelisches Krankenhaus, Hamm, Germany, [4]Klinikum Darmstadt, Darmstadt, Germany, [5]Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany

Purpose: Cardiac disease is a major contributor to disease-related death in Churg-Strauss Syndrome. This study aimed to determine the prevalence and clinical impact of cardiac involvement in CSS patients.

Method: A multi-centre, cross-sectional analysis of patients diagnosed with CSS was performed. Cardiac work-up included electrocardiography, echocardiography, cardiac magnetic resonance imaging (MRI) and endomyocardial biopsy.

Results: We analyzed 49 CSS patients: 22 patients had clinical evidence of cardiac involvement. A negative ANCA test and much higher eosinophil counts (9947 vs. 3657/µl, $p<0.001$) distinguished patients with and without cardiac involvement. Impaired left ventricular function (50%), mild to severe valvular insufficiencies (73%) and pericardial effusions (41%) were common findings in these patients. Endomyocarditis was found in 13 patients (59%) as detected by cardiac MRI, cardiac thrombus formation and endomyocardial biopsy and was associated with impaired cardiac function. After a mean follow-up of 47 months, most patients had regained or maintained a good cardiac function. However, patients with endomyocarditis had a more severe outcome. 2 patients died (61 and 99 months after diagnosis) both due to severe cardiomyopathy and heart failure.

Conclusion: Cardiac involvement is common in CSS and is associated with the absence of ANCA and high eosinophil counts. Endomyocarditis may represent the most severe manifestation eventually causing fatal outcome. A structured clinical assessment incorporating cardiac imaging with echocardigraphy and MRI can identify impaired cardiac function and endomyocardial abnormalities.

Investigation of Target Organ Associations in Patients with Familial Behçet's Syndrome Using Factor Analysis. Mehmet Karaca, Gulen Hatemi and Hasan Yazici, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

Purpose: We have previously shown that Behçet's syndrome (BS) patients with arthritis are more likely to have acne-like skin lesions and there are distinct symptom clusters such as “papulopustular lesions and joint involvement” or “superficial vein thrombosis and deep vein thrombosis” in our patient population (1, 2). Presence of these clusters suggests that pathogenesis of BS may involve different mechanisms. Increases in frequency of such clusters in familial BS cases would back up the notion that some pathogenetic mechanisms may have a heritable component. To test this hypothesis we aimed to compare the frequency of symptom clusters between familial and non-familial cases of BS.

Methods: We identified 380 patients with BS who reported a first and/or second degree relative among the 6031 patient charts reviewed. Of these 380 patients, 186 had attended the clinic within the previous 3 months (Group F). Eighteen first-degree relative pairs (14 siblings and 4 offspring-parents) were identified in group F. None of these patients reported a second degree or more distant relative with BS. From the same initial pool of 6031 patients 500 were randomly selected using a random number generator (RNG). Of those, only patients who did not report a family history of BS and who also had attended the clinic within the previous 3 months made up the non familial (NF) group (n=221). Using the same RNG, we constructed 110 unrelated pairs among the NF group. Data were analyzed using factor analysis and symptom clusters were extracted from each group. Cluster frequencies and shared cluster ratios were compared using chi-square tests.

Results: Frequency of a first and/or second degree family history of BS for our patient population was 6.8% in the total pool and 7.4% among the 500 patients randomly selected. Clusters we identified in groups F and NF were similar to those previously reported from our clinic (2). Of these clusters only the frequency of the “papulopustular lesions and joint involvement” symptom cluster was significantly higher in Group F as compared to Group NF (39.2% vs. 21.5%, $p<0.000$). Furthermore, the “papulopustular lesions and joint involvement” cluster was shared in 5 of the 17 pairs from Group F and only in 5 of the 110 pairs from Group NF (29% vs. 4.5%, $p=0.004$; OR=8.75, 95% CI 2.2-34.6).

Conclusion: The “papulopustular lesions and arthritis” cluster in BS appears to cluster in familial BS as well. This further supports the notion that the pathogenesis of BS may entail several distinct mechanisms producing separate phenotype clusters.

Early Death in Wegener's Granulomatosis: Disease and Treatment Factors. Fernando H.C. Souza, Ari S. Halpern and Samuel K. Shinjo, Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil

Purpose: Few studies have focused in early death in Wegener´s granulomatosis (WG) and the only systematic study was restricted to patients with severe organ involvement. We therefore have evaluated disease and treatment factors for death in all patients followed during 20 years in a single tertiary center.

Method: A retrospective chart review of all 114 WG patients (at least two ACR criteria), 87.7% diffuse, followed from 1989 to 2009, was performed evaluating clinical and treatment parameters associated to death exclusively in the first three years of diagnosis.

Results: There were 23 (20.2%) deaths, all in the diffuse subgroup, in the first 3 years of follow-up. This early death group had higher mean age at WG´s diagnosis (54.3±14.7 *vs.* 42.3±13.7 years; p=0.001) with a similar female gender (34.8 *vs.* 55.0%; p=0.084) and white ethnicity (95.7 *vs.* 85.7% whites; p=0.195) distribution compared to 91 who remained alive. The frequency of variables describing kidney function such as dialytic renal insufficiency (47.8 *vs*. 9.9%, p<0.001) and initial creatinine levels (4.8±3.5 *vs*. 2.4±2.9mg/dL, p=0.006) were significantly higher in the early death group, in spite of a similar frequency of glomerulonephritis (87.0 *vs*. 72.5%, p=0.151). No other distinct features were identified comparing the two groups regarding disease extend index (8.3±3.1 *vs*. 8.7±3.0, p=0.568), constitutional symptoms (65.2 *vs*. 64.9%, p=0.973), ear/nose/throat involvement (56.5 *vs*. 67.0%, p=0.345), pulmonary involvement (93.4 *vs*. 83.5%, p=0.170), neuropathy (21.7 *vs*. 19.8%, p=0.834) or the frequency of cytoplasmatic ANCA reactivity (69.6 *vs*. 67.0%, p=0.817). The early death group had a significantly lower frequency of cyclophosphamide use (56.5 *vs*. 82.4%, p=0.008) with an almost universal use of any immunosuppressor (82.6 *vs*. 92.3%, p=0.159) and glucocorticoid therapy (91.3 *vs*. 97.8%, p=0.130) in both groups. In multivariate analysis, renal insufficiency requiring dialysis (HR 7.59; CI 95% 2.24-25.79) was an important risk to mortality and cyclophosphamide use had a protective effect (HR 0.25; CI 95% 0.08-0,77). The three causes of mortality were infection (65,2%), alveolar hemorrhages (17,4%) and myocardial infarction (17,4%).

Conclusion: Severe renal impairment was identified as the major risk factor for early WG mortality whereas cyclophosphamide use had a protective effect.

1851

Identification of Target Antigens of Anti-Endothelial Cell Antibodies in Patients with ANCA-Associated Systemic Vasculitis: a Proteomic Approach. Hanadi Dib[1], Luc Camoin[2], Cédric Broussard[2], Véronique Witko-Sarsat[3], Loïc Guillevin[4] and Luc Mouthon[5], [1]Paris Descartes University, UPRES-EA 4058, Paris, France, [2]Inserm U 567, CNRS UMR 8104, Cochin Institute, Paris, France, [3]Inserm U 845, Paris, France, [4]Université Paris Descartes, Paris, France, [5]Paris Descartes University, UPRES-EA 4058, Department of Internal Medicine, Cochin Hospital, Paris, France

Purpose: Anti-endothelial cell antibodies (AECA) are frequently detected in anti-neutrophil cytoplasm antibodies (ANCA)-associated systemic vasculitis and are considered to play pathological roles but their antigenic specificities are still unknown. We used a proteomic approach combining two-dimensional electrophoresis and immunoblotting to identify the target antigens of AECA in patients with ANCA-associated vasculitis.

Method: Sera from 36 ANCA-associated vasculitis patients (15 with Wegener's granulomatosis (WG), 12 with microscopic polyangiitis (MPA), 9 with Churg Strauss syndrome (CSS)), tested in pools of 3 sera, were compared to a sera pool from 12 healthy controls (HC). Serum IgG reactivity was analyzed by use of a 2-D electrophoresis and immunoblotting technique with normal human umbilical vein endothelial cell (HUVEC) antigens.

Results: Serum IgG antibodies in the pools of patients with WG with anti-proteinase 3 (PR3) ANCA (n=5), MPA with anti-myeloperoxydase (MPO) ANCA (n=2), MPA without anti-MPO (n=2), CSS with anti-myeloperoxydase (MPO) ANCA (n=1) and CSS without anti-MPO (n=2), recognized 107±17, 148, 211, 128, and 101 protein spots respectively, whereas serum IgG antibodies from HC recognized 79 protein spots. Serum IgG antibodies from patients with WG with anti-PR3, MPA with anti-MPO, MPA without anti-MPO, CSS with anti-MPO and CSS without anti-MPO specifically recognized 37, 12, 22, 15 and 23 protein spots, respectively. Target antigens were identified by mass spectrometry (MALDI-TOF-TOF) including Proteasome subunit alpha type-5, Adenine phosphoribosyltransferase, Growth factor receptor-bound protein 2 and GMP synthase [glutamine-hydrolyzing]. These antigens are involved in cell energy metabolism, and other key cellular pathways.

Conclusion: AECA detected in patients with ANCA-associated vasculitis recognize cellular targets playing key roles in cell biology and maintenance of homeostasis.

Moderate to Severe Rheumatoid Arthritis (RA) Is Associated with Significant Work and Activity Impairment in Brazil: Findings From An Observational Study. R. Khandker[1], GRC Pinheiro[2], S. Kay[3], J. Cristino[3] and M. Tedeschi[4], [1]Wyeth Pharmaceutcials, Collegeville, PA, [2]Rio De Janeiro State University, Brazil, [3]Adelphi Real World, [4]Wyeth Pharmaceutcials

Purpose: The impact of RA on work and non-work productivity is not well documented in Brazil. This analysis evaluates the humanistic and economic burden of RA and its severity on productivity as well as health care resource use.

Method: Adelphi's RA Disease Specific Programme (DSP) is an observational cross-sectional study involving 55 rheumatologists in Brazil. Data elements included - physician global rating of severity (mild, moderate, and severe); the Work Productivity and Activity Impairment (WPAI) questionnaire; frequency of hospitalization and rheumatologist visits; and percent of patients needing help with daily activities. WPAI is a validated instrument that measures work time missed and work and activity impairment due to a specified health problem during the past 7 days. This study compared productivity and resource use across physician-rated RA severity groups using ANOVA and t-tests for continuous variables and Chi-square test for proportions.

Results: The primary findings are summarized below:

Variable	Mild (n=219)	Moderate (n=227)	Severe (n=55)
Age (yrs)	51	52	50
Disease Duration (yrs)	5.7	6.3	9.3 [a,b]
WPAI - Currently employed (%)	33	39	16 [a,b]
WPAI - Impairment while at work (%)	16	33 [b]	67 [a,b]
WPAI - Overall work impairment (%)	20	38 [b]	65[b]
WPAI - Activity impairment (%)	26	44 [b]	65 [a,b]

Any hospitalization in 6 months (%)	5	10	20 [b]
# of rheumatologist visits in 6 months	2.65	2.94	3.98 [a,b]
Needed help with daily activities (%)	11	26 [b]	57 [a,b]

a P<0.05 vs. Moderate

b P<0.05 vs. Mild

In this analysis, severe RA patients experienced more impairment in work and daily activities compared to mild patients. Likelihood of hospitalization and visits to rheumatologists were also significantly higher for patients with severe RA. The overall low employment rates may be partially attributable to lower work force participation among women in Brazil.

Conclusion: This study demonstrates that moderate to severe RA is associated with significant work and activity impairment. Healthcare resource utilization also increases directly with the RA severity. Effective medical management and improved treatment strategies may mitigate the burden of RA in Brazil.

"Is Working with Arthritis Bad for Your Health?" Outcomes Associated with Arthritis-Work Role Overload. M. Gignac[1], X. Cao[2], D. Beaton[1], Diane V. Lacaille[3], C. Bombardier[1], A. Anis[4] and Elizabeth M. Badley[1], [1]Univ of Toronto, Toronto, ON, [2]Univ Health Network, Toronto, ON, [3]University of British Columbia, Vancouver, BC, [4]Univ of British Columbia, Vancouver, BC

Purpose: Employment research finds that perceptions of role overload are a critical mediator in whether individuals remain working and in their health and well-being. Yet, perceived role overload or “spillover” has not been well examined in individuals working with arthritis. This study uses longitudinal data from two samples to examine: 1) role spillover from arthritis to work and work to arthritis; and 2) health-related outcomes of spillover at 3, 9, and 18 months.

Method: Participants with osteoarthritis (OA) or inflammatory arthritis (IA) were drawn from 2 separate studies. Sample 1 (S1) was recruited largely from rheumatology clinics (n = 250) and used baseline, 3 month, and 9 month data. Sample 2 (S2) was recruited largely using community advertising (n = 490) with data collected at 4 time points, 18 months apart. Both samples assessed age, gender, illness (diagnosis, pain, fatigue), and work context variables (job sector, work hrs, activity limitations). S2 also collected data on self-rated health, health care utilization, depression, disease duration, joints affected, job control and physical demands of work. Spillover was measured using the Arthritis-Work Spillover (AWS) scale (6 items: 3 items assess arthritis impact on work; 3 items assess work impact on arthritis; strongly disagree-strongly agree). Greater agreement reflects greater spillover. Longitudinal analyses using generalized estimation equations examined the relationship of AWS to subsequent reports of fatigue and pain severity and frequency (S1) and fatigue, pain, self-reported health, depression, and health utilization (S2), controlling for demographic, illness, and work variables.

Results: Half of participants had OA (S1 = 52%; S2 = 56.7%), most were female (S1 = 82.7%; S2 = 77.8%) and were on average 51 yrs old. Participants in both samples reported employment in a range of job sectors. At baseline, 32.6% (S1) and 47.1% (S2) of participants agreed or strongly agreed with half or more AWS items. Greater AWS was associated with later reports of greater fatigue severity and frequency at 3 and 9 months (S1) ($p < .05$). AWS was also associated with fatigue in S2. S2 analyses found those perceiving that arthritis affected their work reported greater fatigue and depression, and lower self-rated health 18 months later. Perceptions of work affecting arthritis were associated with greater health care utilization (all $p < .05$). AWS was not associated with pain in either sample.

Conclusion: Many respondents reported spillover, with arthritis interfering with work and work interfering with caring for arthritis. This may lead to role overload and suggests greater attention needs to be paid to helping people with arthritis balance work and health demands. Spillover may have particularly negative consequences for fatigue and mood in the short- and long-term, even after controlling for disease and job factors. Future research needs to examine whether increased health care utilization related to AWS may ameliorate role overload.

Pain On the Job: Prevalence and Site of Recent Joint Pain Among U.S. Adults with Arthritis-Attributable Work Limitations (AAWL). Kristina A. Theis and Louise Murphy, Centers for Disease Control and Prevention, Atlanta, GA

Purpose: To estimate the prevalence and site of recent joint pain in U.S. adults with AAWL overall and stratified by age and sex.

Method: We analyzed data (2002, 2003 and 2006 combined) from the National Health Interview Survey, an annual interview-administered survey representative of the U.S. civilian, non-institutionalized population. Our sample was restricted to 19,213 adults ≥ 18 years with arthritis ("yes" to: "Have you EVER been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?") We estimated, among adults with arthritis, 1) the prevalence of AAWL (limited in: *whether you work, the type of work you do, or the amount of work you do)* and 2) the prevalence of recent (within the past 30 days) joint pain among people with and without AAWL, overall and stratified by age group (18-44; 45-64; 65+) and sex. Data were analyzed in SAS v9.1 survey procedures to account for the complex sampling design.

Results: Approximately 28% of US adults ≥ 18 years old (12.5 million people) with arthritis reported AAWL. Across all joint sites, recent joint pain was significantly more common among those with AAWL compared with those without. For those with and without AAWL, the top five sites of joint pain were right and left knees, right and left shoulder, and right hand. Among people with AAWL, women reported recent pain in left and right hips and left and right hands significantly more often than men (e.g., right hip pain 38.0% [95% confidence interval (CI)=35.6-40.4] vs. 29.0% [95% CI=26.2-31.9], right hand 42.9% [95% CI=40.7-45.2] vs. 34.0% [95% CI=31.0-36.9]). For all sites, the prevalence of recent joint pain across all age groups was higher among women than men. For both men and women, the prevalence of joint pain, regardless of site, was among highest among adults ages 45-64 years and lowest among those age 18-44 years.

Conclusion: We found a high prevalence of recent knee and shoulder joint pain among adults with AAWL, suggesting that joint pain in these sites may be a useful clinical indicator for job interference due to arthritis. The increased prevalence of joint pain among adults 44-64 years indicates the importance of interventions that enable middle aged adults with arthritis to stay in the workforce and avoid economic insecurity (e.g., premature retirement). People with AAWL may benefit from a combined strategy: public health interventions like self-management education that may be effective in countering pain, worksite accommodations, and increasing availability of ergonomic equipment designs.

The Association Between Hand Impairment and Hand Function in Rheumatoid Arthritis. Nancy A. Baker and Joan C. Rogers, University of Pittsburgh, Pittsburgh, PA

Purpose: Healthcare professionals frequently measure impairments in range of motion (ROM), grip, or dexterity to help quantify hand function limitations in people with rheumatoid arthritis (RA). This study examines the association between impairments and functional hand use.

Method: 45 people with RA were recruited from the University of Pittsburgh Medical Center Arthritis Network Disease Registry. Hand function was measured with the 4 bilateral applied dexterity tasks (number of seconds to: lace a shoe, button 5 buttons, cut simulated meat with a knife, and manipulate coins) and 1 bilateral strength task (lifting up to 12 cans on a tray) of the Arthritis Hand Function Test (AHFT). Impairments were measured with the Keitel Hand Function Index (KHFI) (ROM), the grip and dexterity from the AHFT, and the number of hand problems as determined by observation of structural deformities by a hand therapist.

AHFT applied task scores were transformed into one of 4 categorical scores and summed to develop a total AHFT score, in which a higher score indicated greater hand function. Total strength and dexterity impairment scores were developed by summing the right and left hand scores for grip and dexterity. Each KHFI item score was summed to develop a total KHFI score in which a higher score indicated greater impairment.

Backward stepwise multiple regression models were developed with applied hand tasks as each outcome, and grip, dexterity, total KHFI, hand problems, and age as the predictors.

Results: Subjects were 56.2 (±8.5) yrs. RA duration was a mean of 16.7 (±10.3) years.

All models were significant except for manipulating coins. Models explained from .30 to .79 of the variance in hand function for each task. Grip and dexterity were most often associated with hand function (*partial* r^2 grip: lacing shoe -.45, cutting meat -.59, lifting .55, total AHFT -.41; dexterity: lacing shoe .60, buttons .41, total AHFT .64). Age and number of hand problems were each significant in only one model (*partial* r^2 age: lacing shoe .38; hand problems: buttons .45).

The total KHFI was not significant in any model.

Conclusion: For tasks requiring strength, such as cutting meat, grip had the strongest association, while dexterity had the strongest association for tasks requiring manipulation. Overall hand function (AHFT) was more strongly associated with dexterity, suggesting that the ability to manipulate items is a better predictor of function than strength. This study suggests that although measuring impairments provides some indication of hand function, practitioners should measure both impairment and function to fully understand performance.

Problems and Coping Strategies Reported by Computer Users with RA. Nancy A. Baker, Joan C. Rogers, C. Kent Kwoh and Thomas Songer, University of Pittsburgh, Pittsburgh, PA

Purpose: Rheumatoid arthritis (RA) is associated with significant work disability. Computer use can be an important option for preventing work disability. This cross-sectional study describes the type and frequency of problems and coping strategies reported by computer users with RA when using two input devices, the keyboard and mouse.

Method: The Computer Problems Surveys (ComPS) requires each respondent to select from a list the problems they encounter and the coping strategies they use during keyboard and mouse use. The ComPS was mailed to registrants with RA in the Arthritis Institute Network Disease Registry. This registry does not give investigators access to registrants' names, so all mailings are one time and anonymous. Of the 502 mailed, 201 were returned, yielding a response rate of 40%. Differences between the number of problems and coping strategies reported for the keyboard and mouse were assessed using Wilcoxon Signed Ranks Test.

Results: The sample was 83% female and 89% were over the age of 45. They had been diagnosed with the disease for 16 years. Of the 178 respondents who reported using a computer (88%), 119 (67%) reported at least one problem with either the keyboard or mouse. Respondents reported significantly more coping strategies with the keyboard than the mouse ($p < .001$), but not having significantly more problems ($p = .12$). The most common types of problems for both devices were positioning the hand, fatigue, and manipulation (Figures 1A, 2A). The most common coping strategies were those that changed the user's performance: using the device for a shorter time and moving more slowly (Figures 1B, 2B). Respondents rarely reported using alternative input devices.

Conclusion: Although computer users with RA have a similar number of problems using the mouse and keyboard, they use significantly fewer coping strategies for the mouse. Although many of the most common problems reported by computer users with RA could be addressed by using alternative input devices, such as angled keyboards or voice recognition software, study respondents tended to use performance altering coping strategies. Further research is needed to determine why particular coping strategies are adopted and to identify which alternative input devices would best reduce computer use problems.

Acknowledgements: This research was supported by a Chapter Grant from the Arthritis Foundation of Western Pennsylvania

Beliefs and Practices of Occupational Therapists (OTs) and Physical Therapists (PTs) about Their Role in Addressing the Health-Related Work Problems of Patients with Chronic Health Conditions. S. Allaire[1], N. Baker[2] and Julie J. Keysor[3], [1]BUSM, Boston, MA, [2]UPMC, Pittsburgh, PA, [3]Boston UniversityHRS, Boston, MA

Purpose: Solving health-related work problems can help patients with rheumatic conditions stay employed, but little assistance with this is available. Occupational therapists (OTs) and physical therapists (PTs) could provide this help, but it's not clear to what extent therapists perceive they should, or do, address patients' work problems. We assessed therapist beliefs and practices in addressing patients' health-related work problems.

Method: We surveyed OTs and PTs by mail about their beliefs and practices concerning the health-related work problems of patients with chronic health conditions. A random selection of names of professional therapists in U.S. hospital or private practice settings were obtained from the American Physical Therapy Association and American Occupational Therapy Association. 300 each of OTs and PTs were contacted; recruitment is ongoing. A 12 item questionnaire was developed for this study. Besides beliefs and practices, questions assessed confidence in addressing patients' work problems, time available, and the frequency of seeing relevant patients. Questions had ordinal or 10 point scale response measures.

Results: 34% response rate; 12% did not treat employment aged adults and so were ineligible. 46 OT and 63 PT respondents provided consent and data. Both professionals strongly believed they should address patients' health-related work problems. 95.4% believed this was

in their professional scope of practice. Importance of determining patients' employment status was a mean of 9.5 on a 1-10 scale, and the mean score for importance of determining wheher patients' health affects their work was 9.6. PTs and OTs did not differ in their beliefs: in their scope of practice, 95.2 vs. 95.6%; importance of determining employment status, mean 9.3 vs. 9.6; and importance of determining if health affects work, mean 9.5 vs. 9.7. In their practices, 92.7% of therapists always (83.5%) or usually (9.2%) determine patients' employment status, and 94.5% always (76.2%) or usually (18.3%) ask about possible effects of health on work. Proportions of PTs engaging in these practices were slightly lower than OTs, 88.9 vs. 97.8% determine employment status, and 90.5 vs. 100% ask about health effects. 80.7% of all therapists agreed or strongly agreed they were confident in addressing health-related work problems, and PTs and OTs differed little on this. 24.8% of therapists did not have enough time for patients' work problems, with PTs more likely to state this than OTs. Only 7.3% of the sample had not treated patients with a rheumatic condition in the past month.

Conclusion: Therapists in this sample strongly believed they had a role in addressing the health-related work problems of patients with chronic health conditions, and their reported practices closely followed their beliefs. Generalizability of findings is limited given the response rate and subject self-selection from professional organization members.

Work Barriers Encountered by Employed Persons with Scleroderma. Janet L. Poole[1], Sahar Anwar[1], Cindy F. Mendelson[2] and Saralynn J. Allaire[3], [1]1 University of New Mexico, Albuquerque, NM, [2]Univ of New Mexico, Albuquerque, NM, [3]Boston Univ School of Medicine, Boston, MA

Purpose: Systemic sclerosis, or scleroderma (SSc), is an autoimmune connective tissue disease that affects thousands of Americans. Pain, finger ulcers, contractures, Raynaud's phenomenon, esophageal reflux, and internal organ involvement, particularly decreased pulmonary function, make it difficult to perform daily tasks, including work. The economic cost of not working is high in persons with SSc. However, there is no information about the work barriers they experience. The purpose of this study was to identify work barriers faced by persons with SSc.

Method: Persons with SSc who are employed 8 hours or more per week and reported difficulty working due to self-perceived symptoms from SSc were included in this study. Participants completed the Work Experience Survey, a survey that contains lists of potential work barriers including the ability to get to and from work, get around at work, perform essential job functions including physical, cognitive and task related activities. work with others, and handle work conditions.

Results: Results from the first 15 participants are presented (14 females, 1 male; mean age 47.6 years, mean disease duration 7.23 years; 50% working 20 hours or more per week). Temperature (54%) and using stairs (32%) were cited as the most common barriers in regard to work site accessibility. The most common job functions barriers that required physical activity were using hands (54%), lifting (32%), kneeling (32%), prolonged sitting (31%), working 8 hours (27%), prolonged standing (27%), pulling (27%), and pushing (27%). The task related barriers posing the most difficulties were writing (40%) and performing under stress (36%). The only work condition barrier was too cold (63%), but this was the most commonly cited of all barriers. Participants did not cite any barriers in regard to cognitive activities, social activities or company policies. Data from the remaining 15 participants will be included in presentation of the final results.

Conclusion: The most common cited work barriers were cold temperature and hand use (including writing, endurance (working 8 hours), and performing under stress. The barriers identified are similar to those identified by Allaire and colleagues in a study of adults with a variety of rheumatic diseases. The barriers are amenable to job accommodations.

The Effectiveness of a Scleroderma Self Management Program Delivered Via Booklet and DVD. Janet L. Poole[1], Cindy F. Mendelson[2] and Betty Skipper[3], [1]1 University of New Mexico, Albuquerque, NM, [2]Univ of New Mexico, Albuquerque, NM, [3]Albuquerque

Purpose: To determine the effectiveness of a self management program for persons with scleroderma delivered via booklet and DVD.

Method: Persons with scleroderma were recruited from the Scleroderma Foundation website. This study was a pre-test post-test design where participants were evaluated before and after participating in the program. Participants completed questionnaires regarding self-efficacy (Arthritis Self-Efficacy Scale), performance of daily activities, (Health Assessment Questionnaire), hand function (UK Scleroderma Functional Score), fatigue (Multi-dimensional Assessment of Fatigue Scale), depression (Center for Epidemiologic Studies Depression Scale) and pain (Visual Analogue Scale). Participants were also interviewed about their satisfaction with the program. The intervention program consisted of a booklet with modules on scleroderma, coping, self-advocacy, fatigue and energy conservation, activities of daily living, mouth and teeth care, dysphagia, Raynaud's phenomenon, exercise and a DVD showing face, hand, arm and leg exercises.

Results: Sixty one people with scleroderma competed baseline questionnaires while 49 (80%) completed the program and post intervention questionnaires. Of the participants who completed the program, the mean age was 53.9 years with a mean duration of 6.9 years and mean education level of 15.2 years. Ninety two percent were female, 82% Caucasian, and 73% were married. Depression, fatigue, and pain decreased while hand function, self efficacy to control other symptoms, and self efficacy for controlling pain improved; however, the only significant change was in self efficacy for pain. Participants were enthusiastic about the program and felt the program was needed especially for persons who were newly diagnosed. The most informative topics were the self advocacy module and the exercise DVD.

Conclusion: The findings suggest that self management program delivered via the booklet and DVD may not be as effective as a small group format. However, given the rarity of scleroderma, a small group format may not be available for those who live outside larger metropolitan areas. Thus, research is needed to determine the most effective method to deliver self management programs for this population.

LANtern (Lupus Asian Network): Evaluation of An Innovative National Program. M. Tran, R. Horton, A. Yee and S. Paget, Hospital for Special Surgery, New York, NY

Purpose: Launched in 2003 with a mission to support, empower, and enhance quality of life for Asian-Americans with SLE and their loved ones, Hospital for Special Surgery's LANtern (Lupus Asian Network) is a national resource for its peer based telephone SupportLine and bilingual Chinese educational publications. This complex illness affects Asian-Americans 2-3x as often as whites.

Method: We developed a telephone evaluation for the 101 SupportLine users with lupus or family members who used the program from 2003 – 2006. The 31-item survey consisted of Likert scale and open-ended questions to assess user demographics, program satisfaction, SLE impact, and service recommendations. Interviews were conducted in users' preferred language, English or Chinese (Mandarin/Cantonese), by 2 volunteers not otherwise linked with the program.

Results: We completed 24 interviews. Attrition was due to address change, lack of return calls, or refusal. Of our sample, 22 were female; 18 with SLE; 5 were parents and 1 adult child; 21 were born in other countries, with the majority from China (50%) and Hong Kong (21%). Most callers (42%) were between ages 46-55, followed by 26-35 (25%). More than half (54%) were monolingual in their native language/dialects, in contrast with a few (13%) in English only.

Fifty percent had SLE < 5 yrs and 33% had SLE >10 yrs. Almost half (46%) stated that SLE interfered with their everyday life or the lives of their loved ones with SLE *most* of the time, employment (63%), relationship with spouse/partner (42%), and social activities (42%). Considerable anxiety about the future was expressed (63% sometimes/very often). A majority of those with lupus (59%) reported being a burden to their family sometimes/very often, while 50% reported sometimes feeling down, depressed or hopeless.

Most users (55%) learned of LANtern via Chinese media, health fairs and word of mouth; an additional 37% were referred by social service/health care agencies. Initial contact was prompted very much by a desire to learn more about the illness (54%) and to relieve psycho-social concerns (34%). A significant number (71%) indicated a better understanding about lupus and the receipt of emotional support, and 55% felt less alone, despite the contacts being brief, with 63% reporting 1-2 contacts and 25% 3-5. 67% reported "very important" that the person they spoke with has a similar cultural or language background. Program satisfaction was high, with 92%

reporting being extremely/satisfied, and 96% would recommend the program to others. Additional service needs were also assessed, with recommendations consistent, culturally and linguistically, with their reported desire of peer connections, and family/group oriented activities.

Conclusion: Our results, though limited by a small sample size, underscore that a culturally relevant service need is being met through our telephone peer counseling model for a community reporting significant impact of SLE on their lives. Additional program modalities have since been explored and enhanced for service expansion.

An Innovative Support and Education Program for Early and Newly Diagnosed RA Patients: Emerging Themes. D. Kurtz, A. Batterman, R. Horton, L. Leff, J. Reyes-Canu, T. Fields and Stephen Paget, Hospital for Special Surgery, New York, NY

Purpose: Present treatment models in RA emphasize early medical intervention. Similarly, research indicates that early psychosocial interventions may positively affect long-term functional status and adaptive coping (Evers et al, 2003, Dobkin et al, 2008). Previously we reported on a needs assessment of newly diagnosed (<1year) RA patients which indicated the need for an education and support program to meet their specific psychosocial needs. Based on these results, we designed a unique program within a hospital based early arthritis center. We report now on salient themes that have emerged two years after the program's implementation.

Method: The program was developed using data from a multi-level needs assessment and modeled after a successful program for patients with chronic RA. 16 monthly workshops were convened as a forum for newly diagnosed patients to gain essential RA-related information and to have access to peer support. 4 series consisting of 4 sessions each have met to date. Each featured a lecture by an RA expert and a support group co-facilitated by an MSW and RN. Topics included: Drugs in early treatment, coping skills, joint protection and nutrition. After each session, structured written evaluations with Likert-type and open-ended questions were given to assess program impact. Focus groups were also held to elicit participant feedback and inform future planning.

Results: 114 evaluations were completed from an average of 10 participants per session. Demographics. Gender: 75% f, 25% m. Ethnicity: African American 25%, Asian American 6%, Caucasian 63%, Latino 6%. Mean age: 49.6 yrs. Education: 94% college or higher. 89% agreed (“completely” or “a great deal”) they were satisfied with group discussions. 92% agreed (“completely” or “a great deal”) that the “group is relevant to daily coping with RA.” Salient themes were: new awareness of the importance of early, aggressive treatment; need to address the psychosocial impact of RA; need for social support and improved MD/patient communication. The following patient statements are illustrative of these themes: “I will consider biologics sooner rather than later,” “I recognize that depression needs to be addressed and not ignored,” “Others deal with the same issues,” “This group is helpful in bringing out emotions I had been repressing,” “I will talk to my doctor about how to best evaluate [treatment] progress.”

Conclusion: Current research and our 2 year program experience lead us to believe that discussion of these themes in a structured setting soon after diagnosis offers a window of opportunity for cognitive reframing, which can enhance adaptive coping. This type of intervention is an integral part of a comprehensive treatment plan for the newly diagnosed patient and may serve to inform others in implementing similar programs.

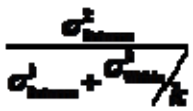
Number of Days Necessary to Wear Portable Activity Monitors in Patients with Rheumatoid Arthritis. Gustavo J. M. Almeida[1], M. C. Wasko[2], KwonHo Jeong[1], Charity G. Moore[1] and Sara R. Piva[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Purpose: Sedentary lifestyle characterizes patients with rheumatoid arthritis (RA) and is associated with morbidity and mortality. Objective measures of physical activity (PA) are needed to measure real-time activities performed by patients with RA**.** Individuals typically vary their level of PA throughout the week. Therefore, it is difficult to establish what days of the week are preferable to monitor PA and also the amount of days necessary to have a consistent estimation of PA. The information about the number of days necessary to obtain reliable estimates of energy expenditure (EE) is conflicting due to different statistical approaches and devices used. Studies of this nature have not been done in patients with RA. Thus, the purpose was to determine the minimal number of days needed to wear a portable activity monitor to obtain consistent measures of PA in patients with RA.

Method: Forty seven women with RA participated in this cross-sectional study. Subjects were asked to wear an activity monitor (Sensewear Armband Pro3, BodyMedia INC, Pittsburgh, PA) on the right upper arm, over the triceps muscle, for 7 days. In addition, they were instructed to take it off during shower and/or water activities, and to report activities they performed on a log-sheet. Variables of interest were daily total EE (TEE), EE during PA (EEPA), and daily number of steps. Analysis: First, an ANOVA was performed to determine if daily values of TEE, EEPA and #of steps were different among weekdays. Then, multiple linear regressions were used to determine the minimal number of days were needed to predict 80% of variability in 7-day of activity monitor use. The criterion was 7-day average and all combinations of continuous days were the predictors. Finally, intra-class correlation (ICC) coefficients were calculated using a one-way model taking repeatability into account. Total error was split in 2 error components: $y_{ij} = \square + \mu_i + \square_{ij}$; where μ_i is a random intercept with zero mean and var $(\mu_i) = \sigma^2_{Between} = \psi$, and $\square_{ij}$ is the random deviation of y_{ij} from subject i's mean with zero mean and var $(\square_{ij}) = \sigma^2_{Within} = \theta$. ICC (k) was then calculated using 7 days of single measurement with the following formula: _, where k is the number of days. ICCs above .80 were considered adequate.



Results: Mean age and BMI were 58±6 years and 28±7 respectively. The magnitude of daily values of TEE, PAEE, and number of steps were not different among the 7 weekdays (p = 0.93). To have a reliable estimation of TEE, it is necessary for the patients to wear the activity monitor for 2 days (ICC=0.83, Adjusted $R^2 \geq 0.86$), 4 days to have reliable estimation of EEPA (ICC=0.82, Adjusted $R^2 \geq 0.84$), and 3 days for number of steps (ICC=0.83, Adjusted $R^2 \geq 0.87$). These results were consistent across all days of the week.

Conclusion: The combination of any 4-day wearing the portable activity monitor predicted more than 80% of the variance across 7 days of data collection, and allowed for consistent measures with ICCs above .80. By minimizing the number of days necessary for data collection will reduce patients' burden and probably improve adherence.

Lessons Learned From Community-Based Arthritis Physical Activity and Behavior Change Interventions: Reaching "Hard-to-Reach" Populations. Laura O. Houenou, Britta Schoster, Mary Altpeter, Jean Goeppinger and Leigh F. Callahan, University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose: To provide researchers and practitioners with recommendations for overcoming recruitment challenges for hard-to-reach populations for physical activity and behavior change interventions.

Method: We conducted evaluations of four community-based interventions among more than 1,600 individuals with self-reported arthritis in over 40 urban and rural counties in a Southeastern state. We reviewed our intervention protocols for overarching themes, common challenges, and successful adaptations and solutions for overcoming barriers to recruiting hard-to-reach populations in community-based research.

Results: For all four interventions, our hard-to-reach populations included **rural residents (62%), African Americans (AA) (45%), males (14%),** and **those without a high school degree (18%)**. One of these studies purposefully recruited **employed (30%)** participants, who are typically underrepresented in arthritis interventions. We found that multipronged approaches were necessary to recruit a diversity of research participants. We partnered with local community leaders who shared similar characteristics as the target populations, which allowed us to access these groups. For **rural** representation, we aligned with statewide agencies, such as the Area Agencies on Aging, as well as Parish

nurses and health departments serving rural areas. Word-of-mouth was the most productive recruitment strategy for rural-dwelling persons. **AA** participation in our interventions was higher in sites where the leader was also AA. Recruitment efforts focused on social and cultural organizations primarily comprised of AAs (e.g. churches and sorority chapters). Men were more likely to participate in the interventions when their female partners enrolled; thus, recruiting men through their partners was an effective recruitment method. Those without a high school degree were recruited by word-of-mouth and by working with local community leaders who could seek out those individuals and refer them to the research team. Because younger (<65 years old), employed individuals are not well represented in similar studies, we recruited from worksites and scheduled assessment activities during lunch and before and after typical work hours.

Conclusion: Increased representation of understudied populations in community-based interventions requires the use of multiple recruitment strategies. Based on our experience, we compiled a set of recommendations that may direct researchers and practitioners in addressing these recruitment challenges. It is imperative that researchers include understudied populations in community-based research so that their perceptions and social norms can be incorporated into interventions. Our lessons learned in community-based arthritis research may be applicable to other disease management intervention frameworks.

Fit and Strong!: Dissemination of An Evidence-Based Intervention for Older Adults with Osteoarthritis. Susan L. Hughes[1], Rachel B. Seymour[2] and Pankaja Desai[1], [1]Center for Research on Health and Aging, Chicago, IL, [2]University of Illinois Chicago, Chicago, IL

Purpose: Osteoarthritis (OA) is the most common condition affecting older people today. Lower extremity joint impairment caused by osteoarthritis (OA) is a link through which disability has been shown to develop. Fit and Strong! is an award winning evidence-based, multi-component exercise/behavior change program for older adults with osteoarthritis that is being diffused throughout the United States. The translation of evidence-based programs for older adults is a major public health priority.

Methods: Currently, two collaborative efforts are underway to translate and diffuse Fit and Strong!. The first effort is funded by the Centers for Disease Control and Prevention (CDC) and supports dissemination of the program in two states (1R18DP001140). Fit and Strong! is being diffused in two areas on aging in Illinois and two areas on aging in North Carolina with a minimum of 30 providers, involving the enrollment of 1,200 new participants. The Fit and Strong! team is also partnering with the National Arthritis Foundation (NAF) to translate and diffuse the program within four chapters: Northern and Southern New England, Northern California, Michigan, and Western Missouri/ Kansas. The goal of this partnership is to have 24 new providers (6 per state) adopt the program, train and evaluate the implementation of the program by 24 new instructors (6 per state) and enroll an additional 480 persons in the program.

Results: As a result of these efforts, we now offer the program in 7 states at 26 sites with 54 trained instructors and 292 participants. Pre-post outcomes and program evaluations are currently being collected. Preliminary analyses on outcome and mediator variables indicate a significant improvement on exercise participation ($p=0.025$), energy/fatigue ($p=0.035$) and self-efficacy for exercise ($p=0.020$). Factors which facilitate and impede program adoption, fidelity and adaptation and sustainability will be discussed. Practical issues involved in providing Fit and Strong! in the community will be discussed, including space, equipment, recruiting, training and monitoring exercise instructors, and methods for monitoring fidelity of Fit and Strong!.

Conclusion: As a result we now have a Website and a cadre of Master trainers available that make it possible for us to more broadly disseminate the program to other communities that seek to adopt the program.

1865

Knowledge of Best Practice Guidelines for Management of Rheumatoid Arthritis Among Physiotherapy Students in a Problem-Based Curriculum. Christina Hallett[1], Jake Tumber[1], Nalin Fernando[1], Magdalena Hul[1], Sydney C. Lineker[2] and Norma J. MacIntyre[1], [1]McMaster University, Hamilton, ON, [2]The Arthritis Society, Toronto, ON

Purpose: A national partners group developed best practice guidelines (BPG) for health professionals in primary care who treat clients with early or late stage rheumatoid arthritis (RA). This study determined whether Physiotherapy (PT) students learned these BPG within their problem-based learning curriculum (PBL). A secondary objective was to pilot a supplemental learning module developed to address knowledge gaps.

Method: Of the 65 eligible senior PT students invited to participate, 49 consented and attended two testing sessions. Knowledge regarding BPG was evaluated using the ACREU Primary Care Survey administered before and after completing the usual PBL content related to physiotherapeutic management of clients with RA. Students were asked to indicate what interventions and referrals they would recommend in response to two case scenarios on early and late stage RA. Changes from baseline were assessed using McNemar's test for dependent proportions. To address identified gaps in learning, a video was developed to educate students regarding BPG. Three months later, a subgroup of participants (n=11) completed the same survey before and 1 week after viewing the video. Changes in scores were evaluated descriptively.

Results: Most students correctly recorded best practices relating to PT/exercise, education, and Occupational Therapy/joint protection before and after PBL (>83% and >95%, respectively). Knowledge related to referral to rheumatology and need to provide psychosocial support improved following PBL ($p<0.05$, Figure 1). Few students considered use of disease-modifying drugs (DMARDS) and non-steroidal anti-inflammatory drugs (NSAIDS) (Figure 1). Most students knew that referral to a surgeon is not best practice for early RA; however, the same number did not recognize this as best practice for late RA (Figure 1). After 11 students watched the educational video, at least 10 retained knowledge of best practice regarding PT/exercise, education, and Occupational Therapy/joint protection. An increased number reported the need for psychosocial support (from 5 to 10 for early RA; from 8 to 11 for late RA), referral to a rheumatologist (from 7 to 10 for both stages), use of DMARDS (from 0 to 8 for early RA; from 1 to 8 for late RA), use of NSAIDS (from 0 to 4 for both stages) and referral to a surgeon for late RA (from 1 to 4).

Conclusion: PT students about to become primary care practitioners have gaps in knowledge regarding best practices for managing clients with RA. Pilot data suggest that an educational video discussing BPG facilitates learning. Future research will assess the effect of incorporating the video into PBL as a supplemental learning module. Other strategies for improving knowledge regarding effective drug regimes and timely surgical consult for people with RA may be needed.

The Arthritis Educational Needs Assessment Tool: Will It Work in the Community? Mwidimi Ndosi[1], Jackie Hill[1], Jo Cumming[2] and Claire Hale[1], [1]University of Leeds, Leeds, United Kingdom, [2]Arthritis Care, London, United Kingdom

Purpose: Educational Needs Assessment Tool (the ENAT) was developed in the UK to help clinicians identify individual patients' educational needs in order to plan relevant and timely patient education. The ENAT is an easy to complete questionnaire with 39 items grouped into 7 domains: managing pain, movement, feelings, arthritis process, treatments, self-help measures and support. It has been validated for use across rheumatic diseases in the clinical settings but it has not been tested in the community. The purpose of this analysis was to assess how well the ENAT could capture the educational needs of people with arthritis in the community.

Methods: The ENAT was used to collect data from patients with ankylosing spondylitis (AS), psoriatic arthritis (PsA), scleroderma (Ssc), Lupus (SLE), osteoarthritis (OA), rheumatoid arthritis (RA) and fibromyalgia (FM) attending 4 hospitals in the UK (ENAT data). The educational needs were summarised into their respective ENAT domains namely: Pain, Movement, Feelings, Arthritis process, Treatments, Self-help and Support.

Arthritis Care is a UK patient organisation which offers free confidential service to people affected by arthritis using their helplines. Telephone helpline enquiries were collected from January to June 2008 and were summarised and categorised by type of arthritis and what their enquiry was about (Community data).

The community data were matched with the ENAT domains and were transformed and expressed in terms of x/y; where x = frequency of enquiries for each domain and y = sum of enquiries for all domains. The transformed community data were modelled against the ENAT data and correlational statistics were applied to explore their domain-domain correlation.

Results: The ENAT cohort comprised 911 with male/female ratio 1:2.5 while the community cohort comprised 5443 people with male/female ratio of 1:3. The ENAT cohort had roughly equal number of patients with AS, PsA, Ssc, SLE, OA, RA and FM. The community cohort had varying proportions of all the above diagnoses in addition to polymyalgia, juvenile idiopathic arthritis and people with no diagnosis.

Out of 16187 telephone inquiries 15475 (95.7%) could be matched with all the ENAT domains. The remaining 4.3% of the unmatched data included: self-management training, employment, sex/relationship and education.

The priority order of needs from the ENAT data was: arthritis process (0.122), treatments (0.114), pain (0.111), feelings (0.109), movement (0.109), self-help (0.110) and support (0.095). For the community data, the priority order was: self-help (0.217), arthritis process (0.192), treatments (0.185), pain (0.174), feelings (0.116) support (0.059) and movement (0.056).

When modelled against the ENAT data, the community data displayed a strong domain-domain correlation ($r = 0.678$) with the ENAT data ($p = 0.047$).

Conclusion: The results suggest that the ENAT could capture well the educational needs of people with arthritis in the community. This opens the possibility of the ENAT use in the community settings such as patient organisations or the web. Despite this potential, further validation of the ENAT for such uses will be necessary before its application.

1867

Improving Quality of Referrals From Primary to Specialty Care in An Underserved Community. Heather M. Greysen and Mark F. Gourley, NIH, Bethesda, MD

Purpose: Communication between the primary care provider (PCP) and specialist is important in the management of chronic rheumatic conditions and leads to improved patient care. Rapid referral to a rheumatologist and early treatment improves patient outcomes; however, inappropriate or excessive referrals to the specialist can strain clinic resources. Evidence suggests that distributing standardized guidelines for referral and providing education to primary care providers improves the referral process.

Method: Thirty-six PCPs in 5 clinics in the Washington DC area who refer patients to an NIH community clinic received a standardized referral sheet and a 40 minute educational intervention about common rheumatic diseases, taught by a rheumatology physician and nurse practitioner. The standardized referral sheet included guidelines for when to refer a patient and what information should be included in the referral. Referral quality was assessed pre- and post-intervention and compared to a control group that did not receive the guidelines sheet or the intervention. Quality was assessed by means of a scoring system, ranging from 0 to 3, developed for this study.

0 = PCP did not provide clinical data nor direction; 1 = PCP provided direction and no clinical data or provided clinical data without direction; 2 = PCP provided direction and one piece of clinical data. 3 = PCP provided direction and more than one piece of clinical data. Scores of 0-1 are considered poor, and 2 to 3 are considered good. Direction is awarded for formulating a specific clinical question. Clinical data includes recent progress note, lab results, and x-rays. The scoring system was validated by 4 other rheumatologists in the practice. Statistical significance was calculated using a paired t-Test.

Results: From June 2008 – June 2009, we analyzed referrals from each intervention clinic 3 months pre- and post-intervention. Control group referrals were gathered from September 2008 – February 2009. More than half (63%) of pre-intervention referrals were scored 0-1 (poor) compared with only 15% post-intervention. Most (85%) of post-intervention were scored 2-3 (good) compared with 37% of pre-intervention referrals. Referrals received after the intervention improved significantly ($p < 0.05$). The control group, without any intervention, sent primarily poor quality referrals; 72% were poor and 28% were good.

Conclusion: Our results show that this standardized tool and intervention improved referral quality, which helps the specialist deliver better quality care. Poor referrals lead to long wait lists and delay in initiation of therapy. Others authors have found that a guidelines tool was inadequate without a personal interaction between the PCPs and the specialist. Our intervention sessions increased communication by opening up a dialog between primary and specialty care providers.

Number of Referrals	0 or 1 = Poor	2 or 3 = Good
Control, n=58	42 (72%)	16 (28%)
Pre, n=30	19 (63%)	11 (37%)
Post, n=34	5 (15%)	29 (85%)

1868

Organization and Provider Factors That Influence Utilization of Arthritis Best Practices in Primary Care. Sydney C. Lineker[1], Janice A. Husted[2], K. Stephen Brown[2] and Steve R. Manske[2], [1]The Arthritis Society, Toronto, ON, [2]University of Waterloo, Waterloo, ON

Purpose: The dissemination of clinical practice guidelines (CPGs) has been suggested as one method for improving primary care delivery. An inter-professional educational program was developed to disseminate best practices based on CPGs for the management of osteoarthritis (OA) and rheumatoid arthritis (RA). Primary care organizations were invited to enroll providers in 1 of 27 workshops on arthritis best practices (ABP) followed by 6 months of reinforcement activities. This study developed and tested 2 models of knowledge utilization (KU) to determine which organizational and individual level factors contributed to improved provider use of ABP following the workshops.

Method: To evaluate their use of ABP, workshop participants were surveyed at baseline and six months following the workshops using the ACREU Primary Care Survey. The survey assessed providers' responses on how they would manage patients described in 3 hypothetical case scenarios on early RA, late RA, and moderate knee OA. One point was given for each recorded best practice and totaled for each case with the highest possible score being 8 for the late RA and moderate knee OA cases and 7 for the early RA case. The survey also assessed provider satisfaction with their ability to deliver arthritis care and confidence with their ability to manage arthritis. Each participating organization also completed a practice profile. For Model 1, two-level hierarchical linear modeling was used to determine the direct effects of organization and provider level variables on intended use of ABP six months following the workshops. In Model 2, logistic regression was used to determine the influence of organization level factors on one specific ABP, dissemination of educational materials.

Results: Two hundread and seventy-five providers from 131 organizations completed baseline and 6 month follow-up surveys. For all 3 case scenarios, total ABP scores were predicted by the discipline of the providers, the model of care in which they worked, and baseline ABP scores (P<.05). Baseline confidence also predicted the 6 month scores for moderate knee OA (P=.05) and baseline satisfaction predicted the total score for late RA (P=.04). The estimated probability of disseminating educational materials was >82% for providers working in community health centres, physician networks and regionally funded organizations compared to 30% for federally funded organizations (P<.01) and was 88% for organizations that sent interdisciplinary team members to the workshops compared to 70% for those that did not (P=.07).

Conclusion: Use of ABP may be influenced by provider (discipline, satisfaction, confidence) and organization characteristics (model of care, team learning experience). These results have implications for the training and education of health professionals and the design and staffing of models of primary care to enhance arthritis care delivery.

Racial and Ethnic Differences in the Prevalence, Impact and Management of Doctor-Diagnosed Arthritis—United States, 2002, 2003 & 2006. Julie Bolen, Charles G. Helmick, Jennifer M. Hootman, Louise Murphy and Gary Langmaid, Centers for Disease Control and Prevention, Atlanta, GA

Purpose: : By 2010 about one in three US residents will belong to a minority group (one in two by 2050). Previous studies have shown racial and ethnic differences in arthritis prevalence and impact (e.g., prevalence is similar between whites and blacks, but impact is more severe for blacks). We describe the prevalence, impact and management of arthritis among six racial groups (White, Black, Hispanic, American Indian, Asian and other) and 8 Hispanic subgroups.

Methods: We combined data from the 2002, 2003 and 2006 National Health Interview Survey (NHIS), an in-person national sample of the U.S. civilian, non-institutionalized population aged >18 years (N=85,897). Respondents were asked about health conditions, including doctor-diagnosed arthritis, arthritis-attributable activity and work limitations, arthritis-related pain, and health care provider counseling to lose weight, be more physically active or to take a class to manage arthritis symptoms. Non-Hispanic blacks, Hispanics and Asians were oversampled.

Results: Overall about 21.2% of US adults have doctor-diagnosed arthritis; of these 37.8% report an arthritis attributable activity limitation and 25.6% report severe joint pain. Of adults of working age (18-64) who had arthritis 31% reported arthritis-attributable work limitations. White non-Hispanics have less arthritis-attributable limitation (36.3%, 95% C.I. 35.3-37.3) than Black non-Hispanics 44.7, CI 42.6-46.7), or Hispanics (43.2%, CI 40.2-46.3). Similar patterns were observed for work limitation and severe joint pain. Differences remained when estimates were age-adjusted. Health care provider counseling to lose weight to help arthritis symptoms was 30.7% overall and was highest for black non-Hispanics (39.6%, CI 37.5-41.8) and Hispanics (38.6%, CI 35.9-41.2). Counseling to increase physical activity was 53.6% overall but lower among American Indians (38.8%, CI 30.6-47.6). Counseling to take a class to manage arthritis symptoms was only 10.5% overall and differences between racial groups were not significant.. Estimates varied among the 8 Hispanic subgroups but, due to small sample sizes, no differences were significant.

Conclusion: There is considerable racial and ethnic variation in arthritis prevalence, impact, and management. Possible reasons include 1) lack of health care access and/or utilization leading to delays in seeking medical attention for joint problems, 2) the presence of co-morbid conditions such as obesity, diabetes, heart disease and cancer, 3) cultural differences in perception of pain or willingness to report pain, and

4) employment in jobs that are physically demanding. Arthritis interventions may need to target minority populations in different ways to help reduce arthritis related impact.

1870

To Measure Patients' Adherence and Factors Influencing Adherence with Prescribed Medications for Rheumatoid Arthritis.
Christina Doyle[1] and Georgina Gethin[2], [1]Our Lady's Hospice Ltd, Harolds Cross, Dublin, Ireland, [2]Royal College Surgeons Ireland, Dublin, Ireland

Purpose: Rheumatoid Arthritis (RA) affects 1% of the population, with increasing numbers of individuals being diagnosed every year. It is a treatable illness, which includes adherence with prescribed medication. The World Health Organisation identified between one third to a half of medications prescribed for long-term medical conditions are not taken as directed. There is a lack of studies in an Irish context which profiles patients level of adherence and understanding which prescribed medication in the management of RA. The aim is to measure patients' adherence and factors influencing adherence with prescribed medications for Rheumatoid Arthritis.

Method: A Self-report questionnaire was administered to 200 randomly selected patients attending a Rheumatology Rehabilitation Unit. Data collection included demographic details, disease profile, medication usage, MARS score, MTQ score, and health beliefs.

Results: Response rate of 40% (n=80) achieved. 82% were over 50 years of age and a ration of female to male of 3:1 was recorded. 55% (n=44) had disease duration > 10 years. 64% (n=51) self-reported that they were adherent to their medications as prescribed. 80% (n=57) frequently seek information about their RA while 97% (n=72) believe they themselves were responsible for their own health. 34% reported having been seen by the Rheumatology Nurse Specialist.

Conclusion: This is the first designated Irish study exploring patients' adherence with prescribed medications for RA. It has revealed there was no relationship found between gender, disease duration, education or visits to the Rheumatology Nurse Specialist and adherence. Patients are requesting more education into their disease and disease management. More structured education needs to be developed by healthcare professionals and disseminated to the patients. Further research that is more extensive is required into this phenomenon.

Decision Aid Formats to Communicate the Effect of DMARDs On Structural Joint Damage in Rheumatoid Arthritis.
Matthew E. Brower[1], Donald J. Tellinghuisen[1], Patience J. Gallagher[1] and Richard W. Martin[2], [1]Calvin College, Grand Rapids, MI, [2]Michigan State University College of Human Medicine, Grand Rapids, MI

Purpose: A discussion regarding changing disease modifying anti-rheumatic drugs (DMARD) takes place in about 25% of rheumatology office visits.[1] The power to slow progression of structural joint damage (SJD) is a distinguishing DMARD attribute considered in this discussion. Rheumatoid arthritis (RA) patients, like most people, have difficulty accurately interpreting numeric statements of risk.[2] This study explored how potential presentation formats used in a patient decision aid effected comprehension of a DMARD's ability to slow RA SJD.

Method: Ninety-one healthy volunteers were presented with one of four written scenarios. Each contained a brief introduction to RA, description of SJD, and a statement of the % reduction in SJD progression rate associated with a hypothetical drug. Participants were randomly assigned to narrative only (N), or one of three alternative formats: N + graphic representation of SJD over time, N + natural frequency pictograph, and N + speedometer metaphor. Each of these formats combined N with a visual depiction of SJD progression and provided identical risk information. All four experimental groups' participants then answered 5-point Likert scale questions derived from the COMRADE[3], rating the quality and participant satisfaction with the information. In addition, verbatim recall of the rate SJD would progress (0-100) and rate SJD would be reduced (0-100) was evaluated. Average responses to COMRADE questions were evaluated with one-sample T-test to compare mean response to 3 (neutral value) for each group. Between group differences recalling SJD progression rates were evaluated with one-way ANOVAs.

Results: One-sample t-tests indicate that responses did not significantly differ from the neutral value (3) to the statement, "materials gave enough explanation about how the medicine slows joint damage" in the N + graphic, N + natural frequency and N + speedometer conditions. In the N condition, however, participants significantly disagreed with that statement ($M = 2.40$, $p = .004$). A similar, although non-significant, pattern was shown regarding whether materials left participants "adequately informed" about decision issues. One-way ANOVAs indicated that across all conditions, participants underestimated the slowing in rate of progression associated with use of the hypothetical drug. Participants tended to more accurately rate the progression in the N + natural frequency pictograph and N + speedometer metaphor compared to N and N + graphic representation of SJD over time. These differences, however, were not significant ($p < .05$).

Conclusion: Patient decision aid risk presentation format can enhance patient acceptance of numeric statements of risk and may potentially affect accuracy of subject recall of the benefits of anti-rheumatic drugs to slow structural joint damage in RA.

1872

Exploring the Ways People with Early Rheumatoid Arthritis (RA) Medically Self-Manage. Paul M. Adam[1], Anne F. Townsend[2], Susan M. Cox[2], Catherine L. Backman[2], Zubin Amarsi[3], Linda C. Li[2] and ERAHSE team, [1]Mary Pack Arthritis Centre, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Purpose: The Chronic Care Model (Wagner, 2001) aims to provide patients with timely and effective health care. Successful self-management is a key element of this approach. In this study we focus on the various ways study participants medically self-managed their rheumatoid arthritis (RA) early post-diagnosis.

Method: 46 (8 pilot study, 38 ERAHSE study) adults with early RA defined as ≤ 12 months post-diagnosis were recruited from rheumatologists, family physicians, and patient advocacy newsletters. In-depth face-to-face interviews were organized around three overlapping sections: onset of symptoms and initial illness actions; seeking help from health professionals leading to diagnosis; and post-diagnosis experiences. Follow-up phone calls were made to check and elaborate on data gained at interview. Two researchers read the initial transcripts independently. Emergent themes were identified through discussion and negotiation, constant comparisons made between and within transcripts, and both diverse and common experiences sought. Subsequent transcripts were read with initial findings and the literature in mind. To aid conceptual clarity, we used Koch and colleagues (2004) three models of self-management (the medical, collaborative, self-agency models), as a heuristic device.

Results: The data revealed several emerging and cross-cutting themes showing that post-diagnosis medical self-management is complex and dynamic. Personal beliefs and values, past medical experiences, knowledge of others with RA, media sources, and relationships with practitioners impacted how people interpreted and understood their symptoms, disease, and treatment options; gained information; and made treatment decisions. Against the backdrop of Koch's self-management models, our results revealed that (1) people move between models over time, (2) people use a combination of models depending on the type and nature of the treatment intervention, and (3) there are inherent difficulties in practicing each model of self-management, such as knowing what questions to ask practitioners, where and how to seek reliable information, and how to attribute cause and effect when assessing treatment benefits. An improved sense of body awareness, recording of treatments and outcomes, and trial & error are all techniques that were found to support medical self-management.

Conclusion: People medically self-manage in a range of ways, and move between models. Practitioners need to be aware of these variations in order to provide support and care that is consistent with patient needs and priorities as they self-manage.

Clinical Correlates of Sexual Impairment in Women with Systemic Sclerosis. Ruby Knafo[1], Brett D. Thombs[2], Fredrick M. Wigley[3] and Jennifer A. Haythornthwaite[4], [1]McGill University, Montreal, QC, [2]McGill University and Jewish General Hospital, Montreal, QC, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD

Purpose: The objective of this study was to assess the correlates of sexual impairment in a sample of women with systemic sclerosis (SSc).

Method: Female SSc patients completed measures of sexual function (Sexual Relationships subscale of the Psychosocial Adjustment to Illness Scale – Self-Report; PAIS-SR), body image (Satisfaction With Appearance Scale; SWAP), and pain (Visual Analog Scale; VAS). Sociodemographic and disease specific variables were recorded. Pearson correlations and multiple regression analyses were run to assess the associations between body image, pain, and sociodemographic and disease variables, with sexual function.

Results: 117 female SSc patients were sampled (33 [28.2%] diffuse; mean age 51.4±11.9 years; mean time since diagnosis 9.1±8.5 years). Unadjusted analyses revealed a moderate positive correlation between sexual function and pain ($r = 0.439$, $p < 0.001$), satisfaction with appearance ($r = 0.350$, $p < 0.001$), and a moderate negative correlation with being married ($r = -0.338$, $p = 0.000$). Adjusted analyses revealed that being married ($\beta = -0.228$, $p = 0.006$), disease duration ($\beta = 0.171$, $p = 0.046$), and pain ($\beta = 0.290$, $p = 0.001$) are independent predictors of sexual function. Satisfaction with appearance was not independently associated with sexual function ($\beta = 0.158$, $p < 0.067$).

Conclusion: This is the first empirical study to investigate the clinical correlates of sexual impairment in women with SSc, and the first to document the association between sexual impairment and pain in women with SSc. Pain, longer disease duration, and not being married are associated with increased sexual impairment in women with SSc.

1874

Sexual Relationships in Rheumatoid Arthritis: The Development and Use of the ASBLA Model. Gill Grundy[1], Robert J. Moots[1], John A. Goodacre[2], Alan Riley[3] and Lynne Goodacre[2], [1]University Hospital Aintree, Liverpool, United Kingdom, [2]Univ of Central Lancashire, Preston, United Kingdom, [3]UCLAN, Lancashire, United Kingdom

Purpose: Rheumatoid arthritis [RA], a chronic inflammatory joint disease, impacts on all aspects of peoples' lives, including their sexual relationship. This study aimed to explore the impact of RA on the sexual relationships and sexual function of patients and partners of people with RA, and to investigate communication between couples and healthcare professionals on this issue.

Method: A mixed method approach, within a phenomenological paradigm was adopted, comprising semi-structured interviews and validated questionnaires. Interviews were used to collect detailed insights of participants' experiences and questionnaires to provide demographic, clinical and relationship data. Purposive sampling ensured a heterogeneous population in terms relationship status, disease duration and disease activity. Interpretative phenomenological analysis facilitated by ATLAS-ti guided analysis of the qualitative data. Questionnaire data was analysed using descriptive statistics. Ethics approval was obtained and participants were recruited from 2 out-patient rheumatology departments.

Results: Fifty-one participants, 16 male and 15 female patients 10 male and 10 female partners were recruited. Age range 27–70 years, disease duration 1-30 years. Data analysis identified 5 super-ordinate themes: Adjustment, Self-image, Balance, Limitation Acceptance [ASBLA] which informed the ASBLA model. This model highlights the importance of locating sexual activity within the wider relationship context. It represents the major challenges RA posed to sexual relationships: the need to adjust to the impact of the impairment: challenges to self image: limitations placed on sexual activity: acceptance of the changing status of RA. Informed by individual participant approaches to these challenges it also identifies mediators to the impact of RA: knowledge, understanding, communication and commitment. Communication between patients, partners and healthcare professionals [HPCs] was found to be limited.

Conclusion: Whilst highlighting the relationship challenges participants faced, this study provided insights into their positive experiences providing a reminder that positive sexual relationships are possible and that, given the right support, challenges can be overcome. The ASBLA model has the potential to be used as a tool to facilitate dialogue between patients/partners and HCPs and could be used to help HCPs develop an understanding of the relationship challenges patients with RA and their partners face.

1875

Depression and Couple Mutuality in Prospective Data From Rheumatoid Arthritis Patients. Shelley Kasle[1], Patrick E. McKnight[2] and Mari S. Wilhelm[1], [1]Univ of Arizona, Tucson, AZ, [2]George Mason University, Fairfax, VA

Purpose: Social support, including couple relationship quality, has important implications for the health of Rheumatoid Arthritis (RA) patients. Depression is prevalent in RA and predicts increased inflammation. Mutuality, measured as the frequency of engaged, empathic, authentic responses during important couple communications, has been inversely linked with depression in RA patients in cross-sectional data. The purpose of this study was to test the hypothesis that higher levels of mutuality are consistently linked with lower levels of depression in prospective data from RA patients.

Method:

Married/partnered RA patients (N=156; 76% female, mean age = 56 yrs, mean RA duration = 8 yrs) completed 4 questionnaires at 0, 6, 12, and 18 months. Packets included valid, reliable measures of couple mutuality (Mutual Psychological Development Questionnaire),depression (CES-D), and control variables: daily hassles (Daily Stressors Checklist), affect (Positive and Negative Affect Scales), and counts of chronic health conditions. Hierarchical regression was used to estimate additive effects on depression of the variables (in order): intercept, timepoint, health conditions, daily hassles, positive affect, negative affect, mutuality, and a mutuality X timepoint interaction.

Results: All predictors in the model had significant effects on depression (Table 1). Timepoint had an inverse effect, equal to a 6.084-point decrease in the depression score for each wave (P <.001). After accounting for prior predictors in the model, mutuality exerted a significant inverse effect, with each point increase in the mutuality score associated with a 3.74-point decrease in the depression score (P < .001). A positive interaction of mutuality with timepoint reflected a floor effect in depression scores at later timepoints.

Conclusion: Consistent with hypothesis, RA patients who reported more couple mutuality reported less depression at each timepoint. This consistent inverse effect of mutuality on depression emerged after accounting for other effects, including a large effect of timepoint. These results suggest a potentially protective effect of mutuality on depression. As depression is a risk for worse RA outcomes, mutuality may be a useful prognostic indicator. With more research, mutuality may emerge as a therapeutic target for psychosocial interventions.

Table 1. Hierarchical Regression of Depression (N=156)

Predictors	Estimates*	(SE)	P
Intercept	29.363	3.816	<0.001
Timepoint	-6.084	1.287	<0.001
Health Conditions	0.385	0.157	0.014
Daily Hassles	0.562	0.114	<0.001
Positive Affect	-3.570	0.277	<0.001
Negative Affect	5.583	0.405	<0.001
Mutuality	-3.742	0.776	<0.001
Mutuality X Timepoint	1.044	0.285	<0.001

*Unstandardized regression coefficients

1876

Younger Subjects with Chronic Musculoskeletal Pain and High Depression Scores Benefit the Most From a Cognitive Rehabilitation Programme. Ann B. I. Bremander and Stefan Bergman, R&D Center Spenshult, Oskarstrom, Sweden

Purpose: Chronic musculoskeletal pain is a major health care problem. The recommended treatment is multimodal with a cognitive approach to maintain the effects over time. However, it is not clear as to who will benefit the most from a specific form of treatment. The aim of this study was to explore who a multimodal treatment with a cognitive approach will benefit the most concerning health related quality of life outcome (HRQoL).

Method: 131 subjects who participated in a rehabilitation programme with a non pharmacological cognitive approach were followed by patient reported outcome measures. The Hospital Anxiety and Depression Scale (HADS), the Short Form 36 question health survey (SF-36), pain and global health measured with a visual analogue scale (VAS) and a pain mannequin were administered at admission and 6 months later at the end of the treatment period. For analysis of change due to intervention t-test was used and categorical values were analyzed using chi-square tests. Multivariate analysis was performed to study associations between explanatory personal characteristics and an improved outcome in HRQoL measured by the SF-36 subscales physical function, bodily pain, vitality and mental health.

Results: Complete data were available for 97 patients (85 women, mean age (SD) 44.6 (9.7)). VAS pain improved significantly ($p<0.05$) during the rehabilitation period, so did HADS and SF-36 subscales physical function, general health, vitality, social functioning and mental health.

In the multivariate analysis scores suggesting a probable depression (≥ 11) were associated with a favourable outcome of the SF-36 subscale physical function (OR 4.6, p 0.04), bodily pain (OR 2.5, p 0.12), vitality (OR 4.7, p 0.03) and mental health (OR 2.8, p 0.11). Sex, age, anxiety, pain and pain distribution were not associated with improved outcome of HRQoL. However, there was a stronger association for younger subjects (20-45 years) with probable depression scores and a favourable HRQoL outcome in the subscales physical function (OR 21.6, p 0.01), bodily pain (OR 5.9, p 0.04) and vitality (OR 8.1, p 0.04).

Conclusion: This multidisciplinary rehabilitation programme with a non pharmacological cognitive approach seemed to yield a better outcome concerning HRQoL measures in younger patients with higher depression scores at baseline. This is important information to the clinics when tailoring a multidisciplinary rehabilitation programme for patients with musculoskeletal chronic pain.

1877

Body Composition and Disability Among Women with RA and Lupus. Patricia Katz, Holly Wing, Sandi Kaplan, Rachel Diskin, L. J. Julian, Laura Trupin, J. Yazdany, L.A. Criswell and E.H. Yelin, UCSF, SF, CA

Purpose: Body composition has been linked to disability in the general population. Less research has focused on the role of obesity or body composition in rheumatic conditions, but there is preliminary evidence that body composition may be related to functioning. We examine the relationship between body composition and valued life activity (VLA) disability among women with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Method: Women (RA: n=81, mean age 56; SLE: n=128, mean age 46) underwent dual-energy x-ray absorptiometry (DXA) for measurement of body composition (fat and lean mass). Height-adjusted fat mass (FM) and lean mass (LM) were calculated. Sarcopenia (low muscle mass) was also determined from DXA[1]. Height and weight to calculate body mass index (BMI) were collected at the same visit. VLA disability because of RA/SLE was defined in 3 ways: the mean difficulty rating of 33 activities (range 0 [no difficulty] – 3 [unable to perform]; proportion of activities affected to any degree; and proportion of activities individuals were unable. Associations between body composition and disability were assessed separately for each disease cohort with linear regression, controlling for age.

Results: For RA, mean VLA difficulty was 0.54, VLAs affected 44.7%, and VLAs unable to perform 1.6%. For SLE, mean VLA difficulty was 0.77, VLAs affected 57.8%, and VLAs unable to perfor m 3.6%. In both cohorts, greater FM from DXA and BMI obesity were each associated with greater difficulty and a higher proportion of VLAs affected (Tables 1, 2). Lower LM was associated with greater difficulty and a higher proportion of VLAs affected only in the RA cohort. Sarcopenia was present in 11 women with SLE and 12 with RA, and was associated with both greater difficulty performing and a higher proportion of VLAs unable to perform (Table 3).

Table 1. Association of Disability and Height-Adjusted Fat and Lean Mass

		VLA difficulty	% VLAs affected	% VLAs unable
RA	FM	0.01 (.05)*	1.4 (.01)	-0.02 (.75)
	LM	-0.02 (.03)	-1.5 (.006)	0.03 (.97)
SLE	FM	0.03 (.03)	1.8 (.05)	.22 (.21)
	LM	-0.02 (.68)	0.1 (.97)	-.32 (.51)

Cells are coefficients (p-values) from regression analysis

Table 2. Disability by BMI categories

	BMI category	n	VLA difficulty	% VLAs affected	% VLAs unable
RA	Underweight	0			
	Normal	43	0.50	41.0	2.0
	Overweight	20	0.47	36.8	1.7
	Obese	16	0.75*	67.4*	0.6
SLE	Underweight	3	1.01*	57.5	15.0*
	Normal	48	0.66	51.7	2.0
	Overweight	21	0.67	53.0	2.7
	Obese	36	1.02*	73.8*	5.8

* p<.05 compared to normal BMI

Table 3. Disability by Sarcopenia

	Sarcopenia	n	VLA difficulty	% VLAs affected	% VLAs unable
RA	No	67	0.50	42.1	0.9
	Yes	12	0.82	63.0	5.7*
SLE	No	107	0.74	57.5	2.7
	Yes	11	1.13*	69.5	10.9*

*p<.05 compared to no sarcopenia

Conclusion: Body composition is significantly associated with disability in both RA and SLE. Greater fat mass is associated with increased difficulty performing activities, but low muscle mass appears to be associated with greater activity disruption.

1878

Decreased Physical Activity in RA Women Is Associated with Cardiovascular Risk Factors but Not with Body Fat Mass. Ann-Charlotte Elkan[1], Niclas Håkansson[2] and Ingiäld Hafström[3], [1]Karolinska Institute, Stockholm, Sweden, [2]The National Institute of Environmental Medicine at Karolinska Institute, Stockholm, Sweden, [3]Karolinska Institute, Stockholm, Stockholm, Sweden

Purpose: Many patients with RA have increased fat mass (FM) often associated with decreased fat free mass (FFM), i. e. rheumatoid cachexia (ref). We evaluated if total physical activity (MET-hours) was associated with body composition and cardiovascular risk factors in women with RA.

Methods: Sixty-one out-ward RA women answered a short self-administered physical activity questionnaire, to measure mean long-term (1 year period) total daily physical activity. The physical activity level was measured as metabolic equivalents (MET) x h/day. Mean values (SD) for healthy Swedish women are 40.8 (3.9). Body composition, FM% and FFM, was estimated by whole-body dual-energy X-ray absorptiometry (DXA). Blood lipids, oxidized low-density lipoprotein (oxLDL) and antibodies against phosphorylcholine (anti-PC) were determined. The diet content was assessed by a food frequency questionnaire.

Results: The RA women were 60.8 (57.3-64.4) years, mean (CI), and had a median disease duration of 6 years (range 1-52). DAS28 was mean (CI) 3.3(3.0-3.6), HAQ 0.7(0.5-0.8), BMI 25.0 (23.6-26.3) and total FM% 37.8 (35.7-39.9). Forty-one percent of the women had BMI >25. The median (IQR) total physical activity was 40.0 (37.4-47.7), and 48% of the RA women were less active than healthy Swedish women in the same age. Total physical activity did not significantly correlate with DAS28, HAQ-score, BMI, FM% or FFM at this level of activity. Patients in the lowest quartile of total physical activity did not differ in BMI, FM% or FFM from those in the highest quartile. The women in the lowest quartile had significantly lower values of HDL ($p=0.05$), Apo A1 ($p=0.028$), the atheroprotective natural anti-PC ($p=0.011$) and higher levels of insulin ($p=0.039$) than those in the highest quartile. Insulin resistance was present in 30% of the patients in the lowest quartile and in 13% in the highest. Patients in the lower quartile consumed significantly higher quantities of saturated fatty acids, than those in the highest quartile ($p=0.042$).

Conclusion: This cross sectional study demonstrated that about half of RA women with fairly low disease activity and a good functional capacity were less physically active than healthy Swedish women in the same age. The amount of physical activity was not associated with disease activity, functional capacity or body composition. However, low physical activity was associated with dyslipidemia and insulin resistance, which is of interest in the context of CVD in RA.

Association of Cardiovascular Disease Risk Factors with Ischaemic Manifestations of Giant Cell Arteritis. Esther F. Vicente, Amparo Casado, María J. García-Arias, Juan P. Lopez-Bote, Alicia Humbria, Jesús A. Garcia-Vadillo and Santos Castañeda, Rheumatology. Hospital de la Princesa, Madrid, Spain

Purpose: To describe the prevalence of classical cardiovascular disease risk factors (CVDRF) and the clinical characteristics of a population of giant cell arteritis (GCA) at diagnosis, and to analyse the association of the CVDRF with the ischaemic manifestations of the disease.

Method: Cross-sectional study including 58 patients with biopsy-proven GCA (age at diagnosis: 74.2±7.2 yrs; 86.2% women). Demographic, clinical, analytical (hemoglobin, ESR and biochemistry), arterial ischaemic manifestations, CVDRF [smoking, hypercholesterolemia, diabetes mellitus (DM) and hypertension (HT)] and therapy with immunosupressants (IS) and corticosteroids (CS) were collected. Anemia was defined as Hb<11 g/dl and elevated ESR if >40 mm/h. Arterial ischaemic manifestations were classified as moderate (jaw claudication, “amaurosis fugax”, transient visual loss [TVL] and diplopia) and severe (blindness, stroke, ischaemic heart disease [IHD] and peripheral arteriopathy). Statistical analysis: continuous variables are expressed as mean±SD and categorical as number of cases and percentage (%). The factors associated with the ischaemic manifestations of GCA were evaluated using the Student’s t test, the Fischer exact test or the Pearson’s $\chi 2$ test. Statistical significance was assumed for $p< 0.05$ two-tail tests (Stata, v 10.0).

Results: Follow-up time from diagnosis was 5.5±4.7 yrs. Clinical characteristics: 33 patients (58.9%) headache, 29 (50.8%) polymyalgia rheumatica (PMR) and 20 (37%) pathologic temporal artery examination. Anemia was detected in 25 patients (43%) and elevated ESR in 56

(98.2%). CVDRF were found in 44 patients (75.8%): HT (62.5%), hypercholesterolemia (55.2%), DM (14%) and smoking (5 active [9.6%] & 28 previous [53.8%]). Ischaemic manifestations occurred in 29 patients (50%): 20 jaw claudication (35.1%), 5 “amaurosis fugax” (8.6%), 6 TVL (10.3%), 6 blindness (10.3%), 1 stroke, 1 peripheral arteriopathy and 1 IHD. None had diplopia. Seven patients were classified as severe (12.1%) and 22 as moderate (37.9%). Among severe cases, 4 associated jaw claudication. Bivariate analysis by gender showed an older age at diagnosis in women (p=0.004). HT was associated with higher initial dose of CS (p=0.017) and active smoking with TVL (p=0.044). Multivariate analysis identified HT (p=0.016) and hypercholesterolemia (p=0.018) as the factors associated with moderate ischaemic manifestations. Age at diagnosis and initial CS dose were the only factors associated with blindness (p=0.018 & p=0.028, respectively).

Conclusion: Clinical characteristics of our series are close to previous descriptions by other authors. Jaw claudication and visual impairment are the most frequent ischaemic manifestations in our patients. Our study suggests that classical CVDRF could be associated with some ischaemic manifestations in GCA.

Chronic Foot Symptoms in Relation to Self-Reported and Performance-Based Physical Function. Y.M. Golightly[1], M.T. Hannan[2], X. Shi[1], C.G. Helmick[3], Jordan B. Renner[4] and Joanne M. Jordan[4], [1]Thurston Arthritis Research Center, Chapel Hill, NC, [2]BUSPH, IFAR HSL, Boston, MA, [3]Centers for Disease Control an, Atlanta, GA, [4]The University of North Carolina, Chapel Hill, NC

Purpose: This cross-sectional analysis examines associations of chronic foot symptoms with self-reported and performance-based measures of functional status in a large, community-based sample, controlling for confounders, including presence of radiographic osteoarthritis (rOA) and symptoms in the knee and hip.

Method: Of the 2,705 Johnston County Osteoarthritis Project participants clinically evaluated in 1999-2004, 2,700 had data available for analyses (mean age 63.6 years). Presence of chronic foot symptoms was defined as pain, aching, or stiffness of at least one foot on most days. Physical function was assessed by the Stanford Health Assessment Questionnaire (HAQ) and by two performance-based measures: timed 5 repeated chair stands and 8-foot walk time. Total HAQ score was categorized into 3 levels (0; greater than 0 but less than 1; and ≥1). Timed chair stands was coded into 3-levels (< median completion time of 12 seconds (s), ≥ 12 s, and unable). Timed 8-foot walk was dichotomized at the median completion time (< 3.35s and ≥ 3.35 s). Separate multivariable logistic regression models examined associations between foot symptoms and the three functional status measures, controlling for age, race, gender, measured body mass index (BMI), knee and hip rOA, knee and hip symptoms, and depressive symptoms (CES-D Scale). Interaction terms between each of the self-reported and performance-based measures with each demographic and clinical characteristic were examined.

Results: Participants with chronic foot symptoms were more likely than those without foot symptoms to report greater difficulty with function, as indicated by higher HAQ scores (adjusted odds ratio [aOR]=1.79, 95% confidence interval [CI] 1.50-2.12), and to require more time to complete the 8 foot walk (aOR=1.32, 95% CI 1.08-1.61). Among obese (BMI >30 kg/m2) participants, those with foot symptoms required more time to complete the chair stands (aOR=1.38, 95% CI 1.03-1.86) than those without symptoms, a difference not seen among non-obese (aOR=0.88, 95% CI 0.66-1.18).

Conclusion: Chronic foot symptoms were independently and significantly associated with self-report of greater functional difficulty and longer completion times for performance-based measures. Interventions for chronic foot symptoms may be important for helping patients prevent or cope with an existing decline in perceived and performance-based functional abilities.

Exercise Effects On Self-Reported Functional Tasks in Knee Osteoarthritis. Paulo E.P Teixeira, Sara R. Piva and G. Kelley Fitzgerald, University of Pittsburgh, Pittsburgh, PA

Purpose: Exercise therapy is commonly recommended for people with knee osteoarthritis (KOA). Although this intervention has been beneficial to KOA patients, in general it has yielded only modest improvements on measures of self-reported function[1]. A potential explanation for these modest effects may be that exercise therapy is typically impairment-based and may only improve some functional tasks while not having much effect on other tasks included in self-reported function measures. Understanding whether or not exercise therapy can influence self-reported ratings of various functional tasks may lead to refinement of rehabilitation programs to improve physical function in people with KOA. Therefore the purpose of this study was to determine the effect of exercise on the specific functional tasks assessed in self-reported function measures.

Method: Sample:159 KOA patients (65%female, mean BMI: 30.1 ± 6.3) aged between 40 - 85 years old who completed a standard KOA rehabilitation program consisting of lower extremity stretching and strengthening, aerobic activities, and balance and agility activities. Using baseline and post-treatment (2 months) data from 3 questionnaires of self-reported function (Western Ontario and McMaster Universities – WOMAC; Lower Extremity Functional Scale – LEFS; Activities of Daily Living Scale - ADLS), the level of change in the specific functional tasks (e.g. "climbing stairs", "walking" or "rising from a chair") assessed in each questionnaire was calculated. Using statistical methods for paired ordinal categorical data, the probability of an improvement in specific functional task performance after treatment was determined using relative position (RP) analysis[2]. The RP value is an estimation of the probability that subjects will rate their ability to perform a specific functional task as changed following the intervention period. RP values range from -1 to 1. Positive RP values reflect the probability of an improvement in function. Negative values reflect the probability of worse function.

Results: RPs for all functional tasks reported on the WOMAC, LEFS and ADLS items were low and ranged from 0.14 – 0.23, 0.05 – 0.28, 0.08 – 0.15 respectively. The probability of an improvement in specific functional task performance after treatment was never greater than 23% for the WOMAC, 28% for the LEFS and 15% for the ADLS. **Conclusion:** Impairment-based exercise therapy does not seem to have more than small effects on subject perception of ability to perform task-specific functional activities. Our findings may indicate the need for current KOA rehabilitation programs to incorporate task-specific training to better improve functional outcomes.

Exercise Program Elements Deemed Important by Physiotherapists in Exercise Prescription Following Osteoporotic Fracture. Lynne M. Feehan[1], Linda C. Li[1], Donna MacIntyre[1], Susan Harris[1], Amy Kirkham[1] and Osteo-fx review team[2], [1]University of British Columbia, Vancouver, BC, [2]Vancouver, BC

Purpose: Exercise is a complex intervention. A major challenge to exercise prescription is identification of the optimal exercise program elements for favorable treatment outcomes. The purpose of this study was to identify those components that physiotherapists (PTs) deem most effective for people recovering from osteoporotic fracture.

Method: We conducted an online survey of members of a national physiotherapy association. The survey was targeted at those members who participated in a teleconference on exercise prescription following osteoporotic fracture. The survey evaluated 15 exercise program components, which were identified through a review of post-fracture exercise intervention themes from a scoping review of over 9,500 articles exploring exercise prescription following osteoporotic fracture. The PTs were asked to identify the importance of each program element to clinical practice in their facility and the element most effective for optimizing health outcomes in four domains: *fracture healing, functional recovery, secondary fall and fracture prevention and health care costs*. Findings were used to specify key exercise program elements as a focus for data extraction, and will inform a Bayesian multivariable meta-regression analysis of a systematic review of exercise after osteoporotic fracture.

Results: 188 PTs responded to this survey. The majority (56%) of PTs had over 15 years of clinical experience. Over 90% of PTs ranked the following elements as somewhat or very important in their clinical practice: 1) timing of exercise initiation after fracture, 2) a regional exercise focus (e.g. ROM or strengthening exercises), 3) a physical performance exercise focus (e.g. balance training or walking) and 4)

dosage (e.g. number of exercise sessions). Whereas, less than 70% of PTs identified location of exercise facility, monitoring of exercise adherence, specialized training and a physical activity exercise focus (e.g. yoga or aquatic) as somewhat or very important in thier clinical practice. 53% of participants ranked timing of exercise initiation as the most effective factor contributing to favorable post-fracture healing outcomes. A physical performance exercise program was ranked most effective by 39% and 24%, respectively, for post-fracture functional recovery and for secondary fall or fracture prevention outcomes. 34% ranked the design of the program, such as an individualized, standardized or multidisciplinary exercise program, as the most effective factor for influencing post-fracture health care cost.

Conclusion: Identifying exercise characteristics deemed important by PTs provided valuable clinician input regarding the effect of specific elements of an exercise program on post-osteoporotic fracture recovery. Incorporating the perspective of practicing clinicians is an informative and important strategy to guide the analysis of systematic reviews of complex interventions like exercise.

Falls Prevention in Persons with Osteoporosis: A Randomized Clinical Trial. Ellen Smulders[1], Vivian Weerdesteyn[2], Jacques Duysens[3], Roland Laan[2] and Wim Lankveld[1], [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]K.U.Leuven, Leuven, Belgium

Purpose: Persons with osteoporosis are particularly at risk for fall-related fractures, because of decreased bone strength. It has been shown that exercise programs can prevent falls and fall-related injuries in the elderly. [1] For instance, the 'Nijmegen Falls Prevention Program' ('NFPP') has shown to be successful with a 46% reduction in the number of falls in community-dwelling elderly. [2] However, patients with osteoporosis were excluded from this program, because of safety reasons. The benefits of a falls prevention program for patients with osteoporosis, however, are expected to be large. Therefore, the NFPP was adjusted for patients with osteoporosis and evaluated for its efficacy in a randomized clinical trial.

Method: A total of 92 persons with osteoporosis (mean age (SD): 71.0 (4.7), 86 female, 6 male; T-score $\leq$ -2.5) participated. After a baseline measurement (M1), participants were randomly allocated to an exercise (n=47) and control group (n=45). Subsequently, the exercise group participated in the NFPP for persons with osteoporosis (5.5 weeks) whereas the control group received usual care. After the program had ended the second measurement took place (M2) followed by the third (M3) after one year. Primary outcome measure was fall incidence, measured for one year with monthly fall registration cards. At M1, M2 and M3 balance confidence (ABC-scale), quality of life (qualeffo-41) and activity level (pedometer) were assessed.

Results: Fall incidence rates decreased by 39% in the exercise group compared to the control group (0.72 vs. 1.18 falls/year, IRR= 0.61 (95% CI 0.40-0.94)). There was a significant GroupxTime interaction (p=0.038) for balance confidence. Quality of life and activity levels remained the same in both groups for all three measurements.

Conclusion: Since the results show that the program was effective in reducing the number of fall incidents and increasing the balance confidence of the participants, it is concluded that it is a valuable new alternative tool for the prevention of falls and fractures in elderly subjects with osteoporosis.

Health Disparities in Rheumatic Disease

Tuesday, October 20, 2009, 9:15 AM - 10:15 AM

1884

Severity of Rheumatoid Arthritis in Oklahoma Native Americans. Angela D. Genovese[1], Joe C. Rawdon[2], Sheryl Delancy[2], Sanober Malik[2], Nicholas Knowlton[3], Stephen Apel[2], Debbie Gladd[2], Joan T. Merrill[3] and Ewa Olech[3], [1]Oklahoma Med Rsrch Foundation, Oklahoma City, OK, [2]Oklahoma Med Resrch Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: Rheumatoid arthritis (RA) is prevalent in Native American populations, and severe disease is often described. Few publications have systematically compared disease activity between Southwestern Native Americans and other groups.

Methods: A cross-sectional analysis of 160 patients referred from Indian Health Services (IHS) and Primary Care Offices to the Oklahoma Rheumatoid Arthritis Cohort was performed. Medical history, medications, and serologies were reviewed. Disease activity was assessed with 28 Tender and Swollen Joint Counts, duration of AM Stiffness, pain scale, and Physician Global Assessment. Patients were selected for this study by self-reported ethnicity in three categories: Native Americans (NA) (n=62), Caucasian (CAUC) (n=81) and African descent (AA) (n=17).

Results: There were no differences in gender, age, disease duration, or the likelihood of taking prednisone or methotrexate between the groups. The dose of methotrexate was lower in NA than other patients: 15 vs 17.5 mg/wk ($p < 0.05$) . Exposure to biologics was significantly different, only 3 NA were prescribed anti-TNF and none received Rituximab or Orencia ($p <0.005$ vs all others, $p=0.002$ vs CAUC). There were modest trends towards increases in most inflammatory markers, serology titers, and DAS 28 vs other pts (p=ns). NA had higher ANA titers ($p =0.045$ vs AA and 0.07 vs CAUC) and higher anti-CCP titers than AA ($p=0.01$). NA were similar to CAUC in median length of AM stiffness (60 vs 60 min), median tender jts (11 vs 13) and swollen jts (12 vs 12), but had higher values than AA ($P < 0.03$ in each case). Numbers of tender and swollen joints do not necessarily reveal severity of inflammation. NA reported more pain with VAS = 64.1 vs 54.3 for CAUC ($p=0.055$) and 42.4 for AA ($p=0.012$) and median physicians global assessments were significantly higher for NA: 64.1 vs 53 for CAUC ($p=0.05$) and 50 for AA ($p=0.014$).

Conclusion: These data suggest consistent, but modest trends towards worse disease activity in NA pts compared to CAUC and increased severity compared to AA. A significant discrepancy in access to biologic treatments at a similar stage of disease, and increased patient-reported pain as well as physician assessment of global disease severity confirms that NA may be a particularly vulnerable population with RA.

1885

Associations of Education, Occupation and Community Poverty with Knee Osteoarthritis (OA). Leigh F. Callahan, Jack Shreffler, Todd Schwartz, Britta Schoster, Jordan B. Renner and Joanne M. Jordan, University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose: Education and occupation, individual level measures of socioeconomic status (SES), have been demonstrated to be associated with OA outcomes in numerous studies, but to date community SES measures have not been evaluated in OA. In other chronic diseases and in self-report arthritis of any type, the poverty rate of one's community was found to be associated with disease prevalence and health status outcomes independent of a person's education level. This study examined associations between education, occupation, and community poverty with radiographic knee OA (rOA), knee symptoms, and symptomatic knee OA (sympOA) in the Johnston County OA Project.

Method: A cross-sectional analysis was conducted on 4098 individuals (65% White and 35% African American [AA]) who resided in 67 of the 68 census block groups of Johnston County NC. Education (<high school (HS) degree or ³HS) and occupation (physically demanding or not) were used as individual measures of SES. Census block group household poverty rate (<12%, 12-25%, >25%) was used as a measure of community SES. Covariates included age, gender, race, current smoking, and BMI. Three outcomes were assigned as a finding in one or both knee joints: rOA defined as Kellgren-Lawrence grade ³2, knee symptoms (pain, aching or stiffness on most days), and sympOA (symptoms and rOA in the same joint). Race was evaluated for effect modification and not found so multiple logistic regression models of the whole sample were used to determine associations of outcomes with each of the main SES effects, adjusting for covariates. Multivariate analyses were also conducted with all 3 SES variables in the model simultaneously, adjusting for the covariates and allowing for random intercepts based on block groups.

Results: In bivariate analyses with education and the covariates, <HS was significantly associated with rOA (OR=1.4, CI 1.2, 1.6), symptoms (OR=1.7, CI 1.5,2.0), and sympOA (OR=1.6, CI 1.3,2.0). In bivariate analyses, occupation was significantly associated with symptoms (OR=1.5, CI, 1.3,1.8) and sympOA (OR=1.3, CI 1.03,1.6). Residing in a block group with >25% poverty (with referent <12% poverty) was significantly associated with rOA (OR=1.8, CI 1.3,2.5) and sympOA (OR=1.5 CI 1.1, 2.1) in bivariate analyses. In the multivariate regression models including all 3 SES variables simultaneously, adjusting for the covariates, <HS (OR=1.4, CI 1.1,1.6) and poverty >25% (OR=1.8 CI 1.3,2.4) were significantly associated with rOA. <HS (OR=1.6, CI 1.3, 1.9) and a physically demanding occupation (OR=1.3, CI 1.1, 1.5) were associated with symptoms, but poverty rate was not. And, <HS (OR=1.6, CI 1.3, 1.9) and poverty >25% (OR=1.5, CI 1.1, 2.0) were associated with sympOA.

Conclusion: Both individual and community SES measures were independently associated with knee OA in a population-based study of individuals from a rural community, after adjusting for some of the primary risk factors for knee OA including age, BMI, gender and smoking.

1886

Associations Between Individual and Community Socioeconomic Status (SES) Measures with Psychosocial Outcomes in Individuals with Arthritis. Leigh F. Callahan[1], Jack Shreffler[1], Britta Schoster[1], Jay Kaufman[2] and Todd Schwartz[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]McGill University, Montreal, QC

Purpose: To examine associations between individual level (education, income, occupation and home ownership) and census-based community-level (% poverty rate) SES measures with psychosocial outcomes in individuals with self-reported arthritis.

Method: In 2004-2005, 1307 arthritis participants from urban and rural areas in the southeast completed a telephone survey assessing health status, chronic conditions, health attitudes and beliefs, and socio-demographic variables. Education [< high school (HS), HS degree, and > HS], income [<15, 15-45, >$45K] , occupation [professional, or not], and home ownership were individual level SES measures. The 2000 U.S. Census block-group-level variable "% of individuals living below the poverty line" (trichotomized into low, medium, high) was used as the community SES measure. Outcomes included the SF-12v2 Mental Component Summary (MCS), the CDC Health Related Quality of Life (HRQOL) Healthy Days mental health component, and the CES-D depression measure. Regression analyses with clustering on study sites were performed with STATAv9 and included adjustment for race, gender, BMI, and age in all cases.

Results: When entered separately, lower education, lower income, non-professional occupation, and no home ownership were significantly (all p<.05) associated with poorer MCS, mental health days, and CES-D scores. Income, however, was more strongly associated with the outcomes than the other individual SES variables. For example, the MCS score is 7.2 higher for people in the high income group and 3.4 higher for people with >HS (both compared to <0.05). The highest block group poverty is significant (p<0.05) for high CES-D score when education, homeownership, or occupation are in the model, but becomes non-significant when income is in the model. Finally, a complete model with all 4 individual SES measures and block group poverty shows income significant for each of the 3 outcomes of mental health, with the MCS score 6.05 higher for the high income group. There was no significance for homeownership, and marginal significance only for occupation associated with MCS and block group poverty associated with mental health days.

Conclusion: When 4 individual SES measures are examined for associations with psychosocial outcomes in people with arthritis, poorer status on all outcomes is associated with lower SES levels. Income, however, is the strongest predictor of poorer psychosocial status. Community SES measured by block group poverty rate is mainly associated with CES-D when individual income is not included as a modeling variable.

1887

Socioeconomic Burden of Psoriatic Arthritis in Hong Kong: Direct and Indirect Costs and the Influence of Disease Pattern. Tracy Zhu[1], Lai-Shan Tam[1], Ying-Ying Leung[2], Lai Wa Kwok[3], Kong-Chiu Wong[3], Emily W. Kun[4] and Edmund K. Li[1], [1]The Chinese University of Hong Kong, Hong Kong, China, [2]North District Hospital, Hong Kong, China, [3]Prince of Wales Hospital, shatin,NT, Hong Kong, [4]Tai Po Hospital, Hong Kong, China

Purpose: There is less information about the economic burden of illness in psoriatic arthritis (PsA). We performed a cost-of-illness analysis on patients with PsA in Hong Kong to estimate the direct costs and indirect costs of PsA. We also attempt to identify the independent costs predictors for the whole cohort, as well as patients with peripheral and axial disease respectively.

Methods: A retrospective cost-of-illness study was performed on 125 PsA patients, diagnosed according to ClASsification critera for Psoriatic ARthritis. Participants completed questionnaires on sociodemographics, employment status and out-of-pocket expenses. Health resources consumption was recorded by chart review and patient self-reported questionnaire. Details relating to direct costs of the disease were collected for the preceding 12 months, consisting of use of all types of hospital or clinic services. Human capital approach was used to calculate indirect costs Patients were grouped according to disease pattern, i.e. peripheral and axial disease. Multiple regression was used to determine the predictors of the costs.

Results: The mean (SD) age of the cohort was 47 (12) years old. The average annual direct costs were $4,275 (2006 USD) per patient. Costs of inpatient care accounted for 26% of direct, followed by costs of visits to healthcare providers (24%). The estimated average indirect costs were $3,127 per patient-year. Forty-eight (42%) patients incurred no indirect costs. One hundred and one patients were defined as having peripheral disease, whereas 24 with axial disease. No difference in demographics, clinical characteristics and annual direct costs was found between the two groups. Sixty percents of patients with peripheral disease were still employed, compared to 39% of patients with axial disease. Patients with axial disease incurred almost twice indirect costs than those with peripheral disease (p=0.005). Increased pain and poor function were independently associated with increases direct costs. Worse physical health status, determined whether indirect costs were incurred. Once they were incurred, poor function and old age predicted high costs.

Conclusion: Both direct and indirect costs of PsA are substantial. Patients with axial disease had lower employment rate and generated higher indirect costs compared to those with peripheral disease. There was no difference in peripheral joint involvement between the two groups. The higher indirect costs in patients with axial disease are probably due to the burden incurred by spondyloarthritis, which may further impair patients' capability of being employed. Increased pain and poor function predict high direct costs, and poor physical health and function, and old age predict high indirect costs. Our results justify appropriate monetary expenditure for research and therapy in PsA.

ARHP Concurrent Abstract Session

Pediatrics and Parenting

Tuesday, October 20, 2009, 10:45 AM - 11:45 AM

1888

Pediatric Rheumatology Improvement Network for Clinical Excellence and Safety - PRINCES. E. Morgan DeWitt[1], M. Passo[2], Y. Kimura[3], T. Beukelman[4], Beth S. Gottlieb[5] and P. Margolis[6], [1]Duke University Medical Center, Durham, NC, [2]MUSC, Charleston, SC, [3]Hackensack Univ Medical Ctr, Hackensack, NJ, [4]Univ of Alabama, Birmingham, AL, [5]Schneider Childrens Hospital, New Hyde Park, NY, [6]Cincinnati Children's Hospital, Cincinnati, OH

Purpose: Currently, there is tremendous variability in care of patients with juvenile idiopathic arthritis (JIA). Determinants of patient outcomes, or key drivers, are not systematically collected, measured or tracked in most pediatric rheumatology centers. PRINCES will use a population registry and population management report to plan delivery of care and improve care for JIA patients.

Method: The PRINCES Collaborative will engage clinical improvement teams to work together over two 18-month periods to achieve measurable improvements in the care provided to patients with JIA. Participating sites will develop local improvement teams, with a physician champion. Teams will receive quality improvement training and support from the Cincinnati Children's Center for Health Care

Quality. Teams will receive expert coaching on applying well established, evidence based strategies for chronic disease management to JIA, including self-management support, delivery system design, decision support and clinical information systems. Teams will meet at periodic intensive Learning Sessions. In between, they will submit performance data monthly along with summaries of changes being tested; this information will be posted on a project "extranet" for shared learning across the Collaborative. Benchmarking can be identified by analysis of the data from participating practices and shared information can improve the processes of care in collaborating centers. Teams will be supported and connected via a listserv and monthly conference calls. Teams will use a Collaborative population registry and a population management report to plan and deliver care.

Results: Quality measures derive from the ACR supported Quality Measures Workgroup study through nominal group techniques. The Collaborative will focus on the following domains over the two project phases: Measurement and evaluation of the proportion of patients meeting criteria for "inactive disease", safe use of therapeutics, consistent best practice care, satisfactory optimization of health status and functional outcomes, patient/family satisfaction with care.

Conclusion: Quality improvement methods can reduce variation in care by identifying and testing approaches to care delivery. This reduction in variation leads to practice efficiency by improving processes of care, increased patient safety, and improved outcomes for patients. Reduction in variation also facilitates research by increasing statistical power. PRINCES will apply the science of quality improvement to the treatment of JIA. Participation in this improvement collaborative will fulfill Maintenance of Certification requirements for QI work needed for recertification by the American Board of Pediatrics.

Pain and Mood as Predictors of Sleep Quality in Children with Polyarticular Arthritis. Maggie Hood Bromberg[1], Karen M. Gil[1], Kelly K. Anthony[2] and Laura E. Schanberg[3], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Duke Unvi Medical Ctr, Durham, NC, [3]Duke University Medical Center, Durham, NC

Purpose: Since pain and depressed mood are associated with sleep problems in children with chronic illness, we examined the role of mood and pain in predicting sleep quality in children with polyarticular arthritis.

Method: The sample consisted of 51 children with polyarticular arthritis (31 girls; 84% Caucasian; mean age 12.4 years). All children were participating in a larger study that included a baseline assessment and daily reports of pain, mood, stress, coping and disease symptoms completed over a two month period, from which the present data were gathered. An active joint count and a physician global assessment (PGA) were completed by a pediatric rheumatologist at baseline. Children rated their current pain and sleep quality during the previous night on 100mm visual analogue scales. Daily mood was assessed via the *Facial Affective Scale* (FAS). Descriptive statistics were performed and daily reports were aggregated to produce an average score on each daily variable for each child. Following Pearson-product moment correlations, a hierarchical regression using the aggregate data was conducted to examine predictors of sleep quality.

Results: Children had mild to moderate disease severity (mean PGA = 31.5mm) with active arthritis in 9 joints on average. Across the diary reporting period, children endorsed moderate to high sleep quality (mean = 75.3mm) and positive mood (mean FAS = 2.8). Correlations revealed no significant relationships between disease-related variables and sleep quality. Both aggregated pain (r = -.61, p < .0001) and mood (r = -.58, p < .0001) were highly correlated with sleep quality. Hierarchical regression revealed that both pain (ΔR^2 = .34, p < .0001) and mood (ΔR^2 = .14, p < .001) predicted a significant proportion of variance in children's sleep quality ratings after controlling for disease severity and active joint count Indicating that increased pain and less positive mood are associated with poor sleep. The interaction between pain and mood did not significantly predict variance in sleep quality. The final model uniquely accounted for 49% of the variance in sleep quality.

Conclusion: These results provide further support for the relationship between pain and sleep in children with arthritis. Furthermore, mood plays a significant role in predicting sleep quality. Health care professionals should assess for sleep difficulties as part of clinical care and future research should investigate longitudinal relationships between pain, sleep, and mood, as well as the impact of sleep difficulties on daily function in children with arthritis.

Parenting Experience of Mothers with and without Inflammatory Arthritis. Catherine Backman[1], Andrew Chalmers[1], Pam Montie[2] and Diane V. Lacaille[1], [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Vancouver

Purpose: Arthritis may limit participation in life roles such as parenting. This study compared self-reported performance of parenting tasks, parenting satisfaction and parenting efficacy in mothers with and without inflammatory arthritis (IA), and explored factors associated with parenting outcomes.

Method: This is the second part of a mixed methods study where the initial qualitative phase informed the content of a cross sectional mailed survey. Invitation letters were sent to women with IA who attended an out-patient arthritis clinic or rheumatology practices in the past 3 years. Community advertising and word-of-mouth was used to recruit women without chronic illness. All women had at least one child ≤18 yrs living at home. Reminders sent at 2 and 4 weeks maximized returns. The Parenting Disability Index (PDI) and Parenting Sense of Competency Scale (PSOC) were used to measure parenting outcomes. Surveys also inquired about employment, household work, social support, family quality of life, health status and demographics. Descriptive, t-tests and chi squared statistics were used for between group comparisons. Multiple regression analyses (with variables entered stepwise in blocks) identified predictors of parenting outcomes (PDI and PSOC scores).

Results: 342 women participated: 190 with IA and 152 in the comparison group (CG), aged 21 to 60 yrs. Of those with IA, 58% had RA, 15% psoriatic arthritis, 13% ankylosing spondylitis, 4% juvenile arthritis, and 3% lupus. Disease duration ranged from 6 mos to 45 yrs, (mean=12 yrs ± 10). Participants' children were ages 4 months to adults; typically, mothers were caring for 2 children (range 1 to 6). Regardless of the age of the children (≤5, 6-12, or >12 years), mothers with IA reported greater difficulty with parenting tasks on the PDI ($p<.02$). Average parenting satisfaction (PSOC subscale) scores did not differ ($p=0.74$); a very small difference in parenting sense of efficacy (PSOC subscale) was statistically significant at $p=0.05$, with the IA group reporting lower scores (IA=4.4, CG=4.6 on a 5-point scale). Women with IA were less likely to be employed outside the home, reported fewer hours of paid and unpaid work, and had lower household income than the CG. There were no significant differences in family quality of life. Mothers reporting better physical function and family quality of life and less fatigue had lower PDI scores (adj. $R^2 = .59$). Those reporting greater resilience, sense of accomplishment and positive affect, and lower mental health scores had higher PSOC parenting satisfaction (adj. $R^2 = .35$) and efficacy (adj. $R^2 = .29$), although the relative contribution of each variable differed in the two models.

Conclusion: Despite greater limitations experienced in performing parenting tasks, mothers with arthritis report as much satisfaction with their parenting role as do mothers without arthritis. A better understanding of factors associated with participation in life roles, like parenting, is necessary to select outcomes that are meaningful to people living with arthritis.

Children of Parent's with Chronic Inflammatory Musculoskeletal Diseases (CIMD): Experiences, Needs and Resources. Elizabeth Hale[1], Gareth Treharne[2], Yvonne Norton[3] and George D. Kitas[4], [1]Dudley Group of Hospitals NHS Trust, Dudley, England, [2]University of Otago, Dunedin 9054, New Zealand, [3]Lupus UK, [4]Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom

Purpose: CIMD such as systemic lupus erythematosus are chronic multisystem rheumatic disorders characterised by periods of exacerbation and remission. The children or grandchildren of people with SLE may find the disease and its impact within the family unit confusing and frightening. People with SLE may themselves have their own fears about disease progression, heritability and the subsequent consequences for the family unit. Whilst there are information leaflets available for SLE patients, there are no educational resources available for the children of patients with the condition.

Method: Pilot study: In-depth semi-structured interviews were carried out with 10 women with SLE whose age ranged from 32 to 68 years. All women had children whose ages ranged from 14 months to 18+ and some of the women had grandchildren. The participants were recruited from routine care and an open-access lupus clinic in secondary care. Time since diagnosis with SLE ranged from 1 to 12 years. The

interviews were audio-recorded and transcribed verbatim. Data were analysed using interpretative phenomenological analysis (IPA) to investigate what potential problems existed for the children of parents and grandparents with SLE.

Results: Five themes emerged from the data regarding lupus and parenting. These concerned children taking the role of carer for the participant; children taking self-care roles; participant worries about loss of social roles; heredity issues and the impact of SLE on the family unit and relationships. Children fetched shopping, kept the house tidy and helped themselves to convenience food. Participants were worried about losing their own social role as mother when friends and relatives had to take over tasks they usually performed, such as brushing their children s hair. They were worried about heritability, particularly in the case of daughters. There were also fears for the impact of the disease on the family unit both now and in the future. Pain, distress and frustration could cause angry outbursts from the participant when their children misbehaved causing guilt and regret later

Conclusion: Although patients said that their children understood they were unwell, it appears that there is no literature available for children and parents to read and discuss together those concerns that they may have about a parent with SLE. In the next stage of our study we will investigate what information would be useful to these children and the format in which they would like this delivered. The children will drive this part of the study and formats are likely to be varied given the developmental age of the child

Mir-203 Regulates the Expression of IL-6 and Matrix Metalloproteinase(MMP)-1 in RA Synovial Fibroblasts. Joanna Stanczyk Feldges[1], Emmanuel Karouzakis[1], Astrid Jungel[1], Caroline Ospelt[1], Christoph Kolling[2], Beat A. Michel[1], Renate E. Gay[1], Steffen Gay[1] and Diego Kyburz[1], [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland

Purpose: MicroRNA (miRNA) have emerged as a new class of modulators of gene expression and have been shown to be involved in the development of cancer and the proper functioning of the immune system. The goal of our study was to assess the expression of miRNA in synovial fibroblasts derived from patients with rheumatoid arthritis (RA), osteoarthritis (OA) and normal individuals.

Method: Synovial fibroblasts have been obtained from patients with RA (RASF; n=6), osteoarthritis (OASF; n=6) and normal subjects (NSF; n=3). Total RNA was isolated by using the mirVana miRNA isolation kit. The human TaqMan Real-time PCR-based miRNA panel comprising 260 individual miRNA was used to determine the profile of miRNA expression in RASF and OASF. For the functional studies a synthetic precursor pre-miR-203 was used. Further the influence of cytokines and the role of DNA methylation on the expression of miR-203 in RASF was studied.

Results: miRNA screening revealed an up-regulation of miR-203 in RASF. RASF showed a 2.6-fold higher level of miR-203 as compared to OASF ($p=0.01$). The increased level of miR-203 in RASF was even more pronounced when compared to the normal synovial fibroblasts (NSF), demonstrating a 7-fold higher expression of miR-203 in RASF. Interestingly, we did not find any change in the expression of miR-203 in RASF after treatment with IL-1β and TNF-α nor with the TLR-4 ligand LPS. However, we observed a stimulatory effect of the hypomethylating agent 5-Azacytidine on the expression of miR-203 in NSF. Over-expression of miR-203 by transfection with pre-miR-203 resulted in the up-regulation of IL-6 in RASF. The level of IL-6 mRNA was increased by 1.8±0.4 (mean±SEM of fold change), 2.4±0.3 ($p<0.01$) and 2.6±0.3 ($p<0.01$) at 24, 48 and 72 hours after transfection. Moreover, RASF treated with the miR-203 precursor produced at 48 hours 58±13% ($p<0.01$) more IL-6 protein as compared to the cells treated with the control negative pre-miR. We could further show that the stimulatory effect of miR-203 on the production of IL-6 is dependent on the NFκB pathway, as treatment of RASF with SC-514 (IKK-2 inhibitor) abrogated the miR-203-dependent increase in the production of IL-6. Also MMP-1 was found to be up-regulated at the mRNA level by 2.2±0.1-fold in RASF after transfection with pre-miR-203, but neither MMP-3, MMP-9 nor MMP-13.

Conclusion: Our data provide for the first time evidence that miR-203 is over-expressed in RASF and involved in the up-regulation of IL-6 and MMP-1 indicating a role of miR-203 in the development of the activated phenotype of RASF. Furthermore, our data suggest that epigenetic mechanisms are involved in the up-regulation of miR-203 in synovial fibroblasts.

1894

Meta-Analysis of Six Genome-Wide Association Studies in >25,000 Case-Control Samples Identifies New Rheumatoid Arthritis Risk Loci. E. Stahl[1], S. Raychaudhuri[1], R. Chen[1], J. Coblyn[1], N. Shadick[1], Michael E. Weinblatt[2], K.A. Siminovitch[3], X. Liu[4], G. Xie[4], L. Klareskog[5], L. Padyukov[5], M. Seielstad[5], AnnetteT Lee[6], P.K. Gregersen[7], J. Worthington[8] and R.M. Plenge[1], [1]Brigham & Women's Hospital, Boston, MA, [2]Brigham & Women's Hosp, Boston, MA, [3]University of Toronto, [4]University of Toronto, Toronto, [5]Karolinska Institutet, Stockholm, Sweden, [6]Feinstein Institute for Medical Research, Manhasset, NY, [7]Feinstein Insititute Med Rsch, Manhasset, NY, [8]arc Epidemiology Unit, Manchester, United Kingdom

Purpose: Approximately one-third of the genetic basis of rheumatoid arthritis (RA) can be explained by validated risk alleles. To identify additional RA risk alleles, we conducted a meta-analysis of six genome-wide association studies (GWAS).

Method: Through an international collaboration, we accessed GWAS genotype data from 5,539 RF or CCP-positive RA cases and 20,169 matched controls, all of self-reported European ancestry: Brigham Rheumatoid Arthritis Sequential Study (BRASS), Mount Sinai Hospital and University Health Network, Toronto, Canada (Canada), Epidemiological Investigation of RA (EIRA), North American RA Consortium (NARAC), and Wellcome Trust Case Control Consortium (WTCCC). We implemented strict quality control filtering of SNPs based on minor allele frequency, Hardy-Weinberg equilibrium and genotype call rate. We filtered individuals based on genotype call rate, identity-by-state, and principal components analysis. We imputed over 2.4 million SNPs from CEU HapMap. To test for association within each of the 6 case-control collections, we used logistic regression at genotyped and imputed SNPs. Association statistics were combined across the 6 collections using inverse-variance weighted beta and standard error values.

Results: Most known RA loci show substantial signal, including $P<5x10-8$ for SNPs within the MHC, PTPN22, TNFAIP3, CTLA4, and CD40 loci. One new locus at 5q11, near the IL6ST and IL31RA genes, was also genome-wide significant (rs10040327, $P=3x10-11$). Ten additional loci had $P<10-6$, whereas only 2 would be expected by chance alone. Fourteen alleles associated with other autoimmune diseases had $P<0.01$ in our RA GWAS meta-analysis, indicating shared etiology with psoriasis, celiac disease, lupus, type 1 diabetes, multiple sclerosis, and Crohn's disease. We found little evidence for association at PADI4 ($P=0.02$ for rs2240340), and no evidence for association at CD244 ($P=0.27$ for rs3753389), both of which have been implicated in RA pathogenesis among patients of Asian ancestry. Independent replication is ongoing in >10,000 additional case-control samples.

Conclusion: Our GWAS meta-analysis has identified new RA risk alleles among patients of European ancestry. These genetic discoveries provide fundamental insight into the pathogenesis of RA.

TEAR: Treatment of Early Aggressive RA: A Randomized, Double-Blind, 2-Year Trial Comparing Immediate Triple DMARD Versus MTX Plus Etanercept to Step-up From Initial MTX Monotherapy. Larry W. Moreland[1], James R. O'Dell[2], Harold Paulus[3], Jeffrey R. Curtis[4], S.L. Bridges Jr.[4], Xiao Zhang[4], George Howard[4] and Stacey S. Cofield[4], [1]Univ of Pittsburgh, Pittsburgh, PA, [2]University of Nebraska Med Ctr and Omaha VA, Omaha, NE, [3]UCLA School of Med, Los Angeles, CA, [4]The University of Alabama at Birmingham, Birmingham, AL

Purpose: No direct data compares triple DMARD (methotrexate [MTX], sulfasalazine [SSZ], hydroxychloroquine [HCQ]) to MTX + anti-TNF therapy (etanercept) in patients with early RA. The relative benefit of a strategy of either combination vs MTX monotherapy with step-up after 6 months is also uncertain. The TEAR trial evaluates both issues.

Methods: The investigator-initiated, multi-center, randomized TEAR trial began in 2004 and enrolled 755 participants to compare immediate (I) vs step-up (S) strategy with MTX, etanercept (E) and triple DMARD (T) in 4 arms: immediate MTX + E (IE) or triple therapy (IT); step-up from MTX to MTX+E (SE) or to T (ST). In SE/ST, if DAS28 ≥ 3.2 at 6 months of MTX, patients were blindly stepped-up to IE/IT. Inclusion criteria: disease duration ≤ 3yrs, diagnosis by ACR criteria; RF+, CCP+ or ≥ 2 radiographic erosions; ≥ 4 tender and 4 swollen joints; MTX naïve. The primary endpoint was mean DAS28 from weeks 48-102. Other endpoints: ACR 20, 50, 70; discontinuation for lack of efficacy, DAS28 remission, QOL and Radiographic progression.

Results: Subjects were 72% female; 80% Caucasian, 11% African American; with a mean age at entry of 49±13 yrs, with 3.6±6.5 months since diagnosis, 90% RF+. The mean DAS28 at entry 5.8±1.1; 28 joint count: 14.3±6.8 painful and 12.8±6.0 swollen joints. As shown in the Table, during the second year of treatment, patients randomized to S arms had clinical responses that were not statistically different than those who received I combination therapy, regardless of treatment arm (p-values: I vs S: 0.95, E vs T: 0.23). There were significant differences in the outcome of ACR response at 6 months between treatment arms: patients initially receiving IE or IT were significantly more likely to achieve an ACR 20/50/70 response at 6 months than those randomized to step-up arms (all $p < 0.0001$), regardless of treatment (E vs T).

Conclusion: A 2-year double-blinded trial of early RA patients found no differences in the mean levels of DAS28 during weeks 48-102 among patients randomized to etanercept or triple DMARD, regardless of whether they received immediate combination treatment or MTX monotherapy with a step-up. At 6 months immediate combination treatment with either strategy was more effective than MTX monotherapy; however, there were no significant differences in groups at 2 years. Initial use of MTX monotherapy with the addition of SSZ/HCQ or etanercept, if necessary after 6 months, is a reasonable therapeutic strategy for early RA.

	DAS28	**ACR response at 6 months**		
Treatment arm	**at week 102**	**ACR 20, %**	**ACR50, %**	**ACR70, %**
IE	3.0 ± 1.4	63.6	35.5	13.1
IT	2.9 ± 1.5	64.0	38.6	11.4
SE	3.1 ± 1.4	45.2	22.1	3.2
ST	2.8 ± 1.3	47.7	21.5	4.7

1896

All-Trans Retinoic Acid Promotes the Differentiation of Itreg Cells Via Smad and Non-Smad Signaling Pathways. Xiao H. Zhou[1], Ling Lu[1], Julie Wang[1], Hejian Zou[2], David A. Horwitz[1], David Brand[3], Huimin Fan[4], Zhongmin Liu[4] and Song Guo Zheng[1], [1]University of Southern California, Los Angeles, CA, [2]Huashan Hospital, Fudan University, Shanghai, China, [3]VA Medical Center, Memphis, Memphis, TN, [4]East Hospital, Tongji University, Shanghai, China

Purpose: Recent studies have revealed that All-trans Retinoic Acid (ATRA), a vitamin A derivative, promotes the development of CD4+Foxp3+ regulatory T cells induced by TGF-β (iTreg), however, the mechanisms by which ATRA regulates the differentiation of iTreg remain poorly understood.

Method: Naïve CD4+CD25- cells isolated from wild type or Smad3 KO or Smad2 conditional KO in T cells were stimulated with anti-CD3/CD28 beads ± TGF-β± ATRA for 5 days. Phenotype and functional activity was determined by FACS. TGF-βRI and TGF-βRII expression was determined by qRT-PCR. Western blot detected the Smad2/3, ERK1/2, P-38 and JNK activation. CHIP assay detected acetylation of Foxp3 protein. A methyl-sensitive PCR was used to analyze the methylation status of the CpG island of the Foxp3 promoter.

Results: We confirmed ATRA markedly increased the conversion of CD4+Foxp3+ iTreg cells in wild type and Foxp3 GFP transgenic mice. Additionally, we observed ATRA increased the Foxp3 binding ability with chromatin although it did not decrease hypermethylation of Foxp3 promoter and increase acetylation of Foxp3 protein. ATRA increased the Foxp3 binding on IL-2 promoter. Both ATRA and TGF-β treated cells developed mote potent anergy status and suppressive activity *in vitro* and *in vivo*. ATRA markedly increased the expression of CD103, alpha4-beta7, alphaV-beta8, CCR-9 on TGF-β treated CD4+ cells although it did not affect TGF-β receptor I and receptor II expression. CD4+ cells treated with both ATRA/TGF-β produced markedly lower amounts of IL-2 but higher amount of IL-10. ATRA also suppressed the apoptosis and sustained the Foxp3 expression. Although ATRA significantly increased the phosphorylated Smad2/Smad3 expression, ATRA still increased the Foxp3 expression and suppressive activity of TGF-β-treated CD4+ cells in Smad3 KO and Samd2 conditional KO mice. In addition, ATRA markedly increased ERK1/2 activation on TGF-β treated CD4+ cells and blockade of ERK1/2 signal significantly decreased the increased Foxp3 expression.

Conclusion: ATRA mainly activate Erk1/2 to promote the differentiation of iTreg cells. ATAR also enhances its binging ability on its target gene and alterations of the distribution and structure of Foxp3 might account for increased suppressive activity.

1897

Toll-Like Receptor 4 Blockade Ameliorates Murine and Humanized Models of Rheumatoid Arthritis; A Comparison with IL-1 and TNF Blockade. Shahla Abdollahi-Roodsaz, Marije I. Koenders, Leo A. Joosten, Fons A. van de Loo and Wim B. van den Berg, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Purpose: Toll-like receptor 4 (TLR4) potently instructs innate and adaptive immune responses. Current evidence including increased expression of TLR4 and its endogenous agonists in rheumatoid joints supports the involvement of TLR4 in RA. The objective of this study was to evaluate the therapeutic efficacy of TLR4 blockade in a murine and a humanized in vivo model of RA in comparison with the well-known interleukin-1 (IL-1) and tumor necrosis factor (TNF) inhibitors.

Method: Mice with established collagen-induced arthritis (CIA) were systemically treated with saline or either TNF, IL-1 or TLR4 inhibitors (Enbrel, Anakinra and purified *B. quintana* LPS, respectively) applied in osmotic minipumps. Clinical and histopathologic parameters of arthritis and cytokine responses were compared. Severe combined immunodeficient (SCID) mice were engrafted with active RA synovial tissue, and spontaneous cytokine production and synovial inflammation were evaluated after treatments.

Results: TLR4 blockade was as effective as the clinically applied IL-1 and TNF blockers in suppressing the clinical manifestations of CIA. On histology, TLR4 inhibition prevented synovial inflammation and bone erosion. Importantly, proteoglycan depletion from cartilage and the irreversible cartilage pathology, i.e. chondrocyte death and cartilage destruction, were effectively blocked as well. The protective effects of TLR4 inhibition on histopathology of established CIA were similar to those of the IL-1 inhibitor, while being more substantial than the TNF blocker. Analysis of the proinflammatory cytokine expression revealed a reduction in both local and systemic levels of IL-1β, IL-6 and IL-23. Interestingly, TLR4 blocker was the only inhibitor that suppressed systemic TNFα expression. In contrast to TNF blockade, inhibition of TLR4 and IL-1 reduced synovial expression of IL-17 and the Th17-related transcription factor RORγt as well as the serum concentrations of IL-17.

The humanized RA-SCID model was used to translate the therapeutic value of TLR4 targeting in CIA into RA. Blockade of TNF, but not IL-1, ameliorated synovial inflammation and reduced serum levels of human cytokines in SCID mice. Interestingly, TLR4 inhibition significantly suppressed the spontaneous cytokine production by transplanted RA synovium. In addition, TLR4 blockade markedly suppressed the severity of inflammation in RA synovial transplants to the same extent as TNF blockade, whereas IL-1 blockade was not effective.

Conclusion: Data in murine CIA and the humanized SCID model collectively indicate that TLR4 is positioned upstream to a number of proinflammatory cytokines with an impact on IL-17 production. The latter might favor TLR4 blockade above TNF blockade. Beneficial effects of TLR4 blockade on synovial inflammation and joint destruction emphasize the relevance of TLR4 as a novel therapeutic target for RA.

ACR/ARHP Combined Abstract Session

Advances in the Care of Children with Rheumatic Disease

Tuesday, October 20, 2009, 2:30 PM - 4:00 PM

1898

Juvenile Dermatomyositis: A Novel Gingival Vessel Alteration Pattern? Cynthia Savioli[1], Clovis A. Silva[2], Gisele M. Fabri[1], Katia Kozu[3], Lucia M.A. Campos[3] and José T. T. Siqueira[4], [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da USP, São Paulo, Brazil, [3]Faculdade de Medicina da USP, Sâo Paulo, Brazil, [4]Faculdade de Medicina da Universidade de São Paulo, Sâo Paulo, Brazil

Purpose: To evaluate oral health in juvenile dermatomyositis (JDM) patients and compare to controls.

Methods: 26 JDM patients were studied and compared to 22 age-matched healthy subjects followed at the Dentistry Division. At study entry all patients were examined by a rheumatologist and a dentist in order to evaluate social and demographic data, clinical manifestations, disease activity [using disease activity score (DAS), childhood myositis assessment scale (CMAS) and manual muscle testing (MMT)], muscle enzymes and treatment. The dental and facial examination included questionnaire, tooth decay (DMFT) index, periodontal assessment [plaque and gingival bleeding index, probing pocket depth (PPD), cementoenamel junction (CEJ) and clinical attachment level (CAL)], Helkimo's index, research diagnostic criteria for temporomandibular disease (RDC/TMD) and salivary flow.

Results: The mean current age of JDM patients was comparable to controls (11.88±3.97 vs. 11.66±2.59 years, p=0.469). The two groups were homogeneous regarding age, gender and Brazilian social-economic class (p>0.05). Alteration of mandibular mobility index was significantly higher in JDM patients than controls (0.5 vs. 0, p=0.007) probably due to higher frequency of low interincisal mouth amplitude in JDM versus controls (31% vs. 0%, p=0.005) and a lower median interincisal mouth amplitude in JDM (42 vs. 45mm, p=0.01). The median plaque, gingival bleeding and DMFT indices were similar in JDM patients and controls (89.42% vs. 80.95%, p=0.323; 21.7% vs. 12.7%, p=0.141; 2.0 vs. 1.5, p=0.151; respectively). Remarkably, a peculiar bushy loop formation in gingiva that spread over teeth was only observed in JDM patients (61% vs 0%, p=0.001). These patients had lower values of median cementoenamel junction (-0.26 vs. -0.06mm, p=0.009) and higher gingival bleeding index compared to patients without this manifestation (27.7% vs. 14.15%, p=0.048). No differences were observed between demographic data, DAS, CMAS, MMT, muscle enzymes and treatment in both groups (p>0.05).

Conclusion: The description of a novel gingival vessel alteration pattern associated with hyperplasia and gingival bleeding, distinct from periodontal disease, suggest that gingiva is a possible target tissue for JDM. In addition, these patients also have a compromised mandibular movement.

1899

Psychiatric Illness of Systemic Lupus Erythematosus in Childhood. Siok Hoon Lily Lim[1], Arlette Lefebvre[1], Susanne Benseler[1], PN Tyrrell[2], Michelle Peralta[1] and ED. Silverman[3], [1]SickKids, Toronto, ON, [2]Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, [3]Hospital for Sick Children and University of Toronto, Toronto, ON

Purpose: 1) To describe characteristic clinical, laboratory and imaging features; 2) To determine distinct entities in the spectrum of psychiatric disease of Juvenile SLE and 3) to report treatment regimens and outcomes.

Method: Single centre cohort study of consecutive JSLE patients followed between 08/1985 and 12/2008 was performed. Patients were evaluated following standardized protocol. All patients were assessed by an experienced psychiatrist. Clinical features of psychiatric disease of Lupus were identified and classified according to ACR nomenclature except cognitive dysfunction. Cognitive dysfunction in this study defined as memory or attention deficits reported by patients/ parents, affecting academic performance. Specific investigations (neuroimaging and lumbar puncture) were extracted. Psychiatric outcomes: 1) response- no psychiatric symptoms, stopped anti-psychotic medications and Prednisone <50% maximal dose for at least 3 months; 2) remission- no psychiatric symptoms, stopped anti-psychotic medications and Prednisone ≤10mg/day for at least 3 months; 3) relapse- recurrence of symptoms (after response) requiring 50% increase in dose of Prednisone, change of 2nd line immunosuppressive not due to adverse effects.

Results: 447 JSLE patients were followed during the study period: 12% (53) developed psychiatric disease of JSLE; 87% (46) females, median follow- up from psychiatric diagnosis 2.0 years (0.5-6.8). Half (27/53) had psychiatric disease at diagnosis of JSLE. Median interval from first psychiatric symptom to diagnosis was 60 days (1- 1460).Clinical features of psychiatric disease of JSLE: Psychosis-like symptoms seen in 75% (40) with hallucinations predominant- 73% visual, 85% auditory and 20% tactile hallucinations. Insight preserved in 70%. Novel symptom of visual distortions seen in 38% of those with Psychosis. Clinically significant cognitive dysfunction present in 25% (13). No patient had isolated depression or anxiety. Specific investigations: 42 had Magnetic Resonance Imaging (MRI): 45% normal, 29% cerebral atrophy and 17% white matter changes. Lumbar puncture performed in 53% (28/53) at diagnosis: 29% had abnormally elevated total protein, 7% had elevated white cells. Treatment: Prednisone was started/ increased following protocol. 60% (24) of patients with Psychosis required antipsychotic therapy. All but 3 were treated with 2nd line agents during their course: 85% (45) Azathioprine, 55% (29) Cyclophosphamide and 28% (14) Mycophenolate. Outcomes: 74%(39) responded by last follow-up, 25 attained remission (but 3 relapsed), 6 relapsed, 8 improved but not attained remission.

Conclusion: Psychiatric illness of JSLE was distinctly different from neuropsychiatric SLE in adults, with mainly psychosis and cognitive dysfunction. All patients with psychosis had hallucinations but insight was intact. Unique symptom of visual distortion was seen. Most patients (74%) responded to standard therapy.

Targeted Nutritional Intervention for Children On High Dose Corticosteroid Therapy. J. Tekano[1], A. Uribe[1], P. Khattra[1] and LB Tucker[2], [1]BC Children's Hospital, Vancouver, BC, [2]BC Childrens Hospital, Vancouver, BC

Purpose: Corticosteroids (CS) are widely used in the treatment of childhood rheumatic diseases, but are associated with morbidity. One of the most troublesome side effects of CS is excessive weight gain. The study aim is to determine the impact of a standardized dietary intervention on total weight gain over the first year of CS treatment in children with newly diagnosed rheumatic disease requiring high dose CS.

Method: This study is a prospective cohort intervention study (1 yr f/u), with a historical retrospective comparison group from the same clinic (treated with similar dose CS and no dietary intervention). Enrollment was at diagnosis of rheumatic disease, with start of high dose prednisone (≥1 mg/kg/day). Study subjects and parents received dietary counseling at the time of prednisone start, with prescription of an individualized dietary plan (low fat, low calorie, low sodium diet with increased calcium and fiber). Subjects had follow-up nutrition visits at each clinic visit (every 3 months) until 12 months. Measurements included: weight, BMI (BMI index>25=obese), body composition using skin fold thickness and waist circumference, and level of routine physical activity by the patient report Habitual Activity Estimation Scale (HAES; score > 3 hrs activity/wk=active).

Results: 20 patients aged 5-17 yrs (13F/7M; 8 systemic lupus, 5 Wegener's Granulomatosis, 5 juvenile dermatomyositis, 1 Takayasu's arteritis, 1 sarcoidosis)who received the nutritional intervention were compared to 15 patients aged 2-16 yrs who received standard care. Mean prednisone doses ranged from 1.1 m/g/d at diagnosis, to mean 0.19 mg/kg/d at 12 mos. Weight gain peaked at 9 mo with a mean(SD) gain of 7.9 (8.2) kg. One subject was obese at study entry with a baseline BMI of >95% and weight gain of 33 kg over 9 mos. When this subject was removed, the intervention group mean weight gain at 9 mo was significantly (p=0.03) less thank the historical comparison group (6.8 vs. 9 kg). At baseline, 2 subjects had BMI index>25; this increased to 5/20 (25%) at 9 mo, whereas 8/15 (53%) of the comparison group

had a BMI index >25 at 9 mo. At diagnosis, 12/20 subjects were scored as active on the HAES; at 9 mos this increased to 17/20. Inactivity was not associated with higher weight gain.

Conclusion: A personalized dietary intervention program was effective in limiting weight gain in a small group of children requiring high dose CS treatment for newly diagnosed rheumatic disease. Nutritional counseling should be included as a standard part of pediatric rheumatology team care.

Safety and Immunogenicity of Varicella Vaccine in Patients with Juvenile Rheumatic Diseases Using Methotrexate and Corticosteroids. Gecilmara S. Pileggi, Cleonice B. S. de Souza and Virginia P. L. Ferriani, School of Medicine of Ribeirão Preto, São Paulo University, Brazil., Ribeirao Preto- Sao Paulo, Brazil

Purpose: To evaluate the safety and immunogenicity of varicella vaccine (VV) in patients with juvenile rheumatic diseases (JRD) using disease modifying anti-rheumatic drugs (DMARDs) and corticosteroids.

Methods: Twenty five patients with JRD (2-19 years) and 18 healthy children and adolescents (3-19 years) received one dose of VV BIKEN (*Aventis Pasteur*). All 25 patients were using methotrexate; 13 were also receiving prednisone, and 5 were on other DMARDs too. None of the vaccinated patients or controls had previous history of varicella.

IgG anti varicella zoster virus antibody (VZV-IgG) titers were measured by ELISA immediately before, 4-6 weeks and one year after vaccination.

Patients and controls were monitored prospectively for adverse reactions related to the vaccine, exposure and occurrence of varicella. Disease activity in JRD patients was assessed 3 months before and 3 months after VV.

Results: Twenty two patients had negative pre-immunization titers of VZV-IgG; 3 patients had equivocal levels and were excluded from the analysis of vaccine response, but were kept in the safety evaluation. Protective VZV-IgG titers were detected in 12/22 seronegative patients (54.5%) and 13/18 controls (72.2%) 4-6 weeks after VV (p=0.12). One year after vaccination, 10/12 patients maintained protective VZV-IgG titers.

No overt varicella episodes and no severe adverse reactions were observed.

No worsening of clinical parameters and flares of JRD or changes in doses of medications used were detected after vaccination. In fact, the number of active joints in JIA patients was significantly lower after VV (p=0.009).

Conclusion: Varicella vaccine seems to be safe in patients with JRD using methotrexate, as long as continuous prospective vigilance for side effects is performed. Lower than expected vaccine response rate in patients and controls suggests the need of using two doses of VV.

1902

Methotrexate Monitoring in Children: What Is Necessary? Maria Gutierrez[1], Svetlana Lvovich[2], C. Martucci[1] and Donald P. Goldsmith[3], [1]St. Christopher's Hospital for Children, Philadelphia, PA, [2]St Christopher's Hospfor Child, Philadelphia, PA, [3]St Christopher Hosp Children, Philadelphia, PA

Purpose: To assess the safety of monitoring for MTX toxicity in children with various rheumatic disorders at 12 week intervals.

Methods: A retrospective random chart review was completed on 66 (52F, 14M) children who had received MTX for the treatment of various rheumatic disorders (JIA-51; JDM-6; Uveitis-3; SLE-2; UCTD-1; Lin Scl-1;Wegeners-1) between 1996 and 2009 and in whom monitoring had been performed at 12 week intervals. The average age at disease onset was 10.8y, the average treatment duration 2.7y, and the average dose (mg/m2) 10.8 mg. Specific laboratory assessments included a basic metabolic panel (BMP), liver function tests (LFT) and complete blood count (CBC). Anemia was defined as a drop in Hgb of more than 2g compared with the baseline value.

Results: Mild elevation of LFT and transient hematological abnormalities were the most common side effects. 18 children had AST elevations, 4 with more than twice the upper limit of normal. 17 had abnormal ALT levels, 6 with elevations greater than twice the normal value. 2 patients with elevation of LFT required a slight decrease in the MTX dose and only 1 patient required temporary discontinuation. 13 developed leukopenia, 1 neutropenia, and 2 anemia. All of these abnormalities were mild and MTX was not permanently discontinued in any child as a result of these laboratory aberrations.

Conclusion: None of these MTX treated children experienced serious side effects. Laboratory abnormalities were mild and required minimal or no intervention. These findings confirm that the incidence of severe MTX toxicity in children with rheumatic disorders is negligible and are also compatible with a prior study (J Rheumatol 2004;31: 2501) which indicated that less frequent monitoring was safe. The formal recommendation for the monitoring of MTX toxicicity in children should be reformulated to reduce the emotional burden of frequent testing and the economic impact for families and the healthcare system.

Ultrasound Abnormalities of Peripheral Joints in Juvenile Idiopathic Arthritis and Correlation with Clinical Examination. Sandrine Jousse-Joulin[1], Sylvain Breton[2], Claire Cangemi[2], Elisabeth Finel[3], Loic De Parscau[3], Alain Saraux[1] and Valerie Devauchelle-Pensec[1], [1]Rheumatology, Brest, France, [2]Radiology, Brest, France, [3]Paediatric, Brest, France

Purpose: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous condition leading to poor prognosis due to joint destruction in long term outcome for 50% of patients. Plain radiographs are commonly used to monitor joint damage but are quite insensitive, revealing narrowing and erosions often with delayed. Ultrasonography (US) with gray scale and power Doppler can allow early detection of synovitis in children. However, in opposite to the adult, there is no standardization of the technique and the correlation with clinical findings is poorly described.

The aim of our study was to define ultrasound abnormalities in the metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints in JIA and to compare US findings with clinical examination.

Method: Patients with recent JIA in according to Durban criteria were included. Ultrasound in B mode and power Doppler was performed with an HDI 5000 ultrasonography system (IU-22 Philipps) using a 12, 5-MHz linear array. 18 peripheral joints were examined for each patient: MCP 2,3,4,5 and MTP 1, 2,3,4,5, both sides. Physical and US examination were performed by two different experimented practitioners (SJJ and VDP). US practitioner was unaware of diagnosis and clinical examination. For clinical examination the tenderness and/or the swelling was noted as present or absent. For US findings, synovitis was considered and scored using the OMERACT criteria validated for adults (grey scale and Power Doppler). Others US findings were also considered as synovial thickness without DE, erosion, cartilage PD vascularity and bursitis.

Results: 25 patients with JIA were included (14 females, median age 12.5 ± 3 years, range 3.6 to 16.9 years). 20% (5/25) had polyarthritis with rheumatoid factors and 36% (9/25) had oligoarthritis. 450 joints were evaluated. 9.3% (42/450) had US synovitis, 50% were (21/42) located at the hand. Overall, US synovitis and physical examination scores were significantly associated ($p<0.001$) for both tenderness and swelling. However, inter-observer agreement between US synovitis and clinical evaluation was poor (kappa 0.18) concerning tenderness and only fair (kappa 0.44) concerning the swelling.60% (25/42) of the US synovitis were undiagnosed by clinical examination. In children the most frequently affected joints were the

MCP 2 (38%) and the MTP 1 (43%). Concerning the others abnormalities described with US, bursitis was not associated with synovitis, but synovial thickness without DE was associated with synovitis. Cartilage PD vascularity was not associated with synovitis, and was also found in a cohort of healthy children.

Conclusion: US of the MCP and MTP joints is a safe procedure in JIA allowing the detection of US synovitis associated with clinical examination. 50% of the US synovitis are not found by clinical examination. The OMERACT definition of active US synovitis can be used for JIA. Cartilage PD vascularity can be found in healthy children

ACR Concurrent Abstract Sessions

Infection-related Rheumatoic Disease

Tuesday, October 20, 2009, 2:30 PM - 4:00 PM

1904

Targeted Delivery of Nanodevices to *Chlamydia Trachomatis* -Infected Tissues in Murine Reactive Arthritis. I. Benchaala[1], I. Sinha[1], S.M. Wykes[1], M. Hali[1], M. Mishra[2], K. Kotta[2], R.M. Kannan[2] and J.A. Whittum-Hudson[1], [1]School of Medicine, Wayne State University, Detroit, MI, [2]College of Engineering, Wayne State University

Purpose: Dendrimers are emerging as a new class of nanoscale drug delivery vehicle because of their well-defined structure, tailored surface properties, and ability to deliver drugs intracellularly. We tested whether dendrimer-folic acid (FA) conjugates could target inflamed tissues in our murine model of chlamydia-associated reactive arthritis (ReA).

Method: Two nanodevices were synthesized for *in vivo* animal imaging experiments: Cy5.5, a near IR imaging agent, was conjugated to PAMAM dendrimer (D-Cy5.5) and compared to FA-D-Cy5.5. Conjugates were injected IV into BALB/c mice genitally infected with *C trachomatis.* Biodistribution of the nanodevices was determined using a Kodak whole animal imager 2h to120h after injection at 7-14 dpi. Paws (major sites of inflammation after dissemination of organism), and various organs were harvested for quantification of dendrimer conjugate uptake. Therapeutic nanodevices based on PAMAM dendrimer-Azithromycin conjugates (D-Z) were evaluated in chlamydia-infected HEp2 cells which were treated with either free Z (control) or D-Z (at equivalent Z concentrations from 2-256ng/ml) at the time of infection.

Results: Image analysis suggested that significantly higher amounts of FA-D-Cy5.5 were taken up into inflamed tissues including paws and genital tracts compared to D-Cy5.5 ($p<0.001$), and supported folate-dendrimer targeting of inflammation. Chlamydial inclusion numbers and size were significantly reduced >50% by D-Z compared to free Z at 16-32ng/ml; dendrimer alone did not reduce infection.

Conclusion: Our *in vivo* results suggest that dendrimers efficiently traffic to inflamed tissues and transport drug into infected cells to reduce infectious loads. To our knowledge this is the first report of folate-dendrimer targeting of infectious arthritic inflammation and in experimental chlamydia-associated ReA. These nanodevices may provide useful new therapeutic and imaging moieties for treatment of reactive arthritis in patients.

Transcriptome Analysis of Chlamydia Trachomatis During the Transition From Active to Persistent Infection Identifies Gene Panels Whose Expression Is Required to Support That Transition. Alan Hudson[1], H. C. Gerard[2], Robert J. Belland[3] and Judith A. Whittum-Hudson[2], [1]School of Medicine, Wayne State University, Detroit, MI, [2]Wayne State University School of Medicine, Detroit, MI, [3]University of Tennessee Health Sciences Center, Memphis, TN

Purpose: *C trachomatis* elicits reactive arthritis when it infects synovial tissue in the persistent form, but we do not understand the genetic basis for persistent vs active infection. We performed a complete transcriptome analysis of this organism over time post-infection in the *in vitro* monocyte model of persistence to assess gene expression during the transition from active to persistent infection.

Method: PBMC were prepared from 4 healthy donors, mixed, and infected with serovar K at MOI 3:1. Infected cultures were harvested at d 0, 1, 2, 3, and 4 post-infection (pi), by which time chlamydiae were in the persistent state. RNA was prepared from each sample and following standard manipulation was hybridized to Affymetrix gene chips that included all chlamydial genes and several thousand host genes. Data were analyzed using GeneSpring as in previous studies.

Results: The initial transcript profile of chlamydiae within monocyte inclusions reflected that of the first 24 hr of normal active infection. However with the exception of the *trp* operon, by d 3 pi genes encoding products required for all amino acid biosynthetic pathways were

severely down-regulated, as was expression of *omp1*, *ftsK, ftsW,* and other genes consistent with published results. Expression from *pmpA, pmpB, pmpC, pmpD* was severely down-regulated; other *pmp* genes were less affected. Genes encoding products required for energy transduction, translation, protein transport, *etc* showed transcriptional attenuation by d 3 pi. K-means clustering analysis identified 38 genes in 4 distinct transcriptional groups showing internally consistent transcript patterns during transition from active to persistent infection. Of those 38 genes, 17 encode products of unknown function. Host cells displayed increased expression from many genes encoding products related to immune system function, and increased expression from genes encoding intracellular signaling systems.

Conclusion: Chlamydiae modify a number of enzymatic, transport, and other systems during the transition to persistent infection. Importantly, a distinct set of bacterial genes products of currently unknown function also are required to complete the transition, and it will be critically important to determine how those gene products do so if we are to design new therapeutic approaches to treat *Chlamydia*-induced ReA. We now are assessing additional details of host and chlamydial gene expression to determine which products from each might elicit a transcriptional response from the other.

1906

The Chemokine CINC-1 Plays a Key Role in Innate Immunity in Reactive Arthritis. R. D. Inman[1] and B. Chiu[2], [1]U of Toronto, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON

Purpose: Innate immunity represents the first line of host defence against pathogens and functions as a key regulator of the development of reactive arthritis. Influx of neutrophils into the joint in experimental Chlamydia trachomatis-induced arthritis (CtIA) is genetically controlled and can be modified by environmental elements. This study addressed what factor may play a central role in the primary inflammatory response in the joint.

Method: Brown Norway rats are resistant to CtIA but rendered susceptible after prior exposure to mercuric chloride. Arthritis was induced by injection of synoviocyte-packaged Chlamydia, either in the absence (resistant phenotype) or presence (susceptible phenotype) of $HgCl_2$.Cellular infiltration was analyzed on H&E-stained sections of infected joints. ELISA was used to measure the following cytokines in serum (reported as mean values) 7 days after the onset of arthritis: IL-4, IL-6, IL-10, IL-17, IL-22, VEGF, TGF-β, IFN-γ, TNF-α, and CINC-1 (cytokine-induced neutrophil chemoattractant) which is equivalent to human Gro-α.

Results: The hallmark of susceptibility to reactive arthritis is an acute neutrophilic infiltration in the synovium which subsequently leads to erosive cartilage changes. This phenotype was associated with significant elevation in serum CINC: 492.9 pg/ml (+/- 67.6) for susceptible animals *vs* 141.6 pg/ml (+/- 48.16) for resistant animals, $p<0.0001$. The aggressive inflammation in susceptible animals was accompanied by significant elevation in serum levels of IL-6 (276.9 pg/ml +/-127.5 *vs* 7.7 pg/ml +/- 5.9, $p<0.001$) and in VEGF (110.6 pg/ml +/-37.4 *vs* 4.5 pg/ml +/- 2.3, $p<0.001$). The resistant phenotype was associated with a significant increase in IL-17 (4.2 pg/ml +/- 2.8 *vs* 1.2 pg/ml +/-0.56, $p<0.05$), in IL-22 (59.0 pg/ml +/- 50.4 *vs* 3.4 pg/ml (+/- 2.8, $p< 0.01$), and in IFN- γ (63.4 pg/ml +/- 18.9 vs 10.0 pg/ml +/- 7.6, $p< 0.005$).

Conclusion: Susceptibility to reactive arthritis after exposure to an arthritogenic pathogen depends critically innate immune responses, and CINC-1 plays a key role in this process by modulating neutrophil influx into the joint. Th-17 cells may play a hitherto unrecognized role in resistance to Chlamydia-related reactive arthritis

1907

Comparison of Two Interferon-Gamma Release Assays to Tuberculin Skin Testing for Latent Tuberculosis Screening in Rheumatic Patients Starting Anti-TNF Treatment. Dimitrios Vassilopoulos, Stamatoula Tsikrika, Emilia Hadziyannis, Anna Kandili, Nikolaos Stamoulis and Athanasios Archimandritis, Athens University School of Medicine, Athens, Greece

Purpose: Tuberculosis reactivation is a potential complication of anti-TNF treatment in patients with rheumatic diseases. Thus, the detection of latent tuberculosis infection prior to treatment initiation is of critical importance. Standard screening with the tuberculin skin test (TST) has its limitations mainly due to frequent false positive and negative results. Newer diagnostic assays such as the interferon – γ release assays (IGRAs) are promising alternatives to TST for more accurate Mycobacterium tuberculosis (MTb) infection diagnosis. Head to head studies

comparing the IGRAs to standard TST in high risk rheumatic patient populations are limited. The purpose of this study was to compare the performance of two commercially available IGRAs (T-SPOT.TB, Oxford Immunotec and QuantiFERON Gold in tube, QFT, Cellestis) to standard TST for TB screening in rheumatic patients starting anti-TNFa treatment.

Method: 55 patients (20 men/35 women) with various rheumatic diseases were screened for MTb infection with TST, two IGRAs (T-SPOT.TB and QFT), chest X-ray, standard questionnaire for demographics, history of TB, pevious MTb contact, BCG vaccination and concurrent immunosuppressive therapy. The majority of patients had been previously vaccinated with BCG (82%).

Results: Among the 55 patients tested (mean age= 53 ± 15 years), the rate of positivity was 45% for TST (25/55), 29% (16/55) for QFT and 24% (13/55) for T-SPOT.TB, respectively. In 56% of patients (31/55) there was agreement between the 3 assays (8 were all positive and 23 all negative). The agreement rate between the 2 IGRAs was moderate (84%, Kappa rate=0.58) whereas the agreement rate between TST and QFT and T-SPOT.TB was poor to fair (58%, κ=0.13 and 71%, κ=0.39), respectively. Previous BCG vaccination was statistically associated only with a positive TST result (OR=1.84, p=0.02) and not with a positive IGRA. Discordant results between the two IGRAs were observed in 9 patients (16%): 6 were QFT+/T-SPOT.TB- and 3 were QFT-/T-SPOT.TB+. Comparing the combination of the 2 IGRAs (T-SPOT.TB and/or QFT) to TST, we identified 24 discordant cases (44%): 7 IGRA+/TST- (13%) and 17 IGRA-/TST+ (31%) cases, who could represent "false negative" and "false positive" results of the standard TST, when it is used as the sole screening test.

Conclusion: In a patient population with high rates of latent TB infection and BCG vaccination, the application of both IGRAs and standard TST revealed discordant results in a significant number of cases. The comparison between the 2 IGRAs showed a good agreement rate. These results indicate the usefulness of these diagnostic assays as screening tools for TB screening in high risk rheumatic patient populations.

1908

Autoantibodies to miRNA-Binding Protein Argonaute 2 (Su antigen) in Patients with Hepatitis C Virus Infection. Monica Vazquez-Del Mercado[1], Laura V. Sánchez Orozco[2], Brad A. Pauley[3], Jason Y.F. Chan[4], Edward K.L. Chan[4], Montserrat Maldonado González[5], Arturo Panduro[5], Erika A. Martínez García[6], Beatriz T. Martín Márquez[6], Jose F. Muñoz-Valle[6], Laura González Lopez[7], Jorge I. Gámez Nava[8] and Minoru Satoh[9], [1]Instituto de Investigacion en Reumatologia y del Sistema Musculo Esqueletico, U de G, , Hospital Civil JIM., Guadalajara, Mexico, [2]Instituto de Biología Molecular en Medicina, U de G, Mexico, [3]Dept. of Oral Biology, Univ. of Florida, Gainesville, FL, [4]University of Florida, Gainesville, FL, [5]Hospital Civil FAA, Mexico, [6]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, U de G, Guadalajara, Mexico, [7]H R 110, IMSS, Mexico, [8]Unidad de Investigación en Epidemiología Clínica, IMSS, Mexico, [9]Dept. of Medicine, Univ. of Florida, Gainesville, FL

Purpose: Chronic liver diseases caused by hepatitis B (HBV) or C virus (HCV) are common worldwide. In addition to viral infection itself, type I interferon (I-IFN, mainly IFN-alpha), a standard treatment for HCV appears to induce or enhance autoimmunity. Despite reports on autoimmunity in viral hepatitis, studies on lupus-related autoantibodies are limited and inconsistent. Autoantibodies associated with rheumatic diseases were tested in patients with HCV and HBV infection.

Methods: Ninety Mexican patients (36 male, 54 female, 58 HCV, 6 HCV+HBV, 26 HBV) with chronic viral hepatitis, confirmed by nested- or RT-nested-PCR, HBsAg and anti-HCV antibodies, were studied. Autoantibodies were tested by immunofluorescence, immunoprecipitation (IP), and ELISA.

Results: Antinuclear antibodies were found in 38% HBV, 17% HBV+HCV, and 28% in HCV. Antimitochondria antibodies (AMA) were found in 10 cases [8 without type I-IFN (I-IFN) therapy, 9 females)]; 12% in HBV, 17% in HBV+HCV, and 10% in HCV. In HCV (and co-infection), all 7 AMA positives were females (17% vs. 0% in males, $P = 0.04$). Antibodies to a microRNA (miRNA) binding protein Ago2/Su were found in HCV (3/58) or HBV+HCV (1/6) but not in HBV (0/26). Anti-Ago2/Su was in 2/8 HCV treated with I-IFN vs. 2/56 in cases without I-IFN, indicating both anti-Ago2 and AMA can be produced in HCV without I-IFN treatment. HCV did not have other lupus autoantibodies whereas 5/26 of HBV had anti-U1RNP+Ku, Ro+La, RNA polymerase II, or U5snRNPs by IP. AMA is more frequent in anti-Ago2/Su positives (3/4) vs. negatives (4/60) ($P = 0.0032$).

Conclusion: Lupus autoantibodies were uncommon in HCV except anti-Ago2/Su. HCV and I-IFN have many ways to affect TLR signaling, miRNA and miRNA binding protein Ago2/Su. HCV replication is regulated via miRNA. HCV envelope protein E2 is known to bind to Ago2. To understand the mechanism of specific targeting of Ago2 in HCV may provide insights to specific autoantibody production.

1909

Rituximab for Severe Cases of Hepatitis C Virus-Associated Mixed Cryoglobulinemia. Dario Roccatello, Simone Baldovino and Daniela Rossi, CMID - Center of Research of Immunopathology and Rare Diseases, Turin, Italy

Purpose: Type II mixed cryoglobulinemia (MC) is a systemic vasculitis associated in most cases with hepatitis C virus (HCV) infection which is sustained by

proliferation of oligoclonal cells. Systemic B cell depletion and clinical remission can be achieved in non-Hodgkin lymphoma by human/mouse chimeric monoclonal antibody that specifically reacts with the CD20 antigen(rituximab). Similar effects could be expected in type II MC.

Method: Twelve patients, mean age 61.9 years (range 37-76), 11 with HCV infection genotype 2a2c (4 cases) or 1b (6 cases) and 3 (1 case) and symptomatic type II MC with systemic manifestations, including renal involvement with biopsy-proven membranoproliferative glomerulonephritis, marrow clonal restriction, large necrotizing ulcers, and polyneuropathy, were considered eligible for rituximab therapy because of resistance or intolerance to conventional therapy or important bone marrow infiltration. Rituximab was administered intravenously at a dose of 375 mg/sm on days 1, 8, 15, and 22. Two more doses were administered 1 and 2 months later. No other immunosuppressive drugs were added. Response was evaluated by assessing the changes in clinical signs, symptoms, and laboratory parameters.

Results: Levels of proteinuria (1.6 g/24h at T0 vs 0.2 g/24h at 18 mths), erythrocyte sedimentation rate (58 mm/h at T0 vs 37 mm/h at 18 mths), cryocrit (2,2% at T0 vs 0.3% at 18 mths), rheumatoid factor (550 UI/ml at T0 vs 250 UI/ml at 18 mths), and IgM (500 mg/dl at T0 vs

200 mg/dl at 18 mths) significantly decreased while C4 values increased (6 mg/dl at T0 vs 15 mg/dl at 18 mths) and HCV viral load remained stable during short, medium and even long-term (until 48 mnths) observation. Bone marrow abnormalities were found to reverse to normal. Constitutional symptoms disappeared or ameliorated. No acute or delayed side effects were seen, including worsening of HCV infection.

Conclusion: Rituximab appears to be a safe and effective therapeutic option in symptomatic patients with HCV-associated MC with signs of systemic vasculitis.

Regulation of the IGFBP-5 and MMP-13 Genes by the Micro RNAs Mir-140 and Mir-27a in Human Osteoarthritic Chondrocytes. Ginette Tardif[1], David Hum[1], Jean-Pierre Pelletier[1], Nicolas Duval[2] and Johanne Martel-Pelletier[1], [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]Duval Orthopaedic Clinic, Charmilles Pavillion, Laval, QC

Purpose: MMP-13 and IGFBP-5 are important factors involved in osteoarthritis (OA). We investigated the potential regulation of these two genes by microRNAs (miRNAs) in cultured human OA chondrocytes.

Method: Gene expression was determined by real-time PCR. The effect of each miRNA on IGFBP-5 and MMP-13 expression/production was evaluated by transiently transfecting their precursors (pre-miRNAs) and inhibitors (anti-miRNAs) into human OA chondrocytes. Modulation of IGFBP-5, miR-140 and miR-27a expression was determined upon treatment of OA chondrocytes with cytokines and growth factors.

Results: IGFBP-5 was expressed in cultured human chondrocytes with levels significantly ($p<0.04$) lower in OA. Computational algorithms identified miR-140 and miR-27a as possible regulators of MMP-13 and IGFBP-5 expression. Data showed that both miRNAs were expressed in chondrocytes. There was a significant ($p<0.01$) reduction in miR-140 expression in OA. Transfection with pre-miR-140 significantly ($p<0.005$) decreased IGFBP-5 expression at 24 hours, while pre-miR-27a did not affect either MMP-13 or IGFBP-5. Treatment with anti-miR-27a, but not with anti-miR-140, significantly increased the expression of both MMP-13 ($p<0.05$) and IGFBP-5 ($p<0.01$) but only after 72 hours incubation. These data indicate that IGFBP-5 is a direct target of miR-140, whereas miR-27a indirectly down-regulates both MMP-13 and IGFBP-5. TGF-β down-regulates miR-140 and up-regulates IGFBP-5.

Conclusion: Data revealed that miR-140 acted directly on decreasing IGFBP-5 expression but that miR-27a indirectly decreased both MMP-13 and IGFBP-5. Data from the study could be the first step in generating more comprehensive knowledge of the regulation of other MMPs and IGFBPs involved in OA, which could open up novel avenues in therapeutic strategies targeting this disease.

Reactive Oxygen Species Contribute to IGF-I Resistance in Osteoarthritic Chondrocytes through Inhibition of the IRS-I-PI3 Kinase-Akt Signaling Pathway. Richard F. Loeser and Weihong Yin, Wake Forest University School of Medicine, Winston-Salem, NC

Purpose: IGF-I stimulation of chondrocyte proteoglycan synthesis requires activation of the PI-3 Kinase-Akt signaling pathway. With aging and during the development of osteoarthritis (OA), chondrocytes become hyporesponsive to IGF-I. We tested the hypothesis that an increase in reactive oxygen species (ROS) causes IGF-I resistance by altering the activation of the IGF-I signaling pathway.

Method: Human articular chondrocytes were isolated from normal ankle cartilage obtained from adult tissue donors or from OA knee cartilage removed during joint replacement. High density serum-free monolayer cultures were stimulated with 50ng/ml IGF-I with or without pre-treatment with hydrogen peroxide (exogenous ROS) or the anti-oxidants MnTBAP or NAC. IGF-I signaling proteins were evaluated by immunoblotting with phosphospecific and control antibodies. Proteoglycan synthesis was measured by sulfate incorporation corrected for cell numbers by DNA and aggrecan and type II collagen expression were measured by real-time PCR. Lentiviral constructs were used to overexpress constitutively active (CA) Akt and MEK and dominant (DN) Akt.

Results: In normal human chondrocytes, IGF-I initiated a strong and sustained phosphorylation of IRS-1 (Y612) and Akt (S473 and T308) which are activating sites, and a transient ERK1/2 phosphorylation. In contrast, in osteoarthritic chondrocytes, which possessed elevated basal IRS-1 phosphorylation at S312 (inhibitory site) and ERK phosphorylation, IGF-I failed to stimulate IRS-1 (Y612) or Akt phosphorylation. In normal human chondrocytes, exogenous ROS triggered strong IRS-1 (S312 and S616) and ERK phosphorylation and inhibited IGF-I-induced IRS-1 (Y612) and Akt phosphorylation. Lentivirus-mediated overexpression of constitutively active (CA)-Akt significantly enhanced proteoglycan synthesis, while both dominant negative (DN)-Akt and constitutively active (CA)-MEK inhibited proteoglycan synthesis. ROS treatment and CA-MEK inhibited both aggrecan and collagen II mRNA expression, while CA-Akt dramatically increased collagen II, but not aggrecan mRNA expression. In osteoarthritic chondrocytes, antioxidants MnTBAP and NAC increased the ratio of Akt to ERK phosphorylation, and promoted IGF-I-mediated proteoglycan synthesis and type II collagen expression. Chemical inhibition of ERK significantly enhanced IGF-I phosphorylation of Akt and alleviated ROS inhibition of Akt phosphorylation.

Conclusion: These results demonstrate for the first time opposing roles for PI-3 Kinase-Akt and MEK-ERK in the IGF-I regulation of chondrocyte proteoglycan synthesis and type II collagen expression and suggest that excessive ROS in OA chondrocytes inhibit IGF-I mediated matrix synthesis by altering the balance of Akt to ERK activation.

Chromatin Protein HMGB2 Regulates Articular Cartilage Surface Maintenance Via Beta-Catenin Pathways. Noboru Taniguchi, Beatriz Caramés and Martin Lotz, The Scripps Research Institute, La Jolla, CA

Purpose: The superficial zone (SZ) of articular cartilage is critical in maintaining tissue function and homeostasis and represents the site of the earliest changes in osteoarthritis. Mechanisms that regulate the unique phenotype of SZ chondrocytes and maintain SZ integrity are unknown. We have recently demonstrated that expression of the chromatin protein HMGB2 is restricted to the SZ of articular cartilage suggesting a transcriptional network involving HMGB2 that regulates SZ cell phenotype. This study addresses potential interactions between HMGB2 and the Wnt/β-catenin pathway in regulating SZ cells.

Method: Activation Wnt/β-catenin signaling in articular cartilage was assessed by immunostaining for β-galactosidase in TOPGAL reporter mice at 3, 6, 12 and 18 months of age, and this was compared with HMGB2 expression. Functional interactions of β-catenin and HMGB2 on cyclin D1 and TOPflash promoters which are responsive to Wnt/β-catenin activation was examined by Luciferase assay, and molecular interactions between β-catenin, Lef-1 and HMGB2 were examined by GST-pull down assays. Gel shift assays were used to determine binding specificity and interactions of HMGB2 and Lef-1. To further test the functional significance of β-catenin signaling, we conditionally inactivated β-catenin in chondrocytes isolated from β-catenin floxed mice (Ctnnb1flox/flox) with adenovirus-GFP-Cre and performed apoptosis assays.

Results: We found that the Wnt/β-catenin pathway is active specifically in the SZ in normal mouse knee joints and co-localizes with HMGB2. Both, Wnt signaling and HMGB2 expression decrease with aging in the SZ of mouse knee cartilage. Our molecular studies show that HMGB2, Lef-1 and β-catenin form a tri-molecular complex on a promoter containing a Lef-1 motif. This complex enhances the binding of Lef-1 to its target sequence and potentiates transcriptional activation of the Lef-1-β-catenin complex. Furthermore, conditional deletion of β-catenin in cultured mouse chondrocytes induced apoptosis.

Conclusion: These findings define a pathway where protein interactions of HMGB2 and Lef-1 enhance Wnt signaling and promote SZ chondrocyte survival. Loss of the HMGB2-Wnt signaling interaction is a new mechanism in aging-related cartilage pathology.

Gdf5 Deficient Mice Have Increased Susceptibility to Osteoarthritis. Melina Daans, Frank P. Luyten and Rik J. Lories, KU Leuven, Leuven, Belgium

Purpose: A functional polymorphism leading to reduced levels of growth and differentiation factor-5 (GDF5) was recently identified as a susceptibility factor for osteoarthritis (OA). GDF5, also known as cartilage derived morphogenetic protein (CDMP1) is a member of the bone morphogenetic protein family originally identified from a chondrogenic extract of articular cartilage. During development the gene is expressed in early stages of chondrogenesis and in the prospective joint interzone. Postnatally, GDF5 biology has not only been associated with cartilage but also with ligaments and tendons. Mice with a spontaneous mutation in the *Gdf5* gene (*brachypodism* mouse, $Gdf5^{Bp\text{-}J/Bp\text{-}J}$) develop a severe phenotype with joint fusions and shortening of the skeletal elements. Here, we studied the role and mechanism of *Gdf5* involvement in OA using haploinsufficient $Gdf5^{Bp\text{-}J/+}$ mice.

Method: $Gdf5^{Bp\text{-}J/+}$ mice were kept on a CD1/Swiss genetic background. OA development was studied in the collagenase-induced arthritis model, the medial meniscus destabilization model, the papain-induced arthritis model and a treadmill running model. Bone density and subchondral bone parameters were determined using DEXA and peripheral quantitative computed tomography (pQCT). Additional *in vitro* and *ex vivo* analyses studied cartilage metabolism, gait and collagen characteristics.

Results: $Gdf5^{Bp\text{-}J/+}$ mice appear phenotypically normal but show discrete signs of haploinsufficiency during limb development and in trabecular bone area. $Gdf5^{Bp\text{-}J/+}$ mice developed more severe OA in the meniscal destabilization model, in the treadmill model and on the contralateral side in the collagenase-induced model but not in the papain-induced model. These data suggest that stability of the joint is impaired in $Gdf5^{Bp\text{-}J/+}$ mice. This was confirmed by gait analysis demonstrating that distances between 2 steps are smaller in $Gdf5^{Bp\text{-}J/+}$ mice as compared to wild-type mice. Cartilage breakdown analysis did not show differences between the mice but analysis of the subchondral bone demonstrated that $Gdf5^{Bp\text{-}J/+}$ mice have a decreased subchondral bone density and a distorted arrangement of collagen fibers.

Conclusion: These data support a role for GDF5 in OA development. Of interest, the observed phenotypes pointed to an effect of decreased GDF5 levels on joint stability and subchondral bone rather than on the articular cartilage. This highlights the importance of the joint as an organ in concepts of joint disease.

Targeted Disruption of Cartilage-Specific microRNA140 Promotes Osteoarthritis-Like Pathology. Shigeru Miyaki[1], Tempei Sato[2], Atsushi Inoue[2], Yoshiaki Ito[2], Shigetoshi Yokoyama[2], Shuhei Otsuki[1], Yoshio Kato[3], Fuko Takemoto[2], Satoshi Yamashita[2], Tomoyuki Nakasa[2], Martin Lotz[1], Hiroe Kudo[2] and Hiroshi Asahara[1], [1]The Scripps Research Institute, La Jolla, CA, [2]Nationa Research Institute for Child Health and Development, Tokyo, Japan, [3]National Institute of Advanced Industrial Science and Technology

Purpose: Osteoarthritis (OA), the most prevalent age-related joint disease, is characterized by degradation in articular cartilage by several proteinases. Small, non-coding microRNAs (miRNAs) play a critical role in development; however, their role in tissue maintenance is largely uncharacterized. We previously observed that miR-140 has an expression pattern suggestive of a role in chondrocyte differentiation and found that reduced miR-140 expression in human OA cartilage and in response to IL-1ß stimulation may contribute to the abnormal gene expression pattern characteristic of OA. The objective of this study was to define the in vivo function of the chondrocyte specific miR-140 in cartilage homoestasis.

Method: To examine the functions of miR-140, we created a mouse deleted for miR-140 and collected knee joints and chondrocytes from wild-type and miR-140-/- mice. To quantify OA-like pathological changes in articular cartilage, we used a validated histological OA scoring system based on Safranin O staining and evaluated expression of cartilage related genes by qPCR or immunohistochemistry. In vitro proteoglycan catabolism was analyzed in cultured femoral head cartilage explants from miR-140-/- mice.

Results: MiR-140-/- mice were born at normal Mendelian ratios and were fertile. Skeletal development during embryogenesis in miR-140-/- mice appeared normal. Postnatally, miR-140-/- mice manifested a mild skeletal phenotype, with short stature and craniofacial deformities characterized by a short snout, short mandibles and domed skull. miR-140-/- mice showed aging-related, OA-like changes characterized by proteoglycan loss and fibrillation in articular cartilage. Cultured miR-140-/- femoral head cartilage explants also showed significantly

increased proteoglycan release compared to wild-type cartilage. Consistent with these phenotypes, ADAMTS-5 was highly expressed in articular cartilage in miR-140-/- null mice and an in vitro reporter assay identified Adamts-5 as a direct miR-140 target.

Conclusion: MiR-140 disruption in vivo induced early onset OA-type changes in articular cartilage, which was associated with increased Adamts-5 expression. Our results indicate that Adamts-5 is directly regulated by miR-140, suggesting that miR-140 plays an important role in regulating the balance between extracellular matrix formation and degradation. This represents one of the first studies to show that a microRNA is required for tissue homeostasis and that its loss contributes to aging-related pathology.

1915

Syndecan-4 Is a Key Regulator of Osteoarthritic Cartilage Damage. Jessica Bertrand[1], Frank Echtermeyer[2], Rita Dreier[3], Martin Fürst[4], Gregor Theilmeier[2] and Thomas Pap[5], [1]University hospital Muenster, Münster, Germany, [2]University hospital Hannover, Hannover, Germany, [3]University Hospital Muenster, Muenster, Germany, [4]University Hospital Hamburg, Hamburg, Germany, [5]Univ Hosp, Muenster, Germany

Purpose: The cleavage of aggrecan is an important step in the breakdown of cartilage matrix in OA. ADAMTS-5 has been shown to be involved in the loss of proteoglycans, but the mechanisms of ADAMTS-5 activation during cartilage remodeling are poorly understood. Here, we analyzed the role of syndecan-4 in human OA cartilage degradation and in a murine OA model.

Method: Cartilage specimens were obtained from 120 patients with knee OA at joint replacement surgery, and analyzed for syndecan-4 and collagen X expression. For functional analysis, OA-like changes were induced in syndecan-4 k.o. mice and wt animals by surgically achieved joint instability. To verify the data of the syndecan-4 k.o. mice and exclude developmental effects, wt mice were treated with intraarticular injections of a blocking antibody against syndecan-4 following the induction of OA. The histological severity of OA as well as the MMP-3 expression was assessed in histological sections of all animals. ADAMTS-5 activity was determined by a sensitive aggrecanase assay. The effect of the MMP-3 inhibitor NNGH on aggrecan cleavage was analyzed in murine cartilage explants. Changes in IL-1 induced expression of MMPs, ADAMTSs and TIMPs were measured by RT-PCR. Syndecan-4 dependent changes in ERK phosphorylation after IL-1 treatment were determined by Western-Blot.

Results: During the development of murine OA, syndecan-4 was induced specifically in type X collagen expressing chondrocytes. The loss of syndecan-4 in the k.o. mice or treatment of wt animals with syndecan-4 antibodies nearly completely protected from a loss of proteoglycans. This correlated with a reduced MMP-3 expression in the cartilage of syndecan-4 k.o. mice and in mice treated with anti-syndecan-4 antibodies. Proteoglycan loss was induced by IL-1 in cartilage caps isolated from 6 weeks old wt and syndecan-4 k.o. mice, and ADAMTS-5 expression was found to be upregulated by IL-1 equally in both groups. However, proteoglycan loss was reduced significantly in syndecan-4 k.o. cartilage or cartilage treated with anti-syndecan-4 antibodies. In the supernatant of syndecan-4 k.o. cartilage, we found a reduced presence of activated ADAMTS. Cartilage that was treated with NNGH showed a reduced ADAMTS-5 mediated proteoglycan cleavage. We found a reduction of phosphorylated ERK in syndecan-4 k.o. cartilage after IL-1 treatment.p> **Conclusion:** Our data demonstrate that syndecan-4 is functionally involved in cartilage degradation by hypertrophic OA chondrocytes through inhibiting the activation of ADAMTS5 mediated aggrecan cleavage. ADAMTS-5 activation depends on both direct interaction with syndecan-4 on the surface of osteoarthritic chondrocytes and syndecan-4 regulated synthesis of MMP-3, which is ERK-dependent. Inhibition of syndecan-4 may, therefore, constitute a promising strategy to interfere with osteoarthritic cartilage damage.

Quality Measures and Innovations in Practice Management and Care Delivery

Tuesday, October 20, 2009, 2:30 PM - 4:00 PM

1916

Closing Osteoporosis Care Gaps through Process Redesign: The Primary Care-Rheumatology DXA Partnership. Eric D. Newman, Jennifer Fernandez, Thomas P. Olenginski, Mark Lentz, Brian DelVecchio, Androniki Bili and Valerie Weber, Geisinger Medical Center, Danville, PA

Purpose: Assessing osteoporosis fracture risk using DXA in women >65 is a national measure of osteoporosis quality care. The Electronic Health Record (EHR) can be programmed to fire a DXA Best Practice Alert (BPA) to help improve this measure. However, a BPA is only helpful at point-of-service (clinic visit), leaving a large number of at risk patients where this quality health measure cannot be addressed. In an attempt to truly "move the bar", our Rheumatology and General Internal Medicine (GIM) departments developed a partnership redesign project to create a more efficient and more effective process for DXA testing in women >65.

Methods: Four GIM physicians agreed to pilot this program. The program process flow redesign and mailing materials were reviewed by all participants. An EHR data extract of all women > 65 who had not had a DXA within the preceding 3 years was obtained. The list was divided into weekly batches of 40 patients. Each week, the GIM physicians were sent telephone encounters with a pended DXA order to sign and return. The physicians were allowed to sign or not sign a DXA order per their discretion. After the signed orders were received, letters were sent to patients inviting them to call in for a DXA. Patients that did not call in within a week of mailing were proactively contacted. DXAs were scheduled, performed, and a consultative interpretation was reported. If the patient's risk was not high, a "normal" letter was sent to the patient on behalf of their GIM physician. High risk patients were managed per the DXA report recommendations. A spreadsheet was used for task management and to track DXA testing and reasons for not testing.

Results: 305 patients met the study criteria. 143 patients (46.9%) underwent DXA scanning. Of the 162 patients (53.1%) who did not get a DXA scan, the most common reasons included: DXA order not signed (51%), patient refused (34%), patient died (10%). Common reasons for orders not signed included frailty, co-morbid diseases, and bed-bound. The subgroup where the DXA orders were not signed was older than the group who underwent DXA (84.7 +/- 0.8 vs. 76.6 +/- 0.6, $p<0.001$), and only 13% of this subgroup was receiving empiric osteoporosis therapy. A significant increase in the quality measure "% women > 65 with DXA" was seen in all 4 physicians – overall increase from 61% pre-partnership to 74% post-partnership ($p=0.001$; see Table).

Conclusion: A proactive process redesign partnership between rheumatology and GIM resulted in a significant improvement in women over 65 receiving a DXA scan. Over half of the at-risk patients were never studied – possible reasons include process issues (physician discretion in signing orders), population issues (chronically ill GIM patients), or simply a ceiling effect on this real world benchmark. Using the data obtained in this pilot and a new process flow, a second pilot is underway with a Family Physician Group in a different population to see if the process can be further redesigned to improve quality and efficiency.

Physician	Pre-Partnership	Post-Partnership	p-value
Physician A	54%	74%	0.0001
Physician B	77%	83%	0.0016

1917

Rheumatology Touchscreen Questionnaire to Improve Efficiency and Patient-Centric Care – Successful Development and Implementation Using Process Redesign. Eric D. Newman[1], Virginia R. Lerch[2], William T. Ayoub[3], J. B. Jones[2] and Walter F. Stewart[2], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA, [3]Geisinger Medical Group, State College, PA

Purpose: Patient-reported outcomes (PRO) are helpful to guide rheumatologic care decisions. Validated questionnaires are rarely used routinely because of workflow challenges using paper-based instruments. Computerized questionnaires offer an advantage in obtaining, aggregating, and reporting data in real time. However, electronic questionnaire administration must take into account existing workflows and resources to be effective in busy clinical practice. We compared two workflow models using a touchscreen questionnaire (TQ) in Rheumatology practices to evaluate completeness of data capture during routine visits.

Methods: The TQ authenticated patients and administered the questionnaire, checked for errors in real time, and scored and stored results. The TQ included functional outcomes (i.e., pain, stiffness, fatigue, and global scales), fall assessment, review of systems, self-reported tender joint counts, social parameters, and 10 probes for events of interest. Two rheumatology sites were studied – a single rheumatologist practice with greater resources (personnel) and a simple exam room-centric flow (Clinic 1), and a multi-provider academic rheumatology practice with fewer resources and a more complex linear flow (Clinic 2). Plan-do-study-act cycle methodology was used for implementation in two defined cycles.

Results: Cycle 1: Authentication required a keyboard. Both sites used a full-time assistant to help patients complete this task. Use of the TQ was rapidly scaled up, with weekly debriefing and feedback to the clinic team regarding TQ completion rate. In Clinic 1, over 90% of patients were able to complete the TQ during the 1st week. Clinic 2 remained well below 70% even at 12 weeks. TQ completion rate was highly dependent on the presence of an assistant to notify the nurses that the patient had completed their TQ. Cycle 2: A 15 minute pre-visit was built into the schedule to allow sufficient TQ completion time. The TQ was redesigned so that patient authentication could be performed by TQ rather than keyboard. An instant messaging and tracking system was developed so that the existing nursing pool could monitor the patients' questionnaire progress – yellow message (questionnaire started), red message (patient needs help), green message (questionnaire completed). These redesigns eliminated the need for an assistant. The new TQ version achieved a completion rate of > 75 % in Clinic 2 in the first week and thereafter. Over 2,000 TQs have been entered to date, and its routine use has been integrated into daily practice.

Conclusion: PROs collected via questionnaire have been shown to improve efficiency and provide patient-centric care. Using process redesign techniques, we have developed a TQ-based PRO collection program and process that allows a complex rheumatology practice to achieve immediate completion rates of >75% using existing resources. The next step is to integrate the TQ results into an electronic visual display.

Touchscreen Questionnaire (TQ) Completion Rate

	Cycle 1 - TQ Version 1				Cycle 2 - TQ Version 2	
	week 1	week 4	week 8	week 12	week 1	week 4
Clinic 1 resource replete simple flow	92%	82%	74%	83%	-	-
Clinic 2 resource deficient complex flow	40%	40%	62%	54%	80%	77%

1918

Quality of Preventive Care for Older Americans with Rheumatoid, Psoriatic and Osteoarthritis. J. R. Curtis[1], T. Arora[1], A.J. Taylor[1], C. O. Bingham III[2], John J. Cush[3], P. Narongroeknawin[1] and E. Delzell[1], [1]UAB, Birmingham, AL, [2]Johns Hopkins University, Baltimore, MD, [3]Baylor Research Institute, Dallas, TX

Purpose: Previous research suggests patients with rheumatoid arthritis (RA) may receive suboptimal care with respect to preventive tests and services such as DXA, vaccinations and screening tests for cancer and cardiovascular risk assessment. We evaluated the proportion of older Americans with RA and psoriatic arthritis (PsA) who received these preventive services and compared them to those with osteoarthritis (OA) (used as an internal control group).

Method: Using data from 1999-2006 from the Medicare Chronic Conditions Warehouse (CCW), we identified persons in the national 5% sample, age ≥ 65 with Medicare part A + part B not enrolled in a Medicare Advantage plan. We classified those with mutually exclusive diagnoses of RA, PsA and OA and required ≥ 2 physician visits in a 1 yr baseline period, also used to assess comorbidities and health services utilization. Over the required 5 year follow-up period, we identified tests and services that are generally recommended for older adults and the specialty of the associated provider. These services included DXA (1+), influenza (yearly) and pneumococcal vaccination (1+), hyperlipidemia testing (1+), mammography (none, 1, 2+) and colonoscopy (1+). We used multivariable dichotomous and ordinal logistic regression to estimate odds ratios to evaluate the likelihood of receiving various services among RA and PsA patients compared to OA patients, adjusting for potentially confounding factors (e.g. demographics, health services utilization, comorbidities and care from a rheumatologist.

Results: After accounting for sampling fraction, there were 139,240 RA, 6160 PsA and 747,620 OA patients who met eligibility criteria. The crude proportion who received various services is shown in Table. After adjustment, RA patients were more likely than OA patients to receive DXA (OR 2.37, 95% CI 2.23-2.51), influenza vaccination (OR 1.09, 95% CI 1.04, 1.14) and pneumococcal vaccination (OR 1.18, 95% CI 1.11-1.24) and less likely to receive mammography (OR 0.78, 95% CI 0.73-0.82) or hyperlipidemia testing (OR 0.63, 0.59-0.68). PsA patients were more likely to receive DXA (OR 2.43, 95% CI 1.87-3.15) compared to OA patients. Receipt of all other services for RA and PsA patients did not differ compared to OA patients. Of those receiving vaccination, rheumatologists administered at least 1 influenza vaccination to 17% (RA), 13% (PsA) and 2% (OA) and provided pneumococcal vaccination to 9% (RA), 5% (PsA) and 1% (OA) of patients.

Conclusion: Among older Americans in Medicare, the absolute proportion of persons with inflammatory arthritis receiving various generally-recommended preventive services and screening tests was substantially less than 100%. Using OA patients as a control group, RA patients were more likely to receive DXA and vaccinations but the same or less likely to receive hyperlipidemia testing or screening for breast or colon cancer. Most vaccinations were administered by non-rheumatologist providers. Given the high burden of comorbidities including cardiovascular disease among RA and PsA patients, strategies to improve the quality of preventive care for patients with inflammatory arthritis are needed.

Table: Proportion of patients with Rheumatoid, Psoriatic and Osteoarthritis Receiving Preventive Services during 5 Yrs of Follow-up

	RA (n = 139,240)	PsA (n = 6,160)	OA (n = 747,620)
DXA, %	61.5	56.2	40.1
Influenza vaccination, %			
None	17.4	15.9	18.5
Only 1 year	8.9	9.4	10.1
Only 2 years	11.8	12.3	12.0
Only 3 years	16.6	15.3	16.8

Besides Disease Activity There Are Many Other Considerations Made in the Decision Whether or Not to Escalate Medication: a Qualitative Study. Laura.T.C. van Hulst[1], Wietske Kievit[2], Piet L.C.M. van Riel[1], Richard Grol[1], Liana Fraenkel[3] and Marlies E.J.L. Hulscher[1], [1]UMC St Radboud, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Yale University, New Haven, CT

Purpose: It is widely recommended that rheumatologists use validated measures to monitor disease activity and adjust medication accordingly. Despite the widespread endorsement that treatment should be escalated in patients with moderate or high disease activity, data suggests that this approach is frequently not followed in daily clinical practice. In order to improve quality of care in RA in daily clinical practice, it is important to understand the factors which influence both patients' and physicians' decisions on whether or not to escalate DMARDs in case of active disease.

Method: Five focus groups were held (3 with RA patients and 2 with rheumatologists) to examine which factors influence rheumatologists' and patients' decisions related to escalation of DMARDs in patients who continue to have moderate to severe disease activity despite treatment with DMARDs. The focus groups were recorded and transcribed verbatim. The transcripts were analyzed on the basis of the grounded theory with Atlas.ti 6.0.11. Two analysts (LvH and WK) independently coded the transcripts. The independent codings were reviewed by the analysts. Codes were redefined until consensus was reached. Categories were derived from the final list of codes.

Results: Disease activity plays a role in the decision to escalate DMARDs for both RA patients as well as rheumatologists. RA patients emphasized that pain and fatigue were important in their decision. In contrast, rheumatologists emphasized the importance of objective disease activity parameters (e.g. joint swelling) in deciding whether or not to escalate DMARDs.

Both physicians and patients discussed the role of numerous additional factors which we divided into 4 categories: rheumatologist-related, patient-related, medication-related and organisational-related (see Figure 1). Rheumatologists felt, for example, that patient willingness to change, coping behaviour, age and patients' experiences with medication changes in the past, were important in their decision. RA patients emphasized that the route of administration, side effect profile and the availability of other options to relieve symptoms were important in their decision. The complete list of factors discussed in the focus groups is illustrated in Figure 1.

Conclusion: Besides disease activity there are many other reasons influencing the decision whether or not to escalate DMARDs which were described by 5 categories. RA patients and rheumatologists consider different factors in their decision. These findings are a first attempt to explain why medication is often not escalated in patients with moderate or high disease activity and will guide future quantitative methods to improve quality of care in RA in daily clinical practice.

Figure 1. Overview of considerations regarding escalation of DMARDs

RAPID3 and Component Measures Are as Likely as a DAS28 and Component Measures to Identify Patients with Rheumatoid Arthritis (RA) Who Have Moderate/High Disease Activity Versus Low Activity at Presentation. Theodore Pincus[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: To analyze two indices, DAS28 (disease activity score) and RAPID3 (routine assessment of patient index data), and their component measures for capacity to identify moderate/high disease activity versus low activity/remission in new patients with rheumatoid arthritis (RA) at presentation. RAPID3 is scored in ~10 seconds, versus 113 seconds for the DAS28.

Method: All patients seen at a weekly rheumatology clinic over a 25-year period from 1980 to 2004 completed a self-report questionnaire which evolved from a health assessment questionnaire (HAQ) to a multidimensional HAQ (MDHAQ). Scores for physical function (MDHAQ-FN) and pain (PN) were included on all versions of the HAQ/MDHAQ. A patient global estimate of status (PTGL) was added in 1996 to provide for a DAS28, based on swollen joint count (SJC), tender joint count (TJC), erythrocyte sedimentation rate (ESR) and PTGL, and a RAPID3 score, based on 3 self-report measures from the Core Data Set for FN, PN and PTGL. A formal 28SJC and 28TJC were performed at certain periods, with no selection for disease severity. Values to identify moderate/high activity were regarded as >2 for SJC, TJC, and PN and PTGL on visual analog scales (0-10), >0.5 for MDHAQ-function (0-3), >28 mm/h for ESR, >3.2 for DAS28 (0-10), and >6 for RAPID3 (0-30) or RAPID3-EST (RAPID3 not including PTGL, also on a 0-30 scale, correlated with RAPID3 at r □ 0.9). The number of patients who had values greater or less than the cutpoints to define moderate/high activity was calculated for each measure and index.

Results: Overall, 82.0% of patients had moderate/high activity according to DAS28 >3.2, and 84.5% according to RAPID3 or RAPID3-EST >6 at first visit. All individual component measures indicated moderate/high activity in >80% of new patients, other than MDHAQ-function in 70.1% and ESR in 52.6% of new patients.

Table. Measurements at first clinic visit of 487 RA patients

	Range	Moderate/ High Cutpoint	Disease Activity (% new patients)	
			Low	Moderate/High
DAS28	0-10	>3.2	18.0%	82.0%
RAPID3 or RAPID3-EST	0-30	>6	15.5%	84.5%
SJC	0-28	>2	16.4%	83.6%
TJC	0-28	>2	21.0%	79.0%
ESR (mm/h)	0-150	>28	47.4%	52.6%
MDHAQ-FN	0-3	>0.5	29.9%	70.1%
PAIN	0-10	>2	15.1%	84.9%
PTGL	0-10	>2	15.0%	85.0%

Conclusion: RAPID3 is as sensitive as DAS28 to identify patients with moderate/high activity in RA who should be considered as candidates for disease-modifying antirheumatic drugs (DMARD), and ultimately biologic agents if persistently high, based on an incomplete response to therapy. These data add further evidence to the value of RAPID3 as an index to monitor status of patients with RA in usual care.

Glucocorticoid-Induced Osteoporosis Program (GIOP): A Highly Successful Care Program with Improved Patient Outcomes After 2 Years. Cynthia K. Matzko[1], Eric D. Newman[1], Thomas P. Olenginski[1], Thomas M. Harrington[1], Gwynne L. Maloney-Saxon II[1] and G. Craig Wood[2], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA

Purpose: Chronic glucocorticoids (GC) users have a high risk of osteoporotic fracture and their osteoporotic care is often suboptimal. Our Rheumatology Department designed a program of care called GIOP (Glucocorticoid-Induced Osteoporosis Program). GIOP uses electronic tools, pathways of care, and dedicated personnel to provide comprehensive osteoporosis care. We report on the first 200 patients entered and their 2 year follow-up.

Method: GIOP candidates were any patients taking GC ≥3 months. Baseline evaluation included demographics, patient knowledge (pre-test), GC use, 25-OH Vitamin D level, DXA, and vertebral fracture analysis (VFA) or spine X-rays. High-risk was defined as T-score below -1.0 or prevalent vertebral fracture. All patients were educated and instructed to take adequate calcium/Vitamin D, do weight bearing exercise, and implement safety strategies. Patients with Vitamin D levels below 30ng/ml were prescribed 50,000 IU supplementation. High-risk patients were prescribed medication. Patient knowledge (post-test), Vitamin D level, medication use and adherence were reassessed at 6 months, 12 months and 2 years.

Results: At baseline (n=200), the mean age was 62.7 ± 12.7 years and 68.5% of the patients were women. Personal history of fracture was seen in 9.5% of patients (2.5% hip, 4.0% spine, 2.5% wrist). The mean GC duration was 5.9 ± 7.1 years and the mean daily dose ranged from 2.5 to 15 mg of prednisone for 84% of the patients. Vitamin D levels of <30 ng/ml were seen in 74% of patients. Baseline DXA, VFA, and spine X-rays categorized 70.5% of GC patients as High-risk. Two year paired follow-up data was available in 132 patients (17 died, 5 refused follow-up, and 46 unavailable). Test scores and vitamin D levels improved significantly (p= 0.001) (Table). Forty-four % of patients were taking a lower dose of steroid at 2 years compared with baseline (p=0.001). Overall adherence to calcium, vitamin D, and prescription medication (if indicated) was 97% at 2 years. Adherence specifically to bisphosphonates or teraparatide was 99% at 2 years.

Of the 132 patients with 2-year follow-up, a baseline and at least 1 follow-up DXA were available for 128 (97%). An increase in BMD at the spine of 2.66% ($p<0.0001$) was seen for the population overall and 3.63% for the high risk patients on medication ($p<0.0001$). Over the two year follow-up, 18 of the 132 patients (14%) sustained a hip, spine, or wrist fracture (hip: n=1, spine: n=17, wrist: n=2; Table). Of these 18 patients, 8 (45%) also had a fracture at baseline.

Conclusion: Most patients entering GIOP are vitamin D deficient, high-risk and require treatment. Significant improvement was observed and sustained over 2 years in patient knowledge, Vitamin D levels following GIOP program treatment, and BMD at the spine. The mean daily steroid dose decreased. Despite the aging, high risk population, only a small percentage of patients sustained a fracture. Overall adherence to the prescribed regimen was excellent at 2 years. This well-organized, patient-centric program represents a highly successful model to improve bone health in patients requiring chronic GC.

	Baseline	2 Years
Test Scores	69 ± 21	88 ± 14
Vitamin D (ng/ml)	20.6 + 11.0	41.1 + 13.6
Patients with fracture		
Hip	2.5%	0.8%
Spine	16.0%	12.9%
Wrist	0.0%	1.5%
Any of above	18.5%	13.6%

ACR Concurrent Abstract Sessions

RA Therapy: Novel Therapies in the Pipeline

Tuesday, October 20, 2009, 2:30 PM - 4:00 PM

1922

AIN457 Shows a Good Safety Profile and Clinical Benefit in Patients with Active Rheumatoid Arthritis (RA) Despite Methotrexate Therapy: 16-Weeks Results From a Randomized Proof-of-Concept Trial. Paul P. Tak[1], P. Durez[2], JJ. Gomez-Reino[3], B. Wittmer[4], V. Chindalore[5], F. Di Padova[6], AM. Wright[6], G. Bruin[6] and W. Hueber[6], [1]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [2]University of Louvain, Brussels, Belgium, [3]University Clinical Hospital, Santiago de Compostela, Spain, [4]Commonwealth Biomedical Research, Madisonville, KY, [5]Pinnacle Research Group, Anniston, AL, [6]Novartis Pharma AG, Basel, Switzerland

Purpose: AIN457 is a fully human IgG1κ monoclonal anti-IL17 antibody that selectively neutralizes IL-17A. IL-17 is overexpressed in synovial tissues in RA and preclinical studies support that IL-17A is a key driver of synovial inflammation and degradation of cartilage and bone. This study explores IL-17A blockade with AIN457 as a novel therapeutic approach to RA. The objective is to determine the safety, tolerability and initial evidence of clinical efficacy of AIN457 in patients with active RA despite methotrexate (MTX) therapy up to 16 weeks.

Method: This was a multicenter, randomized, double blind, parallel-group study. A total of 52 patients with active RA received either, 2 doses of 10 mg/kg AIN457 (*N*=26) three weeks apart or placebo (*N*=26). All patients were followed up to 16 weeks. This abstract expands on the previously reported 6-week results to include secondary endpoints and response rates up to 16 weeks.

Results: Patients characteristics at baseline were comparable between AIN457 and placebo groups (mean age 49.9 *vs* 49.8 yrs, median disease duration 3.9 *vs.* 2.9 yrs; median weekly MTX dose 15 mg *vs.* 12.5 mg, mean DAS28 score 5.88 *vs.* 5.84, mean tender joint count 17.6 *vs.* 17.1, mean swollen joint count 11.6 *vs.* 11.1, median C-reactive protein (CRP) 7.6 *vs.* 9.8 mg/L). AIN457 was well tolerated and has a favorable consistent PK profile with a long elimination half life of 23 days. Adverse event types and incidence rates were comparable

between the groups, with a slightly higher frequency in the AIN457 group (81% *vs.* 65%). The overall rate of infections was identical in the AIN457 and placebo group (9 events [35%] in each). No cases of neutropenia or immunogenicity were reported. Exploratory analysis showed that a greater percentage of patients treated with AIN457 2x10mg/kg achieved an ACR20 response over 16 weeks compared to placebo [*P*=0.08] (Table 1). Both ACR50 and ACR70 rates showed numerical improvements with AIN457 compared to placebo. DAS28 assessment showed greater reductions with AIN457 2x10mg/kg compared to placebo over the16-weeks period (EULAR response rates are shown in Table 1). AIN457 induced fast onset of response and sustained reductions in CRP levels through week 16 (Figure 1). This was paralleled by improvements in the patient global assessment (PGA) (Figure 2) and HAQ scores.

Conclusion: The good safety, rapid onset and encouraging efficacy of AIN457 suggest a novel therapeutic concept with the potential for improved patient outcomes. These positive results support development of AIN457 in RA and potentially other immune-mediated disorders.

Table 1: Rates of ACR and DAS28-based EULAR response in the treatment groups

Weeks since dosing	AIN457 10mg/kg (*N*=26)			Placebo (*N*=26)		
	ACR20	ACR50	ACR70	ACR20	ACR50	ACR70

1923

Phase 2 Study of Safety and Efficacy of a Novel Anti-BAFF Monoclonal Antibody, in Patients with RA Treated with Methotrexate (MTX). MC Genovese[1], E. Mociran[2], M. Biagini[3], S. Bojin[4] and J. Sloan-Lancaster[5], [1]Stanford U, Palo Alto, CA, [2]County Hospital, Baia Mare, Romania, [3]County Hospital, Bacau, Romania, [4]County Hospital, Covasna, Romania, [5]Eli Lilly, Indianapolis, IN

Purpose: B cell activating factor (BAFF) is a survival factor for peripheral B lymphocytes which exists in both cell surface and soluble forms. Dysregulated BAFF expression may contribute to autoimmune diseases via effects on abnormal B lymphocyte activation, proliferation, survival, and immunoglobulin secretion. LY2127399 is a novel monoclonal antibody binding both cell surface and soluble BAFF. This study was designed to explore the tolerability and efficacy of LY2127399 in Pts with active RA.

Method: This was a 24-week, randomized, placebo-controlled, double-blind study which enrolled 136 Pts with active RA despite treatment with MTX. Pts continued stable doses of MTX and received 1 of 3 dose levels (30, 60, or 160 mg) of LY2127399 or placebo (PBO) intravenously for a total of 3 doses at 3-week intervals (Weeks 0, 3, 6). Response was assessed for efficacy, PK/PD and safety. The primary endpoint was ACR20 response vs. PBO at Week 16.

Results: ACR20/50/70 and DAS28 responses showed that RA signs and symptoms improved more in Pts at each LY2127399 dose as compared with PBO. The primary objective was achieved at all LY2127399 treatment levels (Table; one-sided χ^2 test no adjustment for multiplicity), and ACR20 treatment differences remained significant at end of study (69.7%, 67.6% and 63.6% for 30, 60, 160mg respectively vs. 26.5% for PBO, $p \leq 0.001$). Initial transient increases were shown in total ($CD20^+$) B cells in all LY2127399 treatment

groups, followed by significant reductions. Importantly, B cells were not completely depleted. Mean reductions at Week 24 were 33.5%, 50.8% and 33.3% for $CD20^+$ B cells, and 35.8%, 66.9% and 63.6% for $IgD^+/CD27^-$ B cells, for the 30, 60 and 160 mg treatment groups respectively, vs. 18.3% and 17.7% respectively for placebo. Memory ($IgD^-/CD27^+$) B cells also increased in all LY2127399 groups compared with PBO by Week 1, with a return toward baseline by end of study. The nature and frequency (41% to 44%) of AEs were similar across groups; serious AEs were reported in 5 (4.9%) LY2127399- Pts and 3 (9.1%) PBO- Pts; serious infection was reported in 1 (1.0%) LY2127399- Pts and 1 (3.0%) PBO- Pts. IgM levels decreased significantly more in all LY2127399 groups combined vs. PBO; decreases in mean IgG and IgA levels were not significant compared with PBO.

Wk 16 results	**LY2127399 (30 mg) n=34**	**LY2127399 (60 mg) n=34**	**LY2127399 (160 mg) n=34**	**PBO n=34**
ACR20 (Primary) % (p value)	57.6 (0.010)	67.6 (<0.001)	51.5 (0.033)	29.4
ACR50 % (p value)	42.4 (<0.001)	32.4 (0.008)	21.2 (0.077)	8.8
ACR70 % (p value)	12.1 (0.018)	8.8 (0.038)	3.0 (0.153)	0.0
Mean ACR-N % (p value)	35.1 (0.001)	34.8 (0.001)	25.8 (0.101)	14.1
Pts with DAS28 <2.6 %	9.1	14.7	0.0	0.0
Change in DAS28 LS Mean (p value)	-1.54 (<0.001)	-1.84 (<0.001)	-1.41 (0.001)	-0.58
Change in CD20 B Cells (Cells/uL) LS Mean [baseline] (p value)	-75.7 [129.7] (<0.001)	-48.4 [197.1] (0.012)	-40.5 [152.8] (0.040)	-3.6 [173.9]

Conclusion: LY2127399 given intravenously as 3 infusions was well-tolerated and reduced the signs and symptoms of RA. Reduction of RA symptoms was not contingent upon complete B cell depletion. These results support further dose exploration of LY2127399 in RA.

1924

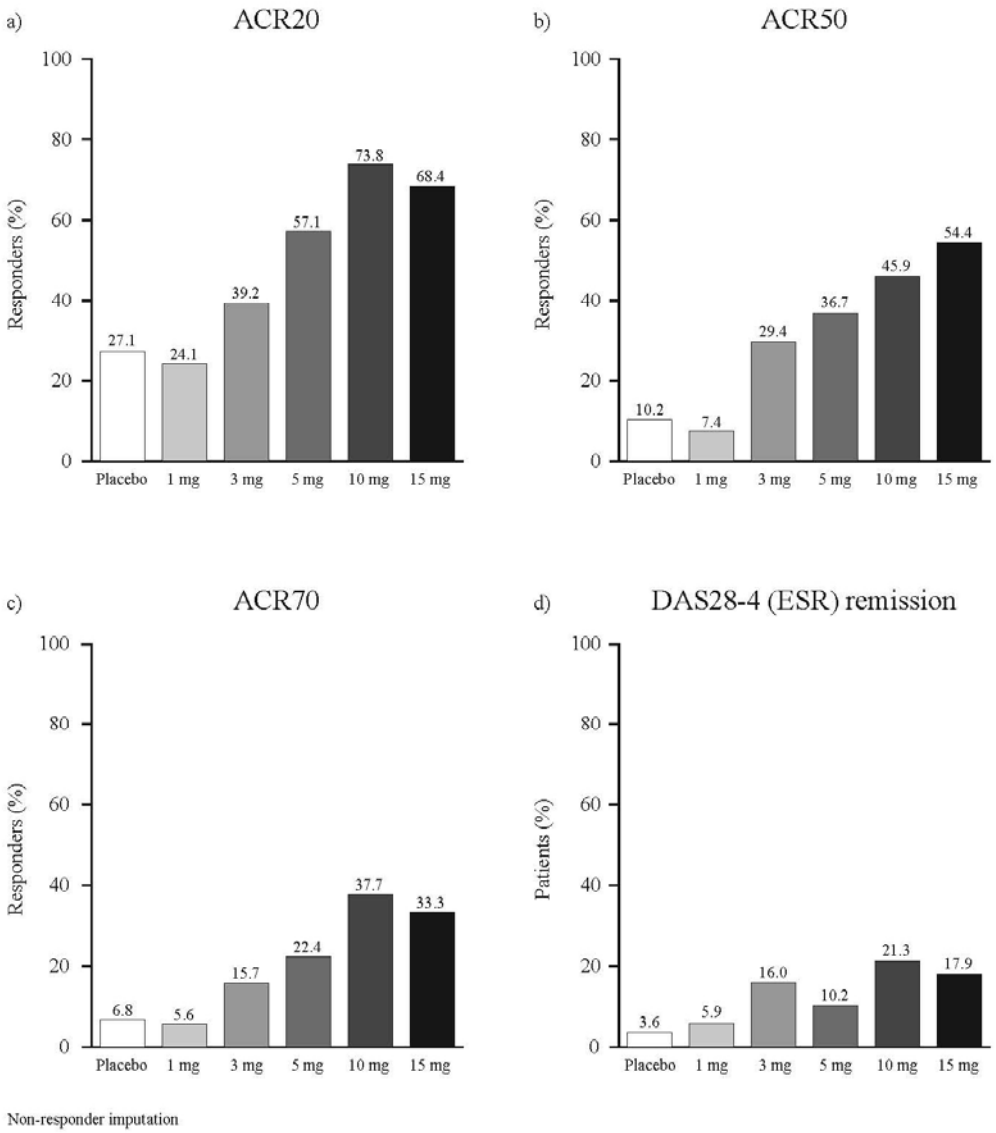
Safety and Efficacy After 24 Week (wk) Dosing of the Oral JAK Inhibitor CP-690,550 (CP) as Monotherapy in Patients (pts) with Active Rheumatoid Arthritis (RA). R.M. Fleischmann[1], M.C. Genovese[2], D. Gruben[3], K.S. Kanik[3], G.V. Wallenstein[3], B. Wilkinson[3], S.H. Zwillich[3] and J. Frain[4], [1]Metroplex Clinical Research Center, Dallas, TX, [2]Stanford University, Palo Alto, CA, [3]Pfizer Inc, New London, CT, [4]Complete Medical Communications, Macclesfield, United Kingdom

Purpose: To compare efficacy, safety, and tolerability of 5 doses of CP or adalimumab (ADA) monotherapy v PBO for treatment of RA in pts with inadequate response to DMARDS.

Methods: This study was a 6-month, double-blind, placebo-controlled Phase 2B study. Pts with active RA (≥6 tender/swollen joints, CRP >7 mg/L or ESR > ULN) were randomized to: CP 1, 3, 5, 10, 15 mg po BID, ADA 40 mg sc every 2 wks, or PBO. Pts receiving CP 1, 3 mg BID, or PBO not achieving ≥20% decrease from baseline in tender/swollen joint counts at Wk 12 were reassigned to CP 5 mg BID for the remainder of the study. All ADA pts were advanced to CP 5 mg BID monotherapy at Wk 12 and hence no ACR response rates for this group are reported after Wk 12. Data are from Wk 24 final analyses.

Results: 384 pts were randomized.

Figure 1. % responders for ACR20 (a), ACR50 (b), ACR70 (c) and DAS28-4(ESR) remission rate (d), at Wk 24



Non-responder imputation

25 (42%), 17 (32%), and 17 (33%) of placebo, 1 mg, and 3 mg BID dose groups respectively advanced to 5 mg at Wk 12 and counted as non–responders in the efficacy analysis. Previous interim results reported pts receiving 5, 10, and 15 mg CP BID consistently demonstrated statistically significant efficacy compared to placebo by ACR 20/50/70 and DAS28 at Wk12. Efficacy continued to be seen at each of these doses at Wk 24 (Fig 1).

208 (54.2%) pts experienced a total of 489 treatment emergent adverse events (TEAEs), and 14 experienced serious AEs (SAEs). The most common TEAEs across all CP arms (n=272) were UTI 20 (7.4%), diarrhea 13 (4.8%), headache 13 (4.8%) and bronchitis 12 (4.4%) and were more common at higher doses. Across all CP arms, 8 (3.0%) pts experienced SAEs. Serious infections were observed in 5 pts: 2 pts with pneumonia (CP 1 mg), 1 pt with pneumococcal pneumonia (CP 15 mg); 1 pt with acute pyelonephritis (ADA [after reassignment to CP 5 mg at Wk 12]); 1 pt with infection of ankle joint (PBO). There were 0 opportunistic infections, malignancies, or lymphomas. One pt died from stroke (CP 15 mg) not considered treatment-related.

6 pts experienced a confirmed >50% increase in serum creatinine levels from baseline (4 CP, 2 ADA; of the ADA pts, this increase occurred prior to reassignment to CP in 1 patient, and after reassignment in 1 patient). 6 (2.2%) pts on CP experienced confirmed severe anemia, and no pts experienced confirmed severe neutropenia (OMERACT criteria). The proportion of CP pts in 5, 10, 15 mg dose groups with LDL <130 mg/dl at baseline that increased to >130 mg/dl during the study were 29%, 36%, and 37%, respectively.

Conclusion: CP monotherapy dosed at 5 mg, 10 mg, and 15 mg BID demonstrated sustained efficacy at the Wk 24 study visit in pts with active RA; and a manageable safety profile.

1925

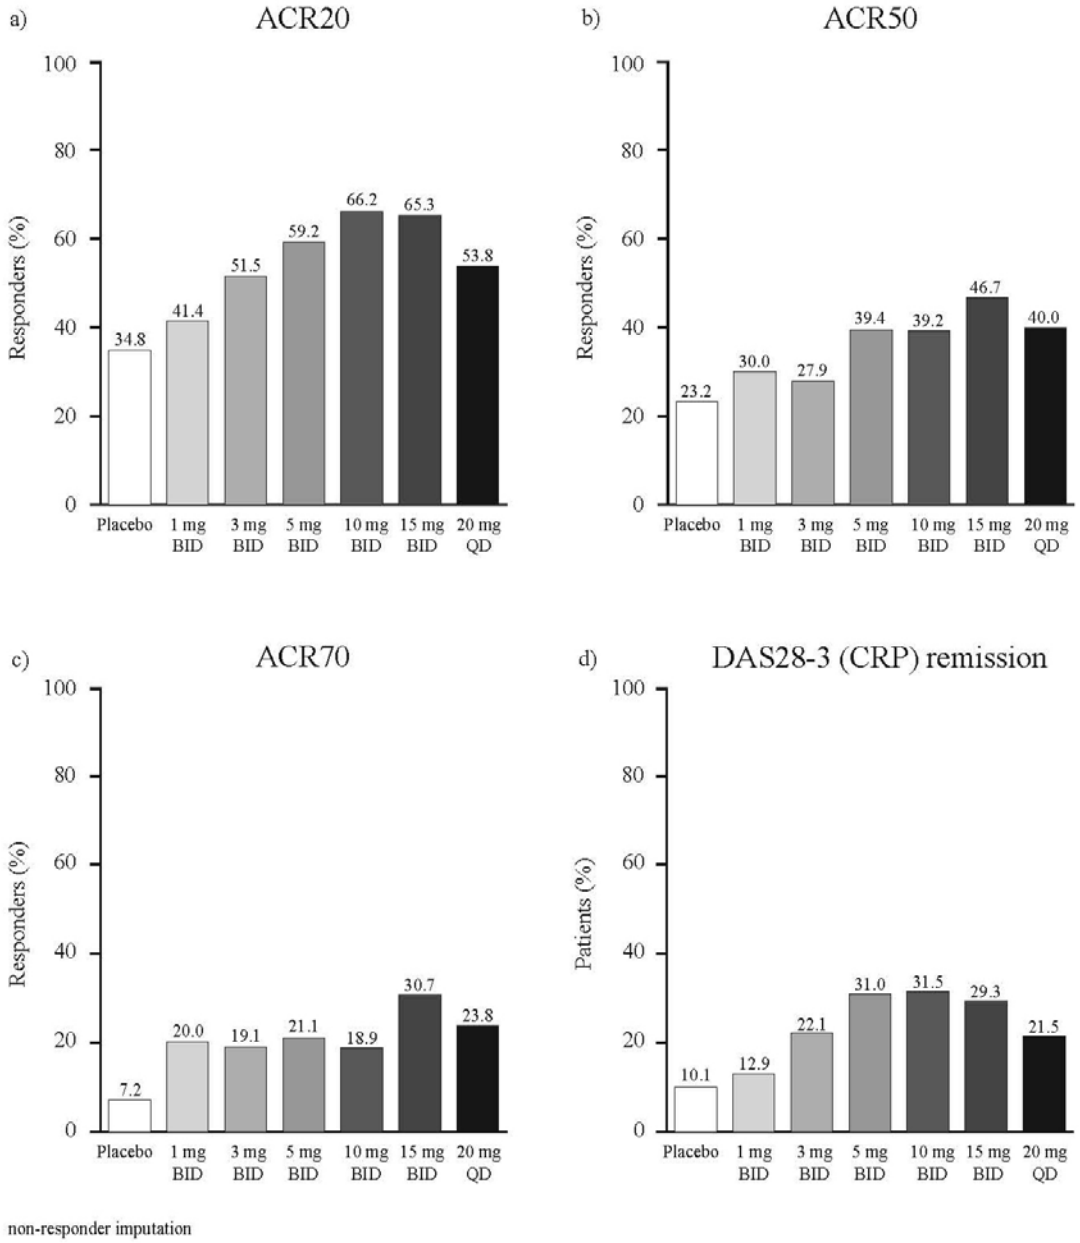
Safety and Efficacy After 24 Week (WK) Dosing of the Oral JAK Inhibitor CP-690,550 (CP) in Combination with Methotrexate (MTX) in Patients (PTS) with Active Rheumatoid Arthritis (RA). J. Kremer[1], S. Cohen[2], B. Wilkinson[3], D. Gruben[3], G.V. Wallenstein[3], K.S. Kanik[3], S.H. Zwillich[3] and J. Frain[4], [1]Albany Medical College, Albany, NY, [2]Metroplex Clinical Research Centre, Dallas, TX, [3]Pfizer Inc, New London, CT, [4]Complete Medical Communications, Macclesfield, United Kingdom

Purpose: To compare the efficacy, safety, and tolerability of 6 doses of CP compared with placebo (PBO) for treatment of active RA in pts with an inadequate response to stable background MTX alone.

Methods: This was a 24-wk, double-blind, placebo-controlled Phase 2B study. Pts with active RA (≥6 tender/swollen joints, CRP >7 mg/L or ESR > ULN) were randomized to: CP 1, 3, 5, 10, 15 mg BID, 20 mg QD, or PBO. Pts receiving CP 1 mg BID, 3 mg BID, 20 mg QD, or PBO not achieving ≥20% decrease from baseline in tender and swollen joint counts at Wk 12 (non-responders) were reassigned to CP 5 mg BID for the rest of the study (13-21 per arm). Pts remained on stable background MTX of 7.5 to 25 mg/wk. Data are from Wk 24 final analyses.

Results: 507 pts were randomized.

Figure 1. % responders for ACR20 (a), ACR50 (b), ACR70 (c) and DAS28-3(CRP) remission rate (d), at Wk 24



non-responder imputation

18 (26%), 21 (30%), 13 (19%) and 13 (16%) of PBO, 1 mg BID, 3 mg BID and 20 mg QD dose groups, respectively, were advanced to 5 mg BID at Wk 12 (non–responders in efficacy analysis). Previous interim results reported pts receiving 3 mg BID and higher had statistically significant efficacy compared with placebo by ACR 20/50/70 and DAS28 at Wk 12. Efficacy was seen at doses of 5 mg BID and higher at Wk 24 (Fig 1).

Overall, 188 (37.1%) pts had a total of 896 treatment emergent adverse events (TEAEs), and 21 (4.1%) had serious AEs (SAEs). The most common TEAEs across all CP arms (n=438) were: UTI 27 (6.2%), headache 26 (5.9%), diarrhea 25 (5.7%), nasopharyngitis 24 (5.5%), and nausea 21 (4.8%) and were more common at higher doses. The most common TEAEs across the PBO arm (n=69) were: UTI 3 (4.3%), nasopharyngitis 3 (4.3%), and pharyngitis 3 (4.3%).

5 (1.0%) pts had serious infections: 3 pneumonia (CP 3 mg BID, 5 mg BID and 20 mg QD), 1 UTI (CP 3 mg BID), and 1 respiratory tract infection (CP 10 mg BID). There were no opportunistic infections, malignancies, or lymphomas. One pt with treatment related pneumonia (CP 3mg BID) died due to complications of respiratory and cardiac failure.

6 pts had confirmed >50% increase in serum creatinine levels from baseline (5 pts in CP groups and 1 pt in PBO [reassigned to CP 5 mg BID at Wk 12]), none discontinued. 13 pts on CP and 1 pt on PBO had confirmed severe anemia (OMERACT criteria, none discontinued), and no pts had confirmed severe neutropenia (OMERACT criteria, none discontinued). There was a dose response in increases in LDL with the highest doses having the highest increase; the proportion of CP pts with a LDL <130 mg/dl at baseline that increased to >130 mg/dl at any time during the study ranged from 32% to 42% for the highest doses. 5 pts had elevations in ALT>3xULN (4 pts CP 15 mg BID and 1 pt each CP 10 mg BID, CP 20 mg QD, and PBO).

Conclusion: In pts with active RA despite MTX, CP dosed at 5 mg, 10 mg, and 15 mg BID showed sustained efficacy and a manageable safety profile through 24 wks.

Cam-3001: A Novel Human Monoclonal Antibody against GM-CSFR-á, in Subjects with Rheumatoid Arthritis (RA)-Results of a Phi Study. Gerd-R. Burmester[1], Frank Wagner[2], Eugen Feist[3], Matthew Sleeman[4], Fabio Magrini[5] and Barbara White[6], [1]Charite, University Medicine Berlin Free University and Humboldt University of Berlin, Berlin, Germany, [2]Charité Research Organisation GmbH, Berlin, Germany, Berlin, Germany, [3]Charite University Hospital, Berlin, Germany, [4]MedImmune Ltd, Cambridge, United Kingdom, [5]Medimmune, Cambridge, United Kingdom, [6]Medimmune, Gaithersburg, MD

GM-CSF is thought to play a significant role in RA. Elevated levels of GM-CSF have been shown in tissue biopsies and synovial fluid from arthritic patients. Furthermore, recombinant GM-CSF has shown to exacerbate disease in RA patients undergoing treatment for neutropenia (1). Using phage display we developed a human monoclonal antibody (CAM-3001) to the GM-CSFR alpha chain that neutralizes GM-CSF activity. We describe the results of a Phase I single ascending dose of CAM-3001 in RA.

Purpose: The primary objective was to assess the safety and tolerability of CAM-3001 in patients with RA. Other objectives included the pharmacokinetics of CAM-3001 and the effect on biomarkers of systemic inflammation.

Method: Thirty-two subjects with mild or inactive RA (DAS28 ≤4.8) on stable methotrexate (≥3 months) received single i.v. doses of CAM-3001 or placebo in ascending doses of 0.01 and 0.03, 0.1, 0.3, 1, 3, or 10 mg/kg. Safety was assessed throughout the study by evaluation of clinical and laboratory parameters.

Results: Adverse events were generally mild or moderate, and balanced between placebo and active treatments with no dose-relationship. There were two treatment-emergent serious adverse events (bilateral hernia, and breast cancer), neither of which was considered related to study drug. Mild transient neutropenia was seen in two subjects, and mild transient elevation of hepatic enzymes was also seen in two subjects. One subject experienced moderate urticaria of the face and neck during the infusion. Pulmonary function was also monitored and showed no clinically significant changes over the study period. Although the study was not designed to demonstrate clinical efficacy, post-hoc analysis of individual subjects with elevated CRP (>5mg/L) and ESR (>20mm/hr) at baseline showed reductions in CRP or normalization of ESR within the first 3 weeks post infusion, suggesting a potential benefit in RA. The pharmacodynamic activity of CAM-3001 pre and post dosing was also confirmed using an ex vivo GM-CSF-induced SOCS3 RT-PCR assay.

Conclusion: This is the first reported clinical study of a monoclonal antibody targeting the GM-CSF pathway in patients with rheumatoid arthritis. In this study, we show that CAM-3001 has an acceptable safety profile. Furthermore, the effects observed on acute phase reactants

following single infusion of CAM-3001 suggest a potential effect on disease activity. This will be formally investigated in future clinical studies.

1927

CH-1504: A Metabolically Inert Antifolate, Is An Effective and Well-Tolerated Treatment for Patients with Moderate to Severe Rheumatoid Arthritis. Edward C. Keystone[1], Lawrence A. Hewitt[2], Lee S. Simon[3], Valery Shirinsky[4] and Simon Pedder[2], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Chelsea Therapeutics, Charlotte, NC, [3]Harvard Medical School, West Newton, MA, [4]RAMS, Novosibirsk, Russia

Purpose: Methotrexate (MTX) treatment of rheumatoid arthritis (RA) is often associated with side-effects and/or safety concerns. MTX metabolites are thought to play a significant role in MTX toxicity. Therefore, theoretically, a metabolically inert antifolate such as CH-1504, should be safer and better tolerated while providing comparable efficacy. We report results of a phase II clinical trial designed to show "Proof of Concept" for this class of compounds.

Methods: MTX naïve patients (N=201) with moderate to severe RA were enrolled in this 16 week, multi-center, randomized and double-blind study. Patients received either CH-1504 (0.25mg, 0.5mg or 1.0mg once daily oral doses) or MTX (titrated to 20.0mg once weekly). All patients received a once weekly 10mg folate supplement. Observations were made at 2, 4, 8 and 12 weeks with a treatment free follow-up at 16 weeks. The primary efficacy endpoint of the study was the ACR20 response at week 12. Secondary endpoints included DAS28 scores and the individual components of the ACR20 composite index as well as the safety and tolerability of treatment.

Results: Demographic parameters were similar in the 4 treatment groups with a mean age at enrollment for the entire study population of 54.3 ± 11.4 years, a majority being female (87%) and a mean DAS28 was 6.6 ± 0.9. At week 12 all CH-1504 treatment groups showed comparable efficacy to MTX as measured by ACR20 and DAS28 response rates. This was also seen in the key indicator sub components of the composite index including tender and swollen joints. A dose-response relationship over the dose range tested was not observed in the timeframe of this trial.

	MTX	CH-1504		
	20mg weekly	0.25mg daily	0.5mg daily	1.0mg daily
Patient Number	52	48	48	53
Efficacy				
ACR 20	38.5 %	43.8%	39.6%	34.0%
Patients with > 20% Reduction in SJC	73.1%	70.8%	83.3%	79.2%
Patients with > 20% Reduction in TJC	65.4%	58.3%	62.5%	71.7%

Mean change in DAS28	- 1.4	- 1. 0	-1.2	-1.1
Safety/Tolerability				
% Patients with ALT (>1 X ULN)	13.5	4.2	6.3	7.5
% Patients with GI related AEs	5.8	2.1	4.2	3.8
% Patents withdrawn for GI AEs	3.8	0	0	0

CH-1504 appeared safe and well tolerated at all dose levels. Adverse events (AEs) were generally mild in all arms of the study. The % of patients with serum ALT elevations above 1X upper limit of normal was lower at all doses of CH-1504 compared to MTX. The % of patients with, and dropouts because of, GI related AEs were lower at all doses of CH-1504 compared to MTX.

Conclusion: This 16 week proof-of-concept study in MTX-naïve RA patients demonstrated that CH-1504 has comparable efficacy to MTX and may be safer and better tolerated. Metabolically inert antifolates are a promising therapeutic option and warrant further study.

ACR Concurrent Abstract Sessions

Systemic Lupus Erythematosus Outcomes-Cardiovascular and Other Outcomes

Tuesday, October 20, 2009, 2:30 PM - 4:00 PM

1928

Effect of Rosuvastatin On Homocysteine, hsCRP and Endothelial Markers in Systemic Lupus Erythematosus (SLE): A Randomized Controlled Trial. Chi Chiu Mok[1], Judy Lai[1], Chun Kwok Wong[2], Christopher Lam[3] and Cheuk Sum Lam[1], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Department of Chemical Pathology,The Chinese University of Hong Kong,Prince of Wales Hospital, Shatin, NT, Hong Kong, [3]Chinese University of Hong Kong, Hong Kong, Hong Kong

Purpose: A randomized controlled trial to study the effect of rosuvastatin (crestor) therapy on homocysteine, hsCRP and markers of endothelial activation / injury in patients with stable SLE

Methods: Asymptomatic SLE patients who had coronary calcification (Agatston score ≥1) or Doppler ultrasound documented abnormal carotid intima-media thickness (IMT) (≥0.8mm at any site) were recruited and randomized in a double-blinded manner into 2 treatment arms: (1) rosuvastatin (10mg/day); or (2) placebo (one tab/day) for 12 months. Levels of homocysteine, hsCRP, sVCAM-1, P-selectin and thrombomodulin were measured at baseline, month 6 and month 12. SLEDAI scores were assessed at 2-month intervals.

Results: 72 patients were studied (97% women). The mean age was 50.8±9.7 years and SLE duration was 11.8±7.1 years. At baseline, their mean Agatston score was 30.9±68 and carotid IMT (all sites) was 0.67±0.13mm. The mean SLEDAI score was 1.68±1.7. The prevalence of traditional risk factors is as follows: smoking(10%), menopause(57%), diabetes mellitus(3%), hypertension(33%). Antiphospholipid antibodies were present in 28% of patients. 36 patients were randomized to receive rosuvastatin and 36 patients were randomized to the placebo arm. No statistically significant differences in clinical characteristics and baseline levels of the biomakers were observed at baseline. At month 12, a significant drop in total and LDL-cholesterol level was observed in the crestor but not in the placebo arm. The changes in the levels of the vascular / endothelial markers over time were summarized below:

Markers	Arms	baseline	Month 6	Month 12	*P
Homocysteine (umol/L)	Crestor	15.2±5.2	14.0±4.5	14.8±5.1	0.50
	Placebo	13.9±3.6	13.4±3.3	14.2±3.7	0.68

hsCRP (mg/L)	Crestor	2.58±2.7	3.07±5.71	1.64±2.0	0.009
	Placebo	3.92±10.6	3.96±9.2	5.19±9.94	0.33
sVCAM-1 (ng/mL)	Crestor	717±410	738±405	883±650	0.11
	Placebo	898±610	809±467	803±472	0.19
P-selectin (ng/mL)	Crestor	47.2±18	48.6±19.2	51.4±17.7	0.27
	Placebo	47.4±18.8	52.5±24.6	51.2±18.4	0.06
Thrombomodulin (ng/mL)	Crestor	1.33±1.07	1.27±1.98	1.19±1.10	0.40
	Placebo	0.94±0.55	0.82±0.52	0.78±0.46	0.05

*P – comparison between baseline and month 12 by paired Students' t-test

A significant decrease in the level of hsCRP was observed in the crestor arm. The difference in hsCRP level between the crestor and placebo arms was significant at month 12 (p=0.03) after adjustment for baseline hsCRP values, risk factors and the mean SLEDAI score. Trend in the levels of other biomarkers was not apparent between the two groups.

Conclusion: In SLE patients with subclinical atherosclerosis, low dose rosuvastatin leads to a significant reduction in hsCRP level after 12 months' therapy and may be beneficial in reducing the risk of arterial thrombosis in the long-run.

1929

Pihdl Is Associated with a 19- Fold Increased Risk of Progression of Subclinical Atherosclerosis in SLE. Maureen A. McMahon[1], Lori J. Sahakian[1], Jennifer M. Grossman[1], Brian J. Skaggs[1], John D. FitzGerald[1], Christina Charles-Schoeman[1], Nagesh Ragavendra[2], Alan H. Gorn[1], George A. Karpouzas[3], Elizabeth R. Volkmann[1], M. Weisman[4], D. Wallace[5] and B H. Hahn[1], [1]Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]Harbor-UCLA Medical Center, Torrance, CA, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Cedars-Sinai Med Ctr, LA, CA

Purpose: Women with SLE have an unexplained increase in atherosclerosis (ATH). We previously reported that 45% of SLE women vs. 5% of controls have pro-inflammatory HDL (piHDL), and that piHDL confers a 16-fold increased risk for the concurrent presence of carotid artery plaque. It is unknown, however, whether piHDL predicts future progression of atherosclerosis. Here we hypothesize that baseline presence of piHDL is associated with longitudinal accumulation of subclinical atherosclerosis.

Methods: Female SLE and healthy age-and gender- matched subjects not taking statins were studied. B-mode and Doppler scanning of carotid arteries was performed at baseline and at 24-36 months. Antioxidant function of HDL was measured as the change in fluorescence intensity caused by oxidation of DCFH by LDL in the presence or absence of test HDL. Fluorescence in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated piHDL.

Results: Follow-up carotid ultrasounds were completed on 83 SLE women and 31 controls. Overall, 26.5% (22) of SLE patients had accumulation of new plaques vs. 16.1% (5) of controls ($p<0.0001$). Among the 22 SLE patients in our cohort with plaque progression, 20 (90.9%) had piHDL, compared to 47.5% of SLE patients with no new plaques ($p<0.0001$). Follow-up intima media thickness (IMT) was also higher in patients with piHDL at baseline than in those without; 0.62 ± 0.14 vs. 0.52 ± 0.07 ($p<0.0001$). After multivariate analysis, the only significant factors predictive of plaque progression in SLE were the baseline presence of piHDL, with an OR of 18.8 (95% C.I. 2.2 - 161.3, p=0.007), the baseline presence of plaque (OR 20.9, (95% C.I. 1.8 – 238.9, p=0.02), and increasing age (OR of 1.1; 95% C.I. 1.03 - 1.22, p=0.004).

Conclusion: piHDL has become apparent as a strong predictor for the future progression of subclinical atherosclerosis in women with SLE.

1930

Baseline EGFR Is Predictive of Arterial Vascular Events in Patients with Systemic Lupus Erythmatosus (SLE). Wendy Zhang[1], Elaheh Aghdassi[1], Heather Reich[1], James Scholey[1], Jiandong Su[2], Wendy Lou[2] and P. R. Fortin[3], [1]University Health Network, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of Toronto, Toronto Western Hospital, University Health Network, Toronto, ON

Purpose: To determine whether baseline renal functions predict the development of cardiovascular disease (CVD) in patients with SLE by using estimated glomerular filteration rate (eGFR).

Method: An inception cohort of 437 female patients was studied between 1970 and 2007. Baseline eGFR (mL/min/1.73m^2) was calculated using serum creatinine and the abbreviated Modification of Diet in Renal Disease Study Group formula (MDRD). Arterial vascular events (VE-A) including myocardial infarction (MI), angina, transient ischemic attacks(TIA), cerebral vascular accidents (CVA) and other arterial events (OAE) were documented at up to 15 years since the first visit. Disease activity was determined using SLE disease activity index (SLEDAI). Patients were classified into those with or without VE-A (VE-A, no-VE-A). VE-A patients were further classified into VE-As that occurred within or after 3 years since the first visit (VE-A<3yr, VE-A≥3yr). Estimated GFR values were compared between groups using the t-test and the Wilcoxon test when only two groups were considered, and using analysis of variance followed by pairwise comparisons via the Tukey-Kramer method for more than two groups. The relationship between eGFR and time to VE-A was investigated using the proportional hazards model.

Results: A total of 437 females, mean age 35.5±13.9 yrs, followed for 11.3±8.24 yrs, with the baseline eGFR of 88.3±29.8 were studied. A total of 50 patients had 52 VE-A events. Among patients with VE-A, 51.9% were VE-A<3yr. VE-A group had a significantly lower baseline eGFR (72.8±27.4 vs 90.3±29.5, P<0.05) and were significantly older (44.1±16.5 vs 34.4±13.1 yr, P<0.05) than no-VE-A.

VE-A<3yr group had a significantly lower baseline eGFR than VE-A≥3yr (61.2±26.0 vs 82.6±22.7, P<0.05) . Patients who were younger than the mean age of the VE-A group and with VE-A<3 had a significantly lower baseline eGFR than the corresponding age group with VE-A≥3(61.5±26.3 vs 85.2±20.8, P<0.05). Furthermore, those who were older than the mean age and with VE-A<3yr had a significantly lower baseline eGFR than the younger patients with VE-A≥3yr (61.0±26.7 vs 85.2±20.8, P<0.05).

The following variables were included in the multivariate model: age, baseline eGFR, baseline SLEDAI, cholesterol and systolic blood pressure. Baseline eGFR, age and baseline SLEDAI were significantly associated with not only VE-A but also with the risks of VE-A (eGFR: Hazard Ratio (HR) =0.986, CI: 0.974, 0.997; age: HR=1.032, CI: 1.012, 1.052; SLEDAI: HR=1.041, CI:1.015, 1.067). For a typical female SLE patient, controlling for other risk factors, every 10 mL/min/1.73m^2 decrease of baseline eGFR increased VE-A risks by 14%, every 10-year increase of age increased VE-A risks by 32%.

Conclusion: Lower baseline eGFR, older age and higher SLEDAI score were significantly associated with increasing odds of develop VE-A sooner. Aggressive management of renal diseases and VE-A risk factors should begin from the early stages of SLE in order to prevent the development of VE-A.

1931

Is Cigarette Smoking Associated with Disease Activity and Damage in Patients with Systemic Lupus Erythematosus? Meenakshi Jolly[1], Ravikumar Patel[1], Rohit Aggarwal[2], Winston Sequeira[1] and Joel A. Block[1], [1]Rush University Medical Center, Chicago, IL, [2]John H. Stroger, Jr. Hospital of Cook County and Rush University Medical Center, Chicago, IL

Purpose: To determine the effect of cigarette smoking on disease activity and cumulative organ damage in patients with systemic lupus erythematosus (SLE).

Methods: The data were extracted from an ongoing prospective study on health related quality of life in patients with SLE. Consecutive consenting adult SLE patients seen in the rheumatology clinic at an academic hospital were enrolled from September 2006 to April 2008 and detailed clinical and demographic variables were collected from 216 enrolled SLE patients. Disease activity was evaluated by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and cumulative organ damage was measured by the Systemic Lupus International Collaborating Clinics Damage Index (SLICC). Smoking was defined as present if the subject reported smoking at the time of the study. Chi-Square test was used to compare the categorical data and the Mann Whitney test was used for non parametric data between the cases 'smoker' and controls 'non-smoker'. $P < 0.05$ was considered significant on one tailed test.

Results: The mean (±SD) age of participants was 42 ± 13 years and 93 % were females. The ethnic composition was: African American 60 %, Caucasian 20 %, Hispanic 14 % and Asian 6 %. Fifteen percent of subjects reported that they were "currently smoking" at the time of the study. The mean (± S.D, range) SLEDAI score was 6.3 (± 6.1, 0-35) and mean SLICC score was 1.9 (±1.9, 0-9). Smokers had greater overall disease activity than nonsmokers (mean ± S.D, median) (7.8 ± 7, 6 vs. 6 ± 6, 4; p 0.047). SLEDAI scores suggested that - presence of arthritis (33.3 % vs. 18.1 %, p 0.044) and low complement levels (45.4 % vs. 28.3 %, p 0.042) were more frequent among smokers than among nonsmokers. There were no statistically significant differences in other components of SLEDAI. There was no statistically significant difference in overall disease damage in between smokers and nonsmokers, but specifically from SLICC skin scarring/alopecia (34.3 % vs. 9.1 %, p 0.001) and skin extensive scarring/ panniculum (34.3 % vs. 6.8 %, p 0.001) were more frequent among the smokers than nonsmokers. There were no statistically significant differences in other components of SLICC.

Conclusion: Cigarette smoking is associated with greater disease activity and cumulative organ damage in SLE. Smoking cessation should be aggressively addressed among patients with SLE.

1932

Evolution of Disease Burden Over 5 Years in a Multicentre Inception SLE Cohort. Murray B. Urowitz[1], Dafna D. Gladman[1], Dominique Ibañez[1] and Systemic Lupus International Collaborating Clinics (SLICC)[2], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto, ON

Purpose: The evolution on an annual basis of disease activity and damage and the annual accrual of key autoantibodies in patients with SLE is unknown. We describe the annual occurrence of these features in an inception cohort of patients with SLE.

Method: An international research network comprising 27 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2009. Of these, 298 patients followed for a minimum of 5 years constitute the study population. Clinical disease activity was assessed using SLEDAI-2K and disease damage using the SLICC/ACR Damage Index (SLICC/DI). ANA, Anti-DNA and anticardiolipin, antibody levels and the presence of the lupus anticoagulant were assessed at each visit. Descriptive statistics were used.

Results: Of the 298 patients followed for at least 5 years, 86.6% were female, 55.4% were Caucasian, 12.1% were Black, 14.4% were Asian, 16.1% Hispanic and 2.0% other. 41.9% were married and 60.4% had at least College education. Their mean age at enrolment was 35.3 years and SLEDAI-2K at enrolment was 5.9. The duration from diagnosis to enrolment was 5.5 months.

FU	**SLEDAI-2K**		**SLICC/DI**	
	n	Mean ± std	n	Mean ± std
0	298	5.93 ± 5.54	143*	0.37 ± 0.80
1	268	3.67 ± 4.11	237	0.55 ± 0.94
2	271	3.71 ± 4.50	270	0.67 ± 1.09
3	265	3.51 ± 3.64	262	0.79 ± 1.16
4	272	3.30 ± 4.05	269	0.94 ± 1.28
5	298	3.37 ± 4.15	295	1.01 ± 1.35

*** SLICC/DI performed only in those with > 6 months disease duration.**

FU	N	ANA	Anti-DNA	ACL	LA
0	298	93.6	29.3	25.6	26.9
1	268	95.3	37.6	21.8	26.7
2	271	95.3	48.3	17.3	24.2
3	265	96.3	50.7	20.2	29.1
4	272	96.3	53.4	23.7	34.2
5	298	97.0	55.4	25.6	32.6

Mean SLEDAI-2K decreases to low levels in the first year and then remains low. SLEDAI-2K was significantly lower at each year in Caucasians compared to the combined "other" ethnicities.

Mean SLICC/DI increases progressively over the 5 years but there was no significant difference at each year between Caucasians and "others". Although ANA positivity is high at enrolment, the percent positivity increases by almost 4% over 5 years. Frequency of anti-DNA positivity is lower at enrolment but increases over 5 years. Anticardiolipin antibody does not increase over 5 years but the lupus anticoagulant increases slightly.

Conclusion: As expected disease activity in newly diagnosed patients decreases over their first 5 years but disease damage increases. However key antibody levels ran variable courses over this period. For example ANA positivity increases only slightly over 5 years. Similarly anti-DNA antibody positivity was low in the first year of disease but rose to 55% by 5 years. Anticardiolipin antibody and the lupus anticoagulant were more constant over the first 5 years of disease.

Histology, Prognostic Factors, Treatment, & Outcome in SLE Patients with Non-Hodgkin's Lymphoma(NHL). S. Bernatsky[1], Rosalind Ramsey-Goldman[2], C. Gordon[3], Susan Manzi[4], O. Nived[5], S.C. Bae[6], G. Ruiz-Irastorza[7], K. H. Costenbader[8], S. Jacobsen[9], G. K Sturfelt[10], J. L. Lee[1], E. Turnbull[1] and A. E. Clarke[1], [1]MUHC, Montreal, QC, [2]Northwestern Univ, Chicago, IL, [3]Univ. of Birmingham, Birmingham, United Kingdom, [4]Univ of Pittsburgh, Pittsburgh, PA, [5]Inst of Clinical sciences, Lund, Sweden, [6]Hanyang Univ Med Ctr, Seoul, South Korea, [7]Universidad del País Vasco, Bizkaia, Spain, [8]Brigham & Women's Hospital, Boston, MA, [9]Univ Hospital, Copenhagen, Denmark, [10]Univ Hospital Lund, Lund

Purpose: To describe histology, prognostic factors, treatment & outcome of NHL in Systemic Lupus (SLE).

Methods: Lymphomas were identified via linkage with cancer registries at 7 centres, and through hospitalization & billing information at 1 centre. Histology, prognostic factors at lymphoma diagnosis, treatment & outcome were assessed from medical records. Prognostic factors were based on the International NHL Prognostic model, including age, elevated serum LDH, advanced stage, extra-nodal involvement, & poor performance status (Eastern Cooperative Oncology Group scale).

Results: Of the 35 patients who developed NHL after the SLE diagnosis, 32 were female. At the time of lymphoma diagnosis, the mean age was 52.8 years (standard deviation, SD 15.3), & mean SLE duration 13.1 years (SD 9.8, median 11.7).

Of the 28 cases where detailed histology information was available, 17 (60.7%) were diffuse large B-cell lymphomas (DLBC). In addition there were 5 follicular lymphomas, 5 marginal zone lymphomas, and 1 Burkitt's lymphoma. None of the patients with marginal zone lymphomas had Sjogren's syndrome. Data on lymphoma stage (Ann Arbor) was available for 26 cases; among these, advanced stage was seen in 18(69%). Among those with sufficient data (N=14), 11 SLE patients had ≥2 risk factors which, according to the NHL Prognostic model, confers a <50% chance of relapse-free & over-all 5-year survival

Treatment data was available for 28 of the 35 cases. Fourteen were treated with chemotherapy alone, 4 with radiation therapy alone, 2 with surgery alone and 6 with more than one therapy. Chemotherapy consisted primarily of standard CHOP (Cyclophosphamide, Adriamycin,

Oncovin, Prednisone). Rituximab was included in chemotherapy of 7 subjects, with an initially favorable response in terms of the lymphoma. Three were treated with stem cell transplants (autologous or allogenic).Two patients were not treated, one due to advanced lymphoma stage and poor prognosis. At the time of data collection, 16 of the 35 cases were deceased, including all but 3 of the subjects with poor prognostic factors at presentation.

Conclusion: These data confirm that the most common lymphoma histology in SLE is DLBC. The DLBC lymphomas make up about a third of NHL in the general population, but were twice as prevalent as this in our SLE sample. The predominance of DLBC histology in SLE may support the role of chronic antigen stimulation in the pathogenesis of lymphoma development in SLE**.** Our preliminary data suggest that SLE subjects with poor prognosis after NHL diagnosis may be identified on the basis of the International NHL Prognostic Factors model. It appears that most SLE patients diagnosed with NHL are offered standard therapy. Continued follow-up of the subjects, & expansion of the study sample, is ongoing.

1934

The Influence of Hip Muscle Strength and Hip Frontal Plane Moment On the Knee Adduction Moment in People with Knee Osteoarthritis. AB Gil, Pj Sparto, Sara R. Piva and G. Kelley Fitzgerald, University of Pittsburgh, Pittsburgh, PA

Purpose: It is believed that increased hip external adduction moment may have a protective effect on progression of knee osteoarthritis (KOA) by inducing a reduction of the knee adduction moment and consequently reducing stress on the knee medial compartment. An assumption is that hip abduction strength might be a contributor to the hip external adduction moment. Although this assumption makes theoretical sense, the relationships between hip abduction strength, hip adduction moment and knee adduction moment in subjects with KOA have not been verified. The purpose of this study was to explore the association of hip abduction strength and hip frontal plane moment with knee adduction moment in subjects with KOA.

Method: Twenty-six subjects with KOA participated in this cross-sectional study. Age 67.7 ± 11 years, 50% female, BMI 29.7 ± 7.3. Hip abduction strength was measured by a hand held dynamometer. Subject was side lying with hip at 0 degrees of abduction and 5 degrees of extension. Three maximum isometric voluntary contractions were performed and the average of 3 trials was calculated. Gait analysis was performed on a level surface using the VICON system. Subjects were asked to walk at their self-selected speed. The average of 5 trials was calculated. Inverse dynamics was used to calculate moment about the hip and knee joints. Data Analysis: A multiple linear regression model was built to predict knee adduction moment. After controlling for the amount of knee varus/valgus alignment obtained from long cassette X-rays, the main effects of hip abduction strength and hip external adduction moment were entered into the model followed by their interaction term (Hip Strength x Hip Adduction moment).

Results: Knee varus/valgus alignment was significantly associated with knee adduction moment (β_{Align}=-.579, R^2_{Align}=.34, $p < .01$). Subjects with greater varus alignment had increased knee adduction moment. Once knee alignment was in the model, hip adduction moment was the only other variable that predicted knee adduction moment ($\beta_{HipAddM}$ = -.353, $R^2Change_{HipAddM}$ = .12, $p < .05$). Subjects with greater hip adduction moment had lower knee adduction moment. The two predictors explained 46% of the variability in knee adduction moment.

Conclusion: Our results confirmed the association between frontal plane hip and knee adduction moments shown by Chang et al, 2005. However hip abduction strength was not associated with knee adduction moment during gait. Hip abduction strength capacity may not be the determining factor in the relationship between hip and knee adduction moments. An alternate explanation of how the hip abductors affect the

relationship between hip and knee adduction moments may be the timing of muscle activation rather than strength. These results have potential implications on rehabilitation in that the focus may be on motor control rather than simply on hip strengthening.

Effectiveness of Neuromuscular Electrical Stimulation On Knee Osteoarthritis Patients: Randomized Clinical Trial. Aline M. Imoto, Stella Peccin, Kelson NG Silva Sr., Lucas E.P.P Teixeira, Marcelo I. Abrahão and Virginia F.M. Trevisani, Federal University of Sao Paulo, Sao Paulo, Brazil

Purpose: The purpose of our study is to verify the effectiveness of an 8-week neuromuscular electrical stimulation (NMES) rehabilitation program on improving the function and pain in knee osteoarthritis' patients in comparison to an exercise program without NMES and educational program.

Methods: study design: randomized clinical trial. The sample of 150 patients was statistically randomized into three groups. The patients were evaluated by a blind assessor before and after intervention. The outcomes used were: visual analogical scale 0-10, Lequesne Index, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Activity of Daily Living Scale and Timed Up and Go Test. The NMES and Exercise groups were performed 2 times a week for 8 weeks. The educational group followed the manual guide for 8 weeks. For statistical analysis, the team used ANOVA to compare groups (continuous outcomes), chi-square for comparison between groups (categorical measures), paired T-test for comparison between before and after intervention. For all tests an alpha=5% was used, being considered significant $p<0,05$.

Results: The sample is described in table 1. The baseline assessment demonstrates the homogeneity of the three groups (age, Body Mass Index (Kg/m^2) gender). Considering that some patients left the study, the end sample size of our study is 125 participants (NMES (n)=42, Exercise(n)=43 , Educational(n)=40). There were statistically significant improvements in NMES and Exercise groups in terms of pain ($p<0,05$), Lequesne Index ($p<0,05$), WOMAC ($p<0,05$) (subscale pain, stiffness and function), ADLS ($p<0,05$) and Timed Up and Go Test ($p<0,05$). There were no statistical differences in any outcomes for the educational group ($p>0,05$). In comparing patients across groups, NMES and Exercise groups improved significantly versus the educational group. There were no statistical differences between the NMES and Exercise groups for the outcomes evaluated.

Conclusion: Based on the findings of our study, we conclude that NMES and Exercises are equally effective in improvement of pain and function on rehabilitation of knee osteoarthritis patients

1936

Factors Associated with Refusal to Participate in a Randomized Controlled Trial of Surgery Vs Non-Operative Therapy for Meniscal Tear in Knee Osteoarthritis. Debra J. Skoniecki[1], Joseph Palmisano[2], E. Losina[3], Angela S. Barraza[4], Christine E. Chaisson[2], Pamela Koeth[5], Julian C. Lagoy[6], Nina N. Niu[7], Emily K. Reinke[8] and J.N. Katz[9], [1]Brigham & Womens Hospital, Boston, MA, [2]Boston University, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Mayo Clinic, Rochester, MN, [5]Cleveland Clinic, Garfield Heights, OH, [6]Hospital for Special Surgery, New York, NY, [7]Brigham and Womens Hospital, Boston, MA, [8]Vanderbilt Orthopaedic Institute, Nashville, TN, [9]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Purpose: Adequate participation rates in surgical randomized controlled trials (RCTs) are crucial for assuring generalizable conclusions. The objective of this study was to evaluate enrollment rates and to identify factors associated with refusal to participate in a surgical RCT in patients with symptomatic meniscal tear and knee OA.

Method: The MeTeOR trial (Meniscal Tear in Osteoarthritis Research) is an NIH-funded, multi-center RCT to establish the efficacy of arthroscopic partial meniscectomy (APM) versus non-operative management of meniscal tear and knee OA. Eligibility criteria included age ≥ 45 and MRI documentation of a meniscal tear and cartilage degeneration. Patients with end stage OA (Kellgren-Lawrence (KL) grade 4) were excluded. Rates of participation were defined as the proportion who enrolled among those patients who were offered participation in the trial. To identify factors that distinguish individuals who refused the trial from those who enrolled, we examined data on demographics, OA severity as defined by KL grade, screening site and number of meniscal symptoms. We used bivariate and linear models (with GEE used to account for site effect) to determine correlates of refusal to participate.

Results: In the first year of recruitment 324 eligible individuals were identified across 5 clinical sites and 276 (85%) were offered enrollment into the trial. These 276 patients had a mean age of 58, 58% were female and 89% were Caucasian. 107 (39%) of them enrolled in the trial and 169 (61%) refused. In bivariate analyses, factors associated with refusing to participate in the trial among those who were offered enrollment included less severe KL grade and fewer meniscal symptoms. Specifically, 69% of those with KL 1refused enrollment in the trial as compared with 59% of those with KL 2 and 53% of those with KL 3 (p=0.02). Patients who refused to enroll in the MeTeOR trial had a mean of 4 ± 2 meniscal symptoms as compared with 5 ± 2 meniscal symptoms among those who enrolled (p=0.0001). The effects of KL grade and meniscal symptoms on the likelihood of refusal were confirmed in the multivariable analysis adjusting for site, race and age.

Conclusion: Participation rates in the MeTeOR trial were similar to other published surgical trials in persons with musculoskeletal conditions. Individuals with less severe OA and fewer meniscal symptoms have higher refusal rates in our surgical trial. These selection effects will need to be considered in interpreting MeTeOR trial results, particularly if OA severity and meniscal symptoms influence the trial conclusions.

1937

Disparities in Post-Acute Rehabilitation Care for Joint Replacement. J.K. Freburger, G.M. Holmes and M.P. Cutchin, University of North Carolina, Chapel Hill, NC

Purpose: To determine the extent to which demographic, socioeconomic, and geographic disparities exist in the use of post-acute rehabilitation care (PARC) for joint replacement and to identify factors that may contribute to these disparities.

Method: Cross-sectional analysis of two years (2005-2006) of population-based hospital discharge data from 355 acute care hospitals located in four geographically and demographically diverse states (AZ, FL, NJ, WI). Data from other sources (e.g., CMS, US Census, Area Resource file, American Hospital Association database) were merged with the hospital discharge data. The sample consisted of 201,319 adults ≥45 years of age (mean age 70 yrs; 62% female; 89% White, 4% Black, 4% Latino, 2% other) who were admitted to a short-term, acute care hospital for a hip or knee joint replacement. Individuals transferred to another acute care hospital or who died during the acute stay were excluded. The primary dependent variable was discharge destination (i.e., skilled nursing facility (SNF), inpatient rehabilitation facility (IRF), home health (HH), or home with no HH). Bivariate and multivariable analyses, including multi-level analyses, were conducted to identify disparities in PARC use and individual-level (e.g., disease severity, comorbidities), hospital-level, and community-level characteristics contributing to the disparities.

Results: 38% of the sample was discharged to a SNF, 13% to an IRF, 28% to HH, and 21% to home with no HH. In bivariate analyses, the percentage of individuals discharged to these settings varied significantly by age, sex, race, socioeconomic status (income, insurance), and geography (urban/rural county, state). After controlling for disease severity, comorbidities, sex, and age, disparities in PARC use remained. Relative to Whites, minorities (Black, Latino, Other) were more likely to be discharged to an institution (IRF or SNF) and they were more likely to receive care in an IRF than a SNF. Of individuals discharged to an institution, rural residents were also more likely to receive care in a SNF than an IRF. Individuals of lower socioeconomic status or rural residence were more likely to be discharged home and were less likely to receive home health. Of individuals discharged home, Blacks were also more likely to use HH relative to Whites. Multivariable analyses are underway to explore interactions and to determine the extent to which hospital (e.g., size, ownership, teaching status, volume, FTEs of rehabilitation staff) and community (e.g., available health care resources and sociodemographic composition at county and zip code levels) characteristics explain the disparities.

Conclusion: Factors beyond disease severity determine the type of PARC individuals receive following joint replacement. Understanding these factors is the first step in improving access to and quality of PARC. We have identified potential areas to target for improving access to PARC.

1938

Understanding Early Recovery Following Primary Total Hip and Knee Replacement. Aileen Davis[1], Elizabeth M. Badley[2], Sheilah Hogg-Johnson[3], Selahadin Ibrahim[3], Anthony V. Perruccio[4], Rosalind Wong[1], Dorcas E. Beaton[5], Pierre Côté[1], Monique A. Gignac[1], David L. Streiner[6], John Flannery[7] and Nizar N. Mahomed[8], [1]Toronto Western Research Institute, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Institute for Work and Health, Toronto, ON, [4]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [5]St Michael's Hospital, Toronto, ON, [6]Baycrest Centre for Geriatric Care, Toronto, ON, [7]Toronto Rehabilitation Institute - Hillcrest Centre, Toronto, ON, [8]University Health Network, Toronto, ON

Purpose: While baseline pain and functional status are known to predict these outcomes post total hip (THR) or knee (TKR) replacement in pre-post study designs, the trajectory of recovery has not been evaluated. This research evaluates the trajectory of recovery of symptoms, mood, physical function, and social and community participation for THR and TKR through six months post surgery.

Method: Participants completed the HOOS or KOOS, measures of pain, physical function, and sports/leisure activities; the Jette Late Life Disability (LLD) and the Calderdale community mobility questions as measures of participation; the POMS (fatigue); and, the HADS

(anxiety and depression) pre surgery, 2 weeks and 1, 3 and 6 months post surgery. Outcomes were all scored such that higher scores represented more problems. Recovery was compared for THR and TKR evaluating the impact of age, sex, and body mass index (BMI).

Results: THR (n=437) patients had a mean age of 63 years, 55% were female, 34% were overweight (BMI=25-29.9) and 35% were obese (BMI>30). TKR patients (n=494) had a mean age of 65 years, 65% were female, 38% were overweight and 45% were obese. Although symptoms, mood, activity and participation levels were similar pre-surgery, THR patients improved more rapidly and had better outcomes across measures than TKR patients at all times (p 0.049 to <0.0001). Age, sex and obesity all affected outcome (p<0.05). Older individuals (>64 years) had better mood and less activity limitations at baseline and to 2 weeks post surgery for THR, and to 1 month post surgery for TKR patients. Females reported worse outcomes irrespective of joint replaced. The exception was mood and activity limitations where women with TKR had worse outcome only to 1 month post surgery. Obese THR and TKR patients had higher pre-surgery scores for all outcomes with the exception of THR patients' mood. Obese TKR patients had more activity limitations at all times.

Conclusion: People with THR and TKR have different trajectories of outcome with TKR patients recovering more slowly and having poorer outcome than THR. Age, sex and obesity differentially affect different outcomes. These data have implications for the optimal timing of TKR surgery and rehabilitation service planning for THR and TKR.

1939

Do Worsening Knee Radiographs Mean More Chance of Poor Functional Outcome? the MOST Study. D. White[1], Yq. Zhang[1], J. Niu[1], David T. Felson[2], Julie J.. Keysor[3], M. Nevitt[4], C. Lewis[5], J. Torner[6] and T. Neogi[1], [1]BUSM, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]UCSF, San Francisco, CA, [5]UAB, Birmingham, AL, [6]UIowa, Iowa City, IA
Purpose: Radiographic knee osteoarthritis (ROA) is a chronic disease with different rates of progression. However, it is not known if people with faster progression are at higher risk of poor functional outcome than those with slower progression. Thus, we compared the incidence of poor functional outcome over 30 months among those with stable, incident, or worsening ROA.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH funded longitudinal study of people who have or are at high risk for knee OA. We included people who had or developed ROA over 30 months and were not functionally limited at baseline. Knee radiographs and functional assessments were completed at baseline and 30 mo. We defined the incidence of two poor functional outcomes at 30 months using cut points shown to be risk factors for 1) total joint replacement (WOMAC physical function ≥ 36/68) and 2) persistent functional limitation (walking speed ≤1.0 m/s). We defined ROA as K/L grade ≥2 in the TF joint or patellofemoral OA based on the lateral view. We categorized ROA progression over 30 mo as follows: 1) stable K/L or JSN grades in both knees, 2) incident ROA in either knee, or 3) increase in K/L or JSN grades with existing ROA in either knee (worsening ROA). Those with new total knee replacements or existing endstage ROA (K/L=4 or JSN=3) were excluded from analyses. We evaluated the relation of ROA incidence or worsening to the incidence of poor functional outcome by calculating risk ratios adjusted for age, sex, BMI, race, depressive symptoms, number of comorbidities, and pain at lower extremity sites other than the knee, in separate analyses for each of the two outcomes.

Results: Of the 1320 subjects with ROA at 30 months (Age 63 ± 8 yrs, BMI 32 ± 6 kg/m^2, female 61%), 30% had stable ROA, 12% incident ROA, and 58% worsening of ROA. Of those without poor functional outcome at baseline, we found 5% of 957 and 10% of 873 subjects to develop poor functional outcomes at 30 mo for WOMAC and walking speed, respectively. Compared with stable ROA, we found higher risk of poor functional outcome in both those with incident ROA (adj RR 2.4-3.0) and worsening ROA (adj RR 2.3-3.3). (See Table).

Conclusion: The development of poor functional outcome is higher in worsening and incident disease, than those with stable ROA. Clinicians should consider the rate of radiographic worsening to identify those who may benefit from rehabilitation.

Table: Relation of ROA progression over 30 months with incidence of poor functional outcome at 30 months.

Incidence of poor functional outcome		WOMAC (n=957)	Walking Speed (n=857)
Stable ROA	n (incident poor functional outcome)/N (subjects without limitation at baseline)(%)	8/289 (3)	13/264 (5)

	Adj RR* [95% CI]	1.0 Ref	1.0 Ref
Incident ROA	n/N (%)	6/121 (5)	12/107 (11)
	Adj RR* [95% CI]	3.0 [0.9-10]	2.4 [1.1-5.3]
Worsening ROA	n/N (%)	33/547 (6)	63/502 (13)
	Adj RR* [95% CI]	3.3 [1.2-9.5]	2.3 [1.2-4.2]

* adjusted for age, sex, BMI, race, depressive symptoms, number of comorbities, and pain at lower extremity sites other than the knee

Early Neuromuscular Electrical Stimulation Improves Strength and Functional Performance After Total Knee Arthroplasty.

Jennifer E. Stevens-Lapsley, Jaclyn E. Balter, Wendy M. Kohrt and Donald G. Eckhoff, University of Colorado Denver, Aurora, CO

Purpose: Muscle weakness and reduced functional capacity are present before and after total knee arthroplasty (TKA). Neuromuscular electrical stimulation (NMES) offers an innovative approach to potentially mitigate quadriceps muscle activation deficits early after TKA and restore normal quadriceps muscle function more effectively.

Method: Fifty-four patients with end-stage osteoarthritis were studied (65.7±8.8 years; 32 women, 22 men). Patients were excluded if they had uncontrolled hypertension, uncontrolled diabetes, body mass index >35, other significant lower extremity orthopaedic problems, or neurological impairments. Patients were randomly assigned to either a standard rehabilitation group (Control, n=25) or NMES group (NMES, n=29).

Quadriceps isometric strength was assessed preoperatively and again at 3wks, 6wks, and 3 months after TKA using an isomechanical dynamometer. Functional performance measures included a timed up–and-go (TUG) test, stair climbing test (SCT), 100ft walk test, and 6 minute walk test (6MW).

Rehabilitation: All patients participated in a standardized rehabilitation program for 9wks following surgery, which included 3-5 days of inpatient PT, 2wks of home PT, and 6wks of outpatient PT. Patients randomized to the NMES group also received NMES treatment (Empi 300PV) 2x/day for 15 minutes/session for 6wks beginning 2 days after surgery. Data analysis involved repeated measures with 2-way ANOVAs using baseline values as covariates for all outcome measures.

Results: Overall, significant main effects of NMES treatment were found for all outcome measures through the 3 month follow-up (quadriceps strength, TUG, SCT, 100ft walk, 6MW; $p<0.05$). Quadriceps strength loss (compared to pre-operative levels) 3wks after TKA was significantly attenuated in the NMES group (21.49±39.9% loss) compared to the control group (47.55±16.6% loss). By 6 weeks, there was a strength gain of 5.2±44.3% in the NMES group compared to a 22.15±28.7% deficit for controls.

Conclusion: Incorporating NMES into rehabilitation 2 days after TKA resulted in better quadriceps strength and functional performance than standard rehabilitation alone. Clinical Significance: Early NMES after TKA may help attenuate quadriceps strength loss and activation deficits to enhance functional performance after TKA.

1941

Dose-Response Vs Threshold Relationship Between Physical Activity and Function in Knee OA. D. D. Dunlop[1], J. Song[1], P. Semanik[2], L. Sharma[1] and R. W. Chang[1], [1]Northwestern University, Chicago, IL, [2]Rehabilitation Institute of Chicago, Chicago, IL

Purpose: It is not known if physical activity has a dose-response or a threshold relationship with function for persons with knee OA. Because physical activity is a key public health intervention, understanding this relationship has important implications for public health recommendations. A dose-response relationship would support advice to increase physical activity regardless of a person's current activity levels. A threshold relationship would support future research to identify what threshold target conveys functional benefits for persons with knee OA.

Methods: The Osteoarthritis (OAI) public data include n=2579 adults (aged 45-79) with radiographic knee OA (KL grade ≥2) at the baseline visit; n=2274 returned for the 1 year visit. Each person was assigned to a baseline physical activity quartile (Q1=low to Q4=high) from PASE (physical activity scores for elderly) scores. Function was assessed objectively by chair stand rate and walk rate over 20 meters. Multiple regression evaluated the relationship of PASE quartiles to functional outcomes controlling for demographics (age, gender, race, education, marital status), knee health (OA severity grade, knee symptoms, WOMAC knee pain, knee injury) and general health (BMI, comorbidity, depression, smoking, alcohol use, any hip, ankle, or foot pain).

Results: Average functional performance consistently increased with higher PASE quartiles for both 20m walk (Q1: 74, Q2: 77, Q3: 79, Q4: 82 meter/min) and chair stand performance(Q1: 25, Q2: 27, Q3: 28, Q4: 30 repetitions/min). To determine if higher physical activity levels consistently corresponds to better function among people with similar demographics and health, we examined functional differences controlling for these factors. These results (Table) showed a strong cross-sectional dose-response relationship and a statistically significant linear trend. The dose-response relationship was sustained over one year.

	Function differences between PASE baseline quartiles adjusted for demographic and health factors			
Baseline Function n=2579	Q2-Q1 (95% CI)	Q3-Q1 (95% CI)	Q4-Q1 (95% CI)	Trend Test
Walk rate	1.5 (0.3, 2.7)	3.00 (1.8, 4.2)	4.22 (2.9, 5.5)	p<.001
Chair stand	1.3 (0.2, 2.4)	1.9 (0.8, 3.0)	2.1 (0.9, 3.3)	p<.001
1 Year Function n=2274				
Walk rate	1.0 (-0.3, 2.3)	2.4 (1.1, 3.7)	3.5 (2.1, 4.9)	p<.001
Chair stand	0.8 (-0.4, 2.0)	2.1 (0.8, 3.3)	2.2 (0.9, 3.6)	p<.001

Conclusion: These findings demonstrate a strong dose-response relationship between physical activity and functional performance in persons with radiographic knee OA that is sustained over one year. This relationship persists controlling for demographic and health factors. These findings support efforts to increase physical activity at all levels to improve functional performance of persons with knee OA.

1942

The Joints On Glucosamine (JOG) Study: A Randomized, Double-Blind, Placebo-Controlled Trial to Assess the Structural Benefit of Glucosamine in Knee Osteoarthritis Based On 3T MRI. C. Kent Kwoh[1], Frank W. Roemer[2], Michael J. Hannon[3], Carolyn E. Moore[4], John M. Jakicic[3], Ali Guermazi[2], Stephanie M. Green[3] and Robert M. Boudreau[3], [1]University of Pittsburgh, VA Pittsburgh Healthcare System, Pittsburgh, PA, [2]Boston University School of Medicine, Boston, MA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Texas Woman's University, Houston, TX

Purpose: Prior studies of the structural benefit of glucosamine in knee osteoarthritis (KOA) as assessed by radiographs have yielded conflicting results. The aim of this study was to determine the short-term efficacy of glucosamine based on decreased worsening of structural lesions in KOA as assessed using 3T MRI.

Method: The Joints on Glucosamine (JOG) study was a 24-week double-blind placebo controlled trial of 1500 mg glucosamine hydrochloride once daily in beverage form compared to placebo. The primary outcome was decreased development of cartilage damage. Eligible participants had mild to moderate knee pain (WOMAC score > = 125). 3T MRI of both knees was performed at baseline and at 24 weeks on a Siemens Trio using the same pulse sequences used in the Osteoarthritis Initiative (OAI): sagittal fat-suppressed (FS) 2D TSE intermediate-weighted (IW); sagittal 3D dual-echo steady state (DESS) WE; and axial and coronal reformations of sagittal 3D DESS WE. Cartilage damage, bone marrow lesions (BMLs) and synovitis in each knee were scored according to the WORMS system. Baseline fixed-flexion knee x-rays were read for Kellgren-Lawrence (K-L) grade and radiographic features such as joint space narrowing using the OARSI grading system. All MRIs and x-rays were read masked to treatment assignment but not to baseline vs. follow-up order. Urinary excretion of C-terminal cross linking telopeptide of type II collagen (uCTX-II) as a biomarker of cartilage synthesis was also assessed. An Intent-to-Treat analysis with last event carried forward was performed. Negative binomial regression for cartilage defects and multivariate logistic regression for worsening BML, taking into account clustering of knees within an individual and adjusted for gender, age, BMI, baseline WOMAC, and K-L grade, were performed to determine the odds (aOR) of worsening based on treatment group assignment. These covariates were used in a linear regression model for uCTX-II.

Results: There were a total of 201 participants (49% women) with a mean age of 52, 98 were block randomized to the treatment group and 103 to the control group. The aOR of worsening cartilage defects in the glucosamine group compared to the control group was 0.9 (95% CI 0.55-1.58). The aOR for worsening in BMLs was 0.73 (95% CI 0.50-1.07).

There also was no indication that glucosamine improved uCTX-II (beta = -0.10, 95% CI -0.21-.001). There was a difference in the proportion of drop-outs by group (i.e., 16.5% in the placebo group vs. 5.1% from the glucosamine group, $p < 0.01$).

Conclusion: This short-term study provided no evidence that glucosamine results in structural benefit in knee OA as assessed using 3T MRI or uCTX.

CRx-102 (Prednisolone/Dipyridamole Combination) Enhances Glucocorticoid (GC) Efficacy and Reduces Adverse Effects in OA Therapy: 3-12 Month Results. Kenneth Huttner[1], William J. Shergy[2], Craig Romney[3] and John C.R. Randle[1], [1]CombinatoRx, Inc., Cambridge, MA, [2]Univ of Alabama, Huntsville, AL, [3]Liberty Research Center, Tacoma, WA

Purpose: High-dose intra-articular GC is used commonly to treat OA, but oral GC is not used due to safety concerns in this patient population. CRx-102 is a combination of very low-dose prednisolone (Pd 2.7 mg/d) and dipyridamole (Dp), demonstrating synergistic enhanced anti-inflammatory GC effects *in vitro* and *in vivo*, without amplification of the GC adverse effects, approaching GC dissociation through a multi-target mechanism rather than medicinal chemistry. In previous RA and hand OA studies, CRx-102 exhibited clinically meaningful anti-inflammatory activity and was generally well-tolerated.

Methods: COMET-1 was a 14-week Ph2, double-blind, placebo-controlled, knee OA trial, with a 1-y follow-on safety extension. Subjects had screening WOMAC knee pain Q#1 VAS score of 30-80 mm with at least 10 mm flare following NSAID/Coxib discontinuation. Three CRx-102 doses (Pd 2.7 mg/d with Dp 90, 180 or 360 mg/d) were compared with Pd (2.7 mg/d) and placebo on knee OA and hand OA efficacy measurements. In the safety extension, all subjects received 1 of the 2 higher doses of CRx-102 and were monitored for long-term GC tolerability and durability of response. Intensive monitoring of weight, lipids, glucose homeostasis, HPA axis, bone density, intraocular pressure and cataract development with FDA-approved intervention rules makes this the first large, prospective, controlled study of the safety of very low-dose GC.

Results: COMET-1 enrolled 279 subjects and 141 continued in the safety extension (74% of eligible completers). With NSAID/Coxib therapy withdrawn, the CRx-102 (2.7/360) group had sustained, significant reductions in median WOMAC pain, function and stiffness scores vs. placebo, greater at D98 than the placebo and Pd groups by 17.2-19.5 mm and 5.5-8.6 mm, respectively. Accordingly, WOMAC 70% response rates were significantly greater for CRx-102 (2.7/360) vs. placebo on all three subscales at D98. Similar trends in hand pain reduction were seen in the subset of OA subjects with baseline hand pain >= 30 mm. The most commonly-reported AE was headache, with 4-5% drop-out in each active treatment arm. CRx-102 at the maximally effective dose (Pd + the vasodilator Dp at 360 mg/d) reduced both SBP and hypertension frequency vs. placebo and Pd alone. Analysis of bone metabolism demonstrated a small but significant decrease in bone formation markers in the Pd group, contrasting with a more balanced effect on formation and resorption with CRx-102 exposure accompanied by a trend to higher mean hip and femoral neck BMD.

Conclusion: COMET-1 is the first prospective RCT to demonstrate the efficacy of the dissociated glucocorticoid CRx-102 and very low-dose oral Pd in the treatment of knee OA. These effects are comparable to those of current OA therapies, including NSAIDs and Coxibs, and in conjunction with the good tolerability and long-term safety support the investigation of CRx-102 as an alternative anti-inflammatory therapy in OA.

1944

The Reduction in Serum Level of MMP-3 Seen in a Phase III Study in Knee Osteoarthritis Patients Is Predictive of the Protective Effect On Cartilage Volume Loss of a DMOAD Treatment. Jean-Pierre Pelletier[1], Jean-Pierre Raynauld[1], François Abram[2], Judith Caron[1], François Mineau[1], B. Haraoui[3], Denis Choquette[4] and Johanne Martel-Pelletier[1], [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]ArthroVision Inc., Montreal, QC, [3]Institut de Rhumatolgie de Montreal, Montreal, QC, [4]University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC

Purpose: Licofelone, a dual inhibitor of 5-lipoxygenase and cyclooxygenase, compared to naproxen was found to be a disease modifying drug (DMOAD) in a phase III study in knee osteoarthritis (OA) patients using quantitative MRI[1]. Very little information is available on the value of predictive and/or prognostic biomarkers in OA trials in which disease progression and cartilage volume loss were assessed using quantitative MRI. The present study explored the relationship between the protective effect of licofelone on cartilage volume loss and symptom relief, using the most relevant OA biomarkers.

Method: A subset of 155 patients selected from a clinical trial evaluating the impact of licofelone (n=81; 200 mg bid) versus naproxen (n=74; 500 mg bid) on OA knee tissue structure, were studied. The patient population had a mean age of 60.5 years, 68% were female, and the average BMI was 32.3 kg/m^2. Patients with KL grade IV were excluded. Only patients who had taken all the study medication according-to-protocol (ATP) throughout the two year period were considered for this sub-analysis. MRI acquisitions of the knee were done at baseline and two years of follow-up and the cartilage volume and bone marrow lesions quantitated. Patients underwent clinical evaluation using the WOMAC questionnaire (pain, stiffness and function). Seven biomarkers, relevant to OA structural progression, were measured at baseline and at two years: CRP, MMP-1, MMP-3, IL-6 and COMP in serum, and CTX-I and CTX-II in urine.

Results: The increase in MMP-3 and MMP-1 levels in the patients was significantly less over time in the licofelone group vs. naproxen ($p<0.0001$ and $p=0.05$, respectively). Moreover, a positive correlation was found between the baseline values of MMP-3 ($p=0.01$) and COMP ($p=0.03$) and the cartilage volume loss at two years. The extent of increase in the levels of MMP-3 ($p=0.02$) and MMP-1 ($p=0.06$) over time was found to be associated with the severity of cartilage loss. CTX-I levels at baseline also correlated ($p=0.02$) with the increase in

bone marrow lesion size in the medial compartment. The CRP levels at baseline were positively correlated with the worsening of symptoms: WOMAC total index (p=0.0009), pain (p=0.002) and function (p=0.001).

Conclusion: This study demonstrated that some serum biomarkers (MMP-3, MMP-1 and COMP) can predict the loss of cartilage in knee OA patients. However, levels of MMP-3 and to a lesser extent MMP-1 are the most useful predictive biomarkers in the monitoring of the DMOAD effect. CRP was found to be the most reliable marker for predicting the evolution of disease symptoms over time.

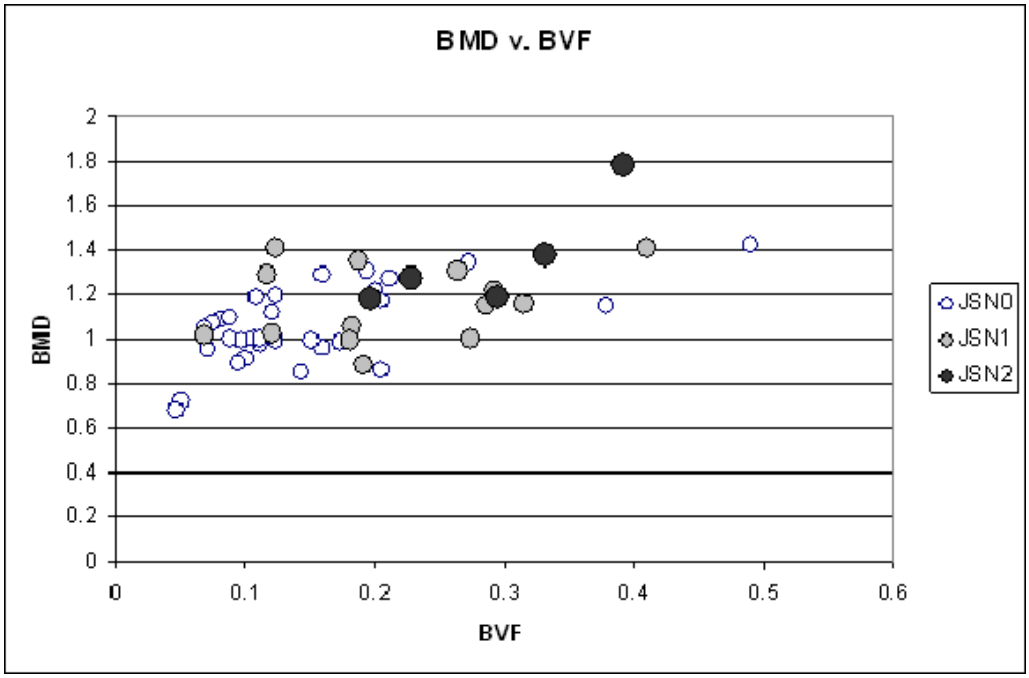
1945

Higher Subchondral Bone Volume Is Associated with Higher DXA Bone Mineral Density and Knee OA Severity. Grace H. Lo[1], Kimberly Carr[1], Lori Lyn Price[1], Erika Schneider[2], Sharmila Majumdar[3] and Timothy McAlindon[1], [1]Tufts Medical Center, Boston, MA, [2]Cleveland Clinic, Cleveland, OH, [3]UCSF, San Francisco, CA

Purpose: There is growing evidence that the subchondral bone changes are pathologic in OA. Radiologic imaging allows for visualization of bone in vivo in humans. Apparent bone mineral density (BMD) as measured by Dual X-ray Absoptiometry (DXA) can assess the amount of mineralization within a region of interest (ROI) while MRI is able to measure bone volume fraction (BVF). Because we expected that there will be changes in mineralization in regions where there is higher bone fraction, we evaluated the relationship of tibial BMD (tBMD) with MRI measured BVF.

Methods: 50 participants of the Osteoarthritis Initiative Bone Ancillary Study who had knee DXAs and knee trabecular bone MRIs obtained at the same visit were included in this study. DXAs were obtained using a customized protocol on GE Lunar Discover Bone Densitometry scanners. We measured medial proximal tibial BMD (tBMD) including 1cm depth of subchondral bone. MRIs were obtained at 3T with 1mm slice thickness, in-plane spatial resolution of 0.2 mm X 0.2 mm, with a 12 cm imaging field-of-view, 512 X 512 matrix, 72 slice coverage with TE 4.92 msec (fat-water in-phase), TR 20 msec, flip angle 50^{o}, phase right/left, interpolation to 1024 X 1024, and no partial Fourier. MRIs were analyzed utilizing proprietary software that measured BVF in the medial proximal tibia (tBVF). We evaluated for a correlation between medial tBMD and tBVF. We then created scatter plots tBMD v. tBVF stratified by JSN and ran ANOVAs of tBMD and tBVF by JSN.

Results: The mean age was 67.2 (9.5), BMI 28.1 (4.1), and 50% were male. 31 had JSN of 0, 14 with JSN of 1, and 5 with JSN of 2. The correlation between the medial tBMD and tBVF was r = 0.64, p <0.0001. The tBMD by JSN were 1.17 g/cm^2, 1.30, and 1.60 for JSN 0, 1, and 2 respectively, p = 0.0003. The tBVF by JSN were 0.15, 0.22, and 0.29 for JSN 0, 1, and 2 respectively, p = 0.0042.



Conclusion: In regions of higher tBMD, there is greater BVF. Knees with a greater medial JSN, a marker of greater OA severity, have a higher medial tBMD and tBVF. A potential explanation for these findings is that regions of high tBMD and tBVF represent compressed subchondral bone. Further characterization of the subchondral bone in OA utilizing diverse radiologic methods will help clarify OA pathophysiology.

ACR Concurrent Abstract Sessions

Pathogenesis of Gout, Allopurinol Dosing, the Hypouricemic Effect of Milk, and the Mortality Impact of Gout

Tuesday, October 20, 2009, 4:30 PM - 6:00 PM

1946

Severity of Gout and Mortality. Fernando Perez-Ruiz[1], Lorea Martinez-Indart[2], Loreto Carmona[3], Ana M. Herrero-Beites[4] and Jose I. Pijoan[5], [1]Hospital De Cruces, Barakaldo, Spain, [2]Hospital de Cruces, Baracaldo, [3]Fundación Española Reumatol., Madrid, [4]Hospital de Gorliz, Gorliz, Spain, [5]Hospital de Cruces, Baracaldo, Spain

Purpose: Recent studies have demonstrated an association of gout with an increased risk of cardiovascular (CV) mortality. The association proven is indirect, through the relation of gout with CV-related comorbidity and risk factors. The objective was to test whether the relation of mortality and gout may be direct, that is, whether the severity of gout may be associated to CV mortality.

Method: Prospective longitudinal study of all gout patients ever attended at a single Gout clinic. Baseline variables included sociodemographics, use of urate lowering drugs (ULD), number of joints affected, presence of tophi, number of flares in the previous year, prevalent CV disease, alcohol intake, and CV risk factors. Vital status was investigated in any patient who did not attend a follow-up visit.

Kaplan-Meier estimates and log-rank test were used to identify variables associated with mortality. Variables found to have a statistical association with mortality in the bivariate analysis were selected for a multivariate Cox proportional hazard regression analysis using a stepwise model. The Standardized Mortality Rate (SMR) was calculated comparing the mortality observed in the sample to the expected rate in the general population of similar age and sex (2005 National Statistics).

Results: From 1992 to November 2008, 706 patients were included, 662 (94%) of whom were men. At baseline, 436 (72%) had never received ULDs, 358 (51%) had 2 to 4 joints involved and 244 (35%) >4, and 215 (31%) had tophi. A CV disease was present in 178 (26%) cases, 153 (22%) used diuretics regularly, 142 (20%) had diabetes mellitus, 291 (41%) had arterial hypertension, and 298 (42%) had hyperlipidemia. During follow-up (range: 1 month to 14 years), 64 (9%) patients died (55 men and 9 women), with 38 (70%) attributed to CV cause. The SMR (any cause) in patients with gout was 2.37 (95% CI: 1.82 to 3.03)[men 1.57 (95% CI: 1.18 to 2.05); women 4.50 (95% CI: 2.06 to 8.54)]. The SMR (CV cause) was 3.88 (95% CI: 2.70 to 5.40). The following baseline variables were significantly associated to mortality in the bivariate analysis: age, gender, number of flares, presence of tophi, number of joints involved, secondary gout, ethanol intake, hypertension, diabetes, renal insufficiency, diuretic use, and previous cardiovascular disease. Only four of these variables were found to be independently and statistically significantly associated with mortality:

Table 1. Variables independently associated with mortality in gout patients.

	Hazard ratio	95% CI	*p*
Age (by year)	1.07	1.04 – 1.10	<.001
Serum urate (per mg/dl)	1.20	1.06 – 1.36	.004
Secondary gout	2.45	1.33 – 4.54	.004
Presence of tophi	1.84	1.12 – 3.02	.016
Prevalent CV disease	2.01	1.06 – 3.81	.033

Conclusion: Patients with gout may have an excess mortality and an excess CV mortality. Severity of gout at baseline is associated to increased mortality as much as prevalent CV disease. These results emphasize the importance of not delaying intense treatment in gout patients.

The Acute Effect of Skim Milk On Serum Urate Concentrations: A Randomized Controlled Cross-Over Trial. Nicola Dalbeth[1], Sumwai Wong[1], Greg Gamble[1], Anne Horne[1], Barbara Mason[1], Lynette Fairbanks[2], Fiona M. McQueen[1], Jillian Cornish[1], Ian R. Reid[1] and Kate Palmano[3], [1]University of Auckland, Auckland, New Zealand, [2]Guy's Hospital, London, United Kingdom, [3]Fonterra Research Centre, Palmerston North, New Zealand

Purpose: Recent observational studies have highlighted the beneficial role of skim milk in prevention of gout. The aims of this study were to determine the acute effects of intact skim milk on serum urate concentrations, and to examine the mechanisms of the urate-lowering effects of skim milk.

Method: This was a short-term randomized controlled cross-over trial of skim milk in 16 healthy male volunteers. The following products were tested (each 80g protein); soy control, early season skim milk, late season skim milk (containing high concentrations of orotic acid, a naturally occurring uricosuric agent), and MPC 85 skim milk (an ultra-filtrated skim milk containing very low concentrations of orotic acid, purines and lactose). Each participant received a single dose of each product in random order. Serum and urine were obtained immediately before ingestion and then hourly over a three hour period after ingestion of each study product. Each study visit was separated by at least a week.

Results: Ingestion of the control soy led to an increase in serum urate by approximately 10%. In contrast, all skim milks led to a decrease in serum urate by approximately 10% ($p<0.0001$) (Figure). All products (including soy) rapidly increased the fractional excretion of uric acid (FEUA). Late season skim milk led to a greater increase in FEUA compared with MPC 85 ($p=0.02$) and early season skim milk ($p=0.052$). There were no significant differences over time or between groups in changes in serum oxypurines (xanthine and hypoxanthine) or purine-containing nucleosides (guanosine and inosine). However, all products led to an increased fractional excretion of xanthine ($p=0.004$).

Conclusion: This study has demonstrated that intact skim milk has a specific acute urate-lowering effect. These data provide further rationale for long term intervention studies to determine whether such dietary interventions play an adjunctive role in management of hyperuricaemia and gout.

Figure: Effects of soy and skim milks on changes in serum urate concentration. Data are presented as mean (95% CI).

1948

Cellular Characterization of the Gouty Tophus: A Quantitative Analysis. Nicola Dalbeth, Bregina Pool, Greg Gamble, Timothy Smith, Karen E. Callon, Fiona M. McQueen and Jillian Cornish, University of Auckland, Auckland, New Zealand

Purpose: The gouty tophus is the hallmark of chronic gout. The aim of this study was to characterize the cellular architecture of the tophus, and to determine the presence of cytokines implicated in initiation and resolution of gouty inflammation.

Method: Sixteen fixed, paraffin-embedded, uninfected tophus samples were surgically obtained from twelve patients with microscopically proven gout. The samples were analyzed by quantitative immunohistochemistry. The number of cells present in the corona and fibrovascular zones of the tophus was analyzed by GENMOD mixed model analysis to account for repeated counts within the same individual.

Results: All results are summarized in the Table. Numerous CD68+ macrophages were present within the corona zone. The majority of these cells were mononucleated, but multinucleated CD68+ cells were also identified. Mast cells were present in all tophus samples, throughout the corona and fibrovascular zones in similar densities. In contrast, neutrophils were rarely observed. Plasma cells were present in very high numbers within the corona zone. The overall number of CD20+ B cells was much lower. However, in 5 of the 12 (42%) patients, at least one B cell aggregate was present in the fibrovascular zone. Large numbers of cells expressing IL-1β were observed, particularly within the corona zone, in both mononucleated and multinucleated cells. TGF-β1-expressing mononucleated cells were also identified. The number of cells expressing IL-1β correlated with the number expressing TGF-β1 ($r=0.59$, $p=0.03$). The number of CD68+ cells correlated with the number of cells expressing IL-1β ($r=0.64$, $p=0.02$) and TGF-β1 ($r=0.63$, $p=0.009$).

Conclusion: The tophus represents a complex and organized chronic inflammatory tissue response to MSU crystals. Both innate and adaptive immune cells are present within the gouty tophus, contrasting with the well recognized, dominant role of innate immunity in the acute gout attack. The co-expression of IL-1β and TGF-β1 within the tophus suggests that both pro- and anti-inflammatory factors present within the same lesion contribute to a cycle of chronic inflammation, attempted resolution and tissue remodeling.

Table: Summary of all results. For all cells, numbers indicate median (interquartile range) number of cells/high power field (at x20 magnification).

	Corona zone	**Fibrovascular zone**	**p**
Macrophage (CD68)	55 (22.5-83)	10 (3.5-16)	<0.0001
CD68+ multinucleated cells	8 (5-38)	0 (0-1)	<0.0001
Mast cell	24 (16-36)	18.5 (13-25.5)	0.38
Neutrophil	0.5 (0-2)	0 (0-2)	<0.0001
T cell	14 (6-32)	8 (4-24)	0.41
CD8+ T cell	9 (7-34)	18 (5-33)	0.74
Plasma cell	73 (36-113.5)	15 (6.5-40.5)	<0.0001
CD20+ B cell	0 (0-3)	8 (4-19)	0.0003
IL-1β	169 (139-228)	26 (21-34)	<0.0001
TGF-β1	27 (16-38.5)	7 (4-18.5)	0.035

1949

Intracellular Calcium Oscillations in Articular Chondrocytes Induced by Basic Calcium Phosphate Crystals Lead to Cartilage Degradation. Christelle Nguyen[1], Hang-Korng Ea[1], Christian Bordat[2], Michèle Lieberherr[3] and Frédéric Lioté[1], [1]INSERM UMR-S 606, Paris-Diderot University, Lariboisière Hospital, Paris, France, [2]INRA UR 909, MIMA 2 Plateform, Jouy-en-Josas, France, [3]INSERM U567, CNRS UMR 8104, Paris-Descartes University, Cochin Institute, Paris, France

Purpose: Basic calcium phosphate (BCP) crystals, including octacalcium phosphate (OCP), carbapatite (CA) and hydroxyapatite (HA), are associated with destructive forms of osteoarthritis. However, mechanisms of cartilage breakdown induced by BCP crystals are incompletely understood. This study was designed to evaluate whether BCP crystals induce intracellular calcium (Ca^{2+}_i) variations and the role of Ca^{2+}_i in BCP-induced glycosaminoglycan (GAG) release.

Method: Bovine articular chondrocytes (BAC) and bovine cartilage explants (BCE) were stimulated by pyrogen-free OCP, CA, HA, or monosodium urate (MSU) crystals. Ca^{2+}_i levels in isolated BAC were determined with the photoactive dye Fura-2/AM, and Ca^{2+}_i oscillations by confocal microscopy using the fluoroprobe Fluo-4/AM. GAG release was measured in the supernatants of BCE cultures by 1,9-dimethylmethylen blue assay. Mechanisms of Ca^{2+}_i oscillations induced by BCP crystals were assessed by a pharmacological approach.

Results: All BCP crystals, contrary to MSU crystals, induced Ca^{2+}_i increase compared to baseline level (OCP: 2.4 ± 0.9-fold the control value, $p < 0.0001$; CA: 2.4 ± 1.8, $p = 0.003$; HA: 1.4 ± 0.4, $p = 0.005$; and MSU: 1.5 ± 0.6, $p = 0.160$). OCP crystals also induced Ca^{2+}_i oscillations within minutes. Ratio of BAC displaying Ca^{2+}_i oscillations increased with time to reach a maximum after 20 minutes of OCP crystal stimulation (49.0 ± 24.3%, $p < 0.005$), whereas no Ca^{2+}_i oscillations were observed in control BAC stimulated only by microscopy laser beam or fluid flow. OCP crystal-induced Ca^{2+}_i increase and Ca^{2+}_i oscillations involved several mechanisms including extracellular Ca^{2+} influx and Ca^{2+}_i storage and exflux. Indeed, Ca^{2+}_i oscillations induced by OCP crystals were completely abolished when experiments were performed in Ca^{2+}-free medium suggesting the role of extracellular Ca^{2+} influx. Extracellular Ca^{2+} influx involved voltage-independent and voltage-dependent Ca^{2+} channels, since Ca^{2+}_i levels decreased when BAC were pre-treated with either nickel (Ni) 5mM or verapamil 1 µM ((OCP + Ni)/OCP = 0.5 ± 0.2, $p = 0.01$; and (OCP + verapamil)/OCP = 0.6 ± 0.2, $p = 0.01$). Similarly, ratio of BAC displaying Ca^{2+} oscillations decreased rapidly when Ni was added, and was completely abolished by thapsigargin, an inhibitor of Ca^{2+}_i storage in endoplasmic reticulum. Finally, BAPTA 1 µM, a Ca^{2+}_i chelator, significantly decreased BCE GAG release induced by OCP crystals (1.1 ± 0.4-fold the control value vs. 1.7 ± 0.1, $p = 0.01$, in presence and in absence of BAPTA, respectively).

Conclusion: These results suggest that Ca^{2+}_i signalling is a major pathway involved in BCP crystal effects on articular chondrocytes. They highlight a new pathophysiological mechanism and give rise to a new therapeutic target in diseases related to BCP crystal deposition.

1950

Increasing Allopurinol Dose Above the Recommended Range Is Effective and Safe in Chronic Gout, Including in Those with Renal Impairment – a Pilot Study. Lisa Stamp[1], J.L. O'Donnell[2], M. Zhang[3], C. Frampton[4], M. Barclay[3] and PT Chapman[3], [1]University of Otago, Dunedin, New Zealand, [2]Canterbury Health Laboratories, Christchurch, [3]Christchurch Hospital, Christchurch, New Zealand, [4]University of Otago, Christchurch, New Zealand

Purpose: Allopurinol is the most commonly used urate lowering therapy. Recommended dosing guidelines based on creatinine clearance (CrCL) have been published. However, many patients fail to achieve adequate serum uric acid (SUA) reduction with recommended doses. The aim of this study was to determine whether using allopurinol above recommended doses leads to adequate reduction in SUA without increase in toxicity.

Methods: Patients with gout on stable dose allopurinol for at least one month were recruited. Recommended allopurinol dose was defined by the Hande criteria based on CrCL. Allopurinol dose was gradually increased to obtain the target SUA ≤6mg/dL. Patients were seen monthly until SUA was ≤6mg/dL for 3 consecutive months. Then patients were seen 3 monthly until at least 12 months after study entry. Data were analyzed using allopurinol mg/day above recommended dose in 50mg increments (R+).

Results: 90 patients were enrolled. Mean age 58.3years (27-83yrs), 87.8% male, and 78% European. At the initial visit, 52 had SUA >6mg/dL, of whom 7 were on lower than recommended doses of allopurinol. 45 patients had the dose of allopurinol increased above the recommended range. Baseline mean CrCl in the dose escalation group was 61.9mls/min (19-132) and mean SUA was 7.4 mg/dL (6-10.8mg/dL). Three patients developed rashes (2 receiving concomitant frusemide) and discontinued allopurinol or ceased dose escalation.

Six patients were lost to follow-up. All patients were included in the analysis until lost or stopped allopurinol. Of the 36 patients who completed the entire 12-month study period, 31 (85%) patients achieved a SUA ≤6mg/dL at the 12 month end point. Of the 5 patients who had SUA>6mg/dL 2 had undetectable plasma oxypurinol indicating non-compliance. There was a significant reduction in SUA at all allopurinol doses above recommended ($p<0.001$). The percentage decrease in SUA from baseline was -12.6% R+50mg, -20.8% R+100mg, -25.9% R+150mg, -36.2% R+200, -30% R+250mg and -35.6% R+300mg. 18/45 patients were receiving frusemide or a thiazide diuretic. There was no significant difference between baseline SUA in those receiving diuretic treatment or not. Baseline doses of allopurinol were higher in those patients on frusemide (248 vs 180mg/d $p=0.003$). Patients on frusemide were just as likely to achieve SUA ≤6mg/dL as patients not on frusemide (72% vs 88.5% $p=0.24$). Other than the three patients with rashes there were no significant toxicities.

Conclusion: Increasing the dose of allopurinol above the recommended range led to a significant reduction in serum urate. 86% of patients achieved a SUA ≤6mg/dL. There was no increase in toxicity with higher doses of allopurinol in this cohort, including those with renal impairment.

Dynamics of Transcription Regulation of Urate Crystal Inflammation in a Synovium-Like Tissue. Christian T. Mayer[1], John W. Tobias[1], Joseph P. Menetski[2], H. R. Schumacher Jr.[3] and Frank Pessler[4], [1]University of Pennsylvania, Philadelphia, PA, [2]Merck Research Labs, NJ, [3]U Penn & VA Med Ctr, Philadelphia, PA, [4]Technical University Dresden Children's Hospital, 01307 Dresden, Germany

Purpose: Monosodium urate (MSU) crystals, the causative agent of gout in humans, elicit acute inflammation driven by innate immunity, including TLRs 2 and 4 and the Nalp3 inflammasome. Whereas much has been revealed about the cellular aspects of MSU crystal inflammation, very little is known about molecular effects of the crystals on intact tissues, including the synovial membrane. We have begun to define major steps in transcriptional reprogramming in the murine air pouch (a structure closely resembling the human synovial membrane) during a complete time course of MSU crystal inflammation.

Method: MSU crystals (2 mg in 1ml PBS) were injected into 6-day-old murine air pouches (n=36). Six pouches each were harvested at 0h (control pouches), 1h, 4h, 9h, 18h, 27h, and 50h after crystal injection. The pouch exudates were obtained by lavage with 2ml PBS, and the pouch membranes then meticulously dissected away from the adjacent subcutaneous tissue. Leukocyte density in the pouch exudates was used to measure the degree of inflammation. Total RNA was extracted from the dissected membranes and reverse transcribed into cDNA. Using custom low-density PCR arrays, we then analyzed the expression of 94 target mRNAs encoding pro- and anti-inflammatory cytokines, inflammasome constituents, MMPs, transcription factors, and factors involved in apoptosis, cell cycle, and prostaglandin metabolism. Normalized expression data were analysed with the Partek Genomic Suite and SpotFire Decision Site bioinformatics software programs.

Results: Averaged over all mRNAs, transcriptional induction was 100-fold, peaked 4h after crystal injection, and gradually returned near baseline by 50h. Euclidian distance similarity calculation confirmed that transcriptional reprogramming was most intense at 4h. Leukocyte density in the pouch exudate also normalized by 50h, but differed kinetically in that it peaked 5h after the maximum of transcriptional reprogramming. Hierarchical clustering analysis revealed 3 clusters of temporally coregulated mRNAs: (1) an early burst that included major pro- (e.g., IL-1b, IL-6, TNFa) and anti-inflammatory (IL-10) cytokines; (2) a more sustained second wave including MMPs, the anti-inflammatory enzyme arginase, surface receptors involved in prostaglandin synthesis, TLR signalling; and (3) a prolonged resolution phase characterized by increased expression of CD68 and the anti-inflammatory factors PPAR-g, h-prostaglandin D synthase, and TGF-b.

Conclusion: On the basis of gene expression analysis, MSU crystal inflammation in a synovium-like tissue can be separated into three distinct phases (Fig. 1). Modulating the relative extent and/or duration of each phase may be a major effect of anti-inflammatory pharmacological interventions.

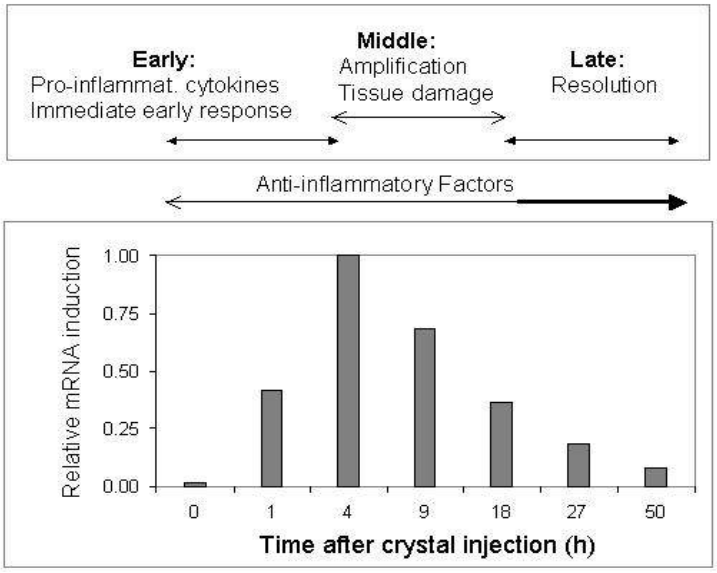

Fig. 1. Summary of the 3 phases of transcriptional reprogramming of MSU crystal inflammation in the murine air pouch membrane.

1952

Long-Term Safety of Rituximab: Long-Term Follow-up of the RA Clinical Trials and Retreatment Population. Ronald F. van Vollenhoven[1], Paul Emery[2], Clifton O. Bingham III[3], Edward C. Keystone[4], Roy M. Fleishmann[5], Daniel E. Furst[6], Katherine Macey[7], Marianne T. Sweetster[8], Patricia B. Lehane[7], Pamela Farmer[9] and Simon G. Long[7], [1]The Karolinska Institute, Stockholm, Sweden, [2]Leeds General Infirmary, Leeds, United Kingdom, [3]Johns Hopkins University, Baltimore, MD, [4]Professor of Medicine/University of Toronto, Toronto, ON, [5]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [6]UCLA, Los Angeles, CA, [7]Roche Products Ltd, Welwyn Garden City, United Kingdom, [8]Biogen Idec Inc., Cambridge, MD, [9]Genentech, Inc., South San Francisco, CA

Purpose: To evaluate the long-term safety of rituximab (RTX) in RA patients (pts) in clinical trials.

Methods: Pooled analysis of safety data from pts treated with RTX in combination with methotrexate (MTX) in a global clinical trial program. All pts were offered retreatment with RTX based on clinical need. Pts receiving placebo during placebo-controlled study periods were pooled to provide a placebo population.

Results: As of September 2008, 3095 pts had been treated with RTX providing 7198 pt-years (pt-yrs) of exposure. Over 750 patients had been followed for >3 years with 2365, 1581, 1038 and 497 pts receiving ≥2, ≥3, ≥4 and ≥5 courses, respectively. Other than infusion-related reactions (IRR), the safety profile of RTX was similar to the pooled placebo population (Table). In the RTX group, the most frequent

adverse event (AE) was IRR (35%), most of which were CTC grade 1 or 2 and occurred after the first infusion of the first course (23%), with <1% considered serious. The rates of serious AEs (SAEs) and infections remained stable over time and also between RTX courses. The rate of serious infection was 4.25 events/100 pt-yrs and was comparable to that observed in the placebo population (4.33 events/100 pt-yrs). The most frequent serious infections were of the lower respiratory tract, predominantly pneumonia (1%). No cases of TB or reactivation of hepatitis B were reported. Serious opportunistic infections were uncommon, but included one confirmed case of *Pneumocystis jiroveci* pneumonia in each of the RTX and pooled placebo groups and one case of progressive multifocal leukoencephalopathy (PML) in the RTX group. The causal relationship of PML to RTX in this case was unclear due to recognized risk factors including carcinoma of the oropharynx treated by chemoradiotherapy. Rates of MI and stroke were consistent with the general RA population. The standardized incidence ratio (SIR) for malignancy compared with the SEER 2008 database was 1.06 (95% CI 0.81–1.37). The most frequently reported malignancy (excluding non-melanoma skin cancer) was breast cancer (SIR 0.69; 95% CI 0.35–1.24).

	All exposure	**Pooled placebo**
No. pts (n)	3095	819
Total pt-yrs	7198	832
IRR (%)	35%	22%
SAE rate/100 pt-yrs	16.5	15.7
(95% CI)	(15.59–17.47)	(13.3–18.7)
Infection rate/100 pt-yrs	97.4	103.7
(95% CI)	(95.14–99.7)	(97–110.9)
Serious infection rate/100 pt-yrs	4.25	4.33
(95% CI)	(3.8–4.75)	(3.1–6)

Conclusion: In prolonged follow-up of RA pts treated with RTX in clinical trials, RTX has remained well tolerated over multiple courses with a stable safety profile similar to the pooled placebo population.

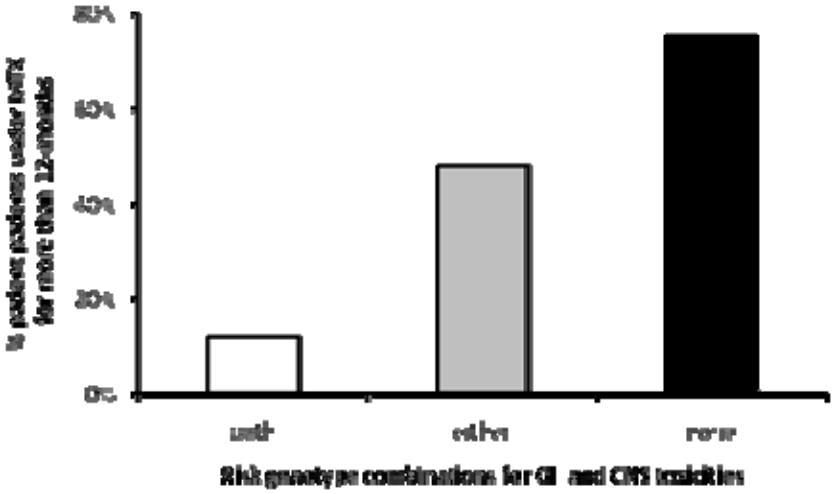
1953

Gene-Gene Interactions Among Folate, Purine and Pyrimidine Gene Pathways Impact Methotrexate Tolerability in Rheumatoid Arthritis. Thierry Dervieux[1], Judith Wessels[2], Tahar van der Straaten[2], Jason Moore[3], Nadia Penrod[3], Henk-Jan Guchelaar[2] and Joel M. Kremer[4], [1]Cypress Bioscience, San Diego, CA, [2]Leiden Medical Center, Leiden, Netherlands, [3]Dartmouth-Hitchcock Medical Center, Lebanon, [4]Albany Medical College, Albany, NY

Purpose: Dose-limiting gastrointestinal and neurological toxicities are common in patients with rheumatoid arthritis (RA) treated with the antimetabolite Methotrexate (MTX). We sought to evaluate whether gene-gene interactions (epistasis) in folate, purine and pyrimidine gene pathways contributed to these idiosyncrasies in RA.

Method: A total of 158 patients under MTX for more than three months were evaluated. MTX side effects were defined as those affecting the gastrointestinal tract (nausea, diarrhea, stomatitis, dyspepsia, elevation of aspartate aminostransferase (AST)>twice the upper limit normal) or the central nervous system (headache, lethargy). Fourteen single nucleotide polymorphisms were measured. Detection and interpretation of non-linear gene-gene interactions was performed using multifactor dimensionality reduction (MDR) which reduces genetic information to one-dimension by combining higher and lower-risk genotype combinations into two separate groups.

Results: Gastrointestinal and neurological side effects were observed in 23% and 21% of patients, respectively. MDR analysis identified epistatic interactions among variants in Methylene Tetrahydrofolate Reductase (MTHFR A1298C), Inosine-Triphosphate Pyrophosphatase (ITPA C94A) and γ-Glutamyl Hydrolase (GGH -354 G/T). These contributed to MTX-induced gastrointestinal idiosyncrasies, with a 7.3-fold higher likelihood of these adverse events in patients having the higher-risk genotype combination (vs. without; CI95%: 3.2-16.8;p<0.001). Interactions among MTHFR A1298C, Thymidylate Synthase (TSER*2/*3), and Serine HydroxyMethyltransferase (SHMT C1420T) variants contributed to neurological toxicities which were 10.1-fold more likely to occur in patients carrier of a predisposing risk-genotype combination (CI 95%: 4.3-23.8; p<0.001). Altogether, the presence of risk genotype combinations for gastrointestinal or neurological toxicities (52%) was associated with an 8.9-fold higher likelihood to present gastrointestinal or neurological toxicities (CI 95%: 3.6-21.9; p<0.001). There was a 2-fold overrepresentation of patients without predisposing risk genotypes in those who received MTX for more than 12-months (72%) versus those who received MTX for less than 12-months (37%) (p<0.001). Seventy-two percent of patients receiving MTX after 12 months did not carry either predisposing risk genotype combinations, while only 12% who carried both predisposing risk genotypes continued treatment beyond this time period (p<0.001).



Conclusion: These hypothesis generating data indicate that gene-gene interactions contribute to MTX-induced adverse events in RA and suggest that the presence of risk genotypes may impact the rate of MTX discontinuation.

1954

Liver Enzyme Levels in Patients Receiving Tocilizumab with Methotrexate: 1-Year Results From the LITHE Study. J. Kremer[1], Alain Cantagrel[2], C. Montecucco[3], R. Malamet[4], R. Pilson[4] and M. H. Schiff[5], [1]Albany Medical College, Albany, NY, [2]JE 2510, Purpan University Hospital, Toulouse, France, [3]IRCCS Policlinico S Matteo, Pavia, Italy, [4]Roche, Nutley, NJ, [5]University of Colorado, Denver, CO

Purpose: The effect of tocilizumab (TCZ) + methotrexate (MTX) on liver enzyme levels was analyzed in patients (pts) in the 2-y, phase 3, double-blind, randomized controlled study LITHE. One-year findings are presented.

Method: Pts with radiographic evidence of joint damage and inadequate response to MTX were randomized to placebo + MTX (control), TCZ 4 mg/kg + MTX (TCZ4), or TCZ 8 mg/kg + MTX (TCZ8). TCZ or placebo was infused every 4 wks; MTX dose was 10-25 mg/wk. Alanine aminotransferase (ALT), aspartate aminotransferase (AST), and total bilirubin (TBILI) levels were assessed at baseline and every 2 wks to wk 8, then every 4 wks to wk 52. Results of liver enzyme testing were not required prior to infusions; TCZ interruption and/or MTX dose reduction/interruption (ie, treatment modification) were applied as deemed necessary by investigators (1-3x upper limit of normal [ULN]) or per protocol prior to later infusions (>3x ULN).

Results: The population included 399 TCZ8, 399 TCZ4, and 392 control pts. ALT and AST increased from normal at baseline to >3× ULN in 9% and 3% of TCZ8 pts, 7% and 2% of TCZ4 pts, and 0.8% and 0.3% of controls during 52 wks, respectively (Table). TBILI shifts occurred in 0.3% of TCZ8 pts. Most pts with single occurrences of ALT or AST elevations normalized without treatment modification in TCZ8 (44/67; 56/72), TCZ4 (64/77; 64/75), and control (37/46; 32/39) pts. More TCZ8 pts than TCZ4 or control pts had ALT or AST elevations >ULN in ≥6 of 12 monthly determinations (Table). More pts with ≥6 ALT or ≥6 AST elevations started the study with normal levels than with elevated levels (Table). Treatment modifications were used for ≥6 ALT and ≥6 AST elevations in 56/95 and 21/34 TCZ8 pts, 17/36 and 5/10 of TCZ4 pts, and 3/11 and 1/3 controls, respectively. In the entire population, 3, 8, and 12 pts were withdrawn due to transaminase level elevations from the control, TCZ4, and TCZ8 groups, respectively. Liver biopsies were conducted at investigator discretion for 3 TCZ8 pts. TBILI (primarily indirect) of >3× ULN was seen in 1 TCZ8 pt and was not associated with ALT/AST level elevations. No drug-induced liver injury (as indicated by hepatic dysfunction or clinical signs of hepatitis) was seen.

Conclusion: Most pts with ALT/AST elevations >ULN ≥6 times in 12 mos underwent some form of treatment modification. These recurrent ALT/AST level elevations were manageable and not associated with known liver injury or hepatitis. Clinicians should obtain liver enzyme levels at baseline, monitor for elevated ALT/AST levels, and adjust treatment accordingly.

Table

	PBO + MTX n=392	TCZ4 + MTX n=399	TCZ8 + MTX n=399
ALT			
Normal at baseline→ >1-3× ULN, % (n)[a]	23.7 (93)	46.1 (184)	51.6 (206)
Normal at baseline→ >3×ULN, % (n)[a]	0.8 (3)	7.0 (28)	9.0 (36)
Patients with ≥6 elevations, % (n)	2.8 (11)	9.0 (36)	23.8 (95)
Normal at baseline, n	5	30	73
Elevated at baseline, n	6	6	22
AST			
Normal at baseline→ >1-3× ULN, % (n)[a]	19.4 (76)	39.6 (158)	50.6 (202)
Normal at baseline→ >3× ULN, % (n)[a]	0.3 (1)	1.8 (7)	2.8 (11)
Patients with ≥6 elevations, % (n)	0.8 (3)	2.5 (10)	8.5 (34)
Normal at baseline, n	1	10	31
Elevated at baseline, n	2	1	3

1955

Long-Term Safety and Tolerability of Tocilizumab Treatment in Patients with Rheumatoid Arthritis and a Mean Treatment Duration of 2.4 Years. Ronald F. van Vollenhoven[1], D. Siri[2], R. Furie[3], J. Krasnow[4], E. Alecock[5] and R. Alten[6], [1]Karolinska Univ Hosp, Stockholm, Sweden, [2]CAICI Institute, Rosario, Argentina, [3]NS-LIJHS, Lake Success, NY, [4]Roche, Nutley, NJ, [5]Roche, Welwyn, United Kingdom, [6]Schlosspark-Klinik, Berlin, Germany

Purpose: The safety of tocilizumab (TCZ) as monotherapy or with DMARDs has been demonstrated in patients with rheumatoid arthritis (RA) in phase 3 clinical trials and long-term extension studies. The objective of this analysis was to assess the longer-term safety of TCZ in patients with RA using pooled data from the ongoing long-term extension studies and an ongoing phase 3 trial.

Method: The study population included all patients who received at least 1 dose of TCZ in the 24-week, phase 3 clinical trials (OPTION, AMBITION, RADIATE, TOWARD), in the phase 3 clinical trial (LITHE), in a phase 1 study, or in the ongoing, open-label extension studies (GROWTH95, GROWTH96). Safety data were pooled and analyzed from the time of the initial TCZ exposure to the cutoff date of February 6, 2009.

Results: TCZ was administered to 4009 patients, mean treatment duration was 2.4 years, and total treatment exposure was 9414 patient-years (PY). The rate of withdrawals because of adverse events (AEs) was 5.8/100 PY and was driven by elevated liver enzyme levels, infections, and benign and malignant neoplasms. Overall rate/100 PY of serious AEs was 14.91, of serious infections was 4.7, of deaths was

0.53, and of deaths from infection was 0.13. Rates/100 PY of upper and lower GI perforations were 0.01 for stomach/duodenum, 0.03 for small intestine, 0.02 for appendix, and 0.19 for large intestine. Malignancies occurred at an overall rate of 1.16/100 PY, without excess of any one type. Overall rates/100 PY for myocardial infarction and stroke were 0.25 and 0.19, respectively, and did not increase with TCZ exposure. Total cholesterol, low-density lipoprotein, high-density lipoprotein, and triglyceride levels increased at week 6 and remained relatively stable over time; 313 (7.8%) patients who initiated lipid-lowering therapy during treatment with TCZ generally responded to treatment without complications. The incidences of ALT and AST elevations >3× the upper limit of normal were 3.6% and 1.4%, respectively, during the first 24 weeks of treatment, and the rates did not increase over time. Transaminase elevations were not associated with clinically apparent hepatitis or hepatic dysfunction.

Conclusion: These results demonstrate that no new safety signals have emerged with prolonged exposure to TCZ. Transaminase elevations were not associated with clinically important events. During longer-term treatment with TCZ (median duration greater than 2.5 years), the risks for AEs and serious AEs were stable over time and laboratory changes could be effectively managed. These data support a favorable benefit/risk ratio for TCZ in patients with moderate to severe RA.

1956

Does the Risk of Infections in Anti-TNF Treated Patients Decrease Over Time? Joachim Listing[1], Anja Strangfeld[2], Matthias Schneider[3], Winfried Demary[4], Hans Joachim Bergerhausen[5], Christina Bungartz[2] and Angela Zink[2], [1]DRFZ, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]MNR-Klinik, Duesseldorf, [4]Rheumatologist in Private Practice, Hildesheim, Germany, [5]Wedau Kliniken, Duisburg, Germany

Purpose: Data of the German biologics register RABBIT were used to determine the influence of anti-TNF treatment, outcome of this treatment, confounding by indication, and dropout processes on the risk of developing serious infections. Our objective was to investigate whether there is a decline in the risk of serious infections in patients with rheumatoid arthritis (RA) receiving TNFα inhibitors and if so what are the reasons for.

Method: RABBIT is an ongoing prospective cohort study. Patients are enrolled in the biologics groups at start of an approved biological therapy or at start of a new DMARD treatment after at least one DMARD failure. At fixed time points at follow-up rheumatologists assess the clinical status, report treatment details and adverse events according to ICH guidelines.

Results: Data of 5,044 RA patients was available for the analysis. Among them 3,270 received TNFα inhibitors and 1,774 DMARDs at study entry. Crude rates of serious infections increased slightly in DMARD treated patients from 2.4 /100 patient years (PY) in the 1st year to 2.5, 2.8/100 PY in the 2nd and 3rd year respectively (p=0.74) whereas in anti-TNF treated patients a significant decrease (p<0.0001) from 5.0/100 (PY) in the 1st year to 3.1/100 PY in the 2nd and to 2.0/ 100 PY in the 3rd year was observed. Already in the first year there were highly significant differences in the crude infection rates of anti-TNF treated patients who completed treatment for at least 12 months (1.8/100 PY), switched to treatment with DMARDs (10.2/100PY) dropped out or switched to non-anti-TNF biologics (16.8/100 PY). This selection process led to a lower exposure time under anti-TNF treatment in the 2nd (56% of time) or 3rd year (68% of time) in patients with serious infections in the 1st year. This process caused a depletion of susceptibles since patients with one serious infection in the first year were at a significantly higher risk of developing a serious infection in the following years. By applying marginal structural models to account for time-varying risk factors and selection processes at follow-up (confounding by indication, dropouts) we could explain the decrease in the relative risk (RR) of serious infections under anti-TNF treatment compared to DMARD in the second year (crude RR: 1.3, adjusted RR: 2.0 (95% CI: 0.8 – 4.9). According to these models the decrease was mainly caused by confounding by indication at follow-up. A similar result was found for the 3rd year (adjusted RR: 1.7 (95%CI: 0.6 - 4.7).

Conclusion: Patients with serious infections were at higher risk of further infections and were less likely treated with anti-TNF agents at follow-up. Our data suggest that the depletion of susceptibles is a main cause for the observed decrease in the serious infection rates of anti-TNF treated patients.

1957

Safety of Rituximab in Combination with a TNF Inhibitor and Methotrexate in Patients with Active Rheumatoid Arthritis: Results From a Randomized Controlled Trial (TAME). M. Greenwald[1], W. Shergy[2], J. L. Kaine[3], M. T. Sweetser[4], K. Gilder[5] and M. D. Linnik[6], [1]Desert Medical Advances, Palm Desert, CA, [2]Univ of Alabama, Huntsville, AL, [3]Sarasota Arthritis Center, Sarasota, FL, [4]Biogen Idec, Cambridge, MA, [5]Biogen Idec, San Diego, [6]Biogen Idec, San Diego, CA

Purpose: Rituximab (RTX) improves signs and symptoms and slows joint damage progression in patients (pts) with rheumatoid arthritis (RA). This study explored the safety of RTX in combination with a TNF inhibitor (etanercept or adalimumab) and MTX in pts with active RA.

Methods: Pts with active RA (swollen joint count ≥5 and tender joint count ≥5) receiving a stable dose of etanercept (50 mg qw) or adalimumab (40 mg q2w) and methotrexate (10-25 mg qw) for at least 12 weeks were eligible. Pts were randomized 2:1 and treated with 500 mg RTX or placebo (PLA) on Days 1 and 15. After Wk 24, eligible pts could enter open-label treatment with RTX. The primary endpoint was the proportion of pts who experience ≥1 serious infection through Wk 24. Secondary endpoints evaluated additional safety and efficacy parameters.

Results: Fifty-one pts received at least one dose of study treatment (33 RTX, 18 PLA). The concomitant TNF inhibitors were balanced between treatment groups: etanercept (76% vs 78%) and adalimumab (24% vs 22%) for RTX and PLA, respectively. Baseline characteristics were balanced between groups, including disease duration (10.5 yrs), duration on TNF inhibitor (2.2 yrs), HAQ (1.4) and CRP (0.92 mg/dL) with the exception of oral steroid use (36% RTX vs. 17% PLA). Through Wk 24, there was 1 (3%) serious infection (pneumonia on Day 45) in the RTX group and 0 in PLA. Any infection was reported in 18 (55%) RTX pts and 11 (61%) PLA pts with an average duration of 12.6 days (sd 9.6) and 14.5 days (sd 5.2), respectively. Grade 3 infections were reported in 3 (9%) RTX pts (pneumonia on Day 45, influenza on Day 105 and postoperative infection on Day 116) and 0 PLA pts. There were no grade 4 infections. There were 2 (6%) pts with serious adverse events in RTX and 0 in PLA. Through Wk 24, there was 1 serious infection in 15.55 pt-yrs of exposure in the RTX group (6.43 events per 100 pt-yrs, 95% CI: 0.91-45.65) and none in PLA. Overall data, including the open label extension phase, revealed no further serious infections in 46.35 pt-yrs (2.16 events per 100 pt-yrs, 95% CI: 0.30-15.32) in pts receiving 1 or 2 courses of RTX. At Wk 24, the percentage of pts with ACR20 and ACR50 responses was 30% vs 17% and 12% vs 6% for RTX and PLA, respectively.

Conclusion: The preliminary safety profile of RTX in combination with a TNF inhibitor (etanercept or adalimumab) and MTX was consistent with the safety profile of RTX with MTX in other RA trials without a TNF inhibitor, with no new safety signals seen. A larger open-label study evaluating the safety profile of RTX in combination with TNF inhibitors and non-biologic DMARDs is in progress.

Sjögren's Syndrome

Tuesday, October 20, 2009, 4:30 PM - 6:00 PM

1958

The Distribution of Inflammatory Cells at the Autoimmune Minor Salivary Gland (MSG) Lesions of Sjögren's Syndrome (SS) Varies According to Lesion Severity: Correlation with Adverse Prognostic Factors. MI Christodoulou[1], Ek Kapsogeorgou[1], NM Moutsopoulos[2] and HM Moutsopoulos[1], [1]Athens Medical School, Athens, Greece, [2]NIDCR, Bethesda, MD

Purpose: The MSG lymphocytic infiltrates of SS patients extend from mild to severe. They mainly consist of T and B cells, while antigen presenting cells have been reported in heavy lesions. However, the variation of the infiltrating mononuclear cell (MNC) types in SS lesions of distinct severity is not well defined. Herein, we study the distribution of the infiltrating MNC types in SS lesions of variable severity and possible correlations with adverse prognostic factors.

Method: SS patients with mild (n=11), intermediate (n=13) or severe (n=15) MSG lesions (Tarpley score 1, 2 or 3/4, respectively) were studied. Total T, $CD4^+$T, CD8+T, Treg, and B cells, macrophages (MΦ), interdigitating (iDC) and follicular dendritic cells (fDC) and natural-killer (NK) cells were identified immunohistochemically by antibodies to CD3, CD4, CD8, FOXP3, CD20, CD68, S100, fascin and CD56, respectively. Positively stained cells were counted field by field in each MSG section and expressed as incidence (% total infiltrating MNC). One-way ANOVA for linear trend, Spearman's correlation, Tukey's multiple comparison statistical tests and multivariate linear regression analysis (backward stepwise) were applied.

Results: T cells were found to predominate in mild lesions, whereas B cells in severe. The differential distribution of T cells was attributed to $CD4^+$T cell variation, while $CD8^+$T cells remained unchanged. Compared to mild or severe infiltrates, higher Treg incidence was detected in intermediate lesions. MΦ and iDC incidence was positively and negatively associated with lesion severity, whereas similar percentages of NK cells were detected in all SS groups (Table). Total T, $CD4^+$T cell and iDC incidence was negatively, whereas B cell and MΦ incidence was positively correlated with biopsy focus score. Multivariate analysis revealed positive correlations between the incidence of Treg / NK cells and serum C4 levels, Treg / B cells and extraglandular manifestations, fDC and cryoglobulinemia, MΦ and purpura, and T/$CD4^+$T cells and arthritis, and negative correlations of T, $CD4^+$T, iDC and NK cells with extraglandular manifestations and MΦ with arthritis.

			Infiltrating	MNCs	(mean	percentage	± SE)		
MSG Lesions	T	$CD4^+$T	$CD8^+$T	Tregs	B	MΦ	iDC	fDC	NK
Mild	58.6±2.9	41.7±2.4	16.4±2.0	1.3±0.4	34.7±3.2	2.4±0.6	1.3±0.2	2.3±0.5	0.03±0.01
Intermediate	48.1±1.9	35.1±2.4	13.3±1.8	2.8±0.5	45.2±2.2	3.8±0.8	0.5±0.1	1.6±0.3	0.04±0.01
Severe	40.3±2.4	23.5±2.7	16.7±0.9	1.4±0.3	50.3±2.7	6.6±1.4	0.5±0.1	1.9±0.4	0.05±0.01

Conclusion: The distribution of the infiltrating MNC populations at the SS lesions varies according to lesion severity and correlates with certain adverse prognostic factors. The significance of this differential distribution and the operating aetiopathogenic factors need to be elucidated.

STAT4 Polymorphism Is a Confirmed Genetic Risk Factor for Sjögren's Syndrome That Could Be Involved in Type 1 Interferon Pathway Signalling. Corinne Miceli-Richard[1], Nicolas Gestermann[2], Pascale Loiseau[3], Xavier Puéchal[4], Eric Hachulla[5], Jacques-Eric Gottenberg[6] and Xavier Mariette[7], [1]Hôpital Bicêtre, Le Kremlin Bicêtre, France, [2]Bicêtre hospital, INSERM U802, Le Kremlin Bicêtre, France, [3]Hôpital Saint-Louis, Paris, France, [4]Centre Hospitalier Du Mans, Le Mans, France, [5]National scleroderma centre, Lille Cedex, France, [6]University Hospital of Strasbourg, Strasbourg, France, [7]Bicetre Hospital, Paris-Sud University, Le Kremlin Bicetre, France

Purpose: Signal transducer and activator of transcription 4 (STAT4) is a transcription factor activated mainly by interleukin 12 (and to a lesser extent by type 1 IFN) which promotes secretion of type 2 IFN by Th1 cells. *STAT4* gene polymorphisms have been significantly associated with various autoimmune diseases – rheumatoid arthritis, lupus and primary Sjögren's syndrome (pSS) by 2 independent groups. The functional consequences of STAT4 associated polymorphisms are poorly understood with limited data available yet. This study aimed to confirm or not the association between *STAT4* gene polymorphism and SSp and to assess the functional relevance of the at-risk genotypes on STAT4 mRNA level of expression (a and b subunits).

Method: We analyzed *STAT4* rs7582694 polymorphism in an exploratory cohort of 190 pSS patients and 152 controls, and in a second independent cohort of 192 pSS patients, all of Caucasian origin. This polymorphism was genotyped by Taqman genotyping assay (Applied Biosystem). STAT4a and STAT4b mRNA levels were assessed in PBMCs from 30 pSS patients and correlated with the level of expression of PKR, MX1 and IFITM1 as surrogate markers of the type 1 IFN induction pathway.

Results: The *STAT4* rs7582694 C allele was found among 28% of pSS patients compared with 17% in controls ($P=1.4.10^{-3}$ - OR 1.83 (95% CI 1.26 – 2.65). In the replication pSS cohort, *STAT4* rs7582694 C allele frequency was comparable (30%). The overall OR for pSS in the combined cohorts was 1.92 (95% CI 1.37 – 2.68 – $P=1.10^{-4}$). This OR was even higher when considering pSS patients and controls homozygous for the rs7582694 C allele, suggesting a recessive effect of the *STAT4* at-risk allele: OR 3.96 (95% CI 1.38 – 11.30.20; $P=6.10^{-3}$). The association was present both in patients with and without anti-SSA/SSB antibodies. *STAT*a and STAT4b mRNA levels in PBMCs were not significantly determined by rs7582694 genotypes (P=0.99 and P=0.17, respectively) but STAT4a was strongly correlated with the IFN type I induced genes mRNA levels: PKR ($P=4.10^{-3}$), MX-1 ($P=2.10^{-4}$) and IFITM-1 ($P=8.10^{-3}$).

Conclusion: These results confirm a replicated association of *STAT4* polymorphism with pSS with a potential recessive effect on disease susceptibility. Our results do not support the functional relevance of the at-risk genotypes on STAT4a and STAT4b mRNA level of expression. Unexpectedly, STAT4a mRNA expression was highly correlated with the level of expression of type 1 interferon induced genes, supporting a possible involvement of STAT4 not only in type 2 IFN but also in type 1 IFN production.

Activation of Innate Immunity Leads to Accelerated Development of Sjogren's Syndrome-Like Disorder in NZB/W F1 Mice.

Seshagiri Rao Nandula, Yogesh Scindia, Harini Bagavant and Umesh Deshmukh, University of Virginia, Charlottesville, VA

Purpose: To determine whether chronic activation of innate immunity in genetically susceptible individual will lead to accelerated adaptive immune response and development of Sjogren's syndrome (SS).

Methods: Female NZB/W F1 mice were treated every other day for 2 weeks, either with TLR3 agonist poly (I:C) or PBS. Mice were monitored for the development of SS-like disorder by checking pilocarpine induced saliva flow. Submandibular glands (SMG) were analyzed for lymphocytic infiltration and cell types within the infiltrates were characterized by immunohistochemistry. Gene expression levels of inflammatory cytokines within the SMG were determined by real time PCR. Sera were analyzed for presence of autoantibodies to Ro60 and La. Antibody deposition within the SMG was studied by immunofluorescence.

Results: Repeated injections of poly I:C rapidly induced salivary gland dysfunction that was independent of systemic or localized adaptive immune response. The glandular function recovered completely within 2-3 weeks after the cessation of poly I:C treatment. However, by 4 months post-treatment, the mean saliva volume in poly I:C treated group was significantly lower than the PBS treated group and was associated with severe lymphocytic infiltration within the SMG. The lymphocytic infiltrates were mainly composed of CD4+ T and B cells. In comparison with PBS treated mice, the SMGs from poly I:C treated mice showed significantly higher levels of Il-12a, IL-21 and IL21R gene expression . While IL-17F expression was detected in both groups, IL-17A expression was undetectable. Characterization of CD4+ T cells within the infiltrates showed presence of ICOS+, CXCR5+ cells. The levels of anti-Ro60 and anti-La antibodies were significantly higher in the poly I:C treated group and the SMG from these mice showed IgM and IgG deposition.

Conclusion: Our data suggests a biphasic model for SS development. In the initial phase, chronic activation of innate immunity causes glandular dysfunction. This predisposes the salivary gland for an assault by accelerated adaptive immune response in the later phase. An ensuing localized T-B cell response causes glandular destruction and loss of function. Our data also demonstrates for the first time that IL-21 producing follicular T helper cells (Tfh) and their interaction with B cells within the SMG could be critical for the pathogenesis of SS. Thus, the Il-21 pathway might provide a promising target for future immunotherapy of SS.

1961

MicroRNA Profiling of Minor Salivary Glands Identifies Disease and Inflammation Biomarkers in Sjögren's Syndrome Patients.

Ilias Alevizos[1], Siddhartha Bajracharya[2], Stefanie Alexander[2], Roy J. Turner[3] and Gabor G. Illei[2], [1]NIH/NIDCR, Bethesda, MD, [2]NIDCR, NIH, Bethesda, MD, [3]Bethesda, MD

Purpose: Sjögren's Syndrome (SS) is an autoimmune disorder characterized by lymphocytic infiltrates in salivary and lacrymal glands, causing xerostomia and dry eyes. The diagnosis of Sjögren's Syndrome is based on a number of diagnostic criteria, including subjective and objective mouth and eye dryness, a minor salivary gland (MSG) biopsy with inflammatory focus and presence of specific autoantibodies. MicroRNAs (miRNAs) are a group of small RNAs, 18-22 nucleotides in length, involved in the regulation of development, cell differentiation, proliferation, function and survival. MicroRNAs are considered master regulators of gene expression, as one microRNA can alter the expression of hundreds of mRNAs. Clinically, the use of microRNAs in biomarker applications is very promising since microRNAs possess characteristics that render them excellent candidates for such applications, i.e resistance to degradation, isolation from all types of body fluids including saliva and urine, and isolation from FFPE samples.

Method: We used 24 Agilent microRNA microarrays to profile miRNAs isolated from healthy volunteers and Sjögren's patients' minor salivary glands (MSGs) with normal and low salivary flows and high (focus score of 12) and low focus scores (focus score of 1 or 2). We developed novel methods for data normalization by identifying microRNAs that can serve as housekeeping genes for this dataset and in extension for minor salivary gland microRNA expression measurements. The results were analyzed with the scope of identifying microRNAs that correlate with the physiologic status of a MSG as it is defined by whether the sample belongs to a healthy volunteer or SS patient, what is the focus score of that minor salivary gland, and if the salivary flow associated with that specimen is normal or decreased

Results: Through intensive bioinformatics analysis we identified disease, functional and inflammatory biomarkers for SS. The expression of the most promising microRNAs was validated in independent samples. For the functional biomarker discovery, of particular interest was the upregulation of several members of the mir-17-92 cluster in normal salivary flow high focus score when compared to low salivary flow high focus score MSGs, denoting that a different type of lymphocytic proliferation might be present in functional salivary glands. For the inflammation biomarkers, we identified two microRNAs, the ratio of expression level of which can give a very good representation of the inflammatory status of the minor salivary glands. The ratio of expression levels of those 2 microRNAs correlated very well with the inflammatory status of the MSGs in independent samples, including intermediate focus scores of 4-7.

Conclusion: Examining changes in miRNA expression can provide biomarkers for both the inflammatory process and the dysfunction associated with Sjögren's syndrome.

Role of the Urokinase Plasminogen Activator Receptor in Mediating Impaired Apoptotic Cardiocyte Clearance by Anti-SSA/Ro-SSB/La Antibodies in the Pathogenesis of Congenital Heart Block. Paraskevi Briasouli, Elena V. Komissarova, David Alvarez, Jill P. Buyon and Robert M. Clancy, NYU School of Medicine, New York, NY

Purpose: Organ injury induced by antibodies characteristic of Sjogren's Syndrome, while varied in the adult and fetus, may share in common a link between apoptosis and ultimate fibrosis. In congenital heart block (CHB), surface binding of maternal anti-Ro/La antibodies to apoptotic cardiocytes decreases removal by healthy cardiocytes. Membrane bound fibrinolytic components and the plasminogen activation cascade are involved in apoptosis. Dysregulation of the urokinase Plasminogen Activator/urokinase Plasminogen Activator Receptor (uPA/uPAR) system leads to cardiac fibrosis in mice and data implicate uPAR as a ‘'don't eat me" signal. The relevance of uPAR to CHB pathogenesis was addressed by investigating whether binding of anti-Ro/La to apoptotic cardiocytes alters uPAR expression thereby providing a molecular explanation for impaired clearance.

Methods and Results: Initial experiments evaluated Ro/La and uPAR localization on healthy and apoptotic cardiocytes. In permeabilized healthy cardiocytes, IgG fractions from mothers whose children had CHB containing anti-Ro and La antibodies (CHB IgG) stained the nucleus while anti-uPAR localized to the plasma membrane and vesicular compartments. In cardiocytes rendered apoptotic (exposure to TNFα, cyclohexamide, IFNγ and plating on pHEMA, or staurosporine), CHB IgG bound the cardiocyte surface and colocalized with anti-uPAR (not isotype control) supporting the proximity of Ro/La and uPAR. After crosslinking, uPAR migrated as a high molecular weight conjugate only on the apoptotic cells supporting an altered distribution of uPAR. Flow cytometry also demonstrated anti-uPAR binding to apoptotic cardiocytes (31 MFU ± 7 vs 19.3 ±8 (isotype control); p =0.008; n=5). The consequence of anti-Ro/La surface binding to the expression/function of uPAR as a “don't eat me” signal was assessed. Preincubation with CHB IgG, significantly increased the binding of anti-uPAR to apoptotic cells (58 MFU ± 8 vs 31 ± 7; p = 0.0013; n= 5). In contrast, binding of anti-HLA, and three other ‘'don't- eat me" molecules: anti-CD31 (pecam-I scavenger receptor), anti-CD47 (thrombospondin scavenger receptor), and anti-calreticulin were not increased after incubation with CHB IgG. To determine the functional effect of increased uPAR expression, apoptotic cells were cocultured with healthy cardiocytes for 5 hours, washed to remove unbound apoptotic cells, and fixed. CHB IgG significantly inhibited efferocytosis (58 ± 4.5% engulfment after incubation with control IgG vs 33 ± 3.0% with CHB IgG ; p= 0.002; n=6). Preincubation of the apoptotic cardiocytes with anti-uPAR but not anti-HLA, significantly reversed the CHB IgG inhibition (33 ± 3.0 % vs 63 ± 3.0 %; p = .001; n=6).

Conclusion: These data suggest that one potential mechanism accounting for the anti-Ro/La inhibition of efferocytosis by healthy cardiocytes exploits enhanced expression/function of uPAR, which may mediate injury in CHB via its capacity to act as a “don't eat me” signal.

1963

Effect of Rituximab Treatment On Salivary Gland Immunohistology in Patients with Primary Sjögren's Syndrome. R.P.E. Pollard[1], J.E. van der Wal[1], S. Ihrler[2], F.K.L. Spijkervet[1], J. Pijpe[1], J.M. Meijer[1], P.M. Kluin[1], C.G.M. Kallenberg[1], A. Vissink[1] and H. Bootsma[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]Ludwig Maximilians Universität, München, Germany

Purpose: To assess the shift in B-, T- and plasma cells in parotid gland tissue induced by rituximab (anti-CD20) therapy in patients with primary Sjögren's syndrome (pSS).

Method: In a double-blinded placebo-controlled trial paired incisional parotid biopsies were taken in 25 patients with pSS before and 12 weeks after rituximab/placebo treatment. Until now, biopsy samples of 5 rituximab-treated and 5 placebo-treated patients were studied. The relative amount of parotid parenchyma, lymphocytic infiltrate and fat, the focus score, and the presence of lymphoid follicles and lymphoepithelial lesions were evaluated. B/T-cell ratio of the lymphocytic infiltrate was analyzed by immunohistochemistry (CD79a, CD20, CD3). In addition, distribution of plasma cells expressing different classes of immunoglobulins (IgA, IgG) was quantified.

Results: In all rituximab-treated patients a reduction in B/T-cell ratio was seen at 12 weeks, while no reduction in B/T-cell ratio was seen in the placebo-treated patients. Moreover, focus score and lymphoepithelial lesions were reduced in rituximab-treated, but not in placebo-treated patients. Finally, rituximab treated patients showed on average an increase in the proportion of IgA positive plasma cells (from 65±19% to 72±23%) while in placebo-treated patients, the plasma cell proportion containing IgA tended to decrease (from 66±18% to 64±16%).

Conclusion: Our preliminary data show a tendency of a rituximab-mediated shift in immunoglobulin class of plasma cells in glandular tissue of pSS patients towards a normally present dominance of IgA-class in conjunction with a decrease in focus score. Extended data are in progress.

ACR Concurrent Abstract Sessions

T cells in Autoimmune Diseases

Tuesday, October 20, 2009, 4:30 PM - 6:00 PM

1964

TL1A-DR3 Interactions: An Attractive Target for Immunotherapy. Yun-Jeong Song[1], Francoise Meylan[1], Ivan Fuss[2], Todd Davidson[3], Ethan Shevach[4] and Richard Siegel[2], [1]NIAMS, NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]Bethesda, MD, [4]NIAID, NIH, Bethesda, MD

Purpose: Molecules in the TNF-Receptor superfamily have diverse roles including regulatory functions in immune system. One of the newer members of the receptor superfamily is DR3 (death receptor-3; TRAMP, LARD, WSL-1, TNFRSF25). Like TNFR1, DR3 recruits TRADD and can mediate dual signals that lead to inflammation through NFκB signaling or cell death through caspase activation. Unlike TNFR1, DR3 is specifically expressed in lymphocytes, with the highest level on T cells. The sole known ligand for DR3 is the TNF superfamily member TL1A (TNF like cytokine 1A; TNFSF15). Using DR3 knockout mice, we have recently shown that TL1A-DR3 interactions play a key role in experimental autoimmune encephalomyelitis (EAE) and in an ovalbumin-induced asthma model, facilitating local T cell accumulation at the site of inflammation, while not affecting systemic priming, T cell polarization or host defense against Toxoplasma gondii (Meylan et al, 2008 Immunity 29:79). Other studies have suggested a role for TL1A and DR3 in various human diseases and animal disease models, including rheumatoid arthritis (RA), collagen-induced arthritis (CIA), and inflammatory bowel disease (IBD).

Method: Given the role of DR3 in mediating local effector T cell function in diverse autoimmune disease models, blocking TL1A-DR3 interactions may be an attractive therapeutic strategy for autoimmune disease. We have generated anti-TL1A antibodies to explore this possibility, and to further assess the role of TL1A-DR3 signaling pathway in normal and pathological T cell immune responses.

Results: We have found these antibodies to be useful in identifying TL1A producing cells and quantifying TL1A in cell supernatants and sera. In addition, selected clones were able to block functional TL1A-DR3 interactions, blocking T cell co-stimulation and apoptosis induced by TL1A in vitro. When administered prior to the onset of disease, anti-mouse TL1A mAb blocks the T-cell dependent TNBS colitis model

and ameliorates collagen-induced arthritis (CIA). We will present data on the efficacy of anti-TL1A mAb in preventing bone erosion in CIA and in other models of arthritis and autoimmunity such as experimental allergic encephalomyelitis (EAE).

Conclusion: These antibodies will be also useful in further studying the role of TL1A-DR3 interactions in the normal and diseased immune system, which may lead to the development of TL1A blockade as a novel therapy for autoimmune diseases.

1965

The Immune Response to Citrullinated Peptides in the Pathogenesis of Rheumatoid Arthritis. Maria Bellatin[1], Donglan Xia[1], Margarita Fallena[2], Nancy J. Olsen[3], David R. Karp[2] and Peter Stastny[1], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Med Ctr, Dallas, TX, [3]Univ ofTX Southwestern Med Ctr, Dallas, TX

Purpose: An immune response against citrullinated peptides is closely associated with the development of Rheumatoid Arthritis (RA). Genetic factors, controlled by the Major Histocompatibility Complex (MHC) and environmental stimuli such as smoking appear to play a role. In the present experiments we wanted to investigate the contribution of B cells to the pathogenesis of RA by analyzing their capacity to produce autoantibodies against citrullinated peptides in vitro.

Method: B-cell enriched preparations were isolated from the peripheral blood of 66 patients with definite RA (with 60 or 91 % CCP-positive) and 54 matched healthy persons (all CCP-negative). Cultures of B cells with a feeder layer of EL4 cells producing CD40-ligand and a supply of T-cell factors were incubated for 14 days under conditions known to allow antibody secretion. Culture fluids were tested for appearance of antibodies against citrullinated peptides by an ELISA assay with a commercially available CCP3 kit. The role of RA-associated MHC genes was investigated by high resolution typing for HLA class II. The possible effect of smoking was determined by taking a smoking history of each of the participants in this study.

Results: Production of antibodies against CCP was detected in many of the cultures. It was found in 44/66 cultures from RA patients (67%) and in 21/54 B-cell cultures from healthy controls (39%). The difference between the two groups was significant ($p=0.003$). The two groups were also different in regards to the amount of anti-CCP antibodies produced ($p<0.02$) and the frequency of positive wells in the cultures ($p<0.0001$). Patients with RA-associated MHC genes were more likely to have B cells producing anti-CCP (Odds ratio (OR) =5.3, $p=0.007$). Interestingly, such a relationship was also seen in the cultures from healthy persons without R.A.; production of anti-CCP was seen more frequently in normal controls having RA-associated MHC genes (OR=4.9, $p=0.008$). Past and present smoking was associated with an increased frequency of cultures producing anti-CCP in these healthy control subjects (OR=3.2, $p=0.04$).

Conclusion: In vitro production of autoantibodies by peripheral blood B cells was investigated in RA patients and controls. The immune response to citrullinated peptides was stronger and more frequent in RA patients, but almost 40% of normal subjects had some B cells capable of producing anti-CCP. Both genetic and environmental factors appeared to influence this immune response in the two groups of persons we have studied. This view of the B cell repertoire may offer a window to the events leading to the development of autoimmunity and disease in persons with susceptibility for the development of RA.

1966

T Cell Lymphopenia Represents a Risk Factor for the Development of $CD4^+$ T Cell-Mediated Autoimmune Arthritis. Ryan Martinez, Na Zhang, Sarada Nandiwada, Bryce A. Binstadt and Daniel L. Mueller, University of Minnesota Medical School, Minneapolis, MN

Purpose: Rheumatoid Arthritis development has been associated with “premature aging” of the naïve $CD4^+$ T cell repertoire, perhaps reflecting dysregulated Ag-dependent T cell clonal expansion and a need for exuberant homeostatic proliferation to prevent frank T cell lymphopenia. Previously, we demonstrated that lymphopenia represents a barrier to T cell clonal anergy induction. We now questioned whether the development of autoimmune arthritis could result from a defect in clonal anergy induction, in the setting of T lymphopenia.

Method: Recipient (B6xB6.g7)F1 mice that naturally express glucose 6-phosphate isomerase (GPI)/I-A^{g7} peptide/MHC class II complexes were injected with purified B6 strain, GPI-reactive KRN TCR-transgenic naïve $CD4^+$ T cells to elicit the production of anti-GPI autoantibodies and development of arthritis.

Results: Wildtype recipients of KRN T cells produced only modest anti-GPI IgG1 Ab, and only rarely developed arthritis. Consistent with this result, the KRN T cells in these mice underwent an abortive clonal expansion, developed an anergic $Folr4^{high}$ $CD73^{high}$ phenotype, and became unresponsive to Ag re-challenge. In contrast, lymphopenic $TCRalpha^{-/-}$ (B6xB6.g7)F1 recipient mice induced a robust and sustained KRN T cell clonal expansion that failed to lead to either high level Folr4 and CD73 expression or proliferative anergy. Furthermore, these mice produced higher levels of anti-GPI Ab and developed intense inflammatory arthritis. Reconstitution of $TCRalpha^{-/-}$ (B6xB6.g7)F1 mice with an adoptive transfer of mature syngeneic polyclonal $CD4^+$ T cells resulted in the appearance of $Foxp3^+$ $CD25^+$ $CD4^+$ T regulatory cells and restored the ability of these mice to induce anergy in the KRN T cells to resist arthritis development.

Conclusion: These experiments demonstrate that T cell lymphopenia and T regulatory cell deficiency predispose the individual to autoimmune arthritis when autoreactive $CD4^+$ T cells fail to develop anergy upon encounter with self-antigen.

1967

Maintenance of T Cell Rap1 Signaling Protects Mice against Collagen-Induced Arthritis. Joana R.F. Abreu[1], Sarah Krausz[1], Wendy Dontje[1], Aleksander M. Grabiec[1], Daphne de Launay[1], Margriet J. Vervoordeldonk[1], Paul P. Tak[2] and Kris A. Reedquist[1], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: The small GTPase Rap1 is inactivated in autoreactive T cells from the synovium of rheumatoid arthritis (RA) patients, contributing to chronic reactive oxygen species by these cells. This suggests an important role for Rap1 in determining the quality of T cells responses *in vivo*. Our goal was to determine if maintaining Rap1 signaling in murine T cells could modify disease onset or severity in collagen-induced arthritis.

Method: Arthritis was induced in wild-type (WT) and RapV12 transgenic (expressing constitutively active Rap1 in the T cell compartment) C57BL/6 mice by intradermal immunization with chicken collagen type II emulsified in complete Freund's adjuvant, and the immunization repeated at Day 21. Arthritis severity was monitored 3 times per week in a blinded manner using a semi-quantitative score (0-4 per paw, 16 points maximum). Hind paw ankle joint thickness was measured using a dial caliper. Mice were sacrificed at day 60 and hind paws preserved for histological and radiological analysis. In a second experiment, mice were sacrificed at Day 40, and blood, spleen and lymph nodes harvested from mice. Serum anti-collagen antibody titers were measured by ELISA. Splenic and lymph node cells were phenotypically assesed for expression of CD3, CD4, CD8, CD44, CD62L, CD103 and FoxP3. Cells were also stimulated for 6 hours with PMA/I, followed by intracellular staining for TNF, IFN-gamma, and IL-17. T cells were stimulated in vitro and assessed for expression of costimulatory proteins needed to direct B cell immunoglobulin (Ig) class switching.

Results: Disease incidence in RapV12 mice (20%) was severely reduced compared to WT mice (100%). Arthritis scores observed in WT mice (8+/- 1.51, mean +/- SEM) were also significantly reduced in RapV12 mice (1+/-0.68) ($p<0.001$). Infiltration of synovial tissue (WT=2.33+/-0.49 ; RapV12=0+/-0) ($p<0.001$) or cartilage erosion (WT= 2.5+/-0.5; RapV12= 0+/-0($p<=0.001$) was not detectable in RapV12 mice. Radiological scores in RapV12 mice (0.643+/-0.199) were also signficantly reduced compared to WT mice (2 +/-0.296) ($p<0.001$). Anti-collagen IgG2a and IgG2b antibody titers were reduced by 75% in RapV12 mice compared to WT mice ($p<0.05$). Total T cell numbers and percentages of CD3+, CD4+, CD8+ T cells (both naive and effector/memory), CD4+FoxP3+ Tregs, and Th17 cells were equivalent in WT and RapV12 mice. RapV12 mice had a significant decrease in the percentage of TNF-secreting CD8+ T cells ($p<0.05$). CD4+ T cells stimulated in vitro failed to upregulate ICOS and CD40L proteins needed by follicular T helper cells to promote B cell Ig class switching.

Conclusion: Maintenance of T cell Rap1 signaling in murine T cells reduces disease incidence and severity in the collagen-induced arthritis model, associated with decreases in the function of cytotoxic T cells, and development of IgG2a and IgG2b auto-antibodies. Strategies aimed at restoring Rap1 function in RA synovial T cells may have therapeutic benefit in RA.

Novel Delineation of Human FoxP3 Expressing CD4+ T Cell Subsets Reveals a Perturbed Homeostasis of FoxP3+ Treg Subsets During Active SLE. Makoto Miyara[1], Alexis Mathian[1], Julien Haroche[1], Guy Gorochov[2] and Zahir Amoura[3], [1]Centre Hospitalier Universitaire Pitié-Salpêtrière, APHP, Paris, France, [2]Inserm Umrs-945, Pitié-Salpêtrière Hospital, Paris, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France

Purpose: Conflicting results are reported in the literature regarding the prevalence of circulating FoxP3 expressing Tregs during active SLE. We have recently demonstrated that human FoxP3 expressing $CD4^+$ T cells are not homogeneous in function[1]. Our results have shown that FoxP3 and CD45RA expression enables the delineation of human FoxP3 expressing cells into three subsets: (1) $CD45RA^+FoxP3^{lo}$ Resting Tregs (rTregs), (2) $CD45RA^-FoxP3^{hi}$ activated Tregs (aTregs) and (3) cytokine-secreting $CD45RA^-FoxP3^{lo}$ non-Tregs[1]. We thus applied this new definition to active SLE.

Method: Our study included 16 patients with a diagnosis of SLE, established according to the American College of Rheumatology criteria, with an active disease (SLEDAI >3) and 31 healthy donors. CD45, CD4 and FoxP3 expression by PBMCs were analyzed by flow cytometry. Statistical comparisons were performed using the non parametric Mann-Whitney U test.

Results: There was a decrease in the proportion of aTregs (1.16 ± 0.71 *vs* 1,63 ± 0,52 % in healthy donors; p=0.002), and an increase in the proportions of rTregs (3.83± 2.02 vs 2,43 ± 0,89 %; p=0.006). Notably, $CD45RA^-FoxP3^{lo}$ non-Treg fraction increased to form a distinct population in active SLE (9.64 ± 9.0 % vs 3.13 ± 1.1; p<0.0001).

Conclusion: These results argue for perturbed homeostasis phenomenon in Treg subsets during SLE. Our recent findings indicate that rTregs are the thymic derived precursor of aTregs and that aTregs are susceptible to apoptosis[1]. Thus, death of aTregs and increased compensatory thymic output of rTreg cells might occur during active SLE. The increase in $FoxP3^{lo}CD45RA^-$ non Treg cells can account for the discrepancy in the prevalence of Tregs found in the literature. The role of cytokine secreting $FoxP3^{lo}$ non Treg CD4+ T cells, that were consistently increased during SLE flares, remains to be determined.

All-Trans Retinoic Acid Restores the Stability and Functionality of Ntregs in the Inflammatory Milieu. Xiao H. Zhou[1], Ning Kong[2], Julie Wang[1], Hejian Zou[3], Huimin Fan[4], David Brand[5], Zhongmin Liu[4] and Song Guo Zheng[1], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA ; Huashan Hospital, Fudan University, Shanghai, China, [3]Huashan Hospital, Fudan University, Shanghai, China, [4]East Hospital, Tongji University, Shanghai, China, [5]VA Medical Center, Memphis, Memphis, TN

Purpose: Natural CD4+CD25+Foxp3+ cells (nTregs) play an important role in the maintenance of immune tolerance. Recent studies revealed that nTregs are plastic and unstable when stimulated with IL-6. They can be converted into either Th1, or Th17 or Th2 cells and lose phenotypic and functional characteristics in inflammatory milieu. all-trans Retinoic Acid (atRA) not only promotes $Foxp3^+$ cell development, but restrains Th17 cell differentiation induced by IL-6+TGF-β. We hypothesize that atRA alters the plasticity of nTregs and restore their suppressive activities in an inflammatory milieu.

Method: nTregs isolated from DBA/1J or Foxp3 knock-in mice were stimulated with IL-6 in the presence or absence of atRA, and intracellular IFN-γ, IL-4, IL-17 expression was determined by FCM. nTregs were also pretreated by anti-CD3/CD28 with atRA or DMSO and these cells were re-stimulated with IL-6. IL-6 R and phosphorylated STAT3 expression in nTregs pretreated with atRA and control were analyzed by FCM and qRT-PCR. The suppressive activity in vitro of both nTregs pretreated with atRA or DMSO was compared using CFSE dilution of T responder cells that were stimulated with anti-CD3 in the presence of IL-6. $3x10^6$ of both pretreated nTregs were i.v. injected

into DBA/1J mice on the day 28 after immunization with CII and CFA. The clinical severity of collagen-induced arthritis (CIA) was evaluated by visual judge, measuring specific anti-CII IgG subsets and histological examination.

Results: While 30% of nTregs were converted to Th17 cells when stimulated with IL-6, addition of atRA blocked Th17 conversion from nTregs. Similarly, atRA- but not DMSO-pretreated nTregs are also resistant to Th17 conversion when stimulated with IL-6. atRA-nTregs expressed lower levels of CD126 (IL-6Rα chain) and phosphorylated STAT3 compared to DMSO-nTregs when stimulated with IL-6. atRA- but not DMSO-nTregs maintained the suppressive activity in the presence of IL-6. Adoptive transfer of atRA- but not DMSO-pretreated nTregs to DBA/1 mice at day 28 after immunization with CII/CFA significantly reduced the severity of CIA. atRA-nTregs also suppressed CII-specific IgG production. Using CFSE-labeled donor cells, we were able to observe that majority of nTreg cells lost Foxp3 expression, converted to IL-17-prodcuing cells, and >20% converted into Th2 cells in draining lymph nodes at one week after adoptive transfer to the established CIA. Conversely, atRA-nTregs maintained Foxp3 expression and did not convert to Th1, Th2 and Th17 cells in a similar inflammatory milieu.

Conclusion: atRA alters Treg plasticity and restores the functionality of nTregs in the inflammatory milieu. Decreased IL-6 receptor and its signal molecule expression on atRA-pretreated nTregs possibly contribute to their stability and functionality in established CIA. This study may provide a novel therapeutic approach for the treatment of Rheumatoid Arthritis.

Hidden Diagnoses in Temporal Artery Biopsy Paraffin Blocks: The GRACG Study. Pierre Duhaut[1], Jean Schmidt[1], Denis Chatelain[1], Fabienne Bellarbre[1], Amar Smail[1], Valery Salle[1], Sylvie Bosshard[2], Jean -Charles Piette[3], Hélène Pellet[2], Henri Sevestre[1], Jean-Pierre Ducroix[1] and GRACG study members[4], [1]Amiens University Hospital, Amiens, France, [2]Claude Bernard University, Lyon, France, [3]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [4]Amiens, France

Purpose: The necessary length of the temporal artery biopsy (TAB) has been largely discussed, but there are currently no guidelines for the management of TAB by the pathologist. Usually, several transversal sections are embedded in the paraffin blocks, leaving a large proportion of the TAB unexplored; then, several levels are cut within each section, leaving a large proportion of each section unexplored. The number of levels cut in the paraffin blocks may vary from 1 to more than 10, and is usually close to 3. Our goal was to assess 1- the proportion of diagnoses left in the paraffin blocks after usual processing; 2- the optimal way of processing biopsies in the laboratory of pathology.

Method: Consecutive bilateral negative TAB were extracted from the laboratory database, and the paraffin blocks were systematically re-processed. First, 6 new levels distant from 50 µm were cut, and then, new levels distant from 100 µm were cut until exhaustion of the blocks. All slides were reviewed by an independent pathologist with a pre-formatted form collecting all pathological items of the TAB. The pathologist was unaware of the final clinical diagnosis of the patients, and clinical charts were reviewed afterward. Pre- and post-review diagnoses were compared.

Results: One hundred and forty five bilateral negative TAB were included. After new slicing, 17 new cases of vasculitis were diagnosed (12% of all TAB). Among these, 5 were located in the 3 layers of the arterial wall (3 of them with giant cells), 3 showed signs of healed arteritis (with small foci of inflammatory cells), 1 showed evidence of necrotizing vasculitis in small vessels distant from the temporal artery, and 8 evidence of small vessel vasculitis surrounding the adventice of temporal artery. Involvement was unilateral in 15 cases out of 17. Thirteen diagnoses were found in the 6 first new levels, and 4, in the last, 100 µm-distant levels.

These new findings confirmed the suspected clinical diagnosis in 7 cases (‘negative’ TAB GCA : 5; ANCA vasculitis:2), and changed the former clinical diagnosis in 10 cases (‘pure’ PMR: 4; unexplained inflammatory syndrome:2; headache without further precision : 2; ‘suspicion of lymphoma’ without pathological evidence: 2).

Conclusion: Undiagnosed vasculitis was found in 12 % of the paraffin blocks after new processing. Although the diagnostic value of small vessel vasculitis may be discussed, the new findings would have modified the initial clinical diagnosis in 10 cases. Since 76 % of newly diagnosed vasculitis were found in the 6 new first levels, we suggest that these levels should be systematically performed in case of negative TAB, and further exploration could depend on the strength of clinical suspicion of temporal arteritis or vasculitis.

1971

Aortic Involvement in Patients with Newly Diagnosed Giant Cell Arteritis (GCA). A Prospective Study Using Computed Tomography (CT) Angiography. Sergio Prieto-González, Pedro Arguis, Ana García-Martínez, Georgina Espígol-Frigolé, Montserrat Butjosa, Itziar Tavera, Josep M. Grau, José Hernández-Rodríguez and Maria C. Cid, Hospital Clínic. IDIBAPS. University of Barcelona, Barcelona, Spain

Purpose: Recent studies have shown that 22.5% of GCA patients develop aortic aneurysms during follow-up. Examination of necropsy or surgically removed specimens has evidenced that GCA may target the aorta. More recently, positron emission tomography has shown to be able to detect fluorodeoxyglucose uptake by the aorta in patients with active GCA, but the prevalence and topography of aortic involvement has not been accurately evaluated by imaging techniques in prospective studies. Our objective was to prospective assess the prevalence, topography and characteristics of aortic involvement (aortitis and dilatation) in patients with newly diagnosed GCA using CT angiography.

Method: From July 2007 to June 2009, 32 patients were diagnosed with biopsy-proven GCA in our institution. Nine patients were excluded because of allergy to iodine (1), no consent to participate (1) or steroid treatment for >3 days (7 patients). Aortic CT angiography was performed to the remaining 24 patients, and the following features were evaluated: presence of aortitis (defined by contrast-enhanced circumferential aortic wall thickness ≥ 2 mm without adjacent atheroma), and significant dilatation (diameter > 4 cm in the ascending aorta, at least 4 cm in the rest of the thoracic aorta and loss of normal progressive reduction in the abdominal aortic calibre). Controls matched for gender, age and cardiovascular risk factors, were consecutively recruited from patients with no chronic inflammatory diseases, who underwent CT angiography for diagnosis or follow-up of neoplasia.

Results: The study group consisted of 13 women and 11 men, aged 80 years (range 67-89). None of the patients had previously diagnosed aortic valvulopathy or aneurysm. Structural abnormalities were detected in 18 patients (75%). Seventeen patients (70%) had aortitis and 3 patients (12,5%) had significant dilatation of the ascending aorta. Two patients had both findings, but dilatation was not coincident with aortitis in the same segment. Aortitis preferentially involved the thoracic descending aorta which was affected in 16 (94%) of patients with aortitis. The aortic arch was involved in 13 (76,5%) patients, the abdominal aorta in 8 (53%), and the ascending aorta in 3 (23%). No aortic abnormalities were observed in the control group.

Conclusion: Aortitis, as assessed by CT angiography, is highly frequent in patients with GCA at the time of diagnosis. Aortic dilatation is already present in 12,5% of patients at baseline evaluation. Aortic dilatation exclusively occurred in the ascending aorta and was no associated with CT angiography evidence of aortitis, suggesting the contribution of hemodynamic factors. Supported by SAF 08/04328. MTV3 06/0710.

Adding Hydroxychloroquine to Prednisone Does Not Improve the Outcome in Giant Cell Arteritis: A Double Blind Randomized Controlled Trial. Laurent Sailler[1], Maryse Lapeyre-Mestre[2], Loïck Geffray[3], Philippe Letellier[4], Eric Liozon[5], Philippe Montané de La Roque[6], Mohamed Hamidou[7], Eric Oziol[8], Nadine Magy[9], Philippe Arlet[10], Jean-Louis Montastruc[11] and and the investigators of the Horton-hydroxychloroquine trial, [1]Université de Toulouse, Laboratoire de Pharmacoépidémiologie, EA3696, Toulouse, France, [2]Université de Toulouse, Laboratoire de Pharmaco-épidémiologie, EA3696, Toulouse, France, [3]CHG de Lisieux, Lisieux, France, [4]CHU Côte de Nacre, Caen, France, [5]CHU de Limoges, Limoges, France, [6]CHG du Val d'Ariège, Foix, France, [7]Hôtel Dieu, Nantes, France, [8]CHG, Béziers, France, [9]CHU, Hôpital jean Minjoz, Besançon, France, [10]CHU Purpan, Toulouse,, France, [11]Université de Toulouse, Laboratoire de Pharmacologie Médicale et Clinique, Toulouse, France

Purpose: Few drugs have corticosteroid sparing effects in the treatment of giant cell arteritis (GCA). Hydroxychloroquine is a well tolerated immunomodulatory drug that may have a corticosteroid sparing potential according to its immuno-pharmacological properties and previous clinical data (*Le Guennec et al, Rev Rhum 1994*). Our objective was to evaluate the glucocorticosteroid (GC) sparing effect of hydroxychloroquine (HCQ) in the treatment of non-complicated GCA.

Method: This was a double blind randomized controlled trial. Patients with a non-complicated, newly diagnosed, biopsy confirmed GCA randomly received corticosteroids plus placebo or plus 400 mg HCQ per day for up to 96 weeks. The primary end point was being in remission with 5 mg prednisone or less for at least 3 months at the end of the follow-up. Analysis was made on an intent-to-treat basis using the Kaplan-Meier method and the log-rank test to compare the survival curves, and the Cox proportional hazard ratio to identify variables associated with the outcome. All patients have given their informed consent. The study has been registered on the clinicaltrial.gov web site (identifier: NCT00430807).

Results: 74 patients were randomized to receive placebo (n=38) or hydroxychloroquine (n=36). Among them, 10 were excluded before beginning the study drug (7 for cancellation of earlier approval, 1 for a severe GC-induced psychosis, 2 due to a major deviation). Among the 64 remaining patients (mean age: 74.4 ± 6.5 years), 32 received the placebo and 32 HCQ. Fourteen out of 32 HCQ and 21 out of 32 placebo patients reached the primary endpoint (log-rank test: p= 0.22). Twenty HCQ patients and 14 placebo patients experienced at least one relapse (p=0.13). The median cumulative corticosteroid doses were 7146 mg (range: 4643-9493) in the HCQ group and 6687 mg (range: 4563-10444) in the placebo group (p=0.9). The study drug was stopped due to adverse reactions in 8 HCQ patients (skin eruption in 6). In a *post hoc* analysis, receiving HCQ was independently associated with an increased risk of relapse after week 24 (HR = 2.52 [IC95% 1.14-5.57], p = 0.02). Polymyalgia rheumatica symptoms at the baseline (HR: 0.38 [0.15-0.96], p=0.04) and male gender (HR: 0.44 [0.17-0.93], p=0.03) were associated with a lower risk of relapse.

Conclusion: The early administration of hydroxychloroquine did not improve the outcome in non-complicated giant cell arteritis and was not always well-tolerated.

1973

Long-Term Surgical and Medical Outcome in Takayasu Arteritis: Vascular Procedures Performed in Active Patients Have a Poor Outcome. Muge Bicakcigil, Kenan Aksu, Sevil Kamali, Servet Akar, Omer Karadag, Huseyin T. Ozer, Fatos Onen, Sibel Z. Aydin, Neslihan Yilmaz, Zeynep Ozbalkan, Askin Ates, Ayse Cefle, Veli Cobankara, Mesut A. Onat, Ercan Tunc, Yasar Karaaslan, Nurullah Akkoc, A. Eftal Yucel, Gokhan Keser, Sedat Kiraz, Murat Inanc and Haner Direskeneli, Turkish Takayasu's Arteritis Study Group, Istanbul, Turkey

Purpose: Takayasu's arteritis (TA) is a rare chronic inflammatory disease of unknown etiology. There are only a few reports discussing the follow-up, course and surgical and medical prognosis of TA patients.We aimed to evaluate long-term outcome of medical and surgical treatments in TA.

Method: 184 patients (F/M: 171/13), mean age: 40.9 years followed at 13 Rheumatology centers are prospectively evaluated in terms of clinical and vascular prognosis. Mean follow-up time was 76 months .We defined active disease using NIH guidelines, and remission and sustained remission were assessed according to criteria defined by *Hoffman et al.*

Results: The great majority of 184 patients (79%) required other immunosuppressive agents, in addition to glucocorticosteroids to achieve and maintain disease remission. After the treatment, remission was observed in 89% of the patients and 51% of those patients that maintain disease remission had sustained remission at the last visit, whereas 18% were still currently active. In 78 (42%) patients, relapse was observed during follow-up. After initiation of treatment, first remission was achieved at 11.3 months. During follow-up, in 127 patients sustained remission was observed at least once.

In serial angiographic evaluations, angiographic progression was observed in 28 % of the patients. Regression analysis have shown relationship only with complete remission duration (p=0.02, OR=0.9 CI=0.92-0.99) and progression. Patients showing progression had significantly less sustained remission duration (66 months vs 32 months, p=0.02). Outcome of angiographically followed 77 vascular interventions were evaluated in terms of restenosis and complications. Restenosis was observed in 27 (35%). There was a significant relationship with the disease activity at the time of vascular procedure in terms of restenosis in regression analysis (p=0.04, OR=3.6, CI=1-13) Restenosis was observed significantly lower in the group with medical treatment started before intervention 8/34 (23%), compared to the non-treated group 19/45 (45%)(p = 0.04). Restenosis was also observed more frequently in active TA patients at the time of procedure compared to inactives(active: 21/45 (80%) vs inactive 6/30 (20%), p= 0.02). During follow-up 10 (5.4%) patients died.

Conclusion: Although glucocorticoids and immunosuppressive treatments are effective in the treatment of TA and complete remission could be achieved in 69% of the patients. Angiographic progression was observed less in patients that have longer periods of sustained remission. This observation suggests that new therapeutic agents in TA treatment. Our results also showed that in terms of restenosis, vascular interventions must be performed at inactive stages and in patients under treatment, except in emergency cases.

1974

Microendothelial Cells Regulate Functional Selection of Proinflammatory T Cells in Takayasu's Arteritis. Jiusheng Deng[1], Kisha Piggott[1], Brian R. Younge[2], Jorg J. Goronzy[1] and Cornelia M. Weyand[1], [1]Lowance Center for Human Immunology and Rheumatology, Atlanta, GA, [2]Mayo Clinic, Rochester, MN

Purpose: Takayasu's arteritis (TA) is a primary vasculitis that targets the aorta and its branches and causes aortic arch syndrome, aneurysm formation, aortic insufficiency, stroke, heart attacks, and hypertension. The typical histomorphology shows T-cell and macrophage infiltrates in the arterial media and adventitia, often clustering around vasa vasorum. T cells with proinflammatory features are end-differentiated effector cells that derive from distinct subsets (e.g. IFN-g-producing Th1 cells, IL-17-producing Th17 cells, IL-4-producing Th2 cells) with specialized differentiation requirements, tissue trafficking patterns, and effector mechanisms. Here, we have explored which T-cell effector subsets contribute to TA and how recruitment of these T cells to the aortic wall is orchestrated.

Method: IL-17- and IFN-g-producing CD4 T cells were quantified in the peripheral blood of patients with active TA and age-matched healthy controls by intracellular staining and FACS analysis. Biopsies from TA-affected aortas were analyzed for IL-17, IFN-g, and chemokine receptor transcripts by qPCR. Cytokine and chemokine production in tissue-residing and tissue-infiltrating cells were examined by immunohistochemical staining. Vessel wall inflammation was induced in noninflamed human aortas after engraftment into SCID mice and adoptive transfer of human peripheral blood mononuclear cells.

Results: In TA patients (n=10) with active disease the frequency of circulating Th17 cells was four-fold increased compared to age-matched controls (n=10) (2.85% vs 0.70%, *P*=0.0001); whereas IFN-g-producing Th1 cells were less than two-fold elevated (19.3% vs 13.3%, *P*=0.0018). In aortic wall extracts, the chemokine receptor most expressed was CCR6, followed by CCR5 and CCR3, suggesting a dominant role for $CCR6^+$ T cells. Functional analysis of wall-infiltrating T cells confirmed strong enrichment of IL-17-producing cells (16.6%) whereas IFN-g producers were represented at frequencies similar to those in the circulating blood (14.8%). Production of the CCR6-attracting chemokine CCL20 was localized to microendothelial cells of the vasa vasorum tree, often favoring microvessels in the proximal adventitia. In adoptive transfer experiments, $IL\text{-}17^+$ T cells preferentially accumulated in the aortic wall. The induction of aortic wall inflammation could be disrupted by blocking the CCL20-CCR6 axis.

Conclusion: T cells occupying the aortic wall lesions in TA are functionally selected and dominated by IL-17-releasing CD4 T cells. Due to the expression of the chemokine receptor CCR6, IL-17-producing T cells are responsive to the chemokine CCL20, which is secreted by

endothelial cells of the vasa vasorum tree. These data place dysfunctional microendothelial cells at the top of the pathogenic cascade of TA and identify the CCL20-CCR6 axis as critical in aortic wall inflammation.

1975

Pediatric Takayasu Arteritis: Significance of Central Nervous System Manifestations. Daniela S. Ardelean[1], Rayfel Schneider[2], Earl D. Silverman[3], Ronald M. Laxer[2], Pascal Tyrell[4], Michael Seed[2], Shi-Joon Yoo[2] and Susanne M. Benseler[2], [1]Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]The Hospital for Sick Children and University of Toronto, Toronto, ON, [4]Division of Rheumatology, The Hospital for Sick Children, Toronto, ON

Purpose: To describe the clinical, laboratory and imaging characteristics of children with pediatric Takayasu arteritis (TA), their treatment regimens and identify risk factors for adverse long-term outcome

Methods and Study: A single-center cohort study of consecutive children diagnosed with TA between 01/1986 and 12/2008. **Inclusion:** 1) Age ≤ 18 year-old; 2) follow-up ≥12 months. **Exclusion:** Follow-up ≤ 12 months (3 patients).

Data: Demographics, clinical, laboratory, magnetic resonance/conventional angiography characteristics and treatment regimens were collected. **Outcome:** 1) *Adverse outcome*: death or persistent disease activity at last 2 follow-ups, 2) *disease flares.* Predictors at presentation for adverse outcome *(*demographic, clinical, laboratory, imaging characteristics and treatment choices) were compared between the group with and without adverse outcome. **Analysis:** Descriptive statistics, uni-/multivariable logistic regression.

Results: Demographics: A total of 18 TA patients were included; 6 boys, 12 girls (ratio 1: 2). Median age at diagnosis was 10.0 years (range 0.6-18); median follow-up 36 months (range 12-156). **Presenting features:** Hypertension (HTN) in 8 (44%). *CNS manifestations in 9 (50%),* all had ≥ 2 distinct CNS features including severe headache in 5 (28%), hypertensive seizures in 5 (28%), arterial ischemic stroke in 5 (28%). Claudication in 3 (17%), murmur in 1 (5%) and 1 unstable angina. Constitutional features in 2 (11%); 1 (5%) had uveitis. Confirmed TB was present in 2/18 (11%). **Inflammatory markers at presentation:** elevated ESR in 9/ 16 tested (56%), anemia in 7/18 (39%), high IgG in 2/13 tested (15%), elevated CRP in 2/9 (22%) and thrombocytosis in 3/18 (15%).**Vascular imaging:** stenoses in 100%, dilations in 4(22%); vessel wall enhancement in 5/18 (28%), aneurysms in 2/18 (11%). Overall 12 (67%) had supra and infra-diaphragmatic vasculitis; 5 (28%) infra-diaphragmatic TA and 1 supra-diaphragmatic vasculitis. **Treatment:** 13 children (72%) treated with corticosteroids; 12 (67%) received an additional agent: MTX in 5 (28%), cyclophosphamide in 6 (33%), azathioprine in 5 (28%), MMF in 1; two refractory patients received infliximab; 7 (39%) required surgical interventions. **Outcome:** 1) *adverse outcome* in 7/18 (39%): 2 deaths, persistently active disease in 5; 2) *flares* in 4/18 (22%), all on immunosuppresion. Infra-diaphragmatic involvement (p=0.01) and anemia (p=0.03) reached statistical significance.

Conclusion: Children with TA commonly presented with CNS manifestations and or HTN. In children with stroke, TA has to be considered. More than one third of children with TA had an adverse outcome. Children with infra-diaphragmatic TA and anemia at presentation have a significantly increased likelihood of adverse outcome.

ARHP Concurrent Abstract Session

Physical Function and Disability in Rheumatoid Arthritis

Tuesday, October 20, 2009, 4:30 PM - 6:00 PM

1976

Association of Physical Function and Disability with Physical Activity in Women with Rheumatoid Arthritis. Sara R. Piva[1], Gustavo J. M. Almeida[1], Yanique Murphy[1] and M. C. Wasko[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Purpose: Measures of physical function (PF) and disability traditionally have been used as the primary outcomes of rehabilitation in patients with rheumatoid arthritis (RA). While informative about the patient's ability to perform everyday tasks, they do not provide information about the amount of everyday tasks one performs, defined as physical activity (PA). Studies demonstrated that PA is associated only to a small degree with PF and disability and perhaps represent independent constructs. The purpose of this study was to determine the cross-sectional associations between measures of PA and measures of PF and disability prior and after controlling for social and biomedical characteristics in women with RA.

Method: Forty seven women with RA, mean age 58 ± 6 years. PA was measured by a portable activity monitor worn for 7 days, and was characterized in 2 ways: daily average # of steps, and daily energy expenditure during moderate levels of PA (EEPA). Disability was measured by the Health Assessment Questionnaire (HAQ). PF was measured by self-selected gait speed and the timed 5-chair rise test. Non-normally distributed variables were square root-transformed. Analyses: Step 1- Pearson coefficients were calculated between PA, PF and disability. Step 2- Pearson or Spearman coefficients were calculated between social and biomedical characteristics and PA, PF and disability. Step 3- partial correlations between measures of PA and measures of PF and disability were calculated controlling for associated social and biomedical characteristics.

Results: Results are reported in the Table. Associations between measures of PA and measures of PF and disability, although significant, were small (r = -.23 to .48). After controlling for social and biomedical characteristics, the associations were not significant (r= .07 to .28).

Conclusion: Small associations between measures of PA and measures of PF and disability are explained by patient's social and biomedical characteristics. The results indicate that measures of PF and disability may represent constructs different than PA and suggest that measures of PA should be included in rehabilitation research in RA.

Step 1. Associations between PA and measures of PF and disability					
			PF		Disability
			Gait Speed	Chair Rise	HAQ
PA	EEPA		.37*	-.23	-.38**

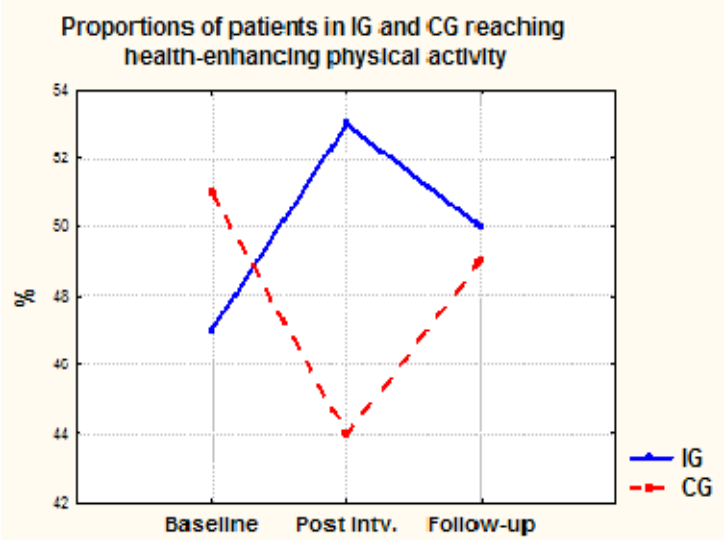
Maintenance of Health-Enhancing Physical Activity in Rheumatoid Arthritis After a One-Year Coaching Intervention – A Long-Term Follow-up. Emma Swärdh[1], Nina Brodin[1], Jon Lampa[2], Christina H. Opava[1] and the PARA Study Group, [1]Karolinska Institutet, Huddinge, Sweden, [2]Stockholm, Sweden

Purpose: The recommendation of at least 30 minutes' moderately intense physical activity on most, preferably all, days may serve as a useful and feasible self-management strategy for individuals with rheumatoid arthritis (RA) to improve or maintain general health. However, support from health professionals is often necessary in adopting and maintaining this behavior. The present aim was to investigate

the long-term effect on perceived general health, physical activity, pain, disease activity, and activity limitation of a one-year coaching program to adopt health-enhancing physical activity in patients with early RA.

Method: At baseline, 228 patients with early RA, from 10 rheumatology clinics in Sweden, were assigned at random to an intervention group (IG, n=94) or a control group (CG, n=134). The intervention was assessed one year after baseline, and followed up two years after baseline. The IG was coached by physical therapists during the first year to adopt health-enhancing levels of physical activity (30 minutes/day, moderately intensive, ≥ 4 days/week). No coaching was given during the subsequent year between post-intervention and follow-up. Follow-up assessment consisted of a postal questionnaire on physical activity behavior and of visual analog scales for ratings of general health perception and pain, the functional disability index of the HAQ and the DAS 28 collected at regular medical check-ups.

Results: Sixty-five (69%) participants in the IG and 92 (69%) in the CG completed the entire study period by filling in and posting the follow-up questionnaire on physical activity behavior two years after baseline. No long-term differences in changes between the IG and the CG in any of the outcome variables were found between baseline and follow-up. However, different variations in physical activity behavior were observed in the two groups.



Conclusion: The present study, which was performed within ordinary clinical practice, is one of the first to evaluate the coaching of individuals with RA to adopt health-enhancing physical activity. Whereas improved self-reported health was found at the end of the one-year coaching program, as previously reported, no long-term increases in self-reported health or in physical activity behavior were found in the present follow-up. This may partly be because the intervention lacked several important behavioral elements for physical activity maintenance.

Adherence to An 8-Week Yoga Program for RA and OA: Who Drops out and Why? Steffany Haaz[1], Clifton O. Bingham III[2] and Susan J. Bartlett[3], [1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins, Baltimore, MD

Background. Physical activity is integral to comprehensive arthritis management, yet long-term adherence averages 50-60% over several months. We have previously shown yoga is a safe, effective and enjoyable physical activity for arthritis patients, though long term-adherence in unknown.

Purpose: To identify factors associated with adherence to yoga tailored for people with rheumatoid (RA) and osteoarthritis (OA).

Methods: In this RCT, 75 persons ages 18-65 with OA or RA were recruited through arthritis clinics and area rheumatologists. Participants were 96% female, 55% Caucasian, aged 52.3±11.9 years. 36 (48%) had RA and 39 (52%) had OA and were randomized to immediate yoga (IY) or waitlist control (WC) followed by participation in the yoga program. Yoga classes, held biweekly for 8 weeks, included poses (asanas), breathing (pranayama), chanting, relaxation and meditation. Poses were designed to accommodate joint limitations and individual abilities. Instruction was provided for weekly home practice.

Adherence was assessed as: 1) attendance at ≥13 classes (protocol) and 2) completion of study requirements (study). Baseline predictors included sociodemographic and disease characteristics, depressive symptoms (CES-D), self-efficacy (ASES) and selected markers of physical fitness (4) and health status (4). Logistic regression was used to identify baseline predictors of protocol and study adherence.

Results: Of 75 patients screened, 40 were assigned to IY and 35 were assigned to WC. There were no differences between treatment groups in sex, race, disease diagnosis or duration. The WC group was slightly older than the IY group (55.9±1.5 vs. 49.2±2.1, p=.01).

There was a trend for those randomly assigned to IY to attend any classes (83% vs. 63% WC respectively p=.059), which did not change when controlling for differences in age between groups.

Overall, 69% were classified as protocol adherent (73% IY vs. 64% WC, p=.48). Caucasian race was the only baseline characteristic associated with starting or completing the yoga intervention (odds ratio [OR] = .33, 95% CI=.11, .97 and OR=.25 95% CI=.09, .94 respectively). Study adherence was 71% (63% IY vs. 80% WC, p=.10). Attending college and Caucasian race were the only predictors associated with study adherence (OR=2.4 95% CI= .10, .75 and OR=.26 95% CI=1.1, 4.9 respectively). However, after controlling for age and race, education was no longer predictive. While race was repeatedly associated with adherence, the contribution to predicting any form of adherence was low. Trends toward significance were found for hypothesized markers of physical function, physical fitness and self-efficacy. Common reasons for attrition were change in eligibility, life events and class logistics (time, location).

Conclusion: Arthritis patients who begin yoga may be likely to persist with it over time. Risk of drop-out appears highest in minority persons and before starting classes. Better understanding of minority barriers to participation and other factors affecting adherence is needed. Clinicians may wish to consider recommending yoga to arthritis patients, particularly when adherence to exercise has been problematic.

1979

Predictors of Physical Therapy Service Use in Persons with Rheumatoid Arthritis. Maura D. Iversen[1], Nancy A. Shadick[2] and Riku Chhabriya[3], [1]MGH Inst of Hlth Professions and Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham & Women's Hosp, Boston, MA, [3]MGH Inst of Hlth Professions, Boston, MA

Purpose: Although physical therapy (PT) is recognized as a key component of rheumatoid arthritis (RA) management and has been shown to improve function and reduce disability in persons with RA, the literature demonstrates that PT services are underutilized. This study aimed to identify factors associated with use of PT among patients with RA.

Method: 772 patients prospectively recruited from a large hospital registry, completed questionnaires, received a physical examination at baseline and completed a 12- month follow-up survey. Measures included: demographic data (age, gender, marital status, race, employment, disability, income, co-morbidities, education) as well as self- efficacy, social support (BSNI), function (MDHAQ), quality of life (EuroQoL), disease activity (RADAI). Self-reported use of PT services (yes/no) was assessed at 12-months. Descriptive statistics were used to characterize the sample. Bivariate comparisons were conducted to identify variables for logistic regression analysis. Using a modified liseral approach, variables were selected and entered into the regression, based on the International Classification of Function (ICF) framework, to develop a parsimonious set of predictors.

Results: 93.6% were Caucasians, 82.3% female with mean age of 56.29 (±13.57) years. 64.7% were married, half of the sample was employed, 9.8% reported to have disability in past 6 months and 36.6% had annual income >= $90,000. Of 772 patients, 118 (15.3%) patients used PT services. The majority of patients had 1 to 8 PT visits. Within our sample, 29.4% of patients reported no prior participation in exercise and 27.1% performed exercises on a regular basis. On average, Patients reported a moderate amount of fatigue (mean VAS 43.23

(± 28.45 SD). and mild disease activity (median RADAI = 3.26; range = 0-10). These patients were fairly independent, reporting only mild restrictions in activities of daily living (median MDHAQ = 0.68, range = 0-3). Despite the limited clinical manifestation of disease impact, these patients reported relatively poor quality of life (median EQ Index = 0.82; range = 0-1).

Using bivariate analysis, factors most predictive of PT use were: disability, RADAI, income, EuroQoL, co-morbidities, MDHAQ and BSNI. In the multivariate regression, the most significant predictors were RADAI (OR=1.14; 95%CI=1.02-1.28); co-morbidities (OR=1.5; 95%CI=1.04 - 2.07); EuroQoL(OR=0.06; 95%CI=0.01-0.32), BSNI (OR=1.05; 95%CI=1.01-1.10) and disability (OR=2.00; 95%CI=1.01-3.93).

Conclusion: Patients with more active disease, higher number of co-morbidities, and who reported being disabled, having a low quality of life and greater social support were more likely to receive PT services. This model explained 86% of the variance in PT service use.

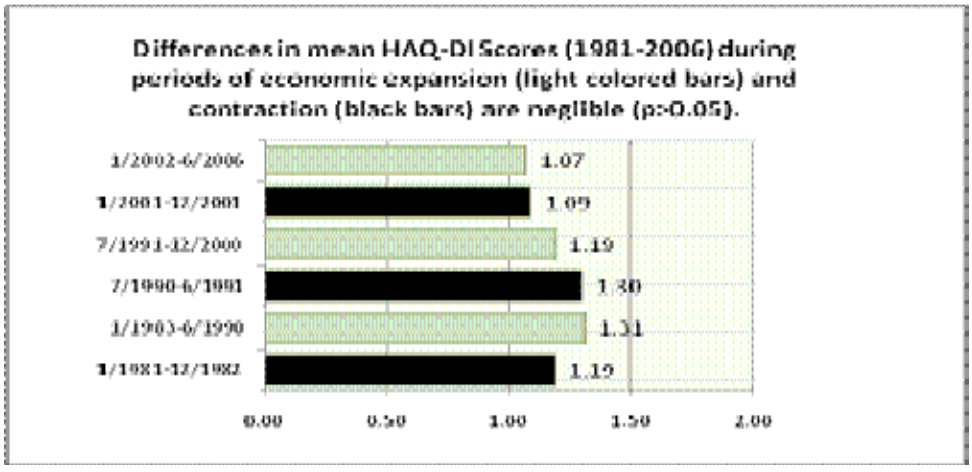
Effects of Economic Fluctuations and Seasonal Variability On HAQ-DI Scores in Rheumatoid Arthritis. Bonnie Bruce[1], James F. Fries[2] and Bharathi Lingala[3], [1]Stanford Dept of Medicine, Palo Alto, CA, [2]Stanford Univ Medical Ctr, Palo Alto, CA, [3]Stanford University, CA

Purpose: Self-reported health status outcomes could be in part influenced by economic fluctuations or seasons (e.g., winter worse than summer) and are largely understudied. We examined 25.5 years of Health Assessment Questionnaire Disability Index (HAQ-DI) administrations to study the effects of economic expansion and contraction and seasonal variability.

Method: We used 6-month HAQ-DI scores (0-3; 3=worst) from 51 semi-annual mailings (1981-2006) collected from a longitudinal panel study of adults with rheumatoid arthritis (RA). We used the National Bureau of Economic Research criteria to define economic expansion and contraction. Periods of economic contraction were defined as 1/1981-12/1982, 7/1990-6/1991, and 1/2001-12/2001. Seasons were defined as Winter/Spring and Summer/Fall. We describe our findings using measures of central tendency and examine the data using parametric and nonparametric statistics as appropriate.

Results: Subjects (n=1413/mailing) were white (90%), female (76%), had 12 education years, RA for 18 years, and a mean HAQ-DI score of 1.21±0.80. There were no differences in subject characteristics between periods of economic expansion or contraction (age – 59 vs. 61 years, disease duration – 17 vs. 18 years, p>0.05). The overall mean physical function score was similar for the 43 HAQs (21.5 years) collected during economic expansion years compared to the 8 HAQs (4 years) collected during periods of contraction (1.21±0.11 vs. 1.19±0.09, p=0.65). HAQ-DI scores were not different for winter-spring (26 HAQs) compared to summer-fall (25 HAQs) (1.20±0.80 vs. 1.21±0.81, p=0.83). Reporting did not differ between males and females for economically or seasonally defined periods.



Conclusion: In this study with large numbers of RA patients, we found consistent reporting of disability scores without effects during periods of economic expansion or contraction or between seasons. The effects of economic fluctuations or seasons on HAQ-DI scores are negligible.

Is Nurse-Led Care for RA Patients Clinically Effective? Mwidimi Ndosi, Jackie Hill and Claire Hale, University of Leeds, Leeds, United Kingdom

Purpose: To determine the effectiveness of nurse-led care (NLC) by comparing the outcomes of RA patients seen by clinical nurse specialists or rheumatologists (RLC). We hypothesized that the outcomes of the NLC would not be inferior to those obtained by RLC.

Methods: This was a 4-centre RCT. Patients were randomised on a 1:1 basis to either NLC of RLC based on their primary outcome, DAS28 scores which were measured at baseline (M0), 3 months (M3) and 6 months (M6). Secondary outcomes were measured at the baseline and 6 months and included the Health Assessment Questionnaire (HAQ), Arthritis Self Efficacy Scale (ASES), Hospital Anxiety and Depression Scale (HAD) and the Leeds Satisfaction Questionnaire (LSQ). The clinical nurse specialist and the rheumatologists saw patients on 3 occasions and undertook their normal practice. An independent assessor performed all joint counts.

Repeated measures models were used to assess:

1) within-subject (time) effects - how DAS28 changed from M0 to M3 & M6

2) between-subjects (group) effects – how differently each group performed over time (group*time effects)

<>For the secondary outcomes, mean differences (MD) were computed and the unpaired t-test was used to test the difference between the groups' MD's

Results: The cohort comprised 14 males and 39 females whose median age was 61 years (Range = 30 – 86). 27 were allocated to NLC and 26 to RLC. On study entry there was no significant difference in any variable between the 2 groups.

On study completion, there were improvements in DAS28 for all patients (M0, M3 & M6 = 3.40, 3.20 & 3.12 respectively; $p = 0$ .34), but this was a small effect size (eta-squared = 0.03). Interestingly, patients under the NLC had consistent improvements (M0, M3 & M6 = 3.29, 3.19 &3.05 respectively) while those under RLC had an improvement by month 3 then a plateau by month 6 (M0, M3 & M6 = 3.53, 3.36 & 3.37 respectively). Despite this difference, group effects were non-significant (p = 0.67, eta squared = 0.01).

The HAQ demonstrated that disability was significantly decreased for all patients (MD = -0.6, p = 0.01) but those under NLC were significantly greater (MD = -0.7) than RLC (MD = -0.5; p = 0.05).

The LSQ showed that overall satisfaction significantly decreased (MD = -1.05, p = 0.01) and there were no between group differences (p = 0.10).

There were no significant improvements in ASES (MD = -0.6, p = 0.78) or HAD scores (MD = 0.2, p = 0.86) and no between group differences (p = 0.66 & 0.87) respectively.

Conclusion: Despite the small effect size on DAS28, NLC demonstrated at least similar outcomes to RLC. In addition, NLC delivered greater improvements on disability than RLC and in this respect NLC provided added value. Surprisingly, satisfaction decreased for both groups which is inconsistent with previous studies which have reported increased satisfaction with NLC.

The overall results suggest that NLC for RA patients is clinically effective and not inferior to RLC. Given that RA is a variable disease, a longer multi-centre study is needed to take account of this.

Cardiovascular Disease in Rheumatic Conditions

Wednesday, October 21, 2009, 7:45 AM - 8:45 AM

1982

Identification of Cardiac Risk Factors in Hospitalized Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis.

Eileen J. Lydon[1] and H. Michael Belmont[2], [1]NYUHJD, New York, NY, [2]Hosp for Joint Disease, New York, NY

Purpose: Patients with systemic lupus erythematosus(SLE) and rheumatoid arthritis(RA) have a higher incidence of coronary heart disease than the general population. Since recent data support the hypothesis that inflammation associated with RA and SLE contributes to accelerated atherosclerosis cardiovascular events are not solely explained by traditional risk factors, but undoubtedly these classic hazards do contribute to the burden of atherosclerosis. Therefore, aggressive efforts to identify cardiac prevention measures are essential in this cohort. Identifying patients in a hospitalized setting is an opportunity to target, educate and treat more patients.

Method: During 2007-2008 in-patients at NYUHJD with RA or SLE had their cardiac risk assessed and were given appropriate treatment recommendations as derived from the 2001 Adult Treatment Panel III National Cholesterol Education Program as well as the 2004 implications of recent clinical trials published in Circulation. A fasting lipid panel was performed then a ten year risk assessment was calculated using the Framingham point scores and LDL goals identified. Patients with metabolic syndrome were also identified. Recommendations included the initiation of LDL lowering therapy, hypertension treatment, smoking cessation, and therapeutic lifestyle changes (TLC) (e.g. diet and exercise intervention).

Results: 87 enrolled,76F,11M; 27SLE, 60RA. Low Risk 40/87(46%), Moderate 32/87(37%), Moderately High 5/87(6%), High 10/87(11%). Unmet LDL: 14/87(16%), Statin initiated 13/14(93%). HTN: 10/87(11%), Treated 9/10(90%). Cigarette Smoking: 6/87(7%). BMI: Under 2/87(2%), WNL 34/87(39%), Over 26/87(30%), Obese 25/87(29%). Metabolic Syndrome:10/87(11%). TLC:19/87(22%).

Conclusion: Cardiovascular disease is the leading cause of morbidity and mortality in patients suffering from SLE and RA and classic risk factors are not adequately managed in the community. Targeting in-patients easily allows for risk factor modification such as initiating LDL lowering and hypertensive therapy, obtaining a fasting lipid panel, educating, assessing learning needs, consulting nutritionists, physical therapists and making appropriate outside referrals. These results also highlight that statins are insufficiently prescribed which is especially relevant in this population as in addition to lipid lowering, they may have anti-inflammatory properties. In conclusion, the in-patient hospital setting can serve as a valuable opportunity to provide effective cardiac prevention strategies in this high risk population.

1983

Cardiovascular Risk and Depression in Systemic Lupus Erythematosus (SLE). L. J. Julian, P.P. Katz, J. Yazdany, A.O. Hersh, L. Trupin, A. Galvin, L.A. Criswell and E.H. Yelin, UCSF, SF, CA

Purpose: Cardiovascular (CV) disease has emerged as a major cause of morbidity and mortality in SLE. In the general population, the link between depression and CV disease is well established; however, few studies have evaluated this relationship in SLE. This study evaluated traditional and SLE-specific factors as predictors of the prevalence and incidence of depression in a large observational cohort of persons with SLE.

Methods: Participants included 725 persons with confirmed SLE (ACR criteria), participating in annual survey interviews over 6 years. Depression symptom severity was evaluated by the Centers for Epidemiological Studies Depression Scale (CESD). Statistical analyses included multivariate linear regression predicting concurrent depression, and logistic regression predicting incident depression (defined as a new onset of CESD score ≥23 over 2 years of follow up). Predictors in both models included sociodemographic characteristics, traditional risk factors (CV event, heart disease, hypertension, hypercholesterolemia, diabetes, obesity, family history, current or past smoking), and SLE-specific risk factors (renal involvement, history of clot, disease duration, disease activity).

Results: Mean age was 50±12, 60% were at least college educated, 74% were Caucasian, and 11% were living below poverty. In multivariate linear regression, living in poverty, history of CV event, traditional CV risk factors and disease activity were significant

predictors of concurrent depression symptom severity, accounting for 34% of the variance (p<.0001). Over the course of the study there were 163 new 'cases' of incident depression. In multivariate logistic regression, predictors of incident depression included poverty status, history of myocardial infarction or stroke, and disease activity (Table 1). The interaction of CV event and poverty neared significance (p=.09). Descriptive analyses suggested that 80% of persons living below poverty with a history of a CV event developed depression during the study period.

Conclusion: Traditional and SLE-specific CV risk factors are associated with concurrent and incident depression. Participants at greatest risk for the development of depression are described by the confluence of sociodemographic and biological risk factors. Importantly, a number of CV risk factors are modifiable, highlighting the potential of both medical and social interventions to prevent the development of depression and/or to reduce the morbidity associated with depression in SLE.

Table 1. Logistic regression analyses predicting "incident depression".

1984

Depression Is a Risk Factor for Subclinical Atherosclerosis in SLE. Carol M. Greco[1], Tracy Li[2], Abdus Sattar[1], Amy H. Kao[1] and Susan Manzi[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Bristol-Myers Squibb, Princeton, NJ

Purpose: Women with SLE have increased rates of subclinical atherosclerosis compared to controls, as measured by coronary artery calcium (CAC) and carotid plaque. Women with SLE also exhibit higher prevalence of depression and depressive symptoms than controls. Although depression and other psychological factors have been linked to atherosclerosis in healthy women, the associations between psychological factors and vascular disease in SLE remain largely unexplored. The purpose of this study was to evaluate biological and psychological risk factors associated with subclinical atherosclerosis in women with SLE, as defined by presence of coronary artery calcium and/or carotid plaque.

Method: In this cross-sectional study, 161 women with SLE without prior history of cardiac events completed comprehensive cardiovascular risk factor assessments, SLE disease activity assessments, and the Center for Epidemiologic Studies Depression scale (CES-D). Participants also completed an electron-beam computed tomography scan of the coronary arteries to determine the presence of CAC, and carotid artery ultrasound to detect presence of plaque. For this study, subclinical atherosclerosis was defined as having either or both of these vascular indicators. In unadjusted logistic regression analyses, risk factors associated with atherosclerosis at $p<0.15$ were evaluated for inclusion in multivariable models. The final model was selected based on Akaike's Information Criteria (AIC).

Results: The mean age of the participants was 50 years, and 88% were Caucasian. Mean SLE duration was 16 years. Most (68%) had taken corticosteroids, with median duration of 10 years of use. The mean CES-D score was 11.6 (SD= 9), with 27% of the participants scoring ≥ 16, a score consistent with clinically meaningful depressive symptoms. One hundred and one (63%) met criteria for subclinical atherosclerosis. Using multivariable logistic regression, SLE women with depression were at nearly four-fold risk for having subclinical atherosclerosis (OR= 3.85, 95% CI =1.37, 10.87) after adjustment for several traditional cardiovascular risk factors (age, hypertension, years of education), C-reactive protein (CRP), and waist-to-hip ratio.

Conclusion: Depression is associated with subclinical atherosclerosis in women with SLE, independent of age, education, hypertension, CRP and adiposity. This is important in that mental health factors are modifiable. Interventions that reduce depressive symptoms may impact cardiovascular disease in SLE.

Multivariable logistic regression analysis of risk factors for atherosclerosis in women with SLE (N=161).

Cardiovascular Disease (CVD) Prevention Counseling Program for Systemic Lupus Erythematosus (SLE) and/or Antiphospholipid Antibody (aPL) Positive Patients. Virginia F. Haiduc, Monica Richey, Sotiria Tzakas, Josephine Park, Lisa Konstantellis, Julie A. Pollino-Tanner and Doruk Erkan, Hospital for Special Surgery, New York, NY

Background: SLE patients have high-risk CVD profiles as they have increased prevalence of both traditional CVD- and other lupus-related thrombosis risk factors. APL-positive patients with or without SLE are at increased risk for arterial and venous thrombosis.

Purpose: To determine the satisfaction of SLE and/or aPL-positive patients who participate in a counseling program that has been developed to increase the awareness of CVD risk factors as well as thrombosis prevention strategies.

Methods: A free-of-charge counseling program, which is partially supported by the New York Community Trust, has been developed to provide a basic *assessment* of and *education* about the CVD and thrombosis risk factors in SLE and/or aPL-positive patients. The *assessment* phase (chart review by the program MD and patient interview/examination by the program nurse) includes the evaluation of blood pressure, blood glucose, cholesterol profile, waist circumference, body mass index, family history of CVD, diet and exercise habits, smoking status, homocysteine and high-sensitivity C-reactive protein (hs-CRP) levels (if available), Framingham 10-year CVD risk calculation, aPL-profile, and medications. The *education* phase includes detailed discussion of the above risk factors as well as CVD and thrombosis prevention strategies. At the end of the counseling, patients: a) receive tailored lifestyle recommendations; b) are referred to the nutrition and physical therapy departments as needed; and c) complete an anonymous survey to evaluate the program. Patients are followed every 3-6 months with official re- assessment of the CVD risk-profiles. We report the results of patients' initial visit satisfaction surveys (Likert Scale; 1: best to 5: worst).

Results: Since the launch of the program in March 2009, 27 patients have received counseling and 25/27 (93%) completed the satisfaction survey. 52% of the participants reported that they were not aware of the CVD risk in lupus patients, 24% had some but limited knowledge; and 24% were aware of the risk. The mean (± SD) scores for the answers were: a) quality of the counseling: 1.2 ± 0.4; b) quality of the educational materials: 1.4 ± 0.9; c) likelihood of recommending the counseling program to others: 1.4 ± 0.8; d) improvement in patient's knowledge about CVD risk factors: 1.8 ± 1.0; e) likelihood of the counseling program improving patients' diet: 1.7 ± 0.9; and f) likelihood of the counseling program improving patients' exercise pattern: 1.8 ± 0.8.

Conclusion: Our preliminary survey demonstrates that lupus and/or aPL-positive patients are well satisfied with a free CVD prevention counseling program. The three-year longitudinal analysis of patients included in the counseling program will determine the true effectiveness of the program with respect to decreasing the prevalence of cardiovascular disease risk factors.

1986

The Importance of APRIL in SLE Disease Activity and Treatment. Kelly T. McNallan, Richard Bram, Cynthia S. Crowson, Kevin G. Moder and Ann M. Reed, Mayo Clinic, Rochester, MN

Purpose: Systemic Lupus Erythematosus is a complex chronic disorder with variable clinical features, treatment response and unpredictable flares of inflammation. Current treatments impact the symptoms, but do not address the underlying mechanisms.

This study targets the underlying abnormal immune responses of myeloid, B and T cell signaling in SLE. Recently, mouse models have expanded the specific functions of APRIL including disease improvement resulting from an APRIL decoy receptor. Others did not find a significant difference in serum levels of APRIL protein in SLE patients, compared to controls. We hypothesized that serum APRIL levels may not truly reflect the extent of its biological actions, because the majority of the protein is typically bound to cell surface proteoglycans. To explore this possibility, we investigated APRIL mRNA levels, as a more accurate predictor of APRIL production than serum protein

levels. We quantitated mRNA expression of B cell receptors BAFFR, TACI and BCMA and their ligands Full Length BAFF (FL BAFF), ΔBAFF, an alternative transcript that inhibits FL BAFF and APRIL in correlation with SLE disease activity, clinical features and medications.

Methods: Total RNA was extracted from Ficoll-Paque enriched PBMCs from 38 SLE patients and 21 healthy controls. Real-Time PCR was performed to assess FL BAFF, ΔBAFF, APRIL, BCMA, TACI, BAFFR and CD20 expression levels and comparisons were performed using Wilcoxon rank sum tests. Correlations with clinical data were performed using Spearmann correlation analyses.

Results: A total of 38 patients with SLE (mean age 43.9 years, 90% female, mean SLAM: 5.4) were studied. Increased SLAM disease index scores correlated with increased APRIL/CD20 (p=.011) and FL BAFF/CD20 (p=.011) levels. Decreased levels of BCMA (p=.039), APRIL (p=.015), FL BAFF (p=.003), ΔBAFF (p=.003) were found in SLE patients taking Hydroxychloroquine (HCQ) therapy. Increased FL BAFF (p=.04), BCMA/CD20 (p=.036) and CD20 (p=.04) were seen in patients with autoantibodies (anti-SSA, SSB, RNP, Smith, dsDNA). In addition, increased APRIL expression was seen in the SLE patients with headaches and seizures (p=.012)

Conclusion: This is the first report showing a positive correlation between APRIL mRNA expression and SLE disease activity and a correlation between a decrease in myeloid derived cytokines APRIL, FL BAFF and ΔBAFF with HCQ treated SLE patients. The use of HCQ in SLE needs to be investigated in a larger cohort to gain a cohesive understanding of its effects. Although we did not find an overall difference in APRIL expression between controls and SLE patients we hypothesize APRIL may be a more potent cytokine due to its increased avidity for TACI and BCMA causing prolonged survival and autoantibody production and T cell activation dependence similar to findings in mouse models. This study implicates APRIL in the disease processes that occur in SLE, and indicates the need for further studies of APRIL's role in a larger sample size.

Reactivity with Dichotomous Determinants of Ro60 Stratifies Autoantibody Responses in Lupus and Primary Sjogren's Syndrome.
Joanne H. Reed[1], Nadine L. Dudek[2], Shannon E. Osborne[1], Kenneth M. Kaufman[3], Michael W. Jackson[1], Anthony W. Purcell[2] and Thomas P. Gordon[1], [1]Flinders Medical Centre, Bedford Park, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Oklahoma Medical Research Foundation, OK, OK

Purpose: Flow cytometric-based analysis of B-cell epitopes of Ro60 exposed on the surface of apoptotic cells (apotopes) and intracellular epitopes provides insight into the structural forms of Ro60 that break immune tolerance. The aim of this study was to fine map a Ro60 apotope that is specific for a subset of systemic lupus erythematosus (SLE) and determine whether differentially expressed forms of this determinant stratify anti-Ro60 responses in SLE and primary Sjögren's syndrome (SS).

Method: Ro60 apotopes were mapped by multi-parameter flow cytometry on early apoptotic cells by inhibition experiments using soluble recombinant fragments of Ro60. Anti-Ro60 IgG from patients with SLE (n=32) and primary SS (n=26) were also assessed for reactivity with the immobilised Ro60 fragments by ELISA or immunoblot. Anti-Ro60 IgG was eluted from early apoptotic cells or recombinant Ro60 immobilised on nitrocellulose and binding to membrane-bound and intracellular forms of Ro60 quantitated by flow cytometry. Three-dimensional modelling of immunoreactive domains was based on the crystal structure of *Xenopus laevis* Ro60.

Results: A homology model was constructed using the crystal structure of *X. laevis* Ro60 and the apotope mapped to a prominent helix-loop-helix region or peg-like region on the surface of human Ro60. This immunodominant structure was recognised by patients with SLE and isolated anti-Ro. Immobilisation of the same domain to a solid phase revealed a second determinant (epitope) that was specific for linked anti-Ro and anti-La-responses. Virtually all patients recognising the Ro60 apotope were negative on the epitope and vice versa. Affinity-purification experiments revealed that the apotope and epitope were expressed in a mutually exclusive fashion on membrane-bound and intracellular forms of the autoantigen, respectively.

Conclusion: Dichotomous determinant recognition within a single domain of Ro60 stratifies anti-Ro60 responses in SLE and primary SS and supports a model of anti-Ro60 autoimmunity in which tolerance is broken by different immunogenic forms of the autoantigen.

1988

Pituitary Tumor-Transforming 1 Interacting Protein (PTTG1IP) Is a Novel Target for Autoantibodies in RA. Hanna Maciejewska Rodrigues, Emmanuel Karouzakis, Hossein Hemmatazad, Renate E. Gay, Beat A. Michel, Michel Neidhart, Steffen Gay and Astrid Jüngel, Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland

Purpose: The identification of novel autoantigens in RA is important for a better understanding of specific disease mechanisms as well as for diagnostic purposes. Pituitary tumor-transforming 1 interacting protein (PTTG1IP) is a co-activator of transcription and is regulated by Runx2, the major regulator of bone morphogenesis.

Method: A modified serological analysis of recombinant cDNA expression libraries (SEREX) using cDNA derived from RA synovium was used for the identification of novel autoantigens. For screening of peptides reactive with autoantibodies synovial fluid from a RA patient was used. An ELISA was established and used to assess the levels of the identified anti-PTTG1IP autoantibodies in synovial fluids and sera from RA (n=30 and 33) and osteoarthritis (OA) (n=14 and 38) patients and in the sera of healthy individuals (n=37). The expression of PTTG1IP was analysed in RA (n=5) and OA (n=4) synovial tissues by Western blot and immunohistochemistry.

Results: PTTG1IP was detected among 18 other novel autoantigenes by the SEREX method. The levels of PTTG1IP reactive autoantibodies were present in 53% (AU range 0-275, mean ± SEM 43 ± 8) of synovial fluids from RA patients and differed significantly from OA patients ($p<0.05$). Only 7% of synovial fluids from OA patients were positive for anti-PTTG1IP autoantibodies (AU range 0-18, mean 2 ± 1). Most interestingly, anti-PTTG1IP autoantibodies were detected in 43% of synovial fluids from rheumatoid factor (RF) negative RA patients (AU range 0-35, mean 12 ± 5) and in 40% of anti-citrulinated antibodies (anti-CCP) negative RA patients (AU range 0-35, mean 12 ± 6). The levels of anti-PTTG1IP autoantibodies in sera of RA patients were significantly higher compared to OA (324 ± 49 vs 80 ± 17, $p<0.01$) while did not differ significantly from the healthy controls (235 ± 33). PTTG1IP protein was expressed to a similar extent in both RA and OA synovial tissues as assessed by Western blot (RA 125 ± 20 AU vs OA 100 ± 40 AU) and confirmed by immunohistochemistry.

Conclusion: Anti-PTTG1IP autoantibodies are also present in the RF- as well as anti-CCP-negative synovial fluids, and therefore, represent a novel promising candidate for defining a specific subset of RA patients. Since PTTG1IP has been suggested to play a role in osteoblast differentiation, and autoantibodies against PTTG1IP were detected at increased levels in RA patients, it might be speculated that these autoantibodies may interfere with osteoblast differentiation and attempted repair processes in the affected joints.

1989

Activation of Interferon and Ubiquitin Pathways in Lupus Memory B Cells. Mikhail Olferiev and Mary K. Crow, Hospital for Special Surgery, New York, NY

Purpose: Memory B cells from patients with systemic lupus erythematosus (SLE) represent an important cell population that is associated with disease activity and contributes to production of pathogenic IgG autoantibodies. To gain further insight into the mechanisms of altered B cell function in SLE, we investigated the molecular pathways activated in SLE and healthy donor (HD) memory B cells using gene expression profiling.

Method: Seven adult female patients with established SLE (100% ANA positive; SLEDAI score >4 and <12) and seven HD participated in the study. B cells were first enriched from peripheral blood and the $CD19^+CD27^+$ memory B cell subset separated from naïve B cells ($CD19^+CD27^-$) on a FACS Vantage cell sorter. Microarray analysis of mRNA derived from SLE and HD samples was performed using the Affymetrix Human U133 2.0 chip. Gene expression analysis was carried out using GeneSpring GX 10 software. Samples were per-chip normalized and transformed to the baseline median level. Student T-test was performed to determine differentially expressed genes between the two groups.

Results: 1183 genes were found to be differentially expressed between SLE and HD $CD19^+CD27^+$ cells [Fold Change (FC) >1.5, $p<0.05$]. Among those, 30 genes showed strong significance for differential expression (FC>1.5, $p<0.01$). Unsupervised cluster analysis clearly

discriminated patients with SLE from HD. Functional analysis revealed enrichment of genes related to Ig synthesis, interferon (IFN) signature, B cell signaling and the ubiquitin pathway. Genes with likely relevance to autoimmunity were significantly overexpressed in SLE memory B cells, including AICDA and GCET2 ($p<0.01$). Increased expression of TLR7 and IRF7 and of type I IFN-inducible genes (STAT1, IFI27, IFIT1, IFITM1, OAS2/3/L) identified lupus memory B cells as active participants in type I IFN production and response, and the expression of CD72 and CD22 inhibitory receptors was low. Expression of several ubiquitin conjugating enzymes and ubiquitin ligases was increased in memory B cells from SLE patients, including TRIM25, an E3 ubiquitin ligase responsible for ubiquitylation of RIGI, a mediator of TLR-independent type I IFN production.

Conclusion: mRNA expression was dysregulated in SLE memory B cells, consistent with an important contribution of those cells to the immunoregulatory disturbances that result in autoimmunity and disease. In addition to patterns characteristic of active Ig synthesis and an IFN signature, we identified activation of the ubiquitin machinery, including a participant in TLR-independent IFN production, in lupus memory B cells, pointing to an additional pathway that may be important in lupus pathogenesis.

1990

The Aortic Adventitia of Coronary Bypass Patients with Rheumatoid Arthritis Provides a Survival Niche, and Antigen Depot, for B Cells. Ammad Ahmed[1], Ivana Hollan[2], Knut Mikkelsen[3], Oystein T. Forre[4], Iain B. McInnes[1] and Carl S. Goodyear[1], [1]University of Glasgow, Glasgow, United Kingdom, [2]1. Feiring Heart Clinic, Feiring, 2. Hospital for Rheumatic Diseases, Lillehammer,, 1. Feiring. 2. Lillehammer, Norway, [3]Lillehammer Hospital for Rheumatic Diseases, Norway, [4]University of Oslo, Oslo

Purpose: Rheumatoid arthritis (RA) is associated with an increase in cardiovascular morbidity and mortality but how the vascular environment affects the immune component of RA is currently unknown. It has previously been shown that inflammatory rheumatic disease patients undergoing coronary artery bypass graft (CABG) have more pronounced chronic inflammatory infiltration in the media and inner adventitia of the aorta. It should also be appreciated that the internal mammary artery (IMA) is protected from atherosclerosis. In this study, we have examined the aortic adventitia of patients with coronary artery disease, in the absence or presence of RA co-morbidity. We assessed the occurrence of B cell infiltrates; expression of B cell survival factors; and the presence of citrullinated protein (CP), an RA-associated antigen.

Methods: Aortic and IMA specimens routinely removed during CABG surgery in 20 RA and 20 non-RA patients were examined by light microscopy for the presence of B cells, BAFF, APRIL and CP. Fisher's exact test and Mann-Whitney U test were used to identify differences between the two groups. Spearman correlation was used to assess the relationships between variables.

Results: B cells, BAFF, APRIL and CP were detectable and significantly increased in the aortic adventitia (AA) of both RA and non-RA patients compared to their matched IMA. Specifically, B cells were detectable in 72% of AA vs 0% of IMA ($p < 0.0001$, odds ratio [OR] 161), BAFF in 97% of AA vs 27% of IMA ($p < 0.0001$, OR 85), APRIL in 68% of AA vs 6.5% of IMA ($p < 0.0001$, OR 30.5), CP in 100% of AA vs 27% of IMA ($p < 0.0001$, OR 173). However, the number/proportion of B cells, BAFF or APRIL in the AA were not significantly different between the RA and non-RA patients. Interestingly, CP was significantly increased ($p = 0.02$) in RA samples compared to non-RA samples. In addition, we also observed a significant correlation between B cells and APRIL ($r2 = 0.49$; $p = 0.002$), B cells and CP ($r2 = 0.56$; $p = 0.02$), and APRIL and CP ($r2 = 0.29$; $p = 0.05$) in RA patients. No association with smoking was found, however, this could be due to small sample size.

Conclusion: The presence of B cell infiltration in the aortic adventitia of RA and non-RA patients indicates that this may be an important pathological mechanism that could contribute to vascular damage/disease. In addition, this study suggest that the aortic adventitia of RA patients, with coronary artery disease, is associated with an environment that is conducive to B cell survival, and harbors a known RA-associated self antigen. Importantly, these inflammatory niches outside of the joint could provide a mechanism for the perpetuation of B cell auto-reactivity and may be amenable to therapeutic intervention.

This study was conducted in association with the Feiring Heart Biopsy Study Group.

ACR Concurrent Abstract Session

Fibromyalgia and Soft Tissue Disorders II - Central Nervous System

Wednesday, October 21, 2009, 9:00 AM - 10:30 AM

1991

Kynurenine Pathway Activity Linked to Fibromyalgia Fatigue. Chad S. Boomershine[1], Dina Titova[2], Chongbin Zhu[1], Annette M. Oeser[1], M. Wade Calcutt[1], Aihua Bian[1], Tebeb Gebretsadik[1], Raymond Johnson[1] and C. Michael Stein[1], [1]Vanderbilt University, Nashville, TN, [2]FMG, Fox Island, WA

Purpose: Fatigue is often the most disabling fibromyalgia (FM) symptom, but its cause is unknown and therapies are limited. FM is linked to decreased levels of serotonin (5-HT) and its precursor tryptophan (TRP), but 5-HT reuptake inhibition does not treat FM fatigue. The kynurenine pathway (KYN-p) decreases 5-HT and TRP by converting TRP to neurotoxins that cause affective symptoms. Since indoleamine 2,3-dioxygenase (IDO) is the rate-limiting KYN-p enzyme, KYN-p activity can be estimated from the KYN/TRP ratio. We hypothesized increased KYN-p activity caused FM fatigue. KYN-p activity and fatigue levels were studied in human FM patients and a mouse FM model.

Method: 48 FM patients and 32 controls ≥18 years were studied. FM diagnosis was confirmed by ACR classification criteria. Fatigue severity in humans was quantified using the fatigue severity scale (FSS). In wild-type (wt) and syngeneic IDO knockout (IDOko) mice, FM was induced by 300mg/kg p-chlorophenylalanine (PCPA) treatment daily for 1 week. Fatigue severity in mice was assessed by meters (m) traveled in 30 minute open field testing (OFT). KYN and TRP levels were measured by stable isotope dilution and ultra-high pressure liquid chromatography (UHPLC) with tandem mass spectrometry in fasting plasma samples. HPLC with electrodetection was used to determine brain 5-HT, norepinephrine (NE) and dopamine (DA) levels. The relationship of disease status with KYN-p activity and FSS scores was assessed using multivariable linear regressions adjusted for age and race. In mouse studies, two-tailed, Mann-Whitney U tests were used to compare measures. Data are reported as median (interquartile range).

Results: KYN-p activity correlated with fatigue severity in all human subjects ($p = 0.0005$) and in FM patients ($p<0.0001$) (Figure 1). PCPA treatment of wt mice increased KYN-p activity [10.7 (8.6-11.7) to 12.2 (11.4-14.9), $p=0.04$] and induced fatigue in OFT [30.8m (27.7-36.9) to 15.7m (13.8-21.6), $p=0.008$]. IDOko mice had lower KYN-p activity than wt at baseline [5.6 (4.7-6.4) vs. 10.7 (8.6-11.7), $p<0.0001$] and after PCPA treatment [4.2 (3.6-4.6) vs. 12.2 (11.4-14.9), $p=0.0002$]. IDOko and wt mice had similar baseline OFT activity levels [38.1m (35.4-47.7) vs. 30.8m (27.7-36.9), $p=0.1$]. IDOko mice were protected from PCPA-induced fatigue, as they had similar OFT activity levels to baseline levels in wt mice [34.3m (19.4-35) vs. 30.8m (27.7-36.9), $p=0.6$]. No differences were found in levels of 5-HT, NE or DA between PCPA-treated wt and IDOko mice in midbrain or frontal cortex regions (data not shown).

Conclusion: Increased KYN-p activity is associated with FM fatigue in humans and a murine model. IDO enzyme inhibition may be a novel method for treating FM fatigue.

1993

Glutamate in the Anterior Insula Is Associated with Working Memory Performance in Fibromyalgia (FM). Paloma Barjola[1], Jennifer Glass[2], Pia Sundgren[2], Steven E. Harte[2], David A. Williams[2], Daniel Clauw[3] and Richard Harris[2], [1]Rey Juan Carlos, Madrid, Spain, [2]U. Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI

Purpose: Glutamate (Glu) is an excitatory neurotransmitter whose concentration within the posterior insula has been shown to be related to pain processing in fibromyalgia (FM) (Harris et al. 2008). The role of Glu in the anterior insula in FM is less understood. Since FM is also associated with multiple cognitive impairments such as reduced working memory (WM), and insular structures have been previously shown to be involved in different aspects of memory function, we hypothesized that anterior insular Glu may be related to WM performance.

Method: 19 FM patients (age 45.2 (15) yrs) participated in a session of H-MRS and single-voxel spectroscopy (SVS) was performed using the following parameters: PRESS, TR 3000ms, TE 30 ms, 90° flip angle, NEX 8, FOV 16cm, and VOI of 2x2x3cm. Two separate SVS sequences were performed, one with the VOI placed in the right anterior insula and another in the right posterior insula. Patients were at rest during the session. Values for Glu were calculated as absolute concentration using water signal as an internal reference, and expressed in arbitrary institutional units (AIU). Raw data were analyzed with LCModel software. WM performance was assessed with the Letter-Number span test (Wechsler Memory Scale). Additionally, reported pain was assessed with the McGill Pain Questionnaire (MPQ). Data were analyzed with SPSS v17.

Results: Concentrations of Glu in the right anterior insula were positively correlated with WM performance ($r=0.626$; $p=0.004$). The sensory subscale, but not the affective subscale, of MPQ was negatively correlated with the scores in WM ($r=-0.495$; $p=0.037$). A stepwise linear regression model with WM performance as a dependent variable was carried out. In the first step pain showed significance as a predictor ($p=0.037$) of WM (worse pain was associated with worse WM). When both pain and Glu levels were entered as simultaneous predictors, the

effect of Glu was significant (p=0.014) and pain displayed a trend towards significance (p=0.104). No such relationships were detected for the right posterior insula.

Conclusion: Consistent with previous literature, the anterior and posterior regions of the insula appear to be functionally distinct. This study suggests that anterior insula Glu may be involved in WM whereas previous studies suggest that the posterior insula is involved in pain processing. Future studies are needed to understand the mechanisms underlying these relationships which may be relevant to other chronic pain populations.

1994

Bilateral Anterior Insular Glutamate (Glu) Is Asymmetrically Associated with Experimental Pain in Individuals with Fibromyalgia and Pain-Free Controls. Richard Harris[1], Pia Sundgren[1], James Hubbard[1], A.D. (Bud) Craig[2] and Daniel Clauw[3], [1]U. Michigan, Ann Arbor, MI, [2]Atkinson Research Laboratory, Barrow Neurological Institute, Phoenix, AZ, [3]University of Michigan, Ann Arbor, MI

Purpose: The insula is involved in processing both sensory and affective aspects of pain. It has been suggested that there is an asymmetric distribution in function within this structure, with the right anterior insula being responsive to pain stimuli and the left playing more of a pain inhibiting role. Using proton magnetic resonance spectroscopy (H-MRS), we examined the relative levels of glutamate (Glu), an excitatory neurotransmitter, within the right and left anterior insula of individuals with fibromyalgia (FM) and pain-free controls (HC). We hypothesized that greater levels of Glu in the right anterior insula as compared to the left, would be associated with more pain sensitivity.

Methods: Subjects from an ongoing acupuncture trial in FM, with complete bilateral insula H-MRS data were studied. 11 patients (ages 47+/-18 yrs) and 14 controls (ages 46+/-11 yrs) underwent single voxel spectroscopy (SVS) using the following parameters: PRESS, TR 3000ms/TE 30ms, 90 degree flip angle, NEX 8, FOV 16, with a volume of interest (VOI) of 2x2x3cm voxel. Four separate SVS sequences were performed in the insula: 1. right anterior, 2. right posterior, 3. left anterior and 4. left posterior. Participants were at rest during the scanning session. Spectra were analyzed offline with LCModel. Values for Glu were expressed in arbitrary institutional units (AIU) using water as an internal standard. The ratio of right anterior insula Glu divided by left anterior insula Glu was calculated and entered into SPSS v.17. Analogous calculations were performed with the right and left posterior insula. Experimental pressure pain testing was performed prior to H-MRS. Data were analyzed with SPSS v.17.

Results: The ratio of right anterior insula Glu versus left anterior insula Glu was significantly correlated with pressure pain sensitivity when both groups were combined (medium pain: r=-0.56, p=0.004; high pain: r=-0.50, p<0.01), and when groups were analyzed separately (HC medium pain: r=-0.57, p=0.04; FM medium pain: r=-0.54; p=0.09). Individuals with greater Glu in the right anterior insula, as compared to the left, displayed lower pressure thresholds. This result was not obtained for the bilateral posterior insula Glu ratio (medium pain: r=-0.36, p>0.05; high pain: r=-0.28, p>0.1).

Conclusion: There appears to be an asymmetric distribution of Glu function in the anterior insulae. Greater excitatory neural activity in the right anterior insula, as compared to the left, is associated with more pain sensitivity. This relationship may represent a general aspect of pain processing.

1995

Fatigue Enhances the Response to Pain through NMDA Receptors in Nucleus Raphe Obscurus. Luis FS daSilva, Lynn A. Rasmussen and Kathleen A. Sluka, University of Iowa, Iowa City, IA, IA

Purpose: Since many people with chronic fatigue present with pain and many people with chronic pain present with fatigue, we tested if fatigue would enhance the response to pain in male and female mice; and if this fatigue-enhancement of pain behaviors was centrally mediated.

Method: We used a mouse-model of fatigue combined with a mouse-model of chronic widespread pain to examine the interactions between pain and fatigue. To model fatigue, whole-body fatigue was induced by having mice spontaneously run in running wheel for 2h. To model chronic widespread pain, two injections of pH 5.0 were injected into the gastrocnemius muscle; the fatigue task was performed for either 30 min or 2h before the second intramuscular injection of acid. The mechanical sensitivity of the paw (von Frey filaments), muscle (tweezers), and grip force were assessed before and 24h after the second injection of pH 5.0. In a separate group of animals, we tested the role of the NMDA receptors in nucleus raphe obscurus (NRO) in this fatigue-enhancement of pain. Brain cannulae were implanted in the NRO for microinjection of AP5 (1nmol) just prior to the fatigue task. In this group pain behaviors were measured before 1st and 2nd injection of acidic saline, and 24h after the second intramuscular injection of acid.

Results: Both male and female mice that performed the fatigue task, before the second intramuscular injection of acid, showed an enhanced mechanical sensitivity of the paw. There was no change in the non-running control mice, or the muscle hyperalgesia in the running mice when compared to the non-running mice. There was also no change in grip force suggesting that mice had no deficit in motor performance induced by the acid. Microinjection of AP5 into the NRO just prior to the fatigue task, prevented the onset of hyperalgesia 24h later to the fatigue-enhanced response to pH 5.0.

Conclusion: We conclude that fatigue enhances pain through central mechanisms that involve NMDA receptors in the NRO.

1996

Neurocortical Representation of Locus of Control in Individuals with Fibromyalgia. David A. Williams[1], Richard Harris[1], Rupal Bhavsar[1], Daniel Clauw[2], Jon Kar Zubieta[1] and Richard Gracely[3], [1]U. Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]U, North Carolina, Chapel Hill, NC

Purpose: Cognitive modulation of pain is thought to involve dorsolateral, ventrolateral, and medial prefrontal cortical regions (PFC) – regions that have been associated with placebo responsively, expectations for pain relief, and perceived control over pain. The perception of pain control associated with PFC activity is thought to initiate downstream modulation of the pain matrix and ultimately brain-stem mediated analgesic responses. One cognitive factor, internal locus of pain control (I-loc), defines a belief in pain as being modifiable via personal effort. This study sought to identify neurocortical regions experiencing greater changes in activity as I-loc increases in individuals with FM exposed to evoked pain stimuli.

Method: 57 females satisfying ACR criteria for FM and participating in non-pharmacological treatment (i.e. exercise and relaxation training) aimed at improving (I-loc) also underwent standardized evoked pressure pain testing (EPP) in the context of fMRI neuroimaging both at baseline and the 12-week endpoint. During 10 minute fMRI sessions, pressures of 2kg were applied to the left thumb by a 1 cm diameter probe. fMRI data were acquired by a GE 3 Tesla scanner at 2.5s intervals and analysis of the BOLD signal was performed using Medx. I-loc was assessed using the Beliefs in Pain Control Questionnaire (BPCQ). Responders to treatment were defined as individuals demonstrating a minimal clinically important difference on I-loc (i.e. improving >=0.5 SD). The assessment of change in BOLD tied to improvement in I-loc used ANCOVA as the analytic approach with baseline BOLD values serving as covariates for specific regions of interest (ROIs).

Results: Significant increases in BOLD activation were observed in I-loc responders (but not non-responders) in left IPL BA40 ($F_{(1,54)}$=6.0, p<.02) and in the left medial pre-frontal cortex (MPFC) ($F_{(1,54)}$=7.19, p<.01). Improvement in I-loc was not associated with BOLD changes in other prefrontal regions.

Conclusion: These data support the hypothesis that perceived control over pain is associated with PFC activation and with semantic regions related to but differentiated from the pain matrix. Non-pharmacological interventions appear to modify perceptions of pain control which in turn influence neurocortical regions important to pain perception and modulation.

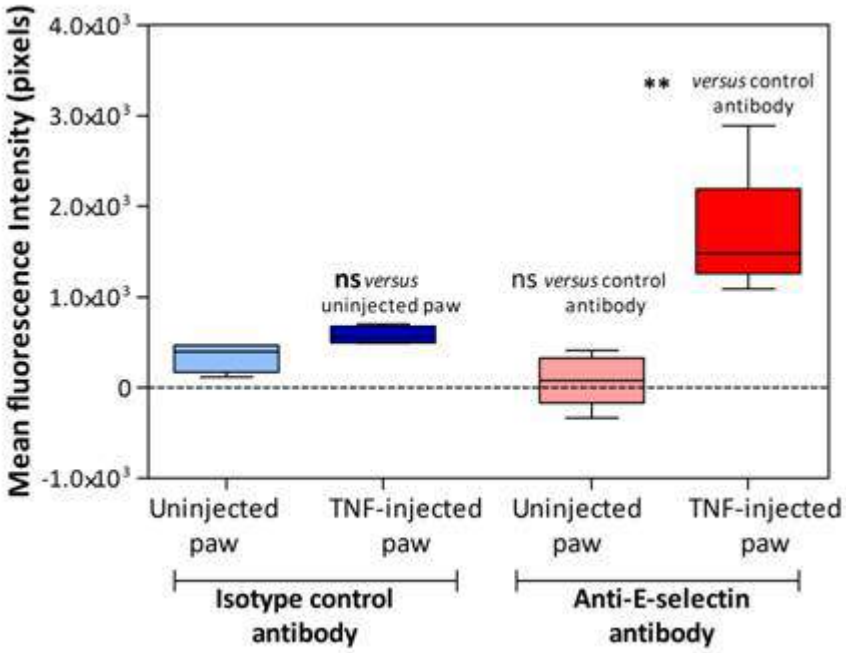
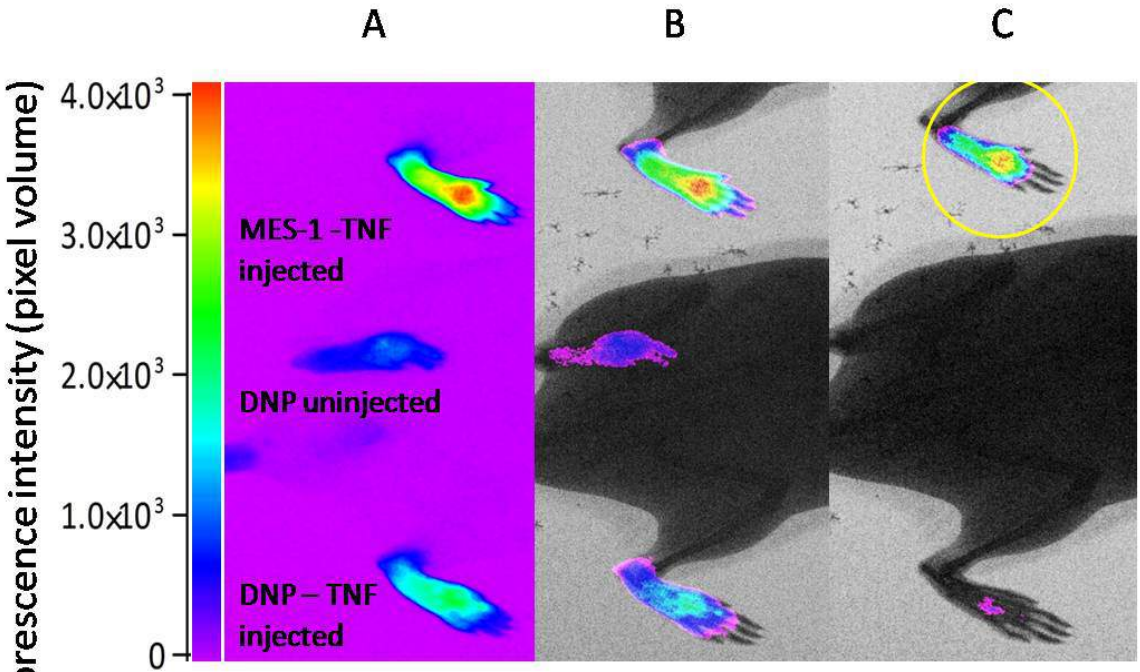
In Vivo Fluorescence Imaging of TNF-Induced Endothelial Inflammation by Targeting E-Selectin. Luke L. Gompels[1], Julia Inglis[1], Tonia Vincent[1], Leigh Madden[1], Kay McNamee[1], Ellen McConnell[2], Dorian O. Haskard[2] and Ewa M. Paleolog[1], [1]London, United Kingdom, [2]Imperial College, London

Purpose: Understanding of the genetic and molecular basis of inflammatory arthritis has advanced rapidly, but non-invasive visualization of specific molecular targets and therapeutic effects *in vivo* remains a challenge. E-selectin is a validated marker of activated endothelium in rheumatoid arthritis. We examined the use of *in vivo* fluorescence imaging, targeting E-selectin expression in mouse TNFα induced paw edema.

Method: Monoclonal anti-murine E-selectin and isotype control antibodies were labeled with a near infrared fluorescent DyLight 750 probe (excitation 752nm, emission 778nm) to maximize probe intensity and signal-to-noise ratio through live tissue. Antibody was injected immediately prior to intraplantar injection of 50ng mouse TNFα, and mice were imaged using the Kodak FX Pro *in vivo* imaging system.

Results: Kinetics of E-selectin expression *in vivo* were used to delineate the sensitivity of optical imaging for differentiating target antibody compared to background/autofluorescence levels, and the specificity of target *versus* control antibody. *In vivo* fluorescent imaging demonstrated specific localization of E-selectin antibody in inflamed joints, with maximal differential effect at 8 hours following TNFα injection, correlating with maximal levels of paw inflammation/edema.





Panel A: Demonstrates fluorescent signal in a representative control (DNP) and MES-1 injected animal at the 8 hr time point
Panels B and C demonstrate X-ray co-registration:
Panel B: Background and auto fluorescence subtracted
Panel C: Average signal intensity from the DNP injected animal inflamed paw subtracted to leave the specific signal from the MES-1 inflamed paw (circled).

Conclusion:

In vivo optical imaging of E-selectin is a sensitive, specific and non invasive method of measuring endothelial activation in inflammation.

The novel use of fluorescently labeled biomarkers has significant potential for visualization of disease states such as inflammatory arthritis. This will facilitate *in vivo* interrogation of molecular pathways and assessment of both local and systemic effects of therapies.

1998

Objective Disease Activity Assessment for Rheumatoid Arthritis Using Optical Monitoring. A.J.L. Meier[1], W.H.J. Rensen[2] and R.N.J. de Nijs[1], [1]Regional Rheumatology Centre (RRC) ZO-Brabant, Eindhoven, Netherlands, [2]Philips, Eindhoven, Netherlands

Purpose: There is a need for an objective, reproducible, fast, quantitative and accurate disease activity monitor for disease progression monitoring in patients with rheumatoid arthritis (RA). Optical spectral transmission is a promising solution, since optical contrast can be related to physiological parameters in the body, such as blood concentration and oxygenation. At relevant wavelengths and intensities, optical radiation is completely harmless. Additionally, the cost of optical methods is low compared to other modalities. Due to the highly scattering nature of tissue, non-invasive optical methods for medical imaging are limited to the extremities of the human body. For application in joint diseases, this is acceptable, because imaging of hands and wrists can provide sufficient clinical information. This study aims to assess feasibility of disease activity monitoring by optical methods.

Method: A device has been developed for optical spectral transmission measurements positioned at the proximal interphalangeal (PIP) joint and at the intermediate phalanx as a reference in a standardized setup. A cross-sectional, non-randomized observational study was performed with this device. In the study, 82 PIP joint measurements in 67 subjects have been performed. Inflammation of these PIP joints was also assessed by a rheumatologist with a score varying from one (not inflamed) to five (severe inflamed), the DAS28-score was used as a reference.

Results: Out of 82 measurements, 30 were performed in moderate or strongly inflamed PIP joints. Correlation between the clinical assessment and a single optical measurement parameter showed $r = 0.59$ ($p < 0.0001$), figure 1. The same optical parameter leads to a ROC curve (AUC= 0.76) that shows that a relative good specificity compared to the sensitivity. Other optical parameters also showed significant differences between inflamed and non-inflamed joints ($p < 0.0001$). Unsurprisingly, both clinical assessment and optical measurements of single joints show a poor correlation with the multi-joint DAS28 score.

Conclusion: Optical spectral transmission measurements correlate with clinical assessment of joint inflammation, and therefore might be useful in monitoring disease activity of RA patients. Further study using a multi-joint device is necessary to demonstrate the usability of optical measurements in clinical practice.

1999

Macrophage PET Imaging as Biomarker for Very Early Rheumatoid Arthritis. Ernst H. Elzinga[1], Alexandre E. Voskuyl[1], Nikie J., Hoetjes[1], Emile FI Comans[1], Dirkjan van Schaardenburg[2], Otto S. Hoekstra[1], Adriaan A. Lammertsma[1], Ben A.C. Dijkmans[1] and Conny J. van der Laken[1], [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Institute, Amsterdam, Netherlands

Purpose: Rheumatoid arthritis (RA) is preceded by subclinical disease activity before development of clinical symptoms of arthritis. Visualization of subclinical disease activity may enable initiation of early treatment. However, visualization of subclinical synovitis requires sensitive advanced imaging methods. Our group has demonstrated the value of positron emission tomography (PET) using [^{11}C]-(R)-PK11195 in visualizing (subclinical) synovitis. The purpose of the current study was to investigate whether subclinical synovitis can be visualized using [^{11}C]-(R)-PK11195-PET in arthralgia patients with presence of anti-CCP antibodies, without clinical symptoms of arthritis. The second purpose was to determine whether the presence of PET abnormalities may predict the development of clinical arthritis.

Method: Patients with anti-CCP positive arthralgia without synovial swelling (n = 28) and the presence of anti-CCP antibodies were included. High-resolution [^{11}C]-(R)-PK11195 PET scans of the hands and wrists were performed. All metacarpophalangeal, proximal interphalangeal and wrist joints (i.e. a total of 22 visualized joints per patient) were scored for positivity. Uptake on PET images was scored semi-quantitatively on a scale of 0 to 3 (minimal- high). Follow-up during one year was performed to detect the presence of clinical joint swelling.

Results: At patients level, at least one PET positive joint (score ≥ 1) was found in 7 of 28 patients, with a maximum of 5 PET positive joints per patient. After one year of clinical follow-up 9 patients had developed arthritis: 6 patients had developed arthritis in hands/wrists, 3 patients only in other joints. At least one evident PET positive joint (score 2 to 3) was found in 3 out of 9 patients developing arthritis. None of the patients who did not develop arthritis within a year showed evident enhanced [^{11}C]-(R)-PK11195 uptake (table 1). At joint level, 19/616 were scored PET positive. Clinical arthritis developed in 7 joints after 1 year of clinicalfollow-up.

Conclusion: A positive [^{11}C]-(R)-PK11195-PET signal was found in 25% of all included anti-CCP positive arthralgia patients. High PET-uptake was found in a subgroup of patients, all of these developed clinical arthritis. These findings suggest that high joint-uptake of [^{11}C]-(R)-PK11195 may aid to predict the development of arthritis in patients at risk of RA.

	PET score 0-1	PET score 2-3

2000

Lentiviral-Based Bioluminescent Imaging of Synovial Inflammatory Subtypes in Experimental Arthritis and Human Synovial Fibroblasts. Jeroen Geurts[1], Eline A. Vermeij[1], Onno J. Arntz[1], Raimund W. Kinne[2], Wim B. van den Berg[1] and Fons A. van de Loo[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University Hospital Jena, Eisenberg, Germany

Purpose: Chronic synovial inflammation is a hallmark of rheumatoid arthritis and gene expression analyses of RA synovial tissues have revealed molecularly distinct, high and low inflammatory subtypes. We evaluated the applicability of lentiviral-based (LV) promoter-luciferase reporters for assessing differential inflammation subtypes in experimental arthritis and primary OA and RA synovial fibroblasts (SF).

Methods: Murine promoters of *Saa3* and *Cxcl1* genes, which are strongly regulated in experimental arthritis, were cloned upstream of the luciferase (Luc) cDNA in LV vectors. Murine synovium was transduced *in vivo* and two consecutive flares of acute arthritis were induced by intra-articular injection with streptococcal cell wall (SCW) material. Kinetics of synovial inflammation were assessed using *ex vivo*

luciferase assays and ^{99m}Technetium (Tc) uptake. Classification of SF (*n*=12) inflammatory subtypes was accomplished using hierarchical clustering of gene expression profiles. SF subtypes were transduced with LV-*Saa3*/*Cxcl1*-Luc and stimulated with IL-1b, TNFa or toll-like receptor (TLR) 2/4 agonists. Promoter activity was measured using luciferase assays.

Results: Luciferase expression was strongly upregulated (50-100 fold) during the first flare and *Saa3*, but not *Cxcl1* promoter activity correlated (*P*<0.0005, Pearson *r* 0.82) with inflammation as measured by ^{99m}Tc uptake. While the *Saa3* promoter could be reactivated in a second flare (500 fold), the *Cxcl1* promoter remained stably activated. Interestingly, using lower SCW dosages the bioluminescent reporters, but not ^{99m}Tc measurements were able to assess synovial activation, which indicated a superior sensitivity of our novel method. Hierarchical clustering of SF gene expression profiles discriminated between two subtypes. The high inflammatory subtype was characterized by predominantly increased expression of chemokines (*IL8*, *MCP1*) and matrix-degrading enzymes (*MMP1/3*). Relative *Saa3* promoter responses to cytokines and a TLR4 agonist were significantly (*P*<0.001) increased in OA/RA SF from the high inflammatory subtype (*n*=5) compared to the low inflammatory subtype (*n*=3). Relative *Cxcl1* promoter responses did not discriminate between inflammatory subtypes.

Conclusion: *Saa3* promoter activity is a more sensitive read-out for synovial inflammation than ^{99m}Tc uptake in experimental arthritis. The *Saa3* promoter response in stimulated primary OA/RA SF can distinguish between molecularly distinct high or low inflammatory subtypes. These results demonstrate the sensitivity and versatility of genetic bioluminescent reporters for quantitative imaging of heterogeneous synovial inflammation.

2001

Near Infrared Lymphatic Imaging and Quantification of Lymphatic Draining Function in a Murine Model of Inflammatory Arthritis. Q. Zhou, R. Wood, E.M. Schwarz, B. Boyce and L. Xing, University of Rochester, Rochester, NY

Purpose: The lymphatic system may play a functional role to limit inflammation in affected joints in rheumatoid arthritis (RA). However, approaches to non-invasively measure lymphatic draining function in murine models of RA are lacking. We have developed a near infrared (NIR) fluorescence lymphatic imaging technique and used it to examine lymphatic flow from affected joints to draining lymph nodes (LNs) of arthritic mice.

Method: We used NIR lymphatic imaging based on published literature and our past experience with large animals and human subjects. Indocyanine green (ICG), a NIR tracer, was injected intra-dermally into mouse footpads and changes in the intensity and distribution of the ICG signal over the entire leg region was visualized under an NIR laser and recorded. NIR imaging was repeated 24 hrs after ICG injection. Regions of interest defining draining popliteal lymph nodes (PLNs) and the injection site were identified, yielding 3 outcome measures of lymphatic function: 1) T-initial (Ti), the time it takes for the ICG to reach the PLN; 2) S-max, the maximum ICG signal intensity in the PLN; 3) T-max, the time it takes for a PLN to achieve maximal ICG signal. K/BxN arthritic mice and non-arthritic littermate controls (N=4-6/group) received NIR-ICG at 1 and 3 months of age. Joint inflammation severity was measured by clinical scoring. Lymphangiogenesis in PLNs was determined using immunohistochemistry (IHC) and a LYVE-1 antibody.

Results: NIR-ICG imaging demonstrated dynamic changes in lymphatic drainage from affected paws to PLNs during the development of joint inflammation. Joint lymphatic flow was significantly increased in 1-month-old K/BxN mice with severe joint inflammation compared to control mice (Ti: 1±0 vs 14±2 min; Tmax: 31±19 vs 51±17min; Smax: 98±56 vs 12±4). Arthritic mice had extensively dilated and irregular lymphatic vessels in their feet and increased numbers of LYVE-1+ lymphatic sinuses with narrow lumens in their PLNs compared with control mice. At 3 months, K/BxN mice had 2-3 fold slower lymphatic flow than 1-month-old mice and they had a network of numerous small lymphatic vessels in their inflamed feet. Clinical scoring showed that they had decreased joint swelling compared with 1-month-old mice (3.3±0.2 vs 4.5±0.5 mm^2) and the number of LYVE-1+ lymphatic sinuses in their PLNs was significantly increased, the majority having extensive, dilated lumens.

Conclusion: NIR-ICG imaging is a powerful new tool to monitor dynamic changes in lymphatic draining function of inflamed joint tissue in mice. In the acute phase of joint inflammation, increased lymphatic flow exceeds lymphatic draining capacity, associated with severe joint swelling. Later enhanced lymphatic drainage from joints and PLNs reduces the degree of joint swelling. This technique could be used to assess the efficacy of intervention therapy to improve lymphatic draining function in models of RA.

2002

Monocyte Scintigraphy in Rheumatoid Arthritis, Dynamics of Monocyte Migration in Immune-Mediated Inflammatory Disease.
Rogier M. Thurlings[1], Carla A. Wijbrandts[2], Roel Bennink[2], Serge Dohmen[3], Elena Izmailova[4], Danielle M. Gerlag[1], Berthe van Eck-Smit[2] and Paul P. Tak[5], [1]Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Sanquin Research, Amsterdam, Netherlands, [4]Millennium Pharmaceuticals, Cambridge, MA, [5]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Macrophages are principal drivers of synovial inflammation in rheumatoid arthritis (RA), a prototype immune-mediated inflammatory disease. Conceivably, synovial macrophages are continuously replaced by circulating monocytes in RA. Animal studies from the 1960s suggested that macrophage replacement by monocytes is a slow process in chronic inflammatory lesions. Translation of these data into the human condition has been hampered by the lack of available techniques to analyze monocyte migration in man. We developed a technique that enabled us to analyze the migration of labelled autologous monocytes in RA patients using single photon emission computer tomography (SPECT).

Method: Peripheral blood was drawn from 8 patients with active RA. CD14+ monocytes were isolated using CliniMACS and labeled with technetium-99m (^{99m}Tc-HMPAO). Monocytes were re-infused into the same patient. Scintigraphy was performed at 1, 2, 3, and 20 hours after re-infusion. The number of positive joints was counted and the exact signal intensity of a large joint was measured selecting a region of interest (ROI).

Results: Scintigraphic scans showed distinct uptake of labeled monocytes in inflamed joints in all patients. Using SPECT we calculated that a very small but specific fraction of 3.4×10^{-3} ($0.95\text{-}5.1 \times 10^{-3}$) % of re-infused monocytes migrated to the inflamed joints, being detectable within one hour after re-infusion.

Conclusion: The results indicate monocytes migrate continuously into the inflamed synovial tissue of RA patients, but at a slow macrophage-replacement rate. This suggests that the rapid decrease in synovial macrophages that occurs after antirheumatic treatment might rather be explained by an alteration in macrophage retention than in monocyte influx and that RA might be particularly sensitive to treatments targeting inflammatory cell retention.

Wednesday, October 21, 2009, 9:00 AM - 10:30 AM

2003

Children with Persistent Oligoarticular Juvenile Idiopathic Arthritis (OJIA) Resistant to Standard Therapy: An Under-Recognized Population.
Alisa C. Gotte[1] and Marilynn G. Punaro[2], [1]Univ of Texas Southwestern, Dallas, TX, [2]Texas Scottish Rite Hospital for Children, Dallas, TX

Purpose: Persistent OJIA is the most common subtype of JIA, accounting for a significant proportion of children managed by pediatric rheumatologists. Although often considered benign, inadequate response to therapy can result in joint deformity and disability. Persistent OJIA is primarily treated with non-steroidal anti-inflammatories (NSAIDs) and/or intra-articular corticosteroid injections (IACI); however, the optimal treatment is unknown. Little is known about the frequency of children with persistent OJIA who fail standard therapy or about features associated with resistance to standard therapy.

Method: The records of all children seen at Texas Scottish Rite Hospital for Children (TSRHC) from 2000-2008 who met International League of Associations of Rheumatologists (ILAR) criteria for OJIA and had at least six months of follow-up were reviewed.

Results: 341 children were seen at TSRHC from 2000-2008 who met ILAR criteria for OJIA. 56 (16%) of these children developed extended OJIA, the remaining 285 (84%) children were classified as persistent OJIA. 106 children with persistent OJIA were treated with IACI with or without concomitant NSAID use. 75 (71%) of children treated with IACI +/- NSAIDs had resolution of all signs and symptoms of arthritis in the treated joint for at least six months, and were defined as IACI-responsive. 31 children (29%) had active arthritis despite IACI, and were defined as IACI-resistant. IACI-resistant children failed a mean of 1.97 injections (range 1-7) before declared IACI-resistant. All but 2 of the IACI-resistant children were then treated with DMARD therapy (usually methotrexate); 18 of the 29 children treated with a DMARD had resolution of arthritis, 11 children had continued arthritis despite DMARD therapy. 9 children who failed DMARDs were treated with anti-TNF agents, all of whom experienced sustained remission of disease activity.

IACI-resistant children were more likely to be of Hispanic ethnicity (IACI-resistant group 32% Hispanic vs. IACI-responsive group 8% Hispanic, p=0.008), had a higher ESR at the time of presentation (37.9 mm/hr vs. 22.6, p=0.012), had more joints involved at initial presentation (1.9 joints vs. 1.3, p=0.022), and were more likely to have involvement of an upper extremity (35% with upper extremity joint involvement vs. 8%, p=0.004) than IACI-responsive children.

Conclusion: Almost one-third of children with persistent OJIA were resistant to standard therapy, suggesting that resistance to standard therapy is more frequent than previously appreciated. Hispanic children with persistent OJIA, an unreported population affected by OJIA, were at particular risk for failure of standard therapy. IACI-resistant OJIA may be responsive to DMARD and anti-TNF therapy, and more aggressive therapy should be considered in children with persistent OJIA resistant to standard therapy.

2004

Optimization of the Provisional Criteria for Clinically Inactive Disease for Select Categories of Juvenile Idiopathic Arthritis. Carol A. Wallace[1], Edward H. Giannini[2] and N. Ruperto[3], [1]Seattle Children's Hospital, Seattle, WA, [2]Children's Hospital Medical Center, Cincinnati, OH, [3]Pediatria-II PRINTO, IRCCS G. Gaslini, Genova, Italy

Purpose: To optimize and begin prospective validation of the provisional classification criteria for *inactive disease* (ID) in patients with select categories of JIA.

Methods: Data from 1096 patient-visits from the Phase III randomized controlled trial of infliximab in polyarticular JIA without systemic features were used to develop 60 patient-profiles. Profiles were selected that either met or came close to meeting the provisional criteria for ID, and contained 7 clinical and 4 laboratory variables. Profiles were supplied via an online-survey to 40 pediatric rheumatologists in 27 countries. Physicians were asked to rate each patient-profile as being in a state of *ID*, *active disease* (AD), or *unable to determine*. To assess intra-physician reliability, a second survey containing 20 of the original 60 profiles was sent to the same physicians 2 months after receipt of results from the first survey. Multivariate statistical approaches were used to identify models that showed the highest area under the ROC curve when physician ratings of patient status were cross tabulated with status as determined by the provisional criteria. The best fit model was then applied to the remaining 1036 profiles from the RCT. A third online-survey containing the modified criteria was sent to 60 pediatric rheumatologists to calculate the quantitative content validity index (CVI) of the criteria set overall, and the face validity index (FVI) of each criterion and its respective critical value. The resulting set of variables is referred to as the optimized provisional criteria set.

Results: All 40 physicians scored all 60 patient-profiles (2400 evaluations) and 37 (92.5%; 740 evaluations) replied to the second e-survey. The best fitting model produced an area under the ROC of .942, indicating excellent sensitivity and specificity. Intra-observer reliability kappa score was 0.7 (95% CI: .63 -.77), indicating *substantial* agreement. 41 of the 60 physicians (68%) replied to the third online-survey. Data from the model development analyses and final survey necessitated three changes to the provisional criteria. The *physician's global assessment of disease activity* (PGA) was modified to read *'PGA of disease activity score of ≤ 0.5 cm on a 10 cm VAS or ≤ 0.5 on an ordinal scale'*. The *ESR* was modified to read *'within normal limits in the laboratory where tested or, if elevated, not attributable to JIA'*. *Duration of morning stiffness* (DMS) was added to the criteria set and reads, *'DMS ≤ 15 minutes'*. The modified criteria have a CVI of 95%. The FVI of each criterion ranged from 93% to 100%.

Conclusion: The provisional criteria for *ID* (now referred to as *clinically inactive disease* (CID) in extended oligo, polyarticular RF + or (-) or systemic JIA without systemic features can be said to have excellent feasibility, face, content, criterion, and discriminant validity. Intra-physician reliability is substantial. The predictive validities of a classification of *CID*, *clinical remission on medication*, and *clinical remission* off medication are yet to be determined.

2005

Candidate Urinary Biomarkers May Predict Histological Features On Lupus Nephritis (LN) Biopsy. Lena Das[1], Michiko Suzuki[1], Prasad Devarajan[1], Brad H. Rovin[2], Jun Ying[3] and Hermine Brunner[1], [1]Cincinnati Children`s Hospital Medical Center, Cincinnati, OH, [2]Ohio State University Medical Center, Columbus, OH, [3]University of Cincinnati, Cincinnati, OH

Purpose: Current non-invasive blood and urine tests do not reliably reflect renal histology in LN. Thus invasive kidney biopsies are needed to establish the diagnosis of and support treatment decisions for LN. The objective of this study was to assess whether recently identified novel LN urinary biomarkers [lipocalin-like prostaglandin-D synthetase (L-PGDS), α1-acid-glycoprotein (AGP), transferrin (Tf), ceruloplasmin (Cp) and neutrophil-gelatinase associated lipocalin (NGAL)] differentiate between certain LN histological features.

Methods: Concentrations of the LN biomarkers by nephelometry or ELISA were measured in the urine samples of patients with LN (n=40), collected within 60 days of a kidney biopsy. The following histological features of LN activity and chronicity as reported in the biopsy reports (present/absent) were considered: mesangial expansion, capillary proliferation, crescent formation, necrosis, wire loops, fibrosis, interstitial cell infiltrate, tubular atrophy and acute tubular necrosis (ATN). Biomarker levels were standardized by urinary creatinine and compared by nonparametric statistics for significant differences with histological features.

Results: As is shown in the table below, levels of biomarkers often significantly differed with certain histological features. Most importantly, features that are highly related to LN activity; crescents were associated with increased levels of CP and AGP (both $p<0.03$), while NGAL and L-PGDS were associated with wire loops (both $p<0.05$). Other features of activity like necrosis correlated with higher levels of TF and AGP ($p < 0.025$). In addition, increases of CP and NGAL were seen with glomerular endocapillary proliferation ($p<0.005$).

None of the biomarkers differentiated between the presence or absence of fibrosis or tubular atrophy. Additional analyses in larger cohorts are in process to assess whether combinations of the biomarkers can more accurately predict histological features of LN.

Conclusion: This pilot study suggests that urinary levels of AGP, NGAL, CP, TF and L-PGDS may predict histological changes and thus activity and chronicity on kidney biopsy with LN. If supported in future studies the above biomarkers may be part of a biomarker panel that will ultimately make invasive renal biopsies redundant.

Table : Ratio of mean urinary biomarker concentrations for presence versus absence (p/a) of each histological characteristic

Histology	N (p/a)	TF	CP	AGP	L-PGDS	NGAL
Mesangial expansion	25/15	0.74	0.56	0.71	**0.40****	**0.21****

2006

The EULAR/PRINTO/PRES Criteria for Childhood Vasculitides. Ankara 2008. Introduction and Methods. Nicola Ruperto[1], Seza Ozen[2], Angela Pistorio[1], Pavla Dolezalova[2], Paul Brogan[2], Ruben Cuttica[2], David Cabral[2], Raju Khubchandani[2], Daniel J. Lovell[2], Kathleen O'Neil[2], Pierre Quartier[2], Angelo Ravelli[3], Silvia M. Iusan[2], Giovanni Filocamo[1], Claudia Saad Magalhães[2] and Alberto Martini[1], [1]Pediatria-II PRINTO, IRCCS G. Gaslini, Genova, Italy, [2]PRINTO, Genova, Italy, [3]IRCCS G. Gaslini, Genova, Italy

Purpose: To validate classification criteria for Henoch-Schönlein purpura (HSP), childhood (c-) polyarteritis nodosa (c-PAN), c-Wegener granulomatosis (c-WG), and c-Takayasu arteritis (c-TA).

Methods: The preliminary Vienna 2005 consensus conference, which proposed preliminary criteria for paediatric vasculitides, was followed by a EULAR/PRINTO/PRES supported validation project divided into 3 main steps. Step 1: retrospective/prospective web-data collection for clinical characterisation of HSP, c-PAN, c-WG and c-TA, with age at diagnosis ≤ 18 years. Step 2: blinded classification by consensus panel of difficult cases enabling expert diagnostic verification. Step 3: Ankara 2008 consensus conference and statistical evaluation (sensitivity, specificity, k-agreement) using as gold standard the final disease attribution of the patients after step 2 (consensus classification or original treating physician diagnosis).

Results: A total of 1,183/1,398 (85%) of the samples collected were available for the analysis: 827 HSP, 150 c-PAN, 60 c-WG, 87 c-TA and 59 c-other. Prevalence, signs/symptoms, laboratory, biopsy and imaging reports were consistent with the clinical picture of the 4 c-vasculitides. A subgroup of 280/1,183 (20%) patients was blinded to the treating physician diagnosis and classified by a consensus panel with a k agreement of 1 (HSP and c-TA), 0.95 (c-WG) and 0.92 (c-PAN) (overall k 0.88 with 95% CI 0.82-0.94). The final definitions showed sensitivity/specificity/k agreement with the consensus classification/original diagnosis of 100%/87%/0.9 for HSP, 73%/100%/0.81 for c-PAN, 97%/98%/0.92 for c-WG and 100%/99%/0.99 for c-TA.

Conclusion: EULAR/PRINTO/PRES propose validated classification criteria for HSP, c-PAN, c-WG and c-TA, with high sensitivity/specificity and almost perfect agreement with the final patient disease attribution.

2007

Genetics, Clinical Features, and Treatment in a Well-Defined Cohort with Periodic Fever, Aphthous Stomatitis, Pharyngitis, and Cervical Adenitis (PFAPA). Sivia Lapidus[1], Puja Chitkara[1], Henry Feder[2], Balu H. Athreya[3], Ivona Aksentijevich[1], Beverly K. Barham[1], Michael M. Ward[1], Karyl S. Barron[4], Daniel L. Kastner[1] and Silvia Stojanov[1], [1]NIAMS/NIH, Bethesda, MD, [2]University of Connecticut Health Sciences Center/Connecticut Children's Medical Center, Hartford, CT, [3]duPont Hospital for Children/Thomas Jefferson University, Wilmington, DE, [4]NIAID/NIH, Bethesda, MD

Purpose: To elucidate the clinical features of PFAPA that may distinguish this condition from the known Mendelian periodic fever syndromes.

Method: Children who fulfilled inclusion criteria of recurrent fever in addition to two of the three defining clinical features of PFAPA (aphthous stomatitis, pharyngitis, and/or cervical adenopathy) were recruited prospectively and had longitudinal follow-up. We analyzed clinical symptoms, response to medications, and hereditability. Patients included in the study had genetic testing to exclude mutations in the known genes associated with hereditary periodic fever syndromes and cyclic neutropenia.

Results: Of forty-nine patients who met inclusion criteria, genetic testing revealed variants in 9 children (18%) in the *MVK* (V377I/I268T, V377I), *MEFV* (G304R, E148Q, K695R/V726A), *TNFRSF1A* (3 with R92Q), and *ELA2* (P257L) genes. Patients with negative genetic testing were included in the clinical analysis. All three defining features of PFAPA were present in the majority of patients. Atypical characteristics of attacks in over half of the PFAPA patients included loss of appetite, headache, myalgia, and abdominal pain. Oral

corticosteroids aborted fevers in all 30 patients treated, with 53% of patients experiencing subsequently shortened intervals between attacks. Three of 12 patients (25%) treated with cimetidine had decreased intensity of fevers and increased intervals between attacks. Seven of 10 patients (70%) who had tonsillectomies went into remission. Eight patients (20%) had affected family members who fulfilled the diagnostic criteria for PFAPA or had recurrent fevers as children.

Conclusion: Three important new findings are shown in this cohort: (1) the high number of genetically positive patients, who resemble PFAPA clinically, emphasizes the importance of excluding hereditary periodic fever syndromes genetically; (2) the familial predilection suggests a genetic etiology of this disease; (3) the data imply a broader clinical spectrum in PFAPA.

2008

Characterization of Osteoclastogenesis in Interleukin-1 Receptor Antagonist Deficiency. Sreelatha Reddy[1] and James W. Verbsky[2], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Medical College of WI, Milwaukee, WI

Purpose: We recently described a case of Interleukin-1 receptor antagonist deficiency (IRAD), a novel autoinflammatory disease characterized by marked systemic inflammation, pustular rash, severe osteopenia, and lytic bone lesions. This infant had a homozygous deletion of six IL-1 family members: *IL-1F5*, *IL-1F6*, *IL-1F8*, *IL-1F9*, *IL-1F10* and IL-1 receptor antagonist. Treatment with anakinra completely resolved all symptoms and lesions. Studies were performed to characterize the aberrant osteoclastogenesis in this patient.

Method: Peripheral blood mononuclear cells(PBMCs) were stimulated with LPS for 4 hours and microarray analysis was performed. Inflammatory cytokine expression was determined by a commercially available bead array. CD14 positive monocytes were isolated with magnetic beads and used to generate osteoclasts by treatment with M-CSF and RANKL. Osteoclasts were detected by staining for multinucleated tartarate-resistant acid phosphatase (TRAP) positive cells.

Results: PBMCs from the IRAD patient spontaneously produced IL-1b, IL-6, and TNF-a. LPS or IL-1b further induced the production of these cytokines that was blocked by the addition of IL-1 receptor antagonist. Microarray gene expression data demonstrated the upregulation of several genes (PTGS2, IL-6, TFPI2, MMP1, CXCL1, CXCL5) with suspected roles in osteoclastogenesis. In addition, this patient demonstrated high levels of serum cytokines all of which are known to promote osteoclast formation and bone resorption. The IRAD patient did not show any spontaneous production of osteoclasts indicating no intrinsic predisposition for the formation of osteoclasts. MCSF/RANKL although induced similar levels of TRAP activity in this patient compared with controls, the IRAD patient demonstrated a significantly higher number of TRAP positive cells displaying greater than 6 nuclei compared with controls . We observed that IL-1b by itself, in the absence of RANKL, was able to significantly drive TRAP activity which could in part contribute to the abnormal bone resorption

Conclusion: IRAD is an autoinflammatory disease characterized by high levels of circulating inflammatory cytokines with the potential to promote osteoclastogenesis. This patient exhibited increased size and hypernucleation of osteoclasts which are hallmarks of bone resorption disorders. We are further investigating the role of deleted genes (*IL-1F5*, *IL-1F6*, *IL-1F8*, *IL-1F9*, and IL-1F10) in formation and function of osteoclasts is being examined.

ACR Concurrent Abstract Sessions

Rheumatoid Arthritis Therapy: Treatment Strategies

Wednesday, October 21, 2009, 9:00 AM - 10:30 AM

2009

Combination Therapy of Leflunomide with Biologics (COLEBI) in Rheumatoid Arthritis: An Observational Study. Jaap Fransen[1], Pauline Knapen[1], Dan Nordstrom[2], Dimitrios Boumpas[3], Ulrich Von Hinueber[4], Georg Schett[5], Zoltan Szekanecz[6], Karel Pavelka[7], Tore K. Kvien[8] and Piet Van Riel[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Helsinki University Central Hospital, Helsinki, Finland, [3]University of Crete, Heraklion, Greece, [4]Rheumatologische Gemeinschaftspraxis, Hildesheim, Germany, [5]University of Erlangen-Nuremberg, Erlangen, Germany, [6]University of Debrecen medical and Health Sciences Center, Debrecen, Hungary, [7]Institute of Rheumatology, Prague, Czech Republic, [8]Diakonhjemmet Hospital, Oslo, Norway

Purpose: Leflunomide (LEF) is an effective agent for the treatment of RA and may be an alternative for Methotrexate (MTX) in the combination with biologicals, if MTX cannot be used. The objective was to determine effectiveness of LEF and anti-TNF compared with MTX and anti-TNF in RA, in a comparative observational study.

Methods: These are preliminary data from an international multi-centre retrospective study, for which already collected data from several biologics databases were combined. A cohort of RA patients exposed to Leflunomide in combination with anti-TNF was compared with a cohort of RA using MTX and anti-TNF. LEF users were selected by complete ascertainment, MTX users were matched by centre on disease duration (+/- 3 years) and calendre year. Effectiveness was determined using drug survival with Cox proportional hazard models and using DAS28 changes after 12 months using linear regression models, both including confounder correction.

Results: There were n=244 LEF users and n=288 MTX users included. There were no differences in age (mean SD), gender (n %) and disease duration (median (P25-P75). LEF users had more severe disease regarding RF positivity (63% versus 57%, p=0.19), erosions (67% versus 49%, p<0.001), nodules (28% versus 20%, p=0.11), median number of previous DMARDs (2 versus 1, p<0.001). Mean (SD) baseline DAS28 was similar in both groups: 5.5 (1.3) versus 5.4 (1.5), p=0.55, as was the median (P25-P75) HAQ: 1.0 (0.5-1.6) versus 1.0 (0.5-1.4), p=0.23.

Mean anti-TNF survival time was 4.3 years for LEF users and 5.8 years for MTX users, with a Hazard Ratio (95%CI) of 1.4 (0.8-2.3) (p=0.20) after correction for RF, erosions, and number of previous DMARDs. DAS28 (0-12 months) reduced with mean (SD) -1.4 (1.4) in the MTX group and -1.6 (1.5) in the LEF group (p=0.34).

Conclusion: Long-time survival of anti-TNF and decrease in DAS28 at 12 months were quite similar for the combination with leflunomide or methotrexate. Worse prognosis at anti-TNF start partly explained a tendency for less anti-TNF survival in leflunomide users.

2010

Efficacy of Initial Methotrexate Monotherapy Versus Combination Therapy with a Biologic Agent in Early Rheumatoid Arthritis: A Meta-Analysis of Clinical and Radiographic Remission. Bindee Kuriya[1], Elizabeth V. Arkema[1], Vivian P. Bykerk[2] and Edward C. Keystone[3], [1]Harvard School of Public Health, Boston, USA, Boston, MA, [2]Mt Sinai Hospital, Toronto, [3]Professor of Medicine/University of Toronto, Toronto, ON

Purpose: A prime objective of treating early rheumatoid arthritis (ERA) is to induce remission and halt radiographic progression. The aim of this meta-analysis was to compare the ability to achieve clinical remission and/or radiographic non-progression in patients with ERA, who have been unexposed or minimally exposed to methotrexate (MTX), and are initially treated with MTX monotherapy or combination therapy (MTX + biologic agent) in randomized controlled trials (RCTs).

Method: A systematic literature search was performed for RCTs published to April 2009 in Medline, Embase, Cochrane Controlled Trials Register and ACR/EULAR abstracts of 2007-2008. Trials reporting at least one remission outcome among ERA patients with no or minimal MTX exposure (</= 4 weeks), randomized to initial monotherapy or combination therapy for > 12 weeks duration were included using predefined in/exclusion criteria. Relative risk (RR) estimates were calculated and a random effects model was used to pool the RR for clinical and radiological outcome at 52-56 weeks of follow-up.

Results: Seven studies involving 2763 ERA subjects, 1152 randomized to MTX alone and 1611 to combination therapy with infliximab, adalimumab, etanercept or abatacept were included. The proportion of patients with prior corticosteroid or MTX exposure was comparable between groups, as was the mean dose of MTX at average follow-up of 1 year. One study reported clinical remission using the ACR remission criteria while the remaining 6 studies defined remission as a DAS28 score </= 2.6. Radiographic non-progression, defined as a modified Total sharp score (TSS) change of < 0.5 units, was reported in 4 trials. All trials demonstrated risk estimates in favor of combination therapy and the pooled RR for clinical remission was 1.74 (95% CI 1.54 to 1.98). The RR for radiographic non-progression was 1.30 (95% CI 1.01 to 1.68). Significant heterogeneity among studies for this outcome was detected ($p < 0.001$) but reasons were not explored due to lack of statistical power.

Conclusion: Current RCT evidence indicates that the efficacy of combination therapy with a biologic agent is greater than for MTX monotherapy for the outcome of clinical remission at 1 year. Data are too heterogeneous to draw firm conclusions about the efficacy on radiographic non-progression. Uniform definitions of remission/non-progression are needed in trials of drug therapy to allow comparison of within and between studies. Furthermore, the proportion of subjects who achieve the combined endpoint of clinical and radiographic remission should be considered as a clinically meaningful outcome in future studies of ERA.

Figure 1. Forest plot of the risk ratios for clinical remission using combination therapy vs. MTX monotherapy at the end of follow-up.

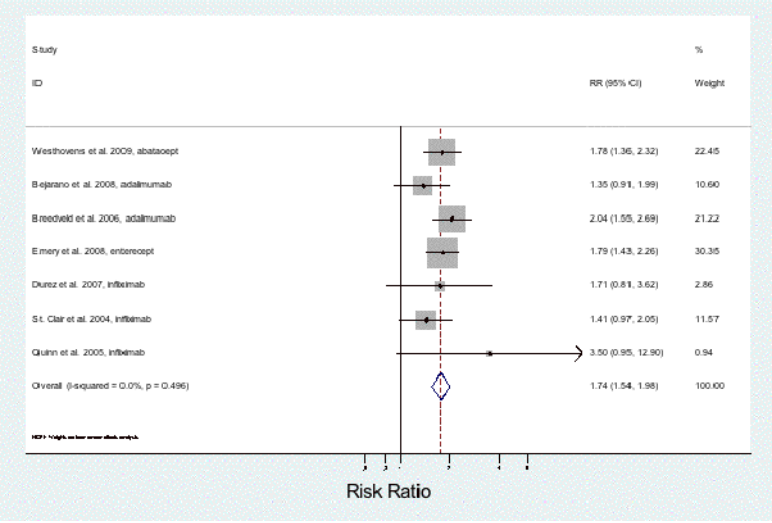

Figure 2. Forest plot of the risk ratios for radiographic non-progression with combination therapy vs. MTX monotherapy at the end of follow-up.

2011

Etanercept (ETN) Plus Methotrexate (MTX) Combination Therapy Resulted in Better Clinical and Radiographic Outcomes Than ETN Monotherapy Even in Patients with Active Rheumatoid Arthritis Despite MTX Treatment: 52-Week Results From the JESMR Study. Hideto Kameda[1], Katsuaki Kanbe[2], Eri Sato[2], Yukitaka Ueki[3], Kazuyoshi Saito[4], Shouhei Nagaoka[5], Toshihiko Hidaka[6], Tatsuya Atsumi[7], Michishi Tsukano[8], Tsuyoshi Kasama[9], Shunichi Shiozawa[10], Yoshiya Tanaka[11], Hisashi Yamanaka[12], Tsutomu Takeuchi[13] and JBASIC study goup, [1]Saitama Medical Ctr, Kawagoe, Japan, [2]Tokyo Women's Medical University Medical Center, Tokyo, Japan, [3]Sasebo Chuo Hospital, Sasebo, Japan, [4]University of Occupational and Environmental Health, Japan, KItakyushu, Japan, [5]Yokohama Minami Kyosai Hospital, Yokohama, Japan, [6]Zenjinkai Shimin-No-Mori-Hospital, MIyazaki, Japan, [7]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [8]Kumamoto Hospital, Kumamoto, Japan, [9]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [10]Kobe Univ School of Med, Kobe, Japan, [11]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [12]Tokyo Women's Medical University, Tokyo, Japan, [13]Keio University School of Medicine, Tokyo, Japan

Purpose: The superiority of the continuation of methotrexate (MTX) to its discontinuation at the commencement of etanercept (ETN) in patients with active rheumatoid arthritis (RA) despite MTX therapy has not been clarified on a long-term follow-up. Therefore, the aim of the JESMR study is to compare the efficacy and safety of continuation versus discontinuation of MTX at the commencement of ETN for two years in patients with active RA despite MTX therapy.

Methods: In total, 151 patients with active RA despite treatment with MTX were randomized to either ETN 25 mg twice a week with 6-8 mg/week of MTX (the E+M group), or ETN alone (the E group). Co-primary endpoints included the radiographic progression assessed by van der Heijde-modified Sharp score at week 52.

Results: Demographic and clinical features between groups at baseline were similar. The cumulative probability plot of ACR-N at week 52 clearly demonstrated the superior response in the E+M group to that in the E group. The ACR 20, 50 and 70 response rates at week 52 were 86.3%, 76.7% and 50.7%, respectively, in the E+M group, all of which were significantly greater than 63.8% ($p=0.003$), 43.5% ($p<0.0001$) and 29.0% ($p=0.01$), respectively, in the E group. The mean health assessment questionnaire (HAQ) score decreased from 1.2 at baseline to 0.6 at week 52 in the E+M group which was significantly better than 0.9 at week 52 in the E group ($p=0.03$). The mean progression of the

erosion score was negative at weeks 24 and 52 only in the E+M group, and a significant difference was observed versus the E group at week 52 (-0.2 versus 1.8, respectively, p=0.02). The mean progression in total score tended to be smaller in the E+M group than in the E group (0.8 versus 3.6, p=0.06), and a significant difference was observed in the radiographic progression between at weeks 24 and 52 (0.3 versus 2.5, respectively, p=0.03).

Conclusion: MTX should be continued at the commencement of ETN therapy even in RA patients who had shown an inappropriate response to MTX.

2012

Discontinuation of Infliximab After Attaining Low Disease Activity in Patients with Rheumatoid Arthritis: An Interim Report On RRR (remission induction by remicade in RA) Study. Yoshiya Tanaka[1], Tsutomu Takeuchi[2], Tsuneyo Mimori[3], Nobuyuki Miyasaka[4], Takao Koike[5] and RRR study group, [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Saitama Medical Center/Univ, Kawagoe, [3]Kyoto Univ Grad Schl of Med, Kyoto, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: TNF inhibitors have enabled high clinical remission rate when used for treatment of RA, which has made us approach to biologic-free remission. Discontinuation of TNF inhibitors after acquisition of remission is an important issue from the viewpoints of safety and economy. However, reports published to date on this topic are confined to those from BeSt study and TNF20 study involving only patients with early stage of RA. The present multicenter study was undertaken to seek the possibility of discontinuing infliximab therapy after acquiring low disease activity of RA and to evaluate progression of articular destruction during infliximab discontinuation.

Method: The study involved 114 RA patients who have received infliximab therapy, whose DAS28 (ESR) remained less than 3.2 (low disease activity, LDA) for 24 weeks and who consented to discontinuation of infliximab treatment. The average disease duration was 6 years and mean DAS28 was 5.5 among all patients. Patients receiving steroid over 5 mg/day were excluded. DAS28 was evaluated, and total Sharp score (TSS) was analyzed in 41 patients for whom articular X-ray records at the start and discontinuation of infliximab therapy and after 1 year of discontinuation were available.

Results: After keeping LDA for more than 24 weeks by infliximab therapy, infliximab was discontinued in 114 cases and DAS28 in 102 cases could be evaluated at year 1. Of them, 29 cases restarted infliximab after 7 months (mean) because of the relapse of symptoms and in 17 cases DAS28 was more than 3.2 at year 1, and thereby 46 cases (45%, mean duration of disease: 7.9 years) failed RRR at year 1. The remaining 56 cases (55%, mean duration of disease: 4.9 years) have kept DAS28<3.2 (LDA) and remained off infliximab and 44 cases (43%) reached DAS<2.6 (remission) for more than 1 year after discontinuation of infliximab. By multivariable logistic analysis, disease duration was shorter in a RRR-achieved group than that in a RRR-failed group. Also, DAS28 at RRR-entry was lower in a RRR-achieved group than that in a RRR-failed one. By logistic regression analysis, the estimated DAS28 at RRR-entry was 2.22 to attain DAS28<3.2 at endpoint in 50% of enrolled patients, suggesting that deep remission may be required to keep LDA for 1 year without infliximab. The mean TSS was 64.5 and the estimated yearly progression of TSS before was 12.6 at the study entry. The yearly progressions of TSS were 0.3 and 1.6, in RRR-achieved group and RRR-failed group, respectively, during RRR study period, implying that articular destruction did not progressed during the discontinuation.

Conclusion: After reduction of disease activity of RA by infliximab treatment, about 55% of the 102 patients could discontinue infliximab for more than 1 year without radiologic progression of articular destruction.

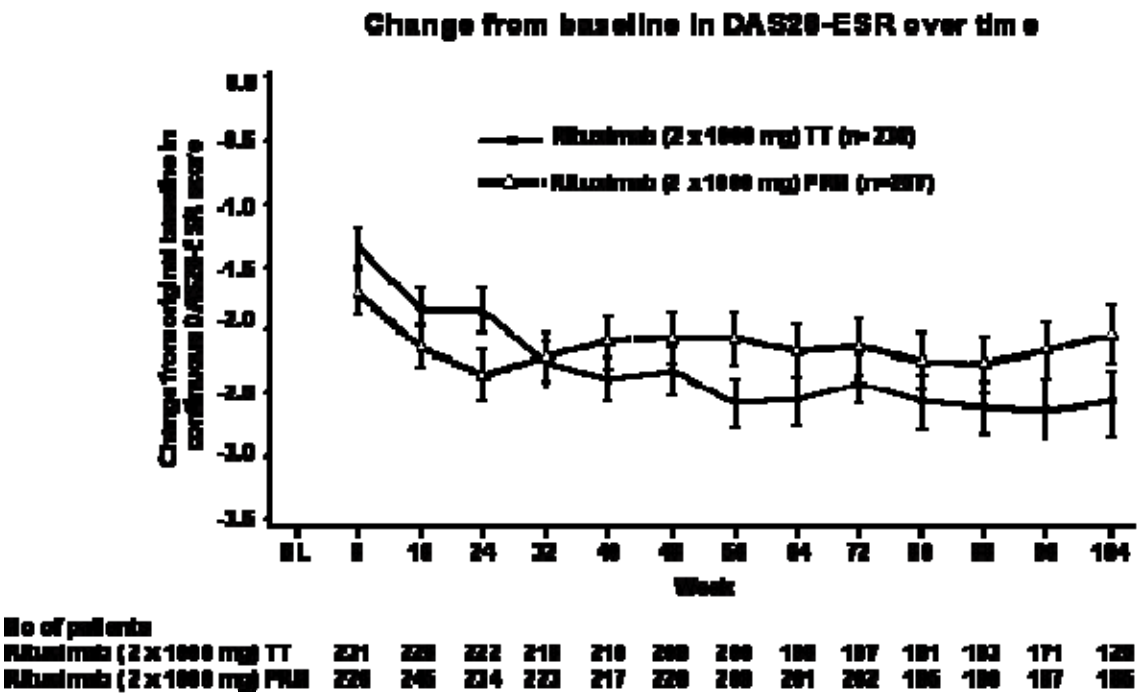
2013

Retreatment with Rituximab (RTX) Based On a Treatment to Target (TT) Approach Provides Better Disease Control Than Treatment as Needed (PRN) in Patients (pts) with Rheumatoid Arthritis (RA). Paul Emery[1], Philip J. Mease[2], Andrea Rubbert-Roth[3], Jeffrey R. Curtis[4], Ulf Müller-Ladner[5], Norman B. Gaylis[6], Gillian K. Armstrong[7], Lachy McLean[8], Mark Reynard[7] and Helen Tyrrell[7], [1]Leeds General Infirmary, Leeds, United Kingdom, [2]Seattle Rheumatology Association, Seattle, WA, [3]University of Cologne, Cologne, Germany, [4]University of Alabama, Birmingham, AL, [5]Kerckhoff Clinic, Bad Nauheim, Germany, [6]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [7]Roche Products Ltd, Welwyn Garden City, United Kingdom, [8]Genentech Inc., South San Francisco, CA

Purpose: Two treatment (tx) strategies have been employed in clinical trials of RTX in RA. Assessing differences in efficacy and safety profiles may be useful in determining an optimal tx regimen.

Methods: RA pts with an inadequate response to methotrexate (MTX) recruited into Phase II or III studies with RTX were permitted to receive further courses of open-label RTX based on 2 approaches: a) TT whereby pts were assessed at 24 weeks (wks) following each course. Those with DAS28≥2.6 were retreated, those with DAS28<2.6 were retreated if and when DAS28 increased to ≥2.6; b) PRN whereby pts were retreated at the physician's discretion after a minimum period of 16 wks if both swollen and tender joint counts were 8. Regardless of tx strategy, study visits were at least every 8 wks with unscheduled visits at any time if required. All courses consisted of RTX (2 x 1000mg) given as IV infusions 2 wks apart in combination with MTX. Observed data were pooled and analyzed according to tx strategy. Clinical outcomes including ACRn, DAS28-ESR and HAQ-DI responses were determined over time. Safety data were compared.

Results: Over multiple courses of RTX, responses were maintained or improved irrespective of tx strategy. However, compared with PRN, TT provided tighter control of disease activity as indicated by greater improvements in DAS28-ESR (Figure), lower HAQ-DI and higher ACRn. PRN resulted in the recurrence of disease symptoms between courses as evidenced by DAS28-ESR scores returning close to pre-RTX treatment levels, together with higher rates of withdrawals due to RA flare. TT also resulted in more pts achieving major clinical response (ACR70 ≥ 6 months) compared with PRN (12.3% vs. 5.9%). TT resulted in more frequent retreatment with a median time between courses of approx. 25 wks compared with approx. 62 weeks for PRN. Despite this, the safety profiles of the regimens were comparable. Importantly, TT was associated with a reduced incidence of RA flare (19 vs 42%) with no increase in the rate of serious infection (2.2 vs 3.5 per 100 pt-yrs), serious adverse events (12.0 vs 16.2 per 100 pt-yrs) or proportion of pts with Ig below normal compared with PRN.



Conclusion: Repeat treatment to a target of DAS28 remission with RTX led to tighter control of disease activity compared with PRN treatment.

2014

An Algorithm Using Genome-Wide SNP Analysis for Prediction of Responders and Non-Responders, and Adverse Events in Tocilizumab-Treated RA Patients. Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], Sayumi Toriyama[3], Kunihiko Nakahara[3], Takafumi Hagiwara[1], Takako Miura[1], Kosuke Okuda[1], Akira Sagawa[4], Takeo Sakurai[5], Hiroaki Matsuno[6], Tomomaro Izumihara[7] and Eisuke Shono[8], [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]HuBit genomix, Inc., Tokyo, Japan, [4]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [5]Inoue Hospital, Takasaki, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [8]Shono Rheumatology Clinic, Fukuoka, Japan

Purpose: Tocilizumab, a human anti-IL-6 receptor antibody, is an efficient biologic agent for inflammatory diseases such as RA. However, there is no method for prediction of responders, non-responders, and adverse events which can occur during the treatment. We established an SNP algorithm for prediction of responders or non-responders, and adverse events among tocilizumab-treated RA patients.

Methods and Patients: One hundred RA patients treated with tocilizumab were included in this study. The efficacy was determined by Clinical Disease Activity Index (CDAI) within 24-30 weeks after the initial treatment. The efficacy of tocilizumab was judged by the scores of CDAI (remission and low disease activity group- 'responders', moderate and high disease activity group- 'nonresponders'). Adverse events such as leukopenia, high total cholesterol, fever, and skin manifestations were documented. Genome-wide SNP genotyping was performed by Illumina HumanHap300K chip technology. Case-control analyses between 285,548 SNPs and CDAI were examined by chi-square tests. We selected 10 SNPs strongly associated with tocilizumab-responsiveness, or adverse events ($p < 0.001$).

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for responsiveness of tocilizumab ranged 92-97%. For adverse events, accuracy, specificity and sensitivity of the algorithm ranged 90-97%. It is, therefore, suggested that the SNP algorithm predict responders and adverse events prior to the initiation of treatment with this biologic agent.

Conclusion: The highly accurate algorithm using SNP analysis may be useful in the prediction of responsiveness and adverse events before treatment of tocilizumab, and in this way can contribute to future tailor-made treatment with biologic agents.

Anti-PD-1 Antibody Reduces CD4+PD-1+ T Cells and Relieves the Lupus-Like Nephritis of NZB/W F1 Mice. Shimpei Kasagi[1], Seiji Kawano[2], Taku Okazaki[3], Tasuku Honjo[4], Akio Morinobu[2], Saori Hatachi[5], Kenichiro Shimatani[4], Yoshimasa Tanaka[4], Nagahiro Minato[4] and Shunichi Kumagai[2], [1]Kobe University Graduate School of Medicine,, Kobe, Japan, [2]Kobe University Graduate School of Medicine, Kobe, Japan, [3]Institute for Genome Research, University of Tokushima, Tokushima, Japan, [4]Kyoto University Graduate School of Medicine, Kyoto, Japan, [5]Kitano Hospital, Osaka, Japan

Purpose: Programmed cell death 1 (PD-1) is an immunosuppressive receptor that transduces an inhibitory signal into activated T cells. Although a single nucleotide polymorphism in the gene for PD-1 is associated with susceptibility to systemic lupus erythematosus (SLE), PD-1's role in SLE is still not well understood. we used NZB/W F1 mice, a model of lupus-like nephritis, to examine the function of PD-1 and its ligands.

Method: Immunohistochemistry, Intracellular cytokine assay, Antibody treatment using anti-PD-1 and anti-PD-L1 mAb, and CDC assay.

Results: PD-1 was predominantly expressed on $CD4^+$ T cells that infiltrated the kidney, and $CD4^+PD\text{-}1^{high}$ T cells produced higher levels of IFN-γ than $CD4^+PD\text{-}1^{low}$ or $CD4^+PD\text{-}1^-$ T cells. Stimulation with PMA/ionomycin caused splenic $CD4^+PD\text{-}1^+$ T cells to secrete high levels of IFN-γ and IL-10, low levels of TNFα, and no IL-2, IL-4, or IL-17. *In vivo* anti-PD-1-mAb treatment reduced the number of $CD4^+PD\text{-}1^+$ T cells in the kidney of NZB/W F1 mice and significantly reduced their mortality rate ($p=0.03$). Conversely, blocking PD-L1 using an anti-PD-L1 mAb increased the number of $CD4^+PD\text{-}1^+$ T cells in the kidney, enhanced serum IFN-γ, IL-10, and IgG2a ds-DNA-Ab levels, accelerated the nephritis, and increased the mortality rate.

Conclusion: $CD4^+PD\text{-}1^{high}$ T cells are dysregulated IFN-γ-producing, proinflammatory cells in NZB/W F1 mice.

Activation of the Nitric Oxide-Mitochondrial Hyperpolarization-mTOR-Rab4 Signaling Pathway Before Disease Development in Lupus-Prone Mice. David Fernandez[1], Tiffany Telarico[1], Ram Raj Singh[2] and Andras Perl[1], [1]Upstate Medical Univ, Syracuse, NY, [2]UCLA, Los Angeles, CA

Purpose: Nitric oxide (NO) dependent persistent mitochondrial hyperpolarization (MHP) and enhanced calcium fluxing underlie aberrant T-cell activation and death pathway selection in patients with systemic lupus erythematosus. Activity of the mammalian target of rapamycin (mTOR), which is a sensor of the mitochondrial transmembrane potential, is increased in lupus T cells which in turn promotes expression of HRES-1/Rab4, a small GTPase that regulates recycling and lysosomal degradation of CD4 surface receptors and TCR . Here, we investigated the activity of the NO-MHP-mTOR-Rab4 signaling pathway in lupus-prone mice.

Method: NZB/NZW(F1) and MRL/lpr lupus-prone female mice and age-matched Balb/c/NZW, C57BL/6, MRL, C57BL/6/lpr female control mice were investigated prior to disease manifestations. NO production, mitochondrial transmembrane potential, and recycling of surface receptors were measured by flow cytometry. Expression and phosphorylation of proteins were studied by western blot.

Results: Increased NO production and MHP as well as over-expression of Rab4 and diminished endocytic recycling of CD4 and CD3 were detected at 4-month of age, while the loss of TCR was observed 7-month of age in NZB/NZW(F1) mice. MRL/lpr mice exhibited increased expression of the mitochondrial voltage-dependent anion channel 1(VDAC1) protein and transaldolase (TAL) and Rab4 but not Rab5 as well as increased mTOR activity at 2 months of age. Rab4 expression was also increased in MRL mice.

Conclusion: T cells from lupus-prone mice exhibit mitochondrial dysfunction characterized by increased NO production, MHP, elevated expression of VDAC1 and TAL, as well as increased mTOR activity. Diminished recycling of CD4 and CD3 were associated with elevated expression of Rab4. The results suggest that mitochondrial and endocytic recycling gene expression signatures and activation of the NO-MHP-mTOR-Rab4 signaling pathway are detectable and precede disease development in lupus-prone mice.

Interferon Regulatory Factor 5 Regulates Murine Lupus Independently of Type-I Interferons. Christophe Richez[1], Kei Yasuda[1], Ramon G. Bonegio[1], Amanda A. Watkins[1], Tamar Aprahamian[1], Patricia Busto[1], Rocco J. Richards[1], Chih Long Liu[2], Regina Cheung[2], Paul J. Utz[2], Ann Marshak-Rothstein[1] and Ian R. Rifkin[1], [1]Boston Univ Schl of Med, Boston, MA, [2]Stanford Univ Schl of Med, Stanford, CA

Purpose: Interferon regulatory factor 5 (IRF5) polymorphisms are strongly associated with an increased risk of SLE. To examine the biological role of IRF5 in lupus pathogenesis, and its potential functions beyond regulation of type I interferon (IFN) expression, we compared the impact of deficiency of IRF5 and the type I IFN receptor IFNAR1 in the C57BL/6 *FcγRIIB* $^{-/-}$ *Yaa* (RII.*Yaa*) model of SLE.

Method: We intercrossed IRF5-deficient mice with *FcγRIIB* $^{-/-}$ *Yaa* mice to generate the following experimental groups: *Irf5* $^{+/+}$ RII.*Yaa* (n=12); *Irf5* $^{+/-}$ RII.*Yaa* (n=12); and *Irf5* $^{-/-}$ RII.*Yaa* (n=14). We intercrossed *IFNAR1*-deficient mice with *FcγRIIB -/- Yaa* mice to generate the *IFNAR1* $^{+/+}$ RII.*Yaa* (n=10) and *IFNAR1* $^{-/-}$ RII.*Yaa* (n=11) experimental groups. At 5 months of age, we compared disease manifestations in these cohorts, using age- and sex-matched C57BL/6 wildtype (WT) mice as controls.

Results: *Irf5* $^{+/+}$ RII.*Yaa* mice developed marked lymphadenopathy and splenomegaly whereas lymph node and spleen size in *Irf5* $^{-/-}$ RII.*Yaa* mice was no different from WT controls. *Irf5* $^{+/+}$ RII.*Yaa* mice produced very high titers of anti-nuclear autoantibodies (ANA) including anti-ribonucleoprotein (SmRNP) and anti-double-stranded DNA antibodies, while ANA were almost totally absent from the sera of *Irf5* $^{-/-}$ RII.*Yaa* mice. As expected, the *Irf5* $^{+/+}$ RII.*Yaa* mice developed a severe proliferative glomerulonephritis. In contrast, *Irf5* $^{-/-}$ RII.*Yaa* mice exhibited a renal phenotype indistinguishable from that of WT mice. *Irf5* $^{+/+}$ RII.*Yaa* mice had a median survival of 27 weeks, while more than 90% of mice in the *Irf5* -/- cohort were alive at 40 weeks of age ($p < 0.0001$, test logrank). Remarkably, *Irf5* $^{+/-}$ heterozygous RII.*Yaa* mice had a phenotype similar to *Irf5* $^{-/-}$ RII.*Yaa* mice. One function of IRF5 is to promote the production of IFN-α, a cytokine linked to lupus pathogenesis. In order to determine if the phenotype observed in *IRF5* $^{-/-}$ mice was mediated only by inhibition of type I IFN production, we compared the phenotype of *Irf5* $^{-/-}$ RII.*Yaa* mice with that of *Ifnar1* $^{-/-}$ RII.*Yaa* mice. In contrast to the *Irf5* $^{-/-}$ mice, there were no significant

differences in ANA levels between *Ifnar1* $^{+/+}$ and *Ifnar1* $^{-/-}$ RII.*Yaa* mice. Furthermore, substantial splenomegaly and renal disease remained in the *Ifnar1* $^{-/-}$ RII.*Yaa* mice, and *Ifnar1* $^{-/-}$ RII.*Yaa* mice had decreased survival compared to either the *Irf5* $^{+/+}$ or *Irf5* $^{+/-}$ RII.*Yaa* cohorts.

Conclusion: IRF5 plays an essential role in pathogenesis in a mouse lupus model and this is mediated through pathways beyond that of type I IFN production. The fact that even IRF5 heterozygous mice developed minimal disease manifestations indicates that a certain threshold level of IRF5 is required for disease development. Thus, IRF5 might be a key therapeutic target in lupus, particularly since a partial reduction in the level of IRF5 could have a meaningful effect on disease severity.

IL-23/IL-17 Contributes to the Expression of Lupus Nephritis. Vasileios C. Kyttaris, Zheng Zhang and George C. Tsokos, Beth Israel Deaconess Med Ctr, Boston, MA

IL-17/IL-23 contribute to the expression of lupus nephritis

Purpose: T cells that express IL-17 (Th17) infiltrate the kidneys of patients with systemic lupus erythematosus. A significant proportion of these cells are CD3+CD4-CD8- double negative T cells (DNT). The mechanisms underlying this phenomenon and its contribution to the expression of kidney pathology is unclear. DNT cells are expanded and form the majority of the T cell population in the well-described murine lupus models MRL/lpr and B6/lpr. We therefore hypothesized that DNT cells expressing IL-17 contribute to the development of disease and in particular nephritis in these mice. Furthermore, we hypothesized that IL-23, a cytokine that is important for the maintenance of Th17 cells, plays a role in sustaining this abnormal autoimmune response.

Method: MRL/lpr and B6/lpr as well as their respective control (MRL/MPJ and B6) mice were used for these experiments. Rag-1-/- mice were used in the adoptive transfer experiments. IL-17 was measured by intracellular cytokine staining. IL-23 receptor (IL-23R) levels were measured by PCR. Kidney pathology was assessed using H&E staining and immunofluorescence.

Results: T cells from MRL/lpr mice expressed significantly higher than control mice levels of IL-17. The majority of these cells were DNT cells. As the mice aged and their disease worsened, the expression of IL-17 as well as that of the IL-23R in lymphocytes increased. IL-17+ T cells were found infiltrating the tubulo-interstitial area of the kidneys in lupus-prone but not the control mice. In order to evaluate the role of IL-17+ cells in the induction of lupus nephritis, lymph node cells from lupus prone–mice and control mice were transferred in non-autoimmune, lymphocyte-deficient Rag-1-/- mice. Surprisingly only lymph node cells from lupus-prone but not control mice, which were pre-treated in vitro with IL-23, induced nephritis in the recipient mice. Lymph node cells not treated with IL-23 did not cause nephritis. Kidney specimens from the recipient mice with nephritis showed significant immunoglobulin and complement deposition. In addition, we found that IL-23 acted as a trophic factor for DNT cells, increasing their percentage among the lymph node cells.

Conclusion: These data indicate that an aberrantly active IL-23/IL-17 axis contributes to the development of nephritis in lupus-prone mice. IL-23 acts as a trophic cytokine for the expansion of DNT cells. These cells in turn exhibit characteristics of Th17 pro-inflammatory cells, able to induce nephritis when transferred to non-autoimmune mice.

2019

Pathogenesis of Proliferative Lupus Nephritis: Different Genetic Control for Acute and Chronic Glomerulonephritis and New Insight Into the Mechanism of Immune Complex Mediated Nephritis. Yan Ge, Chao Jiang, Felicia Gaskin, Sun-Sang J. Sung, Harini Bagavant and Shu Man Fu, University of Virginia, Charlottesville, VA

Purpose: Previously, we have mapped a genetic region on chromosome 1 (chr.1) which controls susceptibility to acute GN (aGN) and chronic GN (cGN) in a mouse model NZM2328. The NZM2328.C57Lc1 (Lc1) congenic line was generated by introgressing a segment of chr.1 from C57L/J to NZM2328. Lc1 females have markedly reduced incidences of GN and ANA. An intrachromosomal recombinant line

NZM2328.Lc1R27 (R27) was generated. In R27, an 8Mb chr.1 segment of C57L/J covering the *Cgnz1* locus which is linked to cGN was introgressed to NZM2328. In this study, pathogenesis and genetics of lupus nephritis were studied using R27 and additional intrachromosomal recombinant lines.

Method: A cohort of R27 female mice was followed to 12 months of age. Urine protein, ANA, anti-dsDNA antibodies, immune complex deposits, and kidney histology were examined. The ultrastructure of R27 kidney was studied by electron microscopy. Additional chr.1 recombinant congenic lines were generated and characterized. Real-time PCR was used to compare gene expression between R27 and NZM2328 mice.

Results: R27 females had aGN and mild to moderate proteinuria without impairment of renal function and markedly reduced incidence of ANA. The affected mice had immune complex deposits of all Ig isotypes, and subclasses of IgG and C3. No progression to cGN was observed in this cohort. Morphological studies of R27 kidneys by immunofluorescence and EM suggest recycling of immune complexes and deposition of these complexes in subendothelial and mesangial regions of glomeruli. Thus, immune complex deposition with complement activation is not sufficient to induce irreversible renal damage in R27 mice. Further studies involving additional intrachromosomal recombinant lines identified a 1.27Mb region controlling cGN, and this region is located within the *Sle1b* locus that was previously identified by Wakeland and Mohan et al. This region also appears to control ANA and anti-dsDNA autoantibodies. By real-time PCR, two candidate genes preferentially transcribed by kidney cells were identified to be genes controlling end organ damage, while the third gene Ly108 preferentially expressed in B cells may be relevant to B cell activation and production of autoantibodies to nucleosome and related antigens.

Conclusion: Our observations support our hypotheses that aGN and cGN are under separate genetic control and that aGN need not progress to cGN leading to end stage renal failure. They also show that normal kidney has significant reserve to repair immune complex induced renal lesions. Factors in addition to immune complex deposition and complement fixation are needed for the progression to renal failure.

Epistatic Interactions Between Lupus Susceptibility Loci On New Zealand Black Chromosomes 1 and 13 Lead to Marked Expansion of Dendritic Cell Populations but Have Little Effect On Autoimmunity. Yui Ho Cheung[1], Evelyn Pau[1], Christina Loh[1], Ginette Lajoie[2] and J. E. Wither[3], [1]University of Toronto, Toronto, ON, [2]Department of Pathology, William Osler Health Centre,, Brampton, ON, [3]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: In previous work we have shown that mice with an introgressed homozygous NZB chromosome 1 interval (63.1 to 192.1 Mb; B6.NZBc1) or chromosome 13 interval (48 to 113 Mb; B6.NZBc13) have high titer IgG anti-nuclear antibodies (Ab) and develop glomerulonephritis (GN). In this study we have produced bicongenic mice with both NZB intervals, to determine whether interactions between these loci lead to exacerbation of the autoimmune phenotype.

Method: Splenic cellular populations were examined by flow cytometry. Serum levels of autoAb were measured by ELISA and the presence of GN determined by light microscopy. BAFF and IFN-α mRNA level in the spleen was examined using real time PCR. Splenic TLR responses were assessed by measurement of cytokine production.

Results: B6.NZBc1c13 mice at 8 mo of age had significantly increased spleen weights and numbers of splenocytes when compared with B6, B6.NZBc1, and B6.NZBc13 mice. Although the proportions of various splenic B and T cell populations and their activation was similar in bicongenic mice to that seen in single congenic mice, bicongenic mice had a 2-3 fold expansion in the absolute number of splenic $CD11c^+$ dendritic cells (DC) as compared to single congenic mouse strains (B6.NZBc1, $p = 0.0004$; B6.NZBc13, $p = 0.0007$). Increases in both the plasmacytoid DC population ($B220^+CD11c^+NK1.1^-$) and myeloid DC population ($CD11b^+CD11c^+$) contributed to this increase. Despite these cellular changes, the levels of IgM and IgG autoAb, and severity of GN in bicongenic mice were similar to single congenic mice. Interestingly, bicongenic mice had significantly elevated levels of total IgA and IgA anti-chromatin, -ssDNA and -dsDNA Ab when compared with single congenic mouse strains. Consistent with the increased IgA production, bicongenic mice had markedly increased levels of BAFF mRNA and BAFF-producing myeloid DC in their spleens. In contrast, mRNA levels of Type I IFN and IFN-inducible genes were reduced in the spleens of 8 mo old bicongenic mice. At 8 mo of age bicongenic splenocytes produced reduced amounts of IFN-α in response to CpG stimulation as compared to B6 controls. This appeared to result from inhibition of IFN-α secretion in older mice, since the splenocytes of 8 wk old bicongenic mice produced normal amounts of IFN-α following CpG stimulation.

Conclusion: Epistatic interactions between the lupus susceptibility loci on NZB chromosomes 1 and 13 lead to marked expansion of DC populations and high levels of BAFF production. Despite this clinical autoimmune disease was not exacerbated, possibly due to the lack of IFN-α secretion.

ACR Concurrent Abstract Sessions

Spondyloarthropathies: Early Diagnosis and Outcome Measures
Wednesday, October 21, 2009, 9:00 AM - 10:30 AM

2021

Screening for Ankylosing Spondylitis and Other Axial Spondyloarthritides-Are Established Criteria for Inflammatory Back Pain Useful in Primary Care? Annalina Braun[1], Ertan Saracbasi[1], Joachim Grifka[2], Jörg Schnitker[3], Franziska Klein[4] and Jürgen Braun[1], [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Asklepios Kliniken, Bad Abbach, Germany, [3]Institut für angewandte Statistik, Bielefeld, Germany, [4]Abbott GmbH & Co. KG, Wiesbaden, Germany

Purpose: The early diagnosis of ankylosing spondylitis and early axial spondyloarthritis (SpA) has proven difficult. The value of the leading symptom, inflammatory back pain (IBP), is unclear- partly because of different definitions. This study analyzes different items and criteria associated with IBP in a large cohort of patients presenting to primary care physicians.

Method: 1012 consecutive patients with back pain > 2 months who were < 45 years old and who presented to orthopaedic surgeons in private practice (n=139) were randomized on the basis of a questionnaire with 4 primary and 4 secondary key questions on IBP for referral to rheumatologists (n=31) after having given informed consent. The randomization was done by an independent statistical institute on the basis of an optimal distribution of the number of positive answers to questions related to IBP and SpA. The vast majoritiy of patients (>80%) was seen within 6 weeks after referral.

Results: Altogether, 303 patients who were representative of the whole cohort were referred to rheumatologists to receive a diagnosis based on the expert's opinion. The mean age of patients was 36 years, the male/female ratio was approximately 1, and the mean duration of back pain was 30 months. AS was diagnosed in 44 patients (14.6%), uSpA in 46 (15.1%) and other SpA in 9 patients (3%). Thus, almost one third of all patients screened was diagnosed with SpA. Almost half (48.5%) of the patients had a relatively short disease duration (≤ 2 years chronic back pain). Of all patients seen by rheumatologists, 64% reported improvement by exercise, not rest, 48% told wakening up in the 2nd half of the night, 34% had morning stiffness >30 minutes, and 56% improvement when treated with NSAIDs (even 77% who really took the medication). No single item was differentiating very well between SpA and other causes of back pain (96% vs 90%), but when more than 2 items were combined , the difference was useful: 73% vs. 29% ($p<0.0001$). This worked better in AS than in other SpA (data not shown).

Conclusion: This study confirms that it is possible to identify SpA patients relatively early on the basis of a systematic referral pattern. Many orthopaedic surgeons were trained by this approach and referred more SpA patients than expected. Our study shows that in this early phase mainly the combination of three and more items helped to differentiate SpA patients from those with other causes of back pain.

Achieving Minimal Disease Activity (MDA) Criteria with Anti-TNF Therapy in Psoriatic Arthritis Can Prevent Progressive Joint Damage. Laura C. Coates and Philip S. Helliwell, University of Leeds, Leeds, United Kingdom

Purpose: Minimal disease activity (MDA) is defined by OMERACT as "that state of disease activity deemed a useful target of treatment by both the patient and physician, given current treatment possibilities and limitations" and criteria for MDA in psoriatic arthritis (PsA) have been developed. The aim was to investigate if achieving MDA can improve radiological outcome.

Methods: The study was an analysis of most patients in the phase III infliximab studies. In both, patients with active PsA (>5 tender & swollen joints) who failed standard therapy (NSAIDs or DMARDs) were treated with infliximab 5mg/kg or placebo. In IMPACT1, patients were given double blind therapy for 16 weeks and open label treatment to week 94. In IMPACT2, patients were given double blind therapy for 24 weeks followed by open label treatment. Early escape was possible at week 16 for non-response.

Patients were classified as MDA if they fulfilled 5 of 7 from: tender joint count²1; swollen joint count²1; psoriasis activity and severity index²1 or body surface area²3; patient pain visual analogue score(VAS)²15; patient global disease activity VAS²20; health assessment questionnaire²0.5; tender entheseal points²1. Radiological progression was assessed using modified PsA Sharp-van der Heijde (S-vdH) scores for the hands and feet. All analysis is on an intention-to-treat basis.

Results: In IMPACT1 full data were available for 63 patients. Of those receiving infliximab, 48% (15/31) achieved MDA at week 16 compared to 3% (1/32) on placebo ($p<0.0001$). At week 50, when all patients were treated with infliximab, 42% were in MDA. At week 50, 96% of those patients who achieved MDA showed no progression of radiological disease (increase in S-vdH score of ²0), compared to 67% of those who did not achieve MDA ($p=0.012$). At week 98, 12/37 (30%) were in MDA. All patients who achieved MDA at week 98 showed no radiological progression, compared to 58% of those who did not achieve MDA ($p=0.03$).

In IMPACT2 data were available for 157 patients. Of those receiving infliximab, 52% (40/77) achieved MDA at week 24 compared to 21% (17/80) on placebo ($p<0.001$). At week 54, when all patients were on infliximab, 63 of 157 (40%) were in MDA. At week 54, 78% of those patients who achieved MDA showed no radiological progression, compared to 57% of those who did not achieve MDA ($p=0.009$). Cumulative probability plots of changes in S-vdH score through week 54 are shown. The curve for IMPACT2 patients consistently in MDA (at week 24 and 52) lies to the right of the control curve indicating less proportion of patients with radiographic progression and a smaller average amount of radiographic progression in MDA patients.

Conclusion: Achieving MDA in PsA using effective therapy reduces ongoing radiological joint damage, even in a DMARD resistant cohort. The new MDA criteria could provide an objective target for treatment in trials and clinical practice.

2023

Is There Subclinical Joint Disease in Early Psoriatic Arthritis? A Clinical Comparison with Power Doppler Ultrasound. Jane E. Freeston, Laura C. Coates, Philip S. Helliwell, Elizabeth M. A. Hensor, Richard J. Wakefield, Paul Emery and Philip G. Conaghan, University of Leeds, Leeds, United Kingdom

Purpose: In line with rheumatoid arthritis (RA), the emphasis in psoriatic arthritis (PsA) is to treat early to minimise damage and functional disability. Traditionally, clinical examination (CE) in the form of tender (TJC) and swollen joint (SJC) counts has been used to assess disease activity. In RA, multiple studies have shown sub-clinical disease using ultrasound (US) assessment of disease activity. The aim of this study was to compare CE and US findings in an early PsA cohort.

Method: 40 patients with new onset PsA, according to the CASPAR criteria, were recruited. They were all DMARD naïve and had a median disease duration of 10 months. All patients underwent grey scale (GS) and power doppler (PD) US as well as TJC and SJC of the most symptomatic hand and wrist (9 joints per patient) and additional target joints that the patients identified as symptomatic. The digits of the 4 fingers on this hand were also scanned for flexor tenosynovitis (FT – defined as presence of GS and/or PD) and clinically assessed for dactylitis. GS and PD were scored separately on a 0-3 semi-quantitative scale for each joint imaged. A GS score of ≥2 and/or a PD score ≥1 were used to identify US active joints.

Results: When considering each joint individually, a total of 431 joints were assessed. Of these joints, 68% had imaging findings consistent with CE. A substantial correlation (rho 0.510, p=0.001) was identified between clinical assessment of activity (tender and/or swollen) and imaging assessment of activity. CE rarely over-estimated activity, particularly the swollen joint count where 95/100 swollen joints showed imaging activity. However, 93 clinically inactive joints scanned showed significant imaging findings.

A total of 160 digits were examined for clinical dactylitis and FT on US. Of these, 88% had consistent findings (2 digits were clinically dactylitic with FT on US). FT was found in an additional 20 digits (13%) that were not clinically considered to be dactylitic.

Conclusion: There was substantial correlation seen between clinical and imaging findings in early PsA. However, CE can underestimate joint activity in over 20% of joints. Likewise, when assessing digits for dactylitis and FT, the majority show consistent findings, but a proportion of digits have FT without clinical dactylitis. These preliminary data confirm the presence of sub-clinical disease in early PsA and have implications for both research and clinical practice, particularly in terms of the classification of PsA patients with either oligoarticular or polyarticular disease.

Table – Comparison of clinical and ultrasound assessment of disease activity by individual joint.

Type of assessment	US active	US inactive	Total

2024

The Diagnostic Utility of MRI in Early Spondyloarthritis: An International Multicentre Evaluation of 187 Subjects (The MORPHO Study). Walter P. Maksymowych[1], Ulrich Weber[2], Mikkel Ostergaard[3], Juerg Hodler[2] and Robert GW Lambert[1], [1]University of Alberta, Edmonton, AB, [2]University Clinic Balgrist, Zurich, Switzerland, [3]Copenhagen University Hospitals, Copenhagen, Denmark

Purpose: Although there is widespread acceptance that MRI constitutes a major diagnostic tool for the assessment of spondyloarthritis (SpA), its utility in early disease is limited to small studies with limited control data and diverse approaches to the evaluation of the sacroiliac joints (SIJ). Summation of this data has provided an estimated likelihood ratio (LR) of 9 for the diagnostic utility of MRI in SpA. We aimed to systematically assess the diagnostic utility of MRI in early SpA using a standardized approach to the evaluation of the SIJ.

Method: Five experienced readers (3 rheumatologists, 2 radiologists) from 3 international centres, blinded to patient and diagnosis, independently assessed MRI scans (T1-weighted and short tau inversion recovery sequences) from the following subjects: 77 patients with AS and symptom duration < 10 years; 26 patients with mechanical causes of low back pain (mLBP) <45 years of age and symptom duration < 10 years; 25 patients with inflammatory back pain (mean (range) symptom duration 26 (4-96) months) who did not meet radiographic criteria for AS; and 59 healthy controls (HC) < 45 years of age. Semi-coronal slices through the SIJ were read systematically as described in a standardized online training module developed by the Spondyloarthritis Research Consortium of Canada (SPARCC). We recorded bone marrow edema, marrow fat replacement, joint erosions, and ankylosis according to standardized definitions using an online data entry system. Readers also answered the following question dichotomously (yes/no) and according to a 0-10 rating for level of confidence: This SIJ scan confirms the presence of SpA? Sensitivity, specificity, and likelihood ratios were calculated according to clinical diagnosis.

Results: Diagnostic utility of MRI was very high for all 5 readers for both early AS and pre-radiographic SpA and much higher than previously recorded. Mean concordance (%) amongst all possible reader pairs (n = 10) for diagnosis by MRI of early AS was 82.2% and only 14.4% were discrepant. For pre-radiographic SpA only 5.6% were discrepant for diagnosis by MRI.

Table. Mean (range) sensitivities, specificities and likelihood ratios for 5 readers.

Comparison groups	**Sensitivity**	**Specificity**	**LR+**	**LR-**
AS vs mLBP+HC	89.3 (81.8-97.4)	97.4 (94.7-98.9)	34.6 (17.8-79.1)	0.11(0.03-0.18)
AS vs mLBP	89.3 (81.8-97.4)	96.9 (92.3-100)	nc (12.3-nc)	0.11 (0.03-0.18)
AS vs HC	89.3 (81.8-97.4)	97.7 (95.7-98.6)	48.3 (22.0-69.6)	0.11(0.03-0.18)
IBP vs mLBP + HC	50.4 (48.0-52.0)	97.4 (94.7-98.9)	28.5 (9.8-47.3)	0.51 (0.49-0.54)
IBP vs mLBP	50.4 (48.0-52.0)	96.9 (92.3-100)	nc (6.7-nc)	0.51 (0.48-0.54)
IBP vs HC	89.3 (81.8-97.4)	97.7 (95.7-98.6)	48.3 (22.0-69.6)	0.11 (0.03-0.18)

LR+/LR-: Positive and negative likelihood ratios, nc not calculable (specificity 100% for at least one reader)

Conclusion: The adoption of a systematic and standardized approach to the assessment of SIJ showed that MRI has much greater diagnostic utility than documented previously.

2025

Frequent Detection of Sacroiliac Joint Abnormalities On MRI in Healthy Subjects and Patients with Non-Specific Back Pain. Ulrich Weber[1], Mikkel Ostergaard[2], Juerg Hodler[1], Robert GW Lambert[3] and Walter P. Maksymowych[3], [1]University Clinic Balgrist, Zurich, Switzerland, [2]Copenhagen University Hospitals at Hvidovre and Gentofte, Copenhagen, Denmark, [3]University of Alberta, Edmonton, AB

Purpose: MRI of the sacroiliac joints (SIJ) is increasingly used to diagnose spondyloarthritis (SpA) and definitions have been proposed for active and chronic abnormalities. However, no systematic study of these findings in young healthy subjects or those with non-specific back pain has determined their frequency or potential for eliciting diagnostic confusion. We aimed to assess the frequency of active and chronic abnormalities of the SIJ in young healthy subjects and those with non-specific causes of back pain.

Method: Five experienced readers (3 rheumatologists, 2 radiologists) from 3 international centres independently assessed T1 and STIR MRI sequences from 187 subjects blinded to patient and diagnosis. These included 77 patients with AS and 26 patients with non-specific causes of low back pain (NSBP) that were <45 years of age and had symptom duration < 10 years, 25 patients with inflammatory back pain but who did not meet radiographic criteria for AS, and 59 healthy volunteers <45 years of age (HV). Semi-coronal slices through the synovial portion of the SIJ were read systematically as described in a standardized online training module developed by the Spondyloarthritis Research Consortium of Canada (SPARCC). We recorded bone marrow edema, marrow fat replacement, joint erosions, and ankylosis according to standardized definitions using an online data entry system which allowed the scoring of active and chronic findings in each quadrant of each

coronal slice on a dichotomous basis (yes = 1, no = 0). Readers also answered the following question: This SIJ scan confirms the presence of SpA? (yes/no). Data was analyzed descriptively.

Results: Bone edema, erosion, and fat replacement were each recorded in a third of NSBP and healthy subjects by at least one reader. More than 1 SIJ quadrant was identified by the presence of bone edema by at least 1 reader in 5 (8.5%) HV and 5 (19.2%) NSBP subjects, by the presence of erosion in 2 (3.4%) HV and 2 (2.9%) NSBP subjects, and by the presence of fat replacement in 12 (20.3%) HV and 5 (19.2%) NSBP subjects. Ankylosis was recorded in 2 subjects with NSBP (1 reader per subject) but was not recorded in healthy subjects. Two (7.7%) patients with NSBP were each recorded by 2 readers as having SpA while 4 (6.8%) Healthy volunteers were recorded as having SpA (one by 3 readers, 2 by 2 readers, 1 by 1 reader).

	Bone edema, No (%)		Erosion, No (%)		Fat replacement, No (%)	
	≤2 readers	>2 readers	≤2 readers	>2 readers	≤2 readers	>2 readers
HV	18 (30.5)	8 (13.6)	17 (28.8)	3 (5.8)	20 (33.9)	7 (11.9)
NSBP	10 (38.5)	5 (19.2)	10 (38.5)	1 (3.8)	10 (38.5)	3 (11.5)

Number (%) of subjects with SIJ abnormalities

Conclusion: Both low-grade active and chronic abnormalities meeting standardized definitions are observed by experienced MRI readers in up to a third of healthy volunteers and subjects with NSBP. The non-specific presence of such SI joint changes should be considered when defining MRI thresholds for the diagnosis of SpA.

2026

The Prevalence of Inflammatory Back Pain, Spondyloarthritis, and Axial Spondyloarthritis in the Community. Ingris Pelaez-Ballestas[1], Eduardo Navarro-Zarza[1], Bernardo Julian[1], Julio Casasola-Vargas[1], Roxanna Flores-Camacho[1], LH Sanin[2], Armando Lopez[3], Lourdes Rivas[3] and Ruben Burgos-Vargas[1], [1]Hospital General de México, Mexico City, Mexico, [2]UACH-INSP, Mexico, Mexico, [3]ABC Medical Center, Mexico

Purpose: To determine the prevalence of SpA in an urban community by ESSG and ASAS criteria

Method: Community-based door-to-door survey of 9,269 subjects >18 years in a pre-determined district in México City.

1st screening (Scr), 6 trained nurses identified subjects with back pain (BP) using the Community Orientated Program for the Control of Rheumatic Diseases (COPCORD) initial phase approach; 2nd Scr, selection of BP COPCORD positive subjects with BP >6 weeks and onset > 50 years; 3rd Scr, 3 GPs and 2 rheumatologists identified subjects with inflammatory (I) BP (Berlin criteria). Finally, 2 hospital-based rheumatologists double-checked IBP positive subjects and grouped them into those with true IBP (double-positive IBP assessment) and false positive IBP (IBP negative in the 2nd assessment). True positives were considered “cases” and those negatives “controls”. The two groups underwent a SpA oriented study including HLA-B27 typing, sacroiliac joint (SIC) x-ray and magnetic resonance (RM) including the lumbar spine. Clinical evaluations were made independently from HLA-B27, x-ray, and MR results. X-ray and MR interpretations were made by two-blinded observers. Classification criteria included ESSG for SpA and ASAS criteria (sets 1 & 2) for axial SpA.

Results: Scr 1: 4,059/9,269 (43.8%) subjects (2,795 [68.8%] females; 1,264 [31.1%] males; 44.7 ± 17.9 years; married 2,822 [69.5%], jobless 2,582 [63.6%]) accepted the invitation to participate in the study.

Scr 2: 553 (13.6%; 95%CI 12.5, 14.7) had BP. Scr 3: 180 (4.4% IC95% 3.8, 5.1) subjects (112 [68.4%] females; 68 [31.6%] males; 43.8 ± 15.4 years) had BP >6 weeks and onset > 50 years. 87 additional subjects fulfilled either of such two criteria, but were not further analyzed.

Until now, 65/180 with IBP in the first survey have been double-checked; 36 of them were cases and 29 controls. According to ESSG 36/3,944 subjects (0.009 %, 95%CI 0.0063, 0.0125) as well as 39 according to ASAS-1 (0.009%, 95%CI 0.007, 0,013), and 10 to ASAS-2 had SpA (0.002%, 95%CI 0.001, 0.004). Compared with ESSG, ASAS-1 had high sensitivity and low specificity (LR+ 1.75) and ASAS-2 low sensitivity and very high specificity (LR 7.0) in this population.

Conclusion: The prevalence of IBP in this population was 4.4%. The prevalence of SpA according to ESSG and axial SpA according to ASAS-1 is about de same (0.009%), but according to ASAS-2, the prevalence of axial SpA is much lower (0.002%). The use of ASAS criteria to identify axial SpA in subjects with IBP from the community seems feasible, but cost of this approach should be considered.

2027

Crossing the Threshold: Help-Seeking for Early Symptoms in People with Rheumatoid Arthritis. Linda C. Li[1], Anne F. Townsend[1], Paul M. Adam[2], Susan M. Cox[1], Zubin Amarsi[3], Catherine L. Backman[1] and ERAHSE team, [1]University of British Columbia, Vancouver, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Purpose: Recent research suggests that up to 38% of people with rheumatoid arthritis (RA) waited longer than three months to initiate a consult with a family physician for joint symptoms[1]. However, little is known about factors associated with the initiation of medical consults. The current study aims to understand the process of help-seeking for early symptoms in people with RA.

Method: 38 people (37 women, 1 man), who were diagnosed with RA within the past 12 months, were recruited from offices of rheumatologists and family physicians and from newsletters of patient advocacy groups. In-depth face-to-face interviews were organized around three overlapping topics: 1.) onset of symptoms and initial illness actions; 2.) seeking help from health professionals leading to diagnosis; and 3.) post-diagnosis experiences. Follow-up phone calls were made to check and elaborate on data gained at the interviews. Analysis was informed by grounded theory and a narrative approach.

Results: The decision to seek help for early arthritis symptoms was influenced by the complex interplay of disease-related, environmental and personal factors: 1.) severity and nature of symptoms, e.g., mild vs. severe; presence of pain and/or fatigue; 2.) impact of symptoms on function and participation in social roles; 3.) prior experience with medical professionals; and 4.) knowledge about arthritis and other chronic diseases. A key theme to the action of seeking help was the process of 'normalization of symptoms'[2], in which participants attempted to explain away the early signs and symptoms, and only sought medical help when they were no longer able to cope (i.e., crossing the threshold). Initially, some individuals sought care for symptoms which they believed were other debilitating chronic diseases such as osteoarthritis. In some participants, this normalization process led to a delay in seeking help from medical professionals.

Conclusion: Severity of symptoms was only a part of the puzzle in understanding people's decision to seek help. Given the importance of early diagnosis and treatment in RA, multi-faceted interventions may be required to address environmental and personal factors, in addition to improving people's ability to recognize early RA symptoms. Further research should focus on understanding the contribution of these factors to timely help-seeking in RA.

Engaging Providers to Recommend Community-Based Self Management Programs to Their Patients: Results From a Survey of Primary Care Practices. Teresa J.. Brady[1], S. Price[2], C. Ryan[2], P. Eidson[3] and T. Savage[2], [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Westat, Rockville, MD, [3]Directors of Health Promotion & Education, Atlanta, GA

Purpose: Community-based self management programs are crucial adjuncts to clinical care but previous research suggests physicians have limited awareness of community-based programs. The purpose of this study was to determine how to increase providers' awareness of and willingness to recommend community-based programs to their patients with arthritis.

Methods: Data was collected from a convenience sample of primary care practitioners (PCPs), (e.g.; physicians, nurse practitioners and physician assistants) and practice managers through an on-line survey (N=404). Stratified recruitment of various practitioner type; practice types, sizes, and locations (rural, suburban, urban); and patient demographics assured a mix of perspectives. Descriptive statistics were calculated using SPSS. Open ended questions were thematically coded.

Results: By design, approximately 50% of respondents were physicians, 25% were nurse practitioner/physician assistants, and 25% were office managers. 54% were from family practice offices, 47% were from practices with fewer than 5 clinical staff, 52% were from suburban settings, and 22% indicated that at least half their patient population was racial/ethnic minorities.

60% of respondents recommend a community-based program at least several times per week. Among program features that influence a practice's decision to recommend a program, low cost (X=4.64, 1 = no, 5 = great influence), convenient location and time (X=4.63; X=4.47), led by trained instructors (X=4.49), and programs evidence-based (X=4.43) emerged as the most influential.

80% of respondents indicated that a personal visit by program staff bring information to the practice was somewhat/very effective for getting the practice to consider these programs (X=4.17; 1= not at all; 5 = very effective). Disseminating materials at conferences (X=3.21); through newsletters, e-mail, and journals (X=3.15); and via postal mail (X=3.07) were all considered substantially less effective.

A program fact sheet listing program goals, instructor qualifications, and patient activities was identified as the most useful practitioner-oriented material. More than three quarters (82%) also rated patient handout materials (brochures and flyers) to be useful.

Conclusion: PCPs do recommend community-based programs, but have specific questions and concerns that need to be addressed and prefer a personal introduction to the program. Introducing community-based programs to PCP offices will require in-person visits for the initial introduction and materials that specifically address practitioner questions/concerns about the cost, credibility, and convenience of the programs.

Improving Osteoporosis Knowledge and Health Bone Habits of Rural-Dwelling Older Adults. Terri L. White[1] and Gail C. Davis[2], [1]Texas Woman's University, Dallas, TX, [2]Texas Woman's University, Denton, TX

Purpose: The purpose of this study was to compare three community-based bone health interventions with rural-dwelling older adults (age 65 years and over) by comparing participants' knowledge and osteoporosis-related behaviors. Changes in knowledge and behaviors of those participating in the different interventions were also of interest. The conceptual framework guiding this study was Fleury's Wellness Motivation Theory. Kiresuk, Smith, and Cardillo's Theory of Goal Attainment Scaling provided a methodological guide for the intervention.

Method: The research design was quasi-experimental using four groups. The first group was included as a control and did not receive an intervention (Group 1). The remaining groups received the following specific bone health intervention: (Group 2) bone health educational booklet; (Group 3) bone health educational booklet, 2 educational sessions, and 2 follow-up phone calls; and (Group 4) all components of Group 3 plus an individualized bone health goal-setting session and their results of the Short Food Questionnaire estimates of daily dietary calcium and vitamin D intake. All participants received a calcaneus qualitative ultrasound (QUS), Groups 2, 3, and 4 at the beginning and Group 1 at the end of the study. Seven weeks intervened between the pre- and posttests which assessed osteoporosis-related knowledge, osteoporosis self-management behaviors, and readiness to use positive health behaviors. Participants were recruited from 8 senior centers in rural Central Texas communities; the centers were randomized to study groups. The sample ($N = 85$) included 69 women and 16 men (M_{age} = 78, range 65 – 95). ANOVA and *t*-tests were used to calculate the differences between and among the groups.

Results: Major findings indicated there were significant increases in osteoporosis knowledge from pretest to posttest in Group 3 [t (18) = -4.89, p = <.001] and Group 4 [t (23) = -3.68, p = <.001] with large and medium effect sizes of $\eta 2 = 0.57$ and $\eta 2 = 0.37$, respectively. Group 4 participants significantly increased their performance of healthy bone behaviors [t (23) = -4.15, p = <.001] with a medium effect size of $\eta 2 = 0.43$. The knowledge of Group 3 was significantly different than that of the control group (F (3, 81) = 4.17, p = .008) at posttest. Readiness did not demonstrate a role in the changes.

Conclusion: Increasing osteoporosis knowledge and healthy bone behaviors is more complicated than issuing pre-printed bone health information. The changes that occurred in this study having the greatest likelihood of positively affecting bone heath occurred when participants set individualized bone-health goals. The findings in this study support earlier study findings that osteoporosis knowledge and healthy bone behaviors in older adults can be increased through group educational programs that include goal setting aimed at improving bone health.

Co-Morbidity Status of People with Arthritis Sways Their Self-Management Education Program Preference. Louise Murphy[1], Teresa J. Brady[1], Kristina A. Theis[1], Julie Bolen[1] and Patience White[2], [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]The George Washington University, Washington, DC

Purpose: To characterize, among people with arthritis, who is most likely to be interested in attending self management education programs (SME), and to describe how presence of co-morbidities influences preferred type of SME among people with arthritis.

Method: We analyzed data from a national U.S. phone survey of white and black adults (n=1002), aged 40-70 years old, who have doctor diagnosed arthritis and "some" or "many" limitations due to arthritis. Participants in this survey were those who responded 'yes' to "Have you EVER been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" Both a generic chronic disease and an arthritis-specific SMP were described to participants, who were queried on their preference and receptivity ("very/somewhat likely" or "not very/not at all likely") to participation in each. We estimated the prevalence of receptivity and preference for each SMP type and examined correlates (e.g., demographics, symptoms, number of comorbidities) in multivariable adjusted logistic regression models with odds ratios (ORs) and 95% confidence intervals (95% CI). Comorbidities examined were cancer, cardiovascular disease, depression, diabetes and high blood pressure.

Results: Nearly 60% of respondents reported being very/somewhat likely to participate in either type of SME. Blacks, women, and those reporting severe pain in the past week, and some physical limitations had the greatest interest in SMEs. The multivariable adjusted regression models showed that respondents who were black (OR=1.9; 95% CI=1.2 - 2.9), retired (OR=1.7; 95% CI= 1.2 - 2.6), or had comorbidities preferred the generic SMP (1 comorbidity: OR=1.7 [95% CI=1.0 - 2.9]; 2 comorbidities: OR=3.3 [95% CI=2.0 - 5.7], and at least 3 comorbidities: 6.7 [95% CI=3.8-11.8]), while respondents who experienced moderate or high levels of pain on a typical day were more likely to prefer the arthritis specific SMP (OR=0.3; 95% CI=0.1 - 0.9).

Conclusion: Among people with arthritis, blacks, women, and those with severe pain in the past week and some physical limitations are most likely to be interested in participating in any type of SMP. People with arthritis and comorbid conditions preferred generic to arthritis-specific SMPs, and this preference for a generic SMP was highest among those with multiple comorbidities. Recognizing the high prevalence of comorbidities among people with arthritis, expanding the availability of generic SMPs, particularly among blacks and women, should improve chronic disease self-management skills and improve quality-of-life for people with arthritis.

Self-Management for Osteoarthritis of the Knee; Health Professionals or Lay Leaders? Sophie Coleman[1], Jessica Rose[2], Jean McQuade[2], Graeme Carroll[3], Charles Inderjeeth[4] and N. Kathy Briffa[1], [1]Curtin Health Innovation Research Institute Curtin University of Technology, Bentley, Australia, [2]Arthritis WA, Wembley, Australia, [3]Arthrocare, Mt Lawley, Australia, [4]SCGH, Nedlands, Australia

Purpose: To compare two 6 week self-management (SM) programs for people with OA knee. We have developed a disease specific self-management education program (OAK), for people with OA of the knee[1]. OAK includes specific education and exercise advice- designed for delivery by health professionals (HP's) utilising their knowledge and expertise. We compared this program with the Arthritis Self-Management Program (ASMP)[2]. ASMP is scripted for delivery by lay leaders and is generic in content. There is little evidence to support one approach in preference to the other. We hypothesised that the disease specific OAK would lead to better outcomes than ASMP.

Method: In a registered RCT (ACTRN 12607000031460), 190 people (59 male) of mean age 67 years with OA knee were randomised to either OAK or ASMP. Groups were assessed pre- and post-intervention, and 6 &12 months later. Outcomes measured were health status (WOMAC), quality of life (SF36), balance, mobility, self-efficacy (S-E), and patient global health (PGH). VAS pain was measured each week of the intervention. Differences between groups were examined using an intention to treat analysis with repeated measures ANOVA. P-values are single tail.

Results: Both groups improved over time ($p<0.01$) in WOMAC, balance, mobility, S-E, and SF36 PCS. Improvements were maintained to12mths. There were no between group differences in improvement (group x time $p\geq0.06$) although OAK participants tended to have better improvements in physical outcomes. During the intervention VAS pain decreased more in the OAK group; mean (SE) OAK: 5.5 (0.3) to 4.4 (0.3); ASMP: 5.1 (0.3) to 4.7 (0.3) (group x time $p=0.02$). Neither SF36 MCS or PGH changed significantly (time $p\geq0.08$)

Conclusion: Improvements in health status, function and QOL were comparable between both groups. This information is relevant when planning SM models for use in OA considering the additional costs incurred employing HP's. [1]Coleman S, Briffa K, Conroy H, Prince R, Carroll G, McQuade J: BMC Musc Dis 2008 9:117 [2]Lorig K, Gonzalez V: Hlth Educ & Bhvr 1992 19:355

Evaluation of Group and Self-Directed Formats of the Arthritis Foundation's (AF) Walk with Ease (WWE) Program. Leigh F. Callahan[1], Jack Shreffler[1], Mary Altpeter[1], Kathryn Remmes Martin[1], Laura O. Houenou[1] and Jennifer M. Hootman[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Centers for Disease Control and Prevention, Atlanta, GA

Purpose: To evaluate the effect of a revised 6 week walking program for people with arthritis, WWE, in 2 delivery formats, group instruction or self-directed.

Method: A quasi-experimental pretest-posttest evaluation was conducted in 468 individuals with self-reported arthritis from 27 urban and rural communities. Participants selected either instructor-led group (n=192) or self-directed (n=276) format. All participants received the revised WWE workbook. Baseline and post-WWE program assessments were administered, with 93% group and 83% self-directed participant follow-up rates. Arthritis related self-reported outcomes were: Health Assessment Questionnaire (HAQ), pain, fatigue, and stiffness visual analog scales (VAS), the Rheumatology Attitudes Index (RAI), and Arthritis Self-Efficacy (ASE). Performance measures of function included chair stands, 360 degree turns, single leg stands, normal and fast walking pace, and the 2 minute step test (a measure of endurance). Adjusted mean outcome values for the group and self-directed participants posttest were determined using regression models, adjusting for baseline outcome, age, gender, race, and education. Effect sizes (ES) and 95% confidence intervals (CI) were computed.

Results: Group participants were on average 71 yrs old, 86% female 24% black, with 66% having > high school (HS) education. Self-directed were on average 65 yrs old, 89% female, 24% black, with 74% having > HS education. In both delivery formats (group vs self-directed), significant adjusted mean improvements ($p<0.05$) were seen for all of the self-report and performance measures, except for ASE and the 2 min step. There were no significant differences between the delivery formats. Therefore, the groups were combined and ESs were computed for all outcomes. Moderate effects were seen for the HAQ (ES=.21, 95% CI .15-.27), pain (ES=.34, CI .24-.44), fatigue (ES=.26, CI .17-.35), stiffness (ES=.39, CI .29-.49), and RAI (ES=.25, CI .17-.33). The ASE pain and symptom scales had modest improvements (ES =.13, CI .03-.22 and .12, CI .03-.22, respectively). The performance measures, strength (ES=.37, CI .30-.44), balance (ES= .35, CI .28-.41), and walking pace (ES=.22, CI .15-.30) all showed modest to moderate improvements; the 2 min step showed essentially no improvement (ES= .03, CI -.08-.14). No adverse events were reported for either delivery format.

Conclusion: The AF's revised WWE program appears to decrease disability and improve arthritis symptoms, self-efficacy and perceived control, balance, strength, and walking pace in individuals with self-reported arthritis regardless of whether they are taking an instructor-led group class or doing the program on their own as independent self-directed walkers. This is a safe, easy, inexpensive program for community-based physical activity delivery.

ACR Concurrent Abstract Sessions

Hyperuricemia and Gout

Wednesday, October 21, 2009, 11:00 AM - 12:30 PM

2033

Hyperuricemia as An Early Marker for Type 2 Diabetes Among Young Adults. M. Bennett[1], B. J. Pandya[2], Eswar Krishnan[1], A. Hariri[2], L. Chung[1], Hyon K. Choi[3] and O. Dabbous[2], [1]Stanford University School of Medicine, Palo Alto, CA, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]Boston University School of Medicine, Boston, MA

Purpose: Diabetes mellitus is one of the biggest public health problems in the industrialized world. Early markers that can predict incidence of diabetes would be helpful in instituting preventive strategies. The purpose of this study was to test the hypothesis that hyperuricemia can be used as an early marker of type 2 diabetes mellitus independent of obesity, physical activity, and other known risk factors.

Method: 5,012 diabetes-free men (46%) and women (54%) between ages 18 and 30 at baseline were prospectively followed for 15 years with regular visits every 2 to 3 years. The outcome of interest was incidence of diabetes fulfilling the American Diabetes Association criteria or need for any hypoglycemic medications. The independent variable of interest was serum uric acid level (sUA) at baseline. The relationship between sUA concentration and the risk for subsequent diabetes was studied using logistic regression models adjusted for the

effects of age, gender, ethnicity, body mass index (BMI), diastolic blood pressure, smoking, fasting glucose concentration, family history of diabetes, and a physical activity score.

Results: Half (51%) of subjects were African-American. The mean±SD of age (years), BMI (kg/m^2), diastolic blood pressure (mm Hg), and physical activity score (1 to 5 scale of increasing activity level) were 24.8±3.6, 22.4±4.8, 68.6±9.6, and 3.3±1.1, respectively, at baseline. In multivariable regression models, the highest category of sUA (≥7.0 mg/dL) had statistically higher risk of developing type 2 diabetes, even after excluding patients who met the World Health Organization criteria for metabolic syndrome (Table). When sUA was examined as a continuous variable, each unit increase in sUA was associated with increased overall risk of type 2 diabetes (odds ratio 1.18; 95% confidence interval: 1.04-1.35) and among those without metabolic syndrome (1.22 [1.07-1.38]).

Conclusion: In this study, increased levels of sUA appear to be associated with increased overall risk of type 2 diabetes among our cohort of young adults. These data expand on well-established, cross-sectional associations between hyperuricemia, and the metabolic syndrome and may extend the link to the future risk of type 2 diabetes in young adults.

Serum Uric Acid and the Adjusted Relative Risk for Incidence of Type 2 Diabetes Mellitus

Serum Uric Acid Concentration (mg/dL)	Odds Ratio (95% Confidence Interval)	
	Participants Without Metabolic Syndrome (n=4,752*)	Overall (n=4,762*)
0.4-4.9	1 (referent)	1 (referent)
5.0-6.9	1.26 (0.88-1.81)	1.23 (0.86-1.75)
7.0-13.3	1.99 (1.18-3.36)	1.94 (1.16-3.25)

*Number of individuals included in the regression model; multivariable logistic regressions were adjusted for age, gender, ethnicity, body mass index, diastolic blood pressure, smoking, fasting glucose concentration, family history of diabetes, and a physical activity score.

2034

Incidence of Allopurinol Hypersensitivity Syndrome (AHS) Among Renally Impaired Patients. Dinesh Khanna[1], B. J. Pandya[2], A. O. D'Souza[3], B. L. Meissner[3], R. Kamalakar[2] and V. Harikrishnan[2], [1]UCLA, Los Angeles, CA, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]Xcenda LLC, Palm Harbor, FL

Purpose: It is generally acknowledged that renal impairment is associated with a higher incidence of AHS. However, no study has assessed this in a large population. This study assessed the incidence of AHS among renally impaired patients who are commercially insured through administrative claims data using a clinically validated algorithm.

Methods: This study applied a retrospective cohort design to determine AHS incidence among treatment-naive allopurinol users with and without renal impairment within two large commercial datasets. A 6-month washout period prior to the initial (index) allopurinol prescription was used to define treatment-naive patients. During this washout period, patients were defined as renally impaired based on ICD-9 and HCPCS codes. The presence of AHS was then examined using a multi-step process. First, an uninterrupted allopurinol exposure period was identified. Second, presence of AHS symptoms within the appropriate temporal sequence was applied, and severity of the AHS episode was assessed. Episodes were considered invalid if alternative disease states or medications could account for similar AHS signs and symptoms, or if additional allopurinol exposure periods occurred after the AHS episode. The primary outcome was AHS incidence among the two cohorts (renally impaired vs non–renally impaired) computed as the total number of patients with AHS divided by the total number of allopurinol users within the respective cohort. Logistic regression analyses were conducted to determine statistically significant differences.

Results: A similar proportion in both datasets were found to be renally impaired (10.5% and 12.8%). Overall, renally impaired patients were 2.5 to 4 years older (P<0.001), less likely to be male (P<0.001), more likely to use a diuretic (P<0.001), and had a higher Charlson comorbidity index (P=0.001). Presence of AHS among renally impaired patients ranged from 0.41% (n=24) to 0.72% (n=63). The majority of AHS episodes among renally impaired patients were characterized by acute renal failure (ARF; 20 of 24 and 57 of 63). Unadjusted estimates indicate that the incidence of AHS was 3 to 4 times higher among renally impaired patients compared with non–renally impaired patients (P<0.007). After controlling for age, gender, comorbidity burden, gout diagnosis, and diuretic use, renally impaired patients were significantly more likely to have AHS (OR 2.06; 95% CI 1.21-3.51; P=0.010 and OR 3.29; 95% CI 2.31-4.70; P<0.001).

Conclusion: Similar results were found in both datasets with the incidence of AHS being 2-3 times higher in renally impaired. Also, a majority of AHS episodes were characterized by ARF, suggesting a potential relationship between allopurinol and ARF. Further research is needed to better understand predictors and overall characteristics of patients susceptible to developing AHS, and if there is a causal relationship between allopurinol and ARF.

2035

Serum Cholesterol in Young Men and Risk of Incident Gout. Allan C. Gelber[1], Lucy Meoni, Audrey Chu[1] and Michael J. Klag, [1]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Cholesterol screening in young adults is a common preventive strategy to assess risk for preclinical coronary heart disease (CHD). Several factors related to incident CHD, including hypertension and obesity, are similarly related to the development of gout. We sought to identify whether serum cholesterol, measured in early adult life, might predict incident gout in men.

Method: Serum cholesterol was measured at a mean age of 22 years among 1040 male medical students who graduated from 1948-1964 and have since been prospectively followed to detect incident disease. Cumulative incidence was estimated using Kaplan-Meier analysis. In addition, the risk of incident gout associated with the highest quintile of serum cholesterol was estimated using Cox proportional hazards analysis, with adjustment for body mass index at age 35 years and time-dependent hypertension.

Results: At cohort entry, mean cholesterol was 189.7 mg/dl (5.84 mmol/L). During a median follow-up of 45 years, a total of 139 men developed gout. Sixty participants reporting incident gout were mailed the ACR Criteria for the Classification of Gout, among whom 42 returned the questionnaire. Within this group, 34 fulfilled the ACR criteria; the other 8 satisfied criteria based on medical record review. Median age at gout onset was 58 years. Overall, the cumulative incidence of gout was 20%, and greater in the highest compared to the lowest 4 combined cholesterol quintiles (p=0.01). The relative risk of incident gout associated with the highest quintile of serum cholesterol, >209 mg/dl, was as follows:

Model for all Gout	Relative Risk	95% confidence interval
Cholesterol, unadjusted	1.7	1.1 – 2.5
Time-dependent hypertension, cholesterol-adjusted	1.9	1.2 – 2.9
Weight at age 35, cholesterol-adjusted	1.1	1.0 – 1.2
Cholesterol, hypertension and weight-adjusted	1.6	1.1 – 2.4
Model for Gout onset prior to 60 years	**Relative Risk**	**95% confidence interval**
Cholesterol, hypertension- weight-adjusted	2.2	1.3 – 3.7

Conclusion: During greater than four decades of follow-up, approximately 20% of the cohort developed gout. Moreover, the highest quintile of serum cholesterol, >209 mg/dl at a mean age of 22 years, was related to a 60% increase in risk of incident gout. This heightened risk was most apparent for gout that occurred prior to the age of 60 years. These findings imply that measurement of serum cholesterol in young adults, obtained during health maintenance screening to identify risk for CHD, is also of value to identify men at heightened risk to develop gout.

Weight Loss and the Risk of Hyperuricemia Among Men with a High Cardiovascular Risk Profile. Yanyan Zhu[1], Y. Zhang[1], Eswar Krishnan[2] and Hyon K. Choi[3], [1]BUSM, Boston, MA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Boston University School of Medicine, Boston, MA

Purpose: Hyperuricemia is the precursor of gout, which is the most common inflammatory arthritis for adult men. Furthermore, serum uric acid levels are associated with several major conditions, including cardiovascular disorders, renal function decline, the metabolic syndrome, and type 2 diabetes. Adiposity is a major determinant for hyperuricemia, but little is known about the quantitative impact of weight loss on the risk of hyperuricemia. To estimate this impact, we performed a longitudinal analysis of 12,465 men with a high cardiovascular risk profile, who participated in the Multiple Risk Factor Intervention Trial (MRFIT).

Method: We analyzed the relation between weight change and hyperuricemia using data prospectively collected at baseline and annually over a 6-year period (79,112 observations from 12,465 men). Our primary definition of hyperuricemia was 6 mg/dL, a widely accepted therapeutic target. We performed longitudinal analysis using logistic regression with generalized estimating equations to incorporate correlations of repeated observations in a given participant. Our final multivariate model was adjusted for baseline covariates (age, education, weight) and time-varying covariates (alcohol intake, hypertension, serum creatinine level, diuretic use and fructose use).

Results: The mean age was 46 years and mean BMI was 28 kg/m^2. The mean serum uric acid was 6.79 mg/dl and 73% were hyperuricemic at baseline. Consistent with the intent of the risk factor intervention trial, weight loss was observed in 38% of visits (Table). There was a graded relation between weight loss and reduction in the risk of hyperuricemia, and weight loss of 10 kg or more led to a 51% lower risk of hyperuricemia (Table). Overall, weight change of 1kg led to a 5% change in the risk of hyperuricemia (p for trend <0.0001).

Conclusion: This prospective data indicate that weight reduction could substantially help achieve a widely-accepted therapeutic uric acid target level (6mg/dL) among men with a high cardiovascular risk profile. Weight loss of 10 kg or more could lead to a 51% lower risk of hyperuricemia.

Table. Odds Ratios of Hyperuricemia (6mg/dL) According to Weight Change in the MRFIT Study

Weight Change (kg)	Number of Visits (%)	Univariate OR (95% CI)	Multivariate OR (95% CI)
Loss 10	2844 (3.59)	0.43 (0.39, 0.49)	0.49 (0.43, 0.55)
Loss 5 to 9.9	8524 (10.77)	0.75 (0.70, 0.81)	0.78 (0.73, 0.84)
Loss 1 to 4.9	19089 (24.13)	0.90 (0.86, 0.94)	0.91 (0.86, 0.95)
No Change (-0.9 to 0.9)	25590 (32.35)	1 (Referent)	1 (Referent)
Gain 1 to 4.9	15988 (20.21)	1.16 (1.10, 1.22)	1.15 (1.09, 1.22)
Gain 5 to 9.9	5520 (6.98)	1.61 (1.46, 1.76)	1.57 (1.43, 1.72)
Gain 10	1557 (1.97)	1.65 (1.38, 1.96)	1.55 (1.29, 1.86)

Risk Factors for Incident Gout Among Women: A Prospective Study. Vidula Bhole[1], Mary De Vera[1], M. Mushfiqur Rahman[1], E. Krishnan[2] and Hyon K. Choi[3], [1]Arthritis Research Centre of Canada, Vancouver, BC, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Boston University School of Medicine, Boston, MA

Purpose: Despite recent doubling of the incidence of gout among women and substantial prevalence particularly in the aging female population, little data are available on the risk factors for gout among women. Given the important gender differences in uric acid metabolism, role of sex hormones, and frequency of gout, the risk factors for gout may vary considerably between genders. We examined the relation between serum uric acid level, purported risk factors and the risk of incident gout among women in the Framingham Heart Study (FHS) cohort.

Methods: Using data from FHS (1950-2002), we prospectively examined the relation between uric acid, purported risk factors and incidence of gout in 2,476 women and 1,951 men. We calculated the incidence rates of gout according to uric acid categories. We used Cox proportional hazards model with time-dependent variables to estimate the relative risk (RR) for incident gout by age, education, obesity, hypertension, diuretic use, alcohol use, glucose and cholesterol level, and menopausal status. We explored potential interaction by gender by testing significance of interaction terms added to our final multivariate models.

Results: At baseline mean age of the cohort was 47 years and 50% women were postmenopausal. Mean baseline uric acid level was 4.5 mg/dL for the cohort; and 4.0 mg/dL for women. The proportion of individuals with obesity, hypertension, diuretic use, and heavy alcohol use were 13%, 13%, 4% and 14% respectively; and for women 14%, 15%, 6%, and 6%, respectively. Over 28 year median follow-up, we documented 304 incident gout cases, 104 in women. Incidence rates of gout for women per 1000 person years for uric acid levels of <5.0, 5.0-5.9, 6.0-6.9, 7.0-7.9 and ≥8.0 mg/dL were 0.8, 2.5, 4.2, 13.1, and 27.3, respectively (p for trend <0.0001). The magnitude of this association was significantly lower than that among men (p for interaction, 0.0002). The associations of purported risk factors and incident gout were similar between genders (**Table**), except for a stronger age effect among women (p for interaction, 0.02)

	Multivariate RR	
	Women	Men
Age, per 5 yr	**1.24 (1.08, 1.43)**	**1.14 (1.03, 1.26)**
BMI, kg/m^2

Menopause		
No	1.0	-
Yes	3.54 (0.46, 27.15)	-

Conclusion: Higher levels of serum uric acid increase the risk of gout in a graded manner among women, but the rate of increase is lower than that among men. The latter finding appears to provide another reason behind the lower background incident rates of gout among women that goes beyond their lower baseline serum uric acid levels. Age, obesity, hypertension, alcohol consumption, and diuretic use were associated with the risk of incident gout among women.

Drinking Water Can Reduce the Risk of Recurrent Gout Attacks. T. Neogi[1], C. Chen[1], C. Chaisson[1], D.J. Hunter[2] and Y. Zhang[1], [1]BUSM, Boston, MA, [2]NEBH, Boston, MA

Purpose: Dehydration is thought to be one possible trigger for acute gout attacks. We therefore examined whether water consumption may reduce the risk for recurrent gout attacks.

Methods: We conducted an internet-based case-crossover study to assess a set of putative risk factors thought to trigger recurrent gout attacks. This methodology uses each participant as his/her own control by comparing the frequency of a particular risk factor during periods of gout attacks with that during periods during which they are not having an attack, thereby eliminating between-person confounding. Subjects with gout who had an attack within the past year were recruited online and asked to provide access to medical records pertaining to their gout diagnosis. Data were obtained on the amount of water consumed over the 24-hour period before a gout attack and over the 24-hour period during an intercritical period. We examined the relation of amount of water intake (0-1, 2-4, 5-8, >8 glasses per 24-hours) and the risk of recurrent gout attacks using conditional logistic regression adjusting for diuretic use, alcohol consumption, and purine intake.

Results: 535 participants (78% male, mean age 53) provided information during both times of a gout attack and an intercritical period (median # of attacks/person=2; median # of intercritical period questionnaires/person=2). Increasing water intake was associated with decreased risk for recurrent gout attacks (Table).

Conclusion: Water intake in the prior 24-hours was associated with a significant reduction in risk for recurrent gout attacks. Drinking adequate water may be a simple, safe, and effective way for individuals with gout to prevent recurrent gout attacks, and can easily be recommended to patients with gout by healthcare providers. Future work will examine the effects of other concurrent beverage intake.

Table: Relation of water intake in prior 24-hours to risk for recurrent gout attack

Amount of water intake in prior 24-hours	N case periods	N control periods	Crude OR	*Adjusted OR (95% CI)
0-1 glass	163	159	1.0 (ref)	1.0 (ref)

2-4 glasses	487	579	0.82	0.84 (0.59-1.18)
5-8 glasses	356	441	0.57	0.60 (0.40-0.90)
>8 glasses	116	138	0.52	0.54 (0.32-0.90)

Novel Aspects of Intercellular Cytokine Signaling

Wednesday, October 21, 2009, 11:00 AM - 12:30 PM

2039

The Fibronectin III 13-14 Domains Activate Catabolic Pathways in Joint Tissue Via TLR4. Nidhi Sofat[1], Robin Wait[2] and Hideaki Nagase[3], [1]St. George's, University of London, London, United Kingdom, [2]The Kennedy Institute of Rheumatology, London, United Kingdom, [3]Kennedy Institute for Rheumatology, London, United Kingdom

Purpose: Fibronectin is an extracellular matrix (ECM) molecule implicated in a number of processes during physiology and inflammation. Expression of full-length FN is upregulated in chronic conditions such as rheumatoid arthritis and osteoarthritis and fibronectin fragments induce specific biological effects. The aggrecanases (ADAMTSs) and MMPs are believed to be the key enzymes mediating joint damage in arthritis. The C-terminal heparin-binding region of fibronectin has been implicated in regulating aggrecanase activity in vitro, but the activation of aggrecanase activity by this region has not been investigated in experimental models of arthritis.

Methods: The expression of fibronectin and its fragments was investigated in normal and arthritic tissue by Western blotting. Normal porcine articular cartilage was then used to test recombinant fragments of fibronectin, either alone, or in combination with the cytokines IL-1 and TNF, for their ability to induce aggrecanase and MMP activity. Enzyme activity was measured by RT-PCR and neoepitope assays by Western blotting. The ability of recombinant fragments to regulate the production of other proteins in chondrocytes was established by metabolic labelling using cysteine and methionine-free medium and then probing for newly synthesised proteins using one-dimensional gels analysed by mass spectrometry. The receptor for the most active fibronectin fragment was established using cultures from hip explants of TLR-4 knockout mice.

Results: Our data showed that full-length fibronectin and its fragmented forms are highly upregulated in arthritic cartilage from subjects with rheumatoid arthritis and osteoarthritis. Here, we show for the first time, that the fibronectin III 13-14 domains in the C-terminal heparin-binding region are potent inducers of aggrecanase activity at micromolar concentrations in articular cartilage. The FN III 13-14 domains also induced aggrecananase activity in a synergistic manner with the cytokines IL-1 and TNF, which was 5-6 fold higher than each of these molecules alone. We also show that the FN III 13-14 domains induce release of MMP-1, MMP-3, hsp 70, gp 38 and serum amyloid A-like protein in chondrocytes, an effect that was not observed for full-length FN. Furthermore, the III 13-14 domains increased IL-6, IL-8 and PGE2 production in monocytes. In studies using knockout mice, wild-type, but not TLR4 knockout murine cartilage showed the induction of aggrecanase activity by fibronectin domains III 13-14.

Conclusion: Our data describes a new mechanism of activation of TLR4 in articular cartilage which may be a significant activation pathway during joint damage. These findings show how the release of endogenous matrix proteins such as fibronectin maintains the persistence of chronic inflammation by the activation of pro-inflammatory pathways in diseases such as rheumatoid arthritis and osteoarthritis. Targeting pathways involving the imbalance of ECM proteins may provide new therapeutic options for the treatment of arthritis in the future.

Type-I Interferon Modulates Monocyte Recruitment and Maturation in Chronic Inflammation. Pui Lee, Yi Li, Jason S. Weinstein, Dina Nacionales, Edward Butfiloski, Eric S. Sobel, Minoru Satoh and Westley H. Reeves, University of Florida, Gainesville, FL

Purpose: Chronic inflammation, characterized by the continuous recruitment and activation of immune cells such as monocytes in response to a persistent stimulus, occurs in the rheumatoid synovium and at other sites of autoimmune attack. Although chemokine gradients play a prominent role in monocyte migration, the mechanism(s) responsible for the sustained chemokine production and subsequent influx of monocytes in chronic inflammation are not well defined. Intraperitoneal administration of TMPD (2,6,10,14-tetramethylpentadecane; pristane) in mice potently induces chronic inflammation and potentiates the development of autoimmune manifestations. Influx of monocytes to the peritoneal cavity persists for months after a single injection. Using TMPD-induced chronic peritonitis as a model, we aimed to identify specific mediators and pathways responsible for the persistent recruitment of monocytes.

Method: Wild-type or cytokine-deficient mice were treated (i.p.) with TMPD or thioglycollate. Surface markers on peripheral blood and peritoneal exudate cells were analyzed by flow cytometry. Monocyte labeling and tracking was performed using fluorescent labeled liposomes two weeks after TMPD treatment. Chemokine expression in peritoneal exudate cells was analyzed by quantitative PCR and cytokine production *in vitro* was measured by ELISA.

Result: TMPD treatment resulted in the persistent recruitment of $Ly6C^{hi}$ "inflammatory" monocytes, but not $Ly6C^{lo}$ "residential" monocytes, into the peritoneum for more than two months. Interestingly, this response was abolished in type-I interferon (IFN-I) receptor deficient mice but was unaffected by the absence of IFNγ, TNFα, IL-6 or IL-1. IFN-I signaling stimulated the production of monocyte chemoattractants (CCL2, CCL7, and CCL12), which recruited $Ly6C^{hi}$ monocytes via interactions with the chemokine receptor CCR2. Injection of recombinant IFNα directly induced the migration of $Ly6C^{hi}$ monocytes to the peritoneal cavity. In tracking studies, we found that rapid turnover of inflammatory monocytes in the inflamed peritoneum of wild-type mice was associated with a lack of differentiation into $Ly6C^{lo}$ monocytes, a more mature subset with enhanced phagocytic capacity and diminished secretion of proinflammatory cytokines. Curiously, $Ly6C^{hi}$ monocytes differentiated normally into $Ly6C^{lo}$ cells in IFN-I receptor deficient mice. The effects of IFN-I were specific for monocytes as granulocyte migration was unaffected in the absence of IFN-I signaling.

Conclusion: Our findings reveal a novel role of IFN-I in persistently recruiting inflammatory monocytes through the direct induction of chemokines that interact with monocyte CCR2. The continuous recruitment of monocytes and their inability to terminally differentiate due to the effects of IFN-I sustain the chronic inflammatory response in this model of chronic autoimmune inflammation. This mechanism may be relevant to chronic autoimmune inflammation in rheumatoid arthritis and other disorders.

IL-21R-Deficiency During Experimental Arthritis Increases Local Expression of Inflammatory Mediators, but Protects against Joint Pathology by Suppressing Th17 Cells. Marije I. Koenders[1], Renoud J. Marijnissen[1], Cheryl Nickerson-Nutter[2] and Wim B. van den Berg[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Wyeth Research, Cambridge, MA

Purpose: One of the cytokines that contributes to the formation of Th17 cells is IL-21, a pleiotropic cytokine produced by Th17 cells themselves. The purpose of this study was to investigate the effect of IL-21R-deficiency on joint pathology in relation to Th17 cells during chronic experimental arthritis.

Method: In IL-21R-/- mice, chronic SCW-arthritis was induced by intraarticular (i.a.) injections of Streptococcal Cell Wall (SCW) fragments at day 0, 7, 14, and 21.

Results: At day 28, histological analysis showed significantly reduced inflammation in IL-21R-/- mice compared to wild-types. Although IL-21R-/- mice demonstrated suppressed levels of IL-6 in the serum, this proinflammatory cytokine tended to be increased in the local patella-washouts.

This increased local activation in IL-21R-/- mice was studied in more detail in the early phase of SCW-arthritis. Before and 4 days after the first i.a. injection with SCW fragments, the expression level of various receptors and regulators was determined by QPCR. No differences were found in the expression of TLR2 and NOD2, the most import receptors for SCW. However, while the WT showed a massive upregulation of SOCS1/3 at day 4 of arthritis, IL-21R-/- mice were significantly less capable in upregulating these genes. This failure to upregulate SOCS expression in the joint might contribute to the increased local expression of inflammation and destruction markers in IL-21R-deficient mice.

Interestingly, despite the increased local activation in the IL-21R-/- mice, detailed histological analysis of the joints at day 28 of the chronic SCW-arthritis demonstrated the IL-21R-deficiency protected against cartilage proteoglycan depletion and chondrocyte death. FACS analysis of synovial cells showed a significant reduction of the percentage IL-17+ T cells. These findings were confirmed in a second model of chronic destructive arthritis, the mBSA antigen-induced arthritis (AIA). Also in this model, IL-21R-deficiency resulted in a significant reduction of joint inflammation and destruction, again in striking contrast to the local increase in cytokine expression, but accompanied by suppressed numbers of Th17 cells.

Conclusion: Despite the local suppressive role of IL-21 via SOCS, IL-21 has a more dominant prodestructive role driving Th17 cells and joint pathology during chronic experimental arthritis.

Opposing Roles for BAFF and CTLA-4 in the Development of IL-17-Producing or Foxp3+ T Regulatory (Treg) Cells. Xiaohui Zhou[1], Julie Wang[2], William Stohl[3] and Song Guo Zheng[4], [1]University of Southern California, Los Agneles, CA, [2]CA, [3]Univ Southern California, Los Angeles, CA, [4]University of Southern California, Los Angeles, CA

Purpose: Excessive Th17 cell and/or insufficient Foxp3+ Treg cell responses likely contribute to multiple autoimmune and inflammatory diseases, including RA, SLE, and psoriasis. CTLA-4 is not only a potent down-regulator of Th1 and Th2 responses but also mediates Treg activity., Its effects on Th17 responses are largely unknown. BAFF (BLyS), a potent B cell survival and differentiation factor, augments Th1 responses while suppressing Th2 responses. The effects of BAFF on the generation of Th17 and Treg cells are largely unknown.

Method: T cells were isolated from the spleen, thymus, lymph nodes (LN), blood, lungs, liver, and kidneys of congenic B6 wild-type (WT), BAFF knockout (KO), BAFF transgenic (Tg), APRIL KO, CTLA-4 KO, BAFF/CTLA-4 double KO (DKO) and BAFF KO mice in which a BAFF Tg was introduced (BAFF KO/Tg). These cells were analyzed ex vivo for intracellular IL-17, RORgt, IL-4, GATA-3, IFNg, T-bet, and Foxp3 and for surface CD3, CD4, CD8, CD25, and CCR-6. The effect of BAFF on in vitro differentiation of naïve CD4+ T cells into Th17 cells or Foxp3+ Treg cells was assessed through stimulation with anti-CD3/CD28-coated beads in the presence of IL-2 + TGF-b or IL-6 + TGF-b, respectively.

Results: In comparison to WT mice, Th1 and Th17 cells were increased in the spleens, LN, blood, lungs, liver, and kidneys of both BAFF Tg mice and CTLA-4 KO mice. Th2 cells were also increased in CTLA-4 KO mice. Conversely, Th17 cells were decreased in BAFF KO, but not APRIL KO, mice. Th17 cells in BAFF/CTLA-4 DKO mice were intermediate between BAFF KO and CTLA-4 KO mice. In vivo development of Th17 cells was restored in BAFF KO/Tg mice, suggesting soluble BAFF plays an important role in promoting Th17 cell development. Although there were no significant changes in CD4+CD25+Foxp3+ cells in the thymus, spleen and LN, in vitro generation of Foxp3+ cells was greater in cells from BAFF KO mice than in cells from WT mice. Conversely, Th17 generation in vitro was lesser in cells from BAFF KO mice than in cells from WT mice.

Conclusion: BAFF and CTLA-4 have opposing effects on Th17 cells. Moreover, absence of BAFF impedes Th17 cell generation but promotes Foxp3+ Treg cell generation. Taken together, these results suggest that manipulation of the BAFF and CTLA-4 signaling pathways may have a beneficial role in treating Th17-mediated autoimmune and/or inflammatory diseases.

Synergy Between IL-32γ and Streptococcus Pyogenes Cell Wall Fragments Results in Destructive Arthritis Which Is IL-1-Dependent. Bas Heinhuis[1], Marije I. Koenders[1], Fons A. van de Loo[1], Peter L.E.M. van Lent[1], Soo-Hyun Kim[2], Charles A. Dinarello[2], Leo A.B. Joosten[1] and Wim B. van den Berg[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Colorado Health Sciences Center, Denver, CO

Purpose: IL-32 might play an important role in the pathogenesis of RA by inducing cytokines, and chemokines. IL-32 is highly expressed in RA synovial tissue and strongly correlates with synovial inflammation, TNFα and IL-1 expression. IL-32 alone is not that potent, but it appears to enhance sensitivity of synovial cells to proinflammatory stimuli. Here, we investigated potential synergistic effects of IL-32γ with *Streptococcus pyogenes* cell wall (SCW) fragments, which contain predominantly TLR2/NOD2 ligands, in human fibroblast like synoviocytes (FLS). In addition, we explored the synergistic arthritogenicity of IL-32γ and SCW fragments in wildtype and IL-1 deficient mice.

Method: FLS from 4 arthritis patients were isolated and transduced with an adenoviral vector encoding for IL-32γ (AdIL-32γ) followed by SCW stimulation. To investigate *in vivo* synergy, we injected AdIL-32γ virus together with SCW fragments intraarticularly into knee joints of wildtype and IL-1 deficient mice.

Results: In human FLS synergistic upregulation of the proinflammatory cytokines IL-1β, IL-6, and TNFα was found and similar observation was made for the chemokines CCL2, CCL20, and CXCL8. Of great importance, we also identified synergistic upregulation of matrix degrading enzymes, including MMP1 and MMP3, linking the IL-32 synergy to erosive processes. Part of the synergy may be related to the marked increase of the pattern recognition receptors TLR2 and NOD2. In wildtype mice we observed a prolonged and severe arthritis injected with AdIL-32γ/SCW compared to AdControl/SCW. Furthermore, histological analysis showed apart from enhanced numbers of inflammatory cells, severe cartilage proteoglycan depletion, and irreversible chondrocyte death in mice exposed to IL-32γ and TLR2/NOD2 ligands. Remarkably, IL-1 deficient mice injected with AdIL-32γ/SCW were completely protected against the destructive arthritis observed in wildtype mice.

Conclusion: The observed synergistic effect between IL-32γ and TLR2/NOD2 ligands identifies an important amplifying pathway in the development of destructive arthritis which is IL-1 dependent. Both IL-32γ and TLR2/NOD2 are potential novel therapeutic targets in RA.

Pathogenic Role of IL-17 in Atherogenesis: A Cross Link Between Rheumatoid Arthritis and Atherosclerosis. Arnaud Hot, Vanina Lenief, Marie-Angélique Cazalis and Pierre Miossec, Research Unit Immunogenomics and Inflammation, Hôpital Edouard Herriot, Lyon I university, Lyon, France

Purpose: Cardiovascular events remain the leading cause of death in Rheumatoid Arthritis (RA). RA and atherosclerosis share common pathway and cytokines involved in RA could play a role in atherogenesis. To better understand the mechanisms involved in atherogenesis during the course of RA, we investigated if IL-17, now seen as a key player in RA, had an effect in endothelial dysfunction, a critical step of atherosclerosis.

Method: Primary endothelial cells (EC) were treated with IL-17 (100ng/ml) alone or combined to TNF-α (1ng/ml). mRNA expression was quantified by qRT PCR and by Affymetrix microarrays HG133 A+2. The role of IL-17 was assessed using functional assays. EC migration and invasion was evaluated using a chemoinvasion assay through BM Matrigel in Boyden chambers. The ability of IL-17 to promote thrombosis through platelet aggregation was evaluated using Platelet rich Plasma (PRP). Hundred microliters of supernatant from IL-17, TNF-α or both -treated EC were added to 1 mL of PRP and platelet aggregation was measured with a Lumi-Aggregometer. Coagulation activation was assessed by the expression of tissue factor and plasminogen activator.

Results: IL-17 alone induced pro-inflammatory changes in EC, inducing changes of 248 genes. A clear synergistic effect was seen with TNF-α and their combination enhanced the expression of 9803 genes. Among the critical genes induced, IL-17 plus TNF-α induced synergistically the expression of chemokine genes such as CCL20, IL-8 and cytokine genes such as IL-6 and IL-15. In contrast, IL-17 decreased the expression of genes involved in the regulation of inflammation such as IL-4-Receptor and IL-33. Regarding invasion, IL-17 alone induced the expression of genes of metalloproteases such as MMP2 and MMP 9, known to be involved in atherosclerosis. The effect of

IL-17 was tested in a chemo invasion assay with the use of Matrigel as a matrix to study not only cell motility, but also their ability to cross tissue barriers. IL-17 not only induced migration, but also induced the same level of EC invasion that induced by TNF-α alone. Furthermore, treatment with the combination of IL-17 with TNF-α resulted in a 5-fold increase in invasive activity. IL-17 inhibited the endothelial CD39/ATPDase expression, which is critical in the inhibition of platelet activation by keeping adenosine nucleotide levels low. Indeed, CD39 mRNA expression was reduced in IL-17 treated EC. Supernatants of IL-17-treated EC induced a strong platelet aggregation (61.25±1.25%), as for TNF-α treated EC (58, 5% ±1.2%). Finally, IL-17 was able to enhance the expression of genes critical for coagulation such as tissue factor and plasminogen activator, leading to a thrombotic state.

Conclusion: Our data show the effects of IL-17 on EC. IL-17 induced a pro-inflammatory phenotype in EC and enhanced their migration, with extra cellular matrix destruction. Finally, IL-17 induced a prothrombotic phenotype.

Lupus Susceptible Gene Polymorphisms in Patients with Antiphospholipid Syndrome. Tetsuya Horita, Hisako Nakagawa, Kenji Oku, Hiroshi Kataoka, Shinsuke Yasuda, Tatsuya Atsumi and Takao Koike, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: Genetic factors are hypothesized to play a role in the susceptibility to antiphospholipid syndrome (APS) based on several family studies. However, genetic background of APS is not well known. APS can occur alone (primary APS) or in conjunction with systemic lupus erythematosus (SLE). Therefore, APS and SLE may, in part, share a common mechanism for disease onset or progression. Recent genome wide association studies in patients with SLE in Caucasian population revealed several novel lupus susceptible genes in addition to previously reported genes such as human leukocyte antigen (HLA), interferon regulatory factor 5 (IRF5), signal transducer and activator of transcription 4 (STAT4) and so forth. In this study, we investigated the possible association between novel lupus susceptible gene polymorphisms and APS in Japanese population.

Method: We enrolled 341 SLE patients, 90 APS patients (41 primary APS and 49 secondary APS complicated with SLE), and 428 ethnically matched healthy controls. Written informed consent was obtained from each participant. All the SLE patients fulfilled the American College of Rheumatology classification criteria for SLE and all the APS patients fulfilled the Sydney-revised Sapporo criteria for APS. Genomic DNA samples were extracted from peripheral blood. Single nucleotide polymorphisms (SNPs) of B-cell scaffold protein with ankyrin repeats 1 (BANK1), B lymphocyte specific tyrosine kinase (BLK), Phox homology domain containing serine/threonine kinase (PXK), tumor necrosis factor alpha induced protein 3 (TNFAIP3), tumor necrosis factor ligand superfamily member 4 (TNFSF4) and rs10798269 in 1q25.1 region were genotyped using TaqMan Genotyping Assay kit. Allele frequencies in each group were compared using chi-square test and the related risk was approximated by the odds ratios.

Results: The allele frequencies of each SNP in SLE and APS groups were presented in the Table. BANK1 (rs10516487), BLK (13277113) and rs10798269 in 1q25.1 region were associated with not only SLE but also APS in Japanese population. TNFSF4 (rs844644) association were found only in APS population whereas TNFAIP3 (rs2230926) association was found only in SLE. PXK (rs6445975) was associated with neither SLE nor APS in Japanese population.

Conclusion: Our results suggest that APS and SLE, in part, share a common genetic background.

Table. Allele frequencies of novel lupus susceptible gene polymorphisms in Japanese SLE and APS patients

Gene	SNP ID	disease	risk allele frequency		OR	95%CI	p value
			case	control

Up-Regulated Expression of Phospholipid Scramblase 1 On Monocytes in Patients with Antiphospholipid Syndrome. Olga Amengual, Tatsuya Atsumi, Eriko Suzuki, Kenji Oku, Toko Hashimoto, Masaru Kato, Kotaro Otomo, Yuichiro Fujieda, Hiroshi Kataoka, Tetsuya Horita, Shinsuke Yasuda and Takao Koike, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Purpose: It is worldwide accepted that the interaction between phospholipid (PL)-binding proteins and antiphospholipid antibodies (aPL) triggers tissue factor expression, leading to thrombotic events in patients with antiphospholipid syndrome (APS), but the precise mechanisms underlying thrombosis in APS are not yet clarified. Normal circulating cells show an asymmetric distribution of PL in the membranes with amino-PL, such as phosphatidylserine (PS), restricted to the cytoplasmic leaflets. Externalization of PS occurs in activated cells and is crucial for the activation of the coagulation cascade, as PS serves as an assembly site for coagulation factors. Moreover, PS exposure is essential for the binding of PL-binding protein-aPL complexes to pro-coagulant cells, favoring aPL-mediated cell activation and thrombosis. One of the key molecules involved in the regulation of PS externalization is phospholipid scramblase 1 (PLSCR1) which catalyzes rapid transbilayer movement of PL between membrane leaflets. PLSCR1 was reported to be up-regulated by interferon alpha, but its role in APS pathogenesis is unknown. In this study, we examined the expression of PLSCR1 on pro-coagulant cells in patients with APS.

Method: The study includes 40 patients with APS (35 women, mean age 50 yrs, [range 26-76 yrs]). 17 patients had primary APS and 23 were diagnosis as having systemic lupus erythematosus (SLE). Forty-three healthy individuals were included as a control group. Heparinized venous blood was collected from all the subjects. PBMC were isolated and monocytes purified using CD14 micro beads (Miltenyi Biotec). Total RNA was isolated and reverse- transcribed using SuperScript™ First-Strand Synthesis System (Invitrogen). Quantitative Real-Time PCR was performed using gene-specific PLSCR1 Taq Man MGB Probe and the ABI PRISM 7000 Sequence Detection System. PS exposure on monocyte surface was evaluated by flow-cytometry using the Annexin-V Fluos labeling kit (Roche).

Results: Monocytes from APS patients had higher levels of PLSCR1 mRNA expression than those from healthy controls (mean ± SD; 2.4 ± 1.2 vs. 1.3 ± 0.4, $p < 0.00001$). Levels of PLSCR1 mRNA were significantly elevated in both group of APS patients compared to controls (2.2 ± 0.9, 2.6 ± 1.4, $p= 0.001$, $p= 0.0003$, primary APS and APS/SLE, respectively). However, the increased PS expression in patients with APS was minor compared to controls (20.6 ± 8.2 vs. 17.8 ± 5.8).

Conclusion: Patients with APS have enhanced expression of PLSCR1 on monocytes. Even though the presence of PS on monocytes may be related not only to PLSCR1 expression but to several mechanisms, the up-regulation of PLSCR1 expression in APS might represent a contributing factor in the hypercoagulability in APS.

2047

Interaction Between Nicked β2-Glycoprotein I and Angiostatin 4.5: Novel Role of Nicked β2-Glycoprotein I in Angiogenesis *in Vitro* and *In Vivo*. Hisako Nakagawa[1], Shinsuke Yasuda[1], Eiji Matsuura[2], Kazuko Kobayashi[2], Masahiro Ieko[3], Hiroshi Kataoka[1], Tetsuya Horita[1], Tatsuya Atsumi[1] and Takao Koike[1], [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Okayama University Graduate School of Medicine, Denstry, and Pharmaceutical Sciences, Okayama, Japan, [3]School of Dentistry, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Japan

Purpose: β2-glycoprotein I (β2GPI) is a major target of pathogenic antiphospholipid antibodies detected in patients with antiphospholipid syndrome. β2GPI is proteolytically cleaved by plasmin in its domain V (nicked β2GPI), which results in binding to plasminogen Kringle 5 via cleaved domain V of β2GPI. Recently, anti-angiogenic properties have been reported in nicked β2GPI as well as in intact β2GPI at relatively high concentrations. Angiostatin was first discovered as a plasminogen fragment with anti-tumor/anti-angiogenic property. Although several isoforms have been known, angiostatin 4.5 (AS4.5) that consists of kringle 1-4 and ~ 85% of kringle 5, is produced by autoproteolysis and is present in human plasma. In the present study, we intended to clarify the interaction between nicked β2GPI and AS4.5 and its property in angiogenesis.

Method: Binding between nicked β2GPI and AS4.5 was tested using BIACORE X. Proliferations of human aortic endothelial cells (HAECs) and human umbilical venous cells (HUVECs) ware evaluated using formazan assay in the presence or absence of 50 nM of AS4.5 and various concentrations of intact/nicked β2GPI. Matrigel-invasion assay and tube-formation assay were done using HUVECs. Finally, *in vivo* angiogenesis assay using directed *in vivo* angiogenesis assay was performed using athymic nude mice. In this assay, semi-closed plugs fulfilled with extracellular matrices including various combinations of AS4.5 (0.2 μM) and nicked β2GPI were inserted subcutaneously and blood vessels formed into these plugs were evaluated and quantified after 11 days.

Results: Significant binding of nicked β2GPI to AS4.5 ($K_D = 3.27 \times 10^6 M^{-1}$) was observed. At concentrations from 0.1 to .04 μM, nicked β2GPI attenuates the anti-angiogenic functions of AS4.5 in the proliferation of HAECs/HUVECs, in the extracellular matrix invasion and the tube-formation of HUVECs, and in our *in vivo* angiogenesis assay. In contrast, intact β2GPI neither binds to AS4.5 nor inhibits its anti-angiogenic activity. At higher concentrations (1-4 μM), both intact and nicked β2GPI inhibited angiogenesis in Matrigel-invasion assay and tube-formation assay.

Conclusion: Nicked β2GPI exerts dual effects on angiogenesis, i.e., nicked β2GPI promotes angiogenesis in the presence of AS4.5, whereas nicked β2GPI inhibits angiogenesis at concentrations high enough to neutralize AS4.5. Once thrombus is formed in a blood vessel, collateral blood flow needs to be generated. At sites of thrombus, both nicked β2GPI and AS4.5 become abundant by fibrinolysis. Plasmin-nicked β2GPI is likely to up-regulate angiogenesis by interacting with AS4.5 at sites of thrombosis.

2048

Autoantibodies to Heat Shock Protein 60 Are Associated with Arterial Vascular Events in Patients with Anti-Phospholipid Antibodies. Mélanie Dieudé[1], José A. Correa[1], Carolyn Neville[1], Christian A. Pineau[1], Jerrold S. Levine[2], Rebecca Subang[1], C. Landolt-Marticorena[3], Jiandong Su[3], Jeannine Kassis[4], Susan Solymoss[1], Paul. R. Fortin[3] and Joyce Rauch[1], [1]McGill University, Montreal, QC, [2]University of Illinois at Chicago, Chicago, IL, [3]University of Toronto, Toronto, ON, [4]Université de Montréal, Montreal, QC

Purpose: Anti-heat shock protein 60 autoantibodies (anti-HSP60) are associated with coronary artery disease and atherosclerosis, and are known to affect endothelial cells *in vitro*. However, their association with other vascular events (VE) remains unclear. We have recently shown that anti-HSP60 promote thrombosis in a murine model of arterial injury. Based on these findings, we hypothesized that the presence of anti-HSP60 autoantibodies, alone or in combination with other thrombogenic risk factors (e.g., anti-phospholipid antibodies [aPL]), would be associated with an elevated risk of VE.

Method: The study population was derived from the databases of three ongoing cohort studies: two systemic lupus erythematosus (SLE) registries and one cohort of individuals with aPL. Only individuals with aPL testing performed on at least two occasions were included. aPL positivity was defined as: anti-cardiolipin (aCL) IgG/IgM >40 APL units, and/or lupus anticoagulant (LA) positive, and/or anti-β2-glycoprotein I (aβ2GPI) IgG/IgM positive, each on ≥ 2 occasions ≥ 12 weeks apart. Data from a total of 406 participants was captured and four groups were identified: (1) aPL-positive with VE (n=85); (2) aPL-positive without VE (n=83); (3) aPL-negative with VE (n=119); and (4) aPL-negative without VE (n=119). Arterial VE (VE-A) (n=123) or venous VE (VE-V]) (n=97) were confirmed from medical records. Serum anti-HSP60 were determined by enzyme-linked immunoassay and values exceeding the 75th percentile of the healthy controls (n=25) were considered to be high-titer positive. Clinical and demographic variables captured included age, race, gender, family history of cardiovascular disease, smoking, SLE, hypertension, and diabetes mellitus.

Results: Multivariate analyses revealed that total VE were associated solely with age or hypertension. However, analysis of the VE according to their origin showed an association of VE-A, but not VE-V, with anti-HSP60 (OR=2.326 [95% CI=1.157-4.673]). Furthermore, the concomitant presence of aPL with anti-HSP60 increased the risk of VE-A (OR=6.19 [95% CI=2.02-18.91]), but not VE-V (OR=1.09 [95% CI=0.36-3.28]). Finally, the presence of individual aPL (i.e., aCL, LA, or aβ2GPI) with anti-HSP60 also increased the risk of VE-A, with the strongest association observed for aCL (OR=8.67 [95%CI=1.97-38.08]).

Conclusion: Our results demonstrate that anti-HSP60 are associated with VE-A, and that the concomitant presence of aPL (particularly aCL) with anti-HSP60 further enhances the risk of these events.

ß2 Glycoprotein I (ß2GPI) Binds Platelet Factor 4 (PF4): Implications for the Pathogenesis of Antiphospholipid Syndrome. MP Sikara[1], J G. Routsias[2], M. Samiotaki[3], G. Panayotou[3], HM Moutsopoulos[1] and P G. Vlachoyiannopoulos[2], [1]School of Medicine,National University of Athens, Athens, Greece, [2]School of Medicine, National University of Athens, Athens, Greece, [3]Al. Fleming, Greece

Purpose: Antiphospholipid syndrome (APS) is an autoimmune thrombophilia. It has been suggested that antiβ2GPI antibodies, in the presence of β2GPI, activate platelets. This study aims to reveal platelet proteins that can act as receptors of β2GPI.

Method: Platelets from 3 healthy donors and 7 APS patient were isolated and membrane proteins were extracted. Affinity chromatography using CNBr-Sepharose-β2GPI was performed and captured proteins from different platelet preparations were analyzed with Mass Spectrometry. Since PF4 appeared as the dominant protein bound to β2GPI-affinity column, in vitro and in silico methods were used. The interaction between β2GPI and PF4 was defined using saturation binding assays. The specificity of the interaction was confirmed with homologous inhibition assay and co-precipitation study. The antigenicity of β2GPI-PF4 complex was examined using a modified anti-β2GPI ELISA.

In silico docking was evaluated using the crystal structures of β2GPI and PF4 tetramer. Finally, the activation of platelets, induced by anti-β2GPI-β2GPI-PF4 complexes, was examined by the production of thromboxane A2 (TXB2).

Results: β2GPI-coupled to CNBr-Sepharose selectively binds PF4 from all the platelet protein extracts; in patients' membrane protein extracts (n=7), PF4 was the only protein bound to β2GPI, while in healthy controls' extracts (n=3) several non specific cytoskeletal proteins along with PF4 were bound. Saturation binding assays revealed that PF4 directly binds to β2GPI, in a dose dependent manner with a KD of 105.3±9.8nM, and this binding was abrogated up to 80% in the inhibition experiments.

Docking simulations revealed that positively charged surface of PF4 tetramer interacts with negatively charged regions in domains III – V of β2GPI. Hydrogen bonds were also formed. PF4 tetramer tends to bind 2 β2GPI molecules, leading to the dimerization of the latter. Our

attempt to study the β2GPI-PF4 antigenicity showed that the reactivity of APS sera was higher against PF4-β2GPI complex, than against β2GPI alone. APS patients' sera recognized PF4-β2GPI with a mean of OD increase ~32%, comparing to β2GPI alone ($p<0.0001$).

Finally, platelets exposed to immobilized anti-β2GPI+β2GPI+PF4, display significantly more TXB2 metabolite production (6.6 ± 1.45 pg/μl,) compared to platelets exposed either to anti-β2GPI+BSA+PF4 (0.9±0.16pg/μl) or to isotype control+β2GPI+PF4 (0.87±0.20pg/μl) ($p<0.005$). This demonstrates that antiβ2GPI-β2GPI-PF4 complex exhibits the optimum condition for platelet activation.

Conclusion: This study demonstrates the binding of β2GPI with PF4, both in solid phase and in solution, as well as the *in vitro* sensitization of platelets by anti- β2GPI-β2GPI-PF4. A potential interaction in vivo between PF4 and β2GPI leading to the dimerization of the latter, could mediate platelet activation in the APS.

2050

A C5a Receptor Antagonist Ameliorates In Vivo Effects of Antiphospholipid Antibodies. Ana Laura Carrera-Marin[1], Zurina Romay-Penabad[1], HongChang Qu[2], Elizabeth Papalardo[1], John Lambris[2], Elba Reyes-Maldonado[3], Ethel Garcia-Latorre[4] and Silvia S. Pierangeli[1], [1]University of Texas Medical Branch, Galveston, TX, [2]Univeristy of Pennsylvania, Philadelphia, PA, [3]Instituto Politecnico Nacional/ ENCB, Mexico D.F., Mexico, [4]Instituto Politecnico Nacional, Mexico D.F., Mexico

Purpose: Studies in mouse models have shown involvement of C3 and C5 on antiphospholipid (aPL)-mediated thrombosis and endothelial cell (EC) activation. It has been proposed that in addition to their direct effects on target cells, aPL antibodies may further enhance endothelial cell activation and a pro-infllammatory/procoagulant state [upregulation of tissue factor (TF)] by activation of complement and interaction of complement split products (i.e. C3a and C5a), with specific receptors on the cell surface. The aim of this study was to examine the effects of a specific C5a receptor antagonist peptide (C5aR-AP) on aPL-mediated thrombosis and upregulation of TF in vivo.

Method: C57BL/6J mice were injected i.p. twice with 500 μg of IgG isolated from a patient with Antiphospholipid Syndrome (APS) or with control IgG (IgG-NHS) preceded by i.p. injection of 25 μg of C5aR-AP (Ac-Phe-c[Orn-Pro-DCha-Trp-Arg] or control peptide (CP) (Ac-Phe-c[ORn-Pro-DCha-Ala-DARg]). Seventy-two hours after the first injection, the size of an induced thrombus was measured in the treated and control mice. TF activity in pM/mg/ml protein was determined in carotid artery homogenates and in lysates of peritoneal macrophages. Anticardiolipin (aCL) and anti-β2glycoprotein (anti-β2GPI) activity was determined by ELISA in the sera of the animals.

Results:

Treatment	Thrombus size (μm^2)	TF carotid (pM/mg/ml)	TF Macrophages (pM/mg/ml)	aCL (GPL)	anti-β_2GPI (SGU)
IgG-APS + CP	3236.0 ± 1729.8	69.3 ±13.8	16.6 ± 3.0	57.8 ± 29.7	57.9 ±16.1
IgG-APS + C5aR-AP	802.8 ± 271.2	33.8 ± 4.1	6.7 ± 2.1	51.2 ± 8.7	61.0 ± 27.3
IgG-NHS + CP	604.7 ± 94.0	39.1 ± 5.0	11.0 ± 1.0	1.2 ± 0.19	4.9 ± 0.3
IgG-NHS + C5aR-AP	623.2 ± 117.4	25.3 ± 8.2	7.2 ± 1.1	0.9 ± 0.1	5.1 ± 0.6

Treatment of the mice with IgG-APS + CP induced significantly larger thrombi, TF in carotids and macrophages when compared to IgG-NHS + CP treated mice (p values=0.027, 0.045, 0.063, respectively). Mice treated with IgG-APS and C5aR-AP had significantly smaller

thrombi and lower TF activity in carotid arteries and macrophages when compared to IgG-APS + CP-injected animals (p values= 0.034,0.036,0.045, respectively).

Conclusion: The data provide relevant information on the involvement of complement activation in aPL-mediated pathogenic effects and underscore the possibility of utilizing complement inhibitors to ameliorate APS clinical manifestations.

ACR Concurrent Abstract Sessions

Pediatric Rheumatology - Advances in Therapy

Wednesday, October 21, 2009, 11:00 AM - 12:30 PM

2051

Aggressive Combination Drug Therapy in Very Early Polyarticular Juvenile Idiopathic Arthritis (A-CUTE-JIA): A Multicenter Randomized Clinical Trial. Pirjo Tynjälä[1], Paula Vähäsalo[2], Maarit Tarkiainen[1], Kristiina Aalto[1], Liisa Kröger[3], Merja Malin[4], Anne Putto-Laurila[5], Visa Honkanen[6] and Pekka Lahdenne[1], [1]Helsinki University Central Hospital, Helsinki, Finland, [2]Oulu University Hospital, [3]Kuopio University Hospital, [4]Tampere University Hospital, [5]Turku University Hospital, [6]Rheumatism Foundation Hospital, Heinola

Purpose: We compared the efficacy of two combination treatment strategies, methotrexate with infliximab (TNF) and synthetic DMARD combination therapy with methotrexate, sulfasalazine and hydroxychloroquine (COMBO) on methotrexate alone (MTX) in early polyarticular juvenile idiopathic arthritis (JIA). The protocol did not include the use of systemic steroids.

Methods: We performed multicenter randomized clinical trial in 60 patients with polyarticular JIA aged 4-16 years with the duration of JIA less than 6 months. Primary endpoint was American College of Rheumatology Pediatric (ACR Pedi) 75 response at 54 weeks. Secondary endpoints included inactive disease at 54 weeks and the time spent in the state of an inactive disease. Outcome was illustrated by Kaplan-Meier analysis and comparison of therapies was performed by Mantel-Cox test, or Kruskall-Wallis and Dunn's test.

Results: Of the 60 patients, 59 completed the trial (64% females). Twenty-two (37%) had ANA, 13 (22%) were HLA-B27 positive, and one (2%) RF positive. At baseline their mean (± SE) duration of JIA was 0.10 ± 0.02 years, age 9.6 ± 0.4 years, ESR 36 ± 4 mm/hr, active joints 18 ± 1, physician's global 55 ± 2 mm, and CHAQ 0.763 ± 0.082.

Primary endpoint: 42 patients (71%) had ACR Pedi 75 response; 19 (100%) receiving TNF, 13 (65%) COMBO and 10 (50%) MTX ($p<0.0001$). The difference was significant between TNF and MTX ($p<0.0001$), and TNF and COMBO ($p=0.0005$), but not between COMBO and MTX.

Secondary endpoint: At 54 weeks, 13 patients (68%) receiving TNF, 8 (40%) receiving COMBO and 5 (25%) receiving MTX ($p=0.002$) had inactive state of the disease. Those on TNF reached inactive disease more often than those on MTX ($p=0.02$), but the response between COMBO and TNF ($p=0.050$), or COMBO and MTX ($p=0.220$) was not significant. During the 54-week follow-up, those on TNF spent a mean of 26 weeks (95% CI 18-34) in inactive state of disease. This was longer than those on COMBO (13 weeks, 95% CI 6-20; $p=0.044$ compared with TNF), or those on MTX (6 weeks, 95% CI 2-10; $p=0.001$ compared with TNF), but the difference between COMBO and MTX was not statistically significant.

Conclusion: When the target was ACR Pedi 75 response within the first year of therapy in early polyarticular JIA, infliximab plus methotrexate turned out to be superior to synthetic DMARD combination, and even more clearly, superior to MTX monotherapy.

2052

Abatacept IN Refractory ANTI-TNF Resistant Juvenile Idiopathic ARTHRITIS-RELATED Uveitis. Francesco Zulian[1], Marta Balzarin[1], F. Falcini[2], Ginevra Fiori[3], Maria Alessio[4], Rolando Cimaz[5] and Maria Elisabetta Zannin[1], [1]University of Padua, Padua, Italy, [2]Italy, Italy, Italy, [3]University of Florence, Italy, Florence, Italy, [4]Dpt of Pediatrics, Rheumatology Unit, University of Naples Federico II, Naples, Italy, [5]University of Florence and Anna Meyer Children's Hospital, Florence, Italy, Florence, Italy

Purpose: Anterior uveitis is a serious complication of Juvenile Idiopathic Arthritis (JIA) with the potential for significant ocular damage and eventually blindness. Recently, Abatacept, a selective T-cell co-stimulation modulator, has been used in children with JIA who had failed previous treatments, including anti-TNF agents.

We report the short-term results on safety and efficacy of Abatacept in a cohort of patients with severe JIA-related uveitis refractory or intolerant to other anti-TNF agents.

Method: Patients with JIA-related uveitis refractory to previous immunosuppressive treatments (MTX, CyA, MMF) and to anti-TNF agents, Infliximab (IFX) and Adalimumab (ADM), have been treated with Abatacept (ABT) at a monthly dosage of 10 mg/kg (up to 750 mg), administered intravenously. Uveitis course and side effects have been carefully monitored. Absolute frequencies of flares before and after ABT treatment and/or new ocular complications have been reported.

Results: Six patients (5 female, 1 male), aged 9-24 years, have been treated, with a mean follow-up of 7.2 months (range: 6-9 months). The mean uveitis duration, at the beginning of Abatacept treatment, was 11 years (range: 3-17 years). All patients failed previous immunosuppressive (MTX, CyA, MMF) and anti-TNF agents (Infliximab and Adalimumab) treatment. Two patients shifted from IFX to ABT for systemic reactions. Four patients shifted from IFX and ADM for inefficacy. No side effects were reported in all but one patient, who developed serious oral mucous reaction after 3 months of treatment. The mean frequency of uveitis flares went down from 3.3 (range: 2-5) during the six months before ABT to 0.6 (range: 0-2) post ABT. At the end of the follow-up no new ocular complications appeared and the pre-existing ones remained stable in all patients.

Conclusion: Abatacept induced a rapid and sustained improvement of refractory JIA-related uveitis and was well tolerated in 5/6 patients. Abatacept represents a treatment of choice for patients failing both immunosuppressive and anti-TNF agents and a possible candidate for the early treatment of severe course JIA-related uveitis.

2053

Long-Term Safety and Efficacy of Rilonacept in Patients with Systemic Juvenile Idiopathic Arthritis (SJIA). Daniel J. Lovell[1], Edward H. Giannini[1], Yukiko Kimura[2], Suzanne C. Li[2], Philip J. Hashkes[3], Andreas O. Reiff[4], Carol A. Wallace[5], Karen Onel[6], Dirk Foell[7], Douglas R. Nadler[8], Stephanie Biedermann[8], Jennifer D. Hamilton[8] and Allen R. Radin[8], [1]Children's Hospital Medical Center, Cincinnati, OH, [2]Hackensack Univ Medical Ctr, Hackensack, NJ, [3]Cleveland Clinic, Cleveland, OH, [4]Childrens Hosp LA MS60, Los Angeles, CA, [5]Seattle Children's Hospital, Seattle, WA, [6]Univ of Chicago, Chicago, IL, [7]University of Muenster, Muenster, Germany, [8]Regeneron Pharmaceuticals, Inc., Tarrytown

Purpose: To obtain long-term data following a double-blind (DB) placebo (PBO)-controlled study of rilonacept, a long-acting soluble receptor-based IL-1 blocker, in patients with active SJIA during an open label (OL) 24 month extension phase.

Methods: 23 subjects aged, 5-20 yrs old with a mean disease duration of 3.1 yrs, with both active articular and systemic features, were randomized to receive once weekly 2.2 mg/kg (max. 160 mg), 4.4 mg/kg (max. 320 mg) rilonacept or PBO SC for 4 wks in the DB phase. After 4 wks in the DB or a min. of 2 wks, if rescue in DB was clinically warranted, rilonacept and PBO treated patients were eligible to receive OL treatment at their DB cohort allocated dose. Patients receiving the 2.2 mg/kg dose could escalate after a min. of 4 wks in the OL to the 4.4 mg/kg dose at the investigator's judgment. Data from the OL are presented for all 23 pts.

Results:

Variables	Baseline	6 Months (n = 19)	12 Months (n = 21)	24 Months (n = 12)

	(n = 23)

* Median % change

Improvement in median scores was seen in all 6 ACR Pedi core variables upon OL treatment. At 6 mos, OL ACR Pedi 30/50/70 responses were seen in 87%/78%/61%, respectively and at 24 mos, were seen in 70%/70%/57%, respectively. Fever and/or rash observed in all pts at baseline completely resolved. WBC, platelet, Hb and fibrinogen improved substantially. D-dimer and MRP 8/14 were dramatically reduced; elevated CRP was nearly normalized. By 24 mos, steroids were able to be stopped in all pts. Three patients were reported with a total of 6 SAEs including MAS (2), pulmonary fibrosis (1), anemia (1) and arthritis flare (2). AEs were ISRs (30%) and URIs (22%). No deaths, malignancies, or serious infections occurred. Withdrawals were due to AEs and L.O.E.

Conclusion: In this long-term OL extension study sustained responses were observed in clinical and laboratory assessments in over 50% of patients with SJIA at 2 years. There was a significant reduction in daily prednisone dose. Chronic IL-1 blockade was generally safe and well-tolerated.

2054

Drug-Free Remission of Patients with Systemic Juvenile Idiopathic Arthritis Receiving Tocilizumab for Treatment. Shumpei Yokota[1], Takuma Hara[1], Masako Kikuchi[2], Takayuki Kishi[2], Ryoki Hara[1], Rumiko Kurosawa, Remi Ozawa[2], Takako Miyamae[1], Tomoyuki Imagawa[1] and Masaaki Mori[1], [1]Yokohama City University, Yokohama, Japan, [2]Yokohama City University Hospital, Yokohama, Japan

Purpose: In patients with systemic juvenile idiopathic arthritis (sJIA) who received long-term treatment with tocilizumab, the possibility of complete withdrawal from drug therapy was studied.

Method: Among 67 patients with sJIA, 11 participating in a phase II study of tocilizumab and 56 participating in a phase III study, 24 patients, who had been monitored at our hospital for 3 year or longer, were analyzed. Of the 24 patients, those who maintained remission and were successfully withdrawn from steroid therapy, and whose interleukin-6 (IL-6) level continued to be at low levels for 1 year or longer were identified to study the possibility of complete withdrawal from drug therapy by discontinuing tocilizumab.

Results: The age of the 24 patients was 2 to 18 years, and 10 of these were boys. The follow-up period was 3.2 to 6.2 years, the duration of sJIA was 0.4 to 8.2 years. The IL-6 level was 0.4 to 102 pg/mL, the CRP level was 0.3 to 29 mg/dL, and the steroid dose administered was 3.8 to 40 mg/body. Among the 24 patients, 8 were successfully withdrawn from tocilizumab during the follow-up period. In these 8 patients, the age was 3 to 10 years, and 4 of these were boys. The duration of sJIA was 0.5 to 8.2 years, the IL-6 level was 1.7 to 96 pg/mL, the CRP level was 0.3 to 15 mg/dL and the steroid dose administered was 3.8 to 30 mg/body. These 8 patients discontinued treatment with tocilizumab 2.6 to 4.9 years after the initiation of treatment. Two of them maintained withdrawal from tocilizumab for 3 years or longer, without recurrence, while the remaining 6 patients resumed treatment with tocilizumab due to recurrent symptoms. The period from discontinuation to resumption of treatment with tocilizumab in the 6 patients was 46 to 571 days. At recurrence, 1 patient resumed both steroid and tocilizumab, but the other 5 patients resumed only tocilizumab and succeeded in achieving ACR pedi 90 within 7 to 66 days. During the tocilizumab-free period, 22 adverse events including upper respiratory tract infection occurred in 8 patients. Most of these were mild in severity and resolved without medical intervention. However, in 2 patients upper respiratory infection was suspected to lead the recurrence of sJIA.

Conclusion: Long-term withdrawal from drug therapy was successful in some patients receiving tocilizumab for 3 years or longer and maintaining remission. In addition, the recurrent symptoms could be controlled properly by the resumption of treatment with tocilizumab in such patients. Further studies to monitor patients who fail to achieve remission and cannot be free from drug therapy despite long-term medication are needed.

2055

Evaluation of Safety and Preliminary Efficacy of Canakinumab (ACZ885), A New IL-1-Beta Blocking Monoclonal Antibody, in Children with Systemic Juvenile Idiopathic Arthritis (sJIA). N. Ruperto[1], P. Quartier[2], N. Wulffraat[3], P. Woo[4], A. Loy[1], R. Mouy[2], B. Bader-Meunier[2], B. Prakken[3], E. Noseda[5], R. Belleli[5], J. Lecot[5], C. Rordorf[5] and A. Martini for PRINTO[1], [1]Pediatria-II PRINTO, IRCCS G.Gaslini, Genova, Italy, [2]Hopital Necker-Enfants Malades, Paris, France, [3]University Medical Center, Utrecht, Netherlands, [4]Pediatric & Adolescent Rheumatology, London, United Kingdom, [5]Novartis, Basel, Switzerland

Purpose: Canakinumab provides potent, rapid, and sustained blockade of IL-1β. Here we report interim results of a Phase II dose-range finding study including efficacy, safety and tolerability in sJIA patients.

Method: This was an open-label, staggered dose-escalation study. Patients received a single canakinumab sc injection (dose range 0.5–9 mg/kg), followed by an observation period and re-dosing upon relapse. Response was measured using adapted ACR ped criteria (ACR ped criteria+absence of fever). Relapse: reappearance of fever and/or systemic manifestations of disease with elevated CRP or as per ACR ped criteria for flare.

Results: 23 children (4–19 y) with active disease were enrolled (median baseline physician's and parent/patient's global assessment of disease activity–68.5 and 67.0 mm [VAS], respectively; CHAQ disability index–2.1; number of joints with active arthritis–20.6; number of joints with limitation of motion–23.7; CRP–136 mg/L; median prednisone equivalent dose–0.33 mg/kg [n=18]. 13/22 (59%) patients responded to canakinumab, all these achieved ACRped50 or better at Day 15. In 4 cases (18%) inactive disease status was reached. In 1 patient, responder status was not evaluated due to bolus steroids injections to treat an SAE. 17/23 patients were previously treated with anakinra. 6/11 anakinra non-responders achieved at least ACR50 at Day 15 after a single dose of canakinumab (4 ACR50, 2 ACR70). The best baseline parameter to predict response was the number of active joints (median: 33.5: non-responders, 9: responders). All responders could be correctly identified with 100% sensitivity and 70% specificity using 26 joint counts. The observed time to relapse varied from 1–12 weeks. Median time to relapse was 56 (95% CI: 32–100), 60 (38–95) and 90 (45–181) days for doses <3, 3, >3 mg/kg, with a 19 (95% CI: 6–41), 17 (6–34) and 7% (1–23) probability of relapse in 1 month, respectively. Steroid was tapered in 70% of responders, in 10/13 patients on steroids at baseline. On average steroid dose was decreased by 0.054 mg/kg (95% CI: 0.013–0.121) per month in the first 5 months. 1 patient completely discontinued steroids at end of month 5. Injections were well tolerated, no anti-canakinumab antibodies were detected. Adverse events (AEs) based on the 18 months interim analysis were mild–moderate in severity and mainly infections and gastrointestinal disorders. 3 patients experienced drug related serious AEs (resolved during treatment). No patients discontinued due to AEs.

Conclusion: Canakinumab provides rapid improvement of signs and symptoms in sJIA patients with efficacy in more than 50% of anakinra non-responders and allows steroid reduction in the majority of responders. Canakinumab was well tolerated.

2056

Safety and Efficacy of Canakinumab (Ilaris) in Children Across Different Disease Severity Phenotypes of Cryopyrin Associated Periodic Syndrome (CAPS): Interim Results of An Ongoing Study. J.B. Kuemmerle Deschner[1], R. Cartwright[2], M. Gattorno[3], F. Zulian[4], P. Quartier[5], J. Hoyer[6], I. Foeldvari[7], E. Ramos[8], P.N. Hawkins[9], K. Leslie[10], G. Krammer[11], S. Malfait[11], R. Preiss[12], A. Widmer[11] and E. Hachulla[13], [1]Universitätsklinikum, Tübingen, Germany, [2]Allergy Center at Brookstone, Columbus, [3]Istituto Giannina Gaslini, Genova, Italy, [4]University of Padova School of Medicine, Padova, Italy, [5]Hopital Necker-Enfants Malades, Paris, France, [6]Univ.-Klinikum Gießen und Marburg, Marburg, Germany, [7]Hamburger Zentrum füer Kinder- und Jugendrheumatologie, Hamburg, Germany, [8]Hospital Central de Asturias, Oviedo, Spain, [9]Royal Free and University College Medical School, London, England, [10]UCSF, School of Medicine, San Francisco, [11]Novartis, Basal, Switzerland, [12]Novartis, East Hanover, [13]Hôpital Claude Huriez CHRU, Lille, France

Purpose: Canakinumab provides sustained interleukin 1-beta (IL-1β) blockade and is effective in the treatment of CAPS (comprising of FCAS, MWS, CINCA/NOMID). We report the interim results of pediatric patients enrolled in an ongoing open-label, single-treatment arm study to evaluate long-term safety, tolerability and efficacy of canakinumab in CAPS.

Method: Pediatric patients (n=19; 5–17 years; ≥15 kg) were canakinumab naïve (n=11) or rolled over (n=8) from earlier conducted Phase II/III studies. Patients received canakinumab 150 mg s.c. or 2 mg/kg s.c. (≤40 kg) every 8 weeks. Complete response was defined as physician's global assessment of disease activity and assessment of skin disease ≤minimal with normal serum inflammatory markers (C-reactive protein or Serum Amyloid A <10 mg/L). Complete response was assessed for canakinumab naïve patients, while roll-over patients entered the study allowing continuous treatment every 8 weeks. In case of incomplete response patients received an additional dose of canakinumab 300 mg s.c. or 4 mg/kg s.c. (≤40 kg).

Results: Of 19 patients (11 children; 8 adolescents [≥12 years]), 2 were diagnosed with FCAS, 13 with MWS, 3 with MWS/NOMID overlap and 1 with cold urticaria (discontinued as protocol violator). Complete response was achieved in most (n=9, 81.8%) of canakinumab naïve patients by Day 8. The median duration of exposure to study drug was 86 (29–176) days at the data cut off for this interim analysis. Majority of canakinumab treated pediatric patients were relapse free (11 out of 18), 3 MWS patients experienced one relapse, 3 had missing relapse assessments and 1 MWS/NOMID patient did not achieve complete response and dose was up-titrated. 7 patients (36.8%) received at least one protocol-defined dose adjustment (first dose doubled) or at least one frequency adjustment. The most frequent adverse events were headache, joint sprain and pyrexia. One SAE was reported at the interim data cut off: 1 child was hospitalized due to appendicitis (recovered and continued in the study). Most patients (94.7%) had no injection site reactions. No anti-canakinumab antibodies were detected.

Conclusion: Canakinumab every 8 weeks induced rapid and sustained clinical and biochemical remission in pediatric patients across all severity of CAPS phenotypes. Canakinumab was well tolerated and no differences in safety and efficacy compared to adult patients were observed.

Rheumatoid Arthritis Clinical Aspects: Treatment Outcomes

Wednesday, October 21, 2009, 11:00 AM - 12:30 PM

2057

Hydroxychloroquine (HCQ) Eye Examination Frequency, Risk Categories, and the Risk of HCQ Toxicity. Frederick Wolfe[1], Michael F. Marmor[2] and Kaleb D. Michaud[3], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Stanford University, Stanford, CA, [3]University of Nebraska Medical Center and NDB, Omaha, NE

Purpose: HCQ toxicity is of clinical concern because of the seriousness of visual loss and possible medico-legal consequences. The ACR and American Academy of Ophthalmology (AAO) currently recommend a baseline examination and no other examinations in the first 5 years of therapy for patients in low risk categories, and annual examination for those in higher risk categories. In this report we examined the prevalence of self-reported toxicity and eye doctor confirmation in a large cohort of HCQ users, relative to risk factors and screening frequency.

Methods: We studied 3,738 patients with rheumatoid arthritis or systemic lupus erythematosus who had used HCQ, including 1,432 current users. We screened for self-reported toxicity, and followed-up on positive cases with detailed interviews and ophthalmologist/optometrist confirmation. We defined toxicities as specialist designated HCQ toxicity and Bull's eye lesions. We extrapolated from these results to incomplete cases. Risk categories were defined according to published risk recommendations for dosage, duration or use, and complicating medical factors.

Results: 8% of patients reported any HCQ visual toxicity, but only1.8% retinal toxicity. Follow-up confirmation found 1.7% toxicity and 0.7% bull's eye lesions. 7.7% of patients were in the low risk category, 57.7% in high risk, and 36.5% in the very high-risk category. Overall, eye examinations were obtained every 6 months by 40.4%, with almost all of the remaining examinations occurring yearly. There was no statistical relation between risk category (or the individual components of risk) and examination frequency. However, a 10-year reduction in age was associated with the probability of more frequent eye examinations (odds ratio (OR) 1.2 (95% CI 1.1, 1.3), and males were more likely to have a less frequent examinations (OR 1.4 (95% CI 1.1,1.9). Using median regression, adjusted for age, sex, and RA diagnosis, patients with a bull's eye lesion used hydroxychloroquine 4 (95% CI 0.3, 7.7) years longer that patients without self-reported hydroxychloroquine toxicity (p= 0.034). For specialist reported toxicity, there was a non-significant increase in duration of hydroxychloroquine use, 2 (95% CI -2.0, 6.0) years, p = 0.333. Adjusted for age, sex, and RA diagnosis, the median duration of therapy was: specialist bull's eye lesion 7.5 (95% CI 3.8, 11.2) years, specialist toxicity 5.5 (95% CI 1.1, 9.6) years, and patients not reporting hydroxychloroquine toxicity 3.5 (95% CI 3.3, 3.7) years.

Conclusion: We identified HCQ in toxicity 1.7 % and bull's eye lesions in 0.7% .92.3% of patients are in high or very high-risk categories. Risk categories appeared to be weakly related to observed toxicity. There was no relation between risk categories and screening examination frequency.

2058

Risk of Infection in Rheumatoid Arthritis Associated with Use of Anti-TNF Agents, Dmards and/or Prednisone. Eduardo Bonilla Trejos[1], Michael J. Hannon[2], Melissa Skanderson[1], Chester Good[1] and C. Kent Kwoh[2], [1]Pittsburgh VA Healthcare System, Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

Purpose: To compare the risk of infection associated with different treatment options for RA taking into account the potential combinations of DMARDs, anti-TNF agents and corticosteroids

Method: Data from both the VA National Patient Care Database and the Pharmacy Benefits Management Database dating from Oct. 1, 2000 to Sept. 30, 2007 were utilized to identify cases of RA. The definition of RA was based on ICD-9 codes 714* (either two outpatient codes at least 30 days apart or one inpatient code) and having ever had at least one prescription for a DMARD. A nested case-control study design was utilized to examine 3457 cases of RA patients with a serious infection that were identified based on their corresponding ICD-9 codes from an inpatient admission. Controls with RA but without a serious infection were matched 2:1 by year of initial RA visit, an inpatient or outpatient visit in the same month and year as the inpatient visit for RA case, and location in the same VA region (VISN). Conditional logistic regression was used to examine the risk of serious infection based on DMARD exposure in the 100 days prior to the inpatient admission while controlling for age, gender and the Deyo modification of the Charlson Comorbidity score. The exposures were DMARD1 (i.e., methotrexate/leuflonomide), DMARD2 (i.e., sulfasalazine/hydroxychloroquine/azathiprine), TNF (i.e., infliximab/etanerecept/adalimumab) and Prednisone equivalents (PRED, i.e., categorized as none, low dose (mean of 1-10mg/day) or high dose (mean of >10mg/day)). The reference group consisted of RA patients not on any TNF, DMARDs or PRED.

Results: The results are summarized in the table below.

RA treatment	aOR*	95% CI
TNF and DMARD1 and high PRED	5.18	3.66-7.33
TNF and DMARD2 and any PRED	4.80	3.01-7.66
TNF and DMARD1 and low PRED	4.23	2.95-6.08
TNF and DMARD1 and DMARD2 and any PRED	4.00	2.70-5.92
DMARD1 and high PRED	3.69	2.97-4.58
DMARD2 and high PRED	3.63	2.88-4.57
TNF and any PRED	3.42	2.44-4.81
DMARD1 and DMARD2 and high PRED	3.25	2.52-4.19
TNF alone	3.06	2.03-4.60
DMARD2 and low PRED	3.02	2.40-3.80

DMARD1 and low PRED	2.96	2.40-3.67
Any PRED alone	2.36	1.85-3.00
TNF and DMARD1	2.33	1.60-3.38
DMARD2 alone	2.13	1.71-2.64
TNF and DMARD2	2.06	1.10-3.85
DMARD1 alone	2.02	1.64-2.50
DMARD1 and DMARD2	2.01	1.64-2.50

*adjusted for age, gender and Charlson Comorbidity score

Conclusion: The use of any PRED, especially high dose PRED, is associated with an increased odds of infection in RA when added to a TNF or DMARD. The risk of serious infection with TNF alone is similar to that of DMARD1 or DMARD2 combined with low dose PRED. The combination of TNF, any DMARD and any PRED is associated with the highest odds of serious infection and should be used with special caution.

2059

The Risk for Hospitalized and Outpatient Infections Related to Anti-TNF Therapy and Newer Biologics. Jeffrey R. Curtis[1], Lang Chen[1], John J. Cush[2], Kathryn H. Dao[3], Elizabeth Delzell[1], D. E. Furst[4], J. Greenberg[5], Marc C. Hochberg[6], Archana Jain[1], Joel M. Kremer[7], Nivedita Patkar[1] and Daniel H. Solomon[8], [1]UAB, Birmingham, AL, [2]Baylor Research Institute, Dallas, TX, [3]Texas Health, Dallas, TX, [4]UCLA, Los Angeles, CA, [5]NYU, New York, NY, [6]University of Maryland School of Medicine, Baltimore, MD, [7]Albany Medical College, Albany, NY, [8]Brigham & Women's Hospital, Boston, MA

Purpose: There have been inconsistent results regarding the association between anti-TNF therapies and the risk of serious infection. Several prior studies had relatively poor adjustment for RA disease severity, while other analyses may have had biased ascertainment of infectious outcomes. We compared the risk of infection associated with anti-TNF therapies and other biologics to non-biologic DMARDs in a cohort with substantial information about disease severity.

Method: Data from the Consortium of Rheumatology Researchers of North America (CORRONA) registry was used to identify a cohort of rheumatoid arthritis (RA) patients, RA disease factors, and their relevant DMARD exposures. For patients with reported hospitalized infections, medical records were requested. Cox proportional hazards models estimated the risk for hospitalized infections associated with current use of various biologic DMARDs compared to non-biologic DMARDs. Disease activity (CDAI), functional status (mHAQ), duration of RA, diabetes, lung disease, prior infection, prednisone dose, and number of previous infections were included in adjusted analyses. Sensitivity analysis considered how recently each of the drugs was initiated (< 1 year, ≥ 1 year), and also restricted eligible participants to new users of various medications. Additional analyses using Poisson regression evaluated the risk for all infections (hospitalized and outpatient).

Results: Among 18,305 RA patients with 32,911 years of observation, 586 hospitalized infections and 21,258 outpatient infections were reported. A total of 91% of the hospitalized infections had hospital record evidence to confirm the event; the remaining 9% were not counted as cases. In adjusted analyses, no significant increase in serious infection risk associated was observed for anti-TNF therapy or other biologics compared to non-biologic DMARDs. Factors that were associated with infections included age, RA clinical disease activity index (CDAI), mHAQ, duration of RA, lung disease, prior infection, prednisone dose, and number of previous non-biologic DMARDs. Consistent with the hospitalized infection results, there was no significant difference in the rate associated with the various biologics for the endpoint of all infections.

Conclusion: In an observational cohort of RA patients, we found no significant increase in the adjusted risk for hospitalized or outpatient infections associated with anti-TNF therapy or other biologics compared to MTX and other non-biologic DMARDs. The

infection-related safety profiles of the various biologic agents appear to be similar.

2060

Risk of Septic Arthritis in Patients with Rheumatoid Arthritis Treated with Anti-TNF Therapy: Results From the BSR Biologics Register (BSRBR). J. B. Galloway[1], K. L. Hyrich[1], L. K. Mercer[1], W. G. Dixon[1], A. P. Ustianowski[2], K. D. Watson[1], M. Lunt[1], D. P. Symmons[1] and On behalf of the BSRBR[1], [1]arc Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]North Manchester General Hospital, Manchester, United Kingdom

Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of septic arthritis (SA). Clinical trials of anti-TNF therapy have not suggested an increased risk of SA, but there have been case reports suggesting a potential association.

Method: Consecutive RA patients treated with anti-TNF therapy recruited between 10/01 and 5/08 by the BSRBR were followed 6 monthly via consultant and patient questionnaires until 12/31/08, end of follow up or death. A comparison cohort with active RA on disease modifying anti-rheumatic drugs (DMARD) was recruited and followed up in the same way. Incident cases of SA were identified from follow-up questionnaires and verified via medical records. SA was attributed to anti-TNF if it was diagnosed while on anti-TNF or within 90 days of the last dose. SA event rates in the anti-TNF and DMARD cohorts were compared using Cox proportional hazard ratio estimates adjusted for age, gender, disease severity, prior joint replacement, co-morbidity and steroid use. Missing baseline data were replaced using multiple imputations.

Results: 246 cases of SA were reported during the follow up period: 229/11757 in the anti-TNF cohort and 17/3515 in the comparison cohort. 179 cases could be attributed to anti-TNF using the “on drug plus 90 day” model. Incident rates were 5.0/1000 pyrs (95% CI 4.3, 5.8) in the anti-TNF cohort and 1.9/1000 pyrs (1.1, 3.0) in the controls. At least 51% of the SA in patients on anti-TNF occurred in native joints (Table). Patients on anti-TNF therapy were twice as likely to develop SA as controls (adjusted HR 2.0, 95% CI 1.1, 3.5). The individual anti-TNF drug adjusted results were etanercept HR 2.3, (CI 1.2, 4.4), infliximab HR 1.6, (CI 0.8, 3.2), and adalimumab HR 1.8, (CI 1.0, 3.5). Staphylococci were the most common organisms in both cohorts (DMARD 50%; anti-TNF 75%). 5 cases of intracellular infection (2 *Listeria*, 3 *Salmonella*) and 11 cases of Streptococcal SA (including 4 *Streptococcus pyogenes*) were reported (all in the anti-TNF cohort).

Conclusion: Exposure to TNF inhibitor therapy is associated with an increased risk of SA in patients with RA. Careful vigilance for joint infections remains important with awareness of the potential range of pathogens. Antibiotic guidelines should incorporate this information.

Table

	DMARD **n=3513**	**Anti-TNF** **On drug + 90 days**

		n=11757

2061

Clinical Synovitis Is Associated with Progression of Erosions and Joint Space Narrowing in Individual Joints, but Not in Patients Treated with Initial Infliximab. N.B. Klarenbeek[1], M. Güler-Yüksel[1], W.M. de Beus[2], Désirée M.F.M. van der Heijde[3], H.M.J. Hulsmans[4], P.J.S.M. Kerstens[5], T.W.J. Huizinga[1], B. A. C. Dijkmans[6] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]MC Haaglanden, The Hague, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Haga Hospital, The Hague, Netherlands, [5]JBI, Amsterdam, Netherlands, [6]VUMC, Amsterdam, Netherlands

Purpose: To assess for individual joints the relationship between joint tenderness and swelling and progression of erosions and joint space narrowing and to evaluate the influence of initial treatment

Methods: In the BeSt study, recently diagnosed active RA patients were randomized to treatment with: 1. sequential monotherapy, 2. step up combination therapy, 3. initial combination with prednisone, or 4. initial combination with infliximab. X-rays of baseline and year 1 were scored in random order by two readers using the Sharp-van der Heijde score. Using Generalised Estimating Equations (GEE), threemonthly tender and swollen joint counts (44) of year 1 were related to Sharp-van der Heijde progression at the individual joint level (ever/never swollen and ever/never tender vs erosion and joint space narrowing (JSN) progression (yes/no) in year 1, corrected for SHS baseline, age, gender, BMI, treatment, and accounting for within patient correlation for multiple joints per patient).

Results: In total, 13895 joints were analyzed. During year 1, 59% of all joints were ever tender, 45% swollen, 2% showed erosion progression (>0.5 SHS units) and 2% JSN progression (>0.5 SHS units). In treatment groups 1, 2 and 3 but not in 4 both swelling and tenderness were independently associated with erosion progression with a ‘dose effect’ and with ORs comparable for swelling and tenderness. Similar results were found for JSN progression (table). There was no interaction between swelling and tenderness. Odds ratios were higher in the hands than in the feet (ORs for erosion progression: 15.5 for swelling and 8.1 for tenderness in hands vs 1.5 and 1.3 in feet, ORs for JSN progression: 3.6 and 3.3 for swelling and tenderness hands vs 2.2 and 1.6 for feet).

Conclusion: Clinical signs of synovitis are associated with both erosion and joint space narrowing progression in the same joint after 1 year treatment in recent onset RA patients. These associations are stronger in hands than in feet, possibly due to difficult joint evaluations in the feet. We found a disconnect between clinical signs of synovitis and damage progression in patients who received infliximab as initial treatment, confirming the disconnect between synovitis and the development of joint damage in TNF-blockers.

Table: GEE results with ORs for erosion and JSN progression

		Erosions		**JSN**	
		OR	**95% CI**	**OR**	**95% CI**
All patients	Swelling 1x	1.4	0.98 -1.9	1.7	1.2 – 2.4
	Swelling ≥2x	3.1	2.1 – 4.6	3.5	2.4 – 5.2
	Tender 1x	1.5	1.0 – 2.3	1.5	1.0 – 2.2
	Tender ≥2x	4.0	2.7 – 5.9	3.7	2.4 – 5.7
Group 1	Swelling ever	3.0	1.8 – 4.9	3.8	2.5 – 5.9
	Tender ever	3.5	1.9 – 6.7	2.2	1.1 – 4.4
Group 2	Swelling ever	1.6	0.86 – 3.0	1.7	0.97 – 3.1

2062

The Influence of Anti-TNF Therapy Upon Incidence of Non-Melanoma Skin Cancer (NMSC) in Patients with Rheumatoid Arthritis (RA): Results From the BSR Biologics Register (BSRBR). L. K. Mercer[1], J. B. Galloway[1], M. Lunt[1], W. G. Dixon[1], K. D. Watson[1], BSRBR Control Centre Consortium, D. P. Symmons[1], K. L. Hyrich[1] and On behalf of the BSRBR[1], [1]arc Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Purpose: RA is associated with an increased risk of NMSC. Anti-TNF therapy may intensify this risk, although evidence to date is conflicting. Our aim was to explore the influence of anti-TNF therapy on the incidence of NMSC using data from the BSRBR, a prospective cohort study set up in 2001 to monitor the long-term safety of anti-TNF therapy in the UK.

Method: 11757 consecutive anti-TNF treated patients with RA were followed 6 monthly and compared to 3515 biologic-naïve subjects with active RA receiving traditional disease modifying therapy (DMARD). Patients were followed until 12/31/2008 or death, whichever came first. Incident NMSC were identified from consultant and patient questionnaires and record linkage with the UK national register for cancer. Local recurrence was included but carcinoma-in-situ (Bowen's disease) excluded as an incident NMSC. NMSC occurring after stopping anti-TNF was attributed to the most recently received anti-TNF drug. The rates of NMSC in the anti-TNF and DMARD cohorts were compared using multivariate Cox proportional hazards models adjusted for age, gender, disease duration, disease activity, HAQ, baseline steroid use, number of prior DMARDs, smoking and year of registration.

Results: 221 NMSC were verified: 175 in 149 anti-TNF patients (4.2/1000 pyrs) and 46 in 40 DMARD patients (5.1/1000 pyrs). Histology data were received for 135 NMSC in the anti-TNF patients of which 122 (90%) were basal cell carcinoma (BCC) and 12 (9%) squamous cell carcinoma (SCC). A similar ratio of BCC:SCC was seen in the DMARD cohort. The strongest predictor for NMSC was prior NMSC (HR 9.8 (95% CI 5.6, 17.0)), with other known risk factors (age, male gender and steroids) also associated with increased risk. Limiting the analysis to patients with no prior NMSC the fully adjusted hazard ratio (aHR) for anti-TNF vs. DMARD was 1.7 (0.9, 3.4). The aHR was 1.7 (0.8, 3.4) for etanercept (ETA), 2.9 (1.4, 6.1) for infliximab (INF) and 1.1 (0.5, 2.5) for adalimumab (ADA).

Conclusion: In patients with no prior NMSC, the risk of NMSC was increased by 70% in patients with RA treated with anti-TNF therapy, although this was not significant. INF was associated with an almost 3 fold increase in risk of NMSC in this group. Vigilance for NMSC should be maintained in all patients with RA, especially when treated with anti-TNF therapy.

Table:

No of patients ever received the drug	**DMARD N=3515**	**All Anti-TNF N=11757**	**ETA**	**INF**	**ADA**
Person years follow up	9058	41716	18133	11212	12371
No of patients with prior NMSC (%)	83 (2.4)*	159 (1.4)*	64 (1.6)	38 (1.1)	57 (1.4)
Rate / 1000 pyrs (95% CI) in patients with no prior NMSC	2.4 (1.5, 3.6)	3.5 (2.9, 4.1)	3.0 (2.2, 3.9)	5.5 (4.2, 7.1)	2.4 (1.6, 3.4)

Increased Proportions of CD4+CD25+CD127-FoxP3+ T Cells with Superior Suppressive Capacity Are Present in the Peripheral Blood of Early RA Patients. Y. García-Carmona, M. Benito-Miguel, Alejandro Balsa, C.P. de Ayala, E. Martin-Mola and M. E. Miranda-Carús, Hospital La Paz, Madrid, Spain

Purpose: To assess the frequency and function of CD4+CD25+CD127-FoxP3+ T cells in the peripheral blood of early RA patients.

Method: Peripheral blood was drawn from 30 healthy controls (HCPB) and 30 early RA patients who had not received treatment with steroids or DMARDs (RAPB). In addition, 10 patients donated blood for a second time, after remission had been achieved with treatment (RAPB-R). The frequency of CD4+CD25+CD127-FoxP3+ T cells was assessed by flow cytometry. CD4+CD25+CD127- T reg and CD4+CD25- Tresp cells were isolated by Ficoll-Hypaque gradient, followed by sorting. Treg cell function was assessed using two different approaches: A.The regulatory function of natural proportions of Tregs was inferred by comparing the proliferative and cytokine responses of total CD4+ T cells (TCD4T) versus CD25+ depleted CD4+ T cells (CD4+CD25-T cells); B. The per cell suppressor potency of Tregs was

assessed in cocultures of isolated Tregs with Tresp, established at different Treg/Tresp ratios. Proliferation was determined by 3Hthymidine incorporation and CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants.

Results: When compared with HCPB, the proportion of CD25+CD127- T cells was significantly increased among RAPB CD4+ T cells (mean + SD, 6.4+2.1 vs 9.8+2.7, p<0,05; range 4.1-8.6 vs 8.9-16.3). These RAPB CD4+CD25+CD127- T cells expressed FoxP3 but did not express CD69. We then tested the suppressive function of the naturally increased proportion of Treg cells in RAPB. When compared with HCPB, TCD4 T cells from RAPB showed a lower proliferative response. In contrast, RAPB CD4+CD25-Tresp cells demonstrated higher proliferation rates. Subsequently, the calculated inhibitory potency of RAPBTreg on Tresp proliferation resulted significantly increased. This suggests that the low proliferative response of RAPB TCD4T cells is attributable to the superior suppressive potency of RA Tregs. In parallel, IFN-γ and TNF-α secretion were higher for TCD4T and also for Tresp cells from RAPB, when compared with HCPB. That is, despite their low proliferative response, RAPB TCD4 T cells secrete more IFN-γ and TNF-α. At the same time, the potency of inhibition of RATreg on RATresp cytokine secretion was significantly increased. That is, the increased suppressive potency of RA Treg cells is not able to overcome the increased Tresp IFN-γ and TNF-α secretion in these patients. We next sought to determine the per cell suppressive potency of RA Tregs. On a per cell basis, RAPB Tregs were significantly more potent suppressors of proliferation, TNFα and IFNγ secretion when compared with HCPB Tregs. The frequency and function of RAPB-R Treg cells were not different from HCPB Tregs.

Conclusion: Increased proportions of CD4+CD25+CD127-FoxP3+ T cells with superior suppressive capacity are present in the peripheral blood of early RA patients. However, this higher suppressive action is not able to overcome the increased Tresp IFN-γ and TNF-α secretion.

Dendritic Cell-Derived Dopamine Induces IL-6-Th17 Axis in Rheumatoid Arthritis. Kazuhisa Nakano, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Purpose: It is emerging that Th17 cells among various T cell subsets play important roles in the inflammatory processes including rheumatoid arthritis (RA). Although certain factors and immune cells such as dendritic cells (DCs) are known to be involved in the induction of Th17 cells in murine system, precise mechanisms in human diseases remain unclear. The neuron system is supposed to affect the immune system by releasing neurotransmitters and among them dopamine is a major one in the brain and the first catecholamine synthesized there. We found that DCs secrete dopamine and assessed the role of dopaminergic-signaling in the T cell differentiation and its involvement in the pathogenesis of RA using SCID mice co-implanted with synovium and cartilage from RA patients (SCID-HuRAg mice).

Method: T-cell response to dopamine was assessed by the levels of intracellular cAMP and IFN-g, IL-4, IL-5, IL-17, IL-1b, IL-6 and TGF-b production. Catecholamine concentrations in synovial fluid were analyzed by *HPLC*. Expression of dopamine in synovium from patients with RA was analyzed by immunostaining. Antagonists of either D1-like or D2-like dopamine-receptor were administered subcutaneously twice a week into SCID-HuRAg mice. The implants were removed after 30 days and histologically evaluated.

Results: Dopamine increased cAMP levels via D1-like dopamine receptors in human naïve $CD4^+$ T cells and production of induced IL-6 and IL-17 from T cells under the presence of anti-CD3 and anti-CD28 antibody stimulation in a concentration-dependent manner. This dopamine-mediated IL-17 production was completely inhibited by pretreatment with human IL-6 receptor (IL-6R) mAb tocilizumab. D2-like receptor antagonists significantly induced DC-mediated Th17 differentiation in a mixed lymphocyte reaction with human Mo-DCs and allogenic naïve $CD4^+$ T cells. On the other hand, dopamine concentration was significantly higher in synovial fluid from RA patients compared with osteoarthritis patients. In RA synovium, large amount of dopamine was detectable in DC cytoplasm, whereas dopamine-receptors could be detected on $CD4^+$ T cells, but not on synovial fibroblasts. In SCID-HuRAg mice, all mice treated with SCH-23390, a D1-like receptor antagonist, showed protective effects on cartilage destruction. In contrast, all mice treated with haloperidol, a D2-like receptor antagonist, showed accumulation of IL-6 and IL-17 positive cells, proliferation of synovium, remarkable neo-vasculization and exacerbated cartilage destruction in the SCID-HuRAg mice.

Conclusion: These findings indicate that DC is a major source of dopamine in RA synovium and that DC-derived dopamine induces IL-6 – Th17 axis, resulting in aggravation of RA.

Gene Signatures That Predict Development of Arthritis. Lisa G.M. Van Baarsen[1], Wouter H. Bos[2], Francois Rustenburg[1], Tineke C.T.M. van der Pouw Kraan[1], Gertjan. Wolbink[2], Ben A.C. Dijkmans[3], Dirkjan van Schaardenburg[2] and Cornelis L. Verweij[1], [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Institute, Amsterdam, Netherlands, [3]VU Medical Centre, Amsterdam, Netherlands

Purpose: Recognition of the preclinical phase of rheumatoid arthritis (RA) allows a timely start of treatment with the ultimate goal of primary prevention. We aimed to identify molecular features that are associated with the development of RA in order to understand the pathophysiology of preclinical development and to assign predictive biomarkers.

Methods: In total, 25 RA patients and 109 ACPA and/or RF positive arthralgia patients at risk for RA and with definitive absence of arthritis (swollen joint count [SJC] =0) in 44 joints at physical examination at the baseline visit determined by two experienced rheumatologists, were included in this study. Exclusion criteria for the arthralgia group were: the presence of recent infections, autoimmune rheumatic diseases, cancer, arthritis revealed by chart review or baseline physical examination, erosions on hand or feet X-ray examination and previous treatment with DMARD or corticosteroids. Gene expression profiles of blood samples were determined by DNA microarray analysis and qPCR. Significance Analysis of Microarrays (SAM) was used to determine significantly differential expressed genes. PANTHER Classification System was used to interpret our data. Cox-regression hazard analysis assessed the relative risk for arthritis development in subgroups of autoantibody positive arthralgia patients.

Results: Gene expression profiling of peripheral blood cells revealed molecular heterogeneity among autoantibody positive arthralgia patients at risk for arthritis development based on differential expression of genes that are involved in diverse arms of the immune response. Interim analysis revealed that 20 at risk patients have developed arthritis after a median of 7 months (IQR 4-15; median follow-up of all patients is 30 [IQR 22-39] months) in a median of 3 joints (IQR 3-5). Here, we report for the first time gene signatures relevant to development of arthritis. Signatures significantly associated with arthritis development (HR 4.5; 95% C.I. 1.3-15.4; P=0.016) involved IFN-mediated immunity, hematopoiesis and cytokine activity. These processes were reminiscent of those present in RA patients, implying that the preclinical phase of disease already carries features of established disease. Genes involved in B-cell immunology were associated with protection from progression to arthritis.

Conclusion: Our results imply that, IFN-mediated immunity, hematopoiesis and cell trafficking specify the processes relevant to progression to arthritis besides autoantibody positivity. These findings strongly suggest that gene signatures have predictive value for progression to arthritis, which will pave the way to preventive medicine.

CXCR3 Regulates the Invasive Properties of Synovial Fibroblasts Via Akt Signaling, Collagenase Activation and Actin Reorganization. Teresina Laragione, Adriana Mello, Max Brenner, Barbara Sherry and Percio S. Gulko, Feinstein Institute for Medical Research, Manhasset, NY

Purpose: The in vitro invasive properties of fibroblast-like synoviocytes (FLS) in a Matrigel assay correlate with joint damage and erosions in pristane-induced arthritis (PIA) in rats and in rheumatoid arthritis (RA) in humans. We have identified a unique mRNA gene expression signature associated with highly invasive FLS obtained from PIA-susceptible DA rats. This signature includes genes implicated in cancer phenotypes such as cell invasion and metastasis. Among the genes up-regulated in DA FLS, as compared with minimally invasive FLS obtained from the arthritis-protected Cia5d strain, is the chemokine CXCL10. Therefore, we hypothesized that the interaction between CXCL10 and CXCR3 plays a role in the regulation of FLS invasion and joint damage.

Method: FLS were obtained from DA and Cia5d synovium 21 days after the induction of PIA, and cultured for at least three passages. Supernatants were used to measure CXCL10 protein levels. FLS were also isolated from synovial tissues from RA patients. FLS invasion

was studied in a 24h Matrigel assay in the presence or absence of recombinant CXCL10 (1µg/mL), anti-CXCR3 blocking antibody, isotype control antibody, or the small molecule CXCR3 inhibitor AMG487. Supernatants were collected for quantification of matrix metalloproteinase (MMP) activity (MMP-1, 2, 3, 9 and 13). Total cell lysates were tested for Erk and Akt phosphorylation by western blot. Actin filament organization was detected by immunofluorescence in presence or absence of AMG487.

Results: Supernatants from DA FLS had 30% higher levels of CXCL10, compared with Cia5d FLS, confirming the previous mRNA data. DA and Cia5d FLS had similar levels of CXCR3 protein and also similar CXCR3-CXCL10 binding. The addition of CXCL10 to 24h Cia5d FLS cultures significantly increased invasion by nearly 2.5-fold, and was specifically blocked by anti-CXCR3 antibodies. Both anti-CXCR3 antibodies and the small molecule CXCR3 inhibitor AMG487 reduced DA FLS invasion by as much as 85%. AMG487 also significantly reduced the invasion of RA FLS (n=6) by 60%. Anti-CXCR3 antibody and AMG487 reduced levels of active MMP-1, and levels of phospho-Akt both in rat and RA FLS. AMG487 treatment prevented actin cytoskeleton reorganization and the polarized formation of lamellipodia, which is required for cell invasion, both in rat and RA FLS.

Conclusion: We describe for the first time a new autocrine/paracrine role for CXCL10 in the regulation of FLS invasion in arthritis, including RA. Antibody neutralization and a small molecule inhibitor of the CXCL10 receptor, CXCR3, both in rats and human cells significantly reduced FLS invasion as well as key processes known to regulate cell invasion such as levels of phospho-Akt and MMP-1, and the polarized formation of lamellipodia. These observations suggest that the CXCL10-CXCR3 pathway is a promising new target for therapies aimed at reducing joint damage and pannus invasion and destruction in RA.

2067

mTOR Regulates the Invasive Properties of Synovial Fibroblast. Teresina Laragione, Adriana Mello, Keren Amir and Percio S. Gulko, Feinstein Institute for Medical Research, Manhasset, NY

Purpose: The invasive properties of fibroblast-like synoviocytes (FLS) correlate with disease severity and radiographic damage in rheumatoid arthritis (RA), and with histological articular damage in pristane-induced arthritis (PIA). We have recently determined that highly invasive FLS obtained from PIA-susceptible DA rats have a gene expression signature similar to that detected in highly invasive and metastatic cancers. Among the genes up-regulated in DA FLS, is ezrin, a member of ERM (ezrin-radixin-moesin) family. Ezrin promotes cancer cell invasion and metastasis via the mammalian target of rapamycin (mTOR) pathway. In the present study we used Rapamycin, an inhibitor of mTOR, to assess the role of the ezrin-mTOR pathway on the invasive properties of FLS from DA rats with PIA and patients with RA.

Methods: FLS were collected from DA rat synovial tissues 21 days after the induction of PIA. Human FLS were isolated from synovial tissues obtained from RA patients. After the third passage, cells were treated with Rapamycin for 24 hours and tested on the Matrigel invasion assay. Supernatants were assayed for matrix metalloproteinase (MMP) activity. Cell lysates from Rapamycin or DMSO-treated FLS were used for detection and quantification of mTOR, p70S6K1, 4EBP1, FAK, and their respective phosphorylated subsets by western blot. Actin filament organization and FAK localization were determined by immunofluorescence 20 minutes and 24 hours after incubation with rapamycin or control.

Results: Rapamycin decreased both DA (10 µM) and RA (0.1 µM) FLS invasion through Matrigel. Rapamycin treatment reduced mTOR, p70S6K1 and 4EBP1 phosphorylation confirming the inhibition of the mTOR pathway. The activity of MMP-1, MMP-2, MMP-3 and MMP-13 was not significantly affected by rapamycin. Rapamycin prevented actin reorganization in both DA and RA FLS and inhibited the formation of directional lamellipodia protrusion, compared with DMSO. Phosphorylation and polarization of the lamellipodia marker FAK was also reduced by rapamycin.

Conclusion: Rapamycin significantly reduced FLS invasion in rat and human RA FLS through the suppression of ezrin-mediated mTOR signaling pathway. This is the first time that mTOR is implicated in the invasive properties of FLS. These observations suggest that rapamycin could have a role in RA therapy aimed at reducing the articular damage and erosive changes mediated by FLS.

2068

Expression of Ang-1 and Engagement of Tie2 Is Related to Development of Persistent and Erosive Disease in Early Arthritis Patients. Marleen G.H. van de Sande[1], Daphne deLaunay[1], Gijs P.M. van de Sande[1], Paul P. Tak[2] and Kris A. Reedquist[1], [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Angiopoietin (Ang) -1 and -2, and their receptor Tie2, are important mediators of angiogenesis, a process which promotes inflammation, supplies nutrients, and contributes to tissue destruction and remodeling in synovial tissue. Previous reports have indicated that Ang-1 and Ang-2 are differentially expressed in patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA). In vitro, Ang-1 can promote fibroblast-like synoviocyte production of matrix metalloproteinases, and under certain experimental conditions, Ang-2 can antagonize Ang-1 signaling. Therefore, differential expression of Ang-1 and Ang-2, and engagement of Tie2, in an early phase of the disease might play a role in the development of persistent (erosive) disease.

We investigated the value of synovial tissue expression of Ang-1, Ang-2, Tie2 and active phosphorylated Tie2 (pTie2) in predicting outcome in early arthritis patients.

Methods: We analyzed synovial tissue biopsies of 48 disease-modifying antirheumatic drug (DMARD) -naïve early arthritis patients. Patients were selected from our early arthritis cohort based on diagnosis of RA or undifferentiated arthritis (UA) at baseline. Patients were prospectively followed and diagnosed after 2 years according to established classification criteria and according to outcome (self-limiting, persistent or persistent erosive disease). Baseline synovial tissue expression and activation of the angiogenic markers was examined by immunohistochemical analysis, using quantitative computer-assisted digital imaging. Predictors of outcome were identified by logistic regression analysis.

Results: 21 patients fulfilled ACR criteria of RA at baseline, 8 patients had undifferentiated arthritis (UA) at baseline and fulfilled ACR criteria of RA after 2 years of follow-up, and 19 patients had UA after 2 years of follow-up. The relative activation of Tie2 (pTie2/Tie2) was significantly related to development of erosions in the RA patients (all RA patients at 2 years follow-up) (P=0.01) with an explained variance of 50% (Nagelkerke R^2 =0.502). Tie2 (P=0.03), pTie2 (P=0.03) and Ang1 (P=0.03) were all significantly related to development of persistent disease compared to self-limiting disease in the patients with UA at baseline, with a combined explained variance of 69% (Nagelkerke R2 =0.69).

Conclusion: Our study provides the first evidence that engagement of the Ang-1/Tie2 axis in synovial tissue is related to development of persistent and erosive disease. Therefore, targeting Ang-1 and Tie2 therapeutically may be useful in improving outcome in arthritis. Furthermore, these markers might be of use as a biomarker for predicting outcome.

ACR Concurrent Abstract Sessions

Systemic Lupus Erythematosus Therapy

Wednesday, October 21, 2009, 11:00 AM - 12:30 PM

2069

Four-Year Experience of Belimumab, a BLyS-Specific Inhibitor, in Systemic Lupus Erythematosus (SLE) Patients. Michelle Petri[1], R. Furie[2], Joan Merrill[3], D. J. Wallace[4], E. M. Ginzler[5], W. Stohl[6], W. Chatham[7], J. McCune[8], A. Weinstein[9], L. Pineda[10], Z. J. Zhong[10], J. Klein[10], D. Hough[10], W. Freimuth[10] and LBSL02/99 Study Grp, [1]JHU, Baltimore, MD, [2]NSLIJHS, Lake Success, NY, [3]OK Med Research Foundation, OKklahoma City, OK, [4]Cedars-Sinai UCLA, West Hollywood, CA, [5]SUNY-Downstate, Brooklyn, NY, [6]USC, Los Angeles, CA, [7]UAB, Birmingham, AL, [8]Univ of Mich, Ann Arbor, MI, [9]Wash Hosp Ctr, Washington, DC, [10]HGS, Rockville, MD

Purpose: Provide 4-yr safety and efficacy data in SLE patients (pts) treated with belimumab.

Methods: 449 SLE pts with SELENA SLEDAI (SS) ≥4 enrolled in a phase 2, 52-week (wk), double-blind trial of belimumab (1, 4 or 10 mg/kg,

q28d) vs placebo (plc) plus background SLE therapy. At wk 56, plc pts received belimumab 10 mg/kg; belimumab pts could remain on their current dose or receive 10 mg/kg (investigator's discretion). At wk 80, all remaining pts (296) received belimumab 10 mg/kg in a continuation trial. The 4-yr dataset was divided into eight 6-mo intervals for reporting adverse event (AE) and flare rates. Interval 1 includes the initial belimumab treatment which for plc pts began at wk 56. Analyses of disease activity included the SS SLE Flare Index (SFI) and a post-hoc SLE Responder Index (SRI): improvement in SS (≥4 pt decrease), no new BILAG A or 2 new B flares, and no Physician's Global Assessment (PGA) worsening (< 0.3 pt increase) vs baseline. Post-hoc analyses identified a serologically active (ANA titer ≥1:80 and/or anti-dsDNA ≥30 IU/mL) pt subgroup (321) for whom belimumab demonstrated increased response.

Results: By 4 yrs, overall belimumab exposure was 1,192 pt yrs. The incidence rates (per 100 pt-yrs) of AEs remained the same or decreased over 4 yrs (Table 1). In serologically active pts, SRI rate was 46% at wk 52 (vs plc 29%, $p<0.05$) which increased to 55% by wk 76 and was maintained through wk 208 (original belimumab pts); the frequency of new BILAG A or 2 B flares decreased from 30% at 6 mo to 23% at 1 yr (vs plc 33% and 25%, respectively) and declined to 5% at 4 yrs; the frequency of flares by SFI decreased from 72% at 6 mo to 62% at 1 yr (vs plc 76% and 73%, respectively) and declined to 16% at 4 yrs. Flare data included plc-to-belimumab pts after yr 1.

Table 1: AE Incidence (rate per 100 pt-yrs)

	All belimumab-treated pts							
Interval / Yrs	**1** (0 – 0.5 yr)	**2** (0.5 – 1yr)	**3** (1 – 1.5 yr)	**4** (1.5 – 2 yr)	**5** (2 – 2.5 yr)	**6** (2.5 – 3 yr)	**7** (3 – 3.5 yr)	**8** (3.5 – 4 yr)
No. pts [pt-yrs]	424 [206]	398 [183]	353 [166]	314 [147]	284 [136]	261 [128]	252 [122]	237 [103]
Overall AEs	400 (194)	337 (184)	304 (184)	271 (184)	244 (179)	226 (177)	203 (166)	179 (173)
Serious AEs	43 (20.8)	33 (18.0)	28 (16.9)	25 (17.0)	24 (17.6)	26 (20.4)	13 (10.6)	17 (16.5)
Overall Infections	246 (119)	197 (108)	170 (103)	165 (112)	145 (107)	131 (103)	106 (87)	105 (102)
Serious Infections	14 (6.8)	10 (5.5)	6 (3.6)	8 (5.4)	4 (2.9)	5 (3.9)	2 (1.6)	5 (4.8)
Malignant Neoplasms	0 (0)	1 (0.5)	3 (1.8)	2 (1.4)	0 (0)	1 (0.8)	1 (0.9)	2 (2.1)

Conclusion: Belimumab added to standard of care therapy was generally well tolerated over 4 yrs. Serologically active pts treated with belimumab showed sustained improvement in disease activity and a decline in BILAG and SFI flares over 4 yrs.

2070

Treatment of Systemic Lupus Erythematosus (SLE) with Rituximab: 78-Week Safety Data From the Phase II/II EXPLORER Trial.

Joan T. Merrill[1], D.J. Wallace[2], K.M. Latinis[3], T.O. Utset[4], R. Furie[5], C. Michael Neuwelt[6], Richard J. Looney[7], H. Hsieh[8], B. Wagner[9] and P. Brunetta[8], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Cedars-Sinai Medical Center/UCLA, West Hollywood, CA, [3]Kansas University Medical Center, Kansas City, KS, [4]University of Chicago, Chicago, IL, [5]North Shore-LIJ Health System, Lake Success, NY, [6]Alameda County Medical Center, Oakland, CA, [7]University of Rochester, Rochester, NY, [8]Genentech, Inc., South San Francisco, CA, [9]Genentech, Inc., South San Francisco

Purpose: In RA patients (pts), multiple courses of rituximab (RTX) are well tolerated. Analysis of safety for 12 months after receipt of the 2nd course of RTX in SLE has not yet been performed. Our objectives were to highlight the safety data obtained in EXPLORER through 78 wks.

Methods: Pts on background immunosuppressants and corticosteroids were randomized to placebo (PLA) or RTX (1000 mg IV on days 1, 15, 168, and 182). Adverse events (AEs), serious AEs (SAEs), deaths, and antibodies to RTX (HACAs) were recorded from screening to wk 78, or to termination visits. HACA responses were measured at baseline and every 3 mo. Immunoglobulin (Ig) levels were measured at baseline and days 112, 168, 308, 364, 455, and 546.

Results: Eighty-eight PLA and 169 RTX pts were included in the safety-evaluable populations. AEs and SAEs were comparable between PLA and RTX groups. Infection and infestation treatment-emergent SAEs were higher in the PLA than in the RTX group (18.2% vs 11.2%). Rates of infections were 227 and 224 events/100 pt-yr (patient-years) for PLA and RTX. Rates of serious infections were 16.7 and 13.6 events/100 pt-yr for PLA and RTX. Herpes virus infection-related AEs occurred in 8 (9.1%) pts in the PLA group vs 26 (15.4%) in the RTX group. The % of pts with infusion-related AEs during course 1 was comparable between groups, but during course 2 a higher % of RTX-treated pts had infusion-related AEs. HACAs were present in 3 (3.4%) and 48 (28.4%) pts in the PLA and RTX groups. At the 4th infusion, 11 (22.9%) of the 48 HACA+ RTX-treated pts experienced an infusion-related AE (1 SAE), vs 14 (11.0%) of the HACA- RTX-treated pts. Neutropenia occurred in 6 RTX pts. Four cases of serum sickness (1 serious) occurred in the RTX group. At any time during the study, IgG levels were below the lower limit of normal (LLN) in 8.5% of PLA, and 6.3% of RTX pts. IgM levels were below the LLN in 9.7% of the PLA group, and 28.7% of the RTX group. Mean IgG levels did not significantly change in the RTX group during the trial. Low Ig levels did not correlate with serious infectious AEs.

Conclusion: The numbers of pts who developed AEs and SAEs were comparable between the PLA and RTX groups. Whereas overall infection rates were also comparable, infectious SAEs were higher in PLA. The percent of pts with infusion reactions was similar between groups after the 1st and 2nd infusions, however, more pts experienced infusion reactions in the RTX group after the 3rd and 4th infusions. No clear associations were observed between HACAs and safety. Herpes viral infections, neutropenia, and serum sickness occurred more frequently in the RTX group.

2071

Evaluation of CD4+ Lymphopenia and Infection Risk in Systemic Lupus Erythematosus (SLE) Patients: Data From Rituximab Clinical Trials. K.M. Latinis[1], E.F. Chakravarty[2], P. Brunetta[3], H. Hsieh[3], J. Garg[3], R. Maciuca[3] and B. Wagner[3], [1]Univ. Kansas Medical Center, Kansas City, KS, [2]Stanford Health Services/Blake Wilbur Clinic, Palo Alto, CA, [3]Genentech, Inc., South San Francisco, CA

Purpose: Previous reports have suggested that a substantial portion of SLE patients (pts) have CD4+ lymphopenia. We evaluated the proportion of SLE pts with CD4+ lymphopenia enrolled in EXPLORER (extra-renal SLE) and LUNAR (lupus nephritis) and the relationship of sustained CD4+ lymphopenia (CD4+ T cell counts < 200/uL) to serious infections.

Methods: All pts enrolled in EXPLORER and LUNAR had moderate-to-severe disease activity, were treated with a background immunosuppressant (mycophenolate mofetil, azathioprine, or methotrexate) plus corticosteroids, and were randomized to either placebo or rituximab (1000 mg) given on days 1, 15, 168, and 182. The levels of CD4+ T cells at baseline and over 1 year were evaluated on days 1, 15, 28, 84,112, 168, 182, 196, 252, 308 and 364. Pts with sustained lymphopenia over 2 consecutive visits, at least 4 weeks apart, were evaluated for serious infection rates.

Results: At baseline, the mean level of CD4+ T cells for the combined cohort (n=401) was 524±387 cells/uL. Sixty-four (16.3%) pts had CD4+ counts < 200 cells/uL. Although CD4+ counts initially decreased to a mean level of 456.9 cells/uL at Day 28, likely due to protocol-mandated steroid administration, they were not significantly different from baseline at week 52 (figure). The mean percentage change from baseline to week 52 was -16.2±4.6%. During the trial, 100 (24.9%) pts experienced sustained lymphopenia. The mean duration of lymphopenia was 111.3 +/- 83.7 days. There was no significant difference in rate of serious infections between sustained lymphopenia pts,

who had 22 events over 103.2 patient-years (p-y) (21.3/100 p-y, 95% CI: 14.0, 32.4) of follow-up, and those without sustained lymphopenia, who had 438 events over 299.5 p-y (16.0/100 p-y, 95% CI: 12.1, 21.3; p=0.27) of follow-up.

Conclusion: Sixteen percent of SLE pts had CD4+ counts < 200 cells/uL at baseline. Although CD4+ counts fluctuated over time, likely due to concomitant therapy, levels stabilized near baseline values by the end of the treatment period. Sustained CD4+ lymphopenia occurred in a quarter of pts but did not appear to significantly increase the risk of serious infections. Further analysis by treatment group will be conducted.

2072

Dose-Dependent Modulation of Interferon Regulated Genes with Administration of Single and Repeat Doses of Rontalizumab in a Phase I, Placebo Controlled, Double Blind, Dose Escalation Study in SLE. Jacqueline M McBride[1], Daniel J Wallace[2], Zhenling Yao[1], Alyssa Morimoto[1], Jenny Jiang[1], Romeo Maciuca[1], Iain McLean[1], Jorn Drappa[1] [1] Genentech Inc, 1 DNA Way, South San Francisco, CA, [2]Cedars-Sinai / David Geffen School of Medicine, UCLA, CA.

Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by diverse autoantibodies and inflammation in multiple organ systems. Elevated mRNA levels of interferon-regulated genes (IRGs) have been identified in the peripheral blood of the majority of SLE patients and are thought to be associated with disease pathogenesis.

Method: The safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of rontalizumab, a humanized IgG1 monoclonal antibody that neutralizes human interferon alpha, was assessed in a Phase I dose escalation study of single and repeat doses in adults with mild-moderate SLE. Dose levels ranged from 0.3 mg/kg to 10 mg/kg administered by the intravenous (IV) and subcutaneous (SC) routes. Expression levels of seven IFN-regulated genes (IRGs) were measured by quantitative RT-PCR throughout the dosing and follow up periods for all patients.

Results: The PK profiles of rontalizumab at all dose levels exhibited apparent biphasic distribution and appeared dose proportional following both single dose IV and SC administrations. The clearance, volume of distribution and terminal half-life were 2.8 mL/day/kg, 64 mL/kg and 18 days, respectively, similar to other humanized monoclonal IgG1 antibodies that bind soluble ligands. The bioavailability was approximately 40% in the SC cohorts. Interim analysis identified elevated IRGs in approximately 50% of patients as compared to normal healthy donors. There was a rapid decline in expression of all seven IRGs in the majority of patients after dosing with 3 mg/kg and 10 mg/kg IV cohorts. In general, the reduction was sustained for one month following a single dose; a similar trend was observed during the repeat dose phase. PK/PD correlations were performed with available single dose data and using an Emax model to describe the dose response curve. The integrated gene expression reduction over time (AUEC) started to deviate from placebo at 1-3 mg/kg and appeared to reach maximum at 10 mg/kg.

Conclusion: Rontalizumab has PK properties favorable for use in further SLE studies. The PD results demonstrate a dose-dependent reduction in the IRGs consistent with the expected down-modulation of the IFN signaling pathway, suggesting the possibility of clinical benefit in SLE.

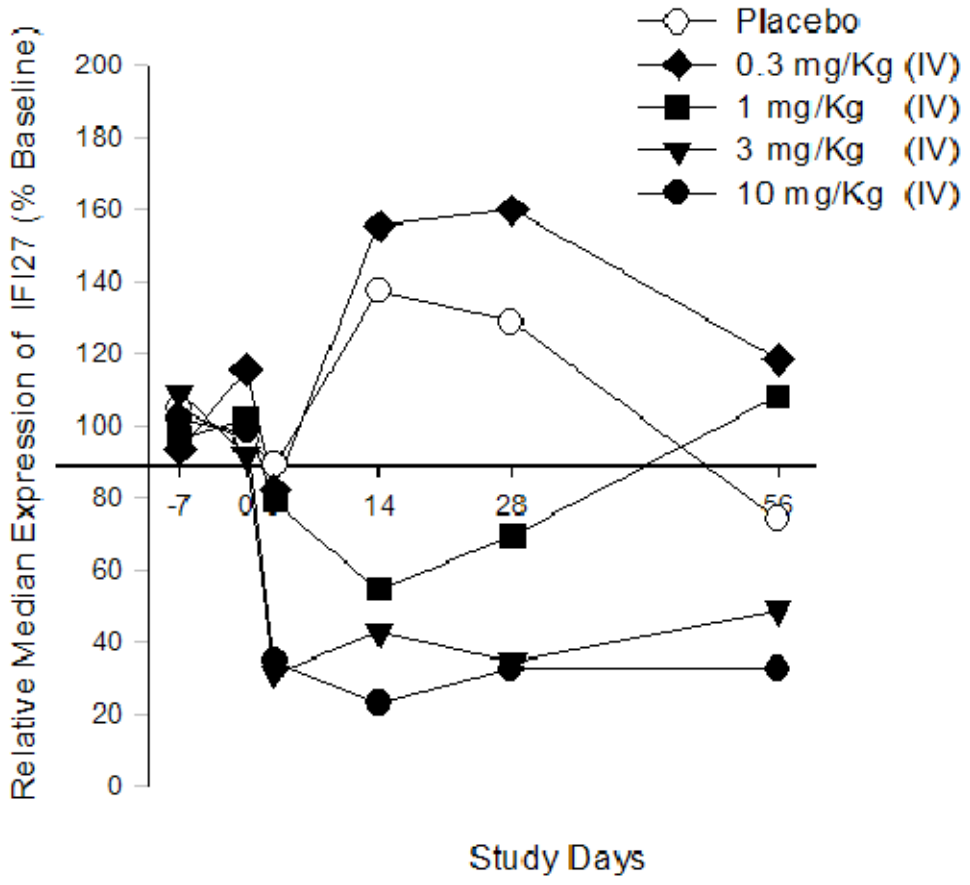

Figure 1. Single dose IV administration of rontalizumab induces a dose-dependent reduction in expression of IFI27, a representative interferon regulated gene (IRG). All patients from each cohort are shown; placebo (n=12) and all other dose groups (n=8).

Identification of Biomarkers That Predict Response to Treatment of Lupus Nephritis with Mycophenolate Mofetil (MMF) or Pulse Cyclophosphamide (IVC). David H. Stone[1], Maria Dall'Era[1], Victoria Levesque[2], Miriam G. Cisternas[3] and David Wofsy[1], [1]UCSF, San Francisco, CA, [2]Vifor Pharma, Victoria, BC, [3]MGC Data Services, Carlsbad, CA

Purpose: There is a great need to identify clinical characteristics and/or biomarkers that can serve as predictors of treatment outcome in patients with SLE. Toward this end, we used data from the Aspreva Lupus Management Study (ALMS) to identify possible baseline and early clinical predictors of renal response to MMF or IVC among patients with lupus nephritis.

Method: In the ALMS trial, patients with Class III-V lupus nephritis were randomized to MMF or IVC in addition to prednisone starting at 60mg/d. Renal response was defined as a decrease in urine prot:creat ratio to <3 in patients with baseline nephrotic range proteinuria, or by ≥50% in patients with subnephrotic range proteinuria, and stabilization or improvement in serum creatinine at 24 weeks. Univariate predictors of renal response were assessed retrospectively and included baseline demographic, clinical, serological and histological characteristics as well as early clinical and serological data obtained within the first two months of therapy. Odds ratios and 95% confidence intervals (CI) for renal response were calculated for each putative predictor in the overall study population and within each treatment group.

Results: A total of 370 patients were randomized in this trial. Among patients with low baseline complement in the overall study population (n=285), normalization of C3, C4, or both by week 8 was strongly predictive of meeting the renal response criteria at 24 weeks (odds ratio=2.5, 95% CI 1.4-4.2; odds ratio= 2.6, 95% CI 1.5-4.5; odds ratio=2.9, 95% CI 1.7-5.2, respectively). The response rate was 76% among subjects with early normalization of C3 and C4, vs 51% in patients without early normalization. Similarly, reduction in proteinuria by at least 25% by week 8 was predictive of a renal response at 24 weeks (68% response rate vs 40% response rate in those without early improvement; odds ratio=3.2, 95% CI 2.1-5.1). Among patients with elevated anti-dsDNA at baseline, a reduction in anti-dsDNA by week 8 was not predictive of renal response (odds ratio=1.2, 95% CI 0.8-2.0). There were no significant differences between treatment arms in these outcomes.

We previously reported that baseline levels of C3 and anti-dsDNA were not predictive of response. We now add that age, age of lupus onset, sex, biopsy class, presence of anti-cardiolipin IgG, and baseline use of an angiotensin converting enzyme inhibitor, a statin, and/or hydroxychloroquine did not predict response.

Conclusion: The ALMS trial, the largest trial to date for the treatment of lupus nephritis, determined that the induction renal response rate was similar for MMF and IVC. A retrospective review of the data has shown that normalization of complement and reduction of proteinuria by 8 weeks were both predictive of renal response at 24 weeks whereas reduction in anti-dsDNA levels by 8 weeks was not predictive of renal response.

Allogenic Mesenchymal Stem Cells Transplantation for Patients with Systemic Lupus Erythematosus: One-Year Fellowup. Lingyun Sun[1], Huayong Zhang[1], Xuebing Feng[1], Dandan Wang[1], GS Gilkeson[2] and Richard M. Silver[2], [1]the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Medical University of South Carolina, Charleston, SC

Purpose: To assess the efficacy and safety of allogenic bone marrow or umbilical cord derived mesenchymal stem cell transplantation (MSCT) for patients with refractory systemic lupus erythematosus (SLE).

Method: 13 patients with SLE refractory to immunosuppressive therapies were enrolled from March 2007 through May 2009, 11 female and 2 male, aged 16~42(mean 28±8.8 years). All the patients fulfilled the 1997 American Collage Rheumatology (ACR) SLE criteria and 12 had lupus nephritis (LN). Disease duration was from 12 to 192 months.The study was approved by the Ethics Committee of the Affiliated Drum Tower Hospital of Nanjing University Medical School. Bone marrow derived mesenchymal stem cells (MSCs) were aspirated from related healthy donors and expanded in vitro, and umbilical cord derived MSCs were obtained from National Engineering Research Center of Cell

Products, Tianjing, China (NECCP). 12 patients were given cyclophosphamide (CTX) 0.6~2.2g divided by two to four times except for one patient with severe myelosuppression and poor health condition, then MSCs were administered 1.0×10^6/kg body weight intravenously, for 11 patients with bone marrow derived MSCs and 2 patients with umbilical cord derived MSCs. The clinical manifestations and laboratory parameters were compared before and after MSCT with a follow-up of 12 to 25 months(mean19 months).

Results: Remission of disease activity (Systemic Lupus Erythematosus Disease Activity Index, SLEDAI less than 3 and prednisone dose less than 10mg/d) was seen in 7/13 (54%) evaluable patients at 1 year and 3/5 (60%) at 2 year after MSCT . Two patients with drug withdrawal relapsed at 1 year post MSCs transplantation. Amelioration of LN was found for the 12 patients, including significant decline of 24-hour proteinuria at 1 year (2162.5±796.0 *vs* 724.3±313.5mg, $P<0.01$), and at 2 years (281.5±120.5mg , n=4) after transplantation. The high serum creatinine levels of three patients also returned to normal at 6 months after transplantation. A significant improvement of glomerular filtration rate (GFR) was found in two patients at 4 months after MSCT. In addition, serum albumin and complement 3 (C3) increased combined with the significant decline of autoantibodies as well as normalization hematological disorder. One relapsed patients has been given a second MSCT and remission of lupus has been also found. No transplant related mortality or any significant toxicity was observed and overall survival was 100%.

Conclusion: This study demonstrates that allogenic MSCT has a potential effect and safety for refractory SLE.

Health-Related Quality of Life Among US Adults Aged 65+ with Arthritis. Sylvia E. Furner[1], Jennifer M. Hootman[2], C. G. Helmick[3] and Matthew A. Zack[3], [1]University of Illinois Chicago School of Public Health/Centers for Disease Control and Prevention, Chicago, IL, [2]Arthritis Program, Atlanta, GA, [3]Centers for Disease Control an, Atlanta, GA

Purpose: To determine how demographics, social or healthcare factors, health behaviors, and health conditions are associated with health-related quality of life (HRQOL) among persons aged 65+ years with arthritis.

Methods: Data came from the 2003, 2005, & 2007 Behavioral Risk Factor Surveillance System, a state-based, random-digit dialed telephone survey of U.S. adults. Analysis was restricted to persons aged 65+ (n=254,311). Persons were classified as having arthritis if they reported ever being told by a doctor or other health care professional they had arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia. Three *healthy days* measures (past 30 days) were evaluated to assess HRQOL: physically unhealthy days (PUD), mentally unhealthy days (MUD), and activity limitation days (LIMDAY), each categorized in groups of 0, 1-13, or 14+ days. Fair or poor self-rated health status was the fourth HRQOL outcome assessed. Independent variables included demographics (age, sex, race/ethnicity); social factors (marital status, education, employment, income); healthcare factors (health insurance, cost a barrier to care); health behaviors (smoking, drinking, physical activity); and health conditions (diabetes, hypertension, obesity). Means, proportions and ordinal logistic regression analyses were conducted using sampling weights and SUDAAN to account for the complex sample design. Factors were included in final models based on statistical significance ($\alpha=0.05$) in domain-specific models or the literature.

Results: The median prevalence of arthritis among persons 65+ for the 50 states and District of Columbia was 56% for the 3 years. Compared to those without arthritis, those with arthritis reported more PUD (7.0 ± 0.12 vs. 3.5 ± 0.10), MUD (2.6 ± 0.08 vs. 1.5 ± 0.06), LIMDAY (3.5 ± 0.08 vs. 1.7 ± 0.0.8), and fair or poor self-rated health (33.2% ± 1.6% vs. 19.2% ± 1.0). Lower income, being out of/unable to work, ever smoking, cost being a barrier to care, and diabetes or hypertension were associated with poor HRQOL across all HRQOL. Women with arthritis reported more MUD and PUD but better self-rated health than men. Compared to non-Hispanic whites, Hispanics reported poorer self-rated health, and black non-Hispanics, fewer PUD. Compared to normal weight, those underweight had more PUD, LIMDAY and poorer self-rated health, and obese persons had more MUD, PUD, and LIMDAY but better self-rated health. Being physically

active resulted in fewer PUD and LIMDAY and better self-rated health. Alcohol consumers had fewer PUD and LIMDAY and better self-rated health.

Conclusion: Those factors consistently associated with poor HRQOL in persons 65+ with arthritis are modifiable. Social, health education, and public health policies targeted to this population may help reduce the HRQOL burden associated with arthritis. Increasing physical activity in this population is associated with many health benefits and may also positively influence HRQOL.

Shut in? Impact of Arthritis and Other Chronic Conditions On Community Participation Among Older Adults. Sylvia E. Furner[1] and Kristina A. Theis[2], [1]University of Illinois Chicago School of Public Health/Centers for Disease Control and Prevention, Chicago, IL, [2]Centers for Disease Control and Prevention, Atlanta, GA

Statement of Purpose: To estimate the prevalence of participation restriction (PR) in community activities due to physical environmental barriers among older adults and to compare the impact among those with arthritis versus other chronic conditions.

Methods: Data were obtained from the 2002 National Health Interview Survey, an annual interview-administered survey representative of the US civilian, noninstitutionalized population. Respondents ≥50 years were included (n=12, 376). Information on condition status was obtained for: arthritis, depression/anxiety, diabetes, hearing impairments, heart conditions, hypertension, neurological conditions, respiratory conditions, stroke, vision impairments, and psychological distress. PR due to 6 environmental barriers from 2 categories ("built environment" [building design, lighting, sound]; "walkability" [crowds, sidewalks/curbs, transportation]) was examined in the community setting for adults ≥50 years by chronic conditions and sex. Weighted frequencies and standard errors, taking into consideration the complex sampling design, were obtained with SUDAAN software.

Results: Across conditions, prevalence of PR due to environmental barriers ranged from 5%-20%. Building design was the most commonly reported built environment barrier overall and for women, with the exception of those with hearing impairments who most often reported sound as a barrier. The same exception was true for men with hearing impairments and psychological distress. Men who reported stroke identified lighting as the most common built environment barrier. Women with arthritis or diabetes reported sidewalks/curbs as the most common walkability barrier; transportation was the biggest barrier for women with stroke. Women with all other conditions and men regardless of condition reported crowds as the most frequent walkability barrier. Hypertension and arthritis were the most prevalent conditions overall (44% and 40%, respectively), representing 34 and 30 million adults ≥50 years; however, respondents with these conditions reported the lowest prevalence of any community barrier, 5% and 6%. In absolute numbers, PR has the greatest impact among people with arthritis, affecting 1.9 million adults ≥50 years.

Conclusion: Arthritis prevalence is projected to increase by ~19 million Americans by 2030 and is already most common among older adults. These findings suggest that increasing numbers of adults ≥50 years with arthritis will experience PR due to modifiable environmental characteristics. Moreover, many of these built environment and walkability features are barriers to older adults with other chronic conditions and are expected to be exponentially limiting in people with comorbid conditions. Promising targets for interventions to reduce community PR among adults ≥50 years with chronic conditions, particularly arthritis, are building design, sidewalks/curbs, and crowd control.

Quality of Non-Pharmacological Care for People with Osteoarthritis in the Community. Linda C. Li[1], Eric C. Sayre[2], Jacek Kopec[1], John Esdaile[3], Sherry Bar[4] and Jolanda Cibere[5], [1]University of British Columbia, Vancouver, BC, [2]Simon Fraser University, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC, [4]BC Ministry of Health Services, Vancouver, BC, [5]University of British Columbia and ARC, Vancouver

Purpose: To describe the quality of non-pharmacological care received by people with knee and/or hip osteoarthritis (OA) in the community and to assess the associated factors.

Method: We evaluated four OA quality-of-care indicators for knee and/or hip OA[1]: 1) advice to exercise; 2) advice to lose weight (for body mass index ›27); 3) assessment for ambulatory function; 4.) assessment for non-ambulatory function, using a postal survey. Eligible participants were those identified from the provincial administrative database between 1992 and 2006 as meeting the case definitions for OA, and had two or more medical visits or one hospitalization for OA within a 365-day period. From 1,713 participants, we collected information on the WOMAC, demographics and quality of care. The passing rate for a quality indicator was calculated by dividing the number of people who received the care with those who were eligible for the care. Logistic regression models were developed to explore the associations between quality of care (yes/no to passing a quality indicator) and the functional/demographic variables (WOMAC, age, sex, education, employment status).

Results: Participants were majority females (61.8%) with a mean age of 67.2 (SD=11.1) years. 66.0% were diagnosed six years ago or more. 16.3% had a university degree, and 30.6% were employed in the previous year. 1,088 participants (63.5%) had knee OA and 648 (37.8%) had hip OA. The mean normalized WOMAC aggregate score was 66.9 (SD=20.2), indicating a moderate level of disability. Overall the quality of non-pharmacological care for OA was poor: exercise (needed advice: n=1,165, received advice: n=294; passing rate=25.2%); weight loss (needed advice: n=660, received advice: n=165; passing rate=25.0%); ambulatory activities (needed assessment: n=120, received assessment: n=35; passing rate=29.2%); non-ambulatory activities (needed assessment: n=403, received assessment: n=28; passing rate=7.0%). Logistic regression revealed that receiving exercise advice was associated with having a university degree (versus high school diploma; OR=2.6, 95% CI=1.6, 4.2) and higher WOMAC scores (for every 10-point increment; OR=1.1, 95% CI=1.0, 1.2). Receiving weight loss advice was associated with being female (OR=2.7, 95% CI=1.7, 4.3) and higher WOMAC scores (for every 10-point increment; OR=1.2, 95% C=1.0, 1.3).

Conclusion: Quality of non-pharmacological care for people with knee/hip OA in the community is suboptimal. Further, inequity may exist in providing advice on exercise and weight management. Given the evidence supporting the use of these interventions to improve OA symptoms and function, and the potential to reduce the progression of joint damage, investment in future research to enhance the provision of OA care is warranted.

Participant Perception of the Importance of Social and Built Environmental Resources for Osteoarthritis Management (OA): Formative Work in a Rural, Southeastern County. Kathryn Remmes Martin, Britta Schoster and Leigh F. Callahan, University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose: Community social and built environment resources have been shown to influence health outcomes, yet little research has examined these resources for an arthritis population living in a rural area. The purpose of our study was to query African Americans (AA) and Whites with OA about community resources for OA management.

Method: We conducted 6 focus groups with thirty-six community dwelling adults with self-reported OA residing in a rural county in a southeastern state. Groups were stratified by race (AA/White). Participants discussed the aspects of the social and built environments of their communities that helped or hindered their ability to manage their OA. They also marked their social, medical, physical activity, and shopping activity areas on a map of the county. Descriptive analyses of participant characteristics were conducted (Stata v8), and verbatim transcripts of the focus groups were reviewed for key themes.

Results: The sample had a mean age of 71 years (range 50-90), was 83% female, 55% White, and 66% had greater than a high school education . Nearly 78% reported knee OA and 80% reported hip OA; with 53% reporting both knee and hip OA. The majority, 67% reported moderate/severe arthritis, and 43% reported fair or poor general health. The map activity indicated that participants used community resources and had social interactions within and beyond county boundaries. Four themes emerged from the focus group discussions, with no differences by race. The two primary themes most often discussed as important for OA management were *community*

resources for physical activity and *social resources.* Participants cited the availability of community parks, a local health facility and senior centers for providing space and programs for physical activity, yet some of these physical activity opportunities (e.g. aquatics) had high fees. Participants listed family, friends, neighbors, and community members, who assisted with transportation, chores, food preparation, and provided emotional support, as primary facilitators in management of OA. Two secondary themes also emerged: *community services* (e.g., churches, pharmacies, food banks, and senior centers) and elements of the *built environment* (e.g., sufficient lighting, sidewalk condition and availability, access ramps, curb-cuts, traffic, automatic doors, availability of store motorized scooters and community handicapped parking). These secondary themes highlighted resources that enabled or hindered participants' ability to navigate built and social environments to manage their OA.

Conclusion: A greater understanding of the community environmental resources and social support structures that may facilitate arthritis management can assist city and regional planners, public health programmers, and policy makers in developing context appropriate interventions to improve arthritis outcomes.

The Effect of Adherence Support From Social Network Members On Depression and Patient Medication Adherence. Delesha M. Carpenter[1], Robert F. DeVellis[1] and Jm Jordan[2], [1]University of North Carolina, Chapel Hill, NC, [2]UNC, Chapel Hill, NC

Purpose: Relatively little is known about how different sources of support affect depression and medication adherence in rheumatic populations. Our goal was to determine whether adherence support from vasculitis patients' physicians, partners/spouses, other family members, and other vasculitis patients influences depressive symptoms and medication adherence.

Method: We used data from the Accessing Social Support in Symptom Treatment (ASSIST) Study, in which vasculitis patients (n=232) completed baseline and 3-month follow-up online surveys. Demographic variables and adherence support were measured at baseline while medication adherence (Morisky adherence scale: α=.60 and .63) and depressive symptoms (CES-D: α=.93 and .92) were measured at baseline and follow-up. We conducted regression analyses cross-sectionally and longitudinally controlling for age, gender, education, race, disease duration, health insurance status, and disease status. Depressive symptoms and medication adherence were modeled separately.

Results: Physician and partner adherence support were negatively associated with depressive symptoms cross-sectionally (B: -4.18 and -3.66, $p<.05$) and longitudinally (B: -4.03 and -3.83, $p<.05$). However, when we controlled for baseline levels of depression, only gender and health insurance were predictive of depression at follow-up. For medication adherence, partner adherence support (B=0.12) was associated with greater adherence cross-sectionally, whereas family support (B=0.08) was positively associated with adherence longitudinally controlling for baseline levels of adherence.

Conclusion: Adherence support from physicians and partners may act as a protective factor against depressive symptoms. Partners and family members appear to positively affect patient medication adherence.

Perceived Restrictions in Participation in Life Situations Among Patients with Rheumatoid Arthritis. Erik Taal[1], Petra Hagens[1], Louise Braakman-Jansen[1] and Martin A.F.J. van de Laar[2], [1]University of Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente & University Twente, Enschede, Netherlands

Purpose: Social consequences of rheumatoid arthritis (RA) can be classified along the lines of the International Classification of Functioning, Disability and Health (ICF), in terms of participation restrictions. Previous research on participation has focused primarily on the impact of RA on paid employment and recreation and leisure, and many measures of participation do not address the evaluative aspects of participation. Purpose of this study was to examine the impact of RA on the patient's perceived participation in life situations and analyse associations between impairments, activity limitations, coping styles (a contextual factor) and participation restrictions within the framework of the ICF.

Method: Cross-sectional data were collected from 143 outpatients with RA who participated in the ongoing Dutch Rheumatoid Arthritis Anti-TNF Monitoring (DREAM) cohort (mean age 55 years, 64% female) and from 119 subjects without RA (mean age 52 years, 67% female). The Impact on Participation and Autonomy (IPA) questionnaire was used to assess person-perceived restrictions in five participation domains: autonomy indoors, family role, autonomy outdoors, social relations, and work and education. Impairments were measured by a pain score (NRS 0-10), disease activity score (DAS28), and fatigue score (SF-36 vitality scale). Activity limitations were measured with the HAQ-DI. Coping was measured by two higher-order coping styles: "active, problem-oriented", and "passive-avoidant" with the Utrecht Coping List (UCL).

Results: Patients experienced more restrictions in all participation domains compared to non-RA subjects ($P<0.001$). Hierarchical regression analyses revealed that the impairment variables accounted for 42-59% of the variance in participation domain scores. Fatigue and pain were more important predictors of participation restrictions than disease activity. Disease activity was not a significant predictor of restrictions in autonomy outdoors, social relations, and work and education. Activity limitations explained up to 13% of the variance in participation scores and partially mediated the relationships of pain and disease activity with restrictions in participation. Together the coping styles accounted for a significant proportion (3-6%) of the explained variance in participation scores. Higher use of active, problem-oriented coping was related to less participation restrictions with regard to autonomy indoors, family role, social relations, and work and education. Higher use of passive coping was related to more restrictions in social relations.

Conclusion: RA patients experienced more restrictions in participation compared to people without RA. This study highlights the importance of fatigue as an independent predictor of participation restrictions next to pain and disease activity, and suggests that activity limitations act as a pathway to explain the association between impairments and participation in life situations. Finally, coping styles (a contextual factor in the ICF model) are independent predictors of participation.
