Reliability, Validity, and Minimally Important Differences of the UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract (UCLA SCTC 2.0) Instrument. Dinesh Khanna[1], Ron Hays[1], Paul Maranian[2], James R. Seibold[3], Ann J. Impens[3], M. Mayes[4], Philip J. Clements[5], Nihal Fathi[6] and Daniel E. Furst[1], [1]UCLA, Los Angeles, CA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]University of Michigan, Ann Arbor, MI, [4]U.Texas Houston, Houston, TX, [5]UCLA School of Medicine, Los Angeles, CA, [6]Assiut University Hospital, Assiut, Egypt

Purpose: We developed a scleroderma gastrointestinal tract (SSC-GIT 1.0) instrument. The present study refines the SSC-GIT 1.0 by differentiating reflux symptoms from distention/bloating, adding a rectal incontinence scale, and creating a composite score of overall GIT burden of SSc In addition, we estimate minimally important differences of the new instrument.

Method: We administered the SSC-GIT 1.0 and SF-36v.2 to 152 patients with SSc at 3 scleroderma centers; 1 item was added to SSC-GIT 1.0 to assess rectal incontinence. In addition, subjects completed a rating of the severity of their GIT (very mild to very severe) and physicians noted the GIT diagnosis. We evaluated internal consistency reliability, test-retest reliability (1.1 week mean time interval in 25 patients) and performed multitrait scaling analysis. 115 of the 152 patients completed the questionnaires again at Time2 (25.2 week mean time interval). Patients also completed ratings of their overall, upper, and lower GIT involvement. For example: “Compared to your last visit, how would you rate your overall/upper/lower gastrointestinal symptoms? Much better, a little better, almost the same, a little worse, or much worse.” The minimally changed group was defined by those reporting they were a little better.

Results: Study participants (n=152) were female (84%) and Caucasian (81%); 55% had diffuse SSc and mean age was 51 years. Self-rated severity of GIT ranged from no symptoms to very mild (39%), to mild (21%), to moderate (31%), to severe or very severe (9%). Of an initial 53 items in SSC-GIT 1.0, 19 had low item-total correlations (<0.40) or poor discrimination among scales and were excluded, leaving a 34-item final instrument (UCLA SCTC GIT 2.0). Analyses supported 7 multi-item scales: reflux, bloating/ distention, diarrhea, soil, constipation, emotional well-being, and social well-being. Test-retest reliability estimates were >= 0.68 and coefficient alphas >=0.67. Participants who rated their GIT disease as mild had lower (better) scores on all 7 scales and those with "severe" had the higher scores on a 0-3 scale. In addition, symptom scales were able to discriminate subjects with corresponding clinical GIT diagnosis. The total GIT Score, developed by averaging 6 of 7 scales (excluding constipation), was reliable (test-retest 0.81 and Cronbach's alpha 0.71) provided discrimination between mild, moderate, and severe self-rated GIT involvement. MID estimates for improvement in the Total GIT score ranged from 0.16-0.28 (on a 0-3 scale; effect size estimates 0.40-0.52).

Conclusion: This study provides support for the reliability and validity of the UCLA-SCTC GIT 2.0, an improvement over the original instrument designed to assess GIT involvement in patients with SSc. An overall GIT Score was also developed to capture overall burden (severity) of SSc-associated GIT.

Improving Survival Despite Greater Disease Burden in Systemic Sclerosis. Svetlana I. Nihtyanova[1], Edward C. Tang[1], Carol M. Black[1] and Christopher P. Denton[2], [1]Royal Free and University College Medical School, London, United Kingdom, [2]UCL Medical School, London, United Kingdom

Purpose: To determine whether the ascertainment of major organ complications of systemic sclerosis (SSc) has changed over time and if this is associated with better 5 year survival in two groups of cases seen a decade apart at a single tertiary SSc centre.

Methods: Subjects under regular review at our centre with a definite diagnosis of SSc were identified. We analysed patients with disease onset between years 1990 and 1993 (historical cohort) and patients with disease onset between 2000 and 2003 (contemporary cohort). Case notes were reviewed and demographic and clinical data were recorded. Kaplan-Meier estimates of survival and cumulative frequency of moderate to severe organ-based complications in the different subgroups observed over the first 5 years from disease onset were compared.

Results: A total of 520 SSc patients (234 in the historical cohort and 286 in the contemporary cohort) were included. As there was a significant difference between the two cohorts in terms of subset distribution, with the contemporary cohort having larger proportion of patients with the diffuse cutaneous (dc) subset compared to the historical cohort (45% v 32%, p=0.002), survival and frequency of organ complications were compared separately for the limited cutaneous (lc) SSc and dcSSc subjects. There were no significant differences between the historical and contemporary cohorts in terms of gender, age at onset or proportion of patients lost to follow-up.

We found reduction in all cause mortality among the dcSSc patients from the contemporary cohort with estimated 5-year survival probability of 85% compared to 69% for the historical cohort (p=0.012). There was no significant improvement in survival among the lcSSc patients (92% for the 2000-03 group and 91% for the 1990-93 group, p=0.639).

At 5 years from disease onset, a higher proportion of the patients from the contemporary cohort had a diagnosis of clinically significant pulmonary fibrosis (17% of the lcSSc and 39% of the dcSSc subjects) compared to 3% and 7% (limited and diffuse subset respectively) of the historical cohort, p<0.001. Similarly, the diagnosis of pulmonary arterial hypertension was more frequent among the patients from the contemporary cohort compared to those from the historical cohort over the first 5 years of disease (8% v 1%, p=0.002 for lcSSc and 7% v 1%, p=0.132 for dcSSc). Analysis of the proportion of patients who developed scleroderma renal crisis (SRC) or cardiac scleroderma during

the first five years of follow-up showed no significant difference between the historical and the contemporary cohorts. In particular among the dcSSc subjects, the cumulative incidence of SRC was 16% and 19% for the 2000-03 and 1990-93 cohorts respectively, p=0.815.

Conclusion: Despite the absence of proven disease modifying therapy, survival has substantially improved for dcSSc. There is also more complete ascertainment of lung complications of SSc, probably through greater awareness and more systematic annual screening for organ based complications.

Course of Lung Physiology in Patients with Scleroderma and Active Interstitial Lung Disease: Results From the Scleroderma Lung Study (SLS). Dinesh Khanna[1], Niloofar Farmani[2], Chi-Hong Tseng[1], Philip J. Clements[2], Donald Tashkin[2], Michael Roth[2] and Daniel E. Furst[2], [1]University of California Los Angeles, Los Angeles, CA, [2]UCLA, Los Angeles, CA

Purpose: Patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD) usually have the greatest decline in pulmonary function tests in early years of disease onset. Our objective was to assess the natural course of FVC% predicted and DLCO % predicted of 79 patients in the placebo (PLA) group of SLS stratified by 0-2, 2-4 and >4 years of SSc disease duration (defined from first non-Raynaud's symptoms).

Methods: We use 2-sample t-test to compare the rate of decline of FVC between 2 groups and ANOVA for the comparison of 3 groups. We also explored whether decline in the FVC% was different in patients with baseline FVC≥70% vs. < 70% and different degrees of fibrosis on HRCT. A mixed effects model repeated measurement analysis was carried out to compare the time trend FVC for patients with baseline FVC≥ 70% vs. < 70% and baseline fibrosis on HRCT (none to mild vs. moderate to severe) stratified by 0-2, 2-4 and >4 years of SSc disease duration.

Results: Of 79 patients, 77 had baseline disease duration. Of these, 22 (29%), 33 (43%) and 22 (29%) patients were in the 0-2, 2-4 and >4 years disease duration, respectively. There were no statistical differences in the baseline FVC% and DLCO% among 3 groups (p=0.6 for both). The mean (SD) decline in the FVC% predicted during the period of 12 months was -2.9 (8.3). Rate of decline in FVC at 12 month was not significantly different in the 3 groups (p value=0.75, Figures A and B). The mean (SD) decline in DLCO% predicted in the same time period was -3.4 (8.0), which was not significantly different in the 3 groups (p value=0.20). In the sensitivity analysis, rate of decline in the FVC% at 12 month was similar in patients with baseline FVC≥70% vs. < 70% (P value=0.62). However, a greater extent of baseline fibrosis was associated with greater decline in FVC% predicted (p=0.03). For analysis stratified by disease duration, we found significant time trend differences between patients with baseline FVC≥70% vs. < 70% for disease duration > 4 years and fibrosis on HRCT for disease duration 0-2 years, with greater declines in patients with FVC< 70% and greater fibrosis , respectively (p< 0.05).

Conclusion: SLS patients in the PLA group had the same rate of progression of lung disease irrespective of their disease duration or their baseline FVC % predicted. Baseline fibrosis on HRCT was associated with greater decline in FVC% over 12 months. This has implications in design of future SSc-ILD RCTs.

Imatinib Mesylate (Gleevec) in the Treatment of Systemic Sclerosis: Interim Results of a Phase IIa, One Year, Open Label Clinical Trial. Jessica Gordon[1], Jamie Mersten[1], S. Lyman[1], S.A. Kloiber[1], H. F. Wildman[2], M. K. Crow[1], K. A. Kirou[1] and R.F. Spiera[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medical College, New York, NY

Purpose: Imatinib mesylate has been shown in preclinical studies, mouse models, and case reports to decrease fibrosis in Systemic Sclerosis (SSc). We present here the interim results of an investigator initiated phase IIa, single center, single arm, open label clinical trial examining safety and efficacy of imatinib to treat patients with diffuse cutaneous (dc)SSc (NCT00555581.)

Methods: Patients with severe dcSSc are treated with imatinib 400 mg orally per day. Patients are evaluated monthly for 12 months during treatment and are seen in follow-up 3 months after discontinuing imatinib. The primary endpoint is safety as assessed by number of serious adverse events (SAEs) and adverse events (AEs.) Secondary endpoints are change in the Modified Rodnan Skin Score (MRSS), forced vital capacity (FVC), and diffusion capacity (DLCO.) Additional endpoints include the HAQ-DI, SF-36, echocardiogram, and skin histology.

Results: We have completed enrollment with 30 patients. Four patients (13.3%) are African American, and 26 (86.7%) are Caucasian, 4 of whom are Hispanic. Twenty patients have disease duration of less than 4 years and 10 have more than 4 years. Six patients have dropped out of the study.

There have been 156 AEs at least possibly related to imatinib. There have been 24 SAEs including one death from community acquired pneumonia in a patient with preexisting severe pulmonary fibrosis. The most common AEs related to imatinib are fluid retention (80%),

nausea (73%), fatigue (53%), and elevation of creatine kinase (37%). These AEs are frequently self-limited or resolve with dose-adjustment, but fatigue led to discontinuance of drug in two patients.

In the 16 patients who have completed 12 months of treatment, mean MRSS improved from 30.8 ± 9.7 to 23.5 ± 11.1, ($p < 0.001$.) Improvements of MRSS are not seen at 3 months ($\Delta = -0.4 \pm 3.2$ points, $p=0.42$, $n = 26$), but were apparent beginning at 6 months ($\Delta = -4.9 \pm 5.0$, $p < 0.001$, $n = 21$), 9 months ($\Delta=-6.5 \pm 4.3$, $p < 0.001$, $n = 19$), and 12 months ($\Delta = -7.3 \pm 4.6$, $p < 0.001$, $n=16$.) Indices of pulmonary function improved at 1 year. Mean FVC improved from 84 ± 22 to 90 ± 23, $p = 0.039$. Mean DLCO improved from 80 ± 21 to 88 ± 27, $p = 0.037$. Skin histology showed improvement at the 12 month time point and is presented separately.

Conclusion: Our interim analysis demonstrates safety and efficacy of imatinib in the treatment of dcSSc. Imatinib is well-tolerated by most patients. Improvements in MRSS, FVC, and DLCO were observed. Translational investigations are ongoing to delineate mechanisms of action and predictors of response. Placebo-controlled investigation is warranted to better define the role of imatinib in the treatment of SSc.

Figure 1. Change in MRSS is seen starting at 6 months of treatment and further improves at 12 months of treatment.

Rappaport Faculty of Medicine, Technion, Haifa, Israel, [10]Rheumatology, Bialystok, [11]Rheumatology, Pecs, Hungary, [12]Rheumatology, Roma, Italy, [13]Rheumatology, L'Aquila, Italy, [14]Rheumatology, Ancona, Italy, [15]Rheumatology, Berlin, Germany, [16]Rheumatology, Florence, Italy, [17]Rheumatology, Paris, France, [18]Dermatology, Cologne, Germany, [19]Rheumatology A, Cochin Hospital, Paris, France

Purpose: Systemic sclerosis (SSc) is associated with a significant reduction in life expectancy. A simple prognostic model to predict 5-year survival was developed in a British centre in 1999 in 280 patients, but it was not validated in other samples. Usually, a prognostic model is less accurate in new patients, especially from other centres or countries.

To validate the prognostic model to predict 5-year survival in SSc provided by Bryan et al. (1999) in other SSc centres throughout Europe.

Method: A European multi-centre cohort of SSc patients diagnosed before 2002 was established. Data were collected in clinical practice and stored in clinical charts or databases. Patients with Scleroderma according to the preliminary ACR criteria were eligible for this study when they were followed for at least five-years or shorter if they died. Patient-observation time started at the moment the diagnosis of SSc was secured (baseline) and ended at 5-years follow-up or at the moment of death, whichever came first. The primary outcome was 5-year survival after diagnosis of SSc. For the prognostic logistic regression model, the following baseline variables were used: age, gender, urine protein presence, ESR, and carbon monoxide diffusing capacity (DLCO).

Results: Data were available for N=1049 patients,119 (11.2%) of them died within 5 years after diagnosis. Of the patients there were 85% female, mean (SD) age at diagnosis was 50 (13.4), and 30% were classified as having diffuse SSc. At diagnosis, the median (P25-P75) ESR was 17 (9-33), elevated ESR (>25) was present in 298 (33.6%) patients, urine protein was present in 56 (6.5 %) patients, the median (P25-P75) DLCO in '% expected' was 75 (60-80), low DLCO (<70%) was present in 324 (42.8%) patients. The prognostic model with age (OR 1.03), gender (OR 1.93), urine protein (OR 2.29), elevated ESR (1.89) and low DLCO (OR 1.94) had an area under the ROC curve of 0.73. Of the patients with no risk factors, 9/232 (3.9%) died, with 1 risk factor 29/219 (14.2%) died, with 2 risk factors 20/93 (21.5%) died, and with 3 risk factors 4/16 (25%) died.

Conclusion: A simple prognostic model using 3 disease factors to predict 5 year survival at diagnosis in SSc showed reasonable discriminatory performance upon validation in a European multi-centre study. Update of the formula may increase discrimination and precision of the predictions.

A Proof of Concept Trial of Gleevec (Imatinib) in Active Diffuse Scleroderma (DSSc). Janet Pope[1], Donna L. McBain[2], Lisa Petrlich[1], Sharon Watson[1], Louise Bender[1], Faye Deleon[3] and Kelly Summers[4], [1]St Joseph Health Care, London, ON, [2]St Josephs Health Care, London, [3]McMaster University, Hamilton, ON, [4]University of Western Ontario, London, ON

Purpose: There has been interest in tyrosine kinase inhibitors in systemic sclerosis (SSc) due to the effects on PDGF, TGFbeta, adhesion molecules and other factors.

Method: We performed a 6 months proof of concept double blinded RCT of imatinib in active diffuse SSc with skin biopsies using 2mm biopsy on abdomen at time 0 and repeated beside original biopsy at 6 months; and plasma (0,3,6 months) analyzing PDGF, RANTES, E-Selectin, VCAM-1, ICAM-1, MMP-9, tPAI-1, IFN-gamma, IL-1alpha, IL-1beta, IL-4, 6, 10, 12p70, 13, 17; MCP-1,3, MIPs, CD40L, VEGF, TNFalpha, and TGFbeta, and patient and physician outcomes including HAQ, and modified Rodnan skin score (mRSS). We used 4:1

randomization and planned to enroll 20 patients, stratifying by presence or absence of stable background Methotrexate use. Novartis supplied imatinib and placebo for this investigator initiated study.

Results: After enrolling 10 patients mean age (9 active and one placebo);7 Female, mean age 51, 3.1 years disease duration (0.5 to 6 years) and mRSS skin score: 32 (SD 8), 3 had tendon friction rubs, patient global 66 (on 100 mm VAS), MD global 46, and HAQ 1.7; we found poor tolerability and high AEs (5 had to stop due to AEs or interrupting dose including fluid retention, weakness, nausea, vomiting, chest pain, worsening anemia, and hair loss), only 4 patients completed the 6 months on study drug at recommended dose. There was also one SAE (active drug marked fluid retention) so we stopped enrolling further subjects. Using ITT analysis, at 6 months, we found: no difference in any parameter with all p values (none were near significance) including: skin score (6 months mRSS 30. P=0.6), CRP, ESR, MD global (36) and patient global (39), HAQ (1.5), tissue (skin biopsy) and plasma cytokines and other factors. The 6 months health transition was rated by two who dropped out as much worse, and one more as much worse, another worse, 4 the same and 2 better. The plasma and tissue cytokines in those on active treatment were not statistically different from 0 to 6 months except sVCAM-1(plasma $p<0.001$) and sICAM-1 (tissue $p=0.009$).

Conclusion: In relatively early active disuse SSc, imatinib was not well tolerated and did not change any clinical or skin biopsy parameters over 6 months. It is unlikely that imatinib will be a feasible treatment for early SSc with respect to modifying skin sclerosis or inflammation.

Glucocorticoid-Induced Fat Accrual Is Mediated by the Osteoblast. Holger Henneicke[1], Markus Herrmann[1], Janine Street[1], James Modzelewski[1], Frank Buttgereit[2], Hong Zhou[1] and Markus Seibel[1], [1]Bone Research Program, ANZAC Research Institute, The University of Sydney, Sydney, Australia, [2]Charite University Med-Berlin, Berlin, Germany

Purpose: Osteoblasts may be involved in the regulation of energy metabolism. To define whether the metabolic effects of glucocorticoids (GC) are mediated via the osteoblast, we used a transgenic mouse model in which a GC inactivating enzyme, 11ß-hydroxysteroid-dehydrogenase type 2 (11ßHSD2), has been targeted exclusively to mature osteoblasts via the 2.3kb collagen type Ia1 promoter. This transgene is expressed in osteoblasts/osteocytes but not in fat, pancreas, liver, muscle or the CNS.

Method: Transgenic (tg, n=16) and wild type (WT, n=16) mice received either corticosterone (CS) or placebo (PLC) via s.c. pellet implantation for 28 days. In a second experiment, WT mice (n=29) received either CS, CS + warfarin (1.25mg/L drinking water), PLC, or PLC + warfarin for 4 weeks. At day 28, body composition was measured by DXA. Gonadal (GF), retroperitonal (RF) and inter-scapular (IF) fat pads were dissected and weighed. Serum total and uncarboxylated (uc) osteocalcin (OCN), PINP (a marker of bone formation) and cholesterol were measured on day 0, 14 & 28.

Results: At day 28, CS treatment resulted in significant bone loss in WT but not in tg mice. Body weight gain over 28 days was greater in CS-treated WT mice (3.7g) than in CS-treated tg animals (1.9g). Fat masses (total body: 12.1 vs. 8.1g, $p< .01$; GF: 1.41 vs. 0.81g, $p< .01$; RF: 0.29 vs. 0.18, $p< .05$; IF: 0.60 vs. 0.36, $p< .01$) as well as serum cholesterol levels ($p<.05$) were all lower in CS-treated tg than in WT mice. None of these parameters differed significantly between PLC-treated tg and WT mice.

Serum OCN decreased in both CS-treated WT (-75%) and tg (-58%) animals, with total OCN levels remaining higher in tg than in WT mice during CS-treatment ($p< .01$). At day 28, serum ucOCN levels were reduced in CS-treated WT mice ($p<.01$) with no difference between CS-treated tg mice and controls (Fig.1). In contrast, serum PINP levels changed similarly in tg and WT animals during CS exposure.

In pilot studies, warfarin increased the ucOCN fraction from 29% to 54%. Total body fat (11.5 vs. 10.4; NS), GF (1.34 vs. 1.16, NS), RF (0.27 vs. 0.21, p< .05) and IF (0.43 vs. 0.36, p= .08) masses were lower in CS+warfarin-treated WT mice as compared to CS only-treated mice.

Conclusion: Osteoblast-targeted disruption of GC signalling attenuates GC-induced fat accrual and hyperlipidaemia in mice. Some of the effects of GC on energy metabolism appear to be, at least in part, mediated by osteocalcin.

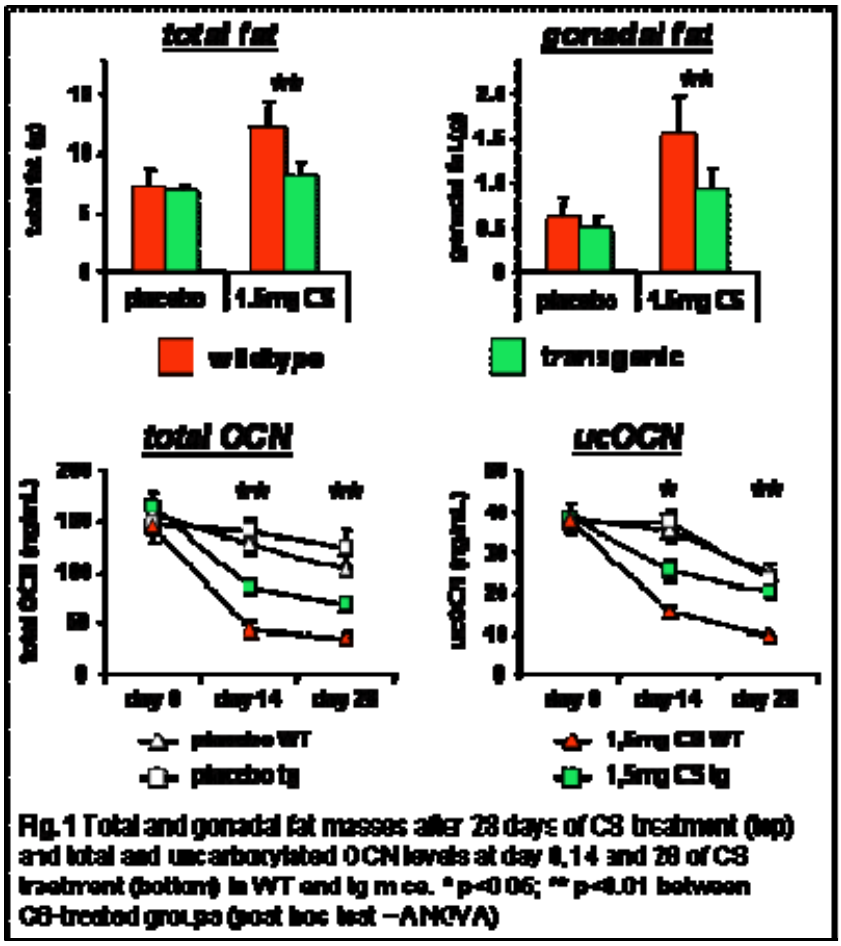

Fig.1 Total and gonadal fat masses after 28 days of CS treatment (top) and total and uncarboxylated OCN levels at day 0,14 and 28 of CS treatment (bottom) in WT and tg mice. * p<0.05; ** p<0.01 between CS-treated groups (post hoc test –ANOVA)

The Surface Expression Level of DC-STAMP Defines the Fusogenic Potential of Osteoclast Precursors (OCP): RANKL-Induced DC-STAMPlo OCP Are the Master-Fusogens. Kofi A. Mensah[1], Yahui Grace Chiu[1], L. Xing[1], Christopher Ritchlin[2] and E.M. Schwarz[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY

Purpose: Osteoclasts (OC) form by fusion of heterogeneous OC precursors (OCP). As OCP heterogeneity can be phenotyped by fusogenic potential (multinucleated master fusogens vs. mononuclear OCP donors) we hypothesized that DC-STAMP, a 7-transmembrane protein receptor required for OCP fusion, mediates this heterogeneity. To test this we evaluated the expression of fusogenic genes and the fusogenic potential of DC-STAMP^{hi} vs. DC-STAMP^{lo} OCP after culture with RANKL. We also evaluated DC-STAMP as an OCP biomarker in patients with inflammatory-erosive psoriatic arthritis (PsA).

Methods: FACS with a monoclonal antibody against DC-STAMP (1A2) was used to purify DC-STAMPlo and DC-STAMPhi RAW 264.7 cells and human peripheral blood mononuclear cells (PBMC). Gene expression before and after culture with RANKL was determined by real time RT-qPCR and flow cytometry. Fusogenic potential was determined by TRAP osteoclastogenesis assay. 2-color immunocytochemistry (ICC) for DC-STAMP and actin were performed on mouse and human OC cultures. Flow cytometry was also used to analyze PBMC from healthy controls (n=14) and PsA patients (n=21).

Results: Incubation of homogeneous DC-STAMPhi RAW cells for 3-days with RANKL produced DC-STAMPlo and DC-STAMPhi heterogeneous cultures. Independent RT-qPCR of these populations showed that *cd9*, *cd47*, and *oc-stamp* were up-regulated 1.5, 1.9, and 21-fold in DC-STAMPlo. These markers were down-regulated or unchanged in the DC-STAMPhi cells. *Trap* was significantly up-regulated 11.3 fold in the DC-STAMPlo population compared to the DC-STAMPhi group. In both groups, *rank* expression was down-regulated 97-99%, and *trem2* expression was up-regulated 7-10 fold. RANKL and M-CSF treatment of human PBMC generated similar DC-STAMP^{lo} and DC-STAMP^{hi} OCP. ICC of OC cultures confirmed that mononuclear OCP are DC-STAMP^{hi} and mature OC are DC-STAMP^{lo}. Consistent with this, we showed that only DC-STAMP^{lo} are pseudopodia producing OCP that have fusagenic potential, while DC-STAMP^{hi} can only serve as mononuclear donors. DC-STAMP+ freshly-isolated PBMC was significantly higher in PsA patients compared to controls (MFI = 3501±229 vs. 1259±85).

Conclusion: Although the DC-STAMP ligand remains unknown, this RANKL-induced factor delivers a critical signal to DC-STAMPhi mononuclear OCP, which induces the expression of genes involved in cell fusion while down-regulating DC-STAMP surface expression. The resulting DC-STAMPlo OCP are "master fusogens" that express higher levels of OC markers and pseudopods that seek out and attach to DC-STAMPhi OCP to form multinucleated OC. The higher frequency of DC-STAMP+ cells among PsA patients versus healthy controls suggests that DC-STAMP surface expression on PBMC, prior to RANKL exposure, may be a dynamic biomarker to assess the aggressiveness of erosive arthritis.

Anticonvulsant Use, Falls, Fractures and BMD : Findings From the Women's Health Initiative. Laura Carbone[1], Karen Johnson[2], John Robbins[3], Joseph Larson[4], J. David Curb[5], Kathleen Watson[6], Margery Gass[7] and Andrea LaCroix[8], [1]Univ of Tenn at Memphis, Memphis, TN, [2]University of TN, Memphis, TN, [3]University of California, Davis, CA, [4]Fred Hutchinson Cancer Research Center, Seattle, WA, [5]University of Hawaii, HI, [6]University of Washington, Seattle, WA, [7]University of Cincinnatti, [8]Fred Hutchinson, Seattle, WA

Purpose: Anticonvulsants, particularly those that inhibit the cytochrome P450 enzyme- inducing system, may be associated with risks for fracture. The purpose of this study was to determine the relationship of anticonvulsant use to falls, fractures and bone mineral density (BMD) in postmenopausal women.

Methods: We included 138,667 women (1,385 users of anticonvulsants and 137,282 non users of anticonvulsants) aged 50-79 who enrolled in the Women's Health Initiative (WHI) from 1993-1998. Women who had BMD measurements at baseline and year 3 (84 anticonvulsant users and 8,677 non users of anticonvulsants) were also examined. Incident falls and fractures were determined over an average of 7.7 years of follow-up. BMD changes from baseline to year 3 at the total hip, lumbar spine and total body were calculated.

Results: After adjustment for covariates including age, ethnicity, BMI, calcium and vitamin D intake, prevalent fractures and falls, medication use, smoking and alcohol use, parental history of hip fractures, age of menopause, physical activity levels, physical function, self reported health, other medical conditions and WHI trial participation, use of anticonvulsants was positively associated with total fractures (HR 1.44 (95% CI 1.30,1.61), site specific fractures including hip fractures (HR 1.51 (95% CI 1.05, 2.17), clinical vertebral (HR 1.60 (95% CI 1.20, 2.12), lower arm or wrist (HR 1.40 (95% CI 1.11, 1.76) and other clinical fractures (HR 1.46 (95% CI 1.29, 1.65) and 2 or more falls ((HR 1.62 (95% CI 1.50, 1.74) but not with baseline BMD or changes in BMD at the total hip, lumbar spine or total body ($p \geq 0.064$ for all sites). Use of more than one and use of enzyme-inducing anticonvulsants were significantly associated with total fractures (HR 1.55 (1.15, 2.09) and (HR 1.36 (95% CI 1.09, 1.69) respectively.

Conclusion: After adjustment for potential confounders, users of anticonvulsants had an increased risk for total fractures and site specific fractures including hip, clinical vertebral and wrist fractures. The association of anticonvulsant use with fractures was stronger with use of more than one anticonvulsant, and use of enzyme-inducing anticonvulsants. Whether the association of anticonvulsants with fractures is a function of the drug itself or rather, the condition it is being prescribed for merits further study. In clinical practice, however, postmenopausal women who use anticonvulsants should be considered at increased risk for fracture, and attention to fall prevention in these women may be particularly important.:

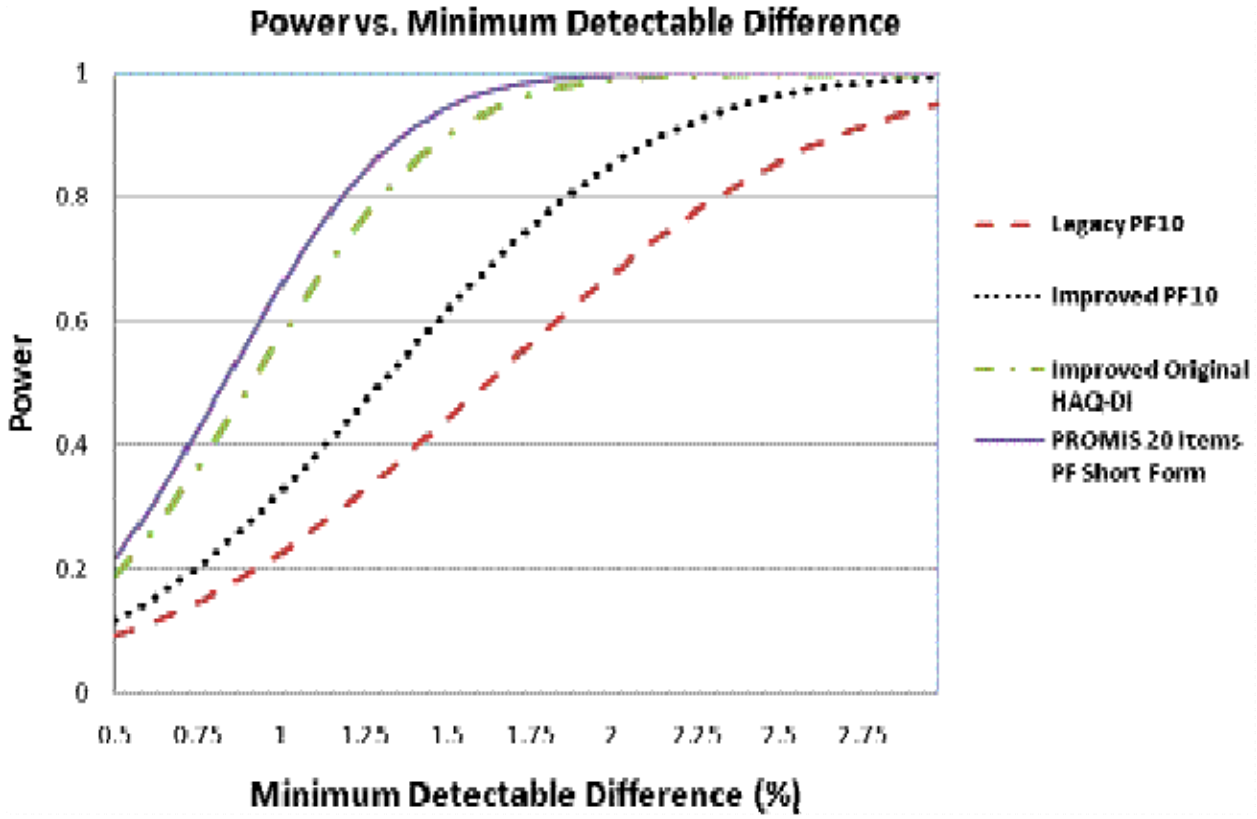
Improved Responsiveness of Physical Function (Disability) Scales Based Upon Item Response Theory (IRT). James F. Fries[1], Eswar Krishnan[2], Matthias Rose[3], Bharathi Lingala[4] and Bonnie Bruce[5], [1]Stanford Univ Medical Ctr, Palo Alto, CA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]QualityMetric, Inc., Waltham, MD, [4]Stanford University, CA, [5]Stanford Dept of Medicine, Palo Alto, CA

Purpose: The original Health Assessment Questionnaire (HAQ-DI) and PF-10 items from the SF-36 have yielded familiar, sensitive and valid clinical Physical Function (PF) endpoints. Now, Item Response Theory (IRT) permits major instrument improvements. IRT analyses can calibrate items with the greatest information content for deployment in more powerful instruments. The NIH Patient Reported Outcomes System (PROMIS) is charged with development of improved IRT-based tools. We compare the original HAQ and PF-10 instruments with successor IRT-based instruments

Methods: We compared six PF (Disability) scales (Original PF-10, Original HAQ, IRT-improved PF-10 and IRT-based HAQ, and the PROMIS 20-item Short-Form using items selected by IRT for maximal information content. We assessed sensitivity to detect six-month longitudinal self-reported improvement, and intensification of treatment in patients with Rheumatoid Arthritis (RA). Metrics for sensitivity were the p-value, the Standardized Response Mean (SRM), Cohen and Guyatt Effect Sizes, minimally detectable differences, and required sample sizes. Questionnaires each contained all items from all instruments but the order of original and new items was randomized to eliminate order effects. Of 521 subjects, 467 (90 %) completed baseline and six-month assessments.

Results: Patients met ACR criteria, averaged 65 years of age and 14 years of education, were 80 % female and 87 % Caucasian, and had baseline original HAQ scores of 0.9 with an SD of 0.7. All instruments were sensitive to changes over time, with p-values ranging from 0.04 to 0.0002 and SRM and Effect Size computations mirroring these results. The most sensitive to change were the improved 20-item Short Forms, regardless of the scoring algorithm or endpoint used. Under study conditions, IRT-Improved instruments could detect a 1.2 % difference with 80 % power, while reference instruments could detect only a 2.3 % difference ($p < 0.01$). The Figure compares instruments on the minimally detectable difference as a function of study power. Under test conditions, detection of a 2.3 % difference with IRT-improved instruments required only 26 % of the sample sizes of the reference instruments (106 vs. 404).



Conclusion: Development of outcome assessment instruments from IRT-calibrated items results in greater sensitivity and efficiency. This can improve the science of outcome assessment, the precision of results from clinical studies, and reduce sample size requirements, thereby reducing recruitment time and reducing costs, and markedly improving study efficiency.

Does the Benefit of Medication Adherence Relate More to a Drug Effect or the Behavior Itself? Quantifying the Effect of Adherence Behavior Using Data From the Placebo Arms of the WHI. Jeffrey Curtis[1], Joseph Larson[2], Elizabeth Delzell[1], Suzanne Judd[1], Monika M. Safford[1], Andrea LaCroix[2] and Rowan Chlebowski[3], [1]UAB, Birmingham, AL, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]UCLA, Los Angeles, CA

Purpose: The relationship between medication adherence and various outcomes including fracture is of substantial interest, particularly in the osteoporosis community. The extent to which adherence to medications as a behavior is a proxy for other healthy behaviors that affect outcomes is unclear. To better understand the magnitude of the effect of adherence as a behavior, we examined the relationship between adherence to placebo in the hormone therapy (HT) arm of the Women's Health Initiative (WHI) on the risk of fracture, cardiovascular events, malignancy and death.

Method: We used data from those randomized to placebo in the HT arm of the WHI. Adherence was represented as time-varying based upon pill counts and quantified as a medication possession ratio (MPR). Outcome events were identified and validated using medical records as per the original WHI protocol. Confounders were selected a-priori and based upon the ability to adjust the main exposure-outcome relationship by > 10%. Cox proportional hazards models were used to evaluate the relationship between adherence (≤ 50%, 50-80%, ≥ 80%) and each of the various outcomes, with low adherence as referent. Analyses were censored at the first event specific to each outcome.

Results: A total of 13485 women were randomized to placebo in the HT arm of the WHI and were under observation for 86091 person-years (without respect to censoring). The median (IQR) cumulative adherence to placebo at the end of the trial was 91.3% (81.4, 96.0%). There was a consistent relationship between adherence to placebo and a protective effect of all outcomes that was strongest for death and hip fracture, although not all results were statistically significant (see table). Results were not substantially affected by multivariable adjusted for various confounders.

Conclusion: Medication adherence appears to be a proxy for other unmeasured behaviors and health habits that have important effects on numerous outcomes. The magnitude of this effect was greatest for hip fracture and death. Results of future studies evaluating outcomes related to adherence to specific medications should be interpreted cautiously in light of these results.

Table: Relationship between Medium & High Adherence to Placebo and Various Events, referent to Low Adherence

	Medium Adherence (MPR 50—80%)		High Adherence (MPR >= 80%)	
	Crude HR	Adjusted* HR	Crude HR	Adjusted* HR
Death	0.81 (0.61, 1.08)	0.82 (0.62, 1.10)	0.48 (0.38, 0.60)	0.51 (0.41, 0.64)
Hip fracture	0.76 (0.41, 1.41)	0.66 (0.36, 1.23)	0.61 (0.39, 0.96)	0.50 (0.32, 0.79)
Clinical vertebral fracture	1.06 (0.54, 2.10)	1.02 (0.51, 2.02)	0.92 (0.54, 1.57)	0.81 (0.48, 1.39)
Non-hip, non-vertebral fracture	1.11 (0.87, 1.41)	1.10 (0.86, 1.41)	1.17 (0.97, 1.42)	1.11 (0.92, 1.34)
Cardiovascular event (e.g. AMI)	0.96 (0.63, 1.47)	0.93 (0.61, 1.42)	0.90 (0.65, 1.24)	0.91 (0.65, 1.26)
Invasive breast cancer	1.00 (0.62, 1.59)	0.98 (0.61, 1.56)	0.75 (0.52, 1.08)	0.72 (0.50, 1.05)
Total breast cancer	0.84 (0.54, 1.31)	0.83 (0.53, 1.29)	0.80 (0.57, 1.11)	0.76 (0.55, 1.06)
Colorectal cancer	2.35 (1.08, 5.11)	2.32 (1.07, 5.04)	1.44 (0.72, 2.86)	1.40 (0.70, 2.80)

MPR = medication possession ratio; HR = hazard ratio; AMI = acute myocardial infarction. All models are stratified by randomization arm of the WHI Dietary Modification trial (Active, Comparison, Not Randomized) and prevalent condition.

* adjusted for age, ethnicity, body mass index, self-reported health, education, current smoking, and history of fracture after 55.

Farm History, Insecticide Use and Risk of Autoimmune Rheumatic Disease in the Women's Health Initiative Observational Study.

Christine G. Parks[1], Brian T. Walitt[2], Mary Pettinger[3], Jiu-Chiuan Chen[4], Anneclaire de Roos[3], Julie Hunt[3], Gloria Sarto[5] and Barbara V. Howard[6], [1]National Institute of Environmental Health Science, Research Triangle Park, NC, [2]Washington Hospital Center, Washington, DC, [3]Fred Hutcinson Cancer Research Center, Seattle, WA, [4]USC Keck School of Medicine, Los Angeles, [5]University of Wisconsin Medical Center, Madison, [6]Medstar Research Institute, Washington, DC

Purpose: Farming has been previously associated with the autoimmune rheumatic diseases (ARD), including rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). The exposure(s) underlying this association are not well-understood, and few studies have directly addressed the role of pesticides, including personal and residential insecticide use. **Method:** Using data from the Women's Health Initiative Observational Study (n=76,861, aged 50-79 years), we examined self-reported lifetime personal or commercial residential insecticide use and having lived or worked on a farm in relation to risk of incident ARD, confirmed by use of disease modifying anti-rheumatic drugs at year 3 of follow-up (n=213; 178 with RA only, 27 with SLE only, and 8 with both RA and SLE), and excluding unconfirmed cases. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated by multivariate models adjusting for age and covariates, including race, region, education, occupation, history of smoking, asthma, other autoimmune diseases, co-morbidity, and reproductive factors. **Results:** Compared with never use, personal insecticide use (mixing or applying) was associated with ARD risk, with stronger associations among those with a greater frequency (age-adjusted HR=2.47; 95%CI 1.51, 4.03 for ≥ 6 times per year) and duration of use (age-adjusted HR=2.07; 95% CI 1.31, 3.25 for ≥ 20 years). Increasing cumulative insecticide use (years X applications) also showed a significant trend of association (p=0.0004) with ARD risk, and these associations persisted after adjusting for farming and covariates. Having lived or worked on a farm was also associated with ARD risk (age-adjusted HR=1.97; 95% CI 1.14, 3.42 for ≥20 years), but the effect size was diminished after adjusting for covariates and insecticide use. Despite the small number of SLE cases, disease-stratified analyses indicated similar associations as seen for RA. In those who had lived or worked on a farm, frequent commercial application to home or garden was also associated with ARD risk, even after adjusting for covariates and personal insecticide use (adjusted HR=2.73; 95%CI 1.1, 6.78 for ≥6 times per year). Long-term commercial residential insecticide exposure was significantly associated with ARD risk regardless of farming history (age-adjusted HR=1.85; 95% CI 1.13, 3.04 for ≥20 years). **Conclusion:** Insecticide exposure may increase risk of ARD in post-menopausal women. These findings, based on self-report, provide rationale for further investigation of specific personal and environmental insecticide exposures in relation to ARD.

The Relationship Between Bisphosphonate Adherence and Fracture: Is It the Behavior or the Medication? - Results From the Placebo Arm of the Fracture Intervention Trial. Jeffrey R. Curtis[1], Suzanne Judd[1], Doug Bauer[2], Dennis Black[2], Elizabeth Delzell[1], Kristine Ensrud[3], Monika M. Safford[1] and Ann Schwartz[2], [1]UAB, Birmingham, AL, [2]UCSF, San Francisco, CA, [3]University of Minnesota Medical School, Minneapolis, MN

Purpose: Several observational studies have demonstrated a relationship between compliance to osteoporosis medications and fracture. While medication compliance would be expected to reduce risk, compliance may also be a surrogate for other healthy behaviors that affect fracture risk. Little is known about the size of this potential effect; thus we evaluated the relationship between compliance to placebo and clinical fractures among women participating in the Fracture Intervention Trial (FIT).

Method: Compliance to placebo among participants in the placebo arm of the FIT was evaluated using pill counts. Women were defined as having high compliance if they took ≥ 80% of dispensed placebo. Cox proportional hazards models analyzed the relationship between placebo compliance and various types of clinical fractures. Factors that could affect fracture outcomes were included in multivariable models and included age, baseline bone mineral density, height, body mass index, general health, smoking status, calcium intake, prior clinical fracture, and baseline radiographic vertebral fracture.

Results: Among 3169 women randomized to placebo, 81.8% had high compliance. Among placebo treated women, there were 45 hip, 111 wrist, 75 clinical vertebral and 489 total clinical fractures over a median follow-up period of 4.03 years. For wrist, hip or spine fractures combined, high compliance was associated with a statistically significant 30% lower fracture incidence after adjustment, with similar trends for individual fracture types (Table).

Conclusion: Women participating in a clinical trial of alendronate that were highly compliant to placebo had significantly reduced risk for wrist, hip or clinical spine fractures, suggesting that adherence may be a proxy for other behavior that confers benefit independent of the effect of the medication. Previous observational studies that have reported benefit of bisphosphonates may in part be confounded by healthy behaviors associated with medication adherence.

Table: Relationship between compliance* and fracture

	Crude fracture rate per 100 person years		Hazard Ratio unadjusted	Hazard Ratio adjusted‡
	Compliant	Non-compliant		
Hip fracture	0.35	0.52	0.65 (0.34, 1.31)	0.82 (0.40, 1.69)
Wrist fracture	0.90	1.10	0.82 (0.52, 1.29)	0.75 (0.47, 1.19)
Spine fracture	0.55	1.00	0.55 (0.33, 0.91)	0.66 (0.93, 1.11)
Wrist, hip or spine fracture	1.68	2.51	0.67 (0.49, 0.92)	0.70 (0.51, 0.96)
Any clinical fracture	4.31	4.90	0.88 (0.71, 1.10)	0.90 (0.72, 1.13)

‡ adjusted for age, baseline BMD, height, BMI, general health, smoking status, baseline calcium intake, baseline vertebral fracture, other clinical fracture after age 45

* compliance measured using ≥ 80% threshold

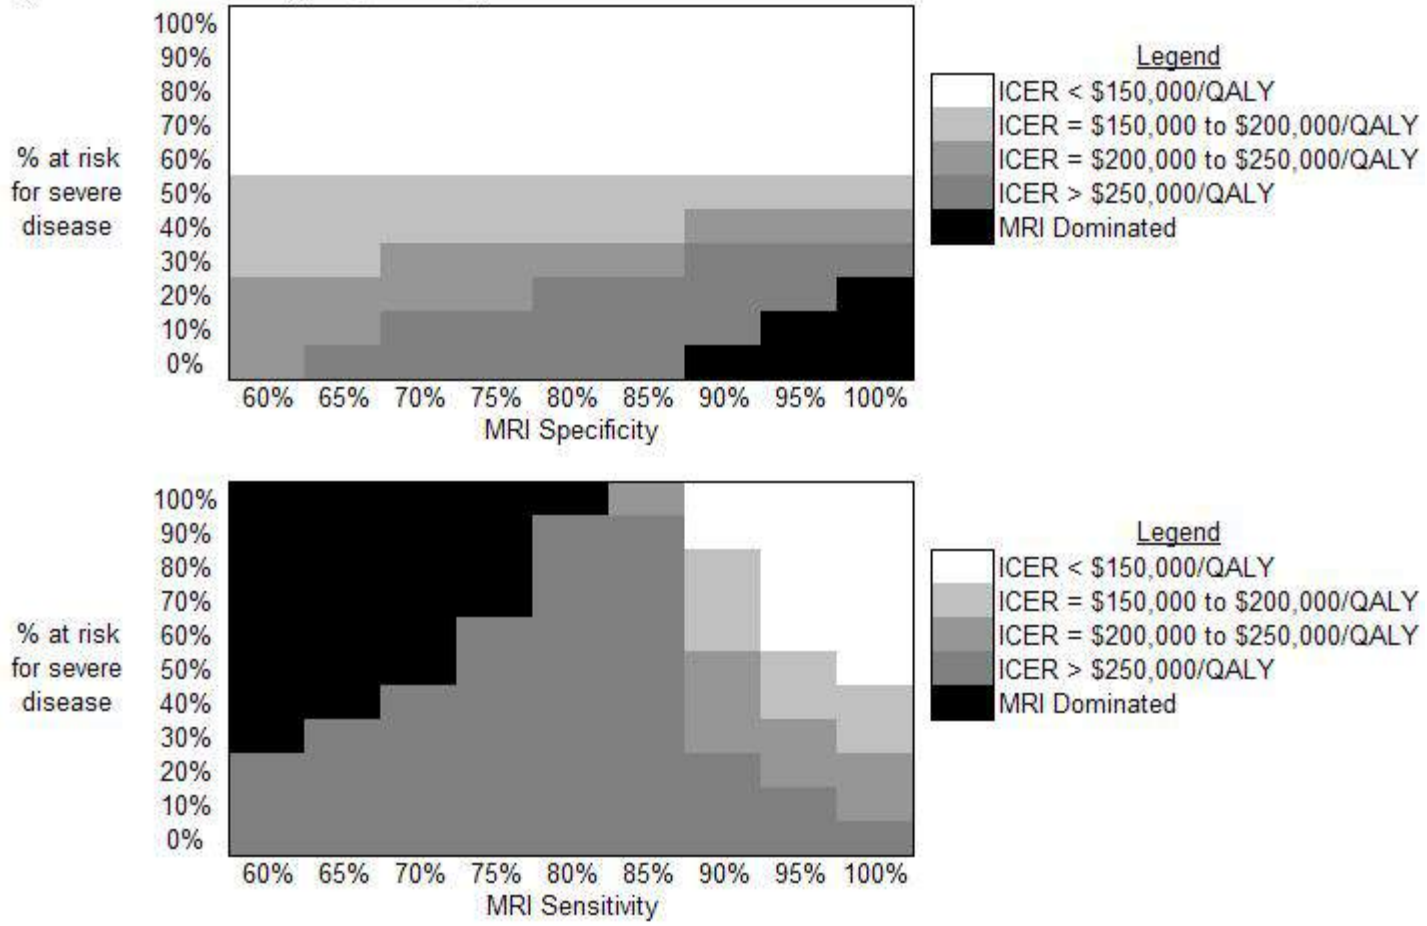
Examining the Cost-Effectiveness of Adding MRI to Early RA Management. L.G. Suter[1], L. Fraenkel[1] and R. S. Braithwaite[2], [1]Yale University, New Haven, CT, [2]Veterans Affairs Health Care System, West Haven, CT

Purpose: Data supports that early treatment for rheumatoid arthritis (RA) improves outcomes, but this approach requires accurate risk stratification to identify those most likely to benefit and avoid over-treatment. MRI has been suggested as a potential tool for risk stratifying early RA patients. Our objective was to explore the cost-effectiveness of adding MRI to standard early RA prognostic markers.

Methods: Using TreeAge® decision analysis software (v. 1.0.2), we created a simulation model of early RA management comparing the addition of MRI to standard assessment (i.e., RF status, CCP antibodies, baseline disease activity) in a population with disease duration <2 years and no erosions on plain radiographs. The model estimated total costs (in 2007 USD) and quality adjusted life years (QALYs). Clinical assessments were performed at 3 month intervals to determine the need for treatment escalation based on disease activity (DAS28) and change over time (ACR50). Adverse events (AEs) were classified as mild (with no associated cost or mortality) or moderate to severe (e.g., requiring treatment or hospitalization and resulting in cost and mortality increases). Cost, quality of life, treatment response, and AE estimates represent the range of data published in randomized trial and observational studies. The model was constructed from the societal perspective with 3% discounting. Sensitivity analyses examined the impact of varying all input estimates, in addition to best and worst case scenarios.

Results: In the base analysis, adding MRI to standard testing increased average per person costs for the first year of treatment from $7,079 to $7,835 and quality of life from 0.810 to 0.815 QALYs, yielding an incremental cost-effectiveness ratio (ICER) of $151,200/QALY gained. Increasing the proportion of individuals at risk for severe disease or increasing the proportion of individuals receiving more aggressive treatment (e.g., by decreasing MRI specificity or improving sensitivity) improved the cost-effectiveness of MRI (Figure 1).

Figure 1. ICERs for adding MRI, according to % at risk for severe disease and MRI characteristics



Conclusion: This model provides a formal framework for evaluating the cost-effectiveness of MRI in early RA management. Short-term analyses suggest that, despite conferring small quality of life gains in the first year of treatment, MRI is unlikely to be cost-effective in the short-term at currently acceptable thresholds among individuals at low risk for severe disease (e.g., very early RA or undifferentiated inflammatory arthritis). Longer-term analyses are needed to better define the populations, treatment regimens and MRI characteristics for which MRI is cost-effective.

Chronic TLR9 Activation Initiates Secondary Macrophage Activation Syndrome without Hemophagocytes and in the Absence of Foreign Antigen. Edward M. Behrens[1], Tara T. Donnelly[2], Portia A. Kreiger[3], Michele Paessler[2] and Gary A. Koretzky[4], [1]Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Phila, Phila, PA, [3]A.I. DuPont Hospital, Wilmington, DE, [4]Univ of PA School of Medicine, Phila, PA

Purpose: Macrophage Activation Syndrome (MAS) is a potentially fatal complication of many rheumatic illnesses, most notably Systemic Juvenile Idiopathic Arthritis. Previous animal models suggest that an inability to adequately clear foreign antigen (Ag) presented to CD8+ T-cells results in MAS. These models are limited by the fact that they require infection to generate disease, making it difficult to separate infectious pathology from MAS pathology. Furthermore, they all require a background of genetic defects in CD8+ T-cell cytotoxicity, defects not generally found in the secondary MAS seen in humans. We describe the first animal model of secondary, non-infectious MAS utilizing chronic TLR9 stimulation.

Method: Mice were treated with every other day i.p. injections of 50 μg of CpG (TLR9 agonist) +/- Ag (ovalbumin (OVA), 100 μg). Complete blood counts were done on day 9, and mice were taken for necropsy on day 11. The following parameters were measured: splenic weight and cellularity; splenic leukocyte numbers and activation status; bone marrow, spleen, and liver histology; CD163 immunostaining of bone marrow and spleen; and serum ferritin and IFNγ levels. Statistical analysis used t-tests or Mann-Whitney tests where appropriate.

Results: Mice treated with repeated doses of CpG, but not a single dose, nor with PBS developed the following: splenomegaly, pancytopenia, hyperferritinemia, fibrin microthrombi consistent with consumptive coagulopathy, without evidence of malignancy (all $P < 0.05$). Thus, these mice developed 5/8 necessary criteria for MAS, sufficient for diagnosis. Also consistent with MAS were elevated serum IFNγ, splenic architecture disruption, and hepatic inflammation (all $P < 0.05$). Chronic CpG treatment led to CD8+ T-cell activation as measured by $CD69^{hi}CD62L^{lo}$ surface markers ($P < 0.05$), CD4+ T-cells and B-cells were unaffected. Total spleen cell counts were increased. Although absolute numbers of lymphocytes and macrophages were unaffected, splenic dendritic cells were decreased in chronic CpG treated mice ($P < 0.05$). Surprisingly, hemophagocytes (HPCs) were not observed in the bone marrow of CpG treated mice, and CD163 immunostaining was negative, separating the presence of HPCs from the initiation of disease. Addition of the foreign Ag OVA resulted in the additional activation of CD4+ T-cells and B-cells, but still did not result in HPCs.

Conclusion: Chronic TLR9 activation leads to a clinical syndrome indistinguishable from MAS. Surprisingly, these mice develop MAS without developing HPCs. Therefore, with this model we have separated bonafide MAS from the development of HPCs, arguing against a role for HPCs in disease initiation. Current models propose that prolonged antigemia leads to MAS. Based on our results we suggest that adjuvantemia, particularly TLR9 adjuvants, may lead to MAS. Intriguingly, this may explain the association of EBV infection, a DNA virus capable of triggering TLR9, with the development of MAS.

Shared Loci Between Juvenile Idiopathic Arthritis and Other Autoimmune Diseases. Susan D. Thompson[1], Paula S. Ramos[2], Marc Sudman[1], Miranda C. Marion[2], Cornelia Mueller[3], Johannes-Peter Haas[4], Sampath Prahalad[5], Andrew S. Zeft[6], John F. Bohnsack[6], Carol A. Wise[7], Marilynn G. Punaro[7], Carlos D. Rosé[8], Jasmin Divers[2], Carl D. Langefeld[2] and David N. Glass[1], [1]Childrens Hospital Med Ctr, Cincinnati, OH, [2]Wake Forest University Health Sciences, Winston-Salem, NC, [3]University Hospital, Greifswald, Germany, [4]German Centre for Rheumatology in Children and Adolescents, Garmisch-Partenkirchen, Germany, [5]Emory University, Atlanta, GA, [6]University of Utah, Salt Lake City, UT, [7]Texas Scottish Rite Hospital for Children, Dallas, TX, [8]duPont Hospital for Children, Wilmington, DE

Purpose: The basis for susceptibility to common autoimmune diseases (AD) including Juvenile Idiopathic Arthritis (JIA) is a complex interplay between multiple genetic and environmental risk factors. The use of genome-wide association studies has identified both disease-specific mechanisms and common pathways across diseases. This study tests for association between JIA and SNPs reported in AD studies.

Method: A list of SNPs reported in the AD literature (not including the MHC region) was compiled. After adjusting population substructure, association testing was done for the candidate SNPs using Affymetrix SNP6.0 GeneChip data comprising 809 JIA subjects (ILAR revised criteria; European ancestry), 531 regionally matched controls and 3004 out-of-study controls (Wellcome Trust Consortium, Affymetrix 500K data). SNPGWA was used for association testing. Missing data proportions, minor allele frequency and departure from HWE were calculated. Replication of statistically significant SNPs ($p < 0.005$) utilized independent JIA (n=1006) and control cohorts (n=1340) from Centers in the U.S. and Germany.

Results: Evidence for association was seen for SNPs within or near genes encoding intracellular signaling molecules PTPN2: rs2847297 ($p=1.29x10^{-6}$, OR=1.34), rs7234029 ($p=7.19x10^{-11}$, OR=1.74), PTPN22: rs6679677 ($p=8.66x10^{-8}$, OR=1.57), rs2488457 ($p=5.05 \times 10^{-5}$, OR=1.39), rs1132200 ($p=1.13x10^{-4}$, OR=0.71) and TRAF1: rs2416804 ($p=2.46x10^{-4}$, OR=1.24), rs10984447 ($8.79x10^{-4}$, OR=1.26). In addition, evidence was also found for SNPs within or near cytokine/cytokine receptor genes including the IL2-IL21locus: rs17388568 ($p=1.59x10^{-4}$, OR=1.16), rs13143866 ($p=8.87x10^{-3}$, OR=0.87), IL23R: rs10489629 ($p=7.58x10^{-6}$. OR=0.83), and IL2RA: rs2104286 ($p=3.83x10^{-5}$, OR=0.74), rs12251307 ($p=9.18x10^{-5}$, OR=0.69). Finally, evidence of association was found for SNPs located outside of genes included: rs1010824 ($4.92x10^{-3}$, OR=0.78) which is near the gene ANGPT1, rs17696736 ($3.26x10^{-3}$, OR=1.38) on chr12, rs7151781 ($p=1.55x10^{-4}$, OR=1.27) and on chr14. The associated alleles are the same and odds ratios are similar to those seen in other autoimmune diseases. **Conclusion:** These data support the idea that AD share common biological mechanisms; albeit, in most cases the causal SNP has not been unequivocally identified. Therefore additional studies are needed to determine the mechanism by which these polymorphisms contribute to JIA specifically and to AD as a whole.

Putative Autoimmune Susceptibility Loci: TENR-IL2-IL21, AFF3 and CTLA4, Are Associated with Juvenile Idiopathic Arthritis.

Anne Hinks[1], S. Eyre[1], Anne Barton[1], Paul Martin[1], Edward Flynn[1], Xiayi Ke[1], Jon Packham[2], J. Worthington[1] and W. Thomson[1], [1]University of Manchester, Manchester, United Kingdom, [2]University Hospital of North Staffordshire, Stoke-on-Trent, United Kingdom

Purpose: The strategy of utilising information from autoimmune disease genome wide association studies or candidate gene studies has facilitated the search for novel JIA susceptibility loci. Indeed two recently identified confirmed JIA susceptibility loci, *PTPN22* and *IL2RA* are putative autoimmune susceptibility genes as they show association to rheumatoid arthritis, type 1 diabetes, and Graves' disease. Several novel putative autoimmune susceptibility loci have recently been identified with association to more than one autoimmune disease. We hypothesise that SNPs within these genes may also be associated with susceptibility to JIA. The aim of the study was to test whether markers at four putative autoimmune susceptibility loci, *TENR-IL2-IL21*, *CTLA4*, *AFF3* and *IL7R*, are associated with JIA.

Method: Previously associated SNPs for each of the four regions (4 SNPs in total) were selected for investigation. Genotyping was performed using Sequenom MassArray. DNA was available for 1054 UK Caucasian JIA cases and 3531 controls. Genotype frequencies were compared between cases and controls using the trend test implemented in PLINK.**Results:** Strong evidence for association was seen for both *TENR-IL2-IL21* (rs6822844 OR 0.78 95%CI 0.67-0.9, ptrend= 0.0006) and *AFF3* (rs1160542 OR 1.25 95%CI 1.13-1.39, ptrend=2.05 x 10^{-5}). The *CTLA4* SNP, rs3087243 showed suggestive evidence for association with JIA (OR 0.9 95% CI 0.81-1.0, ptrend=0.05). The *IL7R* SNP, rs6897932, showed a trend towards association with JIA (OR 0.9 95% CI 0.8-1.01, ptrend=0.06). In all cases the associated allele is the same and odds ratios similar to those seen in other autoimmune diseases.

Conclusion: We present evidence for two novel JIA susceptibility loci, *TENR-IL2-IL21 and AFF3* which will require validation in independent JIA datasets. In addition, we present evidence supporting *IL7R* and *CTLA4* as JIA susceptibility genes. *CTLA4* has been investigated previously in JIA with conflicting results. This may reflect true genetic heterogeneity at this locus or may be due to the modest sample sizes used in previous investigations. For all genes the causal SNP has not been unequivocally identified and therefore fine mapping and functional studies will be required to elucidate how these polymorphisms contribute to JIA and autoimmune disease as a whole.

B-Cell Signature in Patients with JIA Is Associated with Age of Onset Suggesting Biologically Relevant Classification Criteria. Michael G. Barnes[1], Susan D. Thompson[1], Thomas A. Griffin[1], Alexei A. Grom[1], David N. Glass[1] and Robert A. Colbert[2], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]NIAMS/NIH, Bethesda, MD

Purpose: Genetic differences influence age of onset in juvenile arthritis but are not currently considered in the JIA classification. Gene expression data were analyzed to determine if there are patterns associated with early (< 6 years) or late (= 6 years) disease onset in patients with juvenile idiopathic arthritis (JIA).

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from 39 oligoarticular and 45 polyarticular subjects with recent onset JIA, and 56 control subjects. Patient samples were collected prior to treatment with DMARD or biologic agents. PolyA RNA was labeled using NuGEN Ovation and hybridized to Affymetrix HG U133 plus 2.0 arrays. Data were preprocessed using robust multichip analysis and statistics used a false discovery rate of 5%.

Results: Gene expression analysis identified 832 probe sets (of 54,676 total) detecting differential expression between early (n=23) and late (n=16) onset oligoarticular JIA patients. B-cell related markers (CD19, CD22, CD38, CD40, CD72, CD79A, CD79B, CD200), B-cell transcription factors (TCF3, EBF, EIF5B), and other B-cell related genes (BCL7A, BCL11A, BCNP1, BLNK, BRDG1, BTLA, BANK1, SP100, Ig's) were highly represented in the 324 probe sets with increased expression in early onset oligoarticular patients. As expected, the 832 probe sets were able to segregate the patients by age at onset. Unexpectedly, when both oligoarticular and polyarticular patients were analyzed together, the early onset JIA patients (oligoarticular, n = 23; polyarticular, n = 18) clustered together regardless of the number of joints involved. On the other hand, of the late onset polyarticular patients (n=27) some had expression patterns that resemble early onset oligoarticular while others had patterns that resemble late onset oligoarticular patients.

To ensure the differences were not simply due to the age of the donor, samples taken from controls before (n=20) or after (n=36) age 6 were compared and identified only 22 probe sets (12 overlapping) detecting differential expression. The 22 probe sets separated either control or patient samples by age indicating that it is possible to identify a different set of gene expression changes related to age.

Conclusion: PBMC gene expression differences, in part representing a B-cell signature, were able to distinguish early and late onset JIA. The genes were able to identify early onset but not late onset polyarticular patients. These results suggest underlying pathologic mechanisms independent of the currently defined JIA criteria and could lead to alternative treatment options for early onset JIA patients. Age of onset should be considered in revising classification criteria.

A Systems Biology Analysis of PFAPA Syndrome Reveals a Distinct Disease Entity with Interferon-Inducible Protein 10 (IP-10) and Interleukin-1 (IL-1) as Novel Links for Pathogenesis and Therapy. Silvia Stojanov[1], Sivia Lapidus[1], Puja Chitkara[1], Henry Feder[2], Juan C. Salazar[2], Michael M. Ward[1], Robert A. Colbert[1], Geryl Wood[1], Ivona Aksentijevich[1], R. Goldbach-Mansky[1], Beverly K. Barham[1], Balu H. Athreya[3], Karyl S. Barron[4] and Daniel L. Kastner[1], [1]NIAMS/NIH, Bethesda, MD, [2]University of Connecticut Health Sciences Center/Connecticut Children's Medical Center, Hartford, CT, [3]duPont Hospital for Children/Thomas Jefferson University, Wilmington, DE, [4]NIAID/NIH, Bethesda, MD

Purpose: Periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) attacks are associated with an aberrant cytokine profile, suggesting a dysregulated innate and adaptive immune response. Using a systems biology approach we attempted to shed more insights into pathogenesis and treatment.

Method: We collected blood samples from three pediatric cohorts: PFAPA patients whose genetic testing excluded hereditary periodic fevers (HPFs) during flares and asymptomatic intervals (N=21), healthy controls (N=21), and HPF patients with flare (N=12). We performed analyses using whole blood microarray, quantitative PCR (qRT-PCR), serum cytokines, and lymphocyte immunophenotyping**.**

Results: Principal component analysis of the overall mRNA expression revealed that PFAPA flares were remarkably distinct from asymptomatic intervals and HPF flares. Genes that were significantly overexpressed in PFAPA attacks compared to inactive PFAPA included interferon-induced (*IP-10*) and IL-1-related (*IL-1B, CASP1*), as well as complement (*C1QB, C2, SERPING1*) genes, whereas T

cell-associated transcripts (*CD3, CD8B*) were downregulated. Leukocytosis with neutrophilia and monocytosis during PFAPA flares was accompanied by a relative reduction of T lymphocytes. Serum IP-10, a chemokine for activated T lymphocytes, was significantly increased during flares and correlated with a decrease in circulating CD4+/CD25+ lymphocytes (Spearman r = -0.8257, p = 0.0001). Serum G-CSF, IL-18, IL-6 and MIP-1b were significantly elevated during PFAPA flares, with IP-10 and G-CSF being the strongest flare predictors. Based on our results, two patients were treated with the IL-1 receptor antagonist, anakinra, during febrile attacks with a prompt clinical response.

Conclusion: Gene expression profiling revealed PFAPA as a distinct entity from HPFs. The overexpression of complement genes suggests an infectious trigger with a strong IP-10, and IL-1/IL-18-mediated response of the innate immune system. Activation and probable recruitment of T cells to peripheral tissues underline the involvement of the adaptive immunity in the pathogenesis of PFAPA, with IP-10 as a potential new biomarker. Preliminary results of the clinical response in two patients support IL-1 inhibition for treatment of PFAPA attacks.

Genetic Polymorphisms in Key Methotrexate (MTX) Pathway Genes Associated with Response to MTX Treatment in Juvenile Idiopathic Arthritis. Anne Hinks[1], Halima Moncrieffe[2], Paul Martin[1], S.D. Lal[1], Simona Ursu[2], Laura Kassoumeri[2], L. R. Wedderburn[2] and W. Thomson[1], [1]University of Manchester, Manchester, United Kingdom, [2]UCL Institute of Child Health, London, United Kingdom

Purpose: The primary disease modifying therapy in use in juvenile idiopathic arthritis (JIA) is methotrexate (MTX). However, around 35% of children will fail to respond to MTX treatment. The main determinates of MTX response in JIA remain unclear although evidence suggests there may be a genetic component. Genes within the MTX metabolic pathway represent good candidates as predicators of response.

Objectives: To investigate the effect of SNPs across 13 MTX pathway genes on the efficacy of MTX in patients with JIA.

Methods: Subjects were recruited from the SPARKS Childhood Arthritis Response to Medication Study (SPARKS CHARMS) whose response to MTX had been determined over a 6 month period. The cohort included 314 UK Caucasian children whose response was measured using the ACR Paediatric response criteria. Patients were included if they were either ACR Ped 70 (n=72) or non-responders (n=51). Tagging SNPs were selected for ABCG2, ADORA2A, AMPD1, ATIC, DHFR, FPGS, GGH, ITPA, MTHFD1, MTHFR, SHMT1, SLC19A1 (RFC) and TYMS using an r^2 cutoff ≥ 0.8 and MAF ≥ 0.05 within 10kb up and down stream of each gene giving an average coverage after QC of >89%. Genotyping was performed using the Sequenom iPlex® MassARRAY platform. Genotype frequencies were compared between non-responders and responders (ACR70) using the trend test implemented in PLINK and allelic Odds ratios with 95 % confidence intervals calculated in STATA 9.2.

Results: Of the 193 SNPs tested, 3 were found to be significantly associated (pTREND ≤ 0.05) with MTX response. Interestingly 2 of these (rs12995526 & rs4673990) were found in the 5-aminoimidazole-4-carcoxamide ribonucleotide transformylase (ATIC) gene which encodes an enzyme that is important in the de novo purine synthesis pathway. Individuals carrying these SNPs had an increased risk of not responding to MTX (OR 1.79, 95% CI 1.07-3.00 and OR 1.69, 95% CI 1.01-2.83, respectively). Another association was found in the ITPA gene (rs2295553) which again conferred an increased risk of not responding to MTX (OR 1.73, 95%CI 1.03-2.89). In addition there were a further 10 SNPs with a trend towards association ($p<0.1$) in the genes encoding MTHFR, AMPD1, ATIC, DHFR, SHMT1, ITPA and SLC19A1, which are worthy of further follow up.

Conclusion: Genetic variations in a number of key MTX pathway genes have been found to be significantly associated with MTX response in JIA patients. Further studies will be required to validate these findings. If confirmed these results could contribute towards a better understanding of and ability to predict MTX response in JIA. .

Beyond MyD88 and TRIF: Syk/SLP-76 Signaling as a Third Adaptor Pathway Downstream of Toll-Like Receptors. Sheila Rao[1], Edward M. Behrens[2], Tara T. Donnelly[2], Gregory Wu[1], Terri M. Laufer[1], Uma Sriram[2], Stefania Gallucci[2] and Gary A. Koretzky[1], [1]Univ of PA, Philadelphia, PA, [2]Childrens Hospital of Phil, Philadelphia, PA

Purpose: Toll-like Receptors (TLRs) are important initial sensors of pathogens in infections. TLR activation leads to pro-inflammatory responses including cytokine release, type I interferon responses, and antigen presenting cell activation. Two major signaling pathways have been well characterized downstream of TLRs, named for their respective adaptors MyD88 and TRIF. We have characterized a third pathway for TLR signaling in dendritic cells (DCs) that utilizes the tyrosine kinase Syk and its adaptor molecule SLP-76.

Method: DCs were generated from the bone marrow of mice by 6 days of culture in medium conditioned with 3 ng/mL of GM-CSF. DCs were stimulated with TLR4 agonist (LPS, 100 ng/mL),TLR9 agonist (CpG, 10 μg/mL), or TLR3 agonist (pI:C,10 μg/mL). Production of TNFα, IL-12, and IL-6 were analyzed by ELISA in cell supernatants. IFNβ production was assessed by real time RT-PCR. Phosphorylation of ERK1/2 and Akt were assessed by western blotting of cell lysates with phospho-specific antibodies. Syk phosphorylation was assayed by Syk immunoprecipatation, followed by immunoblotting with phospho-specific Syk antibody. T-cell proliferation was assessed by CFSE dilution.

Results: Syk is phosphorylated between 2 and 5 minutes after stimulus with TLR3, 4, or 9 ligands. Inhibition of Syk with piceatannol prevents TLR4 induced TNFα and IL-6 secretion, but does not affect IFNβ production after 3 hours of stimulation. Syk inhibition prevents TNFα, IL-6 and IL-12 secretion after overnight stimulation of both TLR4 and TLR9. SLP-76 deficient DCs have attenuated TNFα and IL-12 secretion after TLR4 stimulation, but not TLR9. IL-6 and IFNβ are not affected by SLP-76 deficiency. Either MyD88 deficiency or Syk inhibition leads to attenuation of ERK phosphorylation downstream of TLR4 or TLR9; Syk inhibition combined with MyD88 deficiency results in complete abrogation of ERK phosphorylation in both TLRs. Akt phosphorylation is Syk dependent, MyD88 independent downstream of TLR4, but requires both pathways downstream of TLR9. SLP-76 deficient DCs are suboptimal in inducing antigen specific CD4+ T-cell responses, however this occurs in a TLR independent fashion, suggesting SLP-76 also has TLR independent functions in antigen presentation.

Conclusion: Syk signaling is important for multiple TLR signaling events and functions, however its degree of crosstalk with other TLR pathways differs between different TLRs. Absence of SLP-76 results in deficiency in a subset of these functions, suggesting a role for other Syk adaptors in TLR signaling. These results provide new potential pharmacologic targets for the modulation of TLR function in inflammatory disease states.

The Role of Uric Acid in Inflammation to Sterile Cell Death. Hajime Kono[1], Chun-Jen Chen[2], Fernando Ontiveros[1] and Kenneth L. Rock[1], [1]UMass Med School, Worcester, MA, [2]National Taiwan Univ., Taipei, Taiwan

Purpose: When cells undergo necrosis *in vivo*, they stimulate acute inflammatory responses. Neutrophils are the first cells to be recruited to the site of necrosis followed by monocytes. Inflammation to necrotic cell death is medically important because it contributes to the pathogenesis of a number of diseases. It is thought that necrosis stimulates inflammation because dying cells release proinflammatory molecules that are recognized by the immune system. However, there is relatively little known about the molecular identity of these molecules and even less about their contribution to responses *in vivo*. We had previously found that uric acid released from dying cells acts as an adjuvant to promote the generation of adaptive immune responses through dendritic cells. Independent of this, monosodium urate crystal can evoke gout, an acute inflammatory condition characterized by neutrophil infiltration to the affected joint. Here we investigate the role of uric acid in the inflammatory response to necrotic cells *in vivo*.

Method: We recently developed 2 lines of transgenic mice that express intracellular or secreted uricase gene under the beta-actin promoter to deplete uric acid intracellularly and/or extracellularly. We also utilized recombinant uricase (Rasburicase) or Allopurinol to reduce the amount of uric acid *in vivo*. Neutrophil recruitment towards the sites of cell death was examined by monitoring the neutrophil numbers in the peritonium 15 hours after injection of sterile necrotic cells, or by measuring the myeloperoxidase activity of liver in mice that received 300 mg/kg of Acetaminophen to induce sterile necrosis of hepatocyte.

Results: We find that dead cells not only release intracellular stores of uric acid but also produce it in large amounts *post mortem* as nucleic acids are degraded. The production of uric acid from dying cells depends on xantine oxidase activity. Using the uricase transgenic mice that have reduced levels of uric acid either intracellularly and/or extracellularly, we find that uric acid depletion significantly reduces the cell death-induced inflammatory responses. Myeloperoxidase activities in liver of Acetaminophen challenged mice were 157±20 mOD/min in WT, 73±15 in secreted uricase Tg, 36±4 in intracellular uircase Tg, and 15±3 in PBS control ($P<0.001$, One-way ANOVA with Tukey's test). These results were confirmed with pharmacological treatments that reduced uric acid levels either by blocking its synthesis (Allopurinol) or hydrolyzing it in the extracellular fluids (Rasburicase). Importantly, uric acid depletion selectively inhibited inflammation to dying cells but not to microbial molecules.

Conclusion: Collectively the data identify uric acid as a proinflammatory molecule released from dying cells that contributes significantly to the cell death-induced acute inflammatory responses *in vivo*.

Correlation of Disease Activity Change Due to Anti TNF Alpha Treatment with Galactosylation Status of Serum IgG in Inflammatory Arthritis. Emily S. Collins[1], Jodie L. Abrahams[2], Marie Galligan[2], Chin Teck Ng[1], Matthew P. Campbell[2], Barry Bresnihan[1], Douglas J. Veale[1], Pauline M. Rudd[2] and Oliver M. FitzGerald[1], [1]St Vincent's University Hospital, Dublin, Ireland, [2]National Institute for Bioprocessing Research and Training, Dublin, Ireland

Purpose: Previous studies have identified a relationship between decreased galactosylation of IgG and inflammatory arthritis (IA)(1). The extent of the decrease has been shown to correlate with disease severity in rheumatoid arthritis (RA) and to reverse in remission. Traditionally IgG galactosylation has been measured by purification of IgG from serum. The effect of anti-TNFα therapy on the galactosylation status of serum IgG of IA patients was investigated using a method developed in the Dublin–Oxford Glycobiology Laboratory, NIBRT, for the analysis of whole serum (2). We were aiming to establish whether the decreased galactosylation observed in IA reverses upon anti-TNFα treatment and whether the changes in the level of IgG G0 correlate with disease response and thus could be a useful biomarker.

Method: Serum samples were collected from a cohort of 56 inflammatory arthritis patients on anti-TNFα therapy at baseline, 1 month and 1 year after starting treatment and clinical data were collected over this time. Serum samples were analysed using HPLC-based analysis of serum N-glycans after enzymatic release and labelling of N-glycans from whole serum by an in-gel block method(2). The galactosylation of IgG was calculated using a ratio between the IgG FG0 core fucosylated nongalactosylated and FG1 core fucosylated monogalactosylated HPLC peak volumes and is given as a ratio G0/G1 with an increased value indicating a decrease in galactosylation of IgG.

Results: The G0/G1 ratio for IgG decreased following anti-TNFα therapy (indicating an increase in galactosylation) and showed a greater decrease in patients who responded to therapy compared to non-responders, with levels returning to those expected for healthy individuals. Responders: average G0/G1 ratio at baseline=0.91 at 1 year=0.72 ($p=2.4x10-6$); Non-responders: average G0/G1 ratio at baseline =1.08 at 1 year=1.05 ($p=0.76$). The change in G0/G1 by 1 month is very small and no correlation with response is seen. Similar results were obtained when the patients were grouped according to disease type.

The galactosylation level of IgG correlated with disease activity (DAS 28) and severity (HAQ) at baseline ($r2= 0.96$ and 0.92 respectively) and at 1 year ($r2= 0.82$ and 0.92 respectively).

Conclusion: The change in galactosylation of IgG of IA patients on anti-TNFα therapy is correlated to their decrease in disease activity over 1 year. This indicates that the status of IgG galactosylation using whole serum could be a useful marker of disease response.

Interaction Between ASC and Estrogen in the Regulation of Inflammation in Murine Arthritis. Laeticia Kolly[1], Sharmal Narayan[1], Jurg Tschopp[2], Alexander K. So[3] and Nathalie Busso[1], [1]Service of Rheumatology, Lausanne, Switzerland, [2]University of Lausanne, Lausanne, Switzerland, [3]CHUV, Lausanne, Switzerland

Purpose: The inflammasome is a multiprotein complex that triggers caspase dependent activation of IL-1b. ASC (apoptosis-associated speck-like protein), a common component of the inflammasome, functions as an adaptor for caspase recruitment, and the NLR (Nod-like receptor) acts as the sensor of the complex. The inflammasome is implicated in inflammatory and autoimmune diseases, including gout and vitiligo. Some of these diseases show a strong gender effect. To determine whether ASC differentially modulates inflammation in males and females mice in models of experimental arthritis.

Method: K/BxN serum transfer-induced arthritis (KRN) and Antigen-Induced Arthritis (AIA) was induced in 8-10 weeks old ASC-deficient mice and their corresponding +/+ littermates (all in a C57Bl/6 background). The severity of arthritis was assessed by clinical scoring (in KBN) and technetium uptake measurement (for AIA). Histological analysis and serum amyloid A (SAA) ELISA were also performed.

Results: In the KRN model, ASC deficiency conferred protection to female mice, as female ASC -/- mice, but not male ASC-/-, had a significant delay in onset of arthritis compared to the corresponding +/+ mice. To investigate whether estradiol is directly responsible for this difference, we castrated female and male ASC -/- mice and supplemented half of them with estradiol. Castration removed the protective effect of ASC deficiency, and supplementation with estradiol restored the protective effect of ASC deficiency.

The effect of estrogens was further confirmed in the AIA model. ASC -/- mice showed a significant decrease of technetium uptake in the arthritic knee. Upon ovariectomy, female ASC -/- mice had the same severity of arthritis as female ASC+/+ mice. Furthermore, supplementation of ovariectomized female ASC -/- mice with estradiol decreased the severity of AIA.

In both models, caspase-1 activation did not seem to have a major role since the levels of active caspase-1 were similar between arthritic male and female mice and since caspase-1 deficiency did not lead to decreased arthritis severity in both the KRN and the AIA model.

Conclusion: ASC, a component of the inflammasome complex, modulates synovial inflammation in females in both the KRN and AIA models. This effect is mediated by estrogens and is independent of caspase-1 activity. These findings suggest that ASC interacts with other proteins beside the classical inflammasome complex in regulating inflammatory responses *in vivo*.

FK506 Pretreated Dendritic Cells Induce Enduring T Cell Hyporesponsiveness. Dana E. Orange[1], Nathalie Blachere[2] and Robert Darnell[2], [1]HSS, New York, NY, [2]Rockefeller University, New York, NY

Purpose: It has become clear over the past several years that dendritic cells (DCs) play a critical role in peripheral tolerance. In the periphery, immature DCs are particularly efficient at phagocytosing dying cells. Low dose antigen captured from these dying cells is constantly being processed and presented in the context of MHC to delete self-reactive T cells. However, if a DC has been licensed, the immunologic outcome of antigen presentation is T cell activation. In searching for compounds that modulate this outcome, we have discovered that FK506 abrogates CD4 and CD8 T cell activation by directly interfering with cross-talk occurring at the T cell - DC interface. Furthermore, FK506 treated DCs induce a lasting effect on the T cell population, rendering an enduring hyporesponsive state despite subsequent antigen encounter. This study reveals a pharmacologically sensitive pathway that can be exploited to induce antigen-specific tolerance to self-reactive cells.

Method: Healthy donor PBMCs were cultured with IL 4 and GMCSF. Immature DCs phagocytosed flu infected apoptotic 3T3 cells and were then matured with TNF and PGE2 and treated with either no drug treatment or FK506. DCs were analyzed by flow cytometry for markers of maturation. Antigen presenting DCs were then cocultured with MACS purified CD8 or CD4 T cells and either plated in an IFNγ elispot directly or cultured for seven days. At the end of a week, the cocultured T cells are assayed for IFNγ production in response to a directly influenza infected DC via elispot.

Results: DCs pretreated with FK506 were blocked in their ability to activate CD4 and CD8 T cell responses to exogenously acquired antigen in the IFNγ elispot assay. To evaluate whether this lack of response was because those T cells remained ignorant or whether they had been actively tolerized, the T cells were kept in culture for seven days. One week later they were recultured with flu infected DCs. If they remained ignorant the expected outcome upon subsequent antigen encounter with such a maximally inflammatory stimulus would be activation. However, T cells which had been previously cocultured with an FK506 pretreated DC, remained blocked in their ability to respond, indicating that they had indeed been tolerized.

Conclusion: This work implies a novel therapeutic approach to tolerizing antigen specific T cells through manipulation of DCs. Previously it has been shown that immature DCs presenting antigen lead to tolerance, but these DCs do not express CCR7 or traffic to lymph nodes. The FK506 pretreated DCs used in the above assays have been matured ex-vivo and despite expression of all markers of maturation, lend a tolerogenic phenotype which endures even upon subsequent stimulation with a maximally inflammatory stimulus. The significance of this project is that it is possible that FK506 pretreated DCs could be used as a vaccine which upon injection, would allow for DCs which would traffic to lymph nodes and efficiently tolerize aberrant T cell responses.

Regulatory Natural Antibodies to Apoptotic Cell Membrane Determinants Inhibit Pro-Inflammatory Responses to Activating IgG Autoantibody Immune Complexes Implicated in Autoimmune Pathogenesis. Jaya Vas, Caroline Gronwall and Gregg J. Silverman, UC San Diego, La Jolla, CA

Purpose: Immune complexes (IC) containing Fc-receptor activating IgG autoantibodies, in combination with released nuclear antigens released from dying cells, have been implicated in autoimmune pathogenesis. We have recently demonstrated that naturally arising IgM antibodies (NAbs) to apoptotic cell membrane (ACM) determinants, such as phosphorylcholine, recruit early complement factors and suppress pro-inflammatory responses of dendritic cells and macrophages to purified agonists to TLR3, TLR4, TLR7 and TLR9. A monoclonal IgM PC-specific anti-ACM antibody was also shown to inhibit in vivo TLR responses and block the induction of collagen-induced arthritis. To better understand the potential functional roles of regulatory anti-ACM NAbs, we investigated the effects on IgG autoantibody-IC driven responses.

Method: For in vivo studies, we assessed the effect on IgG anti-collagen type II (CII) induced inflammatory arthritis. For in vitro analyses, we investigated the effects on IgG IC- that result from dual stimulation through activating FcgR and TLR9, in which bone marrow-derived DC dendritic cells (BMDCs) were stimulated with titrated concentrations of the anti-chromatin Moabs PL2-3(IgG2a) or PL2-8(IgG2b).

Results: In a standard passive transfer model in which arthritis was induced by i.v. administration of 2 mg of IgG anti-CII mixture, weekly treatment with 2 mg of the IgM anti-ACM regulatory antibody significantly prevented the development of clinical arthritis in BALB/c mice, compared to saline or isotype control treatment. These effects correlated with inhibition of cartilage destruction and boney erosions. For in vitro studies, we found that either the IgG2a and IgG2b anti-chromatin Moabs, or supernatants from primary necrotic cells alone, induced TNF-alpha and IL-6 production from BMDCs, with further increases induced by co-stimulation with IgG autoantibody and necrotic supernatants. Importantly, incubation with IgM anti-ACM NAb, but not isotype control, significantly blunted the production of TNF-a and IL-6 by DCs induced by necrotic cell supernatants, and also inhibited these responses to IgG anti- chromatin autoantibodies, or incubation with both IgG anti-chromatin antibody and necrotic cell supernatant. The level of cytokine inhibition by the regulatory anti-ACM Ab was comparable to that associated with dexamethasone, a potent glucocorticoid.

Conclusion: Our studies demonstrate that regulatory IgM anti-ACM NAb can suppress inflammatory arthritis induced by pathogenic IgG autoantibody-immune complexes, and similarly inhibit autoantibody-mediated activation and cytokine production by conventional dendritic cells. These studies support a potential physiologic role for regulatory anti-ACM NAbs for maintaining homeostasis and for opposing pathogenic IgG autoantibody-IC mediated inflammatory responses.

The Relationship Between Weight Maintenance and Incident Radiographic Knee Osteoarthritis: The Johnston County Osteoarthritis Project. Lauren M. Abbate[1], June Stevens[1], Todd A. Schwartz[1], Leigh F. Callahan[1], Jordan B. Renner[1], Charles G. Helmick[2] and Joanne M. Jordan[1], [1]The University of North Carolina, Chapel Hill, NC, [2]Centers for Disease Control and Prevention, Atlanta, GA

Purpose: On average, adults gain weight throughout most of their life span. Weight loss is difficult to achieve, and it is possible that weight maintenance is a more attainable goal for some individuals. The purpose of this study is to determine if weight maintenance is an effective strategy to reduce the risk of incident radiographic knee osteoarthritis (rKOA).

Methods: Data were from the Johnston County Osteoarthritis Project, a longitudinal study of African-Americans and Whites aged 45 years and older in Johnston County, NC from T_0 (1990-1998) to T_1 (1999- 2003 (n=1,480). Weight change was defined as change from initial weight and was coded as a 5-level variable with categories defined as: ≥5% loss, >3 to <5% loss, ± 3%, >3 to <5% gain, and ≥5% gain. Indicator variables were used to make contrasts between ≥5% loss (weight loss), ± 3% (weight maintenance), and ≥5% (weight gain) with weight gain as the referent. Incident rKOA was defined as Kellgren-Lawrence (K-L) grade of 0 or 1 at T_0 and K-L ≥ 2 at T_1. Knee-based Weibull proportional hazards models with adjustment for the correlation between knees were used to calculate hazard ratios and 95% confidence intervals for the association between weight change incident rKOA. All models were adjusted for age, race, sex, height, and the mean of weights from T_0 and T_1.

Results: Of the 1,480 individuals, 63.2% were female and 25.9% were African-American with mean (SD) age and BMI of 59.4 (9.4) years and 28.6 (5.5) kg/m^2, respectively. Mean (SD) follow-up time was 5.9 (1.3) years (range 3.6 to 13.2), during which rKOA developed in 415 (14.9%) of 2,788 knees. Compared to those who gained weight (31.4%), those who maintained weight (32.8%) were no less likely to develop incident rKOA [HR=1.02 (95% CI=0.77, 1.35)], but those who lost weight (16.7%) were at reduced risk [0.71 (0.49, 1.01)].

Conclusion: Weight loss, but not weight maintenance, may be an effective strategy to reduce the risk of incident rKOA.

Incidence of Severe Knee and Hip Osteoarthritis in Relation to Dietary Intake of Antioxidants Beta–Carotene, Vitamin C, Vitamin E and Selenium: a Population-Based Prospective Cohort Study. Gunnar Engström[1], Maria Gerhardsson de Verdier[2], Peter M. Nilsson[3], Elisabet Wirfält[3], Carl Mellström[2], Jan Rollof[2] and Stefan Lohmander[3], [1]Lund University, Sweden, [2]AstraZeneca R&D, Lund, Sweden, [3]Lund University, Lund, Sweden

Purpose: The relationship between dietary factors, in particular antioxidants, and osteoarthritis (OA) remains unclear. This prospective population-based study explored the relationships between intake of antioxidants and incidence of severe hip and knee osteoarthritis.

Method: The Malmö Diet and Cancer cohort (n=28098, age 45-73 years, 61% women) was established between 1991 and 1996. A modified diet history method was used to assess dietary habits. Incidence of severe knee and hip OA, defined as new cases of arthroplasty due to hip or knee OA, was monitored until 2005, in relation to energy-adjusted intakes of Vitamin C, Vitamin E, β–carotene and selenium.

Results: A total of 465 incident cases of knee OA and 554 of hip OA occurred during the follow-up. After adjustments for risk factors, high dietary intake of Vitamin C and selenium was significantly associated with incidence of hip OA [hazards ratio: 1.45 (95%CI:1.09-1.9) and 1.32 (95%CI: 1.01-1.7), respectively, for the highest versus lowest quintile of the antioxidant]. When consumption of antioxidant

supplements was taken into account, high selenium intake was significantly associated with incidence of both hip and knee OA. There was no evidence of any protective effect for any of the antioxidants.

Table 3. Intake of four antioxidants in relation to knee or hip OA during follow-up.

	Knee OA			**Hip OA**		
	yes	**no**	**P**	**yes**	**No**	**P**
N	465	27196		544	27055	
Beta-carotene	4.1+3.6 (3.2)	3.8+3.4 (2.8)	0.03	4.0+3.1 (3.2)	3.8+3.4 (2.8)	0.11
Beta-carotene*	4.2+3.6 (3.2)	3.9+3.9 (2.8)	0.05	4.1+3.4 (3.2)	3.9+3.9 (2.8)	0.10
Vitamin E	10.4+4.2 (9.6)	10.6+4.3 (9.8)	0.26	10.5+4.0 (9.5)	10.6+4.3 (9.8)	0.94
Vitamin E*	17.1+27 (10.9)	16.1+28 (11.1)	0.14	15.4+16 (11)	16.1+28 (11)	0.90
Vitamin C	114+62 (103)	110+62 (98)	0.01	116+59 (105)	110+62 (98)	0.01
Vitamin C*	174+243 (124)	175+267 (116)	0.24	166+194 (120)	176+268 (116)	0.39
Selenium	40.3+14 (38)	39.3+14 (37)	0.007	41.7+16 (39)	39.2+14 (37)	<0.001
Selenium*	49.1+27 (41)	46.9+26 (40)	0.02	51.8+29 (43)	46.8+26 (40)	<0.001

*including supplements

Values are crude mean±SD (median). Log transformed values used for calculation of p-values, adjusted for age, sex, method, log energy, season

Conclusion: In this population-based study, there was no evidence of a protective effect of antioxidants against severe knee or hip OA leading to arthroplasty. The association between high intake of Vitamin C and selenium and incidence of severe OA needs to be confirmed by other prospective studies with data on diet and intake of supplements.

Association of Osteoarthritis-Related Knee Pain with a Functional Polymorphism of the Catechol-O-Methyltransferase Gene. T. Neogi[1], K. Wang[1], C. Kammerer[2], R. Ferrell[2], M. Garcia[3], C. K. Kwoh[2], T. Harris[3], S. Satterfield[4], P. Caserotti[3] and M.C. Nevitt[5], [1]BUSM, Boston, MA, [2]UPittsburgh, Pittsburgh, PA, [3]NIA, Bethesda, MD, [4]UofTennessee, Memphis, TN, [5]UCSF, San Francisco, CA

Purpose: Pain related to musculoskeletal complaints is the most common reason for outpatient visits, with knee being the primary site of pain, yet little is understood about pain in musculoskeletal conditions. It is well known that in osteoarthritis (OA) there are individuals in whom their symptoms appear to be discordant with the degree of disease on radiographs. Some of this between-person variability may be related to genetic factors that contribute to the experience of pain. Recently, a functional polymorphism of the catechol-O-methyltransferase (*COMT*) gene has been reported to be associated with pain sensitivity, as well as hip-OA related pain. We evaluated the association of a functional polymorphism of *COMT* with knee pain, particularly OA-related knee pain, among well-functioning older adults.

Methods: Health, Aging and Body Composition Study is a longitudinal study of well-functioning elders. Genotypes of the Val158Met (rs4680) *COMT* polymorphism were determined by the TaqMan procedure (Applied Biosystems, Inc), with 5% blind duplicate procedures, and quality control with direct sequencing of a subset of samples. At baseline, participants were asked whether they had knee pain on most days: 1) of a month in the past 12 months; 2) of the past 30 days; or 3) moderate or worse pain with any activity by WOMAC. Those with knee pain and selected controls had knee x-rays. Presence of radiographic OA was defined as Kellgren and Lawrence grade ≥2 or presence of patellofemoral OA. We evaluated the association of having ≥1 methionine (Met) allele of the rs4680 SNP (dominant mode of inheritance) with presence of knee pain on most days of the month in the past 12 months, and of the past 30 days using logistic regression, adjusting for age, sex, BMI, depressive symptoms (CES-D), race and presence of radiographic OA.

Results: There were 1128 individuals who had x-rays taken (mean age 74.6±2.9, 58.5% female, mean BMI 27.7±5 kg/m^2, 66% with ≥1 Met allele, 50% with knee OA). Having ≥1 Met allele in the rs4680 SNP was associated with presence of knee pain on most days of a month of the past 12 months (adj OR 1.44, 95% CI 1.09-1.91), as well as pain on most days of the past 30 days (adj OR 1.43 95% CI 1.08-1.89), with effects attenuated after adjustment for race due to allele frequency differences (past 12 months: adj OR 1.31 (0.98-1.74); past 30 days adj OR 1.26 (0.95-1.68)), but with no effect measure modification by race noted (similar effect estimates in both races). Similar effects were noted for pain among those with knee OA ((past 12 months: adj OR 1.29 (0.84-1.99), past 30 days: adj OR 1.27 (0.83-1.95)).

Conclusion: The Val158Met functional polymorphism of *COMT* was associated with knee pain. This *COMT* polymorphism may explain in part the observed variation in pain and structural abnormalities noted in persons with OA, and needs to be replicated in larger samples.

Pain in One Knee Increases the Risk of Tibiofemoral Osteoarthritis in the Contralateral Knee: The MOST Study. J. Niu[1], David T. Felson[2], M. Nevitt[3], P. Aliabadi[1], C. Lewis[4], B. Sack[1], J. Torner[5] and Yq. Zhang[1], [1]BUSM, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]UCSF, San Francisco, CA, [4]UAB, Birmingham, AL, [5]UIowa, Iowa City, IA

Purpose: Several studies have reported that painful nonosteoarthritic knees have an increased risk of radiographic tibiofemoral osteoarthritis (TF OA). As gait usually changes when a person develops knee pain, we expect the risk of TF OA would also increase in a contralateral nonpainful knee due to unloading of the painful side. We examined the relationship of knee pain on one side to the risk of TF OA on the contralateral side in the Multicenter Osteoarthritis (MOST) Study.

Method: The MOST Study is a NIH-funded longitudinal observational study of subjects who have or are at high risk for knee OA. PA and lateral view knee X-rays were taken at baseline and 30-month follow-up. Among knees without whole knee OA (K/L grade <2 and no patellofemoral (PF) OA) at baseline, we defined a knee as having incident TF OA if its K/L grade ≥2 at 30-month or had knee replacement during follow-up period. Frequent knee pain (FKP, pain on most days of the past 30 days) and severity of knee pain (SKP, WOMAC knee pain subscale, categorized as 0, 1-5, 6-20) were collected at baseline. We divided knees into 4 groups based on which side was affected by FKP and 9 groups based on the side of their SKP. We examined the relation of FKP and SKP categories to the risk of TF OA using logistic regression model adjusting for age, sex, BMI, history of knee injury and surgery, depression (CES-D≥16), whole knee OA status of the contralateral side at baseline while accounting for the correlation between two knees using GEE. We repeated the analyses among the knees without any OA feature at TF and PF joints at baseline (i.e., K/L grade, osteophyte, joint space narrowing score =0).

Results: Of 3094 knees (from 1844 subjects, mean age 61.3 years, mean BMI 29.6 kg/m^2, 57.2% women) without whole knee OA at baseline, 191 developed TF OA over 30-month period. Compared with those without FKP on both sides, odds ratios (OR) of developing TF OA were 4.7 (95% CI: 2.9, 7.4) in the ipsilateral knee and 2.1 (95% CI: 1.3, 3.2) in the contralateral knee among persons with unilateral knee pain, while the OR was 2.7 (95% CI 1.8, 4.1) among persons with bilateral knee pain. A similar pattern was also observed for SKP (see Table). Results did not change much when analyses were restricted to the knees without any OA feature at baseline.

Conclusion: We confirmed that knees with pain had a higher risk of TF OA than those without pain. In addition, we observed that the contralateral knee in persons with unilateral knee pain was also at higher risk of TF OA than the knees in persons without knee pain. Our findings provide support for the concept that knee pain may change knee loading and increase the risk of TF OA in a contralateral nonpainful knee.

Table. Severity of knee pain and risk of TF OA

Severity of pain in the same knee	Severity of pain in the other knee		
	0	1-5	6-20
0	1.0 (Ref)	1.8 (0.9, 3.7)	2.3 (1.0, 5.3)
1-5	2.8(1.3, 6.0)	2.2(1.2, 3.8)	3.8 (2.0,7.2)
6-20	11.9 (5.2, 27.2)	7.8 (4.1, 15.1)	4.1 (2.2, 8.0)

Bone Mineral Density Is Associated with Dynamic Joint Loads in Osteoarthritis Predisposed Knees. Anisha Dua[1], Laura E. Thorp[1], Joel A. Block[1] and Najia Shakoor[2], [1]Rush-University Med Ctr, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

Purpose: We have previously shown that subjects with endstage unilateral hip osteoarthritis (OA) more commonly develop endstage OA of the contralateral knee rather than the ipsilateral knee, and that these subjects have higher dynamic joint loads at the contralateral knee than the ipsilateral knee. Local bone mineral density (BMD) reflects the loading history of that bone; hence, BMD may be a marker of excessive loading of the knee joint as well as of early asymptomatic OA. Here, we evaluated subjects who had unilateral hip OA but who were asymptomatic at their knees, to test the hypothesis that asymmetric loading of the knees induced by unilateral hip OA results in elevated BMD at the medial tibial plateau of the contralateral knee compared with the ipsilateral knee, and that these BMD asymmetries correlate with dynamic joint loading at the knees.

Method: Fifty subjects with symptomatic unilateral hip OA and asymptomatic knees were evaluated. Subjects had moderate to severe radiographic unilateral hip OA using the Kellgren Lawrence (KL) grading system. Subjects were asymptomatic at the knees (WOMAC pain during walking <20 mm out of 100 mm). Subjects underwent DXA scanning of bilateral knees and these scans were evaluated in a blinded manner by a trained investigator using a previously validated method. The BMD of the medial and lateral regions of the tibial plateau and the distal tibial shaft were measured in each knee. Subjects also underwent gait analyses using an optoelectronic camera system and multicomponent force plate. Inverse dynamics were used to calculate dynamic joint loads and the peak external knee adduction moment, a validated marker of medial compartment knee loading, was used as the primary load parameter. Paired t-tests were used to evaluate differences in BMD and loading between the knees and Spearman correlations were used to evaluate correlations between BMD and loading. $p<0.05$ was considered significant.

Results: Bone mineral density was significantly increased at the contralateral medial tibial plateau compared with the ipsilateral medial tibial plateau (0.912g/cm^2±0.208 vs 0.869g/cm^2±0.196 p=0.040). Furthermore, a direct correlation was found between the medial knee load (peak external knee adduction moment) and BMD at the contralateral medial knee (rho=0.381, p=0.008). No significant differences were noted for BMD at the lateral compartments of the two knees.

Conclusion: This study demonstrates that unilateral hip OA is associated with increased BMD at the contralateral medial knee when compared with the ipsilateral medial knee, that BMD alterations are directly correlated with loading alterations at the OA-predisposed knee (contralateral knee), and that these events occur even in asymptomatic, clinically uninvolved knees. These findings suggest that BMD alterations may be a surrogate marker for joint loading and OA progression, even in asymptomatic subjects. Although further investigation is necessary to delineate causal relationships, BMD may be a useful tool to follow structural progression in longitudinal OA studies.

The Association Between Patella Alta and Structural Features of Patellofemoral Joint Osteoarthritis (OA) On MRI: The MOST Study. J.J. Stefanik[1], Y. Zhu[1], A.C. Zumwalt[1], K.D. Gross[2], M. Clancy[1], J. A. Lynch[3], L.A. Frey Law[4], C.E. Lewis[5], F.W. Roemer[1], C.M. Powers[6], A. Guermazi[1] and David T. Felson[7], [1]BUSM, Boston, MA, [2]MGH Inst Health Prof, Boston, MA, [3]UCSF, San Francisco, CA, [4]UIowa, Iowa City, IA, [5]UAB, Birmingham, AL, [6]University of Southern California, Los Angeles, CA, [7]Boston University School of Medicine, Boston, MA

Purpose: Research on risk factors for patellofemoral joint (PFJ) osteoarthritis (OA) has focused on PFJ alignment and trochlear morphology. Patella alta (PA), a high riding patella, has received much less attention despite being a known risk factor for patellar subluxation and dislocation in young persons. PA is measured by the Insall-Salvati ratio (ISR), the ratio between the length of the patellar tendon and length of the patella. One possible mechanism for PFJ OA development is decreased contact area between opposing joint surfaces causing increased stress on cartilage and bone. Recently the ISR, but not patellofemoral alignment, has been shown to be associated with decreased contact area in the PFJ. The purpose of this study was to examine the relation of the ISR to prevalence of cartilage damage and measures of bone damage, specifically bone marrow lesions (BMLs) and subchondral bone attrition (SBA), in the lateral PFJ compartment.

Methods: The MOST study is an NIH funded cohort study of persons aged 50-79 years with or at risk for knee OA. We measured the ISR on the baseline flexed and weight bearing lateral radiographs in 486 knees, one knee per subject. Cartilage damage, BMLs, and SBA were graded at baseline on MRI using the WORMS scale (0-6, 0-3, and 0-3 respectively) on the patellar and trochlear facets. We divided the ISR into quartiles and dichotomized cartilage damage (≥2), BMLs (≥1), and SBA (≥1) into presence or absence of pathology. We examined the association between the ISR and cartilage damage, BMLs, and SBA in the lateral PFJ using logistic regression with GEE to account for the correlation between patellar and trochlear readings from the same knee. All analyses were adjusted for age, sex, and BMI.

Results: The mean age of the sample was 62, mean BMI 30, mean ISR 1.10, and 60% of subjects were female. Of the 486 knees studied, 35% had cartilage damage, 21% BMLs, and 14% SBA. Compared with subjects in the lowest ISR quartile, those in the highest quartile had 2.7 (95% CI 1.8, 4.4), 3.2 (1.9 5.4), and 6.0 (3.0, 12.4) times more likely to have lateral PFJ cartilage damage, BMLs, and SBA respectively.

Conclusion: Subjects with a high ISR, indicative of patella alta, are more likely to have cartilage damage, BMLs, and SBA in the lateral PFJ, supporting the hypothesis that subjects with an increased ISR have increased PFJ stress. Future research is needed to evaluate whether a high ISR increases the risk of PFJ OA and to investigate the association between the ISR, measures of PFJ alignment, PFJ OA, and pain.

Rheumatoid Arthritis Therapy: Biologic Therapy

Sunday, October 18, 2009, 4:30 PM - 6:00 PM

635

Smoking Is Associated with Non-Response to Methotrexate and to Anti-TNF Treatment in Patients with Rheumatoid Arthritis. Results From the Swedish EIRA Study. Saedis Saevarsdottir[1], Sara Wedrén[2], Maria Seddighzadeh[2], Johan Askling[1], Leonid Padyukov[2], Lars Alfredsson[2] and Lars Klareskog[1], [1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

Purpose: Smoking is a well established risk factor for rheumatoid arthritis (RA), and the aim of this study is to evaluate whether smoking influences response to methotrexate (MTX) and anti-TNF therapy.

Methods: Clinical data for patients participating in a Swedish population-based study of incident RA (Epidemiological Investigation of Rheumatoid Arthritis, EIRA), who have received routine care, where retrieved from the Swedish Rheumatology and Biologics Registers (SRR/ARTIS, n=1756). Cigarette smoking (never, past or current and pack-years), RF and anti-CCP positivity and the presence of the shared epitope allele (SE) was defined by standard procedures. The primary endpoint was non-response to MTX or anti-TNF therapy at 3 months according to the EULAR response criteria, which is defined as less than 0.6 DAS28 units improvement or DAS28>5.1. Clinical data and information about anti-CCP, RF and SE status were available for 815 out of 965 patients started on MTX monotherapy at baseline and for 320 out of 375 patients that had started anti-TNF therapy as the first biological treatment until the end of the follow-up period. The data were analysed using logistic regression with uni- and multivariate models and presented as odds ratios with 95% confidence interval (OR[95%CI]).

Results: Smoking was associated with non-response to both MTX and anti-TNF treatment. For MTX treatment, 40% of current smokers and 28% of never smokers were non-responders (OR 1.8[1.2-2.7]). However, no clear dose response effect was observed between number of pack-years and response. For anti-TNF therapy, 40% of current smokers and 25% of never-smokers were non-responders (OR 2.0[1.1-3.7]). Whether the patients had concurrent MTX therapy did not influence these findings. When the patients were grouped according to number of pack-years of cigarette smoking into 0, 1-15, 16-30 and >30 pack-years; the frequency of non-response to anti-TNF therapy was 25%, 31%, 40% and 43%, respectively (OR: Ref., 1.3[0.72-2.5], 2.0[1.0-4.0] and 2.3[1.0-5.4]). The risk associated with smoking was significant after adjustment for clinical co-variables, anti-CCP, RF and SE in a multivariate model.

Conclusion: Cigarette smokers had a higher risk of non-response to both MTX and to anti-TNF treatment in this population based study on incident RA receiving real-life care.

Rituximab in Combination with Methotrexate (MTX) Significantly Inhibits Joint Damage and Improves Clinical Outcomes in Patients with Early Active RA Who Are Naïve to MTX: A Randomized Active Comparator Placebo-Controlled Trial (IMAGE). Paul P. Tak[1], William F. C. Rigby[2], Andrea Rubbert-Roth[3], Charles G. Peterfy[4], Ronald F. van Vollenhoven[5], William Stohl[6], Eva Hessey[7], Annie C. Chen[8], Helen Tyrrell[7] and Tim M. Shaw[7], [1]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [2]Dartmouth Hitchcock Medical Center, Lebanon, NH, [3]University of Cologne, Cologne, Germany, [4]Synarc Inc., San Francisco, CA, [5]The Karolinska Institute, Stockholm, Sweden, [6]Univ Southern California, Los Angeles, CA, [7]Roche Products Ltd, Welwyn Garden City, United Kingdom, [8]Genentech, Inc, South San Francisco, CA

Purpose: To evaluate clinical and radiographic outcomes with rituximab (RTX) plus MTX compared with MTX alone in patients (pts) with active rheumatoid arthritis (RA) not previously treated with MTX.

Methods: Key inclusion criteria were: no prior exposure to MTX; disease duration <4 years; swollen and tender joint count each ≥8; C-reactive protein (≥1.0 mg/dL), rheumatoid factor positive, or erosive damage. Pts were randomized to either placebo (Plc) + MTX, RTX (2 x 500mg) + MTX or RTX (2 x 1000 mg) + MTX. MTX was initiated in all groups at 7.5 mg/wk and titrated to 20 mg/wk by Wk 8. RTX was given by IV infusion on Days 1 and 15 with a 24-week repeat treatment schedule based on DAS28≥2.6. Radiographs, taken at screening, Wks 24 and 52, were read centrally using the Genant-modified Sharp method (mTSS). The primary endpoint was the change from screening in the mTSS at Wk 52. Secondary endpoints included Major Clinical Response (MCR; ACR70 maintained for at least 6 months).

Results: 755 pts were randomized (715 radiographically evaluable). Groups were balanced at baseline (mean RA duration of 0.9 years and DAS28 >7). At 52 wks, only RTX (2 x 1000 mg) + MTX was associated with both a significant decrease in radiographic progression and improved clinical outcomes as compared with Plc + MTX (Table). Notably, the radiographic and clinical benefits in the RTX (2 x 1000mg) + MTX group were observed by Week 24 with evidence of increased inhibition of joint damage from Wk 24–52.

	Plc + MTX	**RTX (2 x 500 mg) + MTX**	**RTX (2 x 1000 mg) + MTX**
Radiological	n=232	n=239	n=244
Mean change in mTSS at 24 wks	0.70	0.58	0.33*
Mean change in erosion score at 24 wks	0.49	0.40	0.22**
Mean change in mTSS at 52 wks	1.08	0.65	0.36**
Mean change in erosion score at 52 wks	0.74	0.45	0.23***
Clinical	n=249	n=249	n=250
ACR50 (%)	41.8	59.4***	64.8***
ACR70 (%)	24.9	42.2***	46.8***
MCR (%)	8.0	17.3*	18.4**
DAS remission (%)	12.6	25.4**	30.5***
Mean change in DAS28	n=244	n=247	n=248
	-2.06	-3.05***	-3.21***

**p<0.05, **p<0.001, ***p<0.0001 compared with Plc + MTX.*

Safety data were consistent with those previously reported. The rate of serious infections was 6.09, 4.61 and 3.73 events/100 pt-years in the Plc + MTX, RTX (2 x 500 mg) and RTX (2 x 1000 mg) groups, respectively. Three deaths occurred (pneumonia [2] and cerebral infarct): all were in the Plc + MTX arm.

Conclusion: In pts with early active RA, RTX (2 x 1000 mg) + MTX significantly improved clinical outcomes and inhibited joint damage, compared with MTX alone.

LITHE: Tocilizumab Inhibits Radiographic Progression and Improves Physical Function in Rheumatoid Arthritis (RA) Patients (Pts) at 2 Yrs with Increasing Clinical Efficacy Over Time. Roy Fleischmann[1], R. Burgos-Vargas[2], P. Ambs[3], E. Alecock[4] and J. Kremer[5], [1]Metroplex Clinical Research Center, Dallas, TX, [2]Hospital General de México, México, Mexico, [3]Roche, Basel, Switzerland, [4]Roche, Welwyn, United Kingdom, [5]Albany Medical College, Albany, NY

Purpose: To report results of a 2-yr planned analysis of a double-blind, randomized controlled, phase 3 trial of TCZ in pts with moderate to severe RA who remained on MTX despite inadequate response.

Method: Pts were randomized (1:1:1) to receive TCZ + MTX (4 mg/kg [TCZ4] or 8 mg/kg [TCZ8]) or placebo + MTX (control [CON]) every 4 wks. Stepwise rescue therapy starting at wk 16 was allowed if pts did not respond (<20% improvement in SJC and TJC). At wk 52, all pts were required to initiate open-label TCZ8 for yr 2, unless they had achieved ≥ 70% improvement in SJC and TJC, allowing them to continue the blinded therapy they were receiving at the end of yr 1 to wk 104. Primary 2-yr end points were change from baseline in Genant-modified Total Sharp Score (GmTSS) and physical function (AUC of change from baseline in HAQ-DI). Linear extrapolation (GmTSS) or standardization (change in HAQ-DI) was used for missing data (post-rescue data set to missing). To examine impact of 2 yrs of treatment, efficacy end points were assessed over time for pts randomized to TCZ8, with LOCF for SJC and TJC for pts who received rescue therapy or withdrew from that time point.

Results: The ITT population consisted of 398 TCZ8, 399 TCZ4, and 393 CON pts. At 2 yrs, exposure rate per pt-yrs (PY) were 1320, 521.9, and 284.8 in TCZ8, TCZ4, and CON pts. More CON pts required rescue vs TCZ pts, and more TCZ pts remained on initial randomized therapy (Table A). At yr 2, pts in the TCZ8 group had significantly less radiographic progression (81% inhibition) vs CON pts (based on linear extrapolation of mean change in GmTSS on initial treatment for post-rescue data). Significantly more TCZ8 pts had no radiographic progression vs CON pts ($p \leq 0.0001$). AUC of change from baseline in HAQ-DI showed significant improvement in physical function in TCZ4 and TCZ8 vs CON pts (Table A). In pts initially randomized to TCZ8, low disease activity score (LDAS; DAS28 □3.2) was seen in >60%, and DAS28 remission (DAS28 <2.6) rates were ~50% at wk 52 and continued to increase to wk 104 (Table B). By wk 52, in pts treated with TCZ8, clinically significant improvements in SJC occurred (–10) that were maintained through wk 104. Rates/100PY for adverse events (AEs) were higher in TCZ8 and TCZ4 (263.6, 275.4) vs CON pts (251.4) while rates for serious AEs were comparable (11.4, 12.1, 10.9). Rates per 100PY of AEs leading to withdrawal and treatment modification were higher in TCZ8 and TCZ4 (7.4 and 32.5; 8.4 and 30.7) vs CON pts (4.8 and 20.4) and rates for death were comparable (0.6, 0.2, 0.4).

Conclusion: TCZ + MTX continues to inhibit radiographic progression and improve physical function with a clinical effect, as evidenced by improving DAS28 remission, LDAS, and SJC at 2 yrs and with a manageable safety profile.

Table A. Disposition and selected endpoints at 2 yr in ITT pts

Disease Remission Is Achieved within Two Years in Over Half of Methotrexate Naive Patients with Early Erosive Rheumatoid Arthritis (RA) Treated with Abatacept Plus MTX: Results From the AGREE Trial. R. Westhovens[1], M. Robles[2], S. Nayiager[3], J. Wollenhaupt[4], P. Durez[5], J. Gómez-Reino[6], W. Grassi[7], B. Haraoui[8], W. Shergy[9], SH Park[10], H. Genant[11], C. Peterfy[12], J.-C. Becker[13], A. Covucci[13], R. Helfrick[13] and J. Bathon[14], [1]UZ Gasthuisberg, KU Leuven, Leuven, Belgium, [2]Centrol Medico Toluca, Mentpec, Mexico, [3]St Augustine's Hospital, Durban, South Africa, [4]Klinikum Eilbek, Hamburg, Germany, [5]Univ Catholique de Louvain, Brussels, Belgium, [6]Hospital Clinico Univ De Santiago, A Coruna, Spain, [7]Univ Politecnica delle Marche, Ancona, Italy, [8]Institut de Rhumatolgie de Montreal, Montreal, QC, [9]Univ of Alabama, Huntsville, AL, [10]Kangnam St Mary's Hosp, Seoul, South Korea, [11]University of California, San Francisco, CA, [12]SYNARC, Inc, San Francisco, CA, [13]Bristol-Myers Squibb, Princeton, NJ, [14]Johns Hopkins Univ Sch of Med, Baltimore, MD

Purpose: Intensive treatment of patients early in the RA disease process is becoming a standard of care making disease remission, as a treatment goal, more attainable. Here we report the clinical and safety outcomes in methotrexate naïve patients with early erosive RA treated with a combination of abatacept + methotrexate through 24 months.

Method: The AGREE trial was a 24 month study with a 12 month double-blind period (DB) and 12 month open label period (OL). During DB, patients were randomized to ABA (~10 mg/kg dose based on weight range) + MTX (dosed up to 20 mg) or placebo (PLA) + MTX. All patients completing DB and entering OL received ABA + MTX. Safety was assessed in all pts receiving ≥1 dose of ABA in OL. Clinical outcomes evaluated included DAS28 remission (DAS28 <2.6), low disease activity state (LDAS, DAS28 <= 3.2), and ACR responses.

Results: All 459 pts completing DB entered OL; 94.3% completed OL. Remission, LDAS, and ACR responses were sustained or increased from 12 to 24 months in original ABA + MTX arm (Table), with over half (55.2%) in remission at 24 months. Proportion achieving these outcomes in the original MTX alone arm increased after initiating ABA in OL, with 44.5% in remission at 24 months. Rates (per 100 pt yrs) of serious AE (6.42 vs 8.35) and serious infections (1.73 vs 2.04) were similar in the OL vs DB respectively. Autoimmune events occurred at a similar rate in OL as in DB (1.30 vs 2.47, respectively). Two deaths occurred. No malignancies or TB were reported.

Clinical Outcomes, (%)

	ABA + MTX (DB & OL) (N=232)		**MTX Alone (DB) → ABA + MTX (OL) (N=227)**	
	Baseline to Yr 1	**Yr 1 to Yr 2**	**Baseline to Yr 1**	**Yr 1 to Yr 2**
DAS(28) Remission	46.1	55.2	26.9	44.5
LDAS	60.8	71.1	43.2	60.4
ACR 50	64.7	74.1	50.2	67.0
ACR 70	48.3	53.9	31.7	49.8
ACR 90	18.5	22.0	7.5	22.9

Conclusion: Sustained disease remission is an achievable goal for many patients with early RA when treatment with combination of ABA + MTX is initiated early. Consistent with the long-term safety experience in patients with longer standing disease no new or unexpected safety signals occurred in this population. These data support the use of ABA + MTX in an early RA population.

Reduced Radiographic Progression in Patients with Early Rheumatoid Arthritis (RA) Treated with Abatacept + Methotrexate Compared to Methotrexate Alone: 24 Month Outcomes. J. Bathon[1], H. Genant[2], S. Nayiager[3], J. Wollenhaupt[4], P. Durez[5], J. Gómez-Reino[6], W. Grassi[7], B. Haraoui[8], W. Shergy[9], SH Park[10], M. Robles[11], C. Peterfy[12], J.-C. Becker[13], A. Covucci[13], R. Helfrick[13] and R. Westhovens[14], [1]Johns Hopkins Univ Sch of Med, Baltimore, MD, [2]University of California, San Francisco, CA, [3]St Augustine's Hospital, Durban, South Africa, [4]Klinikum Eilbek, Hamburg, Germany, [5]Univ Catholique de Louvain, Brussels, Belgium, [6]Hospital Clinico Univ De Santiago, A Coruna, Spain, [7]Univ Politecnica delle Marche, Ancona, Italy, [8]Institut de Rhumatolgie de Montreal, Montreal, QC, [9]Univ of Alabama, Huntsville, AL, [10]Kangnam St Mary's Hosp, Seoul, South Korea, [11]Centrol Medico Toluca, Mentpec, Mexico, [12]SYNARC, Inc, San Francisco, CA, [13]Bristol-Myers Squibb, Princeton, NJ, [14]UZ Gasthuisberg, KU Leuven, Leuven, Belgium

Purpose: Radiographic progression early in the course of RA disease may translate into long term detrimental outcomes. Here we report the 24 month radiographic outcomes in methotrexate (MTX)-naïve patients with early, erosive RA and poor prognostic factors who are treated early with abatacept (ABA) + MTX compared to MTX alone.

Method: The AGREE trial was a 24-month study, with a 12-month double-blind (DB) and a 12-month open-label (OL) period, in adult MTX-naïve patients with early, erosive RA and poor prognostic factors. During the DB, patients were randomized to ABA (~10 mg/kg dose based on weight range) + MTX (dosed up to 20 mg) or placebo (PLA) + MTX. All pts received ABA + MTX during the OL. Radiographic outcomes were assessed using Genant-modified Sharp scores. Changes in erosions [ES], joint space narrowing [JSN] and total score [TS] are reported. A change in TS <= 0 defined nonprogressors.

Results: Of the 459 pts completing DB and entering OL, 94.3% completed the study. Changes in radiographic outcomes from baseline to year 1 and year 1 to year 2 are presented in the table. From baseline through 24 months, patients originally randomized to the ABA + MTX arm experienced less progression of structural damage as measured by change in TS (0.84 vs 1.75) and a greater proportion of nonprogressors (56.8% vs 43.8%) compared to those originally randomized to MTX monotherapy. Moreover, among patients originally randomized to ABA + MTX arm, there was an increasing degree of inhibition of progression seen in year 2 compared to year 1 (TS = 0.18 vs 0.66, respectively, P<0.0001), with 91.1% of year 1 nonprogressors remaining nonprogressors in year 2 compared to patients initiated on MTX alone.

Radiographic Outcomes*				
Mean change Genant-modified Sharp Score	**ABA + MTX (N=213)**		**MTX Alone (DB) → ABA + MTX (OL) (N=192)**	
	Baseline to Yr 1	**Yr 1 to Yr 2**	**Baseline to Yr 1**	**Yr 1 to Yr 2**
ES	0.50	0.09	1.26	0.13
JSN	0.16	0.09	0.22	0.12
TS	0.65	0.18	1.48	0.25
* Data are reported as observed for all treated subjects in open label				

Conclusion: Early use of combination therapy with ABA and MTX results in greater long-term sustainable radiographic benefit in MTX-naïve early RA patients than MTX alone and supports the use of abatacept earlier in the RA disease process.

Golimumab and Radiographic Progression in Rheumatoid Arthritis: Results of GO-BEFORE and GO-FORWARD Studies. P. Emery[1], R. Fleischmann[2], Désirée M.F.M. van der Heijde[3], Edward C. Keystone[4], M. C. Genovese[5], P. G. Conaghan[6], E. C. Hsia[7], W. Xu[8], A. Baratelle[9], A. Beutler[8] and M. U. Rahman[7], [1]Univ Leeds, Leeds, United Kingdom, [2]U of Texas Southwest Med Center, Dallas, TX, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Professor of Medicine/University of Toronto, Toronto, ON, [5]Stanford University, Palo Alto, CA, [6]U of Leeds, Leeds, United Kingdom, [7]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [8]Centocor R&D, Inc, Malvern, PA, [9]Centocor, Malvern, PA

Purpose: To evaluate the effect of golimumab (GLM) on radiographic progression in pts with RA.

Methods: In both GO-BEFORE (MTX-naïve pts; n=637) and GO-FORWARD (MTX-inadequately responding (IR) pts; n=444) pts were randomized to PBO+MTX, GLM 100mg+PBO, GLM 50mg+MTX, or GLM 100mg+MTX. Subcutaneous injections were administered q4 wks. The GO-BEFORE had a control period of 52 wks with early escape [EE] at wk 28 and GO-FORWARD had a control period of 24 wks with EE at wk 16. Pts. in control grps meeting EE criteria start receiving GLM 50 mg + MTX. Radiographs of hands and feet at baseline, wk 24 (wk 16 for EE pts) and wk 52 in GO-FORWARD, and baseline, wk 28, and wk 52 in GO-BEFORE were scored by 2 independent readers and an adjudicator using the van der Heijde -Sharp score (vdHS). Different readers were used for the two trials. Linear extrapolation was used for radiographs taken at EE visits.

Results: In the MTX-naïve population, vdHS changes from baseline to wk 52 (co-primary endpoint) in both the 50mg and 100mg GLM+MTX grps were significantly lower compared with those in the PBO+MTX grp (Table). In the MTX-IR population, vdHS changes from baseline to wk 24 (primary analysis) were minimal in all grps, preventing any significant effect of GLM to be detected. The proportion of pts with change in vdHS above the smallest detectable change (SDC=2.58 for the study) was 4 % in the PBO+MTX grp. The lack of progression in the PBO grp may have been due to the short placebo-control period (in PBO+MTX gr 32% EE at wk 16 and remaining pts crossed over at wk 24 to receive GLM) and relatively less active pt population (median CRP of 0.9, lower joint counts, lower baseline vdHS scores) than in previously reported trials in similar populations.

Conclusion: Both GLM 50 + MTX & 100 mg + MTX demonstrated statistically significant and comparable inhibition of radiographic progression in MTX-naïve population compared with MTX alone. In the MTX-IR population the minimal radiographic progression in the MTX alone grp prevented any effect of GLM to be detected.

Table: Total vdHS for pts in GO-BEFORE and GO-FORWARD

	PBO + MTX	GLM 100 mg + PBO	GLM + MTX 50 mg	GLM + MTX 100 mg	GLM + MTX Combined
MTX-naïve (GO-BEFORE)

Mononuclear Phagocytes That Upregulate ITGAM Are Markers of SLE Nephritis Onset and Remission. Ramalingam Bethunaickan, Meera Ramanujam, Haiou Tao and Anne Davidson, Feinstein Institute for Medical Research, Manhasset, NY

Purpose: The onset of lupus nephritis is associated with activation of renal mononuclear phagocytes. Macrophage/DC populations in the nephritic kidney are heterogeneous and may have different effector functions. Our goal was to characterize the major subpopulations of these cells in pre-nephritic, nephritic and remission kidneys of 3 lupus prone murine models that develop different forms of the disease.

Methods: We used multiparameter flow cytometry to phenotype renal CD11b cells and immunohistochemistry to localize the cell types. We sorted the major subpopulations and performed electron microscopy and real time PCR studies. Turnover rate of the subpopulations was determined using BrDU. We used a fluorescent sensor for cathepsin to stain staining of kidneys in vivo. We labeled peripheral blood monocytes in vivo with fluorescent beads and analyzed kidneys by flow cytometry 96 hrs later.

Results: Microarray analysis of nephritic SLE kidneys from mice and humans revealed a macrophage/DC activation signature with marked upregulation of ITGAM (α chain of CD11b) in both mice and humans. Young kidneys contained two CD11b+ populations, a dominant $CD11b^{hi}/F4/80^{hi}/CD11c^{int}/Gr1^{lo}/CD62L^{lo}/VLA\text{-}4^{int}$ population and a much smaller $CD11b^{hi}/F4/80^{int}/CD11c^{int}/Gr1^{hi}/VLA\text{-}4^{hi}$ population, previously described as renal dendritic cells (rDC) and inflammatory macrophages respectively. The rDC population had small dendrites and was located in the renal interstitium in all three strains. Phenotypic analysis of nephritic kidneys showed global activation and expansion of these rDCs with marked upregulation of ITGAM, F4/80 and Ox-40L in all three strains, that reversed completely after remission induction. rDCs became very swollen at onset of proteinuria with large numbers of vacuoles and they secreted inflammatory chemokines and cytokines and displayed increased cathepsin activity. The onset of proteinuria in NZB/W and NZW/BXSB mice with proliferative nephritis was also associated with renal influx of $CD11b^{hi}/CD11c^{hi}/F/480^{int}/GR1^{lo}/CD43^{hi}/CD62L^{lo}/VLA\text{-}4^{hi}$ ($CD11c^{hi}$) cells that disappeared upon remission induction. This population had a veiled cell morphology typical of myeloid DCs. $CD11c^{hi}$ cells secreted inflammatory cytokines but did not become vacuolated or display cathepsin activity. They were located in lymphoid aggregates in NZB/W mice, in glomeruli in NZW/BXSB mice but were rare in NZM2410 mice that have only glomerulosclerosis. BrDU labeling indicated that the rDCs had a turnover rate of 45-60 days whereas the $CD11c^{hi}$ cells turned over in 15 days. Fluorescent bead labeling indicated that rDCs derive from circulating $Gr1^{lo}$ monocytes whereas the $CD11c^{hi}$ DCs derive from a different source.

Conclusion: Lupus nephritis, unlike acute inflammatory nephritis in which there is an influx of $Gr1^{hi}$ inflammatory macrophages, is associated with reversible activation of intrinsic renal dendritic cells expressing increased levels of ITGAM. In mice with proliferative nephritis myeloid dendritic cells migrate into the kidneys, turn over rapidly and disappear upon remission. These two cell types constitute different targets for therapeutic intervention.

Novel Proteasome Inhibitors Have a Beneficial Effect in Murine Lupus. Travis Ichikawa[1], Tony Muchamuel[2], Jing Jiang[2], Teresa Owen[1], Christopher J. Kirk[2] and Jennifer H. Anolik[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Proteolix, Inc., South San Francisco, CA, [3]University of Rochester, Rochester, NY

Purpose: Most therapies currently used to treat systemic lupus erythematosus (SLE) and B cell targeted therapies under development do not effectively target plasma cells and autoantibodies. We postulated that proteasome inhibition, particularly selective targeting of the immunoproteasome, may be useful in the treatment of SLE by targeting plasma cells and other immune cells critical to disease pathogenesis.

Method: Nephritic NZB/W F1 lupus-prone female mice were treated with the proteasome inhibitors (targeting both the constitutive β5 and immunoproteasome LMP7 subunits) carfilzomib (twice in 24-hour interval) and bortezomib (twice in 36-hour interval), the LMP7-selective inhibitor PR-957 (3 times in 48-hour intervals), or vehicle control intravenously. Spleen (SP) and bone marrow (BM) lymphocytes were

harvested and analyzed by flow cytometry using standard markers, including intracellular kappa light chain and CD138 for identification of plasma cells (PCs). Nephritis was monitored by proteinuria (Uristix) and kidney harvest. Serum anti-dsDNA levels were measured by ELISA (IgG, Alpha Diagnostic International). Total IgG and dsDNA antibody secreting cells (ASC) were measured by ELIspot. MRL/lpr mice with active proteinuria (age 11 weeks) were also treated with proteasome inhibitors for 13 weeks.

Results: Lupus prone mice with active nephritis had a lower tolerance for the dual targeted proteasome inhibitors than previously reported while immunoproteasome inhibition was well tolerated in these animals. Short-term treatment of NZB/W F1 mice with established nephritis (durable proteinurea >=3 or 300mg/dl) with carfilzomib (twice in 24-hour interval), PR-957 (3 times in 48-hour intervals), or bortezomib (twice in 36-hour interval) had profound effects on plasma cells. Specifically, carfilzomib and PR-957 reduced the SP PCs 2.4 and 2.1-fold respectively (1.95% carfilzomib treated vs. 2.2% PR-957 treated vs. 4.71% untreated [n=5]). Strikingly, carfilzomib and PR-957 reduced the frequency of total IgG and anti-dsDNA IgG secreting cells by up to 90% in the spleen (dsDNA ASC frequency: 1.4/10E5 for carfilzomib vs. 10.6/10E5 for PR-957 vs. 21.5/10E5 cells for untreated mice). Anti-dsDNA IgG secreting plasma cells in the BM were reduced to undetectable levels after proteasome inhibitor treatment. The effects of longer term treatment on nephritis are under investigation in this model. However, all 3 agents prevented progression to severe proteinuria in MRL/lpr mice. Bortezomib and PR-957, but not carfilzomib, significantly reduced the levels of serum autoantibodies.

Conclusion: Carfilzomib and PR-957 significantly decrease autoreactive plasma cells in lupus prone mice. Of note, inhibition of the immunoproteasome was equally efficacious to dual targeting agents in preventing lupus disease progression. These results support the utility of proteasome inhibition in the treatment of SLE.

Gender Specific Association of X-Linked TLR7 with Male SLE. N. Shen[1], Q. Fu[2], Y. Deng[1], J. Zhao[2], X. X. Qian[1], K M. Kaufman[3], Y J. Tang[1], J Y. Chen[4], W L. Yang[5], A. Kawasaki[6], N. Tsuchiya[6], Y. Kawaguchi[7], C Y. Yu[8], H S. Howe[9], Mok MY[5], Y K. Sung[10], J B. Harley[3], J M. Guthridge[3], J M. Grossman[2], R M. Cantor[2], Y W. Song[11], S C. Bae[10], S L. Chen[1], B H. Hahn[2], Y L. Lau[5] and BP. Tsao[2], [1]Ren Ji Hosp, Shanghai, [2]UCLA, LA, CA, [3]Oklahoma Medical Res Fnd, [4]Chang Gung Memorial Hosp, Taiwan, [5]UHK, Hk, [6]Univ of Tsukuba, [7]Tokyo Women's Medical Univ, [8]Ohio State Univ, [9]Tan Tock Seng Hosp, Singapore, [10]Hanyang Univ, [11]Seoul National Univ

Purpose: Duplicated *Tlr7* promotes lupus-like disease in male BXSB-*Yaa* mice, prompting us to evaluate *TLR7* in SLE patients especially in males.

Method: SNP genotyping was conducted using the Illumina Infinium platform in the discovery panel, and Taqman or pyrosequencing in replication panels. Relative expression of *TLR7* mRNA in PBMC was measured by RT-qPCR.

Results: Fine-mapping the 23-kb *TLR7* region using 11 SNPs in 1434 SLE cases of Eastern Asian (EA) descent vs. 1591 EA controls showed association of 2 *TLR7* SNPs with SLE (rs5935436 in the promoter, $p=1.8\times10^{-3}$; rs3853839 in the 3'UTR, $p=6.7\times10^{-4}$). In this discovery panel, the association signal of the 3'UTR SNP was mainly found in Chinese (cases/controls; 563/522, $p = 6.3\times10^{-6}$) with a higher OR in males than females (OR = 5.6 vs. 1.5), but not detected in Koreans (845/1022). This association with SLE with a stronger male effect was replicated in both independent panels of Chinese (2133/2069, $p = 1.8\times10^{-5}$, OR = 3.1 vs. 1.3) and Japanese (560/913, p=0.007, OR = 3.5 vs. 1.2). In the combined analysis of 4127 cases and 4573 controls, the G allele of the 3'UTR SNP was associated with SLE ($p = 2.4 \times 10^{-12}$) exhibiting a higher OR in males than females (OR = 2.5[1.7-3.5]) vs. 1.3[1.2-1.4]). Healthy Chinese controls of either gender carrying only the risk G allele had significantly higher mRNA level of *TLR7* in PBMC than those carrying allele C only, which was similarly found in female Chinese SLE patients, suggesting regulation of *TLR7* expression by this SNP or its linked variants.

Conclusion: Association between the X-linked *TLR7* SNP and SLE with a stronger male effect was identified in EA and replicated in independent Chinese and Japanese panels. This risk allele may confer elevated expression of the RNA-binding TLR7, predisposing to the development of SLE, especially in male Chinese or Japanese.

Association of rs3853839 with SLE in EA population.

A Cross Sectional Study Comparing the CDA to the VDI for the Assessment of Damage in Vasculitis. R. Suppiah[1], O. Flossmann[2], C. Mukhtyar[1], A. Judge[1], D. Brown[1], B. Baslund[3], D. Jayne[2], Mark A. Little[4], J. Holle[5], N. Hasan[1] and R. Luqmani[1], [1]Nuffield Orthopaedic Centre, Oxford, United Kingdom, [2]Addenbrooke's Hospital, Cambridge, United Kingdom, [3]The National University Hospital, Copenhagen, Denmark, [4]University of Birmingham, Birmingham, United Kingdom, [5]University of Schleswig–Holstein, Bad Bramstedt, Germany

Purpose: The Vasculitis Damage Index (VDI) measures damage related to vasculitis, but it may not capture all relevant damage, especially in ANCA associated vasculitis, compared to a more comprehensive assessment measure: the Combined Disease Assessment index (CDA). The aims of the study are to compare the CDA and VDI to measure damage in vasculitis and to validate the CDA for truth, discrimination and feasibility.

Methods: In a cross sectional study, patients with vasculitis were assessed for disease activity using the Birmingham Vasculitis Activity Score 3 (BVAS) and for damage using the VDI and CDA. Inter and intra-observer differences were measured in a sub group and by using paper cases. Feasibility questionnaires for the VDI and CDA were applied.

Results: We evaluated 288 patients from 11 European centres (disease duration 0-480 months). Wegener's granulomatosis (58%) and microscopic polyangiitis (10.4%) were the most common diagnoses. The CDA has already satisfied face and content validity during initial development. The degree of agreement between the VDI and CDA scores (measured using Spearman's rank correlation coefficient) was 0.89 (95%CI 0.87-0.91) confirming their convergent validity. There was good correlation between individual systems (0.71-0.94) except for skin and mucous membranes which was 0.53 (95%CI 0.45-0.60), mainly attributed to the inclusion of easy bruising (18.5% of patients) and cutaneous scarring (10.2%) in the CDA (items not present in the VDI). Inter observer reliability using Lin's concordance correlation coefficient was 0.90 (95% CI 0.83-0.96) for VDI, and 0.70 (95%CI 0.55-0.85) for CDA. Intra observer reliability was 0.89 (95% CI 0.77-1.0) for VDI and 0.86 (95%CI 0.72-1.0) for CDA. Assessing the use of items in the cohort, 9 items were never recorded in the VDI compared to 26 in the CDA. Neither VDI nor CDA correlated with BVAS, CRP or ANCA. Most observers reported that the CDA covered the full spectrum of damage attributable to vasculitis and that it could be used to record the natural history of vasculitis. Only 66% thought that it was useful for measuring damage in clinical trials compared to 100% for the VDI. The CDA took longer to complete (mean 17mins vs. 8mins); it was difficult to complete (67%); and not practical for routine clinical use (83%). By contrast, VDI was easy to complete (100%) and practical for daily clinical use (83%). Overall, 83% preferred to use the VDI when considering all factors.

Conclusion: The CDA measures damage in more detail but the increased complexities result in inferior intra and inter observer reliability and more redundant items than in VDI; CDA is not feasible for daily clinical practice and therefore does not fulfill the requirements of the OMERACT filter. We propose an improvement in VDI, by removing the 9 redundant items identified and adding easy skin bruising and scarring.

Risk of Malignancy in Patients Treated for ANCA-Associated Vasculitides: Follow-up Data From Clinical Trials of the European Vasculitis Study Group (EUVAS). Caroline Heijl[1], Lorraine Harper[2], Oliver Flossmann[3], Isabelle Stücker[4], David GI Scott[5], Richard Watts[6], Peter Höglund[7], Kerstin Westman[1] and Alfred Mahr[8], [1]University Hospital MAS, Malmö, Sweden, [2]School of Infection and Immunity, Birmingham, United Kingdom, [3]Royal Berkshire Hospital, Reading, United Kingdom, [4]INSERM U754, Villejuif, France, [5]Norfolk and Norwich University Hospital, Norwich, United Kingdom, [6]University of East Anglia, Ipswich, United Kingdom, [7]Lund University Hospital, Lund, Sweden, [8]Hospital Cochin, Paris, France

Purpose: Standard immunosuppressive treatment for the ANCA-associated vasculitides (AAV), Wegener's granulomatosis (WG) and microscopic polyangiitis (MPA), may pose a significant risk for the development of malignancies. Previous studies suggested that WG treatment was associated with higher incidences of bladder cancer, non-Hodgkin lymphoma (NHL), leukemia and/or non-melanoma skin cancer (NMSC). This study assessed the malignancy risk for patients treated for AAV in the framework of 4 EUVAS trials.

Method: This analysis was based on the 535 patients with newly diagnosed WG or MPA from 14 European countries (and Mexico) who had been enrolled between 1995 and 2002 in the NORAM, CYCAZAREM, CYCLOPS and MEPEX trials. The 4 trials covered the wide spectrum of severities in AAV presentation and evaluated distinct severity-adapted treatment regimens. Over the period 2004–2007, study participants' follow-up events, including cancers diagnosed, were updated by a cross-sectional mailing survey. Age-, sex- and area-

standardized incidence ratios (SIR) were calculated by linkage to 5 European cancer registries. Cumulative malignancy rates were computed using the Kaplan–Meier method.

Results: Follow-up data were obtained for 467 (87.3%) patients. The overall cohorts' median time of observation was 5.16 years (range: 0.01–11.46), corresponding to 2648 person-years. During that time, 50 malignancies were diagnosed in 46 patients, including 14 NMSC, 4 bladder cancers, 1 NHL and 2 leukemias. The cumulative 5-year cancer rate was 8.6% (95% CI: 5.7–11.5). SIR were: all-sites malignancies, 1.48 (95% CI: 1.10–1.96); all-sites malignancies excluding NMSC, 1.28 (95% CI: 0.89–1.77); bladder cancer, 2.26 (95% CI: 0.62–5.78); NHL, 1.02 (95% CI: 0.03–5.69); and leukemia, 3.25 (95% CI: 0.39–11.75). Subgroup SIR for all-sites malignancies were 1.79 (95% CI: 1.23–2.53) for WG, 1.14 (95% CI: 0.67–1.80) for MPA, and 1.48 (95% CI: 1.08–1.97) for cyclophosphamide-treated patients.

Conclusion: Cancer rates for AAV patients treated with conventional immunosuppressive therapy exceeded the expected general population numbers. The smaller magnitude of malignancy risk in this patient cohort compared to previous studies might reflect less extensive use of cyclophosphamide in current treatment protocols.

Proteinase 3 Transcription in Peripheral Blood Mononuclear Cells Predicts Disease Activity in Wegener's Granulomatosis. Chris Cheadle, Alan E. Berger, Felipe Andrade, Regina James, Kristen Johnson, Tonya Watkins, Yu-Chi Chen, Eva Ehrlich, Marissa Mullins, Kathleen C. Barnes and Stuart M. Levine, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Wegener's granulomatosis (WG) is a systemic inflammatory disease that can lead to substantial morbidity. Its immunologic hallmark is the generation of anti-proteinase 3 (PR3) antibodies, although their levels do not reliably correlate with disease activity in the majority of patients. Whether changes in PR3 transcription could be used to assess disease activity in WG is unknown.

Method: Gene expression profiling using Illumina bead arrays was performed using total RNA from the separated PBMC and granulocyte (PMN) fractions from 41 WG patients and 23 healthy controls. Quantitative signature analysis was performed using gene set matrix (GSMA), gene set enrichment (GSEA), and principal component analyses (PCA) to search for candidate WG-associated molecular pathways and disease activity biomarkers. Differentially expressed genes satisfied the significance threshold criteria of: (i) t-test p-values ≤ 0.01 (10^{-2}); (ii) a false discovery rate ≤ 0.1; and (iii) a fold change > 1.5 or $< 1/1.5$. Longitudinal changes in PR3 expression were evaluated in 5 patients using RT-PCR, and clinical outcomes including remission status, persistent disease activity, and flare were determined using BVAS-WG scores.

Results: We identified 86 significantly up-regulated genes in WG PBMCs and 40 in WG PMNS relative to controls. Up-regulated genes in WG PBMCs were largely comprised of genes involved in myeloid differentiation, and included the major WG autoantigen, PR3. The coordinated regulation of myeloid differentiation genes in WG PBMCs was confirmed using gene set analysis. PR3 transcription was highly correlated with the myeloid signature as a whole ($r^2=0.78$), and was significantly up-regulated in the PBMC ($p=1.3 \times 10^{-5}$, FDR=0.0021), and not the PMN (p=0.03, FDR=0.28) fraction of WG patients compared to controls. Increased PR3 transcription was seen in all patients with active disease, and both patients in remission and healthy controls expressed similarly low levels of PR3 in the peripheral blood. Changes to and from remission were associated with corresponding decreases or increases in PR3 RNA levels in all patients, whereas changes in ANCA titer correlated with disease activity status in only one case.

Conclusion: These data suggest that PR3 transcription in the peripheral blood mononuclear cells of WG patients might represent a novel marker for assessing disease activity in WG.

Comparison of Disease Manifestations of ANCA-Associated Vasculitis Based On ANCA Type Among Participants in a Multicenter Clinical Trial. U. Specks[1], P.A. Merkel[2], P. Seo[3], R. Spiera[4], C. A. Langford[5], C.G.M. Kallenberg[6], E. William St. Clair[7], B.J. Fessler[8], N. Tchao[9], L.V. Webber[10], L. Ding[10], W. Wu[11], D. Ikle[12], D. Weitzenkamp[12], F.C. Fervenza[1], K.A. Keogh[1], P. Brunetta[13], E. Y. Kissin[2], K.S. Mieras[1], P.A. Monach[2], T. Peikert[1], L. Seismundo[3], C. Stegeman[6], S.R. Ytterberg[1], J. H. Stone[14] and The RAVE-ITN Research Group[9], [1]Mayo Clinic, Rochester, MN, [2]BU, Boston, MA, [3]Johns Hopkins, Baltimore, MD, [4]HSS, New York, NY, [5]Cleveland Clinic, Cleveland, OH, [6]Med.Univ., Groningen, Netherlands, [7]Duke University Medical Center, Durham, NC, [8]UAB, Birmingham, AL, [9]ITN, San Francisco, CA, [10]NIH, Bethesda, MD, [11]PPD, Wilmington, NC, [12]Rho, Chapel Hill, NC, [13]Genentech, Inc, South San Francisco, CA, [14]MGH, Boston, MA

Purpose: To compare disease phenotypes based on ANCA type (PR3 vs. MPO) among patients with severe ANCA-associated vasculitis (AAV).

Method: Baseline demographic data, AAV history, disease activity, and organ involvement of participants in the Rituximab in ANCA Vasculitis Trial (RAVE) were compared by ANCA type. RAVE is a multicenter, randomized, double-blind, placebo-controlled trial designed to determine whether rituximab is not inferior to cyclophosphamide for remission induction in severe AAV. ANCA were measured by ELISA. Organ involvement and disease activity were recorded using the Birmingham Vasculitis Activity Score for WG (BVAS/WG).

Results: Of the 197 trial participants, 131 (66.5%) had PR3-ANCA and 66 (33.5%) had MPO-ANCA. Ninety-nine trial participants (50.3%) were men, 75 with PR3-ANCA and 24 with MPO-ANCA (P<0.006). Among the 98 women enrolled, 56 had PR3- and 42 MPO-ANCA, respectively. The mean (SD) time from diagnosis to enrollment was 47.4 (61.1) months in patients with PR3-ANCA versus 14.7 (32.2) months with MPO-ANCA (p<0.001).

96 of 197 patients (49%) were newly diagnosed at enrollment. Fifty of these were men; 50 (52%) had PR3-ANCA and 46 (45%) had MPO-ANCA. Subsequent analyses are based on this subset of newly diagnosed patients with major results in the Table. Compared to PR3-positive patients, MPO-positive patients were significantly older, more commonly female, had lower BVAS/WS scores but had more major (severe) manifestations. Major renal disease was more common in patients with MPO-ANCA, but the frequencies of alveolar hemorrhage (27%) and nervous system involvement (24%) did not differ between ANCA types. Joint, mucous membrane, ENT, and granulomatous lung involvement were more common in patients with PR3-ANCA.

Conclusion: The clinical disease phenotype of patients presenting with new-onset severe AAV in a clinical trial differs depending on the ANCA type. These data support the decision to stratify treatment assignment by ANCA type in RAVE and justify use of stratification by ANCA type in future clinical trials.

Table: Clinical manifestations of by ANCA type for patients with new-onset AAV

New-Onset AAV	Age mean (sd)	Male n (%)	PGA (0-100 mm)	BVAS/WG	Minor Items mean (sd)	Major Items mean (sd)
PR3 (n=50)	49 (16)	32 (64%)	57	9.8 (3.0)	5.1 (2.3)	1.6 (1.0)
MPO (n=46)	61 (15)*	18 (39%)*	61	8.3 (3.1)*	2.2 (1.7)*	2.0 (0.9)*

* = p < .05 compared to PR3-positive patients. PGA = Physician Global Assessment

The Value of Rise in Anti-Neutrophil Cytoplasmic Antibody (ANCA) Measurements for Predicting Relapse Among Patients with ANCA-Associated Vasculitis - A Meta-Analysis. Gunnar Tomasson[1], Peter C. Grayson[1], Alfred Mahr[2], Michael P. LaValley[1] and Peter A. Merkel[1], [1]Boston University, Boston, MA, [2]Hospital Cochin, Paris, France

Purpose: Testing for the presence of anti-neutrophil cytoplasmic antibodies (ANCA) has an undisputed role in diagnosing ANCA-associated vasculitis (AAV) but the value of serial ANCA measurements to guide disease management remains controversial. The objective of this study was to perform a meta-analysis to explore whether serial ANCA measurements predict subsequent disease relapse.

Methods: A comprehensive literature review was performed, focused on studies of serial ANCA measurements for prediction of relapse in subjects with established AAV. Articles cited in MEDLINE and conference abstracts were reviewed as were relevant references. Studies were included in the analysis if i) at least 10 participants with established AAV had serial ANCA measurements; ii) data was reported on rises in ANCA values prior to flares or conversions from ANCA-negative to ANCA-positive status during remission; and iii) the number of individuals with ANCA rises and flares could be extracted. For each study, positive- and negative likelihood ratios (LR) were calculated and pooled separately using random-effects models and reported with 95% confidence intervals (CI). To evaluate between-study heterogeneity and publication bias, the arcsine data transformation was used, I^2-value was calculated with 95% CI, a funnel plot was constructed, and the Egger test performed.

Results: 31 articles were identified for full-text review of which 8 studies with a total of 448 subjects were included for the analysis. Frequencies of ANCA measurements ranged from monthly to every 3 months. Follow up for disease relapse ranged from 12 months to 54 months. A rise in ANCA gave a pooled positive likelihood ratio of 3.39 (95% CI: 1.69-6.82) for future flare, absence of a rise in ANCA gave a pooled negative likelihood ratio of 0.45 (95% CI: 0.23-0.87) **(Figure).** If there is a clinically estimated 40% relapse risk, these results indicate a post-test probability for subsequent relapse of 69% in situations of an ANCA measurement rise and a post-test probability for subsequent relapse of 23% in situations of no ANCA measurement rise. There was high heterogeneity among the included studies (I^2 = 0.90 [95% CI: 0.83-0.94]). The funnel plot was asymmetric but Egger's test for publication bias was not statistically significant (p=0.36).

Conclusion: Rise in ANCA values during remission of AAV showed modest predictability for future relapse of disease with some relapses occurring more than one year after the rise in ANCA. Treatment decisions based on a rise in ANCA titer alone would likely result in exposure to unwarranted and potentially harmful therapy in a significant number of situations. In addition, there was considerable heterogeneity in the included studies, along with some suggestion of publication bias.

Behçet Syndrome (BS) in the US: Clinical Characteristics, Treatment and Ethnic/Racial Differences in Manifestations in 347 Patients with BS. Yusuf Yazici[1], Elizabeth Schimmel[1] and C.J. Swearingen[2], [1]NYU Hospital for Joint Diseases, New York, NY, [2]MUSC, Charleston, SC

Purpose: Behçet syndrome (BS) is a systemic vasculitis that is common in the old Silk Route but rare in northern Europe and the US. Previous reports have suggested that there may be ethnic and racial differences in disease presentation and possible clustering of manifestations. We started a dedicated Behçet clinic in 2004 and now report on the disease characteristics of the first 347 patients, we believe representing thus far the largest cohort in the US

Methods: All patients seen at the center have complete a MDHAQ, and a questionnaire about past medical history, medication use, Behçet specific history, ethnic and demographic information. These data are prospectively collected and updated each visit. About 2/3 of patients live within driving distance of NYC while patients from over 30 states have been seen. Patients were analyzed as the whole cohort and then also separated into to 2 groups: Group A= with ethnic background in northern Europe and North America and /or self declared Caucasians without background around the Mediterranean and/or the Far East; Group B= Patients with an ethnic background in the Mediterranean, Middle East, North Africa, and Far East. These groups were compared for disease manifestations, demographic information and medication use.

Results: 347 patients (76% female, mean (SD) disease duration 3.8 (5.4) years, mean (SD) age 53 (13)) of whom 88% fulfilled the International Behçet classification criteria, were analyzed. For the whole cohort most common symptoms were oral ulcers (94%), genital ulcers (76.2%), skin involvement (70.2%), arthritis (54.7%), GI disease (37.9%) and eye disease (27.9%). 15.2% had CNS, 9.7% had vascular/DVT involvement. Less than 10% were positive for pathergy test and 11% had a positive HLA B51. None of the patients were blind. Group A had statistically more significant GI disease (47.5% vs. 27.4%, $p<0.001$). There were also more females in Group A, compared to Group B (Group A: 85%, Group B:69%, $p<0.001$). Most commonly used medication was low dose prednisone (69.6%), in most patients as needed for flares, followed by colchicine (50.9%), TNF inhibitors (23.3%) and azathioprine (22.5%). 17.6% were on methotrexate, the only medication with significantly different frequency of use among the two groups (Group A=26.8%, Group B=8.6%, $p<0.001$).

Conclusion: In this cohort of 347 BS patients, largest cohort in the US to the best of our knowledge, some clinical differences were noted between patients with different ethnic backgrounds. There were significantly more female patients in the non-ethnic groups and GI disease was significantly more among these patients also. Eye disease prevalence for both groups was less than reported from other centers and may be less severe as none of the patients were blind. These finding may have implications regarding the pathogenesis and the effect of nature vs nurture on the presentation of BS in different geographic areas.

Essential Role of MASP1/3 in Activation of the Complement Alternative Pathway in Collagen Antibody-Induced Arthritis in Mice.

Nirmal K. Banda[1], Brandt Levitt[1], Minoru Takahashi[2], Magdalena J. Glogowska[3], Kazue Takahashi[4], Gregory L. Stahl[5], Teizo Fujita[2], William P. Arend[1] and V. Michael Holers[1], [1]Division of Rheumatology, University of Colorado Denver, Aurora, CO, [2]Department of Immunology, Fukushima Medical University School of Medicine, Fukushima, Japan, [3]University of Colorado Denver, Aurora, CO, [4]Developmental Immunology, Massachusetts General Hospital for Children, Boston, MA, [5]Center for Experimental Therapeutics and Reperfusion Injury, Brigham and Women's Hospital, Boston, MA

Purpose: Sera from mice genetically lacking mannose-binding lectin-associated serine proteases 1/3 *(MASP1/3$^{-/-}$)* unexpectedly have been shown by Takahashi and Fujita to contain only inactive, pro-factor D (pro-Df) and not proteolytically generated active factor D. Active factor D is required for function of the alternative pathway (AP) of complement by promoting formation of the AP C3 and C5 convertases. AP is both necessary and sufficient for mediation of collagen antibody-induced arthritis (CAIA) in mice. The objective of this study was to examine the hypothesis that *MASP1/3$^{-/-}$* mice will be resistant to CAIA due to an impaired AP.

Method: Wild type (WT), *MASP1/3*$^{-/-}$ and *Df*$^{-/-}$ C57BL/6 mice were used. CAIA was induced by injecting 4 anti-type II collagen (CII) mAb intraperitonally (i.p.) on day 0 and LPS i.p. on day 3. Clinical disease activity scores (DAS) were determined daily and histopathology was performed on joint tissues from mice sacrificed on day 10. The absolute levels of C1q, C4, C3, factor B, and factor D in sera from *MASP1/3*$^{-/-}$ and WT mice were measured by ELISA. Sera from *MASP1/3*$^{-/-}$, *C4*$^{-/-}$, *Bf*$^{-/-}$, *Df*$^{-/-}$ were reconstituted with human recombinant Df (hu-rDf), and anti-CII mAb-induced C3 deposition, C3a and C5a generation were measured.

Results: DAS were significantly decreased between days 4 and 10 ($p < 0.05$) both in *MASP1/3*$^{-/-}$ and *Df*$^{-/-}$ mice with a 93% and 88% decrease, respectively, compared to WT mice at day 10. The incidence of disease was 50%, 60% and 100% in *MASP1/3*$^{-/-}$, *Df*$^{-/-}$ and WT mice, respectively. Histopathology scores were consistent with the DAS. C3 deposition in the synovium and cartilage at day 10 was also reduced in *MASP1/3*$^{-/-}$ and *Df*$^{-/-}$ mice with CAIA ($p < 0.05$). There were no differences in the absolute levels of C1q, C4, C3, factor B, and factor D using sera from *MASP1/3*$^{-/-}$ and WT mice. However, the factor D present in the sera of *MASP1/3*$^{-/-}$ mice was entirely in the form of pro-Df, as determined by immunoblot analysis. Anti-CII mAb-induced C3 deposition, C3a and C5a generation in vitro were all absent using sera from *MASP1/3*$^{-/-}$ or *Df*$^{-/-}$ mice under conditions where only the AP was active. However, significant ($p < 0.05$) increases in C3 deposition, and in C3a and C5a levels were observed when sera from *MASP1/3*$^{-/-}$ or *Df*$^{-/-}$ mice were reconstituted with as little as 0.5 ng/ul of hu-rDf. These results indicate that *MASP1/3*$^{-/-}$ mice have an impaired AP of complement due to a lack of active factor D in the serum.

Conclusion: Our studies show that *MASP1/3*$^{-/-}$ mice are resistant to CAIA because of an inability to generate active factor D that is essential to activate the AP in vivo.

The Role of MR1-Restricted MAIT Cells in the Pathogenesis of Arthrhtis. Asako Chiba, Ryohsuke Tajima, Yusei Miyazaki, Daiju Ichikawa, Takashi Yamamura and Sachiko Miyake, Natl Institute of Neuroscience, Tokyo, Japan

Purpose: Mucosal associated invariant T (MAIT) cells are a subset of T cells which are restricted MR1, a MHC class Ib molecule, and express an invariant TCRα chain (Vα19-Jα33 in mouse and Vα7.2-Jα33 in human). Previously, we reported the regulatory role of Vα19i T cells in experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis. However, their role in other autoimmune disease models is still unclear. We sought to understand the role of Vα19i T cells in murine models of arthritis.

Method: Antibody-induced arthritis was induced in C57BL/6 wild-type (WT) and MR1$^{-/-}$ mice by injecting either K/BxN serum i.p. or anti-type II collagen antibody i.v. followed by lipopolysaccharide i.p.. To induce collagen-induced arthritis (CIA), MR1$^{-/-}$ DBA/1J mice or WT littermates were immunized intradermally at the base of the tail with 150μg of bovine type II collagen (CII) emulsified with an equal volume of Freund's complete adjuvant containing 250μg of H37Ra *Mycobacterium tuberculosis*. Mice received booster immunization with 150μg of bovine CII emulsified with incomplete Freund's adjuvant on day 21. To evaluate CII-specific T cell responses, lymph node (LN) cells were isolated and were stimulated with CII. Vα19i T cells were sorted from liver or spleen cells of Vα19iTCR-Transgenic (Vα19iTg) CD1d$^{-/-}$ mice by using anti-TCRVβ and anti-NK1.1 monoclonal antibodies. For adoptive transfer studies, $5x10^5$ NK1.1$^+$ TCRVβ$^+$ Vα19i T cells sorted from Vα19iTg CD1d$^{-/-}$ mice were injected i.v. into naïve WT mice on the day before the induction of arthritis. Cytokines in culture supernatants were measured by ELISA or cytokine bead assay kit.

Results: The severity of clinical and pathological features of K/BxN serum transfer arthritis and anti-CII antibody-induced arthritis were reduced in MR1$^{-/-}$ mice compared to control WT mice. MR1$^{-/-}$ mice reconstituted with sorted Vα19i T cells developed severe forms of arthritis to the similar level of arthritis in WT mice. MR1$^{-/-}$ DBA/1J mice were more resistant to CIA compared to WT littermates, as demonstrated by clinical and histological scores of arthritis. LN cells from CIA-induced MR1$^{-/-}$ DBA/1J mice produced less IL-17 and MCP-1 upon in vitro re-stimulation with CII, compared to littermate controls. The cytokine production by anti-CD3mAb-stimulated Vα19i T cells was augmented in the presence of IL-1 or IL-23.

Conclusion: Vα19i T cells contribute to the pathogenesis of arthritis by augmenting autoimmune T cell responses. Inflammatory cytokines which are abundant in inflammatory conditions including arthritis may activate Vα19i T cells, which in turn amplify autoimmune responses.

Mycobacterium-Derived Heat Shock Protein 70 Induces Anti-Citrullinated Protein/Peptide Antibodies. Hirofumi Shoda[1], Keishi Fujio[2] and Kazuhiko Yamamoto[3], [1]Graduation School of medicine, the University of Tokyo, Tokyo, Japan, [2]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Graduate School of Medicine, the University of Tokyo, Tokyo, Japan

Purpose: Rheumatoid arthritis (RA) is characterized by sustained and destructive joint inflammation, and several autoantibodies appear in the serum of RA patients. Paticularly, anti-citrullinated protein/peptide antibodies (ACPAs) are highly specific for the diagnosis of RA. However, it remains unclear how APCAs develop and what kinds of antigens relate to this process. In this study, we propose *Mycobacterium*-derived heat-shock protein 70 (MycHSP70) as a candidte of ACPA inducible antigen.

Method: We immunized MycHSP70, coupled with CFA, to DBA/1J mice, and serum were obtained after 28 days. To indude collagen-induced arthritis (CIA), bovine type 2 collagen with CFA was immunized 14 days after MycHSP70 immunization, and clinical and histological scores of joint inflammation were measured. Serum ACPAs were measured by ELISA (anti-cyclic citrullinated peptide (CCP) antibody and anti-citrullinated fibrin antibody) and immunostain of rat-esophageal tissues. In RA patients, serum antibodies to MycHSP70 and anti-CCP antibody were measured. To assay T cell response, CD4+ T cells were isolated from peripheral blood mononuclear cells (PBMCs) by MACS system, and were incubated with MycHSP70 for 3 days. Cell proliferation was measured by 3H-thymidine uptake.

Results: MycHSP70 immunized mice developed ACPAs, including anti-CCP antibody, anti-citrullinated fibrin antibody, and anti-citrullinated fillagrin antibody. And CIA got worse in MycHSP70 pre-immunized mice. In RA patients, serum titers of anti-MycHSP70 antibodies and anti-CCP antibodies were significantly collerated. CD4+ T cells from RA patients proliferated in response to MycHSP70.

Conclusion: In RA patients, immune response to MycHSP70 was observed both in B and T cells. In mouse models, immunization of MycHSP70 could induce ACPAs and exacerbate experimental inflammatory arthritis. We suggest that MycHSP70 could be a good candidate antigen for the inducer od ACPAs.

Natural IgM Is Required for the Suppression of Arthritis Mediated by Transfer of Apoptotic Cells. Clare Notley and Michael R. Ehrenstein, University College London, London, United Kingdom

Purpose: The clearance of apoptotic cells has been implicated in the maintenance of immune homeostasis. Efficient clearance of apoptotic cells leads to production of IL-10 and TGF-beta, whilst defective apoptotic cell clearance has been linked to the development of autoimmunity. Since natural IgM plays a key role in the clearance of apoptotic cells, we investigated whether the immune modulatory effects of apoptotic cells were altered in mice lacking secretory IgM.

Method: Arthritis was induced using methylated bovine serum albumin (BSA) administered subcutaneously with adjuvant, followed by intra-articular injection 7 days later, in genetically targeted mice deficient in secretory IgM or wild type littermates. Severity of arthritis was assessed by measurement of knee swelling and by histology. Apoptotic cells were generated in vitro using dexamethasone. FACS was used to analyse different cell populations and their cytokine profile, the latter confirmed by ELISA.

Results: Intravenous injection of apoptotic cells at the time of BSA immunisation significantly reduced arthritis severity ($p=0.005$). A profound reduction in joint inflammation and damage, as assessed by histology, was accompanied by suppression of the Th17 response, and increased IL-10 production by both marginal zone (MZ) splenic B cells ($p=0.01$) and T cells ($p=0.01$). No changes in TGF-beta production or the number of Foxp3+ Treg was found following apoptotic cell administration. In contrast, the protective effect of apoptotic cells on the development of inflammatory arthritis was completely abrogated in mice lacking secretory IgM. The marked Th17 response during the course of arthritis were unaltered following injection of apoptotic cells and no induction of IL-10+ MZ B cells or T cells occurred in secretory IgM deficient mice.

Conclusion: Our results indicate that natural IgM is necessary for the protective effects of apoptotic cells in inflammatory arthritis. We propose a model whereby clearance of apoptotic cells by natural IgM drives IL-10 production by MZ B cells and T cells, which in turn can suppress inflammatory arthritis.

Disturbed Communication Between the Brain and the Immune System and Adrenal Insufficiency During Collagen Type II Induced Arthritis in Rats. Christine Wolff[1], Johannes Wildmann[2], Anja Hahnel[1], Hugo O. Besedovsky[2], Adriana del Rey[2] and Rainer H. Straub[1], [1]University Hospital Regensburg, Regensburg, Germany, [2]Institute of Physiology, Medical Faculty, Philipps University, Marburg, Germany

Purpose: Disruption of brain-immune system-joint communication (BISJC disruption) has been demonstrated in rheumatoid arthritis. In this study, BISJC was experimentally disrupted in rats before immunization and the influence on collagen type II arthritis (CIA) was studied. It was also part of this project to analyze the behavior of the adrenal cortex because one feature of BISJC disruption is inadequate corticosterone secretion.

Method: Arthritis was induced in rats by injection of collagen type II in incomplete Freund's adjuvant. Noradrenergic and serotonergic neurons in the brain were depleted with 6-hydroxydopamine and 5,7-dihydroxytryptamine fourteen days before immunization. Plasma corticosterone was evaluated by RIA, adrenal cholesterol was quantitatively studied by Sudan-III staining, scavenger receptor class BI (SR-BI) by immunohistochemistry, and joint innervation by immunofluorescenc.

Results: Depletion of hypothalamic noradrenergic neurons had anti-inflammatory effects during a short time window between day 15 and day 24, which is interpreted as a progressive BISJC disruption during this period. Interestingly, serotonin depletion demonstrated a longer lasting anti-inflammatory effect. Both initially increased plasma corticosterone levels and SR-BI expression in the adrenal cortex were reduced to baseline or lower levels in the later phase of arthritis (day 28 onwards). Cholesterol in the adrenal cortex was only slightly increased at the start of overt arthritis and remained stable. Sympathetic nerve fibers in the joint area were rapidly diminished already on day 28.

Conclusion: This study demonstrated that BISJC disruption happens shortly after the manifestation of symptomatic disease between day 15 and day 28. Disruption is visible in form of adrenal insufficiency and loss of sympathetic nerve fibers in the joint.

Splenic DC Subsets During Collagen-Induced Arthritis in Mice: a Role for Inflammatory Conventional DC? M.C. Lebre[1], L. Bevaart[2], M.I.P. Ramos[1], S. Aarrass[1] and Paul P. Tak[3], [1]Div. of Clinical Immunology & Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Arthrogen BV, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Dendritic cells (DC) play a pivotal role in the orchestration of T cell immunity and tolerance due to their ability to stimulate naive T cells and direct effector cell function. Immunomodulated and tolerogenic DC could be used to ameliorate arthritis. Therefore, in order to gain insight into the characteristics of DC subsets in murine collagen-induced arthritis (CIA) we analyzed the frequencies and phenotype of conventional (c)DC and plasmacytoid (p)DC in a murine C57Bl/6 CIA model during different stages of the arthritis process.

Methods: Arthritis was induced in female C57Bl/6 mice on day 0 (i.d. injection of a chicken collagen/CFA emulsion at the base of the tail) and on day 21 i.d. injection with this emulsion was repeated. Mice were inspected daily from day 20 on for signs of arthritis by two independent observers. Clinical scores were assigned using an established method. At different time points (at days 20, 30, 41 and 63 after CIA induction), mice were sacrificed and spleens were collected. The frequency and phenotype of cDC and pDC was assessed by FACS using specific antibodies: CD11c (total cDC), CD8a (to distinguish 2 cDC populations: $CD8a^+$ and $CD8a^-$) and PDCA-1 together with B220 and Ly-6C (pDC). In addition, isolated cDC and pDC were stimulated for 48h with LPS or CpG, respectively, and cell-free supernatants were analyzed for the contents of inflammatory cytokines using a cytokine-bead assay (CBA).

Results: As expected clinical signs of arthritis started at day 22 (mean±SEM, 0.125±0.125). On days 30, 41 and 63 the mean clinical scores were 1.000±0.555, 2.563±0.922 and 6.500±0.945 respectively. At all the time points studied, the frequencies of splenic cDC (total $CD11c^+$, $CD8a^+$ or $CD8a^-$) exceeded significantly those of pDC ($PDCA\text{-}1^+B220^+Ly\text{-}6C^+$) except $CD8a^-$ at days 20 and 30. Within CIA mice the frequencies of $CD8a^-$ increased significantly (compared to day 20) starting from day 30 while the frequencies of $CD8a^+$ and pDC were

significantly increased on day 63 only. When all the DC subsets from CIA mice were compared to those present in mice without CIA the frequencies of total CD11c, $CD8a^+$, $CD8a^-$ and pDC were significantly increased on day 63. Interestingly, within CIA mice activated cDC produced significantly higher levels of IL-6 on days 41 and 63 while TNF-a was increased only on day 63 (compared to day 20). In contrast, IL-6 and TNF-a-derived from pDC decreased on day 63.

Conclusion: The observation that cDC subsets and their inflammatory cytokines are significantly increased during the development of CIA and that pDC-derived inflammatory cytokines are decreased suggests an inflammatory role for cDC and an regulatory role for pDC in the arthritic process. Thus, cDC rather than pDC may represent an important therapeutic target in arthritis.

Chromosome 15 Carries Sex-Specific Loci Controlling the Effector Inflammatory Phase of Arthritis. Elena Kudryavtseva[1], Toni Forde[2] and Vyacheslav A. Adarichev[3], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein Collage of Med, New York, NY, [3]Albert Einstein College of Med, Bronx, NY

Purpose: Gender differences in susceptibility to autoimmune diseases including rheumatoid arthritis (RA) are well recognized. Mouse chromosome 15 (chr15) harbors two loci, Pgia8 and Pgia9, that regulate proteoglycan-induced arthritis (PGIA) in a sex-dependent manner. These two loci cluster with arthritides induced with collagen type II, pristane and *Borrelia burgdorferi*. The present study was undertaken to dissect mechanisms of chr15 loci sex-specificity and clustering with diverse types of arthritides.

Method: Congenic strains C.D2-Pgia8 and C.D2-Pgia9 were generated using genetic transfer of DBA/2 loci into BALB/c genetic background in a series of back-crosses. Collagen antibody-induced arthritis (CAIA) was induced in male and female congenic mice by intravenous injection of a cocktail containing four monoclonal antibodies to type II collagen followed by LPS stimulation. Mice were scored for paw inflammation on a daily basis. Paws were collected for differential gene expression analysis at the end of the observation period.

Results: Congenic strains were susceptible to CAIA, however, the significant strain differences were found in arthritis severity. C.D2-Pgia8 congenic mice showed significant sex-related suppression of arthritis. Severity of inflammation in C.D2-Pgia8 males was 30% lower ($p < 0.005$) than in wild-type BALB/c males. Arthritis suppression was significant from day 8 and persisted until the end of observation. No genetic effect of the Pgia8 locus upon CAIA was observed in congenic females. On the contrary, C.D2-Pgia9 congenic mice did not show any sex-related differences in CAIA severity when they were compared to wild-type BALB/c of the same sex. Pgia9 locus promoted CAIA inflammation in both males (12% up-regulation, $p < 0.05$) and females (24% up-regulation, $p < 0.02$).

Conclusion: Our data indicate that two separate regions of chr15 are involved in the effector stage of arthritis (CAIA). These two chromosome intervals are similar to Pgia8 and Pgia9 loci by their locations and sex-related effects, which might provide an explanation for clustering of diverse RA animal models loci on chr15.

TNFalpha-Induced Adipose-Related Protein (TIARP) in Experimental Autoimmune Arthritis. Asuka Inoue[1], Isao Matsumoto[1], Yoko Tanaka[1], Reiko Minami[2], Kayo Yamamoto[1], Naoto Umeda[1], Taichi Hayashi[1], Daisuke Goto[1], Satoshi Ito[1] and Takayuki Sumida[1], [1]University of Tsukuba, Graduate School of Comprehensive Human Sciences, Tsukuba, Japan, [2]University of Tsukuba, Tsukuba, Japan

Purpose: TNFα is a pivotal factor of the inflammatory and tissue destructive pathways in rheumatoid arthritis (RA). Therapeutic effectiveness of anti-TNFα mAb was denoted in glucose-6-phosphate isomerase (GPI) -induced arthritis, suggesting the similar etiology to RA. We recently demonstrated that TNFα-induced- adipose related protein (TIARP) was highly expressed in spleens and joints from GPI-induced arthritis. In this study, to elucidate the role of TIARP in arthritis, we used two experimental models of arthritis such as GPI-Induced arthritis and collagen type II-induced arthritis (CIA).

Method: (1) DBA/1 mice were immunized with 300ug recombinant human GPI emulsified in complete freund's adjuvant (CFA). The expression of TIARP mRNA and proteins in spleens, lymph nodes (LNs) and joints were evaluated in GPI-induced arthritis (on day0, 7, 14,

28) by RT-PCR and immunoblotting methods. (2) Splenocytes (on day 0,7) from GPI-induced arthritis were separated into four groups (CD4+, CD19+, CD11b+, CD11c+) by MACS and the expression of TIARP mRNA was compared by quantitative PCR. (3) Anti-TIARP polyclonal Abs were prepared and administrated to GPI-induced arthritis on day8, and the clinical score of arthritis was monitored. In vitro, splenocytes (on day 8) were cultured for 24h with GPI plus anti-TIARP Abs or control Abs, and TNFα, IL-6 and MCP-1 in their culture supernatant were measured by ELISA. (4) CIA was induced by immunization with 100ug of bovine type□ collagen and CFA to DBA/1 mice, followed by boost immunization after 21days of primary immunization. In the same way, the fluctuation of TIARP mRNA in spleens and joints were monitored in CIA (on day 14, 23, 28, 40). We also evaluated TIARP-dominant cells of splenocyte in CIA by the method (2) on day 23.

Results: (1) The TIARP mRNA and proteins were dominantly expressed in splenocytes on day 7. On the other hand, the expression of TIARP in joints was accompanied with the joint swelling, especially elevated on day 14 and 28. (2) The splenic CD11b+ cells were mainly expressed TIARP mRNA on day 7. (3) Arthritis was exacerbated in mice administrated with anti-TIARP Abs comparing to control Abs. The amount of TNFα and IL-6 increased twice by the addition of anti-TIARP Abs in vitro, although the amount of MCP-1 was comparable. (4) In CIA model, the expression of TIARP mRNA in splenocytes was the highest in early phase of arthritis (on day23), the expression in joints was accompanied with the joint swelling as well as GPI-induced arthritis. Splenic CD11b+ cells were also mainly expressed TIARP mRNA in CIA.

Conclusion: TIARP expression in spleens and joints are fluctuated in the same manner within two different arthritis models. The administration of anti-TIARP Abs exacerbates arthritis as well as induces the high expression of TNFα and IL-6, suggesting TIARP might be a new regulatory molecule against arthritis by controlling the production of inflammatory cytokines.

NOD2 and TLR2 Function Independently in Arthritis Triggered by Intra-Articular Peptidoglycan. Holly L. Rosenzweig[1], Monica J. Jann[2], Emily E. Vance[1], Stephen R. Planck[1], James T. Rosenbaum[1] and Michael P. Davey[3], [1]Oregon Health & Science University, Portland, OR, [2]VA Medical Center, Portland, OR, [3]VA Medical Center/Oregon Heath & Science University, Portland, OR

Purpose: NOD2 is linked with joint pathology as mutations in *NOD2* cause Blau syndrome, an autoinflammatory disease affecting joints. In the bowel, NOD2 functions as a negative regulator of inflammation and different polymorphisms in *NOD2* predispose to Crohn's disease. Here, we investigated the role of NOD2 in an experimental model of arthritis and the potential interplay between NOD2 and TLR2.

Methods: Mice deficient for TLR2, MyD88, or NOD2 and their wild-type controls were administered an intraarticular injection of peptidoglycan (PGN), muramyl dipeptide (MDP) (a ligand for NOD2 and a derivative of PGN), or Pam_3CSK4 (a synthetic TLR2 agonist). Neutrophil depletion was performed using an anti-Ly6G antibody. Joint inflammation was assessed by near-infrared fluorescence imaging and histopathology.

Results: PGN results in arthritis, which depended on TLR2 and its signaling mediator MyD88. As opposed to what is reported in bowel inflammation, NOD2 is essential in promoting joint inflammation because NOD2 deficiency significantly diminished PGN-induced arthritis. TLR2 and NOD2 are capable of eliciting inflammation independently as deficiency in either TLR2 or MyD88 did not influence arthritis induced by the NOD2 agonist, MDP. Conversely, NOD2 deficiency did not alter TLR2-dependent joint inflammation elicited by Pam_3CSK4. Neutrophils are present in the joint; however they are not necessary mediators of PGN-induced arthritis as measured by fluorescence imaging.

Conclusion: Whereas NOD2 and TLR2 are both critical for the development of arthritis, they appear to elicit inflammation independently of each other. Our data support an inflammatory role for NOD2 in arthritis in contrast to what is reported for colitis.

Studies of Combination of IMO-3100, An Antagonist of TLR7 and TLR9, and Etanercept, a TNF-α Inhibitor, in a Mouse Model of Collagen-Induced Arthritis (CIA). Fu-Gang Zhu, Dong Yu, Ekambar R. Kandimalla and Sudhir Agrawal, Idera Pharmaceuticals, Inc., Cambridge, MA

Purpose: IMO-3100 is an antagonist of Toll-like receptors (TLRs) 7 and 9 and has potent activity in preclinical studies of prevention as well as treatment models of collagen-induced arthritis (CIA) in mice. We have studied the efficacy of the combination of IMO-3100 and etanercept, a TNF-a inhibitor, which have complementary and distinct mechanisms of action, for the treatment of CIA in a DBA/1 mouse model.

Method: Arthritis was induced in DBA/1 mice by intradermal administration of bovine collagen type II (BCII) with complete Freund's adjuvant (CFA) on day 0 and with incomplete Freund's adjuvant (IFA) on day 21. Mice were divided into six groups (n=8). Mice received IMO-3100 (s.c.) at 100 or 300 µg/mouse, or etanercept (i.p.) at 100 or 300 µg/mouse, or the combination of IMO-3100 (100 µg/mouse) and etanercept (100 µg/mouse), or PBS on days 28, 31, 34, 37, 40, 43, and 46. Mice were monitored for arthritic symptoms in the paws from day 21 until the last day of the study (day 58). Following termination of the study, serum levels of anti-BCII antibodies and spleen cell cytokines were determined, and paw joint tissues were examined for histopathological changes.

Results: Mice treated with IMO-3100 or etanercept had lower arthritic scores than did untreated (PBS) mice; the effect was dose-dependent. Mice treated with the combination of IMO-3100 and etanercept had lower arthritic scores than did mice treated with either agent alone at the highest dose. Mice treated with IMO-3100 or the combination of IMO-3100 and etanercept had lower serum anti-BCII IgG1 and IgG2a antibodies and lower IFN-g levels in spleen cell cultures; the IMO-3100 effect was dose-dependent. Histological examination of foot joint tissues of mice in IMO-3100 and etanercept treatment groups showed a dose-dependent reduction in inflammation and bone destruction. Lower levels of inflammation and bone destruction were observed in the foot joint tissues of mice treated with the combination of IMO-3100 and etanercept than in mice treated with either agent alone.

Conclusion: These results suggest that the combination of IMO-3100 and etanercept, which have complementary and distinct mechanisms of action, is effective in this model of CIA in mice. This study provides a rationale for combination therapy with IMO-3100 and etanercept for potential treatment of rheumatoid arthritis in humans.

Pten Deficiency in Myeloid Cells Protects From Collagen Induced Arthritis. Stephan Blüml[1], Gernot Schabbauer[2], Michael Bonelli[1], J. S. Smolen[1] and Kurt Redlich[1], [1]Medical University Vienna, Dpt. of Rheumatology, Vienna, Austria, [2]Dpt. of Vascular Biology, Vienna, Austria

Purpose: Pten is a lipid phosphatase, whose substrate is phosphatidylinositol 3,4,5-trisphosphate. Therefore, pten is one of the main antagonists of the PI3-kinase, which plays a major role in many important cellular functions, such as proliferation, migration or response to inflammatory stimuli.

Here we investigated the role of pten in collagen induced arthritis.

Methods and **Results:** We show that conditional deletion of pten under the LysM promoter (LysMCrePten$^{flox/-}$) leads to a significant reduction in clinical severity of collagen induced arthritis. Histological analysis of CIA, LysMCrePten$^{flox/-}$ mice displayed significantly reduced joint inflammation as well as erosive bone destruction. Total anti-collagen antibodies, however, as well as anti-collagen IgGs were identical in both groups. Upon analysis of inflammatory cytokines in serum after immunisation we found a significant reduction of IL-6 as well as IL-8 levels. Furthermore, pten deficient macrophages and dendritic cells showed reduced induction of IL-6 as well as IL-12 and IL-23 upon stimulation with various TLR-ligands. Since these cytokines play an important role in the induction of pathogenic Th-17 T cells, we measured Th-17 cytokines in lymph nodes after immunisation with collagen. Although dendritic cell and macrophage recruitment to the draining lymph node was comparable in both groups, there was a slight reduction of IL-17 and a strong reduction of IL-22 in the draining lymph node of immunized LysMCrePten$^{flox/-}$ compared to wild-type mice, whereas the levels of IL-4 as well as the numbers of regulatory T cells were increased.

Conclusion: These data point to a potent regulatory role of pten in antigen presenting cells in the development of CIA by skewing T cells polarisation away from pathogenic Th17, favouring Th2/ regulatory T cell development instead.

Overexpression of Tristetraprolin Regulates Collagen Induced Arthritis. Takashi Jingu[1], Takeshi Suzuki[1], Makoto Sugihara[1], Eiji Suzuki[2], Yuya Kondo[1], Isao Matsumoto[1], Taichi Hayashi[1], Daisuke Goto[1], Satoshi Ito[1], Satoru Takahashi[1], Akito Tsutsumi[3] and Takayuki Sumida[1], [1]University of Tsukuba, Tsukuba, Japan, [2]Ohta-Nishinouchi Hospital, Koriyama, Japan, [3]Takikawa city hospital, Takikawa, Japan

Purpose: Tristetraprolin (TTP) is a widely expressed protein with two zinc finger domains that act as active RNA-binding sites. TTP is an immediate early response gene expressed in fibroblasts and other cells upon induction by a variety of stimuli. TTP is posttranscriptional regulation molecule that downregulates tumor necrosis factor-α (TNF-α) production by binding to AU-rich element on TNF-α mRNA, and promoting TNF-α mRNA degradation. TTP-knockout mice display an inflammatory phenotype characterized by inflammatory arthritis, dermatitis, cachexia, autoimmunity, and myeloid hyperplasia and this phenotype can be prevented by administration of anti-TNF-α antibodies. We developed transgenic mice overexpressing zinc finger (ZF-Tg DBA/1 mice), a part of TTP, and investigated TTP mRNA expression in several organs, TNF-α mRNA stability, and production by lipopolysaccharide (LPS) stimulation in vitro. Furthermore, we examined the development of collagen induced arthritis (CIA) in vivo.

Method: (1) We investigated TTP mRNA distribution in joint, muscle, heart, thymus, lung, liver, small intestine, colon, spleen, and inguinal lymph nodes of ZF-Tg DBA/1 mice by RT-PCR. (2) We investigated TTP mRNA stability in the splenocytes of ZF-Tg DBA/1 mice. (3) We investigated TNF-α production in splenocytes of ZF-Tg DBA/1 mice after LPS stimulation by ELISA. (4) We induced CIA by immunization of type II collagen to DBA/1 mice and ZF-Tg DBA/1 mice at twice (day 0 and day 21), and monitored the clinical score of arthritis.

Results: (1) TTP-ZF transgene mRNA was expressed in these all tissues. (2) TNF-α mRNA in ZF-Tg DBA/1 mice was more instable than DBA/1 mice. (3) TNF-α production in ZF-Tg DBA/1 mice was more decreased than DBA/1 mice. (4) The clinical score of arthritis in ZF-Tg DBA/1 mice was significantly suppressed.

Conclusion: We identified that the overexpression of zinc finger part of TTP caused the instability of TNF-α mRNA and the downregulation of TNF-α production, and resulting in the suppression of CIA. These findings open a new strategy for the regulation of autoimmune arthritis through TTP induction.

Active Immunization against VEGF Improves Joint Inflammation and Destruction in Collagen-Induced Arthritis. Eric Assier[1], Luca Semerano[2], Laure Delavallée[1], Géraldine Grouard-Vogel[3], Emilie Bernier[3], Daniel Zagury[3] and Marie-Christophe Boissier[2], [1]EA 4222 Paris 13 University, Bobigny, France, [2]AP-HP, Avicenne hospital, Bobigny, France, [3]NéoVacs, Paris, France

Purpose: Cytokines play a key role in the development of rheumatoid arthritis (RA), allowing hypertrophy of the pannus by neovascularisation, articular inflammation and destruction. We recently demonstrated in experimental models the efficacy of vaccination against cytokines, using a heterocomplex of keyhole limpet hemocyanin (KLH) and human TNF, called TNF kinoid (K). VEGF is a potential target in RA, since it plays a major role in angiogenesis and pannus formation. We aimed at demonstrating an inhibitory effect of a sustained inhibition of VEGF by an anti-VEGF vaccine in collagen-induced-arthritis (CIA).

Method: Anti-murine VEGF immunization was performed by injecting intra-muscularly VEGF-K formulated in incomplete Freund adjuvant (IFA) in DBA/1 mice. Control groups received KLH or PBS at the same dates. A fourth group received a chemical angiogenesis inhibitor in drinking water from D28 to sacrifice (Ammonium Tetrathiomolybdate, TM, 0.03mg/ml). Arthritides were induced by two subcutaneous injections of bovine type II collagen, the first at Day 40 in complete Freund adjuvant, the second at Day 61 in IFA. Clinical scores of arthritis were evaluated twice per week. Histological scores of the paws were quantified after sacrifice and Hematoxylin/Eosin staining. Anti-VEGF and anti-KLH antibody (Ab) levels were assessed by ELISA, and the anti-VEGF neutralizing capacity (NC) of sera by HUVEC bioassay.

Results: VEGF-K and TM groups showed lower arthritic scores as compared to KLH and PBS groups ($p<0.005$). At histological analysis, inflammation and destruction scores of the paws were lower in VEGF-K group versus KLH ($p<0.005$) and PBS group ($p<0.001$). VEGF-K group was the only one to show anti-VEGF Ab production as assessed by ELISA at Day 60 and sacrifice. The neutralizing activity of anti-VEGF Ab was confirmed by HUVEC at sacrifice.

Conclusion: These data show that VEGF-K improves arthritis in a murine RA model.

HGF Antagonist, NK4, Inhibits Th1 Immune Response, RANKL Expression On Synovial Fibroblasts and Enhances Osteoblast Generation. Sachi Tsunemi[1], Tsuyoshi Iwasaki[2], Sachie Kitano[1], Kunio Matsumoto[3] and Hajime Sano[1], [1]Hyogo College of Medicine, Nishinomiya, Japan, [2]Hyogo University of Health Sciences, Kobe, Japan, [3]Kanazawa University, Kanazawa, Japan

Purpose: Hepatocyte growth factor (HGF) is a potent pro-angiogenic molecule that induces neovascularization. The HGF antagonist, NK4, encodes the NH_2terminal hairpin and four kringle domains of the HGF subunit. NK4 competitively antagonizes HGF binding to its receptor and also abrogates angiogenesis promoted by other angiogenic inducers, including basic fibroblast growth factor and vascular endothelial growth factor. Previously (ACR/ARHP Scientific Meeting 2007, 2008), we reported that NK4 can inhibit arthritis and bone destructions in joints of rheumatoid arthritis (RA) model mice. In the present study we investigated the mechanisms by which NK4 inhibited arthritis and bone destructions in affected joints.

Method: SKG mice spontaneously develop T cell-mediated chronic autoimmune arthritis as a consequence of impairment of negative selection of autoimmune $CD4^+$ T cells in the thymus. Arthritis was induced by a single intraperitoneal injection of the ß-glucan laminarin (45 mg). Recombinant adenovirus containing NK4 cDNA (AdCMV.NK4) (1×10^9 pfu) was also injected intravenously at the time of laminarin injection. Joint swelling was monitored by inspection and through assessment of paw volume. The ankles bone destructions were examined radiographically. Histopathology of joints were examined by hematoxylin and eosin and immunohistochemical staining. Prostaglandin E2 (PGE_2) production by synovial fibroblast cell line (MH7A) and IFN-γ production by $CD4^+$ T cells stimulated by allogeneic spleen cells were determined by ELISA. RANKL expression on MH7A cells was examined by RT-PCR analysis. Osteoblast generation was examined using murine myoid cell line (C2C12) stimulated with BMP-2 and was analyzed by ALP staining of the cells and osteocalucin production in the culture supernatant.

Results: Intravenous injection of AdCMV.NK4 into SKG mice suppressed the progression of laminarin-induced clinical arthritis, as demonstrated by both paw volume and arthritis score. Bone destructions were also inhibited by NK4 treatment. Histopathological findings of the foot joints revealed that infiltration of Th17 cells and RANKL expressions on synovial cells were significantly suppressed by NK4 treatment. NK4 gene transfection into MH7A cells inhibited PGE2 production and TNF-α-induced RANKL expression by these cells. NK4 gene transfection into C2C12 cells enhanced BMP-2 induced osteoblast generations. Furthermore, NK4 suppressed IFN-γ production by $CD4^+$ T cells stimulated by allogeneic spleen cells.

Conclusion: These results indicate that NK4 can inhibit PGE2 production by synovial cells and IFN-γ production by $CD4^+$ T cells. NK4 can also enhance osteoblast generation and inhibit osteoclastogenesis by inhibiting TNF-α-induced RANKL expressions on synovial cells. Molecular targeting of HGF by NK4 can therefore be potentially applied as a novel therapeutic approach for the treatment of RA.

Multiple Effects of FTY On the Immune System, Inflammation, and Bone Remodeling in Rheumatoid Arthritis. Tsuyoshi Iwasaki[1], Sachi Tsunemi[2], Sachie Kitano[2], Chieri Kanda[2] and Hajime Sano[2], [1]Hyogo University of Health Sciences, Kobe, Japan, [2]Hyogo College of Medicine, Nishinomiya, Japan

Purpose: SKG mice spontaneously develop T cell-mediated chronic autoimmune arthritis as a consequence of impairment of negative selection of autoimmune $CD4^+$ T cells in the thymus. FTY720 (FTY) is a new immunomodulatory agent that decreases peripheral blood

lymphocytes by sequestration of lymphocytes in secondary lymphoid tissues and the thymus. Previously (ACR/ARHP Scientific Meeting 2007), we reported that FTY can inhibit arthritis and bone destructions in joints via sequestration of autoimmune $CD4^+$ T cells in the thymus in SKG mice. In the present study, we investigated the effects of FTY on immune system, inflammation, and bone remodeling in rheumatoid arthritis (RA).

Method: Arthritis was induced by a single intraperitoneal injection of laminarin (45 mg). FTY (1 mg/kg/day) was administered orally from the time of laminarin injection. The numbers of $CD4^+$/$CD8^+$ T cells and $B220^+$ B cells were examined by flow cytometry. RANKL expression on $CD4^+$ T cells in the spleen or on human $CD4^+$ T cells were analyzed by either flow cytometry or RT-PCR analysis, respectively. Hematoxylin and eosin staining and immunoperoxidase staining for IL-6, TNF-α was performed on formalin fixed paw sections. Prostaglandin E2 (PGE_2) production by synovial fibroblast cell line (MH7A) and cytokine production by spleen $CD4^+$ T cells were determined by ELISA.

Results: FTY administration suppressed the progression of laminarin-induced arthritis in SKG mice, as demonstrated by both paw volume and arthritis score. Expression of IL-6 and TNF-α in synovial fibroblast cells and inflammatory cells was significantly decreased after FTY administration. Bone destructions were also suppressed by FTY administration. The numbers of $CD4^+$ and $CD8^+$ T cells were significantly increased in the thymus and decreased in the spleen after FTY administration. Interestingly, RANKL expression on $CD4^+$ T cells in the spleen was increased after FTY administration. In vitro FTY treatment also augmented RANKL expression on human CD4+ T cells. In vitro FTY treatment enhanced IL-4 production but not IFN-γ productions from $CD4^+$ T cells stimulated by allogeneic spleen cells. In vitro FTY treatment also inhibited PGE2 production by TNF-α stimulated MH7A cells.

Conclusion: These results indicate that that this greater anti-arthritis potency of FTY may be due to its multiple effects on the immune system and inflammation in SKG mice that we observed in this study including sequestration of autoimmune $CD4^+$ T cells in the thymus, enhancement of Th2 immune responses, and inhibition of PGE2 production by synoviocytes. FTY can therefore be potentially applied as a novel therapeutic approach for the treatment of RA. However, FTY may have an adverse effect on bone remodeling by the enhancement of RANKL expression on $CD4^+$ T cells infiltrated in synivial tissues.

Disclosure: T. Iwasaki, None; **S. Tsunemi**, None; **S. Kitano**, None; **C. Kanda**, None; **H. Sano**, None.

665

Treatment with Cl-Amidine, A Peptidyl Arginine Deiminase (PAD) Inhibitor, Significantly Reduces the Severity of Collagen Induced Arthritis (CIA). Van Willis[1], Alison Gizinski[2], Bryan Knuckley[3], Nirmal K. Banda[1], Kristen Cordova[1], Yuan Luo[3], Corey Causey[3], Brandt Levitt[1], Magdalena Glogowska[1], Piyanka Chandra[4], Maya BenBarak[4], Liudmila Kulik[1], William P. Arend[1], William Robinson[4], Paul R. Thompson[3] and V. Michael Holers[1], [1]UCDenver, Aurora, CO, [2]Univ of Michigan, Ann Arbor, MI, [3]Univ of S Carolina, Columbia, SC, [4]Stanford School of Med, Stanford, CA

Purpose: Antibodies to citrullinated self proteins are present in the sera of patients with rheumatoid arthritis (RA). The epitopes recognized by antibodies to citrullinated protein antigens (ACPA) are created when proteins undergo a post-translational conversion of arginine to citrulline, a process dependent upon enzymes designated PADs. We and others have shown that ACPA develop in the murine CIA model and contribute to joint damage. The purpose of this study was to determine the effect of a specific inhibitor of all five PAD enzymes, Cl-amidine, on the development of arthritis in the CIA model.

Method: Male DBA/1j mice were immunized with bovine type II collagen (CII) in Complete Freund's Adjuvant at days 0 and 21 to induce CIA. For collagen antibody-induced arthritis (CAIA), male DBA/1j mice received 4 mg Arthrogen IP followed by 50 µg LPS IP 3 days later. Five groups of immunized mice were studied: no drug treatment, vehicle alone by IP injection or 1,10, or 50 mg/kg/day Cl-amidine in PBS IP. Clinical disease activity (CDA), histologic injury and complement C3 deposition were scored in a blinded fashion on a standard scale. CIA and CAIA mice were sacrificed on days 35 and 10 respectively.

Results: Preliminary results by Western blot analysis of splenocyte extracts with the Senshu antibody show inhibition of PAD enzymes *in vivo* by Cl-amidine. Treatment with Cl-amidine reduced the CDA scores in CIA by 55%, 53% and 42% in the 50, 10 and 1 mg/kg/day groups, respectively. Histologic severity and complement C3 deposition scores paralleled the decreases in CDA. No differences were observed in anti-bovine CII antibody titer between treatment groups. However, a significantly lower IgG1 anti-mouse CII antibody titer was observed in the 50 and 10mg/kg/day groups and significantly lower IgG2a anti-mouse CII antibody titer in the 10mg/kg/day groups, compared to controls. Mice receiving Cl-amidine showed reduced epitope spreading by peptide microarray, especially to citrullinated joint

antigens. No changes in the percentages of T cell, B cell or monocyte populations were observed by flow cytometry analysis in treated mice compared to controls. In contrast to the effect in CIA, no change in CDA scores was observed in the CAIA model.

Conclusion: Cl-amidine treatment in mice inhibits PAD activity *in vivo* and substantially decreases CDA scores in CIA without major effects on immune cell populations. In contrast, Cl-amidine treatment has no effect on CDA scores in CAIA, indicating that inhibition of PADs does not alter the effector phase of the immune response. These results suggest that PADs are obligate, rate-limiting participants in the autoimmune process and the loss of tolerance to citrullinated self antigens. In addition, Cl-amidine may represent a novel class of therapeutics for RA that targets citrullination and perhaps other processes necessary for the development of inflammatory arthritis.

Neutralization of Angiopoietin 2 Reduces Disease in Murine Arthritis and Augments Efficacy of Anti-TNF Treatment. Brian Naiman[1], Martyn Foster[2], Chris Stannard[2], ChingChing Leow[1], Steven Coats[1], William Dall'Acqua[1], Nancy Kohut[1], Wendy Trigona[1], Anthony J. Coyle[1], Bahija Jallal[3] and Jane Connor[1], [1]MedImmune, LLC, Gaithersburg, MD, [2]Astra Zeneca, Charnwood, United Kingdom, [3]MedImmune, Gaithersburg, MD

Purpose: In the past 20 years, the development of TNFa-neutralizing biologics has revolutionized the treatment of rheumatoid arthritis (RA). However, in spite of the growing number of anti-TNF treatment options, over 30% of patients receive incomplete or no benefit from anti-TNF therapy. In recent years, RA has become recognized as a disease with an angiogenic as well as an inflammatory drive. Pathological blood and lymphatic vessel growth in the synovium provide nutrients for the hyperproliferative synovium as well as routes of entry for infiltrating inflammatory cells. In this way, angiogenesis is an attractive target for augmenting the anti-inflammatory activity of anti-TNF therapy. Angiopoietin-2 (Ang2) is an important regulator of angiogenesis, blood vessel maturation and integrity of the vascular endothelium. Ang2 and its receptor, Tie2, are localized in the vasculature of joints of RA patients and may contribute to disease maintenance and progression.

Method: To assess the therapeutic potential of neutralizing Ang2 in RA, an anti-Ang2 IgG2 monoclonal antibody with cross-reactivity to mouse was evaluated in the mouse collagen-induced arthritis (mCIA) model of RA. Subsequently, a human anti-Ang2 IgG1 with cross reactivity to mouse, MEDI3617, which has been characterized for its anti-angiogenic activity in a number of angiogenesis and tumor growth models, was evaluated in another model of mouse RA, the glucose-6-phosphate isomerase (G6PI) model.

Results: In mCIA, treatment with anti-Ang2 antibody inhibited clinical signs of disease as well as histopathological changes in the joints in a dose-dependent manner. Importantly, anti-Ang2 treatment inhibited vessel density in the synovium, providing direct evidence of the anti-angiogenic effect of treatment. In G6PI, MEDI3617 partially inhibited the development of clinical signs of joint disease and combination treatment with etanercept, the soluble TNF receptor, provided increased efficacy compared to either agent administered alone. In a model designed to evaluate efficacy in established joint disease, neither MEDI3617 nor etanercept were significantly efficacious, but treatment with the two agents in combination resulted in a measurable inhibition of clinical scores of the joint. In addition, the combined treatment did not result in any observable adverse effects.

Conclusion: These data support the continued development of anti-Ang2 antibody with anti-TNF agents as a possible therapeutic improvement in the treatment of RA.

Treatment of Arthritis by Anti-Inflammatory Effect of E3 Ubiquitin Ligase, c-Mir. Masayasu Toyomoto[1], Satoshi Ishido[2], Nobuyuki Miyasaka[3] and Hitoshi Kohsaka[4], [1]Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Japan, [2]RIKEN Research Center for Allergy and Immunology, Yokohama City, Japan, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]Tokyo Med and Dent Univ, Tokyo

Purpose: c-MIR is a newly defined E3 ubiquitin ligase that ubiquitinates membrane-bound molecules associated with antigen presentation. Its targets include MHC class II and CD86. The ubiquitination results in their endocytosis and down modulation of their expression. Assuming that c-MIR overexpression suppresses antigen presentation and following activation of acquired immunity in the inflammatory synovial tissues, we examined whether forced expression of c-MIR in the synovial tissues suppresses an animal model of rheumatoid arthritis (RA).

Method: DBA/1J mice were immunized with bovine type II collagen (CII) for development of collagen-induced arthritis (CIA). Recombinant adenoviruses expressing c-MIR or LacZ as a control were prepared. After booster immunization on day 21, the mice were subjected to intraarticular adenovirus gene transfer to bilateral hind legs at the ankles, the knees, and the tarsal joints on day 24, 28 and 35. Mice were examined visually for arthritis scoring. The joints were examined histologically. Serum levels of anti-CII antibodies and proliferative responses of the splenocytes to CII were studied. In vitro, fibroblast-like synoviocytes (FLS) were isolated from the joint tissues of the CIA mice and infected with the c-MIR adenoviruses. They were then stimulated with TNF-α or IL-1β. Bone marrow macrophages (BMM) expressing c-MIR derived from c-MIR transgenic mice were stimulated with LPS. The amounts of IL-6 in the culture supernatants and the levels of IL-6 mRNA of the c-MIR expressing cells were quantified with ELISA and real-time PCR, respectively.

Results: The intraarticular c-MIR gene transfer exerted therapeutic effects on CIA. The arthritis score and histological changes were both suppressed. Unexpectedly, the therapeutic effect was not observed in the joints in the forelegs. In accordance with this fact, no difference in the serum anti-CII antibody levels or thereactivity of the splenocytes to CII was observed between the c-MIR gene-treated and control mice. The expression of c-MIR gene suppressed production of IL-6 and level of IL-6 mRNA in the activated FLS and BMM.

Conclusion: The intraarticular c-MIR gene transfer failed to inhibit acquired immunity against CII. Instead, the local treatment exerted local therapeutic effects. Because expression of c-MIR suppressed inflammatory cytokine production, this should have contributed to inhibition of the arthritis. Molecular pathways of this inhibition are now under investigation. c-MIR induction in the synovial tissues may provide an new approach to the effective treatment of RA.

Bim-BH3 Mimetic Therapy Is Effective at Suppressing Inflammatory Arthritis through the Activation Myeloid Cell Apoptosis. John C. Scatizzi[1], Jack Hutcheson[2], Richard M. Pope[3], Gary S. Firestein[4], Alisa E. Koch[5], Melissa Mavers[6], G. Kenneth Haines III[7] and Harris R. Perlman[8], [1]The Scripps Research Institute, La Jolla, CA, [2]UT Southwestern, Dallas, TX, [3]Northwestern University, Chicago, IL, [4]UCSD School of Medicine, La Jolla, CA, [5]Veteran's Affairs and University of Michigan, Ann Arbor, MI, [6]Saint Louis University School of Medicine, St. Louis, MO, [7]Yale University, New Haven, CT, [8]Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Rheumatoid arthritis (RA) is a destructive autoimmune disease associated with increased morbidity and mortality and characterized by an increase in inflammatory cells within the joint. It is clear that therapies which directly activate the apoptotic cascade may have potential as a future therapy for RA, however to date few therapeutics fit this category. Recently, therapies that mimic the action of Bcl-2 homology 3 (BH3) domain-only proteins have shown success in preclinical studies of cancer but their potential for controlling the fate of inflammatory cells, especially in autoimmune disease is unknown.

Method: Synovial tissue from RA and osteoarthritis (OA) patients were analyzed for expression of Bim and CD68 using immunohistochemistry. Macrophages from mice lacking (Bim-/-) were examined for response to lipopolysaccride using flow cytometry, real time PCR, ELISA, and immunoblot analysis. Bim-/- mice were stimulated with thioglycollate or LPS and examined for macrophage activation by flow cytometry and for IL-1b production by ELISA. Experimental arthritis was induced using the serum transfer model. Systemic delivery of a mimetic peptide corresponding to the BH3 domain of Bim (TAT-BH3) were administered as a prophylactic and as a

therapeutic. Edema of the ankles and histopathogical analysis of ankle sections were used to determine severity of arthritis, cellular composition of the joint, and apoptosis.

Results: n RA synovial tissue, the expression of the BH3-only pro-apoptotic protein Bim is reduced, particularly in macrophages. Bim-/- macrophages display elevated expression of markers of inflammation and secrete more IL-1beta following stimulation with LPS or thioglycollate. Analysis of peritoneal cells harvested at 6 hours following injection of K/BxN serum reveal that TAT-BH3 peptide induces apoptosis primarily in the myeloid cell population. In addition, TAT-BH3 peptide treated mice exhibited an increased numbers of TUNEL positive cells in the joints. Further, the reduction of circulating myeloid cells and increased apoptosis corresponded with fewer myeloid cells in the joint of TAT-BH3 peptide treated mice.

Conclusion: These data demonstrate that BH3 mimetic therapy is efficacious in RA-like disease model and suggest that this therapy may have significant potential for RA treatment.

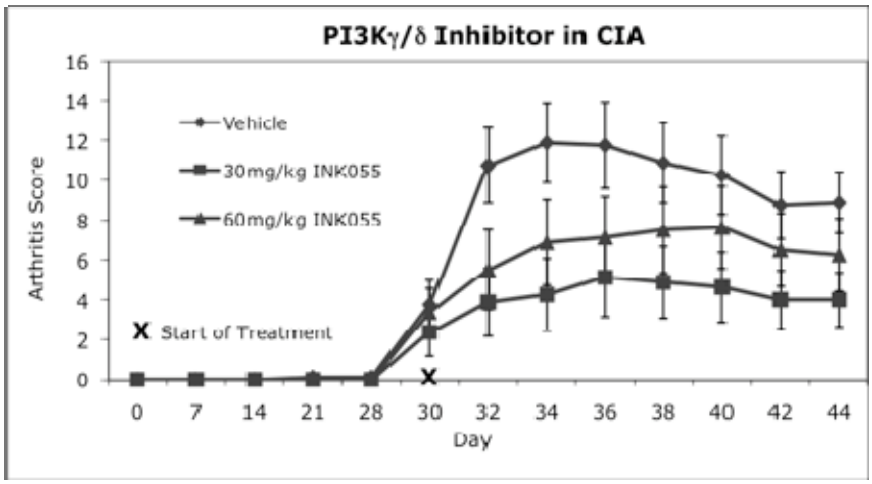
A Novel PI3Kinase γ/δ Inhibitor Suppresses Collagen-Induced Arthritis. David L. Boyle[1], Christian Rommel[2], Katharyn Topolewski[1] and Gary S. Firestein[1], [1]UCSD School of Medicine, La Jolla, CA, [2]Intellikine, La Jolla, CA

Purpose: The four members (α, β, γ, and delta [d]) of the phosphoinositide 3-kinases (PI3K) family transduce a variety of receptor-mediated signals. However, the gamma and delta PI3K isoforms are primarily restricted to leukocytes and act independently to regulate cytokine, chemokine and immunoglobulin responses. The delta isoform is associated with many cell surface receptors while the gamma isoform exclusively associates with G-protein coupled receptors, such as chemokine receptors. While selective γ and d inhibitors have potential for diseases like rheumatoid arthritis (RA), we hypothesized that combined inhibition would be especially effective. Therefore, we evaluated the effect of a dual PI3Kγ/d (INK055) inhibitor on murine collagen induced arthritis.

Method: DBA1/J mice (n=8/group) were immunized with bovine type II collagen in complete Freund's adjuvant and again on day 21 with type II collagen in PBS. On day 28, 5 μg of LPS in PBS was injected intraperitoneally. Paws were scored using a 0-4 scale, maximum 16 per animal. Animals were treated by gavage daily starting day 20 or 30 with vehicle, 30, or 60 mg/kg with a novel dual specific PI3K γ/d inhibitor, INK055 (IC50: PI3Kd: 3.2nM, PI3Kγ: 5.7nM, >600 for PI3Kα and PI3Kβ). ELISA was performed to assess anti-type II collagen levels in serum. Quantitative PCR was used to determine the effect on ankle joints gene expression.

Results: Initiating treatment with INK055 on day 20 in CIA significantly decreased disease severity by day 32 in both treatment groups (peak difference on day 36, vehicle 5.6±1.9, 30mg/kg 2.4±1.0, 60mg/kg 2.6±1.5; $p<0.05$). Serum anti-type II collagen antibody levels were unchanged in the low dose group and only modestly decreased in high dose group (Vehicle 200±3, 30mg/mg 180±20, 60mg/kg 143±12 μg/ml). MMP3 and MMP13 expression was significantly reduced in the ankles after treatment (MMP3 77±41, 46±12, 38±16 relative expression units in vehicle, 30mg/kg, 60mg/kg respectively). Treatment of established disease beginning on day 30 significantly decreased severity compared with vehicle with the peak effect on day 34 (see Figure) (vehicle 11.9±2, 30mg/kg 4.3±1.8, 60mg/kg 6.9±2.2; $p<0.05$). Anti type II collagen antibody levels were not affected in the delayed treatment study despite improved clinical arthritis (vehicle 151±17, 30mg/kg 125±19, 60mg/kg 152±18).



Conclusion: The dual PI3Kγ/d inhibitor INK055 was effective as prophylactic therapy as well as in established arthritis. The modest effect on autoantibody production and benefit observed in established disease suggests that the mechanism is through an effect on innate immunity rather than antibody production. A dual specific PI3Kγ/d inhibitor might be effective in rheumatoid arthritis while limiting systemic toxicity of α and β inhibitors.

Increased Lymphatic Flow Reduces the Severity of Joint Tissue Damage in a Murine Model of Chronic Inflammatory Arthritis. Q. Zhou, R. Guo, R. Wood, B. Boyce, E.M. Schwarz and L. Xing, University of Rochester, Rochester, NY

Purpose: We have demonstrated previously that the blockage of lymphatic flow from joint tissues to the local draining lymph nodes (DLNs) increases the severity of joint inflammation and tissue damage in TNF transgenic (TNF-Tg) arthritic mice, indicating that efficient lymphatic flow is required for controlling the joint lesions of rheumatoid arthritis (RA). In this study, we test the hypothesis that increasing joint lymphatic flow attenuates the progression of arthritis by removing macrophages from inflamed synovium to local DLNs through local lymphatic circulation.

Methods: Human VEGF-C, a potent lymphatic growth factor, was cloned into an AAV expression vector. AAV-hVEGF-C or AAV-Luc control virus (N=5 mice/treatment) was injected intra-articularilly into knee joints of 1.5 month-old TNF-Tg mice before the onset of RA. Three months later, a clinical arthritic assessment was performed and the lymphatic draining function was measured by our newly developed near infrared-indocyanine green (NIR-ICG) lymphatic imaging method in which ICG, a NIR tracer, was intra-dermally injected into footpads and the movement of ICG from foot to the DLN was imaged and recorded. The expression of hVEGF-C in vivo was confirmed by RT-PCR using specific human VEGF-C primers. The joint inflammation, bone erosion, cartilage loss and lymphatic and blood vasculature were examined by histomorphometric analysis.

Results: VEGF-C treatment significantly decreased the arthritic deformation score (1.0+0.5 vs Luc 1.9+0.4) and increased the joint range of motion (110+15o vs Luc 167.5+/2.7o). Lymphatic flow from foot to DLNs was remarkably increased in legs which received VEGF-C virus. ICG signal intensity in DLNs was 8-fold higher in VEGF-C injected legs (58.4+37.3 vs Luc 6.7+7.1) and the clearance of ICG from the footpad was 6-fold faster (77.7+12.5% vs Luc 27.6+16.5%). VEGF-C administration significantly increased LYVE-1+ lymphatic vessels in the synovium (vessel area/synovial area: 0.25+0.12mm2 vs Luc 0.09+0.04mm2), had no effect on CD31+ blood vessels (blood vessel area/synovial area: 0.19+0.04mm2 vs Luc 0.23+0.12mm2), and decreased joint tissue damage including reduced inflammation area (0.099+0.04 mm2 vs Luc 0.171+0.03 mm2), eroded surface (0.34+0.11% vs Luc 0.88+0.11%), and cartilage loss (12+10 % vs Luc 38+18%). In contrast to joints, in DLNs of VEGF-C injected legs, both area of lymphatic vessels and the size of lymphatic sinuses were decreased (area: 0.34+0.08 mm2 vs Luc 0.45+0.05 mm2; size: 0.03+0.017mm2 vs Luc 0.19+0.11mm2).

Conclusion: Intra-articular administration of lymphatic growth factor VEGF-C decreases the severity of joint inflammation, bone erosion, and cartilage loss in TNF-Tg arthritic mice, which is associated with increased local lymphatic drainage from foot to DLNs and reduced inflammtion-induced DLN lymphangiogenesis. Thus, increasing joint lymphangiogenesis and lymphatic flow may represent a novel therapy for RA pathology.

Jun N-Terminal Kinase 1 Is Required for Mast Cell Degranulation and IL-1b Production in Inflammatory Arthritis. Monica Guma[1], Maripat Corr[2], Gary S. Firestein[2] and Michael Karin[1], [1]UCSD, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA

Purpose: Jun N-terminal kinases (JNK) are activated in RA synovium and play a major role in cytokine production and extracellular matrix regulation through the production of metalloproteinases (MMP). We aimed to further analyze the mechanisms through which JNK promotes disease development and to test the ability of a specific JNK inhibitor that targets both JNK1 and JNK2 to improve the arthritis.

Methods: Wildtype (WT), *Jnk1*$^{-/-}$, bone marrow chimeras and mast cell reconstituted mice were injected with K/BxN sera on day 0 to induce arthritis. Ankle thickness and clinical arthritis scores were serially assessed. Joints were evaluated histologically for inflammation and joint damage using a semi-quantitative scoring system. Joint extracts were evaluated by ELISA and quantitative real-time PCR. Joint sections were mounted on slides stained with touluidine blue and scanned using the iCys laser scanning cytometer (CompuCyte) to quantify mast cells. In vitro mast cell cultures were stimulated with IgG and IL-1 release quantified by ELISA. A cell permeable peptide (D-JNKi) JNK inhibitor was injected i.p. on day 0 or day 4 after induction of passive K/BxN arthritis.

Results: *Jnk1*$^{-/-}$ mice had significantly lower clinical scores (peak score: 9.17 ± 0.7 and 5.5 ± 0.3; $p<0.01$ for WT and *Jnk1*$^{-/-}$ mice respectively) and histological changes on day 10 compared to WT mice. IL-1b protein levels, and IL-6, VEGF, MMP3 and MMP13 mRNA expression levels were significantly lower in inflamed *Jnk1*$^{-/-}$ joints compared with WT joints. Bone marrow chimeras and mast cell reconstitution showed JNK1 in bone marrow derived cells and mast cells were critical for passive K/BxN serum transfer arthritis. Histologic analysis showed a decrease in the number of degranulated mast cells (70% ± 8.5% and 40% ± 5.7%; $p<0.01$ for WT and *Jnk1*$^{-/-}$ mice respectively). Moreover, IL-1b secretion through FcgR in vitro was impaired in *Jnk1*$^{-/-}$ mast cells. Finally, D-JNKi successfully prevented arthritis in pre-treatment protocols and effectively decreased joint swelling in established disease.

Conclusion: JNK1 deficiency attenuated arthritis induction and joint destruction in the passive K/BxN model. JNK1 dependence was mediated by bone marrow derived cells, particularly mast cells. In the absence of JNK1, mast cells did not degranulate efficiently after stimulation with through their Fcg receptors, and released diminished amounts of IL-1b. Pharmacologic inhibition of JNK1 in this model effectively prevented arthritis onset and abrogated joint swelling in established disease. Hence, selective JNK1 blockade might prove an effective anti-inflammatory strategy for arthritis or other mast-cell mediated diseases.

Absence of Integrin α2β1 Alters MMP Expression and TNF-Dependent Inflammatory Cartilage Destruction. Marvin A. Peters[1], Simon Strietholt[1], Doreen Wendholt[1], Svetlana Frank[1], Adelheid Korb[1], George Kollias[2], Beate Eckes[3] and Thomas Pap[4], [1]University Hospital Muenster, Muenster, Germany, [2]Biomedical Sciences Research Center Alexander Fleming, Vari, Greece, [3]University of Cologne, Cologne, Germany, [4]Univ Hosp, Muenster, Germany

Purpose: Integrins are main receptors for cell-matrix interactions, and integrin signaling is critical for a variety of cellular functions such as adhesion, cell spreading and inflammatory responses. α2β1 integrin functions as a major receptor for type I collagen on a number of different cells, including fibroblasts and inflammatory cells. Although α2 integrin deficient mice appear normal apart from mild platelet dysfunction and abnormal angiogenesis, it was shown that α2 integrin contributes to the induction of MMPs in tissue remodeling. Based on the hypothesis that under stress conditions such as chronic inflammation, α2 integrin may be involved in the activation of synovial cells, we investigated the role of α2 integrin in inflammatory arthritis.

Method: To determine the role of α2 in TNF-mediated joint disease, we crossed α2-deficient mice with arthritic human TNFalpha transgenic (hTNFtg) mice. Clinical signs of arthritis and weight as well as the histological degree of synovitis and cartilage destruction in hind paws were investigated using standard clinical evaluation and histomorphometric analysis. In addition, we analyzed levels of cytokines and MMPs using serum and synovial fibroblasts from all genotypes. In addition, we used an established in vitro assay to investigate the role of the α2-subunit in the attachment of mouse synovial fibroblasts to healthy and IL-1 damaged articular cartilage.

Results: We found that loss of α2 integrin in hTNFtg mice resulted in improved clinical signs and symptoms as compared to hTNFtg mice arthritis score. hTNFtg/α2(-/-) mice had less paw swelling (1.87 vs. 2.66), increased grip strength (-1.83 vs. -2.66) and a less pronounced weight loss. Histological analysis of these mice revealed that loss of α2 integrin lead to a decrease in synovial inflammation as compared to hTNFtg mice. To evaluate the role of α2 for MMPs we analyzed serum levels of α2-deficient and wt mice and found no significant difference in MMP3 or MMP9. However in α2(-/-) synovial fibroblasts MMP3 expression was downregulated, compared to wt synovial fibroblasts (127.5 vs. 170.5 ng/ml). This downregulation was similar in synovial fibroblasts from hTNFtg/α2(-/-) mice compared to fibroblasts from hTNFtg animals. In addition, we found a diminished attachment of α2-deficient mouse synovial fibroblasts particularly after induction of proteoglycan loss in IL-1 treated cartilage pieces in vitro.

Conclusion: Our findings suggest that although α2 integrin appears to be dispensable for normal development, the loss of α2 leads to a decrease in inflammation and bone destruction in an animal model of inflammatory arthritis.

R-Spondin1 Protects against Bone Loss During Murine Arthritis by Modulating the Wnt Pathway. Gerhard Krönke[1], Stefan Uderhardt[1], Kyung-Ah Kim[2], Georg Schett[1] and Arie Abo[2], [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Nuvelo Inc., San Carlos, CA

Purpose: To test the efficiacy of the secreted Wnt modulator R-Spondin-1 (RSpo-1) in the preservation of joint integrity in a murine model of arthritis

Method: RSpo-1 was applied to isolated osteoblasts and osteoclast/osteoblast co-cultures to evaluate its effect on the differentiation of these celltypes *in vitro*. To test the potency of RSpo-1 as a joint preserving agent *in vivo*, arthritic TNF-transgenic mice were treated with recombinant RSpo-1 by daily subcutaneous injection.

Results: RSpo1 was highly effective in preserving structural integrity of joints in the TNF transgenic mouse model of rheumatoid arthritis by protecting bone and cartilage from inflammatory damage. RSpo1 antagonized the Wnt inhibitor Dkk1 and modulates Wnt signaling in mesenchymal cells. In osteoblasts RSpo1 induced differentiation and expression of OPG thereby inhibiting osteoclastogenesis *in vitro*. In joints, RSpo1 blocked osteoclast development and globally modulated the homeostasis of anabolic and catabolic gene expression. We observed induction of genes involved in both chondrogenesis and osteogenesis, which contributed to the integrity of cartilage and bone during joint inflammation.

Conclusion: Our results demonstrate the therapeutic potential of RSpo1 as an anabolic agent for the preservation of joint architecture.

PLX FK1, A Novel Dual Inhibitor of Kit and Fms Receptor Tyrosine Kinases Reverses Clinical and Histological Disease Parameters in Multiple Autoimmune Disease models. Gaston Habets, Jiazhong Zhang, Betsy Burton, Chao Zhang, Prabha Ibrahim, Bernice Wong, Marika Nespi, Ben Powell, Brian West, Paul Lin, Gideon Bollag and Peter Hirth, Plexxikon Inc, Berkeley, CA

Purpose: PLX FK1 is a potent and highly selective inhibitor of the tyrosine kinase activities of the Kit (K_I = 0.9nM) and Fms (K_I = 1nM) receptors. Kit is a key regulator of mast cells and dendritic cells, and Fms is a key regulator of macrophages, dendritic cells, and osteoclasts. Together, the cellular targets of these receptors control autoimmune processes involved in many diseases, including rheumatoid

arthritis (RA), multiple sclerosis (MS), lupus and inflammatory bowel disease. Knockout studies suggest roles for both Fms and Kit kinases in models of arthritis, through their direction of macrophages and mast cells, respectively. Therefore, PLX-FK1 is a valuable compound to test the role of Fms and Kit target cells in autoimmune diseases.

Methods: and **Results:** In an acute MOG-induced EAE mouse MS-model, a 50 mg/kg q.d. oral dose of PLX FK1 resulted in rapid and substantial regression of disease over a 6 week period, with most mice showing no evidence of disease at study end. In a MLR/lpr mouse lupus-model, treatment with a 50 mg/kg q.d. oral dose of PLX FK1 significantly decreased proteinurea levels from 100 mg/dL: following 8 weeks of treatment proteinurea in PLX FK1-treated mice decreased to 30-50 mg/dl, while proteinurea in vehicle-treated mice increased to 250-300 mg/dl. In addition, auto-antibodies against dsDNA and paw and joint swelling were decreased by PLX FK1 treatment. Based on these data, the same dose of PLX FK1 was chosen to examine its efficacy in an aggressive model of RA: in a rendition of murine collagen-induced arthritis, DBA/1 mice were immunized with Bovine Collagen II in CFA on day 0 and given a Collagen boost ip on day 21. By day 19, disease had progressed to a mean score of 4 (out of 16), and treatment was initiated. Dexamethasone 0.5 mg/kg ip was included as the active control. Within the first week of treatment, the 50 mg/kg q.d. oral dose of PLX FK1 resulted in significant stabilization of disease that continued through the course of treatment. Following three weeks of treatment, the mean disease score of the PLX FK1-treated animals was 5.2, while progressive disease in the vehicle-treated animals reached a mean score of 13.3. Upon histopathological examination of wrist, paw and ankle joints, the disease scores for inflammation, pannus formation, cartilage damage and bone resorption were all significantly lower in the PLX FK1 treated animals versus vehicle treated animals. Also, macrophage and mast cell counts were lower in the PLX FK1 treatment group.

Conclusion: Dual inhibition of Kit and Fms kinase activities by the potent and highly selective inhibitor PLX-FK1 results in substantial efficacy in aggressive models of MS, lupus and RA and warrants further development in clinical studies.

Suppression of Primary SLE B Cells by XmAb®5871, An Anti-CD19 Monoclonal Antibody (mAb) That Co-Engages the B Cell Antigen Receptor (BCR) and the FcγRIIb Inhibitory Receptor. Seung Y. Chu[1], Elizabeth C. Ortiz[2], Erik Pong[1], Holly M. Horton[1], Noam Jacob[2], William Stohl[2] and David E. Szymkowski[1], [1]Xencor, Inc., Monrovia, CA, [2]Univ Southern California, Los Angeles, CA

Purpose: XmAb®5871 is a genetically-engineered humanized anti-CD19 mAb that mimics the immunosuppressive effects of immune complexes through its high-affinity binding (0.2 nM) of CD19 (a component of the BCR complex) and simultaneous high-affinity (4 nM) engagement of the B cell inhibitory receptor FcγRIIb (normally a low-affinity receptor for native IgG Fc). Such co-engagement of BCR and FcγRIIb on human B cells potently suppresses activation responses such as intracellular calcium flux, cell proliferation, and class switching. Since FcγRIIb-mediated inhibition may be perturbed in SLE patients, it is critical to determine whether FcγRIIb is a pharmacologically tractable target in SLE. Therefore, we assessed the ability of XmAb5871 to suppress activation of primary SLE and normal B cells.

Method: SLE patients with elevated circulating levels of at least one SLE-associated autoantibody (anti-dsDNA, anti-Sm, anti-RNP, anti-SS-A, anti-SS-B, anti-cardiolipin) were recruited. B cells were purified from the venous blood of these SLE patients and healthy normal control donors, and cultures containing either XmAb5871 or control mAb were established. In vitro responses of SLE and normal B cells were assessed by suppression of BCR-induced proliferation, intracellular calcium flux, and surface expression of costimulatory molecules. FcγRIIb expression on B cells was measured by flow cytometry and was correlated with the in vitro potency of XmAb5871.

Results: In vitro studies indicated that the FcγRIIb pathway in SLE B cells can be amplified pharmacologically by XmAb5871. Intracellular calcium signaling was suppressed by XmAb5871 in SLE B cells as well as in normal B cells. Inhibition was critically dependent on amplified FcγRIIb engagement, because control anti-CD19 mAb containing native IgG1 or knocked-out Fc domains were inactive.

Conclusion: The normal physiological role of immune complexes in suppressing B cell activation can be mimicked by a novel engineered mAb that co-engages FcγRIIb and BCR with high affinity. This inhibitory pathway is functional in SLE B cells, suggesting that a mAb that amplifies FcγRIIb signaling may represent a new therapeutic strategy to suppress autoreactive B cell populations in SLE and related autoimmune diseases.

Peripheral Blood B Cells Subsets in Patients with Systemic Lupus Erythematosus: Correlation with Disease Activity and Organ Involvement. Elisa Gremese[1], Barbara Tolusso[1], Alessandro Michelutti[1], Marcin Nowik[1], Antonella Laria[1], Graziella D'Antona[1] and Gianfranco Ferraccioli[2], [1]Division of Rheumatology – Catholic University of the Sacred Heart, Rome, Italy, [2]Division of Rheumatology, Catholic University, Rome, Italy

Purpose: Disturbance in peripheral blood (PB) B cells subpopulation have been observed in patients with SLE, but have not been fully delineated in relation to disease phenotype.

The aim of the study was to analyze the frequency and distribution of B cells subsets in a cohort of patients with SLE with different organ involvement and the possible correlation with the disease activity.

Method: 47 SLE patients (41 females; mean age 37.1±10.9 years; 25 with renal, 15 with articular, 3 with SNC, 3 with vascular and 1 with cutaneous involvement; 25 with an active disease-SLEDAI>10) and 15 healthy controls were analyzed for the delineation of circulating PB B cell subpopulations by staining for CD19, CD38, and IgD in combination with the B cell memory marker CD27, by flow cytometry.

Results: Subjects with SLE had a significantly lower frequency of Bm5 cells defined by the expression of IgD and CD38 (12.2±8.1%) than healthy controls (17.2±6.3%, p=0.01).

In SLE patients, disease activity index (SLEDAI) correlated negatively with the absolute number of lymphocytes (r= -0.36, p=0.03), instead positively with the percentage of CD19+ cells (r=0.43, p=0.004).

SLE patients with an active disease had an higher percentage of CD19+ cells compared with patients with inactive disease (12.2±7.6% vs 6.5±7.7% respectively, p=0.001). Patients with active disease had an higher absolute number of memory cells (eBm5+Bm5 42±43/ul, CD27+ 24±33, CD27+/IgD- 19±22) and of the CD19+/CD27+CD38+ (13±16) compared with patients with inactive disease (eBm5+Bm5 15±13, p=0.01, CD27+ 7±7, p=0.01, CD27+/IgD- 5±5, p=0.002, CD19+/CD27+CD38+ 3±3, respectively, p=0.004). The distribution of Bm1-Bm5 subsets was similar in patients with renal and articular involvement, even if considering only the subgroup with active disease, patients with renal involvement showed an higher percentage of memory B cells (eBm5+Bm5 37.5 ± 22.7%) compared with patients with articular involvement (16.4±6.9%, p=0.02). This difference was also confirmed by the ratio Bm2+Bm2'/eBm5+Bm5 in active renal disease (1.4±0.9) compared to 4.7±2.4 in active articular disease (p=0.01).

Conclusion: SLE patients showed a significant reduction of memory B cells compared with controls, regardless of the organ involvement. An increase of memory B cells appeared, however, in patients with renal active engagement, while an higher percentage of active cells was present in patients with active articular involvement.

Prolonged but Variable Effects of B Cell Depletion Therapy in Murine Lupus Nephritis. Kai Bekar[1], Teresa Owen[1], Robert Dunn[2], Travis Ichikawa[1], Jennifer Barnard Hossler[1], Sarah Nevarez[1], Sean Brady[1], Bruce Goldman[1], Marilyn R. Kehry[2] and Jennifer H. Anolik[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Biogen Idec, San Diego, CA, [3]University of Rochester, Rochester, NY

Purpose: The pathogenic significance of B cells in systemic lupus (SLE) has been highlighted by the abrogation of disease in B cell deficient mice. However, the benefit of B cell depletion therapy (BCDT) in human SLE has recently been questioned by lack of clinical efficacy observed in the Explorer and Lunar studies. Development of a murine lupus model of BCD would be helpful to better understand the mechanisms and effects on disease outcomes.

Methods: Young NZB/NZWF1 female (8-12 weeks), early disease (18 weeks), and established nephritis (24-30 weeks with durable proteinuria > 2+ or 100 mg/dl) animals were dosed with anti-CD20 antibody (IgG2a), BR3-Fc, or control antibody (10 mg/kg) i.v. Additionally, normal BALB/c were dosed with anti-CD20, CpG1826, and/or anti-CD40. Peripheral blood (PB), lymph node (LN), bone marrow (BM), spleen and peritoneal cells were harvested and analyzed by flow cytometry. Nephritis was monitored by proteinuria (Uristix) and kidney IHC. Serum IgG anti-dsDNA levels were measured by ELISA.

Results: A single injection of anti-CD20 in normal mice caused rapid depletion of B cell subsets although with a gradation of sensitivity (%depletion): PB>spleen>LN>peritoneum>BM. Germinal center (GC) B cells in immunized mice were relatively resistant to depletion, an effect potentiated by anti-CD40 and a B cell stimulatory TLR9 CpG agonist. B cell reconstitution began ~6 weeks after initial treatment. Administration of a CpG agonist resulted in significantly earlier B cell reconstitution. In young NZB/NZWF1 mice BCD was incomplete with early reconstitution at 3 weeks. A sequential weekly dosing x 4 was subsequently utilized and improved depletion of more resistant subsets, including splenic marginal zone (30% depletion at 1 week to 97% depletion at 4 weeks). Treatment of older mice with established nephritis (2+) resulted in a significant decrease in the %B220+ cells compared to control antibody treated animals (12.19±3.69 vs. 44.40±3.69, $p<0.001$). However, there was significant variability among animals ranging from 7% to 91% depletion in the spleen, with relative resistance of the MZ and GC B cells. Depletion was improved by combination with BAFF blockade (BR3-Fc). BCDT prevented the progression of nephritis, with a significant difference in protein free survival that was maintained 20 weeks beyond completion of treatment ($p<0.01$). Serum anti-dsDNA antibodies were not different between the two groups, but activated and memory T cells were decreased with BCD ($p<0.05$). In a prevention study, treatment of 18 wk mice with 4 wks of anti-CD20 significantly delayed the onset of disease by over 20 wks ($p=0.0007$), a prolonged benefit that extended well after B cell reconstitution.

Conclusion: The lasting benefit of a short course of BCDT in NZB/NZWF1 mice supports a critical role of B cells in this disease model. Resistance of B cell populations to depletion may explain some heterogeneity in clinical response but could be overcome by combination therapeutic approaches. Supported by a Lupus Research Institute grant

Plasmin Cleavage of Beta2-Glycoprotein I Promotes Maternal Anti-Ro60 IgG Opsonisation of Apoptotic Cells: A Permissive Factor in Congenital Heart Block? Joanne H. Reed[1], Bill Giannakopoulos[2], Kenneth M. Kaufman[3], Steven A. Krilis[2] and Thomas P. Gordon[1], [1]Flinders Medical Centre, Bedford Park, Australia, [2]University of New South Wales, Sydney, Australia, [3]Oklahoma Medical Research Foundation, OK, OK

Purpose: Maternal anti-Ro60 autoantibodies are thought to initiate tissue damage in congenital heart block (CHB) by binding to apoptotic fetal cardiocytes. The plasma protein beta2-glycoprotein I (β2GPI) binds to Ro60 (amino acid residues 82-244) on the surface of apoptotic cells via its fifth domain and prevents the formation of pathogenic anti-Ro60 IgG-apoptotic cell immune complexes. The current study was initiated to define the precise Ro60-β2GPI binding sites and determine whether plasmin mediated cleavage of β2GPI influences immune complex formation.

Method: The β2GPI binding site on Ro60 was mapped by ELISA using overlapping soluble recombinant Ro60 subfragments spanning amino acids (aa) 82-244. The Ro60 binding on β2GPI was studied by apoptotic cell flow cytometry inhibition experiments using β2GPI peptides and plasmin-cleaved β2GPI. Binding of anti-Ro60 IgG from mothers of infants with CHB to apoptotic cells was determined by flow cytometry in the presence or absence of plasmin-cleaved β2GPI.

Results: The Ro60 β2GPI-binding site was mapped to a 64 aa region within the middle third of the Ro60 protein. A peptide representing a charged region within domain V (CKNKEKKC) of β2GPI partially inhibited binding to Ro60 on apoptotic cells. Plasmin cleavage of the β2GPI hydrophobic loop (Lys317-Thr318) abrogated binding of β2GPI to both recombinant and apoptotic cell membrane-bound Ro60 by

flow cytometry. Maternal anti-Ro60 IgG opsonised apoptotic cells in the presence of plasmin cleaved β2GPI under conditions where an equivalent concentration of native β2GPI completely inhibited immune complex formation.

Conclusion: β2GPI interacts with a 64 aa region of Ro60 via its hydrophobic loop and adjacent positively charged lysine rich region in domain V. Stimulation of plasmin production by infection or inflammation in the fetal heart may eliminate the protective effect of β2GPI and open the way for maternal anti-Ro60 autoantibody-mediated tissue damage.

Novel Autoantibody Markers for Early and Seronegative Rheumatoid Arthritis. Klaartje Somers[1], Piet P.M.M. Geusens[2], Marieke JH Coenen[3], Marlies Blom[3], Piet Stinissen[1] and Veerle Somers[1], [1]Hasselt University, Biomedical Research Institute, Diepenbeek, Belgium, [2]Maastricht University Medical Center and Hasselt University, Biomedical Research Institute, Diepenbeek, Belgium, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Purpose: Approximately one-third of rheumatoid arthritis (RA) patients are seronegative for the 2 serological RA markers, rheumatoid factor (RF) and antibodies directed against cyclic citrullinated peptides (anti-CCP antibodies). The sensitivities of both markers in early RA are even lower. The aim of this study was to identify novel markers for early RA and for RA patients that are seronegative for RF (RF-) and anti-CCP antibodies (ACPA-).

Method: We applied an autoantibody profiling procedure which entailed the screening of a RA cDNA phage display library, for antigen-reactivity with pooled serum from 10 early RA patients (symptoms of less than 1 year) and 10 RF- ACPA- RA patients.

Results: This approach resulted in the identification of 11 RA-specific and 3 RA-associated novel autoantibody targets for which no immunoreactivity was detected in the HC group (n=38). Antibodies against the panel of 11 RA-specific clones were demonstrated in 37% (34/92) of tested RA patients, with 100% specificity for the disease. By adding 2 RA-associated clones to the panel, 53% (49/92) of RA patients were antibody-positive with an associated specificity of 90% (reactivity in 7/30 rheumatic control patients). Antibody-reactivity against the panel was demonstrated to be associated with early disease (P=0.0087). In addition, as antibodies against the panel were detected in RA patients that were serologically negative for RF and/or ACPA, the detection of these novel antibody markers was of added value to the diagnostic testing for RF and ACPA; testing for the presence of antibodies against the panel increased the sensitivity of serological tests for RA by 25%. Moreover, several of the identified antigens demonstrated exclusive immunoreactivity in ACPA- RA patients, indicating their potential relevance as markers for this RA subtype. Furthermore, the presence of antibodies against our panel was shown to be associated with higher inflammatory disease activity (C-reactive protein levels) (P=0.0146). These findings clearly demonstrate the diagnostic and prognostic potential of the panel. Besides the marker potential of these antigens, the demonstration of increased expression of several of the identified antigens in RA synovial tissue supported a biological rationale for these novel RA antibody targets.

Conclusion: In conclusion, we identified a panel of 13 novel antibody markers for RA and illustrated the usefulness of these markers for improved RA diagnostics and prognostics. Moreover, we provided evidence for a biological relevance of several of the identified novel RA antigens in the RA disease process, providing more insight into the autoimmune processes occurring in RA.

Comparision of Clinical Outcome in Rheumatoid Arthritis Patients Treated with a Fixed or On-Demand Regime of Rituximab: Two Year Follow Up. Janneke Tekstra[1], Onno Y. K. Teng[2], Paco M.J. Welsing[1], Jaap M. van Laar[3], Floris P.J.G. Lafeber[1] and Johannes W. J. Bijlsma[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Newcastle University, Newcastle, United Kingdom

Purpose: Rituximab has proven to be an effective and safe treatment for rheumatoid arthritis (RA). However, the preferred timing and dosage of repeated treatment of Rituximab is still a matter of debate. Our objective was to compare the clinical outcome of two treatment regimes with Rituximab in refractory RA patients.

Method: In a two-center prospective open-label study over 2 years, patients with refractory RA were treated with two different regimes of rituximab. All patients received initial treatment with 2x1gr intravenously, and retreatment with 1gr intravenously. In one center, 26 patients received retreatment every 24 weeks, while 20 patients in another center received retreatment only when disease relapsed (DAS28 >3.2 and decrease of DAS28<1). Clinical response was defined according to the European League Against Rheumatism (EULAR) criteria and the average DAS28 and HAQ over time were calculated and compared. The difference in average DAS28 and HAQ were corrected for baseline prognostic differences between groups using regression analysis. The number of serious adverse events (SAE), aberrant values for leukocytes and total immunoglobulins, and number of rituximab doses were also compared between the groups.

Results: At baseline, both treatment groups differed significantly in DAS28 (5,1 for the fixed retreatment group vs 6,1 for the on-demand group, P=0.01), indicating that the on-demand group had more severe RA. This is further reflected by a significantly higher number of previous anti-TNF medication used (1,54 vs 2,05, P=0.33). EULAR responses at 24 months were not significantly different in the fixed retreatment group resp in the on-demand group: 38.5% resp 21.4% (good responders) and 38.5% resp 35.7% (moderate responders).

The mean DAS28 over time was 0,5 points higher in the on-demand group corrected for baseline DAS28 (p=0.069). No difference in HAQ score between regimes was found. In the fixed retreatment group, a trend toward more SAE's as a reason for study discontinuation was observed (26,9% vs 10%, P=0.054) as well as a significantly higher incidence of (transient) leukopenia (34,6% vs 10%, P=0.044). No differences between the groups were found for total immunoglobulin levels. On average 1.15 fewer rituximab retreatments were used in the on-demand group (p=0.001).

Conclusion: The fixed retreatment regime with rituximab compared to an on-demand retreatment regime in RA patients seemed to result in a modestly lower mean DAS28. It also seemed to result in an increased number of SAE and cases of leukopenia, although transient. Moreover, significantly more doses of rituximab were needed to achieve this difference in DAS28. In practice, these factors must be weighed against the clinical benefit.

Response to Rituximab in Rheumatoid Arthritis Patients: Association with B-Cell Markers. Athina Pyrpasopoulou, Stella Douma, Areti Triantafyllou, Sofia Chatzimichailidou, Magda Samara, Efthymia Parapanisiou and Spyros Aslanidis, Hippokration General Hospital, Thessaloniki, Greece

Purpose: Rituximab is used to deplete B cells, and control disease activity in, mainly, anti-TNF failing RA patients. Response rates and time to relapse vary significantly among treated individuals. The objective of this study was to monitor response of seropositive and seronegative RA patients to rituximab and correlate relapse with B cell markers in the two groups.

Methods: Seventeen patients with RA (8 seropositive and 9 seronegative, aged 25-77 years), with 2-30 years disease duration, received 2 cycles of rituximab. There was no statistically significant difference in the baseline characteristics of the two groups. Rituximab was readministered when disease relapse was confirmed by clinical-laboratory measures (DAS28). CD20(+) cells and CD20 receptor expression were estimated at initiation, relapse, and reevaluation timepoints.

Results: Mean time to relapse after the 1st cycle of rituximab was 337.5+127 for seropositive vs 233.3+59.6 days for seronegative patients (p=0.043), table I. The mean DAS28 score decrease 3 months post treatment respectively was 1.695±1.076 vs 0.94±1.620. At relapse, CD20 receptor quantitative expression was higher in Rf(+) patients compared to the Rf(-) group (122,085.6±86,147.7 molecules/ cell vs 2,450 molecules/ cell [1,100-189,140], despite lower % of CD20+ cells (5.36±4.66 vs 8.62±7.20, p=0.043).

Conclusion: Rituximab treatment is efficient both in seropositive and seronegative RA. However, Rf(+) RA patients tend to exhibit a favorable and more sustained response compared to Rf(-) ones. The differential CD20 receptor expression in the two groups at relapse potentially suggests a different pathogenetic mechanism of relapse and merits further investigation.

Inhibition of Immunoglobulin Light Chains by Rituximab Correlates with Inhibition of Clinical Activity in Patients with RA.

Janneke Tekstra[1], Tom Groot Kormelink[2], Rogier M. Thurlings[3], Maartje J. H. Boumans[3], Koen Vos[3], Paul P. Tak[3], Johannes W. J. Bijlsma[1], Frank A.M. Redegeld[2], Floris P.J.G. Lafeber[1] and Joel A.G. van Roon[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Utrecht Institute for Pharmaceutical Sciences, Fac. Science, Utrecht, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: Immunoglobulin kappa and lambda free light chains (FLCs) are produced physiologically and levels are increased in several inflammatory diseases like asthma, inflammatory bowel disease and rheumatoid arthritis (RA). FLCs are short-lived products of B lymphocytes and have been shown to promote inflammation by activation of mast cells. Our purpose was to investigate how FLC concentrations correlate with disease activity and whether FLC changes upon B cell targeted therapy in RA patients correlate with changes in disease activity.

Method: 50 RA patients with active disease were treated with rituximab. Clinical response was defined according to the European League Against Rheumatism (EULAR) criteria. FLC kappa and lambda concentrations were measured using a sensitive ELISA. FLCs were measured at baseline and 3 and 6 months after treatment. At these time points, total immunoglobulin concentrations, rheumatic factor (RF) and anti-CCP were also measured.

Results: At baseline FLC concentrations significantly correlated with DAS 28 (p=0.006 for kappa and p=0.04 for lambda) and ESR and CRP (all p<0.01). Over time, kappa and lambda FLC concentrations decreased significantly after rituximab treatment (p<0.001 for baseline vs 3 months and p<0.01 for baseline vs 6 months after treatment for both kappa and lambda FLC). Patients without clinical response to rituximab showed no significant reduction of FLC concentrations, whereas patients who responded clinically did show a significant decrease in FLCs. Changes in FLC concentrations (kappa and lambda), 3 and 6 months after treatment, showed a highly significant (P<0.001) correlation with the changes in ESR. As described previously, RF levels and, to a lesser extent, anti-CCP antibody levels decreased after rituximab treatment (45% and 26%, resp). In contrast to FLC concentrations, RF levels decreased significantly in clinical responders as well as in non-responders. Total IgG, IgA and IgM concentrations remained within normal limits.

Conclusion: Rituximab significantly decreases FLCs in RA patients. Changes in FLC concentrations significantly correlate with the clinical response. In contrast, RF levels decrease after treatment in patients with and without clinical response. Our study suggests that inhibition of FLCs may represent a novel anti-inflammatory mechanism of Rituximab treatment.

The FMS-Like Tyrosine Kinase 3 Ligand Is Associated with the Abnormal Blood B-Cell Distribution in Sjögren's Syndrome.
Jacques-Olivier Pers[1], Gabriel Tobon[1], Valérie Devauchelle[2] and Pierre Youinou[1], [1]Brest University Medical School Hospital, Brest, France, [2]CHU Brest, Brest, France

Purpose: Sjögren's syndrome (SS) is a chronic autoimmune epithelitis. The relevance of B-cell in the physio-pathology of SS has been emphasized over the past five years. Recently we demonstrated that the distribution of mature B-cell subsets from Bm1 through Bm5 in peripheral blood of patients with SS is different from other autoimmune diseases and controls, characterized by an increase in Bm2 and Bm2' B cell-subsets. FMS-like tyrosine kinase 3 ligand (FL), a cytokine implicated in the B-cell ontogenesis and malignant hematological proliferation, might be responsible for this abnormal blood B-cell distribution in SS.

Method: Serum levels of FL were evaluated in sixty-four SS patients and 20 matched healthy controls. FL and its receptor Flt3 were quantified in circulating B cells by real time-PCR and fluorescence-activated cell-sorter, but also in salivary gland biopsies by immunofluorescence. The impact of FL on circulating B lymphocytes was then evaluated by co-culture experiments using the human salivary gland cell line HSG.

Results: Serum levels of FL were increased in SS patients compared to controls (135.8 pg/mL ± 43.9 vs. 64.4 pg/mL ± 19.5 ; p < 0,001). Higher serum levels of FL were significantly associated with the abnormal B-cell profile in SS patients (r=0,459; p<0,0006). We found a selective expression of Flt3 in Bm2 and Bm2' B cells, which are also the main cells expanded in SS. B cell culture experiments showed that FL alone is not able to generate an effect on B cell proliferation, but potentiates the proliferative effect of an anti-IgM stimulation. In salivary glands, we have found that infiltrating B cells express Flt3 whereas epithelial cells produce FL. This cytokine was shown to be functional in that survival of co-cultured B cells with HSG cells was abrogated by anti-FL or anti-Flt3 antibodies.

Conclusion: FL is elevated in SS patients which is correlated with an abnormal B-cell profile in the blood. Flt-3 is express by Bm2 and Bm2' (subsets of B cells altered in the disease). The role of FL over the B cell proliferation may explain the clinical evolution to B cell lymphoma observed in some patients. Targeting FL may open new strategies in SS patients therapy.

RNA Recognition Motif (RRM) of La/SSB: The Bridge for Inter-Particle Spreading of Autoimmune Response to RNP.
John G. Routsias, Nikolaos Kyriakidis, Michael Latreille, Haralampos M. Moutsopoulos and Athanasios G. Tzioufas, School of Medicine, National University of Athens, Athens, Greece

The hallmark of SLE is the production of grouped sets of autoantibodies targeting mainly the U1-RNP and/or Ro/La ribonucleoprotein particles. Intra-particle diversification of the autoimmune response is believed to occur via epitope spreading. So far, it remains unsolved how the autoimmune response "jumps" from one particle to another. To the extent that the majority of nuclear autoantigens in lupus are RNA binding proteins and major epitopes were previously mapped within their RRM (RNA recognition motifs), conserved sequences within RRM could be involved in the intermolecular and inter-particle diversification process of autoimmune response.

Purpose: To investigate the potential of RRM of the La autoantigen to induce antibodies that cross-recognize components of U1-RNP particle and therefore its capacity to produce inter-particle epitope spreading.

Method: New Zealand white rabbits were immunized with a peptide corresponding to the epitope 145-164 of La/SSB (belongs to RRM of La/SB), attached in four copies on a scaffold carrier. Sera were drawn from twenty sera of patients with SLE and anti-U1RNP antibodies and 26 sera of SS patients with anti-La antibodies. All sera were evaluated for reactivity against the major epitope of La/SSB (pep349-364), the RNP antigen and the RRM related epitope of La (pep145-164). Specific antibodies against the pep145-164 were purified with immunoaffinity columns from selected sera.

Results: After the immunization of the animals with pep145-164, a specific, IgG, antibody response was detected, directed against the La autoantigen (weeks #3-#7) the immunizing peptide (weeks #3-#27) and the RNP autoantigen (weeks #7-#20). This response gradually decreased to low levels between post immunization weeks #27-#42. Purified antibodies against pep145-164 recognized La/SSB and a 70kD autoantigen in western blot and exhibited significant reactivity in anti-RNP ELISA. In addition, pep145-164 was recognized to a greater extent by autoimmune sera with anti-RNP reactivity as compared to anti-La/SSB positive sera, in contrast to pep349-364 of La/SSB, which was recognized almost exclusively by sera with anti-La/SSB reactivity.

Conclusion: Our data suggest that the RRM region of La can trigger inter-particle B cell diversification to U1-RNP-70 autoantigen via molecular mimicry. Identification of "key sequences" that trigger and perpetuate the autoimmune process is particularly important for understanding pathogenetic mechanisms in autoimmunity.

The Sympathetic Nervous System Promotes the Development of B Cells That Show Regulatory Potential in Collagen-Induced Arthritis. Georg Pongratz, Madlen Melzer and Rainer H. Straub, University Hospital Regensburg, Regensburg, Germany

Purpose: The cells recent success in the treatment of some autoimmune disease, such as rheumatoid arthritis (RA), with depleting anti-CD20 antibodies, led to a revival of the concept that B play a role in the pathogenesis of these disease. However, a complete depletion of CD20+ B cells, no matter if autoreactive or not, is a rather unspecific method and has the potential to cause complicating side effects such as severe infection. To avoid this problem it is important to understand how B cells might be regulated to influence the course of disease more specifically. A known regulator of B cell function is the sympathetic nervous system (SNS), but recent studies also showed a clear influence of the SNS on the development and severity of experimental arthritis.

Therefore, it was hypothesized that the SNS acts via regulating B cell function to modulate the development and severity of arthritis.

Method: Collagen type II-induced arthritis, adoptive transfer of isolated splenic B cells, splenectomy, *in vitro* B cell culture.

Results: We show that the SNS has the potential to support the generation of B cells that possess regulatory potential in collagen induced arthritis (CIA):

1) We activated B cells with anti-CD40 (1mg/ml) / IL-4 (1ng/ml) in the presence or absence of norepinephrine (10^{-6}M), and adoptively transferred 3 Mio. of these cells in arthritic DBA1J mice. Compared to arthritic mice that received PBS, mice that received B cells developed a less severe arthritis *per se*, however, this effect was significantly more pronounced when B cells activated in the presence of norepinephrine were used for treatment.

2) We induced arthritis in sympathectomized mice and control mice. At day 28 after induction of arthritis, we exchanged splenic B cells between the groups by adoptive transfer. *Per se*, sympathectomized mice developed more severe arthritis after splenectomy than control mice. However, transferring B cells from the sympathectomized mice into control mice, and *vice versa*, also changed the course of disease, respectively.

Conclusion: Both findings point to a role of the sympathetic nervous system in generating B cells that possess regulatory potential in the collagen induced arthritis model.

Disclosure: G. Pongratz, None; **M. Melzer**, None; **R. H. Straub**, None.

686

Fine Specificity of the ACPA Response in Arthralgia Patients. L.A. van de Stadt[1], W.H. Bos[1], G.J. Wolbink[1], B. A. C. Dijkmans[2], Dirkjan van Schaardenburg[1] and D. Hamann[3], [1]Jan van Breemen Institute, Amsterdam, Netherlands, [2]M.D., PhD, Amsterdam, Netherlands, [3]Sanquin Diagnostics, Amsterdam, Netherlands

Purpose: Anti-citrullinated peptide antibodies (ACPA) are probably involved in the pathogenesis of RA. Environmental and genetic factors predispose to the formation of ACPA. During the course of disease epitope spreading might occur and the antibody response may expand. Finding the immunodominant epitope in established RA is therefore troublesome. In this study, the ACPA repertoire of arthralgia patients and the association with arthritis development were studied.

Methods: 221 anti-CCP and/or IgM-RF positive arthralgia patients were included. Absence of clinical arthritis at baseline was confirmed by an experienced rheumatologist. Arthritis was defined as development of one or more swollen joints at clinical examination during twice-yearly follow-up. Minimum follow-up was 8 months. Sera were tested at baseline for reactivity to 5 citrullinated peptides derived from fibrinogen (3), vimentin (1) and alpha-enolase (1) and the 5 corresponding arginine peptides in an ELISA. Reactivity was expressed as Δ optical density (OD) between citrullinated and arginine peptides. Sera with ΔOD more than the mean plus 2SD of 40 healthy control sera were considered positive.

Results: 59 patients (27%) developed arthritis in a median of 3 joints after a median follow up of 8 (IQR: 4-18) months. Nine (11%) anti-CCP negative patients and 126 (88%) anti-CCP positive patients showed reactivity to one or more citrullinated peptides. Reactivity to each peptide was significantly associated with arthritis development ($p < 0.002$). However, reactivity patterns did not differ between patients who did or did not develop arthritis (Figure1). Nevertheless, within anti-CCP positive patients, a trend was seen towards more arthritis development in patients who recognized two or more peptides (Figure 2). Furthermore, the number of recognized peptides was positively associated with the anti-CCP level ($p < 0.001$).

Conclusion: The ACPA response in arthralgia patients is already expanded and resembles that of patients with arthritis. This could indicate cross-reactivity between peptides or genuine epitope spreading, a process that might be initiated before onset of arthralgia. The trend towards more arthritis development in patients that recognize more peptides, would fit with the latter. Studying the ACPA response earlier in the course of arthritis development, i.e. before onset of joint complaints, is therefore necessary.

TNF-Induced Expansion of CD23+/CD21hi B Cells in Draining Lymph Nodes Are Associated with the Onset of Inflammatory-Erosive Arthritis in Proximal Joints and Are Targets of Anti-CD20 Therapy. J. Li[1], I. Kuzin[1], S. Moshkani[1], Christopher Ritchlin[2], Jennifer H. Anolik[1], I. Sanz[1], R. J. Looney[1], L. Xing[1], E.M. Schwarz[1] and A. Bottaro[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY

Purpose: B cell depletion therapy (BCDT) with anti-CD20 is an effective treatment for some RA patients. However, the role of B cells in arthritis and the primary target of BCDT are unknown. Previously we utilized the TNF-Tg mouse model of RA and longitudinal contrast enhanced (CE) MRI to evaluate their arthritis, which initiates in distal joints of the ankle and progresses proximally with age. We also noticed that the popliteal lymph nodes (PLN) become enlarged following ankle synovitis, but prior to knee arthritis. Flow cytometry (FC) revealed that PLN enlargement was due to a 4 to 7-fold increase in B cell numbers, accounting for the expansion in cellularity. We proposed that these B cells in inflamed nodes (B-in) could be the primary target of anti-CD20 BCDT. To test the hypothesis we performed a formal phenotypic characterization of B-in and their response to anti-CD20 therapy.

Methods: Multicolor FC with probes for B220, IgM, IgD, CD1d, CD5, CD19, CD21, CD23, CD24, CD25α, CD69, CD80, CD86, CD93 (AA4.1), CD138 and GL7, was performed on cells from spleen, PLN, mesenteric (M)LN and axillary (A)LN from young (<2-months), adult (3-6 months) and old (>8 months) TNF-Tg and wt mice (N= 4 to 13), which were untreated or received anti-CD20 (10mg/kg/i.v. every 2 weeks for 6 weeks). Luminex was performed on B-in and follicular B cells from TNF-Tg PLN, as well as pooled LN follicular B cells and peritoneal B cells from WT mice. 105 cells/well were cultured with CpG, PMA, and ionomycyn for 48 hrs, and the supernatants were assayed for the cytokines IL1β, IL2, IL4, IL6, IL10, IL12p70, IFNγ, RANTES, and muTNF.

Results: TNF-Tg PLN had significantly ($p<0.001$) more IgMhi, IgD+, CD21hi, CD23+, CD1d+, CD24hi, CD93 lo B-in, which increase from 10% to >30% of PLN B cells and localize to the medullary/paracortical areas in mice with overt knee arthritis. No other differences in wt vs. TNF-Tg were detected. PLN of young TNF-Tg with ankle synovitis showed an expansion of B-in before CE-MRI detected changes in PLN or the knee. No increases in B-in were detected in spleen (wt: 12%; TNF-tg: 11-15%), MLN (wt: 10%; TNF-tg: 8-14%) or ALN of TNF-Tg mice <8 months of age (wt: 9%; TNF-Tg: 4-11%), while B-in were significantly increased in ALN of old arthritic TNF-Tg with forelimb arthritis (wt: 9%; TNF-tg: 24%; $p<0.01$). Anti-CD20 treatment resulted in a >90% decrease in PLN B-in. Luminex, confirmed by qPCR, revealed an increase in secretion of IL6, but not other cytokines, by stimulated PLN B cells from arthritic mice.

Conclusion: A unique B cell population – B-in - accumulates in efferent LN that drain inflamed joints in TNF-Tg mice, and is efficiently depleted by BCDT. B-in surface phenotype, but not cytokine profiles, resembles that of B-regs in the spleen of mice with remission-phase collagen-induced arthritis. Based on the cytokine data, a model for B-in derived IL-6 in arthritic progression is proposed.

TNF Alpha Impairs Humoral T Cell Dependent Antibody Responses. Gabriela Franco Salinas[1], Leen De Rycke[1], Tineke Cantaert[1], Mirjam van der Burg[2], Philip Remans[1], Barbara Barendregt[2], Paul P. Tak[3] and Dominique Baeten[1], [1]Academic Medical Centrum, Amsterdam, Netherlands, [2]Rotterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: TNF blockade in spondyloarthritis (SpA) induces antibodies specific for double stranded DNA, which is a T cell independent (TI) antigen. As these antibodies were restricted to the IgM isotype and no antibodies to T cell dependent (TD) antigens were induced, we investigated here if TNF blockade impairs the induction and maturation of TD humoral responses.

Method: 30 SpA patients (20 treated with TNF blockade, 10 untreated controls) were vaccinated with a TD vaccine to Hepatitis B and a TI vaccine to S. pneumoniae. Another 10 SpA patients treated with infliximab were vaccinated with a TD vaccine to S. pneumoniae. Serum and

PBMCs were collected before and after vaccination. Vaccine-specific antibody titers were measured by ELISA. B and T cell populations were evaluated by flow cytometry. Somatic hypermutation was determined by the Igκ REHMA assay (Anderson, Blood 2005).

Results: IgM and IgG responses against TI antigens were moderately decreased in anti-TNF treated patients compared to controls but were still robust. In contrast, IgG responses against TD antigens were almost completely absent in anti-TNF treated patients. The greater suppression of TD versus TI responses by TNF blockade was confirmed by lower anti-S. pneumoniae IgG titers with TD versus TI vaccines. Phenotypic analysis showed a normal number of B cells but a decrease in naïve and memory CD4+ T cells upon TNF blockade. Within the B cell population, TNF blockade significantly increased the frequency of memory B cells, which displayed an activated phenotype with increased expression of CD40 and HLA-DR. In parallel, however, TNF blockade decreased the frequency of CD138+ plasmablasts, suggesting a defective maturation towards antibody-producing cells. Confirming this hypothesis, TNF blockade significantly decreased the degree of somatic hypermutation as evidenced by Igκ REHMA analysis of peripheral blood B cells before and after treatment.

Conclusion: TNF blockade severely impairs TD humoral responses by interfering with the affinity maturation and differentiation of activated B cells towards antibody producing cells. * Both authors contributed equally to this work

Phenotypical and Functional Aberrations of B Cells in Patients Treated with Anti-Tnfa Agents. Maria Karampetsou, Fotini Paliogianni, Andrew P. Andonopoulos and Stamatis Nick C. Liossis, University of Patras Medical School, Patras, Greece

Purpose: To dissect the mechanisms of autoimmunity in anti-TNFa (a-TNFa) treated pts, we analyzed a-TNFa-induced alterations in B cell phenotype and function. We also examined a-TNFa therapy effects on the percentages of B1 B cells, a source of natural autoAb.

Method: PBMCs were isolated from 22 pts (9 with RA, 13 with SpA; 13 men, 9 women; mean age, 48 ±13; range, 24-71 yr) on day 0 and wk 30 following a-TNFa treatment, and from 10 healthy donors using standard Ficoll-Hypaque overlays. MACS isolated B cells were stained with mAbs against CD20,CD21 and CD5 and evaluated using 3-color flow cytometry. Levels of protein tyrosine phosphorylation (P-Y) and expression of Lyn, Syk and SHP-1 were evaluated in whole B-cell lysates[treated with 10μg/1x10^6 cells of F(ab)2 fragment of anti-human IgM or medium at 37 C for 1 min], using Western immunoblots. GAPDH was used as a loading control. Data are expressed as densitometric ratios of Lyn, Syk or SHP-1 O.D. over GAPDH.

Results: Expression of B- cell surface CD20 increased in 14 out of 22 pts following a-TNFa treatment (mean MFI ± SD: 3.312 ±1.611 vs 4.263 ± 2.093 at day 0 and wk 30 respectively, p=0.012) and ANA emerged in 9 out of these 14 pts. Induction of CD20 characterized pts with RA (mean MFI ± SD: 3.148±2.231 vs 4.624 ± 2.306 at day 0 and wk 30 respectively, p=0.039), but not pts with AS (mean MFI ± SD: 3.803 ± 1.187 vs 4.000 ± 1.444 at day 0 and wk30 respectively, p=NS) and was unrelated to disease activity. Expression of CD21 remained unchanged (mean MFI ±SD: 2.286±0.699 vs 2.411±0.644 at day 0 and wk 30 respectively, p=NS).

In 5 out of 9 patients with SpA B cells showed increased levels of protein P-Y without any BCR-initiated activation. Anti-sIgM stimulation further enhanced protein P-Y, suggesting that these B cells were functionally intact. 2 out of these 5 patients developed ANA following a-TNFa treatment.

In 9 out of 10 pts with SpA B-cell Lyn was significantly induced following a-TNFa (mean O.D. ratio Lyn/GAPDH: 0.381± 0.148 vs 0.639 ± 0.182 at day 0 and wk 30 respectively, p=0.003). Expression of Syk and SHP-1 was not altered (Syk/GAPDH: 0.701 ± 0.214 vs 0.729 ± 0.135 at day 0 and wk 30 respectively, p=0.7, and SHP-1/GAPDH: 0.488 ± 0.146 vs 0.485 ± 0.115, p=0.9). Five out of 9 pts developed ANA.

Circulating B1 B cells expanded in 5 out of 6 pts after a-TNFa (mean MFI ± SD: 6.5 ± 4.3 vs. 10.2 ± 6.4 at day 0 and wk 30 respectively, p=0.028) and 3 out of those developed ANA by wk 30.

Conclusion: We report that surface CD20 and cytoplasmic Lyn are induced in B cells from patients receiving a-TNFa agents. Additionally, early signaling events (protein P-Y) are enhanced in such B cells in the resting state and B1 B cells become overexpanded. Such changes may underlie, at least in part, a-TNFa-induced autoimmunity.

Proximal B Cell Receptor Signaling and Tolerance in Autoreactive IgM+CD27+ B Cells. Scott A. Jenks and Iñaki Sanz, University of Rochester School of Medicine and Dentistry, Rochester, NY

Purpose: To understand whether active regulatory mechanisms contribute to censor autoreactive B cells within the unswitched (marginal-zone-like) memory compartment. Unswitched IgM+CD27+ B cells (IgM+CD27+) make up a substantial portion of healthy donor PBL and have been postulated to represent recirculating marginal zone (MZ) cells. In the mouse, the MZ may play a protective role by sequestering low-affinity autoreactive B cells away from the pathogenic germinal center pathway on the basis of low intensity BCR signaling. We postulated that in humans, active inhibitory mechanisms would also contribute to censoring this pathogenic potential. In this study we tested whether the decreased BCR signaling responses we have observed in autoreactive 9G4+ naïve cells and characteristic of anergic follicular B cells would also be present in MZ B cells.

Methods: PBL were stimulated with anti-human IgM, IgD, or control anti-IgG for either 2 minutes or varying time points. Following stimulation cells were fixed with 1.6% paraformaldehyde and permeabilized with 100% ice-cold methanol. Cells were later stained to differentiate the naïve and IgM+CD27+ populations. To determine the degree of phosphorylation cells were stained with phosphorylation specific antibodies against BLNK (pY84,), pSYK (pY348) and pPLC-γ2 (pY759). In some experiments cells were stained with the rat anti-human idiotype 9G4.

Results: 3 fold more phosphorylation was observed after anti-IgM stimulation in IgM+CD27+ as compared to naïve cells while anti-IgD stimulation was decreased. Under basal conditions IgM+CD27+ had slightly higher levels of phosphorylation. Despite having increased phosphorylation after IgM stimulation, the IgM+CD27+ kinetics of phosphorylation was comparable to naïve B cells, with rapid phosphorylation followed by a quick loss and a return to nearly basal levels at 30 minutes. Interestingly, 9G4+ IgM+CD27+ B cell phosphorylation was significantly decreased after stimulation as compared to 9G4- IgM+CD27+ cells.

Conclusion: IgM+CD27+ cells respond more to anti-IgM and less to anti-IgD than naïve cells. This likely reflects the relative level of expression of the corresponding isotypes on the cell surface. The degree of BCR-induced phosphorylation is dependent on the balance between kinase and phosphatase activity as the phosphatase activity quickly diminishes phosphorylation in naïve cells. The similar signaling kinetics of IgM+CD27+ and naïve cells compared to switched memory cells suggests that this is an inherent property of the IgM receptor and associated signaling molecules rather than the differentiation state of the cell. The decreased signaling observed in the 9G4+ fraction of the IgM+CD27+ population strongly suggests that, as in the naïve compartment, these autoreactive B cells are rendered hyporesponsive by chronic self-antigen stimulation. These findings are the first to indicate that B cell anergy may also be operative in the MZ and contribute to the maintenance of B cell tolerance beyond naïve cells.

Unique Tolerance Mechanism Permitting Autoreactivity by Human CD5+ Pre-Naïve B Cells. Jisoo Lee[1], You-Hyun Lee[1], Nancy Longo[2], Colleen Satorius[2] and Peter E. Lipsky[3], [1]Ewha Woman's Univ Schl of Med, Seoul, South Korea, [2]NIAMS, N.I.H, Bethesda, MD, [3]National Institutes of Health, Bethesda, MD

Purpose: $CD5^+$ pre-naïve B cell population is a newly identified unique intermediate between transitional and naïve B cells during human peripheral B cell development. Although developmentally immature, $CD5^+$ pre-naive B cells, at the same time, have capacities of the mature naïve B cells to differentiate and present antigen. Because of functional immaturity, most of $CD5^+$ pre-naïve B cells are predicted to be removed by negative selection at peripheral tolerance checkpoint. However, because they possess functions of mature naïve B cells, inefficient tolerance checkpoint regulation at $CD5^+$ pre-naïve B cell stage, may result in systemic autoimmunity.

The study was performed to determine the tolerance mechanisms operating at $CD5^+$ pre-naïve B cell stage that may contribute to development of autoimmunity.

Method: Comprehensive comparative analysis of Ig H gene repertoire at transitional, $CD5^+$ pre-naïve, and naïve B cell human peripheral B cell developmental check point was performed. V_H rearrangements were amplified from genomic DNA of individual B cells by polymerase

chain reaction. Analysis included 133 V_H rearrangements from the transitional B cells, 371 from the $CD5^+$ pre-naïve B cells, and 185 from the naïve B cells. To predict the autoreactivity of a B cell receptor, presence of long IgH CDR3, and highly positively charged amino acids were analyzed.

Results: By comparing the distribution between the productive and the nonproductive repertoires of transitional, pre-naïve, and the naïve B cells, we found that negative selection for long and highly positive charged $CDR3_H$ occur at all human peripheral B cell developmental stages. However, analysis of the productive repertoires revealed that $CDR3_H$ length of pre-naïve B cells (52.5±12.5bp) was significantly longer compared to that of the transitional (48.9±12.6bp) and the naïve (49.0±10.5bp) B cells ($p<0.01$). This skewing for longer $CDR3_H$ length in pre-naïve B cells was due to maintenance of significantly longer germline D segment. Notably, an increased proportion of $CD5^+$ pre-naïve B cells were found in peripheral blood of patients with systemic lupus erythematosus (SLE).

Conclusion: Distinctive feature of longer $CDR3_H$ in the expressed repertoire of $CD5^+$ pre-naïve B cells suggests auto/poly-reactivity of these cells which may perform beneficial functions in normal immune regulation. However, ineffective tolerance checkpoint regulation at $CD5^+$pre-naïve B cells may contribute to autoimmune pathology in patients with SLE.

692

A Nonfucosylated Human Antibody to CD19 with Potent B-Cell Depletive Activity for Treatment of Autoimmune Diseases. Pina M. Cardarelli[1], Diann Blanset[2], Chetana Rao-Naik[1], Alison Witte[1], Ben Preston[1], Sharline Chen[1] and Michael J. Yellin[2], [1]Medarex, Sunnyvale, CA, [2]Medarex, Bloomsbury, NJ

Purpose: CD19 represents an attractive B-cell target for the treatment of autoimmune diseases with a number of potential advantages over CD20-directed therapies. Studies to characterize the in vitro and in vivo activities of a novel anti-CD19 antibody, MDX-1342, have been undertaken.

Method: A human anti-CD19 antibody was expressed in fucosyltransferase-deficient CHO cells to generate nonfucosylated MDX-1342. Assays measuring antibody binding to CD19-expressing cells and FcgRIIIa (CD16) transfectants as well as antibody-dependent cell-mediated cytotoxicity (ADCC) were conducted. In vivo B-cell depletion was monitored in cynomolgus monkeys following a single intravenous dose of MDX-1342. Flow cytometry was carried out by standard methods.

Results: Binding of MDX-1342 to human CD19-expressing cells was similar to its fucosylated counterpart. However, nonfucosylated MDX-1342 exhibited increased affinity for FcγRIIIa-Phe158 and FcγRIIIa-Val158 receptors and enhanced effector cell function, as demonstrated by increased potency and efficacy in antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis assays. MDX-1342 displayed low nanomolar binding to cynomolgus monkey CD19 and demonstrated increased affinity for cynomolgus monkey FcγRIIIa. Administration of MDX-1342 at 1 mg/kg in cynomolgus monkeys resulted in a 90% depletion of circulating B cells while parental anti-CD19 antibody induced approximately 50% depletion of B cells. Furthermore, the duration of B-cell depletion was longer for MDX-1342 compared to parental mAb. The ability of MDX-1342 to deplete cynomolgus monkey B cells was compared to rituximab. The extent and duration of B-cell depletion was similar for MDX-1342 and rituximab, despite higher levels of CD20 antigen on B cells, although the kinetics of depletion appeared to be initially more rapid with rituximab. B-cell repletion was documented in animals treated with both B cell-specific antibodies and there was no effect of treatment on serum IgG or IgM levels. Preliminary data available from an ongoing Phase 1 study of MDX-1342 in subjects with active rheumatoid arthritis (RA) despite treatment with methotrexate demonstrates potent B-cell depletion with single-dose (10 or 30 mg) administration of MDX-1342. Flow cytometric analysis showed that the $CD20^-CD27^+CD38^+$ plasmablasts, a cell population implicated in the pathogenesis of RA and systemic lupus erythematosus and known to be unaffected by anti-CD20-directed monoclonal antibodies, were also depleted in these human subjects.

Conclusion: MDX-1342 is a promising anti-CD19 antibody with enhanced effector function. Clinical studies of MDX-1342 in patients with RA are ongoing.

Characterization of LY2127399, A Neutralizing Antibody for BAFF. Kristy Kikly, Joe Manetta, Holly Smith, Dan Wierda and Derrick Witcher, Eli Lilly and Co., Indianapolis, IN

Purpose: LY2127399 is a fully human IgG4 monoclonal antibody with neutralizing activity against both membrane-bound and soluble BAFF. Dysregulated BAFF expression may contribute to autoimmune diseases via effects on abnormal B lymphocyte activation, proliferation, survival, and immunoglobulin secretion. Therefore, LY2127399 may be of potential therapeutic benefit in these diseases.

Method: Monoclonal antibodies were generated against human BAFF and screened for the ability to neutralize both membrane-bound and soluble BAFF and then characterized for species specificity and affinity. LY2127399 was tested for the ability to affect circulating B cells and a primary antibody response in cynomolgus monkeys.

Results: The affinity of LY2127399 for BAFF from various species was determined and the data indicate that LY2127399 has a very high affinity for human, cynomolgus monkey, and rabbit BAFF. No binding to mouse BAFF was detected. LY2127399 was able to neutralize soluble human, cynomolgus monkey, or rabbit BAFF with equal potency.

BAFF can exist in both a membrane-bound and soluble form, therefore, studies were undertaken to determine the relative potency of each form of BAFF. Our data demonstrate that membrane-bound BAFF is a more potent stimuli for B cells than soluble BAFF. In addition, LY2127399 was able to neutralize both human and cynomolgus monkey membrane-bound BAFF.

A study was conducted in cynomolgus monkeys to determine the effect of treatment with LY2127399 on the immune system, particularly on the proportion of B lymphocytes in the peripheral blood. To test the effect of LY2127399 on an immune response to a novel T-dependent antigen, tetanus toxoid was administered at the same time antibody treatment was started. LY2127399 had no statistically significant effect on tetanus-specific or total IgG levels following immunization with tetanus.

Serial blood samples were evaluated for flow cytometric assessment of the proportions of CD20, CD3, CD4, CD8, and CD14 cells through Day 171. Changes from baseline (Day 0) in the proportions of these cells were evaluated separately for each animal over the course of the study. The results showed that administration of LY2127399 was able to decrease the number of circulating CD20+ cells.

Conclusion: BAFF can exist in both a membrane-bound and soluble form. Our data demonstrate that membrane-bound BAFF is a more potent stimuli for B cells than soluble BAFF, therefore neutralization of both forms of BAFF is important for full therapeutic effect. LY2127399 is a high-affinity human antibody with neutralizing activity against membrane-bound and soluble BAFF. Administration of LY2127399 to cynomolgus monkeys results in a decrease in the number of circulating CD20+ cells but has no effect on the generation of an antibody response to a novel antigen.

Human Autoreactive Naïve B Cells Are Impaired in Their Response to Activation through the BCR and TLR9 Stimulation. Scott A. Jenks, Nataly Manjarrez-Orduño, Elise M. Palmer, Tam D. Quách and Iñaki Sanz, University of Rochester School of Medicine and Dentistry, Rochester, NY

Purpose: The maintenance of B cell tolerance remains poorly understood in humans. 9G4+ cells represent autoreactive B cells censored at least in part by anergic responses defined by poor Ca++ flux in response to BCR stimulation that renders them unable to form productive germinal centers. Here, we describe the biochemical and cellular responses of naïve 9G4+ cells in response to BCR and TLR9 stimulation.

Methods: Naïve B cells purified from healthy donors were used for CFSE dilution analysis after stimulation with α-IgM plus CpG ODN 2006. Naïve B cells were also stimulated for 18 hours to measure cell death and the induction of apoptosis. Proximal BCR signaling in 9G4 B cells was measured after anti-IgM stimulation for 2 minutes followed by intracellular staining with anti-phosphotyrosine specific antibodies.

Results: Stimulated human naïve 9G4+ cells proliferate significantly less than their 9G4- counterparts as estimated by the fraction of cells undergoing division ($p<0.05$) and the time between consecutive cell divisions (9G4+ cells take on average 22% longer to complete a cell

cycle; $p<0.02$). In addition, 9G4+ cells exhibit higher sensitivity towards activation-induced cell death (AICD), with a three-fold increase in the number of apoptotic cells and four times more total cell death. Moreover, the degree of AICD was dose-dependent for naïve 9G4+ cells but not for 9G4- naïve B cells. To understand the hyporesponsiveness of 9G4+ cells, we analyzed the phosphorylation of Syk, BLNK and PLCγ and found that BCR signaling is significantly attenuated 10%-20% in each of these signaling components. Signaling differences between the two populations were highlighted by a substantial decrease in phopsho-bright Syk/BLNK (64% reduction) and phospho-bright PLCγ (36% reduction) populations observed in 9G4+ versus 9G4- naïve B cells. Of significant interest, an even larger impairment in the response to BCR crosslinking was observed in 9G4+ in the transitional compartment (CD24/CD38 bright) relative to transitional 9G4- B.

Conclusion: Consistent with previous calcium flux studies and their *in vivo* behavior, healthy autoreactive 9G4+ cells display attenuated phosphorylation of BCR-associated signaling molecules. Such attenuation translates into poorer proliferation that cannot be rescued by TLR9 co-stimulation, mechanism known to trigger pathogenic autoreactive B cells in animal models. Enhanced spontaneous apoptotic propensity and increased AICD also contribute to the censoring of 9G4 cells. This report is the first demonstration of attenuated signaling in autoreactive transitional B cells which represent the target of critical tolerance checkpoints enforced at least in part by competition for limited BAFF supplies. Additional studies are underway to understand the ability of BAFF to enhance 9G4 survival and proliferation in the naïve and transitional compartments and to analyze the response of SLE 9G4 cells to similar stimulation conditions.

Identification of Human Anergic Naive B Cells. Tam D. Quách[1], Nataly Manjarrez-Orduño[2], Hongmei Yang[3] and Iñaki Sanz[1], [1]University of Rochester School of Medicine and Dentistry., Rochester, NY, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]University of Rochester

Purpose: B cell anergy represents an important mechanism of peripheral immunological tolerance that ensures functional censoring of mature autoreactive B cells that escape central tolerance checkpoints enforced by receptor editing and clonal deletion. While this mechanism has been well documented in transgenic and wild-type mouse B cells, the extent of its participation in human B cell tolerance remains to be fully established. However, it is well established that a significant fraction of human naïve B cells express low levels of surface IgM, a featured shared by anergic and acutely activated mouse B cells. In this study, we aimed to identify the functional behavior of strictly defined human naïve B cells (CD27-neg, ABCB1-neg, IgD-pos) using IgM expression levels to discriminate different naïve populations.

Method: Naïve B cells were strictly identified in peripheral blood and tonsils using multicolor flow cytometry as CD19+IgD+CD27-Mitotracker+. IgM staining was added to quantify and purify naïve fractions with either low expression of IgM (lower 30% of all naïve cells) or higher expression levels. Proliferation (CFSE dilution), activation and Ca++ flux was measured after BCR stimulation with anti-IgM or IgD antibodies. Autoreactivity was determined using a newly developed ANA-ELISPOT assay.

Results: the ability of naïve B cells to flux calcium in response BCR cross-linking is diminished in a dose-response manner in cells expressing low IgM levels (IgM^{lo}) whether they are stimulated through their IgM or IgD surface receptors. In addition, sorted IgMlo cells consistently display a phenotype characterized by the absence of activation markers (in contrast to SLE IgMlo naïve B cells) and poor response to in vitro stimulation as demonstrated by reduced CD69 upregulation, significantly weaker proliferation (determined by CFSE dilution to measure % of dividing cells and time between consecutive divisions) and poor antibody production. Moreover, the frequency of autoreactive IgM^{lo} cells was significantly increased as compared to similarly defined naïve B cells with higher levels of surface IgM.

Conclusion: BCR hypo-responsiveness due to sIgM downregulation is present in a much larger fraction of all human naïve B cells than previously reported and is likely to reflect a state of anergy induced by chronic autoantigen stimulation. Our results also provide preliminary evidence to suggest that in SLE a much larger fraction of naïve IgMlo cells represent activated cells as compared to the same phenotypic population in healthy controls. Combined, this work establishes anergy as a mechanism of tolerance that impacts a large fraction of all human naïve B cells and is likely to be defective in SLE

Titration of CD45 Expression Reveals Differential Regulation of Antigen Receptor Signaling in T and B Cells and Defines a BCR Signaling Threshold for B Cell Negative Selection. Julie Zikherman[1], Kristin Doan[1], Craig Jenne[1], Susan Watson[1], Christopher Goodnow[2], William Raschke[3] and Arthur Weiss[1], [1]UCSF, San Francisco, CA, [2]ANU, Canberra, Australia, [3]Sidney Kimmel Cancer Center, San Diego, CA

Purpose: Negative selection during lymphocyte development is required to establish a self-tolerant antigen receptor (AgR) repertoire. Here we take advantage of a novel allelic series of CD45 expression in mice which permits precise titration of BCR signal intensity and reveals a BCR signaling threshold for negative selection during splenic B cell development.

The receptor-like tyrosine phosphatase CD45 positively regulates AgR signaling by dephosphorylating the inhibitory tyrosine of the src family kinases (SFKs). It has been previously shown that CD45 is required for normal T and B cell development. Paradoxically, very low levels of CD45 are sufficient to fully rescue T cell but not B cell development. We show here that a negative regulatory role for CD45 that is unique to T cells accounts for this phenomenon.

Method: We have identified a novel allele of CD45, lightning, in which a single residue mutation produces low protein expression levels but normal isoform splicing. We additionally used previously described 'HE' mice that have supraphysiologic levels of CD45 expression. By crossing these two alleles to either wild type or null CD45 alleles, we have generated a series of mice in which CD45 expression levels are titrated across a broad range (0-180% of wildtype).

Results and **Conclusion:** Supraphysiologic doses of CD45 enhance Erk phosphorylation and calcium flux following BCR stimulation, while the opposite is true for T cells. Conversely, low CD45 expression enhances TCR signaling but impairs BCR signaling. We conclude that CD45 plays a negative regulatory role in TCR but not BCR signaling.

Increasing CD45 expression in both T and B cells results in progressive dephosphorylation of the inhibitory tyrosine of the SFKs. However, only in T cells is the activation loop tyrosine of SFKs dephosphorylated with increasing CD45 level. We propose that this provides a biochemical basis for differential regulation of T and B cell signaling by CD45 and, in turn, accounts for the differential capacity of low CD45 expression to rescue T and B cell development.

In mice with increasing CD45 expression and concurrently enhanced BCR signaling, we observe gradual reduction in the MZ B cell compartment, while B1 cell development is preserved. Although splenic T1 B cell numbers are similar across the allelic series, supraphysiologic CD45 expression produces sharp reductions in T2 and in mature (FO) B cell numbers relative to wild type. In contrast, B cell numbers are relatively preserved in CD45 deficient mice, with only a modest decline between T2 and FO B cell compartments. We conclude that the CD45 allelic series reveals a signaling threshold for negative selection at the splenic transitional stages of B cell development. This has important implications for the establishment of a self-tolerant B cell repertoire.

IL-17 and IL-23 Enhanced Il23r Expression in Germinal Center B Cells and Promoted IL-23-Induced Secretion of Plasma B Cells. Hao Li, University of Alabama at Birmingham, Birmingham, AL

Purpose: Interleukin-17 (IL-17) and IL-23 have both been shown to have a role in the development of rheumatoid arthritis, multiple sclerosis, inflammatory bowel disease and psoriasis. We have shown that IL-17 can promote the development of autoreactive germinal centers (GCs) by upregulating the expression of regulator of G-protein signaling (*Rgs*) genes. This enhances T-B cell interaction and development of spontaneous GCs in autoimmune BXD2 mice. Here, we investigated the role of IL-23 and IL-23R on B cells of BXD2 mice

Method: FACS analysis was carried out to determine the cell type that produces IL-23 and to detect $PNA^{+}Fas^{+}$ B cells which represent the germinal center B cells. Confocal imaging analysis was carried out to determine the location of IL-23 secreting cells. Immunohistochemistry staining was carried out to detect released IgM plasma cells in the spleen. B cells were purified using a CD19 MACS column method. Subpopulations of B cells were sorted by a FACS sorter for RT-PCR assay to determine the expression of *Il23r*. *In vivo* enhancement of the

levels of IL-23 and IL-17 was achieved by injection of mice with AdIL-23 and AdIL-17 (2 x 10^9 pfu/mouse, tail IV)**.** B-cell migration response to CXCL12 was determined using a transwell migration assay

Results: IL-23 was highly expressed by follicular dendritic cells (FDCs) that are located in the GCs in BXD2 spleens. The expression of *Il23r* was low in naïve B cells but was highly upregulated in PNA^+Fas^+ B cells in BXD2 mice. *In vivo* administration of AdIL-23 alone to BXD2 mice was enough to lead to a 100-fold increase in *Il23r* on B cells. *In vitro* stimulation of B cells with IL-17 (20 ng/ml) or IL-23 (20 ng/ml) separately resulted in a 1.5 fold increase in *Il23r*. Co-stimulation of B cells with IL-17 plus IL-23 resulted in a furthermore enhancement on the expression of *Il23r* (10 ± 5 fold) in a synergetic fashion. Consistent with this, *in vivo* administration of AdIL-17 plus AdIL-23 to C57BL/6 mice synergistically upregulated the expression of *Il23r* on B cells. Interestingly, IL-23 down-regulated the IL-17-induced *Rgs13* expression and abrogated the IL-17-induced B-cell migration arrest in response to CXCL12. AdIL-23 injection to BXD2 mice lead to increased IgM^+CD138^+ plasma B cells in the spleens and peripheral blood mononuclear cells and decreased PNA^+Fas^+ GC B cells in the spleens on day 14 after infection

Conclusion: The increased expression of *Il23r* on GC B cells of BXD2 mice may be a result of increased local production of IL-17 and IL-23. However, unlike IL-17 which is important for GC formation, IL-23 appears to promote the release of plasma B cells and thereby reduces the number of GC B cells. Suppression of IL-17 or IL-23 may both be beneficial to prevent either the development or the release of autoantibody forming B cells

The Application of Protein Microarrays for Autoantibody Profiling in Morphea Patients. Noori Kim[1], Quan-Zhein Li[2] and Heidi Jacobe[3], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Dallas, TX, [3]Department of Dermatology, Dallas, TX

The Application of Protein Microarrays for the Autoantibody Profiling of Morphea Patients

UTSW Medical Center, Dept. of Dermatology, Dept. of Medicine Division of Rheumatology, Dallas, USA

Purpose: This study utilized protein microarray technology for large-scale analysis of autoantibodies in morphea to: (a) detect multiple autoantibodies in microliter volumes of serum, (b) identify autoantibody profiles specific to morphea, (c) and provide an efficient means to uncover novel antigens by testing the reactivity of morphea sera to candidate antigens.

Method: Sera was utilized from 24 patients enrolled in the UTSW Medical Center Morphea Registry. All subjects had active disease and had not initiated therapy other than topical steroids. We compared the protein microarray signatures of morphea sera with non-immunologic and lupus erythematosus controls, matched for age, sex, and race. 16 new autoantigens were added to the previously published glomerular proteome array used for the evaluation of SLE activity. The added antigen specificities were incorporated based on literature searches linking the antigens to autoimmune sclerosing skin conditions. Manufacture, hybridization, and scanning of autoantigen microarrays and subsequent data analysis were performed according to the protocol previously published. (*Clinical and Experimental Immunology*. 147(2006):60-70.)

Results: Diagrams with row and column clustering were created with the Cluster and Treeview software (http://rana.lbl.gov/EisenSoftware.htm) and found that among the morphea sera, there was a tendency to group according to morphea subtypes, notably linear versus plaque type, for IgG, IgM, and IgA autoantibody profiling. When comparing morphea against SLE, the non-linear types, including plaque, generalized, and mixed, grouped with the SLE while linear morphea exhibited a distinct profile. Of the 92 autoantigens tested, contrary to previous reports, no significant increases were found in all subtypes of morphea of anti-singled stranded, anti-histone, and anti-topoisomerase antibodies. There was a trend toward an autoantibody reactivity pattern for the PDGFR alpha and beta autoantigen in morphea although not statistically significant ($p>0.06$). There was decreased IgG reactivity to aggrecan antibodies in morphea versus both normal and SLE controls ($p=0.0052$).

Conclusion: This study implies morphea subtypes display different autoimmune reactivity profiles across Ig subtypes, suggesting a disease specific signature. The reactivity intensities were greater for the IgG subclass than for IgM and IgA, providing insight into the pathogenesis of morphea on a molecular basis. Previously published data that suggested increased frequency of autoantibodies to single-stranded DNA, histones, and topoisomerase II-alpha in morphea were not duplicated in this larger cohort, while novel antigens like PDGF receptor had notable reactivity intensities in morphea. Protein microarrays for autoantibody profiling in morphea may allow for further characterization of this difficult disorder on a molecular level beyond the cutaneous lesions.

Ethnicity and Gender Differences in the Prevalence of Rheumatic Disease Associated Autoantibodies: The Multi-Ethnic Study of Atherosclerosis (MESA). Darcy S. Majka[1], Thanh Huyen T. Vu[1], Marius C. Teodorescu[2], Pamela J. Schreiner[3], Richard M. Pope[1], Kiang Liu[1] and Rowland W. Chang[1], [1]Northwestern University, Chicago, IL, [2]TheraTest Laboratories Inc, Lombard, IL, [3]University of Minnesota, Minneapolis, MN

Purpose: While ethnicity and gender influences on the prevalence of connective tissue diseases (CTDs) have been examined, the association between ethnicity and gender and CTD-related antibodies in subjects without CTDs has not been established. This study was performed to measure the relationship between ethnicity and gender and presence of CTD-related autoantibodies in a population-based sample from the Multi-Ethnic Study of Atherosclerosis (MESA).

Method: MESA is a multicenter prospective study initiated in 2000 to study subclinical and clinical cardiovascular disease in 6,500 Caucasian, African-American (AA), Hispanic, and Asian men and women aged 45-84.

We included all of the Caucasian (N = 555) and AA (N = 302) participants (47% women) from one MESA study site. We measured antinuclear antibodies (ANA), anti-cardiolipin antibodies (aCL IgM, IgG, IgA), anti-β2 glycoprotein I antibodies (anti-β2-GPI IgM, IgG, IgA), rheumatoid factor (RF IgM, IgA) and anti-cyclic citrullinated peptide antibodies (anti-CCP-2) by ELISA. The Connective Tissue Disease Screening Questionnaire (CSQ), a validated screening instrument with high negative predictive value for CTDs, was administered to identify subjects who might have a CTD. Multivariate logistic regression models measured associations between ethnicity and gender and antibody positivity.

Results: ANA, aCL (any isotype), anti-β2-GPI (any isotype), RF (any isotype) and anti-CCP were positive in 29%, 25%, 21%, 17% and 2% of participants respectively (Table 1 shows frequency by ethnicity/gender). After adjustment for age, education and smoking, AA ethnicity was significantly associated with ANA (OR 1.5 [95% CI 1.1, 2.1]) and RF (OR 1.5 [95% CI 1.0, 2.2]), and marginally associated with anti-CCP (OR 2.7 [95% CI 0.9-8.0]) compared with Caucasian ethnicity. AA ethnicity was also inversely associated with anti-β2-GPI (OR 0.5 [95% CI 0.4, 0.8]). Female gender was associated with ANA (OR 1.8 [95% CI 1.3, 2.5]) independent of the association between ethnicity and ANA. aCL was not associated with ethnicity or gender. The results did not change after excluding 118 participants with CSQ results indicating the possible presence of CTDs.

Conclusion: ANA, RF, anti-CCP and anti-β2-GPI positivity differ by ethnicity, and ANA by gender, in population-based participants without clinical CTDs. Because serum autoantibodies have been shown to predict the subsequent development of clinical CTDs, associations of ethnicity and gender with pre-clinical autoantibody positivity may have relevance for future studies on CTD development.

Table 1. Distribution of CTD-Related Autoantibodies by Gender and Ethnicity

	ANA	**aCL**	**anti-β2-GPI**	**RF**	**anti-CCP**
N*	855	857	847	840	838

Caucasian Men	23%	27%	23%	15%	0.8%
Caucasian Women	30%	27%	24%	14%	1.4%
AA Men	24%	21%	15%	18%	4.3%
AA Women	45%	21%	14%	24%	2.0%

* Analysis samples differ for each antibody after excluding missing values.

Factors Influencing Time Span Between Onset of Symptoms to First Consultation in Outpatient Rheumatologic Care Facilities in Germany. Gisela Westhoff[1], Edmund Edelmann[2], Joern Kekow[3], T. Meng[4], S. Simianer[4] and Angela Zink[5], [1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]Rheumatological Office Bad Aibling, 83043 Bad Aibling, Germany, [3]Univ of Magdeburg, Clinic of Rheumatology, Vogelsang-Gommern, Germany, [4]Wyeth BioPharma, Münster, Germany, [5]German Rheumatism Research Center, Berlin, Germany

Purpose: There is evidence that indicates a critical period of time for early arthritis during which disease processes can be markedly slowed or even halted. This knowledge has evoked multiple efforts to refer patients to rheumatological care as early as possible. We aimed at investigating what influences the time span from onset of symptoms to first rheumatologic consultation in Germany.

Method: 198 German rheumatologists reported in standardised manner information on disease duration, diagnoses, disease severity, and education of patients ≥18 years at their first consultation, as well as the specialisation of the referring physician. They also reported the average time span between making the appointment and the first consultation in their practice. Multivariate logistic regression analysis was performed to investigate the odds ratios for a first consultation within 6 months after symptom onset.

Results: Of the 11,045 patients at initial consultation, 4,973 (45%) were diagnosed with inflammatory rheumatic diseases such as RA (44.7%), PsA (21.1%), PMR (13.7%), AS (5.7%) or SLE (2.6%). Their mean age was 54.9 ±16 years and 67% of them were women. About half of the patients with inflammatory rheumatic diseases had their first rheumatologic consultation within 6 months after symptom onset (49.3%), whereas 31.2% attended only after 12 months (mean disease duration 21 ±47 months; median 6.1). The majority of the patients were referred to rheumatological care by general practitioners (78.5%); the rest by orthopaedic surgeons (12.1%), internists (5.5%) or other physicians (4%).

Factors such as older age, male sex, moderate or severe disease, and being referred to rheumatologic care facilities offering immediate appointments (<2 weeks) for new patients were significantly associated with having the first consultation within 6 months after symptom onset. There was no apparent association with the patients' formal education or the specialisation of the referring physician.

Adjusted odds ratios of being seen by a rheumatologist within 6 months after symptom onset

	adjusted OR	95% CI	P
male vs female	1.14	1.01 – 1.29	0.036
>75 vs <35 years	1.30	1.01 – 1.67	0.042
moderate vs mild activity	1.22	1.07 – 1.40	0.004
severe vs mild activity	1.28	1.08 – 1.52	0.005
average appointment <2 vs >12 weeks	1.93	1.50 – 2.49	<0.001

Conclusion: Neither the patient's educational level nor the specialisation of the referring physician had any influence on the time span until the patients' first visit at a rheumatologist. Consequently, the main focus should be on the appointment regulations of rheumatologists in order to increase their possibilities to see newly referred patients within the 'window of opportunity'.

701

Burden On Society From Low Back Pain- Less Than Previously Shown? A Population-Based Register Study. Anna Jöud[1], Martin Englund[2], Thor Lithman[1] and Ingemar F. Petersson[1], [1]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences, Lund University, Lund, Sweden, [2]Lund University, Lund, Sweden

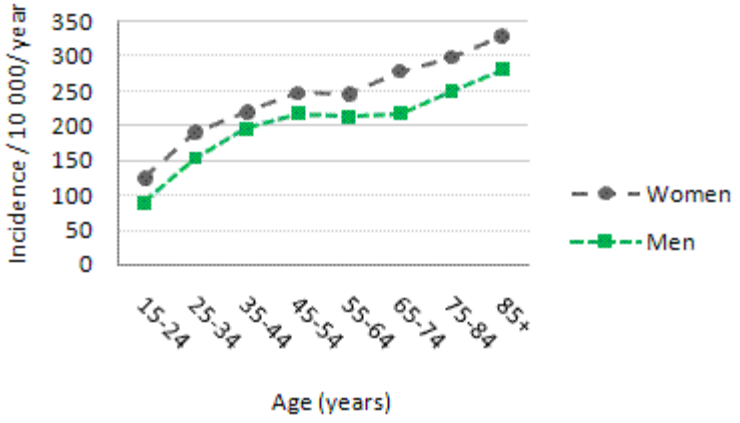
Purpose: Previous data on the occurrence of LBP focus on self assessed complaint. However, less is known about societal consequences of LBP through actual health care consumption. A focus more emphasizing actual health care utilization and costs, will give reliable and more profound figures on the impact of LBP on individual and society. The objective of this study was to study the annual incidence of LBP leading to actual health care seeking and the health care costs associated to this diagnosis.

Methods: Through the population-based Skåne Health Care Register (SHCR) covering nearly 1.3 million inhabitants in a well defined geographic region of Sweden we have access to individual data on e.g., age, sex, health care provider, and ICD-10 codes that are continuously registered for in- and outpatient care (ICD-10 codes for private care not included ~32% of all outpatient care). We identified all individuals who had at least one visit to a physician during 2007 with a primary ICD-10 diagnosis of LBP (M54.3, M54.4, M54.5, M54.8, M54.9) and no health care consultation with a physician due to low back pain 2004 through 2006. We calculated health care seeking incidence estimates for LBP, adjusted for the loss to private care.

Results: We identified 13885 individuals diagnosed with LBP 2007 but not 2004-2006 (56% women). The 2007 crude incidence estimate per 10,000 individuals was 228 (95% CI 227-229) and 186 (95% CI 185-187) for women and men respectively with increasing incidence with age (Figure 1). The overall peak incidence of 315 (95% CI 313-317) per 10,000 was seen in the ages over 85 years. The one year period prevalence of individuals receiving health care by a physician due to LBP was 2.8%.

The costs of all health care consumed in 2007 by patients diagnosed with LBP was €32 000 000, 12 percent of which were directly connected to a LBP diagnosis. The health care consumption and thus the costs of all health care consumed by patients diagnosed with LBP in 2007 was three times higher in the year of diagnosis than three years before with costs gradually increasing up until the year of diagnosis.

Figure 1. Annual incidence of LBP leading to health care seeking



Conclusion: Health care seeking incidence and prevalence of LBP was found markedly lower than previous self assessed estimates of LBP occurrence. Increasing health care seeking incidence with increasing age has not previously been shown suggesting that older people are

more affected by LBP and seek and/or seek health care due to LBP more frequent than young patients do. The health care consumption and the associated costs gradually increased up until first diagnosis of LBP.

Renal Impairment and Poor Outcomes of Allopurinol Therapy in US Gout Patients. B. J. Pandya[1], A. A. Riedel[2], L. K. Becker[2] and E. Krishnan[3], [1]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [2]i3 Innovus, Eden Prairie, MN, [3]Stanford University School of Medicine, Palo Alto, CA

Purpose: Allopurinol has been utilized in the treatment of hyperuricemia and gout for decades. The dose-limiting factor for allopurinol is renal function. The purpose of this study was to examine rates of renal impairment among gout patients and serum uric acid (sUA) management.

Methods: This was a retrospective analysis using pharmacy, medical, and laboratory data from January 2002-April 2008 for commercial enrollees identified with gout in a large US health plan. Patients had 1-year baseline and minimum 1-year (maximum 6-year) follow-up. Case definition of gout was based on at least two claims evidencing gout (medical claim with ICD9 274.x, prescription claims for gout medication, at least one of which was for allopurinol). Chronic kidney disease (CKD) stage was defined based on National Kidney Foundation standards. Patients on dialysis, kidney transplant, stage 5 (severe) CKD, or cancer were excluded. Multivariate logistic regression was used to identify the association between achievement of sUA goal (<6 mg/dL) and patient demographic and clinical factors.

Results: The study sample included 3,363 gout patients (88% male; mean age: 50 yrs; 38% with stage 2-4 CKD; mean follow-up time: 32 months). Prevalence of CKD was 26% (stage 2), 10% (stage 3), and 2% (stage 4). Significant associations between CKD stage, initial allopurinol dose, and sUA level were identified in this population. In unadjusted analysis, average initiation dose for patients whose sUA was successfully controlled was greater than for those whose sUA was not controlled (262 mg/day vs 222 mg/day, $P<0.001$). Average initial prescribed dose of allopurinol declined significantly with increasing CKD, from an average of 245 mg/day among those with no or stage 1 CKD, to 200 mg/day among those with stage 4 CKD ($P<0.001$). Only 28% of subjects with CKD achieved sUA goal ($P<0.001$) vs 37% without CKD, with rates of goal attainment decreasing with increasing CKD stage ($P=0.066$). Fewer than 7% of patients received allopurinol doses greater than 300 mg/day. Patients with stage 2, 3, and 4 CKD had 39%, 54%, and 74% lower odds of achieving goal compared to those without CKD ($P<0.01$), respectively, controlling for patient covariates.

Conclusion: In this population, increasing severity of CKD was associated with decreased allopurinol dosing and decreased likelihood of achieving sUA goal. Serum uric acid control is poor among gout patients in general and worse among those with renal impairment. A novel therapeutic agent to treat gout that does not require dose adjustment may be helpful in improving sUA control.

Pharmacotherapy Trends in a Large Cohort of Patients with Rheumatoid Arthritis. Jason Cooper[1], Lakevia Hall[1], Andrew Krueger[1] and S. Sam Lim[2], [1]Accordant Health Services, a CVS Caremark Company, Greensboro, NC, [2]Emory University, Atlanta, GA

Purpose: Rheumatoid arthritis (RA) is an inflammatory disease, triggered by the body's immune system. Approximately 1.3 million Americans currently have RA. The treatment goal for RA is to minimize joint damage early in clinical management with the use of appropriate disease-modifying antirheumatic drugs (DMARDs), which can be classified into two categories: biologic (BDMARD) and non-biologic (NBDMARD) therapies. This study aims to describe pharmacotherapy trends in these two therapeutic categories from a large cohort of patients with RA.

Method:

A disease management database containing comprehensive claims data from health plans and employer groups nationwide representing approximately 23 million covered lives was utilized for analyses. The RA cohort consisted of 16,175 patients in 2006 and 17,389 in 2008.Each patient was first identified as having RA via a claims algorithm utilizing diagnostic, procedural, medication, and revenue codes.

All patients confirmed their diagnosis and care by a rheumatologist and an introductory kit was sent to each patient's provider allowing them to refute the diagnosis.

RA therapies reviewed included BDMARDs, NBDMARDs and corticosteroids. Three years of medical and pharmacy claims data (service dates between January 1, 2006 to December 31, 2008) were analyzed. Health plan paid amounts were used for cost analyses.

Results:

The table below shows separate BDMARD, NBDMARD and corticosteroid utilization rates and average costs per person, 2006 vs. 2008.

	Utilization (% using therapy)		Costs (per person per year)	
	2006	2008	2006	2008
BDMARDs	32%	37%	$4,293	$5,161
NBDMARDs	60%	74%	$161	$155
Corticosteroids	46%	61%	$25	$19

Each patient's treatment regimen was also analyzed to understand which RA therapies were being employed in tandem. The most common combination utilized was a NBDMARD with a corticosteroid. A BDMARD coupled with a NBDMARD was the next most common regimen.

Conclusion: Pharmacotherapy trends from a large RA cohort derived from health plans and employers across the United States reveal a rise in utilization of BDMARDS, NBDMARDS and corticosteroids. However, BDMARDS are the largest driver of RA pharmacotherapy costs which continue to rise, while costs for the other therapies have dropped. If BDMARD use continues to increase along with costs, the burden on patients and healthcare systems may not be sustainable. Future studies examining cost effective use of biologic vs. non-biologic therapies are needed in this climate of health care utilization and cost containment.

Baseline (BL) Characteristics of Gout Subjects Influence Urate-Lowering (UL) Efficacy During Febuxostat and Allopurinol Treatment. M. A. Becker[1], P. MacDonald[2], S. Chefo[2] and R. L. Jackson[2], [1]University of Chicago, Chicago, IL, [2]Takeda Global Research & Development Center, Inc., Deerfield, IL

Purpose: To assess the impact of BL subject characteristics on the UL efficacy of febuxostat and allopurinol in subjects with gout and hyperuricemia.

Methods: Subjects in the CONFIRMS trial (N=2,269) were randomized (1:1:1) to receive 6 months of daily treatment with either febuxostat 40 mg, febuxostat 80 mg, or allopurinol 300 mg (or 200 mg if BL estimated creatinine clearance <60 mL/min). Effects of BL subject characteristics on achievement of serum urate level (sUA) <6 mg/dL at the final visit were explored via a multivariate regression model. BL factors and treatment were entered into an initial logistic regression model, and the backward selection technique was employed, keeping treatment effect in the model at every step. Model selection was completed once no additional factors were removed at the 0.05 significance level.

Results: Overall proportions of subjects achieving target sUA were 45%, 67%, and 42%, respectively, in the febuxostat 40 mg, febuxostat 80 mg, and allopurinol groups. The following BL characteristics were retained in the final model: treatment, sUA, age, gender, renal function, body mass index (BMI), tobacco use, and presence of tophi. After adjustment for BL factors, endpoint achievement rates with both febuxostat 40 mg and 80 mg were significantly higher than with allopurinol ($p \leq 0.037$), and were significantly higher with febuxostat 80 mg than with febuxostat 40 mg ($p \leq 0.001$). Furthermore, in subjects with BL moderate renal impairment, a significantly higher response rate occurred with febuxostat 40 mg than with allopurinol ($p < 0.05$). UL response did not differ between febuxostat 40 mg and allopurinol

treatment in subjects with mild renal impairment or normal renal function. In all treatment groups, UL response rates were greater in older subjects, women, adherent subjects, and nonsmokers as well as in subjects with lower BL sUA and BMI and no tophi.

Conclusion: After adjusting for multiple BL subject characteristics, UL with febuxostat 80 mg remained superior to UL with either febuxostat 40 mg or allopurinol. UL response rates in the febuxostat group were higher in those with mild/moderate BL renal impairment than in subjects with normal renal function.

Health Care Resource Utilization & Loss of Productivity in a Canadian Population of Patients with & without Lupus Nephritis.

Elaheh Aghdassi[1], Wendy Zhang[2], Yvan St-Pierre[3], Ann E. Clarke[3], Carolina Landolt-Marticorena[4], S. Morrison[2], Jiandong Su[5], Heather Reich[1], A. Herzenberg[4], J. Scholey[4], Christian A. Pineau[6], Janet Pope[7], CA Peschken[8], CaNIOS LuNNET Investigators, Joan E. Wither[9] and P. R. Fortin[2], [1]The University Health Network, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]McGill University Health Center, Montreal, QC, [4]University Health Network, Toronto, ON, [5]University of Toronto, Toronto, ON, [6]McGill University, Montreal, [7]St Joseph Health Care, London, ON, [8]University of Manitoba, Winnipeg, [9]University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: To determine whether Health Care Resource Utilization and Loss of Productivity differs between patients with Systemic Lupus Erythematosus (SLE) with & without Nephritis (LN & NLN, based on renal biopsy or ACR criteria).

Method: LN and NLN patients enrolled in a Lupus Nephritis study in Canada, were classified into those with active (ALN & ANLN) and inactive disease (ILN & INLN) based on SLE disease activity index (SLEDAI). Scores≥6 considered active disease. Patients reported on health care resource utilization and loss of productivity (patients & caregivers) from work and non-work activities in the 4 weeks preceding enrollment

Results: 141 patients (121 female, 20 male), 79 with LN (ALN: 53, ILN: 26) and 62 with NLN (ANLN: 38, INLN: 24) were enrolled. LN patients were significantly younger compared to NLN (36.5±1.5 vs 43.8±1.9 years; p=0.003) and had a higher SLEDAI score (9.5±0.8 vs 5.1±0.5; P=0.0001). SLE duration was similar between the two groups. Compared to NLN, patients with LN were more likely to visit health professionals (88.6% vs 74.2%; p=0.026) and had a higher number of visits to rheumatologists (0.8±0.1 vs 0.6±0.1; p=0.09); family physicians (0.9±0.2 vs 0.5±0.1; P=0.041) and nephrologists (0.3±0.1 vs 0.0±0.0; p=0.001). LN patients were also more likely to undergo diagnostic tests (81% vs 62.9%; p=0.016), most commonly including blood (1.7±0.2 vs 1.1±0.2; P=0.036) and urine tests (1.2±0.2 vs 0.5±0.1; p=0.001).

ALN patients had a significantly higher number of visits to all medical professionals (2.8±0.3 vs. 1.5±0.3; P=0.003), with more visits to rheumatologists and nephrologists compared to ILN. Number of diagnostic tests (X-rays, venipuncture, urine tests) were also significantly higher in ALN compared to ILN (4.3±0.5 vs 1.8±0.4; P=0.003).

In NLN, there was no difference in the number of visits to health professionals between ANLN & INLN, however, ANLN were more likely to have diagnostic tests such as blood (69.4% vs 37.5%; p=0.014) and urine tests (44.7% vs 16.7%; p=0.023).

The use of complementary therapies, assistive devices, emergency hospital visits and hospitalization periods were similar between all patient groups. Only 48% of LN and 45% of NLN were employed. Loss of productivity was similar for both patients and caregivers between all patient groups.

Conclusion: Health care resource utilization is much higher in LN patients, especially in those with an active disease. Although less than 50% of patients were employed, the loss of productivity was similar between all patient groups.

Does the Framingham Score Underestimate Cardiovascular Risk in Rheumatoid Arthritis? Cynthia S. Crowson, Elena Myasoedova, Veronique Roger, Eric L. Matteson, Hilal Maradit Kremers, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: Patients with rheumatoid arthritis (RA) suffer from an excess burden of cardiovascular disease (CVD). CV risk scores for the general population may not accurately predict CV risk for RA patients. The purpose of our study was to examine whether the Framingham risk score underestimates CV risk for RA patients.

Method: A population-based inception cohort of RA subjects who fulfilled 1987 ACR criteria for RA between 1-1-1988 and 1-1-2008 was assembled and followed until death, migration, or 7-1-2008. The presence of CVD (myocardial infarction [MI], CV death, angina, and heart failure [HF]) was ascertained throughout follow-up via medical record review, as was the presence of CV risk factors at RA incidence. The 10 year Framingham risk score for CVD (Circulation 2008;117;743-753) includes MI, CV death, angina, HF, stroke and intermittent claudication (IC). To apply these expected risk estimates to CVD events observed in our study, we multiplied the risk estimates by the ratio of CVD events to the combined stroke, IC and CVD events in the general population. Poisson regression models were used to obtain the standardized incidence ratio (SIR), which is the ratio of observed CVD in RA to expected CVD obtained from the Framingham risk score.

Results: The study included 490 RA patients aged 30-74 years without prior CVD (mean age of 52 years, 69% women). The patients were followed up for a mean of 8.4 years during which 64 patients developed CVD. The 10 year risk of CVD in women was 11.2% (95% confidence interval [CI]: 6.8%, 15.5%) and in men was 26.3% (95% CI: 16.1%, 35.2%). The median Framingham risk score was 4.6% for women (min: 0.6%, max: 31.0%) and 12.0% for men (min: 1.3%, max: 60.8%). The SIR for women was 1.9 (95% CI: 1.3, 2.8; p=0.002) and for men was 1. 6 (95% CI: 1.1, 2.3; p=0.03). This suggests that the Framingham risk score significantly underestimates CV risk in RA in both women (by 86%) and men (by 56%). Analysis of age groups revealed the SIR is largest for women ≥55 years and for men ≥ 45 years. While the Framingham risk score was not designed for patients ≥ 75 years, it is often used in this age-group of patients. Applying the Framingham risk score to RA patients (n=59) aged ≥75 years we found a pronounced underestimation of CV risk for both women (SIR: 5.8; 95% CI: 3.6, 9.5) and men (SIR: 4.8; 95% CI: 2.5, 9.1).

Conclusion: The Framingham risk score substantially underestimates CVD risk in RA patients of both genders, especially in older ages. In patients ≥75 years, the deficit in CV risk estimates was particularly large. This underscores the need for more accurate tools to predict the risk of CVD in RA patients.

Trends in Distal Forearm Fractures Among Older Women in U.S., 1991-2008. Fidel J. Martinez[1] and Carlos H. Orces[2], [1]Laredo Specialty Hospital, Laredo, TX, [2]Laredo Medical Center, Laredo, TX

Purpose: Distal forearm fractures are one of the most frequent osteoporotic fractures among older women. Moreover, this type of fracture increases the risk of sustaining subsequent osteoporotic fractures. Despite these facts, there is scarce data about the incidence of distal forearm fracture among older women in U.S. Therefore, the purpose of this study was to analyze trends in the incidence of distal forearm fractures among women 50 years or older in U.S. from 1991 to 2008.

Method: The National Electronic Injury Surveillance System All Injury Program (NEISS-AIP) was used to estimate emergency department visits for distal forearm fractures. The expanded system, NEISS-AIP, collects data about treatment of patients for all types and causes of injury in U.S. hospitals, regardless of whether the injuries are related to consumer products. The U.S. Census population data were used as the denominator to calculate age-specific distal forearm fracture rates per 100,000 persons. Fracture rates were age-standardized using the direct method for adjustment to the year 2000 U.S. population. Joinpoint Regression Program was used to evaluate temporal trends in fractures. The joinpoint regression starts with no joinpoint and tests whether one or more joinpoints are statistically significant and need to be entered into the model (a maximum of three joinpoints by default) to best fit the data over the period of study. In the final model, annual percentage change (APC) and corresponding 95% confidence interval (95% CI) were estimated for each trend segment detected. In the figure, the observed rates are represented by symbols and the predicted trends from the joinpoint regression model are represented by lines.

Results: An estimated of 304,106 distal forearm fractures occurred among women 50 years of age and older in U.S. during the study period. The number of fractures rose from 10,910 in 1991 to 26,721 in 2008, a 144% increase. The median age of women was 69 years. The

majority of fractures (62%) occurred at home. Thirty percent of distal forearm resulted from falls on the floor and 20% from falls on steps. Ninety percent of women were treated and released from EDs, whereas only 8% of fractures were hospitalized. Distal forearm fractures increased considerably in all age groups between 1991 and 2008. However, the highest increase in incidence rates was observed in women aged 60 to 69 years at an annual rate of 4.3% (95% CI, 4-5.6). After age-adjustment, fractures rates increased from 30.1/100,000 in 1991 to 53.8/100,000 persons in 2008, a 78% increase. Although the age-adjusted rates increased 3.1% (95% CI, 2.3-41) per year between 1991 and 2008, joinpoint analysis demonstrated a significant increase in rates between 1996 and 2005 at an annual rate of 5.3% (95% CI, 2.6-8.2) during this period (Figure 1).

Conclusion: The present study indicates that distal forearm fractures increased considerably among older women in U.S. between 1991 and 2008. The increase in fracture rates can not be explained simply by demographic changes of the population. Preventive measures should be implemented to decrease the burden of this type of fracture.

Which Comes First: Knee Malalignment or Joint Space Narrowing? David T. Felson[1], Yuqing Zhang[2], J. Niu[3] and D.J. Hunter[4], [1]Boston University School of Medicine, Boston, MA, [2]BUMC, Boston, MA, [3]BUSM, Boston, MA, [4]NEBH, Boston, MA

Purpose: While knee malalignment is strongly associated with increasing structural damage in osteoarthritis (OA) progression others have found that malalignment is not associated with knee OA incidence. Clarification of the temporal sequence between knee malalignment and OA occurrence is important because it will help us to understand the etiology of OA and guide us to develop effective clinical and preventive strategies for the disease. We performed sequence symmetry analysis to assess the temporal sequence between the knee alignment and joint space narrowing (JSN) in the Boston Osteoarthritis of the Knee Study (BOKS).

Methods: Subjects in BOKS had semi-flexed weight-bearing AP radiographs at baseline, 15-, and 30-month clinic visits (short-limb). The short-limb radiographs were read using a standard protocol and Efilm viewing software for anatomic axis (AA) (inter-observer ICC=0.96)

and were also read for JSN grade (0-3) in the medial (M-JSN) and lateral (L-JSN) compartments. The same protocols were used to assess JSN and AA across 3 time points. We defined a knee as having malalignment if AA was ≥ -2 (varus) or ≤ -6 (valgus). A knee was defined as having JSN in each compartment if the JSN score was ≥ 1. We performed sequence symmetry analysis to assess the temporal relation between JSN and malalignment using the time sequence symmetry ratio (i.e., the number of knees with JSN occurring before malalignment sequence divided by the number of knees with malalignment occurring before JSN sequence).

Results: Included were 38 knees that had both JSN and malalignment occurred during the 30-month follow-up period and each of these features presented at the different visits. Of them, JSN occurred before malalignment in 23 knees, and malalignment occurred before JSN in 15 knees. The time sequence symmetry ratio was 1.5 (95% CI: 0.8-3.2). When the analysis was limited to knees with both M-JSN and varus alignment (n=26), the time sequence symmetry ratio was 2.7 (95% CI: 1.1-7.6), suggesting M-JSN was more likely to occur before varus alignment.

Conclusion: While the number of knees in which JSN and malalignment occurred at different time points is small in our study, the results suggest that JSN was more likely to occur before malalignment but not in reverse. Further studies with more repeated assessments of JSN and knee alignment in a relatively short time interval are required to confirm the findings.

Assessment of the Adequacy of Conclusions in Superiority RCTs: The Example of 3 Rheumatic Diseases- Rheumatoid Arthritis, Spondyloarthropathies and Osteoarthritis. Sylvain Mathieu[1], Isabelle Boutron[2], Bruno Giraudeau[3], Martin Soubrier[1] and P. Ravaud[2], [1]Rheumatology. Gabriel Montpied Teaching Hospital, Clermont-Ferrand, France, [2]University of Paris VII, Bichat Hospital, Paris, France, Paris, France, [3]INSERM, CIC 202, France ; CHRU de Tours, France, Tours, France

Purpose: To assess the proportion and to define the causes of misleading conclusions in published randomized controlled trials (RCTs) assessing rheumatoid arthritis (RA), osteoarthritis (OA) or spondyloarthropathies (SPA). To determine whether conclusions were based on the primary outcome (PO).

Method: We searched Medline, Embase and the Cochrane Collaboration for RCTs assessing RA, OA or SPA published between January 2006 and April 2008. Characteristics of each article were extracted (journal information, funding source, financial ties of authors, Jadad scale, results for POs and authors' conclusions). The abstract conclusion was judged to be misleading according to the following criteria: PO not reported, conclusion based only on secondary outcome or sub-group results, discrepancy between results and conclusion, negative results suggested as equivalent and lack of balance benefit/risk discussion.

Results: Of the 145 reports selected, 18 (12.4%) were registered with a clear and similar PO in the registry and the published text and no misleading conclusion in the abstract. We analysed the 108 articles with a clear PO. Twenty-seven per cent had a misleading conclusion in the abstract (n=29). Abstract conclusion in disagreement with results (n=10; 34.5%) and lack of PO reporting (n=8; 27.6%) were the most frequent reasons. Negative results suggested as equivalent, conclusion based only on secondary outcome or on sub-group analysis represented respectively 17.2% (n=5); 13.8% and 13.8% (n=4) of cases of misleading conclusions. Finally, lack of benefit/risk balance discussion in cases of serious adverse events was found in 10.3% (n=3) of articles. Of the 108 studies analysed, 63 (53.3%) had positive results and 43 (39.8%) negative results. Studies with negative results had a higher frequency of misleading conclusions in the abstract than those with positive results (22/43 versus 5/63; $p<0.001$). Articles assessing OA, studies with an industrial affiliation of authors or those without clinically relevant results were more likely to report misleading conclusions in univariate analysis. Other factors did not reach statistical significance. In multivariate analyses, only negative results increased the risk of misleading conclusions (OR=9.27 [1.89-45.45]).

Conclusion: This study found a proportion of 27% of misleading conclusions in the abstracts of a sample of RCTs assessing RA, OA and SPA. Negative and clinically irrelevant results were risk factors of misleading conclusion.

The Prevalence of Psoriasis and Psoriatic Arthritis in Sweden – A Health Care Register Study. Sofia Löfvendahl[1], Elke Theander[2], Åke Svensson[3], Martin Englund[4], Aleksandra Turkiewicz[1] and Ingemar Petersson[5], [1]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences, Lund University, Lund, Sweden, [2]Dept of Rheumatology, Malmö University Hospital, Malmö, Sweden, [3]Dept of Dermatology, Malmö University Hospital, Malmö, Sweden, [4]Lund University, Lund, Sweden, [5]Lund University, Department of Clinical Sciences, Lund, Lund, Sweden

Purpose: The occurrence of psoriasis and psoriatic arthritis (PsA) leading to health care contacts is not well described before. The aim of this study is to estimate the prevalence of psoriasis and PsA in Sweden.

Method: In the Skåne Health Care Register (SHCR) (covering 1.2 million people or 1/8 of the Swedish pop.) full coverage on individual data on age, sex, health care provider, date of visit, ICD-10 diagnosis codes are continuously registered for both in- and outpatient care. We identified all individuals (no age restriction) with at least one clinic visit to a physician (both primary care and specialized care) between Jan. 1, 2001 and Dec. 31, 2007 having received any of the following psoriasis diagnoses (ICD-10 codes): psoriasis vulgaris (L40.0), generalized pustular psoriasis (L40.1), guttate psoriasis (L40.4), arthropathic psoriasis (L40.5), other psoriasis (L40.8) and psoriasis unspecified (L40.9). By cross-referencing with personal ID numbers from the Population Register (total pop. in southern Sweden Dec. 31, 2007= 1 199 357) those individuals identified in SHCR as deceased or relocated out of the county by Dec. 31, 2007 were excluded. For the individuals diagnosed with psoriasis between Jan. 1, 2001 and Dec. 31, 2007 we identified the number of patients with any of the following PsA diagnoses (ICD-10 codes): distal interphalangeal psoriatic arthropathy (M07.0), arthritis mutilans (M07.1), psoriatic spondylitis (L40.2), other psoriatic arthropaties (M07.3) and juvenile arthritis in psoriasis (M09.0). Those diagnosed using ICD-10 diagnosis code L40.5 or a combination of a psoriasis and a PsA diagnosis code were defined as having PsA. Prevalence estimate by Dec. 31, 2007 was calculated for psoriasis and PsA. The prevalence estimates were adjusted for the uncertainty generated by the loss of patients only seen by private practitioners for their psoriasis or PsA (appr. 15%).

Results: 13 716 individuals had sought health care, been diagnosed with psoriasis and were still alive and residents in the region by the end of 2007. The prevalence of diagnosed psoriasis in residents of southern Sweden (all ages) was 1.35% (95% CI 1.32, 1.37). Out of the individuals diagnosed with psoriasis, 2 491(18.2%) were identified as having PsA. This indicates a prevalence of diagnosed PsA in residents of southern Sweden of 0.24% (95% CI 0.23, 0.25) by the end of 2007. Among those diagnosed with PsA 1 163 (46.7%) were diagnosed using ICD-10 diagnosis code L40.5 and 1 328 (53.3%) were diagnosed with a combination of a psoriasis and a PsA diagnosis code.

Conclusion: Using register data of true health care consumption gives more relevant prevalence estimates of psoriasis and PsA. Thus, we found that at least one fifth of all individuals diagnosed with psoriasis also had health care contacts for diagnosed PsA.

Developing a Cinical Score for Knee OA in the Osteoarthritis Initiative. Charles B. Eaton[1], Timothy McAlindon[2], Joan M. Bathon[3], Mary Roberts[4], Michael C. Nevitt[5] and C. K. Kwoh[6], [1]Alpert Medical School of Brown University, Pawtucket, RI, [2]Tufts Medical Center, Boston, MA, [3]Johns Hopkins University, School of Medicine, Baltimore, MD, [4]Pawtucket, RI, [5]University of California, San Francisco, San Francisco, CA, [6]UPitt, Pittsburgh, PA

Purpose: There is no validated assessment to measure knee osteoarthritis clinical progression over the long term in an observational setting. Instruments such as KOOS and WOMAC and their subscales are highly inter-correlated and rely exclusively on self-report. We evaluated the use of principal component analysis of the baseline OAI data set in the attempt to define independent or orthogonal factors that could be summed to define the clinical severity of an index knee. Such a knee-specific clinical score could be used to assess clinical progression.

Method: Of the 4796 subjects, 3310 had complete data in the baseline OAI dataset 0.2.2. We evaluated 73 "clinical" variables related to an index knee that could vary from exam to exam in OAI data set that represented symptoms, pain, activity avoidance, KOOS, WOMAC, physical exam, medication use, physical activity, strength testing, walking times to define a non-singular matrix. Using eigenvalues of 1.0 for variable selection, repeated rotated factor pattern analysis was done. Orthogonal factors were defined based upon loading scores >0.5 for each of 38 individual clinical variables. **Results:** Overall sampling frequency was 0.829. We found 8 orthogonal factors that explained 91% of the variance of the clinical symptoms associated with an index knee. Below are the eight factors defined and the percent variance explained by each orthogonal factor.

Factor	Components	% variance
Factor 1	Pain, WOMAC/KOOS subscales, overall pain rating	22.18
Factor 2	Pain ratings compared to past (X-sectional)	14.08
Factor 3	Good Strength Chair- Production/relaxation limits	11.20
Factor 4	20meter and 400 meter walk test	10.41
Factor 5	Good Strength Chair- Maximum Force- flexion and extension;	9.55
Factor 6	Activity limited due to knee pain; limitation of activities to prevent knee pain	9.52
Factor 7	Use of glucosamine and chondroitin in the past six months	7.11
Factor 8	Chondroitin and/or glucosamine current use	7.11
Total		91.15

Conclusion: Eight independent, uncorrelated clinical "factors" defined by 38 variables allow for a summary score to be developed for each knee with excellent explanatory power. Future research will focus on how this clinical score changes over time, responds to therapy, and correlates with radiographic, MRI and biomarker changes.

Prevalence of Staphylococcus Aureus Colonization Among Those Using Biologic Therapy. Atul A. Deodhar[1], Shellie Yamashita[1], Benjamin Ehst[1], Antony Bakke[1], Andrew Blauvelt[1], Brian Andrews[1], Robert Vega[2] and Kevin Winthrop[1], [1]Oregon Health & Science University, Portland, OR, [2]Oregon State Public Health laboratory, Portland, OR, Portland, OR

Purpose: Methicillin-resistant *Staphylococcus aureus* (MRSA) infection rates in the community are increasing. There is little community-level data regarding *S. aureus* colonization prevalence and infectious risk in patients with autoimmune inflammatory diseases, particularly those receiving anti-tumor necrosis factor (TNF) and other biologic immunomodulating therapies.

Method: We prospectively identified patients with autoimmune inflammatory disease within the rheumatology and dermatology clinics of Oregon Health & Science University in Portland, Oregon. Participating patients receiving or being considered for biologic therapy (etanercept, infliximab, adalimumab, rituximab, abatacept) were surveyed for the presence of *S. aureus* infection risk factors and were assessed for *S. aureus* colonization. Specimens collected from the bilateral nares and inguinal folds of all subjects were cultured utilizing standardized laboratory *S. aureus* isolation procedures and further screened for the presence of MRSA utilizing Spectra™ MRSA test media (Remel Scientific®) and mannitol salt agar containing 4 mcgs of oxacillin (MSAO, Remel Scientific). Screen positive organisms isolated from either of these two media were further screened with Mueller Hinter agar containing 6 mcgs of oxacillin and tested for the presence of PBP2' (a penicillin binding protein encoded by the mecA gene).

Results: We have enrolled a total of 222 inflammatory disease patients (rheumatoid arthritis n=58, psorisias or psoriatic arthritis n=140, ankylosing spondylitis n=10, combination of two conditions n=12, other n=2). At baseline, 78 (35%) of patients were colonized with *S. aureus*, of which 4 (5%) were methicillin-resistant (MRSA). One hundred thirty (57%) patients were on biologic therapy at time of assessment. Colonization rates were similar between biologic users and non-users (33% and 38% respectively), between RA and psoriasis patients, and similar to that historically reported for the general U.S. population (30%). Colonization did not differ between biologic agents, but was more common in RA patients if they were receiving prednisone at baseline (RR 0.40, 95% CI 0.1-1.2), but this did not reach statistical significance (p=0.06).

Conclusion: Inflammatory disease patients in Portland, Oregon, have similar rates of *S. aureus* colonization as the general population, and the risk of colonization in this cohort is not modified by the receipt of biologic therapy. Prospective follow-up is necessary to ascertain if colonization increases the risk of subsequent *S. aureus* infection.

The Association of Social Network Factors with Total Hip Replacement (THR) in the SOF Cohort: The Study of Osteoporotic Fractures Research Group. B.L. Wise[1], N. Parimi[2], M. Nevitt[3], J. Cauley[4], R.K. Chaganti[3] and N.E. Lane[1], [1]UCDMC, Sacramento, CA, [2]CPMC, SF, CA, [3]UCSF, SF, CA, [4]U Pitt, Pittsburgh, PA

Purpose: The decision making process that patients use when deciding whether to have a joint replacement is reported to be influenced by their social support. This study examines the association of social network with THR in elderly Caucasian women.

Method: We conducted a nested cohort study among women who were participants in the Study of Osteoporotic Fractures, a cohort of 9704 white women 65 years of age or older at baseline followed for 14 years. At visit 2 and visit 4, the Lubben Social Network Scale was completed, and hip x-rays were obtained at baseline and visit 5. Two sets of participants were selected: the first set included participants who had completed information at baseline and visit 2 with self reported THR ascertained at visit 5; the second set included those with completed information at visit 4 and visit 5 with self reported THR ascertained at visit 8. We restricted the analysis to participants who reported hip pain on most days of the month and had radiographic osteoarthritis defined by a modified Croft grade>=2. Participants who reported rheumatoid arthritis, Paget's disease, had bilateral THR prior to visit 2, or who had hip fracture prior to the reported THR were excluded. The two sets of participants were combined into one dataset with incident THR used as a dichotomous outcome measure. Descriptive analyses and multivariate logistic regression were performed using GEE to account for within-person correlation, with outcome as THR versus no THR and using the Lubben Social Network Scale and other covariates most closely preceding the reported THR. Models were adjusted for age, BMI, education, hip pain while resting and hip pain on internal rotation, and self-reported health change in the prior 12 months.

Results: There were 112 case (THR) hips in 104 women and 301 non-case (no THR) hips in 244 women. At baseline, cases were less obese (BMI 26.2 vs 27.5; p=0.009), had more education (45.2% had >12 years vs. 32.4% in controls; p=0.022), had fewer co-morbid conditions (average of 0.25 conditions vs 0.33; p=0.274), more often had hip pain on internal rotation (16.4% vs 5.2%; p=0.004) and more often had hip pain when resting (56.5% vs 29.7%; p<0.001). Descriptive analyses suggest that those who had a THR were slightly more independent: 25.3% saw their closest friend every day as compared with 28.1% in controls (p=0.123); 37.4% of cases saw their closest relative daily versus 45.2% in controls (p=0.245). However, no individual or summary component of the Lubben Social Network Scale was significantly associated with THR as an outcome in the adjusted regression analysis.

Conclusion: We found no evidence for a significant influence of social network factors on risk of THR. Hypothesis generating trends suggested that those that undergo THR may have fewer social interactions with family and friends, thereby possibly being more independent.

The Georgia Lupus Registry: A Population-Based Estimate of the Incidence and Prevalence of Childhood-Onset SLE. S. Sam Lim[1], Rana Bayakly[2], C.G. Helmick[3], Caroline Gordon[4], Kirk Easley[1], Neeta Shenvi[1], Larry B. Vogler[1] and Cristina M. Drenkard[1], [1]Emory University, Atlanta, GA, [2]Georgia Department of Human Resources, Atlanta, GA, [3]Centers for Disease Control and Prevention, Atlanta, GA, [4]University of Birmingham, Birmingham, United Kingdom

Introduction and Purpose: There are no population-based studies estimating the prevalence and incidence rates of childhood-onset SLE in the US. Our aim was to describe these rates in Atlanta from 2002 through 2004.

Methods: The Georgia Lupus Registry is a population-based registry designed to estimate the incidence and prevalence of SLE in Atlanta, Georgia (Fulton and DeKalb counties). Case-finding utilizes multiple sources. Trained abstractors document nearly 250 demographic and clinical elements from medical records of potential SLE patients. All sources with potential SLE patients (<20 years old) have been abstracted. 31 incident and 51 prevalent patients met the case definition for this study: having either ≥4 ACR criteria or 3 ACR criteria and diagnosis of SLE by a rheumatologist.

Results:

Table 1. Annual average standardized incidence rates in Atlanta (2002-2004)

		Age Group	Population (0-19 years old)	Cases[a]	Age Standardized IR[b] (95% CI)[c]	Crude IR (95% CI)[c]
Overall			1,293,062	31	2.5 (1.6-3.4)	
Black	Total		745,397	27	3.6 (2.3-5)	
	Male		376,039	6	1.6 (0.3-2.9)

		15-19		1		6 (0.2-33.6)

[a] remainder of cases were Asians with CI's too wide and estimates too unreliable to report

[b] incidence rates (IR) and prevalence rates (PR) per 100,000; calculated by direct method using US census data (2000)

[c] calculated by exact method

[d] both of Hispanic ethnicity

Conclusion: This is the first population-based assessment in the US of incidence and prevalence rates in childhood-onset SLE. As in adults, cases were disproportionately female and black. Rates were highest in the late teens (after menarche). The black to white ratio appears to be greater than that reported in the adult literature.

715

The Association of Obesity On Prevalent Hyperuricemia and Incident Gout in Women in the Atherosclerosis Risk in Communities (ARIC) Study. Mara A. McAdams[1], Janet W. Maynard[2], Alan N. Baer[2], Anna Kottgen[1], Allan C. Gelber[2] and Josef Coresh[1], [1]Johns Hopkins School of Public Health, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Previous research in gout has focused on men. The effect of anthropometric risk factors on prevalent hyperuricemia and incident gout in women is unclear. In the Atherosclerosis Risk in Communities (ARIC) Study, we evaluated the association of obesity with hyperuricemia and gout in women.

Methods: ARIC is a population-based cohort of 15,792 individuals (8,710 women) aged 45-64 at enrollment who participated in four examinations (3 years apart). We restricted our study population to Caucasian and African-American women with no history of gout at their first study visit. Serum urate was measured at visits 1 and 2, and we used the mean of these two measures. Hyperuricemia was defined as a mean serum urate greater than 7.0 mg/dL. Anthropometric variables were obtained at baseline and included body mass index (BMI) and waist-to-hip ratio (WHR). BMI was examined as continuous and categorical (<25, 25-30, 30-35, >35 kg/m^2) variables. Obesity was defined as BMI greater than 30. High WHR was defined as > 0.8. Weight change was calculated by subtracting the participant's weight at cohort entry from her self-reported weight at age 25. Weight change was categorized as: no weight change (weight loss or gain <10 lbs), low weight gain (weight gain of >10 to <30lbs), and high weight gain (>30 lbs). The multivariable model was adjusted for baseline age, race, diuretic and oral contraceptive pill use, menopausal status, hypertension, diabetes, and chronic renal insufficiency. Incident cases of gout were identified by self-report at visit 4.

Results: Of the 8,505 women with serum urate measurements, 14.9% were hyperuricemic. Obesity, WHR, and weight change were significantly associated with baseline hyperuricemia. The association remained after adjusting for known risk factors for hyperuricemia. Additionally, 113 women (1.3%) developed gout over nine years of follow-up. At baseline, all of the women who developed gout were obese, yet only 38% were hyperuricemic.

	Unadjusted risk of hyperuricemia		**Adjusted risk of hyperuricemia**	
	PR	CI	PR	CI
BMI (5 kg/m^2) change	1.53	1.49, 1.57	1.40	1.35, 1.45
BMI				
<25 (reference)	1.0		1.0	
25-30	2.68	2.24, 3.21	2.21	1.84, 2.64
30-35	4.90	4.11, 5.85	3.55	2.95, 4.26
35-40	7.33	6.18, 8.70	4.88	4.04, 5.90
Obese	3.33	3.01, 3.69	2.44	2.18, 2.73
High WHR	4.35	3.24, 5.84	3.04	2.26, 4.09
Weight change				
No change (reference)	1.0		1.0	
Low weight gain	1.43	1.14, 1.81	1.41	1.12, 1.77
High weight gain	4.03	3.29, 4.94	3.09	2.52, 3.79

Conclusion: In a population-based cohort of middle-aged women, we found obesity, high WHR and weight gain to be strongly associated with hyperuricemia. Additionally, all women who developed gout over nine years of follow-up were obese at baseline. Obesity is a risk factor for hyperuricemia and may be useful for prediction of incident gout in women.

Health Literacy in Childhood Arthritis. Elizabeth Levey, Jonathan Erlich, Linda Wagner-Weiner and Karen Onel, Univ of Chicago, Chicago, IL

Purpose: Health literacy is defined as an individual's capacity to obtain, process and understand health information. Poor literacy has been associated with worse health status. In adults, low literacy has been linked to a poorer understanding of the disease and worse self-management skills. The degree to which parental health literacy affects outcomes for children with chronic disease is less certain. Juvenile Idiopathic Arthritis (JIA) presents an appropriate model to explore this relationship between parental literacy and child health outcome. We present here results of literacy assessments done in an urban pediatric rheumatology center to establish baseline frequency of poor literacy in families with JIA.

Method: Sixty-eight children with JIA and their parents were recruited for the study. Demographic information was collected. Health literacy skills, including reading, vocabulary and numeracy, were assessed by administration of Newest Vital Signs (NVS), Rapid Estimate of Adult Literacy in Medicine (REALM) and Rapid Estimate of Adolescent Literacy in Medicine for teenagers (REALM-Teen). Disease activity was assessed using the Physician and Parent Global Assessment (GA). Descriptive statistics were performed using Microsoft Excel and STATA. A p-value <0.05 was used to define statistical significance.

Results: 49 (72.1%) parents of children with JIA were considered to have adequate literacy, while 19 (27.9%) parents were considered to have limited literacy using both NVS and REALM. There was a strong correlation between adult and child literacy scores in the same families. There were no differences in ages between both groups. The adequate literacy group had a greater percentage of subjects who lived with two parents (75.5% v. 42.1%, $p<0.01$) and who had a household income above $30,000 (89.4% v. 29.4%, $p < 0.001$). There was a large discrepancy between the two groups for the type of insurance carried; 80% of adequate literacy subjects had private health insurance while only 26% of the limited literacy group did, with the remaining 74% relying on Medicaid, Medicare or out-of-pocket payments ($p<0.0001$). No significant difference was found between the groups for Physician or Parent GA scores, however, while there was a statistically significant correlation between the physicians and parents score for the adequate literacy group, there was not for the limited literacy group ($r=0.42$, $p<0.05$; $r=0.21$, $p>0.05$).

Conclusion: We found significant baseline differences between parental literacy ability when analyzing demographic data. Further, there was strong relationship between limited parental and child literacy. Finally, there was a large discrepancy in insurance types between the two literacy groups. Of concern, there was a lack of correlation between the ratings of parents with limited literacy on GA and the physician's GA. Previous studies have suggested that children with private insurance do better than those without despite seeing the same physicians in the same office. This outcome gap may be explained in part by the disparity in health literacy between the two groups preventing understanding of disease severity. We plan to follow these patients over time to better understand effects of parent/child literacy on health outcomes.

Comparison of Baseline Characteristics and Outcome After One Year in Three European Early Arthritis Clinics. Maria D. Mjaavatten[1], Jennie Ursum[2], Tiina Veldi[3], Dirkjan van Schaardenburg[2], Kati Otsa[3] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Jan van Breemen Institute, Amsterdam, Netherlands, [3]East Tallinn Central Hospital, Tallinn, Estonia

Purpose: To compare baseline characteristics and outcome after one year between early arthritis clinics (EAC) in The Netherlands, Estonia, and Norway.

Method: Adult patients with ≥ 2 swollen joints with symptom duration ≤ 16 weeks included from Jan 1st 2005 and who were eligible for one year follow-up time from three early arthritis clinics (Jan van Breemen Inst., Amsterdam (JBI)/Tallinn/Norwegian Very Early Arthritis Clinic (NOR-VEAC)) were included in this study. The EACs in Estonia and Norway use the same protocol. Baseline characteristics and inflammatory activity (measured by Disease Activity Score-28 (DAS28)) at inclusion and after one year in the three clinics were compared by ANOVA and Chi-square statistics. DAS28 outcome was also compared using ANCOVA adjusted for the following factors: age, sex, anti-cyclic citrullinated peptide (anti-CCP) and rheumatoid factor (RF) positivity, disease duration, and baseline DAS28.

Results: 629 patients were included in the study (JBI 153, Tallinn 71, NOR-VEAC 405). Baseline characteristics differed significantly between the EACs for age, disease duration, gender distribution, percentages of anti-CCP and RF positives, joint counts, DAS28 (table), as well as for ESR, patient global VAS, and HAQ (data not shown). Patients improved substantially over one year in all three EACs. DAS28 after one year was not significantly different between EACs when adjusted for baseline characteristics (p=0.15, ANCOVA), while age, sex, anti-CCP, duration and baseline DAS28 were significant variables in the ANCOVA analysis.

Conclusion: Patients in three European EACs differed significantly with regard to several characteristics and disease activity, possibly due to a higher incidence of reactive arthritis in Tallinn and Norway. A substantial improvement of inflammatory activity was seen after one year in all clinics. DAS28 outcome was similar when adjusted for differences in baseline characteristics. Age, sex, disease duration, anti-CCP positivity and DAS28 level at inclusion had impact on the outcome.

Table. Comparison of baseline characteristics and disease activity in the three EACs.

	JBI	Tallinn	NOR-VEAC	p-value
Age (years)	53.9	46.4	46.7	<0.001
Females (%)	68.0	78.9	55.9	<0.001
Anti-CCP pos (%)	48.4	25.4	20.6	<0.001
IgM RF pos (%)	45.1	25.4	18.2	<0.001
Duration (days)	61.0	42.7	41.4	<0.001
28-SJC	5.85	3.87	4.22	0.001
28-TJC	6.12	6.10	4.71	0.019

718

Frequency and Cost of Joint Replacement Surgery for Patients with Rheumatoid Arthritis: A Population-Based Study in Canada.

R.L. Dobson[1], K. Osenenko[1], SM Szabo[1], Sanjoy Roy[2], Mary Cifaldi[2], Walter P. Maksymowych[3], V. Strand[4] and AR Levy[1], [1]Oxford Outcomes, Vancouver, BC, [2]Abbott Laboratories, Abbott Park, IL, [3]University of Alberta, Edmonton, AB, [4]Stanford University, Palo Alto, CA

Purpose: Rheumatoid arthritis (RA) causes joint damage, often necessitating surgical joint replacement. Clinic- and hospital-based studies have estimated that 7%–27% of patients with RA require total joint replacement surgery; however, variable follow-up periods and/or small sample sizes limit generalizability of these results. This study used a population-based database to estimate the frequency, timing, and cost of joint replacements for patients with RA.

Method: A retrospective cohort study was conducted using the population-based, longitudinal Régie de l'Assurance Maladie du Québec patient-level, physician-billing, provincial database. The incident RA cohort included continually registered patients with ≥2 physician *International Classification of Diseases, Ninth Revision* (ICD-9) diagnoses of RA (714.0, 714.1, or 714.2) from 1998–2007, with first RA diagnosis in 1998. Total joint replacements were classified according to the *Canadian Classification of Diagnostic, Therapeutic, and Surgical Procedures* (CCP) codes 93.5 (hip) and 93.41 (knee), and *Canadian Classification of Health Interventions* (CCI) codes 1.VA.53 (hip) and 1.VG.53 (knee). Frequency of total joint replacements (hip+knee), mean and median time to surgery were estimated. Only 1 hip or

knee replacement per patient was included in the analysis. Direct hospitalization costs were estimated using Case Mix Group resource use and cost data from the Canadian Institute for Health Information.

Results: The incident cohort included 3,340 patients diagnosed with RA in 1998, of which 2,367 (70.9%) were female. The median age at entry was 52 years. Of these 3,340 patients, 300 (9.0%) had ≥1 total joint replacement; 24 (0.7%) had both total hip and total knee replacements; 144 (4.3%) had total hip replacement; and 180 (5.4%) had total knee replacement. The mean and median time to total hip replacement from first diagnosis of RA was 3.7 and 3.2 years (*interquartile range* [IQR], 1.3–5.8), respectively. For total knee replacement, mean and median time from cohort entry were 4.1 and 4.2 years (IQR, 1.7–6.0), respectively. Hip and knee replacement surgeries were estimated to cost approximately $3.18 million Canadian dollars (2009; 95% confidence interval [CI], 3.10–3.30 million) or an average of $9,370 (95% CI, $9,129–$9,735) per knee replacement and $10,367 (95% CI, $10,100–$10,770) per hip replacement.

Conclusion: Joint replacement surgeries contribute substantially to the burden of RA. In this large, longitudinal, population-based study, almost 1 in 10 patients with RA required joint replacement surgery, with 25% of these surgeries occurring within the first 2 years after diagnosis. Early, appropriate treatment of RA may prevent joint damage and result in fewer or delayed joint surgeries.

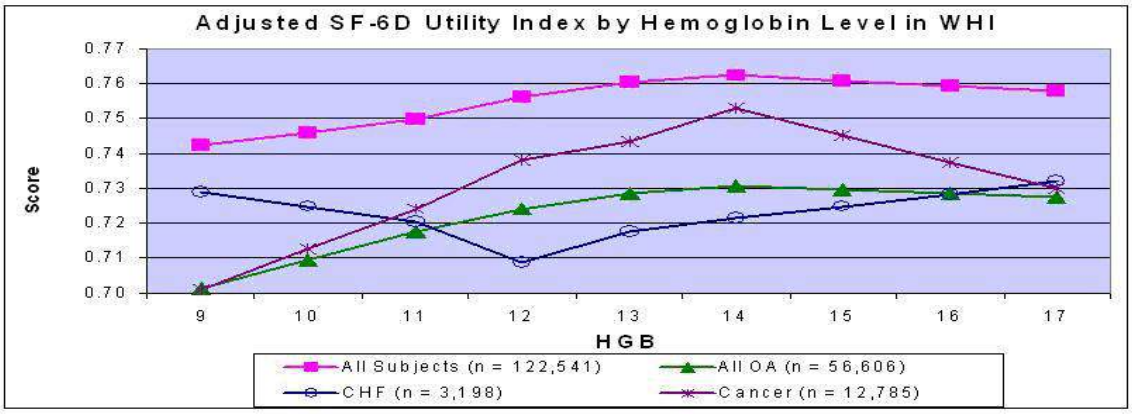
Health Utilities and Hemoglobin Levels in Post Menopausal Women with Osteoarthritis, Cancer and Congestive Heart Failure: The Women's Health Initiative. Brooke Harrow[1], Charles B. Eaton[2], Annlouise R. Assaf[3] and G. Sands[4], [1]Abt Bio-Pharma Solutions, Inc., Lexington, MA, [2]Alpert Medical School of Brown University, Pawtucket, RI, [3]Pfizer, Inc. and Alpert Medical School of Brown University, Providence, RI, [4]Pfizer Global Pharmaceuticals, New York, NY

Purpose: Chronic disease and their treatments can lead to differential blood loss and anemia. The assignment of utility weights to hemoglobin (HGB) levels can provide an excellent resource for future studies of the cost-effectiveness of interventions developed to mitigate blood loss. We examined the mean utility weights adjusted for co-morbidities, as measured by the Short Form Medical Outcomes Health Utility summary scale (SF-6D) for varying hemoglobin levels in post-menopausal women using data from the Women's Health Initiative (WHI). We looked at how these weights vary for women with self-reported CHF, Cancer, or Osteoarthritis.

Method: Health utility weights as measured by the (SF-6D) scale were examined for various HGB levels. Utility weights are preference measures or values that are assigned to health states on a scale from zero to one where one represents perfect health and zero represents death. Multiple linear regression analyses were used to evaluate the independent association between HGB and the SF-6D, while adjusting for potential confounding by socio-demographic characteristics, medication use, depression, associated disease states. Adjusted least squared means were calculated based upon the regression analyses. These mean values for the SF-6D utility weights were stratified by hemoglobin level for the sample as a whole as well as separately for those with self-reported CHF, Cancer and/or “Osteoarthritis”. “Osteoarthritis” was defined as self-reported arthritis and not reporting rheumatoid arthritis.

Results: This figure shows the adjusted mean utility weights for the entire baseline sample, and the Osteoarthritis, CHF and Cancer cohorts within WHI by HGB level.



Conclusion: The relationship between health utility and hemoglobin appears different depending upon the presence or absence of certain chronic conditions. In the anemic range, health utilities associated with osteoarthritis and cancer appears worse than in the non-anemic range especially compared to those without chronic conditions and comparable levels of hemoglobin.

720

Predictors of Serious Infections in Seniors with Rheumatoid Arthritis (RA): Results of the OBRI Administrative Database Analysis.

Sasha Bernatsky[1], J. Michael Paterson[2], J. Carter Thorne[3], Alf Cividino[4], Janet Pope[5], Jessica Widdifield[6] and Claire Bombardier[7], [1]McGill University, Montreal, QC, [2]ICES, Toronto, ON, [3]Southlake Regional Health Centre, Newmarket, ON, [4]McMaster University, Hamilton, [5]St Joseph Health Care, London, ON, [6]University Health Network, Toronto, ON, [7]University of Toronto, Toronto, ON

Purpose: The Ontario Biologics Research Initiative (OBRI) represents a collaboration of rheumatologists, patients & researchers aiming to improve RA management through clinical & administrative database linkages. Our study's purpose was to assess predictors of serious infection using a case-control sample nested within a cohort of seniors with RA.

Method:

Our population-based RA cohort was assembled using billing & pharmacy data (1992-2007) for persons aged >65. Cohort entry criteria were an RA diagnosis based on ≥2 RA billing diagnoses, >60 days apart but within 5 years. Cohort members were required to have ≥1 prescription for a corticosteroid, traditional disease-modifying agent (DMARD), or biologic.

Our primary outcome was a 1st-time infection requiring hospitalization, based on hospital discharge diagnoses, assessed over 1998-2007. Cases were matched (on age, sex, year of cohort entry) to RA controls using risk-set sampling. Multivariate logistic regression assessed the independent effects of factors, including demographics (age, income rurality index), comorbidity & markers of RA severity/activity (rheumatology visits, history of joint replacement, extra-articular features, NSAID use) & RA-related drug exposures. Drug exposures were obtained from electronic provincial prescription data. Measures of comorbidity included the Charlson-Deyo Index & the number of drugs dispensed in the year prior to the index date (date of infection for each case-control set).

Results:

We identified 36,789 individuals aged >65 with RA, who were followed for a total of 267,227 person-years [mean (SD) follow-up: 7.3(5.8) years]. We compared 4,641 RA subjects with first-time serious infections to 10,847 controls. Factors affecting risk of serious infections in this adjusted analysis are presented in the table below:

Characteristics		Cases N=4641	Controls N=10847	Adjusted OR (95%CI)
Comorbidity	Charlson comorbidity score(%)			
	0	16.0	19.3	Ref
	1	21.4	17.1	1.23(1.03,1.47)
	≥2	42.1	21.4	1.51(1.26,1.79)
	Mean # drugs used (SD)	14.8(6.7)	10.6(5.8)	1.08(1.07,1.09)
	Chronic lung disease	44.4%	28.7%	1.59 (1.01, 1.55)
	Diabetes	26.6%	18.3%	1.10(0.96, 1.26)
	Renal disease	11.9%	5.6%	1.25(1.04, 1.40)
Markers of Disease Activity	# of Rheumatology Visits, mean (SD)	21.5(41.9)	11.9(23.5)	1.012(1.011,1.013)
	At least 1 extra-articular feature of RA	27.1%	13.8%	2.49(2.14,2.89)
	Previous Joint Replacement	21.3%	15.0%	1.05 (1.01, 1.09)
Low-income senior, n (%)		1427 (30.7)	2897 (26.7)	1.21 (1.13, 1.21)
Current Glucocorticoid Exposure		34.9%	22.6%	1.42(1.25,1.61)

Conclusion: Comorbidity, more markers of disease activity & glucocorticoids are important independent risk factors for infections requiring hospitalization in RA. Additionally, crude estimates suggested increased risk with current exposures to biologics & most DMARDs, but adjusted estimates were imprecise. Ongoing prospective data collection in the context of the OBRI will provide additional insights.

721

A Faster Clinical Response to Certolizumab Pegol Treatment Is Associated with Better Improvements in Household Productivity in Patients with Rheumatoid Arthritis. R. Westhovens[1], Vibeke Strand[2], Edward C. Keystone[3], O. Purcaru[4], D. Khanna[5], J. S. Smolen[6] and A. Kavanaugh[7], [1]UZ Gasthuisberg, KU Leuven, Leuven, Belgium, [2]Stanford University, Portola Valley, CA, [3]Professor of Medicine/University of Toronto, Toronto, ON, [4]UCB, Brussels, Belgium, [5]UCLA, Los Angeles, CA, [6]Medical Univ Vienna, Vienna, Austria, [7]UCSD, San Diego, CA

Purpose: Certolizumab pegol (CZP), a PEGylated Fab' anti-TNF approved for the treatment of rheumatoid arthritis (RA), has been shown to provide rapid improvements in RA signs and symptoms and disease activity, as well as improvements in productivity at work and home, when added to methotrexate (MTX). The objective of our analysis was to determine if a more rapid clinical response to CZP treatment was associated with better long-term improvements in household productivity in patients with active RA.

Methods: Data from patients treated with CZP 200 or 400 mg + MTX in RAPID 1 were pooled for analysis. Patients who achieved response at Week (Wk) 12 were divided into subgroups depending on response at Wk 6: Wk 6 responders and Wk 12 responders (ie, those who were non-responders at Wk 6). Responder definitions were based on ACR20 response or DAS28 decrease ≥1.2 points from baseline (BL). The

number of household days lost due to RA, days with productivity reduced by ≥50%, the rate of RA interference with household productivity, and days lost of social activities in the last month were compared between responder subgroups using a repeated measures negative binomial regression adjusted for BL score and demographic variables. Analysis of work productivity was not possible due to an imbalance in patient numbers between the Wk 6 and Wk 12 responder groups.

Results: BL demographics were similar between the 2 responder subgroups. Wk 6 DAS28 and ACR20 responders lost significantly fewer days of household work than Wk 12 responders from Wks 4 to Wk 52 (Table). Wk 6 responders also had fewer days with reduced household productivity and a lower rate of RA interference with household productivity.

Conclusion: A faster response to treatment with CZP + MTX is associated with improved household productivity in patients with active RA over 52 wks. Rapid (Wk 6) responders lost fewer days of household work and had fewer days with reduced productivity than the later (Wk 12) responders. These observations are in line with other studies highlighting the importance of a rapid response to RA treatment.

Table. Household productivity in Wk 6 versus Wk 12 responders at Baseline, Wk 4, and Wk 52

Responder definition	**# Household days lost[a]**			**# Household days with reduced productivity[a]**			**# Family, social, leisure days missed[a]**			**Rate of RA interference[b] (0-10)**		
	BL	Wk4	Wk52	BL	Wk4	Wk52	BL	Wk4	Wk52	BL	Wk4	Wk52
Change in DAS28 ≥1.2												
Wk 6 responder (N=378)	5.1	4.4[e]	0.7[c]	7.7	4.9	1.7	2.2	1.8	0.2	5.2	3.6[d]	1.7[d]
Wk 12 responder (N=118)	5.0	6.8	1.5	6.0	5.5	2.3	2.0	1.8	0.3	4.8	4.3	2.3

Delayed Diagnosis Is Associated with Total Hip Replacement in Patients with Spondyloarthritis: Report From the SPARK International Survey. Maxime Dougados[1], Frédéric Lavie[2], P. Mease[3], Joachim Sieper[4], C. Combescure[5] and Désirée M.F.M. van der Heijde[6], [1]Hôpital Cochin, Paris, France, [2]Abbott Laboratories, Rungis, France, [3]Seattle Rheumatology Associates, Seattle, WA, [4]Charite - Campus Benjamin Franklin, Berlin, Germany, [5]University of Geneva, Geneva, Switzerland, [6]Leiden University Medical Center, Leiden, Netherlands

Purpose: Hip involvement is frequent in ankylosing spondylitis (AS) and affects disability and health-related quality of life, often leading to total hip replacement (THR).[1] We evaluated characteristics of patients with AS with and without a history of hip surgery.

Methods: SPondyloarthritis: Assessment of CuRrent Epidemiology, Management, and Knowledge (SPARK) was a multinational survey conducted in the United States, Canada, and 9 European countries to evaluate the epidemiology, diagnosis, and management of spondyloarthritis in rheumatology practices. Characteristics of patients with and without hip surgery were compared between each country. Univariate (Fisher's exact test) and multivariate linear regression analyses were conducted.

Results: Of the 2,703 patients surveyed in SPARK, 68 (2.5%) had ≥1 THR. Of those patients, 55 (80.9%) had at least a diagnosis of AS, according to their rheumatologist. Frequency of THR did not differ significantly between countries (range: 0.0–4.3%). Characteristics associated with THR in univariate analyses were greater age, male sex, HLA-B27 positivity, AS diagnosis (vs. other diagnoses), longer disease duration, poorer physician's satisfaction, and current employment status ($p<0.01$). A delay of more than 10 years between first symptoms of AS and diagnosis of AS was also associated with THR in univariate analysis (table).

Delay Between Diagnosis of AS and Frequency of THR

	1 to 10 Years	**≥11 Years**
Total, N	1,598	160
Patients with THR, n (%)	28 (1.8)	8 (5.0)[a]

[a]$p=0.02$, Fisher's exact test.

THR was associated with worse Work Productivity and Activity Impairment Questionnaire outcomes ($p=0.02$) and greater TNF-antagonist usage ($p<0.01$). Multivariate analyses identified AS diagnosis ($p=0.03$), greater age ($p=0.01$), and longer disease duration ($p<0.01$) as independent factors for THR; delay to diagnosis was also significantly associated with THR in multivariate analyses of the 1,738 patients for whom these data were available ($p=0.01$).

Conclusion: This study confirms that requirement for THR is a marker of SpA severity and suggests that this complication is observed primarily in patients with AS. The relationship between delay to diagnosis and requirement for THR emphasizes the need for earlier diagnosis of axial SpA.

Influenza Immunization Status Among US Adults with Arthritis, 2007. Jennifer M. Hootman and Charles G. Helmick, Centers for Disease Control and Prevention, Atlanta, GA

Purpose: : In April 2009 an outbreak of a novel H1N1 influenza virus was documented in the US and has since spread worldwide. Annual flu immunization is recommended for people age ≥50 years and for those with disease- or drug-induced immunosuppression, who do poorly with an influenza infection. Most arthritis patients are in this target group but little is known about their level of compliance with recommendations. The purpose of this study was to estimate the prevalence and related characteristics of influenza immunization (FLU-IM) among US adults with arthritis.

Method: Data are from the 2007 (n = 430,912) Behavioral Risk Factor Surveillance System, an annual, random-digit dialed national phone survey of US adults conducted in all 50 states and D.C. Arthritis was defined as a 'yes' response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" FLU-IM status was defined as having received a flu shot or flu nasal spray in the past 12 months. Estimates (95% confidence intervals, CI) of FLU-IM by arthritis status were calculated using statistical weights to account for the complex sample design. Multivariate logistic regression (adjusted odds ratios and 95% CI) was used to identify factors that might be significantly ($p<0.05$) related to FLU-IM status, including demographics (age, sex, race/ethnicity, education level), general health indicators (obesity, self-rated health, current smoker, presence of diabetes, heart disease or a disability), and health care factors (have health insurance, have a usual health care provider).

Results: The unadjusted FLU-IM prevalence was 52.3% (CI 51.8 – 52.8; 1.2% received nasal spray, 52.0% received injection) among adults with arthritis, significantly higher than among adults without arthritis (31.4%, CI 31.0-31.7), and in multivariate analyses adults with arthritis were 1.4 (CI 1.4 – 1.5) times more likely to receive FLU-IM. Among adults with arthritis who had seen a health care provider in the past 12 months, FLU-IM was significantly lower among non-Hispanic Blacks (0.7, CI 0.6-0.7), Hispanics (0.6, CI 0.5-0.7), non-Hispanic Other/Multiracial (0.8, CI 0.7-0.9), those with less than a high school education (0.7, CI 0.7-0.8), current smokers (0.7, CI 0.7-0.8), the obese (0.9, CI 0.8-0.9), those with no health insurance (0.7, CI 0.6-0.8), and those with no personal health care provider (0.7, CI 0.6-0.9). FLU-IM was significantly higher among older adults (age 45-64 = 1.6, CI 1.5-1.8; age 65+ = 4.5, CI 4.1-4.9) and persons with diabetes (1.7, CI 1.6-1.8), heart disease (1.3, CI 1.2-1.4), or a disability (1.2, CI 1.1-1.3).

Conclusion: Only 1 in 2 US adults with arthritis received FLU-IM in 2007. Among people with arthritis, race/ethnic minorities, smokers, obese persons, and those with low education are higher risk groups and should be targeted for FLU-IMM, although the live attenuated nasal spray vaccine is not recommended for people with immunosuppression.

What Is the Lifetime Risk of Rheumatoid Arthritis? Cynthia S. Crowson[1], Elena Myasoedova[1], Peter K. Gregersen[2], Terry M. Therneau[1] and Sherine E. Gabriel[1], [1]Mayo Clinic, Rochester, MN, [2]Feinstein Institute for Medical Research, Manhasset, NY

Purpose: Rheumatoid arthritis (RA) is a costly chronic disease. While its incidence and prevalence have been estimated in several populations, there are no available estimates of lifetime risk of RA. To better understand the potential effect of RA disease on the population, we sought to estimate the lifetime risk of developing RA.

Method: Using the incidence rates obtained from our population-based studies of RA from 1955-2005 and mortality rates from life tables for the general population, we estimated age- and sex-specific lifetime risk of RA as the sum of the probability of developing RA each year from ages 18 to 100 years. The yearly probability of developing RA was estimated as the product of the yearly incidence rate of RA and the yearly survival rate. Given the changing RA incidence rates and population mortality rates, lifetime risk was estimated for persons born in a range of calendar years to determine whether lifetime risk is changing over time. The residual lifetime risk for RA was estimated for persons who had no RA at specific baseline ages.

Results: The lifetime risk of RA developing in US adults was 4.3% for females and 2.8% for males. Despite significant changes in the incidence rate of RA over time, as well as the mortality rate over time, the lifetime risk remained remarkably stable over time. The cumulative lifetime risk of RA is higher for females than for males (Figure). The residual lifetime risk for RA was estimated for women without RA at ages 30, 40, 50, 60, 70 and 80 was 4.2%, 3.9%, 3.3%, 2.6%, 1.7% and 0.9%, respectively. Similarly, the residual lifetime risk of RA for men without RA at ages 30, 40, 50, 60, 70 and 80 was 2.7%, 2.6%, 2.4%, 2.0%, 1.4% and 0.7%, respectively. Since some genotypes, such as homozygosity for the shared epitope and/or PTPN22 carry substantially increased risk above the background population rate, it is likely that a significant subset of women in the population have lifetime risks in the range of 10-20%.

Conclusion: The lifetime risk of RA development is significant and is substantially higher in females than in males. Given the increased genetic susceptibility for RA in persons with high-risk genotypes, the lifetime risk may be in the range of 10-20

% for some groups of individuals These findings underscore the need for further investigations to determine whether identification of persons with high genetic risk for RA might justify early detection and intervention to prevent progression to overt clinical disease.

Comparative Effectiveness Studies of Observational Data: Approaches to Address Confounding. E. Morgan DeWitt[1], Y. Li[1], H. Glick[2], J. Kremer[3], J. R. Curtis[4], G. Reed[5], J. Greenberg[6], K. Anstrom[1], K. Schulman[1] and S. Reed[1], [1]Duke Clinical Research Institute, Durham, NC, [2]Univ of Pennsylvania, Philadelphia, [3]Albany Medical College, Albany, NY, [4]Univ of Alabama at Birmingham, Birmingham, AL, [5]U.Mass Medical, Worcester, MA, [6]NYU, New York, NY

Purpose: Comparative effectiveness studies using observational data confer the benefits of increased sample size, and inclusion of patients treated with therapeutics in clinical practice who would not have qualified for clinical trials, at the cost of potential confounding. To address confounding we can: 1) be more inclusive of subjects and analytically adjust for differences (e.g. disease severity, comorbidities); or 2) restrict the study sample to compare homogeneous groups. We demonstrate the potential impact of such restriction on sample size and patient characteristics in a registry study evaluating comparative effectiveness of TNF antagonists ("Biologics") compared to non-biologic DMARDs.

Method: The study cohort consists of patients enrolled in a US-based registry which collects data at clinic visits. The 'unrestricted' study sample included RA patients who had not previously used a Biologic (naïve) and initiated treatment with a DMARD or Biologic during 2002-2008. To derive homogeneous treatment groups for longitudinal analyses of effectiveness measures, the analysis was further limited to: (1) incident DMARD users; (2) patients making an initial treatment switch from 1st DMARD to 2nd DMARD or 1st DMARD to 1st Biologic (+/- DMARD); (3) patients without contraindications (cancer, CHF); (4) patients with similar demographic and disease-related characteristics as determined by propensity scores and a matching (greedy) algorithm.

Results: The table shows sample size and patient characteristics (mean age, CDAI, swollen joint count (SJC), tender joint count (TJC)) by treatment group for each group. The restricted groups have higher CDAI, joint counts, and similarity.

Analysis group	N		Age (yrs)		CDAI		SJC		TJC	
	DMARD	Biol	DMARD	Biol	DMARD	Biol	DMARD	Biol	DMARD	Biol
Unrestricted, (n=4,766)	N= 2073	N= 2677	59.9	56.6	16.1	18.3	5.8	6.1	4.4	5.5

Incident DMARD users (n=1991)	N= 1991	N/A	59.3	N/A	17.3	N/A	6.4	N/A	4.7	N/A
Switchers, (n=625)	N=243	N=382	58.1	56.2	20.0	21.9	7.6	8.0	5.3	6.4
No contra-indication (n=579)	N=217	N=362	57.7	55.9	19.7	21.8	7.7	8.0	5.2	6.4
PS match, (n=244)	N=122	N=122	56.7	54.9	19.1	19.5	6.9	6.9	5.1	5.6

Conclusion: Comparative effectiveness research is methodologically challenging. Deriving comparable treatment groups through restriction reduced our sample size and patient heterogeneity, arguably the main advantages to using observational data, and resulted in a study sample with more severe disease. Alternatively, analytic adjustment allows inclusion of larger, more heterogeneous study samples, but requires modeling assumptions and may raise issues as to whom the results can be generalized. Both methodological approaches can provide useful information on comparative effectiveness, but their limitations and assumptions should be fully transparent to those who may use this information for decision making.

Mortality and Cardiovascular Burden in Rural Lupus Patients. C. M. Bartels[1], M. Visekruna[2], S. Nekkanti[2], K. A. Buhr[3], J. Goldberg[2], R. Greenlee[2] and C. L. Bell[1], [1]Univ of WI School of Medicine and Public Health, Madison, WI, [2]Marshfield Clinic, Marshfield, WI, [3]Univ of Wisconsin - Madison, Madison, WI

Purpose: We aimed to assess the actual mortality and cardiovascular disease (CVD) burden among a population-based cohort of rural patients with systemic lupus erythematosus (SLE) with previously described older onset and milder disease activity.

Methods: This retrospective cohort study investigated all incident cases of SLE 1991-2008 in a population-based cohort to examine rates of death and fatal and non-fatal CVD events including MI, stroke, or hospitalization for congestive heart failure. Recent validation indicated capture of >90% visits and 99% of deaths among nearly 80,000 residents. Incident “definite lupus” was defined by the 1997 revised 1982 ACR SLE diagnostic criteria. Comparison used 2,630 age and gender matched controls present in the cohort at date of case SLE diagnosis. CVD event searches used validated protocols with chart verification. Searches included chart audits, electronic record systems, and state death matches. Kaplan-Meier (KM) survival and CVD event-free survival were calculated. Comparison between SLE cases with and without CVD used Wilcoxon and Chi-Square tests.

Results: From 1991-2008, 71 incident SLE cases showed a mean onset age of 52 years and a mean follow-up of 9 years. Severe lupus was rarely encountered including only 2.8% with CNS disease over the period. Matched controls showed comparability between groups including no significant difference in baseline hypertension, hyperlipidemia and diabetes. However, SLE patients were twice as likely as controls (22.5% vs. 10.2%, p>0.0005) to have CVD codes in the 2 years preceding diagnosis. In 614 years of SLE patient follow-up 19 deaths and 17 new CVD events occurred. Five, ten, and fifteen year KM mortality was 12%, 23%, and 37% for SLE subjects vs. 9%, 16% and 23% for controls (HR 2.06, p=0.002). New CVD events occurred in 17 SLE subjects. Among SLE patients, rates of combined CVD events and death were 22%, 30%, and 43% compared to 14%, 23%, and 31% for controls (HR 1.8, p=0.009).event-free survival was 78%, 70%, and 57% at years five, ten, and fifteen respectively. Comparing SLE cases with and without new CVD events, baseline hypertension,

diabetes, and prior CVD were stronger predictors than any lupus features though adjustments for age and gender mitigated risks of prior CVD.

Conclusion: This well defined rural cohort of older onset, mild SLE patients still demonstrated increased mortality and CVD events compared to peers. Despite similar baseline traditional modifiable risk factors, event risk increased with SLE. Compared to baseline in controls, lupus patients also experienced more CVD in the 2 years preceding lupus diagnosis compared to controls. Increased CVD 2 years prior to diagnosis raises questions of delayed SLE diagnosis versus early accelerated CVD.

Fulfillment of the ACR20 Response Criteria in Patients Receiving Tocilizumab (TCZ) Is Not Influenced by Its Direct Effects On the Acute Phase Response (APR). Daniel Aletaha, Farideh Alasti and Josef S. Smolen, Medical University of Vienna, Vienna, Austria

Background:TCZ is a novel biological agent targeting the interleukin-6-receptor. In addition to its significant effects on clinical and radiographic outcomes of RA, TCZ exerts a direct suppression of the hepatic APR via IL-6 receptors on the hepatocellular membrane. The ACR20 response criteria were the primary endpoint of TCZ clinical trials, and include APR improvement as an optional criterion. It is unclear how the direct effects of TCZ on the APR influence a patient's ability to achieve an ACR20 response.

Purpose: To assess the relevance of APR for the achievement of ACR20 response in patients with active disease despite MTX or other DMARD therapy in clinical trials of TCZ + MTX when compared to the ATTRACT trial on infliximab (INF) + MTX.

Method: We obtained a random 80% of patient level data from 3 TCZ clinical trials on patients with active disease despite MTX or other DMARD therapy (LITHE, OPTION, TOWARD), pooled the 8mg/kg TCZ arms, and evaluated the presence of the ACR20 response at trial endpoints (6 months; n=919). The ACR20 response requires 20% improvement of both tender and swollen joints (SJC, TJC) and improvement of 3 of 5 additional variables: APR (ESR or CRP), patient and evaluator global assessment of disease activity (PGA, EGA), pain, and physical function. Thus all variables other than joint counts are optional as long as 3/5 are fulfilled. We evaluated whether there was a difference in APR representation among the fraction of patients who just fulfilled 3/5 of the optional criteria (patients with 4/5 or 5/5 criteria. would have fulfilled the criteria in any way). We compared these to the results of a similar analysis obtained in an 80% sample of the ATTRACT trial on INF+MTX in established RA (n=211 at 6 months). All analyses were based on completers.

Results: In the TCZ studies and in ATTRACT, the ACR20 response rate at 6 months was ~68% (Table). In only 10.5% and 14.7%, respectively, of ACR20 responders, this response was attained by just fulfilling 3/5 optional criteria. In total, the fraction of patients, in whom the response in APR qualified for the ACR20 response was similar in the TCZ and INF trials, and amounted to 10% and 11%, respectively (Table).

Conclusion: The APR response was crucial for achieving an ACR20 response in only 10% of patients regardless of treatment regimen.

Table. Rates of ACR 20 responses, frequency of fulfilment of additional variables (3/5, 4/5, or 5/5), and frequencies of variables among patients fulfilling only 3/5 additional variables (i.e. variables were crucial for response classification) for patients treated with TCZ (n=919) or INF (n=211).

		Tocilizumab	**INFLIximab**

Biologic Therapy and Health-Related Quality of Life: Treatment Effect Heterogeneity in Patients with RA. M. Neovius[1], A. Gülfe II[2], Le Kristensen[2], Jan-Åke Nilsson[3], J. Karlsson[4], P. Geborek[5] and South Swedish Arthritis Treatment Group (SSATG), [1]Karolinska Institutet, Stockholm, Sweden, [2]Lund University, Lund, Sweden, [3]Department of Rheumatology. Malmö University Hospital, Malmo, Sweden, [4]Lund University, [5]Lund University, Department of Clinical Sciences, Lund, Sweden

Purpose: The average treatment effect of biologics on utility is large in RA, but treatment effect heterogeneity across subgroups remains largely unexplored. We aimed to investigate treatment effect heterogeneity across baseline utility in RA patients treated with biologics.

Method: The population-based SSATG register with data from clinical practice was used to conduct an observational study of health-related quality of life, measured by EQ-5D, in RA patients initiating a biologic and continuing treatment for one year (n=633; 56±13y; 74% women). Treatment effect was defined as utility change over one year and investigated across level of baseline utility.

Results: The average treatment effect at one year was 0.26 (95% confidence interval 0.23, 0.29). However, significant treatment effect heterogeneity was observed. For patients with utility in the ranges <0, 0-0.24, 0.25-0.49, 0.50-0.74, and 0.75-1.0 the one-year utility changes were 0.63 (0.58, 0.68), 0.52 (0.48, 0.57), 0.33 (0.26, 0.40), 0.06 (0.04, 0.08), and 0.00 (-0.03, 0.04), respectively. Four distinct patient clusters could be discerned (Figure), with the first (a) consisting of patients with low pre-treatment utility who experienced major improvements. The second (b) and third group (c) with high or low pre-treatment utility changed little on average, while a small fourth group (d) with high utility at baseline deteriorated.

Conclusion: RA patients with the worst quality of life make the greatest utility gains on biologic treatment, strongly influencing the average treatment effect. Although some heterogeneity may be explained by regression to the mean, the large subgroup differences are likely to be important, not least for cost-utility analyses where utility change may be the sole driver in the denominator.

Stratification of the Individual Five-Year Cardiovascular Risk in Patients with Rheumatoid Arthritis. Inmaculada del Rincon[1], Samvel Pogosian[2], Daniel F. Battafarano[3], Daniel H. O'Leary[4], Joseph Polak[5] and Agustin Escalante[2], [1]UTHSCSA, San Antonio, TX, [2]Univ of Texas HSC San Antonio, San Antonio, TX, [3]San Antonio Military Medical Center (SAMMC), San Antonio, TX, [4]Tufts University School of Medicine, Dorchester 02124-5666, MA, [5]Tufts-New England Medical Center, Boston, MA

Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular (CV) disease. Stratification of individual CV risk would enable efficient application of CV prevention guidelines. Our objective was to develop a method to stratify individual CV risk in patients with RA.

Methods: We studied patients with RA who were free of CV disease. We directly assessed the patients for CV risk factors, clinical and laboratory manifestations of RA, and use of anti-rheumatic medications. We imaged the carotid arteries for plaque using high-resolution ultrasound. We followed patients prospectively until they either developed an acute coronary syndromes (ACS), reached the censoring date of December 31, 2004, or were lost to follow-up. ACS were defined as unstable angina, myocardial infarction, cardiac arrest, or death if ischemic heart disease was listed as first cause of death. Using patient characteristics ascertained at baseline as independent variables, we used logistic regression models to develop a predictive model. We used the area under receiver operating characteristic (ROC) curves to quantify the accuracy of the model in predicting ACS.

Results: We studied 599 patients with RA, who were followed for 3,085 person-years of observation, or an average of 5.15 years (range 0.04 to 8.9 years). During this time, 66 first-time ACS occurred, an incidence of 2.1 per 100 person-years (95% CI 1.7, 2.7). A logistic model that included age, sex and the number of CV risk factors (diabetes, hypercholesterolemia, hypertension and smoking), predicted five-year CV risk with a ROC curve area of 0.70 (95% CI 0.64, 0.77) (model1 in Figure). Adding the baseline erythrocyte sedimentation rate (ESR), the cumulative glucocorticoid dose and the presence of carotid plaque, significantly increased accuracy to a ROC curve area of 0.75 (0.69, 0.82), P = 0.03 (model 2 in Figure).

Conclusion: It is possible to predict ACS with reasonable accuracy in RA. Adding the ESR, use of glucocorticoids and carotid ultrasound data significantly increases predictive accuracy.

Do Patients Hip OA Patients Referred to Orthopedic Surgeons by General Practitioners and Rheumatologists Differ? Maxime Samson[1], Carine Roy[2], Christian Cadet[3], Philippe Ravaud[4] and Jean Francis Maillefert[5], [1]Dijon University Hospital, Dijon, France, [2]AP-HP, Hôpital Bichat, Paris, France, [3]Rheumatology, Paris, France, [4]University of Paris VII, Bichat Hospital, Paris, France, [5]Chu Dijon Hopital General, Dijon

Purpose: There is currently no consensus regarding the indication for total hip arthroplasty (THA) in hip osteoarthritis (OA) patients. In addition, variations in surgical rates have been previously demonstrated. Patients can be referred to orthopedic surgeons either by their general practitioner (GP) or their rheumatologist. The aim of this study was to evaluate whether the views of GPs and rheumatologists regarding the right time to undergo THA differ.

Methods: GPs and rheumatologists were asked to include 1 patient suffering from hip OA and for whom a consultation with a surgeon was planned to determine if THA was indicated. The following variables were collected: age, sex, occupational status, body mass index, comorbidities,duration of hip OA, patient's global assessment, WOMAC pain and function scores, New Zealand (NZ) score, quality of life (SF12), medical treatment of hip OA, and joint space narrowing on radiographs (semi-quantitative 0 to 3 scale). Surgeons' decision was obtained by follow-up questionnaires. Statistical analysis evaluated differences between patients referred by GP and Rheumatologists using univariate then multivariate analysis in which the variable to be explained was the referring physician.

Results: A total of 558 patients were included (377 by GPs and 109 by rheumatologists) and the surgeon's decision was available in 486. GPs and rheumatologists differed in terms of sex (97% versus 74% men; $p<0.0001$) and GPs worked more frequently in a rural area (30.3 versus 0.76%; $p<0.0001$). THA was prescribed in 71.6 % of patients referred by rheumatologists versus 57.6% of patients referred by GP ($p=0.008$). Patients referred by rheumatologists were younger (66.3 versus 69.3 year; $p=0.006$), less frequently retired (72.9 vs 84.2%; $p=0.007$), presented with a more severe NZ score (54.3 versus 48.1; $p=0.0009$), and more structural degradation (severe narrowing in 73.4% versus 52.2 % of patients, $p=0.0004$). The other variables, especially the WOMAC pain and function scores, the comorbidities, and medical

treatments of hip OA did not differ. On multivariate analysis, the only variable related to patients referred by rheumatologists was the NZ score.

Conclusion: Orthopedic surgeons recommended THA more frequently when patients were referred by rheumatologists. Since 1- the patients referred by rheumatologists were younger and less frequently retired, 2- the New Zealand score includes items related to pain, functional impairment, but also to other factors, such as physical examination and ability to work- the difference might be due to differences in pain and functional status captured by the NZ score but not by the WOMAC, or to differences in the handicap, and/or patients' willingness to undergo surgery.

Assessing HRQoL Burden of Disease and Comparison to the U.S. Population in RA Patients Treated with Golimumab: Results From the GO-FORWARD Trial. G. Hammond[1], A. Raju, S. Parasuraman, J. Buchanan and T. Gathany[2], [1]Lincoln, RI, [2]Johnson and Johnson Pharmaceutical Services, LLC, Malvern, PA

Purpose: Assess the disease burden of RA relative to the U.S. population using SF-36 scale, summary measures. To contrast the percentage of individuals meeting or exceeding the age, gender adjusted population means.

Methods: A prospective, multisite, randomized control study of 444 patients with active rheumatoid arthritis despite methotrexate therapy was assessed at baseline, wk 14, and wk 24. Eligible patients were 18 or older with a confirmed diagnosis of active rheumatoid arthritis (RA) despite MTX therapy. Patients were randomized 3:3:2:2 to receive one of four treatments: 1) MTX plus placebo (tx 1), 2) GLM 100mg plus placebo (tx 2), 3) GLM 50mg plus MTX (tx 3), or 4) GLM 100mg plus MTX (tx 4). Comparisons to population and disease specific norms (heart disease and rheumatoid arthritis norms) in continuous SF-36 scores were made at baseline, wk 14 and wk 24 (not displayed) using multiple *t*-tests. Separate χ^2 tests were used to compare proportions of individuals meeting and exceeding pop norms at wks 14, 24.

Results: At baseline all 8 scale and 2 summary SF-36 measures were significantly lower than age and gender adjusted U.S. and disease specific norms, indicating significant impairment. At wk 14 (Table), scores improved, but remained significantly lower than general population norms. Scores were comparable to the heart disease sample with the exception of PF, RP, and RE. The wk 14 trial sample showed increased PF, GH, MH and PCS impairment relative to the rheumatoid sample. At wk 14, 17.4% (tx 4), 17.1% (tx 2), and 25.6%* (tx 3) of individuals exceeded the population average value for PCS, relative to 10.9% for tx 1. At wk 24, 18.4% (tx 4) 28.3%* (tx 2) 27.4%* (tx 3) and 14.0% (tx 1) exceeded norm values (*χ^2 versus tx 1, $p<.05$).

Conclusion: Significant differences were still observed between trial and general population means, despite marked improvement with treatment. Disease specific populations were comparable. Regarding percentage return to normal functioning, results corroborate existing clinical findings that additional improvements are achieved by using GLM in combination with MTX. 50 mg Golimumab + MTX showed best overall profile of improvement, with a significant proportion of patients exceeding norm values relative to MTX plus placebo.

Cytokine Response Profiling Identifies An Immunologic Signature of Myocardial Dysfunction in Rheumatoid Arthritis. John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Elena Myasoedova, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: Persons with rheumatoid arthritis (RA) have an increased risk of heart failure (HF), which may be partially mediated by inflammatory mechanisms. This study sought to develop immunologic signatures that might be useful to identify patients at risk for left ventricular diastolic dysfunction (LVDD), a pre-clinical stage of HF, and to develop hypotheses about pathogenesis.

Methods: A population-based sample of subjects with RA (1987 ACR criteria) was studied. Data on clinical characteristics (i.e. RA features, cardiovascular risk factors) were collected. LVDD was rigorously assessed by 2D/Doppler echocardiography using a validated algorithm and categorized as none, mild, or moderate-severe LVDD. Fresh PBMC from subjects were stimulated *ex vivo* under eight conditions, including: anti-CD3/anti-CD28 (CD3/CD28); phytohemagglutinin (PHA); bacterial CpG oligonucleotides (CPG); or human heat shock protein 60 (HSP60). The profiles of cytokine release were analyzed using 17-plex immunoassays. Differences in the stimulated cytokine values between the 3 categories of LVDD were tested using mixed effects models, adjusting for assay effects and clinical characteristics.

Results: The study included 267 subjects (mean age: 60.8 ± 13.9 yrs; disease duration: 9.6 ± 6.6 yrs) with low disease activity (mean CRP: 2.7 ± 4.9 mg/L). Of these, 134 subjects (50%) had normal left ventricular function, 53 (20%) had mild LVDD, 25 (9%) had moderate/severe LVDD or HF; 55 (21%) with indeterminate data were excluded. A 13-cytokine signature was developed that discriminated patients with moderate-severe LVDD or HF from the remainder. The signature included decreased responsiveness to CD3/CD28 of Th1 (IFN-g, MIP1b, TNFa) and Th2 (IL-10) subsets; increased responsiveness to PHA of Th2 (IL-4, IL-5, IL-13); decreased responsiveness to CPG (IL-7, IL-8); and increased responsiveness to HSP60 of Th17 or myeloid subsets (IL-17A, G-CSF, GM-CSF). These associations remained significant after adjusting for age, sex, cardiovascular risk factors, known coronary heart disease, rheumatoid factor, anti-CCP, HAQ disability index, and CRP.

Conclusion: In patients with RA, a 13-cytokine signature determined by *ex vivo* cytokine response profiling of PBMC discriminated patients with moderate/severe LVDD or HF. Our data support the hypothesis that a blood-based immunologic signature may be useful to identify patients at risk for adverse disease outcomes such as heart failure. Further, the regulation of the Th17/IL-17 pathway may play an important role in the pathogenesis of myocardial dysfunction in patients with RA.

Anti-Destructive Effects of Trichostatin A (TSA) Are Partly Mediated through Altered Expression of Histone Deacetylase 7 (HDAC7). Hossein Hemmatazad[1], Hanna Maciejewska Rodrigues[1], Lars C. Huber[1], Renate E. Gay[1], Christoph Kolling[2], Beat A. Michel[1], Steffen Gay[1] and Astrid Jüngel[1], [1]Center of Experimental Rheumatology, Zurich Center of Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland

Purpose: Joint destruction in rheumatoid arthritis (RA) is mainly mediated by matrix metalloproteinases (MMPs). There are several reports indicating that histone deacetylase inhibitors (HDACi) modulate the expression of MMPs and therefore block cartilage destruction. In the present study, we investigate the role of specific HDACs with respect to the reported anti-destructive effects of TSA in RA synovial fibroblasts.

Method: Synovial fibroblasts were obtained from RA patients undergoing surgical joint replacement and used at passages 4-6. The constitutive and TNF-α (10ng/ml)/IL-1β (1ng/ml) stimulated expression of HDACs (1-11) together with the expression of MMP1 and MMP3 was measured after incubating the cells with TSA (2μM for 24h) by TaqMan Real-time PCR. Specific gene knockdown of HDAC7 was achieved by siRNA. To assess the expression on protein level, antibodies against MMP1 and MMP3 were used for Western blot.

Results: In unstimulated cells (n=3), the expression of HDAC6, 7 and 9 was reduced significantly after treatment with TSA, while the expression of HDAC3 was increased. Furthermore, in TNF-α/IL-1β-stimulated fibroblasts (n=3), TSA down-regulated the expression of HDAC5, 6, 7, 8 and 9 significantly while the expression of HDAC1, 2, and 3 was up-regulated. Of interest, the most considerable change in the expression of HDACs was observed for HDAC7, which was down-regulated by 86 ± 6 and 87 ± 5% (n=3, $p<0.05$) in both, unstimulated and TNF-α/IL-1β-stimulated cells. In addition, TSA could down-regulate the mRNA expression of MMP1 and MMP3 in TNF-α/IL-1β-stimulated cells (n=6) by 89 ± 9 and 85 ± 7% respectively ($p<0.05$), while the expression in unstimulated cells was unaffected. These results were confirmed on the protein level using Western blot. Most interestingly, after specific gene knockdown of HDAC7 in stimulated RASF (n=8), the mRNA expression of MMP1 and MMP3 was significantly reduced by 48 ± 25 and 48 ± 27% ($p<0.05$).

Conclusion: We conclude that the anti-destructive effect of TSA observed in RASF is at least in part, due to the down-regulation of HDAC7. This observation may present HDAC7 as a novel target to prevent joint destruction in RA.

Diagnosing Autoantibody-Negative Rheumatoid Arthritis in An Early Arthritis Clinic Using Peripheral Blood CD4+ T-Cell Gene Expression Profiling. Arthur G. Pratt[1], Daniel C. Swan[2], Gillian Wilson[3], Catharien MU Hilkens[1], David A. Young[1] and John D. Isaacs[1], [1]Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]The Freeman Hospital, Newcastle upon Tyne, United Kingdom

Purpose: Seronegative rheumatoid arthritis (RA) is an important but difficult diagnosis to make in the early arthritis clinic. We aim to develop molecular biomarkers that identify the condition amongst early arthritis clinic attendees, enabling more rapid therapeutic intervention for this diagnostically challenging patient group.

Method: Total RNA from highly purified peripheral blood CD4+ T-cells of consecutive early arthritis patients, naive to immunomodulatory therapies, was expeditiously extracted and stored. Transcriptional profiling of 67 samples, retrospectively selected based on subsequent definitive diagnosis, was undertaken using Illumina WG6v3 BeadChip oligonucleotide array technology. 18 RA samples from patients fulfilling ACR classification criteria for the disease, but negative for anti-citrullinated peptide autoantibodies (ACPA), were compared with a "mixed control group" of 49 alternative diagnoses. Groups were matched for sex and acute-phase response (CRP). After data normalisation, batch correction, and filtering of expressed transcripts (n=17,873), a list of differentially expressed genes was derived based on the t-test. Validation and refinement of the gene list was carried out using quantitative real-time PCR (qRT-PCR) low density arrays, and a putative

ACPA-negative RA "gene signature" further cross-validated by using support vector machines (SVM) and constructing receiver operator characteristic (ROC) curves.

Results: Initial analysis yielded a list of 192 transcripts whose expression differed between ACPA-negative RA and controls (>1.2 fold-change; $p<0.05$). A "leave-one-out" cross-validation (SVM) of 67 of these transcripts led to just a (9%) misclassification rate of samples. 137 transcripts were selected for validation using qRT-PCR, and this was achieved for 60 of them (44%). Based on $2^{-(\Delta Ct)}$ normalised expression data for these transcripts, further SVM cross-validation led to a higher misclassification rate (13%), but the discriminatory utility of the combined 60-gene profile remained good (area under ROC curve = 0.85; SEM = 0.05; $p<0.001$). External validation of this putative diagnostic tool is planned in an independent cohort of ACPA-negative early arthritis patients.

Conclusion: A high-throughput transcriptomics approach holds promise as a potential diagnostic tool in early arthritis.

Host B Cell Gene Expression Responses Following Epstein-Barr Virus Exposure Differ Based Upon IRF5 Genetic Risk Haplotype.

Amanda Templeton[1], Brian Poole[2], Nicolas Dominguez[1], Rufei Lu[1], Gabriel S. Vidal[1], Jeremy Levin[3], Andrea L. Sestak[1], Jennifer A. Kelly[1], Kenneth M. Kaufman[4], Gail R. Bruner[1], Patrick M. Gaffney[1], John B. Harley[4], Judith A. James[5] and Joel M. Guthridge[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Brigham Young University, Provo, UT, [3]OMRF, [4]OMRF, VA & OUHSC, Oklahoma City, OK, [5]OMRF & OUHSC, Oklahoma City, OK

Purpose: Systemic Lupus Erythematosus (SLE) is a complex, systemic autoimmune disease. Both gene and environment interactions are thought to play a role in SLE development. Epstein-Barr virus (EBV) exposure is one environmental factor that has been shown to influence the development of SLE. EBV binds to cell surface receptors such as CR2/CD21 on B cells and EBV remains latent after infection in B cells. B cells also play key roles in SLE development. Some previously described genetic associations with SLE, such as the interferon regulatory factor 5 gene (*IRF5*), regulate the interferon responses of cells, a pathway previously linked with SLE pathogenesis. In this study, we examined the effect of carrying the *IRF5* lupus risk haplotype upon the host's B cell gene expression response to binding or infection with EBV.

Method: Whole genome microarray expression profile data was collected from peripheral blood B cells from lupus cases and healthy controls selected based upon their *IRF5* risk and protective haplotypes based on genotypes at SNPs rs2004640 and rs10954213. B cells isolated by negative selection using magnetic beads were exposed to EBV for 16 hours after which total cellular RNA was isolated. Whole genome gene expression was performed using Illumina whole genome human gene expression chips. Gene set enrichment analysis (GSEA) was utilized to analyze differential gene expression between SLE patients and controls.

Results: *IRF5* haplotypes appear to differentially regulate genes that are part of three biologically relevant pathways in EBV stimulated B cells: 1.) B cell receptor pathway genes, 2.) Interferon pathway genes and 3.) Toll-receptor pathway genes. The haplotype specific regulation by EBV stimulation was seen in both lupus cases and controls with the respective haplotypes. The main SLE specific differences in gene expression among individuals carrying the IRF5 risk and non-risk haplotype, was in a subset of the interferon response gene signatures. Patients with the *IRF5* risk haplotype have a heightened interferon signature under all experimental conditions; whereas, the patients with the *IRF5* protective haplotype have a B cell interferon signature similar to that of unrelated, matched controls.

Conclusion: Over expression of interferon pathway genes in B cells from individuals carrying the *IRF5* risk haplotype following viral exposure suggests that the *IRF5* risk alleles alone can modulate ones biological response to the environmental insult. Patients carrying either the IRF5 risk or non-risk alleles appear to already be predisposed to having a higher interferon signature even without exposure to virus, suggesting the other genetic factors are also influencing the interferon response, independent of virus.

Massive Parallel Sequencing (MPS) Provides Full-Repertoire Analysis of the B- and T-Cell Receptors in Humans and Mice. P.L. Klarenbeek[1], Paul P. Tak[2], M.E. Doorenspleet[1], B.D.C. van Schaik[1], F.M. Wensveen[1], L. Gottschal[1], M.E. Jakobs[1], I.A.M. Derks[1], E. Eldering[1], A.H.C. van Kampen[1], F. Baas[1] and N. de Vries[1], [1]Academic Medical Center/Univ. of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: The adaptive immune-system protects the body from invading pathogens. However, these responses have also been implicated in many autoimmune diseases, e.g. rheumatoid arthritis. During adaptive immune responses, activated T- and B-cells can undergo clonal expansion. Both identification of expanded clones and monitoring of clones has proven difficult due to the extremely high diversity of the T- and B-cell receptor (TCR/BCR) repertoires. Current techniques are laborious, lack resolution, are at best semi-quantitative, and are vulnerable to artefacts. Here, we show that an MPS-protocol overcomes current limitations and can be successfully applied for TCR and BCR repertoire analysis, both in humans and mice.

Method: Primersets were developed that cover all functional V and J gene segments of the TCR β-chain (human and murine) and the BCR heavy-chain (human). Unbiased amplification of all receptor mRNA molecules was developed using a multiplex linear amplification. PBMC's from two healthy donors (HD) and splenocytes from 6 mice were analyzed on a Genome Sequencer FLX (Roche) providing >100,000 receptor sequences per run. Bioinformatic tools were developed to identify gene segments and apply corrections for sequencing errors. Quantification was validated using dilution series of Jurkat T-cells in a background of human CD4 T-cells. The technique was validated against the 'golden standard' of cloning and sequencing (C&S) in murine models of influenza infection and ovalbumin immunization using tetramer responding T-cells as read-out.

Results: The technique successfully yielded the sequences of the V and J segments and the complete CDR3 region in all repertoires. The human TCR analysis recovered 13/13 J and 47/49 functional V genes in the HD blood sample. In a murine blood sample 13/13 J and 22/22 V genes were found. The BCR analysis showed 6/6 J and 44/44 V genes in human blood. The Jurkat dilution experiment showed a linear relation between input (Jurkat cells/CD4) and output (Jurkat/CD4) (R^2=0.99 $p<0.0001$). In the influenza and OVA models all clonal expansions found by C&S (153 reads) in individual mice (defined by CDR3 sequence) were also recovered in the MPS-protocol (6825 reads) in approximately the same distributions.

Conclusion: Our new MPS-protocol rapidly provides unbiased quantitative information about complete TCR and BCR repertoires in humans and mice. Clonally expanded cells could easily be identified in a background of resting cells for all repertoires analyzed. This technique for the first time enables in-depth monitoring of TCR and BCR usage in adaptive immune responses. This will help to monitor individual autoimmune responses and may help to develop more selective therapeutic targeting of such responses in autoimmune disease.

Transcriptomic Profiling of the Arthritic Synovial Macrophage. Lucy E. Ballantine[1], Sabina I. Patel[2], J. Alastair Gracie[1] and Iain B. McInnes[1], [1]University of Glasgow, Glasgow, United Kingdom, [2]Discovery Technology Group, Stevenage, United Kingdom

Purpose: In rheumatoid (RA) and psoriatic arthritis (PsA) pannus tissue is characterised by an infiltration of activated monocyte / macrophages that produce pro-inflammatory cytokines including TNFα, responsible in part for the chronic inflammation and joint destruction seen in both diseases. Little is known about the genetic profile of the synovial macrophage in either disease, or indeed how the genetic profile may change as these cells enter the joint. We have used mRNA microarray technology to examine differentially expressed genes in peripheral blood and synovial fluid $CD14^+$ cells in RA and PsA patients.

Method: Matched synovial fluid and blood was obtained from 8 RA and 8 PsA patients and healthy blood was obtained from 8 donors. $CD14^+$ cells were isolated from each sample by magnetic bead positive selection and placed into Trizol. mRNA was extracted from the samples and hybridized to Affymetrix U9133 plus 2.0 chips. Data were normalised using the GC-RMA algorithm and filtered based on a p value ≤ 0.05 and a fold difference of ≥ 4.

Results: Principle component analysis (PCA), identifying correlations between sample conditions was performed on the microarray data. These analyses demonstrated that the genetic profile of both RA and PsA blood monocytes is very similar to those from healthy donors. Furthermore, the transcriptomes of both RA and PsA synovial fluid monocytes were surprisingly similar to each other. Analysis of the

differentially expressed genes between diseased blood and synovial fluid monocytes revealed that 947 genes were identified in both RA and PsA patients, 365 genes were expressed only in RA and 208 genes only in PsA derived cells. Analysing the genes that are differentially expressed in both RA and PsA synovial monocytes demonstrates significant upregulation of a group of genes which are involved in lipid homeostasis and are often reported present in atherosclerotic plaques.

Conclusion: This is the first report of a microarray on samples of matched blood and synovial fluid $CD14^+$ cells from both RA and PsA patients. PCA indicates that blood CD14 cells are similar in RA, PsA and healthy volunteers. Synovial RA and PsA $CD14^+$ cells are markedly different from blood but share striking similarities between diseases. Upregulation of genes involved in lipid metabolism in both RA and PsA synovial macrophages strongly supports the notion of common effector pathways underlying co-morbid risk in RA and PsA.

Genome-Wide Association Analysis of the Effector Phase of Murine Arthritis Corroborated Complement Component C5 and Kinase Pip4k2c Rheumatoid Arthritis Loci and Identified Novel Genes Related to Lymphocyte Activation and Cartilage Remodeling.
Vyacheslav A. Adarichev[1] and Elena Kudryavtseva[2], [1]Albert Einstein College of Med, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY

Purpose: Genome-wide association studies (GWAS) are very effective for discovering rheumatoid arthritis (RA) susceptibility genes. Experimentally-induced arthritis and antibody or lymphocyte responses can be measured in mice in a systematic and comprehensive way and correlated with RA pathology. This study was undertaken to develop genetic association analysis using inbred murine strains and to find genes controlling murine inflammation.

Method: Computations were based on a single gene model, hence, independent statistical test for every polymorphic genome position was performed using linear regression model for genotype-phenotype association. Information about several million SNPs analyzed in more than 70 inbred murine strains was available via the Center for Genome Dynamics. Two-phase GWAS analysis was proposed. First, 100k SNP genome-wide set was used. On a second phase, all available SNPs within the regions that were found positive after the first phase were tested.

Results: To address the efficiency of gene discovery in inbred murine strains, we performed statistical modeling using coat color trait. Tyrosinase encoding gene was identified as a single major genome-wide peak when more than 45 strains were used. Two SNPs within tyrosinase gene were strongly associated with coat color ($-\log P > 15.3$, corresponding genome wide $-\log Q > 9.9$). Signal-to-noise ratio for the major peak was $10^{\wedge 9}$ to 1; locus size was smaller than 1,500 bp. The two-phase GWAS analysis was applied for murine serum-transfer induced arthritis. Analysis successfully confirmed two RA loci previously found near complement component C5 and phosphatidylinositol-phosphate kinase Pip4k2c encoding genes. Both genes showed highly significant association with clinical score of murine arthritis: $-\log P > 9.4$ and $-\log P > 10$, respectively. Novel genetic loci containing serpine2 ($-\log P > 9$), fibrillin Fbn2 ($-\log P > 8$), nuclear factor of activated T cells Nfatc4 ($-\log P > 7$), and Nfkb1 ($-\log P > 7$) were also found to be significantly associated with the effector phase of murine arthritis.

Conclusion: Resolution of gene mapping for most chromosome loci reaches 1,500 bp when more than 45 strains are included into analysis; this genomic resolution corresponds to the locus size that is smaller than a single gene. The novel approach opens an avenue for discovering genes associated with both arthritis and allied conditions in a short period of time avoiding long and expensive genetic linkage studies.

About Half of S100 Cluster Genes On Chromosome 1q21.1 Are up-Regulated in the RA, SLE, Polyarticular Type Juvenile Idiopathic Arthritis (polyJIA), and Systemic-Onset JIA (sJIA).
Hidehiko Sugino[1], Chieko Aoki[2], Hooi-Ming Lee[1], Yasuo Adachi[2], Kenichi Matsubara[3], Takahiro Ochi[4] and Norihiro Nishimoto[2], [1]Osaka University, Osaka, Japan, [2]Wakayama Medical University, Osaka, Japan, [3]DNA Chip Research Inc., Kanagawa, Japan, [4]Osaka Police Hospital, Osaka, Japan

Purpose: Back ground: S100 gene family encodes the EF-hand super-family of calcium binding proteins including at least 14 family members clustered relatively closely on chromosome 1q21.1. Recently, up-regulation of S100 proteins, S100A4, A8/9 and A12, in RA

patients has been reported. Objective: To know the pathological roles of S100 proteins, we investigated the comprehensive gene expression profiling of 17 kinds of S100 proteins using DNA microarray in paptients with active RA, SLE, polyJIA, and sJIA. These 17 kinds of S100 proteins contain the clustered 14 molecules. Moreover, to clarify the molecular functions of S100 proteins in RA, we compared the amino acid sequence of up-regulated S100 proteins.

Method: Total RNA was extracted from the peripheral blood obtained from 114 patients with RA, 12 patients with SLE, 6 patients with polyJIA, 51 patients with sJIA, and 53 healthy individuals, and used to prepare amino allylRNA (aRNA). aRNA was subjected to Cy3 and Cy5 labeling and hybridized with an oligonucleotide-based DNA microarray. The data among patients and healthy individuals were analyzed by parametric statistical group comparison. The amino acid sequences of S100 proteins were aligned by multi-sequence Clustal X analysis. Evolutionary trees were obtained by NJ analysis (1000 bootstrap).

Results: S100A4, A6, A8/9, A11 and A12 are significantly up-regulated in RA and polyJIA compared to healthy controls. S100A6, A8/9, A11 and A12 were also up-regulated in SLE and sJIA. S100A4 was increased in the groups of RA and polyJIA but not in the groups of SLE and sJIA.Except for these six S100 proteins, other eleven S100 proteins remained stationary among the RA, SLE, sJIA, polyJIA and healthy controls. Phylogenetic tree of S100 proteins shows that the S100A8/9 and A12, which have been frequently reported in inflammation, recently branched off from the same origin and average percent similarity is 74.3 %. In contrast, S100A4, A6 and A11 are diversified with each other in the amino acid levels.

Conclusion: We confirmed the up-regulation of S100A4, A8/9 and A12 in RA and newly found the up-regulation of S100A6 and A11 in RA, SLE, polyJIA and sJIA. All the genes are encoded by human chromosome1q21.1. The structural similarities and diversifications among the 6 kinds of S100 proteins, which up-regulated in RA patients, may reflect the different contributions to the etiologies of RA.

Associations Between Ten Single-Nucleotide Polymorphisms of the Efficacy and Toxicity Rheumatoid Arthritis Patients Treated with Methotrexate. J. Swierkot, R. Slezak and P. Karpinski, Wroclaw, Poland

Purpose: We evaluated the relationship of ten single-nucleotide polymorphisms in genes encoding proteins in folate and transcobalamin pathways to toxicity and efficacy of MTX in patients with RA. MTX remains a cornerstone in the treatment of rheumatoid arthritis (RA). Approximately 10–30% of patients with RA discontinue MTX because of toxicity and 35 -55% because of inefficacy. One possible cause of the differences in the efficacy and adverse drug reactions is genetic variation in how individuals metabolize drugs.

Method: Ten polymorphisms in five cellular pathway genes (RFC 80G>A, GGH 401C>T, MTHFR 1298A>C and 677C>T, TSER*2/*3, TYMS 6 bp deletion, TCII 198M>T, 376L>S, 219I>L and 259P>R) were examined for their effects on MTX efficacy and toxicity in 274 RA caucasian patients who had been treated with MTX (up to 25 mg per week) and folic acid (5-10 mg per week) for at least 6 months or they stop MTX because of adverse events. Adverse events (AEs)(gastrointestinal effects, elevated liver enzymes, pneumonitis, alopecia, infections, hematological AEs and other AEs) were monitored during MTX treatment. Genomic DNA was obtained from the peripheral blood. We use a SNP typing methods based on the RFLP-PCR and ARMS-PCR

Results: The effect of the ten SNPs on MTX-related efficacy and AEs was studied in 274 patients with RA. The SNPs genotypes had no effect on MTX response.

54% of patients described some toxicities during at least one study visit and 21% had AE leading to MTX withdrawal . Overall MTX-related AEs were more frequent in patients with the MTHFR 677T allele (CT and TT genotypes) than in those with the 677CC genotype ($p = 0.03$, OR:1.9) and GGH 401CC genotype than in those with GGH 401 CT and TT genotype ($p=0.05$, OR:3.4).

Furthermore, the 677T allele was associated with aminotransferases elevations among the subgroup of patients with MTX-related liver toxicity ($p = 0.02$; OR: 3.4). Other SNPs did not show significant associations with overall toxicity.

However MTX-related hepatotoxicity and alopecia was more frequent in patients with the RFC80 AA genotype than in those with the RFC 80 GG and RFC 80GA genotype (p=0.01, OR:3.57 and p=0.04, OR: 2.38). In patients with MTHFR 677CC genotype and RFC80GG or AG genotype the possibility of hepatotoxicity was only1% and in the whole group 7,5%. A multivariate model that included the six SNPs showed that three risk genotypes, (GGH 401CC, MTHFR 677TT/CT, RFC80AA) were associated with MTX hepatotoxicity.

Conclusion: There was no relationship between the ten SNPs and the efficacy of MTX treatment. MTHFR 677CC and GGH401 TT and CT polymorphisms were associated with a reduction in MTX related adverse effects.

Composite allele and haplotype analyses may help identify subsets of RA patients with adverse outcomes. Pharmacogenetic studies offer novel approaches to prospectively screen patients for genetic markers for optimal drug selection and minimum toxicity.

Hypoxic Conditions Differentially Modulate Normal and Osteoarthritic Human Articular Chondrocyte Proteomes. Vanessa Carreira, Cristina Ruiz-Romero, Jesus Mateos, Valentina Calamia, Berta Cillero-Pastor, Patricia Fernandez-Puente and Francisco Javier Blanco, INIBIC - Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Purpose: Osteoarthritis (OA) is a degenerative disease characterized by the degradation of articular cartilage. This tissue is avascular, and it is characterized by the low oxygen tension and poor nutrient availability for its cells, the chondrocytes. Hypoxia conditions have been reported to stimulate chondrogenesis and synthesis of extracellular matrix components. We pursued to analyze, by a proteomic approach, the effect of hypoxia on normal (N) and osteoarthritic cartilage cells.

Method: Chondrocytes were obtained from 6 OA patients undergoing joint replacement, and from 6 cartilages (N) from autopsies without history of joint disease. Cultured cells were subjected to normoxia or hypoxia conditions during 96 hours. Whole cell proteins were then isolated and resolved by two-dimensional gel electrophoresis. Gels were stained with SYPRORuby fluorescent dye, images were acquired using a CCD camera and image analysis was performed using PDQuest software. Proteins of interest were picked from the gels and identified by MALDI-TOF/TOF mass spectrometry. Database search and visualization of biological pathways were performed using PathwayStudio 6 software.

Results: We examined a mean of 500 protein spots that were present in the gels. Both qualitative and quantitative changes of protein patterns between normoxia and hypoxia were studied, considering expression changes within 95% confidence interval ($p<0.05$), and standardized average ratios exceeding 1.5. Table 1 shows the number of proteins that were found to be altered under the analyzed conditions. Twenty-eight protein forms were found to be modulated by hypoxia in normal chondrocytes, and 11 in OA cells when compared to their normoxia controls. The more extended modulation that could be detected in normal cells was mainly due to the alteration in these type of cells of several proteins related with metabolism and production of energy (10 out of the 28 modifications), such as nicotinamide methyl transferase, fructose biphosphate aldolase or ATP synthase. On the other hand, the decrease of Heat shock protein beta-1 and Peroxiredoxin-1 was detected in both N and OA cells. Finally, when comparing OA versus normal chondrocytes under hypoxia, we detected differences in abundance on 43 proteins. In this case, the major difference was observed in a group of 9 proteins involved in the glycolysis pathway, which are significantly decreased in OA. On the other hand, cytoskeleton-related proteins such as vimentin, vinculin or gelsolin were found to be increased in OA cells.

Conclusion: Hypoxic conditions induce diverse modifications in the proteomic profile of normal and OA human articular chondrocytes. Our results highlight the different capacity of normal and OA chondrocytes to react under a hypoxic environment.

	Hypoxia vs Normoxia in N Cells	Hypoxia vs Normoxia in OA Cells	N vs OA Cells under Hypoxia
Nº Proteins increased	8 (Actin, vinculin, pyruvate kinase)	1 (Pyruvate kinase)	10 (Gelsolin, vimentin, cyclophilin)
Nº Proteins decreased	20 (ATP synthase, HSPB1, SOD2)	10 (Tropomyosin)	33 (Annexins, glycolysis proteins)

MicroRNA Expression Profiles in Normal and Osteoarthritic Human Chondrocytes. Silvia Diaz-Prado[1], Claudia Cicione[2], Emma Muiños[2], Mª Carmen Arufe[1], Isaac Fuentes[1], Francisco Javier de Toro[2] and Francisco Javier Blanco[2], [1]INIBIC - University of A Coruña, A Coruña, Spain, [2]INIBIC - Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Purpose: MicroRNAs (miRNAs) are single-stranded and small non-coding RNA molecules of 18-24nt in length that negatively regulate the expression of target genes in a post-transcriptional manner. Recent evidences have also indicated that these small RNA molecules play a role in the pathogenesis of human disorders, exhibiting tissue-specific or developmental stage-specific expression patterns associated with human diseases. A number of human diseases are associated with changes in the copy number or expression of microRNAs, indicating that miRNA expression levels are closely associated with developmental and physiological states as well as disease process. However, at present, little is known if aberrant microRNA expression is associated with osteoarthritis (OA) development.

Objective:Identify and characterize the expression profiles of 723 human miRNAs from normal and OA chondrocytes which could have important diagnostic and therapeutic potential

Method: Human chondrocytes from 4 healthy donors and from 4 OA patients were obtained. After S1 passage, cells were moved to aggregate culture for 1 week. Evaluation of in vitro aggregate culture was carried out using histochemical and immunohistochemical stainings. MiRNAs were isolated with miRVana Isolation kit. MiRNA expression levels were studied using Human miRNA Microarray kit ver.2 (Agilent, Spain). Images were scanned and quantified using Feature Extraction (FE) Software ver.10.1.1 and GeneSpring GX10 (Agilent, Spain). All microarray hibridization experiments and data analysis were performed at the CNIO (Spain).

Results: The microRNA profiling of normal and osteoarthritic chondrocytes revealed a few number of miRNAs differentially expressed in normal and OA chondrocytes. As shown in the table, of the 723 human miRNAs immobilized on the array, only 3 miRNA were up-regulated in OA chondrocytes and 6 miRNA were up-regulated in normal chondrocytes.

miRNA name	Accession number	Fold Change	p value
hsa-miR-483-5p	MI0002467	2,04	$2,35 \times 10^{-4}$
hsa-miR-145	MI0000461	3,79	$1,43 \times 10^{-4}$
hsa-miR-630	MI0003644	-2,76	$1,48 \times 10^{-4}$
hsa-miR-149	MI0000478	-1,76	$2,28 \times 10^{-3}$
hsa-miR-582-3p	MIMAT0004797	-1,94	$3,31 \times 10^{-4}$
hsa-miR-1227	MI0006316	-1,80	$2,54 \times 10^{-5}$
hsa-miR-634	MI0003649	-1,75	$7,66 \times 10^{-4}$

hsa-miR-576-5p	MIMAT0003241	-4,74	$6{,}68 \times 10^{-4}$
hsa-miR-641	MI0003656	-2,36	$1{,}71 \times 10^{-3}$

miRNA differentially expressed in OA versus normal chondrocytes.

Conclusion: We identified 9 miRNAs differentially expressed in OA and in normal chondrocytes, whose expression profiling might provide a useful tool for the pathophysiology research of the chondrocytes. Data indicate that these miRNAs might be used as new diagnostic and prognostic biomarkers.

Investigating the Role of the Pain Modulating DREAM Pathway Genes in Musculoskeletal Pain. Kate L. Holliday[1], John McBeth[2] and W. Thomson[1], [1]University of Manchester, Manchester, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom

Purpose: A genetic component to the aetiology of musculoskeletal pain has been reported but the genes involved are yet to be identified. One candidate is the transcriptional repressor, *DREAM*. *DREAM* knockout mice exhibit hypoalgesia as a result of increased dynorphin expression and increased κ opioid tone suggesting a key role for DREAM in pain modulation. The aim of this study was to determine if genetic variation in the DREAM pathway genes influences susceptibility to musculoskeletal pain in the population.

Method: Pain data was collected at 3 time-points over 4 years via a postal survey as part of the EPIFUND study. Subjects indicated the presence of any pain on a blank body manikin from which a total pain score which ranged from 0 (no pain) to 29 (pain in all sites of the body) was derived. For each subject the maximum number of pain sites across the 3 time-points was determined. Chronic widespread pain (CWP) was classified at each time-point using ACR criteria. DNA samples were collected from 1189 subjects. Pair-wise tagging SNPs ($r^2 \geq 0.8$) were selected for 3 genes (*DREAM*, prodynorphin (*PDYN*) and the κ opioid receptor (*OPRK1*)) and their 10 kb flanks. SNPs were genotyped using Sequenom MassARRAY technology. Zero-inflated negative binomial regression (ZINB) was used to test for association between SNPs and the number of reported pain sites. ZINB reports the association with the presence of any pain (Odds ratios (OR) and 95% confidence intervals (CI)) and the proportional change in the maximum number of pain sites in subjects reporting pain (Rate Ratios (RR) and 95%CI). Logistic regression was used to test for association between SNPs and CWP (reported as OR (95%CI)) in a nested case-control study. Cases had CWP at ≥2 time-points and controls were pain-free at all three time-points.

Results: Of the 39 SNPs selected, 35 were successfully genotyped in 1062 subjects. One SNP in *DREAM*, 4 SNPs in *PDYN* and 2 SNPs in *OPRK1* were significantly associated with the maximum number of pain sites in subjects reporting pain e.g. rs6136667 in *PDYN* (RR=0.86 (0.77-0.95) p=0.004 for each copy of the minor allele). In the CWP analysis (n=183 cases and n=179 controls), two SNPs in *OPRK1*, rs1365097 and rs6473797, were associated with an increased risk of having CWP e.g. for rs1365097 OR=1.62 (1.17-2.25) p=0.004 for each copy of the minor allele. These two SNPs were also associated with an increased risk of reporting any pain in the population e.g. rs1365097 OR=1.64 (1.16-2.27) p=0.005 for each copy of the minor allele.

Conclusion: This is the first study to examine and observe associations between genetic variation in the DREAM pathway genes and musculoskeletal pain in the general population. SNPs in *OPRK1* were also associated with CWP and the presence of pain but not the extent of pain in the population. Replication of these findings in an independent cohort is now required. If confirmed these findings may lead to identification of new therapeutic targets for pain or may influence response to therapeutics targeting this pathway.

Investigation of Potential Non-HLA RA Susceptibility Loci in a European Cohort Increases the Evidence for 10 Markers. Darren Plant[1], Francois Cornelis[2], Solbritt Rantapää-Dahlqvist[3], George Goulielmos[4], Merete L. Hetland[5], Lars Klareskog[6], Karim Raza[7], Torsten Witte[8] and Jane Worthington[1], [1]The University of Manchester, Manchester, United Kingdom, [2]Evry University, Paris, France, [3]Norrland University Hospital, Umeå, Sweden, [4]University of Crete, Heraklion, Greece, [5]DANBIO, Copenhagen University Hospital at Hvidovre, Copenhagen, Denmark, [6]Karolinska Institutet, Stockholm, Sweden, [7]University of Birmingham, Birmingham, United Kingdom, [8]Hannover Medical School, Hannover, Germany

Purpose: Genetic factors play a substantial role in determining development of rheumatoid arthritis (RA), and are likely to account for 50-60% of disease susceptibility. In patients of European ancestry, the strongest genetic effects are conferred by the HLA-DRB1 locus on chromosome 6 and protein tyrosine phosphatase 22 (PTPN22) on chromosome 1p13. Recent whole genome and candidate gene disease association studies have identified further RA susceptibility loci (i.e. AFF3, CCL21, CTLA4, CD226, CD40, I2/IL21, IL2RA, IL2RB, KIF5A, PRKCQ, PTPN22, STAT4, TNFAIP3, and TRAF1/C5), defined by single nucleotide polymorphism (SNP) markers, which associate with susceptibility with low-to-moderate risk. The purpose of this study was to investigate recently identified RA susceptibility SNPs using RA cohorts from six European countries, and perform a meta-analysis of these data with all previously published results.

Method: 3,529 patient DNA samples were collected from 6 countries (UK, Germany, France, Greece, Sweden and Denmark). 1,585 control DNA samples were collected from 4 countries (not Sweden or Denmark). Eighteen SNPs were selected for genotyping using Sequenom® MassArray™ technology. Samples with a >85% success rate and only those SNPs with a genotype success rate of >85% were included in the analysis. Scandinavian patient data was pooled and previously published Swedish control data was accessed as a comparison group. Meta-analysis was used to combine results for all cohorts in the current study, and for all cohorts identified in the literature.

Results: 3,423 patients and 1,569 controls were successfully genotyped. 7 SNPs (rs1160542 (*AFF3*), rs1678542 (*KIF5A*), rs2476601 (*PTPN22*), rs3087243 (*CTLA4*), rs4810485 (*CD40*), rs5029937 (6q23) and rs7574865 (*STAT4*) were associated with RA (at the 5% significance threshold) with effect sizes similar to those previously reported. In the meta-analysis incorporating previously published results, all 18 SNPs were associated with RA. Data from the current study increased the significance for association with RA for 10 SNP markers in the meta-analysis and for the first time takes to 12 the number of markers associated with RA at genome-wide significance ($p<5x10^{-7}$).

Conclusion: In a large European RA cohort we provide further evidence to support the association of 18 SNPs with RA, 12 at genome-wide significance.

Genetic Risk Score Predicting Risk of Rheumatoid Arthritis Phenotypes and Age of Symptom Onset. Lori B. Chibnik, Brendan T. Keenan, Jing Cui, Robert M. Plenge and Elizabeth W. Karlson, Brigham and Women's Hospital, Boston, MA

Purpose: Cumulative genetic profiles can help identify individuals at high-risk for developing RA. We examined the cumulative impact of 22 validated genetic risk alleles on the risk of RA phenotypes characterized by serologic and erosive status.

Method: Blood was obtained from 32,826 women in the Nurses' Health Study (NHS) and 29,611 women in the Nurses' Health Study 2 (NHS2). An additional 33,040 NHS participants provided buccal cell samples. Incident RA and erosive changes were confirmed by medical record review for ACR criteria. We evaluated single nucleotide polymorphisms (SNPs) at 13 validated RA risk loci and 8 Human Leukocyte Antigen (HLA) alleles among 484 Caucasian RA cases and 481 age matched Caucasian controls from NHS and NHS2. We created a weighted genetic risk score for 22 alleles (wGRS). The weight for each risk allele was calculated as the log of the published odds ratio (OR) from GWAS analyses with replication or from a comprehensive meta-analysis. We examined wGRS as 7 ordinal groups based on the distribution in controls. We used logistic regression adjusting for age and pack-years of smoking (packs per day X years smoked) to assess the relationship between wGRS groups and the odds of developing seronegative RA (RF- and CCP-), seropositive RA (RF+ or CCP+), erosive RA and seropositive erosive RA phenotypes. A common control group was used for all phenotypes. Each group was compared to the median group. In separate case only analyses, we assessed the relationships between age of symptom onset and continuous wGRS using linear regression and between age of symptom onset and grouped wGRS using an ANOVA.

Results: In 484 RA cases, 289 (60%) were seropositive, 146 (30%) had erosions and 95 (20%) were seropositive and had erosions at RA diagnosis. The mean age at RA onset was 55.7 ± 10.4. In the top wGRS risk group compared to the median group, we found an OR of 1.3 (95% CI = 0.7 – 2.3) for seronegative RA and an OR of 2.9 (95% CI = 1.8 – 4.6) for seropositive RA. The strongest relationships were in predicting erosive RA, with an OR of 3.6 (95% CI = 1.9 – 6.6) for erosive RA and an OR of 5.7 (95% CI = 2.8 – 12.0) for seropositive erosive RA for the highest wGRS group. No significant relationship was seen between continuous or grouped wGRS and age at symptom onset.

Conclusion: We saw significant associations between a cumulative genetic risk score with 22 alleles and odds of seropositive, erosive and seropositive erosive RA. No associations were seen with age of symptom onset. Further studies are needed to assess the potential of the wGRS in predicting other phenotypes of RA.

wGRS Group	OR (95% CI)			
	Sero- RA	Sero+ RA	Erosive RA	Sero+ Erosive RA
1	1.0 (0.5 – 2.1)	0.5 (0.2 – 1.2)	0.6 (0.2 – 1.8)	0.7 (0.2 – 2.8)
2	0.7 (0.4 – 1.3)	0.7 (0.4 – 1.2)	1.0 (0.5 – 2.0)	0.8 (0.3 – 2.2)
3	1.0 (0.6 – 1.7)	0.7 (0.4 – 1.1)	0.8 (0.4 – 1.6)	0.5 (0.2 – 1.4)
4	1.0 (ref)	1.0 (ref)	1.0 (ref)	1.0 (ref)
5	1.1 (0.6 – 1.9)	1.7 (1.0 – 2.8)	1.5 (0.8 – 3.1)	1.5 (0.6 – 3.7)
6	1.7 (0.9 – 3.2)	1.8 (1.0 – 3.2)	2.1 (1.0 – 4.5)	2.7 (1.1 – 6.5)
7	1.3 (0.7 – 2.3)	2.9 (1.8 – 4.6)	3.6 (1.9 – 6.6)	5.7 (2.8 – 12.0)

Rheumatoid Factor Interferes with Multiplex-Based ELISA in Patients with Rheumatoid Arthritis. Derrick J. Todd[1], Nicholas Knowlton[2], Elizabeth W. Karlson[1], Nancy A. Shadick[3], Michael E. Weinblatt[1], Peter H. Schur[1], Ronenn Roubenoff[4], Elena Izmailova[5], M. Centola[6] and David M. Lee[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Biogen-Idec Pharmaceuticals, Cambridge, MA, [5]Millennium Pharmaceuticals, Cambridge, MA, [6]OK Med Research Foundation, Oklahoma City, OK

Purpose: Heterophilic antibodies such as rheumatoid factor (RF) potentially interfere with immunoassays. Multiplex-based ELISA arrays allow serum to be tested for multiple analytes. Data derived from these arrays are published with increasing frequency in RA research. We sought to answer whether serum RF in patients with RA might interfere with multiplex ELISA arrays.

Method: Serum was obtained from 9 patients with RA. Aliquots of each sample were then RF-depleted (RD) or mock-depleted (MD) by affinity absorption against human IgG-conjugated or unconjugated sepharose, respectively. All absorptions were incubated vol:vol for >4 hr at 4°C. RF levels were measured by nephelometry. Using Searchlight™ multiplex ELISA, RD and MD samples were tested in duplicate for 16 analytes: A-SAA, E-selectin, IFNg, ICAM1, IL1ra, IL2R, IL6, IL7, MMP1, MMP3, MMP9, RANTES, TIMP1, TIMP2, TNFRI, and TNFRII (PerBio/ThermoFisher, Woburn, MA). RF interference (RFI) was defined as >2-fold false elevation of analyte signal in the non-RF-depleted sample (MD:RD >2).

Results: RF ranged from 13-680 IU in MD samples and was undetectable in all RD samples (<10 IU). For 16 analytes tested in 5 patients with RF <100 IU, the mean MD:RD ratio was 1.47, and RFI occurred in 15/80 (19%) tests. In 4 patients with RF >100 IU, the mean MD:RD ratio was 3.61, and RFI was present in 43/64 (67%) tests. RFI for MMP1 (Table 1) was representative of that observed for A-SAA, ICAM1,

IL1ra, IL6, IL7, MMP3, MMP9, TIMP2, TNFR1, and TNFRII. Table 1: MMP1 concentration in mock-depleted (MD) and RF-depleted (RD) samples in 9 patients with RA as measured by Searchlight™ multiplex ELISA. RF levels in MD samples are also shown.

Patient	RF (IU)	MD ± SEM (ng/ml)	RD ± SEM (ng/ml)	MD:RD Ratio
1	13	3.5 ± 0.5	2.3 ± 0.1	1.5
2	19	9.0 ± 1.3	4.8 ± 0.3	1.9
3	28	5.3 ± 0.4	4.1 ± 0.4	1.3
4	76	3.1 ± 0.8	4.0 ± 0.1	0.8
5	76	6.7 ± 0.6	4.2 ± 0.1	1.6
6	139	14.9 ± 2.9	3.4 ± 0.0	4.4
7	178	5.3 ± 1.6	2.9 ± 0.1	1.8
8	353	12.0 ± 3.1	1.2 ± 0.0	10.2
9	680	22.7 ± 7.5	0.9 ± 0.0	24.7

Conclusion: In RA patients, serum RF interferes with a portion of analyte measurements in multiplex-based ELISA arrays. In a separate series of experiments, RFI was also present in samples tested by Ray Biotech protein arrays as well as Luminex assays from BioRad, Millipore, and Invitrogen. Additional studies are needed to determine whether RFI is assay-specific or analyte-specific, and whether blocking agents can dampen interference. These findings are important to consider when interpreting data generated by multiplex arrays in patients with RA.

Genome Wide Association Study of Genetic Predictors of Quantitative Anti-CCP Level in RA. Jing Cui[1], Anita DeStefano[2], Michael E. Weinblatt[1], Robert M. Plenge[1], Nancy A. Shadick[3] and Elizabeth W. Karlson[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Boston University Schools of Public Health and Medicine, Boston, MA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Purpose: Anti-cyclic citrullinated peptide (anti-CCP) antibody is a marker for progressive erosive rheumatoid arthritis (RA), and a stable quantitative trait. To identify genes that influence quantitative anti-CCP level in RA patients, we carried out a genome wide association study (GWAS) using 909,622 SNPs genotyped in 507 anti-CCP+ RA patients from the Brigham Rheumatoid Arthritis Sequential Study (BRASS).

Method: Anti-CCP was measured using a second generation ELISA assay (Inova Diagnostics, Inc). Samples were genotyped using Affymetrix 6.0 genotyping platform ("900K array"). To ensure high quality data and to minimize false positive results due to technical artifact, filtering criteria were set as: genotype call rate ≥0.95 per SNP and ≥0.95 per individual), minor allele frequency (MAF) ≥0.01, p-value for Hardy-Weinberg equilibrium test ≥0.0001. There were 734,008 SNPs from 491 self-reported Caucasians (81.9% female) that met the criteria. Anti-CCP measures were transformed to a normal distribution by taking the inverse normal of the rank. Association between SNPs and transformed anti-CCP level was tested using general linear model assuming additive model in PLINK. The empirical p value from permutation was utilized to evaluate genome wide significance.

Results: Mean age was 58.7 and disease duration was 16.7 years. Median anti-CCP titer was 119 (range 20-448). We identified 5 SNPs at p value ~10^{-6}, 46 SNPs at p~10^{-5}, and 721 SNPs at p~10^{-4}. The best SNP within the MHC region has association at p ~10^{-4}. Genome wide

permutation testing was pursued to further evaluate the GWAS findings. Under the null, if there is no genetic determinant for anti-CCP level, by chance, we would expect approximately 728 false positive SNPs to be identified at 10^{-4} significance level, however we observed 775. The excess of observed compared to expected results were significant (p=0.04).

Conclusion: We carried out an initial genome wide scan on the quantitative trait anti-CCP level. The top 5 SNPs association with anti-CCP level did not reach genome wide significance, however we plan to validate our findings using two independent CCP+ RA cohorts.

Table. Top 20 SNPs associations with Anti-CCP level

Variation in Rheumatoid Arthritis (RA) Susceptibility Genes Predicts Response to Anti-Tumour Necrosis Factor Treatment in RA Patients. Laura J. Gibbons[1], Rachael Tan[1], Catherine Potter[2], K. L. Hyrich[1], Ann W. Morgan[3], Anthony G. Wilson[4], John D. Isaacs[2], Braggss and A. Barton[1], [1]arc Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Musculoskeletal Research Group, Newcastle University, Newcastle Upon Tyne, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Sheffield Uni /Medical School, Sheffield, United Kingdom

Purpose: Anti-tumour necrosis factor (TNF) therapy has proven highly successful in the treatment of rheumatoid arthritis (RA); however, 30-40% of patients demonstrate little or no response. The use of genetic predictors of response in addition to clinical data may allow individual tailoring of treatment. In other diseases, such as type 2 diabetes, genes associated with susceptibility to disease have also been shown to influence treatment response. Therefore, we aimed to test the hypothesis that genes influencing susceptibility to RA might also demonstrate effects on anti-TNF treatment response.

Method: Twenty single nucleotide polymorphisms (SNPs) mapping to 15 confirmed RA genetic susceptibility loci were genotyped, using Sequenom® iPLEX technology, in 1,092 RA patients receiving treatment with one of the anti-TNF drugs: etanercept, infliximab or adalimumab. Multivariate linear regression analyses were performed under an additive model, using absolute change in 28 joint-count disease activity score (DAS28) between baseline and 6-month follow-up as the outcome variable and adjusting for confounders: baseline DAS28, baseline Health Assessment Questionnaire (HAQ) score, DMARD co-therapy and gender. Samples and SNPs were subjected to a ≥80% genotyping success quality control (QC) measure and *P* values <0.05 were considered statistically significant. Associated markers were genotyped in an additional 338 samples and a combined analysis of 1,430 anti-TNF treated RA subjects was performed.

Results: In the initial cohort (n = 1,012 after QC), significant associations with response to anti-TNF treatment were observed at 3 loci: *CD226*, *AFF3* and *STAT4*. Analysis of the combined cohort (n = 1,334 after QC) revealed statistically significant evidence of association at *CD226* and *AFF3*. The *STAT4* association was driven by the heterozygous genotype, which seems a biologically implausible model of association. The major allele (G) at rs10865035, mapping to *AFF3*, conferred improved response to treatment (additive coef. -0.14 [95% CI -0.25, -0.03] *P* = 0.015). At rs763361 in *CD226*, the minor allele (C) was associated with reduced response to treatment (additive coef. 0.11 [95% CI 0.00, 0.22] *P* = 0.048).

Conclusion: These results implicate the RA susceptibility genes, *CD226* and *AFF3*, as having additional roles in influencing response to anti-TNF treatment, while further investigation of *STAT4* is warranted. *CD226* encodes a type I membrane molecule involved in T- and natural killer cell-mediated immune responses. The AFF3 protein is a member of a family of transcription factors expressed on lymphoid cells.

Association Between Anti-TNF Treatment Response and Genetic Variants within the TLR and NFκB Signalling Pathways. Catherine Potter[1], Heather J. Cordell[1], Anne Barton[2], Ann K. Daly[1], Kimme Hyrich[2], Derek A. Mann[1], Ann W. Morgan[3], Anthony G. Wilson[4] and John D. Isaacs[1], [1]University of Newcastle, Newcastle, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Sheffield University, Sheffield, United Kingdom

Purpose: To investigate association between response to anti-TNF therapy and genetic variation within genes integral to the toll-like receptor (TLR) and NFκB signalling systems, two cardinal regulators of inflammatory and immune responses, in a large UK-wide cohort of patients with rheumatoid arthritis (RA).

Method: DNA samples from 923 patients receiving anti-TNF therapy (etanercept, infliximab or adalimumab) for the treatment of RA were available from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS). Pairwise-tagging SNPs spanning 24 candidate genes were selected from the HapMap dataset (www.hapmap.org) and genotyped using Sequenom iPLEX™ technology. Multivariate regression analyses were performed to test association between individual SNPs, under an additive model, and treatment response at 6-months follow-up. Treatment response was assessed using both the absolute change in DAS28 and the EULAR response criteria. Separate analyses were also performed to investigate association with individual anti-TNF drugs. P values ≤ 0.05 were considered statistically significant.

Results: A total of 189 SNPs were successfully genotyped and analysed in 909 individuals. These patients had long-standing (mean duration = 14 years), active disease (mean DAS28 = 6.7) with a high degree of disability (mean HAQ score = 2.1). At 6 months follow-up, 20% of patients were non-responders, 53% moderate and 27% good responders according to the EULAR criteria. The mean change in DAS28 was an improvement of 2.5 points. Twelve SNPs spanning 9 genes (*CHUK, IKBKB, IRAK-3, MyD88, NFkB-2, NFKBIB, PTGS2, TLR-2, TLR-10/1/6*) demonstrated association with the absolute change in DAS28 and/or the EULAR response criteria (p≤0.05). In particular, associations to the *MyD88* (rs7744) and *CHUK* (rs11591741) loci were demonstrated under each model applied. These variants map to the

3′UTR and intron 9 of the *MyD88* and *CHUK* genes, respectively. In addition, both SNPs act as tagging markers for additional variants spanning the two genes, signifying a number of potential functional effects. Finally, a greater number of SNPs, including those mapping to *MyD88* and *CHUK*, demonstrated associations specifically in the etanercept subgroup (n=386) compared to the infliximab (n=400) or infliximab/adalimumab combined treatment subgroups (n=523) when analysed separately.

Conclusion: Several SNPs mapping to the TLR and NFκB signalling systems demonstrated association to anti-TNF response as a whole and, in particular with response to etanercept. Validation of these findings in independent datasets is now warranted before additional genetic and functional analyses are performed to identify the true causal variants.

RA Risk Alleles as Correlates of Response to Anti-TNF Therapy in RA. J. Cui[1], S. Saevarsdottir[2], B. Thompson[3], S. Raychaudhuri[1], P. Gregersen[4], F. Batliwalla[4], N. De Vries[5], MM Herenius[5], Paul P. Tak[6], C.F. Allaart[7], N. Shadick[1], M. E. Weinblatt[1], A. Barton[8], A. Morgan[9], L. Klareskog[2], L. Alfredsson[2], S.L. Bridges Jr.[10], L.A. Criswell[11], L. Padyukov[2], T.W.J. Huizinga[7], R.E.M. Toes[7], E. Karlson[1] and R.M. Plenge[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Karolinska Institute, Stockholm, Sweden, [3]Broad Institute, Cambridge, MA, [4]Feinstein Institute for Med Res, Manhasset, NY, [5]University of Amsterdam, Amsterdam, Netherlands, [6]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [7]Leiden University Medical Center, Leiden, Netherlands, [8]arc Epidemiology Unit, Manchester, United Kingdom, [9]University of Leeds, Leeds, United Kingdom, [10]Univ of Alabama, Birmingham, AL, [11]UCSF, San Francisco, CA

Purpose: Anti-tumor necrosis factor alpha (anti-TNF) therapy is a mainstay of treatment in RA, yet there is no effective biomarker predictor of response. The aims of our study are to identify clinical factors and genetic variants that influence response to anti-TNF therapy.

Method: Through an international collaboration consisting of 9 different RA cohorts, we identified 458 EULAR 'good responders' and 349 EULAR 'non-responders' to etanercept, infliximab, and adalimumab: Autoimmune Biomarkers Collaborative Network, Amsterdam Medical College, BeSt study, Brigham Rheumatoid Arthritis Sequential Study, Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate, Epidemiological Investigation of RA, an early RA randomized control trial of etanercept vs MTX, the Karolinska Institute, and the Leiden University Medical Center. EULAR good response was defined as ending Disease Activity Score (DAS)<3.2 and DAS improvement >1.2; EULAR non-response was defined as DAS improvement<0.6 or improvement≤1.2, and ending DAS >5.1. We tested clinical factors such as age, sex, disease duration, RF and CCP positivity, concomitant medications, and start DAS as correlates of treatment response using logistic regression. We genotyped 31 validated SNPs associated with risk of RA, including tag SNPs of *HLA-DRB1* 'shared epitope' alleles. We used univariate and multivariate logistic regression models adjusting for clinical factors and cohort to test for allelic associations with treatment response.

Results: In our univariate analysis of clinical factors, younger age (P<0.0001), male gender (P=0.003), and concurrent MTX (P<0.0001) were associated with EULAR 'good response'. In our univariate analysis of 31 RA risk alleles, two SNPs were associated with anti-TNF treatment response: *PTPRC* gene locus (rs10919563; OR=0.66, P=0.005) and *TNFRSF14* gene locus (rs3890745; OR= 1.32, P=0.01). However, these were not significant after adjusting for multiple hypotheses. The 'shared epitope' tag SNPs were not associated with treatment response. Our findings were unchanged in a multivariable model.

Conclusion: We observed statistically significant associations between response to anti-TNF therapy and three clinical factors (younger age, male gender and concurrent MTX), as observed by others. We found associations between treatment response and two RA risk alleles (*PTPRC* and *TNFRSF14*), although additional genetic studies are required to confirm that associations are true positive results.

TNFalpha Response of Human Synovial Fibroblast Cells Is Strongly Modified by in Vitro Knock-Down of Clusterin. Geraldine Falgarone[1], Abdellatif Essabbani[2], Nicolas Cagnard[2], Sylvie Mistou[2] and Gilles Chiocchia[3], [1]University paris 13; AP-HP, Avicenne hospital, Bobigny, France, [2]INSERM; CNRS; Paris Descartes University, Paris, France, [3]INSERM; AP-HP; CNRS; Paris Descartes University, Paris, France

Purpose: Clusterin (CLU) has been implicated in tumorogenesis, apoptosis, inflammation and proliferation. We recently reported the regulation of CLU, in rheumatoid arthritis (RA) tissue and fibroblast-like synoviocytes (FLS). We and others have reported that CLU was an inhibitor of NF-kB pathway.

This study was designed to decipher the molecular network linked to CLU expression in FLS and evaluate the consequences of its low expression in condition of TNF alpha stimulation.

Method: FLS were transfected with siRNA for CLU or scrambled nucleotides (control). CLU expression was assayed by Q-RT-PCR and Western blot. These cells were cultured for 24H and 48H with TNF alpha or not. Pan-genomic gene expression was then assayed by DNA micro array. Gene network around CLU and gene interations were analysed with the Ingenuity Pathway Analysis Software ™.

Result: SiCLU transfection in FLS induced a lack of expression of CLU both at the mRNA level and protein level. Down-regulation of CLU resulted in a modification of expression of genes known to be directly linked to CLU and of almost 5% of the tested genes (857 out of 17225); the up-regulation of a small group of gene, among them TIAM1, emphasize the hypothetical role of CLU in the pseudotumoral characteristic of FLS. The comparison of gene expression with or without TNF stimulation allowed the classification of sampled with a good concordance both with and without CLU expression. Moreover differential comparison showed that CLU down regulation in RA led to a profound modification of TNF alpha response as 3 sets of genes emerged: 497 genes were modulated mainly by siCLU transfection in the context of TNF stimulation, 356 genes were modified because of TNF stimulation whatever CLU expression, and 484 genes were modulated in FLS during TNF stimulation with CLU expression. These modifications included changes in IL-8 and Wnt signaling gene expressions.

Conclusion: DNA Chips can assay for RA FLS gene expression after CLU inhibition under the TNF alpha pressure. The results showed that CLU inhibition resulted in the modulation of expression of genes linked in networks which are known to be linked to rheumatoid arthritis. These results argue that CLU down-regulation in FLS participate to the aggressiveness of the FLS and incites further explorations on CLU involvement in RA synovitis physiopathology.

Interleukin 2 Receptor, Alpha Is Associated with Radiographic Joint Damage in a Japanese RA Population. Taku Suzuki, Katsunori Ikari, Yano Koichiro, So Tsukahara, Kazumasa Nishimoto, Atsuo Taniguchi, Hisashi Yamanaka and Shigeki Momohara, Tokyo Women's Medical University, Tokyo, Japan

Purpose: The Wellcome Trust Case Control Consortium (WTCCC) published genome-wide association study (GWAS) using 1860 rheumatoid arthritis (RA) patients and 2938 controls in a British population. The WTCCC study confirmed the association of SNPs with previously identified loci within the HLA region and PTPN22 gene, and nine more SNPs were found to be associated at the next level (rs6684865, rs11761231, rs11162922, rs3816587, rs743777, rs2837960, rs2104286, rs6920220, rs9550642). Subsequently, they reported 49 SNPs that were associated with RA in the third level, and three of these could be replicated in a validation cohort of 4106 patients and 11238 controls (rs4750316, rs1678542 and rs3218253). The aim of our study is to investigate the impact of these 12 SNPs on radiographic joint damage in Japanese RA patients.

Method: DNA samples of 628 RA patients with the data of Sharp/ van der Heijde score (SHS) of the hands at 5-year disease duration, which represents joint damage, were obtained from the IORRA (Institute of Rheumatology RA cohort) DNA collection. SNP genotyping were performed with TaqMan genotyping assay (Applied Biosystems Japan). Simple linear regression analysis was performed with SHS as a dependent variable, and the number of minor alleles of each SNPs as independent variables. When the result was significant, we also

performed multiple regression analysis on SHS with the SNP and the number of HLA-DRB1 alleles encoding the shared epitope (SE), which was reported to be a strong genetic factor on joint damage. These analyses were performed using the R software package (http://www.r-project.org/).

Results: Though most SNPs showed negative results, rs2104286 on interleukin 2 receptor-alpha (IL2RA) was found to have impact on radiographic joint damage (P=0.046). The multiple regression analysis using rs2104286 and SE also confirmed the result (P=0.042).

Conclusion: IL2RA has an impact on radiographic joint damage in Japanese RA patients.

Gene Expression Signatures in Synovial Tissue Define Distinct Molecular Subtypes of Rheumatoid Arthritis. Glynn Dennis Jr.[1], Wei Y. Lin[1], Lauri Diehl[1], C. Holweg[1], M. Townsend[1], Judith Endres[2], David A. Fox[3] and Flavius Martin[1], [1]Genentech, Inc, South San Francisco, CA, [2]Univ of Michigan Med Ctr, Ann Arbor, MI, [3]Univ of Michigan, Ann Arbor, MI

Purpose: The study aimed to identify molecular subtypes of rheumatoid arthritis (RA) with linkage to pathological features and therapeutic outcome.

Method: Genome-wide transcriptional profiles for 81 synovial tissue samples obtained by surgery from 50 RA patients were analyzed by bootstrapped hierarchical clustering. Statistical analysis identified differentially expressed genes, over-represented pathways and a gene signature 'proxy' for each molecular subtype. Analysis of tissue histology and immunohistochemistry identified joint pathologies that associated with array-based findings. Gene signatures were tested for association with therapeutic outcome on an independent data set.

Results: Multi-scale bootstrap resampling of 81 samples (10,000 iterations) inferred four molecular subtypes of RA. The largest subtype grouped 34 samples (87% branch support) that shared extensive lymphoid infiltration and follicle-like lymphoid clusters (each $p<0.01$). This signature contained abundant transcripts for immunoglobulins and T cell markers. A second subtype (17 samples, 67% branch support) represented a distinct type of inflammation that was characterized by transcripts involved in respiratory burst and chemotaxis pathways. This signature was inversely associated with joint vascularity ($p<0.05$). Two non-inflammatory subtypes were identified. The first (19 samples, 94% branch support) possessed a signature inversely associated with lymphocyte and CD15+ cell infiltration (each $p<0.01$) and was enriched for wnt-signaling and tumorigenesis pathway genes. The second non-inflammatory subtype (9 samples, 88% branch support), collectively modulated genes involved in cell adhesion and bone remodeling pathways. This gene signature was associated with a higher degree of synovial lining hyperplasia. Finally, this subtype was found to be associated with a poor response to anti-TNF therapy in an independent dataset.

Conclusion: Molecular profiling, bootstrap-resampling and over-representation analysis provided statistical support for four molecular subtypes of RA. Each subtype possessed a unique gene signature that mapped differentially to histology indicators of joint pathology and reflected modulation of distinct signaling networks. One of the molecular subtypes represented patients that responded poorly to anti-TNF therapy, suggesting that RA molecular subtyping has prognostic value for patient response to therapy.

FCRL3-169CC Is Associated with ACPA Positive RA and with Radiographic Progression. Marthe T. Mæhlen[1], Gry Nordang[2], Silje W. Syversen[1], Désirée M.F.M. van der Heijde[3], T.K. Kvien[1], Till Uhlig[1] and Benedicte A. Lie[2], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Oslo University Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands

Purpose: The Fc receptor-like 3 (FCRL3) gene has been reported to be associated with rheumatoid arthritis (RA) in Japanese, Norwegian and Dutch populations with conflicting results in other populations. The CC genotype of a polymorphism in the promoter region -169T>C of FCRL3 showed the strongest association to RA, however associations to Anti-Citrullinated Protein Antibodies (ACPA) and disease severity is unknown. As ACPA positive and ACPA negative RA appear to be two distinct disease entities, with different genetic profile, we aim to investigate the effect of FCRL3 -169T>C on ACPA status and radiographic progression.

Method: 657 patients from two Norwegian cohorts of ACR classified RA patients (Oslo RA registry and the EURIDISS cohort) and 982 Norwegian controls who had previously been genotyped for FCRL3 -169T>C (rs7528684) were included. Presence of ACPA, rheumatoid factor (RF) and shared epitope (SE) were available on all patients. X^2 tests were used to test for associations. The EURIDISS cohort (disease duration <4 years) was followed longitudinally for 10 years with radiographs of hands, assessed at baseline and after 10 years according to van der Heijde modified Sharp score (vdHSS). Patients with average annual progression in vdHSS of hands ≥1.0 units (progressors, n=70) were compared with those <1.0 units (non-progressors, n=47). Logistic regression was used to assess whether the CC genotype predicted radiographic progression.

Results: We found tendency of association with the CC vs. CT/TT genotype for the RA total material (table), and after stratifying for antibody status, the CC genotype was significantly associated with ACPA positive RA and RF positive RA (OR: 1.53; 95% CI 1.12-2.10 p=0.008). No association was found between the FCRL3 polymorphism and the SE. Logistic regression analysis showed that the CC genotype compared to the CT/TT genotype was significantly associated with radiographic progression (OR=3.72; 95% CI 1.17-11.83 p=0.026) in RA patients. This significant association was maintained after adjustment for age, sex and ACPA status (OR 3.91; 95% CI 1.08-14.18 p=0.038).

Conclusion: A promoter polymorphism of FCRL3 was associated to both ACPA and RF positive RA, which supports the proposed association with autoantibody production. In addition we found the FCRL3 -169CC genotype to influence disease severity by conferring increased radiographic progression. This new finding supports that FCRL3 is involved, not only in susceptibility, but also in disease progression.

	CC vs. CT/TT		
	OR	95% CI	P value
RA patients (n=657) vs. Controls (n=982)	1.28	0.99-1.64	0.06
ACPA pos. patients (n=382) vs. Controls	1.57	1.18- 2.10	0.002

Admixture Composition in African-Americans and Its Impact On SLE. Julio Molineros[1], Xana Kim[1], Jennifer A. Kelly[1], Gail R. Bruner[2], Jorge R. Oksenberg[3], Judith A. James[1], GS Gilkeson[4], John B. Harley[5] and Swapan K. Nath[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Rsrch, Oklahoma City, OK, [3]School of Medicine, University of California, San Francisco, San Francisco, CA, [4]Medical University of South Carolina, Charleston, SC, [5]Oklahoma Medical Research Foundation, OK

Purpose: Systemic lupus erythematosus (SLE) disproportionately affects individuals with African ancestry with respect to disease prevalence, manifestation, severity and organ damage. It can be hypothesized that genetic factors together with individual ancestry or admixture proportion could explain these disparities. Since recent admixture can create substantial increase of linkage disequilibrium (LD) in

magnitude and range, these individuals can provide a unique opportunity for admixture mapping (AM) for SLE. We compared and contrasted (a) admixture dynamics, (b) risk of developing SLE, (c) ancestry-phenotype correlation, (d) effect of admixture on 3 associated genes, IRF5 (rs2004640), TNPO3 (rs2280714), and ITGAM (rs11436709), and (e) feasibility and power of AM, between a high admixed (AA) and a low admixed "Gullah" (GH) population with African ancestry.

Method: To estimate individual admixture and ancestry proportion we used 114 ancestry informative markers (AIM) on 1558 AA (722 cases, 836 controls),and 303 GH (163 cases, 140 controls). We applied structured association test (SAT) and logistic regression adjusted for individual admixture to account for population stratification. The power of AM was estimated analytically in AA and GH.

Result: Both AA and GH were best explained by admixture of European and African ancestral populations. Mean European ancestry was significantly higher in AA than in Gullah (19.5% vs 8%, P=3x10-31). Case and control ancestry proportion was significantly different only in AA (P=2.5x10-5). We also found that African ancestry was a risk factor for SLE only in AA (OR=3.1; P=5x10-5). While 3 previously reported SLE associated variants were also replicated the association with SLE (P <0.05) in GH (rs2004640 P=0.001; rs2280714 P =0.04 and rs1143679 P=0.003), only 2 were associated in AA (rs2004640 P=0.0003; rs2280714 P=0.61 and rs1143679 P=0.001), these results were unchanged even after admixture correction. Haplotype and conditional regression analysis using rs2004640 and rs2280714 (16kb apart) identified these variants might be independently associated with SLE. Ancestry association identified no AIMs consistently associated with SLE in both AA and GH. For AM, as expected, case-only design is more powerful than case-control design. For examples, to detect genetic association (80% power) of an allele with ancestry relative risk of 2.0, we need 1474 GH samples as opposed to half (705) the samples required in AA with an affected only design, and we need 4 times more samples in a case-control design.

Conclusion: The admixture effect on SLE increased with admixture proportion. SLE risk was greater in AA that GH. Except TNPO3, both ITGAM and IRF5 associations were replicated in AA and GH. AA population is more suited for admixture mapping than GH.

Novel Modular Analysis of Microarray Data in Adult-Onset Still's Disease. John J. Cush, Virginia Pascual and Florence Allantaz, Baylor Research Institute, Dallas, TX

Purpose: Previous work from our laboratory successfully used microarray analysis to demonstrate the importance of IL-1b in the pathogenesis of Systemic-onset Juvenile Idiopathic Arthritis (SoJIA) and the response to IL-1 blockade at the transcriptional level. A logical corollary to this work was to study blood transcriptional profiles in adults with Still's disease. To this end, we have evaluated the utility and diagnostic accuracy of genomic profiling using microarray technology in patients with manifest fever and systemic features suggestive of adult-onset Still's Disease (AOSD), periodic fever or an autoinflammatory syndrome.

Method: Clinical, laboratory, treatment response data, and biologic specimens on 21 AOSD/periodic fever patients were collected, with longitudinal samples obtained from 10 patients. Disease criteria and activity measures and response to therapy were collected prospectively. Most patients were on prednisone; 10 patients were treated with anakinra, 1 with rilonacept. Whole blood RNA was hybridized to Illumina HT-12 chips and a module-based data mining strategy was used to facilitate biomarker and genomic discovery. Still's patients were compared with 28 healthy adult controls, 12 autoimmune controls, SoJIA patients, and patients with various bacterial and viral infections. Finally, to quantify the overall magnitude of transcriptional changes in individual patients, a molecular distance score was calculated.

Results: Modular analysis showed a significantly increased expression of genes related to cells of the myeloid lineage, including monocytes and neutrophils, inflammation, red blood cells, and coagulation-related genes, reflecting a strong activation of the innate immune response in patients with AOSD. We also observed a consistent downregulation of genes regulating adaptive immunity including genes associated with the function of B cells, T cells, and cytotoxic cells. Finally, a module containing genes involved in immunosuppression was downregulated in those patients. Indeed, all of these findings are similar to those from our genomic studies in SoJIA patients. Dysregulation of these modules rapidly disappeared with anakinra therapy. In fact, for 3 patients treated with anakinra, the modular analysis was able to predict when patients could safely discontinue treatment. This analysis also showed that IFN-regulated genes were induced upon anakinra treatment, again corroborating our findings in the pediatric cohort. Of interest, the molecular score correlated with the severity of systemic disease in

the majority of patients, and approached baseline upon IL-1 blockade. As a final point, analysis of the transcriptional signature in blood from Still's patients can distinguish this disease from other febrile infectious illnesses.

Conclusion: A module-based approach and/or the use of a molecular distance to health score can: 1) differentially diagnose AOSD from other febrile patients; 2) predict responders to IL-1 blockade; and 3) predict when remission has been achieved, heralding the safe discontinuation of biologic therapies,

Novel Biomarkers for Lupus Nephritis. Mehrnaz Hojjati[1], Tawny Herdegen[2], Jason W. Bauer[3], Joseph C. Wilson[3], P.K. Gregersen[4], Michelle A. Petri[5], Timothy W. Behrens[6] and Emily C. Baechler[3], [1]Univ of Minnesota, Minneapolis, MN, [2]university of Minnesota, Minneapolis, [3]University of Minnesota, Minneapolis, MN, [4]Feinstein Insititute Med Rsch, Manhasset, NY, [5]Johns Hopkins University, Baltimore, MD, [6]Genentech, South San Francisco, CA

Purpose: Kidney involvement is a major clinical problem in systemic lupus erythematosus (SLE) due to its asymptomatic presentation and lack of reliable tests for prediction and monitoring. The discovery of biomarkers for lupus nephritis (LN) may permit identification of patients at risk for LN flare, improve monitoring of LN, and prevent kidney damage. Faced with the lack of reliable markers for renal disease activity, the following study was performed with the goal of identifying candidate biomarkers for renal lupus.

Methods: We studied 73 SLE patients enrolled from the Hopkins Lupus Cohort via the Autoimmune Biomarkers Collaborative Network. Global SLE disease activity was scored using the SLE Disease Activity Index (SLEDAI) and physician's global assessment (PGA). Renal-specific disease activity was assessed with the Lupus Activity Index renal subscore. Patients were classified into 3 groups: (1) active LN (renal subscore and urine protein dipstick equal or more than 2; n=29), (2) LN in remission (history of LN with biopsy and proteinuria, current renal subscore = 0 and urine protein = 0; n=27), and (3) active non-renal SLE (no history of LN, renal subscore = 0 and urine protein = 0, current SLEDAI equal or more than 6 or PGA equal or more than 1.5; n=17). Serum samples from 30 healthy controls were also included. Serum levels of IL-18, CXCL13, TWEAK and calprotectin were measured by singleplex ELISA, while MMP-7, TNF-a, CXCL10, CCL2, CCL19, IFN-g, IL-1b and IL-10 were measured on a multiplexed ELISA platform (SearchLight, Aushon Inc.). Data were analyzed using non-parametric statistical tests (Mann-Whitney U-test or Spearman's rank correlation).

Results: Serum levels of both MMP-7 and IL-18 were significantly higher in the active LN group as compared to both LN in remission (MMP-7, $p=0.004$; IL-18, $p=0.03$) and active, non-renal SLE (MMP-7, $p<0.0001$; IL-18, $p=0.01$). Neither of these proteins showed a correlation with the extra-renal activity scores, suggesting that these proteins are LN-specific markers. MMP-7, IL-18, and CXCL13 levels were significantly correlated with the renal activity subscore. Levels of CXCL13 and CCL19 were significantly elevated in active LN when compared to LN in remission, while CCL2 and TNF-alpha were increased in active LN vs. active non-renal SLE ($p<0.05$ for all).

Conclusion: . Serum levels of IL-18 and MMP-7, which has not been previously associated with LN, reflect the activity of kidney disease in SLE patients and may be reliable biomarkers for LN.

Cytokine Response Profiling Identifies Immunologic Signatures of Poor Health Related Quality of Life in Rheumatoid Arthritis. John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: A significant problem in caring for patients with rheumatoid arthritis (RA) is how to determine whether pain, fatigue, or impaired health-related quality of life (HRQOL) are due to the disease or other factors. Therefore, we sought to discover immunologic signatures of the various domains of HRQOL in patients with RA that could be valuable in evaluating response to therapy.

Methods: Patients with early inflammatory arthritis or RA (1987 ACR criteria) seropositive for rheumatoid factor and/or anti-citrullinated proteins were included. Data on HRQOL were collected, including the Health Assessment Questionnaire (HAQ) disability index and the Medical Outcomes Study short form 36 (SF-36). The HRQOL outcomes were dichotomized according to published thresholds for patient-defined 'acceptable symptom states.' Fresh peripheral blood mononuclear cells (PBMC) from patients were stimulated *ex vivo* under eight conditions, including: anti-CD3/anti-CD28 (CD3/CD28); phytohemagglutinin (PHA); bacterial CpG nucleotides (CPG); human heat shock protein 60 (HSP60. The profiles of cytokine release into culture supernatants were analyzed using multiplex immunoassays with a 17-cytokine panel. Mixed effects models were used to analyze the fold changes in cytokine values between poor vs. good HRQOL groups, adjusting for age, sex, and assay effects.

Results: The study included 57 patients (mean disease duration 9.4 ± 10.1 mo), of whom 51 (89%) fulfilled RA criteria. The group had moderate levels of disease activity (mean DAS28: 4.4 ± 1.2), disability (mean HAQ: 0.8 ± 0.8) and pain (mean VAS: 41.9 ± 28.3). Analyses revealed a 12-cytokine profile that discriminated the groups. A signature was identified for high bodily pain (SF-36 bodily pain <35) and high disability (HAQ>1) that was characterized by increased responses to PHA (IFN-g, IL-4, IL-5, IL-13) but decreased responses to CPG (IL-1b, IL-6) and HSP60 (IL-17A, G-CSF, GM-CSF). Poor general health (SF-36 global health <47) was discriminated by reduced HSP60 responses (IL-17A, GM-CSF) but not by PHA or CPG responses. In contrast, poor vitality (SF-36 vitality <40) was correlated with increased responses to CD3/CD28 (IL-8, IL-10, TNF-a) and increased HSP60-induced IL-17A.

Conclusion: Cytokine response profiling of PBMC revealed an immunologic signature of pain and disability in patients with early active RA, involving significantly increased responsiveness of Th1 and Th2 subsets to PHA and significantly decreased responsiveness of myeloid lineages to CPG and of Th17 cells to HSP60. Our findings suggest that cytokine response profiling could be useful to discriminate disease-associated impairments of HRQOL and monitor response to therapy.

Investigation of Coeliac Disease Variants Identifies a Novel Rheumatoid Arthritis Susceptibility Locus. S. Eyre[1], UK RA Genetics (UKRAG) Consortium[2], W. Thomson[3], Jane Worthington[1] and Anne Barton[4], [1]The University of Manchester, Manchester, United Kingdom, [2]Manchester, United Kingdom, [3]arc Epidemiology Unit, Manchester, United Kingdom, [4]University of Manchester, Manchester, United Kingdom

Purpose: Genome wide association studies, replicated by numerous well powered validation studies, have revealed a large number of loci likely to play a role in susceptibility to many multifactorial diseases. It is now well established that some of these loci are shared between diseases with similar aetiology. For example, a number of autoimmune diseases have been associated with variants in the *PTPN22, TNFAIP3* and *CTLA4* genes. Here we have targeted variants associated with coeliac disease (CD) in order to identify novel RA susceptibility loci.

Method: We selected 10 SNPs previously identified as being associated with CD for investigation in a sample of 3,962 RA patients and 3,531 controls. Genotyping was performed using the Sequenom platform and genotype frequencies compared between cases and controls under an additive model, implemented using PLINK software.

Results: We found novel evidence for association of the *TAGAP* locus with RA (Table). Interestingly, the opposite allele is associated with RA susceptibility compared with CD. Studies in type 1 diabetes have also shown association of this locus with susceptibility with the same allele as we have found in RA.

SNP	Locus	Genotype: n (%) Cases	Controls	Trend P	Allelic OR (95%CI)
rs182429	*TAGAP*	600 (17.0)	590 (20.5)	0.0005	0.88 (0.82-0.95)
		1770 (50.2)	1421 (49.3)		
		1159 (32.8)	870 (30.2)		

Table: Genotype comparison for SNP rs182429.

OR = odds ratio; CI = confidence intervals

Conclusion: Exploring the genetic overlap between related diseases may reveal key common pathways that could suggest therapeutic targets applicable to more than one disease. With regards to CD and RA, there is strong evidence that variation within the *CTLA-4* and *IL2_21* genes are associated with both autoimmune diseases. In addition, we present evidence for association of RA with a variant in the *TAGAP* gene, which has not been reported previously.

Polymorphism in NOD1 Causes Aggravated Bone Destruction in Patients with Rheumatoid Arthritis. Theo S. Plantinga[1], Mihai G. Netea[1], Jaap Fransen[1], Jochen Zwerina[2], Piet L. Van Riel[1], Georg Schett[3], Wim B. van den Berg[1] and Leo A. Joosten[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: One of the central disease hallmarks of rheumatoid arthritis (RA) is the onset and progression of cartilage and bone destruction in the joints, which is deleterious for joint motility and results in severe movement disabilities in affected patients. The mechanism underlying this disease process is largely unknown. NOD1, an intracellular pattern recognition receptor expressed by the innate immune system, is involved in microbial recognition. *NOD1* knockout mice developed aggravated joint pathology compared to wild type mice in an arthritis mouse model. Furthermore, the common *NOD1 +32656* insertion/deletion polymorphism in humans has been demonstrated to have clear functional consequences regarding cytokine responses. The aim of this study was to decipher to role of the +32656 *NOD1* in/del polymorphism in RA susceptibility and severity.

Method: RA patients (N=450) and healthy controls (N=431) were genotyped for the *NOD1* +32656 in/del polymorphism. Clinical parameters of disease severity (i.e. inflammation and bone destruction) were correlated with the *NOD1* +32656 genotype. Cytokine production capacity was measured in PBMCs and osteoclasts obtained from individuals with different *NOD1* +32656 genotypes. Furthermore, mRNA profiling of osteoclasts with different *NOD1* +32656 genotypes was performed.

Results: Genetic analysis of the *NOD1* +32656 polymorphism revealed a significant higher number of individuals homozygous for the insertion allele. Furthermore, the insertion allele was demonstrated to be highly correlated with increased bone destruction. Cytokine production capacity of PBMC's and osteoclasts was strongly elevated in cells heterozygous and homozygous for the insertion allele. Gene expression profiling of osteoclasts with different *NOD1* +32656 genotypes demonstrated a increased expression of cathepsin K in osteoclast bearing one or two copies of the *NOD1* +32656 insertion allele.

Conclusion: In the present study we demonstrate for the first time that the *NOD1* +32656 in/del polymorphism is associated with increased bone destruction in RA patients. Functional analysis revealed an increased production of pro-inflammatory cytokines in both PBMCs and osteoclasts from individuals bearing the *NOD1* +32656 insertion allele. Furthermore, osteoclast bone resorption activity was elevated reflected by increased expression of the lysosomal protease cathepsin K. These findings demonstrate the crucial role of NOD1 in RA joint pathology.

761

Investigation of Rheumatoid Arthritis Susceptibility Genes in Psoriatic Arthritis. Pauline Ho[1], I. N. Bruce[2] and A. Barton[3], [1]Manchester Royal Infirmary, Manchester, United Kingdom, [2]arc Epidemiology Unit, The University of Manchester, Manchester, [3]arc Epidemiology Unit, Manchester, United Kingdom

Purpose: Genome-wide association studies have identified a number of susceptibility variants for rheumatoid arthritis (RA), some of which show overlap with susceptibility to other arthritic disorders, such as juvenile idiopathic arthritis. Psoriatic arthritis (PsA) shares with RA the fact that both are characterised by TNF-mediated inflammation usually manifesting as synovitis in peripheral joints and both respond to similar therapies including methotrexate and anti-TNF biologic drugs. The aim of the current study was to explore whether they share genetic susceptibility factors by testing for association of RA genetic loci with PsA.

Method: 20 single nucleotide polymorphism (SNP) markers mapping to 14 RA susceptibility loci were tested in patients with PsA. After imposing strict quality control thresholds, genotype frequencies were compared with publicly available data for 2,024 controls using the trend test, implemented in STATA. A p-value of 0.05 was regarded as significant.

Results: 450 PsA samples passed quality control and were available for analysis. SNPs mapping to the *AFF3* and *IL7R* genes were associated with PsA susceptibility (Table).

SNP	Locus	Genotype: n (%)		Trend P	Allelic OR (95%CI)
		Cases	Controls		
rs1160542	*AFF3*	111 (27.7)	574 (19.4)	0.01	1.19 (1.04-1.37)
		217 (48.3)	1493 (50.3)		
		121 (27.0)	900 (30.3)		0.79 (0.67-0.92)
rs6897932	*IL7R*	25 (5.6)	267 (7.6)	0.003	
		166 (37.0)	1482 (42.3)		
		257 (50.1)	1756 (50.1)		

Table: Genotype comparison for SNPs rs1160542 and rs6897932.

OR = odds ratio; CI = confidence intervals

Conclusion: We have previously reported that there was no association of the major RA susceptibility loci, *HLA DRB1* and *PTPN22* with PsA. Here, we show that two other RA loci are associated with PsA suggesting that some of the genetic predisposition will be shared whilst other loci may determine the pattern / severity of arthritis that develops.

Vitamin D Binding Protein Identified in Synovial Proteome Associated with Disease Extension in JIA Patients. David S. Gibson[1], Laura Pascoli[1], Catherine McAllister[2], Caitriona Scaife[3], Michael J. Dunn[3], Stephen R. Pennington[3] and Madeleine E. Rooney[4], [1]Queen's University Belfast, Belfast, United Kingdom, [2]Belfast Health and Social Care Trust, Belfast, United Kingdom, [3]Proteome Research Centre, Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland, [4]Queen's University Belfast, Belfast, Northern Ireland

Purpose: Juvenile idiopathic arthritis (JIA) comprises a poorly understood group of chronic, childhood onset, autoimmune diseases with variable clinical presentations, outcomes and therapeutic responses. In a prior study, the synovial fluid (SF) proteome of an oligoarticular patient subgroup was compared to patients who show a spread of disease in the first year to involve new joints, the extended oligoarticular subgroup. Current laboratory tests are unable to flag those patients at a higher risk of disease spread to multiple joints, who could benefit form earlier therapy to prevent joint damage.

Method: This study was focused on profiling the SF proteome associated with disease extension from oligo- to polyarticular status by a difference gel electrophoresis (DIGE) approach. To construct a discriminant model, SF samples from 60 JIA patients were analysed: 30 oligo-, 8 extended oligo- and 17 polyarticular disease. Initial SF samples from each patient were labeled with Cy dyes and subjected to protein separation by 2-DE. The abiltiy to distinguish patients at risk of disease extension by a select group of proteins was illustrated by multivariate analysis methods. Protein spots of interest which over expressed beyond a two fold threshold between patient subgroups were identified by MALDI-TOF. Specific antibodies were used to validate putative biomarker expression in synovial fluid by western immunoblotting and in synovial membrane (SM) by immunohistochemistry.

Results: Samespots software analysis of SF gel scans was used to highlight joint-specific proteins which were differentially expressed across disease classifications. Hierarchical clustering based on the expression levels of a previously selected set of 40 proteins matched across the three clinical subgroups segregates the extended oligoarticular patients. Proteolytic fragments of apolipoprotein AII, complement component C3c, and vitamin D binding protein were identified ($p<0.05$) amongst the discriminatory proteins. Apolipoprotein AII and vitamin D binding protein were expressed at significantly higher levels in the polyarticular patients, $p=0.046$ and $p=0.019$ respectively, both with a perivascular distribution in the SM.

Conclusion: Synovial fluid proteome profiles have been used to flag JIA patients at risk of disease spread. The panel of identified proteins may play a role in spread of joint inflammation. With further validation, these putative prognostic biomarkers could improve the clinical management of patients.

Gene Microarray Profiling of Bone Marrow Mesenchymal Stem Cells From Osteoarthritis Patients Reveals a Diminished Expression of Collagen Genes. Benjamin Fernandez-Gutierrez[1], L. Rodriguez-Rodriguez[2], A. González-Vigo[3], Roberto Alvarez-Lafuente[4], P. Lopez-Romero[5], E. Urcelay[6] and José Ramón Lamas[2], [1]Hospital Clinico San Carlos, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain, [3]Immunology Service, Hospital Clinico San Carlos, Madrid, Spain, [4]PhD, Madrid, Spain, [5]CNIC, Madrid, Spain, [6]Immunology Service, Hospital Clínico San Carlos, Madrid, Spain

Purpose: To gain insight in the underlying mechanisms governing the multilineage differentiation and regenerative potential of Bone Marrow Mesenchymal Stem Cells (BM-MSCs) in osteoarthritis (OA).

Methods: Eight OA patients and eight controls were included. Hip OA was defined by ACR criteria. Control group is composed by patients with hip fracture without signs of OA nor osteoporosis (DEXA T score > -2.5).

At the time of surgery BM was obtained and MSCs were isolated and expanded. RNAs were extracted to perform a large-scale comparative gene expression profiling using the Agilent Whole Human Genome Microarray Kit 4 X 44K. Once array data were filtered and normalized, differentially expressed genes at $p<0.05$ level of significance with at least two-fold differences were eligible. These genes were classified according to their Biological Process Gene Ontology using the *Genecodis2* web-based tool. GSEA Molecular Signature Database was used in order to study specific groups of genes. Quantitative-PCR in 11 OA and 10 controls was used to validate array results. SNPs rs495551, rs1931897 and rs11965969 of the *COL10A1* gene were studied in 191 OA patients and 283 controls by Fast Real-Time PCR System.

Results: BM-MSCs from OA patients showed 533 differentially expressed genes, 293 (54.9%) downregulated and 240 (45%) upregulated. Although in unsupervised mode gene ontology clustering did not show a bias to a clearly defined biological process, supervised mode revealed that type IV, VIII, XI and, in particular, type X collagen genes were downregulated in OA. A GSEA analysis of a specific gene set including all collagens showed a significant difference between OA and control groups specially significant in the case of collagen X. Downregulation of mRNA production in OA patients was confirmed by q-PCR in additional samples.

In order to address the contribution of genetics factors in these findings, we analyzed three SNPs related to *COL10A1* gene and we can observe that rs11965969 (T/G) SNP was differentially represented with GG genotype overrepresented in OA patients p=0,013 OR=1,68 (1,09-2,59).

Conclusion: Our findings provide a reference data set of collagen genes altered in BM-MSCs from OA patients and, importantly, indicate that expression of type X collagen, a marker of hyperthrophic chondrocytes, is altered in OA patients. A genetic polymorphism in *COL10A1* gene is also showed in OA patients. We could hypothesized that hyperthropic chondrocytes located at bone-cartilage interface are altered in OA patients promoting an adult modified subchondral bone responsible for OA developing.

Polymorphisms of COTL1 Gene Identified by Proteomic Approach and Their Association with Autoimmune Disorders. Seung cheol Shim[1], Mi-Kyoung Lim[1], Dong-Hyuk Sheen[2], Eun-Heui Jin[3] and Hun-Tag Chung[4], [1]Eulji University Hospital, Daejeon, South Korea, [2]Euli University Hospital, Daejeon, South Korea, [3]Wonkwang University, Iksan, South Korea, [4]Ulsan University, Ulsan, South Korea

Purpose: For rheumatoid arthritis (RA), historically sound epidemiologic data demonstrated the genetic contribution to susceptibility to RA. The automated genotyping technologies that enable the systematic ascertainment of sequence variants in the form of single-nucleotide polymorphisms (SNPs). To identify candidate genes, first, we investigated the protein expressions differentially expressed between RA and healthy controls. After the selection of candidate genes through highly up-regulated or down-regulated proteins, we investigated the association of genetic polymorphisms of target genes with the susceptibility to RA.

Method: We conducted comparative analyses of protein expressions between RA patients and healthy controls using two-dimensional electrophoresis (2-DE) and matrix-assisted laser desorption ionization mass spectrometry (MALDI-TOF-MS). Blood samples and records were obtained from 568 controls (213 females, 355 males), 455 RA patients (371 females, 84 males), and 196 systemic lupus erythematosus (SLE) patients (184 females, 12 males). We performed a case-control study to determine whether the COTL1 gene polymorphisms were associated with the susceptibility to RA or SLE.

Results: We identified 17 proteins up- or down-regulated in RA patients compared to healthy controls. Among them, coactosin-like 1 (COTL1) was highly expressed in

RA patients compared with healthy controls.The COTL1 is a binding partner of 5-lipoxygenase, which is involved in leukotriene biosynthesis in the leukocytes. The genotype frequency of c.-1124G>T and the allelic frequency of c.484G>A in RA patients, and the genotype frequency of c.484G>A in SLE patients were significantly different from healthy controls ($P = 0.009$, 0.027, and 0.025, respectively). We also investigated the association of COLT1 polymorphisms with the levels of rheumatoid factor (RF) or anti-cyclic citrullinated peptide (CCP) antibody in RA patients, or anti-nuclear antibodies (ANA) in SLE patients. The c.484G>A polymorphism in RA patients showed a significant association with the levels of anti-CCP antibody ($P = 0.03$).

Conclusion: Our findings demonstrated that the genetic variances of the COTL1 gene might be associated with the susceptibility to RA and SLE and the development of autoantibodies.

Cia5a Regulates the Synovial Expression of Pro-Inflammatory Cytokines, Proteases and Nuclear Receptors. Max Brenner and Percio S. Gulko, Feinstein Institute for Medical Research, Manhasset, NY

Purpose: Little is known about the genes that regulate disease severity and joint damage in rheumatoid arthritis (RA). Cia5a is a locus on rat chromosome 10 that regulates disease severity and joint damage in pristane and collagen-induced arthritis (PIA and CIA). The specific Cia5a gene has not yet been identified. We hypothesized that cellular processes regulated by the Cia5a gene can be identified using microarray-based gene expression analyses of synovial tissues from DA rats (severe disease) and DA.F344(Cia5a) congenics (mild disease with no erosive changes). These studies could facilitate the identification of the Cia5a gene, and also point to novel pathways involved in the regulation of arthritis severity and joint damage.

Method: Synovial tissues were collected 21 days post-PIA induction from DA and DA.F344(Cia5a) congenics. RNA was treated with DNase, quantified and assessed for purity and integrity, and used for cRNA transcription and labeling. Samples were hybridized to the Illumina RatRef-12 BeadChips (22,523 probes covering 21,922 rat genes) and scanned on a BeadArray reader. Fluorescence intensity was extracted and normalized with the cubic spline algorithm using BeadStudio 2.0 (Illumina). Genes with a difference in intensity between DA and DA.F344(Cia5a) of ≥1.5 fold and p-value ≤ 0.001 (t-test) were considered significantly different and used for pathway detection analyses using IPA 5.5.1 (Ingenuity) and NCBI databases.

Results: Tissues from DA.F344(Cia5a) (n=8) congenics and DA (n=6) rats were analyzed. 8,046 genes were expressed by all synovial samples. 836 genes were significantly up-regulated in DA synovial tissues including cytokines (IL-18, LTB), cytokine receptors (IFNGR1, IFNGR2, IL-17RA), innate immune responses mediators (TLR2, FCER1G, FCGR3A, NCF1, NCF2), proliferation and survival genes (APAF1, BAK, CASP3, CDC2), and proteases implicated in articular damage (MMP-3, MMP-14, MMP-19). 980 genes were up-regulated in synovial samples from DA.F344(Cia5a) congenics, including anti-inflammatory nuclear receptors (PPARG, LXRA, LXRG, RXRG, RORA), genes related to metabolic homeostatic processes such as amino acid synthesis and lipid metabolism. 21 of the differentially expressed genes mapped to the *Cia5a* interval.

Conclusion: The presence of F344 alleles at *Cia5a* was enough to significantly reduce the inflammatory and proliferative gene expression signatures observed in DA, and to increase the expression of anti-inflammatory nuclear receptors. These observations suggest a potential role for the Cia5a gene in maintaining synovial homeostasis and limiting the synovial inflammatory response that contributes to articular damage.

N-Acetyltransferase 2 Slow Acetylator Genotype Associated with Sulfasalazine Hypersensitivity in Korean Patients with Adult Onset Still's Disease. Yeon-Ah Lee[1], Sang-Hoon Lee[1], Chang-Hee Suh[2], Hyoun-Ah Kim[2], Sung Soo Kim[3], Sang-Heon Lee[4], Hyung-In Yang[1] and Seung-Jae Hong[1], [1]Internal Medicine, School of Medicine, Kyung Hee University, Seoul, South Korea, Seoul, South Korea, [2]Ajou University School of Med, Suwon, South Korea, [3]Ulsan Univ Med Sch Gangneung, Gangneung, [4]Konkuk University Hospital, Seoul, South Korea

Purpose: Sulfasalazine (SSZ) has been widely used in the treatment of various autoimmune diseases including rheumatoid arthritis (RA). Although some patients experience adverse events after taking SSZ for 2-3 weeks, SSZ hypersensitivity is relatively uncommon in RA patients. However, since the report that toxicity is common with SSZ in AOSD, use of this agent has not been recommended in AOSD. As N-acetyltransferase 2 (NAT2) is an important enzyme catalyzing SSZ, we investigated the associations of NAT*2* genotypes with SSZ hypersensitivity, as well as with susceptibility to AOSD.

Methods: DNA was extracted from 48 patients with AOSD, 92 patients with RA, and 101 healthy controls. NAT2 genotyping was performed by full sequencing analysis on an ABI Prism 377 automatic sequencer. N-acetylation phenotypes were deduced from previously published genotype/phenotype correlations. Clinical characteristics were obtained by medical record review.

Results: Eight single nucleotide polymorphisms (SNPs) with the minor allele frequency more than 5% were identified within the exon2 of NAT2 gene. Among them, 2 SNPs revealed the strong associations with the risk of AOSD vs. controls: rs1041983 (OR = 2.73, 95% CI:1.31-5.70, *P* = 0.0061); rs1799930 (OR = 4.64, 95% CI:2.02-8.90, *P* <0.0001) and vs. RA: rs1041983 (OR = 6.02, 95% CI: 1.73-20.93, *P* = 0.014); rs1799930 (OR=3.84, 95% CI:1.84-8.03, *P* <0.0001). The wild type allele (NAT2*4) and 6 types of variant alleles (NAT2*5B, NAT2*6A, NAT2*7A, NAT*7B, NAT*12A and NAT2*13) were detected. Healthy controls and RA patients did not differ in composition of NAT2 genotypes. AOSD patients with at least one slow acetylator genotype (NAT2*5B, NAT2*6A, NAT2*7A and NAT*7B) showed the higher levels of hepatic enzymes and experienced rash more frequently than those without (OR=3.19, 95% CI: 1.13-9.03, *P*=0.023). Slow acetylator phenotype was more frequent in AOSD than in healthy control (66.67% vs 45.54%, *P*=0.016). Of 48 patients with AOSD, 3 of the 4 treated with SSZ developed hypersensitivity compared to none in RA patients receiving this agent. Two of three AOSD patients with SSZ sensitivity had the slow acetylator phenotype.

Conclusion: NAT2 slow acetylation genotype may be a risk factor of individual susceptibility to AOSD in Korean. Higher frequency of slow acetylator genotypes could be one mechanism explaining why SSZ hypersensitivity is more prevalent in AOSD than in others.

Association of genetic polymorphism in inflammatory cytokines with radiographic knee OA severity and Generalized Osteoarthritis (GOA). Mukundan Attur[1], Jonathan Samuels[1], Svetlana Krasnokutsky[1], Ken Kornman[1], Nazneen Aziz[1], VB Kraus[2], Gary McDaniel[2], Jeffrey D. Greenberg[3], Jack F. Bukowski[4] and Hwa-Ying Wang[5], [1]NYU - Hospital for Joint Diseases, New York, NY, [2]Duke University Medical Center, Durham, NC, [3]New York University School of Medicine, Millburn, NJ, [4]Harvard Med School, Marlborough, MA, [5]Waltham

Purpose: Osteoarthritis is the most common form of arthritis, and the hereditable component of OA has been estimated to be 50-65%. The IL1 gene cluster region has been repeatedly associated with susceptibility to OA in various joints. This finding is consistent with the notion that inflammatory mediators, particularly IL-1, may be important in the pathogenesis and progression of OA. In these studies we examined the association of SNPs in inflammatory genes with the severity of knee OA and with the presence of generalized OA (GOA, here defined as knee plus hand OA).

Method: One hundred forty-four OA patients (81 knee OA and 63 GOA) from two separate centers (NYUHJD, N=94 and Duke, N=50) met inclusion criteria: Caucasians of either sex, free of chronic disease other than osteoarthrits, and with a radiographic diagnosis of knee OA. Synovial fluid was available for the 50 Duke patients. Patients were genotyped for single nucleotide polymorphisms (SNPs). These subjects were divided into two groups: knee OA and GOA (knee and hand OA).We performed statistical analysis using Chi square and logistic regression, adjusting for age, gender and BMI to search for associations of radiographic knee OA severity and GOA with individual SNPs and with haplotypes.

Results: After adjustment for age, gender, and BMI, individual TNF-a, IL1, IL1 receptor antagonist (IL1RN) SNPs were strongly associated with the presence of GOA (Table 1). In three of the four SNPs, alleles associated with increased incidence of GOA have been previously associated with increased cellular production of inflammatory mediators. These alleles are: IL1B (-3737) rs4848306 TT/CT, IL1B (-511) rs16944 CC/CT, and TNF-a (-308) rs1800629 AA/AG. In a separate analysis of knee OA severity based upon JSW, carriage of either one or two copies of a haplotype consisting of IL-1RN rs9005 (A), IL-1RN rs419598 (C), IL-1RN rs315952(T) was associated with lower odds of radiographic severity (OR 0.16; 95% CI 0.06-0.40), greater joint space width (JSW; p=0.0038) compared to those without these haplotypes. Patients with the “protective” haplotype had lower synovial fluid levels of IL-6 (p=0.018) and IL-10 (p=0.038).

Conclusion: Among the cytokines and receptor antagonist studied for genetic association, IL-1RN SNPs (rs9005, rs419598 & rs315952) predicted low risk for knee OA radiographic severity and haplotypes in IL-1B, TNFa ad IL-1RN (rs 315952) strongly associated with increased prevalence of GOA. These genetic markers provide insight into the possible role of inflammatory mediators in knee OA and could prove to be useful biomarkers in DMOAD drug development.

Reproducibility of MR Biomarkers of Cartilage Structure and Composition in An Osteoarthritis Population at Risk of Progression. Mike A. Bowes[1], D.J. Hunter[2], Charles B. Eaton[3], C. K. Kwoh[4], RA. Maciewicz[5], Jonathan Samuels[6], Christopher J. Taylor[7], John C. Waterton[5], Tomos G. Williams[7] and Chris B. H. Wolstenholme[1], [1]Imorphics, Manchester, United Kingdom, [2]NEBH, Boston, MA, [3]Alpert Medical School of Brown University, Pawtucket, RI, [4]UPitt, Pittsburgh, PA, [5]AstraZeneca, Macclesfield, United Kingdom, [6]New York University/Hospital for Joint Diseases, New York, NY, [7]University of Manchester, United Kingdom

Purpose: Osteoarthritis (OA) is a slowly-progressing disease, and imaging biomarkers of cartilage structure have failed to detect short-term (< 6 months) change. An imaging biomarker of cartilage quality (i.e., tissue composition and function) such as magnetic resonance transverse relaxation time of hyaline cartilage water protons (T_2), may be more a responsive biomarker of OA progression. T_2 is a proxy for disorder and hydration, and is easily measured without a contrast agent, but there are few data on variability of this marker over time in OA. The purpose of this study was to determine the short-term (1 week) reproducibility of cartilage T_2 and thickness obtained from an anatomically-corresponded regional analysis using statistical shape modelling.

Method: We conducted a multi-centre, non-randomized study at 4 sites with a sample at risk of medial tibiofemoral progression including women, BMI≥25 kg/m^2, symptomatic radiographic evidence of medial tibiofemoral OA (K&L grade 2-3, medial JSN≥ lateral JSN), varus malalignment ≥-2° (anatomic axis), and pain. As part of a larger study, eligible participants had MRI scans of the same knee at baseline and 1 week. The OAI protocol for the index knee was deployed on 3T Siemens Trio systems. A trained operator, blind to time-point but not subject, manually segmented the cartilage from the DESSwe MR images using EndPoint (Imorphics). Anatomically corresponding regions of interest were identified on each image by fitting a bone model, and mean cartilage thickness (with areas denuded of cartilage included as having zero thickness - ThCtAB) within each region was calculated. Voxelwise transverse relaxation rates were calculated from a linear least-squares fit of the log of the signal values against echo time. Mean T_2 values were also recorded in each region from the 50% most exochondral and 50% most endochondral voxels. Coefficients of Variation (CoV) were calculated.

Results: The 29 participants had a mean age of 62 years, mean BMI of 36 kg/m^2, with 8 index knees graded as K&L =2 and 21 as K&L=3. Anatomical mal-alignment ranged from -1.9° to 6.3°, with mean 0.9°, where varus mal-alignment is measured in the positive direction. 28 subjects provided data for reproducibility of ThCtAB and 20 for T_2.

Table 1. Reproducibility MR Measures

	Mean T_2 /msec	CoV T_2	Mean ThCtAB/mm	CoV ThCtAB
Medial Femur	49.5	3.1%	1.59	2.2%
Lateral Femur	49.0	2.6%	1.69	2.8%
Medial Tibia	38.7	2.8%	1.35	2.5%
Lateral Tibia	38.8	2.6%	1.66	3.0%

T_2 was approximately 10% higher in the exochondral vs. endochondral layer in each region.

Conclusion: T_2 can be measured reproducibly in an OA population in multicentre studies and with similar variability to a cartilage structural assessment. These results support further evaluation of T_2 as a candidate biomarker of cartilage composition for assessing interventions.

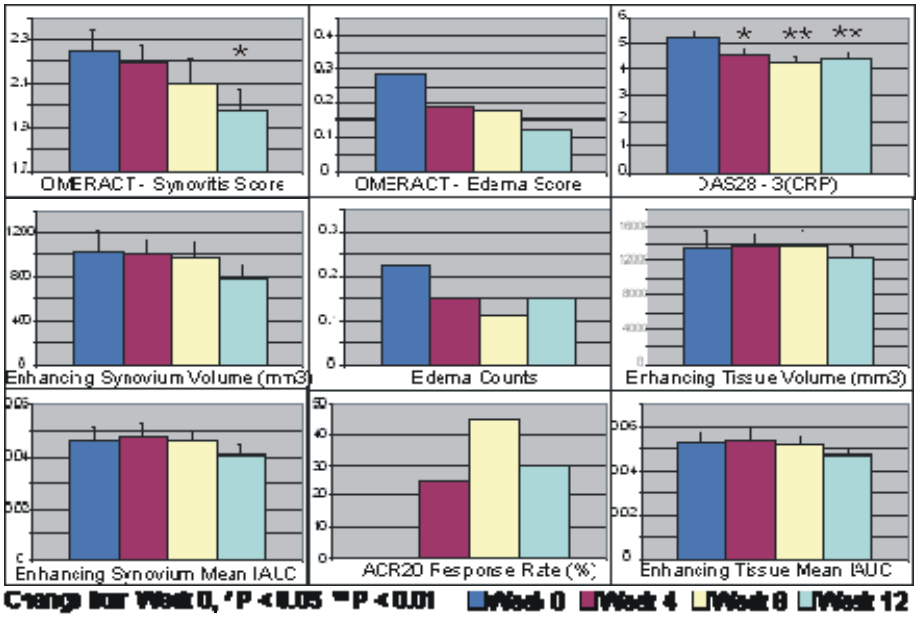
Early Treatment Effects of Anti-TNF Therapy On MRI Biomarkers of RA Activity. Bradley T. Wyman[1], Yanwei Zhang[1], Bradley J. Bloom[1], Orrin M. Troum[2], Nastaran Fatemi[3], Shengong Wu[4], Saara Totterman[4], Ralph E. Bennett[5] and Mark Tengowski[4], [1]Pfizer Inc., New London, CT, [2]Keck School of Medicine/University of Southern California, Santa Monica, CA, [3]Beverly Radiology Medical Group, Los Angelos, [4]VirtualScopics Inc., Rochester, NY, [5]Arizona Arthritis Research PLC, Paradise Valley, AZ

Purpose: X-rays are commonly used to image RA treatment effects in clinical studies but can only monitor the late stage disease effects of bone erosions. MRI, however, has the potential to detect the inflammatory components of RA such as synovitis, and tissue and bone edema. RA treatments target these inflammatory effects, so MRI has the potential to detect efficacy much earlier. The goals of this study were to determine the impact of short term anti-TNF therapy on changes to quantitative and semi-quantitative image endpoints in the MCP joints.

Method: Prior to starting anti-TNF therapy (open-label) 22 RA subjects, at 4 centers, who were on a stable background therapy of methotrexate, were scanned on an OrthoOne 1.0T peripheral MRI scanner. Scans were repeated at 4, 8 and 12 weeks of treatment. MCP joints were imaged with the following sequences: Coronal T2 fat suppressed FSE, coronal and axial 3D GRE, and 2D axial dynamic contrast enhanced (DCE) SPGR acquired continuously starting before bolus injection of 0.1 mmol/kg Gd-DTPA and continuing for 4 minutes.

For all subject visits the semi-quantitative ACR20, EULAR-OMERACT and DAS28 – 3CRP scores were determined. Semi-automated segmentation of the MRI was used to calculate the enhancing synovium, enhancing tissue (synovium, bone, tendons and muscle). Bone edema counts were determined by the average number of distinct edema regions. DCE MRI was used to calculate the initial area under the curve (IAUC) for the enhancing synovium and tissue. All MRI endpoints evaluated the 2^{nd} -5^{th} MCP joints.

Statistical significance was obtained by modeling the log of the follow-up to week 0 ratio of the measure. $P < 0.05$ was significant.



Results: The figure shows the mean and standard error bars for each of the measures at 0, 4, 8, and 12 weeks for the 20 of 22 completing subjects. Only a few of the subjects presented with bone edema, so error bars and significance of change were not calculated. Most measures showed a trend for reduction over 12 weeks but only the OMERACT synovitis score at week 12 and the DAS scores at week 4, 8 and 12 were significant. The OMERACT synovitis score at week 8 and the enhancing synovium volume at week 12 showed a decreasing trend.

Conclusion: The ACR20 response rate at week 12 was unexpectedly low compared to similar anti-TNF studies. This may have also resulted in a lower response rate for the inflammatory MRI biomarkers. However, the DAS-28 and OMERACT synovitis scores showed a statistically significant treatment response

Scintigraphic Studies in the Detection of Pulmonary Involvement in Systemic Sclerosis (SSc) Patients. John Koutsikos[1], Charalampos Kostopoulos[2], Charalampos Mamoulakis[2], Lia A. Moulopoulos[3], Cherry Zerva[1], Myron Mavrikakis[4] and Anastasia Leondi[1], [1]Nuclear Medicine Department, Alexandra University Hospital, Athens, Greece, [2]Department of Clinical Therapeutics, University of Athens, School of Medicine, Athens, Greece, [3]Department of Radiology, University of Athens, School of Medicine, Athens, Greece, [4]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Athens, Greece

Purpose: Gallium (Ga-67) scintigraphy has been shown to be useful in the assessment of patients with interstitial lung disease associated with SSc. HRCT is considered to be the most appropriate non-invasive modality for its diagnosis. Chronic immunological inflammation which results in fibrosis is the major mechanism of pulmonary involvement (PI) in these patients. Tc-99m labeled non-specific human polyclonal immunoglobulin G (HIG) is a radiopharmaceutical that has been used successfully for the detection of focal and diffuse infection and inflammation. The aim of this study was a head-to-head comparison of these radiopharmaceuticals in the detection of the PI in patients with SSc, using HRCT as gold standard method.

Method: We studied 30 non-smoking patients suffering from SSc with no pulmonary event in their medical history other than in terms of SSc. All patients underwent gallium scintigraphy 48 hrs after i.v. injection of 4 mCi Ga-67 and HIG scintigraphy 3 hrs after i.v. injection of 20 mCi Tc-99m HIG. The maximum time interval between scintigraphic studies and HRCT was 10 days. Receiver operating characteristic (ROC) analysis was performed and the respective areas under the curve (AUC) of the two scintigraphies were calculated. A probability $P<0.050$ (two-tailed) was considered to indicate statistical significance. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were also assessed.

Results: PI according to HRCT abnormalities was detected in 15 patients. HIG scintigraphy ROC curve differed significantly from the non-discrimination line (AUC = 0.733 [95% CI=0.548-0.919], $P<0.03$), while for Ga-67 scintigraphy ROC curve did not (AUC=0.667 [95% CI=0.469-0.895], $P=0.12$). Sensitivity, specificity, PPV and NPV of Ga-67 and HIG were: 73.3%, 60%, 64.7%, 69.2% and 93.3%, 53.3%, 66.7%, 88.9% respectively.

Conclusion: HIG scintigraphy demonstrated good clinical performance in contrast to Ga-67 scintigraphy. This may be explained by the different uptake mechanisms of the two radiopharmaceutics. HIG accumulation due to increased vascularity and vascular permeability seems to play an important role.

Differential Distribution of a PEGylated Fab' Into Inflamed Versus Normal Tissue Compared to An IgG in Arthritis and Colitis Models. Massimo Marenzana, Alison Eddleston, Alex Vugler and Andrew Nesbitt, UCB, Slough, United Kingdom

Purpose: PEGylation has been shown to affect protein distribution. For example, certolizumab pegol (CZP), a PEGylated Fab', has been shown to distribute to inflamed versus normal tissue at a ratio of 3.8 in a collagen-induced arthritis (CIA) mouse model, whereas adalimumab (ADA), an IgG, had a ratio of 1.9.(1) The objective of these studies was to further compare PEGylated Fab' and IgG distribution by determining the consequence of TNF binding on the distribution of these reagents, and by investigating the distribution of these reagents in a different inflamed tissue model (the DSS gut colitis model).

Methods: An anti-mouse TNF antibody with an affinity for mouse TNF that is similar to the anti-human reagents CZP and ADA was used for this study. Both the PEGylated Fab' and IgG2a versions of this antibody were labeled with one of 2 fluorescent dyes: Alexa 680 for experiments in the CIA model and Alexa 790 for the DSS model. The potency of the labeled reagents was not affected as measured in a L929 bioassay. The labeled reagents were given intravenously at 2 mg/kg in the CIA model and subcutaneously at 10 mg/kg in the DSS model. In both cases, control animals were similarly dosed. In the CIA model, paws were imaged in vivo at various time points up to 26 hours post-administration using an IVIS imager. In the DSS model, the colons were removed after 24 hours and imaged using the IVIS imager ex vivo by drawing a region of interest around the whole excised colon.

Results: Both the IgG and PEGylated Fab' penetrated inflamed tissue more effectively than the non-inflamed tissue in both the CIA and DSS models. However, in both cases, the ratio of distribution in inflamed versus normal tissue was higher for the PEGylated Fab' than the IgG. In the CIA model, the ratio was 2.3 for the PEGylated Fab' vs 1.7 for the IgG after 1 hour ($p=0.01$ as measured by an unpaired two-tailed T test), while in the DSS model, the ratio was 3.1 vs 2.1, respectively, after 26 hours ($p=0.02$). In the CIA model, the ratio was also measured at various time points out to 26 hours, with significant differences at all times tested.

Conclusion: This innovative method of analyzing protein levels in tissue enabled a comparison of the distribution of an anti-mouse PEGylated Fab' and IgG in two different mouse models. In both models, the PEGylated Fab' had a higher inflamed to normal tissue ratio than the IgG. This result confirmed previous observations concerning the effect of PEG (and other macromolecules) on the distribution of proteins and suggests that antigen binding does not greatly affect distribution. Effective targeting of inflamed tissue is a desired property for an anti-inflammatory agent and may be an important consideration for effective treatment of inflammatory disorders.

The Diagnostic and Predictive Value of Radiographs in Undifferentiated Arthritis: Results of a Systematic Review as Part of the 3E Initiative. R. Koevoets[1], P. Machado[2], C. Bombardier[3] and Désirée M.F.M. van der Heijde[4], [1]LUMC, Leiden, Netherlands, [2]Coimbra University Hospital and LUMC, Coimbra, Portugal, and Leiden, Netherlands, [3]Univ of Toronto, Toronto, ON, [4]Leiden University Medical Center, Leiden, Netherlands

Background: 3E (Evidence, Expert, Exchange) is a multi-national initiative which aims at promoting evidence-based medicine in rheumatology.

Purpose: The 2008-2009 goal was to develop recommendations for the management of undifferentiated arthritis (UA) by integrating evidence with the expert opinion of an international panel of rheumatologists. We present the result of a systematic literature review about the diagnostic and prognostic value of conventional radiographs (CR) in UA.

Method: PubMed, Embase and Cochrane were all searched with an extended search developed in close collaboration with a trained librarian. In addition, the ACR and EULAR abstracts of 2007 and 2008 were hand searched. Articles were included based on predefined inclusion criteria and quality was assessed by using validated quality scales.

Results: In total 6003 references were found. Five articles with a pure UA population were included and 20 articles with a mixed population (mostly UA combined with RA). In studies of UA, inclusion criteria and baseline characteristics were similar and erosions on CR were strong predictors of a diagnosis of RA. In two studies the positive likelihood ratios (LR+) for erosions were 3.5 and 10.9 and negative likelihood ratios (LR-) were 0.7 and 0.8 respectively. One study reported an odds ratio (OR) of 8.7 in a model with anti-CCP and 7.6 in a model without. Another study found that erosions were predictive of RA in a univariate analysis, but not in the multivariate analysis. Only one study addressed the value of erosions on CR for prognosis in UA; Sharp v/d Heijde (SvdH) score at baseline was lower in the mild vs progressive disease group at 1 year. In studies with a mixed population the inclusion criteria and baseline characteristic differed substantially. Twenty studies reporting on 11 cohorts found a relationship between CR findings and a subsequent diagnosis of RA. In four LR+'s for erosions and/or bony decalcifications ranged from 1.8 to 9.7 and the LR-'s from 0.7 to 0.9. In four studies, erosions were found to be less prevalent in patients with UA vs RA at one year. Two additional studies concluded that modified Sharp score was not significantly different between UA and RA at one year and SvdH score was in a univariate analysis associated with diagnosis of RA. In one prognostic study the LR+ for erosions on CR and developing persistent disease was 6.0, the LR- was 0.7. The remaining 9 prognostic studies showed a relation between the level of abnormalities on CR with poor outcome (for example: persistence of disease, low functional outcome, onset of DMARD treatment, radiographic severity).

Conclusion: The limited number of studies in pure UA populations clearly demonstrate that the presence of erosions on radiographs are helpful in predicting a future diagnosis of RA and might be of value in predicting outcomes in RA. However, the absence of abnormalities on radiographs does not rule out a diagnosis of RA.

773

Automatic Computer Aided Quantification of Synovitis in Rheumatoid Arthritis Using Dynamic MRI and the Impact of Movement Correction On Signal to Noise Ratio (SNR) and Region of Interest (ROI) Analysis. Mikael Boesen[1], Olga Kubassova[2], Marco A. Cimmino[3], Mikkel Ostergaard[4], Bente Danneskiold-Samsoe[1] and Henning Bliddal[1], [1]Parker Institute, Frederiksberg, Denmark, [2]Image Analysis, Leeds, England, [3]University of Genova, Genova, Italy, [4]University Hospitals Hvidovre and Gentofte, Copenhagen, Denmark

Background: Dynamic Contrast Enhanced MRI (DCE-MRI), based on repeated imaging of the same few MRI slices with a few seconds' interval after intravenous contrast injection, correlates closely to histological inflammatory activity and is a promising tool to asses the early response to treatment, potentially before volume changes and changes in OMERACT RAMRIS scores occur. Analysis of DCE-MRI is usually done by manual selection of areas with most enhancement (regions of interest, ROIs), but variable ROI positioning and movements during imaging, introduce large variation in the results obtained from the dynamic curves using the ROI method (1-2).

Purpose: To analyse DCE-MRI data from RA patients using a newly developed algorithm that eliminate motion artefacts and to evaluate the impact of motion on SNR and ROI results

Methods: DCE-MRI data were acquired in wrists of 50 RA patients and 5 controls, by repeatedly obtaining 3 axial or coronal T1-weighted images every 10-15 seconds immediately after iv 0.1 mmol/kg Gd-DTPA, using a 0.2T Esaote C-scan or E-scan (22-30 repetitions). Motion artefacts were eliminated using an intensity-based algorithm which corrects for movements and changes in brightness and contrast in every pixel. ROIs of 25mm^2 were positioned automatically in the area of most enhancement using a custom made computer programme. Maximum enhancement (ME) and initial rate of enhancement (IRE) were calculated from the ROIs.

Results: Motion artefacts in all 3 planes were reduced from 1.3mm±7mm to 1mm±1.5mm shift and 7±6degree to 1±0.4degree rotation. This increased SNR by a factor 3 on average, removed image blurring and reduced the variations in the shape of dynamic curves extracted from the ROIs. This consequently reduced variation in measurements of ME and IRE (statistical f-test was applied). In controls, the IRE was reduced from 0.21±0.1 to 0.12±0.02 [%/sec] and in ME from 0.35±0.23 to 0.1±0.01 [%]. In patients, IRE increased from 0.5±0.16 to 0.6±0.02 [%/sec] and ME from 0.53±0.3 to 0.7±0.02 [%].

Conclusion: Elimination of motion artefacts significantly reduced artefactual enhancement and increased SNR. Reduced variation in ROI measurements significantly influenced the accuracy of quantitative analysis of inflammation. This supports the use of DCE-MRI augmented by motion reduction algorithms for more robust and valid analysis of synovitis in RA patients.

F-18 Flurorodeoxyglucose Positron Emission Tomography Can Detect Early Response to Adalimumab in Rheumatoid Arthritis. Denis Mulleman[1], Véronique Eder[2], David Ternant[1], Jean-Camille Méric[2], Maxime Courtehoux[2], François Tranquart[3], Philippe Goupille[4] and Gilles Paintaud[4], [1]Université François Rabelais de Tours; CNRS, UMR 6239; CHRU de Tours, Tours, France, [2]CHRU de Tours, Tours, France, [3]CHRU de Tours; INSERM 806, CIC-IT, Tours, France, [4]Université François Rabelais de Tours, CNRS, UMR 6239; CHRU de Tours, Tours, France

Purpose: To analyse the ability of F-18 flurorodeoxyglucose (FDG) positron emission tomography (PET) to detect an effect of adalimumab on joint inflammation in active rheumatoid arthritis (RA) 2 weeks after treatment initiation.

Method: Patients with a high disease activity score measured on 28 joints (DAS28 > 5.1) were recruited to undergo F-18 FDG PET three consecutive times: before and 2 and 12 weeks after adalimumab initiation. Inflammation was assessed by a semi-quantitative scale and compared to results of clinical and ultrasonography examination of the corresponding joints. A global score was defined by the sum of the

maximal standard unit values (SUV_{max}) of each of the inflammatory joints. **Results:** Six patients participated in the study. Five patients were responders, according to PET assessments, by showing a decrease in median SUV_{max} global score of 62.9% at week 2 and 88.2% at week 12.

Conclusion: F-18 FDG PET is a promising imaging tool able to identify an effect of tumor necrosis factor a antagonists on inflammatory joints as early as 2 weeks

Changes in Patellar Cartilage Morphology and Water Content in Response to An Acute Bout of Loading: A Comparison of Young Females with and without Patellofemoral Pain. Shawn Farrokhi, Patrick M. Colletti and Christopher M. Powers, University of Southern California, Los Angeles, CA

Purpose: Patellofemoral Pain (PFP) is prevalent in a wide range of individuals; however the highest incidence is evident in young, physically active populations. One proposed theory regarding the etiology of PFP may be related to the inability of the patellofemoral joint cartilage to adequately adapt to mechanical loading. An impaired response to loading may result in elevated stress within the cartilage or at the cartilage-bone interface. The purpose of the current study was to compare the adaptive response of articular cartilage following an acute bout of loading between females with PFP and pain-free controls. We hypothesized that females with PFP would demonstrate less cartilage deformation and diminished water content changes post-exercise when compared to control subjects.

Method: Ten females with the diagnosis of PFP and 10 pain-free controls participated. Subjects were matched for gender, age and activity level. Baseline quantitative magnetic resonance imaging of patellar cartilage morphology was performed using an axial plane spoiled gradient recalled echo protocol. In addition, axial transverse relaxation times (T_2) were obtained from a 4-echo sequence with echo times spaced evenly over a range of 20-80 msec. Following the initial imaging session, subjects performed 50 deep knee bends over the course of 90 seconds while wearing a weighted vest equivalent to 25% of their body weight. Subjects were imaged immediately following completion of the exercise protocol (within 2 minutes). Independent sample t-tests were used to evaluate changes in cartilage morphology (volume and thickness) and water content (T_2) pre-post exercise.

Results: Compared to pre-exercise values, post exercise cartilage volume change scores were significantly lower for the PFP group compared to the control group (4% vs. 9%, 4% vs. 14%, and 4% vs. 11% for the lateral, medial, and total patella cartilage, respectively). Similarly, post exercise cartilage thickness change scores for the PFP group were lower compared to the control group (2% vs. 9%, 7% vs. 11%, and 4% vs. 10% for the lateral, medial, and total patella cartilage, respectively). In contrast, post exercise T_2 change scores for the PFP group were less pronounced compared to the control group (0% vs. -8%, 2% vs. -2%, and 1% vs. -5% for the lateral, medial, and total patella cartilage, respectively).

Conclusion: Consistent with our hypothesis, females with PFP demonstrated less cartilage deformation following an acute bout of loading. In addition, females with PFP demonstrated smaller changes in cartilage water content following exercise. This finding suggests an altered interaction between the collagen matrix and the interstitial fluid seen in healthy cartilage. Our findings support the premise that the mechanical response of patella cartilage following an acute bout of loading is impaired in females with PFP.

Periarticular Bone Mineral Density Does Not Distinguish Between Healthy Controls, Established RA and Early Arthritis Patients. C. Alves, E. M. Colin, W. J. van Oort, J. Sluimer, J. M. W. Hazes and J. J. Luime, Erasmus Medical Centre, Rotterdam, Netherlands

Background Early recognition of rheumatoid arthritis (RA) is important, but difficult due to lack of a distinct feature. Loss of periarticular bone mineral density (pBMD) in the hand is thought to be an early feature. The difficulties in pBMD measurement are dilution of BMD loss in the whole hand and less precise measurements in small regions of interest (ROI's). Choosing the size of a ROI is a trade-off between area size and precision error.

Purpose: To identify periarticular ROI's relevant to RA with a low precision-error and sufficient interrater reliability and to test the validity of these ROI's.

Methods: Five ROIs were defined around the MCP and/or PIP joints II-V, II-IV and mid-metacarpal to mid-phalangeal. BMD was estimated using a Lunar Prodigy. Precision was estimated by measuring 5 healthy adults 7 times, after repositioning, using the Root-Mean-Square-Coefficient of Variation (RMS-CV). To determine the interrater reliability 20 patients were analyzed on separate occasions by 2 readers using the ICC. Validity of the ROI's was tested using 2 patient groups and healthy controls matched on sex, age and menopausal status. Patients with established RA were recruited from the rheumatology outpatient clinic, patients with early arthritis via the Rotterdam Early Arthritis CoHort (REACH). Simple descriptive analyses, scatter plots, paired t-tests and ROC-curves were done.

Results: The RMS-CV varied from 0.45% to 1.07%. The ICC was 0.99 for all measurements. Between September 2006 and October 2008 44 patients and 33 healthy controls were recruited. Mean BMDs of the ROI's ranged from 0.321 to 0.372 g/cm^2 in established RA, 0.321 to 0.382 g/cm^2 in early arthritis and 0.342 to 0.401 g/cm^2 in controls. The mean differences ranged from 0.011 to 0.032 g/cm^2 for established RA and 0.028 to 0.033 g/cm^2 for early arthritis patients compared to matched controls. For ROI 1 and 3-5 in early arthritis and the whole hand in established RA the mean differences were significant. The ROC-curves indicated low discriminative power of all ROI's, with AUC's from 0.60 to 0.66.

Conclusion: Periarticular BMD seems not to be a useful diagnostic feature due to the wide distribution in BMD values resulting in strong overlap between healthy controls, established RA and early arthritis patients.

Table 1 One sample T-test on matched differences between BMD patients and controls

	Established RA (n=25)	Early arthritis (n=25)

Reader Reliability of the OMERACT Psoriatic Arthritis Magnetic Resonance Score (PsAMRIS): Results From An OMERACT Workshop. Pernille Bøyesen[1], Frédérique Gandjbakhch[2], Fiona M. McQueen[3], Siri Lillegraven[4], Laura Coates[5], Charlotte Wiell[6], Philip Conaghan[7] and Mikkel Østergaard[8], [1]MD, Oslo, Norway, [2]MD, Paris, France, [3]University of Auckland, Auckland, New Zealand, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]University of Leeds, Leeds, United Kingdom, [6]MD, Hvidovre, Denmark, [7]Leeds, United Kingdom, [8]Hvidovre and Gentofte, Denmark

Purpose: The aim of this study was to test cross-sectional and longitudinal inter- and intra reader reliability of the Psoriatic Arthritis Magnetic Resonance Imaging Score (PsAMRIS) under standardized conditions.

Methods: The exercise was performed using MRI scans from 12 PsA patients (8 acquired in Copenhagen and 4 in Leeds) before and after 12 months of anti-TNFα therapy. The metacarpophalangeal (MCP), proximal interphalangeal (PIP), and distal interphalangeal (DIP) joints of the 2nd–5th fingers were examined, using a 0.6 T MRI unit (Copenhagen) and a 0.2T MRI unit (Leeds). Coronal, axial and sagittal T1-weighted pre- and post-gadolinium-contrast images and sagittal and axial pre-contrast STIR images were obtained, anonymized and blinded for time sequence and read twice by FG, FMQ, MØ and PB on identical PACS workstations. For the second reading the images were re-anonymized and re-randomised. The images were scored according to the PsAMRIS: at MCP, PIP and DIP joint-level synovitis was scored 0-3, tenosynovitis 0-3, bone proliferation 0-2, pariarticular inflammation 0-2, bone marrow edema 0-3 per bone and bone erosions 0-10 per bone. Inter-reader reliability was assessed using average measure intraclass correlations coefficient (ICCa) and intra-reader reliability by single measures intraclass correlations coefficient (ICCs).

Results: The median (IQR) average baseline/1-year follow-up synovitis score was 10.8 (8.5-14.3)/ 8.4 (6.7-9.7), tenosynovitis score 5.7 (1.7-8.5)/ 2.0 (0.9-4.4), bone proliferation 2.2 (1.4-3.9)/ 2.2 (1.4-3.9), periarticular inflammation 1.1 (0.1-3.6)/ 0.5 (0.3-0.6), bone marrow

edema 0.3 (0.1-1.4)/ 0.1 (0.0-0.8) and bone erosions 1.8 (0.2-5.1)/ 1.9 (0.1-5.0). The cross-sectional inter-and intra reader reliability as well as the inter-reader reliability for 1-year change are presented in table 1. The inter-reader ICC was high for all measures except moderate for bone proliferation. Poor ICCs for bone proliferation and erosion change scores are explained by minimal change in the 1-year period.

Conclusion: In this multi-reader exercise testing the PsAMRIS under standardized conditions, very high interreader and intrareader reliability for status and change scores for most parameters and readers were found. Inflammatory parameters performed best. These results suggest that PsAMRIS is a reliable tool for MRI assessment of PsA patients.

Table 1. Cross sectional inter- and intra reader reliability

	Inter-reader reliability (ICCa)		Intra-reader reliability (ICCs) (cross-sectional)			
	Cross-sectional	1-year change	Reader 1	Reader 2	Reader 3	Reader 4
PsA synovitis	0.95	0.95	0.97	0.73	0.93	0.90
PsA flexor tenosynovitis	0.97	0.95	0.81	0.74	0.93	0.73
PsA bone proliferation	0.77	0.10	0.20	0.84	0.79	0.44
PsA periarticular inflammation	0.91	0.91	0.39	0.95	0.88	0.91
PsA bone marrow edema	0.87	0.87	0.98	0.97	0.99	0.03
PsA bone erosion	0.97	0.44	0.91	0.93	0.92	0.91

Is STIR Necessary for Evaluating Synovitis and Osteitis in Rheumatoid Arthritis When Using MRI Protocols That Also Include Gadolinium-Enhanced Magnetic Resonance Imaging? C. Peterfy[1], J. DiCarlo[1], J. C. Becker[2] and H.K. Genant[1], [1]SYNARC, Inc, San Francisco, CA, [2]Bristol-Myers Squibb, Princeton, NJ

Purpose: Magnetic resonance imaging (MRI) is increasingly being used in clinical trials of rheumatoid arthritis (RA) to evaluate severity and progression of bone erosion, osteitis and synovitis. We previously showed that coronal short-tau inversion recovery (STIR) and axial fat-suppressed 3D T1-weighted gradient-echo ± intravenous gadolinium contrast (GRE±Gd) performed similarly for scoring synovitis[1] and osteitis[2] in the wrist and, therefore, that MRI protocols need not necessarily include both techniques. However, bone erosion and osteitis are best evaluated in the same plane, so here we compare the performances of coronal GRE±Gd and coronal STIR in a different cohort of RA patients.

Method: As part of a Phase III double-blind, placebo-controlled, multi-site trial of abatacept in RA, the dominant hands/wrists of 39 patients with early RA were scanned using 1.5T whole-body MRI. Scans of the wrist included coronal STIR (0.47mm x 0.63mm x 3.0mm voxels)

requiring 6 mins, and coronal fat-suppressed GRE±Gd (0.23mm x 0.63mm x 1.5mm voxels; 0.1 mmol/kg Gd-DTPA, iv) requiring 15 mins, including the injection. One radiologist experienced with the RA MRI scoring (RAMRIS) method[3] scored baseline GRE±Gd images for osteitis on a scale of 0 to 3 in 15 bones of each wrist, and for synovitis on a scale of 0 to 3 in the distal radioulnar, radiocarpal and intercarpal-carpometacarpal joints in each wrist. Several days later, the same radiologist scored the STIR images without referring to the GRE±Gd images or the previous scores. Agreement between the two methods was determined by intra-class correlation coefficient (ICC).

Results: GRE±Gd and STIR showed identical results for synovitis scoring and very similar results for osteitis scoring (Table 1). Most of the osteitis visible on STIR, but not GRE±Gd, could be attributed to partial-volume averaging and pulsation artifacts on STIR. The ICCs for total synovitis and osteitis between the two methods were 1.00 and 0.98, respectively.

	STIR	**GRE±Gd**
Patients with synovitis, n (%)	11 (28%)	11 (28%)
Mean synovitis score, mean (SD)	1.1 (1.9)	1.1 (1.9)
Joints with synovitis, n (%)	22 (19%)	22 (19%)
Not visible with the other technique	0	0
Patients with osteitis, n, %	13 (33%)	11 (28%)
Osteitis score, mean (SD)	3.8 (8.7)	3.5 (8.2)
Bones with osteitis, n (%)	52 (9%)	48 (8%)
Not visible with the other technique	7 (13%)	5 (10%)
SD=standard deviation		

Conclusion: These findings confirm that coronal STIR and coronal GRE±Gd perform equivalently, and that STIR may not need to be included in a protocol which already has coronal GRE±Gd. STIR can, however, substitute for GRE+Gd if a Gd-free MRI protocol is preferred or if homogeneous spectral fat suppression is difficult to achieve.

Clinical Disease Activity Scores of Knee Joints in Newly Diagnosed JIA Predicts Reduction in Bone Pixel Value Detected by Computed Radiography. Laura Pascoli[1], Aaron Mc Cann[2], Michael Stevenson[3], Catherine Mc Allister[4] and Madeleine E. Rooney[5], [1]Belfast, United Kingdom, [2]Belfast Hospital Trust, Belfast, United Kingdom, [3]Queens University of Belfast, Belfast, [4]BHT, Belfast, United Kingdom, [5]Queen's University Belfast, Belfast, Northern Ireland

Purpose: . Evaluation of joint radiographs in JIA is highly subjective. We wished to evaluate the relationship between CR Pixel values and disease activity scores obtained for the knees of newly diagnosed JIA children. If we can identify reproducible differences between involved and contra lateral non/less involved knees in early disease we may be able to objectively track changes in serial CR images over time.

Methods: Children with newly diagnosed untreated JIA were recruited. Both knees were scored for disease activity on a score of 0-3. Weight-bearing antero-posterior (AP) images of both knees were captured via CR. A hydroxyapatite phantom was fixed to an unobscured region of the phosphor cartridge during all exposures. Pixel values in the phantom region were used to determine the brightness and contrast settings of the CR system allowing conversion of the whole image to values of absolute attenuation. Scattered radiation, whose random nature interferes with measurement of tissue content, was estimated based on Monte Carlo N-particle (MCNP) simulations. Measurements of bone and soft tissue content were taken at a number of repeatably identifiable regions in AP X-rays of both knee joints. The effect of overlying soft tissue in the bone regions was compensated by extracting the residual values of bone vs soft tissue plots over the full data set. Knee joints for all patients were independently assigned clinical scores (none, mild, moderate, severe). Association of clinical score categories with soft tissue and bone residual parameters was characterized by ordinal regression with the individual subject incorporated as a blocking variable.

Results: Results of 35 children and 70 knees are reported (11 had unilateral knee involvement). Mean disease duration 8.1 months (range 1-24 months). Mean age at visit time 8 years (range 1.6-16.6 years).

The analysis showed a highly significant ($p<0.0001$), direct relationship between clinical score and soft tissue, and a significant ($p=0.003$), inverse relationship between clinical score and bone residuals. Therefore, incremental differences in the clinical scores for a subject's knee joints are reflected both in the soft tissue content and reduced bone content. Regression analysis of contra lateral differences between knees indicates a significant inverse relationship between soft tissue difference and bone residual difference ($p<0.001$, $r^2=0.45$) Thus 45% of variation of the differential in bone content can be explained by the differential in soft tissue.**Conclusion:** Following appropriate image registration CR images can be used to measure peri-articular bone loss in JIA. The results obtained from standard X-rays could be of substantial value to the clinician using serial X-rays to determine joint damage over time. We are currently evaluating the CR images obtained over the 2 years of our prospective study and comparing these with disease outcome during the same time period

Defining Spinal Inflammation in Ankylosing Spondylitis-a Correlation of Magnetic Resonance Imaging Findings with Clinical, Radiological and Laboratory Markers. Ismahan Bozbey, Sebnem Ataman, Elif Ozyurek, Atilla Halil Elhan, Derya Oztuna and Ilhan Erden, Ankara University, Ankara, Turkey

Purpose: To detect spinal inflammation by magnetic resonance imaging (MRI) in patients with ankylosing spondylitis (AS) and to investigate whether there is any relationship between MRI findings and validated methods of disease assessment.

Method: A total of 40 patients were included in this observational cross-sectional study (29 men, 11 women). The main outcome measures were Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Radiology Index (BASRI), measurement of serum erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and MRI of the thoracic and lumbar spine (ASspiMRI-a).

Results: The median ASspiMRI-a scores for the acute lesions were 4.5 (0.0-23.0) for T1/Gd-DTPA MRI images and 5.0 (0.0-21.0) for STIR MRI images. The median BASDAI, BASFI, BASMI and BASRI scores were 3.42 (0.0-8.7), 1.0 (0.0-7.7), 6.0 (5.0-12.0) and 8.0 (5.0-13.0), respectively. The mean ESR and CRP were 14.60±15.15 and 8.87±9.78, respectively. In this study most commonly affected vertebral unit (VU) was found as T11-T12 with both STIR and T1/Gd-DTPA MRI sequences. No singificant difference was found between T1/Gd-DTPA and STIR sequences ASspiMRI-a scores. We found significant correlations between ESR and ASspiMRI-a scores of thoracic spine and total spine, ESR and affected number of VU detected with both T1/Gd-DTPA and STIR MRI sequences. When patients on anti-tumor necrosis (TNF) therapy compared with patients not taking anti-TNF therapy, we found significant relationships with ESR, T1/Gd-DTPA ASspiMRI-a total scores, number of affected VU in thoracic spine and total spine detected with T1/Gd-DTPA MRI sequences. We found significant correlation between BASFI and number of affected VU in total spine with STIR sequences. We also found positive correlation between number of affected VU with T1/Gd-DTPA sequences and BASFI but it was not statistically significant. When we compare patients who have BASDAI ≥ 4 and BASDAI <4, no significant relationship was found between ASspiMRI-a scores.

Conclusion: Our study would suggest that use of MRI techniques in assessment and follow-up uf AS patients along with other validated methods of disease assessment. But there is need for further studies about MRI scoring systems.

Repair of Erosions Occurs Preferentially in Patients Treated with Anti-TNF Therapy and in Joints with Clinical Improvement. C. Lukas[1], Désirée M.F.M. van der Heijde[2], Saeed Fatenejad[3] and Robert Landewé[4], [1]Lapeyronie hospital, Montpellier, France, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Wyeth Research, Collegeville, PA, [4]University Hospital Maastricht, Maastricht, Netherlands

Purpose: Negative radiographic change scores obtained under strictly blinded time-sequence conditions have raised the impression that repair of previously damaged joints may indeed occur. It is likely that – if it truly exists – repair is preferentially seen in joints with clinical improvement and in patients treated with TNF-blocking drugs. We tested this hypothesis in the TEMPO trial.

Method: Radiographs from patients of the TEMPO trial were scored twice by two readers using the Sharp/van der Heijde method, blinded to both treatment and true time sequence. Single-joint change scores in erosions were calculated and matched with single joint swelling scores. Factors expected to increase the likelihood of occurrence of both worsening and improvement of erosion over time were tested by GEE modelling (2 different models were built). The independent influence of clinical response in single joints and treatment (methotrexate, etanercept, or combination of both drugs) on 'progression' and 'repair' in single joints was investigated while adjusting for within-reads correlation.

Results: Multivariate analyses showed that worsening of erosion score in a joint was significantly increased if that joint was already damaged at study entry, clinical swelling was still persistent at the end of trial and MTX was used instead of etanercept (or combination) (data not shown), while repair was independently associated with clinical improvement of that joint and treatment with etanercept or combination ($p \leq 0.007$ for all associations).

Likelihood of single joint 'repair' in patients participating in the TEMPO trial

Compared conditions		**OR [95% CI]**	**p**
Treatment	MTX	1 (reference)	
	ETA	1.28 [1.07-1.53]	0.007
	MTX+ETA	1.33 [1.12-1.58]	0.001
Swelling	Worse/Persistent	1 (reference)	
	Improvement/None	1.57 [1.16-2.14]	0.004

Conclusion: Repair of erosions preferentially occurs in joints that show an adequate clinical response on anti-TNF treatment, while progression is seen more frequently in joints with persistent swelling, and in those receiving MTX monotherapy, preferentially if damage is already present.

Comparison of Structural Bone Alterations in Rheumatoid Arthritis and Psoriatic Arthritis by High-Resolution 3D Quantitative Computerized Microtomography. Christian M. Stach[1] and Georg Schett[2], [1]Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany

Purpose: Alterations in bone structure, such as bone erosions and osteophytes are a typical phenomenon of rheumatoid arthritis (RA) and psoriatic arthritis (PsoA) and are closely linked to bad functional outcome. Morphology of bone structure changes can be used as an important criterion for differential diagnosis between RA and PsoA. Modern therapies aim to prevent progression of structural bone changes. Early detection of bone lesions right from their onset is important for diagnosis and monitoring of disease.

Conventional radiographs have a limited sensitivity to detect very small lesions. Other techniques like ultrasound and magnetic resonance imaging (MRI) are optimal in assessing inflammation but not bone structure.

Objectives: We used a recently introduced novel imaging technique, a high resolution peripheral quantitative computed tomography (HR-pQCT) system, which allows a high-resolution assessment of bone structure and a 3 dimensional (3D) reconstruction of the entire joint surface. With this system we assessed bone structure of PsoA patients compared to RA patients and healthy subjects.

Method: MCP joints 2, 3 and 4 as far as the proximal wrist of the dominant hand from 60 patients with RA, 40 patients with PsoA and 30 healthy subjects were scanned at a resolution of 84 micrometer. Subchondral trabecular structure and cortical shell were studied by cut views and 3D reconstructions.

Results: More than 25% of healthy subjects showed structural bone changes like erosions or osteophytes. However estimating results in consideration of size position and morphology allows to distinguish bone alterations in healthy patients from alterations in patients. RA patients could be identified with a sensitivity of 0.75 and a specificity of 0.85 with a recently suggested combined score. Bone changes in especially older healthy controls resembled to those in PsoA patients However PsoA patients could be identified with a sensitivity of 0.72 at a specificity of 0.69 with the suggested combined score. RA patients and PsoA patients showed significant differences in incidence, morphology and localization of erosive lesions and osteophytes allowing distinction of RA patients and PsoA patients.

Conclusion: These data suggest that HR-pQCT is an interesting method for depicting and measuring structural bone changes in RA and PsoA patients with a high sensitivity and specificity. Evaluating these alterations could be used for differential diagnosis between rheumatoid arthritis and psoriatic arthritis. Furthermore the method could be used for monitoring disease specific lesions under therapy. Beyond this an assessment of bone structure in the ultra-distal radial bone is included in the method delivering information about bone density and potential fracture risk of distal bones.

Prevalence of Systemic Autoimmune Rheumatic Diseases(SARDs): Regional Comparisons. S. Bernatsky[1], L. M. Lix[2], J. G. Hanly[3], M. Hudson[4], CA Peschken[5], A. E. Clarke[1], C. A. Pineau[1], P. Belisle[1] and L. Joseph[1], [1]MUHC, Montreal, QC, [2]University of Saskatchewn, Saskatoon, SK, [3]Dalhousie University, Halifax, NS, [4]McGill University, Montreal, QC, [5]University of Manitoba, Winnipeg

Purpose: Decision-makers are looking to administrative databases as a means of chronic disease surveillance, to aid in planning. Our purpose was to determine the prevalence of systemic autoimmune rheumatic diseases (SARDs) using population-based administrative data, and to compare results in three provinces representing central Canada (Quebec), western Canada (Manitoba) and the Maritimes (Nova Scotia).

Method: Cases of SARDs (including systemic lupus, scleroderma, Sjogren's syndrome, and polymyositis/dermatomyositis) were ascertained using physician billing and hospitalization data from these provinces. We based our case ascertainment approach on three different case definition algorithms, combining information from each definition by using hierarchical Bayesian latent class regression models that account for the imperfect sensitivity and specificity of each case definition. Our methods allow us to estimate SARD prevalence and assess differences across patient demographics.

Results: Using methods that account for the imperfect nature of both billing & hospitalization databases, we estimated the prevalence of SARDs to be approximately 2-3 cases per 1,000 residents. Prevalence was marginally higher in Manitoba at 2.8 cases/1,000(95% credible interval, CrI 2.7, 3.0), compared to Quebec at 2.6 cases/1,000(95% CrI 2.5, 2.6). Stratified prevalence estimates suggested similar demographic trends across provinces (i.e. greater prevalence in females-versus-males, and in persons of older age). The prevalence in older females approached or exceeded 1 in 100, which may reflect the high burden of primary Sjogren's syndrome in this group. Though stratified estimates were somewhat imprecise, they suggested a somewhat higher female:male ratio in Manitoba (approximately 8:1) compared to Nova Scotia(4:1) or Quebec(5:1). Adjusting for demographics, there was a greater prevalence in urban-versus-rural settings(less evident in Manitoba). **Conclusion:** Our results suggest that surveillance of some rheumatic diseases using administrative data may indeed be feasible and useful. Our work highlights the usefulness of using multiple data sources, adjusting for the error in each. Using these methods, we estimate that SARDs are as common as inflammatory bowel disease (estimated prevalence of about 2-3 cases/1000) & more common than HIV-related disease(1.8 cases/1000).

Neutrophilic Dermatosis: An Uncommon Side Effect of Azathioprine. Karen M. Sky[1], Jeff Bidinger[2], David W. Bray[2], J. Scott Henning[2] and Daniel F. Battafarano[3], [1]Brooke Army Medical Ctr, Fort Sam Houston, TX, [2]Lackland AFB, TX, [3]Brooke Army Medical Center, San Antonio, TX

Purpose: Neutrophilic dermatoses, such as Sweet's syndrome, pyoderma gangrenosum (PG) and erythema nodosum, are characterized by a reactive, sterile, pustulopapular rash with an intense neutrophilic dermal infiltrate on biopsy. These disorders can be associated with malignancy, infections, autoimmune diseases and can be drug induced. Our purpose was to report and characterize the seldom recognized association of azathioprine with the neutrophilic dermatoses.

Methods: Three patients receiving azathioprine for autoimmune diseases developed a papulopustular rash. Routine investigations including biopsies were performed. The literature was reviewed for similar cases.

Results: Two patients met revised 1982 ACR diagnostic criteria for systemic lupus erythmatosus and one patient had biopsy-proven Crohn's disease. One lupus patient, while taking 300 mg of azathioprine daily, and the patient with Crohn's, who was taking 50 mg of azathioprine daily, developed papulopustular rashes within 3 weeks of medication initiation. Biopsy results were consistent with Sweet's syndrome and Walker and Cohen criteria were met for drug-induced Sweet's syndrome. The other lupus patient developed lower extremity ulcerative lesions after 1 year of azathioprine 100 mg daily. Biopsy demonstrated a mixed infiltrate of neutrophils, lymphocytes and eosinophils. Clinical diagnosis was consistent with PG. All 3 cases met criteria for a probable adverse drug reaction based on the Naranjo algorithm. The neutrophilic dermatoses resolved after discontinuation of the azathioprine, with time to resolution ranging from 5 days for Sweet's syndrome to 5 months for PG. The patient with PG required 3 months of treatment with dapsone in addition to withdrawal of azathioprine. The patient with Crohn's was rechallenged with azathioprine and again developed the rash within 24 hours; the eruption resolved 3 days after medication discontinuation. All 3 patients had normal thiopurine methyltransferase (TPMT) levels.

Conclusion: Azathioprine may cause drug-induced neutrophilic dermatoses. Our patients developed neutrophilic dermatoses at widely varied dosages and duration of exposure to azathioprine. Azathioprine-induced neutrophilic dermatoses appear unrelated to dosage, disease process, TPMT levels or length of treatment. Physician awareness of this potential side-effect is important as the dermatoses often mimic infectious processes such as viral, atypical mycobacterial, deep fungal or disseminated candidal infections in immunosuppressed patients. Biopsy is necessary to differentiate neutrophilic dermatoses from other etiologies of papulopustular rashes and to avoid delays in diagnosis and treatment. Treatment may consist of cessation of azathioprine, supportive care and may require usual treatment for the particular dermatosis.

Cytokine Profiles of Macrophage Activation Syndrome Associated with Rheumatic Diseases. Junko Maruyama[1] and Shigeko Inokuma[2], [1]Tokyo Metropolitan Komagome Hospital, Tokyo, Japan, [2]Japanese Red Cross Medical Center, Tokyo, Japan

Purpose: Macrophage activation syndrome (MAS) is a potentially life-threatening complication of rheumatic diseases. The aim of this study is to elucidate the cytokine profiles of MAS in relation to underlying diseases and prognosis.

Method: The clinical features and laboratory data of eighteen MAS patients with rheumatic diseases were retrospectively analyzed. Serum levels of macrophage-colony stimulating factor (M-CSF), interleukin-18 (IL-18), tumor necrosis factor-α, interleukin-6, interferon-□, ferritin and □$_2$-microglobulin (□$_2$MG) were obtained. These data were compared between rheumatological conditions and between those with and without a fatal outcome.

Results: Of the 18 MAS patients, 8 had underlying systemic lupus erythematosus (SLE), 7 adult-onset Still disease (AOSD), 1 mixed connective tissue disease (MCTD), 1 rheumatoid arthritis (RA) and 1 antiphospholipid syndrome. Two SLE, 1 MCTD and 1 RA patients had a fatal outcome. The serum M-CSF and IL-18 levels were substantially elevated in all of the patients. In the SLE patients, M-CSF level was higher than IL-18 level (median: 4,224 vs. 1,336 pg/mL, p=0.012), and it was the reverse case in the AOSD patients (5,883 vs. 228,350 pg/mL, p=0.0017). The serum M-CSF and □$_2$MG levels were significantly higher in the patients who died than those who survived (M-CSF: 18,245 vs. 3,404 pg/mL, p=0.019; □$_2$MG: 18.8 vs. 5.4 mg/dL, p=0.0058).

Conclusion: The cytokine profiles associated with MAS differed between SLE and AOSD patients. The SLE patients showed a prominent increase in serum M-CSF level, as did AOSD patients in serum IL-18 level. Patients with a fatal outcome had higher serum M-CSF and □$_2$MG levels. The data suggests that aggressive treatment for patients with MAS and these profiles should be promptly started.

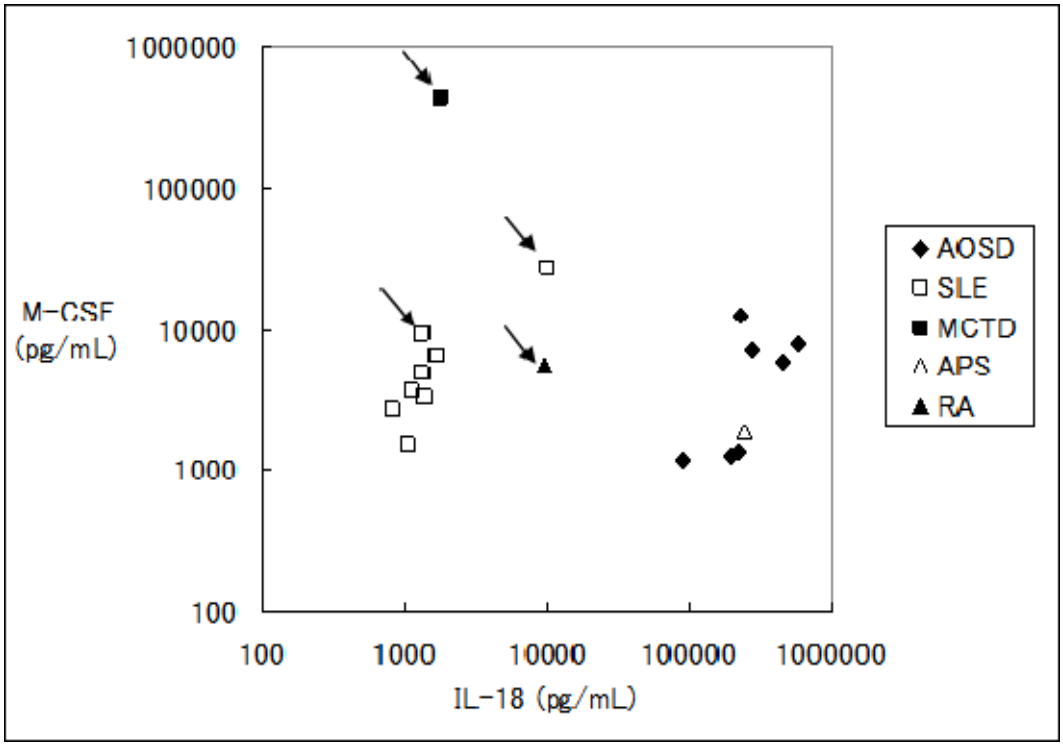

Figure. Serum M-CSF and IL-18 levels in MAS patients with rheumatic diseases. Patients with a fatal outcome (arrows) had higher serum M-CSF levels.

Comparison of Serum Biomarkers Across Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis Patient Populations Prior to and Following Treatment with Golimumab, a Human Anti-TNF Antibody. C. Wagner[1], H. Fan[1], M. U. Rahman[2], A. Beutler[1], B. Hsu[1], M. Elashoff[3] and S. Visvanathan[1], [1]Centocor R&D, Inc, Malvern, PA, [2]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [3]Elashoff Consulting, Redwood City, CA

Purpose: To compare and contrast biomarker profiles prior to and following golimumab (GLM) treatment across 3 populations of pts with rheumatic disease: active rheumatoid arthritis (RA) despite MTX; psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

Methods: Sera were collected at wks0, 4 and 14 from a subset (approx. 100) pts from each of the GLM Phase 3 trials: GO-FORWARD (active RA despite MTX), GO-REVEAL (active PsA despite conventional treatment) and GO-RAISE (active AS despite conventional treatment). Across the 3 studies, pts were randomized to either PBO, 50mg or 100mg GLM in the presence or absence of MTX or other conventional medications. Samples were tested for select inflammatory markers (Quintiles Laboratories) and bone and cartilage markers (Pacific Biometrics) and protein profiling using multi-analyte profiles (Rules Based Medicine). Change from baseline in markers was compared between GLM±MTX and PBO+MTX using ANOVA on the van der Waerden normal scores and t-tests. Pathway analysis comparisons were made using Ingenuity software and data were compared using the Fisher Exact test.

Results: Prior to treatment**,** there were no biomarkers that were significantly different between the GLM±MTX and the PBO±MTX treatment groups that were consistently observed across the 3 pt populations. In the GLM±MTX groups at wk4, there were 7 biomarkers (haptoglobin, CRP, serum amyloid P, thyroxine binding globulin, MMP-3, ICAM-1, TNFRII) that showed significant changes from baseline ($p<0.05$) relative to PBO±MTX that were similarly modulated across the 3 populations. At wk4 following GLM±MTX treatment, there were 4 other commonly modulated biomarkers between the AS and PsA populations, 3 more markers similarly modulated between RA and PSA, and one more commonly modulated marker between the AS and RA populations. At wk14, in the GLM±MTX groups there were 9 markers (CRP, MIP1β, haptoglobin, MMP-3, α1anti-trypsin, thyroxine binding globulin, serum amyloid P, PAI-1 and TIMP-1) that were significantly ($p<0.05$) changed from baseline relative to PBO±MTX across all populations. In the PsA and AS populations, 5 other markers were commonly changed from baseline at wk14 compared with only 1 additional marker for each population relative to the RA pts. Signaling pathways significantly impacted in response to treatment with GLM±MTX at wk4 and 14 across the different populations included the acute phase response, TREM1, hepatic fibrosis, coagulation system, and leukocyte extravasation.

Conclusion: GLM impacts multiple proteins and signaling pathways associated with TNFα in the RA, PsA and AS disease processes. Principal component analysis indicates all 3 diseases are notably different from normal individuals, and pts with RA have a somewhat distinct overall profile compared with AS and PsA. Select markers were modulated across all populations of pts treated with GLM±MTX, with some overlap of modulated markers across all diseases.

A Nucleolar-Pattern ANA in Patients with Idiopathic Interstitial Pneumonia Suggests Underlying Connective Tissue Disease. Aryeh Fischer, Jeffrey J. Swigris, Roland M. du Bois, Joann Z. Gillis, Marc D. Cohen, Richard T. Meehan and Kevin K. Brown, National Jewish Health, Denver, CO

Background: Interstitial lung disease (ILD) comprises a diverse group of disorders characterized histologically by varying degrees of inflammation and fibrosis. Although ILD may have no identifiable etiology, (i.e. idiopathic interstitial pneumonia [IIP]), ILD is a common finding in patients with known connective tissue disease (CTD) or can be the forme fruste presentation of CTD. Recent data suggest that, CTD-related ILD has a more favorable prognosis than IIP, arguing for the careful evaluation of patients presenting with an idiopathic ILD in an attempt to identify underlying CTD.

Purpose: To examine the significance of a nucleolar-pattern ANA in patients presenting with idiopathic ILD, and specifically, to describe the clinical characteristics of 15 patients presenting with IIP and a nucleolar-pattern ANA over a 12 month period at a tertiary ILD referral center.

Method: Retrospective cohort of 21 patients presenting to a tertiary referral center for evaluation of IIP and found to have a nucleolar-pattern ANA. All patients underwent comprehensive ILD evaluation that included consultation with a board certified rheumatologist. The diagnoses of systemic sclerosis (SSc) and undifferentiated connective tissue disease (UCTD) were rendered by the treating physicians and confirmed on retrospective review based on current or proposed criteria.

Results: Based on collaborative pulmonary and rheumatology evaluations, 17 (81%) were diagnosed with SSc and 4 (19%) with UCTD. As a result of the connective tissue disease (CTD) classification, most patients (81%) were treated with medication regimens containing a cytotoxic agent.

	N=21
Median age (range)	66 (35-86)
Female gender	10 (48%)
Smoking history	12 (57%)
Duration of dyspnea in months (range)	12 (1-60)
Median ANA titer (range)	1:640 (80-5120)
Anti-Scl-70	3 (14%)
Other antibodies	2 anti-Ro, 1 with combined PM-Scl, RF, CCP, dsDNA
Arthritis	7 (33%)
Sclerodactyly	5 (24%)
Telangiectasia	12 (57%)
Raynaud's	13 (62%)
Digital edema	8 (38%)
Esophageal dysmotility (N=18)	14 (67%)
FVC%	59 (30-105)
DLCO%	43 (15-82)
ILD pattern by HRCT	12 NSIP (57%), 7 UIP (33%), 2 NSIP/UIP (10%)
Surgical lung biopsy (N=6)	2 NSIP, 2 UIP, 1 NSIP+OP, 1 OP

Conclusion: Cross-specialty collaboration with rheumatology is helpful to detect occult forms of CTD-related ILD. The presence of a nucleolar-pattern ANA in patients with IIP suggests underlying CTD – and SSc in particular – and should prompt rheumatologic evaluation. Clinicians involved in the evaluation of patients with ILD should ensure that ANA testing includes pattern determination in addition to titer.

More precise ILD classification will allow for studies that determine optimal therapy and prognosis based on specific ILD type.

Performance of Three Self-Report Measures in Connective Tissue Disease-Associated Interstitial Lung Disease. Jeffrey J. Swigris, David B. Sprunger, Roland M. du Bois and Aryeh Fischer, National Jewish Health, Denver, CO

Background: Interstitial lung disease (ILD) is a common manifestation of connective tissue disease (CTD) and often associated with significant morbidity and mortality. Dyspnea, a ubiquitous symptom in ILD patients, leads to physical inactivity and a number of adverse downstream effects, including deconditioning, loss of independence, and impaired emotional well-being and overall quality of life. Two patient self-report questionnaires, University of California San Diego shortness of breath questionnaire (UCSD-SOBQ) and Dyspnoea-12 questionnaire (D12Q), have been developed and validated to reflect pulmonary impairment in chronic lung disease – yet have not been validated for CTD-related ILD. The multidimensional health assessment questionnaire (MDHAQ) has proven useful in clinical care of CTD patients and assesses function, pain and patient global estimate of status with a composite "RAPID" score.

Purpose: We conducted this study to assess scores from the MDHAQ, UCSD-SOBQ, and D12Q in patients with CTD-related ILD.

Method: The study cohort was comprised of 48 consecutive subjects with CTD-related ILD who completed the MDHAQ, UCSD-SOBQ, and the D12Q, and underwent pulmonary function testing (PFT). Pearson product moment correlation coefficients were used to examine the relationship between different outcomes.

Results: See table.

Conclusion: There was moderately strong correlation between components of the MDHAQ, FVC correlated significantly with day-to-day functioning but with no other component of the MDHAQ, DLCO did not correlate with any MDHAQ component, there was significant correlation between dyspnea and day-to-day functioning, psychological well-being, fatigue, and global status, there was moderately strong correlation between scores from the two dyspnea instruments. Serial self-reporting with the MDHAQ, UCSD-SOBQ, and D12Q helps with ongoing clinical care of CTD-ILD patients and provides valid and reproducible measures of clinical disease activity.

Synovial Sarcoma Presenting as Soft Tissue Rheumatic Syndrome: A Challenge for the Clinician. Leticia C. Baena-Ocampo[1], Federico Bertrand[2], Saul León[1], L. Miguel Linares[1], Genaro Rico[1] and Carlos Pineda[3], [1]Instituto Nacional de Rehabilitacion, Tlalpan D.F, Mexico, [2]Escuela de Medicina Universidad la Salle, Mexico City, Mexico, [3]Instituto Nacional de Rehabilitacion, Mexico City, Mexico

Purpose: Despite of its name, synovial sarcoma (SS) does not have synovial origin; it arises from the primitive mesenchyme of the tendon sheath and fascial aponeurosis. SS is frequently misdiagnosed as a benign soft tissue condition. Will be described clinical and histopathological features of patients with diagnosis of SS, emphasizing those manifestations that may lead to misdiagnosis of soft tissue rheumatism.

Methods: A retrospective chart, imaging and pathological review of consecutive histopathological proved cases of SS, registered between January 2000 to December 2008 at Pathology department.

Results: 27 patients (17 male 63%; 10 female, 37%). The average age at diagnosis was 28 years (11 – 63 years). Anatomical regions involved were, lower limb in 93% (foot 11, 41%; ankle 4, 15%; knee 4, 15%; thigh 4, 15%; inguinal region 2, 7%) and upper limb in 2, 7%; arm and forearm,). Signs and symptoms at presentation were: pain in all cases, palpable deep-seated swelling or periarticular mass in 22 (81%), decrease range of joint motion in 44%, weight loss in 18%, skin color changes in 7%, and muscle weakness in 4%.

Eleven (34%) were initially diagnosed as benign rheumatologic conditions: synovitis in 3 (11%); fasciitis in 2 (7%); Mortonxs neuroma; arthrofibrosis; chronic bursitis, synovial cyst, bunionette, and tarsal tunnel syndrome 1 (4%) instance each. The time elapsed since onset of symptoms to diagnosis was 40 months (1 – 156 months). The more advantageos imaging studies that helped defining the presence of a soft-tissue tumor were MRI, CT-scan, scintigraphy and X-rays. In all cases a biopsy was necessary to confirm diagnosis. Surgical treatment was: amputation in 11 patients (41%), block resection in 6 (22%) and marginal resection in 5 (18.5%). Five patients (18.5%) refused surgical treatment. The size of the tumors ranged from 1-to 12 cm. Histological subtype was identified as monophasic (24/89%) and biphasic (3/11%). Patients were classified according to the TNM system as follows: T1N0M0 19(70%), T2N0M0 2(7%) T2N1M0 1(4%) and T2N1M1 5(19%). They also were categorized according to the IRSG classification as type I in 18 patients (67%), type II in 2 (7%), type III in 6 (22%) and type IV in 1 case (4%). Ten (37%) patients underwent adjuvant chemotherapy and radiotherapy. The average follow-up was 51 months (6-96), local recurrences and metastases were in 7 patients (26%). Fifteen (55.5%) patients were alive and disease free.

Conclusion: It is essential that the Rheumatologist retain awarness of SS, particularly in young male patients presenting with slow growth, palpable, deep-seated soft tissue swelling or mass in close proximity to joints of the lower extremities. SS should be included in the differential diagnosis of soft tissue rheumatic syndromes.

Safety of Golimumab, A New Human Anti-TNF α Antibody, in Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis: An Analysis of Pooled Data From Randomized, Double-Blind, Placebo-Controlled Studies. Jonathan Kay[1], R. M. Fleischmann[2], Edward C. Keystone[3], M. U. Rahman[4], E. C. Hsia[4], M. K. Doyle[4], B. Hsu[4], M. Mack[5], J. Zrubek[5], A. Beutler[5], J. Braun[6] and Arthur Kavanaugh[7], [1]University of Massachusetts Memorial Medical Center, Worcester, MA, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Professor of Medicine/University of Toronto, Toronto, ON, [4]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [5]Centocor R&D, Inc, Malvern, PA, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]U of California San Diego, San Diego, CA

Purpose: To analyze pooled data from 5 GLM Phase 3 trials (and a Phase 2 trial for serious infections, malignancies, and deaths).

Methods: Placebo (PBO) or GLM(50or100mg) was given SC q4wks in the ongoing Phase3 trials. About half of the pts received MTX; smaller proportions received other DMARDs. Analyses included safety data from randomized pts receiving ≥1 dose of study agent. Since pts could crossover from PBO to GLM or increase GLM dose from 50 to 100mg in cases of inadequate response, pts may appear in more than one column.

Results: As of June 2, 2008,639 pts received PBO,1233 GLM50mg, and 1286 GLM100mg. Most pts (75%RA, 90%PsA, 89%AS) had GLM exposure ≥52wks. Duration of f/u was >2-fold longer for GLM vs PBO. The proportions of pts with any adverse event (AE), AE leading to d/c, serious AEs, and clinically important hepatobiliary events were similar across groups (Table). All cases of tuberculosis (6 pts;3 each for GLM 50&100 mg) and histoplasmosis (1 pt,GLM100mg) were in GLM group. Overall occurrence of injection site reactions was low; most were mild, and only 2 cases led to study agent d/c. No GLM-treated pt developed anaphylaxis or serum sickness-like reaction. There was no statistically significant difference in the incidences of serious infection or death per 100pt-yrs of f/u between GLM 50/100 mg and PBO. Malignancies occurring during the 5 Phase 3 plus 1 Phase 2 trials included skin cancers, solid tumors, and lymphoma. In comparison to

Surveillance Epidemiology and End Results (SEER) database for malignancies, the incidence of malignancies in GLM-and PBO-treated pts was similar to that expected in general US population.

Table:

Pooled GLM safety. Values are mean or %pts.

Adult's Onset Still's Disease: a Review of 41 Cases. Anna Moltó[1], Elena Riera[2], Alejandro Olivé[1], Javier Narváez[3], Susana Holgado[1], Maria M. Bianchi[3], Lourdes Mateo[1], Pilar Santos[3], Xavier Tena[1] and Joan Miquel Nolla[3], [1]Hospital Germans Trias i Pujol, Badalona, Spain, [2]Hospital Universitari Mútua de Terrassa, Terrassa, Spain, [3]Hospital Universitari de Bellvitge, Barcelona, Spain

Purpose: To describe the clinical manifestations, treatment, evolution, prognosis and functional class of 41 patients with Adult Onset Still's Disease (AOSD)

Method: Retrospective study (1984-2006). Multicenter study. Setting: Hospital Universitari Germans Trias i Pujol and Hospital Universitari de Bellvitge. All patients fulfilled Yamaguchi et al Classification criteria. (J Rheumatol 1992; 19: 424-430).

Results: Forty one patients were included (15 men and 25 women). Mean age at diagnosis: 38.19 years (SD 15,59). All patients had spiking fever. Typical exanthema was present in 38 patients (92,6%). Symptoms were preceded by sore throat in 37 (90,2%). Forty patients (97,5%) had polyarthralgia and 36 (88%) had arthritis; polyarticular pattern in 29 (80,5%) and oligoarticular in 7 (19,5%). Knees, wrists and ankles were the joints more often involved. Other clinical manifestations were lymphadenopathy in 17 patients (41%), hepato/splenomegaly in 16 (39%), abdominal pain in 5 (12%), pleuritis in 6 (14,6%), pericarditis in 5 (12%) and interstitial pneumopathy in 2 (4,8%). Most of the patients had leucocytosis and neutrophilia and a remarkable elevation of ESR and CRP. Liver function abnormalities were detected in 50% of the patients . Hyperferritinemia was preset in (83%.)

The course of the disease was monocyclic in 44% of the patients and polycyclic/chronic in 56%.

ASA or NSAID controlled the disease in seven patients (17,5%) and prednisone in eleven (27,5%). Immunosupressors were required in 55% of the patients and in seven of them (17,5%) a biological treatment with TNF-a blockers or anakinra had to be added in order to control the disease.

Currently 17 patients (42,4%) are free of disease without treatment (mean duration of disease 114.74 moths. SD: 105,65) and totally asymptomatic (72.55 moths; SD 30,75). Fifteen patients had a monocyclic patterns and a polycyclic-chronic in two.

Twenty-three patients (57,5%) are still on treatment (duration of disease: 110.96 months. SD: 70,22). Three patients treated with ASA, 1 with NSAID and prednisone, 8 with NSAID, prednisone and methotrexate, 4 with methotrexate alone and 7 with NSAID, prednisone, methotrexate and a biological treatment. Four patients had a monocyclic course and 19 a polycyclic-chronic one.

Erosions were present in nine patients (22%). ACR class were as follows: 29 (72,5%) class I, 7 (17,5%) class II, 2 (5%) class III and 2 (5%) class IV.

Conclusion: The clinical manifestations were similar to other series. A fevered polyarthritis was the most frequent clinical presentation. Patient with monocyclic course tend to have a better prognosis. Fifty six percent of the patients had a polycyclic-chronic course and required an aggressive treatment. Radiological bony erosions were present in 22% of patients. Most patients are in functional class I.

Value of Bone Erosions in Undifferentiated Arthritis. Mohamed M. Thabet, Tom W.J. Huizinga, Désirée M.F.M. van der Heijde and Annette H.M. van der Helm-van Mil, Leiden University Medical Center, Leiden, Netherlands

Purpose: In rheumatoid arthritis (RA) the presence of bone erosions at baseline is the most significant predictor for a severe destructive disease course, while the prognostic importance of erosive joints for disease outcome in undifferentiated arthritis (UA) is unknown. UA has a variable disease course; 40-50% of patients remit spontaneously, while about one third develop RA. Identifying UA patients who will develop RA is essential to initiate early DMARD therapy. This study aims to identify the predictive value of erosive joints for the disease outcome in UA as measured by the development of RA as well as persistent arthritis.

Methods: Baseline radiographs of hands and feet of 518 UA patients were evaluated for erosions using a clinical definition (erosion score of SENSE method) as well as the Sharp-van der Heijde (SHS) method. After 1 year, patients were re-assessed for the fulfilment of the 1987 ACR classification criteria for RA. Persistent arthritis was defined as the absence of sustained remission. The mean follow-up was 8 ± 3 years.

Results: 31% (n= 160) of UA patients fulfilled the 1987 ACR classification criteria for RA within 1 year. During the whole period of follow up 39.6% (n= 205) UA patients achieved clinical remission, while the remaining 60.4% (n= 313) had persistent arthritis (remained UA, developed RA or developed a disease other than RA).

At baseline, 28.6% of UA-patients had erosive joints. The presence of 2 or more erosive joints showed a positive predictive value for RA-development of 53% and for persistent disease of 68%. Patients with erosions that did not develop RA were less often ACPA+, RF+ and had lower CRP, ESR and number of swollen joints compared to those who developed RA. Feet erosions were equally predictive compared to hand erosions. 74% of erosive UA patients who developed RA received DMARDs in their first year compared to 66% in non-erosive UA patients who developed RA, meaning that the presence of erosions didn't affect the physician's decision to start DMARDs. 32.5% of UA patients with two or more erosive joints achieved sustained remission.

Conclusion: Unlike RA, the presence of baseline erosions in UA is not always predictive for an unfavourable disease outcome and are on their own insufficient to establish treatment decisions. Although feet erosions are not part of the 1987 ACR criteria, feet erosions have at least equal predictive performance for RA development and disease persistency.

Table: Predictive value for the progression from UA to RA within 1 year using different cut-off values for erosiveness.

	Nr of Erosive Joints	n	PPV	NPV	Specificity	Sensitivity	LR+	LR-	AUC (SEM)

Catecholamines Are Produced by Immune Cells During Arthritis: New Aspects of Neuro-Immunological Response. Silvia Capellino, Kristina Weber, Alexander Fassold, Christine Wolff and Rainer H. Straub, University Hospital Regensburg, Regensburg, Germany

Purpose: In our previous study, we demonstrated that synovial cells produce catecholamines during chronic inflammation such as rheumatoid arthritis (RA) and osteoarthritis (OA). The modulation of intracellular catecholamine balance by reserpine or other drugs that influence catecholamine handling reduced TNF release by 60% in primary synovial cells and reduced paw swelling *in vivo* in arthritic DBA/1J mice. The aim of our study was to understand whether catecholamine-producing cells differentiate in the synovial tissue or whether external organs can be the source of these cells. Furthermore, we investigated when these cells start to play a role in the inflammatory process.

Method: Collagen type II induced arthritis was induced in DBA/1J mice. Twenty mice were immunized and 20 mice served as controls. At day 0, 7, 14, 21, 28, 35, 42, 49, 60 and 80 after first immunization, two mice of each group were sacrificed. Lymph nodes, thymus, adrenal glands and spleen were fixed and frozen until use. Paws and bone marrow were fixed, decalcified and then frozen until use. Immunofluorescence staining was performed by using a primary antibody against vesicular monoamine transporter-2 (VMAT-2).

Results: Fourteen days after first immunization, the density of VMAT-2 positive cells in bone marrow started to be significantly higher in arthritic mice compared to controls, and density reached the maximum difference at day 42 after first immunization. In the spleen in arthritic mice compared to control animals, the most marked difference in density of VMAT-2 positive cells was found at day 49. The splenic density of VMAT-2 positive cells was higher in arthritic compared to control mice already at day 21. VMAT-2 positive cell density was very low in the joints of control mice compared to arthritic animals, but a difference was already detected 14 days after first immunization. The maximum density of VMAT-2 positive cells in joints from arthritic mice was reached at day 35, and density subsequently decreased until day 80 but still remained higher than in control animals.

Conclusion: These results demonstrate for the first time that catecholamines are produced and stored by immune cells also in the early asymptomatic phase of arthritis. Moreover, catecholamines are produced by immune cells not only at the site of inflammation but also in bone marrow and spleen.

A Study of Myelodysplastic Syndrome Patients and Rheumatologic Phenomena. Christopher M. Burns and Daniel A. Albert, Dartmouth-Hitchcock Med Ctr, Lebanon, NH

Purpose: Patients with myelodysplastic syndrome (MDS) frequently have associated rheumatic diseases, including rheumatoid arthritis and polymyalgia rheumatica. In some (and perhaps all) patients, the cytopenias in MDS are immune-mediated. It is theorized that immune activation in the bone marrow in MDS may lead to systemic autoimmunity and rheumatic manifestations. Additionally, with the advent of stimulating factor therapy to reduce transfusion requirements, treatment-related autoimmune conditions are becoming more common in MDS. We reviewed the rheumatologic findings in all the MDS patients in our institution over a 2 year period.

Method: We conducted an IDX (238.75 myelodysplastic syndrome) based search of the records from Dartmouth Hitchcock Medical Center from 2006 to 2008 to identify patients with MDS, and then reviewed each chart for rheumatologic phenomena

Results: We found 7 patients with bone marrow biopsy-proven MDS. All patients were older, 58 to 87 years of age, and 5 of 7 have died. Two patients had necrotizing vasculitis one with a lung nodule and the other with mononeuritis multiplex. One male patient had palmar fasciitis with exudative pleural effusions (non malignant) similar to ovarian carcinoma. One patient had inflammatory arthritis negative for crystal, malignancy or infection. One patient had steroid responsive extremity pain similar to hypertropic osteoarthropathy with no evidence of periarthritis. One patient had nonmalignant mediastinitis with exudative pleural effusions. One patient had typical ANCA+ Wegener's Granulomatosis.

Conclusion: MDS patients had a wide range of rheumatic findings and every patient had some immune-mediated phenomena, but only one patient had a typical rheumatic disease. In some cases, treatment of the rheumatic disease ameliorated the MDS. Immune activation within the bone marrow milieu is a feature of MDS. A subset of patients responds to immunosuppressive agents with reduced transfusion requirements and slower progression to acute myelocytic leukemia. Multiple components of the immune system are involved, including cytolytic CD8 cells directed at tumor neoantigens expressed on hematopoietic cells with the trisomy 8 mutation, cytokines such as TNF-a, and NK cells. It is postulated that local immune activation induces systemic autoimmunity and rheumatic manifestations. We conclude that a host of rheumatic conditions, both classic and atypical, can occur in the setting of MDS or its treatment. Rheumatologists should be vigilant for MDS when diagnosing rheumatic conditions, particularly atypical presentations or in the setting of unexplained cytopenias. We propose an MDS-related Autoimmune Disease Registry as a data-base for these cases with the hope that patterns will emerge to help elucidate the pathogenesis of both MDS and rheumatic diseases.

Ex Vivo Softlaser Treatment Inhibits the Synovial Expression of Vimentin and á-Enolase, Potential Autoantigens in Rheumatoid Arthritis. Geza Balint[1], Klara Barabas[1], Zsuzsanna Zeitler[2], Jozsef Bakos[2], Akos Pethes[3], Erzsebet Nagy[3], Tamas Lakatos[3], Peter Balint[1] and Zoltan Szekanecz[4], [1]National Institute of Rheumatology and Physiotherapy, Budaoest, Hungary, [2]National Frederic Joliot-Curie Research Institute of Radiation Biology, Budapest, Hungary, [3]Polyclinic of the Hospitalier Brothers pf St John Of God, Budapest, Hungary, [4]University of Debrecen medical and Health Sciences Center, Debrecen, Hungary

Purpose: Softlaser therapy has been used to treat rheumatic diseases for almost 30 years. It has been postulated that the major effects of laser treatment may not be dependent on thermic but rather cellular, photochemical mechanisms. Yet, the exact cellular and molecular mechanism of action has not been elucidated. Thus, in this study, we wished to determine the effects of ex vivo laser irradiation of rheumatoid arthritis (RA) synovial tissues on protein expression profile.

Method: Synovial samples of 5 RA patients undergoing knee surgery were irradiated by near-infrared diode laser. A dose of 25 J/cm^2 was applied. Untreated paired synovial samples obtained from the same patient served as negative controls. Synovial protein expression was assessed using two-dimensional polyacrylamide gel electrophoresis followed by mass spectrometry.

Results: Altogether 12 proteins exerted differential expression after laser irradiation in comparison to untreated controls. Laser treatment resulted in decreased expression of α-enolase in 2, vimentin, haptoglobin and complement component 3 (C3) precursors in 4 samples. The expression of other proteins including HSP70, HSP96, lumican, osteoglycin and ferritin increased upon laser therapy.

Conclusion: Both α-enolase and vimentin have been considered as important autoantigens that are readily citrullinated and drive autoimmunity in RA. Other differentially expressed proteins may also be implicated in the pathogenesis of RA. Softlaser therapy may be effective in RA in part by the suppression of the expression of potential autoantigens in RA.

Rheumatoid Factor and Anti-Cyclic Citrullinated Peptide Antibody Profile in Patients with Morphea. Cristián Vera Kellet and Jan P. Dutz, Univ of BC, Vancouver, BC

Purpose: Systemic autoimmune disease is more common in patients with morphea. Rheumatoid factor (RF) has been reported in a subset of patients with morphea, but the significance of this remains unclear. Anti-cyclic citrullinated peptide antibody (anti-CCP) is a sensitive and specific marker for the diagnosis of rheumatoid arthritis that has not been examined in morphea.The aim of this study was to determine the presence of RF and anti-CCP antibodies in patients with morphea, who attended a Dermatology Connective Tissue Disease Clinic and to assess any association between the presence of RF and anti-CCP, disease activity and clinical manifestations.

Method: This was a retrospective study. We reviewed all the charts of patients with a diagnosis of morphea assessed between January 2006 and December 2008.

Results: 54/72 patients with morphea had at least one RF assessment (43 women and 11 men, mean age 44.3 years). RF was negative (< 10 kU/L) in 48 % (26/54) of patients, and it was positive either at low (>10 kU/L and <30 kU/L) or high (>30 kU/L) titers in 52% (28/54). There was a trend to generalised versus linear morphea in patients with a high positive RF compared to those with a negative RF (9/12 versus 14/26). There was a trend to active disease in those patients with a high positive RF compared to those with a negative RF (12/12 active versus 21/26). In 2 patients, RF reverted from positive to negative when their disease became clinically inactive. Only 7/28 patients with a positive RF had co-morbid diseases previously associated with RF: Hepatitis B or C (3), autoimmune liver disease (1), SLE (1), SLE/ MCTD (2). All patients tested for anti-CCP (including 9/12 with high positive RF and 7/16 with low titre RF) were negative.

Conclusion: RF can be positive in morphea, and it may be used as a marker of disease activity. Anti-CCP was not positive in any of our patients with morphea. RF seropositivity is not a marker of RA in patients with morphea and likely connotes B-cell dysregulation in these patients.

Disclosure: C. Vera Kellet, None; **J. P. Dutz**, None.

Rheumatic Manifestations in Common Variable Immunodeficiency. Satoko M. Kanahara, Leonard H. Calabrese, David Lang and Eamonn S. Molloy, Cleveland Clinic, Cleveland, OH

Purpose: Common variable immunodeficiency (CVID) is a primary humoral immunodeficiency typified by hypogammaglobulinemia and recurrent sinopulmonary infections. A proportion of CVID patients may develop autoimmune diseases, especially autoimmune cytopenias. CVID has been associated with rheumatic diseases, but these have not been well-characterized to date. This study was conducted to evaluate the prevalence, disease course and treatment of rheumatic manifestations in CVID.

Method: Retrospective chart review of patients with diagnosis of CVID from the Rheumatology and Allergy and Immunology Departments at the Cleveland Clinic.

Results: The cohort of 45 CVID patients consisted of 32 females and 13 males, with median age of 51 years (range 19 - 78). 86% of the patients were Caucasian, 8.8% were African American. The median duration of disease since diagnosis was 5 years (range 1 - 41). 23/45 (52%) of the patients had at least one recorded history of moderate to severe joint pain, 85% of whom had multiple joint involvement. 14 patients were considered to have fibromyalgia, 9 were diagnosed with osteoarthritis and 5 patients had a clearcut inflammatory arthropathy. There were no proven cases of septic arthritis. Of the patients with inflammatory arthropathy, all 5 were treated with low doses of glucocorticoids, 4 with hydroxychloroquine, and 2 patients with methotrexate. One patient, with a concomitant diagnosis of ulcerative colitis, was sequentially treated with infliximab and abatacept. No patients developed radiographic erosions or joint deformity. There were no serious infectious complications associated with immunosuppressive therapy, although 4/5 patients were receiving immunoglobulin replacement therapy. One patient underwent synovectomy. Two patients with osteoarthritis had successful total knee replacement, without infectious complications.

Conclusion: Moderate to severe joint pain was noted in 23/45 (52%) in this cohort of CVID patients. Inflammatory arthritis was noted in 11% of the patients. In general, only modest immunosuppressive therapy was required for control of joint inflammation, and no patients developed destructive arthritis. As CVID patients may present initially with autoimmune phenomena even before onset of recurrent infections, rheumatologists should be cognizant of this disease association to facilitate diagnosis of CVID, and to minimize use of immunosuppressive therapy. Judicious use of immunosuppressive therapy appears to be well tolerated, once patients are established on immunoglobulin replacement therapy.

Do Patients with Elderly Onset Rheumatic Chronic Conditions Receive the Same Treatment as Their Younger Counterparts?

Ignacio Villa Sr.[1], Loreto Carmona[2], Miguel Angel Descalzo Sr.[3] and Victor M. Martinez-Taboada Sr.[4], [1]Hospital de Sierrallana, Torrelavega, Spain, [2]Fundación Española de Reumatología, Madrid, Spain, [3]Fundacion Española de Reumatologia, Madrid, Spain, [4]Hospital Universitario Marques de Valdecilla, Santander, Spain

Purpose: To determine whether there are differences in the therapeutic management of patients with chronic rheumatic conditions according to the age of disease onset

Method: Secondary analysis of five nationwide databases from studies on different chronic rheumatic conditions conducted by the Spanish Society for Rheumatology. The conditions included were osteoarthritis (OA), Paget's disease of bone, gout, and rheumatoid arthritis (RA), this latter with and without exposure to biologics. An elderly onset was considered if patients were ≥ 65 years old at the beginning of symptoms. We used propensity score matching to select 1:1 controls with similar disease duration and disease than cases but with onset before 65 years.

Results: OA (n=373 per group): Analgesics, mainly acetaminophen, were more frequently used in elderly patients (p=0.003). By contrast, NSAIDs were more frequently used in younger patients (p=0.02) but also in two thirds of the elderly. We did not find significant differences between the two age groups in the prescription of SYSADOA or hyaluronic acid. **Paget's** (n=223 per group): No differences in the number or type of pharmacologic treatment were found between both age groups. **Gout** (n=87 per group): Patients with elderly onset gout have different predisposing conditions that younger patients, but the treatment of the acute attack and the chronic hypouricemic therapy was similar in the two groups. **RA** (n=109 patients per group): Although young patients were more frequently positive for RF (p=0.008), and despite a similar disease activity, elderly patients had a worse HAQ (p=0.002) and Larsen score (p=0.02). Patients with elderly onset RA (EORA) received less frequently NSAIDs (p=0.0001) and biologics (p=0.03). **RA exposed to biologics** (n=149 per group) There were no differences in the type and survival time of biologics. However, elderly patients receive more frequently other DMARDs different from MTX in combination with biologics. Total adverse events (AE), especially infections, severe AE, and AE leading to death were more frequent in EORA (p<0.05).

Conclusion: Patients with elderly onset rheumatic chronic conditions receive less NSAIDs than young patients. Despite the same disease activity and worse functional capacity and structural damage, EORA patients receive biologics less frequently. Although the survival time of biologics is similar between both age groups, EORA have more severe AE, especially infections.

Therapeutic Potential of Apoptosis Induction by Anti-Fas Antibody in Inflammatory Arthritides. Kazuo Yudoh[1], Rie Karasawa[1], Chika Sawa[1] and Kusuki Nishioka[2], [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]St Marianna University School of Medicine, Kawasaki Kanagawa, Japan

Purpose: We postulated that agents to inhibit synovitis may have a potential as anti-inflammation, pain relief, and also as an anti-arthritis drug to inhibit the bone and cartilage degeneration. Our previous studies demonstrated that the anti-Fas antibody induces cellular apoptosis of synovial fibroblasts in vitro. In the current study, we studied whether or not anti-Fas antibody has a therapeutic potential to protect against the joint destruction in the inflammatory joint disease.

Method: In vitro: To clarify the inhibitory effect of anti-Fas antibody on syovitis, we used the co-culture system with the transwell chamber. Synovial fibroblasts, macrophages and chondrocytes were isolated from synovium and cartilage in patients undergoing arthroplastic knee surgery. In the presence or absence of anti-Fas antibody (CH-11), the cells were incubated with 10 ng/ml TNF-α. Then, catabolic responses were analyzed.

In vivo: We studied whether or not CH-11 reduced bone and cartilage degeneration in the rat model of arthritis. In each rat, the left knee joint was treated by an intra-articular injection of the appropriate CH-11 by 26 gauge needle once weekly over 8 weeks. The right knee joint was also treated by an intra-articular injection of control solution as a control once a week over 8 weeks. The severity of cartilage damage was histologically monitored at 4 and 8 weeks.

Results: 1) To examine the effect of CH-11 on catabolic activity in chondrocytes, the levels of MMPs (MMP-1, -3, -13) in the culture were measured using an enzyme-linked immunosorbent assay kit. TNF-a stimulated the production of MMP-1 and -13 in control cultures. CH-11 significantly decreased the TNF-a-induced excess production of MMP-1 and -13. 2) The effects of CH-11 on chondrocyte apoptosis and production of proteoglycan from chondrocytes were examined in chondrocyte-macrophage co-culture system. Chondrocyte apoptosis was significantly accelerated by treatment with TNF-α. Interestingly, in the presence of CH-11, TNF-α-induced apoptosis was significantly decreased compared with their control counterparts. 3) To study the protective effect of CH-11 on anabolic activity of chondrocytes, the levels of proteoglycan production by chondrocytes were analyzed**.** In the presence of TNF-a, production of proteoglycan was inhibited in the co-culture. Whereas, even in the presence of TNF-α, CH-11 maintained the production of proteoglycan from the cells. 4) In the control right knee of model rat, the joint showed a progression of surface fibrillation of articular cartilage, chondrocyte clustering, abnormal deposition of chondrocytes, a decreased cell density with cartilage thinning and subchondral bone destruction. In contrast, the cartilage in the left knees that had been treated with CH-11 showed less severe bone and cartilage degeneration in comparison with the control knee joint.

Conclusion: Our results indicate that apoptosis induction by anti-Fas antibody may have a therapeutic potential to protect against the progression of bone and cartilage degeneration in inflammatory arthritides.

What Percentage of Patients with UIA Will Evolve to a Classifiable Arthritis in One Year? - A Systematic Literature Review. Pooneh S.Akhavan[1], Louis Bessette[2], B. Haraoui[3], J. Pope[4] and Vivian P. Bykerk[5], [1]university of Toronto, Toronto, ON, [2]Groupe de Recherche en Rhumatologie et Maladies Osseuses, Sainte-Foy, QC, [3]Institut de Rhumatolgie de Montreal, Montreal, QC, [4]St Joseph Health Care, London, ON, [5]Mt Sinai Hospital, Toronto, ON

Purpose: Several studies have been conducted to show the role of early treatment in patients with undifferentiated inflammatory arthritis (UIA) and its potential protective role in disease evolution to a differentiated disease such as rheumatoid arthritis. The objective of this study was to determine what percentage of patients with UIA would evolve to a classifiable arthritis in one year.

Methods: We conducted a systematic literature review of all English language prospective studies, which followed a cohort of early inflammatory arthritis for one year. We searched Medline, EMBASE and the Cochrane Library (up to January 2009), as well as abstracts from ACR (2007-2008) and EULAR (2007-2009). Inclusion criteria consisted of adult patients with clinical evidence of UIA that did not fulfill criteria for any definitive inflammatory disease. If, in a study the cohort was a mixed population of undifferentiated and differentiated

arthritis, it was included if the number (or percentage) of patients who had initially presented as an undifferentiated disease and then evolved to differentiated arthritis at one year, was indicated in the paper. Reviews, guidelines and case reports were excluded.

Results: 25 studies were included. The diagnosis of rheumatoid arthritis was reported in 19 studies at one year. 10.7% - 55% of patients presenting with UIA were diagnosed with rheumatoid arthritis at one year. In 9 studies, 28-72% of these undifferentiated cases remained undifferentiated at one year. Remission was reported in 8-32% of these patients in 6 studies.

Conclusion: A significant percentage of patients who present with UIA may still have evidence of inflammatory arthritis at one year, but the range was wide and may be related to the inclusion criteria of each cohort as many selected for probable RA. This further supports the importance of long term follow up and early therapy initiation in these patients.

Efficacy of Influenza and Meningococcal Vaccinations in Healthy Subjects Exposed to Canakinumab 300 Mg s.c.: Preliminary Study Results. A. Chioato[1], E. Noseda[1], S. D. Felix[2], M. Stevens[3], G. Del Giudice[4], S. Fitoussi[5] and A. Kleinschmidt[6], [1]Novartis Institutes for Biomedical Research, Basel, Switzerland, [2]Novartis, Basel, Switzerland, [3]EMStat Ltd, Leics, United Kingdom, [4]Novartis Vaccines and Diagnostics, Siena, Italy, [5]Medicis, Poitiers, France, [6]Novartis Vaccines and Diagnostics, Marburg, Germany

Purpose: Interleukin-1β (IL-1β), a key mediator of immune and inflammatory responses, is implicated in the etiology of autoinflammatory diseases. Canakinumab, a fully human anti IL-1β antibody, provides selective, potent, and sustained blockade of IL-1β. Since IL-1β is also involved in the immune response triggered by some vaccines, mainly using aluminum salts adjuvant, the aim of this study was to evaluate the efficacy of influenza and meningococcal vaccinations in healthy subjects exposed to canakinumab.

Method: Open-label, parallel group, randomized, single-center study in healthy subjects (aged 18–45 years; weight ≥50 Kg) with negative tuberculin skin test (PPD 5 TU) (<5 mm induration) or at low environmental tuberculosis (TB) risk. Main exclusion criteria: vaccination during previous year; use of prescription drugs and history of autoimmune or other significant systemic diseases. After measurement of antibody (Ab) titers at baseline, subjects were randomized to a single canakinumab 300 mg s.c. dose or no treatment (control group), followed by inactivated influenza or conjugated meningococcal vaccinations i.m. after 2 weeks. The primary efficacy variable was the response (≥2 fold increase in Ab titer in ≥2/3 serotypes) to influenza vaccination at 4 weeks post-vaccination in subjects treated with canakinumab compared to the control group. Secondary efficacy variables were the response to influenza or meningococcal vaccines at different fold thresholds and time points.

Results: 50 out of 112 subjects screened were randomized (1:1) to canakinumab or control groups. Preliminary results for 38 subjects (19 canakinumab, 18 control [1 withdrew, lost to follow up]) are presented. Response to influenza vaccination (≥2 fold in ≥2/3 serotypes) at 4 weeks was shown in 18/19 subjects in the canakinumab group compared to 18/18 subjects in the control group; a response of ≥4 fold increase at 4 weeks was produced in 17/19 subjects and 17/18 subjects in the two groups, respectively. A response of ≥2 fold increase at 6 weeks was produced in 100% of subjects in both groups. Both treatments induced a comparable response to meningococcal vaccine (Table 1). A formal statistical analysis will be completed when the final results are available.

Conclusion: Blockade of IL-1β by canakinumab does not appear to interfere with the efficacy of influenza and meningococcal vaccinations, as measured by the Ab titers, despite the fact that the adjuvant property of aluminum salts is mediated by IL-1β. A protective (more than 4 fold) immune response to influenza and meningococcal vaccinations at 4 weeks has been achieved in 73.7–89.5% of subjects treated with canakinumab. Further studies are needed to replicate the results in patients with autoinflammatory conditions treated with canakinumab.

Table 1. Antibodies titer increase in vaccination groups vs. controls at different time points

Vaccine	Fold increase in titer	Time post-vaccination (weeks)	Canakinumab (%)	Control (%)
Influenza (≥2/3 serotypes)	≥2	4	94.7	100.0
	≥2	6	100.0	100.0
	≥4	4	89.5	94.4
Meningococcal	≥4	4	73.7	72.2
	≥4	6	73.7	72.2

Rheumatoid Arthritis Patient Self Assessment of Disease Activity as Determined by Joint Count Compared to Clinical Joint Count Assessment by Trained Master's Student. Juliana Tricta, Maggie J. Larché, Karen A. Beattie, Andy KO Wong, William G. Bensen, Viktoria Pavlova, George Ioannidis and Jonathan D. Adachi, McMaster University, Hamilton, ON

Purpose: To assess the correlation between rheumatoid arthritis (RA) patients' self assessment of swollen and tender joint count and clinical joint count performed by a trained Master's student in order to better understand patients' awareness of disease activity.

Methods: In a cross-sectional study, 126 rheumatoid arthritis patients were asked to perform a 28 joint count assessment on themselves. These patients were not given any instructions on how to perform the joint count. They were simply asked to indicate which of the 28 joints they thought were swollen and/or tender upon performing a self examination. Once the RA patients had completed the self assessment a Master's student performed the joint count. The Master's student received training on completing a 28 joint count assessment from a Registered Nurse Specialist, with close agreement in their findings.

Results: The mean (SD) age and symptom duration of the 126 patients was 56.9 (14.5) years and 11.3 (12.2) years, respectively. On the self assessment of 28 joint count the median (range) swollen joint count and tender joint count was 2 (0-25) and 6 (0-28) respectively. For the trained Master's student the results were 5 (0-19) swollen and 5 (0-28) tender. There were high levels of correlation between patients' self assessment and trained Master's student for tender joint counts (0.72, $p<0.01$) and lower correlation for swollen joint counts (0.43, $p<0.01$) (Spearman's).

Conclusion: Patients' self assessment shows significant correlations with trained assessor's joint count, with higher levels of correlation for tender than swollen joint counts. However, at the moment, it is not known if there is an agreement regarding which joints assessed as swollen and/or tender by the patient and the Master's student.

The Microvasculature in the Vicinity of the Fascia as the Primary Target in Myopathy of Dermatomyositis: Detection of Fasciitis and Analysis of the Process of Inflammatory Progression by En Bloc Biopsy and Magnetic Resonance Imaging. Ken Yoshida, Maimi Yanagimachi, Eigo Takahashi, Kenichiro Hirai, Kentaro Noda, Kazuhiro Furuya, Taro Ukichi, Isamu Kingetsu, Daitaro Kurosaka and Akio Yamada, Jikei University School of Medicine, Tokyo, Japan

Background: It is generally known that inflammatory cells are concentrated around the intramuscular blood vessels in dermatomyositis (DM). However, in some cases, muscle biopsies reveal no inflammatory cells in the muscle. In such cases, short tau inversion recovery (STIR) magnetic resonance imaging (MRI) occasionally shows the abnormal hyperintensity of the fascia and perimuscular sites. Although in DM, histological findings of intramuscular inflammation have been well documented, those of inflammation in the vicinity of the fascia have hardly been reported.

Purpose: To investigate whether the fascia is a common site of inflammation, and to analyze the process of inflammatory progression.

Method: STIR MRI and en bloc muscle biopsy, which involves resection of muscle, fascia, subcutaneous tissue, and skin altogether, were performed on ten patients with newly diagnosed adult onset DM. Paraffin sections from the biopsy specimens were stained with hematoxylin-eosin. Immunohistochemistry was performed to identify T lymphocytes (CD3, CD4, CD8), B cells (CD20, CD79a), and macrophages (CD68). Severity of inflammatory cell infiltration around the small blood vessels in the vicinity of the fascia and in the muscle (vascular inflammation score: VIS) was evaluated using a four-grade scoring system.

Results: In all cases, STIR MRI revealed abnormal hyperintensity in predominantly peripheral sites of the muscle compared with central sites. En bloc biopsy showed no inflammatory cell infiltration around the small blood vessels in the muscle in three cases, but in all cases, it showed inflammatory infiltrates in the vicinity of the fascia (i.e. fasciitis). Immunohistochemistry showed that CD4+ T and CD20+ B cells were mainly present among inflammatory cells. In cases where the period from muscle symptom appearance to en block biopsy on the site was less than eight weeks (“early group”), VIS of the fascia was significantly higher than that of the muscle. On the other hand, in cases where en block biopsy was performed more than eight weeks after appearance of muscle symptoms (“late group”), VIS of the fascia did not differ significantly compared with that of the muscle.

Conclusion: Fasciitis was histologically observed in all of ten patients with adult onset DM. Our study showed that microvasculature in the vicinity of the fascia is a favorite site of inflammation in similarity with intramuscular microvasculature and likely to be the primary target in myopathy of DM. These results suggest that the inflammatory cell infiltration around the small blood vessels originates from the vicinity of the fascia into the muscle in myopathy of DM.

Increased Ferritin Predicts Development and Severity of Acute Interstitial Lung Disease as Complication of Dermatomyositis. Takahisa Gono, Yasushi Kawaguchi, Kae Takagi, Yasuhiro Katsumata, Ikuko Masuda, Akiko Tochimoto, Yuko Ota, Masako Hara and Hisashi Yamanaka, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Dermatomyositis (DM) is characterized by the inflammation of skin and muscle, occasionally complicated with interstitial lung disease (ILD), which is classified into two subsets, acute/subacute interstitial pneumonia (A/SIP) and chronic interstitial pneumonia (CIP). A/SIP is of prime importance in the clinical management of patients with DM because it is an intractable and a life-threatening complication. It is imperative to establish a novel strategy for the diagnosis of early-stage A/SIP as a complication of DM. The aim of this study is to determine whether serum ferritin is a potential predictive indicator of the occurrence of A/SIP in DM.

Method: Sixty-four patients with DM were enrolled, including 19 with A/SIP, 24 with CIP and 21 without ILD. The study also enrolled 35 patients with polymyositis (PM), including 3 with A/SIP, 14 with CIP and 18 without ILD. Clinical manifestations and laboratory data were obtained from medical records.

Results: Serum ferritin on admission was significantly higher in DM than that in PM (median 269 ng/mL versus 73.6 ng/mL, $P = 0.0003$ by Mann-Whitney U test). Particularly, it was extremely high in DM with A/SIP (median: 790 ng/mL, range: 121-8330 ng/mL), which was the highest value among those in all subsets of patients with DM/PM ($P < 0.0001$ versus DM with CIP; $P = 0.0002$ versus DM without ILD; $P < 0.0001$ versus DM without A/SIP; $P < 0.0001$ versus PM; $P < 0.0001$ versus PM with ILD). Moreover, we evaluated the association of patients with high concentrations of serum ferritin with the complication of A/SIP. High level of serum ferritin was defined as □ 500 ng/mL according to diagnostic and therapeutic guidelines for hemophagocytic lymphohistiocytosis 2004. As the result of the comparison in the occurrence of A/SIP between the groups with high and low concentrations of serum ferritin in DM patients, the frequency of A/SIP was significantly higher in the group with high concentrations of serum ferritin ($P = 0.0009$, odds ratio = 6.9 and 95% confidence interval = 2.1-22.4). The cumulative survival rate for 6 months was 62.7% in patients with DM with A/SIP. Moreover, the cumulative survival rate was significantly lower in the group with ferritin levels □1500 ng/mL than the rate in the group with ferritin levels <1500 ng/mL ($P = 0.016$).

Conclusion: Serum ferritin can be useful as a predictor of the occurrence of A/SIP and correlates with the prognosis of A/SIP in DM. Because elevated ferritin levels can be associated with macrophage activation, we speculate that alveolar macrophage activation may be involved in the pathogenesis of AIP/SIP with DM.

The Relationship Between the Vitamin D Receptor Gene and Anti-155/140 Antibodies in UK Caucasians with Idiopathic Inflammatory Myositis. Sabrina Kapoor[1], Robert G. Cooper[2], Hector Chinoy[2], William Ollier[3], L. R. Wedderburn[4], Neil J. McHugh[5] and Chester V. Oddis[6], [1]Russells Hall Hospital, Dudley, England, [2]Hope Hospital, Salford, [3]University of Manchester, Manchester, United Kingdom, [4]UCL, London, United Kingdom, [5]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [6]University of Pittsburgh, Pittsburgh, PA

Purpose: Idiopathic inflammatory myopathy (IIM) is a complex disease and is due to the interaction of environmental and genetic risk factors. A latitudinal gradient exists for IIM, whereby increasing ultraviolet (UV) exposure is associated with the preferential development of dermatomyositis (DM), rather than polymyositis (PM). IIM also displays seasonal variation which may be related to UV exposure. A further DM-specific antibody, anti-155/140, has recently been described in adult and juvenile DM. VDR and other single nucleotide polymorphisms (SNPs) putatively related to UV susceptibility are associated with other conditions where UV exposure is an aetiological risk factor, including prostate cancer and multiple sclerosis. We hypothesise that such polymorphisms are associated with the development of IIM.

Method: 362 UK Caucasian adult and juvenile onset cases were recruited from the UK Adult Onset Myositis Immunogenetic Collaboration and the Juvenile Dermatomyositis (JDM) National Registry and Repository. They were compared to 287 matched Caucasian controls: PM, n=112; DM, n=98; myositis/overlap, n=64; JDM, n=88, females 71%, mean age of disease onset adults 49+/-14 years, juveniles 6+/-3.6 years. SNPs were selected from the following genes: VDR, glutathione S-transferase pi 1, melanocortin 1 receptor and tyrosinase due to their putative functional role or because they had been used in previous studies. SNPs were removed from further analysis where the assay success rate was <90% and sample success <80%. **Results:** were thus available for 38 SNPs. Circulating antibodies (anti-Jo-1, PL-7, PL-12, EJ, OJ, KS, Mi-2, SRP, U1/U3-RNP, Ku, PM-Scl, 155/140) were detected using immunoprecipitation.

Results: All 38 SNPs conformed to Hardy Weinberg equilibrium in controls. No SNP was associated in the overall or traditional clinical sub-groups. Anti-155/140 antibodies were detected in 29 patients, all of whom had DM. Possession of the A allele in a VDR haplotype tagging SNP (rs2254210) was associated with possession of anti-155/140 antibodies (51%), compared to both controls (33%) (odds ratio 2.1, 95% confidence interval 1.2-3.8, p=0.006) and anti-155/140 antibody negative cases (36%) (1.9, 1.1-3.4, p=0.01). Associations for this SNP were observed independently in the juvenile and adult 155/140 (+) sub-groups. No other significant associations were observed in any of the remaining serologically-defined sub-groups.

Conclusion: The rs2254210 polymorphism in the VDR gene is a possible risk factor in juvenile and adult anti-155/140 positive DM patients.

High Burden of Cardiovascular Risk in Patients with Inflammatory Myositis. Irene Z. Whitt and Steven R. Ytterberg, Mayo Clinic, Rochester, MN

Purpose: To determine cardiovascular (CV) risk and its predictors in patients with inflammatory myositis.

Methods: We performed a cross-section, observational study of adult patients seen in our clinic in the past year with probable or definite dermatomyositis, polymyositis, or connective tissue disease associated myositis based on Bohan and Peter criteria. Patients with inclusion body myositis and cancer-associated myositis were excluded. Standard CV risk factors were assessed and a determination was made of low, moderate, or high CV risk based on the current guidelines outlined by the Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III-revised or ATP III R). Univariate relationships between each potential predictor and each risk group were examined. A multivariable linear regression model was then developed for each significant ($p < 0.05$) risk marker.

Results: 63 patients met the inclusion criteria and had CV risk assessment. The distribution of CV risk is tabulated below.

	Framingham Risk of CV Event in 10 years		
Patients	Low Risk (<10%)	Moderate Risk (10-20%)	High Risk (>20%)
Total, n (%)	19 (30.2)	24 (38.1)	20 (31.8)
Candidates for lipid-lowering agent, %	11	54	89
With hypertension, %	6	67	63
With SBP < 130, %	74	58	50

Across all risk levels, 51% of patients would be placed on a lipid-lowering agent according to the current ATP III R guidelines.

Several variables were assessed in univariate analysis with ordered logit regression. Significant correlations were found for: hypertension (HTN) ($p=0.001$) and age ($p=0.005$). Nonsignificant correlations were observed for: gender, hyperlipidemia, BMI, disease duration, current prednisone dose, current smoking status, chronic renal insufficiency, and family history of coronary heart disease. In a multivariate analysis, HTN was the only independent predictor of higher CV risk ($p=0.004$, $R^2=0.155$).

Conclusion: Patients with inflammatory myositis have a high burden of CV risk. HTN was the only independent predictor of CV risk. However, only about 50% of high-risk hypertensive patients achieved the recommended goal of SBP<130. Although 51% of patients in this cohort would be candidates for a lipid-lowering agent, there is concern for worsening myositis with lipid lowering therapy. Further research is needed to determine the safety of using statins in patients with inflammatory myositis.

Development of the Novel Assay System for Detecting Anti-SRP Autoantibodies: The Clinical, Histopathological, and Immunogenetic Features in Japanese Patients. Michito Hirakata[1], Tetsuya Takada[1], Yuko Kaneko[1] and John A. Hardin[2], [1]Keio University School of Medicine, Tokyo, Japan, [2]Albert Einstein College of Medicine, New York, NY

Purpose: The signal recognition particle (SRP) is a cytoplasmic ribonucleoprotein consisting of the 7SL RNA and six associated polypeptides (72, 68, 54, 19, 14 and 9 kDa) which mediates the translocation of newly synthesized proteins across the endoplasmic reticulum. Autoantibodies to the SRP are known to be associated with a distinct clinical subset of refractory myositis characterized histologically by "necrotizing myopathy". Definitive detection of anti-SRP autoantibodies requires imunoprecipitation of HeLa cell extracts, a complicated technique not available in clinical laboratories. Previous studies have shown that anti-SRP antibodies recognize predominantly the SRP-54 kDa subunit on immunoblots. For this reason, we examined the usefulness of a new enzyme-immunoassay method using the human recombinant SRP-54 kDa protein as the test substrate.

Method: We developed a fluoroenzyme-immunoassay (Elia: Phadia, Germany) for detecting antibodies against the biotinylated human SRP-54 kDa protein expressed by recombinant baculovirus (AcMNPV) infection of Sf9 insect cells (Diarect AG, Germany). We studied18 Japanese patients identified among 1,500 patients with polymyositis /dermatomyositis and various other connective tissue diseases whose sera immunoprecipitated the 7SL RNA. These sera were tested in the Elia system and results were correlated with clinical, immunogenetic, and myopathic histopathological features in the patient donors.

Results: All 18 sera that immunoprecipitated 7SL RNA, strongly recognized the recombinant SRP-54 kDa in Elia. This result was confirmed by immunoblots, while none of 50 anti-SRP-negative sera whose sera contained other myositis–specific antibodies including anti-synthetase, and anti-U1 RNP antibodies, showed any reactivity. Sixteen of 18 (89%) patients with anti-SRP antibodies had myositis. Among them, 9 of 14 (64%) showed refractory myositis resistant to corticosteroid therapy, and all 8 patients whose muscle biopsy specimen were studied histologically in detail, showed muscle fiber necrosis and regeneration without inflammatory infiltration. It should be noted that two patients (11%) had rheumatoid arthritis without any features of myositis. Eight of 18 patients (44%) with anti-SRP had DR 8 (DRB1*0802/08032), compared to 20% of healthy controls.

Conclusion: These studies indicate that the novel Elia assay is a useful tool for detecting anti-SRP autoantibodies. Patients who are positive in this assay system have a clinical profile that is consistent with the features of myositis, and identify a subgroup of patients with necrotizing myopathy resistant to corticosteroid therapy, consistent with the patient group identified by the classical immunopreicpitation assay.

Peripheral Immunological Biomarkers and Laser Doppler Imaging in Idiopathic Inflammatory Myopathy. Nora Anna Szabo[1], Peter Szodoray[2], Szilveszter Lukacs[3], Sandor Sipka[4], Margit Zeher[1] and Katalin Danko[1], [1]Division of Clinical Immunology, 3rd Department of Internal Medicine, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, [2]University of Oslo, Oslo, Norway, [3]East Surrey Hospital, Redhill, United Kingdom, [4]Laboratory of Immunology, 3rd Department of Internal Medicine, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary

Purpose: Polymyositis (PM), dermatomyositis (DM) and antisynthetase-syndrome (aSS) are members of Idiopathic Inflammatory Myopathies (IIM). In the pathogenesis of IIMs microvasculature abnormalities often present, partly driven by autoimmune processes.

Method: Evaluation of immunological parameters from blood samples, as well as laser Doppler imaging was carried out in 28 PM, 12 DM and 12 aSS patients and 20 age and sex-matched healthy individuals. Comprehensive analysis was performed between IIM patients and healthy control group; also subgroup analysis was carried out among the three different group of IIM patients. Peripheral blood samples were measured and assessed for number and percentage of CD4+ and CD8+ T cells, activated T-cells, naïve- and memory T-and B cells, intracellular and solubile IFN-g, IL-4, and IL-10 levels. Laser Doppler imaging was performed in every case, by assessing the steady state cutaneous perfusion (SSCP) of the non-dominant hand.

Results: Regarding CD3+, CD4+, CD8+ T lymphocytes there was no significant difference in the cell numbers and percentage between IIM and healthy control group. Among subgroup analysis CD4+ T cells were increased in DM compared to PM ($p=0.032$). There was a predominance of CD8+ T cells in PM patients compared to results of DM patients ($p=0.012$). Elevated percentage of CD4+ and CD8+ CD45RA+/CD62L- (terminally differentiated effector memory) T cells was found in IIM ($p<0.0001$), while in the control group the percentage of CD4+ and CD8+ CD45RA-/CD62L+ (central memory) T lymphocytes were significantly higher ($p<0.0001$). The comparison of LDI values of IIM patients with the control group indicated that all subgroups of IIM had decreased SSCP ($p<0.05$). Within subgroup analysis, SSCP was non-significantly decreased in PM and DM compared to aSS.

Conclusion: Our findings support the idea that patients with IIMs have microcirculation abnormalities, reflected by decreased SSCP detected by LDI and specific peripheral immunological defects. We believe that the therapeutical modulation of these immunological irregularities might be an important element in the future management of microcirculation abnormalities in IIMs.

Anti-p155/140 (anti-TIF1γ) Autoantibodies in Patients with Cancer Associated Myositis Detected in a Single Centre. Jiri Vencovsky[1], Herman Mann[2], Ivana Putova[1], Zoe Betteridge[3], Harsha Gunawardena[3] and Neil J. McHugh[3], [1]Institute of Rheumatology and Department of Rheumatology of the 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, [2]Institute of Rheumatology, Prague 2, Czech Republic, [3]Royal National Hospital, Bath, United Kingdom

Purpose: Polymyositis (PM) and dermatomyositis (DM) are autoimmune inflammatory diseases of striated muscles. About 10-20% cases are associated with various forms of cancer (CAM). No specific signs and symptoms can distinguish between patients with CAM from patients without malignancy. Recently described autoantibodies to p155/140 antigen (Anti-TIF1γ = transcriptional intermediary factor 1-γ) have been associated with an increased frequency of cancer in patients with DM. The aim of this study was to determine the frequency of anti-p155/140 antibodies in the cohort of patients with PM/DM and relate the presence of these antibodies to an occurrence of cancer.

Method: Patients with definite or probable diagnosis of PM/DM (n=153) from a single centre were investigated for the presence of a cancer. CAM was defined as any cancer occuring within the timeframe of 3 years of the onset of myositis. Sera were mixed with protein-A-sepharose beads and immunoprecipitated with [^{35}S]-methionine-labelled K562 cell extract. Proteins were fractionated by SDS-PAGE and analysed by autoradiography.

Results: Seventeen patients (11%) were diagnosed with CAM. Sixteen patients (10.5%) had anti-p155/140 antibodies. In patients with CAM, 7 (41%) had anti-p155/140, whereas in non-cancer patients the frequency of anti-p155/140 was 6.6% ($p<0.0001$; OR=9.9). Testing for anti-155/140 antibodies was 41% sensitive for the detection of CAM with a 44% PPV; and 93% specific for non-CAM with high NPV 93%. Four out of 17 CAM patients had polymyositis; however, none of these had anti-p155/140 antibodies. Only 1 patient from anti-p155/140+ group had PM and this patient was non-CAM. There was no apparent difference in the type of cancer between anti-p155/140 positive and negative patients, although data are somewhat suggestive to a more disseminated process in positives.

Conclusion: Possession of anti-p155/140 (anti-TIF1γ) antibodies represented a significant risk for cancer associated dermatomyositis. This fact may provide a strong argument for thorough search of malignancy in patients diagnosed with DM and anti-p155/140 antibodies. Routinely available testing is needed since it will have significant clinical implications.

Modification of the Myositis-Specific Jo-1 Autoantigen by Reactive Oxygen/Nitrogen Species. Sander H.J. van Dooren[1], Reinout Raijmakers[2], Angelique M.C. Lokate[1], Tom Koemans[1], Walther J. van Venrooij[1] and Ger J.M. Pruijn[1], [1]Nijmegen Center for Molecular Life Sciences, Institute for Molecules and Materials, Radboud University Nijmegen, Nijmegen, Netherlands, [2]Bijvoet Center for Biomolecular Research and Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands

Purpose: The idiopathic inflammatory myopathies are a heterogeneous group of chronic skeletal muscle diseases often characterized by muscle weakness and inflammatory muscle damage. The etiology and pathogenesis of this group of diseases, also called myositis, remain unknown. Myositis can be classified into three main subgroups, polymyositis (PM), dermatomyositis (DM), and inclusion body myositis (IBM) all with distinct clinical and histopathological features that are important for diagnosis, prognosis and treatment. Autoantibodies are found in up to 80% of PM and DM patients and are directed against a variety of cellular components. They can be divided into myositis-specific autoantibodies (MSA) and myositis-associated autoantibodies (MAA), of which the latter are also found in other rheumatic diseases. In approximately 25% of myositis patients MSAs are found that are directed against the Jo-1 (histidyl-tRNA synthetase) protein. The aim of

our research is to unravel the mechanism by which immunological tolerance to Jo-1 is broken in myositis patients. We investigate whether protein modifications, e.g. resulting from (inflammation-associated) cell death, affect the autoantigenicity of Jo-1.

Method: The effect of cell death on Jo-1 protein function, localization and modification in cultured cells as well as myositis patient materials was investigated and compared with healthy controls. Western blotting, mass spectrometry and ELISA were used to determine specific cell death-induced Jo-1 modifications in apoptotic and necrotic Jurkat cells.

Results: Necrosis resulted in retarded Jo-1 migration in SDS-PAGE, which is due to the oxidation of several amino acids as well as enhanced dimerization. Five oxidized residues in the amino acid sequence of Jo-1 were mapped by mass spectrometry. Enhanced Jo-1 dimerization was also observed in cells treated with SIN-1, an inducer of reactive oxygen/nitrogen species. Up to now, no autoantibodies specifically targeting oxidatively modified Jo-1 were detected in established myositis sera.

Conclusion: The Jo-1 protein is oxidatively modified under necrotic conditions. Elevated levels of reactive oxygen and/or nitrogen species in the muscle microenvironment might result in the modification of the Jo-1 protein. In predisposed individuals the resulting neo-epitopes might trigger the initial immune response in the early stages of myositis. Further investigations using especially early patient sera are required to elucidate the existence of modification-specific autoantibodies and to study their role in the development of myositis.

Rituximab Is An Effective Therapy for Anti-Signal Recognition Particle (Anti-SRP) Myopathy. Ritu Valiyil, Livia Casciola-Rosen, Grace Hong, Andrew Mammen and Lisa Christopher-Stine, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: The myopathy associated with anti-signal recognition peptide (SRP) is a severe necrotizing immune-mediated disease characterized by rapidly progressive proximal muscle weakness, markedly elevated serum creatine kinase (CK) levels, and poor responsiveness to traditional immunosuppressive therapies. Currently, reports on the efficacy of B cell depletion therapy for anti-SRP associated myopathy are mixed. We describe eight patients with anti-SRP associated myopathy and their clinical response to treatment with the anti-CD20 monoclonal antibody rituximab.

Method: We identified eight patients with myopathy who tested positive for anti-SRP antibodies by immunoprecipitation and had been treated with rituximab as part of clinical care between 2006 and 2009. We reviewed their medical records to assess clinical, serologic, and histologic characteristics of their muscle disease and response to therapy. In five of the eight patients, serum samples were also collected before and after rituximab treatment. In those patients, autoantibodies were detected by immunoprecipitation and quantitated by densitometry, and the percent decreases in anti-SRP autoantibody levels were calculated.

Results: In our cohort, the mean age was 37 years, 75% were female, and 50% were African-American. All patients presented with severe, rapidly progressive proximal muscle weakness with myalgias, dysphagia, and high CK levels with a mean maximum CK of 18,900 IU/l (3,148-56,000 IU/L). Six of the eight patients refractory to standard immunosuppressive therapy demonstrated improved manual muscle strength and/or decline in CK levels as early as two months after receiving two doses of rituximab. Three patients sustained the response for twelve to eighteen months after initial dosing. All patients were continued on adjunctive corticosteroids, but dosages were substantially reduced after rituximab. In four of the five patients tested, quantitative levels of serum anti-SRP antibodies also decreased after rituximab treatment.

Conclusion: B cell depletion therapy with rituximab is an effective therapy for patients with anti-SRP myopathy. The substantial decrease in anti-SRP antibody levels after rituximab treatment also suggests that B cells and anti-SRP antibodies may play a role in the pathogenesis of this myopathy.

Patient	CK prior to therapy	Highest prednisone dose (mg/day)	Prior treatments	Lowest prednisone dose post-therapy	Lowest CK post-therapy	Outcome post B cell depletion, duration of remission
1	2710	60	AZA, MTX	20	622	CK decline, improved strength, 10 months

2	1000	160	AZA, MTX, IVIg, plasma exchange	5	163	Normalized CK, improved strength, 18 months
3	550	40	AZA, MTX, IVIg, MMF	15	126	Normalized CK, improved strength, 19 months
4	1063	80	IVIg, plasma exchange	50	22	Died 1 month later from pneumonia
5	2900	80	MTX, IVIg	10	963	CK decline for 12 months, then re-dosed for increased CK
6	2100	60	MTX, MMF, IVIg	30	1144	CK decline, improved strength, 9 months
7	1250	60	MTX, MMF	N/A	1080	CK decline, 5 months
8	3110	60	AZA, MTX, IVIg, plasma exchange	15	2100	CK decline for 6 months, persistent weakness

Classification Criteria for Idiopathic Inflammatory Myopathy: Comparison of the Performance of Accepted Criteria. Helen Linklater[1], Nicolo N. Pipitone[2], Michael R. Rose[1], Fiona Norwood[1], David L. Scott[1] and Patrick A. Gordon[1], [1]Kings College Hospital, London, United Kingdom, [2]Arcispedale Santa Maria Nuova, Bari, Italy

Purpose: A large number of classification criteria have been proposed for the inflammatory myositides (IIMs) polymyositis (PM) and dermatomyositis (DM). However, none have received universal acceptance and clinical trials have used a variety of classification criteria. Recently the European Neuromuscular Diseases Collaboration (ENMC) has begun the process of developing international and multidisciplinary criteria with the publication of a set of preliminary criteria. This study aimed to assess the the performance of the ENMC criteria against the main previously published criteria [Bohan and Peter(1975), Dalakas (1991, 2003), Tanimoto (1995) and Targoff (1997)] using specialist consultant diagnosis as the gold standard.

Method: Patients attending Kings College Hospital (KCH) or the Rheumatology Unit, Reggio Emilia Hospital (REH) since 1990 with a diagnosis of IIM or non-inflammatory myopathy, were identified, and their records and laboratory investigations were retrospectively reviewed. Patients without complete data available were excluded. The project received ethics committee approval. Data were analysed using SPSS (version 15.0). Agreement between specialist consultant diagnosis and classification criteria was measured using Cohen's kappa statistic. Cohen's kappa values of 0.41 – 0.60 indicate moderate agreement.

Results: 44 patients had a complete set of investigations available, and a specialist diagnosis of IIM (PM, DM, IBM) or non-inflammatory myopathy.

Classification Criteria	**Cohen's kappa**	**Sensitivity (95% CI)**	**Specificity (95% CI)**
Tanimoto (1995)	0.16	90% (73-97%)	23% (6.0-54%)
Bohan & Peter	0.20	94% (77-99%)	23% (6.0-54%)

(1975)			
ENMC (2004)	0.44	68% (49-83%)	85% (54-97%)
Dalakas (1991)	0.48*	100% (84-100%)	58% (29-84%)
Dalakas (2003)	0.54	90% (73- 97%)	62% (32-85%)
Targoff (1997)	0.59	94% (77-99%)	62% (32-85%)

* Analysis of subset of 38 patients

The Targoff criteria had moderate agreement with specialist diagnosis, but other criteria performed less well.

Conclusion: Older classification criteria are sensitive but not specific for IIM, although they are still used predominantly in clinical studies. There is therefore a potential risk that these study populations may contain cases of non-inflammatory myopathy.

One of the strengths of the Targoff criteria is that they require disease specific findings (either positive muscle biopsy, cutaneous DM, myositis-specific antibody) to be present in order to make a diagnosis.

Consensus in the use of classification criteria for the purposes of clinical trials would lead to improvements in knowledge of prognosis and treatment in IIM. This analysis demonstrates the limitations of retrospective studies and the need for a multi-centre prospective myositis cohort. The International Myositis Assessment and Clinical Studies group (IMACs) is currently studying a prospective cohort of patients with IIM and non-inflammatory myopathy in order to examine the performance characteristics of commonly used classification criteria.

Muscle Interstitial Levels of Pro- and Anti-Inflammatory Cytokines in Polymyalgia Rheumatica: Impact of Short-Term Prednisolone Treatment. Frederik Kreiner, Henning Langberg and Henrik Galbo, Bispebjerg Hospital, Copenhagen, Denmark

Purpose: The pathophysiology of symptomatic muscle in polymyalgia rheumatica (PMR) is disputed. In this study, interstitial levels of pro- and anti-inflammatory cytokines in symptomatic muscle were measured before and after short-term prednisolone treatment.

Methods: Twenty patients (12 females and 8 men; age 74±9 years, BMI 24±5 kg/m^2) with PMR just diagnosed according to the Chuang criteria (Ann Intern Med 1982;97:672-80) and 20 controls (11 females and 9 men; age 73±5 years; BMI 25±6 kg/m^2) were included. Subjects were studied before and after treatment for 14 days with 20 mg prednisolone/day. Interstitial concentrations of various interleukins (IL), IL-1 receptor antagonist (IL-1Ra), tumor necrosis factor-α (TNF-α), and monocyte chemoattractant protein 1 (MCP-1) were measured in aching quadriceps and trapezius muscles using the microdialysis technique. Plasma levels were measured too.

Results: Prednisolone treatment abolished symptoms in all patients within a few days; erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were normalized at day 14. Controls had normal ESR and CRP before and after treatment. In both patients and controls, the interstitial levels (table) of most cytokines were markedly higher ($p<0.05$) than in plasma; exceptions were IL-1α, which was lower in both groups, and TNF-α, which did not differ. However, in both studied muscles interstitial concentrations of all cytokines were significantly higher in patients than in controls (table). Furthermore, in patients concentrations were considerably reduced by prednisolone treatment (table).

	Patients		Controls	
	Untreated	Treated	Untreated	Treated
IL-1α (pg/ml)				
Quadriceps	*16.0±6.1	#2.05±1.21	2.31±0.87	3.78±1.82

Elevated Circulating CD40L Levels in Patients with Dermatomyositis. Shintaro Maeda, Kanazawa University School of Medical Science, Kanazawa, Japan

Purpose: Dermatomyositis (DM) is a connective tissue disorder characterized by muscle weakness, myalgias, vascular changes in skin and other internal organs, and autoimmunity. CD40L /CD40 interactions play a role in the regulation of autoimmunity and vascular function. A recent study revealed that myoblasts and muscle cells in DM patients highly expressed CD40, suggesting that increased CD40/CD40L interactions contribute to muscle inflammation in patients with DM.

Method: Serum sCD40L levels were examined by enzyme-linked immunosorbent assay of serum samples in 75 Japanese patients with DM, in 52 control patients with systemic sclerosis (SSc), and in 16 healthy control (CTL). A retrospective longitudinal study was also performed in 30 serum samples from 9 DM patients.

Results: Serum sCD40L levels were significantly elevated in DM patients compared with normal controls (3.0 ± 3.8 ng/ml vs. 0.5 ± 6.7 ng/ml, $p<0.01$). Serum sCD40L levels were similar for patients with DM and those with SSc (2.7 ± 1.3 ng/ml, $p > 0.05$). The DM patient sample was divided into two groups with sCD40L levels of greater than 2.5 ng/ml (the mean + 3SD of the control serum samples) and 2.5 ng/ml or less. Forty % (30/75) of DM patients were thus classified as having elevated levels of sCD40L. In comparison between the two

groups, the frequency of elevated erythrocyte sedimentation rates (ESR) in DM patients with elevated sCD40L levels was higher than those with normal sCD40L levels (43% vs. 13%, $p < 0.05$). Moreover, patients with an ESR that was greater than 25mm/hr had higher sCD40L compared to those patients with an ESR less than 25mm/hr ($p < 0.05$). In longitudinal studies, patients with elevated ESR levels had higher levels of sCD40L compared to those patients with normal ESR levels ($p < 0.05$). The serum sCD40L levels in DM patients paralleled the ESR levels during the follow up period.

Conclusion: The results of the current study demonstrate that serum sCD40L levels are elevated in patients with DM, and the sCD40L levels correlate with ESR levels at both the initial and the follow up visits. The serum sCD40L levels in this study may reflect the disease activity in the DM patients. In addition, interactions of CD40/CD40L were previously shown to be a therapeutic target in connective tissue diseases with low risk in preclinical studies and clinical trials. Therefore, our results suggest that CD40/CD40L interactions may be potential therapeutic targets in DM.

Autoantibodies to the p140 Autoantigen NXP-2 in Adult Dermatomyositis. Zoe E. Betteridge[1], Harsha Gunawardena[1], Hector Chinoy[2], Jiri Vencovsky[3], Simon Allard[4], Patrick A. Gordon[5], Robert G. Cooper[2] and Neil J. McHugh[1], [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Hope Hospital, Salford, [3]Institute of Rheumatology and Department of Rheumatology of the 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, [4]West Middlesex University Hospital, Middlesex, United Kingdom, [5]Kings College Hospital, London, United Kingdom

Purpose: Myositis-specific autoantibodies (MSAs) define dermatomyositis (DM) and polymyositis (PM) into more homogeneous clinical subsets. Recently, anti-p140 has been demonstrated to form a major autoantibody subset in juvenile DM (JDM) [1-2]. The aim of this study was to investigate if autoantibodies to the same p140 autoantigen, nuclear matrix protein NXP-2, are present in adult myositis sera.

Methods: Sera from 393 adults with myositis based on the Bohan and Peter diagnostic criteria recruited to Adult Onset Myositis Immunogenetic Collaboration (UK) and Institute of Rheumatology, Prague were autoantibody typed by immunoprecipitation using ^{35}S-labelled K562 cells. Serum samples immunoprecipiating a 140-kd protein band were immunodepeleted with reference adult and JDM anti-p140 sera. Disease and normal control sera were screened using the above method. Clinical data was collated using standardised proformas. Probabilities were calculated using Fisher's exact test.

Results: Sera from 11 (3%) of 393 patients with myositis were positive for anti-p140 autoantibodies, which were detected exclusively in 6% of DM. No anti-p140 antibody-positive patients were positive for other recognized autoantibodies. Immunodepletion using reference sera suggested that the identity of p140 was consistent with NXP-2. The major clinical features of anti-p140-positive patients were heliotrope rash (73%), Gottron's lesions (82%), periungal erythema (91%) and systemic involvement including weight loss or fever (78%). In particular, the frequency of interstitial lung disease (ILD) in anti-p140-positive DM patients was 64% in comparison to 28% in anti-p140-negative DM patients ($p=0.018$), and 30% in anti-p140-negative group overall ($p=0.04$). There was no cancer-associated myositis in the adult anti-p140 positive subset. In contrast to anti-p140-positive JDM patients where calcinosis is a significant feature, this was only present in one patient (9%).

Conclusion: Anti-p140 autoantibodies form a further serological subset in adult DM, although the frequency of this MSA is much lower than observed in JDM [1]. In addition, our preliminary data suggests that the clinical associations of anti-p140 autoantibodies in adults differ from JDM. In particular, ILD appears to be a major feature of anti-p140-positive adult DM associated with hallmark cutaneous disease.

Positive Correlations Between Serum Levels of B-Cell Activating Factor of the TNF Family / BLyS (BAFF), Anti-Jo-1 Autoantibodies and Muscle Enzymes in Patients with Polymyositis or Dermatomyositis. Olga Krystufkova[1], Marta Modra[1], Herman Mann[1], Ivana Putova[1], Ingrid E. Lundberg[2] and Jiri Vencovsky[1], [1]Institute of Rheumatology and Department of Rheumatology of the 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, [2]Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden

Purpose: Anti-histidyl-tRNA synthetase (anti-Jo-1) is a myositis specific autoantibody. A correlation between serum levels of anti-Jo-1 autoantibodies and disease activity has been reported in patients with myositis. BAFF is crucial for B-cell maturation and survival and plays a role in autoantibody production.

We have reported elevated serum levels of BAFF in patients with dermatomyositis (DM) and in anti-Jo-1 positive, polymyositis (PM) patients and a correlation between levels of BAFF and serum creatine kinase (CK).

The aim of this study was to find out if serum levels of BAFF correlated with anti-Jo-1 antibody levels and if serum levels of BAFF and anti-Jo-1 antibody levels correlated to laboratory and clinical markers of disease activity in patients with myositis.

Method: BAFF and anti-Jo-1 autoantibody levels were detected by ELISA in 70 anti-Jo-1 autoantibody positive serum samples from 21 patients with DM and 28 with PM. Longitudinal follow-up paired samples from 11 DM and 10 PM patients were also included. The anti Jo-1 positivity was confirmed by line-blot and western blot assays. Serum levels of CK, myoglobin, lactate dehydrogenase (LDH) and CRP serum were retrieved from patients' records or measured in the same sera. Clinical disease activity was assessed by the IMACS core set measures.

Results: A significant correlation between serum levels of anti-Jo-1 antibodies and BAFF ($rs=0.42$; $p<0.0005$) was found. Both BAFF and anti-Jo-1 serum levels correlated with CK ($rs=0.4$ and $rs=0.39$; $p=0.001$), myoglobin ($rs=0.28$ and $rs=0.29$; $p<0.05$) and CRP ($rs=0.48$; $rs=0.4$; $p<0.001$). Serum levels of CK, LDH and myoglobin correlated with each other, but no correlation was found with CRP except a weak correlation with myoglobin.

In paired longitudinal samples there was a weak correlation between the changes of BAFF and anti-Jo-1 levels ($rs= 0.44$; $p<0.05$). Apart from a correlation between BAFF levels and activity of cutaneous involvement ($rs=0.34$; $p<0.02$), no association was found between BAFF or anti-Jo-1 antibodies and activity of clinical symptoms.

Conclusion: The correlation between serum levels of BAFF and anti-Jo-1 antibodies could indicate that BAFF may be involved in the production of anti-Jo-1 autoantibodies. Another interpretation is that anti-Jo-1 could cause elevation of serum levels of BAFF eg via its type I interferon inducing capacity. The correlation between serum levels of BAFF and anti-Jo-1 antibodies and markers of muscle involvement (CK and myoglobin) might indicate a relationship between these two proteins and pathways implicated in the pathogenesis of myositis with anti-Jo-1 autoantibodies.

Gene Expression Analysis of Proteasomal Catalytic Subunits Allows the Definition of a Specific Profile in Patients with Inflammatory Myopathies. Lorena Martinez Gamboa[1], Marie Fettke[1], Sabine Krause[2], Khetam Ghannam[1], Lydia Naumann[1], Ulrike Kuckelkorn[1], Gerd R. Burmester[1] and Eugen Feist[1], [1]Charite University Hospital, Berlin, Germany, [2]Ludwig Maximilians Universität, Munich, Germany

Purpose: Idiopathic inflammatory myopathies (e.g. polymyositis PM, dermatomyositis DM, inclusion body myositis IBM) are diseases with unknown etiology, probably autoimmune. Expression of components of the ubiquitin proteasome system (UPS) is altered in PM and other autoimmune disorders. UPS is a crucial catalytic system involved in antigen presentation, cell cycle and apoptosis. A simultaneous analysis of constitutive and inducible proteasomal catalytic subunits in inflammatory and non-inflammatory myopathies has not been done yet. Thus, we analysed gene expression of these subunits in muscle samples from patients with PM, DM, IBM and control patients with non-inflammatory myopathies (e.g. mitochondrial myopathy, deficiency of myoadenylat desaminase).

Method: Inflammation degree was estimated in histological stainings. RNA from muscle biopsies was used for relative quantification of gene expression by real time PCR. Transcript levels of proteasomal constitutive catalytic beta subunits b1 (Delta), b2 (Z), b5 (MB1) and corresponding inducible subunits b1i (LMP2), b2i (MECL) and b5i (LMP7) were measured by comparison with the house keeping genes beta actin and GAPDH. For statistic analysis, the non-parametric Mann-Whitney test and P values <0.005 were applied. Ratios were calculated using values of expression of corresponding constitutive:inducible subunits.

Results: In inflammatory myopathies, DM patients showed the strongest significant differences in the expression of all constitutive and inducible proteasome subunits when compared to non-inflammatory controls. PM patients showed differences especially in expression of b1 and b5i. In general, gene expression of constitutive proteasome subunits was significantly higher than of inducible ones, especially for b1:b1i and b5:b5i. Notably, the magnitude of this relation calculated as ratio of expression of corresponding constitutive:inducible subunits showed a typical pattern according to the inflammatory degree (e.g. inflammatory, weak inflammatory or non-inflammatory). In detail, ratio for b1:b1i was 70.7 in non-inflammatory, 17.2 in weak inflammatory and 6.6 in inflammatory cases; for b5:b5i it was 5.3, 1.5 and 0.5, respectively. Ratio of expression of b2:b2i showed no differences between the different inflammatory cases (5.8, 5.9 and 6.0, respectively).

Conclusion: Our results show that gene expression of b1:b1i and b5:b5i proteasome subunits is altered in inflammatory myopathies. Calculation of expression ratios of constitutive vs inducible subunits allowed a clear differentiation between non-, weak- or inflammatory states in the analyzed myopathies and therefore, could be a useful tool for monitoring of disease development. Further implications of these alterations for the disease, including expression at protein level, should be analysed.

The Holster Sign: A Specific but Under Recognized Skin Finding in Dermatomyositis. Dean H. Stephens[1], Kathryn Schwarzenberger[2] and Sheldon M. Cooper[1], [1]Fletcher Allen Health Care, Burlington, VT, [2]Fletcher Allen Health Care

Purpose: Characteristic skin findings in dermatomyositis (DM) include Gottron's papules (Gp), heliotrope rash (He) and shawl and V (S/V) sign. An erythematous and violaceous rash over the lateral hip, called the "Holster sign," has been noted occasionally in the dermatology literature, but is absent from rheumatology publications. The objective of this study was to evaluate the incidence of the holster sign (HS) in DM patients, to determine the sensitivity and specificity of this and other classic skin findings by comparing DM patients with polymyositis (PM), mixed connective tissue disease (MCTD), and scleroderma (SS) patients.

Method: We identified patients seen by our rheumatology and dermatology services from January 2003 to December 2008 with ICD-9 codes for DM, PM, MCTD and SS. Patients were mailed a survey that included separate pictures of He, Gp, S/V and HS, and were asked to check if they "had any of the following skin findings?" Patients who completed the survey and signed the informed consent were enrolled. Chart reviews were performed to confirm the diagnosis and to look for any description of the above cutaneous findings in the provider's notes. The incidence rate for each skin sign was calculated by diagnosis, and the sensitivity and specificity of each sign for DM was calculated.

Results: Out of a total of 315 surveys mailed, 117 were returned. Positive self-reporting of the HS was 22/28 in DM, 2/13 in PM, 0/21 in MCTD, and 6/55 in SS. Positive reporting of 78.5% for the HS in DM was comparable to S/V (75%), Gp (85%), and He (71%). In the PM, MCTD and SS patient groups, HS self-reporting was lowest (0-15%), with higher responses for Gp (22-33%), S/V (15-33%), and He (5-23%). Of all the skin findings, the HS had the highest specificity for DM at 91% (range 75-91% for all signs). Sensitivity of the HS was 79%, and comparable to other signs (71-85%). Chart review of the patients seen by both a rheumatologist and dermatologist suggested that dermatologists noted the HS more frequently than the rheumatologist, whereas other skin findings were recorded equally.

Conclusion: This patient survey and chart review indicates that the Holster sign has a comparable incidence to the more established cutaneous findings in DM. Description of the HS is not mentioned in rheumatology texts and reviews, suggesting a low recognition of the HS by rheumatologists. Looking for the distinctive HS should be part of the exam in all patients with suspected DM.

Isolated Elevation of Aldolase in the Serum of Myositis Patients: A Biomarker of Damaged Early Regenerating Muscle Cells. Livia Casciola-Rosen, Lisa Christopher-Stine, Andrea Corse, Grace Hong, John Hall and Antony Rosen, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Increased serum aldolase levels in the absence of increased serum creatine kinase (CK) levels occurs in patients with myositis, but the mechanism underlying this phenomenon is unclear. Recent studies have demonstrated that regenerating muscle cells express the highest concentrations of myositis autoantigens, and are likely major targets of immune attack in this disease. We therefore examined the gene and protein expression of aldolase and CK in differentiating muscle cells.

Methods: Cultured human myoblasts were induced to differentiate into myotubes over 10 days *in vitro*. Total RNA was isolated on each day of culture and microarray analysis was performed using human Illumina Refseq8 beadchip arrays. Present genes were Z-transformed and normalized, and significant changes in gene expression were calculated by performing Z tests. Gene expression data for aldolase and CK was verified by performing QPCR using the TaqMan assay system. Detergent containing lysates, prepared at various times during differentiation, were immunoblotted with antibodies against aldolase, CK, vinculin and other differentiation markers. Muscle paraffin sections from patients with elevated aldolase levels and normal CK levels were stained with a polyclonal antibody against aldolase.

Results: Gene expression analysis performed on differentiated human myoblasts demonstrated that aldolase expression was highest in myoblasts, and decreased slightly during differentiation into myotubes; however, levels remained robust. In contrast, CK mRNA is expressed at very low levels in undifferentiated myoblasts, but is strikingly upregulated by day 2 of culture, with expression levels peaking by day 3. A marker of muscle differentiation, embryonic myosin heavy chain (MYH3), displayed a similar expression pattern. Consistent with this, we showed by immunoblotting that aldolase protein expression is highest in myoblasts, and, although it decreases during differentiation, it is prominent throughout. In contrast, CK expression is absent in myoblasts and during the early stages of differentiation (the period of highest aldolase expression), and is only detected from day 4 onwards. Immunohistochemical staining confirmed that muscle cells with the highest levels of aldolase have features consistent with regeneration.

Conclusion: In undifferentiated muscle cells, and those early in the differentiation process, aldolase is expressed in the absence of CK. This is a period in muscle cell differentiation in which autoantigen expression is also highest. Thereafter, both aldolase and CK are expressed. We propose that isolated serum aldolase elevation in myositis patients reflects preferential immune-mediated damage of early regenerating muscle cells. Such targeted damage may have important implications in terms of prognosis and therapy.

Increased Mast Cells in Untreated JDM Skin Compared to Paired JDM Muscle: Association with Mature Plasmacytoid Dendritic Cells. Sheela Shrestha[1], Barry Wershil[2], John F. Sarwark[2] and Lauren M. Pachman[1], [1]Children Memorial Research Center, Chicago, IL, [2]Children's Memorial Hospital, Chicago, IL

Purpose: To investigate mast cell distribution in association with dendritic cell subsets in muscle and skin (lesional and non-lesional) pairs from untreated juvenile dermatomyositis (JDM) patients.

Methods: Seven untreated patients diagnosed as probable/definite JDM (Bohan-Peter criteria) (mean age=4.91 ± 2.58 yrs, 1 male, 6 female) were enrolled. MRI directed muscle and skin biopsies (4/7 from active JDM rash) were obtained from each patient. Otherwise healthy children with idiopathic scoliosis donated thoracic skeletal muscle, n=4 and skin, n=6 with their consent (mean age=10.77 ± 5.70 yrs, 6 male, 4 female). Mast cell distribution and number were assessed by staining with toluidine blue. Student's t-test was performed with $p<0.05$ as significant. Using immunohistochemistry, the presence of dendritic cells (myeloid [mDC] or plasmacytoid [pDC]) and their maturation state were examined using antibody to BDCA-1, BDCA-2 and DC-LAMP respectively. MxA staining was used as an indicator of type I interferon (IFN) signaling. The expression of these markers was scored semi-quantitatively (0 = none; 1 = weak; 2 = moderate; 3 = strong expressions). Mann-Whitney U-test was used for statistical analysis. Probabilities <0.05 were considered significant and $p<0.01$ as highly significant.

Results: Mast cell infiltrations in JDM skin ($43.16\pm39.90/mm^2$) were significantly elevated compared to skin from control children ($7.90\pm3.63/mm^2$), $p=0.029$ and did not differ between lesional and non-lesional skin rash, $p=0.40$. No significant difference was seen in the number of mast cell infiltrating JDM muscle ($0.35\pm0.21/mm^2$) and control muscle ($0.28\pm0.26/mm^2$), $p=0.341$. Within the JDM group, the

number of mast cells in skin was significantly higher than in the corresponding muscles, p=0.014. pDC were localized mainly in the perivascular and perifascicular area in JDM muscle as compared to control muscle, p=0.042 and were predominantly mature, p=0.006. MxA protein was preferentially expressed by myofibers in JDM muscle and significantly different from control muscle, p=0.042. In JDM skin, the staining for DC-LAMP, BDCA-2 and MxA was present throughout the epidermal and dermal layers, including perivascular area as compared to control skin, p = 0.001. Both JDM and control muscle were negative for mDC, but a few were sparsely scattered in the dermis of JDM and control skin.

Conclusion: The increased numbers of mast cells in the skin, but not in the muscle, from untreated children with JDM suggests that the pathophysiology of the disease in skin and muscle are distinct, as we have suggested previously (Smith et al 2004). The lack of association between the number of mast cell and the degree of rash severity indicates that immune activation may precede the clinical dermal manifestation of JDM. The predominance of pDC along with type I IFN induced proteins suggests a selective influence on T-cell differentiation and subsequent effector functions. Support: RO-1 AR48289 and Cure-JM (to LMP).

The Expression of IL-23and IL-23R Are Increased in Patients with Dermatomyositis. Park Young-Eun[1], Baek Seung-Hoon[1], Kim Ju-In[1], Kim Jeong-Hee[1], Lee Joung-Wook[2], Kim Geun-Tae[3], Lee Jun-Hee[4] and Kim Sung-Il[1], [1]Pusan National University Hospital, Busan, South Korea, [2]Busan St. Marys center, Busan, South Korea, [3]Kosin University Gospel Hospital, Busan, South Korea, [4]Choonhae Hospital, Busan, South Korea

Purpose: Dermatomyositis (DM) is chronic autoimmune muscle disorders characterized by inflammatory infiltrate in muscle tissues. IL-23, promotes Th17 cell differentiation and induces proinflammatory cytokines, has key roles in autoimmune disease. IL-23R is unique receptor of IL-23 and plays roles on autoimmune disease.

Method: We measured the IL-23 and IL-23R mRNA level of muscle tissues from 9 patients with DM by real-time RT-PCR and compared with controls. We also performed immunofluorescence stain with confocal micoscope to detect IL-23R expression.

Results: In 9 patients with DM (6 male and 3 female patients), mean age was 42±15 years and clinical and laboratory characteristics are in table 1. The relative expression levels of IL-23 (12.2±14.7 in DM, 1 in control) and IL-23R (6.0±6.0 in DM, 1 in control) were significantly enhanced in DM than controls. In immunofluorescence stain with confocal microscope, IL-23R was expressed in vessel walls, infiltrating inflammatory cells and muscle tissues of DM (figure 1).

Conclusion: These results suggest IL-23 and IL-23R play a role in the immunopathogenesis of DM.

Table 1. Clinical and laboratory characteristics, and the expression levels of IL-23R in 9 patients with dermatomyositis

Age(year) /sex	Disease durations (months)	CK (U/L)	Aldolase (U/L)	ESR (mm/h)	CRP (mg/dl)	Relative expression levels compared to controls

Early Employed Exercise in Recent Onset Polymyositis or Dermatomyositis – A Randomized, Controlled 2-Year Follow Up Study.

Helene Alexanderson[1], Anne-Marie Noren[2], Li Alemo Munters[1], Christina H. Opava[3] and Ingrid E. Lundberg[4], [1]Rheumatology Unit, Department of Medicine and Department of Physical Therapy, Karolinska Institutet, Stockholm, Sweden, [2]Health Care Department, Stockholm City Council, Stockholm, Sweden, [3]Karolinska Institutet, Huddinge, [4]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Purpose: To evaluate the safety and the benefits of a resistive home exercise program in patients with recent onset polymyositis (PM) or dermatomyositis (DM).

Method: Nineteen patients with recent onset PM/DM (median age of 56 Q1-Q3 (45-65) years) were included. A muscle biopsy from the vastus lateralis was performed and all patients were given 0.75 mg/kg body weight, md 40 (30-40) mg of Prednisone together with Methotrexate or Azathioprine. Measures of muscle endurance (Functional Index), aerobic capacity (treadmill test), perceived health (Nottingham Health Profile)(NHP) and CPK-levels were performed at baseline and after 12, 24, 36, 52, 64, 76 and 104 weeks. Four weeks after diagnosis patients were randomized to an exercise group (EG, n=10) performing a resistive home exercise program five days/week for 12 weeks or to a control group (CG, n=9) performing a range of motion program five days/week for 24 weeks. A second muscle biopsy was performed after 24 weeks. Patients in the CG without inflammatory infiltrates in the second biopsy were then instructed in the resistive home exercise program for 12 weeks. Patients filled out an exercise diary and telephone support was provided weekly during the 12-week exercise. All patients were encouraged to keep on exercising twice a week throughout the 2-year follow-up. The Kruskal-Wallis ANOVA was used for between-group analysis and the Friedman's ANOVA and the Wilcoxon Signed Rank test were used for within-group analysis.

Results: The exercise program was well tolerated. There was no difference between the groups at baseline, except for the EG rating poorer health in three NHP domains compared to the CG ($p<0.05$). A within-group improvement was revealed for both groups in muscle endurance and aerobic capacity at 12-64 weeks compared to baseline ($p<0.01 – p< 0.05$). In the EG, this improvement lasted up to the 104-week follow-up ($p<0.05$), but not in the CG. The EG improved in the NHP domain Energy at 12 and 104 weeks compared to baseline ($p<0.05$) while the CG improved in the domain Sleep at 24 weeks compared to baseline ($p<0.05$). There was no between-group difference in any measures at any follow-up and the number of responders (>20% improvement) was equal in both groups at all follow-ups. No signs of increased muscle inflammation were revealed.

Conclusion: Our study further supports the safety of resistive exercise in patients with active PM/DM but could not reveal any difference in treatment effects between the two groups. As improvements lasted up to the 2 year follow-up in the EG, but not in the CG, our results indicate that early employed exercise might be more effective in a longer perspective than medical treatment alone. There is a need for larger multicenter RCT trials are needed to establish exercise effects in these patients.

Patients with Idiopathic Inflammatory Myopathies Have Low Muscle Endurance Rather Than Low Muscle Strength. Helene Alexanderson[1], Jenny Bergegård[2], Li Alemo Munters[1], Maryam Dastmalchi[3] and Ingrid E. Lundberg[3], [1]Rheumatology Unit, Department of Medicine and Department of Physical Therapy, Karolinska Institutet, Stockholm, Sweden, [2]Department of Physical Therapy, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Purpose: To investigate degree of muscle strength and muscle endurance in patients with active, recent onset and chronic idiopathic inflammatory myopathies.

Method: Two cohorts of patients with diagnosis polymyositis (PM), dermatomyositis (DM) or inclusion body myositis (IBM), registered at the Rheumatology clinic at Karolinska University Hospital, were included in this study. Cohort 1 (n=32) is all adult patients that were newly diagnosed with PM, DM or IBM during 2004-2008 who performed both the Manual Muscle test (MMT) (maximal isometric strength) and the Functional Index 2 (FI-2) (muscle endurance assessed as maximal number of repetitions) at the time of diagnosis with no more than two weeks apart. Fourteen patients had PM, 16 DM, and two had IBM and their median diagnosis duration was 0 range (0-3) month. They had median 0 (0-70) mg of Prednisone per day (18 patients were assessed before introduction of medical treatment). Cohort 2 (n=49) is all patients with chronic disease registered at the clinic who performed both the MMT and FI-2 with no more than two weeks apart at a yearly check-up visit during 2004. Twenty-two patients had PM, 24 DM, and three had IBM, with median diagnosis duration of 9 (1-36) years and median 5 (0-20) mg of Prednisone per day. The MMT was conducted by either of two experienced and trained physicians and the FI-2 was performed by either of 4 experienced and trained physical therapists. Comparisons between the MMT and the FI-2 measures were analyzed using the non-parametric Mann Whitney Test.

Results: Patients in cohort 1 with active, recent onset disease had statistically significant and clinically relevant lower muscle endurance with a median of 26 (0.5-86) % of maximal score of the FI-2 compared to a median of 87 (0-100) % of maximal score of the MMT ($p<0.001$). Patients in cohort 2 with chronic disease had statistically significant and clinically relevant lower muscle endurance with a median value of 26 (0-100) % of maximal score of the FI-2 compared to a median value of 94 (46-100) % of the maximal score of the MMT ($p<0.001$). The lowest scores of the MMT and the FI-2 represented the patients with IBM in cohorts 1 and 2.

Conclusion: Patients with inflammatory myopathies with active, recent onset as well as chronic disease have a larger degree of impairment regarding muscle endurance than muscle strength. These results indicate that it is very important to also assess muscle endurance to better capture impairment in these patients in clinical practice and research.

ACR/ARHP Poster Session B

Osteoarthritis Therapeutics & Clinical Aspects

Monday, October 19, 2009, 9:00 AM - 6:00 PM

824

Analysis of a Broad Spectrum of Urinary and Serum Biomarkers in a Large Cohort of Patients with Early Osteoarthritis of Hip and/or Knee (CHECK): The First Results. Willem E. van Spil, Floris P.J.G. Lafeber and Nathalie W.D. Jansen, University Medical Center Utrecht, Utrecht, Netherlands

Purpose: Biomarkers to diagnose OA in an early stage and/or to predict its course would be of great value. Therefore, we selected a broad spectrum of serum and urinary biomarkers representative of cartilage, bone and synovium turnover for evaluation in CHECK (Cohort Hip & Cohort Knee). This multi-centre cohort consists of 1002 participants with pain and/or stiffness of knee and/or hip, aged 45-65 yrs, and who had never or no longer than 6 months before visited their physician for these symptoms for the first time. Hip and knee radiographs as well as clinical parameters and multiple questionnaires are evaluated at regular intervals. Furthermore, serum (s) and urine (u) samples are collected at 0, 2, 5, 8, and 10 yrs. Baseline biomarker measurement has recently been completed and would provide a unique opportunity to study the diagnostic and prognostic properties of biomarkers in early-stage OA. This abstract covers quality aspects of this large biomarker set.

Method: Baseline samples were thawed for the first time. Commercially available ELISA assays were performed to measure uCTX-II, uCTX-I (ImmunoDiagnostic Systems Ltd.), uNTX-I (Wampole Laboratories), sCOMP (Anamar Med AB), sOC (IDS), sHA (Corgenix Inc.), sPIIANP (Millipore Corp.), sCS846, and sC1,2C (IBEX) and RIA assays for sPINP and sPIIINP (Orion Diagnostica). There was no commercial involvement and kits were from the same badge for each biomarker. Each biomarker was measured in all samples by the same technician in 8 days in a period of 6 wks using 14 kits.

Results: Quality of the assays, checked by using a randomly distributed pooled reference sample, controls as supplied by manufacturers, and blank samples in-between patient samples, was acceptable, except for the COMP assay. The COMP assay showed a remarkably variable biomarker concentration within and between assay plates.

When biomarker concentrations of all patient samples were plotted in chronological order of assaying, it appeared that there was a sufficient window of variation within a positively skewed distribution. There was no evident variation over time and between serial kits of the same assay, except for two remarkable observations: part of the sCOMP kits showed biomarker concentrations that were a 10-fold higher and showed significantly more variation than the other kits. For the sC1,2C and sCS846 assays, there was a relationship between measured biomarker concentration and sample position within assay plates. It appeared that the variation in the COMP assays was due to the coating procedure and the assay will be run again with new kits. For the C1,2C and CS846 assays there is still ongoing research to specify the problem.

Conclusion: Reliable measurement seems possible for the majority of the studied biomarkers in this large sample set. However, there remain some challenges for some of the assays before actual correlations with clinical and radiographic data can be made.

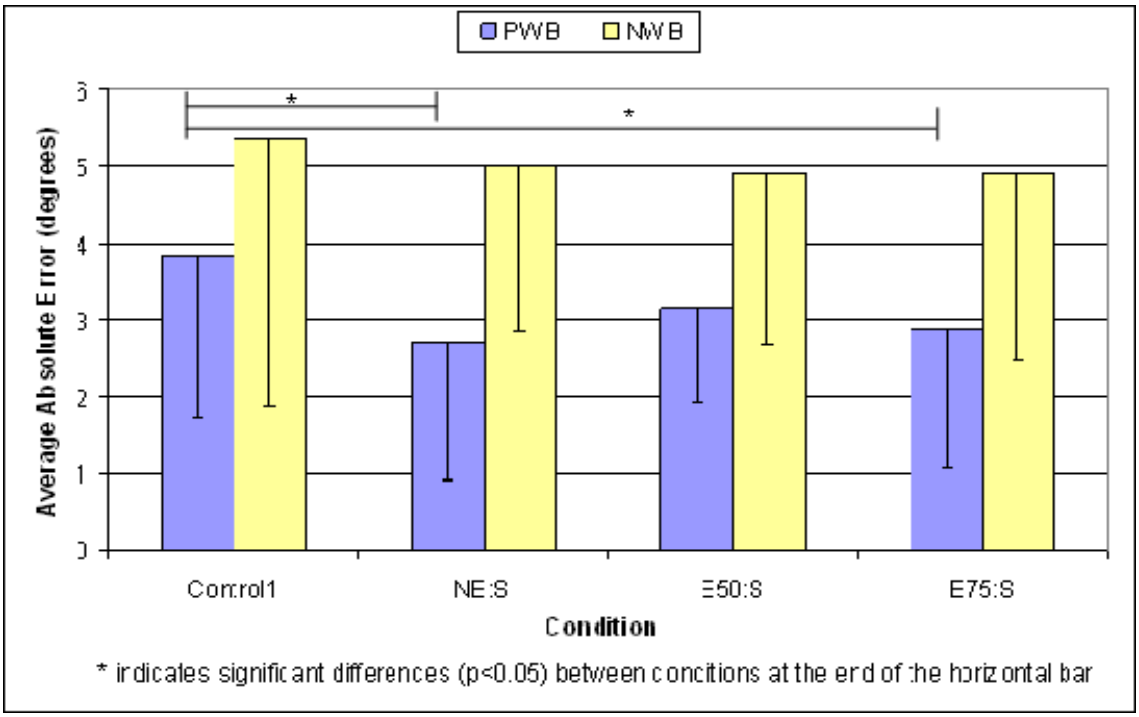
Stochastic Resonance Electrical Stimulation to Improve Proprioception in the Osteoarthritic Knee. A. Collins, T. Blackburn, C. Olcott, J. Miles, J. Jordan, D. Dirschl and P. Weinhold, UNC Chapel Hill, Chapel Hill, NC

Purpose: Proprioception deficits are known to occur with knee osteoarthritis (OA) and it has been proposed that correction of these deficits may help to slow disease progression. While knee sleeves have shown some evidence to improve proprioception in the nonweightbearing knee, a novel means to enhance such effects may be by incorporating a type of electrical stimulation (stochastic resonance) that has been demonstrated to enhance the sensitivity of mechanoreceptors. The purpose of this research was to determine whether proprioception measured by joint position sense (JPS) is improved through the use of electrical stimulation and a neoprene knee sleeve in a population with mild to moderate medial knee OA.

Method: JPS was measured in 24 subjects (18 females, 6 males) with mild to moderate (KL grade 1-3) knee OA under four conditions (control, 50μA stimulation/sleeve E50/S, 75μA stimulation/sleeve E75/S, and no stimulation/sleeve NE/S) during both a partial weight bearing (PWB) and a non-weight bearing (NWB) task using a counterbalanced design. Electrical stimulation consisted of either a 50μA or 75μA Gaussian white noise signal (zero mean, s.d. = 0.05mA, 0-1000Hz bandwidth) applied at superior and inferior electrode pairs placed about the knee. During both tasks the absolute difference (error) between the target knee angle and the reproduction angle was calculated and averaged across the 5 trials within each condition. One-way repeated measures analysis of variance followed by Tukey's post-hoc analysis was used to determine differences between conditions ($p<0.05$). Regression analysis was used to assess correlations between the control condition error and the improvements in proprioception with the treatment conditions or the subject's WOMAC score.

Results: Proprioception was found to be improved ($p<0.05$) relative to the control condition for both the sleeve alone (NE/S) and E75/S conditions in the PWB task (see figure). No significant differences were found in the NWB task. Regression analysis revealed a modest correlation between the improvement of the absolute error of the NE/S and E75/S conditions and that of the control condition in PWB task. No correlation was found between the error of the control condition and the subject's WOMAC score.



Conclusion: Electrical stimulation combined with a knee sleeve (E75/S) as well as the sleeve alone (NE/S) condition improved proprioception compared to a control condition during the physiologically relevant PWB task. The correlation observed between the improvement in proprioception with the E75/S and NE/S treatment conditions and the error of the control condition are suggestive that subjects with larger proprioceptive deficits may benefit most from these therapies.

Gait Variability Across the Spectrum of Knee Osteoarthritis. Kharma Foucher[1], George Kannankeril[1], Joel A. Block[1], Najia Shakoor[1], Markus Wimmer[1] and Laura E. Thorp[2], [1]Rush University Medical Center, Chicago, IL, [2]Rush University Hospital, Chicago, IL

Purpose: The etiology of knee OA has biomechanical and neuromuscular components. The knee adduction moment (KAddM) during gait is a biomechanical marker of knee OA. The magnitude of gait variability may be a marker of neural control with important consequences on load history; and thus be related to disease severity. Here we evaluated variability in gait parameters across the spectrum of OA severity.

Method: Data from three IRB approved studies were examined: 1) 52 subjects (39 F/13M, age 52.4±6.0 yrs) with no clinical evidence of OA at the knee or hip; 2) 34 pre-OA subjects (18F/18M, age 63.8±9.9 yrs) at high risk for knee OA due to existing contralateral hip OA; 3) 86 subjects (65F/21M, age 57.9±10.2 yrs) with mild/moderate symptomatic radiographic medial knee OA. Walking speed, peak KAddM, and dynamic knee range of motion (KROM) from 3 gait trials at self-selected normal speeds were analyzed for each subject. Intra-subject coefficients of variation (CV=100* standard deviation / mean) were calculated for these variables. Kruskal-Wallis and Mann-Whitney tests were used to detect group differences.

Results: Average walking speed (m/s) for groups 1 through 3 were: 1.3±0.22 (normal), 1.17±0.15 (pre-OA), 1.18±0.23 (OA) (p=0.002); both the pre-OA and the OA groups were slower than normal (p=0.002). CVs for speed were 4.3±2.9% normal, 2.5±1.8% pre-OA, 3.2±2.5% OA (p=0.004); pre-OA and OA groups' CVs (p=0.215) both were reduced compared to normal (p= 0.002 and p= 0.014, respectively). Although there were no differences in KROM among the groups (p=0.234) the CV showed group differences (p=0.012). Variability was significantly less in the OA group than among normals (2.3±1.9% v. 3.6±2.6%, p=0.003). KAddM was 2.27±0.58 %BW*Ht in the normal group,

2.44±0.72 %BW*Ht in the pre-OA group, and 2.84±0.68 %BW*Ht in the OA group ($p<0.001$). The OA group had significantly higher KAddM than both the pre-OA ($p=0.006$) and the normal group ($p<0.001$). The variability decreased from 9.5±6.5% in the normal group to 7.5±4.6% in the pre-OA group to 6.2±4.1% in the OA group ($p=0.003$). KAddM CV was significantly lower in the OA group than the normal group ($p=0.001$) but was not significantly different from the pre-OA ($p=0.129$).

Conclusion: Variability in both loading and motion variables decreased incrementally with knee OA risk and definitive evidence of knee OA, suggesting that a more restricted walking strategy is adopted in response to increased pain, stiffness, or changes in alignment. Decreased variability could potentially exacerbate local cartilage degeneration, as the same areas of cartilage are consistently subjected to abnormally high loads. While decreased step-to-step variability has been documented in knee OA, the reduced trial-to-trial variability of several gait markers in this study suggests a detrimental, neuromuscular adaptation.

The Effects of Specialized Footwear in OA of the Knee: Clinical and Biomechanical Results of a 6-Month Pilot Study. Najia Shakoor, Roy Lidtke, Rachel Mikolaitis, Robert Trombley, Louis Fogg and Joel A. Block, Rush University Medical Center, Chicago, IL

Purpose: The onset and progression of knee OA are mediated by high dynamic loading of the knee. We recently demonstrated that in knee OA, footwear has a significant effect on knee loads, and that use of a novel "mobility" shoe substantially reduced dynamic joint loads during walking compared to conventional shoes (*Arthritis Rheum* '08). Here, we performed a pilot investigation to test the effects at 6 months of chronic use of "mobility shoes" on pain and dynamic knee loads in symptomatic knee OA.

Methods: Subjects with radiographic (Kellgren Lawrence grades ≥ 2) and symptomatic (at least 30mm pain on a 100mm scale while ambulating on a flat surface) medial compartment knee OA were recruited. At baseline, subjects: 1) had AP standing knee radiographs 2)completed site-directed WOMAC evaluations of their hips, knees and ankles and 3) underwent gait analyses using an optoelectronic camera system and multi-component force plate while wearing their own shoes, "mobility shoes", and barefoot. Subjects were instructed to wear the mobility shoes for a minimum of 6 hours daily for at least 6 days each week. Pain and gait evaluations were performed at baseline, 6 weeks, 12 weeks, and 6 months. WOMAC pain and peak knee adduction moment (PAddM) represented the primary endpoints. An intent to treat analysis (ITT) was performed using repeated measures analyses of variance, $p<0.05$ was considered significant.

Results: Complete data are available for 9 subjects. Three terminated early: two due to lack of efficacy (one each at 6 and 12 weeks), and one was unable to return for study visits and terminated at 8 weeks. All data were carried forward for the ITT analysis. In comparison to the subjects' own shoes, the "mobility" shoes induced significantly decreased loads during gait at all time points ($p=0.012$)(Figure 1), with an overall reduction in PAddM of 17% with "mobility shoes" at 6 months compared to conventional shoes at baseline. There were no significant differences between the mobility shoes and barefoot walking at any time point ($p=0.603$)(Figure 1). Concomitant with the load reductions, there were significant and durable improvements in pain at all study time points compared to baseline, with an overall 46% reduction at 6 months (245±109 vs 137±131 vs 161±126 vs 132±127, $p=0.001$).

Conclusion: This pilot study demonstrates that use of novel "mobility" footwear results in durable reductions in both dynamic knee loading and in pain during 6 months of use by subjects with medial knee OA. Footwear design may be an important therapeutic strategy for OA of the knees.

A Randomized Trial of Realignment Therapy for Treatment of Medial Tibiofemoral Osteoarthritis. David J. Hunter[1], K. Gross[2], Paula I. McCree[1], Ling Li[1], Kelly Hirko[1], Bin Zhang[3] and William Harvey[1], [1]New England Baptist Hospital, Boston, MA, [2]MGH Inst Health Prof, Boston, MA, [3]Boston Univ School Medicine, Boston, MA

Purpose: Biomechanical studies of persons with medial tibiofemoral OA demonstrate that even with appropriate valgus knee bracing, large medial forces remain, suggesting that the addition of other interventions to further improve limb alignment may be of therapeutic value. The objective of this 30-week randomized crossover trial was to determine whether a multi-modal realignment therapy (consisting of *valgus knee brace + motion control shoes + neutral foot orthoses*) would be successful in relieving pain and improving function among persons with medial tibiofemoral OA.

Method: We conducted a double blind, *randomized crossover trial* of a multi-modal realignment therapy for persons with medial tibiofemoral OA. Trial participants met ACR criteria for OA with knee pain, aching or stiffness on most of the past month and radiographic evidence of a definite osteophyte. We tested two different treatments: A) CONTROL TREATMENT consisting of a neutral knee brace (no valgus angulation), flat unsupportive foot orthoses, and shoes with a flexible midsole; and B) ACTIVE TREATMENT consisting of a valgus knee brace, customized neutral foot orthoses, and shoes designed for motion control. For each subject, the *trial lasted 30 weeks*, including 12 weeks each of active and control treatment separated by a 6-week washout period. The primary outcome was change in knee pain and function as assessed by the WOMAC Osteoarthritis Index (VAS version). An unstructured correlation matrix for observations within subjects was used in generalized estimating equation fitting. The final linear regression model was conducted with exclusion of the differential carryover effect.

Results: 80 participants with medial tibiofemoral OA were randomized. 63% were female. Their mean age was 62 years, mean BMI was 34 kg/m^2 and mean WOMAC pain score was 8.9 (0-20 scale). The main effects are depicted in the table below. There was no evidence of a

carryover effect in the initial analyses. After removing the potential for carryover effect, the model demonstrated that the mean difference in pain between the active and control treatments was -0.86 units (95% confidence interval 1.74, 0.01 [p=0.05]) on the WOMAC pain scale (range 0-20), indicating a small decrease in pain in association with the multi-modal active treatment.

Predictor	B coefficient for end of treatment WOMAC pain (negative values indicating a decrease in pain)
Active treatment (control as reference)	-0.86
(95% confidence interval)	(-1.74, 0.01)
p-value	0.05
Baseline WOMAC pain score	0.38
(95% confidence interval)	(0.19, 0.57)
p-value	0.0002
Treatment, period 1 vs. period 2	-0.04
(95% confidence interval)	(-0.92, 0.84)
p-value	0.93

Conclusion: The effects of multi-modal realignment therapy on pain and function in persons with medial tibiofemoral OA are small and of equivocal clinical and statistical significance.

Varus Malalignment Diminishes the Structure-Modifying Effects of Doxycycline (Doxy) in Patients with Knee Osteoarthritis. Rafael Chakr[1], Kenneth D. Brandt[2], Dennis C. Ang[1] and Steven A. Mazzuca[1], [1]Indiana University, Indianapolis, IN, [2]Kansas Univ Medical Center, Fairway, KS

Purpose: The inconsistent results of clinical trials of structure-modifying osteoarthritis drugs (SMOADs) may be due to the presence of abnormal intra-articular stresses that preclude potential benefit from pharmacotherapy. Because varus malalignment increases loading of the medial tibiofemoral compartment and, hence, the risk of OA progression, it may attenuate the benefit of a SMOAD aimed at slowing joint damage. Herein we describe results of a recent subgroup analysis of our previously published randomized clinical trial (Arthritis Rheum 2005;52:2015) asking whether varus malalignment reduced the structure-modifying effect of doxy in OA.

Method: In this placebo-controlled trial, 379 subjects underwent an interim (16-mo) and/or close-out (30-mo) x-ray exam. All were obese, 45-64 year old women who had unilateral Kellgren and Lawrence grade 2-3 knee OA at baseline. The primary outcome was medial compartment joint space narrowing (JSN) measured manually in semiflexed anteroposterior radiographs acquired with standardized fluoroscopic positioning. The anatomic-axis angle (AAA) was measured in each baseline radiograph by one of two readers (inter-reader ICC = 0.95) and transformed to an estimate of the mechanical-axis angle (MAA) using a validated regression equation (MAA=0.915*AAA+13.895, R^2=0.77) (Arthritis Care Res 2006;55:306). Knees with MAA<178° were classified as varus. Treatment group comparisons were performed using a mixed-effect linear model and adjusted for age, BMI, visit (16- or 30-month), clinical center and baseline joint space width.

Results: In our published comparison with placebo, doxy slowed the annualized rate of medial JSN in index (OA) knees by 39% at 16 months (0.11 vs. 0.18 mm/yr, P=0.027) and by 33% at 30 months (0.12 vs. 0.18 mm/yr, P=0.017). Our current subgroup analyses of non-annualized JSN (table) indicated, however, that among varus OA knees, JSN occurred at similarly rapid rates in both treatment groups over both intervals (0.20 - 0.27 mm/yr). In contrast, among non-varus knees, 16-mo JSN in the doxy group was 43% slower than in the placebo group (0.09 vs. 0.16 mm/yr, P=0.080), and 30-mo JSN was 38% slower (0.10 vs. 0.17 mm/yr, P=0.026).

Non-annualized medial compartment JSN (*Mean* ± *SD*, mm) by treatment group: results in varus and non-varus OA knees						
	Varus OA Knees			**Non-varus OA Knees**		
	Doxycycline	**Placebo**	***P***	**Doxycycline**	**Placebo**	***P***
16-mo JSN	0.26 ± 0.39	0.36 ± 0.57	0.230	0.12 ± 0.42	0.21 ± 0.52	0.080
N of knees	37	45		151	146	
30-mo JSN	0.49 ± 0.64	0.55 ± 0.62	0.448	0.26 ± 0.58	0.42 ± 0.73	0.026
N of knees	37	42		146	138	

Conclusion: These *post hoc* analyses show that varus malalignment negated the slowing of structural progression of medial compartment OA by doxy. Given the prime importance of abnormal intra-articular stress in the etiopathogenesis of common, garden-variety OA (Brandt et al. Seminars Arthritis Rheum. In press), it is likely that other conditions which, like malalignment, increase joint loading (e.g., genetic or developmental abnormalities in joint shape, neuromuscular abnormalities that impair micro-coordination [sarcopenia, proprioceptive defects]) can also render SMOADs ineffective.

Effect of Cane Use On Lower Limb Biomechanics and Pain in Knee Osteoarthritis. Sarah M. Lee[1], Constance Heiney[2], Karen L. Perell[3], Sulabha Masih[2], Nancy D. Harada[2], Jennifer M. Yentes[2] and Meika A. Fang[2], [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [3]California State University, Fullerton, CA

Purpose: Dynamic loading of the medial knee is associated with progression of knee osteoarthritis (OA). Therefore interventions that lessen the load of the medial knee may minimize the risk of disease progression. Previous studies have shown that walking with a cane has an immediate effect of reducing the peak knee adduction moment and peak vertical force in people with knee OA. The objective of the current study is to determine whether short-term cane use will lead to persistent alterations in gait biomechanics and improve pain and physical activity in individuals with painful knee osteoarthritis.

Method: Twenty-one overweight or obese participants with symptomatic knee OA were given a single point cane to use contra-lateral to the painful limb for eight weeks. All participants underwent gait assessment with and without a cane at baseline and at 8 weeks by using a three-dimensional motion capture system and an in-shoe dynamic pressure distribution system. The peak vertical force and mean lateral deviation of the center of pressure (COP) of the painful limb were measured. OA-related pain was assessed with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and physical activity level was measured with the Physical Activity Scale for Elderly (PASE).

Results: Twenty-one participants (mean age 62.6 ± 7.9 years, male) completed the study. Cane users who used the cane frequently (≥ 4 days per week) had greater pain at baseline than those who used the cane less frequently and 50% of the frequent cane users demonstrated a 20% or greater decrease in pain. The frequent cane users also had a 22% increase in the mean lateral deviation of COP for the painful limb when walking with a cane compared to walking unaided during the baseline visit (P=0.002). After 8 weeks of walking with a cane, the frequent cane users maintained this increase in mean lateral COP deviation when walking with and without a cane. Peak vertical force decreased 11.9% on the painful limb with cane use after eight weeks of walking with a cane. There were no significant changes in physical activity level as measured with the PASE.

Conclusion: To our knowledge, this is the first study to demonstrate that frequent cane use in people with painful knee OA display an immediate lateral shift in the center of pressure; this effect is maintained in frequent cane users after walking with a cane for 8 weeks. Furthermore, we show that frequent cane use may reduce pain and decrease peak vertical force in the painful limb. These findings suggest that regular cane use may be potential cost-effective and noninvasive interventions for knee OA by unloading the medial compartment of the knee and decreasing pain.

Varus Thrust Is Associated with Pain in Knee Osteoarthritis. Grace H. Lo, Timothy McAlindon, Kimberly A. Carr, Melanie A. Ripley, Melynn Nuite and William F. Harvey, Tufts Medical Center, Boston, MA

Purpose: With its lack of effective treatment and high prevalence, the public health impact of osteoarthritis (OA) is substantial. Varus thrust (VT) is the rapid lateral bowing of the knee visualized during ambulation. VT is predictive of longitudinal medial joint space narrowing in knee OA; however, there are no data on its relationship with pain. We hypothesized that those with VT would have more pain, especially with weight-bearing activities, as compared to those without VT.

Method: This is a cross-sectional study of a convenience sample selected from participants of a randomized controlled trial of vitamin D for symptomatic radiographic knee OA. The parent study is currently still blinded to treatment allocation. All those in the RCT were eligible to participate in this study. Those using ambulatory devices were excluded. Participants were video recorded using a standard digital video camera (60 Hz) walking at a self-selected speed. These videos were viewed at separate reading sessions by two rheumatologists trained to evaluate VT. Videos were scored for VT definitely present, possibly present, or absent. Disagreements were adjudicated by consensus of both evaluators. At the same visit, weight, and height, and the WOMAC pain questionnaire (Likert) was administered evaluating the study knee.

For analytic purposes, VT was dichotomized (VT-d) as either definitely present or (possibly present or absent). We calculated LSMEANS for the total WOMAC pain score by VT-d adjusting for age, sex, height, and weight. We performed ordinal logistic regressions with *individual WOMAC pain questions* as the outcomes and VT-d as the predictor, subsequently adjusting for age, sex, height, and weight.

Results: Participants (N=82) (age 63.0 (±8.5), BMI 30.2 (±5.4), 60% female, 31% with definite VT, 18% with possible VT, and 51% with absent VT. Those with versus without definite VT had a mean total WOMAC pain score (0-20) of 6.3 versus 3.9, p = 0.007. Shorter participants had more pain. Heavier and male participants had a higher prevalence of definite VT. The table shows the proportional odds ratios for each WOMAC pain question.

Individual WOMAC pain questions		***Unadjusted Proportional Odds Ratio for Pain with v. without definite VT***	****Adjusted Proportional Odds Ratio for Pain with v. without definite VT***
Weight-bearing Questions	Pain with walking	5.0 (1.9 – 12.8)	5.5 (2.0 – 15.1)
	Pain standing upright	5.5 (2.2 – 13.9)	6.0 (2.2 – 16.2)
	Pain with stairs	1.9 (0.8 – 4.6)	2.0 (0.8 – 5.2)
Non-weight-bearing Questions	Pain at night in bed	2.0 (0.8 – 4.9)	3.0 (1.1 – 8.3)
	Pain sitting or lying	1.5 (0.5 – 3.8)	1.8 (0.7 – 4.9)

*adjusted for age, sex, height and weight

Conclusion: In those with symptomatic knee OA, the presence of definite VT was associated with greater overall knee pain, but specifically during weight-bearing activities. The evaluation of individual WOMAC pain questions allows for better characterization of the heterogenous pain that occurs in knee OA. These findings suggest that direct treatment of VT (e.g. via bracing or gait modification) may lead to improvement of symptoms.

Acute Meniscal Injury Is Associated with Synovial Inflammation: Cellular and Molecular Characterization of Synovitis. Carla R. Scanzello[1], Brian P. McKeon[2], Eva Umoh[3], Bryan Swaim[2], Edward F. DiCarlo[3], David J. Hunter[2], John C. Richmond[2], Jeffrey N. Katz[4], Mary K. Crow[3] and Steven R. Goldring[3], [1]Rush University Med Ctr, Chicago, IL, [2]New England Baptist Hospital, Boston, MA, [3]Hospital for Special Surgery, New York, NY, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Purpose: Synovitis is related to pain in patients with osteoarthritis (OA), but little is known regarding synovial responses in patients with acute meniscal injury, which predisposes to development of OA. A prospective study was designed to examine histological and molecular changes in synovium (SM) in patients with acute meniscal injury presenting for menisectomy.

Method: 24 patients (16 M/8F, median age 47, range 21-60) with acute meniscal tears without clinical or radiographic evidence of pre-existent OA underwent arthroscopy. SM biopsies were obtained from the medial and lateral gutters and suprapatellar pouch. Biopsies were processed for histology and RNA analysis. On H&E staining, six histopathologic features were scored: perivascular inflammation, vascularity, detritis, fibrosis, perivascular edema and SM hyperplasia. Scores were compared to patients with pre-existing OA (n=18) from an additional study sample. RNA was prepared for microarray analysis from a subset of patients. Affymetrix U133 + 2.0 chips were used, data analyzed using Genespring software, and pathway over-representation analysis carried out with a focus on innate immune responses.

Results: 23 biopsies at each location (n = 69) were analyzed. Of the histologic features evaluated, synovial hyperplasia (40/69, 58%) was most common, and perivascular inflammation was observed in 32% of biopsies. The spectrum of histologic change was similar to OA, though inflammatory scores were lower in the acute meniscal injury group. From histology, we identified patients with or without inflammation and performed microarray analysis on 8 representative samples. Comparative analysis of gene expression in inflammatory vs. noninflammatory samples demonstrated 260 genes differentially expressed ≥ 2.0 fold, $p<0.05$. Molecular signatures consistent with lymphocyte activation and recruitment were observed. Of note, chemokines involved in cellular trafficking and common-gamma chain cytokine signaling components were enriched in the inflammatory biopsies.

Conclusion: Comparison of expression patterns in patients with or without histologic inflammation revealed enrichment of chemokine and cytokine signaling pathways associated with lymphocyte recruitment and activation in the inflammatory SM biopsies. These patients are being followed longitudinally to determine whether SM inflammation patterns are predictive of post-operative clinical course. Characterization of the cellular and molecular processes associated with joint injury could lead to novel therapeutic approaches for reducing the risk of post-traumatic OA.

Comparative Clinical Trial of S-Adenosylmethionine Versus Nabumetone in the Treatment of Knee Osteoarthritis: An 8-Week, Multicenter, Randomized, Double-Blinded Study. Jin Hyun Kim[1], Eun Young Lee[1], Eun-Mi Koh[2], Hoon-Suk Cha[2], Bin Yoo[3], Chang Keun Lee[4], Yun Jong Lee[5], Heejung Ryu[5], Ki Hoon Lee[6] and Yeong Wook Song[1], [1]Seoul National University Hospital, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [4]University of Ulsan Collage of Medicine, Asan Medical Center, Seoul, South Korea, [5]Seoul National University Bundang Hospital, Seongnam, South Korea, [6]Jeonju University, Jeonju, South Korea

Purpose: S-adenosylmethionine (SAMe) has an anti-inflammatory and analgesic effect, and was reported to ameliorate pain and dysfunction of knee oteoarthritis (OA). We compared the efficacies and safeties of SAMe and nabumetone in Korean patients with knee osteoarthritis.

Method: This study was a multicenter, 8-week, randomized, double-blinded, double-dummy, phase IV clinical trial. Symptomatic OA patients were randomized to receive SAMe 400 mg three times a day or nabumetone 1000 mg once a day with dummy placebo for 8 weeks. The primary end point was patient assessment of pain intensity using a visual analog scale (VAS) and the secondary end points were an improvement of functional class, patient's global assessment of disease status, physician's global assessment of response to therapy, and WOMAC index. Efficacies after 4 and 8 weeks of treatment were evaluated between two groups, and all patients were evaluated for adverse events.

Results: One hundred and thirty four patients were randomly allocated to receive SAMe 400 mg (n=67) three times a day or nabumetone 1000 mg (n=67) once a day for 8 weeks. Twenty three patients in SAMe group and 14 patients in nabumetone group withdrew during the study. An analysis of changes in pain intensity between week 0 and week 8 demonstrated that SAMe and nabumetone were effective to decrease pain intensity in each group (mean ± SD, SAMe, 13.0 ± 20.8, p<0.001; nabumetone, 15.7 ± 20.9, p <0.001) and the difference in efficacy between two groups was not significant (p=0.451). The secondary end points showed the significant improvement between week 0 and week 8. The differences of efficacies in secondary endpoints between two groups were not significant (patient's general assessment of disease, p=0.276; physician's assessment of treatment response, p=0.140; WOMAC index, p=0.459). No significant differences between the incidences of drug-related clinical or laboratory adverse events were observed.

Conclusion: SAMe was found to be as effective as nabumetone and well tolerated by knee OA patients in Korea.

Alanine Aminotransferase (ALT) Activity During Early Acetaminophen Therapy in Patients with Osteoarthritis. Edwin Kuffner, Kimberly Cooper, Jeffrey Baggish, Joseph M. Lynch, Brenda Zimmerman and Anthony Temple, McNeil Consumer Healthcare, Fort Washington, PA

Purpose: Acetaminophen (APAP) is a first-line analgesic for the management of OA pain, recommended in the OA Guidelines of the American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR). Over-the-counter (OTC) analgesic labels instruct patients not to use these medications for pain for more than 10 days without consulting a doctor.

Some healthy volunteers given APAP 4000 mg/d for up to 2 wks were reported to have ALT elevations ›3 times upper limit of reference range (ULRR) which continued for several days after stopping therapy but then decreased. To determine whether this phenomenon was transient or persistent with the continued use of APAP, we retrospectively analyzed ALT data collected within approximately 2 wks of initiating therapy with the maximum recommended daily dose (MRDD) of APAP (3900-4000 mg/d) and determined elevated ALT and rates of resolution while the patients remained on APAP therapy.

Methods: 3 McNeil-sponsored, controlled OA trials included ALT measurements within approximately 2 wks of initiating APAP monotherapy. Patients with elevated ALT at screening or baseline were excluded from the analysis. Maximum ALT for each patient was stratified by degree of elevation: >ULRR, >1.5X ULRR, >3X ULRR, >5X ULRR, or ALT >3X ULRR and bilirubin ≥2X ULRR. Resolution of ALT elevation was defined as an ALT ≤ULRR after the last dose of study drug. If ALT at study completion was lower than the maximum ALT observed during the trial but >ULRR, the ALT elevation was considered to be decreasing.

Results: All trials had double-blind study designs and were at least 12 wks in duration. Patients in 2 placebo-controlled trials received extended-release APAP 3900mg/d; patients in the active-controlled trial received extra-strength APAP 4000mg/d. ALT remained within the normal range throughout the 2 wk analysis period for 376 (80.7%) of 466 patients. At some point during the 2 wk analysis period, 90 (19.3%) patients had an ALT >ULRR; 21 (4.5%) patients had an ALT >1.5X ULRR; and 4 (0.9%) patients had an ALT >3X ULRR. No patient had ALT >5X ULRR, or >3X ULRR with bilirubin ≥2X ULRR. No patient exhibited signs or symptoms of hepatotoxicity or hepatic failure. ALT resolution was observed for 62 (68.9%) of 90 patients with elevations and decreasing ALT was observed for 19 (21.1%) patients. Incidence of adverse events possibly of hepatic origin was similar between patients without and with elevated ALT during the 2 wk analysis period.

Conclusion: Fewer than 5% of OA patients taking the MRDD of APAP for 2 wks had elevated ALT (>1.5X ULRR). These elevated values resolved or were decreasing during continued APAP therapy in >95% of patients and were not accompanied by signs or symptoms suggestive of liver toxicity. These data show that while some individuals who take APAP may experience increased ALT during treatment that is consistent with OTC labeling, nearly all of these elevations resolved with continued APAP use.

835

A Walking Model of Osteoarthritis (OA) Knee Pain: A Double-Blind, Placebo-Controlled, 3-Period Crossover Study to Evaluate the Analgesic Effects of Naproxen and Tramadol/Acetaminophen in Patients with OA of the Knee. Elena Peeva[1], CR Beals[1], JA Bolognese[2], A. Kivitz[3], L. Taber[4], A. Harman[1], H. Chung[1], Steven S. Smugar[1] and Roland W. Moskowitz[5], [1]Merck & Co., Inc., Rahway, NJ, [2]Cytel, Inc., MA, [3]Altoona Arthritis & Osteo Ctr, Duncansville, PA, [4]Pivotal Research Ctrs, Peoria, AZ, [5]University Hospitals, Beachwood, OH

Purpose: New clinical trial designs for OA pain that can be conducted faster and with fewer patients would speed the testing of novel therapeutic agents. We developed a walking model of OA that takes advantage of the clinical observation that patients frequently report an increase in OA pain during and following exertion. The model is based on standardized series of controlled walks over a short period of time that are used to reproducibly elicit specific knee pain in patients with OA. The objective of this study was to validate the walking model in OA by evaluating the acute efficacy of an NSAID and a weak opiate in patients with OA.

Methods: Randomized, placebo-controlled, 3-period balanced cross-over study comparing naproxen 500 mg bid and tramadol/acetaminophen 37.5/325 mg per tablet in titration over a three day period to full dose (75/650 mg/mg) in patients ≥45 years with OA of the knee (N=21). Patients performed a set of standardized 20-minute treadmill walks at 2, 4, 5 and 6 hours post-drug administration on Day 1, and at 4, 5 and 6 hours post-dose on Day 3. The 2, 4 and 6-hour walks were identically paced at a speed set by the patient (self-pace) at pre-study; the 5-hour walks were at a pace 10-30% faster than the self-pace (high-pace). The primary endpoint was change from baseline in time-weighted average pain intensity (TWA PI), on a numerical scale from 0-10, for tramadol/acetaminophen and naproxen vs. placebo for the self-paced walks on Day 3. Time to moderate pain was also evaluated.

Results: Results are shown in the **Table**. For the primary endpoint of TWA PI change from baseline for self-paced walks on Day 3, the comparison was statistically significant for tramadol/acetaminophen ($p<0.05$), but not for naproxen ($p=0.089$). When excluding an outlier patient with PI increase >3 standard deviations above the mean PI, both tramadol/acetaminophen ($p<0.001$) and naproxen ($p<0.01$) were significantly more effective than placebo for the primary endpoint.

Conclusion: The walking model is a promising method for identifying acute treatment effects of drugs for OA pain.

Endpoint	**Tramadol/ acetaminophen**	**Naproxen**	**Placebo**
TWA PI change from baseline, self-paced walks Day 1	-1.5***	-1.0*	-0.4

Long-Term Tanezumab Use for Treatment of Moderate to Severe Osteoarthritic Knee Pain: An Open-Label Extension Study. Nancy E. Lane[1], Thomas J. Schnitzer[2], Charles A. Birbara[3], Michael D. Smith[4], Sue Simpson[4], Mark T. Brown[4] and Christina J. McManus[5], [1]Univ of California at Davis, Sacramento, CA, [2]Northwestern Univ, Chicago, IL, [3]Univ of Massachusetts, Worcester, MA, [4]Pfizer Inc., New London, CT, [5]UBC Scientific Solutions, Southport, CT

Purpose: Elevated nerve growth factor (NGF) levels in injured or inflamed tissue are associated with increased pain perception. Tanezumab, a humanized monoclonal antibody, inhibits NGF with high specificity and affinity. This open-label extension study (1009) following a Phase II, placebo-controlled, multiple-dose study (1008), was conducted to evaluate long-term use of tanezumab in patients with osteoarthritis (OA) of the knee. **Method:** Patients from 1008 who had received 2 infusions of tanezumab or placebo and were followed for ≥8 weeks after last infusion were eligible to enroll in 1009 at Week 16 of 1008. In 1009, all patients received tanezumab 50 µg/kg (IV) at Weeks 0 and 8 and subsequent 8-week intervals at the discretion of the investigator. Analyses included change from 1008 baseline in overall pain intensity in index knee, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) subscales, and Subject Global Assessment (SGA) all on 100 mm VAS scales, and Short-Form 36 (SF-36) general health status measure. **Results:** Similar numbers of patients from each of the 1008 treatment groups (placebo, tanezumab 10, 25, 50, 100, and 200 µg/kg) were enrolled in 1009 (n=281; 39% male, 89% white, mean age 59 [SD±8] years). Median duration of treatment was 198 days. Few patients (11%) discontinued due to lack of efficacy indicating that treatment had a persistent beneficial effect. Patients from 1008 placebo, 10 or 25 µg/kg groups reported improvement in overall pain intensity after switching to 50 µg/kg tanezumab (Table). In contrast, patients switched from higher doses of tanezumab (100 or 200 µg/kg) reported slightly decreased efficacy at Week 4, consistent with a reduction in tanezumab dose from 1008 to 1009. Mean pain scores between Wks 8-32 were similar regardless of treatment received in 1008. Similar trends were observed for SGA and WOMAC scores. No notable changes in SF-36 were found in 1009. The most frequently reported treatment-related AEs for 1009 were hypoesthesia, paraesthesia, dizziness, and peripheral edema. AEs of abnormal peripheral sensation, reported by 6% of subjects in 1009, were mostly rated as mild and were transient. Allodynia and dysesthesia were not reported. **Conclusion:** Repeated doses of 50 µg/kg tanezumab were generally safe and well tolerated. Persistent beneficial efficacy similar to that observed in study 1008 was demonstrated and maintained in OA patients over the long term.

Effect of Hypertensive Status and Antihypertensive Treatment-On Cardiovascular Outcomes in Patients Receiving Etoricoxib or Diclofenac: An Analysis of the MEDAL Program. A. Gammaitoni, Sean P. Curtis, A. Kaur, H. Wang, Q. Dong, Steven S. Smugar and Paul Peloso, Merck & Co., Inc., Rahway, NJ

Purpose: It has been postulated that excess CV events observed in patients receiving NSAIDs may be related to COX-2 mediated effects on blood pressure. In the MEDAL program, the rate of thrombotic CV events was similar between etoricoxib and diclofenac despite an ~2 mm Hg average increase in systolic BP (SBP) on etoricoxib. We previously found that CV events were significantly related to baseline SBP but not on-treatment change in SBP. ~26% of those assigned to etoricoxib and 20% of those on diclofenac had changes in BP treatment (new or added therapy) during the trial. Here we explore the effect of investigator management of hypertension (HTN) on confirmed thrombotic CV serious adverse experiences.

Method: Patients receiving etoricoxib or diclofenac were pooled (N=34,699) and classified by baseline HTN status (SBP≥140mmHg or DBP ≥90mmHg), baseline antihypertensive (antiHTN) drug use, and new antiHTN use or adjustment during the trial. Hazard ratios (HR) for the 8 possible categories of patients were calculated using a Cox proportional hazard model with terms for treatment, patient category, and stratification factors baseline aspirin use, protocol/disease status for confirmed thrombotic CV events within 14 days of therapy discontinuation.

Results: Results are shown in the Table. HRs for CV events were largest in patients with a diagnosis of pre-existing HTN, who used baseline antiHTN drugs and who also needed further BP medication adjustments during the trial. Patients who did not require on-treatment antiHTN adjustment had relatively lower HRs.

Conclusion: HTN at the baseline visit, or need for management of HTN throughout the trial was associated with higher CV event rates. Given our previous finding that short term changes in BP associated with therapy was a less relevant predictor, these data emphasize the need for close monitoring of blood pressure and adequate HTN management for patients receiving traditional NSAIDs or COX-2 inhibitors.

Table. Effect of baseline and on-treatment hypertensive status and antihypertensive use or adjustment on thrombotic CV events

Covariate			Relative Risk ‡	95% CI for Relative Risk	p-Value
Etoricoxib vs. Diclofenac			0.94	(0.81, 1.09)	0.402
Baseline hypertension*	Baseline antihypertensive use	On-treatment antihypertensive adjustment

The Comparative Safety of Analgesics in Older Adults with Arthritis. Daniel H. Solomon[1], Jeremy Rassen[2], Robert Glynn[2], Joy Lee[2], Raisa Levin[2] and Sebastian Schneeweiss[2], [1]Brigham & Women's Hospital, Boston, MA, [2]Pharmacoepidemiology, Boston, MA

Purpose: The safety of analgesics, such as nonsteroidal anti-inflammatory drugs (NSAIDs) and opioids has recently been called into question. However, there is little information on their comparative safety across a broad range of clinically morbid adverse events. We examined the comparative safety of non-selective (ns) NSAIDs, COX-2 selective NSAIDs (coxibs), and opioids.

Methods: We assembled a cohort of Medicare beneficiaries with diagnoses of osteoarthritis (OA) or rheumatoid arthritis (RA) who initiated an nsNSAID, coxib, or opioid. Participants were matched on a comprehensive propensity score, and hazard ratios (HRs) were calculated among propensity-matched cohorts. These analyses focused on morbid adverse events (AEs) commonly related to analgesics, including cardiovascular (CV) events (MI, stroke, HF, re-vascularization or cardiac death), gastrointestinal (GI) bleeding, and fractures (hip, wrist, humerus, and pelvis). Several global safety measures were assessed, including AE leading to hospitalization, AE leading to hospitalization and death, and all-cause mortality. Finally, the numbers needed to harm (NNH) with a coxib or opioid compared with an nsNSAID were calculated to observe one of these AEs at 30, 180, and 365 days.

Results: The average age of participants was 80 years, 84% were female, 89% had OA and the rest RA. After propensity score matching, the three analgesic cohorts were very well balanced on baseline covariates. Compared with nsNSAIDs, coxibs and opioids both exhibited elevated HRs for CV events (see **Table**). GI bleeding risk was similar for coxibs compared with nsNSAIDs and for opioids compared with nsNSAIDs. Coxib use had a similar risk for fracture as nsNSAIDs, however the HR was elevated with opioid use. Both coxibs and opioids increased the HR of AEs requiring hospitalization compared with nsNSAIDs. The HR for all-cause mortality was elevated for both coxibs and opioids compared with nsNSAIDs. At 30 days, the NNH to observe an excess fracture for treating with an opioid compared with nsNSAIDs was 43 (95% 35 – 54). The NNH at 30 days to observe an excess death was 114 (95% CI 78 – 212) for an opioid versus an nsNSAID. At 365 days, the NNH to observe an excess AE leading to hospitalization was 31 (95% CI 18 – 122) for an opioid and 35 (95% CI 20 – 135) for a coxib compared with nsNSAID.

Conclusion: In this non-randomized analysis, the comparative safety of analgesics varies depending on the specific AE. On balance, coxibs and opioids exhibit an increased hazard ratio for many AEs and for several global measures of safety as compared with nsNSAIDs. The NNH suggest that the risks observed are clinically relevant.

Table: Hazard Ratios (95% CIs) for Major Adverse Events Among Propensity Matched Cohorts

	nsNSAIDs	Coxibs	Opioids
Any cardiac	1.00	1.32 (1.06-1.66)	1.50 (1.19-1.91)
Any GI bleed	1.00	0.92 (0.58-1.45)	0.89 (0.53-1.47)
Any fracture	1.00	0.98 (0.64-1.49)	4.91 (3.47-6.96)
Any hospitalized AE	1.00	1.22 (1.00-1.49)	1.48 (1.21-1.82)
Hospitalized AE leading to death	1.00	1.59 (0.92-2.77)	1.43 (0.78-2.62)
All-cause mortality	1.00	1.37 (1.03-1.83)	2.12 (1.58-2.83)

Biochemical Markers of Bone and Cartilage Remodelling: Interest in the Prediction of Lumbar Disc Degeneration Progression and Effects of Strontium Ranelate Over a 3-Year Period. Olivier Bruyere[1], Julien Collette[1], Rita Deroisy[1], Véronique Rabenda[2], Audrey Neuprez[1], Mickaël Hiligsmann[2] and Jean Y. Reginster[1], [1]University of Liege, Liege, Belgium, [2]University of Liège, Liège, Belgium

Purpose: We previously reported that strontium ranelate could prevent lumbar spinal osteoarthritis (OA) progression in postmenopausal osteoporotic women with prevalent lumbar disc degeneration (LDD). The aim of the present analysis is to assess (1) the effect of strontium ranelate on biochemical markers of bone and cartilage remodelling in patients with prevalent LDD and (2) if the baseline value or the short-term changes in these markers were associated with the progression of LDD.

Method: This study is a post-hoc analysis of the SOTI and TROPOS trials including osteoporotic women with prevalent LDD treated for 3 years with strontium ranelate or placebo. Four biochemical markers were assessed at baseline, after 3, 6, 12, 24 and 36 months of follow-up: serum CTX I, urinary CTX II, serum COMP, and serum YKL-40. At baseline and 3 years, four lumbar inter-vertebral spaces were evaluated for the presence and severity of osteophytes, disc space narrowing and sclerosis, leading to the calculation of a global LDD score for each intervertebral space.

Results: 1105 patients completed the study. In the placebo group (n=539), the level of u-CTX II was highest in women with prevalent LDD compared to women without LDD (p=0.0003). However, the levels of s-CTX I, COMP and YKL-40 were not significantly different between patients with prevalent LDD compared to patients without LDD. Out of these 539 placebo-treated patients, 17.1% experienced a disease progression (i.e. the global LDD score increased by at least one grade of severity (in one or more intervertebral spaces) during the 3-year follow-up period). There were no significant differences in the baseline level of the biochemical markers between patients with and without LDD progression. However, patients with a progression of the disease experienced a decrease in COMP of 1.6 (10.5) % after 3 months compared to an increase of 1.9 (12.7) % in patients without LDD progression (p=0.04). The 3-month changes in the other biochemical markers were not predictive of the progression of the disease in the placebo group. After 3 months of treatment, strontium ranelate was able to significantly decrease, compared to placebo, the level of s-CTX I (p<0.001) and u-CTX II (p<0.001). Strontium ranelate also increases, compared to placebo, the level of COMP (p<0.001). However, no significant effect on YKL-40 was observed. During the 3 years of follow-up, the same trends were observed.

Conclusion: The positive effect of strontium ranelate on LDD progression could be partly explained by the observed decrease in bone (s-CTX I) and cartilage (u-CTX II) resorption. The exact clinical interest of COMP change must be further evaluated as a recent study has shown that a decrease of COMP, previously suggested as being a markers of cartilage destruction, was associated with an increased risk of OA progression.

Safety and Efficacy of Diclofenac Sodium Gel for Knee Osteoarthritis in Patients Aged <65 Years Versus ≥65 Years. Roy Altman[1], F. Michael Gloth[2], Morris S. Gold[3] and Richard Petruschke[3], [1]University of California, Los Angeles, CA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Novartis Consumer Health, Inc., Parsippany, NJ

Purpose: Evaluate the efficacy and safety of topical diclofenac sodium 1% gel (DSG) vs vehicle (placebo) in subjects with knee osteoarthritis (OA) aged <65 years vs subjects aged ≥65 years.

Method: This was an analysis of pooled data from three 12-week, randomized, double-blind, parallel-group, multicenter trials comparing DSG with vehicle in patients (aged ≥35 y) with mild to moderate (Kellgren-Lawrence grade 1–3) knee OA. After a 1-week analgesic washout, patients applied DSG 4 g or vehicle 4 times daily to 1 knee. Rescue acetaminophen ≤4 g/d was allowed. Efficacy outcomes common to the 3 trials were the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale (0–20) and physical function subscale (0–68), a global rating of disease (GRD; 100-mm Visual Analog Scale [VAS]), and pain on movement (POM; 100-mm VAS). Analysis of variance (ANOVA) was used to compare efficacy outcome differences by age (<65 y vs ≥65 y). All adverse events (AEs) were recorded.

Results: A total of 602 subjects aged <65 y and 374 subjects ≥65 y were randomized. Among patients <65 y, at 12 weeks, all efficacy outcome scores were significantly superior (lower) with DSG (LS mean DSG [SE]) versus vehicle (LS mean vehicle [SE]): WOMAC pain (6.4 [0.3] vs 7.4 [0.3], *P*=0.007), WOMAC physical function (22.1 [0.9] vs 25.9 [0.9], *P*=0.002), GRD (33.0 [1.6] vs 38.7 [1.7], *P*=0.01), and POM (37.5 [1.8] vs 45.8 [1.8], *P*<0.001). Among subjects aged ≥65 y, most efficacy outcome scores were significantly superior (lower) with DSG versus vehicle: WOMAC pain (6.9 [0.3] vs 8.0 [0.4], *P*=0.02), WOMAC physical function (24.5 [1.1] vs 29.1 [1.1], *P*=0.004), and POM (41.1 [2.2] vs 48.4 [2.2], *P*=0.02), but the difference in GRD (38.8 [2.0] vs 43.8 [2.1]) was not statistically significant (*P*=0.07). Efficacy of DSG did not differ significantly between patients aged ≥65 y and <65 y: WOMAC pain (*P*=0.85), WOMAC physical function (*P*=0.70), GRD *P*=0.86), (POM (*P*=0.81). In both younger and older groups, more subjects treated with DSG (56.6% and 55.8%, respectively) than placebo (50.8% and 43.9%) had ≥1 AE. Application site reactions were more common with DSG compared with vehicle in both younger (5.6% vs 1.8%) and older (8.8% vs 1.1%) subjects. Gastrointestinal AEs were infrequent and similar to placebo in both age groups. 1 serious AE (deep vein thrombosis/pulmonary embolism) in an 80-year-old woman was considered possibly related to treatment. The event was mild and managed successfully with medication. Patients in each age group applied >90% of scheduled doses.

Conclusion: DSG was effective and generally well tolerated regardless of age. These data support the topical application of DSG for relief of arthritic knee pain in seniors and younger patients.

The Effect of Intraarticular Injection Devices On Outcomes of Osteoarthritis of the Knee: A Pilot Study. Suzanne Delea[1], Kye S. Park[1], Natalia Chavez[1], Philip A. Band[2], Wilmer L. Sibbitt Jr.[1] and Arthur D. Bankhurst[3], [1]University of New Mexico, Albuquerque, NM, [2]New York University Medical Center, New York, NY, New York, NY, [3]University of NM Med Ctr, Albuquerque, NM

Purpose: True intraarticular positioning of the needle tip is considered important for outcome of intraarticular injections; however, there are few studies demonstrating that technologies that improve needle positioning actually improve injection. The present pilot study investigated whether devices that facilitate accurate placement of the needle affect the outcomes of intraarticular injections of the osteoarthritic knee.

Method: 128 subjects with primary osteoarthritis of the knee were randomized to intraarticular corticosteroid injection (triamcinolone acetonide) with standard syringe or the reciprocating procedure device (RPD), a new safety procedure syringe. Primary outcome measures included baseline pain, procedural pain, and pain at outcome (2 weeks post-injection and 6 months post-injection) as measured by the 0 to 10 cm Visual Analogue Pain Scale (VAS) and well as secondary outcome measures.

Results: Significant reductions in pain scores following intraarticular injection occurred with both devices at 2 weeks (Syringe: 63.7±38.2% VAS reduction from baseline, $p < 0.0001$; RPD: 80.0±30.4%, $p < 0.0001$) and 6 months (Syringe: 16.7±49.4% VAS reduction from baseline, $p < 0.004$; RPD: 30.5±58.8%, $p < 0.0001$). However, relative to the conventional syringe, the RPD procedure syringe provided a 37.2% greater reduction in procedural pain ($p = 0.005$), a 53.8 percent reduction in significant procedural pain (VAS ≥ 5 cm) ($p = 0.016$), and a 109.7% increase in aspirated fluid volume. At the 2 week outcome, relative the conventional syringe, the RPD group demonstrated 43.1% less joint pain (RPD VAS: 1.40±2 cm.11, Syringe VAS: 2.46±2.48, $p = 0.04$), a 25.6% greater reduction in VAS score from baseline (RPD: 80.0±30.4%, Syringe VAS: 63.7±38.2%, $p = 0.025$), 76.4% more asymptomatic individuals (VAS ≤ 1 cm) (RPD: 65.1% (41/63); Syringe: 36.9% (24/65), $p = 0.005$), 26.7% fewer non-responders (VAS ≥ 2 cm) (RPD: 34.9% (22/63); Syringe: 47.6% (31/65), $p = 0.005$), and a longer duration of therapeutic effect (RPD: 4.43±2.00 months, Syringe: 3.16±2.18 months, $p = 0.006$). As expected pain scores at the 6 month outcome were not significantly different between the two syringe treatment groups ($p = 0.11$).

Conclusion: The present study demonstrates that intraarticular injection technologies that permit more accurate placement of the procedure needle significantly improve the outcomes of intraarticular injections for osteoarthritis of the knee**.**

PN400 Significantly Reduces the Incidence of Gastric Ulcers Compared with Enteric-Coated Naproxen in Patients Requiring Chronic NSAID Therapy Regardless of Low-Dose Aspirin Use: Results From Two Prospective, Randomized Controlled Trials. Jay L. Goldstein[1], Marc C. Hochberg[2], John G. Fort[3], Ying Zhang[3], Mark Sostek[4] and Lynsey Stevenson[5], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Maryland School of Medicine, Baltimore, MD, [3]POZEN Inc., Chapel Hill, NC, [4]AstraZeneca, Wilmington, DE, [5]Complete Medical Communications Ltd, Glasgow, United Kingdom

Purpose: Co-therapy with proton pump inhibitors reduces the risk of NSAID-associated ulcers but, in practice, adherence is often sub-optimal, leading to poor long-term clinical outcomes (Van Soest et al. *Aliment Pharmacol Ther* 2007;26:265-275). Two Phase 3 studies evaluated the upper gastrointestinal (UGI) efficacy and safety of PN400, a fixed-dose combination tablet designed to provide sequential delivery of immediate-release (IR) esomeprazole (20 mg) and enteric-coated (EC) naproxen (500 mg), compared with EC naproxen (500 mg) alone in at-risk patients.

Method: Two randomized, double-blind, controlled, multicenter studies enrolled *H. pylori*-negative patients with OA, RA, or any other condition requiring chronic NSAID therapy at risk of ulcers (age ≥50 yrs or 18-49 yrs with a history of gastric ulcer [GU] or duodenal ulcer [DU] within the past 5 yrs). Patients were randomized to PN400 BID or EC naproxen 500 mg BID for 6 months. The primary endpoint was the cumulative incidence of GUs (≥3 mm diameter with depth) observed by endoscopy at 1, 3, and 6 months. A planned pooled analysis to assess the effect of low-dose aspirin use (LDA ≤325 mg) on GU incidence, and an analysis of pre-specified NSAID-associated UGI AEs (including DU) were also conducted.

Results: Study A: 438 patients were randomized, 434 were treated; Study B: 423 patients were randomized, 420 were treated. Baseline demographics were similar between groups in both studies. Approximately 82% of patients had OA and 6% had RA. In both studies, the incidence of GUs over 6 months was significantly lower in the PN400 groups vs the EC naproxen groups (Table). The pooled incidence of GUs was significantly lower in the PN400 group vs the EC naproxen group in LDA users (n=201) (3.0% vs 28.4%, p<0.001) and non-users (n=653) (6.4% vs 22.2%, p<0.001). The previously described pre-specified secondary endpoint was significantly lower in the PN400 groups (Table).

Conclusion: PN400 significantly reduces the incidence of GUs, regardless of concomitant LDA use, and DUs in at-risk patients. PN400, a fixed-dose combination of EC naproxen 500 mg and IR esomeprazole 20 mg, provides built-in gastroprotection and offers a treatment option for decreasing NSAID-ulcer occurrence in an appropriate target patient population.

Analgesic Effects of Intra-Articular Botulinum Toxin Type B (BoNT B) in a Murine Model of Chronic Degenerative Knee Arthritis Pain. Stephanie R. Anderson[1], Pari McGarraugh[2], Sandra Frizelle[2], Hollis E. Krug[2] and Maren L. Mahowald[1], [1]U of MN, Mpls, MN, [2]VAMC, Mpls, MN

Purpose: Studies have shown joint inflammation may cause peripheral and central sensitization of neurons leading to spontaneous joint pain at rest and hyperalgesia with stimulation. Inflammatory mediators induced by neuropeptide release activate peripheral nerve receptors. Given this peripheral sensitization we hypothesize arthritis pain may be treated by intra-articular (IA) neurotoxins. Efficacy of IA botulinum toxin (BoNT) Type A for refractory arthritis pain has recently been reported, prompting interest in screening other botulinum toxins that may prove more effective for arthritis pain. BoNT B may produce greater pain relief and may be effective in different types of pain than BoNT A. We hypothesized that BoNT B would reduce chronic arthritic knee pain and tested this hypothesis in a murine model of chronic degenerative arthritis.

Method: Chronic arthritis was produced in 12 C57Bl6 mice by IA injection of 10 IU Collagenase. BoNT B (MYOBLOC) 0.02 was given IA in the left knee 3 days before testing. Normal right knee served as internal control. Mice were studied before, after induction of arthritis and after IA BoNT B. Video gait analysis was performed using Treadscan™ hardware and software.Evoked pain behavior was measured by tallying fights + vocalizations/1 min in response to repeated firm palpation of the knee. Gait and strength were observed visually and graded. Strength was measured as ability to grasp and cling. Student's t-test was used for statistical comparisons.

Results:

	BASELINE Mn (SEM)	**ARTHRITIC** Mn (SEM)	*P* c/w Baseline	**TREATED** Mn (SEM)	*P* c/w Arthritic
Gait	3.50 (.17)	2.08 (.14)	**0.0001**	3.33 (.15)	**<0.0001**
Evoked Pain Response	1.83 (.81)	5.50 (1.14)	**0.0009**	3.58 (.87)	0.21
Variability in Stance/Stride	.102 (.007)	.126 (.009)	**0.003**	.099 (.006)	**0.02**
Variability in Lt Rear Propel time	62.8 (4.36)	75.0 (2.49)	**0.02**	63.7 (3.36)	**0.02**
Variability in Rear Tract Width	2.76 (.26)	3.37 (.28)	**0.03**	2.55 (.19)	**0.02**
Grasp	3.83 (.07)	2.54 (.38)	**0.007**	3.12 (.16)	0.11
Cling	3.66 (.13)	2.7 (.37)	**0.04**	3.04 (.27)	0.53

Conclusion: Chronic degenerative arthritis pain can be quantitated in a murine model using visual and computerized gait analysis, and evoked pain scores. Visual and computerized gait analysis both showed a significant impairment in gait in arthritic mice, improving after IA BoNT B suggesting a substantial analgesic effect. Evoked pain responses increased overall with arthritis, decreasing with IA BoNT B, but not reaching statistical significance in this small sample.

These results support the hypothesis that chronic arthritis pain is amplified by neuropeptide release in the periphery due to efferent neurogenic signals. Interruption of neuropeptide release by IA BoNT B appeared to decrease pain behaviors and improve gait abnormalities. No limb weakness was noted. These results support further investigation of this novel approach to treatment of arthritis pain with IA neurotoxin.

Intra-Articular Injection (Tribosupplementation) with Native and Recombinant Lubricin (PRG4) Prevents Cartilage Degeneration in the Rat ACL Injury Model. Gregory D. Jay[1], Raphael Nir[2], Bryn Watkins[3], Karen McHugh[3], Scott Anderson[3], Braden C. Fleming[4], Ling X. Zhang[1], Erin Teeple[5], Kimberly Waller[6] and Khaled A. Elsaid[1], [1]Rhode Island Hospital Department of Emergency Medicine, Providence, RI, [2]SBH Sciences, Natick, MA, [3]Biomodels, Inc., Watertown, MA, [4]Division of Orthopaedics, The Warren Alpert School of Medicine at Brown University, Providence, RI, [5]Division of Orthopaedics The Warren Alpert School of Medicine at Brown University, Providence, RI, [6]Brown University-Department of Engineering, Providence, RI

Purpose: To determine if cartilage degeneration is prevented or minimized in a rat ACL transection (ACLT) model following intra-articular injection of human synovial fluid lubricin (HSFL), recombinant human lubricin (rhLub) or human synoviocyte lubricin (SynL).

Method: Surgical transection of the ACL of the right knee was performed on 19 eight week old Lewis rats. The rats were sacrificed on post-operative day 32. Intra-articular injections of HSFL from patients undergoing knee reconstructive surgery, rhLub expressed in Chinese hamster ovary cells or SynL from human synoviocyte culture began on post-operative day 7. Injection of lubricin was at a concentration of 200µg/ml in a 40µl volume and was repeated twice weekly for a total of 7 injections. Histology was scored using OARSI modified Mankin criteria by investigators blinded to treatment group. Collagen type II degradation epitope (CTX-II) was assayed in lavaged synovial fluid by ELISA (Cartilaps, Nordic BioSciences).

Results: ACLT joints receiving SynL demonstrated significantly lower OARSI histology scores 2.7 ± 2.3 than both the untreated ACLT joints 5.4 ± 1.9 (p =0.03) and placebo (PBS) treated ACLT joints 5.5 ± 1.8 (p=0.05). Both rLub and HSFL also demonstrated lower OARSI scores 3.8 ± 2.2 and 2.8 ± 1.9 but were not statistically significant. Joints which were chondroprotected by any lubricin showed more Safranin O staining in the superficial and intermediate zone and smoother articular surfaces. Immunostaining for lubricin showed preservation of lubricin expressing superficial zone chondrocytes across the three lubricins. SF lavage CTX-II concentration in PBS treated joints was 608±303 pg/ml compared with 226 ± 152 in SynL, 347 ± 213 in HSFL, 260 ± 72 in rhLub and 1100 ± 154 in untreated joints. CTX-II levels in SynL-treated joints were significantly lower (p=0.045) than CTX-II levels in PBS-treated joints, while HSFL and rhLub treatments did not result in significant differences in CTX-II levels compared to PBS. Only joints receiving any lubricin showed reactivity with mAb 3B3(-) in peri-cellular areas of chondrocytes, indicating the presence of non-sulphated isoforms of chondroitin-6-sulphate which is consistent with repair activity.

Conclusion: Intra-articular injection of lubricin prevents cartilage degeneration in the rat ACLT model and may promote repair activity. The practice of tribosupplementation with lubricin may be translatable to humans.

The Effect of Glucosamine On Glucose Metabolism in Humans: A Systematic Review of the Literature. Nathaniel Dostrovsky[1], Tanveer E. Towheed[2], Robert W. Hudson[2] and Tassos P. Anastassiades[3], [1]Queen's University, Internal Medicine Training Program, Kingston, ON, [2]Queens Univ, Kingston, [3]Etherington Hall Rm 2050, Kingston, ON

Purpose: Glucosamine (GlcN) is a commonly used nutraceutical for the treatment of osteoarthritis. There is concern from animal experiments that GlcN may alter glucose metabolism through the hexosamine biosynthetic pathway.

Method: An English-language literature search of MEDLINE, EMBASE and EBM Reviews (1950 – December 2008) was conducted for studies that evaluated the effect of exogenous GlcN on glucose metabolism in humans. The bibliographies of selected papers were manually searched for additional references. All types of study designs published in English language, peer-reviewed journals were included. Unpublished data as well as animal studies were excluded. Two reviewers independently analyzed studies for quality and content using a standardized data extraction form.

Results: 11 studies were found which met our inclusion and exclusion criteria. Six studies were randomized controlled trials and the remaining 5 were prospective studies with or without controls. Six of the studies used GlcN sulphate, two used GlcN hydrochloride and three did not report the type of GlcN used. Two studies included diabetic subjects and seven included obese subjects. Overall, 4 out of the 11 studies demonstrated decreased insulin sensitivity or increased fasting glucose in subjects taking GlcN. More studies using glucose

tolerance tests and composites of fasting insulin and glucose detected an effect on glucose metabolism than those using fasting insulin, fasting glucose or hemoglobin A1c (see table 1).

Conclusion: Four out of 11 studies detected decreased insulin resistance or increased fasting glucose in humans taking GlcN while seven studies did not. Differences in subject characteristics, type of GlcN and study design do not explain this discrepancy. Thus, research to date suggests GlcN may have a clinically relevant effect on glucose metabolism in humans. Additional studies are needed which include subjects with diabetes or risk factors for diabetes and that use sensitive methods to measure glucose metabolism before a firm conclusion can be made.

Table #1: Tests of glucose metabolism and study outcome

	# Studies	# Positive[1]
Fasting glucose	10	0
Fasting insulin	9	1 (11%)
Hemoglobin A1c	4	0
Oral glucose tolerance test	2	1 (50%)
Intravenous glucose tolerance test	2	1 (50%)
Composites of fasting glucose and fasting insulin[2]	3	2 (66%)
Hyperinsulinemic- Isoglycemic Glucose Clamp	3	0

[1] Demonstrated an effect of glucose metabolism

Effectiveness of Pulsed Electrical Stimulation in the Treatment of Osteoarthritis of the Knee: a Randomized Controlled Trial. RE Fary[1], Graeme Carroll[2], TG Briffa[3] and NK Briffa[4], [1]School of Physiotherapy, CHIRI, Curtin University of Technology, Bentley, Australia, [2]Arthrocare, Mt Lawley, Australia, [3]University of Western Australia, Nedlands, Australia, [4]Curtin Health Innovation Research Institute, Curtin University of Technology, Bentley, Australia

Purpose: Evidence suggests that short term, sub-sensory, pulsed electrical stimulation (PES) is effective in reducing OA knee pain. The purpose of this study was to examine its effectiveness over a longer duration.

Method: A double-blind, randomized, placebo-controlled, repeated measures trial was conducted to examine the effectiveness over 26 weeks of sub-sensory PES in people with OA of the knee. The trial was registered (ANZCTR: ACTRN12607000492459) and conformed to CONSORT guidelines for clinical trials. Seventy people (mean age 70 years, 53% male) with clinician diagnosed (100%) and radiologically confirmed (91%) OA knee were randomized to either active treatment or placebo, stratified for age, gender and baseline pain levels. PES electrodes were worn inside a neoprene brace. Participants were directed to wear the device for $\geq$ 7 hours/day, usually overnight, for 26 weeks. The primary outcome measure was change in pain (100mm VAS) from baseline to 26 weeks. Secondary outcome measures included pain (WOMAC 3.1), function (WOMAC 3.1), stiffness (WOMAC 3.1), total WOMAC score, patient global assessment - PGA (100mm VAS) and quality of life (SF-36). These outcomes were measured at baseline, 4, 16 and 26 weeks. Physical activity (Human Activity Profile and accelerometer) were measured at baseline and 16 weeks. A patient global perceived effect scale (11-point Likert) was completed at 16 and 26 weeks.

Results: Both groups achieved statistically significant improvement in pain VAS ($p \leq 0.001$) but there was no difference between the groups ($p = 0.89$). Similarly no difference was noted between the groups in WOMAC pain ($p = 0.23$), stiffness ($p = 0.45$), function ($p = 0.62$), WOMAC total score ($p = 0.74$), PGA ($p = 0.62$), SF-36 physical and mental component scores ($p = 0.29$, $p=0.55$, respectively), from

baseline to 26 weeks. Similarly there was no difference between groups at baseline and 16 weeks in any activity measure ($p > 0.16$). More participants in the treatment group achieved the minimal clinically important improvement (MCII) in pain VAS of 19.9 (treatment 56%: placebo 44%) but the difference between the two groups was not significant ($p = 0.47$). Similarly there was no difference in the proportions of those achieving the MCII in WOMAC function of 9.1 ($p = 1.00$) and PGA of 18.3 ($p = 0.78$). Results were unaffected after adjustment for age, gender, BMI and radiological disease severity.

Conclusion: Sub-sensory PES over 26 weeks did not improve symptoms of OA knee. However, given that baseline mean scores for pain and function were of only moderate severity and that more than 90% of participants achieved recommended activity levels, our findings do not preclude the possibility of PES providing clinically meaningful improvements in samples with other characteristics.

Disclosure: R. Fary, None; **G. Carroll**, None; **T. Briffa**, None; **N. Briffa**, None.

847

Evaluation of the Structure-Modifying Effect of Avocado-Soybean Unsaponifiables (ASU) in Hip Osteoarthritis (OA): Results of the ERADIAS Study, a 3-Year, Prospective, Randomized, Double-Blind, Placebo Controlled Trial. E. Maheu[1], C. Cadet[2], M. Marty[3], D. Moyse[4], I. Kerloch[5], P. Coste[5], M. Dougados[6], B. Mazières[7], TD. Spector[8], E. Vignon[9], Jm. Grouin[10] and M. Lequesne[11], [1]Saint Antoine Hospital - AP-HP, Paris, France, [2]Cabinet médical, Paris, France, [3]Henri-Mondor Hospital, Creteil, France, [4]DM Consultant, Tours, France, [5]Expanscience Labs, Courbevoie, France, [6]Hospital Cochin, Descartes Univ, Paris, France, [7]CHU Larrey, Toulouse, France, [8]St Thomas Hospital, London, United Kingdom, [9]Claude Bernard University, Lyon, France, [10]Rouen University, Rouen, France, [11]Rheumatology, Paris

Purpose: To assess the long-term ability of ASU to slow radiographic progression in symptomatic Hip OA.

Method: This was a prospective, randomized, double-blind, placebo-controlled 3-year trial. Symptomatic patients (pain ≥ 1 year, Lequesne index ≥ 3), aged ≥ 45 years, with primary hip OA fulfilling the ACR criteria, and a minimum joint space width (JSW) of the target hip between 1 and 4 mm on a pelvic radiograph were randomized into 2 strata (baseline JSW: < 2.5 or ≥ 2.5 mm) and assigned to receive either ASU 300 mg or placebo once daily. 3 standing radiographs were taken annually: pelvis, target hip anteroposterior (AP), and oblique views. JSW was measured at the narrowest point on pelvic or target hip AP view by manual measurement using a 0.1 mm-graduated magnifying glass. This method was deemed the most sensitive to change in a pilot study and the best of 2 readers was selected prior to unblinding. The primary outcome was based on the change in the narrowest JSW over 3 years. *Statistics:* All patients having at least 2 radiographs of the same view were included in the Full Analysis Set (FAS). An Analysis of Covariance Mixed Model for Repeated Measurements (MMRM) was performed and Missing At Random used to handle missing data. The minimum JSW change was compared between groups by both a continuous approach: 3-year JS narrowing mean in millimeters and a comparison of the percentage of "progressors" defined by a JSW loss ≥ 0.5 mm (based on the smallest detectable change of the reader).

Results: 499 patients were selected, 399 randomized, 345 in the FAS (166 ASU and 179 placebo). Baseline demographic and hip OA characteristics were similar in the 2 groups. Patients were aged 62 (8) years, 54% women, mean BMI 27 (4), 0-100 normalised Lequesne index 30 (9), VAS global pain 37 (23) mm. Mean baseline JSW was 2.8 (0.9) mm in both groups. 166 patients discontinued the study (41%), 55% of these for lack of efficacy.

Mean JSW change and % of progressors at year 3 are below.

	% progre	**ssors**		**Mean JSW**	**change (sem)**	
Group	ASU	Placebo	*P*	ASU	Placebo	*P*
Total	40%	50%	0.039 *	- 0.64 (0.07)	- 0.67 (0.06)	0.72 #

sem: standard error of the adjusted mean in the MMRM Model ; *: Cochran-Mantel-Haenszel Test p-value ; #: t-test p-value in the MMRM

Although no significant intergroup difference was observed on JSW change, the number of progressors was 20% lower in the ASU group ($p = 0.039$). ASU had no evident effect on the symptoms in this study.

Conclusion: This study shows that 3-year treatment by ASU appears to reduce the percentage of JSW deteriorating patients compared to placebo, indicating a potential structure-modifying effect of ASU in progressive hip OA. The clinical relevance of these encouraging radiographic results requires further assessment.

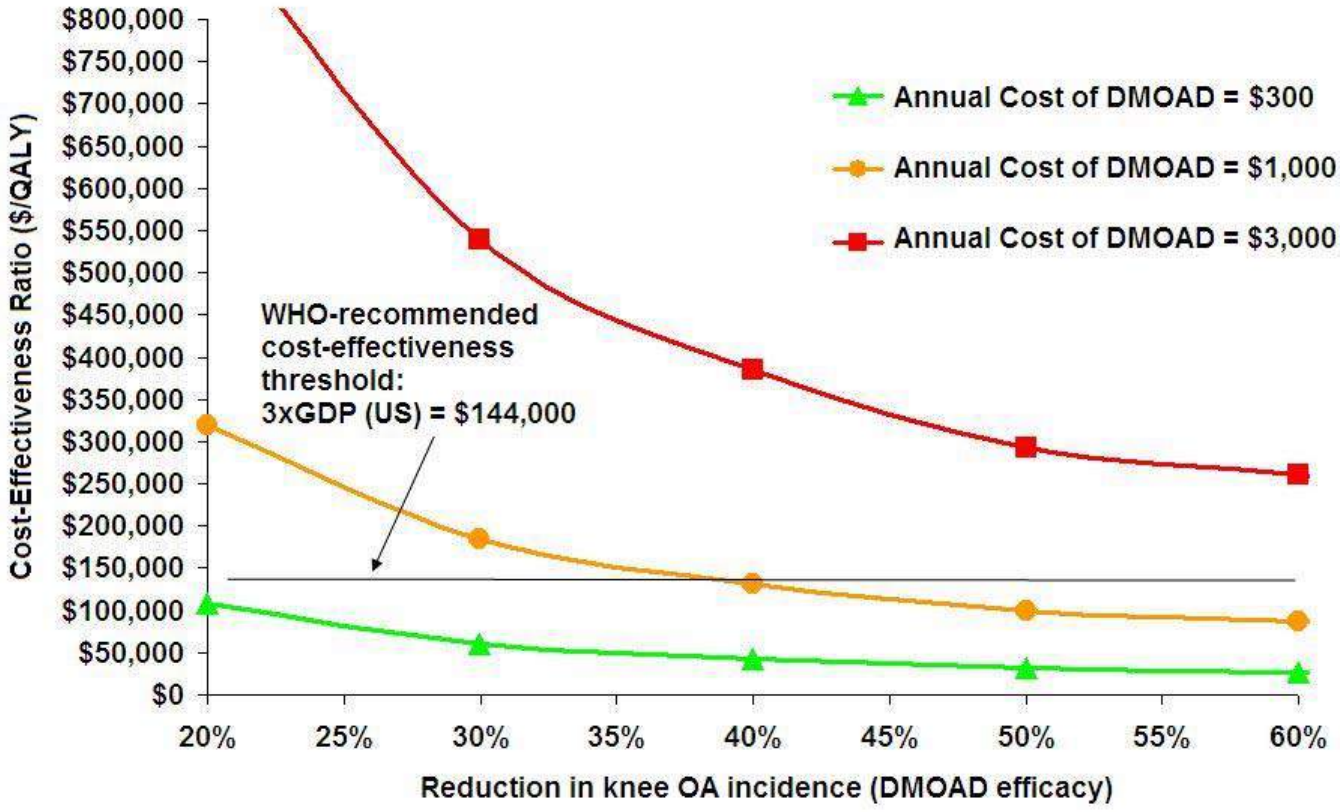
Disease Modifying Drugs to Prevent Knee OA: Can They Be Cost-Effective? E. Losina[1], H. Gerlovin[2], H.L. Holt[2], L.G. Suter[3], D.J. Hunter[4], N.N. Niu[5], D.H. Solomon[2], R.P. Walensky[6], A.D. Paltiel[7] and J.N. Katz[5], [1]Brigham and Women's Hospital, BU School of Public Health and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Yale University and VA Healthcare System, New Haven, CT, [4]New England Baptist Hospital, Boston, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [6]Brigham and Women's Hospital and Massachusetts General Hospital, Boston, MA, [7]Yale University, New Haven, CT

Purpose: In theory, disease modifying osteoarthritis drugs (DMOADs) will slow structural change and thus may be used to prevent or delay incident knee osteoarthritis (OA). We sought to determine the efficacy and cost thresholds under which DMOADs would be cost-effective as knee OA prophylaxis.

Method: We used a validated computer simulation model of knee OA to examine costs and effectiveness of DMOADs as knee OA prevention. We considered three cohorts: 1) General population, 2) High-Risk (1 risk factor, e.g. obesity, relative rate [RR] for knee OA 2.8), 3) Highest Risk (2 risk factors, e.g. obesity and history of knee injury, RR 7.4). We introduced prophylactic DMOADs at the time of entry to the model (mean age 58 ± 8 years, knee OA free). We examined DMOAD characteristics along two domains: efficacy (defined as reduction in knee OA incidence) and cost. We varied DMOAD efficacy across a wide range from 20 -- 60% and considered costs from $300 -- $3,000/year. We assumed DMOAD toxicity similar to NSAID toxicity. Cost-effectiveness (C-E) was estimated as the ratio of incremental costs to incremental effectiveness (difference in quality-adjusted life years, QALYs). Both costs and QALYs were discounted at 3% per

Figure. Cost-effectiveness of DMOAD prophylaxis for the Highest Risk Cohort



Results: In the General population, 10-year cumulative incidence of knee OA decreased from 16.7% (no prophylaxis) to 14.3 -- 10.3% for DMOAD efficacies ranging from 20 -- 60%. DMOAD prophylaxis in this population increased costs and either decreased QALYs (efficacy <40%) or led to negligible improvement in QALYs (efficacy ≥40%), resulting in incremental cost-effectiveness ratios (ICER) >$500,000/QALY, under all cost scenarios. In the High-Risk cohort, 10-year cumulative incidence decreased from 39.0% (no prophylaxis) to 34.5 -- 25.5%. In this population, ICERs <3xGDP were obtained only when DMOAD efficacy was ≥40% and cost was $300/year or when DMOAD efficacy was >50% and cost was $500/year. For the Highest Risk cohort, 10-year cumulative incidence changed from 76.3% (no prophylaxis) to 69.9 -- 49.4%. ICERs for DMOAD-based prophylaxis in the Highest Risk group are presented in the Figure, showing that DMOADs costing >$3,000/year have ICERs >$200,000/QALY regardless of efficacy.

Conclusion: Using DMOADs for preventing or delaying knee OA may improve quality adjusted life expectancy at cost-effectiveness levels comparable to other accepted therapies in persons at high risk of developing knee OA. DMOADs priced at $2,000/year or higher are unlikely to be cost-effective by current US standards, even for Highest Risk groups.

849

Variations of Responders Rates According to Response Criteria Used in a Randomized Controlled Trial (RCT) in Knee Osteoarthritis (OA). E. Maheu[1], Mohammed Zaïm[2], François Aubin[3] and Francis Berenbaum[4], [1]Saint Antoine Hospital - AP-HP, Paris, France, [2]Pierre Fabre Laboratories, Ramonville, France, [3]Cardinal System, Paris, France, [4]Faculty of Medicine P&M Curie, Paris, France

Purpose: The results of clinical trials in OA are usually reported as group comparisons of the mean (+/- standard deviation, sd) in score of the selected outcome. It might be more clinically relevant to show the results at a patient level, using a response criterion. Several response criteria are available: OARSI/OMERACT modified set of responder criteria (1), the Patient Acceptable Symptom State (PASS) (2) and the Minimum Clinically Important Improvement (MCII) (3).

Objectives: To assess differences in responder rates using various response criteria in a RCT in knee OA.

Method: Data were extracted from a prospective, multicentre, double-blind RCT comparing two hyaluronans over 24 weeks (F60027-Structovial and Hylan G-F 20-Synvisc) according to a non inferiority design. The main outcome was the Lequesne index score (LFI). The secondary outcome was global pain on a Visual Analog Scale (VAS). 236 patients were available in the main analysis (per protocol analysis, PP). Demographic and knee OA characteristics were identical to those usually reported in knee OA trials. Since no value of the PASS is validated for the LFI yet, the results on pain VAS were used to classify patients as responders or not using OMERACT/OARSI modified criteria, PASS and MCII (using absolute value or % of improvement). **Results:** are reported as mean (sd) and number (%).

Results: Table 1 shows the response rates according to the different criteria. Rates of responders varied considerably: from 60 to 80% in each group and from 63% to 78% in the overall population (both treatment groups can be merged since non-inferiority was proven). The most liberal definition seems to be MCII (absolute), while the strictest appears to be PASS.

Responder rates according to various definitions of response in a RCT in knee OA

PP dataset	F60027 group	Hylan G F-20 group	Global population
Baseline pain score (0-100, mm) (sd)	68.6 (13.2)	67.5 (11.6)	68.1 (12.5)
Mean change from baseline at week 24 (mm) (sd)	-38.8 (24.7)	-37.1 (25.4)	-38.0 (25.0)
N (%) of patients at PASS for pain at week 24 </= 32.3 mm	71 (59.7%)	78 (66.7%)	149 (63.1%)

N (%) of patients achieving MCII(absolute) on pain at week 24 >/= 19.9 mm	96 (80.7%)	88 (75.2%)	184 (78%)
N (%) of patients achieving MCII (%) on pain at week 24 >/= 40.8% improvement	83 (69.7%)	83 (70.9%)	166 (70.3%)
OMERACT/OARSI response criteria	77 (64.7%)	79 (67.5%)	156 (66%)
Baseline LFI score	13.6 (3.2)	13.2 (2.9)	13.4 (3.1)
Mean LFI score change from baseline at week 24	-5.7 (3.8)	-5.6 (4.0)	-5.7 (3.9)

Conclusion: Reporting clinical trial results at a patient level using response rates might be meaningful in knee OA. However this study clearly demonstrate that results significantly vary according to the response criterion used which is likely to lead to "positive" or "negative" results accordingly. More work is needed to help assessing the most clinically relevant response definition in knee OA.

Effects of Tapentadol Extended Release On the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Pain Intensity in Patients with Chronic Osteoarthritis Pain: Results of a Randomized, Phase 3, Active- and Placebo-Controlled Study. Kathleen Kelly[1], Alison Greene[1], Brigitte Kuperwasser[2], Bettyanne McCann[2], Bernd Lange[3], Achim Steup[3], Akiko Okamoto[1], Mila Etropolski[2] and Christine Rauschkolb[1], [1]Johnson & Johnson Pharmaceutical Research and Development, L.L.C., Raritan, NJ, [2]Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan, NJ, [3]Grünenthal GmbH, Aachen, Germany

Purpose: Tapentadol is a new, centrally acting analgesic with 2 mechanisms of action, μ-opioid receptor agonism and norepinephrine reuptake inhibition.

Method: This study evaluated the efficacy and safety of controlled, adjustable, oral bid doses of tapentadol extended release (ER; 100-250 mg), oxycodone HCl controlled release (CR; 20-50 mg), or placebo over a 12-week maintenance period preceded by a 3-week titration period in patients with moderate to severe chronic osteoarthritis pain. Efficacy endpoints included the change from baseline to Week 12 of the maintenance period in average pain intensity scores (using an 11-point numerical rating scale and last observation carried forward to impute missing values) and the change from baseline to Week 12 in the WOMAC (24 items scored from 0 = least disability to 4 = greatest disability). WOMAC results were analyzed using mixed effects models.

Results: Efficacy and safety were evaluated for patients (n = 1,023) who received ≥1 dose of study drug. Compared with placebo, tapentadol ER and oxycodone CR both significantly reduced average pain intensity from baseline to Week 12 of maintenance (least squares

mean difference vs placebo: tapentadol ER, –0.7 [P <0.001]; oxycodone CR, –0.3 [P = 0.049]). Mean global WOMAC scores improved significantly from baseline to Week 12 of maintenance compared with placebo for tapentadol ER (P = 0.005) and oxycodone CR (P = 0.038); numerical improvements were seen in all 3 WOMAC subscales and improvements were statistically significant on the pain (P <0.001) and physical function (P = 0.006) subscales for tapentadol ER and on the physical function (P = 0.019) subscale for oxycodone CR (**Table**). Treatment-emergent adverse events (TEAEs) were reported by 61.1%, 75.9%, and 87.4%, of patients in the placebo, tapentadol ER, and oxycodone CR groups, respectively; the most common TEAEs in the active treatment groups were nausea, constipation, vomiting, dizziness, and headache.

Conclusion: Tapentadol ER was effective for the management of moderate to severe chronic osteoarthritis pain over 15 weeks of treatment. Compared with placebo, improvements in pain intensity, physical function, and global WOMAC scores were significant for tapentadol ER (100-250 mg bid).

Table. Mean Change in WOMAC Scores From Baseline to Week 12 of Maintenance (Patients in the Intent-to-treat Population With WOMAC Assessments at Week 12)

	Placebo (n = 158)	Tapentadol ER (n = 149)	Oxycodone CR (n = 92)

26-Week Efficacy and Safety Evaluation of Naproxcinod, A First-in-Class Cyclooxygenase Inhibiting Nitric Oxide Donator (CINOD), in Patients with Osteoarthritis of the Knee. CE Marrero[1], C. Tuten[2], T. Shamin[3], V. Awasty[4], J. Agaiby[5], D. Hassman[6], J. Sutphen[7], A. Pivodic[8], B. Duquesroix[8] and Thomas J. Schnitzer[9], [1]Deep South Clinical Research, Nederland, TX, [2]Clinical Center of Asheville, Asheville, NC, [3]Heartland Clinical Reserach, Omaha, NE, [4]Internal Medicine R&R Research, Marion, OH, [5]Clinical Investigation Specialist Inc., Gurnee, IL, [6]Comprehensive Clinical Research, Berlin, MD, [7]NicOx inc., NJ, [8]NicOx SA, Sophia Antipolis, France, [9]Northwestern University, Chicago, IL

Purpose: Naproxcinod is a first-in-class Cyclooxygenase Inhibiting Nitric Oxide Donator (CINOD) under development for the relief of signs and symptoms of osteoarthritis (OA). Naproxcinod has shown anti-inflammatory and analgesic properties similar to traditional NSAIDs and COX-2 inhibitors, as well as a good safety profile in previous trials in knee OA.

Method: 1011 patients with primary knee OA with a pain flare after analgesic washout were randomized at 129 US sites to naproxcinod 375mg or 750mg, naproxen 500mg or placebo (all *bid*). After 13 weeks, patients randomized to placebo received naproxcinod 375mg or 750mg. Naproxcinod efficacy was compared with placebo during the first 13 weeks and with naproxen during the 26-week period, using the co-primary efficacy assessments of WOMAC™ pain and function, and patients' global assessment of disease status. Several other secondary efficacy assessments were evaluated. The co-primary efficacy variables were analyzed using an ANCOVA model with treatment group as factors, and the appropriate baseline value as covariate. Safety was assessed by adverse events (AEs), standardized blood pressure (BP) monitoring and orthostatic tests, ECGs, laboratory assessments, and physical examinations.

Results: 1011 patients were randomized: 71% female, 79% Caucasian, mean age 60 years. At Week 26, 6.1% patients in naproxcinod 750mg group, 10.4% in naproxcinod 375mg group and 8.1% in naproxen 500mg group discontinued due to lack of efficacy/worsening of disease. Naproxcinod 750mg was non-inferior to naproxen 500mg for WOMAC™ pain and function subscale scores at Week 26 in the intent-to-treat population, with the upper limit of the 95% CI less than the 8mm margin for non-inferiority (pain scores: difference in LS means -2.8±2.45mm, 95% CI [-7.6, 2.0]; function scores: difference in LS means -2.3±2.36mm, 95% CI [-6.9, 2.4]). The percentage of patients with ≥1 AE was similar for all groups (ranging from 59.9% to 63.7%). Most AEs were mild or moderate in severity. BP mean changes from baseline for naproxcinod 750mg remained similar to placebo at each time point and, on average, did not increase over 26 weeks.

Conclusion: Naproxcinod 750mg was non-inferior to naproxen 500mg at Week 26 based on WOMAC™ pain and function assessments. Both doses of naproxcinod administered for 26 weeks were well tolerated.

Effect of Blood Loss On Physical Functioning: Pooled Analysis of Patients with Osteoarthritis or Rheumatoid Arthritis. V. Strand[1], X. Luo[2], AG Bushmakin[2], J. Cappelleri[2], AR Assaf[2], B. Cuffel[3] and G. Sands[4], [1]Stanford University, Palo Alto, CA, [2]Pfizer Inc, New London, CT, [3]Pfizer Inc, New York, NY, [4]Pfizer Global Pharmaceuticals, New York, NY

Background: It is well recognized the use of non-steroidal anti-inflammatory drugs (NSAIDs) in patients with arthritis may cause gastrointestinal (GI) blood loss, but the impact of blood loss on quality of life has not been well established in this patient population.

Purpose: To assess the effect of clinically significant blood loss on physical functioning and other aspects of health-related quality of life in patients with osteoarthritis (OA) or rheumatoid arthritis (RA).

Method: Data from 14 pooled clinical trials ranging in length from 2 to 52 weeks assessing celecoxib vs placebo or active comparators were analyzed. Only trials that included data on both Hemoglobin (Hb) and Short Form Health Survey SF-36 were included in these analyses.

Clinically significant blood loss was defined as a decrease from baseline in Hb ≥2g/dL. The effect of blood loss was evaluated by mixed-effects modeling of the change in SF-36 domain scores from baseline as a function of change in Hb, baseline Hb, gender, and Hb change-by-gender interaction.

Result: The median number of subjects with data across SF-36 domains was 9,850. On average, most domain scores improved from baseline. Improvements in Physical Functioning domain scores were lower in patients with Hb decreases ≥2g/dL compared with those with lesser changes in Hb (from -1 to 1 g/dL). Differences between the two groups were statistically significant and clinically meaningful, defined by changes ≥5 points in domain scores in both female (p=0.02; 6.3) and male (p=0.01; 6.8) subjects. In the subgroup of females with baseline Hb ≤14g/dL, this effect was even more pronounced (p=0.001; 12.1); and in males with baseline Hb ≤15g/dL (p=0.001, 12.6). Statistically significant and clinically meaningful group differences in improvements from baseline were also observed in Role-Physical domain scores among male subjects (p=0.01; 13.7). Differences between improvements in the other domain scores with respect to blood loss were neither statistically significant nor clinically meaningful.

Mean change from baseline	Decrease in Hb ≥2g/dL (p-value)	Change in Hb -1 to 1g/dL (p-value)	Difference (p-value)
Physical Function (n=9864)			
Female	4.6 (0.21)	10.9 (<0.01)	-6.3 (0.02)
Male	2.3 (0.54)	9.0 (<0.01)	-6.8 (0.01)
Role-Physical (n=9826)			
Female	25.2 (<0.01)	26.5 (<0.01)	-1.3 (0.81)
Male	8.4 (0.26)	22.2 (<0.01)	-13.7 (0.01)

Conclusion: Subjects with blood loss characterized by decreases in Hb ≥2g/dL did not report clinically meaningful or statistically significant improvements in physical functioning, whereas those lesser Hb changes of -1 to 1g/dL reported statistically significant and clinically meaningful improvements during treatment. This impact appears to be dependent upon baseline Hb levels.

May An Intervention On Clinical Inertia Influence the Perception of Pain, Functionality and Quality of Life in Patients with Knee and/or Hip Osteoarthritis? Agustín Gómez de la Cámara[1], Alejandro Tejedor Varillas[2] and Fernando León Vázquez[2], [1]Research Unit, Hospital Universitario Doce de Octubre, CIBERESP, Madrid, Spain, [2]Sociedad Española de Medicina de Familia y Comunitaria (semFYC), Madrid, Spain

Purpose: Despite the availability of evidence-based guidelines for the management of asymptomatic chronic diseases such as osteoarthritis, physicians often do not initiate, intensify or optimize therapy when indicated, so that patients are not treated effectively. This phenomenon is known as clinical inertia. The main objective of this study was to evaluate whether an intervention on primary care physicians to avoid clinical inertia, could improve the perception of pain, functionality and quality of life in patients with hip and/or knee osteoarthritis (OA).

Method: In this prospective, randomized, multicenter, parallel-group study, clusters of primary care physicians working at the same healthcare center, for a period of time longer than six months, were randomly assigned to one of two study groups (i.e. Group 1 or proactive intervention and Group 2 or control). Each physician included three patients with knee and/or hip OA who fulfill eligibility criteria. Physicians in the proactive intervention group (Group 1) received a 45-60 minute training session on the latest European League Against Rheumatism recommendations on OA management, therapeutic goals, and motivational techniques. Both groups were trained on the use of the Visual Analog Scale (VAS), Western Ontario and McMaster Universities (WOMAC) and Short Form-12 (SF-12) questionnaires. All

patients were scheduled for two visits (Visit 1 and Visit 2), six-months apart. During the visits, a complete medical evaluation was carried out, and the VAS, WOMAC and SF-12 questionnaires were filled-out.

Results: A total of 1,361 (Group 1 n=403; Group 2 n=958) physicians were selected to participate in the study. A total of 4,076 patients (Group 1: n=1,208; Group 2: n=2,868) with hip and/or knee OA were included. No significant differences were observed between Group 1 and Group 2 when we compared the results of VAS, WOMAC and SF-12 questionnaires obtained in Visit 1 and Visit 2. On the contrary, after grouping the results of Group 1 and Group 2, a significant improvement was observed in Visit 2, compared to Visit 1, in the VAS ($p<0.001$), WOMAC ($p<0.001$) and SF-12 ($p<0.001$) questionnaires.

Conclusion: Patients did not seem to obtain any benefit from the proactive intervention addressed to reduce physicians' clinical inertia. Yet, small variations in the usual clinical practice generated an important improvement in the patients' pain, functionality and quality of life. Other potentially modifiable factors contributing to clinical inertia, besides physician-related factors, should be further investigated in patients with OA.

Total Hip and Knee Joint Replacement for OA and Sick Leave Patterns. Martin Englund[1], Leif Dahlberg[2] and Ingemar F. Petersson[3], [1]Lund University, Lund, Sweden, [2]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences, Lund University, Lund, Sweden, [3]Section of Orthopedics and Section of Rheumatology, Department of Clinical Sciences, Lund University, Lund, Sweden

Purpose: Total knee and hip joint replacement (TKR/THR) are well established treatments for painful OA when other treatments are unsatisfactory. However, in younger patients the effect on sick leave has been insufficiently studied. Our objective was to assess the patterns of sick leave before and after total joint replacement in OA patients.

Method: We identified all hip and knee OA patients in southern Sweden aged 58 years or younger who have had a TKR or THR between Jan 2003 and Oct 2006 using the Skåne Health Care Register. Subjects who died, started on disability pension, or had had more than one TKR/THR during the study period were excluded. The sample included n=276 with THR (46% women) and n=199 with TKR (56% women). Data were cross-referenced individually with data for sick leave from the National Insurance Agency. We calculated the proportion of patients with ongoing sick leave in 30-days intervals from 360 days before until 360 days after the TKR/THR. We compared the 6 month preop. period (day -210 to -30) vs. the 6 month postop. period (day 180 to 360) for the total sample using paired statistics. We also created two subgroups for graphical presentation; those without sick leave in the period 360 to 30 days before surgery, but were then sick listed at time of surgery =“more healthy” and those subjects who had had a sick leave episode in the 360 day period before surgery =“less healthy”.

Results: The proportion of subjects with sick leave pre- and postop. was higher among patients with TKR compared to patients with THR. The percentage of patients on sick leave returned towards the preoperative level by the end of the study period but almost 20 to 30% were still sick-listed, the higher share being in persons with TKR. Hip OA patients tended to have more sick days before than after the THR (mean [SD] 98 [74] vs. 83 [82], p=0.08), while there was no such trend for TKR patients (96 [79] vs. 104 [79], p=0.3). The sick leave patterns (proportion of patients on sick leave) for subjects “more healthy” and “less healthy”, respectively, are illustrated (Figure).

Conclusion: The return to work is quicker after THR than TKR. About 5% to 10% of patients who were not sick listed preoperatively are sick-listed 1 year after surgery, the higher share being in patients after TKR. The contributing effect of comorbidities associated with prolonged sick leave needs to be further studied.

Psychosocial and Educational Barriers to Surgical Success After Knee Arthroplasty. Maria Lopez-Olivo[1], Michael Kallen[2], Chong Pak[1], Sherwin J. Siff[3], Glenn C. Landon[4], David Edelstein[4], Kausha C. Robinson[2], Hong Zhang Zhang[2] and Maria E. Suarez-Almazor[2], [1]MD Anderson Ctr Univ of TX, Houston, TX, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [3]St. Luke's Episcopal Hospital, Houston, TX, [4]Kelsey Seybold, Houston, TX

Purpose: The objective of this study was to identify psychosocial and educational barriers to surgical success after total knee arthroplasty (TKA).

Method: We assessed 252 patients with knee osteoarthritis (OA) at baseline and 24 weeks post TKA. The assessments included 4 questionnaires and a physical evaluation of the affected joint. An objective outcome was obtained by measuring knee range of motion, using the ROM - Knee Society Rating System. Patient's subjective outcomes included pain, stiffness, and activity limitation and were measured using the WOMAC (Western Ontario MacMaster) scale. The WOMAC is a well-known and validated instrument designed specifically for the assessment of lower extremity pain and function in osteoarthritis (OA) of the knee or hip.

Results: In our sample, 65% of patients were female; mean age was 65 (8.9) yrs. Sixty-five percent lived with a significant other, 70% were White and 25% African American, and 73% were seen in a Kelsey Seybold clinic. Multiple regression models were estimated to evaluate the association of patient demographics (e.g., age, gender, socioeconomic status, education, hospital where surgery was performed) and

psychological factors (i.e., depression, anxiety, and stress as measured using the DASS scale) with absolute change of surgical success (i.e., 6 months outcome score minus baseline score). Other independent variable included: number of co-morbidities, post-operative complications, and affective factors (as measured using the Medical Outcome Study Social Support Scale). Regression analysis indicated that gender (female), psychological factor-anxiety, and number of co-morbidities were associated with changes in ROM (p=.020, .007, .050, and .007, respectively). Higher education (i.e., more than high school), low depression scores, and more tangible social support (i.e., provision of material aid or behavioral assistance) were associated with better WOMAC scores (p=.005, .010, and .070, respectively).

Conclusion: Patients' level of depression, education, tangible social support, number of co-morbidities, and gender are associated with outcomes in total knee arthroplasty. Further analyses are needed to determine if these findings are mediated through the effect of patient expectancies of improvement, high self-efficacy, goals, and compliance with rehabilitation recommendations.

Preliminary Results of a Phase II Placebo Controlled Trial with Adalimumab in Erosive Hand Osteoarthritis: Predictors of Erosive Evolution and the Potential Effect of Adalimumab in Specific Subgroups. Gust Verbruggen, Ruth Wittoek, Bert Vander Cruyssen and Dirk Elewaut, University Hospital Ghent, UGent, Ghent, Belgium

Purpose: Investigate a therapeutic role of TNFα-blocking agents, adalimumab, in erosive osteoarthritis (OA) of the Interphalangeal (IP) finger joints.

Methods: A total of 60 patients were allocated to adalimumab 40 mg sc every other week, or placebo. To be eligible, the patient had to present with at least one IP finger joint with the appearance of an erosive ('E') phase joint on XRays as defined by the anatomical phase scoring system [1]. Posteroanterior XRays of both hands were taken at 3 time points (baseline, after 6 and 12 months). The anatomical phase of all IP joints was characterized on the XRays. Potential changes in phase were recorded. Joints presenting in the 'E' phase at baseline or presenting new erosions over the year were scored by a novel quantitative radiographic scoring system, the Ghent University Scoring System, GUSS™ [2], with better ability to detect progression over a shorter period of time in erosive OA. Erosive progression and signs of repair or remodelling in this particular scoring system were scored by indicating the proportion of normal subchondral bone, subchondral plate and joint space on 10 point incremental Likert scales. A difference between baseline scores and scores after 12 months of more than 40 units is considered to be more erosive or showing more repair, depending on the direction of the difference.

A two-step method was used to evaluate subgroups of patients that might benefit from the anti-TNF therapy. First, predictors of erosive progression were evaluated. This was done by the calculation of odds ratios. Variables that showed a 50% difference in odds between erosive and non-erosive joints where retained as potential predictors. Second, interaction terms between the potential predictors and therapy (placebo or adalimumab) were evaluated by regression analysis (GEE, Generalized Estimated Equations, modeling with a logit link function).

The study was registered at Clinical trial.gov (EudraCT number: 2006-000925-71).

Results: Preliminary analysis of the data retained the following potential predictors for erosive evolution: age, proximal IP involvement, a tender joint at baseline and palpable synovial effusion at baseline.

Of those variables, only palpable synovial effusion at baseline showed a significant interaction effect with adalimumab therapy ($p<0.005$, figure 1).

Conclusion: The preliminary results of this phase II-study show that adalimumab can reduce the occurrence of erosive progression in joints showing palpable synovial effusion at baseline. This is the first report of an obvious disease modifying effect by a therapeutic agent in this severe form of hand OA.

Disability and Knee and Hip Osteoarthritis (OA): Associations with Individual and Community Socioeconomic Status (SES). Joshua B. Knight, Leigh F. Callahan, Jack Shreffler, Jordan B. Renner and Joanne M. Jordan, The University of North Carolina, Chapel Hill, NC

Purpose: Individual level SES measures have been shown to associate with disability and restricted function in OA and limited studies have also demonstrated associations with community level SES measures independent of one's individual SES. To date this has not been evaluated in knee and hip OA. This study examined associations between education, occupation, and community poverty with disability in persons with knee or hip radiographic OA (rOA) in the Johnston County OA Project.

Method: A cross-sectional analysis was conducted on 1037 individuals (63% White, 37% African American [AA]) with knee rOA and 824 individuals (67% white, 33% AA) with hip rOA, rOA defined as Kellgren-Lawrence ≥ 2. Education (^{3}HS) and occupation (physically demanding or not) were the individual SES measures. Census block group poverty rate (<12%, 12-25%, >25%) was the community SES measure. Disability was measured by the Health Assessment Questionnaire (HAQ). Covariates were age, gender, race, and BMI. Race was not an effect modifier and was included as a covariate. Bivariate analyses with and without covariates were used to find associations of disability with each of the SES effects separately. Multivariable analyses were conducted with all SES variables, adjusting for covariates and allowing for random intercepts based on block group. Separate models were run for people with knee or hip rOA.

Results: In persons with knee rOA, education (β=0.101, C.I.= [0.024, 0.178]) and occupation (0.115, [0.034, 0.197]) were significantly associated with disability in unadjusted bivariate models. Adjusting for covariates, education and occupation were no longer significant. In persons with hip rOA, unadjusted and adjusted bivariate models both revealed associations between disability and education (adjusted 0.111, [0.025, 0.196]), occupation (0.127, [0.039, 0.215]) and residing in a block group with >25% poverty (0.173, [0.048, 0.298]). In multivariable models, no SES variables correlated with disability in persons with knee rOA, but occupation and >25% poverty per block group were both significant in those with hip rOA (Table 1).

Table 1. Regression analyses of HAQ on all SES variables and covariates (not shown) in those with knee or hip rOA

	Knee rOA		**Hip rOA**	
	β	95% C.I.	β	95% C.I.
Education,	0.057	[-0.030, 0.144]	0.056	[-0.039, 0.151]

Occupation, LI	0.057	[-0.030, 0.144]	**0.101**	**[0.007, 0.196]**
Poverty (<12% ref.)				
12-25%	-0.037	[-0.141, 0.066]	0.086	[-0.023, 0.195]
>25%	0.029	[-0.091, 0.149]	**0.181**	**[0.053, 0.310]**

Conclusion: In persons with knee rOA, neither individual nor community SES variables are associated with disability when adjusting for key risk factors like age and BMI. However, in those with hip rOA, both occupation and residing in a high poverty area are independently associated with disability. These data underscore the importance of SES variables with outcomes in OA and indicate that in some cases community may have impact as well.

Primary Health Care Use in Osteoarthritis: Link with Depressed Mood. Yehoshua Gleicher[1], Ruth Croxford[2] and Gillian A. Hawker[3], [1]University of Toronto, Toronto, ON, [2]Institute for Clinical Evaluative Sciences, Toronto, ON, [3]Women's College Hospital, Toronto, ON

Purpose: Depressed mood has been associated with chronic painful osteoarthritis (OA). In other chronic conditions, concomitant depression has been linked to higher health care use. We examined the contribution of depressed mood to primary health care use in older individuals with OA.

Methods: A population cohort with hip/knee OA were interviewed annually to assess socio-demographics, health status (SF-36), comorbid conditions, including prior/current treatment for depression/other mental illness, and arthritis severity (WOMAC). Survey data were linked to administrative health databases using anonymized patient identifiers. Primary health care use was evaluated as the number of primary care visits over a 2 year period overall and for a mental health diagnosis (defined using a validated algorithm). Using the SF36 Mental Component score (MC score) to define depressed mood, the relationship between depressed mood and the log-transformed number of overall and mental health-specific physician visits was assessed using ordinary least squares regression and zero-inflated Poisson regression, respectively, adjusting for confounders. Interactions between MC score and other covariates were included.

Results: 2,204 individuals with OA participated (mean age 71 years; 72% female, 62% ≤ high school education). WOMAC scores indicated moderate OA severity. The mean MH score was 68.2/100 (lower scores indicate worse mental health); scores were significantly lower for those with a prior history of depression/other mental illness, greater arthritis severity, worse general health status, and less education ($p<0.0001$ for all). Participants experienced 37,363 primary care visits over the two-year period. Adjusting for age, comorbidity, education, sex, living arrangements and general health status, MC score was independently predictive of the number of primary care visits (adjusted parameter estimate 1.04 per 10 point decrease in MC score, 95% CI 1.03-1.05). Interactions were observed between MC score and each of education and region of residence; the relationship between MC and number of physician visits was stronger for those with post-secondary education and those residing in a rural versus urban region. Over the two-year period, 589 (26.7%) cohort members experienced 1,979 mental health-related primary care visits. Among those with no history of depression/mental illness, 23% experienced at least one mental health visit compared with 45% of those with a prior history. For every 10 point decrease in MC score, there was a 20% increase in the odds of having one or more mental health visits (unadjusted OR 1.20, 95% CI 1.17-1.22).

Conclusion: Among older individuals with symptomatic hip/knee OA, concomitant depressed mood is associated with greater primary care use both overall, and for mental health diagnoses. Even among individuals without a self-report past diagnosis of depression or other mental illness, over one quarter experienced at least one mental health-related primary care visit over the following two-year period.

Predictors of Assistive Walking Device Use and Association with Changes in Knee Osteoarthritis and Falls: Findings From the Health ABC Study. Laura Carbone[1], Suzanne Satterfield[2], Grant W. Somes[3], Elizabeth A. Tolley[3], C. Kent Kwoh[4], Hepei Chen[5] and Michael C. Nevitt[6], [1]Univ of Tenn at Memphis, Memphis, TN, [2]University of Tennessee, Memphis, TN, [3]The University of Tennessee Health Science Center, Memphis, TN, [4]University of Pittsburgh, Pittsburgh, PA, [5]NIH, Rockville, MD, [6]University of California, San Francisco, San Francisco, CA

Purpose: Few studies have examined the effect of factors that predict, and are concurrently associated with, new use of assistive walking devices in people with osteoarthritis (OA) of the knee. The purpose of this study was to determine factors that predicted incident use of an AWD and to determine the relationship of use of these devices by those with knee pain to WOMAC pain scores, x-ray changes of osteoarthritis and falls in elderly men and women.

Methods: We examined clinical predictors of incident use of an assistive walking device in all 3075 Health Aging and Body Composition (Health ABC) participants (n=258 AWD users and n=2769 nonusers of assistive walking devices (NAWD)) and predictors of incident use of an AWD in Health ABC participants with prevalent knee pain who had knee x-rays (n=823) (n=91 AWD users and n=732 NAWD) that preceded use of an AWD. Among these participants with prevalent knee pain, we also examined the association of incident use of an AWD with changes in knee pain (WOMAC pain score); medial and lateral x-ray joint space narrowing and falls, over an average of 3 years of follow-up.

Results: After multivariable adjustment, the common predictors of use of an AWD in the entire Health ABC cohort and in the subset with prevalent knee pain were older age (≥ 73 (OR 1.75 (95% CI 1.23-2.49) and (OR 1.42 (95% CI 1.21-2.84), black race (OR 1.27 (95%CI 1.59-3.23) and (OR 5.04 (95% CI 2.39-10.62) and a history of visual impairment (OR (1.53 (95% CI 1.10-2.14) and (OR 1.95 (95% CI 1.01, 3.79) respectively. In those with knee pain, the presence of at least one knee with x-ray evidence of whole knee osteoarthritis was also a significant predictor of AWD use (p=0.047; univariate analysis); but not in multivariate analysis. Longitudinally, after adjustment for age, race, sex and BMI, incident use of an AWD was not significantly associated with concurrent changes in WOMAC pain scores or medial or lateral tibiofemoral joint space narrowing on x-ray. An increase in the number of falls was significantly associated with AWD use (p=0.005).

Conclusion: Among elderly men and women, including those with and without knee pain, those who are older, Black and who have impaired vision are most likely to initiate use of an AWD. Among those with knee pain, the presence of knee OA on x-rays was also a predictor of initiation of use of an AWD. Use of an AWD was not significantly associated with progression of knee pain. Prevention of falls may be particularly important to consider in AWD users.

Association Between Medication Adherence and Risk of Fracture Among Women Initiating Osteoporosis Therapy. Rachel Halpern[1], Laura K. Becker[1], Sheikh Usman Iqbal[2], Enkhe Badamgarav[2] and David Macarios[2], [1]i3 Innovus, Eden Prairie, MN, [2]Amgen, Thousand Oaks, CA

Purpose: Adherence to osteoporosis medication is frequently low and may result in increased risk of non-traumatic fracture. This study examined the relationship between adherence to osteoporosis medication and risk of fracture among women initiating osteoporosis therapy.

Methods: This retrospective analysis used medical and pharmacy claims from a large US health plan. Subjects were female commercial health plan enrollees ≥45 years old who initiated treatment on alendronate, risedronate, teriparatide, ibandronate, or raloxifene from 6/30/2002 to 12/31/2006. The date of the first medication claim was the index date. Subjects were continuously enrolled for 1 year pre-index (baseline) and ≥180 days post-index. Non-traumatic fractures were identified with diagnosis codes and ICD-9 or CPT procedure codes. "Outcome" fractures were those that occurred ≥90 days after index date. Early fractures occurred within 90 days after index date. Prevalent

factures occurred during baseline. Adherence was measured with medication possession ratio (MPR), the number of days with osteoporosis medication divided by number of days observed; adherence categories were “high” (MPR≥0.8), “medium” (0.5≤MPR<0.8), and “low” (MPR<0.5). Control variables included: age; prevalent fracture; early fracture; baseline steroid use; Charlson comorbidity index score; fracture risk-related comorbidities, and geographic region. Time to fracture ≤720 days after index date was modeled with Cox regression with time-dependent adherence.

Results: The study sample included 88,122 women with mean age of 58.6 (±8.3) years; 5,404 (6.13%) subjects had outcome fractures ≤720 days after the index date. Bivariate comparison adjusted for time-dependent adherence showed that low adherence was associated with an 11.2% higher risk of fracture compared with high adherence (p=0.0006). When covariates were included, patients with low adherence had 8.3% higher risk of fracture relative to patients with high adherence (p=0.0110), as shown in Table 1. Other covariates associated with fracture included early fracture (hazard ratio (HR) =5.939, 95% confidence interval (CI) =5.453-6.467), prevalent fracture (HR=2.020 CI=1.865-2.188), and baseline steroid use (HR=1.088, CI=1.017-1.163).

Conclusion: The results indicate that low adherence to osteoporosis therapy is associated with increased risk of fracture. Research to examine factors related to medication non-adherence could inform treatment interventions and may subsequently impact rates of fracture.

Table 1. Role of Adherence in Fracture Risk: Regression Results

Regression (Reference: High Adherence)	Hazard Ratio	95% Confidence Interval	p-value
Bivariate comparison			
Low adherence (MPR<0.5)	1.112	(1.047-1.182)	0.0006
Medium adherence (0.5 <0.8)	1.073	(0.999-1.153)	0.0544
Adjusted for all covariates			
Low adherence (MPR<0.5)	1.083	(1.019-1.152)	0.0110
Medium adherence (0.5 <0.8)	1.052	(0.979-1.131)	0.1651

Switching the Dose Regimen of Oral Bisphosphonates, Adherence and Fractures. Becky Briesacher[1], Susan Andrade[2], Leslie R. Harrold[1], Hassan Fouayzi[2] and Robert A. Yood[3], [1]Univ of Massachusetts Med Schl, Worcester, MA, [2]Meyers Primary Care Institute, Worcester, MA, [3]Fallon Clinic, Worcester, MA

Purpose: To assess adherence and fracture risk in patients who switch dose regimens of oral bisphosphonates.

Method: This is a population-based interrupted times-series analysis using a nationwide administrative health data from 2003-2006. We identified 1835 switchers of once-weekly to once-monthly oral bisphosphonates and matched them to two comparators using propensity-score methodology: switchers of different once-weekly oral bisphosphonates, and nonswitchers assigned a random switch. We measured adequate adherence as a monthly medication possession ratio >/=0.80 and calculated monthly incidence rate ratios [IRR] of osteoporotic fractures. We tested for pre- and post-switch differences in adherence and fractures rates.

Results: All study groups experienced considerable attrition in adherence: 1 year post-switch, the proportion of adequate adherers was 41% regimen switchers, 47% drug only switchers, and 37% nonswitchers. The regimen switch was associated with decelerated nonadherence (absolute change in monthly attrition rate, -4% pre-switch vs. -1% post-switch, p<.000). There were no significant changes in nonadherence for nonswitchers (absolute change in monthly attrition rate, -4% pre-switch vs. -2% post-switch, p=.578) or drug only switchers (-1% pre-switch vs. -1% post-switch, p=.745). The regimen switch was not associated with reduced fracture risk: 1 year post-switch, the incidence risk ratios for regimen switchers relative to drug only switchers were 0.85, 95% CI 0.52-1.36, and 0.92, 95% CI 0.56-1.58, relative to nonswitchers).

Conclusion: Reducing the dosing demands of oral bisphosphonates from once-weekly to once-monthly decelerated but did not halt adherence failure. The regimen change did not translate to reduced fracture risk.

Associated Factors for Falls and Fear of Falls in Japanese Patients with Rheumatoid Arthritis. Takefumi Furuya, Kiyotaka Yamagiwa, Tetsuo Ikai, Eisuke Inoue, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of fractures and falls compared to healthy controls. Utilizing data from our observational study of RA in Japan (IORRA, Institute of Rheumatology Rheumatoid Arthritis), we have previously reported that the incidence of fractures in Japanese women (J Rheumatol 2007;34:303-10) and men (J Bone Miner Metab 2008;26:499-505) with RA was mainly caused by falls. Limited data exist in the literature concerning the risk factors for falls in RA patients. We attempted to determine factors associated with falls in Japanese patients with RA.

Method: Among the Japanese patients who participated our IORRA observational study, 4996 (male 765, female 4231, median age 60 yrs) responded to questions related to falls during the previous 6 months in April or May 2008. Logistic regression was used to determine the association between variables and falls.

Results: Five hundred and five (10.1%), 110 (2.2%), and 958 patients (19.2%) reported at least one fall, multiple falls, and fear of falling, respectively. Those who fell tended to report incident fractures during the same 6 months compared to those who did not (14.7% versus 1.1%, $P < 0.001$). In multivariate models, Japanese health assessment questionnaire (J-HAQ) scores (odds ratios [OR] 1.52, 2.49, and 3.88), tender joint counts (OR 1.39, 1.72, and 1.36), patient-reported visual analog scale (VAS) for general health (OR 1.08, 1.16, and 1.20) and body mass index (BMI) (OR 1.05, 1.08, and 1.04) were associated ($P < 0.05$) with at least one fall, multiple falls, and fear of falling, respectively (Table). Other clinical variables and medications were also associated with falls and fear of falling (Table).

Conclusion: HAQ disability score, tender joint counts, and impaired general health appear to be associated with falls in Japanese patients with RA as previously reported in other ethnicities. BMI appears to be related to falls and fear of falling in Japanese patients with RA. Since our cross-sectional study design may not have been adequate to evaluate the efficacy of medications, further randomized controlled or prospective observational studies are needed to conclude the associations.

Table. Adjusted odds ratios (OR) and associated 95% confidence intervals (CI) for at least one or two falls, and the fear of falling in Japanese patients with rheumatoid arthritis: logistic-regression models with step-wise selection

Variables	At least one fall	At least two falls	Fear of falling
Age, years	1.01 (1.00, 1.01)	not selected	1.03 (1.02, 1.04)
BMI, kg/m^2	1.05 (1.02, 1.08)	1.08 (1.02, 1.15)	1.04 (1.01, 1.07)
J-HAQ score, 0-3	1.52 (1.31, 1.77)	2.49 (1.82, 3.42)	3.88 (3.33, 4.55)
VAS-general health, 0-10cm	1.08 (1.03, 1.13)	1.16 (1.00, 1.34)	1.20 (1.14, 1.26)
Tender joint counts	1.39 (1.14, 1.70)	1.72 (1.26, 2.32)	1.36 (1.05, 1.76)
Swollen joint counts	0.64 (0.43, 0.92)	0.48 (0.19, 1.05)	0.85 (0.60, 1.21)

Prednisolone dose, mg/day	1.02 (0.99, 1.05)	not selected	1.04 (1.01, 1.08)
Methotrexate use	0.85 (0.69, 1.05)	0.53 (0.35, 0.80)	not selected
Active vitamin D_3 use	1.43 (1.10, 1.84)	1.69 (1.02, 2.72)	not selected

Serum Hydroxyvitamin D, Parathyroid Hormone, and the Risk of Falls: The Osteoporotic Fractures in Men (MrOS) Study. Jeffrey R. Curtis[1], Annette Adams[2], J. Cauley[3], Peggy Cawthon[4], Steven Cummings[5], Kristine Ensrud[6], Andrew Hoffman[7], Suzanne Judd[1], Cora E. Lewis[1], Pongthorn Narongroeknawin[1] and James M. Shikany[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Oregon Health and Science University, Portland, OR, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]California Pacific Medical Center, San Francisco, CA, [5]SFCC, CPMC Research Institute & UCSF, San Francisco, CA, [6]University of Minnesota Medical School, Minneapolis, MN, [7]Stanford University, Stanford, CA

Purpose: Vitamin D deficiency has been associated with falls in frail older persons, but this relationship and the relationship between parathyroid hormone and falls in community-dwelling older men has not been well established. We tested the hypothesis that lower 25(OH)D and increased intact parathyroid hormone (iPTH) is associated with the risk of subsequent falls.

Method: A total of 1592 community-dwelling men age > 65 years participating in MrOS with baseline 25(OH)D(mass spec, Mayo) and iPTH (radio-immunoassay, Columbia) were eligible for analysis after excluding 14 individuals with Parkinson's disease. Poisson regression with generalized estimating equations (GEE) was used to evaluate the relationship between at least 1 self-reported fall (collected via postcard every 4 months), 25(OH)D quintile and intact parathyroid hormone (iPTH) quintile in the subsequent 1 and 5 years of follow-up. We also evaluated the relationship between 25(OH)D and ≥ 2 falls vs. 0-1 falls in the first year of follow-up. Potential confounders were selected based upon a-priori interest and associations with exposure and outcome (univariate $p < 0.10$).

Results: At baseline, 20.4% of men reported a baseline history of falls. In the first one and five years of follow-up, 26.4% and 38.0% men reported falling at least once, respectively. There were no significant differences in the risk for falls among men in the lowest quintile of 25(OH)D (range 3 – 18 ng/ml) compared to the highest quintile (31 – 58ng/ml) in either crude or adjusted results (relative risk = 1.25, 95% CI 0.87 – 1.79, adjusted for age, site, and season). The relationship between 25(OH)D and ≥ 2 falls was only slightly stronger (adjusted relative risk = 1.39, 95% CI 0.91 – 2.11). iPTH also was unrelated to risk for ≥ 2 falls (RR for highest quintile referent to lowest = 0.93, 95% CI 0.63-1.38), and we found no evidence that the relationship between 25(OH)D and falls differed by iPTH levels (interaction p-value= 0.59).

Conclusion: Among participants in MrOS with 25-OH(D) and iPTH measured, there was no significant relationship between 25(OH)D or iPTH and falls. The previously-reported relationship between vitamin D insufficiency and fall risk may not be generalizable to community-dwelling older men.

The Longitudinal Relationship Between Intact Parathyroid Hormone Levels and BMD Loss: The Osteoporotic Fractures in Men (MrOS) Study. Jeffrey R. Curtis[1], Susan Ewing[2], Douglas C. Bauer[3], Peggy Cawthon[4], Suzanne Judd[5], Elizabeth Haney[6] and Areef Ishani[7], [1]University of Alabama at Birmingham, Birmingham, AL, [2]San Francisco Coordinating Center, San Francisco, CA, [3]University of California at San Francisco, San Francisco, CA, [4]California Pacific Medical Center, San Francisco, CA, [5]UAB, Birmingham, AL, [6]Oregon Health and Science University, Portland, OR, [7]University of Minnesota, Minneapolis, MN

Purpose: The longitudinal effect of intact parathyroid hormone (iPTH) levels on hip bone mineral density (BMD) loss in older men has been minimally studied. We evaluated the relationship with a particular interest in conditions associated with increased iPTH including low total serum 25(OH)D and decreased renal function.

Method: We selected a random sample of 1477 community-dwelling men age ≥ 65 yrs participating in MrOS with baseline iPTH data for analysis. Of these, 1144 had at least 2 BMD measurements at the femoral neck (FN) and total hip (TH) over mean follow-up of 4.5 years. Men taking osteoporosis medications were excluded (n = 86). Annualized BMD change associated with iPTH quartile was estimated using mixed effects regression models. We measured 25(OH)D using mass spec (Mayo); iPTH using radio-immunoassay (Columbia) and estimated glomerular filtration rate (eGFR) by the MDRD equation. Effect modification was assessed for race, serum 25(OH)D and eGFR. Multivariable models were adjusted for age, study site, weight change over the study period, history of cardiovascular disease, use of loop diuretics, season of blood draw, serum 25(OH)D and eGFR.

Results: Among the 1058 men eligible for analysis, 33 (3.1%) had iPTH > 65pg/ml and 3 also had serum calcium > 10.2mg/dL. There was a significant relationship between iPTH and BMD loss in Caucasians (Table) but a non-significant relationship in non-Caucasians, although an interaction term for race was not significant (p=0.25). Among Caucasians in the highest quartile of iPTH, the rate of BMD loss was approximately two-fold greater than in the lowest quartile. Results were similar for FN BMD (not shown). There was some evidence for effect modification by eGFR (interaction p-value=0.08). In stratified analysis (Table), men in the highest quartile of iPTH with reduced eGFR (< 60cc/min) had a 1.4 times higher rate of BMD loss compared to the corresponding men with normal eGFR. No effect modification by 25(OH)D was observed (interaction p value=0.95).

Conclusion: Older Caucasian men with higher baseline levels of iPTH had greater subsequent BMD loss; many had iPTH values within the accepted laboratory "normal" range. Concomitant reduced renal function further increased the rate of BMD loss. Based upon our results, iPTH < 38pg/ml is more optimal for maintaining BMD.

Table. Association between iPTH and Total Hip BMD Loss in Caucasian Men

Adjusted* Change in Total Hip BMD, %/yr	Quartiles of Intact PTH Q1 (< 23pg/ml)	Q2 (23-29 pg/ml)	Q3 (29-38 pg/ml)	Q4 (≥ 38 pg/ml)	Adjusted p for trend
Overall	-0.25	-0.25	-0.34	-0.52	0.0003
Stratified Results by eGFR					
eGFR<60 cc/min	-0.26	-0.27	-0.28	-0.71	0.06
eGFR≥60 cc/min	-0.24	-0.24	-0.35	-0.49	0.002

Bisphosphonates and Risk of Atrial Fibrillation: a Meta-Analysis. Seo Young Kim[1] and Daniel H. Solomon[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Brigham & Womens Hospital, Boston, MA

Purpose: Bisphosphonates are the most commonly used drugs for the prevention and treatment of osteoporosis. There have been discordant reports with regard to the risk of atrial fibrillation (AF) in patients on bisphosphonates. A recent meta-analysis of four clinical trials reported that bisphosphonates exposure was significantly associated with risk of AF serious adverse events [odds ratio (OR): 1.47; 95 % confidence interval (CI): 1.01-2.14], but not with all AF events [OR: 1.14; 95% CI: 0.96-1.36].

Methods: We aimed to conduct a meta-analysis of observational (cohort or case-control) studies, using a random-effects model, to evaluate risk of atrial fibrillation associated with bisphosphonates use. Studies were identified by searching MEDLINE using a combination of the Medical Subject Headings and keywords. Our search was limited to English language articles.

Results: Five eligible studies of 180,055 patients were identified. 2 were cohort and 3 were case-control studies (Figure 1). Only one of the studies found a statistically significant elevation in risk. Bisphosphonate exposure was not associated with an increased risk of AF [pooled OR: 1.03; 95% CI: 0.91-1.15]. Moderate heterogeneity was noted (I^2= 51.2%). Stratified analyses by study design yielded similar results. Egger's and Begg's test did not show an evidence of publication bias (p=0.23, 0.45 respectively).

Conclusion: Our study was unable to find an association between bisphosphonate exposure and atrial fibrillation. This agrees with the FDA's findings.

Effect of Once-Monthly Oral Ibandronate On Hip Cortical and Sub-Cortical Quantitative Computed Tomography (QCT) Parameters in Postmenopausal Osteoporosis. Harry K. Genant[1], Thomas Fuerst[2], Klaus Engelke[3], Richard Y. Davies[4] and Gorana Dasic[5], [1]University of California, San Francisco, CA, [2]Synarc, Inc, San Francisco, CA, [3]Synarc, Inc., Hamburg, Germany, [4]Glaxo Smith Kline, Collegeville, PA, [5]GlaxoSmithKline, King of Prussia, PA

Purpose: Once-monthly oral ibandronate for 12 months was previously found to increase hip integral and trabecular bone mineral density (BMD) assessed by QCT. Finite element analysis (FEA) showed significantly increased peripheral (outer 3 mm of bone), trabecular, and total femur strength. We examined cortical, sub-cortical, and extended-cortical QCT parameters for potential contributions to the FEA peripheral strength gains.

Method: Postmenopausal women with osteoporosis (N=93) received 150 mg once-monthly ibandronate or placebo for 12 months. QCT BMD, BMC, and cortical volume were measured at baseline (BL) and month 12. Treatment differences in mean percent changes from BL were determined by analysis of variance. This study was not powered for statistical testing; all *P*-values were post hoc, exploratory, and uncorrected for multiple comparisons.

Results: Ibandronate numerically improved cortical BMC and volume versus placebo, and to a lesser extent cortical BMD (Table). Total hip sub-cortical (endosteal surface and underlying trabecular bone to 1.5 mm depth) and extended-cortical BMD (cortical + sub-cortical) significantly improved with ibandronate versus placebo. Within-group ibandronate responses were significant for total hip cortical BMC and volume, femoral neck cortical volume, and trochanter extended-cortical BMD. Placebo within-group changes were significant only for total hip cortical volume.

Conclusion: Significant gains in sub-cortical total hip and extended-cortical total hip and trochanter BMD appear to contribute to the ibandronate-induced FEA peripheral strength improvements, within the limitations of sample size and measurement variability.

Relationships Between Presence, Severity, and Location of Prevalent Vertebral Fractures and Health Related Quality of Life (HRQoL). S. Silverman[1], H. Viswanathan[2], Y. Yang[2], S.R. Eis[3], P. Fardellone[4], N. Gilchrist[5], P. Lips[6], M. Nevitt[7], S. Palacios[8], K. Pavelka[9], D. Revicki[10], J. Simon[11], D. Macarios[2] and E. Siris[12], [1]Cedars Sinai/UCLA, Beverly Hills, CA, [2]Amgen Inc., Thousand Oaks, CA, [3]CEDOES Diagnóstico e Pesquisa, Vitória, Brazil, [4]Hôpital Nord, Amiens, France, [5]Princess Margaret Hospital, Christchurch, New Zealand, [6]VU University Medical Center, Amsterdam, Netherlands, [7]University of California San Francisco, San Francisco, CA, [8]Palacios Institute of Women's Health, Madrid, Spain, [9]Charles University, Prague, Czech Republic, [10]United Biosource Corporation, Bethesda, MD, [11]Women's Health Research Center, Laurel, MD, [12]Columbia University Medical Center, New York, NY

Purpose: The objectives were to examine 1) the relationship between presence of prevalent vertebral fractures and HRQoL in the FREEDOM trial, and 2) the relationships between number, location, and severity of prevalent vertebral fractures and HRQoL in women with at least 1 prevalent vertebral fracture.

Methods: Baseline data from 7,808 women (60-90 years, lumbar spine and/or total hip T-score < –2.5 and not <–4.0) included in the phase 3, denosumab FREEDOM trial were used. Prevalent vertebral fractures were assessed by radiography. The 34-item Osteoporosis Assessment Questionnaire-Short Version (OPAQ-SV) was used to measure physical function, emotional status, and back pain with higher scores representing better HRQoL (subscale scores range from 0 to 100). Multiple regression was used to examine relationships between prevalent vertebral fractures and OPAQ-SV scores in all women, and relationships between number, location, fracture severity, and OPAQ-SV scores in women with at least 1 prevalent vertebral fracture, adjusting for age, race, region, and body mass index.

Results: Presence of one vertebral fracture vs no fracture was significantly associated with worse physical function (coefficient [coeff] = –1.3, SE=0.5), emotional status (coeff = –2.0, SE=0.6), and back pain (coeff = –3.0, SE=0.8), adjusting for covariates. Presence of ≥2 vs no fracture was significantly associated with worse emotional status (p<0.05) and back pain (p<0.05) but not physical function. In women with at least 1 prevalent vertebral fracture (N=1,844), no differences were found in OPAQ-SV dimensions for those with ≥2 (mean [SD], 2.5 [1.1]) vs 1 fracture (Table). Moderate or severe fractures were associated with lower scores in all OPAQ-SV dimensions (p<0.05) compared to mild fractures (Table). Prevalent lumbar (L2 to L4) fractures were associated with significantly lower scores in all OPAQ-SV dimensions (p<0.05) compared to thoracic (T4 to T9) fractures (Table). Thoracolumbar fractures (T10-L1) were associated with worse physical function (p<0.05) compared to thoracic fractures (Table).

Conclusion: Consistent with published literature, presence of prevalent vertebral fractures was significantly associated with worse physical function, emotional status, and back pain. Moderate or severe prevalent vertebral fractures and those in the lumbar compared to thoracic location showed significantly lower scores in all OPAQ-SV dimensions.

Table: Relationships between the number, severity, or location of prevalent vertebral fractures and baseline QPAQ-SV scores in women with at least one prevalent vertebral fracture

	Physical Function n = 1,826 β (SE)	Emotional Status n = 1,826 β (SE)	Back Pain n = 1,461 β (SE)
Models examining number of prevalent vertebral fractures [a]			
Intercept	146.4 (6.5)*	128.3 (7.3)*	93.6 (9.6)*
≥2 vs 1	0.4 (0.9)	-0.6 (1.0)	-1.2 (1.3)
Models examining severity of prevalent vertebral fractures [a]			
Intercept	147.0 (6.6)*	128.9 (7.3)*	94.6 (9.6)*
Moderate or Severe vs Mild	-2.0 (0.8)*	-2.2 (0.9)*	-2.6 (1.2)*
Models examining location of prevalent vertebral fractures [a,b]			
Intercept	148.0 (7.1)*	128.9 (8.1)*	96.0 (10.7)*
Lumbar (L2-L4) vs Thoracic (T4-T9)	-4.9 (1.4)*	-3.4 (1.6)*	-6.8 (2.0)*
Thoracolumbar (T10-L1) vs Thoracic (T4-T9)	-2.2 (1.0)*	-1.5 (1.1)	-2.8 (1.5)

n = Number of subjects with observed data included in the ANCOVA model.
[a] All regression models also included age, race, region, and BMI as covariates.
[b] Women with prevalent vertebral fractures at multiple locations (thoracic, thoracolumbar, or lumbar) were excluded.

Systematic Review of the Risk of Fracture with Medication Non-Adherence in Post Menopausal Osteoporotic (PMO) Women. E. Samuels[1], Ethel Siris[2], Sheikh Usman Iqbal[3], K. Gairy[1], S. Ross[4] and E. Badamgarav[5], [1]Heron Evidence Development, Luton, United Kingdom, [2]Columbia University Medical Center, New York, NY, [3]Amgen, Thousand Oaks, CA, [4]SD Ross Consulting, Cohasset, MA, [5]Amgen, California, CA

Purpose: In the US, as many as 8 million women and 2 million men have osteoporosis. In 2005, osteoporosis was responsible for more than 2 million fractures, costing an estimated $19 billion in direct medical care costs. Osteoporosis drug treatments have shown to increase bone mass and significantly reduce the risk of fracture in clinical trials. However, real world adherence (compliance and persistence) to currently available therapies is suboptimal and may reduce the effectiveness of these interventions. This systematic review assessed the risk of fracture in women who were non-adherent to medication for PMO.

Method: Three databases were searched (Medline, Embase, CINAHL) for English-language publications from 1998 to 2009. Recent symposia were also searched. Key study selection criteria were: observational studies of PMO patients ≥ 45 years, receiving bisphosphonates, parathyroid hormone, and/or SERMs, and reporting fracture risk in relation to adherence, as defined by the individual authors. The medication possession ratio [MPR] was the primary measure of interest. Two independent reviewers evaluated all identified studies, with disagreements reconciled by a third reviewer.

Results: The database search yielded 487 citations, of which 18 studies were eligible. The vast majority of patients were prescribed bisphosphonates. The MPR at an 80% threshold was most commonly used to assess adherence, and, in the 7 studies using this metric, the proportion of study subjects who were adherent ranged from 43% to 48%, for follow-up times ranging from 40 to 140 weeks (see Table). The hazard ratio of fracture in non-compliant versus compliant patients in these MPR studies ranged from 1.17* to 1.41.

Conclusion: Poor medication adherence (as measured by MPR) is a common occurrence in women treated for PMO. Poor adherence to osteoporosis medication is associated with significantly increased risk of osteoporotic fracture in women, and thus enhancing adherence may lead to a greater reduction in fracture. Table: Studies reporting data for <80% (non-compliance; NC) vs. MPR ≥80% (compliance; C)

Denosumab and Risk of Fractures in Subgroups of Women with Osteoporosis. Michael McClung[1], Henry G. Bone[2], Jonathan D. Adachi[3], Steven Boonen[4], Claus Christiansen[5], Richard Eastell[6], Jordi Farrerons[7], Nathalie Franchimont[8], Kurt Lippuner[9], Zulema Man[10], Salvatore Minisola[11], Ian Reid[12], Rene Rizzoli[13], Javier San Martin[14], Ethel Siris[15], Ove Torring[16], Andrea Wang[14] and Steven Cummings[17], [1]Oregon Osteoporosis Center, Portland, OR, [2]Michigan Bone and Mineral Clinic, Detroit, MI, [3]McMaster University, Hamilton, ON, [4]University of Leuven, Leuven, Belgium, [5]CCBR, Ballerup, Denmark, [6]University of Sheffield, Sheffield, United Kingdom, [7]Hospital de la Santa Creu I Sant Pau, Barcelona, Spain, [8]Amgen Inc., Zug, Switzerland, [9]Inselspital Bern, Bern, Switzerland, [10]Centro T.I.E.M.P.O., Buenos Aires, Argentina, [11]Universita' Di Roma “Sapienza”, Rome, Italy, [12]University of Auckland, Auckland, New Zealand, [13]University Hospital, Geneva, Switzerland, [14]Amgen Inc., Thousand Oaks, CA, [15]Columbia University Medical Center, New York, NY, [16]Karolinska Institutet Sodersjukhuset, Stockholm, Sweden, [17]SFCC, CPMC Research Institute & UCSF, San Francisco, CA

Purpose: Denosumab reduces the risk of new vertebral fracture and nonvertebral fracture. Previous trials suggest that the efficacy of antiresorptives on nonvertebral fractures might differ by patients' bone density, age, presence of vertebral fracture or other characteristics.

Methods: In FREEDOM 7,868 women aged 60-90 years with osteoporosis were randomly assigned to denosumab 60 mg every 6 months or placebo; all received daily calcium (≥ 1g) and vitamin D (≥ 400 IU). Nonvertebral and new vertebral fractures were radiologically confirmed. We prospectively planned 9 subgroup analyses of the effect of denosumab on new vertebral and nonvertebral fractures. Statistical significance was based on tests for quantitative interactions.

Results: Denosumab reduced all nonvertebral fractures by 20% (95% CI, 5 to 33%) over 3 years. The effect was significantly greater in women with low BMI, femoral neck BMD T-score ≤-2.5, and those without prevalent vertebral fracture (Table) but did not differ by age (< 75 vs. ≥ 75 years; p = 0.64) or prior nonvertebral fracture (p = 0.61). Compared with placebo, denosumab decreased the risk of new vertebral fracture by 68% (95% CI, 59 to 74%) over 3 years. This effect did not significantly differ by age, prevalent vertebral fracture, prior nonvertebral fracture and BMI (P>0.29 for all potential interactions).

Conclusion: Denosumab 60 mg for 3 years in women with osteoporosis reduced the risk of new vertebral fractures to a similar degree in all subgroups tested. However, as observed in several other trials, treatment reduced the risk of nonvertebral fractures significantly more in women with femoral neck BMD T-score ≤-2.5 (RRR: 35%) than in those with higher BMD. It was also more effective in thin than heavier women and those without existing vertebral fractures.

Reduction in Risk (Hazard Ratio) for Nonvertebral Fractures in Subgroups

Subgroup		Hazard ratio (95% CI)	Interaction P-value
Femoral neck BMD T-score	< -2.5	0.65 (0.51, 0.83)	
	> -2.5	0.97 (0.76, 1.23)	0.02
BMI (kg/m2)	<25	0.62 (0.48, 0.80)	
	25 to <30	0.98 (0.75, 1.30)	
	>30	1.13 (0.71, 1.78)	0.01
Baseline vertebral fracture	Yes	1.06 (0.78, 1.44)	
	No	0.71 (0.58, 0.88)	0.04

Relationship Between the Effect of Denosumab On Bone Turnover Markers and Change in Bone Mineral Density in Postmenopausal Osteoporosis. M. McClung[1], C. Christiansen[2], A. Grauer[3], S. Kutilek[4], C. Libanati[3], H. Resch[5], I. Reid[6], E. Siris[7], D. Uebelhart[8], A. Wang[3], G. Weryha[9], S. Cummings[10] and R. Eastell[11], [1]Oregon Osteoporosis Center, Portland, OR, [2]CCBR, Ballerup, Denmark, [3]Amgen Inc., Thousand Oaks, CA, [4]CCBR, Pardubice, Czech Republic, [5]St. Vincent Hospital Vienna, University of Vienna, Vienna, Austria, [6]University of Auckland, Auckland, New Zealand, [7]Columbia University Medical Center, New York, NY, [8]University Hospital of Zurich, Zurich, Switzerland, [9]CHU de Nancy, Vandoeuvre, France, [10]SFCC, CPMC Research Institute & UCSF, San Francisco, CA, [11]University of Sheffield, Sheffield, United Kingdom

Purpose: Denosumab (DMAb), an investigational human monoclonal antibody to RANKL, reduced the risk of vertebral, nonvertebral and hip fractures in the FREEDOM trial. With DMAb treatment, levels of bone resorption markers (BRM) were reduced below the premenopausal reference range in all women tested. In a subset of women, the level of BRM reduction attenuated at the end of the 6-month dosing interval, while other women had sustained BRM reduction throughout the study. We evaluated the relationship between change in bone turnover markers (BTM) and change in BMD and if there were similar BMD increases in women with sustained BTM reduction vs those with a transient attenuation of BTM.

Methods: FREEDOM was a phase 3 trial in women ages 60-90 years with postmenopausal osteoporosis randomized to sc DMAb 60mg or placebo (Pbo) every 6 months for 36 months with daily calcium (1000mg) and vitamin D supplements (400-800 IU). Osteoporosis was defined as a T-score <-2.5 at the spine or hip but not <-4 at either site. We measured BTM (serum CTX [ELISA, Osteometer] and PINP [RIA, Orion]) in 944 women (505 DMAb, 439 Pbo) at baseline, 1, 6, 12, 24 and 36 months, and BMD of the proximal femur annually and lumbar spine at baseline and 36 months.

Results: DMAb decreased CTX and PINP at 6 months and increased BMD at the lumbar spine and total hip at 36 months (Table). Overall, BTM changes in DMAb and Pbo groups at 6 months were negatively correlated with BMD changes at 36 months (Table). Mean (SD) BMD changes with DMAb at 36 months were identical (+0.08 [0.04] g/cm^2 at the lumbar spine, and +0.04 [0.02] g/cm^2 at the total hip) in women treated with DMAb who had sustained reduction in BTM (n=146 CTX, n=103 PINP) vs those who had transient attenuation of BTM levels before repeat dosing (n=359 CTX, n=402 PINP).

Conclusion: There were weak to modest correlations between changes in BTM and changes in BMD. Additionally, there were similar increases in BMD whether or not BTM remained below the premenopausal reference range throughout the study or showed attenuation of BTM before the next dose.

	Placebo	DMAb
CTX Absolute Change (ng/mL) at 6 mo, median (interquartile range)	-0.07 (-0.20 to +0.04)	-0.40 (-0.59 to -0.26)†††
PINP Absolute Change (ng/mL) at 6 mo, median (interquartile range)	-14 (-26 to -5)	-39 (-54 to -25)†††

Relationship of Baseline Bone Turnover Marker Levels and Month 12 Bone Mineral Density Change in Postmenopausal Women Transitioned From Alendronate to Denosumab. M.A. Bolognese[1], C. Roux[2], G. Bianchi[3], J. Supronik[4], I. Valter[5], M.C. de Vernejoul[6], D.L. Kendler[7], H.G. Bone[8], S. Ortolani[9], S. Siddhanti[10], H.S. Man[10], J. San Martin[10] and M.L. Brandi[11], [1]Bethesda Health Research Center, Bethesda, MD, [2]Paris Descartes University Hôpital Cochin, Paris, France, [3]Azienda Sanitaria Genovese, Genova, Italy, [4]Niepubliczny Zaklad Opieki Zdrowotnej Centrum Medyczne, Bialystok, Poland, [5]Center for Clinical and Basic Research, Tallinn, Estonia, [6]Hôpital Lariboisiere, Paris, France, [7]Clinical Research Centre, Vancouver, BC, [8]Michigan Bone and Mineral Clinic, Detroit, MI, [9]Istituto Auxologico Italiano, Milan, Italy, [10]Amgen Inc., Thousand Oaks, CA, [11]Azienda Ospedaliera Careggi, Firenze, Italy

Purpose: Denosumab is an investigational fully-human monoclonal antibody that reduces bone resorption by inhibiting RANKL, an essential mediator of osteoclast formation, function, and survival. In previous studies in postmenopausal women, denosumab increased bone mineral density (BMD) and reduced the risk of fracture.

Methods: Subjects were eligible for this randomized, double-blind, double-dummy study if they were postmenopausal women ≥55 with a lumbar spine or total hip T-score ≤–2.0 and ≥–4.0 and were receiving generic or branded alendronate for ≥6 months. After a 1-month alendronate run-in phase, subjects were randomized to treatment with continued alendronate (70 mg weekly) or denosumab (60 mg every 6 months subcutaneously) and the effects on BMD were compared. The relationship between baseline bone turnover marker levels and month 12 percent changes in BMD at the total hip or lumbar spine was also evaluated.

Results: The 504 enrolled women (251 alendronate, 253 denosumab) had a baseline mean age of 68, a mean lumbar spine BMD T-score of –2.63, and a median sCTX-I level of 0.20 ng/mL (range, 0.05-0.89 ng/mL). As previously reported, transition to denosumab resulted in greater increases in total hip, lumbar spine, femoral neck, and 1/3 radius BMD compared with continued alendronate (P□0.012). For subjects receiving alendronate, month 12 BMD gains were generally similar across quartiles of baseline bone turnover marker levels. For subjects transitioned to denosumab, month 12 BMD gains at the total hip and lumbar spine were largest and significantly differed from the alendronate group among subjects in the 2 highest quartiles of baseline sCTX-I or PINP levels (Table – total hip vs. sCTX-I).

Conclusion: In postmenopausal women with low bone mass who were previously receiving alendronate, transition to denosumab 60 mg every 6 months increased BMD. The greatest BMD increases as compared with continued alendronate occurred among women with the two highest quartiles of baseline levels of bone turnover markers.

Table: Percent Change in Month 12 Total Hip BMD by Baseline sCTX-I

Baseline sCTX-I (ng/mL)		Alendronate	Denosumab

Development of Natural Calcium and Phosphate-Donating Molecules and a New Iontophoretic Device for the Topical Treatment of Osteoporosis. Lajos Pap[1], Izabella Gomez[2], Lajos Pap Jr.[3], Andrea Szabó[4] and Zoltan Szekanecz[2], [1]University of Debrecen, Debrecen, Hungary, [2]University of Debrecen medical and Health Sciences Center, Debrecen, Hungary, [3]Digitaltechnik, Vienna, Austria, [4]University of Szeged, Szeged, Hungary

Purpose: Apart from systemic treatment of osteoporosis, topical treatment may be useful to treat local bone defects, fractures and other bone disorders. We have developed a novel iontoforesis device and a topical treatment protocol. Two natural-based, chemically modified molecules including bentonites and montmorillonites have been developed. In addition, a novel 3-electrode electrophoretic device has been constructed.

Method: This device 'knocks out' Ca2+ and PO43- ions from the molecules with its impulse-like positive and negative charges transmitted through its electrodes placed on the skin. The current and the voltage of the electrodes can be adjusted separately in both leads. Subsequently, these 'knocked out' ions are channelled into the porotic bones with the help of the thirs - reference – electrode. In our preliminary in vitro studies, we used porcine tissues to test their calcium and phosphate content after iontophoresis; with or without using nanomolecules. In addition, we performed preliminary in vivo experiments in ovariectomized rats.

Results: Our major results are the development of two molecules that are able to donate calcium and phosphorous into the bone. Also, a new 3 electrode iontophoresis apparatus has been developed. In vitro studies revealed that both calcium and phosphate ions became incorporated into the porcine bone. When only iontophoresis was applied without using molecules, the calcium content of the muscle tissue on the anode side decreased after iontophoresis (235.7 ± 66.7 μg/g) compared to controls (278.2 ± 33.2 μg/g) ($p<0.05$). When molecules were also applied in addition to iontophoresis, calcium content of the skin and bone significantly increased in treated tissues (793.0 ± 108.6 μg/g and 207628 ± 16198 μg/g, respectively) in comparison to controls (319.7 ± 38.9 μg/g and 124560 ± 15551 μg/g, respectively) ($p<0.05$). Similar results were found regarding the phosphate content. In the rat in vivo studies, quantitative ultrasound indicated significant bone loss in the tibia in ovariectomized rats compared to sham-operated animals. Five courses of iontophoresis resulted in increased bone density as indicated by significantly higher AD-SoS values in both ovariectomized and sham-operated animals in comparison to untreated rats ($p<0.05$). This favourable effect of iontophoresis was sustained even 150 days after treatment ($p<0.05$).

Conclusion: A three-electrode new iontophoretic apparatus, as well as calcium- and phosphate-donating molecules have been developed. Preliminary in vitro experiments using pig tissues suggest that calcium and phosphate ions indeed penetrate into the bone during iontophoresis. In vivo studies in rats suggest that iontophoresis may increase local bone density. Further in vivo biomechanical and fracture studies in rats have also been performed and will soon be demonstrated.

To What Degree Does the FRAX Case Finding Algorithm Underestimates Fracture Risk in Patients with a Recent Fall? Piet P.M.M. Geusens, Maastricht University Medical Center and Hasselt University, Biomedical Research Institute, Diepenbeek, Belgium

Purpose: Identifying patients at highest risk for fracture starts with clinical case finding, based on the presence of well-documented bone and fall-related clinical risk factors for fractures. The FRAX algorithm does not include risk factors for falls. The Fracture Prediction Tool in Glucocorticosteriod users (FIGS) includes a history of recent falls and the Garvan algorithm the number of recent falls.

Method: We compared FRAX with FIGS and Garvan to calculate the 10-year risk of major fractures (FRAX: clinical spine, hip, forearm an humerus; FIGS: also rib, femur and pelvis fractures; Garvan: all low-trauma fractures).

Results: In 60 yr old subjects with a body weight of 70 kg without clinical fracture risks, calculated fracture risk was 6.0% with FRAX, 6.9% with FIGS and 9.4% with Garvan. After a recent fall, the fracture risk increased with FIGS (14.3%) and Garvan (11.4% after one fall up to 16.7% after 3 falls). After a history of fracture, the fracture risk increased with all algorithms compared to patients without a recent fall (FRAX: 12.0%, FIGS: 12.0%, Garvan:16.1%), but further increased substantially if they had a recent fall (FIGS: 24.0%. Garvan: 19.3% after one fall up to 27.6% after 3 falls). Similar differences in fracture prediction between the algorithms were found in 70 or 80 yr old subjects and in subjects with a low or high body weight.

Conclusion: We conclude that FRAX substantially underestimates fracture risk in subjects who have as only risk factors a history of a recent fall or a recent fall-related fracture.

Bisphosphonate Use Increases Risk of Transverse Minimal Trauma Fracture of Femoral Diaphysis. Michael H-Y. Tjeuw, Stephen P. Oakley, Zsolt Balogh and Gabor AC. Major, Newcastle Bone & Joint Institute, Newcastle, Australia

Purpose: While bisphosponates (BP) protect against osteoporotic fracture recent case series have suggested that BP may actually increase the risk of a sub-type of fracture - Simple Transverse Minimal Trauma Fracture (MTF) of Femoral Diaphysis[1-2]. However, a recent register-based case-controlled study found no such association[4]. Our Orthopaedics Department have maintained a database of all femoral fractures presenting between March 2005 – September 2008, providing an opportunity to conduct a retrospective cohort analysis. We used this data to evaluate whether BP increased the risk of Simple Transverse MTF of Femoral Diaphysis.

Method: We identified 112 diaphyseal MTF in patients over 50 years old. MTF was defined as "a fall from standing height". Records were reviewed for information regarding BP use, medications and co-morbidities. X-rays were reviewed by a second investigator blind to BP status and classified according to the AO Classification as: 1. Simple (further grouped as transverse, spiral or oblique) 2. Non-simple (further grouped as wedge or complex) or 3. Peri-prosthetic.

Results: Within the simple fracture group, BP use was associated with a RR of 2.09 (CI: 1.12-3.89) for transverse diaphyseal fractures as opposed to spiral or oblique fractures. When non-simple fractures were included in the analysis, the RR was 1.43 (CI: 1.07-1.90) and with the further addition of peri-prosthetic fractures the RR was 1.89 (CI: 1.01-3.55). Spiral, oblique, non-simple and peri-prosthetic fractures were not associated with BP use.

Conclusion: We found that BP use was associated with double the risk of transverse MTF of the femoral diaphysis. While BP use clearly reduces the overall risk of osteoporotic fracture, our results support the notion that it may change the fracture type. Prospective clinical research is needed to confirm these results, to determine whether there is a dose-effect and to see if this risk is associated with all bisphosphonates.

The Clinical and Economic Burden of Non-Adherence with Oral Bisphosphonates in Osteoporotic Patients. Mickaël Hiligsmann, Véronique Rabenda, Olivier Bruyere and Jean Y. Reginster, University of Liège, Liège, Belgium

Purpose: Poor compliance and failure to persist with oral bisphosphonates are common, but the clinical and economic consequences have not been well described. This study aims to estimate the clinical and economic burden of nonadherence with oral bisphosphonates in osteoporotic patients and to examine the scope for adherence-enhancing interventions.

Method: A validated Markov microsimulation model estimated costs and outcomes (i.e. the number of fractures and the quality-adjusted life-year (QALY)) for three adherence scenarios: no treatment, real-world adherence and full adherence over 3 years. Simulated patients matched the populations where osteoporosis medications are reimbursed. The real-world adherence scenario employed adherence data from a published observational studies and adherence was divided into persistence and compliance. The incremental cost per QALY gained was estimated comparing the three adherence scenarios. We also examined the clinical and economic implications of adherence-enhancing interventions assuming that adherence failure would be reduced by 10%, 20% or 30%.

Results: The estimated number of fractures prevented and the lifetime QALY gained in the real-world adherence scenario represents only 42.0% and 41.9% to that obtained under full adherence scenario, respectively. The cost per QALY gained of real-world adherence versus no treatment was estimated at €11,175, and full adherence was found to be cost-saving compared to real-world adherence. An intervention that

decreases adherence failure by 20% was associated with a 28% increase in the number of fractures prevented and the costs per QALY gained compared to real-world adherence were respectively €29,350 and €46,275 if the intervention costs €100 and €150 per year.

Conclusion: This study suggests that more than half of the potential benefits from oral bisphosphonates in patients with osteoporosis are lost due to poor compliance and failure to persist. Depending on its cost, interventions that improve adherence to therapy have the potential to be an attractive use of resources. So, therapies that optimize adherence should remain cost-effective compared to oral bisphosphonates even if they cost up to €150 more, per year, and may therefore represent a promising approach to reduce clinical and economic consequences of osteoporosis.

Key-words : adherence, economic analysis, osteoporosis

Physiologically Optimal Vitamin D Levels in African Americans Based Upon Intact Parathyroid Hormone Suppression: What Vitamin D Should Be Considered "Normal"? J. R. Curtis[1], L. Chen[1], J. Niu[2], E. Delzell[1], David T. Felson[3], M.K. Javaid[4], C. Katholi[1], M. A. Nevitt[5] and C. E. Lewis for the MOST Group[1], [1]UAB, Birmingham, AL, [2]BUSM, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]University of Oxford, Oxford, United Kingdom, [5]UCSF, San Francisco, CA

Purpose: 'Normal' 25(OH) vitamin D levels are commonly accepted in Caucasians to be approximately 30-35ng/ml based upon physiologic outcomes including maximal suppression of intact parathyroid hormone (iPTH). The optimal 25(OH)D level among non-Caucasians, including African-Americans, is unclear. We evaluated the relationship between serum 25(OH)D and iPTH among older community dwelling adults, hypothesizing that African-Americans would have a lower normal 25(OH)D level than Caucasians based upon maximal iPTH suppression.

Method: The Multicenter Osteoarthritis Study (MOST) is a longitudinal observational study of individuals who have or are at high risk for knee OA. Using data from MOST, we evaluated serum 25(OH)D [Diasorin RIA] and iPTH [Immulite CIA; Diagnostic Products Corp]. Those with self-reported chronic kidney disease were excluded; we also excluded 24 persons with iPTH > 120 pg/ml (~2x the upper limit of lab normal) due to concern that increased iPTH was from other than low 25(OH)D.

We modeled the relationship between 25(OH)D and iPTH in 3 ways. First, we did a segmented regression with grid search by sequentially placing the knot (i.e. joinpoint) at 0.1 unit increments of 25(OH)D from 5-50ng/ml. The comparative fit of the models that varied the knot was evaluated by determining mean squared error (MSE) of each model, looking for local minimums. Secondly, we used Helmert contrasts to identify 25(OH)D thresholds at which iPTH values increased. Our third approach used OLS regression to evaluate the relationship between 25(OH)D and iPTH by race, using 25(OH)D categories. OLS results were adjusted for age, gender, body mass index, education, and season.

Results: Among 1263 Caucasian and 437 African Americans, mean age was 62.8±7.9 and 59.8±8.2 years respectively. After exclusions, the range of 25(OH)D and iPTH values was 4-51ng/ml and 2-120 pg/ml for Caucasians and was 3-32ng/ml and 3-119pg/ml for African Americans. Local minimums of the MSE for Caucasians were observed at 25(OH)D levels of 12, 24, 31, and 40ng/ml, indicating better model fit with joinpoints at these values. In contrast, only one minimum MSE among African Americans was observed, at 9ng/ml. Plots of the race-specific Helmert contrasts were concordant with these results. The relationship between vitamin D and iPTH by race in the Table showed a continual decrease in iPTH as 25(OH)D increased among Caucasians. In contrast for African Americans, there was no further decline in iPTH if 25(OH)D was at least 20ng/ml.

Conclusion: In this sample of community-dwelling older adults, and in contrast to results for Caucasians, we observed minimal incremental benefit in suppression of iPTH for 25(OH) vitamin D levels greater than 20ng/ml in African Americans. The common clinical practice of using 30-35ng/ml to define a 'normal' vitamin D level based upon studies conducted in Caucasians may not be applicable to African Americans.

Hypophosphatasia: Treatment of Life-Threatening Disease Using Bone-Targeted Human Recombinant Tissue Non-Specific Alkaline Phosphatase. MP Whyte[1], Cheryl R. Greenberg[2], Terence Edgar[3], Bradley J. Van Sickle[4], Mohammad Hamdan[5], Nada J. Salman[5], Michael B. Bober[6], William H. McAlister[7], Deborah Wenkert[1] and Hal Landy[8], [1]Shriners Hospital for Children, St Louis, MO, [2]University of Manitoba, Winnipeg, MB, [3]Prevea Allouez Health Center, Greenbay, WI, [4]Vanderbilt University, Nashville, TN, [5]Tawam Hospital, Al Ain, United Arab Emirates, [6]Nemours, Wilmington, DE, [7]Washington University School of Medicine, St Louis, MO, [8]Enobia Pharma, Montreal, QC

Purpose: Hypophosphatasia (HPP) features low serum alkaline phosphatase (ALP) activity due to deactivating mutation(s) within the gene that encodes the "tissue nonspecific" isoenzyme of ALP (TNSALP). Consequently, inorganic pyrophosphate, a natural substrate for this ectoenzyme, accumulates extracellularly and blocks skeletal mineralization. HPP severity spans stillbirth from profound skeletal hypomineralization to osteomalacia presenting in adult life. There is no established medical treatment. ENB-0040 is a bone-targeted, human recombinant, TNSALP fusion protein that preserved skeletal mineralization and survival and prevented vitamin B6-responsive seizures and dental defects in a tnsalp knockout mouse model of infantile HPP (JBMR 23:777, '08). Patient trials began in the summer '08. In a phase 1, month-long, multi-center, open-label protocol, 6 adults received 1 IV infusion of 3 mg/kg ENB-0040 followed by weekly SC injections of 1 or 2 mg/kg (Endo Soc, abstract, in press).

Method: Here, we report findings from our 6-mo, open-label protocol involving 5 patients with life-threatening HPP (ages 0.5-36 mo at baseline), with up to 6 mo of ENB-0040 treatment. Previously, each had shown worsening skeletal disease and respiratory symptoms predicting a lethal outcome.

Results: At age 7 mo, pt 1 with infantile HPP received a single IV infusion of 2 mg/kg of ENB-0040 followed by 1 and then 3 mg/kg SC 3X/wk. During therapy, there was substantial remineralization of the skeleton, weaning from ventilatory support, and improved growth and motor development. After receiving only 3 wk of treatment, pt 2, also with infantile HPP, showed skeletal remineralization, and then improved ventilation. Both patients 1 & 2 have been released from hospital to continue ENB-0040. Patient 3 with perinatal HPP has also shown substantial radiographic and respiratory improvement, and corrected hypercalcemia soon after treatment began. There have been no drug-related serious adverse events, or development of anti-ENB-0040 antibodies. SC dosing has resulted in ENB-0040 activity in the therapeutic target range.

Conclusion: Substantial skeletal remineralization and improved clinical status has been demonstrated in association with ENB-0040 bone-targeted enzyme replacement therapy in 3 severely affected infants with HPP in this short term study.

Hypophosphatasia: Natural History of 177 Pediatric Patients. Deborah Wenkert[1], Fan Zhang[1], Marci C. Benigno[1], Janice A. Zerega[1], Karen E. Mack[1], Vivienne T. Lim[1], Stephen P. Coburn[2], Karen Ericson[2], William H. McAlister[3], Steven Mumm[3] and Michael P. Whyte[1], [1]Shriners Hospital for Children, St. Louis, MO, [2]Indiana University - Purdue University, Fort Wayne, IN, [3]Washington University School of Medicine, St. Louis, MO

Purpose: Hypophosphatasia (HPP) is the inborn-error-of-metabolism caused by deactivating mutation(s) within the gene that encodes the tissue nonspecific isoenzyme of alkaline phosphatase (TNSALP). Consequently, inorganic pyrophosphate (PPi) and pyridoxal 5'-phosphate (PLP), natural substrates for this ectoenzyme, accumulate extracellularly. Excess PPi blocks skeletal mineralization causing rickets or osteomalacia. Pediatric HPP spans stillbirth (profound skeletal hypomineralization) to premature loss of primary teeth without skeletal disease. An indepth, longitudinal evaluation of untreated HPP patients was undertaken not only to provide a greater understanding of the role of TNSALP in bone development, but also to serve as a basis for the assessment of future pharmacotherapy.

Method: During the past 26 years, 177 pediatric HPP patients had 1 or more inpatient evaluations when fasting blood and 24-hour urine collections were obtained while we matched ad libitum dietary calcium intakes. Disturbances in endochondral bone formation were followed radiographically using single views of wrists and knees. We evaluated the following pediatric forms of HPP: 65 odonto-HPP (dental disease only), 99 childhood HPP (41 mild), 12 infantile HPP, and 1 perinatal/infantile HPP. To date, 52 of the 177 patients had 4-14 admissions (usually occurring once every few years).

Results: Principal complications identified were premature tooth exfoliation, joint hypermobility, lower extremity malalignment or bowing, skeletal pain, muscle weakness, craniosynostosis, chest deformity, scoliosis, clubfoot, and fractures. Serum total ALP activity, analyzed for ages ≤10 yr, correlated with HPP severity; lower values reflected more severe disease, but also showed 'physiological' decrements after puberty. Elevated plasma PLP levels correlated with skeletal disease severity and the number of teeth lost prematurely, but in contrast to serum ALP, did not change over time according to a 2-stage statistical analysis. This indicates that plasma PLP is a good diagnostic test that correlates with HPP severity even when only measured once. Height z-scores were without gender differences, reflected HPP severity, and showed no significant changes over time; height assessments at >2 yrs of age predicted adult heights. Radiographic features were highly individualized (physeal widening, irregularity of zones of calcification, “tongues of radiolucency”, metaphyseal osteopenia or osteosclerosis, and cortical thinning), but typically changed little during follow-up.

Conclusion: Accordingly, we have defined major clinical, biochemical and radiographic features of HPP which will serve as a basis for assessment of future therapies.

Chromosomal Localization of Four Autosomal Dominant Skeletal Diseases, Including Osteogenesis Imperfecta Type V and Metachondromatosis. Michael P. Whyte[1], Deborah Wenkert[1], Fan Zhang[1], William H. McAlister[2], Peter Tebben[3], Anne Bowcock[2] and Steven Mumm[2], [1]Shriners Hospital for Children, St Louis, MO, [2]Washington University School of Medicine, St. Louis, MO, [3]Mayo Clinic, Rochester, MN

Purpose: In recent years, the genetic basis of rare bone diseases has revealed novel pathways involved in bone metabolism opening new avenues to potential drug therapy. We chose four highly penetrant autosomal dominant skeletal diseases of unknown etiology to identify additional chromosomal locations critical to bone metabolism. Two 4-generation kindreds had unique disorders featuring either (Kindred A) diffusely dense and painful bones, cranial nerve compromise, and brittle and translucent teeth (JBMR 19:S464, '04), or (Kindred B) short stature, abnormally modeled bones, and dentition with enamel hypoplasia and dwarfed roots (JBMR 21:S430, '06). One 3-generation kindred

and two smaller unrelated families had osteogenesis imperfecta (OI) type V (OMIM % 610967). One 4-generation family had metachondromatosis (OMIM 156250).

Method: Chromosomal mapping was performed by contract with deCODE Genetics using a medium density genome-wide scan at an average of 8 cM density with a standard marker set of 500 validated microsatellites. Peripheral leukocyte DNA from 88 individuals within the 6 families was analyzed using one 96 well plate. The reaction volume was 5 µl, and for each PCR 20 ng of genomic DNA was amplified in the presence of 2 pmol of each primer, 0.25 U AmpliTaq Gold, 0.2 mM dNTPs, and 2.5 mM MgCl2 (buffer was supplied by Applera). Cycling conditions were: 95°C for 10 min, followed by 37 cycles of 94°C for 15 sec, 30 sec at 55°C, and 1 min at 72°C. Alleles were automatically called using the deCODE Allele Caller and the program deCODE GT was used to fractionate called genotypes according to quality, and to edit when necessary.

Subsequently, we performed genome-wide linkage analysis for the deCODE Genetics data using Merlin software for singlepoint linkage analysis (http://www.sph.umich.edu/csg/abecasis/MERLIN/download), and then verified the findings and refined the analyses using Allegro software for multipoint linkage analysis (www.decode.com/software/allegro).

Results: The two dento-osseous disorders localized, using multipoint analysis, to chromosomes 11 (distant from *LRP5*) with peak LOD score of 2.6 (Kindred A) and to chromosome 6 and 8 with peak LOD score of 6.1 and 6.0 (Kindred B). Therefore, they are unique conditions and not variants of Albers-Schonberg osteopetrosis or OI caused by chromosomal defects elsewhere. Multipoint analysis of the data combined from the 3 families with OI type V mapped the disorder to chromosome 4 with a peak LOD score of 2.8. Metachondromatosis mapped to chromosomes 9 and 12 where peak LOD scores were 3.8 and 3.6 respectively.

Conclusion: Accordingly, we have mapped two unique dento-osseous disorders as well as OI type V and metachondromatosis to chromosomes 11, 6 or 8, 4, and 9 or 12, respectively, in order to pursue the underlying gene defects.

Biochemical Response to Bolus Oral Cholecalciferol Treatment. Helen Linklater and Patrick D.W. Kiely, St George's Hospital, London, United Kingdom

Purpose: Hypovitaminosis D is increasingly recognized in patients attending a rheumatology clinic. There is no consensus concerning the optimum target minimum concentration of serum 25(OH)D3 to be achieved with replacement therapy. Neither is there a validated standard protocol to either replenish or maintain serum 25(OH)D3 in an acceptable ‘normal' range. Vitamin D replacement using daily oral calcium and cholecalciferol tablets is limited by unpalatability and a disappointing biochemical response, possibly related to poor long term adherence. We have studied the serum 25(OH)D3 response to single high dose bolus supplementation of cholecalciferol.

Method: Patients attending the rheumatology department of St George's Hospital, London, UK found to have hypovitaminosis D (< 55nmol/L), despite prescription of conventional oral supplements of vitamin D3 800U, were treated with oral bolus cholecalciferol 300,000U in 100ml sunflower oil (Martindale pharmaceutical, Essex, UK). Serum calcium, phosphate, PTH and 25(OH)D3 (IDS ELISA assay, ImmunoDiagnostics systems Ltd, Tyne and Wear, UK) were measured at regular intervals over the following 32 weeks.

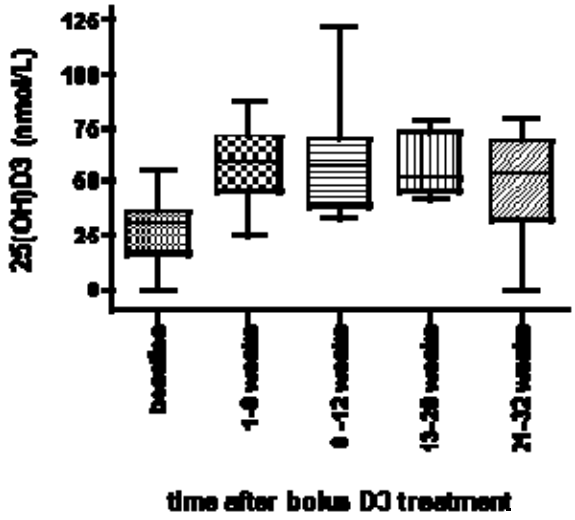
Results: 37 patients were treated, mean age 54 years (range 17–86, 95% CI 48-59), 8 male. 25/37 were of Asian or Black African origin. Mean baseline 25(OH)D3 concentration was 25.5 nmol/L (range 0–55, 95% CI 20 - 30). The bolus cholecalciferol drink was well tolerated, with no subjective or biochemical hypercalcaemic adverse effects. Total serum 25(OH)D3 (nmol/L) and change from normalized baseline values (nmol/L) at successive time intervals following treatment are shown in Table 1.

Table 1

Time	Baseline	1-8 weeks	9-12 weeks	13-20 weeks	21-32 weeks
Number	37	17	12	13	13
Mean D3	25.5	58.3	58.0	58.0	49.5
95% CI	20-30	49-67	42-73	49-66	36-62

Change from baseline		31.6	31.4	32.5	23.7
95% CI		22-41	14-48	21-44	10-37

Figure 1 shows a box and whisker pot of serum 25(OH)D3 at each time interval. Season had no effect on baseline 25(OH)D3 concentration or the response to bolus treatment. PTH was elevated in 10/27 patients, and found to normalize in 5/7 who had repeat PTH measurement within 6 months. Figure 1



Conclusion: In patients with hypovitaminosis D, bolus treatment with 300,000U cholecalciferol in sunflower oil is safe and well tolerated. In the majority of patients this results in a rise in serum 25(OH)D3 to within the normal range (> 55 nmol/L) within 8 weeks. Serum 25(OH)D3 concentrations remain in the normal range for up to 28 weeks but in some patients fall below 55 nmol/L within 12 weeks. Therefore measurement of serum 25(OH)D3 should be performed regularly from at least 12 weeks after bolus replacement to determine the time for repeat treatment in individual cases.

Does Use of the FRAX Tool Change Management in Female Patients with Osteopenia? Israa Al-Shakarchi, A. Louise Dolan, Jehan Karim and Lucy Powell, South London NHS Trust, London, United Kingdom

Purpose: Many patients suffering from fractures are osteopenic rather than osteoporotic. Those with fractures are at increased risk of further fractures and fracture risk also increases with age. FRAX is a tool that computes the 10-year probability of a fracture from clinical risk factors. Could this change management? The aim of this study is to assess the 10-year fracture risk in female patients with osteopenia using FRAX.

Method: 1446 women aged 55 – 87 years with osteopenia confirmed on DEXA scans (T score of ≤ -1 to ≤2.4) at the femoral neck were identified on our hospital osteoporosis service database based on referrals from primary and secondary care. The FRAX score was computed using risk factors previously recorded on the database and bone mineral density (BMD) at the hip, using the FRAX website calculator.

Results:

Age range	Number of patients	Previous history of any fracture	Previous hip fracture	FRAX 10-year hip fracture risk ≥ 3%	FRAX 10-year all fracture risk ≥20%
55 – 87 (All patients)	1446	781/1446 (54.0%)	67/781 (8.6%)	581/1446 (40.2%)	250/1446 (17.3%)
55 – 64	529/1446 (36.6%)	260/529 (49.2%)	14/260 (5.38%)	68/529 (12.9%)	57/529 (10.8%)
65 – 74	564/1446 (39.0%)	307/564 (54.4%)	19/307 (6.2%)	232/564 (41.1%)	106/564 (18.8%)
>75	353/1446 (24.4%)	214/353 (60.6%)	34/214 (15.9%)	281/353 (79.6%)	87/353 (24.7%)

Conclusion: Currently treatment decisions on osteoporosis and osteopenia are based largely on BMD measurement via DEXA scanning. DEXA scanning is specific but not sensitive, and as such DEXA BMD measurement alone is insufficient to identify all patients at risk. Our results concur with previous studies that show that fractures are common in those with osteopenia (54%) and increase with age. Hip fractures are more common in those over 75 years of age (15.9%). International guidance based on FRAX recommends treatment for those with a 10-year hip fracture risk of ≥ 3% and all fracture risk of ≥ 20%. Our results identified that 40.2% of patients required treatment based on FRAX score who would not have been treated based on DEXA alone (T score ≥ -2.5). Those over 75 years of age had the highest 10-year hip fracture risk with 79.6% having a score of ≥ 3%. These results suggest that FRAX increases the sensitivity of fracture risk assessment and has the potential to improve treatment intervention strategies.

Risk of Atypical Subtrochanteric Fractures in Older Veterans at High Risk for Osteoporosis. Monika M. Safford[1], Kelly Richardson[2], Mary Sarrazin[2], Peter Cram[2], Jeffrey R. Curtis[1], Elizabeth Delzell[1], Andrei Barasch[1] and Kenneth G. Saag[1], [1]UAB, Birmingham, AL, [2]Iowa City VAMC, Iowa City, IA

Purpose: Atypical subtrochanteric fractures may be a risk for longer-standing bisphosphonate (BP) users. We examined the risk of these atypical fractures associated with BP therapy among veterans at high risk of osteoporotic fracture.

Method: National administrative VA data from 1999-2008 included inpatient and outpatient utilization files and pharmacy data. We included individuals presumed to have osteoporosis, i.e., admitted for a non-trauma fracture to a VA facility at age ≥45. We excluded individuals with enrollment in the VA system for < 180 days prior to 1st fracture, metastatic cancer, and history of chemotherapy. The primary outcome was a subsequent "atypical" subtrochanteric fracture, defined by ICD-9 code "fracture of subtrochanteric section of femur, closed" [820.22] in the absence of trauma ICD-9 codes or open fractures. Cumulative BP use was the main exposure of interest, and only individuals who initiated BP use at least 365 days after first appearance in VA data were included to better define duration of use. We constructed Cox proportional hazards models to examine associations between BP and risk of subsequent atypical fracture or more typical hip fracture. Available covariates included demographics (age at 1st fracture, sex, and race), baseline comorbid medical conditions, medications associated with osteoporosis, fall risk, and distance to the nearest VA Medical Center. Covariates bivariately associated with p<.20 were included in multivariable models.

Results: Of 80,684 eligible veterans, 95% were men, 3.6% used BPs before their 1st fracture, and another 6.4% had BPs initiated afterward. We detected 45 atypical subtrochanteric and 1,805 typical hip 2nd fractures over a mean follow-up of 4.2 years. BP use duration of individuals with atypical subtrochanteric, typical hip and those with no 2nd fractures are shown in the Table. Compared with nonusers, BP users had the following hazard ratios (HR) for subsequent atypical subtrochanteric fractures: <1 year of BP use, HR 1.4 (95% CI 0.18-10.46); 1-6 years, HR 0.47 (95% CI 0.06-3.57); >6 years, HR 4.5 (95% CI 0.58-34.24). In contrast, compared with nonusers, BP users had the following HR for subsequent typical hip fractures: <1 year of use, HR 1.27 (95% CI 0.98-1.66); 1-6 years, HR 0.80 (95% CI 0.65-.099); >6 years, HR 0.39 (95% CI 0.16-0.95).

Conclusion: While BP use >6 years trended towards an association with increased risk for atypical subtrochanteric fractures, atypical fractures were rare, and long-term BP use was associated with a substantially decreased risk for hip fractures, which were 40 times more common than atypical fractures. These findings should be confirmed to provide information for long-term BP users and their physicians about overall risks and benefits.

		Type of 2nd fracture		
		Atypical subtrochancteric (N=45)	Typical hip (1,805)	No 2nd fracture (70,305)
Total BPs up to time of 2nd fracture or end of observation	None	41 (91%)	1,618 (90%)	64,083 (91%)
	<1 yr	1 (2%)	71 (4%)	1,344 (2%)
	1-6 yrs	1 (2%)	85 (5%)	2,811 (4%)
	>6 yrs	2 (4%)	31 (2%)	2,067 (3%)

Relationship Between Increases in BMD On Denosumab and Reduction in Fracture Risk. Michael McClung[1], Steven Cummings[2], Yu-Ching Yang[3], Eric Vittinghoff[4], Silvano Adami[5], Gerolamo Bianchi[6], Michael Bolognese[7], Claus Christiansen[8], Andreas Grauer[3], Federico Hawkins[9], David L. Kendler[10], Cesar Libanati[3], Carlos Mautalen[11], Ian Reid[12], Jose Zanchetta[13], Cristiano A. F. Zerbini[14], Richard Eastell[15] and for the FREEDOM Trial, [1]Oregon Osteoporosis Center, Portland, OR, [2]SFCC, CPMC Research Institute & UCSF, San Francisco, CA, [3]Amgen Inc., Thousand Oaks, CA, [4]UCSF, San Francisco, CA, [5]University of Verona, Verona, Italy, [6]Ospedale La Colletta, Genoa, Italy, [7]Bethesda Health Research Center, Bethesda, MD, [8]CCBR, Ballerup, Denmark, [9]Hospital Universitario, Madrid, Spain, [10]Clinical Research Centre, Vancouver, BC, [11]Centro de Osteopatías Médicas, Buenos Aires, Argentina, [12]University of Auckland, Auckland, New Zealand, [13]Instituto de Investigaciones Metabolicas and University of Salvador, Buenos Aires, Argentina, [14]Hospital Heliopolis, Sao Paulo, [15]University of Sheffield, Sheffield, United Kingdom

Purpose: Previous studies suggest changes in BMD in response to osteoporosis treatment with bisphosphonates and raloxifene explain only a small portion of the observed fracture risk reductions.

Methods: The FREEDOM trial randomly assigned 7,868 women aged 60-90 years with spine or total hip BMD T-score <-2.5 and not <-4.0 at either site to placebo or subcutaneous denosumab 60 mg every 6 months. Total hip BMD was measured at baseline and annually. New vertebral fractures were defined as ≥ 1 grade increase in semiquantitative grade of fracture on annual lateral spine films from a baseline grade of 0. Nonvertebral fractures were confirmed by imaging. The proportion of treatment effect on fracture risk explained (PTE) by percent change in total hip BMD was estimated as proposed by Li et al (2001) and by a novel approach of using percent changes in BMD corresponding to scheduled and unscheduled fracture assessments (time-dependent models).

Results: Compared with placebo, denosumab increased total hip BMD by 3.2% at 12, 4.4% at 24, and 5.0% at 36 months. Denosumab decreased the risk of new vertebral fractures by 68% (P<0.0001) and nonvertebral fracture by 20% (P=0.01) over 36 months. Using time-dependent models, change in total hip BMD explained about half of denosumab's effect on risk reduction of new vertebral fractures (table). It seemed to explain most of the reduction in risk of nonvertebral fracture although the confidence limits were wide.

Conclusion: Using time-dependent models, change in total hip BMD with denosumab explained about half of the reduction in new vertebral fracture risk. Change in total hip BMD may explain a substantial portion of the reduction in risk of nonvertebral fracture observed with denosumab treatment.

Percent of treatment effect on fracture risk explained by % change in total hip BMD

	Percent of treatment explained (95% CI)	
Timing of hip BMD	New vertebral fracture	Nonvertebral fracture
12 months	23% (13%, 40%)	35% (9%, *)
24 months	30% (16%, 54%)	89% (37%, *)
36 months	35% (20%, 61%)	87% (35%, *)
At fracture measurement/occurrence	51% (39%, 68%)	72% (24%, *)

*Upper Limit of CI was >100%

Fracture Incidence in Postmenopausal Women at Higher Risk of Fracture After 3 Years of Denosumab Treatment. Jonathan D. Adachi[1], Michael McClung[2], Salvatore Minisola[3], Kurt Lippuner[4], Ove Torring[5], Rene Rizzoli[6], Zulema Man[7], Henry G. Bone[8], Jordi Farrerons[9], Claus Christiansen[10], Richard Eastell[11], Ian Reid[12], Ethel Siris[13], Steven Cummings[14], Andrea Wang[15], Nathalie Franchimont[16], Javier San Martin[15] and Steven Boonen[17], [1]McMaster University, Hamilton, ON, [2]Oregon Osteoporosis Center, Portland, OR, [3]Universita' Di Roma “Sapienza”, Rome, Italy, [4]Inselspital Bern, Bern, Switzerland, [5]Karolinska Institutet Sodersjukhuset, Stockholm, Sweden, [6]University Hospital, Geneva, Switzerland, [7]Centro T.I.E.M.P.O., Buenos Aires, Argentina, [8]Michigan Bone and Mineral Clinic, Detroit, MI, [9]Hospital de la Santa Creu I Sant Pau, Barcelona, Spain, [10]CCBR, Ballerup, Denmark, [11]University of Sheffield, Sheffield, United Kingdom, [12]University of Auckland, Auckland, New Zealand, [13]Columbia University Medical Center, New York, NY, [14]SFCC, CPMC Research Institute & UCSF, San Francisco, CA, [15]Amgen Inc., Thousand Oaks, CA, [16]Amgen Inc., Zug, Switzerland, [17]University of Leuven, Leuven, Belgium

Purpose: FREEDOM, a randomized double-blind placebo-controlled phase 3 trial, showed denosumab (DMAb) significantly reduced risk of new vertebral, hip, and nonvertebral fractures over 3 years. In this analysis, we studied the fracture rates in FREEDOM subjects identified as having higher fracture risk.

Methods: Postmenopausal women (60-90 years old) with a spine or hip T-score <-2.5 and not <-4.0 were randomized to twice yearly DMAb (60 mg) or placebo injection for 3 years. Established clinical criteria were used to identify subgroups of women at higher fracture risk. Prespecified analyses included women with ≥2 risk factors: age >70; baseline spine, hip, or femoral neck T-score ≤-3.0; and prevalent vertebral fracture. Post hoc analyses used known risk factors for hip (age >75 or baseline femoral neck T-score ≤-2.5) or vertebral (≥2 prevalent vertebral fractures, prevalent vertebral fractures of moderate or severe severity, or both) fractures.

Results: Of 7808 women analyzed, 45% were at higher fracture risk by the prespecified criteria. Greater fracture rates in the higher risk placebo group suggest relevant risk factors were used. DMAb reduced hip, new vertebral, and nonvertebral fracture risk in women at higher risk, although nonvertebral fracture reduction was not statistically significant (Table). The risk factors used in the posthoc analyses also showed that DMAb significantly reduced risk of fractures in women specifically at higher risk for hip (by age or low BMD) or new vertebral fractures (Table).

Conclusion: Twice yearly DMAb for 3 years reduced fracture risk in women with osteoporosis. Reduction in risk of hip fracture in women ≥ age 75 could be of particular clinical relevance.

Table. Fracture Incidence and Risk Reduction With Denosumab Treatment Over 3 Years

	Fracture Incidence				
Fracture	Overall Placebo Group	Higher Risk Placebo Group	Higher Risk Denosumab Group	Risk Reduction With Denosumab % (95% CI)	*P*-value
Prespecified Criteria[a]					
Hip fracture	1.2%	2.1%	1.1%	48% (9%, 71%)	0.0209
New vertebral fracture	7.2%	10.0%	3.8%	62% (53%, 70%)	< 0.0001
Nonvertebral fracture	6.0%	8.3%	6.2%	12% (-11%, 30%)	0.2901
Posthoc Criteria					
Hip fracture - age[b]	1.2%	2.3%	0.9%	62% (23%, 82%)	0.0065
Hip fracture - BMD[c]	1.2%	2.0%	1.4%	47% (6%, 70%)	0.0237
New vertebral fracture[d]	7.2%	10.0%	7.0%	62% (51%, 71%)	0.0002

[a]Women with ≥2 of the prespecified risk factors: age > 70 years, baseline BMD T-score ≤ -3.0 at lumbar spine, total hip, or femoral neck, and/or prevalent vertebral fracture at baseline; number of women in each group: overall placebo = 3906; higher risk placebo = 1762, and higher risk denosumab = 1762. [b]Women ≥75 years old (higher risk placebo = 2870; higher risk denosumab = 2837); [c]Women with baseline femoral neck T-score ≤ -2.5 (higher risk placebo = 1400; higher risk denosumab = 1384); [d]Women with ≥2 prevalent vertebral fractures, moderate or severe vertebral fracture, or both (higher risk placebo = 372; higher risk denosumab = 387)

Zoledronic Acid After 2-Years of Teriparatide: Bone Density and Bone Turnover Markers in 35 Patients. C. Deal[1], K. Tuthill[1] and A. Kriegman[2], [1]Cleveland Clinic, Cleveland, OH, [2]Novartis Pharmaceuticals, East Hanover, NJ

Purpose: Teriparatide (TPTD) is an anabolic agent approved for patients at high risk for fracture and significantly increases bone density (BMD) over a two year course of treatment. After discontinuation of TPTD, BMD declines if antiresorptive therapy is not initiated. Treatment with alendronate has been shown to prevent bone loss and further increase bone mass after TPTD discontinuation. Zoledronic acid 5mg (ZOL) is an IV bisphosphonate approved as a once-yearly infusion for the treatment of osteoporosis. We tested the ability of ZOL to maintain bone mass after treatment with TPTD.

Methods: We treated 35 postmenopausal women with ZOL immediately after finishing a course of TPTD. The primary endpoint was change in bone density (g/cm^2) in the lumbar spine at 12 months. Secondary endpoints were change in bone density at the total hip (TH), femoral neck (FN), and total body (TB). Markers of bone turnover (BTO), serum c-telopeptide type I collagen (CTX) and procollagen type 1 n-terminal propeptide (P1NP) were measured in all patients at baseline and days 10, 60,180, 270 and 365. We report the bone density results on 35 patients, changes in markers of bone turnover are available for the first 24 patients.

Results: The study cohort had a mean age of 68.8 +/- 11.2, a mean T-score of -2.1 for the LS and TH, -2.3 for FN, and -1.7 for TB. Table 1 summarizes the number of patients exhibiting stable, increased or decreased BMD at the LS, TH, FN and TB (LSC +/-0.03g/cm2). In the 35 patients at 140 skeletal sites, 131 sites (93.6%) had stable or increased bone mass. After treatment with ZOL, levels of CTX were significantly lower at day 10, P1NP at day 60 and all subsequent time points. Changes in BMD at 12 Months: N=35 (LSC +/- 0.03 g/cm2)

BMD Site	LS	TH	FN	TB
Stable/Increased	32	32	33	34
Decreased	3	3	2	1

Change in BTO Markers Day 10 to Day 365: % Decline from Day 0, N=24

Day	10	60	180	270	365
CTX	-90% (sd 10.1)	-77% (sd 20.9)	-63%	-63%	-60%
P1NP	-15% (sd 25.1)	-72% (sd 14.9)	-74%	-56%	-56%

Conclusion: A single infusion of zoledronic acid 5mg preserved or increased bone mass in patients after TPTD treatment in the LS, FN, TH and TB in 91%, 91%, 94%, and 97% respectively.

The Effect of Proton Pump Inhibition On Urinary N-Telopeptide Levels and Urinary Calcium Levels: A Prospective Randomized Cross-Over Study Comparing Use of Calcium Carbonate and Calcium Citrate. Linda M. Burns, Joseph M. Grisanti, Michael W. Grisanti, Mary Brennan and James Hatem, Buffalo Rheumatology, Orchard Park, NY

Purpose: An increased risk of osteoporotic fractures has been reported in patients on proton pump inhibitor (PPI) therapy. Theories for the explanation of these findings have centered around the decreased bioavailability of calcium while on PPI therapy. The purpose of this study is to evaluate the biochemical evidence of the proton pump inhibitor (PPI) class of antacids effect on bone metabolism. The primary endpoint is to determine if the bioavailability of calcium citrate is superior to calcium carbonate in subjects taking proton pump inhibitors.

Method: To analyze the absorption of calcium, a urinary calcium (Ca) to creatinine (Cr) ratio was measured. An assessment of osteoclastic activity was measured using urinary type I collagen N-telopeptide (NTX) before and after proton pump inhibitor (PPI) administration. A total of 31 healthy postmenopausal women were enrolled after meeting inclusion criteria. Requirements for study entry included a normal 25-OH Vitamin D level, a normal baseline urinary NTX, absence of corticosteroid exposure and anti-resorptive therapy for 8 weeks prior to study entry.

All subjects were randomly assigned to receive calcium citrate or calcium carbonate, 600mg twice daily. After four weeks of calcium supplementation, a baseline urinary NTX, urinary Ca, and urinary Cr were obtained on all subjects. Following these baseline measurements, all subjects were started on PPI therapy in the form of omeprazole 20mg twice daily while continuing calcium supplementation. After four weeks of PPI use, the urinary studies were repeated. The last phase of the trial involved continuing the PPI but switching subjects to the alternative calcium supplement for an additional four weeks and repeating the urinary studies a third time.

Results: Baseline urinary data on calcium alone was compared to urinary data obtained post PPI use. Data analysis was done using a paired t-test with a p-value of <0.05 deemed statistically significant. We found the mean urinary NTX increased from 29 to 40 nmol/mmol Cr ($p=0.0003$) in the calcium citrate group and increased from 29 to 40 nmol/mmol Cr ($p=0.0011$) in the calcium carbonate group. There was no difference in calcium excretion after PPI addition as reflected by the Ca to Cr ratio in either calcium citrate or calcium carbonate users.

Conclusion: This study shows a 37.9% increase in urinary N-telopeptide within 4 weeks of initiation of PPI use in healthy postmenopausal women. Our data does not identify a superior calcium supplement in patients concomitantly using proton pump inhibitors. The dramatic increase in bone turnover seen in this study following PPI administration demonstrates biochemical evidence supporting an association of PPI's to osteoporosis. Considering this study in conjunction with others that have implicated an increased fracture risk with PPI use, we suggest that PPI's be deemed an independent risk factor for osteoporosis.

A Novel Oral Parathyroid Hormone Formulation, PTH134, Demonstrated a Potential Therapeutically Relevant Pharmacokinetic and Safety Profile Compared with Teriparatide s.c. in Healthy Postmenopausal Women After a Single Dose. Markus R. John, Sibylle Haemmerle, Aino Launonen, Evita Harfst, Moise Azria, Michel Arnold and Linda Mindeholm, Novartis Pharma AG, Basel, Switzerland

Purpose: Parathyroid hormone (PTH), currently the only anabolic treatment for osteoporosis, is available as the full-length hormone, PTH_{1-84}, or as the PTH_{1-34} fragment (teriparatide). Both must be given subcutaneously (s.c.). A new oral formulation of PTH_{1-34} (PTH134) is being developed as a more convenient option for patients. In this single-centre, partially-blinded, incomplete cross-over study, the safety, tolerability, and exposure of oral PTH134 (teriparatide combined with 2 different quantities of the absorption enhancer 5-CNAC) were assessed in 32 healthy postmenopausal women.

Method: 16 subjects were randomized to receive single doses of up to six different treatments: placebo, teriparatide 20µg s.c., or 1, 2.5, 5 or 10mg of oral PTH134 formulated with 200mg 5-CNAC. Subsequently, another 16 subjects were randomized to receive up to six different treatments: placebo, teriparatide 20µg s.c, or 2.5 or 5mg of oral PTH134 formulated with either 100 or 200mg 5-CNAC. Doses were given ≥ 6 days apart.

Results: All doses of PTH134 were rapidly absorbed, and showed robust blood concentrations in a dose-dependent manner. Interestingly, PTH_{1-34} was eliminated faster after oral versus s.c. administration. Specifically, 2.5 and 5 mg PTH134 (containing 200 mg 5-CNAC) demonstrated C_{max} and AUC_{0-last} values closest to those of s.c. teriparatide 20µg. The geometric mean estimate for PTH134 2.5mg/200mg 5-CNAC was 98.7 pg/ml (90% CI 67.3-144.7) for C_{max} and 28.3 hr*pg/ml (90% CI 16.4-49.0) for $AUC_{(0-last)}$, while for PTH134 5mg/200mg 5-CNAC the estimated geometric mean values were 502.7 pg/ml (90% CI 304.5-829.6) for C_{max} and 175.4 hr*pg/ml (90% CI 86.0-358.0) for $AUC_{(0-last)}$. The corresponding estimates for teriparatide 20 µg s.c. were 143.6 pg/ml (90% CI 123.7-166.7) for C_{max} and 229.9 hr*pg/ml (90% CI 198.9-263.7) for $AUC_{(0-last)}$.

Ionized calcium remained within normal limits in all treatment groups. Nine subjects withdrew due to treatment-related AEs. Of those, seven were taking PTH134 2.5 or 5mg: three withdrew for symptomatic hypotension (two of whom were in the 200mg 5-CNAC group), three because of delayed vomiting (two from the 200mg 5-CNAC group), one withdrew for symptomatic, but unconfirmed, hypercalcemia

(receiving 2.5mg/100mg 5-CNAC). One subject receiving teriparatide and one receiving placebo withdrew for symptomatic hypotension. No serious AEs were reported.

Conclusion: The study demonstrated potential therapeutically relevant PTH_{1-34} systemic exposure levels after oral administration of PTH_{1-34} formulated with the absorption enhancer 5-CNAC. Doses of 2.5 and 5mg of oral PTH134 achieved exposure levels closest to those of teriparatide 20µg s.c., with a comparable incidence of AEs in healthy postmenopausal women. PTH134 warrants further investigation

Is the FRAX Tool Useful in Assessing Fracture Risk in Female Rheumatoid Arthritis Patients? Israa Al-Shakarchi, A. Louise Dolan, Lucy Powell and Jehan Karim, South London NHS Trust, London, United Kingdom

Purpose: Rheumatoid arthritis (RA) is a known risk factor for osteoporosis and fractures are common in those with RA. FRAX is a new tool developed by the WHO to compute the 10-year probability of a fracture from clinical risk factors (CRFs) with or without the measurement of BMD at the femoral neck. This project aims to use FRAX to assess the 10 year fracture risk in female patients with RA.

Method: 349 women aged 40 – 85 years with RA referred for DEXA scans were identified on our hospital osteoporosis service database based on referrals from primary and secondary care. The FRAX score was computed using risk factors previously recorded on the database and bone mineral density (BMD) at the hip.

Results:

Age Range	Number of Patients	Previous history of any fracture	Previous hip fracture	FRAX 10-year hip fracture risk >3	FRAX 10-year all fracture risk >20	% Osteoporotic (T score ≥ 2.5)	% Osteopenic (T score -1.0 – ≤2.4)
40 – 84 (All patients)	349	144/349 (41.3%)	18/349 (5.2%)	125/349 (35.8%)	93/349 (26.7%)	48/349 (13.8%)	140/349 (40.1%)
40 - 54	67/349 (19.2%)	21/67 (31.3%)	3/67 (4.5%)	4/67 (6.0%)	3/67 (4.5%)	1/67 (1.5%)	21/67 (31.3%)
55– 64	110/349 (31.5%)	41/110 (37.3%)	1/110 (0.9%)	17/110 (15.5%)	13/110 (11.8%)	7/110 (6.4%)	41/110 (37.3%)
65– 74	113/349 (32.4%)	47/113 (41.6%)	6/113 (5.3%)	60/113 (53.1%)	43/113 (38.1%)	20/113 (17.7%)	56/113 (49.6%)
> 75	59/349 (16.9%)	35/59 (59.3%)	8/59 (13.6%)	44/59 (74.6%)	35/59 (59.3%)	20/59 (33.9%)	22/59 (37.3%)

Conclusion: Our results concur with previous studies that show that fractures are common in RA (41.3%) and increase with age. A number of non-BMD factors have been identified as contributing to an increased risk of fracture. These include advancing age, a family history of hip fracture, a personal history of fragility fracture, glucocorticoid therapy and current smoking. These CRFs are incorporated within the FRAX tool. Current U.S guidance based on FRAX recommends treatment for those with a 10-year hip fracture risk of ≥ 3 or a 10-year all fracture risk of ≥ 20. Our study identified a greater number of patients requiring treatment based on a FRAX 10-year hip fracture score, than would be suggested by DEXA alone (T score ≥-2.5) (35.8% vs 13.8%). These results suggest that FRAX increases the sensitivity of fracture

risk assessment and has the potential to improve treatment intervention strategies. We recommend that FRAX becomes a routine part of assessment in patients with rheumatoid patients.

Once Monthly Oral Ibandronate Provides Significant Improvement in Lumbar Spine Bone Mineral Density in Postmenopausal Women Treated with Glucocorticoids for Inflammatory Rheumatic Diseases. Leena Paimela[1], Markku Hakala[2], Tuija Hienonen-Kempas[3] and ONCE study group, [1]ORTON hospital, Invalid Foundation, Helsinki, Finland, [2]Rheumatism Foundation Hospital, Heinola, Finland, [3]Roche Finland, Espoo, Finland

Purpose: To assess the efficacy of once monthly oral ibandronate 150mg in the prevention of glucocorticoid-induced osteoporosis in postmenopausal women with any inflammatory rheumatic disease, including polymyalgia rheumatica.

Method: The ONCE (Osteoporosis preventioN in glucoCorticoid-treated womEn) study was a randomized, double-blind, placebo-controlled, parallel-group study in postmenopausal women in Finland. Women aged 50–85 years, ≥1 year since menopause, with a mean lumbar spine (L1–L4) bone mineral density (BMD) T-score ≥–2.0, receiving treatment with 5-15mg/day of prednisone equivalent were randomized 1:1 to receive either monthly oral ibandronate 150mg or monthly placebo for 12 months. In addition, all patients received vitamin D (800IU/day) and calcium (1000mg/day) supplements. The primary endpoint, the relative change (%) from baseline at 12 months in mean lumbar spine (L1-L4) BMD, was analyzed using ANCOVA. The primary model included treatment, center, duration of glucocorticoid treatment, diagnosis of rheumatic disease and baseline BMD as covariates. Treatment difference was assessed using least square means with a 95% confidence interval (CI).

Results: In total, 140 postmenopausal women were randomized, and 124 completed the study. Mean age was 64 (range 50–83) years and mean BMI was 29 (range 19–45) kg/m^2. At baseline, mean lumbar spine BMD was 1.14 (range 0.90-1.61) g/cm^2. Primary diagnoses were rheumatoid arthritis (48%), polymyalgia rheumatica (36%), or other inflammatory rheumatic disease (16%). The intent-to-treat (ITT) analyses showed a significant mean change from baseline in mean lumbar spine BMD with ibandronate (2.6% and 3.3%) compared with placebo (0.3% and -0.2%) at 6 and 12 months, respectively. Estimated treatment difference versus placebo at 12 months was 3.25 (95% CI: 2.09 to 4.41], $p<0.001$. Results were similar in the per protocol population (estimated treatment difference at 12 months versus placebo 3.66 [95% CI: 2.37 to 4.95], $p<0.001$).

Conclusion: Once monthly oral ibandronate provides a significant increase in lumbar spine BMD after 6 months of treatment in postmenopausal women treated with glucocorticoids for inflammatory rheumatic diseases.

Change in Serum 25(OH)D Levels Over 2.6 Years in Older Adults: Predictive Effects of Body Fat, Physical Activity, Leptin, Interleukin-6 and Total Cholesterol/HDL Ratio. Changhai Ding[1], Flavia Cicuttini[2] and Graeme Jones[1], [1]University of Tasmania, Hobart, Australia, [2]Monash University, Melbourne, Australia

Purpose: To determine the associations between body fat, physical activity and change in serum 25(OH)D levels over 2.6 years, and if these associations are mediated by serum measures including leptin, interleukin 6 (IL-6) and cholesterol in older adults.

Methods: In a total of 859 randomly selected subjects (mean 62 years, range 51-80, 49% female), serum 25-hydroxyvitamin D [25-(OH)D] were assessed by radioimmunoassay at baseline and 2.6 years later. Baseline serum levels of leptin and IL-6 (assessed by radioimmunoassay in the first 183 subjects), and total cholesterol and high-density lipoprotein (HDL) were determined. Fat mass was measured by dual energy x-ray absorptiometry (DXA). Body mass index (BMI) was calculated, and physical activity measures including steps per day and lower limb muscle strength were measured.

Results: At baseline, the prevalence of vitamin D deficiency [defined as 25-(OH)D of < 50 nmol/L] was 45%. Over 2.6 years, incidence of vitamin D deficiency was 23% and rate of recovery from vitamin D deficiency was 40%. Seasonal variation between baseline and follow-up was associated with change in 25-(OH)D levels (ρ=0.59, P<0.001) so all the analyses were adjusted for this and other potential confounders (including age, sex, BMI, smoking, sunlight exposure and/or steps per day). Change in 25-(OH)D levels per annum [(follow-up value – baseline value)/years between 2 measures] was significantly associated with baseline age (β: -0.06 unit/year, 95% CI: -0.12, -0.004), BMI (β: -0.13 unit/ kg/m^2, 95% CI: -0.22, -0.04), total body fat percentage (β: -0.13, 95% CI: -0.22, -0.05), trunk fat percentage (β: -0.11, 95% CI: -0.17, -0.05), winter physical activity (β: 0.68/grade, 95% CI: 0.11, 1.25), summer physical activity (β: 0.60/grade, 95% CI: 0.03, 1.18), steps per day (β: 0.14/1000 steps, 95% CI: 0.03, 0.25) and lower limb muscle strength (β: 0.19/10 kg, 95% CI: 0.06, 0.33). It was also associated with baseline serum measures such as leptin (β: -0.09/unit, 95% CI: -0.17, -0.03), IL-6 (β: -0.68/quartile, 95% CI: -1.35, -0.02), HDL (β: 1.39/unit, 95% CI: 0.21, 2.57) and total cholesterol/HDL ratio (β: -0.51, 95% CI: -0.88, -0.14).The associations between body fat and change in 25-(OH)D levels all became non-significant after adjustment for leptin, partly decreased (10% to 20%) after adjustment for IL-6, but still remained significant after adjustment for total cholesterol/HDL ratio. In contrast, the associations between physical activity measures and change in 25-(OH)D levels were largely independent on serum measures.

Conclusion: Instead of solely being related to sun exposure and diet, vitamin D levels appear to have many determinants including body composition, hormonal factors and inflammation.

Bone Mineral Density Alone Fails to Recognize Seventy Percent of Men Who Are at High Risk of Fracture Compared to a Global Risk Assessment (Bone DESTINY) That Leads to Significant Undertreatment in This Population. Viktoria Pavlova, Karen A. Beattie, George Ioannidis, Juliana Tricta, Maggie J. Larché, William G. Bensen and Jonathan D. Adachi, McMaster University, Hamilton, ON

Purpose: Diagnosis of Osteoporosis is generally perceived as a simple diagnosis and decision to treat mostly driven by the BMD score alone. Fragility fracture is a major risk factor for Osteoporosis and should be a trigger for diagnosis and therapy. In the Ontario Fracture Program only 30% of people with fracture have Osteoporosis on a BMD.

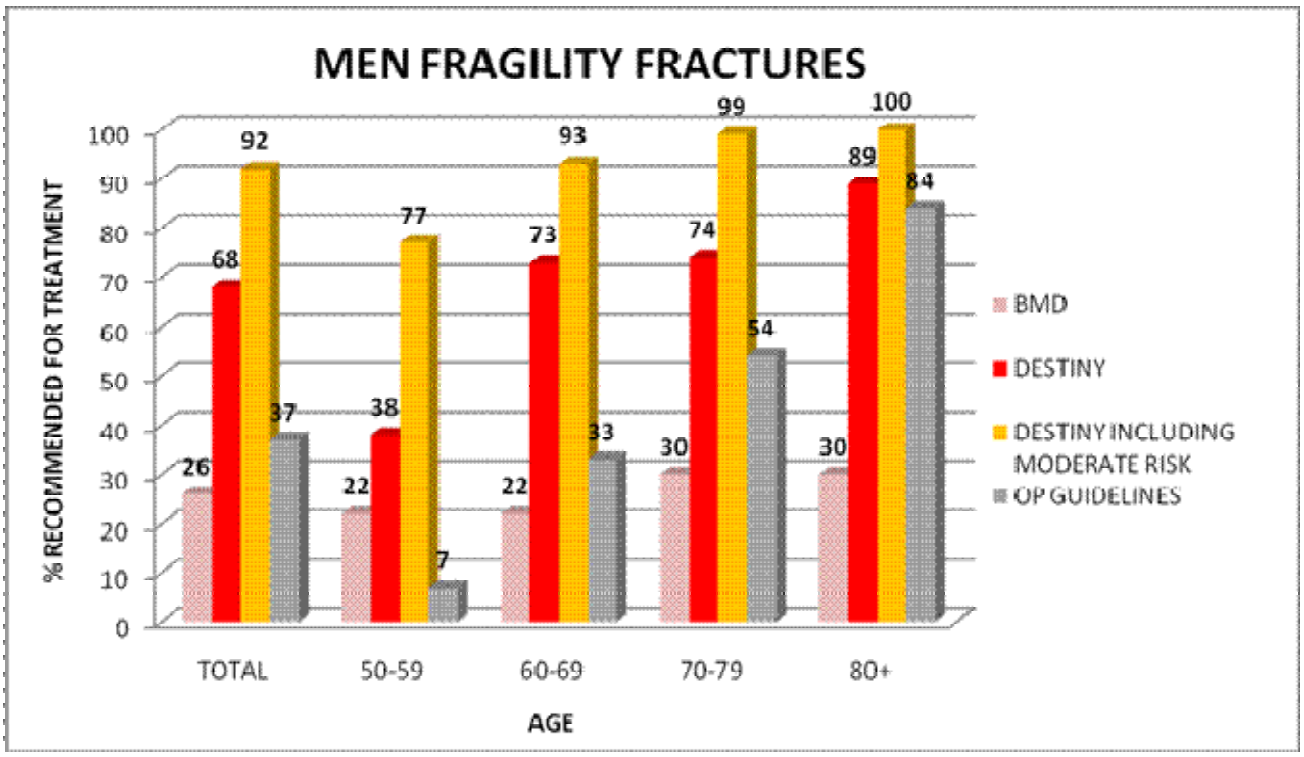
Most studies of Osteoporosis have focused on postmenopausal women, however, older men are also at increased risk of fragility fractures. Undertreatment of osteoporosis in men, even those who have sustained a fracture, remains a significant problem.

Methods: We analyzed our data, one of the largest databases in Canada, of 36,360 patients over 50 years of age who had their BMD done in the greater Hamilton area, Ontario, Canada, from May 2006 and June 2009. We identified 5,519 men total and 777 of whom sustained a fragility fracture.

Primary objective was to determine the proportion of male patients who have already had clinical fracture and would be recommended treatment based on the BMD alone, Bone DESTINY and Osteoporosis Canada guideline (OCG).

According to guidelines, males with BMD less than -2.5, a DESTINY fracture risk and OCG in high risk categories are those who would be recommended for treatment.

Bone DESTINY is a computerized fracture prediction tool that combines BMD, age, steroid use, propensity to fall, previous history of falls and BMI<20kg/m2 while OCG included sex, BMD, age, history of fragility fracture and steroid use.



Results: Of 777 males included in the analysis, 167 were 50-59 years old, 235 were 60-69 years old, 239 were 70-79 and 136 were 80 and older. In the youngest group, 22% would be recommended for treatment according to BMD alone, 38% according to high risk bone DESTINY and 7% according to OCG. In 60-69 year old group, 22%, 73% and 33% would be recommended for treatment according to BMD alone, high risk bone DESTINY and OCG, respectively. In 70-79 year old group, 30%, 74% and 54% respectively. In the eldest group, 30%, 89% and 84% respectively.

To further improve sensitivity of the bone DESTINY fracture risk assessment tool analysis of men in a moderate risk group was performed that resulted in significant fracture prediction improvement above 90% with exception the youngest group of 50-59 years old.

Conclusion: Appropriate recognition of male patients with reduced bone mass who are at high risk for developing fractures and as a result of that, appropriate management of osteoporosis requires a complex assessment. We have showed that BMD alone is only a part of the equation of global fracture risk assessment. Bone DESTINY is a tool that allows to predict risk of fracture to a significantly higher degree compared to BMD alone or OCG. Using a comprehensive tool will help to diagnose osteoporosis in men and reduce a "treatment gap" in this population group.

Zoledronic Acid Substantially Reduces the Risk of Morphometric Vertebral and Clinical Fractures. Ego Seeman[1], Dennis Black[2], Christina Bucci-Rechtweg[3], Richard Eastell[4], Steven Boonen[5] and P. Mesenbrink[6], [1]Austin Health, University of Melbourne, Melbourne, Australia, [2]UCSF, San Francisco, CA, [3]Novartis Pharmaceuticals Corp, East Hanover, NJ, [4]University of Sheffield, Sheffield, United Kingdom, [5]University of Leuven, Leuven, Belgium, [6]Novartis Pharmaceuticals Corp, New Jersey

Purpose: In the HORIZON- Pivotal Fracture Trial (PFT), zoledronic acid (ZOL) was shown to reduce vertebral, hip, and all clinical fractures by 70%, 41%, and 33%, respectively. As the fracture risk is not reduced completely, these fractures can lead to more fractures. Thus we aim to determine if ZOL reduces the increased risk conferred by further fractures. In a pre-planned analysis, we studied the effect of once-yearly ZOL in preventing a second morphometric vertebral fracture over 3 years and the recurrence of clinical fractures

Method: In this double-blind, placebo controlled study, 7765 postmenopausal women (PMW) with osteoporosis were randomly assigned to receive ZOL 5 mg (once-yearly) (n=3889) or placebo (n=3876) for 3 years. Clinical fractures reports from patients were collected every 3 months, and lateral spine x-rays were performed at randomization and yearly in patients not receiving concomitant osteoporosis therapy (stratum 1) and at randomization and end of study in patients receiving concomitant osteoporosis therapy (stratum 2). A multivariate proportional hazards regression model was used to evaluate the recurrence of clinical fractures in all patients stratifying for the usage of concomitant osteoporosis therapy (all intent-to-treat patients). Multiple morphometric vertebral fractures were evaluated using logistic regression adjusting for treatment and number of baseline prevalent fractures (stratum 1 and stratum 2 separately).

Results: In ZOL group, 308 (7.95%) women sustained a clinical fracture of which 36 (11.7%) experienced 2 or more fractures. In the placebo group, 456 (11.81%) women sustained a clinical fracture of which 94 (20.6%) experienced 2 or more fractures. This corresponds to 38% reduction (95% CI: 28%, 46%) in the risk of multiple fractures (p<0.0001). ZOL reduced the risk of two or more morphometric vertebral fractures by 89% (95% CI: 77, 95) in stratum I and by 61% (95% CI: -23, 88) in stratum 2. The most common adverse events were transient post-infusion symptoms.

Conclusion: Once-yearly ZOL substantially reduces the risk of multiple morphometric and clinical fractures suggesting treatment mitigates the worsening fragility accompanying a fragility fracture.

Sarcopenia: a Relevant Factor for Bone Mineral Density in Elderly Men Community-Dwelling. Camille F. Danilevicius, Jaqueline B. Lopes, Liliam Takayama, Valéria F. Caparbo and Rosa M.R. Pereira, Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil

Purpose: The term sarcopenia is used to describe loss of skeletal muscle mass and strength that occurs along with biological aging. The aim of this study was to determine the association between sarcopenia with clinical parameters (including: falls and clinical fractures), lifestyle, bone mineral density (BMD) and body composition in elderly men community-dwelling.

Method: Three hundred and ninety nine men (>65 years-old) were selected in a well established elderly community in the São Paulo city. Body composition and BMD were measured by DXA-HOLOGIC-QDR 4500 (*Discovery A)*. Sarcopenia was defined as a relative skeletal muscle mass index (RSMI: appendicular skeletal muscle mass divided by height) below 7.26 Kg/m² in men (Baumgartner, 2000). Mann-Whitney test, for continuous variables, and Chi-squared test, for categorical variables were used to compare patients with and without sarcopenia and clinical variables and BMD. Logistic regression analysis was performed with the variables that were significant (p<0.05).

Results: The mean of age was 72.71±5.06 years. Fifty four (13.53%) men had sarcopenia. The univariate analysis showed that men with sarcopenia compared with those without this complication had lower weight (55.60±8.07 vs. 72.36±11.61 kg, p<0.001), BMI (21.38±2.50 vs. 27.26±3.66 kg/m^2, p<0.001); physical activity (1.93±0.70 vs. 2.11±0.55 times/week, p=0.035), L1-L4 BMD (0.91±0.2 vs. 1.02±0.2 g/cm^2, p<0.001), femoral neck BMD (0.64±0.1 vs. 0.76±0.1 g/cm^2, p<0.001), total femur BMD (0.78±0.1 vs. 0.95±0.1 g/cm^2, p<0.001), total body lean mass (41,264±4,801.6 vs. 52,523±6,631.9 g, p<0.001), total body fat mass (11,939±4,718.7 vs. 17.617±5,847.5 g, p<0.001), percentage of fat (21.16±5.6 vs. 23.78±4.8 %, p<0.001) and higher frequency of fragility fractures (19 vs. 6%, p=0.002). Logistic regression analysis revealed that sarcopenia was negatively associated with BMD in all sites (lumbar spine: OR=0.04, 95%CI= 0.01-0.25, p=0.001; femoral neck: OR=0.0002, 95%CI= 0.0000-0.0049, p<0.001; total femur: OR=0.0000, 95%CI= 0.0000-0.0007, p<0.001) and percentage of fat (OR=0.91, 95%CI= 0.86-0.97, p=0.004).

Conclusion: In conclusion, our study suggests that an interventional program to prevent sarcopenia will contribute to bone healthy in elderly men community-dwelling.

Vertebral Fracture Assessment by a Fracture Liaison Service in Patients with Incident Non Vertebral Fractures. K. Briot[1], F. Sailhan[2], A. Babinet[2], JP Courpied[2], P. Anract[2] and C. Roux[1], [1]Paris Descartes University; Rheumatology Department, Cochin hospital, Paris, France, [2]Paris Descartes University; Orthopaedics Department, Cochin hospital, Paris, France

Purpose: Despite vertebral fractures, are a significant risk factor for further fractures, they are often unrecognized. Vertebral Fracture Assessment (VFA) technology using current dual-energy X-ray absorptiometry (DXA) scanners is a convenient method to assess vertebral deformities, with lower radiation and lower costs than standard X-rays. This study aimed at evaluating the prevalence of vertebral fractures, using VFA, in patients presenting with non vertebral fractures.

Method: A cohort study undertaken patients aged 50 years or over who presented with non vertebral fractures and who underwent routine post-fracture assessment by a Fracture Liaison Service (FLS) was conducted. Bone mineral density (BMD) was measured by DXA and osteoporosis was defined as T score£ -2.5 at either lumbar spine or hip. The number and severity of vertebral fractures were defined using VFA performed during the same exam from TV4 to LV4.

Results: Among 190 patients hospitalized for low trauma non vertebral fractures from February 2009 to May 2009 in Orthopaedics department, the post fracture assessment was not possible for 70 patients (severe cognitive impairment (n=30), living in a foreign country (n=15), patients missed (n=14), patient's refusal (n=8), deaths before evaluation (n=3)). Data were available for 120 patients (mean age 74.3±11.7 years) presenting with low trauma non-vertebral fracture; 100 were female. 38% of patients reported a previous low trauma fracture. 25% of patients received calcium±vitamin D and 8.3%, an antiosteoporotic treatment. Hip fractures (n=57) and wrist fractures (n=25) were the most frequent fractures. 45.0% of patients were osteoporotic (T-score -2.5 or lower). The overall prevalence of vertebral deformity established by VFA was 53%; 23.5% of patients with vertebral fractures had deformities of more than one vertebra. 40% of patients with an osteopenic T-score or a normal T-score had at least one vertebral fracture.

Conclusion: Half of the patients hospitalized for non vertebral fracture have an undiagnosed vertebral fracture. Our results support the recommendation to perform vertebral fracture assessment in patients who are referred for DXA after a non-vertebral fracture.

Systemic Lupus Erythematosus Assessment /Activity: Antibodies, Biomarkers, Nephritis, and more
Monday, October 19, 2009, 9:00 AM - 6:00 PM

895

SLICC Revision of the ACR Classification Criteria for SLE. Michelle Petri and Systemic Lupus International Collaborating Clinic (SLICC), Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: The ACR Classification Criteria for SLE date from 1982 with a 1997 revision that was not validated. Because of new knowledge of autoantibodies, neuropsychiatric lupus, the importance of low complement and the need for lupus nephritis to be a "stand alone" criterion, the SLICC group undertook a revision.

Method: An initial set of relevant variables was determined. Real patient scenarios (n=716) of SLE and non-SLE controls were submitted by SLICC centers. A consensus diagnosis was arrived at for each scenario. The consensus diagnoses were used to identify the variables that were most predictive of SLE. Recursive partitioning was employed to derive a classification rule based on multiple candidates predictor

variables. This preliminary classification rule was discussed at three SLICC meetings, independently validated by a SLICC steering comittee and further refined.

Results: Classify a patient as having SLE if: The patient has biopsy-proven lupus nephritis with ANA or anti-dsDNA OR the patient satisfies four of the criteria, including at least one clinical and one immunologic criterion.

Clinical Criteria
1. Acute or subacute cutaneous lupus
2. Chronic cutaneous lupus
3. Oral/Nasal ulcers
4. Nonscarring alopecia
5. Inflammatory synovitis with physician-observed swelling of two or more joints OR tender joints with morning stiffness
6. Serositis
7. Renal: Urine protein/creatinine (or 24 hr urine protein) representing at least 500 mg of protein/24 hr or red blood cell casts
8. Neurologic: seizures, psychosis, mononeuritis multiplex, myelitis, peripheral or cranial neuropathy, cerebritis (acute confusional state)
9. Hemolytic anemia
10. Leukopenia (< 4000/mm^3 at least once) OR Lymphopenia (< 1000/mm3 at least once)
11. Thrombocytopenia (<100,000/mm3) at least once

Immunologic Criteria
1. ANA above laboratory reference range
2. Anti-dsDNA above laboratory reference range (except ELISA: twice above laboratory reference range)
3. Anti-Sm
4. Antiphospholipid antibody lupus anticoagulant false-positive test for syphilis anticardiolipin – at least twice normal or medium-high titer anti-b2 glycoprotein 1
5. Low complement low C3 low C4 low CH50
6. Direct Coombs test in absence of hemolytic anemia

When applied to our patient scenarios, this classification rule had better sensitivity than the ACR 11 (94% vs. 86%), and roughly equal specificity (92% vs. 93%), and resulted in significantly fewer misclassifications (p=.0082).

Conclusion: The SLICC SLE classification criteria address the major deficiencies of the ACR. Currently, ongoing validation will determine if they perform better than the ACR criteria.

SLE Patients with Quiescent Disease Have Comparable but More Stable Type I IFN Scores Than Active Patients. Julie Cherian[1], Emma J. MacDermott[1], Annie Santiago[1], Ziad A. Taimeh[1], Lilliana Barillas-Arias[2], Stephanie Gold[1], Nina Blank[1], Roland Duculan[1], Mary K. Crow[1] and Kyriakos A. Kirou[1], [1]Hospital for Special Surgery, New York, NY, [2]Schneider Childrens Hospital, New Hyde Park, NY

Purpose: We previously reported that SLE patients with Severe and Mild/Moderate SELENA SLEDAI flares had higher IFN scores and greater fluctuations of IFN scores compared to patients with quiescent disease. We also reported that a closely followed group of 15 patients with >7 visits each, showed wide fluctuation of IFN scores that either paralleled (47%), or preceded SLE flares (40%) in the majority of cases. With the expansion and continued follow-up of our cohort of quiescent patients, we now present a comparison of magnitude and fluctuation of IFN scores in SLE patients with active disease (n=15) and those with quiescent disease (n=9).

Method: We defined the quiescent group as those patients with no severe SELENA-SLEDAI scores, either on immunosuppressive medications (n=4) or on no such therapy (n=5). Each SLE patient had a median of 7 visits and was followed from 2/06 until 5/09. The subjects were studied at every rheumatology visit or hospitalization. Research blood was collected at least every 3 months and PBMC were isolated, lysed, and frozen. Relative expression (RE) of three type I IFN inducible genes (IFIT1, IFI44, and PKR) was calculated for each subject and their average value was used as their IFN score. Type I IFN score fluctuation was determined for each patient as the fold increase from the lowest score to the highest score.

Results: All but one of the quiescent patients were female and races included: 77% Caucasian (57% Hispanic) and 22% African American. The mean age was 31 years old, and median disease duration was 7 years. The median IFN score fluctuation in the stable and active groups was 2.02X and 18.1X respectively (p=0.0074). However, median IFN scores were not significantly different in the two groups (18.4 in the active group and 21.1 in the quiescent group). Similarly, there was no difference in the peak IFN scores. The median IFN fluctuations for the quiescent patients did not differ whether they were on or off immunosuppressive medications (3.5 X and 2X respectively). Interestingly, all of our quiescent patients demonstrated a “parallel pattern” between IFN and SLEDAI scores.

Conclusion: Fluctuations in type I IFN scores, assessed by IFN-inducible gene expression in PBMC, were less in SLE patients with quiescent disease compared to patients with active disease and paralleled disease activity. Therefore, fluctuations of IFN scores rather than absolute IFN score values may be more clinically relevant when evaluating SLE patients with severe disease flares.

Outcomes in Patients with Systemic Lupus Erythematosus (SLE) with and without a Prolonged Serologically Active Clinically Quiescent (SACQ) Period. Amanda Steiman[1], Dafna Gladman[1], Dominique Ibañez[1] and Murray Urowitz[2], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: SACQ SLE patients constitute a subset of SLE whose clinical-serologic discordance presents a clinical dilemma. There is debate over whether these patients’ active serology alone warrants treatment. We explore outcomes in patients with and without a prolonged SACQ period by comparing the rate of damage accrual, as measured by the SLICC/ACR Damage Index (SDI), and the incidence of renal damage and of coronary artery disease (CAD).

Method: SLE patients followed between July 1970 and April 2008 with visits ≤18 months apart were identified. SACQ was defined as a ≥2-year sustained period without clinical activity but with persistent serologic activity (increased anti-dsDNA and/or hypocomplementemia), during which antimalarials were permissible, but neither steroids nor immunosuppressives. SACQ patients were then matched for age, sex, disease duration, decade of entry to clinic, and SDI at the beginning of the SACQ period, with non-SACQ SLE controls, in 1:2 ratio. The two groups were compared on the bases of change in SDI over 3-10 years, and incidences of CAD (defined as myocardial infarction, angina, sudden cardiac death) and of renal damage (defined as creatinine doubling or creatinine > 120 at ≥ two consecutive clinic visits and/or proteinuria for ≥ 6 months) at 5 and 10 years from the beginning of the SACQ period. Descriptive statistics were used; comparisons were made using paired t-tests and McNemar tests.

Results: 55 SACQ patients and 110 matched controls were identified. The median SACQ period was 158 weeks. Fewer SACQ patients used antimalarials (60% vs 77.3%) (p=0.004) and, fewer used steroids (18.2% vs 76.4%) or immunosuppressives (5.5% vs 43.6%) (p<0.0001 for both) over the 5 year period following study start.

SLICC damage index scores:

	SACQ (mean ± STD)	**Control (mean ± STD)**	**P-value**
SACQ Start	0.56 ± 1.21	0.56 ± 1.21	n/a
3 years	0.70 ± 1.27	1.13 ± 1.54	< 0.0001
5 years	0.89 ± 1.37	1.36 ± 1.66	< 0.0001
7 years	0.94 ± 1.28	1.71 ± 1.86	0.0001
10 years	1.26 ± 1.68	2.26 ± 2.23	0.001

Incidence of CAD:

	SACQ	**Control**	**P-value**
Start of study	2 (3.6%)	7 (6.4%)	0.32
Incidence @ 5 years	1 (1.8%)	6 (5.5%)	0.16
Incidence @ 10 years	1 (1.8%)	8 (7.3%)	0.06

There was no difference between baseline serum creatinine in the two groups (p=0.90). By definition, baseline proteinuria was not found in any SACQ patient, while it was present in 13 (12.3%) controls (p<0.0001).

Incidence of renal damage:

	SACQ	**Control**	**P-value**
Renal damage @ 5 years	1 (1.8%)	17 (15.5%)	0.0006
Renal damage @ 10 years	2 (3.6%)	26 (23.6%)	<0.0001

Conclusion: SLE patients with a prolonged SACQ period have significantly less damage accrual over 5-10 years compared to matched SLE controls. This supports the practice of active surveillance without treatment (with steroids or immunosuppressives) during the SACQ period.

SLEDAI-2K 10 Days Versus SLEDAI-2K 30 Days in a Longitudinal Evaluation. Zahi Touma, M.B. Urowitz, Dominique Ibañez and Dafna Gladman, University of Toronto, Toronto Western Hospital, Toronto, ON

Background: The SLEDAI (Systemic Lupus Erythematosus Activity Index) was developed in 1985 through a nominal group process and is based on the presence of 24 features in 9 organ systems over the patient's past 10 days. An updated version SLEDAI-2000 (SLEDAI-2K) was introduced and validated in 2002 again documenting findings in the past 10 days. We showed previously in a cross-sectional study a concordance between SLEDAI-2K scores when descriptors where documented for a 10-day window and for a 30-day window in the same visit.

Purpose: To evaluate SLEDAI-2K 30 days over time and to compare with the original SLEDAI-2K 10 days.

Method: Forty one patients seen at a single centre were followed at monthly intervals for 12 months. A complete history, physical examination and laboratory tests were performed to allow the determination of SLEDAI-2K. The SLEDAI-2K score was completed twice, once for a 10-day window and the second for a 30-day window using the same definitions for the descriptors.

Results: Among the 41 patients 37 were female and 4 were male. 419 patients-visits in 41 patients were recorded for both SLEDAI-2K for a 10-day window and the second for a 30-day window. Patients were 90% female, 56% Caucasian, 17% Black, 7% Chinese, and 20% other. The mean age at SLE diagnosis was 30.5±10.3 years, age at study start 45.4±13.2 and disease duration at study start 14.9±10.3. 268 patient-visits had varying levels of disease activity (3 patients-visits had SLEDAI-2K of 1; 133 had 2, 2 had 3, 68 had 4, 9 had 5, 35 had 6, 11 had 8, 4 had 10, 2 had 12 and 1 had 15) (Table 1 and 2).

In all but 1 patient-visit there was an agreement between the SLEDAI-2K 10 and 30 days. This patient experienced skin rash as a minor lupus flare, however in the last 10 days prior to the visit his rash completely faded.

Table 1. SLEDAI-2K 30 days in all patients-visits

	Inactive	**Active SLEDAI-2K**									
		Distribution by SLEDAI-2K score									
SLEDAI-2K total weight	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**8**	**10**	**12**	**15**
Number of patient-visits	**151**	**3**	**133**	**2**	**68**	**9**	**35**	**11**	**4**	**2**	**1**

Table 2. Clinical and laboratory manifestations

Clinical descriptors	Patients-visits number (%)	Laboratory descriptors	Patients-visits number (%)
Seizure	2 (0.5%)	Hematuria	7 (1.7%)
Headache	2 (0.5%)	Proteinuria	12 (2.9%)
Vasculitis	2 (0.5%)	Pyuria	8 (1.9%)
Arthritis	20 (4.8%)	Low complement	122 (29.2%)
Rash	37 (8.9%)	Increased DNA	179 (42.8%)
Alopecia	10 (2.4%)	Thrombocytopenia	3 (0.7%)
Mucosal Ulcers	11 (2.6%)	Leukopenia	14 (3.4%

Summary: This study confirmed that it is unusual to have a manifestation of active lupus present at 11 to 30 days prior to a visit and have complete resolution in the 10 days prior to the visit.

SLEDAI-2K 30 days scores were concordant with SLEDAI-2K 10 days scores, both in patients in remission and in patients with a spectrum of disease activity levels followed monthly over 1 year.

Conclusion: SLEDAI-2K 30 days was validated against SLEDAI-2K 10 days and may now be used in clinical studies and clinical trials to describe disease activity over the previous 30 days.

SLEDAI-2K Responder Index-50 (SRI-50). Zahi Touma[1], Dafna Gladman[1] and Murray Urowitz[2], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: A number of outcome measures to assess disease activity in SLE patients have been developed. SLEDAI-2K (Systemic Lupus Erythematosus Activity Index-2K) is a reliable valid, simple, one-page activity index recording features of active lupus as present or not present. Thus its utility in clinical trials is limited as it cannot reflect partial improvement in a disease manifestation. The objective of this study is to develop a SLEDAI-2K responder measure which could document a minimum 50% improvement in disease manifestations among lupus patients.

Method: Derivation of SRI-50 (SLEDAI-2K Responder Index-50) from SLEDAI-2K. A new definition for each of the original descriptors of SLEDAI-2K was created to reflect a minimum improvement of 50%. The definitions of descriptors of SRI-50 were constructed based on a literature review for each specific organ system. The new assigned scores for the descriptors of SRI-50 were derived by dividing the score of SLEDAI-2K by 2.

Assessing the content validity of the draft instruments; SRI-50 form was assessed by expert rheumatologists reviewing the instruments and providing critical feedback.

Testing of SRI-50: One hundred patients who had experienced lupus flares or had persistently active disease were assessed initially and then reassessed after treatment was initiated. SLEDAI-2K was determined on the first visit and again at the second visit along with SRI-50.

Results: SRI-50 and the data retrieval form to accurately document the clinical and laboratory findings of each descriptor were developed.

Seventy two patients didn't change their SRI-50 because their manifestations resolved or didn't meet the definition of SRI-50 (table 2). Twenty eight patients with varying levels of disease activity at the first visit (3 had SLEDAI-2K 2, 3 had 4; 6 had 6; 6 had 8; 3 had 10; 2 had 12; 1 had 16, 1 had 18; 2 had 20; 1 had 21) were further studied with SRI-50 (Table 1). SRI-50 was able to demonstrate incomplete (but ≥50%) improvement which would not have been discerned using SLEDAI-2K. Such incomplete improvement was demonstrated in 13 of the 24 SLEDAI-2K descriptors and in 6 of the 9 organ systems that were present in these patients.

Table1. Characteristic of the patients

Sex (F/M)		90%/10%
Race	Caucasian, Black, Chinese, Other	53%, 16%, 10%, 21%
Age at diagnosis		31.6 ± 13.5
Age at 1st visit in study		44.6 ± 15.7
Disease duration at 1st visit in study		13.0 ± 9.7
SLEDAI-2K at 1st visit in study		4.89 ± 4.66
AMS in interval		6.33 ± 4.20
SDI at 1st visit in study		1.69 ± 2.22

Table 2. SLEDAI-2K/SRI-50 on initial and follow up visit with partial improvement

SLEDAI-2K visit 1	2	6	10	4	4	8	6	6	6	2	16	12	8	8	4	6	20	8	8	21	8	20	10	18	10	12	6	2
SLEDAI-2K visit 2	2	6	6	4	4	8	6	6	6	2	16	8	8	4	4	4	10	8	8	3	8	18	10	18	10	12	4	2
SRI-50 visit 2	1	5	4	3	2	6	5	4	4	1	8	4	7	3	2	3	6	4	4	1.5	4	10	9	10	6	6	2	1

Conclusion: SLEDAI-2K Responder Index-50 is a promising instrument that can describe partial improvement in disease activity between visits in lupus patients.

Characterization of Systemic Lupus Erythematosus Patients with Low or Normal Complement Levels: Longitudinal Evaluation of Disease Flares. Julie Cherian[1], Emma J. MacDermott[1], Annie Santiago[1], Ziad A. Taimeh[1], Lilliana Barillas-Arias[2], Stephanie Gold[1], Rolando Duculan[1], Mary K. Crow[1] and Kyriakos A. Kirou[1], [1]Hospital for Special Surgery, New York, NY, [2]Schneider Childrens Hospital, New Hyde Park, NY

Purpose: SLE is the prototypic systemic autoimmune disease characterized by immune complex (IC) formation and tissue deposition with inflammation. Low C3 and C4 levels are thought to represent active IC formation and complement consumption. Although most SLE patients are presumed to form IC, there are some SLE patients that have active disease without apparent complement activation. We sought to compare typical SLE patients with evidence of IC formation as judged by low complement levels (below the normal level for the testing lab; LC) and others without such evidence (normal complement; NC) in order to identify unique characteristics of the 2 groups.

Method: From our cohort of 77 longitudinally followed SLE patients, all selected to express one or more of anti-Ro/La/Sm/RNP antibodies, we chose 52 patients with data from more than 3 visits available and studied their C3 and C4 levels over a median of 2 years, from 2/06 until 5/09. We also recorded anti-dsDNA titers at least every 3 months. Disease activity was evaluated using the SELENA-SLEDAI and BILAG instruments. Patients were categorized as having low complements at any point of their follow-up (LC; n=28) or normal complement levels at all times of observation (NC; n=15). Nine patients with no severe SELENA-SLEDAI flares and no BILAG A or two concurrent BILAG B flares were excluded from the NC group as the normal complement would simply reflect low disease activity.

Results: There were 4 males in the group and races included: 59% Caucasians (67% Hispanic), 30% African Americans (12.5% Hispanic), 7.6% Asians and 1.9% Other. Demographics were similar between the two groups. Neither the median SLEDAI scores (4.5 and 4) nor the SLICC scores (0.5 and 1) were statistically different in the LC and NC groups, respectively. There were 16 (57%) severe flares in the LC group and 8 (53%) in the NC group. Interestingly, there was perhaps a tendency for more (n= 9; 32%) BILAG A renal flares in the LC group compared to the NC group (n=2; 13%; p=0.3). All renal flares consisted of proliferative disease. With regard to type I IFN expression, median IFN scores were higher in the LC than in the NC group (19.4 vs 7.3; p=0.02).

Conclusion: Patients with SLE may exhibit severe disease without the typical drop in complement levels, a presumptive measure of IC formation. However, SLE patients with low C3 and C4 levels demonstrate higher type I IFN scores and have more renal BILAG A flares. This likely reflects the important role of IC in both of these disease characteristics.

901

Type I Interferon Pathway Activation Parallels Therapeutic Response in Patients with SLE. Stephanie Gold, Julie Cherian, Annie Santiago, Nina Blank, Mary K. Crow and Kyriakos A. Kirou, Hospital for Special Surgery, New York, NY

Purpose: Previous cross sectional studies have demonstrated that SLE disease activity is correlated with activation of the type I interferon (IFN) pathway. Our study of a longitudinal lupus cohort indicates that IFN pathway activation fluctuates in many lupus patients. To assess whether clinical response to a defined therapeutic intervention is associated with a decrease in IFN pathway activation, we compared changes in IFN- inducible gene expression and disease activity in lupus patients started on Mycophenolate Mofetil (MMF) or Azathioprine (AZA).

Methods: From our cohort of 77 SLE patients, 15 (8 on AZA and 7 on MMF) were selected for study based on the availability of data prior to the initiation of therapy and a minimum of 4 months follow-up. 3 patients were excluded from the AZA group due to incomplete data. Clinical disease activity (measured by SELENA SLEDAI) and IFN scores were analyzed prior to and following initiation of AZA or MMF. Blood was collected before the drug was started, at the first follow-up (2.9±1.2 months) and at a final follow-up visit on drug (7.3±3.7 months). PBMC lysates were analyzed by real time PCR. Relative expression (RE) of 3 type I IFN inducible genes (IFIT1, IFI44, PKR) was determined, and the mean was used as the IFN score.

Results: 53% of the patients were Caucasian (62.5% Hispanic), 33% African American and 13% Asian. Mean age and disease duration were 32 and 10.1 years respectively, and 93% were female. Baseline SLEDAI scores were similar for MMF and AZA patients (Mean=6.4 and 5.6; p=.28). From the initiation of AZA until the first follow-up, the IFN score and SLEDAI increased 89.4% and 2.6 points respectively. At the last follow up the IFN score increased 161% from drug initiation and the SLEDAI increased 2.6 points. For patients on MMF, the type I IFN score decreased by 21.3% with a corresponding SLEDAI score decrease of 3.14 points from the initiation of drug to the first follow up. At the final follow up the IFN scores had decreased 35.7% from the initial value and the SLEDAI had decreased 1.71 points.

Conclusion: Initiation of lupus therapy with MMF or AZA resulted in changes in disease activity that were reflected in parallel changes in IFN score, based on quantification of IFN inducible gene expression in PBMC. In this cohort, the MMF treated patients showed a superior clinical and IFN response compared with those on AZA. These data support the potential for IFN pathway activation to serve as an informative biomarker of change in lupus disease activity in response to therapy.

902

Revision of the SELENA Flare Index. Michelle Petri[1], Jill Buyon[2], K. C Kalunian[3], M.B. Urowitz[4], V. Strand[5], Joan Merrill[6], B H. Hahn[7], J M. Grossman[7], H. Michael Belmont[8], Mary Anne Dooley[9], Joan Marie Von Feldt[10], Mary E. Cronin[11], Lisa R. Sammaritano[12], Graciela S. Alarcon[13] and LM Hanrahan[14], [1]JHU, Baltimore, MD, [2]NYU School of Medicine, New York, NY, [3]UCSD School of Medicine, La Jolla, CA, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]Stanford University, Palo Alto, CA, [6]OK Med Research Foundation, OKklahoma City, OK, [7]UCLA, [8]Hosp for Joint Disease, New York, NY, [9]Univ of NC at Chapel Hill, Chapel Hill, NC, [10]University of Pennsylvania, Philadelphia, PA, [11]Medical College of WI, Milwaukee, WI, [12]Hospital for Special Surgery, New York, NY, [13]University of Alabama at Birmingham, Birmingham, AL, [14]Lupus Fnd of America, Washington, DC

Purpose: The original SELENA Flare Index (SFI) performed well in the SELENA trials to separate severe from mild/moderate flares. However, in current clinical trials it is important to also separate mild from moderate flares.

Method: As part of the Lupus Foundation of America's International Flare Definition and Validation initiative, the SELENA Flare Index (SFI) was revised through a series of consensus conference calls. There was an initial review and discussion of the strengths and weaknesses of the SFI in SELENA and industry trials. Each call reviewed organ specific definitions of mild, moderate and severe flare. Definitions were discussed and re-reviewed until consensus was reached.

Results: The revised SFI is organ-system based, and is not linked to the SLEDAI. For each organ system, suggested clinical manifestations are given for each category, but the intended treatment decision (if it is higher) overrides the clinical description in each category. Specifically, a mild flare is assigned if there is either no treatment, or initiation of hydroxychloroquine, prednisone ≤ 7.5 mg/day or a non-immunosuppressive therapy. Definition of a "Moderate flare" is consistent with use of prednisone > 7.5 mg/day but less than 0.5 mg/kg/day,

or immunosuppressive therapy (other than cyclophosphamide), and "Severe flare" prednisone (or equivalent) ≥ 0.5 mg/kg/day, cyclophosphamide, biologic treatment, or hospitalization. Three "mild" flares are considered a "moderate" flare.

Conclusion: The new SFI is organ system-based. The choice of recommended treatment overrides the clinical definition when the treatment choice is higher.

Using the CLASI to Assess Disease Severity and Responsiveness to Therapy in Cutaneous Lupus Erythematosus. Rachel Klein, Siamak Moghadam-Kia, Jonathan LoMonico, Joyce Okawa, Katherine Chilek, Elizabeth Gaines, Chris Coley, Lynne Taylor and Victoria P. Werth, University of Pennsylvania, Philadelphia, PA

Purpose: The CLASI (Cutaneous Lupus Erythematosus Disease Area and Severity Index) is a clinical tool that quantifies disease activity and damage. The purpose of this study was to determine how the CLASI could be used to classify patients according to disease severity (mild, moderate, and severe) and to identify patients who responded to therapy.

Method: To determine how the CLASI could be used to assess disease severity, subsets of patients were classified as having "mild", "moderate", and "severe" disease based on the principal investigator's subjective assessment. Corresponding CLASI activity scores were also calculated. A crosstabs was done to determine the optimal range of CLASI activity scores that corresponded with each severity group. To determine how the CLASI could be used to identify improvement, the CLASI activity score and the physician's skin score were completed at every visit. A change ≥ 2 in the physician's skin score was considered the gold standard for a clinical improvement. Subjects were divided into severity groups and screened for an improvement between consecutive and non-consecutive visits. The mean change in the CLASI activity score was calculated for patients that improved and patients that did not improve. A ROC analysis was done to determine the sensitivity, specificity, and percentage of patients correctly classified for the severity groups and each change in CLASI activity score.

Results: Disease severity was assessed in 45 clinic visits (n=37 patients). Mild, moderate, and severe disease corresponded with CLASI activity score ranges of 0-9 (sensitivity 93%, specificity 78%), 10-20, and 21-70 (sensitivity 80%, specificity 95%), respectively. 91 subjects were included in the responsiveness analysis for a total of 505 comparisons between clinic visits. For moderate and severe disease, a mean change in the CLASI activity score of 7.5 points ($p<0.0001$, sensitivity 58%, specificity 80%) and 13.8 points ($p=0.0002$, sensitivity 59%, specificity 97%), respectively, corresponded with a clinical improvement. A ROC analysis demonstrated improved sensitivity and similar specificity when changes in CLASI activity scores of 7 points (sensitivity 61%, specificity 79%) and 12 points (sensitivity 65%, specificity 97%) were used to identify improvement in moderate and severe disease, respectively. For mild patients, there was no statistically significant difference in the change in CLASI activity scores for patients who improved versus those who did not improve.

Conclusion: The CLASI can be used to categorize patients into severity groups and to identify a clinical improvement in patients with moderate or severe disease.

Smoking Is Not Associated with Autoantibodies in Unaffected First-Degree Relatives of SLE Patients. J.A. James[1], S.A. Stewart[2], D. Terrell[3], J.M. Guthridge[4], G.R. Bruner[4], D.L. Kamen[5], G.S. Gilkeson[5], D.R. Karp[6], N.J. Olsen[6], M.L. Ishimori[7], M.H. Weisman[7], V.M. Holers[8], J.B. Harley[9] and J.M. Norris[8], [1]OMRF, OU, Oklahoma City, OK, [2]OMRF, [3]OUHSC, [4]Oklahoma Medical Res Fnd, [5]Medical Univ South Carolina, [6]Univ Texas Southwestern, [7]Cedars Sinai, [8]Univ Colorado, [9]Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: SLE is a complex human autoimmune disease with interacting genetic and environmental risks. Epidemiologic studies have identified an association between smoking and the presence of SLE; however, the mechanism by which smoking is associated with SLE in select individuals is not understood. One working model is that smoking modifies select autoantigens leading to a loss of tolerance and autoimmunity. This model suggests that autoantibody-positive family members should be smokers. This study tests whether smoking is associated with autoantibody production in SLE or unaffected first-degree blood relatives (FDRs).

Method: Detailed clinical, serologic, demographic and treatment information was extracted from a coded database from a diverse collection of 1,242 SLE patients and 981 FDRs [55% EA, 23% AA, 16% HI]. Serum samples from each were tested for standard lupus autoantibodies by immunofluorescence and luminex bead-based assays. ANA positivity and the 13 select autoantibody test results were then analyzed on the basis of smoking status at the time of sample. Categorical values included never-smoker, ever smoker, and current smoker. Statistical analysis was conducted using chi-square and ANOVA methods.

Results: SLE cases were less likely to have ever smoked (49% vs 53%) compared to their blood relatives (p=0.031), but not significantly less likely to be current smokers (18% vs 20%). No association was identified between smoking and having a positive ANA when SLE patients who were current smokers were compared with those who never smoked. Among FDRs, 19.1% of current smokers tested positive for at least one of 10 autoantibodies commonly associated with SLE, while 25.8% of never smokers (p=0.053) and 25.6% of former smokers tested positive for one or more autoantibody (p=0.086). Interestingly, the group of SLE patients who had ever smoked had a lower prevalence of autoantibodies against nRNP 70K (p<0.0012), ribosomal P (p=0.003), and dsDNA (p=0.01) than the group of SLE patients who had never smoked. Similarly, the prevalence of dsDNA positivity is lower in unaffected relatives who are current smokers than in unaffected relatives who are non-smokers (p = 0.045).

Conclusion: SLE patients have no significant association between ANA positivity and smoking; moreover, SLE patients with antibodies against nRNP 70K, ribosomal P and dsDNA, as well as FDRs with antibodies against dsDNA, are more likely not to smoke in this cross-sectional cohort. No other strong correlation between smoking and the production of autoantibodies exists in FDRs. Therefore, the epidemiologic association of smoking with SLE may manifest its risk through mechanisms outside of autoantibody production.

Emergence of Circulating Anti-Double Strand DNA (dsDNA) Antibody-Secreting Cells Predicts Disease Flare in Patients with Systemic Lupus Erythematosus. Hironari Hanaoka, Yuka Okazaki, Takashi Satoh, Yuko Kaneko, Hidekata Yasuoka, Noriyuki Seta and Masataka Kuwana, Keio University School of Medicine, Tokyo, Japan

Purpose: It is increasingly appreciated that circulating B cells are functionally altered and involved in pathogenic process in patients with systemic lupus erythematosus (SLE). In this study, we developed an assay to detect circulating anti-dsDNA antibody-secreting cells and examined for their clinical impact on SLE patients.

Methods: We studied 130 patients with SLE, 49 with non-SLE connective tissue disease (32 rheumatoid arthritis, 15 Sjögren syndrome and 2 systemic sclerosis), and 18 healthy controls. Clinical findings at blood examination, including SLEDAI and SLAM, were obtained from all SLE patients. Disease remission was defined as SLEDAI < 5. Serum anti-dsDNA antibody was measured using a commercial enzyme-linked immunosorbent assay (ELISA) kit. Anti-dsDNA antibody secreting-cells were quantified by an enzyme-linked immunospot (ELISPOT) assay, in which peripheral blood mononuclear cells (PBMCs) were cultured on lambda phage DNA-coated PVDF membranes, followed by incubation with alkaline phosphatase-conjugated anti-human IgG. To examine identity of anti-dsDNA antibody-secreting cells, PBMCs depleted of CD19+ or CD138+ cells were subjected to the ELISPOT assay.

Summary of the Result: Anti-dsDNA antibody-secreting cells were detected in 29 patients with SLE, but in none of disease controls or healthy controls, resulting in higher specificity (100% vs 90%) and lower sensitivity (22% vs 80%), compared with serum anti-dsDNA antibody detected by ELISA. Circulating anti-dsDNA antibody-secreting cells were either CD19+ B cells or CD138+ plasma cells. The number of circulating anti-dsDNA antibody-secreting cells was significantly correlated with serum anti-dsDNA antibody titers ($r = 0.48$, $p < 0.05$). When clinical findings were compared between SLE patients with and without anti-dsDNA antibody-secreting cells, an increased amount of proteinurea and high SLEDAI and SLAM were associated with the presence of circulating anti-dsDNA antibody-secreting cells (p

< 0.02 for all comparisons). Serial analysis in 22 SLE patients showed that the presence or absence of anti-dsDNA antibody-secreting cells was correlated with disease activity scores. Moreover, we prospectively followed 28 anti-dsDNA antibody-positive patients in remission and found that cumulative disease remission rates were significantly lower in patients with anti-dsDNA antibody-secreting cells, than in those without them ($p < 0.001$, Figure).

Conclusion: In SLE patients, anti-dsDNA antibody-secreting B cells and plasma cells were recruited into circulation in active disease phase. Detection of circulating anti-dsDNA antibody-secreting cells is useful in predicting disease flare in patients with SLE.

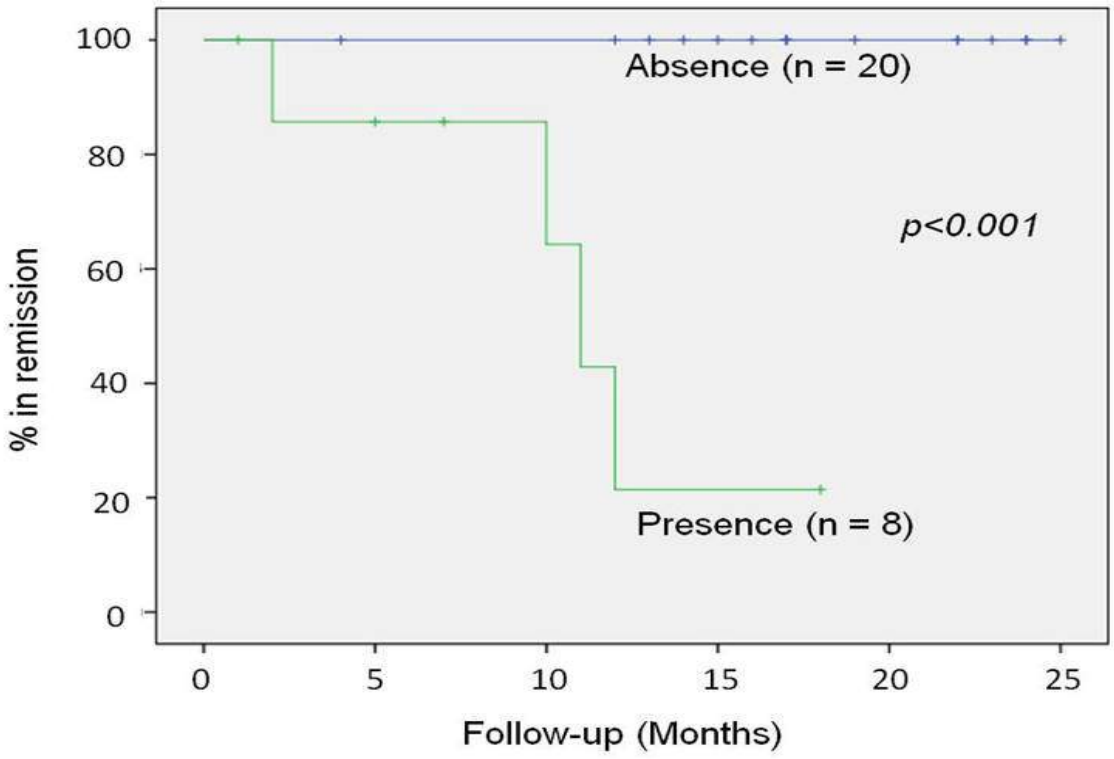

Figure. Cumulative rates for disease remission in patients with anti-dsDNA antibody in the presence or absence of circulating anti-dsDNA antibody secreting cells.

Urinary Cytology Evaluation in SLE: Implications for Identification of Active Nephritis and Scoring Renal Domains On Activity Indices. Anca D. Askanase[1], David B. Thomas[2], Aspee Chowdhury[1], John Purcell[1] and Jill P. Buyon[3], [1]Hospital for Joint Diseases, New York, NY, [2]Nephrocor, Uniondale, NY, [3]NYU School of Medicine, New York, NY

Purpose: Perhaps with the exclusion of the elusive RBC cast, there is no single laboratory test that can unambiguously predict the presence of active renal disease in patients with SLE. Evaluation of urinary cytology is a valuable tool in identifying early transplant rejection with urinary lymphocytes (>20/10 high power field) preceding the rise in creatinine. This study addressed the value of urinary cytology as a marker of active renal disease in a consecutive sampling of SLE patients.

Method: Seventy spot urine specimens were obtained from the first 50 patients fulfilling 4 ACR criteria seen in an outpatient setting. These were subjected to cytological evaluation in addition to protein/creatinine ratios.

Results: Of the 50 patients, 19 have lupus nephritis defined by a kidney biopsy, 11 of which were active at the time of study as defined by a 24 hour protein excretion of >1 gram. As expected, the average protein/creatinine ratio on the spot urinalysis (UA) of patients with active nephritis compared to patients without active nephritis was 2.71 compared to .41. Clinical data on these patients further substantiated the presence of active renal disease; mean serum albumin (3.3 vs. 4.1), creatinine (1.36 vs 1.11), complement C3 (84 vs. 107), and C4 (16 vs. 21), and anti-dsDNA (228 vs. 52). Examination of the urinary cyto-diagnostic sediments (evaluated per 10 high power fields) revealed that in patients with active nephritis, there were significantly more acantocytes (dysmorphic RBCs), target, and isomorphic RBCs per high powered field compared to inactive patients 8/0, 27/1, 127/7 respectively. However, acantocytes, known to have the highest predictive value for glomerular injury, were only present in 2 patients with active nephritis, whereas all the others had none. The urinary neutrophils were higher in patients with active disease (235 vs. 63) but there was a high incidence of vaginal contamination (substantiated by the presence squamous epithelial cells in 9 of the 17 samples from active nephritis patients, and 33 of 53 inactive), After eliminating the contaminated samples, the PMNs were 131 vs 58 p=NS. The most striking difference between groups was in the number of lymphocytes, 81 vs 3 which remained significant even after removing the contaminated samples (92 vs 5, p=0.008). Of all the patients without active nephritis only 1 had urinary lymphocytes above 20 (21). Since contamination with vaginal fluid can have an impact on the presence of isomorphic RBCs we also examined the average number of RBCs after eliminating the contaminated samples, 62 vs. 12, p=NS.

Conclusion: The presence of increased lymphocytes, not total WBC, on cytological urine exam suggests the diagnosis of active nephritis which may provide insight to activity vs chronicity, a critical clinical dilemma. The value of total RBCs and WBCs is diminished by contamination with vaginal fluid implying caution regarding scoring of renal domains.

907

Proteomic Identification of Several Novel Autoantibodies Associated with Systemic Lupus Erythematosus. Yasuhiro Katsumata[1], Yasushi Kawaguchi[1], Sayumi Baba[1], Seisuke Hattori[2], Koji Tahara[3], Kaori Ito[3], Nozomi Yamaguchi[3], Hiroaki Hattori[3], Kinya Nagata[3], Takahisa Gono[1], Kae Takagi[1], Yuko Ota[1], Hisashi Yamanaka[1] and Masako Hara[1], [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Kitasato University, Tokyo, Japan, [3]BML Inc., Tokyo, Japan

Purpose: By using proteomic approach, we aimed to find out novel serum autoantibodies associated with systemic lupus erythematosus (SLE), especially CNS syndromes of SLE.

Method: Autoantigens were screened by 2 methods of proteomic analysis; immunoprecipitation followed by LC-MS/MS shotgun analysis and 2D-PAGE-western blot followed by MALDI-TOF/MS analysis. In immunoprecipitation, total IgG from sera of SLE patients with active CNS syndromes was isolated and purified by using protein G-Sepharose. Total protein extracted from human tumor cell lines and whole human normal brain, was mixed and immunoprecipitaed with isolated IgGs crosslinked to the protein G-Sepharose. Eluted antigens from the immunoprecipitates were analyzed by LC-MS/MS shotgun method and indentified using the MASCOT database search algorithms. Alternatively, after total protein was separated by 2D-PAGE and western blot analysis with the patient's sera, autoantigens were identified by MALDI-TOF/MS analysis. The recombinant proteins of identified antigens were produced in transformed *Escherichia coli*. The IgG reactivities against these recombinant antigens in sera from original SLE patients were confirmed by western blotting. Finally, autoantibodies against the several recombinant human brain antigens in sera of patients with SLE and normal healthy controls were quantified by solid phase direct ELISA.

Results: Among many candidate antigens, these antigens showed positive reactivities against several SLE patients' sera in western blotting: crystallin αB, esterase D, multifunctional DNA repair enzyme (APEX nuclease) 1, nucleophosmin, acidic ribosomal protein P0, proeasome activator subunit 3 isoform 1 (PSME3), YARS, TPI1, PGK1, PEBP1, NFIB, PGAM-B, ERAB, and GFAP. Autoantibodies in serum samples of SLE patients (n = 106) including 32 patients with active CNS syndromes and normal healthy controls (n = 100) were quantitatively examined by ELISAs using these antigens. The O.D. values of SLE patients' serum samples were significantly higher than those of normal healthy controls' in ELSIAs using following antigens: crystallin αB ($p = 0.0002$), esterase D ($p = 0.0002$), APEX1 ($p < 0.0001$), nucleophosmin ($p = 0.0070$), acidic ribosomal protein P0 ($p < 0.0001$), and PSME3 ($p = 0.0005$). Among these results, associations of SLE and autoantibodies against crystallin αB, esterase D, and APEX1 have not been previously reported in literatures as far as we searched. Unexpectedly, none of these autoantibodies were associated with active CNS syndromes.

Conclusion: Associations of SLE with several novel and previously reported autoantibodies were demonstrated. This study shows that our immunoproteomic approach is a reliable method to identify autoantigens in SLE.

Risk Factors Associated with Development of SLE Among Anti-RNA Helicase A Positive Patients. Jason Y.F. Chan, Yi Li, Eric S. Sobel, Mark S. Segal, Michael R. Bubb, Edward K.L. Chan, Westley H. Reeves and Minoru Satoh, University of Florida, Gainesville, FL

Purpose: Autoantibodies to RNA helicase A (RHA) is a new serological marker of early stage of SLE. Although anti-RHA appears highly specific for SLE among patients with an established diagnosis, some anti-RHA positive individuals do not meet SLE criteria. We evaluated the clinical association of anti-RHA in unselected patients seen in an autoimmune disease clinic, focusing on identifying risk factors associated with the development of SLE.

Method: Sera from the initial visit of patients seen at our autoimmune disease clinic (n = 1542, including 368 SLE, 105 SSc, 72 PM/DM, 56 RA, 61 Sjogren's syndrome: SjS) were screened by immunoprecipitation (IP) of 35S-labeled cell extract and western blot using anti-RHA reference sera. Levels of anti-RHA in sera from sequential visits were measured based on the integrated density (volume) of the protein band acquired with phosphorimager. Clinical information was from a comprehensive database.

Results: Forty-four anti-RHA positive patients (23 Caucasian, 10 African American, 6 Latin, 2 Mixed, 1 Asian, 2 unknown) were identified. Eighty percent (35/44) of cases had SLE (4 or more of criteria), one case each had SSc-PM overlap and SjS. Demographic information and levels of anti-RHA were comparable between SLE vs. non-SLE groups. Among 7 cases that did not meet any disease criteria, 3 cases had 3 items of SLE criteria. Sixty-seven percent (21/32) of anti-RHA positive SLE were within one year of diagnosis consistent with its association with an early stage of SLE. Levels of anti-RHA were reduced over time in 20/23 SLE whose sequential sera were available; however, the correlation between the disease duration vs. levels of anti-RHA at initial visit was not strong. As a whole, the non-SLE group was characterized by lack of other specific autoantibodies by IP (73% vs. 19% in SLE, p = 0.002). Anti-U1RNP (p = 0.008), Sm, ribosomal P (rP), or La (44, 22, 13, and 16%, respectively) were found only in the SLE group whereas anti-Ro and -phospholipid antibodies were found at similar prevalence in both groups. Anti-dsDNA was rare in non-SLE (11% vs 81% in SLE, p = 0.043). In the SLE group when sequential (>6 month apart) sera were tested, 22% (5/23) of patients developed new autoantibody specificities during follow-up (anti-U1RNP+Sm, anti-rP, and anti-Su, one case each, anti-Ro, 2), within 1 year from initial visit in 4/5 cases and within a year of diagnosis of SLE in 3 cases. None of the non-SLE patients with anti-RHA developed new autoantibodies.

Conclusion: Anti-RHA is highly specific for SLE; however, certain anti-RHA positive cases without other coexisting autoantibodies may not fulfill SLE criteria and have a milder/undifferentiated disease. Anti-RHA positive patients who also have anti-U1RNP, Sm, ribosomal P, or dsDNA may have higher risk of developing SLE.

909

Detection of Anti-dsDNA in Subjects Referred for Inflammatory Rheumatic Disease Associates with Differing Clinical Phenotypes Depending On the Assay Used. Soren Jacobsen[1], Gunnar Sturfelt[2], Anders Bengtsson[3], Michele Compagno[3], Niels Heegaard[4], Andreas Jönsen[2], Rasmus S. Jacobsen[1], Lennart Truedsson[3], Ole Petter Rekvig[5] and Hans Nossent[5], [1]University Hospital, Copenhagen, Denmark, [2]Inst of Clinical sciences, Lund, Sweden, [3]University Hospital, Lund, Sweden, [4]Statens Serum Institut, Copenhagen, Denmark, [5]University Hospital, Tromsø, Norway

Purpose: Determination of anti-dsDNA antibodies is a serological cornerstone in diagnosis and classification of systemic lupus erythematosus (SLE) but may also be detected in other conditions. Furthermore, there is no present consensus on which assay to use. Purpose of the study was to establish which clinical features regardless of the SLE diagnosis that were associated with anti-dsDNA determined by various assays assays.

Method: In a Scandinavian tri-center study, subjects were recruited from 1082 patients referred due to suspicion of rheumatic disease. 292 were ANA positive and 292 sex- and age-matched ANA negative controls were selected from the original cohort. All 584 subjects were phenotyped according to active manifestations including the current SLE classification criteria and a broad range of other clinical manifestations. In all subjects determination of anti-dsDNA was performed by means of 1-3) Chrithidiae luciliae immunofluorescence test (CLIFT, ImmunoConcept) in 3 different laboratories, 4) solution phase ELISA (SPADE, Tromsø), 5) Varelisa (Pharmacia), 6) EliA (Pharmacia) and 7) ELISA (Pharmacia). Cut-off levels according to instructions of the manufacturer or the performing laboratory were used. Statistical analysis included logistic stepwise regression analysis using dichotomized anti-dsDNA results as the dependent variable and clinical manifestations as explanatory variables.

Results: The prevalence of positivity for the 7 anti-dsDNA tests ranged from 5.3 to 14.2 %. The five most common SLE classification manifestations were non-erosive peripheral arthritis (28%), photosensitivity (10%), oral/nasal ulcers (6.0%), hematuria (3.8%) and proteinuria (3.1%). The five most common other manifestations were arthralgias (58%), morning stiffness (24%), headache (14%), Raynauds phenomenon (13%) and xerostomia (13%). Statistically significant hazard ratios deriving from the regression analyses are shown in the table:

	Butterfly rash	Alo-pecia	Cutaneous vasculitis	Livedo reticul	Morning stiffness	Axial arthritis	Pleuritis	Protein-uria	Oral/nasal ulcers	Lympho-penia	Lymph-adenopathy
CLIFT 1	11	3.9	6.6	4.8	-	-	7.8	4.7	-	-	-
CLIFT 2	-	-	-	-	-	-	17	6.7	-	8.5	-
CLIFT 3	4.3	13	-	-	0.04	12	29	11	-	27	-
SPADE	-	6.1	-	-	0.34	-	25	8.5	-	-	-
VARELISA	3.3	4.1	-	-	0.13	-	24	22	-	-	-
ELIA	-	9.0	-	-	0.15	-	37	23	-	-	-
ELISA	-	-	-	-	0.22	-	48	8.4	5.1	-	-

Conclusion: Positive results in all 7 anti-dsDNA tests associated with pleuritis and proteinuria. However, the remaining clinical manifestations shown in the table had varying associations with the anti-dsDNA tests used. The results indicate that the correlation between clinical features and any anti-dsDNA test may vary depending on the assay used and on the laboratory performing the test, as shown for CLIFT.

ANA-Positive Healthy Individuals and Autoimmune Rheumatic Patients Present Distinctive Pattern and Titer Profiles at the ANA HEp-2 Assay. Henrique A. Mariz[1], Silvia H. Rodrigues[1], Silvia H. B. Campos[2], Gilda A. Ferreira[3], Emilia I. Sato[1] and Luis Eduardo C. Andrade[1], [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Fleury Health and Medicine, Sao Paulo, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Purpose: We sought for distinctive ANA HEp-2 features in ANA-positive healthy controls (HC) and patients with autoimmune rheumatic diseases (ARD).

Method: 918 HC [32.1±10.3 years old; 634 (69.0%) women], from two large cities in the western southern hemisphere were retrieved among workers in a hydroelectric power plant (n=444) and among blood donors (n=474). HC were defined after a clinical questionnaire to

exclude current or past ARD, infections and neoplasia. A subset of the HC group was re-evaluated after 3.6 to 5.0 years (mean 3.9±0.3 years). Sera from 153 randomly selected ARD patients comprised the control group: systemic lupus erythematosus (n=87), systemic sclerosis (n=45), Sjögren's syndrome (n=10), and dermato/polymyositis (n=11). HEp-2 ANA was determined at 1:80 and successive dilutions by two blinded independent observers. ANA-positive sera were screened for antibodies against extractable nuclear antigens (ENA: Sm, U1-RNP, SS-A/Ro, SS-B/La) by double immunodiffusion against calf spleen extract.

Results: ANA was positive in 138 ARD patients (90.2%) and 118 HC (12.8%). ARD patients presented predominantly high titer (≥1:1280) and HC presented essentially low titer (≤1:160) but exceptions did occur (Table 1). ANA pattern profile was distinct in the two groups. Nuclear homogeneous (Ho), nuclear coarse speckled (NCS), centromere, and cytoplasmic dense fine speckled (Cyto DFS) patterns were exclusively observed in ARD patients. Nuclear dense fine speckled (NDFS) pattern was present only in HC. The most frequent ANA pattern in both groups was the nuclear fine speckled (NFS), which occurred at significantly lower titer among HC (median 1:80) as compared to ARD patients (median 1:1280) ($p<0.001$). Anti-ENA was present in 1 HC (SS-A/Ro) and in 35 (25.3%) ARD patients. At follow-up none of the 40 re-evaluated HC developed ARD and 29 (72.5%) remained ANA-positive. All HC that became ANA-negative had baseline ANA titer of 1:80. Table 1 – Distribution of ANA HEp-2 titer and pattern in HC and ARD patients

Titer	**HC (%)**	**ARD (%)**	**P**	**Pattern**	**HC (%)**	**ARD (%)**	**P**
1:80	54 (45.7)	10 (7.3)	< 0.001	NCS	0	36 (26.0)	<0.001
1:160	9 (7.7)	5 (3.7)	0.259	Ho	0	10 (7.2)	0.008
1:320	15 (12.7)	23 (16.7)	0.477	Centromere	0	11 (7.9)	0.005
1:640	21 (17.7)	0	< 0.001	NFS	54 (45.8)	58 (42.0)	0.636
≥1:1280	21 (17.78)	100 (72.5)	0.002	NDFS	39 (33,0)	0	<0.001

Conclusion: The ANA HEp-2 assay offered distinctive titer and pattern profiles for ANA-positive individuals and for ARD patients. ANA pattern seemed to be more reliable than ANA titer for discriminating ANA-positive HC and ARD patients. Some ANA patterns (NCS, Ho, Centromere) were exclusively observed in ARD patients while the NDFS pattern was restricted to HC. The NFS pattern was equally frequent in both groups and showed different titer distribution in HC and ARD patients. ANA-positive HC tended to keep ANA reactivity but did not develop evidence of ARD after a 4-year follow-up period.

Comparison of Three dsDNA Antibody Tests in a Cohort of Rheumatology Patients. Michael W. Ettore and Melissa R. Snyder, Mayo Clinic, Rochester, MN

Purpose: Autoantibodies to double-stranded DNA (dsDNA Ab) are a serological marker strongly correlated with systemic lupus erythematosus (SLE). Several distinct methodologies are available to laboratories for the quantitative measurement of dsDNA Ab. In this study, we compared the performance of a radioimmunoassay, an enzyme immunoassay (EIA), and a multiplex immunoassay in a population of rheumatic disease patients.

Methods: Serum samples (n=188) were collected for a study on inflammatory biomarkers from patients seen in the Mayo Clinic Division of Rheumatology for evaluation of suspected connective tissue disease. All diagnoses were established based on clinical evaluation; patients diagnosed with SLE and rheumatoid arthritis (RA) fulfilled the diagnostic criteria established by the American College of Rheumatology. Patients without a specific diagnosis, but with evidence of an inflammatory rheumatologic disorder, were classified as having undifferentiated connective tissue disease. Samples were tested for dsDNA Ab using the Anti-dsDNA Radioimmunoassay Kit (Farr method; Diagnostic Products Corporation), the Anti-dsDNA EIA Kit (Bio-Rad), and the dsDNA analyte of the Bioplex 2200 ANA Screen (Bio-Rad), according to respective manufacturer's instructions. A consensus result was determined for each sample, defined as the qualitative interpretation (positive or negative) agreed upon by a majority of the three methods. Sensitivity, specificity, and concordance rates between the three methods were calculated, first using cutoff values specified by the manufacturer, and second using cutoff values empirically chosen to optimize concordance.

Results: Using manufacturer specified cutoff values, the following sensitivity, specificity, and concordance rates with consensus results were observed.

Table 1.

	Farr	EIA	Multiplex
Sensitivity	74.3%	52.2%	35.4%
Specificity	49.3%	84.0%	92.0%
Positive Concordance	100.0%	93.0%	63.4%
Negative Concordance	56.4%	95.7%	99.1%
Overall Concordance	72.9%	94.7%	85.6%

After empirically raising the Farr and lowering the EIA and multiplex cutoff values, the following sensitivity, specificity, and concordance rates with consensus results were observed.

Table 2.

	Farr	EIA	Multiplex
Sensitivity	54.0%	60.2%	47.8%
Specificity	81.3%	82.7%	77.3%
Positive Concordance	87.3%	98.6%	81.7%
Negative Concordance	88.9%	90.6%	88.9%
Overall Concordance	88.3%	93.6%	86.2%

Conclusion: In our cohort of rheumatology patients, using manufacturer's suggested cutoff values, the Farr assay had the highest sensitivity and the Bioplex 2200 ANA Screen had the highest specificity, while the Bio-Rad EIA showed the best concordance with the consensus result. Changing cutoffs resulted in the Bio-Rad EIA attaining the best combination of sensitivity and specificity, while maintaining the best concordance. Laboratories should carefully weigh the clinical needs of their patient populations when selecting a dsDNA Ab method.

Disclosure: M. W. Ettore, None; **M. R. Snyder**, None.

912

IgG Anti-Pentraxin 3 Antibodies in Systemic Lupus Erythematosus. Andrea Doria[1], Nicola Bassi[1], Anna Ghirardello[1], Miri Blank[2], Margherita Zen[1], Michele Tonon[1], Yehuda Shoenfeld[3] and Leonardo Punzi[1], [1]University of Padova, Padova, Italy, [2]Center for Autoimmune Diseases, Sheba Medical Center, Ramat Gan, Israel, [3]Sheba Medical Center, Ramat Gan, Israel

Purpose: To evaluate the prevalence and correlates of anti-pentraxin 3 (PTX3) antibodies in patients with systemic lupus erythematosus (SLE).

Method: Sera of 130 SLE patients (ACR criteria), 130 healthy subjects (HS), and 130 patients affected with other autoimmune diseases (oARD), including 27 with rheumatoid arthritis, 26 with polymyositis, 27 with systemic sclerosis, 26 with Sjögren's syndrome, and 26 with psoriatic arthritis (all healthy and disease controls were age- and sex-matched with SLE patients), were analyzed by home-made ELISA tests, using as substrate human recombinant PTX3 and 2 peptides obtained from the complete protein, identified as potential antigenic sites using Lasergene DNA program (DNA Star) (PTX3_1 from N-terminal domain, and PTX3_2 from central domain). Inhibition tests were performed to evaluate potential interferences between BSA and anti-PTX3 or anti-PTX3 derived peptides; between C reactive protein and PTX3_2; and between PTX3 or PTX3 derived peptides and anti-PTX3 or anti-PTX3 derived peptides. SLE activity was measured using ECLAM score. Statistics were performed using ROC curves, Fischer's exact test, two-tailed t test and Person's correlations.

Results: All inhibition tests were negative, apart from PTX3 against anti-PTX3 and PTX3_2 against anti-PTX3_2 (maximum optical density reduction: 83%, 82%, respectively). SLE patients had higher prevalence of anti-PTX3, anti-PTX3_1 and anti-PTX3_2 antibodies than healthy controls or patients with oARD (Table). No differences were observed between healthy controls and patients with oARD. A correlation was found between anti-PTX3 and anti-PTX3_2 antibody levels ($r=0.615$, $p<0.001$). No association between these antibodies and disease activity was observed. The prevalence of anti-PTX3, anti-PTX3-1, and anti-PTX3_2 antibodies were lower in patients with glomerulonephritis than in those without (anti-PTX3 11.5% vs. 34.6%; anti-PTX3_1 9.2% vs. 27.7%; anti-PTX3_2 21.5% vs. 39.2%; all $p<0.001$) and higher in patients who were antiphospholipid antibody (aPL) positive than in those aPL negative (anti-PTX3 33% vs. 17.9%, $p=0.041$; anti-PTX3_2 42.5% vs. 21.7%, $p=0.032$). These associations were confirmed by multivariate analyses. No other significant relationship between anti-PTX3 and anti-PTX3 derived peptides and serological or clinical abnormalities, including the drugs taken by the patients, were observed.

	HS		SLE		oARD
	%	p	%	p	%
Anti-PTX3	6.2	<0.001	46.2	<0.001	5.3
Anti-PTX3_1	8.2	<0.001	36.9	<0.001	1.5
Anti-PTX3_2	5.1	<0.001	60.8	<0.001	2.5

Conclusion: Anti-PTX3 antibodies are significantly prevalent in SLE patients where they might provide protection from renal involvement. The antigenic properties of PTX3_2 peptide are similar to those of PTX3 suggesting its potential use for further analysis.

Disclosure: A. Doria, None; **N. Bassi**, None; **A. Ghirardello**, None; **M. Blank**, None; **M. Zen**, None; **M. Tonon**, None; **Y. Shoenfeld**, None; **L. Punzi**, None.

913

Prevalence and Clinical Significance of the Anti-p53 Antibody in Systemic Lupus Erythematosus. Kenjiro Yamanaka[1], Soichiro Nakano[2], Yoshinori Kanai[1], Masanao Asano[2], Keigo Ikeda[2], Syouko Thoyama[2], Kentaro Ishiyama[1] and Yoshinari Takasaki[2], [1]Sasaki Institute Kyoundo Hospital, Tokyo, Japan, [2]Juntendo University School of Medicine, Tokyo, Japan

Purpose: p53 is a tumor suppressor protein and plays an important role in controlling cell proliferation and apoptosis by binding to DNA. There have been many reports on anti-p53 antibodies in cancer patients. However, only several studies have reported on the clinical significance of anti-p53 antibodies in patients with connective tissue diseases. The prevalence of serum anti-p53 antibodies in connective tissue diseases is still controversial. Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of autoantibodies against various nuclear components of cells. In this study, we investigated the prevalence and clinical significance of the anti-p53 antibody in patients with SLE.

Method: The anti-p53 IgG titer in the serum of patients with various connective tissue diseases was assayed by using an enzyme-linked immunosorbent assay (ELISA); MESA CUP anti-p53 test (Medical & Biological Laboratories Co. Ltd, Nagoya, Japan). Wild-type human p53 protein produced by a baculovirus was used in this ELISA kit. The minimum detectable true activity value of the anti-p53 antibody is 0.05 U/ml, and the cutoff value is considered to be 1.30 U/ml, as determined from the 95% distribution range of the antibody titer in a physically unimpaired person.

Results: Anti-p53 antibodies were detected in 59.5% of the patients with SLE ($n = 42$), and the prevalence of these antibodies was significantly higher than in patients with other connective tissue diseases such as mixed connective tissue disease ($n = 13$), scleroderma ($n = 16$), polymyositis or dermatomyositis ($n = 9$), Sjögren's syndrome ($n = 15$), and arthritis rheumatism ($n = 16$) (7.7%, 6.3%, 11.13%, 13.3%, and 6.3%, respectively; all $p < 0.001$). The anti-p53 antibody titer was also significantly higher in patients with SLE than in patients with

other connective tissue diseases (SLE, 7.8 ± 15.42; other, 0.56 ± 0.73; $p < 0.0001$). Next, the SLE patients (n = 42; 98% female; mean age, 46.8 ± 15.7 years) were divided into an anti-p53 antibody-positive or -negative group. The frequency of anti-dsDNA antibodies was higher in the anti-p53 antibody-positive group (42.9% vs 4.8%; $p = 0.00043$). The mean anti-dsDNA antibody titer was higher in the anti-p53 antibody-positive group (36.8 ± 50.3 vs 3.2 ± 7.4 IU/ml; $p = 0.00945$), and it was found to correlate positively with the anti-p53 antibody titers ($r = 0.611$; $p < 0.01$; Spearman). The mean value of CH50 was lower in the anti-p53 antibody-positive group (28.5 ± 11.8 vs 36.2 ± 11.8; $p < 0.05$), and the values correlated negatively with the anti-p53 antibody titers ($r = 0.323$; $p < 0.05$; Spearman). The frequency of SLE with flare was higher in the anti-p53 antibody-positive group (38.1% vs 2.4%; $p = 0.0057$). The peripheral blood lymphocyte counts correlated negatively with the anti-p53 antibody titers ($r = 0.349$; $p < 0.05$).

Conclusion: The anti-p53 antibody is a useful marker not only for diagnosing SLE in connective tissue diseases but also for detecting the disease activity of SLE.

Clinical-Serologic Discordance in An Multicentre Inception SLE Cohort. Murray Urowitz[1], Dafna Gladman[1], Dominique Ibañez[1] and Systemic Lupus International Collaborating Clinics, [1]University of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Anti-DNA antibodies and serum complement levels are considered important biomarkers for disease activity in SLE. Despite this many patients present serologically active but clinically quiescent (SACQ) while others present as clinically active but serologically quiescent (CASQ). These states create therapeutic dilemmas for clinicians. We aim to determine the frequency of SACQ and CASQ in a large international inception cohort of patients with SLE.

Method: An international research network comprising 27 centres from 11 countries has followed an inception (within 15 months of diagnosis) cohort of SLE patients yearly according to a standardized protocol between 2000 and 2009. Of these, 232 patients followed for a minimum of 5 years constitute the study population. Anti-DNA antibody levels and serum complement values are assessed at each visit. Clinical disease activity was assessed using SLEDAI-2K minus anti-DNA antibody and complements. SACQ is defined as presence of elevated anti-DNA ± decreased complement variables of SLEDAI-2K only and CASQ as SLEDAI-2K > 0 in the absence of both anti-DNA and complement variables. Descriptive statistics were used.

Results: Of the 232 patients followed for at least 5 years, 86.2% were female, 61.2% were Caucasian, 13.4% were Black, 17.2% were Asian, 6.5% Hispanic and 1.7% Other. 44.4% were married and 59.7% had at least College education. Their age at diagnosis was 36.5 years and SLEDAI-2K at enrolment was 5.63. The duration from diagnosis to enrolment was 5.2 months.

At some point in their 5 visits 121(52.2%) were SACQ and of the 232, 47(20.3%) were SACQ on no medication other than antimalarials. In 17(7.4%) patients this state was sustained for at least 2 consecutive years. At some point in their 5 visits 137(59.1%) were CASQ and in 63(27.2%) this state was sustained for at least 2 consecutive years.

Conclusion: Clinical-laboratory discordance regarding anti-DNA antibodies and complement levels presenting as SACQ or CASQ represent a significant subgroup of SLE patients who require close clinical follow-up. New biomarkers to better reflect disease activity in SLE are required.

IFN-Driven Genes but Not Chemokines Correlate with Clinical SLE Predictors in ANA Positive Subjects. Hatice Bilgic[1], Patt Carlson[1], Joseph C. Wilson[1], Thearith Koeuth[1], Abby Montague[1], Kevin G. Moder[2], Emily C. Baechler[1] and Erik J. Peterson[1], [1]Univ. of Minnesota, Minneapolis, MN, [2]Mayo Clinic, Rochester, MN

Purpose: Virtually all Systemic Lupus Erythematosus (SLE) patients display ANA positivity. However, ANA positive status in the absence of disease (ANA+) is a poor predictor of a future autoimmunity-related diagnosis. Whole blood "signatures" comprising Type I interferon (IFN) driven transcripts and chemokines were described in a number of autoimmune diseases, including SLE. IFN "signatures" are promising biomarkers for SLE. We evaluated the hypothesis that IFN-driven peripheral blood gene and **chemokine "signature" derived scores** will assist in stratification of ANA+ persons at risk for SLE or other autoimmune disease.

Method: Peripheral blood samples and clinical data were obtained from 124 ANA+ subjects with no autoimmune disease diagnosis. A whole-blood derived IFN gene expression score was defined as the normalized sum of the expression levels of 3 IFN-driven genes (IFIT1, G1P2, IRF7) measured by AB.Taqman Low Density Arrays (n=124). Multiplexed ELISAs were used to quantify serum levels of 3 IFN-driven chemokines (IP-10, MCP-1, MIP-3B, n=67). The IFN chemokine score was defined as the normalized sum of the 3 chemokine levels. Gene expression and chemokine levels were also determined in 23 healthy controls and 168 SLE patients. Subjects with score values 2 standard deviations above the control subject mean were designated "IFN high". We used the Mann-Whitney rank sum test for group comparisons and Spearman`s rank coefficient to determine significance of correlations.

Results: High IFN gene expression scores were observed in 9% of ANA+ individuals, compared to 4.3% of healthy controls and 51.5% of SLE cases. An IFN high **chemokine score was observed in 46.3% of the ANA+ individuals, 0% of healthy controls, and 82.9% of SLE cases. IFN gene scores were significantly higher in ANA+ subjects with immunologic disorder (presence of anti-dsDNA or anti-Sm; p=0.052). No other clinical parameter differences were detected between IFN gene or chemokine score high and low groups. However, IFN gene score high individuals displayed a statistically non-significant trend toward increased number of SLE diagnostic criteria satisfied (p=0.084). IFN chemokine scores did not correlate with presence of any individual diagnostic criterion or the number of diagnostic criteria met. Although the IFN gene score was highly correlated with the chemokine score in SLE patients (r=0.514, p<0.0001), these scores did not correlate in the ANA+ group.**

Conclusion: IFN gene score is elevated in a subgroup of ANA+ subjects, and immunologic disorder correlates with IFN high gene scores. Although a high fraction of ANA+ subjects also show high IFN chemokine scores, the observed correlation between IFN gene and chemokine signatures in SLE patients is lacking in ANA+ persons. Ongoing longitudinal followup of disease-negative ANA+ subjects will shed light on the prognostic utility of IFN gene or chemokine scores in this clinical subset.

Measurement of Serum Free Light Chains Performs Better Than Known Immunological Biomarkers for Systemic Lupus Erythematosus Disease Activity. Rohit Aggarwal, Winston Sequeira, Rachel Mikolaitis, Rediet Kokebie, Joel A. Block and Meenakshi Jolly, Rush University Medical Center, Chicago, IL

Purpose: To compare serum free light chains (FLC) with total IgG, complement (C3,C4) & double-stranded DNA (Ds-DNA) as a biomarker of disease activity in Systemic Lupus Erythematosus (SLE).

Method: 75 patients with SLE & 41 age and gender-matched control patients with RA were enrolled. Disease activity was assessed using Selena-SLEDAI and physician global assessments (PGA) for SLE and the DAS-28 for RA. PGA was categorized into 'no activity' PGA =0, 'mild' 0< PGA ≤ 1, 'moderate' 1< PGA ≤ 2, 'severe' 2< PGA ≤ 3. For RA subjects, disease activity was dichotomized into inactive (DAS-28 <3.2) and active disease. Finally, SLE flares were defined by Selena-SLEDAI. Serum FLC (Kappa (κ), Lambda (λ) and total FLC (κ + λ)) was measured using nephelometry (Binding site,UK). IgG, C3, C4, Ds-DNA were also measured. Mann-Whitney or Kruskall Wallis test was used to compare a) FLC and IgG in SLE vs. RA, b) FLC, C3, C4, Ds-DNA and IgG in patients with different levels of PGA in SLE as well as patients with and without flares in SLE, c) FLC in active vs. inactive RA. Spearman correlation was used to correlate FLC, C3, C4, Ds-DNA, IgG with SLEDAI and adjusted SLEDAI (adjSLEDAI= SLEDAI – [C3C4 and Ds-DNA score]).

Results: Serum FLC and IgG levels were higher in SLE than RA [FLC: median mg/L (IQR), total FLC in SLE: 46.2 (30.9–64.5) vs. RA: 32.3 (22.0-44.9), p< 0.01; IgG: SLE: 18.4 (14.9-24.1) vs. RA: 15.4 (11.8-18.24), p<0.01]. FLC and IgG in SLE and RA exceeded those of healthy normal controls. Total FLC (median, IQR) were significantly higher in subjects whose PGA was "severe" (179.8, 122.1-211.5) than in those with mild (38.2, 27.7-61.49) or no activity (39.1, 29.5-46.9), P<0.01 for each, and had a non-significant magnitude greater than those with moderate PGA (56.2, 42.7-106.3). Serum total FLC were significantly different between severe flare and no flare [severe flare

(204.3, IQR 122.1-219.2) vs. no flare (37.9, IQR 28.3-49.8), p<0.01]. There were no significant differences in IgG, C4 or Ds-DNA levels among different levels either of disease flare or of PGA, though C3 levels were significantly higher in those with flare or with severe PGA. Table 1 includes correlations. In RA, there was moderate correlation between total FLC and DAS-28 (rho 0.35, P=0.04), though no differences were detected between "active" and "inactive" RA; individually, κ and λ had results similar to total FLC. Finally, controlling for GFR, age and gender did not alter the results.

	Total FLC	Lambda FLC	Kappa FLC	Ds-DNA	C3	C4	CRP	IgG
SLEDAI	Rho: 0.66 P < 0.01	Rho : 0.68 P < 0.001	Rho : 0.58 P = 0.002	Rho : 0.45 P <0.001	Rho : -0.56 P < 0.001	Rho : -0.37 P = 0.001	Rho : 0.29 P = 0.01	Rho 0.27 P=0.06
adjSLEDAI	Rho: 0.45 P < 0.01	Rho : 0.49 P < 0.001	Rho : 0.39 P = 0.002	Rho :0.16 P = 0.20	Rho : -0.32 P = 0.005	Rho : -0.18 P = 0.12	Rho : 0.18 P = 0.10	Rho: 0.14 P=0.23

Conclusion: Serum FLC levels are highly correlated both with disease activity and with flare in SLE. Serum FLC performed better than C3, C4, Ds-DNA and IgG levels as a marker for disease activity in SLE.

Table 1.Spearman correlation (rho) between SLEDAI and biomarkers (C3, C4, dsDNA, Hs-CRP, FLCs)

Lupus Nephritis: Urinary Biomarkers. Adnan Kiani[1], John Arthur[2], Laurence Magder[3], Jim C. Oates[2] and Michelle Petri[4], [1]Johns Hopkins University, Baltimore, MD, [2]MUSC, Charleston, SC, [3]University of MD, Baltimore, MD, [4]JHU, Baltimore, MD

Purpose: Lupus nephritis (LN) occurs in over 50% of SLE patients and is frequently associated with a poor long-term prognosis. A diseased kidney may lead to the generation of certain proteins in the urine, either in an intact form or, more likely, as peptide fragments. In either case, identifying urine proteins and cytokines would help identify the pathologic process and could lead to future primary or secondary preventive measures. We investigated different potential biomarkers for LN.

Method: Eotaxin, IP-10, GM-CSF, IFNa2, IFNy, IL-1a, MIP1B, PDGF, IL-6, IL-8, MCP-1, OPG, CysC, NAG, NGAL and sIL-2RA were measured by ELISA during 1 to 2 clinic visits in 30 SLE patients (93% female, 43% African-American, 37% Caucasian, and 20% other ethnicity). Ages ranged from 20-64 years (median 51). At each visit, the SLICC renal activity score (RAS) was calculated as proteinuria of 0.5 to 1 gm/day (3 points), proteinuria of 1 to 3 gm/day (5 points), proteinuria of > 3 gm/day (11 points), urine red blood cells ≥5 /hpf (3 points), urine white blood cells ≥10 /hpf (1 points). We looked at the relationship between these urinary biomarkers and the urine Protein/Creatinine Ratio (urine Pr/Cr), the renal activity score, and concurrent renal biopsies.

Results: The Spearman correlation coefficients between biomarkers and renal activity are shown in the table for urinary biomarkers that correlated with both Urine Pr/Cr and SLICC RAS.

Table 1: Spearman Correlation Coefficients between biomarkers and renal activity (p-values are based on a mixed effects model appropriately accounting for the fact that there are multiple measures from the same person)

Variable	IL-1a (n=41)	MIP1B (n=27)	IL-6 (n=42)	IL-8 (n=42)	MCP-1 (n=42)	sIL-2RA (n=42)
Urine Protein/Creatinine	0.62****	0.74****	0.69***	0.56****	0.61***	0.47*

Ratio						
SLICC Renal Activity score	0.56*	0.79*	0.69**	0.50***	0.57**	0.33***

* p<.05, ** p<.01, *** p<.001, **** p<.0001

Eotaxin, GMCSF, IFNy, PDGF correlated well only with the Urine Pr/Cr ratio, where as CysC correlated well only with SLICC renal activity score. We then looked at the association of these biomarkers with concurrent renal biopsies. Table 2: Mean log-transformed, normalized biomarker levels, by biopsy findings among those with concurrent biopsies

Variable	logIL-8 (pg/ml)	logMCP-1 (pg/ml)
ClassIV No(n=11) Yes(n=6)	-1.8* -0.5	2.1 2.7
ClassV No(n=9) Yes(n=8)	-0.5*** -2.2	2.8* 1.9

Urinary IL-8 was significantly higher in Class V, whereas urinary MCP-1 was significantly lower in Class V.

Conclusion: There is an immediate need of non-invasive urinary markers which associate with renal activity and are predictive of renal outcome. Validation of these urine biomarkers in LN patients followed longitudinally and with larger numbers of concurrent biopsies, may allow their eventual use in routine SLE care.

ADAMTS5 Is a Biomarker for Prediction of the Response to Infliximab in Patients with Rheumatoid Arthritis. Kensei Tsuzaka[1], Yuka Itami[1], Koichi Amano[2] and Tsutomu Takeuchi[3], [1]Ichikawa General Hospital, Tokyo Dental College, Ichikawa, Chiba, Japan, [2]Saitama Medical Center, Saitama Medical School, Kawagoe,Saitama, Japan, [3]Keio University School of Medicine, Tokyo, Japan

Purpose: To identify a biomarker for prediction of the response to infliximab (INF) in rheumatoid arthritis patients, we focused on a disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) that seems to play a key role in aggrecan degradation in cartilage.

Method: Fourty-four randomly selected active RA patients were treated with INF. Peripheral blood samples were collected at baseline and ADAMTS5 mRNA was quantified using real-time PCR.

Results: Baseline ADAMTS5 mRNA levels in the responder (1.461 ± 0.817) was significantly (p=0.0090) lower than that in the non-responder (2.246 ± 1.350) at 62 weeks' treatment with INF. The DAS28 at 62 weeks' treatment was significantly (p=0.0003) lower in the Low-ADAMTS5 group (2.47 ± 1.50) than in the High-ADAMTS5 group (4.46 ± 1.76). The percent reduction of the DAS28 (%DAS28 reduction) was significantly (p=0.0015) higher in the Low-ADAMTS5 group (52.8 ± 7.25) than in the High-ADAMTS5 group (22.5 ± 5.21). Interestingly, significant correlations were observed between the DAS28 and %DAS28 reduction at 62 weeks (p<0.001; r= 0.56 and -0.60, respectively) and the baseline ADAMTS5 mRNA level. Furthermore, ΔHAQ, an estimate of the improvement in the HAQ score, at 62 weeks' treatment was significantly (p=0.0305) higher in the Low-ADAMTS5 group (0.70 ± 0.68) than in the High-ADAMTS5 group (0.25 ± 0.35). The positive predictive value of a low baseline ADAMTS5 level for predicting good response and remission (DAS28<2.6 at 62 weeks) was 80.0% and 73.3%, respectively.

Conclusion: The baseline ADAMTS5 mRNA level is a candidate biomarker for prediction of the response to INF in RA patients.

VCAM-1 Is a Better Measure of SLE Renal Activity Than NGAL and CXCL16. Adnan Kiani[1], Chandra Mohan[2], Tianfu Wu[2], Laurence Magder[3] and Michelle Petri[4], [1]Johns Hopkins University, Baltimore, MD, [2]Univ of Texas SW Med Ctr, Dallas, TX, [3]University of MD, Baltimore, MD, [4]Johns Hopkins Univ, Baltimore, MD

Purpose: VCAM-1, an adhesion molecule, is involved in the progression of glomerular and tubulointerstitial injury. Lipocalin-2 (NGAL, a member of the lipocalin superfamily) levels have been shown to rise in both acute and chronic kidney damage and in lupus nephritis (LN). CXCL16 is a chemokine whose levels are increased in both murine and human lupus. We investigated these three as potential biomarkers for LN.

Method: VCAM-1, CXCL16 and NGAL were measured during 1 to 3 clinic visits in 81 SLE patients (90% female, 49% African-American, 40% Caucasian, 4% Asian, 5% Hispanic and 2% others, mean age 46, 109 total visits) by ELISA (R&D). At each visit, the SLICC renal activity score was calculated as proteinuria of 0.5 to 1 gm/day (3 points), proteinuria of 1 to 3 gm/day (5 points), proteinuria of > 3 gm/day (11 points), urine red blood cells ≥5 /hpf (3 points), urine white blood cells ≥10 /hpf (1 points). We looked at the relationship between these biomarkers and the urine Protein/Creatinine Ratio (urine Pr/Cr), the renal activity score, and SLEDAI renal descriptors.

Results: The Spearman correlation coefficient between an individual's mean urine Pr/Cr (across visits) and their mean VCAM-1 was 0.60 ($p<.0001$) indicating that those with high mean VCAM-1 tend to have high mean urine Pr/Cr. The Spearman correlation coefficient between the individual's mean SLICC renal activity score and their mean VCAM-1 was 0.43 ($p<.0001$) indicating that those with high mean VCAM-1 tend to have high renal activity scores.

Table : Mean (SD) log-transformed and normalized (by urine creatinine) VCAM-1, NGAL and CXCL16, by clinical variables at each visit

Clinical variables at each visit	NGAL		VCAM-1		CXCL16	
	Mean (SD)	P-value[1]	Mean (SD)	P-value[1]	Mean (SD)	P-value[1]
Physicians Global Estimate	0.05 (0.05)	.41	3.26 (0.87)	.0022	0.25 (0.23)	.37
≥1.5 (n=35)	0.04 (0.04)		2.52 (0.78)		0.20 (0.21)	
< 1.5 (n=74)						
SLICC Renal Activity Score	0.07 (0.06)	.0024	3.54 (0.80)	<.0001	0.28 (0.28)	.041
High (4+ points) (n=21)	0.04 (0.03)		2.54 (0.72)		0.19 (0.13)	
Low (< 4 points) (n=78)

SLE Patients Show Evidence of Premature Biological Senescence. Sahena Haque[1], Chadi Rakieh[2], Fiona Salway[3], Rachel Gorodkin[4], Pauline Ho[4], Lee-Suan Teh[5], Philip J. Day[3] and Ian N. Bruce[4], [1]arc Epidemiology Unit, Manchester, United Kingdom, [2]Manchester Royal Infirmary, Manchester, United Kingdom, [3]Univeristy of Manchester, Manchester, United Kingdom, [4]Manchester Royal Infirmary, Manchester, [5]Consultant Rheumatologist, Blackburn, United Kingdom

Purpose: Patients with SLE have premature mortality compared to the general population. The main causes of death include coronary heart disease and infection. These observations suggest a phenotype of premature senescence in SLE. Telomere length can be used to assess overall biological ageing. Our hypothesis is that patients with SLE will demonstrate reduced telomere length compared to a control population.

Method: Telomere length was measured in a cross sectional study using real-time quantitative PCR in females with SLE (4 or more ACR 1997 criteria) and age-matched healthy female controls recruited from the local community. SLE factors and traditional cardiovascular risk factors were noted and assessed against telomere length in a larger cross-sectional SLE population.

Results: We studied 63 SLE patients *vs.* 63 controls with a median (IQR) age of 50.8 (37, 59) and 49.9 (32, 60) yrs respectively. The median relative telomere length was significantly reduced in SLE patients (0.97 *vs.* 1.5, p=0.0017). In our cross-sectional study we assessed 144 SLE patients with a median (IQR) age of 52.6 (44.0, 60.8) years; disease duration of 13.0 (7.8, 23.1) years; SLEDAI 2 (0, 6) and SLICC DI 1 (0, 2). 33 (23%) had renal involvement and 68 (47%) were current steroid users. After correction for multiple testing, factors significantly correlated with telomere length were C3 complement (Spearman's correlation coefficient 0.23, p = 0.0051) and estimated GFR (-0.22, p= 0.0075). Therapy and traditional cardiovascular risk factors were not correlated with telomere length.

Conclusion: Whole blood telomere length, a marker of biological senescence, is significantly reduced in SLE patients. Shorter telomeres associated with low C3 complement may reflect increased replicative senescence with active inflammation. The cross-sectional association of longer telomeres with renal impairment/damage may be a surviving cohort effect. The predictive value of telomere length as a biomarker of future risk of damage/mortality requires prospective evaluation. .

Expression of CD44 Isoforms Correlates with SLE Disease Activity and Nephritis. Jose C. Crispin[1], George C. Tsokos[1] and Karen H. Costenbader[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Brigham & Women's Hospital, Boston, MA

Purpose: T cell CD44 variants v3 and v6 have been associated with increased T cell migration to sites of inflammation and active lupus nephritis. We assessed relationships between T cell CD44 (v3 and v6) levels and SLE disease activity and nephritis.

Method: We recruited 72 subjects with SLE by ACR criteria and 36 age-, race-, and sex- matched controls. Clinical data, including SLE history, autoantibodies and SLE disease activity (SLEDAI) were collected. CD44, CD44v3 and CD44v6 expression on CD4, CD8 and total T cells was quantified by flow cytometry. We examined Pearson correlations between clinical variables, SLEDAI scores and nephritis, and CD44 levels. Wilcoxon rank sum tests and conditional multivariable regression analyses were used to test for differences in CD44 levels in SLE cases compared to controls, controlling for clinical variables.

Results: Mean subject age was 42.1 (± 13.5) years in SLE cases and 43 (± 11.8) years in controls. 94% were female, 68% white, 10% Black, 7% Asian, 13% other/mixed race. Mean SLE duration was 11 (± 0.9) years. Mean SLEDAI score was 2.7 (± 3.4). Of SLE cases, 28 (39%) had antidsDNA antibodies, 22 (31%) were receiving corticosteroids and 18 (25%) immunosuppressive medications. Total CD44 on CD4 and CD8 cells was higher in SLE cases than controls, but no correlations with SLEDAI or nephritis were found. CD44 or its variants did not correlate with age, race, sex, smoking, or recent infection. CD44v3 and v6 on CD3, CD4 and CD8 cells were significantly higher in cases than controls (**Table**). Among SLE cases, strong positive correlations between CD44v3 and v6 levels and SLEDAI, nephritis, anti-dsDNA antibodies were found. In multivariable regression models, adjustment for clinical variables did not affect these relationships.

Conclusion: CD44v3 and v6 levels were strongly correlated with SLEDAI, nephritis and anti-dsDNA antibodies. Future studies will assess these biomarkers longitudinally in relation to SLE disease activity.

Clinical Utility of Changes in Cyto/Chemokines as Markers of Disease Activity in Systemic Lupus Erythematosus. Carolina Landolt-Marticorena[1], S. Morrison[2], H. Reich[1], E. Aghdassi[2], A. Herzenberg[1], J. Scholey[1], Dafna Gladman[3], Murray Urowitz[3], Paul. R. Fortin[1] and Joan E. Wither[1], [1]University Health Network, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Lupus patients have elevated plasma levels of a number of cytokine/chemokines suggesting that fluctuations in the concentration of these soluble mediators may mirror changes in SLE disease activity. In a preliminary screen of 20 cyto/chemokine plasma concentrations in SLE patients, IP-10, MCP-1 and sVCAM were found to be elevated in active SLE patients. We therefore examined the relationship between changes in disease activity and alterations in cyto/chemokine plasma levels.

Methods: Patients (n = 74) satisfying 4 or more ACR criteria were recruited from the University of Toronto Lupus Clinic. 21 healthy controls were also recruited. The plasma concentration of the 3 analytes was determined by Luminex assay. All patients underwent at least 2 assessments during the study period. Disease activity was measured by the SLEDAI-2K and used to segregate patients into a high ($\geq$ 7) and low/moderate (< 7) disease activity groups. A modified SLEDAI-2K was calculated by subtracting the contribution of anti-dsDNA antibodies and complement from the global score. The Mann Whitney non-parametric test was used for comparisons between groups. The statistical significance of correlations was determined by linear regression analysis.

Results: IP-10, MCP-1 and sVCAM were significantly elevated in SLE patients versus controls ($p < 0.0001$ for all). The concentration of all 3 analytes was significantly increased in patients with high versus low/moderate disease activity (IP-10; $p = 0.02$: MCP-1; $p = 0.007$: sVCAM; $p = 0.0002$). There was a moderate positive correlation for IP-10 ($r = 0.42$, $p = 0.0002$), MCP-1 ($r = 0.50$, $p < 0.0001$) and sVCAM ($r = 0.48$, $p < 0.0001$) and the SLEDAI-2K at inception. This association was comparable to that seen for traditional biomarkers (anti-dsDNA antibodies or complement (C3)) and the modified SLEDAI-2K (anti-dsDNA ($r = 0.52$, $p < 0.0001$) and C3 ($r = 0.40$, $p = 0.0004$)). There was a moderate positive correlation between the change in concentration of each analyte and the change in SLEDAI-2K, between the first and 12-month visits (IP-10 ($r = 0.56$, $p < 0.0001$), MCP-1 ($r = 0.58$, $p < 0.0001$) and sVCAM ($r = 0.59$, $p < 0.0001$)). This was stronger than the association between the change in the modified SLEDAI-2K and the change in anti-dsDNA ($r = 0.43$, $p = 0.0001$) or C3 ($r = 0.33$, $p = 0.0041$). Longitudinal analysis ($\geq$ 3 or more assessments) of 34 patients showed that changes in IP-10 mirrored changes in disease activity with high fidelity in 50% of cases.

Conclusion: This study suggests that IP-10, MCP-1 and sVCAM may be useful biomarkers to monitor disease activity, functioning as well, if not better, than traditional biomarkers.

Factors Determining Response in Patients with Active Lupus Nephritis Treated with Glucocorticoids and Mycophenolate Mofetil (MMF). Chi Chiu Mok[1], Shirley Ying[2], Cheuk-wan Yim[3], Chi Hung To[4] and Eric WL Ng[5], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Princes Margaret Hospital, Hong Kong, China, [3]United Christian Hospital, Hong Kong, Hong Kong, [4]Tuen Mun Hospital, Hong Kong SAR, Hong Kong, [5]United Christian Hospital, Hong Kong

Purpose: To evaluate the clinical variables associated with response after induction treatment of active lupus nephritis with combined prednisolone and MMF.

Method: Data were extracted from an open randomized controlled trial of the efficacy of MMF vs tacrolimus for induction treatment of lupus nephritis. All patients who were recruited into the MMF arm were treated with a standard protocol of prednisolone (0.6mg/kg/day for 6 weeks and then slowly tapered) and MMF (2-3g/day in 2 divided doses). Clinical response and remission was assessed at 6 months and factors associated with the achievement of a good clinical response were studied by logistic regression analysis.

Results: Data from 53 patients who had completed the induction phase of the controlled trial were analyzed. The mean age was 34.2±11.3 years and the mean SLE duration was 56.4±64 months. 33(62%) patients had first time nephritis. The histological classes of lupus nephritis (RPS/ISN) were IVg (36%), IVs (8%), III (19%) and V/V+III/IV (38%). The activity and chronicity scores were 7.6±3.8 and 2.8±1.6, respectively. 21(40%) patients were hypertensive and 23(43%) were nephrotic at presentation of nephritis. The mean daily MMF dosage

administered was 2.23±0.42g (2g in 74% and ≥2.5g in 26%). At the end of 6 months, 31(58%) patients achieved good clinical response (defined as urine P/Cr <1.0, improvement in lupus serology and urinary sediments and no deterioration of creatinine clearance [CrCl]) by ≥10%) and 5(9%) patients achieved ACR renal remission (CrCl ≥90ml/min, urine P/Cr <0.2 and inactive urine sediments). Regression analysis revealed that the presence of membranous component in the renal histology (RR 0.29[0.09-0.93]; p=0.04) and increasing anti-dsDNA titer at presentation (RR 1.01[1.001-1.012]; p=0.03) were unfavorable factors for a good clinical response. More serious proteinuria at onset was also less likely to respond well to the treatment regimen. 25(47%) patients reported ≥1 adverse events. The distribution of these adverse events was: diarrhea / nausea (13%), major infections requiring hospitalization (13%), minor infections including herpes zoster (62%), transient hyperglycemia (5%) and others (8%).

Conclusion: Combined prednisolone and MMF is a reasonably safe and effective regimen for the initial treatment of active lupus nephritis. Patients with histological evidence of membranous nephropathy, lower anti-dsDNA titer and more serious proteinuria at onset are less likely to achieve a good clinical response. Alternative initial regimens may be considered.

Efficacy of Combination Therapy with Tacrolimus Plus Mizoribine for Early Lupus Nephritis. Hisanori Shimizu, Hiromichi Tamaki, Eishi Uechi, Ken-ichi Yamaguchi, Yukio Matsui and Masato Okada, St. Luke's International Hospital, Tokyo, Japan

Purpose: The ideal treatment of early lupus nephritis remains to be determined. A regimen including cyclophosphamide has been studied intensively for advanced cases with recurrent and chronic courses, but the long-term adverse effects including risk of malignancy or infertility are not acceptable for reproducitve age women. High dose tacrolimus (0.1mg/kg/day) with corticosteroid have been shown to be effective as an induction regimen but the nephrotoxicity is problematic. We examine low dose tacrolimus in conjunction with mizoribine, which shares the mechanism of action as purine production with MMF, as an initial treatment of early lupus nephritis. This case series described remarkable efficacy in induction and maintenance of lupus nephritis.

Method: In our case series, 8 patients with lupus nephritis received a combination therapy with tacrolimus (0.06mg/kg/day), mizoribine (150mg/day) and corticosteroid. Complete remission was defined as a value of proteinuria < 0.1 g/24 h, normal urinary sediment, serum albumin ≥ 4 g/dl, and a normal value of serum creatinine or no more than 15% above baseline values. A secondary efficacy parameter was partial remission, defined as the resumption of normal or at least a 50% improvement in proteinuria and hematuria, serum albumin ≥ 3.0 g/dl, and a normal value of serum creatinine or no more than 15% above baseline values.

Results: At 6 months, seven of the 8 patients receiving the combination therapy had satisfactory early responses. Seven of the 8 patients had complete remission, and partial remission occurred in the rest one of the 8 patients (Table 1).

Conclusion: In this study, the combination therapy of tacrolimus and mizoribine was effective in inducing and also maintaining remission of lupus nephritis without significant adverse events.

Parameter	Baseline	Week 1	1 Month	3 Months	6 Months
Urine protein (g/24h)	0.64	0.64	0.37	0.10	0.06
eGFR (ml/min)	93.9	95.3	97.3	100.7	116.8
Serum albumin (g/L)	3.66	3.83	3.86	4.00	4.18
Trough of tacrolimus (ng/ml)	-	3.62	3.98	2.64	2.90
Prednisolone (mg/day)	21.8	21.4	13.9	12.7	8.8

Flare Assessment in Systemic Lupus Erythematosus (SLE) Patients Treated with Rituximab in the Phase II/III EXPLORER Trial. Joan T. Merrill[1], J.P. Buyon[2], R. Furie[3], K.M. Latinis[4], C. Gordon[5], H. Hsieh[6] and P. Brunetta[6], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]NYU School of Medicine, New York, NY, [3]NSLIJHS, Lake Success, NY, [4]Univ. Kansas Medical Center, Kansas City, KS, [5]Univ. of Birmingham, Birmingham, United Kingdom, [6]Genentech, Inc., South San Francisco, CA

Purpose: SLE patients (pts) with moderate to severe disease activity (≥ 1 BILAG A or ≥ 2 BILAG B domain scores) despite background immunosuppressives and corticosteroids, were randomized to placebo (PLA) or rituximab (RTX). Although differences in primary and secondary outcome measures were not observed, an exploratory analysis was performed to evaluate the impact of RTX on the intensity and frequency of disease flares. Our objectives were to assess in those pts who achieved response whether RTX affected: 1) time to moderate or severe flares, 2) annualized flare rates, and 3) prednisone usage during flares.

Methods: The BILAG index was scored every 4 wks for 52 wks after the first study drug treatment. Only pts who achieved response (BILAG C, D, or E scores for all domains before wk 52) were included in this analysis. A severe flare was defined as ≥ 1 BILAG A or > 3 BILAG B domain scores in a pt who previously achieved response; an A flare was defined as ≥ 1 new BILAG A domain scores; a moderate flare was defined as 2 BILAG B domain scores following response. Kaplan-Meier estimates were used to assess time to flare. Annualized flare rates were calculated using the number of flares a patient experienced during the study; the p-value was based on Poisson regression model. Only flares that occurred after the protocol-mandated prednisone taper at 12 wks were incorporated into the analysis of prednisone usage during flares.

Results: A response was achieved in 58 (66.0%) of 88 PLA-treated and 127 (75.1%) of 169 RTX-treated pts during the study, and these patients qualified for subset analysis. Whereas the times to first moderate or severe flare were not different in the two treatment groups, there was a trend towards a prolonged time to first A flare in the RTX group (HR=0.612; p=0.052). Annualized severe and moderate flare rates were similar in both groups, but the mean annualized A flare rate in the RTX group was significantly lower than in the PLA group (0.86 vs 1.41; p=0.038). Prednisone was increased in 20 of 101 (20.7%) of the A flares and was not significantly different between the RTX and PLA groups (24% vs 14%; p=0.204). Pts with the highest initial prednisone dosing (> 60 mg/day) had lower treatment rates (14.0%). In one month, 44/81 (54.3%) of the untreated A flare improved to B or better.

Conclusion: There was no difference between PLA and RTX in preventing moderate or severe flares after a response was achieved. However, RTX treatment was associated with a lower annualized A flare rate, and a trend towards prolonging the time to A flare. Prednisone rescue following A flares was low compared to observational cohorts, possibly reflecting a reluctance to reinitiate prednisone, or reduced BILAG A severity, in this trial.

SLE Transplanted Patients Have Inferior Patient Survival Compared to Matched Controls. Gudrun E. Norby, Torbjoern Leivestad, Jan Tore Gran and Hallvard Holdaas, Oslo University Hospital, Rikshospitalet, Oslo, Norway

Purpose: Cardiovascular disease is a common cause of morbidity and mortality in systemic lupus erythematosus (SLE), including those treated with renal transplantation. Outcome following renal transplantation in SLE patients is still debated, but most studies report similar outcom for SLE patients and patients transplanted for other causes of end stage renal disease.

The aim of the study was to analyse the outcome of renal transplanted SLE patients with special emphazise on patient and graft survival in a large singe transplant centre unit.

Method: Ninety transplantations were performed in 79 SLE recipients from 1972 to 2005. SLE patients were matched for recipients transplanted for glomerulonephritis diagnosis, excluding recipients transplanted for diabetic nephropathy. For each case, 2 controls were matched for age, donor source (living donor/deceased donor), era (date of transplantation) and sex (when possible).

Results: SLE transplanted patients were mainly women (77%) with an age of 37±13 years at transplantation (controls 37±13 years). This age at transplantation is 20 year younger than the general transplant age in Norway. Living donors were 52% in SLE patients versus 53% in the controls. Death censored graft survival was equal for SLE transplanted patients and matched controls with 1, 5 and 10 years graft survival of 89%, 82% and 71% for SLE recipients, and 91%, 83% and 74% for matched controls (p=0.69).

Patient survival at year one was 94% and 96% for SLE recipients and controls respectively. Corresponding survival at 5 years was 83% and 91% and at 10 year 68 % and 84%. (p=0.023). Of deaths occurring in the control group 34% was due to cardiovascular disease versus 58% in the SLE transplanted patients (p=0.103).

Conclusion: Although graft survival are equal in SLE transplanted patients compared to matched controls, SLE patients have inferior patient survival. Cardiovascular causes were numeric more frequent as a death cause in SLE transplanted patients which have to be focused strongly in the future.

Neutrophil Gelatinase-Associated Lipocalin (NGAL) as a Urinary Biomarker of Disease Activity and Severity in Lupus Nephritis. M. Torres-Salido, J. Cortés-Hernández, M. Urquizu-Padilla, A. Pedrosa, E. Balada, M. Vilardell-Tarrés and J. Ordi-Ros, Systemic Autoimmune Diseases Research Unit. Research Institute Vall d'Hebron. Vall d'Hebron Hospital, Barcelona, Spain

Purpose: : To evaluate urinary (uNGAL) and serum (sNGAL) NGAL levels as a biomarker of active lupus nephritis (LN) in SLE patients. To study the association of uNGAL and sNGAL levels in patients with active LN, partial (PR) and complete (CR) response as well as in patients with non-renal flare and inactive SLE. To establish the relationship between uNGAL levels, the clinical and biological parameters in patients with active LN and to calculate the specificity/sensitivity of this biomarker for distinguishing active renal from non-renal lupus.

Methods: All patients fulfilled the ACR classification criteria for SLE. Active renal disease was defined by active renal sediment, a urinary protein:urinary creatinine ratio (uP/C)>0.5 and/or a biopsy-proven renal disease. Complete remission (CR) was defined by an uP/C<0.2 with an inactive sediment and partial remission (PR) by an uP/C between 0.2-2.0. A non-renal flare was defined by a SLEDAIs≥6 and inactive disease by a SLEDAIs<6. This cross-sectional study included 5 groups of patients and one healthy group control (n=35). Groups are as follow: a group of active LN (n=38), a group of patients with PR (n=56), with CR (n=29), with non-renal flare (n=23) and inactive SLE (n=39). For each patient laboratory parameters (anti-dsDNA, C3, C4, FBC, serum creatinine (sCr) and albumin, estimated glomerular filtration rate (eGFR by Cockcroft-Gault equation) and uSLEDAIs were measured. Both uNGAL and sNGAL levels were measured by ELISA kits according to the manufacturer's instructions (Bioporto, Denmark). ROC curves were used to calculate the specificity/sensitivity.

Results: : The uNGAL values were expressed as median (ng/mL), interquartile range (IQR). In patients with renal flare, uNGAL was significantly higher (47.25 (25.08-88.05) than in those with CR (28.00 (17.10-47.50), PR (34.30 (15.63-61.10), non-renal flare (24.00 (16.30-41.60), inactive SLE (20.00 (12.50-37.80) and healthy control subjects (16.30 (9.14-28.70). Whereas, no significant differences in uNGAL values were found between active LN and patients with PR, the differences were statistically significant with the rest of groups ($p< 0.05$). On the other hand, the sNGAL levels only could differentiate the active LN from the inactive SLE group ($p= 0.0084$). The uNGAL values in patients with active LN correlated significantly with uSLEDAIs ($R= 0.3527$, $p< 0.0001$), and uP/C ratio ($R= 0.2282$, $p= 0.0018$), eGFR ($R= -0. 1784$, $p=0.0151$), and serum albumin ($R= -0.2306$, $p= 0.002$). The uNGAL levels showed ROC profiles, with AUC values equal to 0.69, reflecting an acceptable sensitivity and specificity for discerning active LN from non-renal flare SLE patients.

Conclusion: uNGAL is a promising potential biomarker of activity and severity in LN. Our results indicate that uNGAL can be a useful tool in the management of the patients with LN.

Renal Outcome and Risk Factors for End-Stage Renal Disease in a Cohort of 100 Patients with Lupus Nephritis: A Very Long-Term Follow-up Study. Mikkel Faurschou[1], Anne-Lise Kamper[1], Henrik Starklint[2] and Søren Jacobsen[1], [1]Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [2]Vejle Hospital, Vejle, Denmark

Purpose: While the short- and medium-term outcome in lupus nephritis (LN) has been described in a range of studies, data on the very long-term prognosis of LN patients are scarce. The aim of the present study was to describe the renal outcome and identify baseline predictors of end-stage renal disease (ESRD) in an unselected cohort of patients diagnosed with LN between 1971 and 1995 and followed throughout 2007.

Methods: 100 patients with LN (WHO classes I-VI) were included in the study. For all patients, a variety of clinico-pathological variables were recorded at date of first renal biopsy (study baseline). Predictors of ESRD were identified through univariate and multivariate analyses.

Results: The median duration of follow-up was 13.7 years (range: 0.01-36.9 years). In total, 25 patients (25%) progressed to ESRD. New cases of ESRD occurred throughout the follow-up period, and the cumulative renal survival after 5, 10, 15, and 20 years was 86%, 83%, 76%, and 73%, respectively. In univariate analyses, statistically significant baseline predictors of ESRD included: duration of nephritis manifestations before renal biopsy ≥6 months; systolic blood pressure ≥180 mmHg; s-creatinine ≥140 µmol/L; advanced sclerosing (WHO class VI) nephritis; tubular atrophy; and glomerular sclerosis. Duration of nephritis manifestations prior to renal biopsy ≥ 6 months and s-creatinine ≥140 µmol/L emerged as the strongest combination of independent risk factors for ESRD in sex-, age-, and treatment-adjusted multivariate analyses (relative hazard ratios: 4.5 and 4.6, respectively). Patients treated with cyclophosphamide for induction of remission (n=44) did not have a lower risk of progression to ESRD than patients treated otherwise.

Conclusion: In the present LN cohort, new cases of ESRD continued to appear even after prolonged follow-up. The current data confirm the importance of early diagnosis and therapy in LN. However, our findings also underscore the limitations of traditional immunosuppressive regimens used for the treatment of patients with LN.

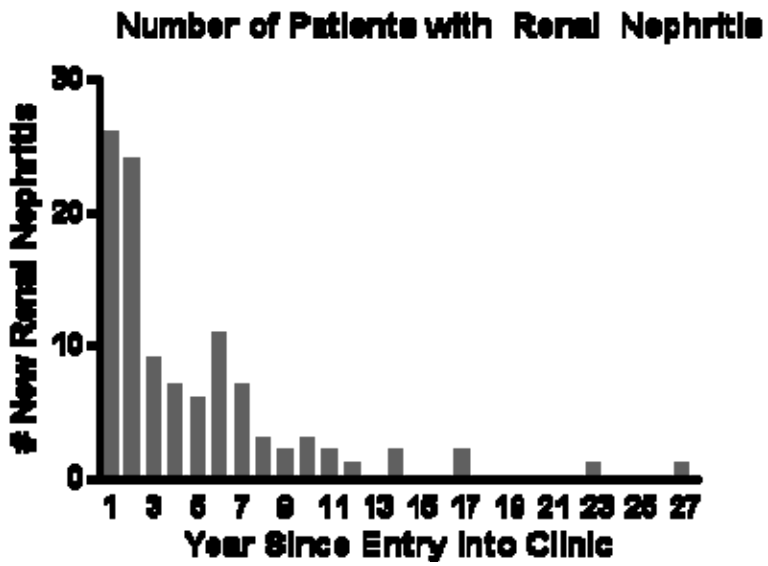
Time to Development of Nephritis in Patients with SLE. Debra Dye-Torrington[1], Dominique Ibañez[1], Murray Urowitz[2] and Dafna Gladman[1], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: Lupus nephritis is a frequent and serious complication of SLE and is seen in approximately 50% of patients with SLE. This complication is often present at time of diagnosis but in some patients it may occur later in the course of disease. We investigate the first occurrence of nephritis at inception and over the course of the disease in an inception cohort of patients followed in a single centre and examined predictive factors for late occurrence of nephritis.

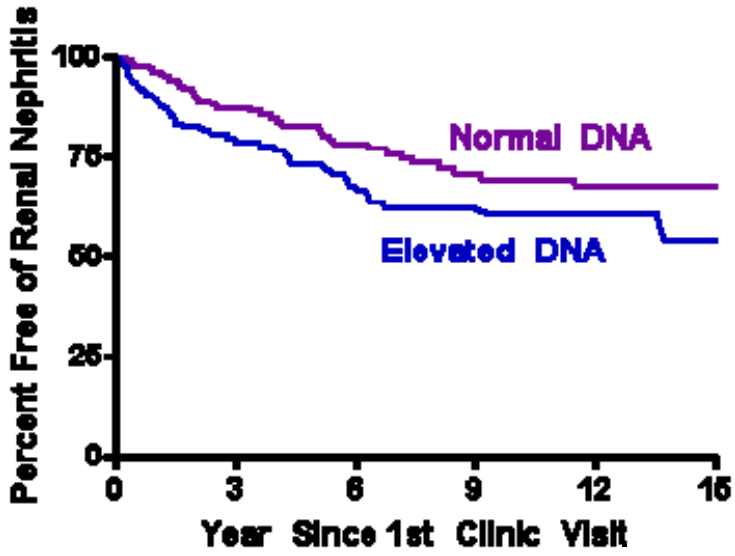
Methods: Inception patients seen in clinic within one year of diagnosis of SLE were selected from a single centre cohort followed in an observational cohort study. Lupus nephritis was defined as sterile hematuria and/or pyuria, granular casts, proteinuria (>500mg/24hr), or elevated serum creatinine (defined as greater than 120µmols/l) on two or more consecutive visits, or dialysis, transplant or WHO renal biopsy ≥ class 2. Incidence of lupus nephritis was determined for each year following entry into the clinic. In patients with no lupus nephritis at entry into the clinic, a Cox survival regression analysis was run, using the values at 1st clinic visit to predict development of future renal nephritis. Included in the model were sex, disease duration, SLEDAI-2K, SLICC/ACR damage index (SDI), steroids, antimalarial, immunosuppressant, race, complement and dsDNA. Selection of variables retained in the model was done through the stepwise approach. Kaplan-Meier curves were done for significant predictors

Results: In a cohort of 633 patients with SLE, 382(57 %) did not have lupus nephritis at inception. These were 87% female, mean age at SLE diagnosis 36yrs. 77% Caucasian, 8% Black, 65% Chinese, 10% Other. Their disease duration at first clinic visit was 0.24 yrs, SLEDAI-2K was 8.63 and SDI 0.07. 46% were taking glucocorticoids, 35% antimalarials and 8% immunosuppressants. The mean serum creatinine

was 73, 46% had low complement and 48% elevated anti-DNA antibodies. Of the 382 patients, 107 (28%) eventually developed lupus nephritis – 77% of them within the first 5 years.



Cox regression analysis revealed that only anti-DNA antibody was a statistically significant predictor with HR = 1.59 (95% CI 1.01, 2.48, p=0.04). Kaplan-Meier curve comparing the development of nephritis between patients with normal vs. elevated anti-DNA antibody at 1st clinic visit showed a statistically significant difference (Wilcoxon p=0.04)



Conclusion: 28% of patients with SLE without nephritis at inception develop lupus nephritis later in their course. The majority occur within the first 5 years, but some patients develop nephritis later. The only predictor for future development of lupus nephritis is the presence of anti-DNA antibody at inception.

930

Renal Outcome of Lupus Nephritis Is Different Between Class IV-G (A) and IV-G (A/C). Takashi Kuroiwa, Noriyuki Hiramatsu, Ken Kayakabe, Noriyuki Sakurai, Takayuki Matsumoto, Akito Maeshima, Keiju Hiromura and Yoshihisa Nojima, Gunma University Graduate School of Medicine, Maebashi, Japan

Purpose: We previously reported that in the international Society of Nephrology/Renal Pathologist Society (ISN/RPS) 2003 classification of lupus nephritis (LN), renal outcome was worst in cases in diffuse global LN involving glomerular chronic lesion (class IV-G (A/C)). In contrast, cases in class IV-G with active lesion alone (IV-G (A)) had good renal outcome. In this study, we reevaluated this observation in the cohort of increased patients and extended follow-up period. We also compared difference of clinical characteristics between class IV-G (A) and IV-G (A/C).

Method: A total of 110 patients with LN who underwent renal biopsy during 1986 to 2007 in our hospital were classified according to ISN/RPS 2003 criteria. Outcome was compared across histological classes by Kaplan-Meier analysis with endpoint as survival without end-stage renal disease and doubling of the serum creatinine. Complete or partial remission (CR or PR) was defined as proteinuria <0.5 g/creatinine (g/Cr) or <3.0 g/Cr with >50% decrease, respectively, in the presence of stabilized renal function.

Results: Mean patient age was 36.3 yrs and the median observation period was 7.4 yrs. The relative frequency for each class was as follows: class I (minimal mesangial LN) 0%, class II (mesangial proliferative LN) 13%, class III (focal LN) 17%, class IV (diffuse LN) 59% and class V (membranous LN) 11%. Within class IV, diffuse segmental (class IV-S) was 25% and diffuse global (class IV-G) 75%. Patients who reached endpoint was 14% in class II, 5% in class III, 13% in class IV-S, 14% in class IV-G, and none in class V. Statistically significant difference in outcome by Kaplan-Meier analysis was not observed among all classes and between class IV-S and IV-G. However, when compared between class IV-G (A) and IV-G (A/C), outcome was significantly worse in IV-G (A/C) cases (p=0.014). Response to the therapy was better in class IV-G (A), as ratio of patients who achieved CR/PR 6 months after induction therapy was 89% in IV-G (A) and 63% in IV-G (A/C). There was a trend that treatment was more intensive in IV-G (A), as the use of immunosuppressant was 68% in IV-G (A) and 52% in IV-G (A/C). Ratio of patients who started treatment within 12 months from LN onset was 86% in class IV-G (A) and 48% in class IV-G (A/C), suggesting that the delay in diagnosis/treatment is in part associated with development of glomerular chronic lesions. Coexistence of class V and frequency of renal flare during the observation period were comparable between both groups.

Conclusion: This study confirmed our previous observation that in Class IV-G cases, renal outcome differed in the presence of chronicity. Thus, the revised classification of LN is clinically valuable in identifying different renal outcomes among patients with diffuse L.

The ISN/RPS Classification of Renal Biopsy as a Determinant of Prognosis in a Prospective Lupus Cohort. D. M. Tulloch-Reid, D.D. Gladman, P. R. Fortin, A. Herzenberg, Edward Cole and M.B. Urowitz, University Health Network, Toronto, ON

Purpose: The International Society of nephrology/renal pathological Society(ISN/RPS)classification system for lupus nephritis was introduced in 2003 to reduce ambiguities and to provide a clearer standardized framework for clinical-pathological correlation. Prognostic studies utilizing this classification have been limited by sample size, follow-up time and methodology producing conflicting results. We aimed to assess the ISN/RPS classification as a determinant of prognosis in a prospective cohort.

Method: Patients followed prospectively in a single centre were studied. All met American College of Rheumatology (ACR) criteria for systemic lupus (SLE) and had a renal biopsy following entry into the cohort and a minimum of 3 years follow-up. Patients had clinical and laboratory assessment at 2-6 month intervals according to a standard protocol. The first available biopsy suitable for ISN scoring was used for each patient. Survival analysis was used to assess patient event-free survival with respect to outcomes of death and sustained renal deterioration (ESRD, sustained creatinine doubling or increase to >200mmol/l from baseline at time of biopsy, dialysis or tranplantation) for each ISN/RPS class.

Results: 189 patients biopsied between 1970 and 2004 were included, 84.1% female and 66.7% Caucasian. The mean age at biopsy was 35.5 years, median disease duration 2.9 years. 49% of patients had purely proliferative classes, 12.7% membranous and 5.9% combined classes,

Over a follow-up period of up to 30 years, 59 patients experienced a composite outcome of death/ESRD. Most cases of renal deterioration occurred in the first 5 yrs and predominantly in classes III and IV, while most deaths occurred later and at a similar rate across classes. No significant difference in median time to event were detected among the individual ISN classes with respect to death, renal deterioration or a composite of the two.

No difference was found between Class III and Class IV compared in the rate of any outcome, or between Class III /IV biopsies occurring with class V vs. those without. However, within class IV, ESRD occurred more frequently (RR 1.31 [1.10, 1.56]) in patients with predominantly global vs. segmental lesions. On crude bivariate analysis ISN classes III & IV together were associated with increased 10 year event rates for ESRD (RR 1.16 [1.06, 1.26]) but not for death, compared with classes I, II and V.

Persons who experienced the outcomes of interest were significantly older, had longer disease duration, higher blood pressure, higher creatinine at time of biopsy, higher chronicity index (CI)and were more likely to have been biopsied prior to 1985.

On survival analysis using the composite outcome, a trend toward decreased survival with class III/IV compared with remaining classes was lost in a multivariate model that controlled for baseline creatinine, age, CI and the presence of hypertension. However, when assessed using ESRD only, Class III/IV was a strong predictor of ESRD [HR 3.4] with only CI significantly influencing the model.

Conclusion: The ISN/RPS classification is a useful independent predictor of renal deterioration but not mortality in our cohort.

Outcomes in Biopsy-Proven Lupus Nephritis. Evaluation of 190 Caucasian Patients From a Single Center. Manuel Ramos-Casals[1], Rafael Belenguer[2], Antoni Siso[3], Albert Bove[1], Pilar Brito-Zeron[1], Candido Diaz-Lagares[1], Marta Perez-de-Lis[1], Myriam Gandia[1] and Antonio Coca[4], [1]IDIBAPS, Hospital Clinic, Barcelona, Spain, [2]Hospital 9 d'Octubre, Valencia, Spain, [3]CAP Les Corts, Barcelona, Spain, [4]ICMiD, Hospital Clinic, Barcelona, Spain

Purpose: To describe the natural history of lupus nephritis (LN) in a historical cohort of 190 Caucasian patients diagnosed with biopsy-proven LN followed in a single reference center.

Method: Six hundred and seventy patients with systemic lupus erythematosus (SLE) consecutively followed in our department from 1970 until 2006 were evaluated. All patients fulfilled the 1997 revised criteria for the classification of SLE. Caucasian patients (white, Spanish-born) with biopsy-proven LN were selected as the study population.

Results: One hundred and ninety patients (170 females and 20 males) were included. The mean age at LN diagnosis was 31 years at diagnosis of LN. Renal biopsy showed type I LN in 8 (4%) patients, type II in 33 (17%), type III in 46 (24%), type IV in 72 (38%), type V in 28 (15%) and type VI in 3 (2%) patients. Induction remission was achieved in 85% of patients with types I and II, in 78% of those with type III, in 70% of those with type IV and in 32% of those with type V. After a mean follow-up of 2391 patient-years, 62 (33%) patients developed chronic renal failure and 18 (9%) evolved to end-stage renal disease. Adjusted multivariate Cox regression analysis identified male gender (HR 4.33) and raised creatinine at diagnosis of LN (HR 5.18) as independent variables for renal failure. After a mean follow-up of 2391 patient-years, 19 (10%) patients died at a mean age of 46.5 ± 4.1 years. Survival was 92% after 10 years of follow-up, 80% after 20 years and 72% after 30 years. The 10-year survival rate according to the LN types was 100% for type II, 91% for type III, 93% for type IV and 95% for type V. Patients who died had received antimalarials less frequently (5% vs 30%, p=0.027) in comparison with survivors.

Conclusion: Our results suggest that biopsy-proven LN in Caucasian patients has an excellent prognosis. Ethnicity should be considered a key factor when the prognosis and therapeutic response to different agents is evaluated in patients with LN.

933

Lupus Nephritis: Outcome After Discontinuation of Immunosuppression. Oier A. Barrutia, Shirish.R Sangle, Jose Vargas, David P. D'Cruz and Munther A. Khamashta, Lupus Research Unit, The Rayne Institute, St Thomas' Hospital, London, United Kingdom

Purpose: Lupus nephritis (LN) remains the strongest predictor of morbidity and mortality in SLE patients. Management of LN involves long term immunosuppression. It is not clear how long and in whom the immunosuppressive therapy should be continued and which are the best predictors for flares after the withdrawal.

Method: We retrospectively reviewed 49 patients, since 1985 in our dedicated lupus nephritis clinic with lupus nephritis patients who received remission maintaining therapy such as azathioprine, mycophenolate mofetil, cyclophosphamide along with prednisolone and antimalarials. All had discontinued the therapy due to stable LN and/or pregnancy desire. All of them were stable when immunosuppressive therapy was stopped. Patients who remained without therapy at least for 6 months were included. Patients' data regarding serology, complement levels, urinary protein creatinine ratio (PCR), estimated glomerular filtration rate (EGFR), antiphospholipid antibody status, previous remission inducing and maintenance therapy, type of renal biopsy (WHO criteria) and other drugs were collected retrospectively and analyzed. Longitudinal regression model was used as multivariate analysis, controlled for age at flare, anti-dsDNA, complement level, serum albumin,PCR ratio and EGFR.

Results: All but 2 patients (4.1%) were female. 59.2% were Caucasian, 30.6% Afro-Caribean and 10.2% Asian. Median age of the patients was 29.33 ± 3.32 years. Median follow up period was 51.67 ± 48.05 months. Nine of 49 (18.4%) patients had renal flare;. There was no correlation between type of LN, previous therapy, complement levels, aPL status and drugs such as hydroxychloroquine. A univariate analysis showed positive correlation between older age at flare, persistent positive anti-dsDNA antibodies, hypoalbuminaemia, high PCR ratio and an EGFR under 85 ml/min. At multivariate analysis, PCR ratio was the best predictor (OR:1.03, CI:1.003-1.05).

Patient (n=49)	**Without flare (n=40)**	**Flared-up (n=9)**	**p value**
Median age (median)	**29.33 ± 3.32**	**36.67 ± 4.93**	**0.03**
Persistent anti-dsDNA	**5 (12.5%)**	**4 (44%)**	**0.046**
Positive aPL	**26 (65%)**	**4 (44%)**	**0.25**
Median Serum albumin (g/L)	**43.20 ± 2.94**	**37.33 ± 3.33**	**0.016**
Median EGFR<85 (mL/min)	**16 (40%)**	**8 (89%)**	**0.007**
Pr/Cr ratio* (median)	**27.93 ± 13.65**	**180.44 ± 113.07**	**<0.0001**
Biopsy (WHO class II – V)	**40**	**9**	**0.61**
Antimalarials	**23 (57%)**	**7 (78%)**	**0.24**
Median duration of immunosuppression (years)	**5.06 ± 1.72**	**5.33 ± 2.69**	**0.68**

Notes. aPL: antiphospholipid antibodies; AZA: azathioprine; CPA: cyclophosphamide; MMF: mychophenolate mofetil; MTX: methotrexate; CYC: cyclosporine; EGFR: estimated glomerular filtration rate; Pr/Cr: Protein/Creatinine. ***:** significant at multivariate analysis.

Conclusion: In patients with LN old age, positive anti-dsDNA antibodies, high protein creatinine ration and low albumin may indicate adverse outcome in whom immunosuppressive therapy was discontinued.

Comparison of Different Formulas to Estimate Renal Function in Mexican Systemic Lupus Erythematosus Patients. Marco U. Martínez-Martínez, Martín Magaña-Aquino, Jaime A. Borjas-García, Lilia Llamazares-Azuara and Carlos Abud-Mendoza, Faculty of Medicine, Universidad Autónoma de San Luis Potosí and Hospital Central, San Luis Potosí, Mexico

Purpose: The National Kidney Foundation (NKF) and the European Consensus of Lupus Nephritis (ECLN) suggest evaluate the glomerular filtration rate (GFR) with the Modification of Diet in Renal Disease (MDRD) study equation. This formula agrees with the gold standard for GFR mainly in patients with low GFR (< 60 ml/min/1.73 m^2 of body surface index [BSI]); recently the Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) was published with excellent correlation between iothalamate in low and high GFR. In spite of the NKF and ECLN recommendation, CCl is still used in practice. *Objective:* Assessment of the performance of the simplified MDRD equation (sMDRD), 24 h creatinine clearance (CCl), Cockcroft Gault equation (CG), CG equation calculated with ideal body weight (CGi), Mayo Clinic Quadratic equation (MCQ) and the CKD-EPI to estimate the GFR in Mexican patients with systemic lupus erythematosus (SLE).

Methods&Patients: Cross sectional analysis. In ≥18 years old Mexican patients with SLE (ACR) demographic data, serum and urine creatinine (24 h collection) were taken to calculate GFR using the different equations. We consider the CKD-EPI as the gold standard and this equation was compared with all the others to evaluate bias (differences in median), correlation (r), r square statistic (R^2), sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), percentage of measurement of GFR between 70-130% of the GFR measured by the CKD-EPI formula (P30) and computed the receiver operating characteristic (ROC) curves. We evaluated 24 h urine collection for creatinine excretion compared with those calculated for weight (between 80-120% was considered adequate). All the patients were classified into 1-5 NKF stages.

Results: We included 302 SLE patients. With the CKD-EPI, 181 (59.9%) were in stage 1, 71 (23.5%) in stage 2, 37 (12.3%) in 3, 10 (3.3%) in 4 and 3 (1%) were in stage 5. (Table 1).

Formula	GFR (1.73 m^2)	r	R^2	AUC
sMDRD	90.2	0.958	0.918	0.999
CCl	84.5	0.727	0.529	0.865
CG	102.2	0.931	0.866	0.973
CGi	87.9	0.929	0.863	0.968
MCQ	101.5	0.877	0.769	0.913
CKD-EPI	93.48			

The best sensitivity (98%), specificity (98%) and NVP (99.6%) to classify in NKF stages 3-5, were for the sMDRD, best PPV was for CGi (97.1%). P30 was 99.3% for sMDRD, 77.2% for CCl, 91.1% for CG, 96.6% for CGi and 74.5% for MCQ. Only 52% (157/302) were considered to have had adequate urine collections, and when we re-evaluated these 157 patients, the different statistical results improved for CCl (r, R^2, AUC and P30); r, R^2 and AUC was better for sMDRD in low GFR.

Conclusion: In Mexican SLE patients the different formulas had a good global correlation, but the different formulas can misclassify the patients in different stages of renal function, and although the NKF and the ECLN suggests MDRD to estimate GFR, we suggest the new CKD-EPI as the best option to estimate the GFR in SLE patients either in low or high GFR. Moreover CCl should not be considered as safe to calculate GFR. Higher cost of CCI should also be considered.

No Increase in the Incidence of Malignancy with Immunosuppressive Use in SLE. Michelle Petri[1] and Laurence Magder[2], [1]Johns Hopkins Univ, Baltimore, MD, [2]University of MD, Baltimore, MD

Purpose: SLE itself increases the risk of malignancy, including non-Hodgkins lymphoma. Immunosuppressive drug use has increased the risk of later malignancy in transplant recipients. We determined the risk of malignancy in a prospective SLE cohort, based on use of immunosuppressive drugs, mycophenolate mofetil (MMF), azathioprine (AZA), and methotrexate (MTX).

Method: 1667 SLE patients, with 6849 person-years of follow up were included.

Results: Cancer rates during cohort participation, by age, sex, race, and exposure to immunosuppressive drugs are shown in the table.

Group	Number of person-years observed	Number of incident cases of cancer	Rate (95% CI) per 1000 person-yrs,	Age-adjusted Rate Ratios	Age-adusted P-value
All	9830	92	9.4 (7.6, 11.5)		
Agegroup					
18-39	4932	26	5.3 (3.6, 7.7)		
40-49	2633	30	11.4 (8.0, 16.3)		
50-59	1508	21	13.9 (9.1, 21.4)		
60-69	566	10	17.7 (9.5, 32.8)		
70+	139	5	26.4 (11.0, 3.4)		
Sex					
Female	8108	80	8.8 (7.1, 10.9)	Reference	
Male	722	12	16.6 (9.4, 29.3)	1.8 (1.0, 3.3)	.059
Ethnicity					
African-American	4385	39	8.9 (6.5, 12.2)	Reference	
Caucasian	4975	52	10.5 (8.0, 13.7)	1.1 (0.8, 1.7)	
Other	469	1	2.1 (0.3, 15.1)	Too few	.51
Prior MMF exposure					
None	8671	77	8.9 (7.1, 11.1)	Reference	
Only in last 2 years	487	4	8.2 (3.1, 21.9)	1.1 (0.4, 3.0)	.87
Some 2+ years ago	672	11	16.4 (9.1, 29.6)	1.8 (1.0, 3.4)	.071
Cumulative MMF					
None	8671	77	8.9 (7.1, 11.1)	Reference	.35
< 1 year	433	5	11.5 (4.8, 27.7)	1.5 (0.6, 3.8)	.16

1-3 years	411	6	14.6 (6.5, 32.4)	1.8 (0.8, 4.2)	.69
3+years	313	4	12.8 (4.8,34.1)	1.2 (0.5, 3.4)	
Prior AZA exposure					
None	8768	79	9.0 (7.2, 11.2)	Reference	
Only in last 2 years	392	5	12.7 (5.3, 30.6)	1.6 (0.7, 4.0)	.29
Some 2+ years ago	669	8	12.0 (6.0, 23.9)	1.4 (0.7, 2.9)	.38
Cumulative AZA					
None	8768	79	9.0 (7.2, 11.2)	Reference	
< 1 year	397	4	10.1 (3.8, 26.8)	1.4 (0.5, 38)	.54
1-3 years	319	5	15.7 (6.5, 37.7)	1.9 (0.8, 4.6)	.17
3+years	346	4	11.6 (4.3, 30.8)	1.2 (0.5, 3.4)	.68
Prior MTX exposure				Too Few	
None	9321	88	9.4 (7.7, 11.6)		
Only in last 2 years	203	2	9.9 (2.5, 39.4)		
Some 2+ years ago	305	2	6.6 (1.6, 26.2)		
Cumulative MTX				Too few	
None	9321	88	9.4 (7.7, 11.6)		
< 1 year	208	3	14.4 (4.6, 44.7)		
1-3 years	189	0	0		
3+years	111	1	9.0 (1.3, 64.2)		

Conclusion: Use of MMF or AZA did not significantly increase the risk of malignancy over the reference group of non-users. There was no difference between MMF and AZA. However, MMF exposure 2 or more years in the past did have a non-significant increase (p = 0.071, age-adjusted rate ratio 1.8).

Seasonal Variation in the Incidence of Disease Flares in Systemic Lupus Erythematosus (SLE): Relationship with Weather Parameters and Ultraviolet Light Intensity. Chi Hung To[1], Chi Chiu Mok[2], Ling Yin Ho[3] and Carrel Yu[1], [1]Tuen Mun Hospital, Hong Kong SAR, Hong Kong, [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Tuen Mun Hospital, Hong Kong SAR

Purpose: To examine the seasonal variation in disease flares of SLE with regard to individual organ systems and their relationship with weather parameters and environmental ultraviolet light intensity

Method: SLE patients who were followed up in our clinics between 2000 and 2008 were studied. Details of disease flares, defined by the SELENA-SLE flare instrument, were retrieved from review of the electronic medical records. Disease activity scores during the flare episodes were measured by the SELENA-SLEDAI. The monthly rates of disease flares (mild / moderate and severe) and of individual organ systems were calculated. Flares in five organ systems (cutaneous and musculoskeletal, serositis, hematologic flare, renal and neuropsychiatric) were defined by using the individual components of SLEDAI and the SELENA-SLE flare instrument. The rate of SLE

flares was correlated by Pearson's correlation with a number of weather parameters which included mean and maximum temperature, relative humidity, total rainfall, duration of sunshine and mean ultraviolet light intensity index each month as released by the Royal Observatory of Hong Kong.

Results: 452 SLE patients were studied. There were a total of 425 mild / moderate SLE flares (0.87/100 patient-months) and 314 severe flares (0.64/100 patient-months) recorded. There were a total of 300 cutaneous and musculoskeletal flares (0.61/100 patient-months), 51 serositis flares (0.11/100 patient-months), 196 hematologic flares (0.41/100 patient-months), 196 renal flares (0.41/100 patient-months) and 49 neuropsychiatric flares (0.10/100 patient-months). The monthly rate of severe SLE flare was lowest in June and highest in January and the difference was statistically significant (p=0.042). Renal flare was significantly more frequent in the months January to March compared to June (p=0.041, 0.048, 0.043, respectively). The monthly rates of severe lupus flare and renal flare were negatively associated with the mean daily temperature (r=-0.73, p<0.01; r=-0.68, p=0.015, respectively), mean daily maximum temperature (r=-0.72, p<0.01; r=-0.67, p<0.016), total monthly rainfall (r=-0.73, p<0.01; r=-0.75, p<0.01) and mean ultraviolet light intensity index (r=-0.63, p=0.03; r=-0.69, p=0.012). The monthly total duration of sunshine was associated positively with cutaneous and musculoskeletal flare (r=0.62, p=0.03), but negatively with neuropsychiatric flare (r=-0.65, p=0.021).

Conclusion: Seasonal variation in lupus flares in different organ system exists. Skin and joint lupus flares were more frequent in periods of more prolonged sunshine but were not associated with environmental ultraviolet light intensity. Severe lupus flare and renal lupus more commonly occurred during the winter months which were associated with lower temperature, humidity and ultraviolet light intensity.

A Role for APRIL in the Development of SLE- and RA-Associated Lymphomas? Ingrid E. Lundberg[1], Björn Löfström[2], Carin Backlin[3], Christer Sundström[3], Tom Pettersson[4], Anders Ekbom[5] and Eva Baecklund[6], [1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [3]Uppsala University, Sweden, [4]Helsinki University Hospital, Helsinki, Finland, [5]Karolinska Institutet, Stockholm, Sweden, [6]Rheumatology clinic, Uppsala, Sweden

Purpose: Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) are associated with an increased lymphoma risk, in particular diffuse large B cell lymphoma (DLBCL). Involved biologic mechanisms are still unknown. A PRoliferating-Inducing Ligand (APRIL), a cytokine of the TNF superfamily, regulates B-cell activation and survival. It is overexpressed both in lymphomas like DLBCLs and in RA/SLE-patients. We hypothesise that APRIL may have a role in the development of DLBCL in RA and SLE.Investigate APRIL expression in lymphoma tissue from RA/SLE patients with DLBCLs using general population DLBCLs as controls and correlate to clinical characteristics.

Method: Linked, previously presented, registry studies of the Swedish Hospital Discharge Register and the Swedish Cancer Register between 1964 and 1995 yielded 98 patients with RA and 13 with SLE who developed DLBCL. (One SLE-DLBCL Helsinki patient also included). Diagnoses were verified using current ACR criteria for RA and SLE and the WHO classification of lymphoma. General DLBCL patients from Uppsala Region without chronic inflammatory disease were used as controls (n=63). Lymphoma specimens were sectioned and stained with Aprily-2 (Alexis). Percentage APRIL positive staining lymphoma cells were counted in light microscope. The results of the controls were divided in quartiles and the result of the RA/SLE lymphomas compared to the controls using the χ^2test. Cumulated disease activity (from clinical data abstraction) in RA was scored and measured as area under the curve (AUC).

Results: Mean percentage of stained cells in SLE-, RA- and control-DLBCLs was 25, 11 and 12 %. The quartile distribution of the stainings was significantly different in RA DLBCLs (45,14,11,28) and SLE DLBCLs (1,0,0,13) compared to controls. In RA, an association was seen between high cumulated disease activity and high % APRIL positive cells (mean AUC in quartile 1= 636, quartile 4=968).

Conclusion: Our data reflect the heterogeneity of the DLBCL subtype and suggest that APRIL could be of particular importance in the development of lymphoma in SLE and in development of lymphoma in a subset of RA patients with high cumulated disease activity.

Assessment of Lupus (SLE) Mortality in a Patient-Based Community Data Bank. Frederick Wolfe[1], KD Michaud[2], Tracy Li[3] and RS Katz[4], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]U Neb Med Cntr and NDB, Omaha, NE, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Rheumatology Associates, Chicago, IL

Purpose: SLE studies usually derive from the clinic where the emphasis is on physician and laboratory assessments. Although patient-based assessments may be ideal for assessment of patient reported outcomes and mortality, there have been only rare and small systematic, longitudinal studies of SLE patient outcomes. We have reached into rheumatology practices to develop a community SLE databank to assess SLE outcomes, to determine the risk and predictors of mortality, and to confirm the utility of patient-based databanks in SLE.

Methods: We studied 1,324 patients with SLE, 2,809 with fibromyalgia (FM), 3,825 with non-inflammatory rheumatic disorders (NIRD), and 14,444 with rheumatoid arthritis (RA). Patients were assessed semi-annually by questionnaires that included detailed demographics, all patient-reported outcomes, treatments, and comorbid conditions. The risk of mortality was assessed by age and sex adjusted time-varying Cox regression analyses, expressed as hazard ratio (95% confidence interval). The discriminatory ability of baseline predictors was assessed by Harrell's c (C).

Results: At entry, median age and disease duration of SLE patients was 48.9 and 11.8 years, and 94% were women. Lifetime treatments included corticosteroids (CS) 81.3%, hydroxychloroquine, 82.9%, methotrexate 28.6%, azathioprine 26.0%, and cyclophosphamide 13.0%. During a mean follow-up of 2.5 years, range (0.5 to 10.1 years), 30 of the 1,324 SLE patients died. The resultant estimated 5-year survival was 94.9% (91.5% to 97.0%). Compared with patients with NIRD, FM, and RA, the hazard ratio (HR) for mortality was 2.8 (1.9, 4.1), 3.6 (2.4, 5.4), and 2.1 (1.5, 3.1). In general, the strength of comorbidity predictors was similar across all rheumatic disorders. The HR for stroke was 7.7 (1.7, 31.3), for myocardial infarction 3.3 (0.4, 25.1), and for GI ulcer 3.6 (1.1, 12.2). But confidence intervals overlapped between SLE and the other disorders, and no definite differences among disorders could be identified. Using baseline predictors in patients with SLE, we found that age (HR 1.5 (1.1, 2.1)) per 10 years and being male (HR 3.5 (1.4, 8.8)) increased mortality risk. After adjustment for age and sex, only household income (HR 1.2 per $US 10,000 reduction in income), among demographic predictors, was significantly associated with mortality. In particular, education, ethnicity, and marital status were not significant in this model. Mortality was best predicted by baseline HAQ-II (HR 3.9 (2.1, 7.3), C=0.82), compared with HAQ (HR 1.7 (1.0, 2.7), C=0.67), and SF-36 PCS (HR 0.95 (0.92, 0.99), C=0.75). In multivariable analyses only HAQ-II was significant. Other significant multivariable predictors of mortality included age sex, household income, preexisting renal, cardiovascular and GI ulcer conditions, and azathioprine (HR 1.9 (1.4, 2.6)), prednisone (HR 1.7 (1.0, 2.9)), and hydroxychloroquine (HR 0.5 (0.3, 0.7)). C for the combined model was 0.89.

Conclusion: Patient-based outcomes are highly discriminative for mortality, and functional assessment (HAQ-II) is the best overall predictor of SLE mortality. Patient-based databanks are effective in assessing lupus mortality and other outcomes.

Effects of SLE Activity On Lymphoma Risk: Preliminary Results of a Case-Cohort Study. S. Bernatsky[1], R. Ramsey-Goldman[2], Murray Urowitz[3], Dafna Gladman[4], G. Ruiz-Irastorza[5], S C. Bae[6], P. R. Fortin[4], S. Manzi[7], Y. St. Pierre[1], J. L. Lee[1], E. Turnbull[1], A. E. Clarke[1] and Systemic Lupus International Collaborating Clinics, [1]MUHC, Montreal, QC, [2]SLICC, Chicago, IL, [3]U of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]Universidad del País Vasco, Bizkaia, Spain, [6]Hanyang Univ, South Korea, [7]University of Pittsburgh, Pittsburgh, PA

Purpose: It is increasingly recognized that persons with autoimmune rheumatic diseases have heightened risks for certain cancers, particularly lymphoma. The role of immune system activity in driving cancer risk is incompletely understood. Our purpose was to examine if, in systemic lupus erythaematosus (SLE), disease activity increases lymphoma risk.

Methods: A case-cohort study was performed within a multi-site international SLE cohort; subjects were linked to regional tumour registries to determine lymphoma cases occurring after entry into the cohort. Controls represented a sub-cohort randomly selected at cohort entry. Disease activity was assessed using the adjusted mean SLE Disease Activity Index (AMS) scores in each case-control set, as of the index time for each event. We calculated the hazard ratio (HR) for lymphoma related to AMS scores (as a continuous variable), in models that

controlled for drugs (immunosuppressive medications, anti-malarial drugs, glucocorticoids), smoking, age, sex, race/ethnicity, geographic location, and SLE duration. Drug exposures were treated categorically (ever/never) and as time-dependent.

Results: Preliminary results are presented for 13 lymphoma cases and 152 cancer-free controls. The proportion female were similar in cases (85%) versus controls (86%). The average age at time of lupus diagnosis for cases was 38.5 (standard deviation, SD=17.7) and 34.5 (SD=14.0) in controls. The lymphoma cases occurred a mean of 8.7 years after SLE diagnosis (5.8 years after cohort entry). The adjusted HR for the effect of AMS on lymphoma risk was 1.19 (1.04, 1.36). Increasing age was also an independent risk factor for lymphoma risk.

Conclusion: These preliminary findings suggest the importance of disease activity in influencing lymphoma risk in SLE. However, more in-depth analyses are required to establish the relationship definitively. These further efforts are in progress, and will help define the independent influences of medication exposures and disease activity on the risk of malignancy in SLE.

Variable	**Adjusted HR (95% CI)**
Residence outside North America	1.33 (0.11, 16.2)
Male sex	0.58 (0.07, 4.55)
Age (Continuous, time-dependent)	1.05 (1.00, 1.11)
Disease duration (Continuous)	0.99(0.81, 1.21)
Tobacco use (ever/never)	3.22(0.64, 16.2)
White race	0.85(0.05, 13.3)
Corticosteroids	0.07(0.01, 1.21)
Immunosuppressive agents*	7.3 (0.62, 85.2)

Plasma Myeloperoxidase Predicts Mortality in Women with Systemic Lupus Erythematosus. Kimberly P. Liang[1], Abdus Sattar[2], Stanley Hazen[3], Jennifer R. Elliott[4], Linda C. Santelices[5], Amy H. Kao[2], Susan Manzi[2] and Kathleen Maksimowicz-McKinnon[2], [1]Univ of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Cleveland Clinic, Cleveland, OH, [4]Rheumatology & Osteoporosis Se, Lincoln, NE, [5]Magee-Womens Hospital UPMC, Pittsburgh, PA

Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk of cardiovascular disease (CVD), in part related to excess inflammation. Myeloperoxidase (MPO), an abundant leukocyte enzyme, is elevated in persons with angiographically documented CVD and within culprit lesions prone to rupture, and previous studies suggest mechanistic links between MPO and both inflammation and CVD. Single initial measurement of plasma MPO has been shown to independently predict the early risk of cardiovascular (CV) events in patients presenting with chest pain. The objective of our study was to determine whether plasma MPO levels, a potential novel marker of plaque vulnerability, are associated with CV events and/or mortality in patients with SLE.

Method: We performed a longitudinal study of 213 SLE women with no prior CV events. Cox models were used to estimate the influence of baseline plasma MPO levels on time to CV events, including cardiac arrest, myocardial infarction (MI), angina, coronary artery bypass grafting (CABG), percutaneous transluminal coronary angioplasty (PTCA), cerebrovascular accident (CVA); and time to death. Multivariable Cox models were used to adjust for traditional CV risk factors, SLE disease activity measures, and disease duration.

Results: At baseline, the median age was 44 years and the majority was Caucasian (89.9%). Mean lupus disease duration was 10 years, mean Systemic Lupus Activity Measure (SLAM) score was 6.5, and 42.3% were on steroids (median 8.9 years duration). Median follow-up was 10.1 years. Thirty-seven percent were hypertensive, 65% had hypercholesterolemia, 5.5% had diabetes, and 42% were ever smokers. There were 24 CV events (cardiac arrest, angina, MI, PTCA, CABG), 6 CVA events, and 22 deaths. While plasma MPO levels did not predict time to non-fatal MI or need for revascularization (CABG or PTCA) in women with SLE ($p>0.05$), plasma MPO levels did predict time to fatal events (all-cause mortality) with hazard ratio (HR) 2.01 (95% CI 1.17, 3.46, $p=0.01$). This association remained significant even after adjusting for age, CV risk factors, inflammatory markers and disease activity measures (C-reactive protein, low-density lipoprotein, duration of steroid use, and creatinine), with HR 2.32 (95% CI 1.14, 4.72, $p=0.02$).

Conclusion: These findings indicate that plasma levels of MPO predict increased risk of overall mortality in SLE even following adjustments for CVD risk factors. However, no significant association was noted between MPO and non-fatal MI or need for revascularization in SLE women. Further studies are needed to determine whether MPO levels may be pathophysiologically linked to causes of death in SLE.

Rheumatoid Arthritis Clinical Aspects: Cardiovascular co-morbidity

Monday, October 19, 2009, 9:00 AM - 6:00 PM

941

Preclinical Atherosclerosis Is of Similar Severity in Rheumatoid Arthritis and Diabetes Mellitus Despite Differential Impact of Traditional Risk Factors and Systemic Inflammation. Kimon S. Stamatelopoulos[1], George D. Kitas[2], Christos M. Papamichael[1], Elda Chryssochoou[1], Christina G. Katsiari[3], George Georgiopoulos[1], Athanasios Protogerou[1], Vasileios F. Panoulas[2], Aamer Sandoo[2], Nikolaos Tentolouris[3], Myron Mavrikakis[1] and Peter P. Sfikakis[3], [1]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Athens, Greece, [2]Dudley Group of Hospitals NHS Foundation Trust, Dudley, and Arthritis Research Campaign Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [3]First Department of Propaedeutic and Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece

Purpose: The extent to which atherosclerosis is accelerated in chronic inflammatory diseases is not established. We compared preclinical atherosclerosis in rheumatoid arthritis (RA) with diabetes mellitus (DM), a known coronary heart disease (CHD) equivalent.

Method: Vascular studies were performed in 84 RA patients without overt cardiovascular disease or DM vs 84 matched (1:1 for age, gender and classical CVD risk factors) healthy controls. In addition, 48 DM patients matched for age, gender, and disease duration with 48 RA patients were studied. Vascular studies included measurements of endothelial function (flow-mediated dilatation - FMD), arterial stiffness (pulse wave velocity - PWV), carotid intima-media thickness (cIMT) and analysis of atheromatous plaques.

Results: All markers of preclinical atherosclerosis were significantly worse in RA patients compared to controls. RA duration associated with arterial stiffening, whereas RA activity associated with carotid plaque vulnerability. The prevalence and severity of functional and structural vascular abnormalities was similar in RA and DM of equal duration (mean of 10 years), despite the fact that DM patients had a worse classical CVD risk profile. Both RA and DM were associated independently with increased IMT; RA, but not DM, was independently associated with decreased FMD.

Conclusion: Preclinical atherosclerosis appears to be of equal frequency and severity in RA and DM of similar duration. RA activity impacts upon endothelial function, and disease duration upon arterial stiffness. Modifiable CVD risk factors may need to be targeted as aggressively in RA as is currently recommended for DM, but this may need to be accompanied by sustained control of systemic inflammation. These strategies require prospective evaluation in RA.

Infraclinical Atherosclerosis Is Correlated to Hypertension and Parameters Reflecting Systemic Inflammation (CRP, CD40L and oxydative stress) in a Cohort of Very Early Inflammatory Rheumatisms (VErA). Thibault Vandhuick[1], Yannick Allanore[2], Jean Pierre Louvel[1], Philippe Dieudé[3], Elisabeth Flipon[4], Patrice Fardellone[4], Gaelle Clavel[4], Patrick Boumier[4], Jean Daniel Allart[5], Corinne Lesage[1], Sophie Pouplin[1], Catherine Krzanowska[1], Jean-François Ménard[1], Mary Jan[6], Xavier Le Loët[7] and Olivier Vittecoq[1], [1]CHU Rouen, Rouen, France, [2]Paris Descartes Univ, Paris, France, [3]Bichat hospital APHP, Paris, France, [4]Hopital Nord Amiens, Amiens, France, [5]Pauchet Hospital, Amiens, [6]CHU, Rouen, France, [7]CHU Rouen - INSERM U 905, France

Purpose: Rheumatoid arthritis (RA) is an independent cardiovascular risk factor (CVRF). However, the link between RA and cardiovascular events has only been proven in active and severe forms of RA, but not in early inflammatory rheumatisms. The objectives of our study were: (i) to assess infra-clinical atherosclerosis in a cohort of early RA and undifferentiated arthritis; (ii) to identify specific parameters likely to predict the development of atherosclerosis.

Methods: Patients, prospectively recruited from 1998 to 2002 in a cohort (VErA) of untreated early inflammatory rheumatisms evolving for less than 6 months, accepted to undergo a carotid sonography, measuring the intima-media thickness (IMT), at 7 years of the first symptoms. Clinical, biological and radiological parameters have been notified at the inclusion and every 6 months: Disease Activity Score (DAS44), ESR, CRP, Rheumatoid Factors (RF), anti-CCP2 antibodies, markers of oxydative stress and endothelial dysfunction, van der Heijde modified Sharp score… Traditional CVRF were collected for each patient. RA treatment was standardized at the onset of the disease and corticosteroids were avoided if possible.

Results: One hundred and five patients were included in our study (80 RA fulfilling the ACR criteria). At the inclusion mean age was 51.7 ± 12.8 years, DAS44 3.23 ± 1.25, ESR 25.9 ± 23.6 mm/h, CRP 22.0 ± 32.2 mg/l; 38 % of patients had RF and 36 % antiCCP2 abs. Mean number of CVRF after a 7-year follow-up was 1.67 ± 1.09 with a mean carotid artery IMT measured at 0.67 ± 0.12 mm. Increased IMT was correlated with age ($p<10^6$), swollen joint count ($p=0.01$) and DAS44 ($p=0.048$) at the inclusion. It was also associated with persistent elevated CRP during the first three years ($p=0.005$). Hypertension and android obesity were the only classical CVRF significantly correlated with elevated IMT (respectively $p=0.006$ and $p=0.03$). Mean levels of advanced oxidation protein end products (AOPP) and CD40L during the first 2 years were both specific biological markers associated with increased IMT (respectively $p=0.041$ and $p=0.02$). On the other hand the presence of antiCCP2 abs (related to erosions in this study) is associated with a significant reduced carotid IMT ($p=0.009$). No relationship was found between IMT and genetic background or structural damages.

Conclusion: In this very early arthritis cohort, the 2 events, structural damages and infraclinical atherosclerosis, usually observed in RA, seem to be related to different mechanisms: the first one to the presence of antiCCP abs and the second one to baseline as well as mean levels over the first years of parameters reflecting inflammatory process (AOPP, CD40L and CRP)

Systolic Blood Pressure Is An Independent Modifiable Risk Marker Associated with Subclinical Atherosclerosis in Early Inflammatory Polyarthritis- Results From the Norfolk Arthritis Register (NOAR). H. Mirjafari[1], T. Farragher[1], P. Pemberton[2], V. Charlton-Menys[3], D. Bunn[4], T. Marshall[4], P. Wilson[4], D. P. Symmons[1] and I. N. Bruce[1], [1]arc Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Manchester Royal Infirmary, Manchester, United Kingdom, [3]The University of Manchester, Manchester, United Kingdom, [4]Norfolk and Norwich University Hospital, Norwich, United Kingdom

Purpose: Patients with inflammatory polyarthritis (IP) experience excess cardiovascular (CVD) mortality due to accelerated atherosclerosis. It is important to have accessible and reliable predictors of subclinical atherosclerosis, as early as possible in the disease process. The aim of this study was to identify markers of subclinical atherosclerosis in patients with IP

Methods: Consecutive patients aged 18-65 years with early IP (≥2 joints swollen for ≥4 weeks) within 24 months of symptom onset were recruited as part of a primary-care-based inception cohort. Patients completed a questionnaire including history of diabetes, smoking and family history of MI. Clinical examination included joint count and measurement of blood pressure and BMI. Blood was taken for rheumatoid factor (RF), C-reactive protein (CRP), anti-cyclic citrullinated peptide antibodies (ACPA), fasting glucose and lipid profile. Patients underwent B mode Doppler ultrasound examination of the carotid arteries to assess intima-medial thickness (cIMT). In univariate analyses we identified factors associated with a cIMT above the median; after age and gender adjustment. We then entered the significantly associated parameters into a multivariable model.

Results: 326 patients were recruited, of whom 226 (70%) were female. Median (IQR) age at study entry was 50 (41-57) years and median symptom duration was 6 (4-11) months. Mean (SD) blood pressure was 134/ 84 (16/10) mmHg. The median (IQR) cIMT was 0.6 (0.5-0.7) mm. Age, male gender, family history of MI, systolic blood pressure (SBP) and BMI were significantly associated with above median cIMT in the univariate analysis (Table). In a multivariable model age, male gender, family history of MI and SBP remained significant independent predictors of above median cIMT (OR (95% CI) 1.1 (1.1, 1.2), 1.9 (1.0, 3.4), 3.4 (1.3, 9.0), 1.0 (1.0, 1.0) respectively). These results were revalidated using linear regression with cIMT as a continuous variable as outcome. The relationship between SBP and cIMT was linear and no threshold effect was found.

Table: Univariate association with above median cIMT at baseline

Variable	**OR (95% CI)** (age and gender adjusted)
Age (years)	1.1 (1.1, 1.2) *
Male gender	1.9 (1.1, 3.4) *
Smoker	1.5 (0.8, 3.0)
Diabetes	1.3 (0.5, 3.3)
SBP (mmHg)	1.0 (1.0, 1.0) *
Family history of MI	3.6 (1.4, 9.2) *
LDL (mmol/l)	1.2 (0.9, 1.6)
HDL (mmol/l)	0.6 (0.3, 1.2)
BMI	1.1 (1.0, 1.1) *
IP disease duration (months)	1.0 (1.0, 1.0)
Steroid therapy	0.6 (0.3, 1.1)
DAS28	1.1 (0.9, 1.3)

RF	1.1 (0.6, 1.8)
ACPA	1.0 (0.6, 1.7)
HAQ score	1.1 (0.7, 1.5)
CRP (mg/l)	1.0 (1.0, 1.0)

*Statistically significant

Conclusion: In our dataset SBP was the only modifiable risk factor for subclinical atherosclerosis (as assessed by cIMT). This underlines the importance of regular measurement of BP in patients with early IP with a view to starting and adjusting anti-hypertensive therapy in accordance with national guidelines.

944

Determinants of Hypertension in Rheumatoid Arthritis. Siriporn Manavathongchai[1], Young-Hee Rho[1], Annette M. Oeser[1], Joseph F. Solus[1], Ginger L. Milne[1], Aihua Bian[1], Tebeb Gebretsadik[1], Ayumi Shintani[1], Yu Asanuma[2] and C. Michael Stein[1], [1]Vanderbilt University, Nashville, TN, [2]Saitama Medical University, Saitama, Japan

Purpose: Hypertension (HT) is one of the most common modifiable cardiovascular risk factors and is associated with increased atherosclerosis and cardiovascular risk. HT is more common in patients with rheumatoid arthritis (RA) and inflammation is postulated to play a role. In the general population, oxidative stress, insulin resistance, homocysteine (Hcy), osteoprotegerin (OPG), C-reactive protein (CRP) and leptin (all of which are elevated in RA) have been associated with HT. The contribution of these factors to HT in RA is not known. The aim of this study was to define the contribution of these factors to HT in RA.

Methods: We studied 169 patients with RA enrolled in a study of cardiovascular risk factors and outcomes. HT was defined as systolic blood pressure ≥ 140 mmHg and/or diastolic blood pressure ≥ 90 mmHg and/or currently receiving antihypertensive therapy. We measured inflammatory markers (serum CRP, tumor necrosis factor alpha (TNF-α), interleukin-6 (IL-6)), insulin resistance (homeostasis model assessment (HOMA) index), oxidative stress (serum myeloperoxidase (MPO) and urinary F_2-isoprostane excretion), Hcy, leptin and OPG concentrations. Factors were compared between patients with and without HT using Wilcoxon rank-sum tests and Pearson's chi-square tests. The association of each factor of interest on HT status was examined using separate multivariable logistic regression models. Covariates for adjustment include age, sex, race, smoking status, body mass index (BMI), and corticosteroids and non-steroidal antiinflammatory drugs (NSAIDs) use.

Results: The prevalence of HT in patients with RA was 53.3%. Hypertensive patients (n=90) were significantly older than those without HT (n=79) (median [IQR] 58.5 [51.2-67.0] years vs. 46.0 [41.0-56.0] years) and had longer disease duration (11.0 [2.0-20.0] years vs. 2.0 [1.6-11.5] years) (P<0.001). BMI and smoking history did not differ significantly between patients with and without HT (P>0.05). Concentrations of Hcy (11.1 [8.5-13.5] µmol/L vs. 9.3 [7.8-11.0] µmol/L and OPG (1778 [1300-2602] pg/ml vs. 1304 [961-1626] pg/ml) were significantly higher in hypertensive patients (P<0.001). After adjustment for age, sex, race, smoking status, BMI, and corticosteroids and NSAIDs use, increased concentrations of Hcy (OR 2.9, CI 1.5-5.5, P<0.001), OPG (OR 2.1, CI 1.2-3.7, P=0.01) and leptin (OR 2.0, CI 1.0-3.8, P=0.046) remained associated with HT. DAS28, HOMA, MPO, F_2-isoprostane excretion, IL-6, CRP and TNF-α were not significantly associated with HT among RA patients (all P values >0.05).

Conclusion: HT in patients with RA is not associated with insulin resistance, oxidative stress or non-specific markers of inflammation, but with increasing concentrations of Hcy, OPG and leptin. The pathogenesis of HT in RA may involve pathways more usually associated with the maintenance of bone, fat and vascular homeostasis.

Assessment of Cardiac Involvement in Rheumatoid Arthritis Using a Comprehensive Cardiac Magnetic Resonance Approach: Association of Myocardial Abnormalities with Disease Activity. Hitomi Kobayashi[1], Jon T. Giles[2], Isamu Yokoe[3], Masaharu Hirano[4], Tsubasa Onishi[3] and Yasuyuki Kobayashi[5], [1]Itabashi Chuo Medical Center, Itabashi-ku, Tokyo, Japan, [2]Johns Hopkins University, School of Medicine, Baltimore, MD, [3]Itabashi Chuo Medical Center, Japan, [4]Tokyo Medical University, Tokyo, Japan, [5]St. Marianna University, Kawasaki, Japan

Purpose: Rheumatoid arthritis (RA) is a multi-organ inflammatory disorder associated with high cardiovascular morbidity and mortality. Using contrast enhanced cardiac magnetic resonance imaging (cMR) with pharmacologic stress, we sought to identify microvascular impairment and myocardial inflammation/fibrosis in a group of RA patients and explore the association of these outcomes with RA disease characteristics.

Methods: RA patients with no history and/or clinical findings of systemic hypertension, coronary artery disease, severe valvular heart disease, atrial fibrillation, diabetes mellitus, or echocardiographic abnormalities underwent contrast-enhanced cMR on a 1.5T scanner. Adenosine triphosphate was used to assess perfusion defects due to microvascular impairment or ischemia, and delayed enhanced imaging was obtained for the assessment of myocardial inflammation/fibrosis. We evaluated the associations of cMR abnormalities with RA disease activity and severity measures.

Result: Eighteen patients (72% female) with a mean age of 57 ± 10 years were studied. The mean DAS28 for the cohort was 3.96, with 6 participants (33.3%) falling into the low disease activity category (DAS28<3.2) and 6 participants (33.3%) falling into the high disease activity category (DAS28>5.1). Eight patients (45%) demonstrated a myocardial abnormality. Stress perfusion defects were seen in two patients (11%), one of whom had a circumferential subendocardial perfusion defect and one had a non-segmental subendocardial perfusion defect. Seven patients (39%) were found to have delayed enhancement (indicating myocardial inflammation or fibrosis), only one of whom also demonstrated a perfusion defect. Mean DAS28 was significantly higher in the group with delayed enhancement compared to the group without by an average of 1.32 DAS28 units (4.77 vs. 3.44 units, respectively; p=0.011). Corresponding trends to statistical significance were noted in systemic inflammatory markers, with both CRP and ESR quantitatively higher in the group with delayed enhancement. Despite higher disease activity overall, TNF inhibitors were prescribed in only one participant with delayed enhancement (14.3%) compared to 6 without delayed enhancement (54.6%); however, this difference was not statistically significant (p=0.15). Other RA characteristics were not significantly associated with myocardial abnormalities.

Conclusion: Myocardial involvement, as detected by cMR, was frequent in RA patients without known cardiac disease. Myocardial inflammation/fibrosis was observed more frequently than microvascular impairment and, combined with its association with higher RA disease activity, suggests a mechanistic connection between articular and myocardial inflammation in RA.

Methotrexate Reduces Cardiovascular Risk in Rheumatoid Arthritis: A Systematic Review. J. Gupta[1], W.F. Harvey[1] and D.H. Solomon[2], [1]Tufts Medical Center, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

Purpose: Rheumatoid arthritis (RA) is known to be associated with an excess of cardiovascular (CV) risk. RA and atherosclerosis both have important inflammatory underpinnings and may share a common etiopathogenesis. Methotrexate (MTX) effectively decreases inflammation in RA and therefore may have similar effects on the inflammatory aspect of CV disease, thereby decreasing CV risk. Our goal was to conduct a systematic review of the literature analyzing the effects of MTX on CV outcomes.

Method: We searched Medline (Jan 1950-May 2009) using the terms (rheumatoid arthritis and methotrexate) and (cardiovascular or stroke or atherosclerosis or myocardial infarction (MI) or coronary disease or congestive heart failure or mortality). Inclusion criteria were that the population studied had a diagnosis of RA, reported exposure to MTX, and reported a CV outcome, including MI, stroke, congestive heart failure, CV mortality or CV intervention rates.

Results: Our search yielded 340 articles, and an initial screen of the abstracts resulted in 17 articles chosen for detailed review. Ultimately, 6 articles were chosen that fulfilled our inclusion and exclusion criteria. All were observational designs and their heterogeneity prevented a meta-analysis. The included studies are described in the table. The studies ranged in size from 623 to 107,908 patients. In three of the studies, data were collected from outpatient clinics and three (Suissa, Prodanovich, and Bernatsky) used large administrative databases. Median follow up time was reported in only three studies (Choi, Suissa, and Bernatsky). Only Choi reported mean weekly MTX dosage (13mg). Studies did not uniformly report or adjust for RA severity, disease activity or traditional CV risk factors. Despite this heterogeneity, all of the studies showed a reduction in CV risk for patients using MTX, though not all results were statistically significant.

Conclusion: While multiple limitations with the observational nature of this literature exist, our systematic review reveals a decreased CV risk associated with MTX use in RA patients. It is not clear whether this association would hold true across all DMARDs.

Author, year, Country	**N, years studied, source of data**	**Mean follow-up (SD)**	**Comparison**	**Endpoint**	**Key Outcomes (95% CI)**
Choi 2002 US	n=1240 1981-1999 Outpt Clinic	6 yrs (5)	MTX vs. No MTX	CV death	HR 0.3 (0.2-0.70)

Formal Cardiovascular Risk Determination in Rheumatoid Arthritis Suggests Suboptimal Use of Statins. Tracey Toms[1], Vasileios F. Panoulas[1], Karen.M.J. Douglas[1], Helen Griffiths[2], Naveed Sattar[3], Deborah Symmons[4] and George D. Kitas[1], [1]Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom, [2]Aston University, Birmingham, United Kingdom, [3]BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom, [4]arc Epidemiology Unit, University of Manchester, United Kingdom

Purpose: Rheumatoid arthritis (RA) associates with an excess cardiovascular morbidity and mortality. This can partially be attributed to traditional risk factors. Thus, the risk of developing cardiovascular disease (CVD) can be reduced if traditional risk factors are identified and managed aggressively. Several algorithms have been developed to calculate CVD risk and guide treatment with lipid lowering agents, including the Framingham Risk Score (FRS). In this study we aimed to identify the degree of CVD risk in an RA population, and whether patients identified at risk were optimally managed.

Method: 400 well-characterised RA patients were recruited from outpatient clinics held at the Dudley group of Hospitals NHS Foundation Trust. Patients with a prior history of CVD were excluded, leaving a total of 314 patients for subsequent analysis. Patients at high risk of developing CVD were identified, by applying the FRS and statin use was then assessed amongst those in the at risk category. **Results:** Of the patients without a history of CVD 17/314 (5.4%) had a FRS 10 year risk of greater than 20% and required primary prevention as per current UK guidelines. Of the 17 high risk patients, only 3 (17.6%) were recieving lipid-lowering therpay (statins/fibrates), leaving a total of 14 (82.3% of the at risk patients or 4.5 % of the total population) untreated and at risk.

Conclusion: Many RA patients are at high risk of developing CVD. Despite this, the use of lipid lowering agents remains suboptimal. We would recommend that all patients undergo annual screening for CVD risk and are managed agressively if deemed to be at high risk.

Raised Traditional Cardiovascular Risk Factors in Indians with Rheumatoid Arthritis. Firdaus Fatima[1], Rao RK Uppuluri[2], Robert J. Moots[3] and Nicola Goodson[4], [1]Dr, Hyderabad, India, [2]Director, Srideepti Rheumatology Centre, Hyderabad, India, [3]University Hospital Aintree, Liverpool, United Kingdom, [4]Liverpool, United Kingdom

Purpose: The increased cardiovascular disease (CVD) in rheumatoid arthritis (RA) is thought to be mediated by elevated traditional CVD risk factors, and the effects of inflammation. South Asian populations have a high prevalence of traditional CVD risk factors and CVD events[1]. We have investigated the prevalence of CVD risk factors in South Asian patients with RA.

Method: 800 consecutive RA patients (fulfilling ACR classification criteria) and 800 age matched controls without RA were identified. Subjects on therapy for CVD or lipid lowering agents were excluded. The prevalence of individual traditional CVD risk factors and 10 year coronary heart disease (CHD) risk score[2] were compared between cases and controls using age and gender adjusted logistic regression.

Results: 83.5% of RA cases were female Vs 83.3% controls. Mean age of cases was 46.2 yrs SD (11.3) Vs controls 46.1 yrs SD (12.1). RA cases had a 4 fold increased odds of having an elevated CVD risk score (Table 1). Individual risk factor analysis revealed that this was predominantly due to elevated diastolic BP, total cholesterol (TC) and a trend for lower High Density Lipoprotein Cholesterol (HDL C) in

RA. There was a high prevalence of diabetes mellitus (DM) in this population but RA cases had higher triglycerides (trig) and higher fasting blood sugar (FBS) compared to controls.

Table 1 Comparing CVD risk factors between RA cases and controls

CVD Risk factor	RA n	Non RA n	OR	95% CI
DM	252	242	1.06	0.86, 1.32
Smoking	12	5	2.58	0.88, 7.54
Systolic BP ≥140	219	201	1.13	0.89, 1.44
Diastolic BP ≥ 95	91	29	3.46	2.25, 5.34
Waist : Hip ratio>0.9	451	443	1.04	0.85, 1.28
BMI>25	481	514	0.82	0.67, 1.02
TC >200mg/dl	203	84	2.96	2.23, 3.91
HDL C<40mg/dl	47	31	1.56	0.98, 2.48
Trig >150mg/dl	319	176	2.38	1.91, 2.97
FBS >100mg/dl	220	91	3.07	2.34, 4.03
CHD risk score(>15% 10 yr risk of CHD event)	45	13	4.01	2.10, 7.67

OR: Odds ratio (adjusted for age & sex)

Conclusion: We have observed that this young, predominantly female, South Asian population has a high prevalence of CVD risk factors. However, there was a 4 fold increase in elevated CHD risk associated with RA. This was predominantly due to increased risk factors associated with the metabolic syndrome. Screening and treating modifiable CVD risk factors in South Asian patients with RA is strongly recommended.

A-SAA Levels in Inflammatory Arthritis Patients Prior to Biologic Therapy Are Associated with Increased Cardiovascular Events in Longterm Follow-up. Chin Teck Ng, Ronan Mullan, Mary Connolly, Oliver FitzGerald, Barry Bresnihan, Ursula Fearon and Douglas J. Veale, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Purpose: The acute phase apoprotein Serum Amyloid A (A-SAA) is elevated in serum and is the best marker to correlate with disease activity in inflammatory arthritis. Several studies show that atherosclerotic cardiovascular (CV) disease is the primary cause of premature death in RA patients. A-SAA has been proposed as a potential prognostic biomarker for RA disease activity, however it may also be relevant as a biomarker for cardiovascular disease, possibly comparable to hs-CRP. The collagen cleavage neo-epitopes, C2C and C1-2C are specific for the destruction of type I and II collagens by the collagenases MMP-1, MMP-8 and MMP-13 and are elevated in arthritis and may be associated with CV remodelling. Aim: To determine serial serum A-SAA levels, collagen neoepitopes and CV events in a follow-up cohort

of inflammatory arthritis patients, 4 years after starting on biologic therapy. **Method:** Patients were assessed at baseline, 1, 3, 6, 9, 12 and 48-months (m) after commencing anti-TNFα therapy. Twenty eight tender and swollen joint count (28-TJC, -SJC), CRP, DAS28-CRP score, and HAQ were measured at each assessment. Cardiovascular (CV) events were recorded at 48m. A-SAA levels were measured by ELISA at baseline, 1m and 3m. C2C and C1-2C were measured at baseline, 1, 3, 6, 9, and 12m. Statistical analysis was performed using SPSS 12 statistical software. **Results:** RA (n=45) and PSA (n=17) were followed up. At 48m, 8 patients developed one or more cardiovascular events since starting on anti-TNF therapy. Baseline A-SAA levels were significantly higher in patients with new CV events (CV+) at 48m follow-up compared to patients without CV events (CV-) [927.01ug/ml (285.88-3524.67) vs. 137.51ug/ml (2.44-1648.29), $p< 0.05$]. High A-SAA levels persisted at 1m and 3m post therapy in CV+ compared to CV-, where A-SAA levels decreased significantly after treatment at 1m and 3m ($p<0.05$). In contrast, there was no significant difference in CRP at baseline between the two groups. In addition, C2C and C1-2C levels remained higher at all time points in CV+ patients, and were associated with lower clinical responses (DAS28-CRP and HAQ) to anti-TNF therapy. **Conclusion:** High A-SAA levels at baseline, but not CRP, were associated with CV events in this long-term follow-up cohort. A-SAA may be a biomarker, but may also reflect a mechanism of action of CV disease in inflammatory arthritis.

Do Rheumatoid Arthritis (RA) Patients without Cardiovascular Disease (CVD) Have More Metabolic Syndrome Than Subjects without RA? Cynthia S. Crowson, Elena Myasoedova, Veronique Roger, Richard J. Rodeheffer, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: Patients with RA suffer from an excess burden of CVD. Metabolic syndrome and its components are known to significantly increase risk of CVD. The purpose of our study was to examine whether RA patients without CVD have a higher prevalence of metabolic syndrome than subjects without RA and no history of CVD.

Method: A sample from a population-based cohort of RA patients who fulfilled 1987 ACR criteria for RA between 1-1-1980 and 1-1-2008 were studied, as were a sample of subjects from the same underlying population who did not have RA. Data on waist circumference, body mass index [BMI], blood pressure [BP] and current medications were obtained during the study visit. Data on CVD (physician diagnosis of coronary artery disease, heart failure, hospitalized myocardial infarction, revascularization, or angina), lipids and glucose measures were ascertained by review of medical records. Metabolic syndrome was defined based on AHA criteria as 3 or more of: high waist circumference (≥102 cm in men, ≥88 cm in women), elevated triglycerides (TG ≥150 mg/dL or treatment), reduced high-density cholesterol (HDL<40 mg/dL in men or <50 mg/dL in women or treatment), elevated BP (≥130 mmHg systolic or ≥85 mmHg diastolic or treatment) or elevated fasting glucose (FG ≥ 100 mg/dL or treatment). Subjects with CVD were excluded from both samples. Logistic regression models adjusted for age and sex were used to examine differences between the RA and non-RA cohorts.

Results: The study included 232 RA patients (mean age [SD] 58.8 [13.0] years, 75% women) and 1235 subjects without RA (mean age [SD] 62 [9.2] years, 55% women) who had no CVD. The median duration of RA was 7.0 years (range: 0.7 – 27 years) and 50% were rheumatoid factor positive. RA patients were more likely to have a high waist circumference than non-RA subjects (odds ratio [OR]: 2.3; 95% confidence interval [CI]: 1.7, 3.0; $p<0.001$), even though BMI was similar in both groups (mean 29 vs 28 kg/m^2 in RA and non-RA, respectively; $p=0.22$). RA patients were more likely to have elevated BP (OR: 1.4; 95% CI: 1.1, 2.0; $p=0.02$) and somewhat more likely to have elevated FG (OR: 1.4; 95% CI: 1.0, 1.9; $p=0.05$). The proportion of patients with low HDL was similar in both groups ($p=0.8$). However, RA patients were less likely to have high TG levels (OR: 0.7; 95% CI: 0.5, 0.9; $p=0.02$). More RA patients were classified as having metabolic syndrome (32% vs. 25% in non-RA). This difference remained significant after adjustment for age and sex (OR: 1.6; 95% CI: 1.2, 2.3; $p=0.002$).

Conclusion: Among subjects without CVD, RA patients are more likely to have metabolic syndrome than non-RA subjects. This suggests a potential impact of RA disease and/or treatment on the development of metabolic syndrome in RA. More research is needed to understand the reasons for these metabolic changes in RA and the impact of metabolic syndrome on development of CVD in RA patients.

Is Brain-Type Natriuretic Peptide (BNP) Associated with Left Ventricular Diastolic Dysfunction (LVDD) in Rheumatoid Arthritis (RA) Patients without Cardiovascular Disease (CVD)? Cynthia S. Crowson, Elena Myasoedova, John M. Davis III, Veronique Roger, Barry L. Karon, Richard J. Rodeheffer, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: Patients with RA are at increased risk of CVD. Elevated BNP is associated with CV abnormalities in the general population. We compared BNP levels in RA and non-RA subjects without CVD, to evaluate whether BNP is associated with LVDD in RA.

Method: In a population-based incident cohort of RA patients (1987 ACR criteria fulfilled between 1-1-1980 and 1-1-2008) and a cohort of non-RA subjects from the same underlying population, we assessed BNP, C-reactive protein (CRP) and body mass index (BMI). LVDD was assessed by 2D/Doppler echocardiography using a validated algorithm and categorized as none, mild, moderate/severe or indeterminate. For RA patients, RA characteristics (health assessment questionnaire, interleukin-6, tumor necrosis factor α, rheumatoid factor [RF] and anti-cyclic citrullinated peptide antibody) were collected. Subjects with CVD (diagnosis of coronary disease, heart failure, hospitalized myocardial infarction, revascularization, or angina), ascertained from medical records, were excluded from both cohorts. Linear regression models were used to assess differences in log-transformed BNP for RA compared to non-RA cohort adjusting for age, sex, BMI and CRP. Proportional odds models evaluated the association between LVDD and BNP in the RA patients.

Results: The study included 232 RA patients (mean age 58.8 years, 75% women) and 1730 non-RA subjects (mean age 61.3 years, 55% women) who had no CVD. The median RA duration was 7.0 yrs (range 0.7 – 27 yrs); 50% were RF positive. Among the RA patients, 121 (52%) had normal, 48 (21%) mild, 16 (7%) moderate/severe LVDD and 47 were indeterminate. Among the non-RA subjects, 1172 (68%) had normal, 286 (17%) mild, 82 (5%) moderate/severe LVDD and 190 were indeterminate. More RA patients had elevated BNP (above the upper limit of normal) than non-RA subjects (18% vs. 9%, respectively, $p<0.001$). RA patients without LVDD had higher BNP than non-RA subjects without LVDD (fold change 1.9; $p<0.001$). Similarly, BNP was higher in RA compared to non-RA subjects with mild LVDD (fold change 2.0; $p<0.001$) and with moderate/severe LVDD (fold change 2,2; $p=0.04$). RA patients with elevated BNP were more likely to have LVDD (OR 2.7; 95% CI 1.1, 6.5 adjusted for age, sex and BMI) as compared to those with normal BNP. This association persisted after adjustment for CRP and RA characteristics (OR 3.5; 95% CI 1.3, 9.2).

Conclusion: Among subjects without CVD, RA patients were more likely to have elevated BNP than non-RA subjects and abnormal BNP was associated with LVDD, even after adjustment for RA characteristics, including inflammatory markers. This suggests BNP may be a useful marker of LVDD in RA patients without CVD. More research is needed to understand the mechanisms influencing BNP levels in RA and the role of this molecule in myocardial dysfunction in RA.

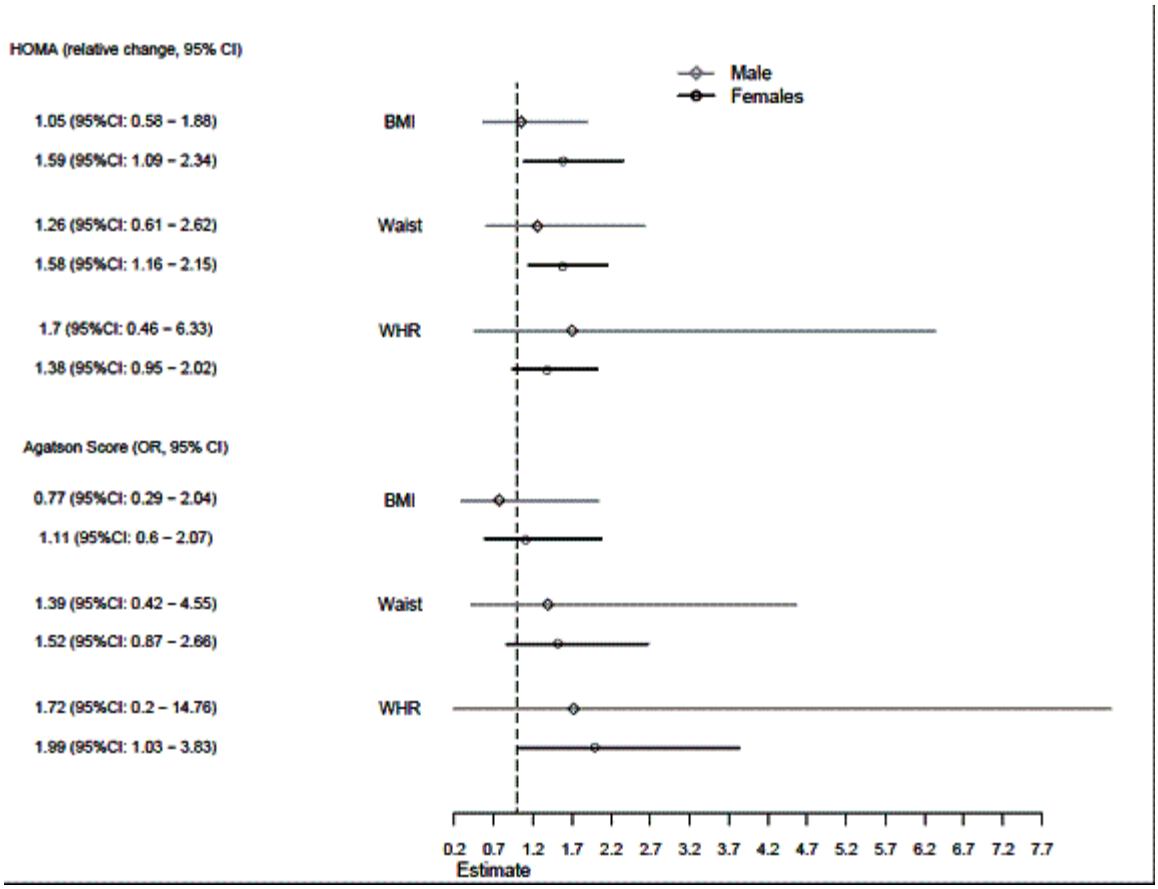
Effects of Body Fat Distribution On Insulin Resistance and Coronary Atherosclerosis in Rheumatoid Arthritis. David Brey[1], Young-Hee Rho[1], Annette M. Oeser[1], Joseph Solus[1], Paolo Raggi[2], Tebeb Gebretsadik[1], Ayumi Shintani[1] and C. Michael Stein[1], [1]Vanderbilt University, Nashville, TN, [2]Emory University, Atlanta, GA

Purpose: Rheumatoid arthritis (RA) is associated with insulin resistance and increased coronary atherosclerosis. In the general population, it is known that body mass index (BMI) is associated with insulin resistance and cardiovascular risk, whereas waist circumference (WC) and waist-to- hip-ratio (WHR), measures of abdominal adiposity, better predict adverse metabolic and cardiovascular outcomes. We examined the hypothesis that in patients with RA, anthropometric measures that encompass abdominal adiposity are more strongly associated with insulin resistance and coronary atherosclerosis than BMI.

Methods: We studied 169 patients with RA who are part of an ongoing cohort to define the relationship between RA and cardiovascular disease. Height, weight, hip circumference, and WC were measured, and BMI and WHR were calculated. Insulin sensitivity was measured by the homeostasis model assessment (HOMA). Patients underwent chest computed tomography, and Agatston coronary artery calcium scores (CAC) were calculated. Gender specific effects of anthropometric measures on HOMA and CAC were assessed using multivariable regression adjusting for age and race.

Results: There were 52 men (age 54.6±11.2 yrs, BMI 28.1±6.82 kg/m^2, WC 101.1±17.2 cm, WHR 0.94±0.07) and 117 women (age 54.1±12.1 yrs, BMI 29.6±6.7 kg/m^2, WC 93.1±16.8 cm, WHR 0.85±0.09). In women, BMI (p = 0.02) and WC (p = 0.004) were associated with HOMA; WHR (p =0.04) alone was associated with CAC. In men, there was no significant association between BMI, WC, and WHR and the outcomes of HOMA and CAC (Figure).



The Figure shows adjusted means ratio for HOMA, or the odds ratio for Agatston scores for a change of one interquartile range of BMI, Waist, and WHR with 95% CI for men (◊) and women (○).

Conclusion: In women with RA, WHR is significantly associated with coronary calcification, and BMI and WC with insulin resistance. Anthropometric measures of obesity may provide information additional to that provided by BMI about the metabolic and cardiovascular consequences of obesity in RA.

Risk of Tuberculosis in Patients with Rheumatoid Arthritis in Hong Kong- a Multi-Center Study. Lai-Shan Tam[1], Chi-Chiu Leung[2], Shirley Ying[3], Gavin K. Lee[4], Cheuk-wan Yim[5], Ying Y. Leung[6], Emily W. Kun[6] and Edmund K. Li[7], [1]The Chinese University of Hong Kong, Hong Kong, China, [2]Department of Health, Hong Kong, China, [3]Princes Margaret Hospital, Hong Kong, China, [4]Union Hospital, Hong Kong, China, [5]United Christian Hospital, Hong Kong, Hong Kong, [6]Tai Po Hospital, Hong Kong, China, [7]Chinese University of Hong Kong, Hong Kong

Purpose: Data on risk of TB in patients with RA exposed to TNF blockers from countries of high TB burdens are lacking. The aim of this study is to elucidate the incidence rate and relative risk of active TB in patients with RA compared to the general population in Hong Kong between 2004-2008, and to assess whether this risk is associated with exposure to TNF blockers after adjusting for other known risk factors.

Method: We used the mean incidence rate of TB in the general population from 2004 to 2008. To determine the relative risk of TB in RA patients with or without TNF blockers versus the general population, we reviewed all the medical records of RA patients. In order to ascertain the independent explanatory variables associated with active TB in RA, potential explanatory variables (including socio-demographic, co-morbidity, disease severity and immunosuppressive treatment) in RA patients with and without active TB were compared.

Results: A total of 2442 RA patients followed at 5 centers were recruited. The female to male ratio was 4.3 (1979 female, 81%) to 1 (463 male, 19%). Majority (96.5%) of the patients were Chinese. The mean age at the diagnosis of RA and at the start of follow up was 50 +/- 15 and 56 +/- 14 years respectively, with a median disease duration of 3.0 (0.1-8.8) years. The TNF naïve cohort consisted of 2425 patients, including 64 patients who were subsequently started on TNF blockers. Altogether, 2361 patients had never been exposed to TNF blockers, and 81 were treated with at least one TNF antagonists. The total treatment exposure rate for the TNF naïve and TNF treated cohorts was 6,617 and 185 patient-years respectively. Active TB developed in 21/2442 (0.9%) RA patients, including 17/2425 (0.7%) TNF naive patients and 4/81 (4.9%) TNF treated patients. Compared to age- and sex-matched population controls, the standardized incidence ratio (SIR) of active TB was significantly increased (SIR for all RA: 2.6, 95% CI 1.4-5.0, p=0.003; SIR for TNF naïve cohort: 2.0, 95% CI 1.0-4.3, p=0.053; SIR for TNF treated cohort: 34.9, 95% CI 8.9-137.2, p<0.001). Independent explanatory variables associated with an increase risk of active TB in RA patients included older age at study entry (RR 1.04, 95% CI 1.01-1.08, p=0.025), a past history of pulmonary TB (RR 9.53, 95% CI 3.51-25.84, p<0.001), extra-pulmonary TB (RR 20.09, 95% CI 4.84-83.35, p<0.001), chronic renal failure / dialysis (RR 47.0, 95% CI 8.36-264.13, p<0.001), prednisolone > 10mg daily (RR 4.11, 95% CI 1.27-13.36, p=0.019) and the use of TNF blockers (RR 12.53, 95% CI 3.67-42.77, p<0.001).

Conclusion: There was at least a 2 fold increased risk of active tuberculosis in Chinese RA patients. Exposure to TNF blockers remained to be an independent risk factor after adjusting for other known risk factors.

How Reliably Can Rheumatoid Arthritis Patients Calculate DAS28? A Comparison Study with Ultrasonography, Physician and Nurse. P. Cheung[1], A. Ruyssen-Witrand[1], L. Gossec[1], S. Paternotte[1] and Maxime Dougados[2], [1]Cochin Hospital, Paris, France, [2]Hospital Cochin, Descartes University, Paris, France

Purpose: Evaluation of swollen (SJC) and tender (TJC) joints are an integral part of indices measuring disease activity such as the DAS28 in rheumatoid arthritis (RA). Until now, health professionals are in charge of this data collection. Whether this can be optimally performed by patients is uncertain. SJC/synovitis can also be detected by ultrasonography (US), which is more sensitive than clinical examination. The purpose is to:

1. Evaluate the inter-observer reliability of patient self-assessed SJC ie. comparing to SJC assessed by the physician, nurse and B-mode US (gold standard)
2. Evaluate the inter-observer reliability of patient self-assessed TJC ie. comparing to TJC assessed by the physician (gold standard) and nurse
3. Assess the level of correlation of DAS28 derived by patients, comparing this to physician, nurse and US-derived DAS28

Method: Forty two RA patients (76% female, 64% RF positive, mean disease duration 16 ± 8 years, age 57 ± 12 years) were recruited to self-assess 28 joints (shoulders, elbows, wrists, MCPs, PIPs, knees) for swelling and tenderness in a question/mannequin format, with a short training session by a nurse prior to starting. Joints were then evaluated independently by a physician, another nurse and an ultrasonographer (B-mode and Power Doppler). Intra and inter-observer reliability was assessed at the patient level (28 joints) by the intra-class correlation coefficient (ICC). The Kappa test evaluated the level of agreement at the joint level. ICC was used to express correlation of the patient-derived DAS28 with those derived by US, physician and nurse.

Results: Intra-observer reliability for TJC was excellent for patient, physician and nurse (ICC 0.95 [0.87; 0.98], 0.98 [0.95; 0.99], 1 [0.99; 1] respectively), but for SJC, ICC ranged from 0.45 [0.02; 0.75] to 0.85 [0.65; 0.94]. Inter-observer reliability of self-assessed TJC was good when compared to physician and nurse (ICC 0.83, 0.73 respectively). However, inter-observer reliability of self-assessed SJC was poor when compared to physician and nurse (ICC 0.47, 0.36). There was poor agreement of SJC in all groups when compared to B-mode US, especially with self-assessed SJC (ICC 0.29). However, excellent correlation was reported in patient-derived DAS28 when compared to US-derived DAS28 (ICC 0.95 [0.88; 0.98]).

Table 1

	TJC		SJC		DAS28
	ICC [IC95%]	Kappa [IC95%]	ICC [IC95%]	Kappa [IC95%]	ICC [IC95%]
Patient vs Physician	0.82 [0.61;0.93]	0.47 [0.41;0.53]	0.47 [0.03;0.76]	0.30 [0.24;0.37]	0.90 [0.76;0.96]
Patient vs Nurse	0.73 [0.42;0.89]	0.46 [0.40;0.52]	0.36 [-0.11;0.69]	0.30 [0.23;0.38]	0.87 [0.69;0.95]
Physician vs Nurse	0.85 [0.65;0.94]	0.48 [0.41;0.55]	0.40 [-0.06;0.72]	0.29 [0.22;0.35]	0.90 [0.75;0.96]
Patient vs US	-	-	0.29 [-0.19;0.65]	-	0.95 [0.88;0.98]
Physician vs US	-	-	0.38 [-0.08;0.71]	-	0.98 [0.94;0.99]
Nurse vs US	-	-	0.47 [0.02;0.76]	-	0.98 [0.96;0.99]

Conclusion: Patient-derived DAS28 is at least as reliable as the other modalities despite poor intra and inter-observer reliability in SJC.

Economic Aspects of Treatment Options in Rheumatoid Arthritis (RA). Results of a Systematic Literature Search. M. Schoels[1], J. Wong[2], D. L. Scott[3], A. Zink[4], P. Richards[5], R. Landewé[6], J. S. Smolen[7] and D. Aletaha[7], [1]KH Hietzing, Vienna, Austria, [2]Division of Clinical Decision Making, Tufts University School of Medicine, Boston, MA, [3]Kings College, London, United Kingdom, [4]Deutsches Rheuma-Forschungszentrum, Berlin, Germany, [5]University of Bristol, Bristol, United Kingdom, [6]University Hospital, Maastricht, Netherlands, [7]Medical University, Vienna, Austria

Purpose: Recommendations for the management of RA with synthetic and biologic drugs have been elaborated by a Task Force of the European League Against Rheumatism (EULAR). Initialized in November 2008, the consensus finding for these guidelines also addresses the cost effectiveness of therapeutic options.

Method: To comprise the available health-economic evidence on RA drug treatments, a systematic literature search of the Medline, Embase and Cochrane databases was undertaken, followed by an additional handsearch of retrieved papers. Relevant studies in English language up to December 2008 were included.

Results: Cost-effectiveness analyses (CEA) are a rapidly expanding field of interest in RA, as reflected by a majority of recent publications evaluating new therapies, as compared to the era before biologicals. We incorporated results of 54 CEA, among them, 40 papers dealt with biologic treatment. Despite very diverse methodological approaches, the main results of the analyses are, with some exceptions, concordant.

At onset of disease, DMARD therapy is cost effective, i.e., positive treatment effects outweigh drug costs. Alike, when encountering DMARD failure, treatment escalation with biologics is cost effective. Among the licensed TNFα-inhibitors (TNFi), cost-effectiveness is fairly comparable, with the relative exception of Infliximab treatment when used at increased doses or frequencies after insufficient response to the standard treatment schedule. When a TNFi fails, the implementation of Rituximab or Abatacept is cost effective for both.

Employment of biologics in DMARD naïve patients, as has been shown to be clinically effective in recent RCTs, is a matter of ongoing debate, and the appraisal of cost-effectiveness is controversial mainly due to scarce clinical data evaluating the intensive treatment of defined high risk patient groups in randomised trials. Alike, there is little evidence on cost-effectiveness of switching TNFi after failure of the first substance of this group.

Conclusion: The financial burden of rheumatoid arthritis is substantial, and new biologic therapies have further increased treatment costs. On the contrary, their clinical effectiveness has a large positive impact on indirect costs, by maintaining function and work ability for a high proportion of patients. Furthermore, quality of life is improved at cost levels that are commonly accepted by society for the treatment of chronic diseases. (Usually, these levels refer to thresholds of incremental cost effectiveness ratios between 50000 and 100000 US$). Especially in the light of the very costly late sequela of insufficiently controlled RA, new expensive drug treatments still appear to be cost effective and a prudent employment of resources.

Respiratory Symptoms and Disease Characteristics as Predictors of Pulmonary Function Abnormalities (PFT) in Patients with Rheumatoid Arthritis (RA). Dimitrios A. Pappas, Jon T. Giles, Geoffrey Connors, Noah Lechtzin, Joan M. Bathon and Sonye K. Danoff, Johns Hopkins University, School of Medicine, Baltimore, MD

Purpose: Timely recognition of the pulmonary manifestations of RA is critical given that respiratory involvement is identified as the second leading cause of mortality in patients with RA. We attempted to identify which respiratory symptoms, patient and disease characteristics are most highly predictive of PFT abnormalities in an RA patient cohort.

Method: A total of 159 individuals with RA were evaluated. Respiratory symptoms were assessed with the Lung Tissue Research Consortium (LTRC) questionnaire and all patients underwent evaluation with PFTs. Demographic, lifestyle, RA disease and treatment characteristics were collected. Multivariable regression analysis was used to identify pulmonary symptoms and non-pulmonary parameters predictive of PFT abnormalities. Receiver operator characteristic (ROC) curves were constructed to examine the ability of our models to predict PFT abnormalities.

Results: Of the 159 patients, 45 (28%) demonstrated at least one predefined PFT abnormality. Restrictive lung disease was observed in 12 (7.6%), obstructive lung disease in 18 (11.3%) and isolated impaired diffusing capacity in 31 (19.8%). Only seventeen patients (37.8%) of the 45 patients with abnormal PFTs reported a prior diagnosis of emphysema, asthma or rheumatoid lung disease. Among RA characteristics, seropositivity for RF (p=0.011) and anti-CCP (p=0.003), and current use of glucocorticoids (p=0.018) were significantly higher in patients with PFT abnormalities. Pulmonary symptoms were reported in 78 patients (42%). For any PFT abnormality the predictors retained in the final multivariable model included two pulmonary symptoms (chronic phlegm and breathlessness with walking 100 yards), and four other characteristics (BMI, current smoking, seropositivity for anti-CCP antibodies, and current prednisone use). AUC=0.773 (95% CI 0.679 – 0.857)

For restriction, one symptom (breathlessness with level walking) and two patient characteristics (BMI and current prednisone use) were retained in the final prediction equation AUC=0.786 (95% CI 0.585 – 0.918). For obstruction, 8 predictors were retained in the final model, including one symptom (chronic cough), and six other characteristics (gender, exercise, BMI, current smoking, RF seropositivity, and current prednisone use). AUC=0.905 (0.784 – 0.978).

For isolated impaired diffusion, six predictors were retained in the final model, including one symptom (chronic phlegm), and four other characteristics (age, BMI, current smoking, and current prednisone use). AUC= 0.852 (95% CI 0.749 – 0.934).

Conclusion: Assessment of respiratory symptoms along with a limited number of clinical parameters may serve as a useful and inexpensive clinical tool for identifying RA patients in need of further pulmonary investigation.

957

Being in Remission or in Low Disease Activity in Rheumatoid Arthritis: Different Meaning with the Use of Different Composite Scores. R. Koevoets[1], N.B. Klarenbeek[1], Désirée M.F.M. van der Heijde[2], M. V. van Krugten[3], D. van Schaardenburg[4], B. Dijkmans[5], T.W.J. Huizinga[1], P. Kerstens[6] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Ziekenhuis Walcheren, Vlissingen, Netherlands, [4]Jan van Breemen Intitute, Amsterdam, Netherlands, [5]VUMC, Amsterdam, Netherlands, [6]JBI, Amsterdam, Netherlands

Purpose: To compare the proportions of patients categorized in different levels of disease activity based on 6 composite scores and relate that to radiological progression and physical function among these categories.

Method: In the current analysis, 214 patients with complete data for all scores were analyzed who participated in the BeSt trial, a randomized controlled trial in recent onset RA comparing four DAS steered treatment strategies. At t=1 and t=4 years, percentages of patients in remission, low disease activity (LDA), moderate disease activity (MDA) or high disease activity (HDA) were calculated for 6 different composite scores according to published cut-offs. Mean HAQ scores were calculated at t=1 and t=4 years per category and percentages of patients with radiographic progression (Sharp van der Heijde score (SHS)) in the next year were calculated with two cut-offs: >0 and >5 units/year. Here, MDA and HDA patients were combined because of limited patient numbers.

Results: The percentages of patients in remission, LDA, MDA en HDA for the various composite scores are illustrated in the figure. CDAI and SDAI scores show the lowest % remission with a larger proportion of patients in LDA both at the 1st and 4th year visit.

In general, the progression percentages (>5 SHS) increased with higher disease activity levels at 4 years, with the best 'dose response' for SDAI and CDAI (table). Overall, few patients show progression > 5 units/year if categorized as remission. The same pattern was found for mean HAQ scores with the lowest mean HAQ in the CDAI en SDAI remission group (table).

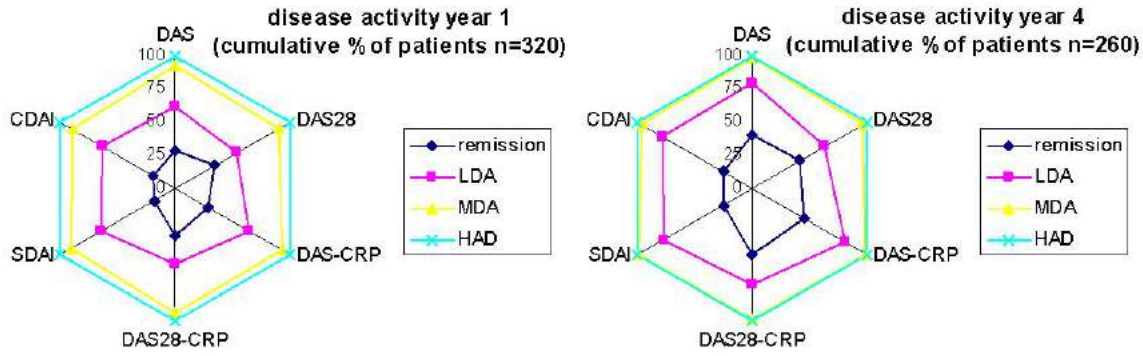

Figure: Cumulative percentage of patients in the different disease activity categories

	DAS		DAS28		DAS-CRP		DAS28-CRP		SDAI		CDAI	
Progression												
>5/year	**n (%)**	**HAQ**	**n (%)**	**HAQ**	**n (%)**	**HAQ**	**n (%)**	**HAQ**	**n (%)**	**HAQ**	**n (%)**	**HAQ**
Remission	8/88 (9.1)	0.38	7/94(7.4)	0.38	8/98(8.2)	0.39	5/108(4.6)	0.42	0/55(0)	0.30	2/55(3.6)	0.27
LDA	8/83 (9.6)	0.56	3/41(7.3)	0.52	9/77(11.7)	0.60	6/52(11.5)	0.56	13/111(11.7)	0.58	14/113(12.4)	0.60

MDA + HDA	9/43(20.1)	1.13	15/79(19.0)	0.90	9/39(23.0)	1.14	14/54(25.9)	1.01	12/48(25.0)	1.00	9/46(19.6)	1.00

Table: Mean HAQ scores and percentage of patients showing progression between year 4 and 5, based on the disease activity status at year 4 (n=214).

Conclusion: The six disease activity indices select different patients for the various levels of disease activity. This has also an impact on the percentage of patients showing radiological progression and mean HAQ scores. SDAI and CDAI scores are the most strict in categorizing remission with the lowest mean HAQ scores and percentage of patients showing radiological progression.

The Effect of a Change in DAS Level On the HAQ Level During 5 Years Follow-up in the BeSt Study. E. van der Kooi[1], N.B. Klarenbeek[1], P.J.S.M. Kerstens[2], P.A.H.M. van der Lubbe[3], P.B.J. de Sonnaville[4], T.W.J. Huizinga[1], B. A. C. Dijkmans[5] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]JBI, Amsterdam, Netherlands, [3]Vlietland Hospital, Schiedam, Netherlands, [4]Oosterschelde Hospital, Goes, Netherlands, [5]VUMC, Amsterdam, Netherlands

Background: Previous studies suggest that functional ability of patients with RA is related to their disease activity. It remains unclear whether any decrease in disease activity will improve functional ability.

Purpose: To assess the influence of a decrease in Disease Activity Score (DAS) on functional ability (Health Assessment Questionnaire, HAQ) during five years DAS-steered treatment in patients with recent onset RA.

Methods: Data of the BeSt study were used, a randomized controlled trial in which medication was adjusted based on threemonthly DAS measurements, aiming at DAS≤2.4. HAQ was measured every three months. A linear mixed model was performed to assess the effect of DAS changes on the outcome $HAQ_{time\ a+1}$ during 5 years follow-up. Covariates were $DAS_{time\ a}$, deltaDAS (=$DAS_{time\ a+1}$ - $DAS_{time\ a}$), logarithm of time, the two way interactions ($DAS_{time\ a}$*deltaDAS, $DAS_{time\ a}$*log time and deltaDAS*log time) and the three way interaction ($DAS_{time\ a}$*delta DAS*log time) corrected for $HAQ_{time\ a}$.

Results: Corrected for age, gender, baseline BMI, rheumatoid factor, symptom duration, treatment strategy, Sharp-van der Heijde Score, baseline CRP and CCP2, the three way interaction (p=0.27) and the two way interaction between log time and deltaDAS (p=0.08) and log time and $DAS_{time\ a}$ (p=0.82) were not significantly related to the outcome HAQ and were omitted from the analysis. Only the $DAS_{time\ a}$ (p<0.001), deltaDAS (p<0.001), log time (p<0.001), $DAS_{time\ a}$*deltaDAS (p<0.001) and the $HAQ_{time\ a}$ (p<0.001) significantly predicted the outcome HAQ. This results in the following regression formula:

Outcome $HAQ_{time\ a+1}$ = -0.042 + (0.199*$DAS_{time\ a}$) + (0.177*deltaDAS) + (0.043*log time) + (0.024*$DAS_{time\ a}$*delta DAS) + (0.290*$HAQ_{time\ a}$)

A larger decrease in DAS is associated with a lower outcome HAQ (p<0.001). This positive relationship did not significantly change over time (p=0.08). A decrease in a high DAS improved the HAQ more than a similar decrease in a lower DAS. However, corrected for the previous HAQ, this effect is the other way around (p<0.001), but still a DAS decrease is associated with a lower HAQ.

Conclusion: A decrease in DAS is significantly associated with a decrease in HAQ at every time point during 5 years of DAS-steered treatment in patients with recent onset RA and a larger decrease in DAS level is significantly associated with a larger decrease in HAQ. These results indicate that at any time during treatment, if the DAS is lowered, patients will benefit with better functional ability.

Assessing the Diagnostic Accuracy of a 3-Component Synovitis Score and Its Components with Receiver Operating Curve (ROC) Analysis. Elisabeth Slansky[1], Jialiang Li[2], Thomas Häupl[3], Lars Morawietz[3], Veit Krenn[4] and Frank Pessler[1], [1]Technical University Dresden Children's Hospital, 01307 Dresden, Germany, [2]National University of Singapore, Singapore, [3]Charite Berlin, Berlin, Germany, [4]Univ. of Trier, Germany

Purpose: To assess the diagnostic accuracy of a 3-component synovitis score and its components (intimal hyperplasia, stromal cellularity, inflammatory infiltration) with receiver operating characteristic (ROC) curve analysis and multi-category ROC analysis.

Method: The histological grade of synovitis was scored in 666 synovial specimens carrying the following clinical diagnoses: normal synovium, n=33; post-traumatic arthropathy (PtA), n=29; osteoarthritis (OA), n=221; psoriatic arthritis (PsA), n=42; and rheumatoid arthritis (RA), n=341. The discriminatory abilities of the complete score and each of its components were quantified with the area under the ROC curve (AUC) in each of the 10 possible paired comparisons. Multi-category ROC analysis was used to rank the complete score and each of its components according to their overall discriminatory abilities.

Results: The score differentiated all arthropathies accurately from normal tissue (AUCs: 0.87-0.98), and RA from OA or PtA (AUCs: 0.85 for both), but could not distinguish well between pairs of inflammatory (RA vs PsA, AUC 0.63) or degenerative (PtA vs OA, AUC 0.59) arthropathies. AUCs of the intimal hyperplasia and stromal cellularity components (r=0.94 and 0.91, respectively) correlated with the AUCs of the complete score markedly more strongly than the inflammatory infiltration component (r=0.60). Multi-category ROC analysis ranked the score and its components in the following order of overall diagnostic accuracy: complete score>stromal cellularity>intimal hyperplasia>inflammatory infiltration, with the complete score being clearly superior to any of its components (Table 1).

Conclusion: This 3-component synovitis score is an accurate tool for differentiating diseased from normal synovium and inflammatory from degenerative arthropathies. Its high discriminatory ability stems more from measuring proliferative than infiltrative aspects of synovitis. The data also suggest that multi-component synovitis scores may be superior to single component scores.

Table. Diagnostic ranks of the synovitis score and its components according to multi-category ROC analysis

Rank	Test	HUM[1]
1	Synovitis score	0.0620
2	Stromal cellularity	0.0140
3	Intimal hyperplasia	0.0075
4	Infiltration	0.0005
5	Nondiscriminatory marker[2]	0.000076

[1]Values represent hyper volumes under the ROC manifolds (HUMs), calculated according to ref. 1.

[2]Hypothetical marker corresponding to the null hypothesis.

Comparison Between Resection and Arthrodesis of the First MTP Joint in the Same Patient (Internal Control) for Rheumatoid Forefoot Deformity. Masahiro Tada[1], Tadashi Okano[1], Yuko Sugioka[1], Shigeyuki Wakitani[1], Akira Shimazaki[2], Kentaro Inui[2], Hiroaki Nakamura[1] and Tatsuya Koike[1], [1]Osaka City University Medical School, Osaka, Japan, [2]Higashisumiyoshi Morimoto Hospital, Osaka, Japan

Purpose: Most of patients with rheumatoid arthritis have problems with their feet. The painful, deformed rheumatoid forefoot may be treated with resection of the lesser metatarsal heads combined with either arthrodesis or resection of the first metatarsophalangeal (MTP) joint. Good results have been observed in previous surgical procedures. Recurrent deformity of both the hallux valgus (HV) and lesser toes were reported, when the HV deformity was managed by resection. This criticism, however, was based on historical observation from previous studies. There was no prospective or randomized study. So we performed the prospective, randomized, internal-controlled clinical study. To compare the clinical results of arthrodesis and resection of the first MTP joint in simultaneous operation for same patient who had the painful, deformed rheumatoid forefoot.

Method: We performed resection of the lesser metatarsal heads for bilateral and arthrodesis of the first MTP joint for one side and resection (LeLievre method) for opposite side in same patient. Between April 2004 and December 2008, 20 patients with severe painful deformed rheumatoid forefoot were operated. We investigated 15 patients (30 feet) who received at least 6 months of follow-up. All patients were assessed for American Orthopaedic Foot and Ankle Society (AOFAS) score, HV angle, M1M2 angle, and M1M5 angle at the point of pre-operation and final follow-up. We evaluated callosities and recurrence at final follow-up.

Results: At the operation, patients were, on average, 64.1 years old, mostly female (86.7%). Patients had mean disease duration of 14.9 years, with DAS28 of 4.33. The mean follow-up period was 36.7 (8~76) months. We found excellent satisfaction and a significant improvement of AOFAS score, HV angle, M1M2 angle, and M1M5 angle. There were no statistically significant differences between the groups, except HV angle. HV angle of arthrodesis side was significantly less than that of resection side at follow-up (table). Two patients in the each groups had callosities at final follow-up, but there was no patient that have recurrence of HV deformity. In the arthrodesis side, there were no complications of pseudoarthrosis and breakage.

Conclusion: In our prospective, internal-controlled clinical study, it revealed that arthrodesis of the first MTP joint provide better results in maintenance of HV angle, although there was no significant difference in AOFAS score. Arthrodesis of the first MTP joint should be reliable option for the treatment of rheumatoid forefoot deformity.

	Arthrodesis	**Resection**	**P-value**
AOFAS* score			
Pre-operation	33.27	33.60	0.86
Final follow-up	86.07	84.60	0.34

Rheumatoid Arthritis (RA) Is Associated with Increased Mortality in Patients Undergoing Total Joint Arthroplasty. Kaleb D. Michaud[1], Edward V. Fehringer[2], Kevin Garvin[2], James R. O'Dell[3] and T. R. Mikuls[3], [1]University of Nebraska Medical Center and NDB, Omaha, NE, [2]University of Nebraska Medical Center and Omaha VA, Omaha, NE, [3]U Nebraska, Omaha, NE

Purpose: Although total joint arthroplasty (TJA) is a commonly used procedure in RA, risks and benefits of TJA in this specific population have not been well defined. The purpose of this study was to examine the association of RA with post-operative mortality following total hip, knee, shoulder and elbow arthroplasty.

Methods: Study subjects were enrolled in the Veterans Affairs (VA) National Surgical Quality Improvement Program (NSQIP) undergoing TJA from fiscal years 1999 through 2006. Dispensed medications and ICD9 codes were indentified using links to the VA Pharmacy Benefits Management (PBM) database. Patients were classified as having RA if they had ICD9 code 714.0 plus use of a DMARD within 1 year before TJA. The osteoarthritis (OA) control group had ICD9 code 715. The association of RA with overall mortality was examined using multivariate Cox proportional hazards regression, adjusting for age, gender, TJA type, calendar year, race, select baseline comorbidity / health behaviors (diabetes, COPD, dyspnea, congestive heart failure, cerebrovascular disease, renal insufficiency, anemia, alcohol use and current smoking), pre-operative functional status, and ASA class. The effects of specific RA medications were examined using sequential models.

Results: There were 37,103 patients (n = 888 with RA) undergoing TJA, with total knee arthroplasty being most common (64%), followed by hip (33%), shoulder (2%), and elbow (0.2%). Patients were predominantly men (96%) and had a mean (SD) age of 64.4 (10.7) years. Glucocorticoid use was much more common in RA cases vs. OA (41% vs. 2%). There were a total of 4,093 deaths over a mean follow-up of 3.7 (2.3) years. After multivariate adjustment, RA was associated with a significantly higher mortality (HR = 1.48; 95% CI 1.24 to 1.76). This risk was attenuated after further adjustment for glucocorticoid use (HR = 1.23; 95% CI 1.02 to 1.49). Factors significantly associated with mortality in patients with only RA are shown in the Table. There was no association of other biologic or non-biologic DMARDs with mortality in RA-only sub-analyses.

Patient factor	**Hazards Ratio (95% CI)**
Glucocorticoid use	1.81 (1.28 to 2.53)
Age (year)	1.06 (1.04 to 1.08)
Chronic obstructive pulm disease	2.10 (1.39 to 3.19)
Congestive heart failure	4.05 (1.62 to 10.12)
Anemia, Hematocrit < 38%	1.57 (1.10 to 2.24)
Current smoking	2.03 (1.39 to 2.96)

Conclusion: RA patients have a higher long-term mortality risk than OA patients following TJA, a risk that is most pronounced among glucocorticoid users in addition to current smokers and those with select comorbid conditions. Perioperative interventions that target high risk patients with RA need to be evaluated and implemented with a goal of reducing postoperative mortality following TJA.

Disclosure: K. D. Michaud, None; **E. V. Fehringer**, None; **K. Garvin**, None; **J. R. O'Dell**, None; **T. R. Mikuls**, None.

962

Rheumatoid Arthritis (RA) Patients Are Not at Increased Risk for 30-Day Cardiovascular Events or Infections Following Total Joint Arthroplasty. Kaleb D. Michaud[1], Edward V. Fehringer[2], Kevin Garvin[2], James R. O'Dell[3] and T. R. Mikuls[3], [1]University of Nebraska Medical Center and NDB, Omaha, NE, [2]University of Nebraska Medical Center and Omaha VA, Omaha, NE, [3]U Nebraska, Omaha, NE

Purpose: Although serious infection and cardiovascular disease are increased in patients with RA, it is not known whether RA impacts the risk for these complications following total joint arthroplasty (TJA). We examined whether RA was associated with the occurrence of 30-day postoperative complications in a large population of patients undergoing TJA.

Methods: Analyses included data from the VA National Surgical Quality Improvement Program (NSQIP) for fiscal years 1999-2006. ICD9 codes and medication dispensing data were obtained from the VA Pharmacy Benefits Management (PBM) database. RA was defined for those with a corresponding ICD9 (714.0) plus receipt of at least one DMARD within 1 year before TJA. All other patients had an ICD9 (715.x) corresponding to osteoarthritis (OA). 30-day complications (major cardiovascular event, infection, and return to the operating room) were compared by diagnosis (RA vs. OA) using multivariate regression. Post-operative infections included systemic sepsis, pneumonia, urinary tract infection, superficial and deep wound surgical site infections. Cardiovascular events included cardiac arrest, myocardial infarction, stroke, pulmonary embolism, and deep vein thrombosis. All analyses were adjusted for age, sex, and clustering by site (n = 104 sites). Additional covariates included sociodemographics, comorbidities, health behaviors, and well defined operative risk factors (up to 44 covariates examined).

Results: There were 37,103 patients (n = 888 with RA) undergoing TJA, with total knee arthroplasty being most common (64%), followed by hip (33%), shoulder (2%), and elbow (0.2%). Patients were predominantly men (96%) with a mean (SD) age of 64 (11) years. Among RA patients, the most frequently used DMARDs included methotrexate (59%), hydroxychloroquine (40%) and sulfasalazine (23%) while 41% were taking glucocorticoids and 24% biologic DMARDs. The frequency of select complications based on diagnosis is summarized in the table below. Compared to OA patients, those with RA were significantly more likely to require a return to the operating room but had similar rates of postoperative infection and cardiovascular events.

Table: The frequency of select complications following TJA in patients with RA and OA

	RA (n = 888)	OA (n = 36,215)	RA OR (95% CI)
Infection	4.17%	4.12%	1.02 (0.72, 1.47)
Cardiovascular event	1.24%	1.98%	0.69 (0.37, 1.28)
Return to operating room	4.50%	3.01%	1.45 (1.08, 1.94)

Conclusion: : RA patients are not at an increased risk for short-term infectious complications or cardiovascular events following TJA. RA patients did have an increased rate of return to the operating room. Reasons for this difference and strategies to address it require further study.

Disclosure: K. D. Michaud, None; **E. V. Fehringer**, None; **K. Garvin**, None; **J. R. O'Dell**, None; **T. R. Mikuls**, None.

Work Instability in Argentinean Patients with Rheumatoid Arthritis: Prevalence and Associated Factors. M. Tamborenea[1], C. Pisoni[1], E. Mysler[2], G. Tate[2], D. Pereira[3], J. Quintero[4], A. Cappuccio[5], O. Rillo[6], A. Baños[7], P. Arturi[8], Jl Velazco Zamora[9], A. Alvarellos[10], J. Ceccatto[11], B. Pons Estel[12], M. Gallo[13], A. Catalan Pellet[14], J. Cavallasca[15], G. Gomez[16], P. Tate[17], V. Malah[18], M. Lazaro[19], D. Sohn[20], J. Moreno[21], M. Larroude[22], S. Toloza[23] and C. Graf[24], [1]OMI, Buenos Aires, Argentina, [2]OMI, [3]HIGA, [4]Hospital de Clinicas, [5]Hospital Cesar Milstein, [6]Hospital Tornu, [7]IMAI, [8]IREP, [9]CER, [10]Hospital Privado, [11]Hospital Cullen, [12]Sanatorio Parque, [13]OSEP, [14]Hospital Rivadavia, [15]Hospital Iturraspe, [16]Instituto Lanari, [17]Hospital Carrillo, [18]CPR, [19]Hospital San Isidro, [20]Instituto Roche, [21]CER, San Juan, [22]Tiempo, [23]Hospital San Juan Bautista, [24]Centro Medico Mitre

Purpose: To determine the prevalence and associated factors to work instability (WI) in Argentinean patients with rheumatoid arthritis (RA) currently working.

Methods: Employment status of RA patients from 31 rheumatology clinics was assessed using a standardized data collection form and a patient questionnaire. RA patients currently working answered the validated Spanish version of RA WIS questionnaire. High risk WI was considered when RA WIS was ≥17 (Total score from 0-23). The association among socioeconomic, demographic, clinical features and comorbidities (diabetes, hypertension, cardiac failure, myocardial infarction, depression and fibromyalgia) with WI was examined by standard statistical tests.

Results: A total of 172 patients answered the RA WIS. Mean age was 49.3±10.8, 81.3% were female; mean disease duration was 8.1±7.2 years. Forty six percent of patients were doing manual work. The mean RA WIS score for the total population was 11.4±6.8 and 40.9 % had a high risk WI.

Univariate analysis:

Variable	Low risk WI N=121	High risk WI N= 84	*p* value
Female, (%)	84.5	79.3	0.347
Manual work, (%)	42.6	50.6	0.270
< 12 years education, (%)	19.8	27.3	0.206
Lack of health insurance, (%)	20.6	29.7	0.137
Below poverty line*, (%)	9.9	19	0.061
Age, mean ± SD	49.9±10.8	48.5±10.6	0.345
Disease duration years, mean ± SD	8 ± 7.5	8 ± 6.7	0.869
Functional class 3 and 4, (%)	7.4	8.3	0.814
Radiological erosions, (%)	**27.2**	**52.3**	**<0.001**
HAQ≥ 1, %	**17.3**	**59.5**	**<0.001**
Rheumatoid factor positive, (%)	84.8	90	0.239

*Monthly household income < 800 pesos/month

None of the extraarticular manifestations, neither any comorbidity was associated with high risk WI.

Multivariate analysis: predictors of high risk WI

Variable	OR	95% CI	*p* value
HAQ≥ 1	**12.31**	**5.38 - 28.18**	**<0.001**
Functional class 1 and 2	**0.151**	**0.036 - 0.632**	**0.010**
Radiological erosions (yes)	**4.848**	**2.22 - 10.54**	**<0.001**
Manual work (yes)	1.429	0.652 - 3.132	0.372
Disease duration> 5years	0.989	0.937 - 1.045	0.713
Below poverty line (*)	**0.301**	**0.096 - 0.943**	**0.039**

Education < 12 years	0.715	0.279 - 1.83	0.485
Extraarticular features (yes)	1.130	0.526 - 2.427	0.752

*Monthly household income < 800 pesos/month

Conclusion: Forty one percent of our patients with RA currently working have high risk WI. The predictors of high RA WIS score in multivariate analysis were HAQ ≥ 1 and radiological erosions; functional class 1-2 and living above the poverty line were protectors for high risk WI.

The Proportion of Patients with Work Disability (WD) Is in Early Inflammatory Arthritis: Results From the CATCH Cohort. L. Mussen[1], V. Bykerk[2], B. Haraoui[3], C. Hitchon[4], S. Jamal[5] and J. Pope[6], [1]University of Western Ontario, London, ON, [2]Mt Sinai Hospital, Toronto, ON, [3]Institut de Rhumatolgie de Montreal, Montreal, QC, [4]University of Manitoba, Winnipeg, MB, [5]St. Michael's Hospital, Toronto, [6]St Joseph Health Care, London, ON

Purpose: It is known that WD is high in established RA and ranges from 30 to 50%. The prevalence of WD in early RA (ERA) and early inflammatory arthritis (EIA) has not been well established.

Method: Data from 655 patients enrolled since July 2007 were collected from the Canadian Early Arthritis Cohort (CATCH) study, a multi-centre observational prospective cohort of patients with EIA. Inclusion Criteria: age >16, symptom duration of 6-52 weeks of persistent synovitis, ≥2 effused joints or 1 swollen MCP or PIP + ≥1 of: positive RF, positive anti-CCP, morning stiffness >45 mins, response to NSAIDs, or a painful MTP squeeze test. 69% are identified as having RA (CRA criteria). At their first visit, patients were asked about employment status with possible answers including employed, retired, unemployed, on sick leave (SL), work disabled, on maternity leave, in school or a homemaker. The Dictionary of OccupationalTitles (DOT) was used to determine the physical demands of each type of employment.

Results: 54% were employed, 22% retired, and 6% reported WD or SL, with the remaining 18% homemakers, students or on maternity leave. Patients who were neither employed nor on WD/SL were excluded from analysis, and baseline characteristics of the remaining 391 are given in the table below. 86% of the employed were in jobs with sedentary or light physical demands. Patients were further classified according to those who met the ACR criteria for ERA and those who did not (designated as EIA). WD/SL was not significantly different in EIA vs ERA (3.9% vs 7.1%, p=0.1). Factors associated with WD/SL in the group of 391 as a whole included TJC, DAS28 and SF-12, whereas SJC, RF and anti-CCP did not differ significantly between the WD/SL and the employed. Factors associated with WD in subgroup analysis were similar to the group overall with the exception of DAS-28, which differed significantly between the employed and WD/SL in ERA only.

	Employed	WD/SL
N	351	40
Age (SE)	47 (0.6)	47 (2.3)
% female	74%	68%
% positive RF	57%	58%
% meeting ACR criteria for RA	68%	80%
DAS-CRP	4.7 (0.1)	5.4 (0.2)

TJC (0-28)	8.3 (0.4)	11.9 (1.1)
SJC (0-28)	7.3 (0.4)	8.2 (1.0)

Standard Error of mean reported in brackets.

Conclusion: WD is low at entry into an ERA cohort and thus there is a chance to intervene effectively in the care of patients early to prevent WD from occuring. As in established RA, WD was related to patient factors, HAQ, damage and disease activity. Both in patients meeting ACR criteria for ERA and those whose disease activity classifies as EIA, WD is especially related to TJC, DAS-28 and SF-12, and elevation in these parameters may indicate a point at which intervention may prevent WD. Although, p=NS, there appears to be more baseline WD in those who met ERA criteria and as the cohort grows, this may become significant.

Validation of Rheumatoid Arthritis Disease Activity Index (RADAI) in a North American Cohort of Patients with Early Rheumatoid Arthritis (RA). Xiuying Li, Maggie H. Chen and Claire Bombardier, University Health Network, Toronto, ON

Purpose: The RADAI is a patient self-administered index measure of RA disease activity. It is easy to complete in a practice setting. The SONORA (Study of new-onset Rheumatoid Arthritis) study was used to validate the RADAI against the DAS28-CRP and HAQ as a measure of change over time in early RA.

Methods: Patients diagnosed as having new onset RA (symptoms≥3 but ≤12 months) by a board-certified rheumatologist across North America were recruited in this study. The correlations between RADAI, DAS28-CRP and physical function (Health Assessment Questionnaire-Disability Index, HAQ-DI) were calculated. The agreement of classification of patients into mild, moderate and severe categories for RADAI and DAS28-CRP was determined at baseline, and year 1. Finally, the change in RADAI, DAS28-CRP and HAQ were compared in patients that achieved ACR20 and ACR50

Results: A total of 936 patients were analyzed at baseline, and year 1. Patients were female (73%), with mean age 53 years (19 to 85 years) and mean duration of RA signs and symptoms of 170 days at the time of baseline evaluation. The correlations between RADAI and DAS28-CRP at baseline and 1 year were 0.44 and 0.45 respectively (both $p<0.0001$), between RADAI and HAQ-DI at baseline and 1 year were 0.64 and 0.65, respectively (both $p<0.0001$). The classification of patients into mild, moderate, and severe categories showed a 52% agreement of RADAI and DAS28-CRP at baseline, and 51% at year 1. At baseline, 31% RADAI were classified better than DAS28-CRP and 17% were classified worse. The change in RADAI, DAS28-CRP and HAQ scores of patients achieving ACR20 and ACR50 is shown in Table 1: For both ACR 20 and 50 the changes in RADAI were similar to the changes in DAS-CRP..

Conclusion: The data shows low agreement in classifying patients as mild, moderate and severe for both patient and physician measures cross-sectionally at one point in time. However, the RADAI shows remarkable similar change over time when compared to DAS28-CRP and HAQ-DI, We conclude that the RADAI is a valid measure of disease progression over time , and therefore, it could be a practical tool in daily practice.

Usefulness of Transient Elastography (Fibroscan) in Assessing Hepatic Fibrosis in Rheumatic Patients Under Long Term Methotrexate Treatment. Dimitrios Vassilopoulos, Spilios Manolakopoulos, Hariklia Kranidioti, Anna Kandili, Maria-Vasiliki Papageorgiou and Athanasios Archimandritis, Athens University School of Medicine, Athens, Greece

Purpose: Liver fibrosis is an infrequent complication of long-term methotrexate (MTX) treatment in rheumatic patients. Current guidelines for MTX monitoring include the periodic measurement of serum aminotransferases (AST/ALT) which do not accurately reflect the degree of liver fibrosis. Liver biopsy which is the current gold standard for the assessment of hepatic fibrosis is an invasive procedure that is rarely used in clinical practice. Transient elastography (TE) is a new, promising, non invasive technique for the evaluation of hepatic fibrosis. The aim of our study was to evaluate the degree of liver fibrosis by TE (FibroScan, Echosens) in rheumatic patients treated with MTX.

Method: This was a prospective study that included consecutive patients with various rheumatic diseases treated with MTX (n=53) and a control group which consisted of age and sex matched patients with rheumatic diseases that had not received MTX (n=11) and patients with osteoarthritis (OA, n=11). Demographic and clinical data, duration and cumulative MTX dose were obtained for all patients. Liver stiffness was assessed blindly using TE by a single experienced operator in all patients. The cut-off point for significant liver fibrosis was set at 7.1 kPa, according to previous publications.

Results: Only patients with valid measurements of liver stiffness by TE were included in the study: 45 rheumatic patients treated with MTX (RA=29, spondyloarthropathies=12, other rheumatic diseases=4) and 19 controls (11 patients not on MTX and 8 with OA). No differences in concurrent liver diseases, alcohol use, BMI, glucose or lipid levels were noted between the two groups. The mean age of MTX treated patients was 55 ± 14 years while the mean cumulative MTX dose was 1349 ± 1036 mg (median=1220 mg). The median duration of MTX therapy was 24 months while 38 % (17/45) of patients had received > 1.5 gm of MTX. 3 patients (7%) and 2 controls (10%) had elevated ALT levels while no patient or control had clinical or imaging evidence of cirrhosis. The mean liver stiffness of patients on MTX was 5.6 ± 1.8 kPa compared to 6.5 ± 3.2 kPa (p=0.6) of the control group. Liver stiffness > 7.1 kPa indicating significant liver fibrosis was observed in 17% of patients (8/45) and 42% of controls (8/19, p=0.06 by Fisher exact test). No correlation between liver stiffness and the cumulative MTX dose was observed (Spearman rho p=0.816 r=-0.136). There was also no difference in liver stiffness between patients that had received > 1.5 gm of MTX (5.7± 2.0 kPa) compared to those treated with < 1.5 gm (5.5 ± 1.3 kPa, p=0.9).

Conclusion: Our data show that long-term MTX administration is not associated with significant liver fibrosis in rheumatic patients. Fibroscan is a useful non-invasive technique to assess liver fibrosis in these patients that should be further investigated as a monitoring tool for MTX-induced liver toxicity.

Level of Gastrointestinal Discomfort in Patients with Rheumatoid Arthritis Is Associated with Indicators of Health Status and Other Measures of Disease Activity. Cathrine Persson, Tore K. Kvien and Till Uhlig, Diakonhjemmet Hospital, Oslo, Norway

Purpose: Patients with rheumatoid arthritis (RA) commonly use anti-inflammatory medication and many suffer from gastrointestinal (GI) side effects. Our aim was to investigate factors other than use of non-steroidal anti-inflammatory drugs (NSAIDs), both non-selective (ns) NSAIDs and selective COX-II inhibitors (Coxibs) that may influence the level of self-reported GI discomfort on a 100 mm visual analogue scale (VAS).

Methods: From the population based Oslo Rheumatoid Arthritis Registry, 914 patients aged 20-79 years responded to a questionnaire in April 2004, prior to withdrawal of rofecoxib. Assessed variables were demographic information, SF-36 with mental (MCS) and physical (PCS) component scores, Arthritis Impact Measurement Scales2 (AIMS2) pain, Health Assessment Questionnaire (HAQ), self efficacy scales, VAS for general and joint pain, GI discomfort, global disease activity and fatigue, past and present use of NSAIDs and Coxibs, and whether or not the patient had experienced a previous gastroduodenal (GD) ulcer. Descriptive statistics, Student t-tests, correlation and linear regression analysis (uni- and multivariate) were applied to identify associations to degree of current GI-discomfort, adjusting for age, gender and disease duration in linear regression analyses.

Results: The 914 respondents had mean age (SD) 58.7 (13.4) years, disease duration 13.6 (10.5) years, 78.8% were females. Level of GI discomfort (VAS) was moderately correlated to VAS fatigue/ patient global/ general pain/ joint pain (r=0.38/0.38/0.35/0.33), and to AIMS2 pain (r=0.32), self-efficacy pain (r=0.20) and MCS (r=-0.30), p<0,001 all variables. Previous/current users of Coxibs had more GI discomfort than non-users (26.0 vs 19.2mm, p<0.001) / 24.7 vs 20.6mm, p<0.05) on VAS. There was no significant difference between past or present users of nsNSAIDs. In a multivariate model adjusting for age, gender and disease duration (table 1) several variables were independently associated with GI-discomfort (R^2= 0.24).

Table 1. Dependent variable: GI discomfort on 100mm VAS.

	B	95% CI for B
VAS fatigue (0-100)	0.18***	0.11 - 0.24
HAQ (0-3)	5.69***	2.72 - 8.65
MCS (0-100)	-0.40***	-0.55 - -0.24
GD ulcer	14.21***	8.22 - 20.21
Previous Coxib user	1.79*	0.05 - 3.54

* p<0.05, *** p<0.001

Conclusion:

GI discomfort in RA patients is independently related to use of anti-inflammatory medications, to earlier GD ulcer, physical and mental function and fatigue. Clinicians should be aware that in RA patients the level of GI discomfort is influenced by indicators of health status in addition to anti-inflammatory medication.

Evidence That Vasculitis Complicating Rheumatoid Arthritis (RA) May Be Becoming Less Common. An Analysis of Extra Articular Features (ExRA) in Two Early RA Inception Cohorts. Gouri Koduri[1], Adam Young[1], Richard Williams[2], Patrick D. Kiely[3], Josh Dixey[4], Sam Norton[5] and Peter Prouse[6], [1]Early RA Study, St. Albans, United Kingdom, [2]Early RA Study, Hereford, United Kingdom, [3]St Georges Hospital, London, United Kingdom, [4]Oswetry, United Kingdom, [5]Hertfordshire, United Kingdom, [6]North Hampshire Hospital, Basingstoke Hampshire

Purpose: Extra articular manifestations have been well documented in RA and previous reports suggest that the presence of ExRA is associated with worse outcomes, measured by erosive disease, physical function and mortality. The aim of this study was to compare baseline prevalence and cumulative incidence of ExRA in two inception cohorts, one started in 1986, the other in 2002.

Method: The Early Rheumatoid Arthritis Study (ERAS) recruited 1460 patients from 1986 to 1998 from 9 centres in England. The Early RA Network (ERAN) has recruited 1060 patients from 21 centres in the UK & EIRE since 2002. Both cohorts recruited patients within 2yrs of disease onset and prior to use of disease modifying drugs. Both have collected the same standardised clinical, laboratory & x-ray measures at baseline, 6 months & yearly. This includes extra articular features and complications of RA, and major co morbid conditions.

Results: For this analysis only patients followed for at least 12 months were included (n=2299). Baseline demographic features in the 2 cohorts were similar: mean age at onset was 55 and 56 respectively for ERAS and ERAN, 66% and 68% were women, rheumatoid factor positive in 65% & 66%, erosions on x-ray of hands & feet in 26% & 29%. Onset of RA to rheumatology consult was median 6 months in both, but time to 1st DMARD was median 3 months & 2 weeks respectively. At least one ExRA feature was recorded at baseline or within 1yr in 264 (19%) & 187 (21%) in ERAS & ERAN respectively. The numbers and baseline prevalence & 5yr cumulative incidence figures (with 95% confidence intervals) for rheumatoid nodules, Sjogren's syndrome, Raynauds, Feltys, rheumatoid lung, neuromyopathy, vasculitis and systemic features (e.g. weight loss) will be displayed graphically. Severe ExRA features were uncommon: baseline prevalence for Interstitial Lung Disease (ILD) was 0.8 for both cohorts, but 5yr cumulative incidence was 2.6 & 1.4 for ERAS & ERAN respectively. Baseline prevalence for vasculitis was 1.1 & 0.4, & 5yr cumulative incidence 3.0 & 2.2 respectively. The 1st drug of choice was sulphasalazine in 73% and 34% in ERAS and ERAN respectively, and methotrexate in 7% and 49%.

Conclusion: Severe ExRA features were uncommon. Vasculitis was more common in the earlier cohort, suggesting that this is becoming less frequent. This could not be explained by smoking history, but may be related to different and the more intensive DMARD use in the later cohort.

What Should We Have to Aim for RA Patients: Remission or Low Disease Activity? Violaine Foltz[1], Frédérique Gandjbakhch[1], Fabien Etchepare[1], Marie Laure Tanguy[2], Agnes Monnier[1], Carole Rosenberg[1], Cecile Poulain[1], Sylvie Rozenberg[1], Pierre Bourgeois[3] and Bruno Fautrel[3], [1]MD, Paris, France, [2]Paris, France, [3]MD, PhD, Paris, France

Low disease activity or Remission: is this the question? Progression of structural damage in a cohort of RA patients in remission or low disease activity

Purpose: Low disease activity (LDA) and remission (REM) are the therapeutic objectives in rheumatoid arthritis (RA). However, studies have shown that structural damage may progress in such patients. **Objective:** To assess the risk of radiographic progression at 1 year in patients in either LDA or REM.

Method: Patients with established RA, satisfying to 1987 ACR criteria, were included between February 2007 and February 2008. Inclusion criteria were: RA diagnosis made after 2000, LDA or REM defined as DAS 44 $\leq$ 2.4 or < 1.6 respectively. All patients were assessed clinically every three months for 12 months. Hand and forefoot X-rays were performed at baseline and 12 months. At baseline, all patients underwent high resolution ultrasonography of the hands and forefeet (ESAOTE technos) and low-field dedicated MRI of the dominant hand (ESAOTE C-scan 0.2T). Structural damage was assessed with the van der Heijde-modified Sharp score (SHS), performed blindly by 2 trained readers aware of X-ray sequence. Progression was defined as a variation of the total SHS of at least 1 point.

Results: 85 patients were included, 38 in LDA and 47 in REM. Main characteristics were: mean age 51 years; mean disease duration 2.9 years without significant differences between groups. At baseline, the main difference between LDA and REM groups was the presence of positive power Doppler on ultrasonography[1].

The structural progression during the 12-month follow-up was not different between the 2 groups (table 1). There was a trend for higher number of progressors in the LDA than in the REM group (64.9 % versus 50%) although not significant.

Table 1 Radiographic, US and MRI parameters (PD: power Doppler; BMO: bone marrow oedema, n : number)

	LDA (n=47)	REM (n=38)	p
Characteristics at baseline			
- Patients with □ 1 synovitis on US, (%)	86.5	89.4	ns
- Patients with positive PD, n (%)	44.4	17.0	0.01
- Patients with □ 1 synovitis on MRI, (%)	95.7	97.0	ns
- Patients with □ 1 BMO on MRI, (%)	34.2	29.8	ns
Radiographic progression			
- Total SHS variation	3.3	3.0	ns
- Progressors, n (%)	31 (64.9)	17 (50.0)	ns

Conclusion: Patients in LDA or REM don't seem to progress differently over a 1-year period. Further analyses are in progress to determine the impact of PD signal and BMO on radiographic progression.

970

Obesity and RA Disease Severity: A Comparison Between European and American RA Patients. A. Finckh[1], A. Scherrer[2], G. Reed[3], J. Greenberg[4], A. Lubbeke[1], H. Schwarz[2], C. Gabay[1] and J. Kremer[5], [1]University of Geneva, Geneva, Switzerland, [2]SCQM Foundation, Zurich, Switzerland, [3]University of Massachusetts, Worcester, MA, [4]NYU, New York, NY, [5]Albany Medical College, Albany, NY

Purpose: Obese individuals experience elevated levels of circulating proinflammatory cytokines. While obesity might be associated with an increased risk of developing RA and with impaired quality of life, the role of obesity in RA disease severity is not well established. The aim of this study was to examine if obesity is associated with more severe RA disease outcomes, in particular with higher levels of disease activity and higher functional disability.

Method: We included all RA patients from a European (SCQM-RA) and a North-American (CORRONA) RA registry with available Body Mass Index (BMI). Patients were categorized according to the WHO BMI categories as “underweight” (BMI < 18.5), “normal weight” (BMI ≥ 18.5, < 25), “overweight” (BMI ≥ 25, < 30), “obese class I” (BMI ≥ 30, < 35) and “obese class II” (BMI ≥ 35). The study’s primary outcomes were functional disability as measured by HAQ-DI (SCQM-RA) or mHAQ (CORRONA) and RA disease activity as measured by DAS-28 (SCQM-RA) or CDAI (CORRONA). We used simple descriptive statistics to analyze the study outcomes in the 5 BMI categories and multivariate regressions to examine potential trends after adjustment for potential confounders.

Results: 3’952 European and 18’640 US RA patients were included. Overall, obesity (BMI ≥ 30) was more prevalent among US patients (38% in CORRONA compared to 15% in the SCQM), and the mean BMI was 25.1 (95% CI: 25.0 – 25.4) in the SCQM versus 29.1 (95% CI: 29.0 - 29.2) in CORRONA. Disease characteristics at inclusion, categorized by BMI categories:

European patients (SCQM-RA):

After adjusting for potential confounders, a significant trend existed for patients with higher BMI to have higher disease activity and greater functional disability in both cohorts. This trend had a quadratic shape, with higher levels of disease outcomes at both extremes of BMI.

Conclusion: Obesity is more prevalent in North-American than in European RA patients, differences which need to be further explored. In both populations, higher BMI scores were associated with somewhat higher disease activity and greater functional disability. Obesity could have pro-inflammatory effects in RA, however further research is needed to understand the impact of obesity on human immunity and identify the effects of BMI on RA disease outcomes.

Increased Prevalence of Erectile Dysfunction in Rheumatoid Arthritis. Barry J. Sheane[1], Donough G. Howard[2] and Gaye Cunnane[1], [1]St James Hospital, Dublin, Ireland, [2]St James's Hospital, Dublin, Ireland

Purpose: The risk of cardiovascular disease (CVD) is elevated in patients with rheumatoid arthritis (RA), who tend to present with sudden events or atypical disease, resulting in poor outcomes. Increased clinical vigilance may result in early detection of covert atherosclerosis. Separate studies have demonstrated a correlation between erectile dysfunction (ED) and vascular disease, but little is known about such

associations in chronic inflammatory conditions. This study was undertaken to ascertain if erectile dysfunction is more common in RA compared with other forms of arthritis

Methods: Consecutive male patients from rheumatology out-patient clinics were interviewed regarding risk factors for vascular disease and for ED, in addition to their routine medical assessment. The presence of ED was determined using the previously published Sexual Health Inventory for Men (SHIM or IIEF-5) where scores ranged from high (22 – 25 = normal erectile function) to low (< 7 = severe ED). Laboratory tests, including acute phase response, blood count, lipids, glucose and testosterone levels were recorded. Ethics approval was obtained. Data were analysed using SPSS for Windows. Associations between categorical and continuous variables were assessed with chi-square and Fisher's exact test and Student's t-test, respectively.

Results: Fifty-seven patients were entered into the study: 33 had RA while had other forms of arthritis (9 psoriatic arthritis, 8 ankylosing spondylitis, 3 osteoarthritis, 2 connective tissue disorder, 1 gout and 1 undifferentiated inflammatory arthritis). Mean age was 59.5 ± 13.5 years. Thirty-nine patients (68%) had ED. Mean ED score was 17.9 ± 5.4 (range 5 – 25). Twenty patients (35%) had mild ED, 12 had moderate ED and 4 had severe ED. Twenty-six patients (67%) with RA had ED versus 13 (33%) patients with other types of arthritis. Of the eighteen patients with known CVD and any form of arthritis, ED was present in 17 (98%). Conversely, in those without identified CVD, ED was present in 15 RA patients (71%) as compared with 8 (42%) of the non-RA cohort. There was no association between ED and disease duration, methotrexate use, smoking or dyslipidemia.

Conclusion: Erectile dysfunction was more common in patients with RA compared with other forms of arthritis, particularly in those with known CVD. Standard ED scoring should be included in the holistic assessment of RA and may be valuable in the early detection of sub-clinical vascular disease in patients with RA

Comorbidities Correlates Better Than Age with CDAI Improvement in RA Patients Using the CORRONA Registry. Veena K. Ranganath, Paul Maranian, David Elashoff, D.E. Furst and Harold E. Paulus, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: To evaluate the effect of age and comorbidities on disease activity in rheumatoid arthritis (RA) patients who start a new DMARD, using a community based cohort, the Consortium Of Rheumatology Researchers Of North America (CORRONA).

Methods: An analysis cohort of 1333 RA subjects enrolled in the CORRONA database (Oct 2001-Aug 2007) met the following inclusion criteria: started a disease modifying anti-rheumatic drug (DMARD) or biologic agent, maintained on the same therapeutic regimen for at least 3 months, and were not in clinical remission at baseline. Subjects were categorized into 3 groups: less than 45 years, between 45-65 years, and greater than 65 years of age. Baseline demographic and clinical characteristics were assessed across age categories using one-way ANOVA (Table 1). We then used linear regression (forward stepwise model) to assess predictors of change in the clinical disease activity index (CDAI) to assess the effect of age and comorbidities.

Results: Many of the baseline characteristics were clinically similar across the three age categories (Table 1). However, ESR, number of patient comorbidities and disease duration increased with increasing age, and the male to female ratio decreased with increasing age. Although CDAI change from baseline to follow-up correlated well with age, disease duration, and baseline CDAI in the univariate analyses, only the number of comorbidities, race and baseline CDAI were statistically significant in the multivariate analysis (Table 2).

Conclusion: In the CORRONA database, a large prospective community based cohort of "real-life" RA, increasing number of comorbidities, non-Caucasian race, and lower baseline CDAI correlates with less improvement over time for the CDAI. Age in itself did not predict improvement in CDAI when accounting for other variables.

Table 1: Baseline Characteristics of Older and Younger RA Patients

	Age < 45 (N=197) Mean (SD)	Age 45-64 (N=711) Mean (SD)	Age >=65 (N=488) Mean (SD)	p-value

Comparison of Morning Stiffness Assessment by Severity with Duration for Rheumatoid Arthritis Activty Assessment. Nasim A. Khan, Kashif A. Mufti, Rachel L. Wayne, Fatima Khan and Zainab Siddiqui, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

Purpose: Morning stiffness is a common symptom of rheumatoid arthritis (RA) and is clinically used for RA activity assessment. We compared MS assessment by duration (MS duration) with MS assessment by severity (MS severity) for disease activity assessment in US Veterans with RA.

Method: We did cross-sectional assessment of 315 patients with RA evaluated at a single VA Medical Center. MS severity, pain, fatigue and patient's assessment of general health (GH) were assessed by a 21-point numeric rating scale (NRS) with a 0-10 score range on a self-report questionnaire. The anchors for MS severity scale were "none" and "very severe". MS duration was assessed (in minutes) from time of waking to time of maximal improvement. Physical function was assessed by Health Assessment Questionnaire II (HAQII). RA activity was assessed by Disease Activity Score based on assessment of 28 joints and erythrocyte sedimentation rate (DAS28-ESR). Correlation of two methods of MS assessment with ACR core data measure and DAS28-ESR was used to assess their utility for RA activity assessment.

Results: The patients were mostly men (92%) with mean (SD) age of 64(8.6) and median (IQR) RA duration of 8.5 (5-18) years. The median (IQR) of MS duration and MS severity were 45 (15-120) minutes and 5 (3-7.5) respectively. Both MS duration and MS VAS had non-normal distribution by Kolmongrov-Smirnov test and hence non-parametric tests were used for analysis. MS severity had good

correlation with MS duration (spearman's rho = 0.66, p < 0.001). Compared to MS duration, MS severity had stronger correlation with patient reported outcomes (pain, physical function, patient global and fatigue) and inflammatory markers (ESR and C-reactive protein). Both methods of MS assessment had almost similar correlation with DAS28-ESR (Table).

Conclusion: MS severity has stronger correlation with patient reported outcomes and inflammatory markers than MS duration. Both MS severity and duration have comparable correlation with a RA severity as assessed by DAS28-ESR.

	Morning stiffness severity		Morning Stiffness duration	
Characteristic	Spearman rho	p Value	Spearman rho	p Value
HAQII	0.64	< 0.001	0.47	< 0.001

The Relationship Between Disease Activity, Sleep, Psychiatric Distress and Pain Sensitivity in Rheumatoid Arthritis. Yvonne C. Lee[1], Lori B. Chibnik[1], Bing Lu[2], Ajay D. Wasan[1], Robert R. Edwards[1], Anne H. Fossel[1], Simon M. Helfgott[1], Daniel H. Solomon[2], Daniel Clauw[3] and Elizabeth W. Karlson[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham & Women's Hospital, Boston, MA, [3]University of Michigan, Ann Arbor, MI, [4]Brigham & Women's Hosp, Boston, MA

Purpose: To examine the association between disease activity, sleep, psychiatric distress and experimental pain sensitivity in rheumatoid arthritis (RA) patients.

Method: Fifty-nine female RA patients completed questionnaires and underwent physical examination, blood work and pressure pain threshold testing for hyperalgesia/allodynia at joint and non-joint sites. The association between disease activity, sleep problems, psychiatric distress and pain threshold was assessed using Pearson/Spearman correlations and multivariable linear regression.

Results: In unadjusted analyses, CRP was not correlated with pain threshold at any site, whereas tender joint count was inversely correlated with pain threshold at all sites (wrist: r = -0.49, p = 0.0001; thumbnail: r = -0.37, p = 0.004; trapezius: r = -0.36, p = 0.004). Sleep problems were inversely associated with pain threshold at all sites (wrist: r = -0.51, p < 0.0001; thumbnail: r = -0.44, p = 0.0005; trapezius: r = -0.43, p = 0.0008). Psychiatric distress was associated with low pain threshold at the wrist (r = -0.42, p = 0.0009) and thumbnail (r = -0.35, p = 0.006). In multivariable analyses, adjusting for age and biologic disease modifying anti-rheumatic drug use, CRP was inversely associated with wrist pain threshold (β = -0.15, p = 0.003). Sleep problems were inversely associated with pain threshold at all sites (wrist: β = -0.04, p = 0.007; thumbnail: β = -0.06, p = 0.002; trapezius: β = -0.04, p = 0.01), but psychiatric distress was not.

Conclusion: Multivariable models are essential in analyses of complex outcomes such as pain. Among RA patients, high CRP levels were associated with low pain thresholds at the wrist (the only joint commonly affected by RA that was evaluated in this study), suggesting that local inflammation may heighten pain sensitivity at joints. In contrast, sleep problems were associated with low pain threshold at all sites, indicating that poor sleep may increase widespread pain sensitivity, as in central pain conditions such as fibromyalgia. Future studies examining hyperalgesia at joint and non-joint sites may identify subsets of patients with differing underlying mechanisms of pain.

Table. The association between CRP, Medical Outcomes Study Sleep Score, Hospital Anxiety and Depression Scale Total Score, and pain threshold at the wrists, thumbnails and trapezius, adjusted for age and biologic DMARD use.

Variables	**Wrist Pain Threshold**		**Thumbnail Pain Threshold**		**Trapezius Pain Threshold**	
	β [1]	**p-value**	**β[1]**	**p-value**	**β[1]**	**p-value**
CRP	-0.15	0.003	-0.13	0.05	-0.03	0.55
Medical Outcomes Study Sleep Score	-0.04	0.007	-0.06	0.002	-0.04	0.01
Hospital Anxiety and Depression Scale Total Score	-0.03	0.48	0.01	0.80	-0.009	0.85

[1] The β-coefficient represents the change in outcome given a one unit change in the predictor, holding all other variables constant.

A State of Sustained DAS Remission Is Determined by Time to Achieve Remission. Lydia G. Schipper[1], Jaap Fransen[1], Alfons A. Den Broeder[2] and Piet L.C.M. van Riel[1], [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands

Purpose: Reaching remission is an important goal in current treatment of early RA. However, the number of patients who achieve and sustain remission in daily practice is still small, and determinants for achieving sustained remission are largely unknown. Therefore, this study analysed the association between time to achieve first remission and sustainability of remission in a cohort of early RA patients, treated according to daily practice.

Method: For this study, three-year follow-up data were used from the Nijmegen Inception RA Cohort of 1985 to 2005. Patients were included upon diagnosis (ACR criteria), were systematically evaluated at three-monthly visits and were treated according to daily practice routine. Remission was defined according to the Disease Activity Score (DAS) < 1.6 and according to the ACR remission criteria. Six months duration of remission or more (three consecutive visits) was defined as sustained remission. Univariate predictors for achieving and sustaining remission were identified using Cox-regression and logistic regression, respectively. The relation between time to achieve first remission and sustained remission was analyzed using longitudinal binary regression, including correction for potential confounders.

Results: There were 753 patients included, with a mean age of 67 years, 63% was female, 77% had a positive rheumatoid factor, and mean baseline DAS was 4.0. Within three years, 398 (53%) patients achieved remission at least one visit. The median time to remission was 12 months. Male patients and younger patients reached remission significantly sooner than female patients or older patients ($P<0.01$). Also, patients with a lower baseline DAS or HAQ achieved remission more rapidly than those with a higher value at baseline ($P<0.0001$). There were 142 (36%) patients who experienced sustained remission (mean 78 weeks). Sustained remission was determined by a shorter time to achieve first remission ($P<0.0001$), besides low DAS and HAQ at baseline ($P<0.05$). There was a significant relation between time to achieve remission and sustained remission (odds ratio 1.11, 95% CI 1.10-1.12, $P<0.0001$, adjusted for baseline DAS), which was constant over the whole period of 1985 to 2005. Results with the ACR remission criteria were similar.

Conclusion: Remission was more often sustained in patients who achieved their first remission rapidly. These results support the use of aggressive treatment to aim for early remission in RA.

Autonomic Nervous System Activity Upon Mental Stress in Patients with Rheumatoid Arthritis with Various Disease Activities. Olga Malysheva, Petra Baum, Anke Voitzsch and Christoph G. Baerwald, University Hospital, Leipzig, Germany

Purpose: To characterize the pattern of the autonomic response to mental stress in patients with rheumatoid arthritis (RA) and healthy controls. Stress is recognized as an important risk factor in the pathogenesis of RA. However, it is still incompletely understood how the autonomic nervous system and the immune system interact in patients with RA.

Method: Heart rate variability (HRV) test was performed in 70 RA patients with various disease activity and 100 matched healthy controls (ProSciCard III, Version 2.2a, Medi-Syst GmbH, Germany). Standard tests of autonomic nervous system function involving mental arithmetic tasks to induce mental stress were performed. HRV measures including frequency domain analysis (employing rapid processing of a 5 minute ECG rhythm strip) yielding measures of parasympathetic and sympathetic activity as well as total power (high frequency (HF), low frequency (LF), and very low frequency (VLF)) heart rate variability, variation coefficient, and square root of the mean of the squares of successive R-R interval differences (RMSSD).

Results: Patients with RA had an impaired response to mental stress with a paradox increase of VLF HRV ($2.1 \pm 0.1 \times 10^{-4}$ Hz at rest vs. $2.7 \pm 0.2 \times 10^{-4}$ Hz after stress, $p < 0.05$). In particular in patients with higher disease activity ($DAS > 3.2 \leq 5.1$) VLF HRV significantly increased upon stress ($1.7 \pm 0.1 \times 10^{-4}$ Hz at rest vs. $2.9 \pm 0.1 \times 10^{-4}$ Hz after stress, $p < 0.01$). Moreover, LF HRV, HF HRV as well as sympathetic/parasympathetic ratio did not differ significantly. However, in RA patients in remission ($DAS \leq 2.3$) mental stress led to a significant increase of LF HRV ($1.0 \pm 0.1 \times 10^{-4}$ Hz at rest vs. $1.5 \pm 0.04 \times 10^{-4}$ Hz after stress) and a tendency to an increase of LF/HF ratio. Interestingly, RA patients receiving a combination therapy of anti-TNF agents with MTX exhibited a decreased level of LF HRV at baseline compared to MTX monotherapy ($1.1 \pm 0.02 \times 10^{-4}$ Hz vs. $1.6 \pm 0.04 \times 10^{-4}$ Hz, $p<0,05$) as well as a decreased LF/HF ratio ($0.7 \pm 0.02 \times 10^{-4}$ Hz vs. $1.17 \pm 0.14 \times 10^{-4}$ Hz, $p<0,001$). In patients with anti-TNF combination therapy HF HRV response to mental stress was significantly increased compared to MTX monotherapy ($1.4 \pm 0.1 \times 10^{-4}$ Hz vs. $1.9 \pm 0.1 \times 10^{-4}$ Hz after stress, $p<0.05$).

Conclusion: Our findings demonstrate that in RA patients the autonomic response to minor psychological stress is characterized by a reduced sympathetic activity which is associated with disease activity. Anti-TNF therapy can actively modify stress reactivity towards predominance of the parasympathetic system. Further studies are under way to determine the role of the autonomic nervous system in the disease process of RA and the modulation of neuro-immune interactions by various medications.

Disease Activity of Rheumatoid Arthritis After Total Knee Arthroplasty : Results of 3-Year Followup. Koichiro Yano, Katsunori Ikari, Atsuo Taniguchi, Hisashi Yamanaka and Shigeki Momohara, Tokyo Women's Medical University, Tokyo, Japan

Purpose: Though excellent clinical results have been reported for total knee arthroplasty (TKA) in rheumatoid arthritis (RA) patients, the medium-term efficacy of TKA on disease activity of RA remains unknown. This analysis aimed to assess the systemic effect of TKA on RA disease activity 3 years after intervention.

Method: The study was part of an observational cohort project that included over 4000 Japanese RA patients, established in the year 2000 by the Institute of Rheumatology, Tokyo Women's Medical University (IORRA: Institute of Rheumatology RA cohort). Out of the registered RA patients, a total of 130 total knee arthroplasty (TKA) patients could be followed for 3 years after the operation. The patients who underwent bilateral TKA were excluded. Disease activity of RA was measured using Disease Activity Score 28 (DAS28). Patients were divided into three groups according to pre-operative baseline DAS28 for sub-analysis: low (DAS28 less than or equal to 3.2, n=8), moderate (DAS28 more than 3.2, but less than or equal to 5.1, n=68), and high (DAS28 more than 5.1, n=54) disease activity. Post-operative DAS28 (a few months [DAS1] and 3 years [DAS3] after operation) of the patients were compared with their baseline DAS28 (DAS0) using paired t-test.

Results: For all patients who underwent TKA, the mean DAS28 decreased from 4.85 (DAS0) to 4.14 (DAS1, P=1.1e-12), and a similar result was still seen at 3 years (DAS3=3.97, P=4.7e-15). Sub-analysis results revealed that a systemic effect of TKA on disease activity was found in patients with moderate or high disease activity (DAS0=4.33 , DAS1=3.72, P=5.9e-6 and DAS3=3.81, P=7.9e-6, and DAS0=5.79,

DAS1=4.86, P=1.1e-8 and DAS3=4.37, P=1.0e-11, respectively), while no effect was found in patients with low disease activity (DAS0=2.86, DAS1=2.75, P=0.26, DAS3=2.6, P=0.14). Moreover, among patients whose DAS28 had been recorded 1 year before surgery, the mean DAS28 remain unchanged prior to surgery (DAS0, 4.71; DAS-1, 4.62 [P=0.22]), but decreased after surgery (DAS1, 4.01 [P=1.70E-08]; DAS3=3.94 [P=4.54E-09]). While no significant changes in medication were noted, the average dose of prednisolone tended to decrease over time.

Conclusion: We conclude that TKA, which is known to result in good clinical outcomes on damaged knees, has a secondary systemic effect on disease activity of RA, especially in patients with moderate to high disease activity at their pre-operative baseline.

Utilizing Electronic Medical Records for Discovery Research in Rheumatoid Arthritis. Katherine P. Liao[1], Tianxi Cai[2], Vivian Gainer[3], Sergey Goryachev[1], Qing Zeng[1], Soumya Raychaudhuri[1], Pete Szolovits[4], Susanne Churchill[5], Shawn Murphy[3], Isaac Kohane[5], Elizabeth W. Karlson[1] and Robert M. Plenge[1], [1]Brigham & Women's Hosp, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Partners HealthCare, Charlestown, MA, [4]MIT, Cambridge, [5]Harvard Medical School, Boston, MA

Purpose: Electronic medical records (EMRs) are a rich resource of clinical data for research, but are underutilized due to the inability to extract data from narrative text and to analyze codified data in conjunction with narrative text. We tested the hypothesis that EMR data can more accurately identify patients with rheumatoid arthritis (RA) than codified data alone, and that EMR data can effectively subset RA patients into relevant phenotypes.

Methods: Our study utilized the EMR of two large academic centers caring for ~4 million patients. We extracted RA clinical features from narrative notes using natural language processing (NLP) and codified EMR data (ICD9 codes, laboratory values, prescriptions). We performed chart reviews on 500 patients with at least one ICD9 code for RA to establish a training set with gold-standard RA status based on rheumatologists' diagnosis of RA. Penalized logistic regression was used to establish an algorithm to classify RA cases using NLP and codified data (goal 97% specificity). Two rheumatologists validated the algorithm by reviewing the medical records of 400 patients classified with RA by the algorithm to confirm RA diagnosis. We performed a case-only analysis to demonstrate the association between RF and anti-CCP positivity and higher risk of erosions in RA patients. To calculate the odds ratio (OR), we constructed contingency tables comparing prevalence of erosions defined by NLP, among individuals with anti-CCP and/or RF laboratory values in the codified EMR.

Results: Our algorithm utilizing both codified and NLP data from the EMR accurately classified 3585 patients with RA (63% sensitivity, 93% positive predictive value (PPV) on validation). In comparison, an algorithm using codified data or NLP only data had lower sensitivity (51%, 56%) and PPV (88%, 89%). The clinical characteristics of our RA patients were comparable to published data from a large cohort study at another center (**Table 1**).

In our case-only analysis the risk of erosions was higher in anti-CCP+ patients (OR 1.5 95% CI 1.2-1.9) than RF+ patients (OR 1.3, 95% CI 1.1-1.6). This elevated risk of erosions in anti-CCP+ patients is established in the literature.

Conclusion: We demonstrate the ability to use codified and narrative data to classify RA patients from the EMR with a PPV of 93%. Furthermore, EMR data can be used to study clinical phenotypes such as the association between anti-CCP and radiographic erosions.

Table 1. Comparison of characteristics of our RA patients and a traditional prospective cohort.

Characteristics (%)	EMR RA, n=3585	CORRONA*, n=7971
Mean age, yrs	57.5	58.9

Mortality Risk in RA: Simple Tools for Mortality Assessment in the Clinic and Research Setting. Frederick Wolfe[1], KD Michaud[2], Montserrat Vera-Llonch[3] and Gerry Oster[3], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]U Neb Med Cntr and NDB, Omaha, NE, [3]Brookline, MA

Purpose: Mortality risk in RA is about 1.5 to 2 times higher than in the general population. Relative risk may vary in relation to age and health status. In this study, we examined two commonly used measures of health status, the Health Assessment Questionnaire (HAQ) and the Short Form-36 (SF-36) Physical and Mental Component Summary scales (PCS, MCS) as potential clinically useful predictors of mortality risk.

Methods: As part of a longitudinal study of RA outcomes, we identified all persons with RA who completed at least 2 semiannual questionnaires between 1999 and 2006. HAQ, PCS, and MCS scores were available for up to 4 years. Deaths were documented using the National Death Index. Changes of >=5 units in the PCS or MCS, or >=0.25 units in the HAQ, were designated as clinically important. Cox multivariate regression was used to estimate mortality risk in relation to age, sex, baseline HAQ, PCS, and MCS, and changes in these measures; alternative model specifications were compared with Harrell's concordance coefficient (C).

Results: We identified 10,319 subjects with RA who had completed at least two semiannual questionnaires. Among these persons, there were 1,317 deaths over 64,888 person-years of follow-up. Age and sex-adjusted mortality risk was strongly associated with baseline PCS, MCS, and HAQ (Table 1), with risk increasing at higher levels of disability. After adjusting for age, sex, and baseline PCS and MCS, declines in PCS also were found to be associated with increased mortality risk; however, improvements in PCS of 5-14 or 15-30 units were not associated with a reduction in mortality. Changes in the HAQ >=0.25 units were associated with small changes in mortality risk while changes in the MCS were not associated with mortality. When change scores were added to baseline PCS, MCS, and HAQ, there was minimal or no improvement in the prediction of mortality. Harrell's C for the final models was 0.778.

Conclusion: Health status as measured by the SF-36 (PCS, MCS) and the HAQ is strongly associated with mortality risk in RA. Age and sex-adjusted mortality risk is significantly higher at lower levels of health status. The SF-36 PCS and the HAQ are approximately equal in their predictive ability.

Table 1. SF-36 (PCS, MCS), HAQ and mortality risk among patients with RA

Variable	*Category*	*% in Category*	*H.R. (95% CI)*
PCS	>=50	14.5	1.0
	41-50	22.6	1.6 (1.2, 2.1)
	31-40	30.6	2.0 (1.6, 2.6)
	21-30	27.3	3.1 (2.5, 4.0)
	<=20	5.1	4.9 (3.6, 6.4)
MCS	>=50	57.2	1.0
	41-50	21.4	1.4 (1.2, 1.6)
	31-40	15.2	1.7 (1.5, 2.0)

	21-30	5.5	2.0 (1.5, 2.5)
	<=20	0.7	1.6 (0.7, 3.8)
HAQ	0.00	12.3	1.0
	0.125-0.375	14.8	1.4 (1.1, 1.8)
	0.500-0.875	25.7	1.5 (1.2, 1.9)
	1.000-1.375	22.3	1.8 (1.4, 2.2)
	1.500-1.875	17.2	2.7 (2.2, 3.5)
	2.000-2.375	6.4	4.0 (3.1, 5.2)

Utility of An Interferon-Gamma-Release Assay to Detect Latent Tuberculosis in Patients Evaluated for Immunosuppressive Therapy with Biologic Agents – a Retrospective Analysis of Routine Clinical Practice in a Low-Prevalence Population. Boris Ehrenstein[1], Felix Nessyt[1], Wolfgang Hartung[2], Rotraud Meyringer[2] and Martin Fleck[2], [1]University Medical Center Regensburg, Regensburg, Germany, [2]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany

Purpose: Screening for latent tuberculosis infection (LTBI) utilizing tuberculin skin test (TST) and chest x-ray (CXR) is mandatory prior to initiating TNF-alpha inhibitors and recommended before initiating other immunosuppressive therapies. Pilot studies suggested better sensitivity and specificity for detecting LTBI of interferon-gamma-release assays (IGRA) compared with TST and CXR in this setting. We aimed to evaluate the diagnostic gain of performing an IGRA in addition to standard screening with TST and CXR in routine clinical practice.

Method: Evaluation for LTBI by TST, CXR and additionally by a commercially available IGRA was introduced in routine clinical practice from April 2008 for all inpatients of a referral tertiary-care facility specializing in rheumatic diseases. A retrospective chart review was performed for all patients receiving IGRA testing as part of diagnostic workup prior to commencing biologic immunosuppressive therapy from April to December 2008.

Results: 205 patients with rheumatic diseases (rheumatoid arthritis n=125; spondyloarthritis n=46; psoriatic arthritis n=19; other n=15) received IGRA testing as part of evaluation for LTBI before initiating biologic immunosuppression. Of the 205 IGRA, 19 (9%) were positive, 168 (82%) negative and 18 (9%) indeterminate. Among the 19 patients with LTBI detected by IGRA, only 3 had a positive TST result (of 16 evaluated), 1 had signs suggestive of LTBI in the CXR (of 16 evaluated), and 5 patients reported risk factors for LTBI (of 17 with sufficient information). Utilizing only results of TST and CXR, 14 (74%) of the 19 patients with LTBI diagnosed by IGRA would have been missed. Only 7 of 158 (4%) performed TST were positive: 4 of those had also a positive IGRA; 2 had no other evidence of LTBI, including a negative IGRA; 1 had classical signs of LTBI by CXR, reported a direct exposure to active tuberculosis, but had a negative IGRA. Indeterminate IGRA results occurred more frequently among patients pre-treated with corticosteroids at doses above 10 mg/d prednisolone-equivalent (8/33, 24%) than among patients who were untreated or pre-treated with lower doses (10/172, 6%), $p<0.001$ by Chi^2 test.

Conclusion: Performing only TST and CXR would have failed to detect nearly three quarters of patients with LTBI diagnosed by IGRA. The rates of false-negative IGRA- (0.5%) and false-positive TST-results (1.0%) were both low. Despite IGRA outperforming TST, it remains unclear whether outright replacement of TST with IGRA is justified. However, our data strongly support augmentation of TST with IGRA to detect LTBI.

Health Literacy Predicts the Discrepancy Between Patient and Physician Global Assessments of Rheumatoid Arthritis Activity at a Public Urban Rheumatology Clinic. Joel M. Hirsh[1], Dennis J. Boyle[1], David H. Collier[1], Abbey Oxenfeld[1], Alison Collier[1], Alyssa Cohen[1] and Liron Caplan[2], [1]Denver Health, Denver, CO, [2]Univ of CO Denver School of Med, Aurora, CO

Purpose: Numerous studies report that significant discordance exists between patient and physician measures of disease activity for patients with rheumatoid arthritis (RA). We undertook a study to determine whether health literacy explains the discordance between patient and physician global measures.

Method: We recruited English-speaking adult RA patients at Denver Health for this cross-sectional study. Subjects completed two versions of patient global assessments of disease activity (PTGA), using standard terminology from the Multi-Dimensional Health Assessment Questionnaire (MDHAQ) and Disease Activity Score 28 (DAS 28). The Physician global assessment (MDGA) was also obtained. The discrepancy between PTGA and MDGA was calculated as the absolute difference between these assessments. We utilized a validated instrument to assess health literacy: The Short Test of Functional Health Literacy in Adults (s-TOFHLA). We employed the unpaired t-test and linear regression, where appropriate.

Results: 110 subjects participated in the study. Patient demographics, results of global assessments and health literacy testing appear in Table 1. PTGA and MDGA showed fair to good correlation (r=0.66-0.68), though both versions of the PTGA were significantly higher than MDGA by the t-test ($p<0.001$). The s-TOFHLA correlated with the absolute difference between the MDGA and PTGA by linear regression, i.e., for each point the s-TOFHLA improves, the difference in PTGA and MGA narrows by one half a point. The relationship between the s-TOFHLA and absolute difference of PTGA and MDGA remained statistically significant in multivariate analysis (Table 2).

Table 1. Patient Demographics, Results of Global Assessments and Health Literacy Testing

Variable	N	Mean	SD
Age	110	53.21	12.39
Sex	110	0.21	0.41
Education (per year)	110	12.35	3.09
Current smoker	110	0.3	0.46
Caucasian	110	0.27	0.45
Married	110	0.24	0.43
Currently employed	110	0.19	0.39
Disabled	110	0.65	0.48
Retired	110	0.07	0.26
Duration of RA, years	110	12.51	10.2
Positive RF	110	0.88	0.32
Positive aCCP	74	0.85	0.36
MD-HAQ	110	1	0.61
DAS 28	110	4.37	1.53
ESR	105	29.39	23.94

CRP	106	15.83	23.29
PTGA (MDHAQ version)	108	44.51	27.38
PTGA2 (DAS version)	110	49.12	25.51
MDGA	110	32.5	25.51
s-TOFHLA	110	27.55	9.2

Table 2. Results of Multivariate Analysis Regarding Relationship Between s-TOFHLA and Absolute Difference of PTGA and MDGA.

Variable	**Coefficient**	**P value**	**95% Confidence Interval**	
			Lower Bound	Upper Bound
s-TOFHLA	-0.39706	0.031	-0.75795	-0.03618
Current biologic use	5.64341	0.059	-.211152	11.49796
Education (per year)	-.450206	0.413	-1.53566	.6352489
Sex (male)	3.690053	0.082	-3.436316	10.81642
Age (per year)	.0503813	0.690	-.199284	.300046

Conclusion: Health literacy was independently associated with the extent of discrepancy between PTGA and MDGA in English-speaking RA patients at an urban safety-net clinic. This finding is relevant to both rheumatology practice and research.

People with Rheumatoid Arthritis Who Smoke or Do Not Smoke Have Similar Clinical Status: Data From the QUEST-RA Multinational Database. Tuulikki Sokka[1], Theodore Pincus[2], H. Makinen[3], A. Naranjo[4] and QUEST-RA Investigators, [1]Central Hospital, Jyvaskyla, Finland, [2]NYU Hospital for Joint Diseases, New York, NY, [3]Tampere University Hospital, Tampere, Finland, [4]Hospital Doctor Negrin, Las Palmas GC, Spain

Purpose: Smoking has been implicated in the pathogenesis and severity of rheumatoid arthritis (RA), particularly according to rheumatoid factor (RF) positivity and nodules. However, conflicting data are reported concerning clinical measures in people with RA according to whether patients never smoked, discontinued smoking, or continue to smoke. The QUEST-RA (Quantitative Standard Monitoring of Patients with Rheumatoid Arthritis) multinational database, with 8,040 patients from 86 sites in 33 countries, provided a resource to analyze clinical severity according to smoking status in 6,870 patients.

Method: QUEST-RA was established in 2005 to promote quantitative assessment in usual rheumatology care and develop a baseline cross-sectional database of consecutive RA patients seen in usual care in many countries. Three or more rheumatologists were asked to assess 100 consecutive unselected patients in each country with a standard protocol to evaluate RA (SPERA), which includes a clinical assessment and 4-page patient self-report questionnaire. Smoking status was assessed by self-report as “never smoked,” “smoked in the past but stopped” and “currently smoking.” Analyses of patients who never vs ever smoked, and stopped vs continued to smoke, were performed for demographic and RA Core Data Set measures, rheumatoid factor, nodules and cardiovascular comorbidity, compared by t tests and chi square tests; Core Data Set measures were adjusted for age, sex, and disease duration.

Results: Among the 6,870 QUEST-RA patients, status as “never smoked,” “current smoker” and “stopped smoking” was reported by 70.8%, 12.8% and 16.3% of women, and 37.3%, 25.9% and 36.8% of men, respectively (Table). Patients who smoked were more likely to be RF-positive, have nodules and/or coronary artery disease (CAD) ($p < 0.001$). By contrast, patients who never smoked had slightly poorer status compared to those who ever smoked according to all 7 Core Data Set measures – 28 swollen and tender joint count, physician global

estimate, erythrocyte sedimentation rate (ESR), HAQ-function, pain, and patient global estimate – as well as DAS28; some differences were statistically significant, although none appears clinically important. No meaningful differences were seen between current smokers vs ex-smokers, although ex-smokers were older and had a higher proportion of CAD.

TABLE

	Never smoked	Ever smoked		P never vs ever	P current vs ex-smoker
		Current smoker	Ex-smoker		
Number of patients	4,406	1,059	1,405	-	-
% of all patients	64.1%	15.4%	20.5%	-	-
Age (years)	54.9	53.1	58.4	<0.001	<0.001
Women (n=5,436)	70.8%	12.8%	16.3%	-	-
Men (n=1,374)	37.3%	25.9%	36.8%	-	-
Rheumatoid factor	71.9%	77.8%	76.3%	<0.001	0.37
Erosions	63.4%	58.7%	61.6%	0.021	0.16
Nodules	17.7%	25.5%	20.9%	<0.001	0.010
Coronary artery disease	6.8%	4.8%	12.1%	<0.001	<0.001
*DAS28 (0-10)	4.4	4.0	4.0	<0.001	0.87
*HAQ-function (0-3)	1.1	0.90	0.93	0.010	0.54
*Swollen joint count (0-28)	4.5	4.1	4.1	0.062	0.76
*Tender joint count (0-28)	7.3	6.0	5.7	<0.001	0.80
*Physician global (0-10)	3.1	2.7	2.6	0.001	0.97
*ESR (mm/h)	32	26	28	<0.001	0.11
*Pain (0-10)	4.2	4.0	3.9	0.28	0.062
*Patient global (0-10)	4.1	4.0	3.8	0.16	0.079

*For Core Data Set variables, analyses adjusted for age, sex and disease duration.

Conclusion: RA patients who had ever smoked were more likely to have rheumatoid factor, nodules, and/or coronary artery disease, but values for other clinical status measures were similar for smokers, ex-smokers and never-smokers – the never-smokers were a little worse. Most RA patients are non-smokers. Potential limitations of these cross-sectional data include patient selection, a probable higher mortality rate among smokers prior to acquisition of these data in a rheumatology clinic, i.e., left-censoring, and lack of data on pack-years.

VAS Scales Might Not Be Appropriate to Measure RA Outcomes Among Patients with Low Education Levels. Joana Vasconcelos[1], Sofia Pedro[1], Ana Rita Marques[2], Irina Chaves[2], Andreia Rodrigues[1], Kaleb D. Michaud[3], Fred Wolfe[4] and Elizabeth Benito Garcia[2], [1]Bioepi, Oeiras, Portugal, [2]Bioepi Clinical and Translational Research Center, Oeiras, Portugal, [3]University of Nebraska Medical Center and NDB, Omaha, NE, [4]National Data Bank, Wichita, KS

Purpose: Visual analogue scales (VAS) are universally and widely accepted to evaluate outcome measures in Rheumatoid Arthritis (RA). In clinical practice, there is some discomfort in relying on these scales to measure RA outcome such as pain and quality of life (QoL). We hypothesized that educational level might influence the performance of these scales.

Methods: 1151 patients from an ongoing biannual cohort of Portuguese RA patients since 2003 (NDB-Portugal) were analyzed. Educational level, dichomotized into groups of 4th grade or lower, and 9 years or higher was used to assess differences in VAS responses to pain (VAS-pain, 0-10) and quality of life (VAS-QOL, 0-1). Patients' responses, stratified by educational level, were compared to higher or lower function (HAQ) and regional pain scores (RPS), that are important RA outcomes and reflect disease severity.

Results: Patients with the lower educational levels' responses to the VAS-pain and VAS-QOL, stratified or not by HAQ or RPS seemed be more concentrated in the middle of the scale (5). Patients in the higher educational level did respond with a wider variation throughout the scales and but also tended to not value pain as much as patients with lower educational levels (See figures).

Conclusion: VAS-scales might not measure pain and quality of life accurately, especially among patients with lower educational levels. For patients with higher educational levels, their perception to pain and quality of life captured by the VAS are much lower than patients in the lower educational level.

The Impact of Comorbidity On Physical Function. Helga Radner[1], Josef S. Smolen[2] and Daniel Aletaha[1], [1]Medical University Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria

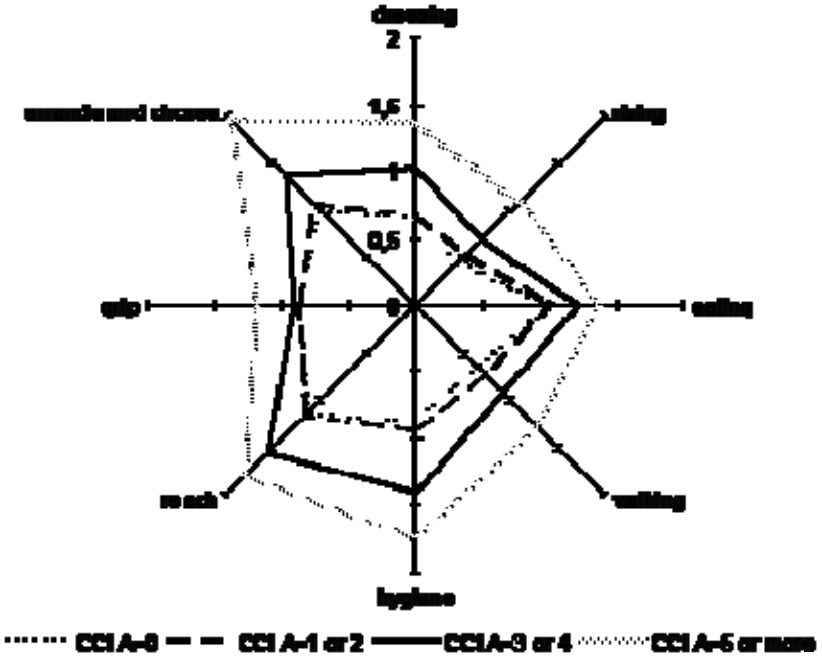
Background: Physical function and activity of daily living are in the center of interest when evaluating chronic diseases like Rheumatoid Arthritis (RA). Disability is not only related to disease activity and joint damage, but also to other factors not primarily associated with the disease process. Comorbid conditions are of particular importance in this context, given their high prevalence in patients with chronic rheumatic disease.

Purpose: To quantify the contribution of comorbidity to physical disability and to activities of daily living in patients with RA.

Method: We ascertained comorbidities in 380 patients with established RA seen at our outpatient clinic over one year, using age adjusted version of the Charlson Comorbidity Index (CCI_A (1)) which ranges from 0-9. Furthermore we collected time integrated clinical disease activity by Clinical Disease Activity Index ($CDAI_T$) as well as physical function using the Health Assessment Questionnaire (HAQ_T). After dividing patients into 4 subgroups by CCI_A (0; 1-2; 3-4; 5-9) we calculated estimated marginal means (EMM) by general linear model (GLM) to explore whether HAQ_T and values of each HAQ-domain (dressing 1, rising 2, eating 3, walking 4, hygiene 5, reach 6, grip 7, errands and chores 8) increase depended on the level of comorbidity (groups of CCI_A). The GLM was adjusted for disease duration, gender and disease activity (based on the CDAI). Furthermore we stratified our patients into different levels of disease activity by $CDAI_T$ (remission: CDAI≤2.8, low disease activity: 2.8<CDAI≤10; and moderate to high disease activity: CDAI>10) and recalculated GLM.

Results: The adjusted GLM showed significant ($p<0.01$) differences of estimated marginal mean (EMM) HAQ_T scores across the 4 subgroups of CCI_A (0.67 (n=67); 0.80 (n=184); 1.24 (n=89); 1.40 (n=40). Results were similar for every single domain of HAQ (Figure 1), showing significant differences of EMM of HAQ-domains within groups of CCI_A. In subgroup analyses stratified by disease activity state, there was a similar increase in mean HAQ_T values across the four levels of CCI_A (Remission: 0.26 vs. 0.31 vs. 0.47 vs. 0.88; Low disease activity: 0.83 vs. 0.78 vs. 0.98 vs. 1.36; moderate and high disease activity: 1.22 vs. 1.33 vs. 1.70 vs. 1.91, respectively; $p<0.01$).

Figure 1. Plot depicts estimated marginal mean of 8 HAQ-domains of respective groups of age adjusted Charlson Comorbidity Index (0; 1-2; 3-4; 5-9)



Conclusion: In patients with RA, all domains of daily living activities represented in the HAQ are increasingly impaired with rising levels of comorbidity. This effect is independent of disease activity with a relatively constant increase of HAQ scores across all disease activity states.

Attaining Public Health Physical Activity Guidelines for Persons with Rheumatoid Arthritis (RA): Does It Improve Their Health Utility? Jae Chul Lee, L. M. Manheim, Jing Song, R. W. Chang and D. D. Dunlop, Northwestern University, Chicago, IL

Purpose: Health utility (HU) is a standard economic measure of effectiveness in clinical trials. Although physical activity can improve the health of persons with RA, it is an open question whether or not attaining public physical activity guidelines improves their HU. This study examines if persons with RA who meet U.S. Surgeon General (USSG) guidelines have improved HU over one year.

Methods: Participants with RA were recruited from the Increasing Motivation for Physical Activity in Arthritis Clinical Trial (IMPAACT), an ongoing randomized clinical trial that evaluates a behavioral intervention to increase physical activity in persons with arthritis. We focused on IMPACCT participants with RA whose data were available at a baseline, a 6-month visit, and a 12-month visit. USSG guidelines attainment was objectively assessed every 6 month using accelerometer monitoring. If persons had ≥150 minutes of moderate or vigorous (MV) physical activity) per week, they were identified as meeting the guidelines. The IMPACCT data included n=77 who have RA and valid physical activity data (aged 23-78) during baseline with a 6 month HU followup; n=42 also had valid physical activity data (aged 24-78) at 6 months with a 12 month HU followup. Regression analysis examined the baseline relationship of guideline attainment with HU. Longitudinal analyses using GEE examined the relationship between USSG attainment and subsequent HU.

Results: Only 18% (n=14) of this RA cohort met USSG guidelines at baseline. Attaining USSG guidelines was not related to HU at baseline or longitudinally. Further analyses examined the relationship between MV physical activity quartiles and HU. This RA cohort had very low activity levels (Q1: 0; Q2: 1-15; Q3:16-90; Q4:>90 min MVPA a week); persons below the median had almost no MV physical activity (<15 min/week). Baseline HU is almost identical for persons with RA below the median (Q1:HU=0.67, Q2: HU=0.69). Those with RA above the median had higher baseline HU (Q3: HU=0.74, Q4: HU=0.74), which suggests attaining even low amount of MV activity is beneficial for those with RA. At baseline having MV activity above the median was associated with significantly higher utility compared to persons below the median (0.72 vs 0.67, p=0.004). Longitudinally, persons with MV activity above the median had better subsequent utility than those below the median (0.72 vs 0.68, p=.012).

Conclusion: Few persons with RA attained USSG guidelines. USSG attainment was not associated with HU at baseline or longitudinally. In contrast, persons who attained even low levels of MV physical activity had significantly better utility at baseline and better subsequent utility compared to persons attaining little or no MV activity. These findings suggest that moving persons with RA from none to some MV physical activity may be a more effective strategy than working to attain USSG guidelines. Separate public health physical activity guidelines should be investigated for persons with RA.

986

In Rheumatoid Arthritis Females Display Higher Disease Activity and Functional Disability, but Have Similar Degree of Joint Destruction Compared to Males. Isabel Castrejón[1], Karen Visser[2], Naomi B. Klarenbeek[2], Isidoro González-Álvaro[1] and Tom WJ Huizinga[2], [1]Rheumatology Department. Hospital Universitario de La Princesa, Madrid, Spain, [2]Leiden University Medical Center, Leiden, Netherlands

Purpose: To evaluate whether disease activity, functional disability and radiographic progression differ between males and females in two cohorts of patients with rheumatoid arthritis (RA) from two different countries.

Method: 217 patients with RA from the Leiden Early Arthritis Clinic (L-EAC) (73.7% women), The Netherlands and 195 patients from the Madrid Early Arthritis Clinic (M-EAC) (76.9% women), Spain were included. At baseline, 1, 2, 3, 4 and 5 year the following data were

collected: the Disease Activity Score (DAS) (including tender and swollen joint counts, erythrocyte sedimentation rate, and VAS general health), C-reactive protein (CRP), health assessment questionnaire (HAQ), patient reported pain (VAS pain 0-100 mm) and radiographs of hands and feet. The radiographs were scored according to the Sharp van der Heijde (SHS) method. At baseline, differences in disease activity measures, function and joint damage were compared between males and females using student t-test or the Mann-Whitney U-test. The pattern of DAS, HAQ and the SHS for males and females over time were compared using linear mixed models, correcting for confounding factors.

Results: Females were significantly younger than males in both cohorts, mean (SD) age 56 (15) and 61 (13) years respectively in the L-EAC and mean (SD) age 51 (16) and 58 (15) in the M-EAC. At baseline, females had higher scores for VAS general health (44.6 vs 35.1, p=0.023), VAS pain (52.7 vs 44.9, p=0.032) and HAQ (1.18 vs 0.99, p=0.014) whereas males had higher CRP (30.2 vs 24.4, p=0.04) in the L-EAC. We found similar results in the M-EAC with higher scores for VAS pain (49.2 vs 35.8, p=0.003), HAQ (1.17 vs 0.75, p=0.001) and DAS28 (4.71 vs 3.76, p<0.001) in females versus males. In contrast swollen joint counts and ESR were not significantly different in both cohorts. In the L-EAC, the females had on average 0.36 units higher DAS44 during 5 years follow up than males (p=0.01), adjusted for the DAS44 at baseline, RF and age. Similarly, the HAQ was 0.21 units higher in females than in males (p=0.04) over time, adjusted for HAQ at baseline, RF and age. The M-EAC showed similar results (data not shown). The radiographic scores (total sharp score, erosion score and joint space narrowing) at baseline were similar for males and females in both cohorts and the radiographic progression over 5 years time was not significantly different.

Conclusion: Female RA patients have higher disease activity and functional disability, but similar degree of radiographic joint destruction, compared with male RA patients, not only at baseline but sustained over 5 years time. This might be due to females perceiving the disease differently, or due to a gender difference in the link between activity and joint damage.

Patient Reported Outcomes in Inflammatory Arthritis: Development and Validation of a Combined Questionnaire for Functional Impairment and Quality of Life Assessment. Yasser El Miedany[1], Maha El Gaafary[2], Deborah Palmer[1] and Sally Youssef[3], [1]Darent Valley Hospital, Dartford, United Kingdom, [2]Ain Shams University, Abbassia, Egypt, [3]Ain Shams University, Cairo, Egypt

Purpose: to develop, assess validity, reliability and sensitivity to change of a new questionnaire for assessment of functional disability as well as quality of life in patients with inflammatory arthritis.

Method: Using Rasch analysis and item pools of 34 questions for functional disability and 29 questions for quality of life; content analysis and semi structured group discussion, the combined inflammatory arthritis questionnaire (CIAQ) was developed including: 10-items scale to assess functional impairment (CIAQ-FI), and 10-items to assess quality of life (CIAQ-QoL). We studied the CIAQ in 534 RA patients, 246 psoriatic arthritis and 241 patients with inflammatory bowel disease associated arthritis. Construct validity was assessed by correlating the score of the questionnaire to parameters of disease activity namely, the joint count (both tender and swollen), Pain score, Patient and Physician Global assessment, Fatigue score, HAQ, psychological score, grip strength, duration of morning stiffness, DAS score, ESR and CRP as well as the occupational status. Sensitivity to change of the developed CIAQ was also assessed. Each patient completed also both Stanford HAQ and HAQ-II questionnaires.

Results: The CIAQ questionnaires showed accepted validity as it correlated significantly with clinical parameters of disease activity, DAS-28 score, as well as CRP (p< 0.01). CIAQ-FI was as well as HAQ II or better correlated to clinical disease outcomes. The CIAQ was also reliable (Cronbach's alpha for CIAQ-FI was 0.90), compared to 0.83 for HAQ and 0.88 for HAQII, and had no misfitting items. Cronbach's alpha for CIAQ-QoL was 0.92. In addition, both the CIAQ-FI and CIAQ-QoL were sensitive to change. A significant correlation (p< 0.01) was observed in percentage change and effect size of both CIAQ-FI and CASQ-QoL with those of disease activity parameters and DAS-28 score.

Conclusion: the CIAQ is a valuable tool which is reliable and valid for assessment of functional impairment and quality of life in inflammatory arthritis patients. The CIAQ is well accepted by patients, sensitive to change, easy to administer and score, and more feasible to monitor the impact of management.

Differences in Inflammatory Arthritis Activity Across Mexican Mestizos, Canadian Native American Indians and Canadian Caucasians: HLA Associations. Carol A. Hitchon[1], Christine A. Peschken[1], Jose Luis Montiel[2], Peter Nickerson[3], David B. Robinson[1], Hani S. El-Gabalawy[1] and Daniel X. Xibille[4], [1]University of Manitoba, Winnipeg, MB, [2]Universidad Autonoma del Estado de Morelos, Mexico, [3]University of Manitoba, MB, [4]Hospital General de Cuernavaca, Cuernavaca Morelos, Mexico

Purpose: Mexican Mestizos (MM) and Canadian Native American Indians (NAI) with inflammatory arthritis are younger at presentation, have higher disease activity and are less likely to achieve remission than Canadian Caucasians (CC). We sought to determine whether these differences in phenotype severity and clinical outcome were associated with HLA DRB1 alleles or anti-CCP status.

Method: Patients with early inflammatory arthritis (EIA< 12 months symptom duration; rheumatoid arthritis (RA) or undifferentiated arthritis (UA)) were followed in outpatient clinics in Central Canada and Mexico and were treated at the discretion of their rheumatologist. Clinical outcomes of remission (DAS28-3ESR<2.6) and EULAR treatment response were determined at one year. Antibodies to citrullinated peptides (anti-CCP2) were measured by ELISA. Rheumatoid factor (RF) was measured by nephlometry. HLADRB1 typing was determined by DNA sequencing (SE alleles: 0101, 0102, 0401, 0404, 0405, 0408, 0410, 1001, 1402; "protective epitope" alleles (PA): 0103, 0402, 1103, 1301, 1302). Statistical associations were tested by Chi2 and non-parametric tests. Values are reported as percentages or mean (SD).

Results: At their baseline visit, MM (n=52; RA 92%) and NAI (n=51; RA 53%) with EIA were younger than CC (n=202; RA 42%) (39(12) and 40(14) vs 48(14) years $p<0.001$), had higher DAS28-3ESR scores (5.6(1.1) and 4.3(1.4) vs 3.8(1.5) $p<0.001$), and were more likely to be anti-CCP2 +ve (89%, 69%, 42% $p<0.001$) or RF+ve (71%, 70%, 54% ($p<0.01$). At one year, MM (1/19), NAI (3/26) and CC (64/108) achieved remission ($p<0.001$). HLA sequencing was available for 176 patients (MM n=72, 22 EIA, 49 Late rheumatoid arthritis (symptoms >12 months at baseline); NAI n=34 all EIA; CC n=127 all EIA). More NAI had at least one SE copy (FN 27/34(79%) vs MM (37/72(51%) (11/22 MM with EIA) and CC 79/127(62%) $p<0.05$). The proportion of NAI, CC and MM with two SE copies was 7/34(15%), 4/72(22%), and 19/127(6%) $p<0.06$). NAI were less likely than MM or CC to have at least one PA 1/34(3%) vs 9/72(13%) (2/22 MM with EIA) vs and 24/125(19%) $p<0.01$). Early UA were more likely than early RA to have at least one PA (26% vs 8% $p<0.001$). In addition EIA subjects with at least one PA (14 REM/18 +ve PA (78%) were more likely to achieve remission than those without PA (29 REM/79 -ve PA (36%) $p<0.01$). EULAR treatment response was not associated with SE or PA. Consistent with previous studies, SE was associated with anti-CCP2 (OR 4 (2-8) $p<0.001$).

Conclusion: The increased severity of EIA seen in Mexican Mestizos and Canadian Native American Indians compared to Caucasians is only partially explained by increased shared epitope, reduced protective alleles and anti-CCP. Further study on environmental factors is required.

ACR/ARHP Poster Session B

Rheumatoid Arthritis Treatment: Strategies and Outcomes

Monday, October 19, 2009, 9:00 AM - 6:00 PM

989

A Faster Clinical Response to Certolizumab Pegol (CZP) Treatment Is Associated with Better 52-Week Outcomes in Patients with Rheumatoid Arthritis (RA). Edward C. Keystone[1], Jeffrey R. Curtis[2], Roy Fleischmann[3], P. Mease[4], D. Khanna[5], J. S. Smolen[6], D. E. Furst[7], G. Coteur[8] and B. Combe[9], [1]Professor of Medicine/University of Toronto, Toronto, ON, [2]Univ of Alabama at Birmingham, Birmingham, AL, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Seattle Rheumatology Associates, Seattle, WA, [5]UCLA, Los Angeles, CA, [6]Medical Univ Vienna, Vienna, Austria, [7]David Geffen School of Medicine at UCLA, Los Angeles, CA, [8]UCB, Brussels, Belgium, [9]Immuno-Rheumatology, Montpellier, France

Purpose: CZP, the only PEGylated anti-TNF approved for the treatment of RA, provides rapid improvements in the signs and symptoms of RA, physical function and relief of pain and fatigue when added to methotrexate (MTX). The objective of our analysis was to determine if a more rapid response to CZP treatment was associated with better long-term outcomes in patients with active RA.

Methods: In the RAPID1 clinical trial, patients treated with CZP 200 mg + MTX who had an ACR20 response or DAS28 change of ≥1.2 points from baseline (BL) at Wk 12 were divided into 2 subgroups depending on response at Wk 6: Wk 6 responders and WK 6 non-responders (who responded at Wk 12). ACR20/50/70 response rates at Wk 52 were compared between responder subgroups using logistic regression; HAQ-DI, Pain-VAS and Fatigue Assessment Scale (FAS) at Wk 52 were compared using ANCOVA, adjusted for BL.

Results: BL characteristics were similar between the 2 subgroups in both analyses. Overall, response to CZP treatment was rapid with the majority of Wk 52 responders achieving a DAS28 or ACR20 responses by Wk 6 (Table). Wk 6 DAS28 and ACR20 responders had higher ACR20/50/70 response rates at Wk 52 than Wk 12 responders (Table). At Wk 52, Wk 6 DAS28 responders also had a significantly greater improvement in Pain VAS than Wk 12 responders, but not in HAQ-DI or FAS. Wk 6 ACR20 responders also reported significantly greater improvements in HAQ-DI and Pain VAS, but not FAS, than Wk 12 responders.

Table. Wk 52 Outcomes in Wk 6 versus Wk 12 responders

Responder definition	**ACR20**	**ACR50**	**ACR70**	**HAQ (0–3)**	**Pain VAS (0–100)**	**FAS (0–100)**
Change in DAS28 ≥1.2						
Wk 6 responder (n=200)	81.5[a]	61.0[a]	37.0[a]	–0.84	–42.8[b]	–3.7
Wk 12 responder (n=57)	56.1	36.8	12.3	–0.71	–34.3	–3.3
ACR 20						
Wk 6 responder (n=178)	83.1[a]	66.7[a]	39.0[a]	–0.87[c]	–44.8 [a]	–3.8
Wk 12 responder (n=87)	66.7	34.5	16.1	–0.69	–34.3	–3.2

[a]$p<0.001$; [b]$p\leq0.01$; [c]$p\leq0.05$ vs Wk 12 responders (adjusted mean difference in change from BL).

Conclusion: A faster response to treatment is associated with improved long-term outcomes at 52 wks in active RA patients treated with CZP + MTX. Rapid (Wk 6) responders demonstrated significantly greater ACR responder rates and greater improvements in physical function and pain relief than later (Wk 12) responders. Largely independent of whether ACR20 or DAS28 change ≥1.2 is used to assess response, these observations highlight the importance of a rapid, 6-wk response in RA outcomes over 1 year.

The Relationship Between Different Isotypes (IgM, IgG and IgA) of Rheumatoid Factor and IgG Anti-Cyclic Citrullinated Peptide Antibody and the Clinical Response to Infliximab in Rheumatoid Arthritis. Ruth Klaasen, Tineke Cantaert, Carla A. Wijbrandts, Danielle M. Gerlag, Theo A. Out, Monique J. de Nooijer, Dominique L. Baeten and Paul P. Tak, Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands

Purpose: It is unclear whether IgM rheumatoid factor (RF) and IgG anti-citrullinated peptide antibodies (ACPA) can predict response to tumor necrosis factor (TNF) blockade in patients with rheumatoid arthritis (RA). We investigated if different isotypes of RF and IgG ACPA (by anti-CCP test) can predict response to infliximab.

Methods: Serum of 104 RA patients with active disease (DAS28 □ 3.2) despite stable methotrexate treatment was collected before and 16 weeks after start of infliximab. IgM, IgG, IgA RF and IgG anti-CCP2 were measured by ELISA. Presence of RF was defined as a level □ 20 U/ml and of anti-CCP □ 25 U/ml. Clinical response was defined as a decrease in DAS28 □ 1.2 at week 16.

Results: Clinical response to treatment was observed in 70% of the patients. At baseline, the level of all RF, but not anti-CCP IgG, was positively correlated to CRP levels, ESR and DAS28. Responders were more frequently IgM RF positive than non-responders (table 1), also when controlling for DAS28 at baseline in a logistic regression analysis. The level of all RF isotypes, but not anti-CCP IgG, at baseline was positively correlated to the absolute decrease in DAS28 after 16 weeks (r between 0.223 and 0.304; P<0.02). This association persisted after adjustment for DAS28 at baseline (multiregression analysis). Patients with IgA or IgG RF levels of □ 100 U/ml all responded to therapy, but numbers were small (5 and 4 patients, respectively). The simultaneous presence of all three isotypes of RF at baseline did not further contribute to prediction of response. During treatment, the level of all RF isotypes (all P < 0.001) as well as the level of IgG anti-CCP (P = 0.041) decreased significantly.

Conclusion: High baseline levels of IgM, IgG and IgA RF are associated with a better response to infliximab treatment in RA patients.

Table 1. Percentage of patients positive for autoantibodies in responders versus non-responders as well as positive predictive value (PPV) and negative predictive value (NPV) for the prediction of clinical response to infliximab treatment in RA.

	All patients	**Responders**	**Non-responders**	**PPV**	**NPV**	**P-value**
IgM RF+ (%)	62%	70%	44%	78%	46%	***P = 0.010***
IgG RF+ (%)	24%	30%	13%	83%	37%	P = 0.06
IgA RF+(%)	34%	37%	26%	76%	34%	P = 0.29
All isotypes RF+(%)	19%	24%	10%	84%	32%	P = 0.09
IgM RF >100 u/ml	28%	35%	13%	86%	38%	***P = 0.018***
IgG RF > 100 u/ml	4%	6%	0%	100%	33%	P = 0.16
IgA RF > 100 u/ml	5%	7%	0%	100%	32%	P = 0.32
IgG CCP+(%)	76%	81%	66%	73%	44%	P = 0.10

Evidence That the Response to Rituximab in RA Depends On B Cell Depletion, as Determined by Highly Sensitive Flow Cytometry, Rather Than Dose of Drug Administered. Edward M. Vital[1], Andrew C. Rawstron[2], Shouvik Dass[1], Karen Henshaw[1], Julie Madden[3], Paul Emery[1] and Dennis McGonagle[1], [1]University of Leeds, Leeds, United Kingdom, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Calderdale and Huddersfield NHS Foundation Trust, Halifax, United Kingdom

Purpose: Published clinical trials showed that responses with rituximab (RTX) 2 x 500mg are similar to 2 x 1000mgs for ACR20, but worse for ACR70 and EULAR Good. All patients in these studies appeared to deplete completely, regardless of dose. Highly sensitivite flow cytometry demonstrates that depletion is more variable than earlier studies indicated. Using 2 x 1000mg RTX, many patients still have incomplete depletion, which is predictive of worse clinical responses(1). Incomplete depletion is predicted by higher circulating preplasma cells, which may correlate with higher synovial or lymphoid B cell activity(2). The relationship between dose of RTX, B cell depletion and clinical response has not previously been investigated.

Method: 21 patients who received 2 x 500mg RTX (RTX500) were compared to 82 receiving 2 x 1000mg RTX (RTX1000, previously reported, 1). All had baseline DAS28 > 5.1 despite 2 or more DMARDs. B cell subsets were measured using highly sensitive flow cytometry as previously described(1). Briefly, 500 000 events were analysed by 6 colour flow cytometry in two tests, using an extensive sequential gating strategy with multiple exclusion markers to allow reproducible enumeration of B cells at 0.002% (equivalent to absolute B cell count 0.0001 cells x109/L) . Complete depletion was defined as B cell count < 0.0001 x109/L after both the 1st and 2nd infusions. Clinical response was assessed using EULAR criteria after 6 months. Categorical variables were compared using Fisher's exact test and B cell levels using Mann Whitney U test.

Results:

Depletion

There was a trend to greater depletion in RTX1000. Rates of complete depletion were 4/16 (25%) and 34/82 (42%) for RTX500 and RTX1000 respectively (p = 0.22). In each group, complete depletion was related to baseline preplasma cell count. For RTX500 median baseline preplasma cells 0.0010 vs. 0.0031 for complete vs. incomplete (p = 0.079). For RTX1000 preplasma cells 0.0013 vs. 0.0021 (p = 0.05).

Clinical Response

For RTX500: mean DAS28 was 5.93 (±0.80) at baseline and 4.01 (±1.78) at 6 months. Overall EULAR Non/Moderate/Good response rates were 33/27/40%.

15/21 RTX500 patients had complete B cell and clinical data. EULAR responses were better in patients with complete depletion and similar to the RTX1000 group with complete depletion. 5 patients failed to respond: all had incomplete depletion (p=0.099). All 4 patients with complete depletion had a Good EULAR response, compared to 2/11 of patients with incomplete depletion (p = 0.01).

Conclusion: In this pilot study there was a trend to less complete B cell depletion using RTX500. Some patients still achieved complete depletion at lower dose, and this was predicted by lower numbers of circulating preplasma cells at baseline. Regardless of dose of RTX, complete B cell depletion is associated with better clinical response, which could have implications for dosing schedules in RA.

Probability to Achieve Low Disease Activity at 52 Weeks in Rheumatoid Arthritis (RA) Patients Treated with Certolizumab Pegol (CZP) Depends On Time to and Level of Initial Response. Désirée M.F.M. van der Heijde[1], M. Schiff[2], Edward C. Keystone[3], R. Landewé[4], T.K. Kvien[5], J. R. Curtis[6], D. Khanna[7], K. Luijtens[8], D.E. Furst[9] and John J. Cush[10], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Univ of Colorado School of Medicine, Denver, CO, [3]Professor of Medicine/University of Toronto, Toronto, ON, [4]Maastricht Univ Medical Ctr, Maastricht, Netherlands, [5]Diakonhjemmet Hospital, Oslo, Norway, [6]Univ of Alabama at Birmingham, Birmingham, AL, [7]UCLA, Los Angeles, CA, [8]UCB, Brussels, Belgium, [9]David Geffen School of Medicine at UCLA, Los Angeles, CA, [10]Baylor Research Institute, Dallas, TX

Purpose: The relationship between an early response to biologic therapy and longer-term clinical outcomes has not been well characterized. We conducted a posthoc analysis to determine the relationship between initial improvement in DAS28(ESR) score within 12 weeks (wks) and probability to achieve low disease activity (LDA; DAS28 ≤3.2) at Wk 52 in RA patients (pts) treated with CZP.

Methods: The proportion of pts treated with CZP (200 or 400 mg) + MTX who had LDA at Wk 52 was assessed among pts who achieved or failed to achieve various DAS28 responses (ie, DAS28 decrease from baseline [BL] <0.3, 0.6, 0.9, 1.2, 1.5 and 1.8 units) by Wks 1, 2, 4, 6, 8, 10 or 12. **Results:** were analyzed for the ITT (LOCF) population. Pts with non-imputable missing data during the first 12 wks of treatment were excluded from the analysis.

Results: Of the 783 pts randomized to CZP + MTX, 98% had DAS28 >5.1 at BL; 30% achieved LDA by Wk 52. By Wk 12, 98%, 87% and 74% of CZP-treated pts had DAS28 decreases from BL ≥0.3, ≥1.2, and ≥1.8, respectively. CZP-treated pts who improved their DAS from BL by <0.3 up to Wk 6 (N=41) had 0% probability of achieving LDA at Wk 52 (Table). Similarly, pts who improved their DAS from BL by <0.6 or 0.9 up to Wk 10 (N=45 and N=76, respectively) had 0% chance to achieve LDA at Wk 52. Pts who had a change of <0.3 at Wk 4, <0.6 and 0.9 at Wk 6, <1.2 at Wk 8, or <1.5 and 1.8 at Wk 12 had a <5% probability of achieving LDA at Wk 52 (bolded rows of Table).

Conclusion: : Long-term response to CZP can be estimated early in the course of treatment. The majority of RA pts respond within the first 12 wks of CZP treatment. Furthermore, the probability of not achieving LDA at Wk 52 can be predicted by a combination of the change in DAS28 from BL and the time at which DAS28 was assessed after starting CZP treatment.

Table. Percentage* of CZP-treated pts with LDA at Wk 52 out of those who failed to achieve DAS decreases up to wk of follow-up for the first 12 wks

The Belgian MIRA (MabThera in Rheumatoid Arthritis) Registry: Clues for the Optimization of Rituximab Treatment Strategies.

Bert Vander Cruyssen[1], Rene Westhovens[2], Patrick Durez[3], Filip De Keyser[4] and MIRA study group, [1]University Hospital Ghent, Ghent, Belgium, [2]University Hosp KU Leuven, Leuven, [3]Univ Catholique de Louvain, Brussels, Belgium, [4]Ghent University Hospital, Ghent, Belgium

Purpose: In Belgium, RA patients are eligible for treatment with rituximab if they failed at least 1 anti-TNF and have a baseline DAS28 > 3.7. From month 6 on, patients can be retreated if they had a moderate or good EULAR response at week 16, and a current DAS28 score of at least 3.2. The Belgian MIRA registry aims to record safety and efficacy data, and to evaluate the retreatment conditions.

Method: All Belgian rheumatologists could participate in the study. Patients entered the registry as from November 2006 and the entry is still open. All patients were treated with 2 infusions per course of rituximab (2 x 1000 mg) in combination with 100 mg of methylprednisolone and MTX. Baseline patient's characteristics, and DAS28-variables were recorded every 2 months

Results: By March 2009, 332 patients had entered the registry with a mean follow-up time of 54 (range 0-122) weeks. Patients (mean age of 57 years, 78 % female) had a mean disease duration of 12 years.

Rituximab therapy decreased the overall mean disease activity from DAS28-ESR 6.1 (SE = 0.1) at baseline to 4.2 (SE = 0.1) at week 16. 82% of patients obtained a good or moderate EULAR response. Further decrease of DAS was observed at the end of year 1 and year 2 with a mean DAS28-ESR of 3.8 (SE = 0.2) and 3.7 (SE = 0.5) at these respective time points. 191 and 75 patients received a 2nd and 3rd course of rituximab respectively. The median time to retreatment was 34 weeks for the first course and 39 weeks for the second course.

At baseline, 83% of the patients had a high disease activity. This percentage dropped to 24% at 16 weeks, with 23% of patients reaching remission or low disease activity status. At the start of the second course, 60% of patients had a high disease activity. With retreatment, this percentage dropped to 19% at 16 weeks, with 31% reaching remission or low disease activity status.

34 patients (10.2%) stopped treatment at a median follow-up time of 21 weeks; 19 due to inefficacy and 15 stopped due to safety issues (allergic infusion reactions in 6 patients, 2 infections and other safety reasons were reported in the remaining 7 patients). 1 patient died after a pneumonia in relation to a hip fracture. 4 patients were lost to follow-up.

Conclusion: This study describes the current follow-up of a daily clinical practice cohort of 332 RA patients with longstanding refractory disease treated with rituximab. Continued decrease of DAS28 scores at each treatment course was obtained with rituximab therapy with a favourable safety profile. Relatively high DAS28 values at the start of each retreatment, compared to values at week 16 of each treatment course, suggest that treatment of RA patients with rituximab could be optimized by earlier retreatment.

TNFα-Inhibitors in Established Rheumatoid Arthritis: The Effect of Age On Treatment Response and Predictors of Remission.

Ludvig L. Dahl, P. Geborek, Martin Englund, Tor Olofsson and Ingemar F. Petersson, Lund University, Department of Clinical Sciences, Lund, Sweden

Purpose: To study the impact of age at treatment start on response and remission in patients with rheumatoid arthritis (RA) receiving anti-TNFα-treatment for the first time.

Methods: Patients with RA receiving their first course of TNFα-inhibitor were enrolled from the South Swedish Arthritis Treatment Group register. Maximum follow-up length was 60 months. The effect of age was examined by comparing patients in the 1st quartile of age with

the rest of the patients. Fulfillment of the EULAR remission criteria at least once during the follow-up was used as the main response measure. Predictors of remission were analyzed using logistic regression.

Results: 2346 patients were included. The 1st quartile of age corresponded to 48 years. At treatment initiation the older group had significantly longer disease duration, a lower proportion of men, worse DAS28- and HAQ-scores and more often used concomitant DMARDs and steroids.

Rapid decreases in DAS28-scores and HAQ-scores were seen within the first 3 months. DAS28- and HAQ-score remained significantly lower in the younger group at all times.

The frequency of patients in remission rose rapidly during the first 3 months and continued to increase during the follow-up period. At all times the frequency was significantly higher in the younger group. After 3 years 31% (95% CI 26-35%) of the older group and 45% (95% CI 37-53%) of the younger group were in remission. The younger group tended to reach remission sooner (8.7 vs. 10.1 months (ns). The older group had significantly worse ACR and EULAR response at 6 and 12 months, and significantly worse mean drug survival time, 54 vs. 66 months.

Multivariate predictors of remission (Figure 1) were: Age ≤ 48 years (OR 1.4 95% CI 1.1-1.7), male gender (OR 1.5 95% CI 1.2-1.9), concurrent DMARD use (OR 1.8 95% CI 1.4-2.4), baseline HAQ-score (OR 0.38 95% CI 0.32-0.46) and baseline DAS28-score (OR 0.55 95% CI 0.50-0.61). In the younger group gender and DMARD use were not significant predictors, but there was a trend for regular NSAID use (OR 1.5, p=0.08) and steroid use (OR 0.7, p=0.11).

Conclusion: Age had a significant impact on treatment outcome in RA patients receiving anti-TNFα-treatment for the first time. DMARD treatment and male gender were positive predictors, while higher age, higher DAS28-scores and higher HAQ-scores were negative predictors of remission. The impact of some predictors was dependent on age.

Figure 1. Baseline predictors of remission: on at least one assessment, not including baseline. Multivariate binary logistic regression, ORs, 95% CI and significance levels. **A)** Whole study population **B)** Predictors in the 2 age groups: < 48 years (black squares) and ≤ 48 years (grey diamonds).

The Time for 6—Month Placebo Trials in Rheumatoid Arthritis Has Passed: A Systematic Comparison of 3— and 6—Month Response Rates in Trials of Biologic Agents. Maarten Boers, VU Univ Medical Center PK6Z165, Amsterdam, Netherlands

Purpose: Most trials in rheumatoid arthritis (RA) are registration trials. These trials traditionally compare an experimental agent with placebo in the setting of an incomplete response to disease-modifying treatment (DMARD-IR) that is continued during the trial. The standard duration of such trials continues to be 6 months or longer in the face of serious methodological and ethical shortcomings. This study compares the contrast in response between the treatment groups at 3 and 6 months.

Method: Secondary use of dataset for meta-analysis of randomized trials of biologic agents in RA. Eligible trials enrolled DMARD-IR patients, and reported data of ACR20, -50, and -70 responses at 3 and 6 months. Trial contrasts were categorized as placebo control or active control (e.g. methotrexate in methotrexate-naive control patients). The ratio of each ACR (20,50,70) response rate between control and experimental groups was summarized separately for the placebo and active control contrasts, by weighted Mantel-Haenzsel random effect risk ratios (i.e. 'risk' of response in the experimental group given the response in the control group).

Risk ratios of responses at 3 and 6 months were compared in a stratified analysis, applying the same weights as in the first step. Finally, for the placebo trials sample size calculations were performed for a range of plausible response rates.

Results: Twenty trials (10 multiple arm) yielded 15 placebo and 18 active control contrasts in 10,514 patients. Most included patients had severe, longstanding RA. Responses were higher at 6 than at 3 months in both control and experimental groups. In placebo trials contrasts were all highly significant for ACR20 and -50 levels at all time points, and the mean contrast did not change significantly between 3 and 6 months (Table). For ACR70 at 3 months the contrast between placebo and experimental groups was not significant in 4 out of 15 trials, decreasing to 1 out of 15 at 6 months, and the 'risk' of a response on experimental compared to placebo treatment increased significantly (3 months: 4.1; 6 months 5.8; p=0,02). This was mainly due to an increase of patients meeting ACR70 only in the experimental groups.

As expected, in active control groups responses were much higher than in placebo groups, and contrasts with the experimental groups correspondingly smaller. For ACR20 contrasts did not change significantly between 3 and 6 months. For ACR50 and-70 contrasts decreased somewhat (significant for ACR50), corresponding with a 'catch-up' response in the control group.

Suggested sample sizes at 3 and 6 months were similar for ACR20 and 50 and well below the 100 patients per group for a range of plausible response rates (power 90%; two-sided alpha 5%). For ACR70 placebo trials of only 3 months duration are likely to be at a disadvantage (i.e., need about twice the number of patients) to show a significant difference between treatment groups.

Conclusion: To detect efficacy for signs and symptoms of RA, the placebo phase of registration trials can be safely limited to a duration of 3 months.

Table		event rate		risk ratio*	P
		control	experimental	(mean, 95%CI)

Usefulness of in Vitro Interferon-γ Release Assays (IGRAS) for Diagnosis of Latent Tuberculosis Infection in Rheumatic Patients Scheduled for Anti-TNF-α Treatment. Lourdes Mateo[1], Sonia Mínguez[2], Irene Latorre[1], José Domínguez[1], Anna Moltó[3], Emma García[2], Dolors Grados[1], Susana Holgado[1], Alejandro Olivé[1], Jerónima Cañellas[1] and Xavier Tena[1], [1]Hospital Germans Trias i Pujol, Badalona, Spain, [2]Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [3]M.D., Resident., Badalona, Spain

Purpose: Detection of latent tuberculosis infection (LTBI) is mandatory in rheumatic patients candidates for treatment with anti-TNF-a agents. Although there is not a "gold standard" for diagnosis of LTBI, tuberculin skin test (TST) is the standardized method worldwide. Spanish Society of Rheumatology recommends the performance of a second-step TST, 1-2 weeks after the first one, and a chest radiograph. However, the existence of false-positive (BCG vaccination, nontuberculous mycobacterias) and false-negative (anergy, immunosuppression) TST results, has led to the development of new *in vitro* techniques in order to improve the sensitivity and specificity in LTBI detection.

Our aim is determining the usefulness of blood interferon-g release assays (IGRAS) and to compare them with TST in patients with different inflammatory rheumathic diseases scheduled for anti-TNF treatment.

Method: The study included individuals with inflammatory rheumatism staring an anti-TNF-a agent. All patients underwent 2 TST, a chest radiograph and 2 IGRAS: One assay, (QuantiFERON GOLD *in tube*) measures IFN-g concentration in supernatant by enzyme-linked immunosorbent assay in response to specific antigens (ESAT-6, CFP-10 and TB7.7); the other enumerates IFN-g-secreting T cells by enzyme-linked immunospot (T-SPOT.TB). We performed a descriptive statistical study and calculated concordance between TST/T-SPOT.TB, TST/QFT and T-SPOT.TB/QFT by Cohen´s kappa test, with k value > 0.75 representing excellent agreement, 0.4-0.75 good-moderate and <0.40 poor agreement.

Results: We included 23 patients (10 males/13 females) with a mean age of 52.4 ± 13.2 years and different rheumatic diseases: 7 rheumatoid arthritis (RA), 4 ankylosing spondylitis, 5 psoriatic arthritis, 3 seronegative arthritis, 2 systemic lupus erythematous, 1 undifferentiated spondyloarthropaty and 1 SAPHO. Average time of disease evolution was 9.6 ± 9 years. All patients with RA had seropositive and erosive forms. Prior to anti-TNF-a treatment, 16 patients had received 2 DMARD (range 0-5) and 10 (43.5%) systemic glucocorticoids. 3/23 (13%) patients displayed positive TST. Only one had positive second-step TST after being negative the first one. T-SPOT.TB was positive in 7 / 23 (30.4%) and QFT in 5 / 23 (21.7%). QFT was undetermined in 3 cases (13%), while none for T-SPOT.TB. Level of agreement (kappa test) between TST/T-SPOT.TB was 0.51; between TST/QFT 0.46 and between T-SPOT.TB/QFT 0.79. Five patients (21.7%) received secondary prophylaxis for tuberculosis, 2 of them with negative TST and positive IGRAS.

Conclusion: 1) IFN-g release assays are more accurate methods for diagnosis of latent tuberculosis infection than tuberculin skin test in rheumatic patients, even using a second-step TST. 2) Correlation between IGRAS and TST is moderate in immunocompromised individuals. 3) T-SPOT.TB seems to have greater sensitivity and lower rate of indeterminate results than QFT.

Direct Comparison of 4 Years' Drug Survival of Adalimumab, Etanercept and Infliximab in Rheumatoid Arthritis Patients. An Observational Study From the DANBIO Registry. M.L. Hetland[1], I.J. Christensen[2], U. Tarp[3], L. Dreyer[1], A. Hansen[1], I.T. Hansen[1], G. Kollerup[1], L. Linde[1], H.M. Lindegaard[1], U.E. Poulsen[1], A. Schlemmer[1], D.V. Jensen[1], S. Jensen[1] and M. Østergaard[1], [1]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Sealand and Capital Region, Copenhagen, Denmark, [2]Copenhagen, Denmark, [3]DANBIO, Copenhagen, Denmark

Purpose: Data on the withdrawal rates of different TNF-inhibitors (TNF-I) in clinical practice are scarce. The aim was to determine 4-year drug survival of the different TNF-I and calculate Hazard Ratios (HRs) of their withdrawal based on the DANBIO registry.

Methods: 2935 RA patients (832 (28%) adalimumab, 703 (24%) etanercept, 1400 (48%) infliximab) were followed from start of first TNF-I treatment to withdrawal of treatment or Oct 1st 2008 (whichever came first). HRs were calculated correcting for baseline disease activity, age, disease duration, concomitant methotrexate and prednisolone, number of previous DMARDs, HAQ score and hospital department. Propensity scores and various subanalyses gave similar results, not shown.

Results: Figure shows 4 years' (unadjusted) drug survival: adalimumab:56%(95%CI:51-61%); etanercept:63%(58-68%); infliximab:44%(41-47%), p<0.0001, log rank test.

Below the figure, numbers of events and numbers of patients at risk at different time points for each drug are shown.

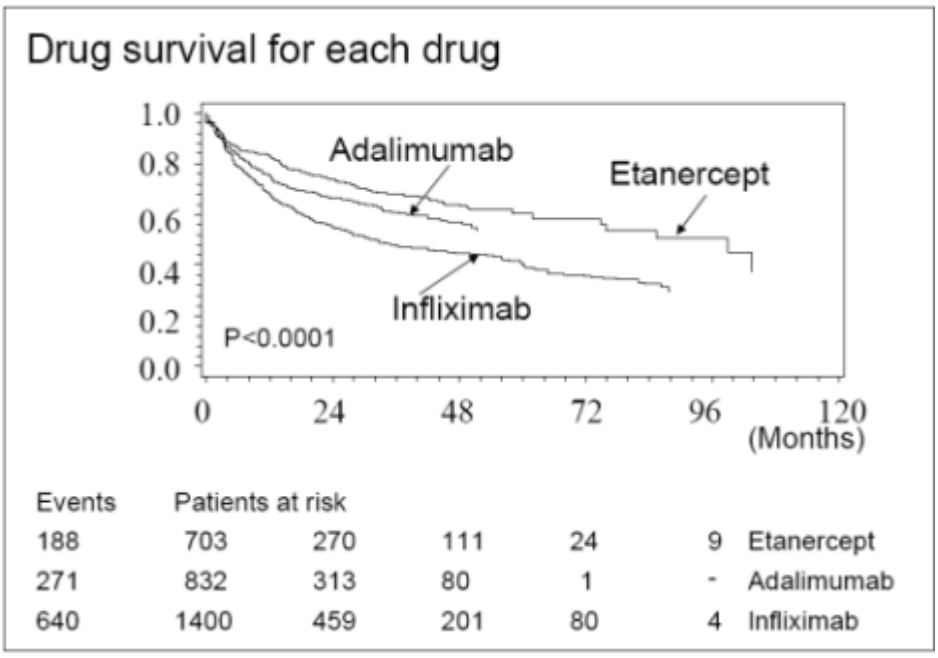
HRs for drug withdrawal, incl. subanalyses by reason for withdrawal, are shown in table.

Table:

Hazard Ratios (95% CI) for drug withdrawal

	Adalimumab vs. etanercept	**Infliximab vs. etanercept**	**Infliximab vs. adalimumab**
All pts (1099 events)	1.56 (1.26-1.94)	2.10 (1.70-2.59	1.35 (1.13-1.61)
LOE (727 events)	1.51 (1.17-1.96)	1.73 (1.35-2.23)	1.15 (0.92-1.42)
AE (327 events)	1.73 (1.14-2.62)	3.19 (2.15-4.72)	1.85 (1.35-2.52)

LOE: lack of efficacy; AE: adverse event



Conclusion: In this nationwide follow-up study of 2935 RA patients, 4 years' drug survival was highest for etanercept. After correcting for differences in baseline characteristics, the hazard ratio for withdrawal was overall highest for infliximab and lowest for etanercept regardless of reason for withdrawal.

Conflict of Interest: The DANBIO registry received unrestricted grants from Abbott, BMS, Roche, Schering-Plough, UCB Nordic and Wyeth.

Focus On Persistent Disease Activity: Experiences From the BARFOT Early RA Cohort After 8 Years. Björn Svensson[1], Kristina Albertsson[2], Sidona Valentina Bala[3], Kristina Forslind[3] and Ingiäld Hafström[2], [1]University of Lund, Villands Vånga, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Helsingborgs Hospital, Helsingborg, Sweden

Purpose: Remission is reported in an increasing proportion of patients and is ascribed to novel treatment options and strategies. However, a substantial number of patients suffer from ongoing active disease. This study focuses on these patients and describes the consequences on clinical symptoms, function and joint destruction.

Method: 628 patients (66% women) from the BARFOT early (duration less than a year) RA cohort have been followed for 8 years. Mean age at baseline was 54 years and disease duration 6.3 months. 60% were anti-CCP positive and 65% RF positive. Disease activity (DA) was defined as low or no (*low*) - DAS28 <3.2 and as medium or high (*high*) - DAS28 ≥3.2. *Persistent DA* was defined as DAS28 3.2 or more on all the three follow-ups at 2, 5 and 8 years. DAS28, HAQ and SOFI (Signals Of Functional Impairment) and radiographs of hands and feet were assessed. The radiographs were scored by the van der Heijde modification of the Sharp score (SHS).

Results: After 8 years almost 40% were in remission while 55% had low and 45% high DA. Patients with high DA had more pain and poorer function as measured by HAQ and SOFI (a performance index) compared with the patients with low DA (p=0.001 for all variables).

27% of the patients had persistent DA, and these patients had remarkably more severe symptoms and worse daily life and physical function compared with the patients without. Thus, mean pain-VAS was 47 vs 24, general health 48 vs 24, swollen joints 5.2 vs 1.6, tender joints 6,0 vs 1,34, HAQ 1.1 vs 0.5 and SOFI 10 vs 5, respectively, all differences p=0.001.

These clinical differences between persistent and no persistent DA were reflected by a marked difference in joint destruction. Thus, the median change in SHS after 2, 5 and 8 years was considerably greater in patients with persistent DA compared with patients without: 4 vs 2, p=0.011, 12 vs 6, p=0.003 and 14.2 vs 5, p=0.001, respectively.

DMARD and biologic treatment was overall statistically different between patients with and without persistent DA at 2, 5 and 8 years of follow-up. At these time points patients with persistent DA got more DMARD combination therapy (16% vs 6%, 19% vs 7% and 13% vs 9%) and at 5 and 8 years also more biologics (9% vs 5% and 19% vs 13%) than patients with persistently low DA. The proportion of patients treated with prednisolone was higher in the persistent DA group at 5 and 8 years (39% vs 23%, p=0.001 and 36% vs 20%, p=0.001, respectively).

In a logistic regression model, including 85% of the patients, female gender independently predicted persistent DA, OR(95%CI) 0,41(0.25-0.66), p=0.001, as well as baseline DAS28, OR(95%CI) 1.35(1.11-1.64), p=0.002, and disease duration 1.09(1.02-1.16), p=0.003.

Conclusion: This study shows that although half of the patients from an early RA cohort did well after 8 years, more than one quarter suffered from persistently active disease with pain, restricted daily life functions, impaired physical function and progressive joint destruction. Obviously increased focus on this particular group of patients is necessary.

Identifying Clinical Features of Disseminated Histoplasmosis in Patients Receiving TNF Inhibitors. P. A. McCroskery[1], A. Verma[2] and C. Blosch[3], [1]Amgen, Thousand Oaks, CA, [2]Amgen, So San Francisco, [3]Amgen, Seattle, WA

Purpose: To identify clinical features of disseminated histoplasmosis in patients receiving TNF inhibitors. Recently the FDA reviewed 240 reports of disseminated histoplasmosis associated with TNF inhibitors and reported that a delay in diagnosis and treatment was possibly associated with fatal outcomes in 12 patients. Methods: All serious adverse events in histoplasmosis cases from the Amgen ARISg safety database were identified and reviewed. Results: Sixteen cases of new disseminated histoplasmosis were identified in patients receiving etanercept (n=12) and/or other immunosuppressants (n=4), including 3 cases with fatal outcomes (2 from multi-organ failure, 1 from splenic rupture) in patients receiving etanercept. All etanercept cases were from post-marketing spontaneous reports in the US and in 15 of 16 cases, patients were from endemic areas. Malaise, non-productive cough, and pulmonary infiltrates were the most frequently reported symptoms in patients with mild disease. In 9 of the 16 cases of severe disease, thrombocytopenia or pancytopenia and abnormal liver function tests (LFTs) or hepatosplenomegaly were present. Three patients underwent cholecystectomy before the subsequent diagnosis of histoplasmosis.

Age (yrs), Gender (M/F)	**Clinical Presentation**	**Exposure* (months)**	**Platelet count**	**LFTs**	**Comments**	**Outcome**
38, M	Pneumonitis, severe pancytopenia	11	Pancytopenia	NA	NA	Recovered
70, M	Weakness, jaundice	36	40,000	Markedly increased	Ascending cholangitis	Fatal
61, F	Pneumonitis and hypoxemia	2	NA	NA	NA	Recovered
60,	Nausea, weakness, fever	6	61,000	NA	Bone marrow asp	Recovered

Age (yrs), Gender (M/F)	**Clinical Presentation**	**Exposure* (months)**	**Platelet count**	**LFTs**	**Comments**	**Outcome**
F					positive for histo	
40, M	Fever, abdominal pain	21	NA	Abnormal	Cholecystectomy	Not recovered
55, M	Dyspnea, fever	2	NA	NA	NA	Recovering
46, M	Dyspnea productive cough	12	Pancytopenia	NA	NA	NA
43, F	Fever, fatigue, dypnea	10	NA	Markedly increased	Jaundice	NA
45, M	Dyspnea, dry cough, fever	31	Pancytopenia	Increased jaundice	Cholecystectomy	Recovered
40, F	Dyspnea, fever, sharp chest pain	NA	Decreased	NA	Nodules in liver	Not recovered
NA, F	Abdominal pain, symptomatic cholelithiasis	84	NA	Abnormal	Cholecystectomy	Recovered
33, F	Diffuse interstitial infiltrate, small pleural effusion	7	Decreased	Increased	Required ventilator	Recovered
64, M	Pancytopenia, fever, hepatosplenomegaly	53	Markedly decreased	Abnormal	Splenic rupture	Fatal
47, M	Abnormal liver function tests, fever	16	NA	Markedly increased	Ascending cholangitis	NA
60, M	Cough, dyspnea, chest pain	36	NA	Increased	Multisystem organ failure	Fatal
Child, NA	Malaise, fever	NA	Pancytopenia	NA	NA	NA

***Exposure to etanercept or another drug;**

NA = insufficient information available

Conclusion: Disseminated histoplasmosis was "very rare" according to CIOMS criteria with etanercept use (0.9 cases reported in 100,000 pt-yrs) in this database, but 3 fatal cases were reported. Thrombocytopenia/ pancytopenia and abnormal LFTs may identify patients with more severe disease and, in endemic areas, should be recognized as possible signs of disseminated histoplasmosis.

Predictors of Radiographic Joint Destruction in Rheumatoid Arthritis Patients During TNF-Inhibitor Treatment in Clinical Practice. L. M. Ørnbjerg[1], M. Østergaard[1], P. Bøyesen[2], A. Thormann[1], U. Tarp[1], H. Røgind[1], W. Böhme[1], H. Lindegård[1], U. Poulsen[1], A. Hansen[1], V. Ringsdal[1], N. Graudal[1], A. R. Andersen[1], J. Espesen[1], G. Kollerup[1], T. G. Christensen[1], R. Pelck[1], O.R. Madsen[1], D.V. Jensen[1], O. Majgård[1] and M. L. Hetland[1], [1]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Copenhagen, Denmark, [2]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

Purpose: Tumour necrosis factor inhibitor (TNF-I) treatment of rheumatoid arthritis (RA) patients in clinical practice reduces radiographic progression(1). This report investigates predictors of radiographic progression in RA patients in the Danish nationwide DANBIO registry during 2 years of TNF-I treatment.

Method: X-rays of hands and wrists obtained at the start of TNF-I (baseline) and approximately 2 years after start of TNF-I treatment (follow-up) were collected from 18 departments in Denmark, and combined with clinical data in the DANBIO registry. The X-rays were scored according to the Sharp/van der Heijde score by an experienced reader blinded to chronology.

Multiple regression analysis with stepwise backward selection with change in Total Sharp Score (ΔTSS) as the dependent variable, and logistic regression analysis with +/- radiographic progression as dependent variable were performed. Explanatory variables were potential predictive baseline variables (28-joint Disease Activity Score (DAS28), TSS, age, gender, IgM Rheumatoid Factor (IgM-RF), disease duration, number of previous Disease-Modifying Anti-Rheumatic Drugs (DMARDs), concomitant methotrexate (MTX), concomitant prednisolone) and follow-up variables (duration of TNF-I treatment and number of TNF-I switches in follow-up period).

Results: 283 patients (78% women, 76% IgM-RF positive, age 54 (23-81) years (median(range)); disease duration 4.5 (0-67), years), TSS 23 (29) (mean(SD)) 11.5 (2-32) (median (inter-quartile range (IQR))) had X-rays. At baseline 66% started treatment with infliximab, 17% with etanercept and 17% with adalimumab. 16% received TNF-I monotherapy, 78% combination therapy with MTX and 6% with other DMARDs. At follow-up (median 561, IQR 389-762days), 62% were treated with the initial TNF-I, 24% had switched to another TNF-I and 14% had withdrawn from TNF-I.

Mean (SD) ΔTSS was 1.0 units/yr (2.9), median 0 (IQR 0-1). 36% of patients progressed radiographically (ΔTSS >0) during TNF-I treatment. Independent predictors of ΔTSS during TNF-I treatment ($p < 0.05$) were IgM-RF and age, while the other variables did not reach statistical significance. Independent predictors of progression were IgM-RF, concomitant prednisolone, age and TSS at baseline (Table).

Table: Final models of multiple(a) and logistic(b) regression analyses

(a) Predictors of ΔTSS	**Regression coefficient**	**P value**
TSS	0.011	0.06
Age	0.029	0.04
IgM-RF	0.84	0.04
(b) Predictors of X-ray progression	**Odds Ratio**	**P value**
TSS	1.02	0.0009
Age	1.03	0.03
IgM-RF	2.56	0.03
Concomitant prednisolone	1.99	0.02

Conclusion: Positive IgM-RF and high age were consistently predictors of radiographic progression in RA patients during 2 years of TNF-I treatment in clinical practice.

The Effect of Smoking History, Gender and Age On Risk of Pneumonia While On Biologic Agents. Margaret E. Fisher[1], Ivan Y. Lim[2], Jackie Blank[3] and Daniel Rourke[4], [1]Mid-Atlantic Permanente Medical Group, Springfield, VA, [2]Mid-Atlantic Permanente Medical Group, Rockville, MD, [3]Kaiser Permanente, Rockville, MD, [4]Ars Analytica, Rockville, MD

Purpose: It is known that the risk of pneumonia is approximately double in patients taking the biologic agents which are prescribed for rheumatic and other diseases. It would be helpful in clinical practice to be able to predict if certain subgroups are at particular risk when being given drugs that are often prescribed electively. Using a retrospective review of our electronic medical record, we undertook to determine whether that risk might be particularly high in smokers or former smokers.

Methods: The Mid Atlantic States region of Kaiser Permanente provides health care for approximately 500,000 people. All patients age 18 or older were identified who had received prescriptions for non-cancer indications through our pharmacies of etanercept, adalimumab or anakinra or who had received infusions in one of our centers of infliximab, abatacept or rituximab. The electronic data base provided us with smoking status, age, gender, co-morbidities (asthma, COPD, CAD, CHF, DM) and the diagnosis of pneumonia. Chart reviews were performed when necessary to clarify the smoking history and on all cases of pneumonia to confirm the diagnosis and recent use of biologic agents.

Results: 993 patients were prescribed one of the above medications from 2001–2008; 52 of those patients (5.2%) were treated for pneumonia. The rate of pneumonia is significantly higher in female former smokers (13.6%) compared to all nonsmokers (4.5%, $p<0.001$) and to all current smokers (4.2%, $p=0.004$) but not compared to male former smokers (7.5%, $p=0.208$). The pneumonia rate for all who ever (current and former) smoked (7.8%) is significantly larger than all nonsmokers (4.5%, $p=0.035$). In addition, the pneumonia rate was significantly higher with increasing age ($p=0.0014$). No relationship was found between co-morbidities and the risk of pneumonia.

Smoking	***Number of Patients and Percent by Sex***			***Mean Age***			***Number and Percent with Pneumonia***		
Status	*Males*	*Females*	***Total***	*Males*	*Females*	***Total***	*Males*	*Females*	***Total***
Current	65 (21%)	103 (15%)	168 (17%)	42.8	49.4	46.9	2 (3.1%)	5 (4.9%)	7 (4.2%)
Former	67 (21%)	110 (16%)	177 (18%)	57.4	56.4	56.8	5 (7.5%)	15 (13.6%)	20 (11.3%)
Never	149 (48%)	410 (60%)	559 (56%)	47.6	50.8	49.9	7 (4.7%)	18 (4.4%)	25 (4.5%)
Unknown	32 (10%)	57 (8%)	89 (9%)	46.0	46.5	46.3	0 (0.0%)	0 (0.0%)	0 (0.0%)
Total	313 (100%)	680 (100%)	993(100%)	48.5	51.1	50.3	14 (4.5%)	38 (5.6%)	52 (5.2%)

Conclusion: Smoking status has an effect on the risk of pneumonia in patients given biologic agents, with female former smokers being at highest risk. In addition, the risk of pneumonia increases with age

Effect of Adherence to the EULAR 2007 Guidelines On Early Arthritis Outcome. Data From the ESPOIR Cohort. Cécile Escalas[1], Marie Dalichampt[2], Bernard Combe[3], Bruno Fautrel[4], F. Guillemin[5], Maxime Dougados[1] and Philippe Ravaud[2], [1]University of Paris V, Cochin Hospital, Paris, France, [2]University of Paris VII, Bichat Hospital, Paris, France, [3]University I of Montpellier, Lapeyronie Hospital, Montpellier, France, [4]University of Paris VI, Pitie Salpetriere Hospital, Paris, France, [5]Nancy-University EA 4003, Nancy, France

Purpose: EULAR 2007 guidelines for management of early arthritis highlight the interest of early DMARD (*e.g*. Methotrexate) initiation and adjustment of therapy in cases of persistent active disease (1). The objective of the study was to assess whether adherence to such guidelines reduces radiographic progression and disability.

Method: *EULAR guidelines adherence* was defined by the 3 following recommendations: 1/ initiation of a DMARD in case of risk of developing persistent or erosive arthritis; 2/ Methotrexate as the DMARD of choice; 3/ remission as the only acceptable goal. *ESPOIR cohort*: Multicenter French prospective cohort of early arthritis, DMARD naïve, of less than 6 months duration, recruited from 2003 to 2005. Disease activity, functional impairment and treatment details were prospectively and systematically collected at baseline and after 6,12,18 and 24 months of follow up at each investigating centre. The reading of the baseline and one year X-rays was performed by one central reader. *Outcome measures*: Radiographic progression defined as the occurrence of at least one new erosion between baseline and year 1 and disability defined as a HAQ score ≥1 at year 2. *Statistical analysis*: Elaboration of a propensity score adjusted on baseline characteristics to model the probability of being treated in accordance with recommendations and analysis using multivariate regressions with the propensity score to assess the impact of guideline adherence on outcomes.

Results: Of the 813 enrolled patients, adherence to EULAR guidelines was observed in 178 (21%). After adjustment for propensity score, centre and confounding factors, risks of radiographic progression (one additional radiological erosion) at year 1 and of functional impairment (HAQ ≥1) at year 2 increased in patients not treated in accordance with the guidelines with OR: 2.04 [95% CI: 1.09 – 3.80] and OR: 2.12 [95% CI: 1.05 – 4.29], respectively.

Conclusion: This study demonstrates the clinical and radiological benefit for patients with early arthritis to be monitored and treated in accordance with the EULAR guidelines.

Sequential Pharmacoeconomic Model of Biologic Strategies for Rheumatoid Arthritis in Sweden Based On Disease Activity. Carl Turesson[1], Annika Teleman[2], Ann Bengtsson[3], Karin Sennfält[4], Danielle Dupont[5] and Ariel Beresniak[6], [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Spenshult, Oskarshamn, Sweden, [3]Linköping University Hospital, Linköping, Sweden, [4]Bristol-Myers Squibb, Bromma, Sweden, [5]Bristol-Myers Squibb, Braine-l'Alleud, Belgium, [6]Data Mining International, Geneva, Switzerland

Purpose: Treatment of moderate to severe Rheumatoid Arthritis (RA) in Sweden includes the use of biologic therapies such as etanercept (ETA), adalimumab (ADA), infliximab (INF), abatacept (ABA) or rituximab (RTX) in various sequences. In absence of clinical trials comparing the efficacy of one biologic treatment sequence over another, simulation models can assess various treatment strategies.

Method: Four simulation models were developed to assess the cost-effectiveness of treatment strategies composed of successive biologic agents over 2 years in patients with an insufficient response (IR) to 1 anti-TNF agent, namely: A) ETA-ABA-ADA, B) INF-ABA-ADA, C) ETA-RTX-ADA, D) INF-RTX-ADA. At the end of each 6-month period, the treatment was maintained in case of good response (LDAS or remission) or switched in case of an IR. The cost-effectiveness was reported as cost per day in Remission State (RS) (strategy A+C) or in Low Disease Activity State (LDAS) (strategy A-D). Data sources included published clinical efficacy data, expert opinion on medical practice and official reimbursement tariffs in Sweden. A probabilistic sensitivity analysis was performed computing all possibilities of distribution parameters.

Results: 6-month medical costs (excluding biologic costs) were estimated at 20’530 SEK (SD 5,773) for patients achieving RS, 22,978 SEK (SD 5,848) for patients achieving LDAS and 51,825 SEK (SD 12,621) for patients in moderate to high disease activity. Over 2 years, strategy A appeared significantly ($p<0.01$) more efficacious over 2 years (102 days in LDAS, 52 days in RS) compared to strategy C (82 days in LDAS, 32 days in RS). Cost-effectiveness ratios showed significantly lower costs ($p<0.01$) per day in LDAS or RS in strategy A (4’271SEK/day in LDAS, 8,324 SEK/day in RS) compared to strategy C (4’977 SEK/day in LDAS, 12,541 SEK/day in RS). Strategy B appeared significantly ($p<0.01$) more efficacious over 2 years (102 days in LDAS) compared to strategy D (82 days in LDAS). Cost-

effectiveness ratios showed significantly lower costs ($p<0.01$) per day in LDAS in strategy B (4’289 SEK/day in LDAS) compared to strategy D (4’999 SEK/day in LDAS).

Conclusion: Medical costs for RA patients in LDAS or RS appear to be 50% lower than patients with moderate to high disease activity levels, suggesting that efficacious treatment strategies contribute to reducing medical costs and use of health care services. Considering both costs and effectiveness over 2 years, these results suggest that strategies including ABA after an insufficient response to one anti-TNF agent appear more efficacious and cost-effective than similar strategies with RTX.

Determinants of TNF Switching in Patients with Rheumatoid Arthritis (RA). J. R. Curtis[1], A. John[2] and O. Baser[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Roche, Nutley, NJ, [3]University of Michigan Health Systems, Ann Arbor, MI

Purpose: Switching among tumor necrosis factor-α inhibitor (TNFi) agents or to another biologic is relatively common, but determinants of choice of drug and drug sequence are largely unknown. In a number of pts, switching from 1 TNFi to another TNFi is not always effective; thus, switching to a different mechanism of action may help optimize treatment for these pts. Among individuals switching from their first TNFi, we identified factors associated with the time to first switch and the choice of dose escalation or switching to a second TNFi or a non-TNFi biologic agent in a retrospective analysis of medical and pharmacy claims and eligibility data.

Method: Eligible pts were ≥18 y of age, were diagnosed with RA (2 diagnoses ≥2 mo apart) from Jan. 2003–March 2008, had initiated a new TNFi prescription after a 6-mo biologic-free period, and had at least 6 mo of continuous enrollment. Kaplan-Meier (KM) analysis and Cox regression were used to analyze time to first switch. Among RA pts who changed biologic therapy, pts were considered as (1) switching to another TNFi; (2) switching to a biologic other than TNFi; or (3) escalating dose (only for adalimumab [ADB] or infliximab [IFX]). Multinomial logistic regression was used to determine factors affecting switching and dose escalation.

Results: A total of 11,903 (6.9%) of 173,533 RA pts were identified as changing biologic therapy after a median (interquartile range [IQ]) treatment duration of 231 (161, 362) days. KM analysis showed time to change in therapy was shorter for pts initially started on IFX compared with etanercept (ETN) or ADB (log rank $p<0.001$). Even after adjustment for baseline differences, IFX and ADB users were more likely than ETN users to switch or escalate dose. Among pts who made a change, various patterns were to (1) a second TNFi (14%, n=1726) after a mean of 336 days; (2) a non-TNF biologic (2%, n=238) after a mean of 455 days; or (3) escalate dose (16%, n=1903) after a mean of 261 days. Comorbidity scores such as claims-based index for RA severity (CIRAS) and Elixhauser were higher for pts switching to another TNFi vs those switching to a non-TNFi, but individual comorbidities were similar across groups. Likelihood of switching to a biologic with a non-TNFi mechanism of action was increased by female sex and baseline use of cytotoxic agent (Table). Baseline use of methotrexate raised the likelihood of dose escalation (relative risk ratio, 1.58) while IV administration raised the likelihood of switching to a non-TNFi.

Conclusion: After initiating TNFi treatment, many RA pts failed to remain on therapy and escalated doses or switched to a second TNFi or another biologic within ~1 y. Factors influencing whether pts received a non-TNFi biologic included gender and use of certain agents at initiation of the TNFi. A limitation of this study was that pts with <6 mo of TNFi treatment were not included.

Table

Effect of first TNFi on time to switch or dose escalation (adjusted hazard ratio)	
Etanercept (referent)	1
Infliximab	6.29
Adalimumab	1.18
Risk of switching to another TNFi (relative risk ratio [IQ])	
Age	0.99 (0.984, 0.995)
Female sex	1.34 (1.184, 1.523)
Baseline use of corticosteroids	1.21 (1.06 , 1.365)
Baseline use of cytotoxic agent	1.40 (1.218, 1.613)
Risk of switching to a non-TNFi biologic (relative risk ratio [IQ])	
Age	1.00 (0.99, 1.02)
Female sex	1.40 (1.03, 1.919)
Baseline use of corticosteroids	1.46 (1.062, 2.00)
Baseline use of cytotoxic agent	1.22 (0.859, 1.73)

Differences in Biologic Patterns of Use Among Rheumatic Arthritis Patients Treated with or without Methotrexate. B. Tang[1], C.T. Carter[1], E. Buysman[2] and C.T. Piech[1], [1]Centocor Ortho Biotech Services, LLC, Horsham, PA, [2]i3 Innovus, Eden Prairie, MN

Purpose: To compare switching, discontinuation, and persistency among biologics used with and without methotrexate (MTX) in RA patients.

Methods: A retrospective claims data study between July 1, 2004 and December 30, 2008 was conducted. Adult patients (aged ≥ 18) with a diagnosis of RA (ICD-9=714.xx), with ≥ 1 claim for a biologic (abatacept, adalimumab, etanercept, or infliximab) were included. Due to the small sample size, rituximab was not included. Patients were required to have continuous enrollment for 24 months post-index and 6 months pre-index date, and patients who used any biologic in the 6 months prior to the index date were excluded. Switch was defined as a new biologic treatment identified during the post-index period. Discontinuation was defined as a gap of >60 days after the last date of supply of the index biologic agent. Patients with evidence of discontinuation prior to switching were defined as discontinuers. Persistence was defined as patients who continued to use their index biologic without discontinuation. Comparisons were made between 2 cohorts: patients with biologics combined with MTX (combination) or without MTX (monotherapy).

Results: Of 1,794 RA patients included in the study, the average age was 50.1 and 77.4% were female. Overall, 945 (52.7%) patients combined a biologic with MTX; 849 (47.3%) received monotherapy. Those receiving combination treatment had a higher switching rate (P= 0.031) compared with the monotherapy cohort, but patients in the combination group also had lower discontinuation and higher persistence rates, in addition to longer times to first switch and discontinuation (P<0.05).

	Monotherapy N=849	Combination N=945	p-value
1st Switch, N (%)	90 (10.6%)	132 (14.0%)	0.031
Time to medication switch	234.9	292.6	0.023
Discontinue, N (%)	549 (64.7%)	397 (42.0%)	<0.0001
Mean days to discontinuation	156.2	254.3	<0.0001
Persist, N (%)	210 (24.7%)	416 (44.0%)	<0.0001

Conclusion: RA patients who were treated with biologics combined with MTX had lower discontinuation rates and longer duration on therapy than patients who received monotherapy.

Efficacy of TNF Inhibitors in Rheumatoid Arthritis Patients with Anti-Ro/SS-A Antibody. Ran Matsudaira, Naoto Tamura, Fumio Sekiya, Michihiro Ogasawara and Yoshinari Takasaki, Juntendo University School of Medicine, Tokyo, Japan

Purpose: Anti-Ro/SS-A (Ro) antibody is frequently detected in rheumatoid arthritis (RA). The prevalence rate of anti-Ro antibody in RA is 3 to 15%, and patients with RA are often complicated with Sjögren's syndrome (SjS) that is thought to be one of clinical poor prognostic conditions of RA. To examine the relationship between anti-Ro antibody and the efficacy of tumor necrosis factor (TNF) inhibitors in patients with RA, we compared the clinical response to infliximab (IFX) or etanercept (ETN) between anti-Ro antibody positive and negative RA patients.

Method: Titers of anti-Ro antibody of sera from 156 patients with RA were measured using double immunodiffusion assay. Clinical response according to the disease activity score 28 (DAS28) EULAR response criteria at 12 to 14, 22 to 24 and 52 to 54 weeks was compared between anti-Ro antibody positive and negative groups. Factors for poor response to TNF inhibitors were estimated by univariate- and multivariate-logistic regression analysis.

Results: The patients treated with IFX and ETN (113 and 43, respectively) were examined. Anti-Ro antibody was detected in 26 of 156 patients (16.7%, IFX 16.8% and ETN 16.3%), and 17 patients were complicated with SjS. The percentage of moderate or more EULAR response at 12 to 14 weeks was not significantly different between anti-Ro antibody negative group and the positive group (86.6% and 73.7%, respectively, P =0.083). On the other hand, at 22 to 24 weeks, the moderate or more EULAR response was recognized in 104 of 127 patients (81.9%) in anti-Ro antibody negative group but only 16 of 26 patients (61.5%) in the positive group (P<0.03). The response rate at 52 to 54 weeks was also lower in anti-Ro positive group than that in negative group (53.8% and 77.7%, respectively, P<0.02). Moreover, TNF inhibitors were discontinued more frequently in anti-Ro antibody positive group compared with the negative group (46.2% and 26.6%, respectively, P<0.05) due to the lack of efficacy. When the response rate was compared between patients treated with IFX and ETN, it was significantly higher in IFX group than in ETN group regardless of the anti-Ro antibody (67.3% and 88.4%, respectively, p<0.008). The logistic regression analysis showed that anti-Ro antibody was an independent factor for poor response to the TNF inhibitors both in the univariate model (OR 3.18, 95%CI 1.32–7.66) and in the multivariate models (OR 5.50, 95%CI 1.39-21.75).

Conclusion: It was suggested that the presence of anti-Ro antibody might be related to the lack of clinical efficacy in patients with RA treated with TNF inhibitors, especially with IFX.

Real World Utilization of Nonbiologic and Biologic Disease Modifying Anti-Rheumatic Drugs in Rheumatoid Arthritis: A Systematic Review of the Literature. Zachary M. Pruhs and Leslie R. Harrold, Univ of Massachusetts Med Schl, Worcester, MA

Purpose: To date, no systematic review of the literature regarding real world use of disease modifying anti-rheumatic drugs (DMARDs) in rheumatoid arthritis (RA) has been performed. Our goals in undertaking this review include 1) provide a comprehensive summary of published studies on real world utilization of DMARDs in patients with RA and 2) identify gaps in our current knowledge regarding medication use patterns.

Methods: Employing the Cochrane Collaboration systematic review guidelines, we conducted a MEDLINE search from January 1, 1989 through March 17, 2009 for English language articles evaluating real world utilization of biologic and non-biologic DMARDs in RA. Search terms included the key words: (rheumatoid arthritis) and (abatacept, or adalimumab, or etanercept, or hydroxychloroquine, or infliximab, or methotrexate, or minocycline, or leflunomide, or rituximab, or sulfasalazine). Articles were then limited to medical subject headings (MeSH) including pharmacoepidemiology or drug utilization or drug therapy.

Results: Our search strategy yielded 1,376 articles, of which 42 articles met inclusion criteria. The included articles were grouped by primary focus into those examining prescribing patterns, persistence, dosing, and adherence. Most articles evaluated prescribing patterns (n=23) and/or medication persistence (n=23). Most studies examining prescribing patterns showed a trend towards earlier and more frequent use of both biologic and non-biologic (particularly methotrexate) DMARDs. However, those studies that focused on patients cared for by primary care providers found lower rates of DMARDs use (range of 13 to 63%). Additionally, very few studies evaluated appropriateness of medication use or the factors influencing use of medications. Studies examining persistence found it was greatest among methotrexate users as compared to other nonbiologic DMARDs. There was conflicting data regarding persistence among the different biologic agents. There were only 6 studies evaluating dosing and all but one were focused on infliximab. Only 3 studies examined adherence, 2 of which found adherence to infliximab superior to methotrexate and etanercept respectively.

Conclusion: Most of the current literature on real world utilization of DMARDs in the management of RA finds earlier and more aggressive use of nonbiologic and biologic agents as well as greater persistence among methotrexate users. Very few studies have examined medication adherence or dosing of DMARDs other than infliximab. Of concern is possible DMARD underutilization based on studies of RA patients cared for by primary care providers. More investigation examining whether there is appropriate use of medications is needed in order to ensure optimal quality of care.

1008

Bone Mineral Density in Patients with Recent Onset, Active Rheumatoid Arthritis: Two-Year Data of the NEO-RACo Study. Heikki Valleala[1], Hannu Kautiainen[2], Timo Möttönen[3], Pekka J. Hannonen[4], Markku Korpela[5], Oili Kaipiainen-Seppänen[6], Leena Paimela[7], Anna Karjalainen[8], Heikki Julkunen[1] and Marjatta Leirisalo-Repo[1], [1]Helsinki University Central Hospital, Helsinki, Finland, [2]Medcare Oy, Äänekoski, Finland, [3]Turku University Central Hospital, Turku, Finland, [4]Central Hospital, Jyvaskyla, [5]Tampere University Hospital, Tampere, Finland, [6]Kuopio University Hospital, Finland, [7]ORTON hospital, Helsinki, Finland, [8]Oulu University Central Hospital, Oulu, Finland

Purpose: We have previously reported that the intensive use of FIN-RACo strategy [initial combination of methotrexate (MTX), sulfasalazine (SSZ), hydroxychloroquine (HCQ) and prednisolone (PRED)] induced strict remission in 53% and sustained remission in 31% of patients with recent onset active rheumatoid arthritis (RA). Radiological progression was rare. Adding Infliximab (INFL) during the first 6 months reflected in higher frequencies of remissions over time and prevented radiological progression during 2 years. Here we report the effect of FIN-RACo strategy on bone mineral density (BMD) in the lumbar spine and the hip in the patients.

Method: In this multicenter (15 centres) trial, we enrolled 100 patients aged <65 y with early (symptoms ≤12 mo) active RA. FIN-RACo therapy targeted to remission was started in all patients. The patients were randomized in a double-blind way to receive INFL (3 mg/kg) or placebo (PLA) at weeks 4, 6, 10, 18 and 26. Doses of MTX (max 25 mg/week) and SSZ (max 2 g/day) were individually tailored, doses of HCQ (35 mg/kg/week) and PRED (7.5 mg/day) were constant. Local glucocorticoid injections were allowed. All patients received 1000 mg calcium and 800 IU vitamin D3 daily. BMD was measured by DEXA at entry and at two years.

Results:

Variable	FIN-RACo + PLA, n =31	FIN-RACo + INFL, n =32
Age (y)	45.8 ± 10.7	47.1± 7.8
Female / Male (n)	19 / 12	23 / 9
Symptom duration (mo)	3.8 ± 2.3	4.1 ± 2.7
DAS28	5.9 ± 1.2	5.5 ± 1.0
Lumbar spine T-score	-0.1 ± 1.6	-0.3 ± 1.2
Femoral neck T-score	-0.2 ± 1.0	-0.4 ± 0.8

Both baseline and 2 year BMD were available for 63 out of 100 patients. Baseline characteristics of these patients are presented above (Mean± SD). At baseline 3 patients in the FIN-RACo + PLA group and none in the FIN-RACo + INFL had T-score below - 2.5. During the 2 years BMD decreased significantly in both treatment groups. A mean (95% CI) change of lumbar spine T-score from 0 to 24 months was -0.2 (-0.4 to -0.1) in the FIN-RACo+PLA and -0.4 (-0.5 to -0.2) in FIN-RACo+INFL. For the femoral neck T-score the mean changes in the 2 groups were - 0.2 (-0.3 to -0.1) and -0.2 (-0.7 to - 0.1), respectively. At 2 years, 3 patients in the FIN-RAco + PLA group and 2 in the FIN-RACo + INFL had T-score below - 2.5. The BMD loss between the 2 groups was not significantly different.

Conclusion: 7.5 mg daily constant PRED led to significant BMD loss despite the marked decline in disease activity. Antiresorptive therapy with bisphosphonates for primary prevention of osteoporosis should be considered when starting long-term PRED ≥ 7.5 mg, daily in RA.

1009

Rheumatologists' Prescribing Patterns for Rheumatoid Arthritis Patients with Active Disease. Leslie R. Harrold[1], Jeffrey D. Greenberg[2], Jeffrey R. Curtis[3], Mary jane Bentley[1], George Reed[4] and J. Timothy Harrington[5], [1]Univ of Massachusetts Med Schl, Worcester, MA, [2]New York University School of Medicine, Millburn, NJ, [3]UAB, Birmingham, AL, [4]University of Massachusetts Medical School, Worcester, MA, [5]Univ of Wisconsin School of Medicine and Public Health, Madison, WI

Purpose: We examined the relationship between disease activity and provider prescribing practices prior to publication of the ACR treatment recommendations using a multi-centered observational registry within the United States (the Consortium of Rheumatology Researchers of North America: CORRONA).

Method: Patients with a diagnosis of rheumatoid arthritis (RA) who were biologic naïve, had a disease duration of <5 years and had ≥ 2 visits within 6 months prior to 6/15/08 were identified. Patients in remission and low disease activity based on the Clinical Disease Activity Index (CDAI) were excluded. Patients with a poor prognosis based on the ACR treatment recommendations (mHAQ >0.5, secondary Sjogren's syndrome, subcutaneous nodules, serologic positivity or bony erosions on radiographs) were identified. The population was divided into two cohorts. Cohort #1 comprised patients currently on methotrexate (MTX) monotherapy or who had used only MTX as a DMARD in the past. Cohort #2 was comprised of patients who were receiving or had received ≥ 2 nonbiologic DMARDs. Initiation of biologic DMARDs in response to disease activity (using the CDAI) was identified.

Results: There were 284 patients in Cohort #1 (Table 1). Among those with moderate disease activity with poor prognostic factors, only 9% received a biologic at the initial visit. In those with high disease activity, 8% received a biologic at the initial visit. Among those in cohort #1 (n=126) with no improvement in disease activity at a follow-up visit, at the conclusion of the 2nd visit a total of 12% were treated with biologics. There were 143 patients in cohort #2 (Table 1). Among those with moderate disease activity with poor prognostic factors, 5% were initiated on a biologic at the initial visit. In those with high disease activity with poor prognostic factors, 8% received a biologic at the

initial visit. Among those in Cohort #2 (n=61) with no improvement in disease activity at a follow-up visit, at the conclusion of the 2nd visit a total of 15% were treated with a biologic.

Table 1.

	Cohort #1 (Methotrexate Only)		**Cohort #2 (≥2 Nonbiologic DMARDs)**	
	Moderate disease activity* N=130	High disease activity N= 154	Moderate disease activity* N=81	High disease activity* N=62
Care consistent with ACR treatment recommendations				
Biologic initiated (N,%)	12 (9)	13(8)	4 (5)	5 (8)
Care not consistent with ACR treatment recommendations				
No DMARD therapy (N,%)	13 (10)	35 (23)	10 (12)	9 (15)
Nonbiologic DMARD therapy maintained (N,%)	99 (76)	105 (68)	67 (83)	47 (76)
A nonbiologic DMARD initiated (N,%)	6 (5)	1 (1)	0 (0)	3 (5)

*associated with poor prognostic factors

Conclusion: Prior to publication of the ACR treatment recommendations, most patients with active disease did not receive recommended therapy. Further exploration of the barriers to optimal medication use is necessary.

1010

In Early RA, Conventional DMARD or Anti-TNF Add-On to MTX Provides Stable Benefits From 12 to 24 Months of Follow-up: Two-Year Results of the SWEFOT Clinical Trial. Ronald F. van Vollenhoven[1], Sofia Ernestam[1], P. Geborek[2], Ingemar Petersson[3], Johan Bratt[4] and SWEFOT Study Group[5], [1]The Karolinska Institute, Stockholm, Sweden, [2]Lund University, Department of Clinical Sciences, Lund, Sweden, [3]Lund University, Department of Clinical Sciences, Lund, Lund, Sweden, [4]Karolinska Univ Hosp Huddinge, Stockholm, [5]Sweden

Purpose: To compare two therapeutic strategies in patients with early RA who after 3-4 months had failed to respond to MTX monotherapy.

Method: In an open, randomized, controlled trial, 487 patients with early RA (symptom duration <1 year) were started on MTX at up to 20 mg/week. After 3-4 months, the 258 patients who had not achieved DAS28≤3.2 (but who could tolerate MTX) were randomized. In arm A (n=130) sulfasalazine (SSZ) 1000 mg BID and hydroxychloroquine (HCQ) 400 mg qD were added. In arm B (n=128), infliximab (INF) was added at 3 mg/kg/infusion, rounded upward to the nearest 100 mg, given at 0, 2, 6 weeks and then q 8 weeks. DMARD dosages could be adjusted for intolerance, and INF infusion frequency but not dosage could be increased based on the response. Moreover, a single switch within each strategy was allowed for intolerance only: SSZ+HCQ could be replaced by cyclosporine A (2.5-5.0 mg/kg as BID dosing), and INF could be replaced by etanercept 50 mg weekly. The primary result, the Eular good response at 12 months based on intention-to-treat (ITT) for all randomized patients has been presented previously and showed arm B to be superior to arm A (39% vs. 25%, p<0.02).

Results: At 24 months of follow-up, 74/130 (57%) patients in arm A and 90/128 (70%) patients in arm B were still on treatment per protocol (p<0.05), the difference being accounted for by drop-outs due to loss of efficacy. In arm A, 43 patients (33%) achieved EULAR good response versus 55 (43%) in arm B (NS). EULAR good/moderate response percentages were 44% in arm A and 55% in arm B (p 0.08). In

arm A, 40 (31%) patients were in remission at 2 years, versus 43 (34%) in arm B (NS). The percentages of patients achieving good responses and favorable disease states were only marginally better at 24 compared to at 12 months.

Conclusion: In patients with early RA who after 3-4 months on MTX do not achieve a DAS28 ≤ 3.2, the addition of INF yields significantly better clinical results at 12 months, and has better survival-on-drug over 24 months than the addition of SSZ+HCQ. However, continuing either treatment from 12 to 24 months provides no meaningful additional benefit, supporting the view that frequent therapy changes are necessary to improve long-term outcomes.

Traditional Cardiovascular Risk Factors in Early Untreated Arthritis Patients From the ESPOIR Cohort: Prevalence and Impact of Inflammation. Jean Frederic Boyer[1], Vanina Bongard[2], Alain Cantagrel[3], Benedicte Jamard[3], Jean Pierre Daures[4], Xavier Mariette[5], Jean Ferrieres[2], Jean Bernard Ruidavets[2] and Arnaud Constantin[2], [1]JE2510, Toulouse, France, [2]INSERM U558, Toulouse, France, [3]Purpan Teaching Hospital, Toulouse, France, [4]Epidemiology unit, Montpellier, France, [5]Bicetre Hospital/Paris Univ, Le Kremlin Bicetre, France

Purpose: The present study was conducted to assess the prevalence of traditional CV risk factors in an early arthritis cohort and to investigate the impact of early inflammatory state on lipid levels.

Method: Untreated early arthritis (EA) patients, aged 30 to 65 years, were selected from the French ESPOIR cohort study. Age- and sex-matched healthy controls from three different French regions were randomly selected in the framework of the MONICA population survey. Traditional CV risk factors (lipid levels, blood pressure [BP], fasting glycaemia and smoking) were recorded according to standard guidelines. Student's t-test or chi-square test was used for comparisons. Spearman's rho was used for measures of correlation.

Results: 609 EA patients (51.1 years, 76% females) and 1827 age- and sex-matched controls were studied (see Table). Total cholesterol was lower in EA patients than in controls (2.07 vs 2.28 g/l; P<0.0001), mainly resulting from a decrease in LDL cholesterol (1.23 vs 1.47 g/l; P<0.0001) and slightly from a non significant decrease in HDL cholesterol (0.59 vs 0.61; P=0.092). Total, LDL and HDL cholesterol were negatively correlated with CRP level in EA patients (-0.25; P<0.0001; -0.14; P=0.01 and -0.28; P<0.0001, respectively). Systolic BP slightly differed between EA patients and controls (129.2 vs 131.0 mmHg; P=0.042), while diastolic BP was lower in EA patients (77.3 vs 81.3 mmHg; P<0.0001). Fasting glycaemia was lower in EA patients than in controls (0.93 vs 0.99 g/l; P<0.0001). Current smoking was more prevalent in EA patients (21.0 vs 16.7 %; P=0.017). Similar results were observed when analysis was restricted to RA patients fulfilling the 1987 ACR criteria (see Table) and after adjustment on body mass index (data not shown).

Conclusion: This case-control study, focused on early untreated arthritis patients, emphasizes a specific lipid profile, which is associated with early inflammatory state and correlated with inflammation level, but not restricted to RA patients. Significant decreases in diastolic BP and fasting glycaemia appear as additional characteristics of early inflammatory state.

	EA patients	RA patients	Controls	P-value	P-value
	N=609 [1]	N=400 [2]	N=1827 [3]	[1] vs [3]	[2] vs [3]
Systolic BP [mmHg] mean (SD)	129.2 (16.1)	129.3 (16.9)	131.0 (19.6)	0.042	0.111
Diastolic BP [mmHg]	77.3 (11.0)	77.0 (10.6)	81.3 (11.6)	<0.0001	<0.0001
Total cholesterol [g/L]	2.07 (0.40)	2.08 (0.41)	2.28 (0.42)	<0.0001	<0.0001
HDL cholesterol [g/L]	0.59 (0.19)	0.60 (0.20)	0.61 (0.18)	0.092	0.481
LDL cholesterol [g/L]	1.23 (0.34)	1.22 (0.34)	1.47 (0.39)	<0.0001	<0.0001

1012

Historical Trends of Patient Characteristics in Anti-TNF Clinical Trials for Rheumatoid Arthritis: An Analysis of the Literature Over the Past 16 Years. J. Buchanan[1], M. U. Rahman[2], M. K. Doyle[2], E. C. Hsia[2], T. Gathany[3], S. Parasuraman, D. Aletaha[4], E. L. Matteson[5], Désirée M.F.M. van der Heijde[6] and J. S. Smolen[4], [1]Malvern, PA, [2]Centocor R&D, Inc/U of Penn School of Med, Malvern, PA, [3]Johnson and Johnson Pharmaceutical Services, LLC, Malvern, PA, [4]Medical University Vienna and Hietzing Hospital, Vienna, Austria, [5]Mayo Clinic, Rochester, MN, [6]Leiden University Medical Center, Leiden, Netherlands

Purpose: To evaluate how the clinical characteristics of patients enrolled in (anti-TNF) trials for rheumatoid arthritis (RA) have changed since the development of the first anti-TNF compound.

Methods: A systematic literature review was performed using predefined inclusion criteria to identify randomized, double-blind, controlled trials that compared etanercept, adalimumab, golimumab, infliximab, or certolizumab with any other agent in adult RA patients. Study entry criteria and baseline clinical characteristics were evaluated over time for disease modifying antirheumatic drug (DMARD)-experienced (including MTX) and MTX-naïve study populations. Enrollment start date for each trial was used as the time metric. The anchor time was the study with the earliest identifiable enrollment start date.

Results: 88 studies met the inclusion criteria. Of these, 44 primary publications (those reporting the primary study endpoint) were identified for certolizumab (4); etanercept (17); adalimumab (8); infliximab (10) and golimumab (5). Enrollment start dates for Elliott 1994 (Aug-1993) and Bathon 2000 (May-1997) were identified as the time anchors for the 37 studies in DMARD-experienced patients and the 7 studies for MTX-naïve patients, respectively. Not all publications reported all clinical variables. For DMARD-experienced trials, the inclusion criteria for swollen joint count (SJC) and tender joint count (TJC) ranged from a high of ≥10 and ≥12 to a low of ≥4 and ≥4, respectively, over the past 16 years; although, the slope of this decline was not statistically significant (SJC, p = 0.442; TJC, p=0.392). Trials with SJC inclusion criteria of ≥10, ≥6 and ≥4 enrolled patients with mean baseline SJCs of 21.7, 18.2 and 16.2 respectively. The mean number of swollen joints at baseline decreased over time (p=0.059). Sixteen DMARD-experienced trials and 5 DMARD-naive trials included minimum CRP levels in the inclusion criteria. These criteria have not changed over time, with trials using ≥2 mg/dl or ≥1.5 mg/dl (p=0.346). Despite this, baseline CRP values have declined significantly over time (p=0.027). For MTX-naïve trials, SJC and TJC inclusion criteria ranged from ≥10 and ≥12, respectively, in the earliest trials to ≥4 and ≥4, respectively, in the most recent trial (SJC, p=0.0187; TJC, p=0.023). Over time, mean number of swollen joints decreased (p=0.055, R^2=0.6436).

Conclusion: Over the past 16 years, inclusion criteria and baseline characteristics of RA patients in studies of anti-TNF agents have changed, with more recent trials enrolling cohorts with lower disease activity as assessed by joint examination and inflammatory markers.

Ability to Regain Normal Function in Moderate Vs. Severe Rheumatoid Arthritis: Analysis From Long-Standing and Early RA Patient Populations. Ronald van Vollenhoven[1], Mary Cifaldi[2], Sanjoy Roy[2], Naijun Chen[2], L. Gotlieb[3] and Michel Malaise[4], [1]Karolinska University Hospital and Karolinska Institute, Stockholm, Sweden, [2]Abbott Laboratories, Abbott Park, IL, [3]Abbott Immunology, Louvain-la-Neuve, Belgium, [4]University Hospital Liège, Liège, Belgium

Purpose: Some studies suggest a window of opportunity for the treatment of rheumatoid arthritis (RA) to regain normal physical functioning.[1] The relationship between RA disease severity and ability to regain normal function during treatment has not yet been studied. We evaluated the effect of combination therapy with adalimumab and methotrexate (ADA+MTX) on physical function of patients who have moderate or severe disease and either early or long-standing disease.

Methods: Observed data were analyzed from patients who received combination treatment with ADA+MTX in 2 long-term clinical trials: DE019 (5 years of treatment for long-standing RA) and PREMIER (2 years of treatment for early RA). Patients were categorized by baseline disease activity as either moderate (3.2<28-joint Disease Activity Score [DAS28]≤5.1) or severe (DAS28>5.1). Mean Health Assessment Questionnaire (HAQ) scores for each group of patients were calculated at baseline, 6 months, 1 year, and 2–5 years. Improvements in physical function were evaluated through 2 different standards: HAQ≤0.49 for the normal population and HAQ≤1.2 for the RA population.

Results: In the long-standing RA population (DE019), patients with moderate disease achieved a 59% reduction of HAQ to a mean of 0.45, which was within the range for the normal population; this improvement was maintained over the 5-year study period. Patients with severe disease improved 43% to a mean of 0.88, which was within the range of normal functioning for RA patients but not for the normal population. By 1 year, >60% of patients with moderate disease but only 34% of patients with severe disease achieved normal population HAQ scores; this difference was maintained over 5 years. In the early RA population (PREMIER), patients with both moderate and severe disease at baseline regained physical functioning to within the range of the normal population at 1 year; patients with moderate disease had a 73% reduction in HAQ to a mean of 0.25, and patients with severe disease had a 71% reduction in HAQ to a mean of 0.44. At 1 year, 70% of patients in the moderate group and 61% of patients in the severe group reached normal functioning.

Conclusion: In both early and long-standing RA, patients with moderate disease who receive combination therapy have a great likelihood of achieving normal physical function. In contrast, for patients with severe disease, the efficacy of combination therapy is greater in the early RA group, suggesting that a window of opportunity for preventing irreversible functional loss exists in patients with highly active disease.

1014

Regained Remission Following Restart of Treatment After Loss of Drug-Free Remission in Patients with Recent Onset Rheumatoid Arthritis. N.B. Klarenbeek[1], S.M. van der Kooij[1], M. Güler-Yüksel[1], J.H.L.M. van Groenendael[2], K.H. Han[3], P.J.S.M. Kerstens[4], T.W.J. Huizinga[1], B. A. C. Dijkmans[5] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]Franciscus Hospital, Roosendaal, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]JBI, Amsterdam, Netherlands, [5]VUMC, Amsterdam, Netherlands

Purpose: To determine the severity and duration of an increase in disease activity in patients who have to restart treatment following a period of drug-free remission.

Methods: In the BeSt study, 508 recent onset RA-patients were randomized into 4 treatment strategies: 1. sequential monotherapy, 2. step-up combination therapy, 3. initial combination with prednisone, 4. initial combination with infliximab. Treatment adjustments were made based on threemonthly DAS measurements aiming at low disease activity (DAS ≤2.4). If DAS was ≤2.4 for ≥6 months medication was tapered to a maintenance dose. After 2 years, when DAS was <1.6 for ≥6 months on a maintenance dose the last DMARD was tapered and discontinued. If DAS increased to ≥1.6 the last DMARD was immediately reintroduced.

Results: During 5 years follow-up, 115 / 508 patients (23%) achieved drug-free remission. Of those 115 patients, 53 (46%) restarted treatment because of a DAS ≥1.6, after a median period of 5 months, 59 (51%) remained in drug-free remission (median duration 23 months), and 3 (3%) were lost to follow-up. Sixty percent of restarters were positive for both ACPA and RF, which was found to be a risk factor for loss of drug-free remission (OR 6.0, $p<0.001$). At restart of the DMARD monotherapy, mean DAS was 2.2 (increased from mean DAS 1.1). Mean increase in ESR was 9 mm/hour. Swollen joint count, tender joint count and VAS general health increased (medians) 2, 2, and 15 mm respectively. Of the 53 restarters, 25 (47%) again achieved clinical remission 3 months later and another 14 (26%) 6 months later. Eleven patients (21%) achieved a DAS ≤2.4, one patient (2%) did not achieve a DAS ≤2.4, and 2 patients (4%) were lost to follow-up. The median (mean) damage progression in the restarters during the year of DAS increase was 0 (0.61) units using the Sharp-van der Heijde score.

Conclusion: During 5 years DAS steered treatment, nearly ¼ of patients achieved drug-free remission. Forty-six percent of them had to restart DMARD monotherapy after an increase in disease activity ≥1.6. The majority of those patients again achieve clinical remission within 3 to 6 months and show no radiological progression.

1015

Real or Perceived Conflicts of Interest in Comparative Effectiveness Research. Gabriela Schmajuk[1] and Eswar Krishnan[2], [1]Stanford University, San Francisco, CA, [2]Stanford University School of Medicine, Palo Alto, CA

Purpose: Comparative effectiveness research (CER) is at the center of early healthcare reform proposed by the Obama administration. Most CER, and specifically cost-effectiveness (CE) research, is based on systematic reviews of existing literature. Consequently, the value of CER depends on the quality and objectivity of the individual studies included in such systematic reviews. This is an especially important issue in the evaluation of high-cost treatments such as the disease modifying anti-rheumatic drugs (DMARDs) used in rheumatoid arthritis, psoriasis, or inflammatory bowel diseases. In this study, we tested the hypothesis that there exists no relationship between study sponsorship and study conclusion among studies of CE of DMARDs.

Methods: We performed a systematic review of CE studies of proprietary DMARDs in English from January 1998 to December 2008. Terms used were: cost-benefit analysis AND (infliximab OR adalimumab OR etanercept OR leflunomide OR rituximab OR abatacept) AND (rheumatoid arthritis OR psoriasis OR inflammatory bowel disease). A study was included if its title or abstract described it as an analysis of CE for at least one of the drugs listed above and it contained a statement of the estimated CE of that drug within the abstract or discussion. Reviews, commentaries, letters, editorials, abstracts, and case studies were excluded. Favorable CE was defined as a value of less than 50,000 USD per quality-adjusted life year, if this was provided.

Results: Eighty five citations were retrieved from the MEDLINE search. Of these, 31 met both inclusion and exclusion criteria. Two additional articles were identified from review articles and references lists, so 33 studies were included in the analysis (see Table 1). CE studies commonly relied on pivotal regulatory trials which were designed to show the drug in best possible light. Pharmaceutical sponsorship was disclosed in 18 (55%) out of 33 included studies. Three studies had authors who were found to have undeclared affiliations with pharmaceutical companies. Studies sponsored by the manufacturers of the studied drug were more than twice as likely to report a favorable CE ratio compared with unsponsored studies (71% vs. 33%, Fisher's exact p=0.06).

Conclusion: Health policy decisions informed by CER that is based on published health-economics studies may be flawed.

Physician-Patient Communication about Rheumatoid Arthritis and Biologic Therapy: Results of An in-Office Linguistic Study. Meaghan Onofrey[1], Atul A. Deodhar[2], J. Eugene Huffstutter[3], Richard W. Martin[4] and Corey Eagan[1], [1]MBS/Vox, CommonHealth, Parsippany, NJ, [2]Oregon Health & Science University, Portland, OR, [3]Arthritis Associates PLLC, Hixson, TN, [4]Michigan State University College of Human Medicine, Grand Rapids, MI

Purpose: Effective rheumatoid arthritis (RA) management is multifactorial, depending on accurate physical examination, laboratory studies, and provider-patient communication. To evaluate current discussions of RA and its treatment, an observational study was conducted using accepted sociolinguistic methodologies.

Method: 696 community-based rheumatologists were sent invitation letters; the first 16 to respond and meet screening criteria were enrolled in the sample. Regularly scheduled visits with patients likely to discuss biologic therapy were recorded without a researcher present. Separate patient and physician post-visit interviews were recorded and demographic questionnaires completed. Recordings were transcribed and analyzed. Analyses included: quantification of topics discussed and time spent on each; quantification and qualification of questions asked and answered; identification of requests for information or making of recommendations; classification of linguistic markers demonstrating level of knowledge.

Results: 45 physician-patient interactions were analyzed. Physicians were 81% male; patients were 71% female, had a mean age 58 (13.7 SD) and a mean duration of RA 11 (10.6 SD). Mean duration of visits was 11.4 minutes (range 2.6-49.0). 87% of patients report using "outside sources" for information about RA, most often "the internet." However, physicians controlled visits, speaking about 1.5 times as many words as patients and driving the majority of treatment decisions. Patients used a variety of linguistic techniques to downplay their symptoms, including hedging, diminutives, negation, and depersonalization. Post-visit, about a third of patients admitted minimizing symptoms; some reported not wanting to be perceived as "complainers." Post-visit, 75% of physicians and patients disagreed about disease severity, possibly due in part to the minimization of symptoms in visits. Benchmarking of progress was idiosyncratic. Validated tools to assess patient progress were not used in any visits. Discussions of progress most often focused on activities and pain relief. 95% of visits contained confirmation of medication inventory; potential barriers to adherence were discussed in 75% of visits. The most often discussed barrier was side effects. Problem-solving took place in 60% of visits in which barriers were discussed.

Conclusion: In-office dialogue is marked by physician-directed discussions of RA and patient minimization of symptoms, which may lead to post-visit disagreement about disease severity. Expanded use of health status instruments as advocated by ACR quality standards may reduce this. Attempts to allow the patient to set the dialogue agenda may increase accurate reporting and lead to more effective partnership in decision making.

Safety of ANTI-Tnfα Blockers In HBcAb-Positive Patients. Francesca Bobbio-Pallavicini[1], Marta Caprioli[1], Roberto Caporali[1], Fabiola Atzeni[2], Donatella Ventura[2], Piercarlo Sarzi-Puttini[2] and C. Montecucco[1], [1]Chair and Division of Rheumatology, Policlinico San Matteo, Pavia, Italy, [2]L. Sacco University Hospital, Milano, Italy

Purpose: It is well known that therapy with anti tumor necrosis factor α(TNF α) blockers can be associated with an increased rate of serious infections. In oncology, reactivation of hepatitis B virus (HBV) replication during immunosuppressive therapy can occur in up to 50% of hepatitis B surface antigen (HBsAg) positive patients with a mortality of 5%-12% . Recently, cases of HBV reactivation have been described in infliximab-treated Chron's disease both in HBsAg positive patients and in HBsAg negative/ hepatitis B core antibody (HBcAb) positive patients. The safety of anti TNF α therapy in rheumatic diseases with chronic HBV infection is still a matter of debate. The aim of this study is to assess the safety of anti TNF α therapy on the course of HBV infection in HBcAb positive patients with inflammatory arthropathies.

Method: From January 2001 to December 2008, serological HBV-markers were done before the first administration of anti TNFα agents in 306 consecutive patients affected by inflammatory arthropathies treated with anti TNF α at two outpatient rheumatologic clinics in Northern Italy. Patients were prospectively evaluated and HBV markers and HBV DNA were done in case of transaminases elevation or at the end of the study. HBV-markers were identified using the following techniques: HBsAg, antibodies to hepatitis B surface antigen (anti-HBs), antibodies to hepatitis B core protein (anti-HBc), hepatitis B e antigen (HBeAg), antibodies to HBeAg (anti-HBe), were detected by the Axsym Abbott, and HBV-DNA by real time PCR technique (<100 copies/ml). Liver function tests and disease activity scores were determined every eight weeks.

Results: At the time of recruitment 69 patients were HBcAb positive; 2 were HBsAg positive and were treated with lamivudine (not included in the study); 2 had HCV co-infection. The male/female ratio of the 67 patients was 26:41, 59 patients were affected by rheumatoid arthritis (RA), 4 psoriatic arthritis (PsA) and 4 ankylosing spondylitis (AS). The mean follow-up was 42.55 months (SD ±21.33). The mean Disease Activity Score 28 was 5.65 (SD ± 0.96) in RA, while the mean BASDAI was 4.31 (SD ± 2.45), in PsA and AS. Out of 67 patients, 25 were treated with infliximab, 23 with etanercept and 19 with adalimumab. 51/67 patients were also treated with methotrexate, 52 with NSAIDs, and 43 with low-dose oral prednisone, 3 of them with a dose >7.5 mg/day. All HBcAb positive patients were HBV-DNA negative at the first observation. During the follow-up 1 patient presented HCV reactivation while no patients presented HBV reactivation; no patients became HBsAg positive one patient died for myocardial infarction. In two patients HBcAb positivity was not confirmed at the end of follow-up.

Conclusion: In our study, anti TNF α therapy in HBcAb-positive patients, did not induce viral reactivation of HBV infection. These preliminary data require a confirmation in further studies on larger cohorts.

Moderate Response to Biologic Treatment After 3 Months May Predict Good Response and Low Disease Activity State in Rheumatoid Arthritis After 6 Months. Till Uhlig[1], Elisabeth Lie[1], Marte S. Heiberg[1], Erik Rødevand[2], Cecilie Kaufmann[3], W. Koldingsnes[4], Knut Mikkelsen[5] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]St Olavs Hospital, Trondheim, Norway, [3]Buskerud Central Hospital, Norway, [4]University Hospital of Northern Norway, Tromsø, Norway, [5]Lillehammer Hospital for Rheumatic Diseases, Norway

Purpose: When prescribing biological medication for RA, rheumatologists are often advised to evaluate effectiveness of the biologic drug after 3 months treatment, in order to achieve rational use of these drugs. We determined in patients treated with a biologic for at least 6 months how response to drug treatment after 3 months could help to predict 6 month outcome as measured by response in disease activity (DAS28) and disease activity state.

Methods: Data were extracted from NOR-DMARD which is an observational study conducted in 5 Norwegian rheumatology departments. Adult patients with inflammatory arthropathies are consecutively included when they start a new DMARD regimen, and they are assessed after 3 and 6 months with core measures of disease activity and health status. In these particular analyses we focused on patients with RA starting with any biologic which who were evaluated at 3 and 6 months follow-up (n=876). Biologics included etanercept (41%), adalimumab (29%), infliximab (23%), rituximab (6%), abatacept (1%). Mean (SD) age was 52.4 (13.1) yrs, 74.9% were females, and mean disease duration was 11.1 (9.2) yrs. DAS28 was calculated based on ESR. We cross-tabulated low, moderate and good response (ΔDAS28 <0.6, 0.6-1.2, and ≥1.2) after 3 months against good response and achieved state of low disease activity (DAS28≤3.2) at 6 months and applied also logistic regression analyses. **Results:** were expressed as odds ratio (OR) with 95% confidence intervals (CI).

Results: No response (ΔDAS28 <0.6) after 3 months of therapy was seen in 27%, moderate response (ΔDAS28 0.6-1.2) in 18%, and good response (ΔDAS28 >1.2) in 55%. Of the patients with no response at 3 months 18% had moderate and 24% good response at 6 months, and of those with moderate 3-months response 51% achieved good response at 6 months. 89% of patients with good response at 3 months had also maintained good response at 6 months.

At 6 months 38% of all patients were at a state of remission or low disease activity (DAS28≤3.2).

Adjusting for age, sex and baseline disease activity, patients with a good response at 3 months had a 9-fold increase in odds for achieving low disease activity state at 6 months vs. patients with no response (OR 9.4, CI 5.3 - 16.6), but also those with moderate response at 3 months had increased odds for achieving low disease activity state (OR 2.5, CI 1.3-4.6) at 6 months. In similar analyses good response at 6 months (ΔDAS28 >1.2) was predicted by good response at 3 months (OR 23.0, CI 13.5 - 39.1) but also by only moderate response at 3 months (OR 3.1 CI 1.8 - 5.4).

Conclusion: Patients with only moderate response during treatment with a biologic drug after 3 months may achieve good response or a state of low disease activity after 6 months. These data support that in real life treatment decisions for patients on biologic treatment should be individualized, and treatment should not be stopped if patients fail to have good response after three months.

Clinical and Radiological Outcomes of Four DAS Driven Treatment Strategies: Six-Year Results of the BeSt Study. N.B. Klarenbeek[1], L. Dirven[1], M. Güler-Yüksel[1], A.H. Gerards[2], P.J.S.M. Kerstens[3], T.H.E. Molenaar[4], T.W.J. Huizinga[1], B. A. C. Dijkmans[5] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]Vlietland Hospital, Schiedam, Netherlands, [3]JBI, Amsterdam, Netherlands, [4]Groene Hart Hospital, Gouda, Netherlands, [5]VUMC, Amsterdam, Netherlands

Purpose: To compare clinical and radiological outcomes of four treatment strategies after 6 years DAS-steered treatment in recent onset rheumatoid arthritis.

Method: 508 recent onset RA patients were randomized into four treatment strategies: 1. sequential monotherapy, 2. step up combination therapy, 3. initial combination with prednisone, 4. initial combination with infliximab. Treatment adjustments were made based on threemonthly DAS measurements (if DAS >2.4: dose increase/switch next treatment step, if DAS ≤ 2.4 during ≥6 months: taper to maintenance dose, next if DAS <1.6 during ≥6 months: stop anti-rheumatic treatment). Functional ability (HAQ), measured threemonthly was analyzed with a linear mixed model (LMM) with time, treatment and time*treatment as independent variables. Joint damage progression (Sharp-van der Heijde Score (SHS) was assessed on X-rays of baseline and year 2, 3, 4, 5, 6, scored by two independent readers in random order, blinded for patient identity.

Results: During 6 years follow-up, 99 patients (19%) withdrew from the study. At t=6 year, 83% had a DAS ≤2.4 and 51% DAS <1.6 (remission), equally distributed among the four groups (table). The initial improvement of function, which occurred earlier in groups 3 and 4 than in groups 1 and 2 but was comparable between all groups from year 1 onwards, was maintained without deterioration of HAQ over 6 years time (LMM: HAQ yr6 – yr1 = +0.02, p=0.58). Radiological progression was higher in the first two years of treatment (median 0.5, mean 4.6), especially in groups 1 and 2**,** than in years 3-6 (medians 0, 0, 0, 0 for year 3-6, means 1.1, 1.2, 1.4, 1.1), reflecting the efficacy of DAS-steered therapy. After 6 years, 15, 16, 14 and 19% of patients in groups 1-4 were in drug free remission with a median (mean) duration of 32 (26) months. Mean SHS progression in patients in sustained drug free remission was 0.13 (median (IQR) 0 (0 - 0)) per person year drug-free.

Conclusion: After earlier improvement and less radiological damage progression with initial combination therapy, functional improvement was maintained and radiological progression stabilized with DAS steered treatment aiming at DAS ≤2.4 irrespective of initial treatment. After 6 years, 51% of patients are in clinical remission and 17% of patients in prolonged drug-free remission without radiological progression.

Predictors of Biologic Response Modifiers Discontinuation in 2,486 RA Patients. Sofia Ramiro[1], Fred Wolfe[2] and Kaleb D. Michaud[3], [1]Hospital Garcia de Orta, Lisbon, Portugal, [2]National Data Bank, Wichita, KS, [3]University of Nebraska Medical Center and NDB, Omaha, NE

Purpose: Biologic response modifiers (BRM) are recognized for enabling sustained improvement in Rheumatoid Arthritis (RA) while discontinuation of these drugs due to several reasons is an emerging problem. Our goal was to determine the discontinuation rate of the first BRM used in RA patients and identify predictors associated with this discontinuation.

Method: Using the National Data Bank for Rheumatic Diseases (NDB) longitudinal study, patients reporting use of a first BRM with at least 6 months of follow-up were followed, and their continuation or discontinuation status was assessed according to self-report. Interruptions longer than 6 months were considered as discontinuations. Patients participating in drug safety registries were excluded to reduce bias. To assess predictors of BRM discontinuation, we collected demographic, clinical and treatment data, comorbidity, VAS scales for pain, global and fatigue, HAQ, quality of life measures (SF-36 physical, PCS, and mental, MCS, scores), Rheumatoid Arthritis Disease Activity Index (RADAI) and calendar year. The influence of these on BRM discontinuation was analyzed using a Cox proportional hazards model and adjusted for potential confounders.

Results: With average (SD) age of 60 (13) years and 19% men, 2,486 patients met our inclusion criteria (mean length of follow-up 3.8 (3.7) years). 46% (1,137 patients) of these discontinued their first BRM with a median time on drug of 4.5 years and a discontinuation rate of 14.7% per year. The specific initial BRM used were etanercept (45%), infliximab (40%), and adalimumab (12%). From the discontinuations, 50.3% of the patients ceased all BRMs, while the other 49.7% started, throughout their follow-up in the registry, on at least a second BRM. As detailed in the table, age at BRM start, RADAI, current use of prednisone, female gender, HAQ, and comorbidity index were associated with discontinuation of the first BRM. Infliximab discontinuation predictors were similar to the predictors of discontinuation of BRM in general, while adalimumab discontinuation was inversely associated with NSAID use (HR 0.50, 95% CI 0.34, 0.75). Apart from the general factors, the number of DMARDs taken (HR 1.31, 95% CI 1.10, 1.55), duration of methotrexate (MTX) therapy at BRM start (HR 1.01, 95% CI 1.00, 1.02) and fatigue scale at BRM start (HR 1.06, 95% CI 1.02, 1.11) were associated with etanercept discontinuation, while the number of DMARDs taken at BRM start (HR 0.79, 95% CI 0.67, 0.94) and duration of MTX therapy (HR 0.99, 95% CI 0.99, 0.99) were inversely associated.

Conclusion: A significant number of RA patients do stay for a reasonably long period on their first BRM, similar to what happened to initial MTX therapy in the 90s and consistent with previous reports. RA severity described by high disease activity, worse function and prednisone intake predicts BRM discontinuation.

Table. Predictors of BRM discontinuation

Predictors	**HR (95% CI)**
Age	0.19 (0.13, 0.27)
Male gender	0.83 (0.70, 0.99)
Age at BRM start	5.35 (3.77, 7.58)
RADAI	1.27 (1.16, 1.39)
Current use of prednisone	1.24 (1.09, 1.41)
HAQ	1.20 (1.00, 1.43)
HAQ at BRM start	0.65 (0.56, 0.76)
Pain scale	0.93 (0.89, 0.98)
PCS	0.98 (0.97, 0.99)
MCS	0.99 (0.99, 0.99)
Comorbidity index	1.05 (1.00, 1.10)

TNF Alpha –308 G>A Polymorphism Is Not Associated with Response to TNF-Alpha-Blockers in Patients with Rheumatoid Arthritis: a Systematic Review and Meta-Analysis. Stephan Pavy[1], Erik JM Toonen[2], Corinne Miceli-Richard[1], Pilar Barrera[2], Piet Van Riel[2], Marieke Coenen[2] and X. Mariette[1], [1]Hopital Universitaire de Bicêtre, Le Kremlin Bicêtre, France, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Purpose: The tumour necrosis factor alpha (TNFA) -308G>A gene polymorphism has been reported as a potential predictor of the clinical response to anti-TNF treatment in rheumatoid arthritis (RA). Nevertheless, these results remain controversial. We performed a meta-analysis to determine whether the TNFA -308G>A polymorphism is associated with response to anti-TNF treatment in patients with RA .

Method: A bibliographic search was performed to identify studies in which the TNFA –308G>A gene polymorphism was investigated in RA patients treated with anti-TNF agents. Complementary data were requested when the DAS28 was not used as the primary outcome measure of clinical efficacy. Odds ratios (OR) for response based on DAS28 and standardized mean difference (SMD) for mean improvement of DAS28 were calculated in order to assess the potential association between TNFA -308 genotypes and response to anti-TNF agents. Studies were combined using fixed effect or random effect depending on the heterogeneity assessed by I2 statistic. Part of the sensitivity analysis was based on detailed patient data of a large unpublished Dutch cohort and a French clinical trial encompassing a total of 814 RA patients.

Results: Twelve studies met the inclusion criteria and were supplemented with the data from the Dutch cohort. The OR based on twelve studies including 1721 patients was 1.24 (95%CI 0.98-1.56) and the SMD based on eleven studies including 2576 patients was -0.15 (95%CI -0.38-+0.07). Sub-group analysis based on the two classes of anti-TNF agents did not demonstrate any association between TNFA -308 genotypes and anti-TNF treatment outcome. The sensitivity analysis based on individual patient data was consistent with the main results.

Conclusion: According to this meta-analysis, the TNFA -308 polymorphism is not a predictor of the clinical response to anti-TNF treatment in RA.

Biologics for Rheumatoid Arthritis: An Overview of Cochrane Reviews. Jasvinder A. Singh[1], R. Christensen[2], GA Wells[3], Marie E. Suarez-Almazor[4], Rachelle Buchbinder[5], Maria Lopez-Olivo[6], Elizabeth T. Ghogomu[7] and Peter Tugwell[8], [1]VA Medical Center, Minneapolis, MN, [2]RC, Copenhagen, Denmark, [3]University, Ottawa, [4]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [5]Cabrini Medical Center, Malvern, Australia, [6]MD Anderson Ctr Univ of TX, Houston, TX, [7]Cochrane Musculoskeletal Group, Ottawa, [8]Institute of Population Hlth, Ottawa

Background: There are no head-to-head comparisons of Biologic DMARD randomized controlled trials.

Purpose: To indirectly compare the efficacy and safety of abatacept (Aba), adalimumab (Ada), anakinra (Ana), etanercept (Eta), infliximab (Inf), and rituximab (Rit) in patients with rheumatoid arthritis (RA) by calculating the number needed to treat (NNT) for benefit and harm [1].

Methods: This ‘Overview of Reviews' was done on the basis of existing Cochrane reviews available in the Cochrane Library (CMSG). We included all Reviews on Biologics for RA; summarizing existing ‘Intervention reviews' rather than finding, summarizing or synthesizing original studies. We included only data on standard dosing regimens for these biologic DMARDs from placebo-controlled trials. The primary efficacy outcome was the ACR50 response; as clinical and statistical evidence shows that this is the preferred endpoint for contemporary RA clinical trials. The number of withdrawals due to adverse events was the primary ‘safety' outcome. Statistical analyses were based on Risk Ratios (RR) for efficacy, and the Peto Odds Ratio (POR) for safety. Using these combined estimates we calculated the NNT for each product by taking the empirical proportion of events across the placebo/control-groups as the Control Event Rate for each product.

Results: From the six available Cochrane reviews, we obtained data from 7 studies on Abatacept, 8 on Adalimumab, 5 on Anakinra, 5 on Etanercept, 4 on Infliximab, and 3 studies on Rituximab, respectively. As expected, all 6 drugs were significantly better than placebo/control: Aba, RR=2.21 (95% CI: 1.79 , 2.74); Ada, RR=2.44 (1.22 , 4.86); Ana, RR=2.13 (1.31 , 3.46); Eta, RR=1.87 (1.19 , 9.95); Inf, RR=1.70 (1.03 , 2.83); Rit, RR=3.54 (1.99 , 6.29). Converting these into NNT's for interpretation of clinical significance, we obtained 6, 4, 7, 3, 6, and 5 for each respective intervention. For safety, Abatacept, Infliximab and Etanercept were statistically not different from placebo with POR of 1.30, 1.58 and 1.56, respectively ($p \geq 0.05$). Adalimumab and Rituximab were significantly different from

placebo/control (*P*=0.005 and P=0.02), with a POR =1.58 (1.14 , 2.17) and 2.95 (1.15, 5.80), respectively; with a corresponding NNT in order to “harm” a patient of 39 for adalimumab and 70 for Rituximab. The primary safety-outcome was not available for Anakinra.

Conclusion: It was evident that all six biological therapies were efficacious. The expected number of patients who responded to therapy was most pronounced for etanercept and least pronounced for anakinra. Thus, we anticipate that in a group of 100 patients initiating biological therapy, between 14 and 33 patients will experience at least 50% disease reduction (i.e. ACR50 criterion).

Immunological Mechanisms Related to Clinical Responsiveness Differ Between Methotrexate Monotherapy and Methotrexate and Etanercept Co-Treatment in Rheumatoid Arthritis. Theo van den Broek, Nicole Schechter, Cathleen Cover, Norma Seaver, Farah Bughio, Nick Shen and Salvatore Albani, Arizona Arthritis Ctr, Tucson, AZ

Purpose: Methotrexate treatment is used as initial treatment for patients with rheumatoid arthritis. If unsuccesful, anti-TNFa therapy is added to methotrexate. The immunological mechanisms triggered in response to both therapies are still not fully understood and most certainly involve a cluster of immune response mechanisms beyond the ones typically purported. Understanding of these mechanisms may optimize current standard practice by discriminating a priori methotrexate responders from methotrexate failures.

Method: 6 rheumatoid arhtritis patients on either anti-TNFa (etanercept) and methotrexate (MTX, n=3) or MTX monotherapy (n=3) were analyzed based on clinical responsiveness., determined as a DAS-score of <3.2. CD4CD127+ (Teff), CD4CD25+CD127- (nTreg) were sorted by FACS. Immune response genes expression was measured by TaqMan real-time PCR after in vitro stimulation. CFSE suppression assay was used to determine the capability of Treg to suppress Teff proliferation.

Results: Table 1: changes in gene expression when clinical control is achieved with stated therapy compared with non responders).

	Methotrexate	Methotrexate and Etanercept
APCs	B7-H1, TNFa downregulation	B7-H1, TNFa downregulation
Teff	No significant changes	IL-10, PD-1
Treg	FoxP3, PD-1, CTLA-4, Granzym B	PD-1, CTLA-4 Granzym B, Perforin, TGF-b

Conclusion: These preliminary studies evidence substantial differences between ETN and MTX responders with respect to Teff, as ETN responses appear to be more related to immune deviation. Common traits can also be identified in both arms toward a functional restoration of Treg activity as a contributor to the mechanisms leading to clinical responsiveness

1024

Geriatric Rheumatoid Arthritis Patients Receive Anti-Tnfa Agents Later, Have Higher Disease Activity and Experience More Often Serious Adverse Events Compared to Younger Adults. Irini Flouri[1], Alexandros A. Drosos[2], Kyriaki A. Boki[3], Fotini N. Skopouli[4], Dimitrios Karras[5], Ioannis Papadopoulos[6], P. Geborek[7], Dimitrios Boumpas[1] and Prodromos Sidiropoulos[1], [1]University of Crete, Heraklion, Greece, [2]Ioannina Medical School, Ioannina, Greece, [3]Sismanogleion General Hospital, Athens, Greece, [4]Athens University Medical School, Athens, Greece, [5]NIMITS, Athens, Greece, [6]Kavala G Hospital, Kavala, Greece, [7]Lund University, Department of Clinical Sciences, Lund, Sweden

Purpose: Anti-TNFa agents are increasingly used to treat rheumatoid arthritis (RA) patients of all ages. There is still scarce data available concerning safety and efficacy of these agents in elderly patients. We aimed to explore the effectiveness and safety profile of anti-TNFa agents in geriatric patients (≥ 65 years old) with rheumatoid arthritis in clinical practice.

Method: The Hellenic Biologic Registry for Rheumatic Diseases collects efficacy and safety data from 7 Academic and State Rheumatology clinics in Greece. Demographics, disease characteristics and treatments are recorded according to a standardized evaluation protocol (South Swedish Arthritis Treatment Group protocol). This report is on behalf of the investigators of the "Hellenic Registry for Biologics in Rheumatic Diseases".

Results: Data were analyzed for 307 geriatric (mean age 71 (SD 7) yrs) and 771 non-geriatric (49 (11)) adults with RA. At baseline geriatric patients had longer disease duration (mean 13 (SD 10) yrs) vs 9 (SD 8), p<0.001), higher activity (DAS28 6,1(1.3) vs 5.8 (1.2), p=0.008) and higher disability (HAQ 1.1 (0.6) vs 1 (0.56), p=0.007). Improvements in disease activity following treatment by the EULAR criteria was comparable for the first 2 years of treatment; however a lower percentage of geriatrics were good responders at 24 months (p=0.05).

A total of 1335 events were recorded, 404 in the geriatrics and 931 in non-geriatrics. The time on therapy up-to the reported adverse event was shorter in geriatrics (515 (446) vs 634 (530) days, p<0.001). Infections were the most common AE reported in both groups accounting for almost half of the reports. As expected, cardiovascular events were more common in geriatrics (p=0.02) while infusion reactions were more common in non-geriatrics (p=0.01). Geriatric patients had higher incidence of a serious adverse event compared to non-geriatric adults (23% vs 11% , p<0.001).

Conclusion: Geriatric RA patients have a delayed treatment with anti-TNFa agents while disease activity is higher. Although response rates are comparable between the two age groups, geriatric patients experience a serious adverse event more often. Physicians treating geriatric patients with anti-TNF should carefully assess for predisposing factors for infections and vascular events.

Rituximab Versus Anti-TNF in Patients Who Previously Failed One or More Anti-TNFs in An Observational Cohort: The SARASTRA Study. K. Chatzidionysiou, C. C. Carli and R. F. van Vollenhoven, Karolinska Univ Hosp, Stockholm, Sweden

Purpose: Rituximab (RTX) is mostly used after the failure of at least one anti-TNF. Another option is to switch to another anti-TNF, and it is not yet clear which of these two options is the more successful strategy. The purpose of this study was to determine if patients who failed one or two anti-TNFs achieve better results when switching to another anti-TNF or when switching to RTX and find potential correlation between reason of discontinuation and efficacy of next treatment.

Method: The Stockholm registry "STURE" was used. Treatment results at 3 and 6 months were analyzed by: 1) biologic used; 2) whether as second or third biologic; 3) reason of discontinuation of the first or second agent (inefficacy or intolerance). Treatment segments with anakinra were disregarded for this analysis; of duplicate segments with the same anti-TNF only the first one was used.

Results: A total of 479 patients switched to a second biologic therapy. 229 of them (47.8%) discontinued their first agent because of inefficacy and 141 (29.4%) because of intolerance. The rest of the patients stopped for other reasons. When used as the 2nd biologic RTX achieved highly significant reductions from baseline in DAS28 at 3 and at 6 months (p<0.001); these changes were numerically but not significantly greater than the change that occurred in patients who switched to another anti-TNF. The subgroup of patients who switched to RTX because of intolerance to the first anti-TNF agent had better response and a higher percentage of them achieved EULAR good/moderate response compared to those who switched to a second anti-TNF after they had not tolerated a first one (table 1).

153 patients switched to a third biologic. The reductions in DAS28 are similar for patients on RTX and an anti-TNF, but numerically higher for those patients on RTX who showed intolerance to a previous TNF antagonist (table 1). Intolerance to the 2nd anti-TNF strongly predicts good response to therapy with RTX when used as third biologic (p=0.007). Higher disease activity at baseline was found to be associated with a higher risk of discontinuation of treatment (p<0.0001).

Conclusion: In patients who failed one anti-TNF, RTX yields results that are as good as, and in some comparisons numerically better than, switching to another anti-TNF. For patients who previously did not tolerate an anti-TNF agent RTX seems to be a better alternative.

Table 1. Improvement in DAS28 and EULAR good/moderate response for patients receiving RTX or an anti-TNF agent according to the reason of discontinuation of their previous biological treatment.

		2nd biologic			3rd biologic		
Biologic used	Reason of discontinuation of previous therapy	N of patients	ΔDAS28 0-6m (mean±SD)	EULAR good/moderate resp at 6 m	N of patients	ΔDAS28 0-6m (mean±SD)	EULAR good/moderate resp at 6 m
anti-TNF	Ineffectiveness	220	1.6±1.4	71.3%	56	1.1±1.3	51.9%
RTX	Ineffectiveness	9	1.9±1.7	50%	24	1.3±0.9	33.3%
anti-TNF	Intolerance	124	1.7±1.2	64.4%	40	1.8±1.3	78.6%
RTX	Intolerance	17	2.1±0.8	77.8%	10	2.5±1.1	83.3%

Non-Responders to Rituximab or Tocilizumab After TNF-Alpha Inhibitor Failure in the Treatment of Rheumatoid Arthritis in the United Kingdom. Maximillian Lebmeier[1], Jane Shaw[2], Volker Koscielny[2] and Maria Deeg[3], [1]Wyeth Pharmaceuticals, Maidenhead, United Kingdom, [2]Wyeth, United Kingdom, [3]Wyeth, Muenster, Germany

Purpose: Anti-TNF agents or rituximab (RTX) are routinely used in clinical practice after failure of a first or second anti-TNF agent in the treatment of rheumatoid arthritis (RA). Recently tocilizumab (TOC), an IL-6 antagonist, has been licensed for the treatment of RA, providing clinicians with potential further options for the treatment of patients failing anti-TNF therapy. In the absence of comparative data models may help to estimate the number of patients not responding to RTX and TOC after failure of a first anti TNF compared to a second anti-TNF. This may provide insights into the most appropriate treatment algorithms and highlight areas requiring further research.

Method: An explorative analysis was conducted using a decision tree model. The model is based on data from RTX, and TOC clinical trials, as well as the British Society for Rheumatology Biologics Registry (BSRBR), which provides the most meaningful datasets on sequential use of biologics to date. The model compares the failure rates for a second anti-TNF, RTX or TOC in patients that have not responded to a first anti-TNF. In the REFLEX trial patients receiving RTX after not responding to at least one anti-TNF 49% of patients did not respond to RTX treatment (defined as not achieving ACR20 response). The RADIATE trial was conducted in patients not responding to at least one TNF. In this trial 50% did not respond to TOC treatment. Failure rates for a second TNF were obtained from the UK BSR, reporting the proportion of patients failing a 2nd TNF to be 27%. These failure rates were applied in the model which also used UK prevalence data for RA to predict potentially anti TNF eligible patients. The prevalence of RA in the UK is reported to be 1.16% in women and 0.44% in men, resulting in potentially 385,266 RA patients.

Results: The base case analysis calculated that 23,116 patients receive TNF inhibitor treatment, of which 4,221 can be expected to fail a first TNF inhibitor. If patients would receive RTX after the failure of a first anti-TNF 2,068 can be expected to fail this regime. If they would receive TOC, 2,110 could be expected fail. If patients would receive a second anti-TNF 1,140 may fail this treatment.

We furthermore calculated failure rates for RTX and TOC after lack of response to a second anti-TNF using data from the same sources. No published data for anti TNF agents in this population is available. Using RTX after a second anti-TNF would result in 559 vs. 570 patients failing treatment.

Conclusion: This exploratory analysis suggests that using 2 anti-TNFs sequentially, rather than switching to RTX or TOC after failure of only one anti-TNF may lead to fewer patients failing treatments. The data also suggests that RTX and TOC are equally effective when used after failure of a second anti -TNF agent. The model is based on limited data and further clinical comparative studies are needed.

TWEAK Stimuation of Kidney Resident Cells in the Pathogenesis of Lupus Nephritis. Alberto Molano[1], Payal Lakhani[1], Adi Aran[1], Linda C. Burkly[2], Jennifer S. Michaelson[2] and Chaim Putterman[3], [1]Albert Einstein College of Medicine, [2]Biogen Idec, Cambridge, MA, [3]Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY

Purpose: The cytokine TWEAK demonstrates potent kidney proinflammatory and proliferative effects. Recently, we have shown that interactions of TWEAK with its receptor Fn14 are instrumental in the pathogenesis of nephritis in the chronic graft-versus-host (cGVH) induced model of lupus. Fn14 is expressed by macrophages and resident kidney cells; we hypothesized that TWEAK binding to both cell types contributes to the pathogenesis of lupus nephritis.

Method: To address the relevant importance of TWEAK activation of macrophages versus resident cells in the pathogenesis of lupus nephritis, we generated bone marrow chimaeras and compared the progression of nephritis during cGVH induced lupus in mice expressing Fn14 only on bone marrow-derived cells, versus mice displaying Fn14 only on non bone marrow-derived cells.

Results: While Fn14 deficiency did not significantly affect autoantibody titers, Fn14 deficiency on bone marrow-derived cells did not inhibit nephritis initiation in mice with Fn14 sufficient non-hematopoeitic cells. Conversely, expression of Fn14 only on bone marrow-derived cells resulted in a delayed, milder disease course. To further explore the role of macrophages, we depleted macrophages during cGVH induction. Surprisingly, we found that macrophage depleted mice displayed significantly increased titers of anti-DNA and other anti-nuclear antibodies, and worse kidney disease.

Conclusion: While macrophage activation by TWEAK may be important later on in the pathogenesis of nephritis, the presence of Fn14 on resident kidney cells alone may be sufficient to initiate nephritis in this murine model of lupus.

Role of Interferon-Inducible Gene IFI202b in the Suppressive Capacity of CD8+ Regulatory T Cells Induced in (NZB x NZW) F1 (BWF1) Lupus Mice. Ram P. Singh, Ravi Dinesh and Bevra H. Hahn, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: The interferon-inducible Ifi 202 gene family has been implicated in the susceptibility of BWF1 mice to SLE, particularly as its increased expression may protect autoreactive B cells from apoptosis. CD8+ Tregs induced by a peptide tolerogen can suppress anti-DNA-producing B cells. We tested the potential role of Ifi202 in the suppressive capacity of CD8+T regulatory cells.

Method: We compared 45,000 murine genes between peripheral white blood cells (WBC), $CD4^+$ T cells, and $CD8^+$ T cells from pCons-tolerized vs. non-tolerized mice using Affymetrix Gene Chip array 430. 2.0. Validation of differentially expressed genes was performed by real-time PCR. Protein expression was determined by intracellular FACS staining and by Western blot analyses. Anti-DNA ab was measured by ELISA. Gene silencing studies were performed by incubation of CD8+T cells with the appropriate si RNA.

Results: 1- In CD8+T cells from BWF1 mice tolerized with pCons, the expression of interferon inducible gene IFI202b was increased more than two-fold beginning at one week following pCons administration and extending through four weeks after treatment, with a decrease at 6 weeks. **2-** *In vitro* re-stimulation with pCons or polyclonal activation significantly increased IFI202b mRNA expression in tolerized $CD8^+$T cells compared to cells from untolerized mice. **3-** Silencing of IFI202b abrogated the suppressive capacity of tolerized $CD8^+$T cells on

syngeneic CD4+CD25- T cells and on anti-DNA production. Silencing did not affect the susceptibility of CD8+Treg to apoptosis. In contrast, the silencing of IFNar1 (also upregulated in expression) did not affect the ability of $CD8^+$T cells to suppress autoantibody production. **4-** Lastly, the silencing of IFI202b decreased mRNA and protein expression of TGFb - a major mediator of suppression by $CD8^+$ T regulatory T cells.

Conclusion: In conclusion, increased expression of IFI202b in induced $CD8^+$ Treg cells contributes to their suppressive capacity, probably by decreasing the expression of TGFb.

Induction of Collapsin Response Mediator Protein 2 Expression During Immune-Mediated Nephritis. Aislinn Kelly[1], Calum Sutherland[2], Salim Merali[1], Michael P. Madaio[3] and Tracy L. McGaha[3], [1]Temple University, Philadelphia, PA, [2]University of Dundee, Dundee, Scotland, [3]Medical College of Georgia, Augusta, GA

Purpose: Protenuria occurs in most forms of glomerular injury and serves as both a marker of altered permeability and a factor that contributes to progressive disease. While proteinuria is a common manifestation in SLE our understanding of the mechanisms by which inflammation manifest this particular pathology is minimal at best. Using the nephrotoxic serum (NTS) nephritis model of immune-mediated glomerular injury, we investigated early time points after disease induction examining the initial stromal response to antibody deposition to gain insight into pathological mechanisms.

Method: Glomeruli were purified from mice 1d post-NTS injection and the proteomic profile was compared to sham-injected mice via 2D electrophoresis and MALDI-TOF mass-spectrophotometeric analysis. Identified proteins of interest were confirmed for differential expression via histological and Western blot analysis. Finally we examined a kidney visceral epithelial cell (podocyte) line for in vitro confirmation.

Results: Proteomic analysis of inflamed glomeruli from NTS-administered mice revealed upregulation of a protein with no previously described function in renal biology, collapsin response mediator protein 2 (CRMP2), an actin binding protein which influences cytoskeletal structure and cell polarity. The proteomic analysis was confirmed by immunofluorescence of renal tissue from nephritic mice demonstrating CRMP2 expression in glomeruli. Furthermore, Western blotting revealed the induction of CRMP2 was rapid, occurring by 1d post-NTS administration in purified glomerular lysates. Similarly, podocytes significantly increased CRMP2 protein levels 6h post-NTS stimulation in vitro suggesting that NTS-mediated injury rapidly induces CRMP2 production, and that this effect may be due to direct action on podocytes. Interestingly, this induction seems to be specific to immune-mediated renal injury as other models of podocyte damage failed to induce CRMP2 expression.

Conclusion: CRMP2 expression is closely associated with protenuria and podocyte damage in immune-mediated nephritis and may represent a previously unknown pathologic mechanism by which antibody deposition in the kidney contributes to disease manifestation and progressive target tissue damage.

Altered Programmed Death 1-Programmed Death Ligand 1 (PD-1-PD-L1) Pathway in T Cells of (New Zealand Black x New Zealand White) BWF_1 Mice with Anti-PD-1 Antibody. Maida Wong, Antonio La Cava, Ram P. Singh and Bevra H. Hahn, Division of Rheumatology, David Geffen School of Medicine, UCLA, Los Angeles, CA

Purpose: PD1-PD-L1 pathway is reportedly a costimulatory pathway that regulates self-tolerance by providing negative signals to T cells, resulting in anergy and decreased cytotoxicity. We have shown that induction of suppressive $CD8^+$ T cells ($CD8^+T_{reg}$) by administration of an artificial anti-DNA Ig-based synthetic peptide pConsensus (pCons), reduces PD-1 expression on the suppressor cells, which have increases in expression of Foxp3 and production of TGF-β. Also, untolerized mice treated with anti-PD-1 have delayed onset of proteinuria and increased survival compared to unmanipulated mice. We therefore studied the kinetics of PD-1 expression in $CD8^+T_{reg}$ *in vivo*, as they moved from permissive to suppressive following administration of pCons to BWF_1 lupus-prone mice.

Method: Antibody against PD-1 or control isotype-matched IgG were injected into naïve vs. tolerized BWF_1 mice intraperitoneally. TGF-b, IFN-γ, IL-6, IL-17A, anti-dsDNA and total IgG production were assessed by flow cytometry and/or ELISA.

Results: In anti-PD1-treated mice, serum anti-dsDNA, IgG and IFN-γ production were reduced compared to unmanipulated controls; the low production was comparable to the levels in tolerized mice. In contrast, anti-PD-1-treated mice had increased TGF-b expression in the serum; they failed to develop the elevations in serum IL-6 and IL-17A levels and proteinuria that are characteristic of the unmanipulated BWF_1 controls.

Conclusion: PD-1 is likely one of the core participants in inherent autoreactivity of T cells and in the mechanisms of immune tolerance in our model. Blocking PD-1 in otherwise unmanipulated mice delays autoantibody production, nephritis and mortality for many weeks; it prevents the increase in pro-inflammatory IL-6, IFN-γ and IL-17A while increasing secretion of anti-inflammatory TGF-b. Such a pattern could result from the ability of PD-1 to participate in suppression of Th17 cells, either directly or by activation of T_{reg}. Complete silencing of PD-1 with siRNA eliminates suppressive capacity of $CD8^+T_{reg}$. In functional suppressive $CD8^+T_{reg}$ from tolerized $mice_i$, PD-1 is down-regulated, but not to zero. We conclude that the interplay between Th1, Th17 and T_{reg} cells depends in part on fine tuning of the expression of PD-1.

IRF9 Influences Isotype Switching by Modulating B Cell Activation and Intracellular Signaling in the Pristane Mouse Model of Lupus. Alvina D. Chu, Jordan V. Price and Paul J. Utz, Stanford University School of Medicine, Stanford, CA

Purpose: Mice injected with pristane develop a lupus-like inflammatory response mediated by type I interferons (IFNs) and Toll-like receptor 7 (TLR7). A crucial component of the type I IFN signaling pathway, interferon regulatory factor 9 (IRF9), is required for B cell activation in response to TLR7 agonism. The mechanisms by which IRF9 enhances the B cell response to TLR7 remain to be elucidated. We aimed to define a role for IRF9 in influencing isotype switching events, testing the hypothesis that IRF9 modulates TLR7-mediated B cell cytokine production and intracellular signaling involved with immunoglobulin isotype switching.

Method: Age and sex-matched BALB/c wild-type (WT) and IRF9-/- mice were injected intraperitoneally with pristane. Sera were collected at 6 months after pristane injection and analyzed for isotype-specific autoantibodies directed against lupus autoantigens by ELISA. Secreted antibody isotypes and cytokines were also measured from WT and IRF9-/- B cells cultured *in vitro* with combinations of a TLR7 agonist, CD40 agonist, and IFN-alpha for 10 days. B cells isolated from pristane-treated mice were incubated with a TLR7 agonist over a 60-minute time course. Cell lysates were generated and analyzed by reverse phase protein microarrays for phosphorylated proteins and validated by Western blot.

Results: IgG antibodies specific for Sm/RNP and Ribo P antigens, particularly of the IgG2a subtype, were detected in pristane-treated WT mice but not in mice lacking IRF9. Isotype switching to IgG2a required IRF9 in the presence of TLR7, CD40, and type I IFN receptor agonism, correlating with IL-6 and IL-10 production. IgG1 production by B cells stimulated with anti-CD40 was not affected by the absence of IRF9. The presence of a TLR7 agonist induced protein phosphorylation within intracellular kinase pathways involving P38 MAPK, SAPK/JNK, and NFkB that was abrogated in IRF9-/- B cells.

Conclusion: Taken together, these results demonstrate that the adjuvant activity of type I IFNs on B cells requires IRF9 for isotype switching to IgG2a antibodies against RNA-containing antigens. Signaling studies suggest that IRF9 modulates intracellular kinase pathways that are activated by TLR7 signaling. P38 MAPK, SAPK/JNK, and NFkB are of special interest because they have been demonstrated to participate in isotype switching events. These results suggest that IRF9 may play a role in modulating these proteins.

Conditional Ablation of Langerhans Cells Exacerbates Lupus Dermatitis: A Novel, Protective Role of Langerhans Cells in Autoimmunity. Jennifer K. King, Anna U. Eriksson, Karen Jou and Ram Raj Singh, UCLA, Los Angeles, CA

Purpose: Skin-resident dendritic cells, called Langerhans cells (LC) maintain tolerance to skin antigens via constant, low migration to cutaneous draining lymph nodes (cLN). However, a novel finding from our lab has shown that LC migrate poorly from skin to cLN in lupus strains (MRL-Fas$^{lpr/lpr}$ [MRL-lpr] and MRL-Fas$^{+/+}$ [MRL+/+]) that develop autoimmune dermatitis *(JI 2008).* Since the LC migration defect precedes the onset of inflammation and correlates with severity of dermatitis, we posit that LCs play a protective role against the development of lupus dermatitis.

Method: We utilized MRL-lpr mice that express enhanced green fluorescent protein (EGFP) driven by a langerin (Lang) promoter by introgressing the Lang-EGFP knock-in from B6 background. Additionally, to determine the role of LCs in dermatitis development, we generated MRL-lpr mice that express diphtheria toxin receptor (DTR) and EGFP driven by Lang promoter. This permits acute ablation of LC with injection of diphtheria toxin A (DTA) for several weeks *(Malissen and colleagues, Imm 2005)*. DTR-EGFP knock-in mice were injected with DTA or vehicle weekly from 7 to 13 weeks of age and monitored for disease. Skin lesions were scored on a scale of 0(none)-3 (severe). Tissues were analyzed for immune cell subsets and skin by histology.

Results: First, we found the proportion of LC (EGFP$^+$) cells is markedly lower in cLN of EGFP MRL-lpr mice compared to B6 mice, thus confirming our report using inbred mice. Preliminary analyses suggest that this defect involves both subsets of skin Lang$^+$ cells (epidermal LC and dermal Lang$^+$ cells), although epidermal LC may be most affected. Such reduction of LC is likely important in dermatitis pathogenesis, as depletion of LC between 7 to 13 weeks of age markedly accelerated the development of skin lesions. Cumulative frequency of any skin lesion was 93% in LC ablated mice (n = 14) as compared to 23% in control wild-type littermates injected with DTA (n = 13; p <0.0003), and 15% in knock-ins injected with PBS (n=14; p<0.0001) at 20 weeks. Cumulative frequency of severe (3+; ulcerations with hemorrhage, >10% BSA) skin lesions was 93% in LC ablated mice compared to respective controls at 7% and 8% (p<0.0001) at 20 weeks. Disease free analysis of cumulative frequency of ≥2+ skin lesions showed significant acceleration of lupus dermatitis in LC ablated mice, with a median of 18 weeks compared to 32 weeks in controls (p=0.0037; Kaplan Meier). Skin sections show increased acanthosis, vacuolar changes, lymphocytic infiltrates, apoptotic keratinocytes, and fibrosis in LC ablated mice compared to controls. No difference in T cell activation, Tregs, or Th1 cytokines were found in cLN. Ongoing studies are determining mechanisms underlying this effect.

Conclusion: We demonstrate that temporal ablation of LC accelerates and worsens onset of lupus dermatitis, suggesting a protective role of LC in the pathogenesis of autoimmune dermatitis.

Pro-Inflammatory High Density Lipoproteins (piHDL) and Atherosclerosis Are Induced in Lupus-Prone but Not Normal Mice by High Fat Diet and Leptin. B. H. Hahn, Elaine V. Lourenco, Maureen A. McMahon, Brian J. Skaggs, Noriko Iikuni and Antonio La Cava, Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Atherosclerosis is accelerated in people with systemic lupus erythematosus (SLE), and the presence of dysfunctional, pro-inflammatory HDL are a marker of increased risk.

Method: We developed a mouse model of multigenic lupus exposed to environmental factors known to accelerate atherosclerosis in humans – high fat diet with or without injections of the adipokine leptin. (NZB x NZW)F_1 (NZB/W) mice were the lupus-prone model; BALB/c were non-autoimmune controls.

Results: High fat diet increased total serum cholesterol in both strains, in BALB/c non-HDL cholesterol levels increased; they did not develop atherosclerosis. In contrast, NZB/W mice on high fat diets developed increased quantities of HDL (P<0.001) as well as high HDL scores (P<0.001) indicating pro-inflammatory HDL; they also developed atherosclerosis (P<0.05 vs controls). Thus, high fat diet rendered more susceptible to pro-atherosclerotic events the NZB/W mice than the BALB/c control mice. Moreover, in the lupus-prone strain, addition of leptin increased piHDL scores (P<0.03) and atherosclerosis (P<0.03) and accelerated proteinuria (P<0.05 vs controls).

Conclusion: These data suggest that environmental factors associated with obesity and metabolic syndrome can accelerate atherosclerosis and disease in a lupus-prone background.

Effects of Apolipoprotein A-1 Mimetic Peptide in the Absence/Presence of Statin in a Murine Model of Accelerated Atherosclerosis in SLE. J. M.P. Woo[1], Z.F. Lin[1], C. Van Dyck[1], Y. Trejo-Lopez[1], K. M.T. Woo[1], X.P. Wang[2], N. Iikuni[1], O. J. Rullo[3], H. Wu[1], M. Navab[4], A. M. Fogelman[5], A. J. Lusis[2] and B. P. Tsao[1], [1]Division of Rheumatology, UCLA, Los Angeles, CA, [2]Divisions of Microbiology, Immunology, and Molecular Genetics, Medicine, and Human Genetics, UCLA, Los Angeles, CA, [3]Department of Pediatrics-Rheumatology, UCLA, Los Angeles, CA, [4]Division of Cardiology, UCLA, Los Angeles, CA, [5]Department of Medicine, UCLA, Los Angeles, CA

Purpose: Evaluate the effects of an apolipoprotein A-1 mimetic peptide, L-4F, in the absence/presence of pravastatin in apoE$^{-/-}$Fas$^{-/-}$ C57BL/6 mice, a murine model of accelerated atherosclerosis in SLE which spontaneously develops IgG autoantibodies, glomerulonephritis, and advanced atherosclerotic lesions on a normal chow diet.

Methods: Female mice, starting at 8-9 weeks of age, were treated for 27 weeks with 1) pravastatin, 2) L-4F, 3) L-4F plus pravastatin, or 4) vehicle control. Following euthanasia, tissues were harvested for disease assessment. Tissue damage and systemic inflammation were determined via histology and immunohistochemical staining, circulating chemokine/cytokine and autoantibody levels, and DEXA and μCT analysis.

Results: Only mice treated with L-4F in the absence/presence of pravastatin developed significantly smaller glomerular tufts ($p_{L,LP} < 0.05$), lower serum levels of IgG anti-dsDNA ($p_L < 0.05$) and anti-oxidized phospholipid ($p_{L,LP} < 0.005$) antibodies—with no significant difference in general immune suppression, elevated BMD ($p_{L,LP} < 0.005$), and lower proinflammatory plasma chemokine/cytokine levels (including CRP, CCL12, CCL19, and VCAM-1). Although all treatment groups presented 47-95% larger mean aortic root lesions, immunohistochemical staining showed a 37% decrease in mean infiltrated CD68 macrophages and a 59% increase in mean α-actin (smooth muscle) stained areas in aortic lesions of combination treatment mice compared to vehicle controls.

Conclusion: Serological and histological analysis suggests that treatment with L-4F in the absence/presence of pravastatin significantly reduces systemic inflammation in our murine model with no significant difference between treatment with L-4F alone and the combination treatment. Compared to vehicle controls, treatment with L-4F plus pravastatin effectively reduced manifestations of lupus-like autoimmunity, glomerulonephritis, and osteopenia. In addition, cellular composition of atherosclerotic lesions was suggestive of plaque stabilization due to the increased smooth muscle tissue content and lower infiltrated CD68 macrophage population, despite larger lesion area, compared to vehicle controls.

Induction of Lupus Like Symptoms in Human 60kD Ro Transgenic Mice by Passive Transfer of Human SLE Ro/SSA Autoantibodies. Timothy F. Gross[1], Harlan M. Gross[1], Jourdan R. Anderson[1], Sherry Hubbell[1], R. Hal Scofield[1], Shannon Maier[2], Joel M. Guthridge[1], Kenneth M. Kaufman[1], John B. Harley[1] and Judith A. James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sci Center; Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: Anti-Ro/SSA antibodies are common, early autoimmune responses in systemic lupus erythematosus (SLE). Autoantibodies to Ro/SSA occur in nearly half the patients with SLE and are associated with leukopenia, thrombocytopenia, photosensitive dermatitis, and renal disease. Extensive work has mapped common antigenic humoral targets of the 60kD Ro response. Although described many decades ago, complete pathogenic mechanisms of these autoimmune responses are still unknown. This study uses human Ro transgenic mice and passive transfer of anti-Ro responses to assess clinical pathogenesis of these human responses.

Methods: Human 60kD Ro/SSA transgenic mice were generated and crossed for 30 generations onto the NOD/ShiLtJ autoimmune-prone background. Human anti-Ro IgG was isolated by affinity purification from SLE patients for passive transfer, and human IgG from healthy controls was used for controls. Human Ro transgenic mice received anti-Ro IgG, human IgG or anti-BSA intraperitoneally at baseline and day 14. Blood was collected at baseline and serially after passive transfers. Each serial blood sample was analyzed for leukocytes, erythrocytes, and thrombocytes. Serial autoantibody evaluations were also performed. Blood samples from each mouse were analyzed by flow cytometry for CD19, CD8 and CD4 cell subsets. At terminal dates, kidneys were collected and antibody eluted for testing for antibodies against Ro/SSA and specific known antigenic peptides of 60kD Ro/SSA.

Results: Human 60kD Ro transgenic mice showed no increased levels of autoantibody production or clinical disease compared to non-transgenic NOD controls. Human 60kD Ro transgenic mice receiving anti-Ro antibodies were more likely to develop leucopenia and

lymphopenia compared to control mice. Select anti-peptide responses were eluted from mouse kidneys passively transferred with human patient anti-Ro. For example, kidney eluates contained antibodies against 60kD Ro humoral epitopes 166-180 and Ro480-498 more commonly than controls. Both of these epitopes were also present in the affinity purified serum anti-Ro of the SLE patients.

Conclusion: Transfer of purified human anti-Ro/SSA antibodies into genetically engineered 60kD human Ro NOD mice resulted in reproduction of select aspects of human SLE-like disease phenotype. In addition, select humoral anti-Ro epitopes deposit in kidneys potentially providing insights to pathogenic mechanisms of anti-Ro SLE disease.

Use of Laser Microdissection in the Analysis of Renal-Infiltrating T Cells in Murine Lupus. Yingge Wang[1], Satoshi Ito[1], Mizuho Suziki[1], Makoto Sugihara[1], Taichi Hayashi[1], Daisuke Goto[1], Isao Matsumoto[1], Sachiko Hirose[2] and Takayuki Sumida[1], [1]University of Tsukuba, Tsukuba, Japan, [2]Juntendo University School of Medicine, Tokyo, Japan

Purpose: To clarify the role of T cells in the kidneys of murine lupus models, cytokine mRNA expression was analyzed, and tissue localization of T cells was examined by immunohistochemistry.

Method: 1) Cells infiltrating the glomeruli and perivascular areas in MRL/lpr (10 female), NZB/W F1 (B/WF1) (4 female), and BXSB (2 male) mice were captured by laser microdissection (LMD). 2) Nested reverse transcription polymerase chain reaction (RT-PCR) of samples was performed with primers specific for β-actin, T-cell receptor β chain (TCR-Cβ), Thy-1, B220, CD4, CD8, interleukin (IL)-2, IL-4, IL-10, IL-13, IL-17, and interferon (IFN)-γ. 3) Frozen sections of lesions were also stained immunohistochemically.

Results: 1) T cells infiltrating the glomeruli and perivascular areas produced IFN-γ, IL-13, and IL-17 predominately. 2) IL-10 was detected only in the perivascular areas of MRL/lpr and B/W F1 mice but not in glomerulus. 3) Thy-1, CD4, CD8, B220, IFN-γ, and IL-17 staining was observed in glomeruli and perivascular areas from MRL/lpr, B/W F1, and BXSB mice. However, IL-10 staining was observed only in perivascular areas from MRL/lpr and B/W F1 mice.

Conclusion: Results of our study suggest that the cytokine balance is complex and not due simply to the Th1 and Th2 balance and IL-17 might play a critical role in murine lupus models. These findings also support the concept of different molecular mechanisms for glomerulonephritis and vasculitis in these mice.

Toll Like Receptor 7 Agonist Promotes the Induction of Ultraviolet Light B Induced Lupus Like Disease in Autoimmune Prone NOD Mice. Mehran Ghoreishi and Jan P. Dutz, Univ of BC, Vancouver, BC

Purpose: The role of environmental precipitants in autoimmunity such as systemic lupus erythematosus (SLE) remains unclear. We wished to determine whether ultraviolet light B (UVB) alone or in the presence of topical TLR7 stimulation would induce lupus-like disease in an autoimmune prone mouse model. Further we wished to determine whether anti-malarial therapy could prevent the skin mediated induction of lupus autoimmunity.

Method: We studied non obese diabetic (NOD) mice, a strain known to have a defect in apoptotic cell clearance and prone to autoimmunity. 6 week old female NOD mice received weekly 5000 j/m^2 UVB radiation with or without 25 μg topical imiquimod. MYD88-/- NOD mice and TLR9 -/- NOD mice were also treated with combination therapy. Sera were collected bi-weekly for detection of anti-nuclear antibodies (ANA) using HEP cells, desmoglein 3 (skin –specific) antibodies by ELISA, blood sugar determination and detection of pro-inflammatory cytokines by cytokine bead array. Treatment was continued until mice were 24 weeks of age. Skin and kidney were then harvested for immunohistochemical and immunofluorescence analysis. Blood was collected for cell surface or intra-cellular staining using flow cytometry

(FACS). Apoptotic cells in the skin were detected using TUNEL assay and IgG deposition in the kidneys was detected by direct immunofluorescence. Immunohistochemical studies were conducted to determine the expression of IFNαinducible gene, myxovirus A (MxA), and high mobility group box 1 (HMGB1) in skin. PAS staining of kidney identified the presence of glomerulosclerois.

Result: UVB exposure but not imiquimod increased apoptotic cells in the skin. Either UVB or imiquimod treatment induced ANA in NOD mice. Combined UVB and imiquimod (UV+Imiq) induced high titers of ANA and Dsg3 Ab. UV+Imiq enhanced MXA expression and HMGB1 expression in the skin. Combined but not single agent therapy induced elevated serum IL-6, TNFα, IFNγ and MCP-1. This treatment resulted in glomerulosclerosis and immune complex depositions in glomeruli. UV+Imiq therapy up-regulated TLR-7 expression on circulating B cells and TLR-7 and IFNα expression in peripheral blood plasmacytoid DCs. These effects were not detectable in MyD88-/- NOD mice. TLR9-/- NOD mice treated with UV+Imiq showed enhanced serum ANA, TNFα, IL-6 and IFNα compared to NOD mice. Conversely, addition of TLR-9 agonist CPG to UVB therapy decreased auto-antibody production in NOD mice. Chloroquine (an inhibitor of endosomal TLR-7 and TLR-9) prevented UV mediated auto-antibody production in NOD mice.

Conclusion: UVB and skin application of TLR7 agonist induce lupus-like autoimmunity in NOD mice and the combination of UVB and TLR7 activation is synergistic in this effect. The skin may thus be a site for the initiation of systemic lupus like disease. Anti-malarial therapy prevents the development of UVB induced autoimmunity in this model.

TLR7-Dependent Accelerated Development of Systemic Lupus Erythematosus in TLR9-Deficient Lupus-Prone Mice. Marie-Laure Santiago-Raber[1], Isabelle Dunand-Sauthier[1], Tianfu Wu[2], Chandra Mohan[2], Brian L. Kotzin[3] and Shozo Izui[4], [1]Medical School, Geneva, Switzerland, [2]Univ of Texas SW Med Ctr, Dallas, TX, [3]University of Colorado Health Sciences Center, Denver, CO, [4]CMU, University of Geneva, Geneva, Switzerland

Purpose: SLE is a systemic autoimmune disorder characterized by the formation of various autoantibodies and subsequent development of immune complex glomerulonephritis. The pathogenesis of SLE is a complex process, in which MHC-linked and multiple non-MHC-linked genetic factors contribute to the overall susceptibility of the disease. More recently, the possible roles of TLR7 and TLR9 in the development of anti-nuclear autoantibodies, because of their respective recognition of RNA and DNA, has been suggested.

Method: To better define the respective contributions of TLR7 and TLR9 to the development of SLE, we introduced the TLR7 or/and TLR9 null mutation into C57BL/6 mice congenic for *Nba2 (NZB autoimmunity 2)* locus (B6.Nba2) and followed the development of SLE (autoantibody production and mortality due to glomerulonephritis).

Results: B6.Nba2.TLR9$^{-/-}$ female mice displayed a markedly accelerated development of SLE (54% mortality at 9 months of age vs. none at 14 months in B6.Nba2 females). This acceleration was associated with an increased production of autoantibodies against nuclear antigens (DNA, histones and ribonucleoproteins, but not chromatin), serum retroviral gp70 and glomerular matrix antigens. Strikingly, the expression of TLR7 was up-regulated in B cells and plasmacytoid dendritic cells in these mice. In a marked contrast, the development of SLE in B6.Nba2.TLR9$^{-/-}$ females was completely prevented by the presence of TLR7 null mutation. No mortality due to GN was observed by 14 months of age, and serum levels of autoantibodies including anti-chromatin autoantibodies were comparable or even lower than those of B6.Nba2 female mice.

Conclusion: Our results indicate that TLR7 played a critical role in a wide variety of autoimmune responses against nuclear, retroviral and glomerular matrix antigens, while TLR9 was only involved in the development of anti-chromatin autoantibodies, and that the accelerated development of SLE in TLR9-deficient mice was due to an enhanced TLR7-dependant B cell and plasmacytoid dendritic cell activation.

Role of Toll-Like Receptor-4 for the Pathogenesis of Lupus-Like Autoimmune Diseases. Takehito Imado[1], Tsuyoshi Iwasaki[2], Sachie Kitano[1], Atsushi Satake[1] and Hajime Sano[1], [1]Hyogo College of Medicine, Nishinomiya, Japan, [2]Hyogo University of Health Sciences, Kobe, Japan

Purpose: Pathogenic T cells that recognize self-antigens and drive B cell hyperactivity play a central role in the pathogenesis of both human and murine lupus. Injection of parental C57/BL6 (B6) (H-2^b) spleen cells into (B6 x Balb/c)F1 (CBF1) (H-$2^{b/d}$) mice resulted in acute immune suppressive disease associated with the replacement of the CBF1 spleen cells with B6 spleen cells. Activated parental B6 $CD8^+$ T cells and Th1 cytokines predominate in this reaction, while this acute disease resolved and parental B6 $CD4^+$ T cells initiate Th2 cytokine profile, inducing detectable autoantibodies to DNA and extractable nuclear Ags, lupus-like nephritis, exhibiting autoimmune disorders that resemble human systemic lupus erythematosus (SLE) (J Immunol 165;2000). Toll-like receptor (TLR)-4 is the receptor for the gram-negative bacterial cell wall component LPS. Unchecked TLR-4 activation might result in autoimmune diseases. The present study we investigated the role of TLR-4 on parental $CD4^+$ T cells for the induction of lupus-like nephritis using this lupus model.

Method: Lupus-like nephritis was induced by the injection of spleen cells from either B6 or C57BL10/ScNB10 (B10/ScNCr) which lacks TLR-4 into CBF1 mice. Proteinuria was assessed semiquantitatively using urine dip sticks. Histopathological examinations were performed using renal tissues stained with hematoxylin and eosin. The numbers of $CD4^+$ T cells and B cells were examined by flow cytometry. Anti-DNA antibodies were examined by ELISA. Cytokine mRNA expressions were examined RT-PCR analysis.

Results: CBF1 mice injected by spleen cells from TLR-4 intact B6 mice developed proteinuria and histopathological changes representing lupus nephritis. In contrast, CBF1 mice injected with spleen cells from B10/ScNCr mice lacking TLR-4 developed less proteinuria and histopathological changes. The numbers of $CD4^+$ T cells and $B220^+$ B cells were significantly increased in the spleen from CBF1 mice injected by B6 spleen cells, while these changes were not significant in CBF1 mice injected by spleen cells from B10ScNCr mice. Serum levels of anti-DNA antibodies and IL-4 mRNA expression in the spleen and kidneys was significantly increased in CBF1 mice injected with B6 spleen cells, while these changes were not significant in CBF1 mice injected with spleen cells from B10ScNCr mice.

Conclusion: These results indicate that TLR-4 is crucial for induction of $CD4^+$ T cells that drive B cell hyperactivity in SLE.

Gender Dependency of Neuropsychiatric Manifestations in Lupus Mice. Hua-xin Gao, Elena Sanders and Chaim Putterman, Albert Einstein College of Medicine, Bronx, NY

Purpose: Neuropsychiatric lupus (NPSLE), is present in more than 70% of SLE patients, and is sometimes evident even before lupus diagnosis. Depression or anxiety are among the most common NPSLE manifestations. While the mechanism is still not known, autoimmunity has been suggested as a primary cause. Previously, we demonstrated that depression is an early neuropsychiatric manifestation as compared to MRL controls. While it is known that certain lupus manifestations (such as nephritis) develop much earlier and are more severe in female MRL/lpr mice than in males, the difference in the development of NPSLE between female and male MRL/lpr mice has not been compared directly. Our objectives were 1) To systemically compare the development of NPSLE in lupus-prone MRL/lpr females and males over time; 2) To further investigate the relation between autoantibody levels and the development of NPSLE.

Methods: Urine protein and serum were obtained serially during the course of the study, from 4 to 21 weeks of age. Circulating autoantibody titers were assessed by ELISA. A battery of behavior tasks, including open field, visual and spatial memory, balance beam crossing, social preference, forced swim, and elevated plus maze tests, were performed on male and female 5 and 18 week old MRL/lpr mice, and age- and gender-matched MRL/+ controls. Two-way repeated measurement ANOVA was used for the statistical analysis.

Results: Compared to control MRL/+ females (n=3), MRL/lpr female mice (n=6) exhibited significant depression-like behavior in the forced swim test as early as 5 weeks of age ($p<0.05$), when they already demonstrate elevated levels of autoantibodies not previously present. In contrast, 5 week old male MRL/lpr mice (n=6), with normal autoantibody titers, performed similarly to controls (n=3). Depressive behavior was noted only at 18 weeks of age in male MRL/lpr mice, when the autoantibody titers were dramatically higher than male MRL/+ controls ($p<0.05$). At 5 weeks of age there was a significant correlation of depression with elevated levels of anti-cardiolipin and anti-NMDAR antibodies ($p<0.05$), while at 21 weeks depression correlated with elevated anti-dsDNA, anti-cardiolipin, anti-chromatin, and anti-NMDAR antibody titers ($p<0.05$).

Both male and female MRL/lpr mice explored more actively than MRL controls in the elevated plus maze test, indicating, paradoxically, less anxiety. In addition, 18 week old female MRL/lpr mice, but not males, showed a trend toward social withdrawal. Both female and male MRL/lpr mice had normal visual and spatial memory as well as locomotor activity and coordination.

Conclusion: With more severe lupus, female MRL/lpr mice developed CNS dysfunction with depression-like behavior earlier than male MRL/lpr mice, correlating with autoantibody levels. Emotional deficits develop in MRL/lpr female mice with a subtle increase in autoantibody titers already at 5 weeks of age, a time point usually considered to be disease-free. Our results provide further support to a primary role for anti-nuclear and other autoantibodies in the pathogenesis of early neuropsychiatric deficits in this lupus model.

Epistatic Suppression of Fatal Autoimmunity in New Zealand Black Bicongenic Mice. Christina Loh[1], Yui Ho Cheung[1], Evelyn Pau[1], Carolina Landolt-Marticorena[2], Ginette Lajoie[3] and J. E. Wither[4], [1]University of Toronto, Toronto, ON, [2]University Health Network, Toronto, ON, [3]Department of Pathology, William Osler Health Centre,, Brampton, ON, [4]U of Toronto, Toronto Western Hospital, Toronto, ON

Purpose: We have previously introgressed NZB chromosomal intervals containing lupus susceptibility genes onto the B6 background and shown that: NZB chromosome 1 congenic mice (denoted, B6.NZBc1(70-100cM)) developed fatal autoimmune-mediated kidney disease and NZB chromosome 4 congenic mice (denoted, B6.NZBc4(8-79cM)) exhibited a marked expansion of immunoregulatory NKT cells in the absence of autoimmunity. In this study, we sought to determine the impact of interactions between these two loci on the development of lupus autoimmunity.

Methods: Bicongenic mice (B6.NZBc1(70-100cM).c4(8-79cM)) were generated by intercrossing B6.NZBc1(70-100cM) with B6.NZBc4(8-79cM) mice and using polymorphic marker assisted breeding to produce mice homozygous for both intervals. B6, parental congenic and bicongenic mice were aged to 4 and 8 mo old. Cellular profiles were assessed by flow cytometry and serum autoantibody (Ab) production was measured by ELISA. Kidney sections were stained by PAS or with FITC anti-mouse IgG $F(ab')_2$ and graded by a renal pathologist (G.L.) that was blinded to the strain of origin.

Results: At 8 mo age, bicongenic mice demonstrated significantly decreased mortality as compared to the B6.NZBc1(70-100cM) mouse strain ($p = 0.0156$). Comparison of kidney pathology in 8 mo old B6, surviving B6.NZBc1(70-100cM), and bicongenic mice revealed equivalent IgG deposition in B6.NZBc1(70-100cM) and bicongenic mice, however the severity of glomerulonephritis (GN) was attenuated. The majority of surviving B6.NZBc1(70-100cM) kidneys displayed diffuse (endocapillary) proliferative GN, whereas bicongenic kidneys primarily demonstrated mesangial expansion and/or proliferation. Serologic analysis revealed that bicongenic mice made IgM and IgG anti-chromatin and –ssDNA Ab, but failed to produce IgG anti-dsDNA Ab ($p = 0.0016$), which was closely associated with renal failure in the parental B6.NZBc1(70-100cM) strain. Furthermore, bicongenic mice produced predominantly IgG1 anti-ssDNA Ab, whereas both IgG1 and IgG2a anti-ssDNA Ab were observed in B6.NZBc1(70-100cM) mice. A reduced proportion of NKT cells was seen in bicongenic mice, as compared to B6.NZBc4(8-79) mice, raising the possibility that chronic activation of this subset results in the switch to less pathogenic autoAb production.

Conclusion: Although a susceptibility locus has been mapped to NZB chromosome 4, this interval suppresses fatal autoimmunity driven by genetic polymorphism(s) located on NZB chromosome 1. Ongoing experiments are seeking to further characterize the role of NKT cells in this suppression.

The Absence of Caspase-Activated Dnase Enhances the Production of Anti-Chromatin Antibodies in the Spontaneous Lupus Models Sle1 and Sle123. Neelakshi R. Jog, Lorenza Frisoni, Qin Shi and Roberto Caricchio, Temple University, Philadelphia, PA

Purpose: Apoptotic cell death has been proposed as the source of autoantigens in SLE. Using pristane induced lupus model, we previously showed that absence of Caspase-Activated DNase (CAD) interferes with apoptotic cellular modifications and prevents the generation of autoantibodies (autoAbs), though CAD-/- have a normal immune system.

Methods: To analyze the role of CAD in the spontaneous generation of lupus Abs, we backcrossed CAD-/- mice onto B6.Sle1 and B6.Sle123 background. The B6.Sle1 model is characterized by loss of tolerance to chromatin, while the B6.Sle123 strain displays high titers of anti-chromatin, anti-dsDNA Abs and proliferative glomerulonephritis.

Results: We found that B and T cell maturation in Sle1 and Sle1.CAD-/- mice was similar to B6 and B6.CAD-/- mice, but both Sle1.CAD-/- and Sle123.CAD-/- mice had significantly higher levels of anti-chromatin Abs when compared to their control CAD sufficient lupus-prone strains. The difference was apparent as early as 5 months of age and was stronger in Sle1.CAD-/- mice. The increase was specific for anti-chromatin and not for anti-dsDNA Abs. We also found that CAD-/- and CAD+/+ mice reconstituted with Sle123 bone marrow showed similar levels of anti-chromatin Abs suggesting that the absence of CAD was relevant only in the immune competent cells.

We then investigated whether the increase of autoAbs affected nephritis development. Sle123.CAD-/- mice had higher immune deposition than Sle123 mice, suggesting that absence of CAD accelerated renal disease in Sle123 mice. However, the absence of CAD did not induce immune complex deposition in Sle1, confirming that in this model anti-chromatin Abs are not nephritogenic.

The absence of CAD profoundly alters the nuclear and cytoplasmic morphological modifications during apoptotic cell death. We therefore asked whether the absence of CAD altered the ability of sera from autoimmune mice to bind apoptotic cells. AutoAbs from both Sle1 and Sle1.CAD-/- mice bound higher number of apoptotic cells from CAD-/- mice compared to apoptotic cells from CAD+/+ mice. Similarly, sera from old MRL/lpr mice, but not B6 mice, stained higher number of apoptotic CAD-/- cells. Thus lupus autoAbs bound more to CAD-/- than CAD+/+ apoptotic cells.

Conclusion: Our data suggest that in lupus prone mice the absence of CAD during B cell development increases the escape of auto-reactive B cells. Moreover better opsonization of CAD-/- apoptotic cells by autoAbs may result in more efficient uptake and presentation of nuclear antigen, which further activates peripheral autoreactive B cells to differentiate into plasma cells. In conclusion, the absence of CAD is an excellent system to investigate systemic autoreactivity in the absence of nuclear Ags' modification during apoptosis. Studies are underway in our lab to determine at which stage of maturation autoreactive B cells need to be exposed to apoptotic autoAgs to be either deleted or rendered anergic.

Narrowing Down Lupus Susceptibility Loci On Chromosome 13: Impaired Clearance of Apoptotic Debris. Evelyn Pau[1], Christina Loh[1], Nan-Hua Chang[2] and Joan E. Wither[2], [1]University of Toronto, Toronto, ON, [2]University Health Network, Toronto, ON

Purpose: Previously, we showed that introgression of a lupus-prone New Zealand Black (NZB) chromosome 13 interval onto a lupus-resistant C57BL/6 (B6) genetic background (B6.NZBc13) recapitulated many of the NZB autoimmune and cellular activation phenotypes. In addition, B6.NZBc13 mice have increased production of antibodies against chromatin and Sm/RNP together with expansion of various dendritic cell subsets, features typically seen in mice with defective engulfment or altered responses to apoptotic debris. We therefore investigated whether these mice have impaired clearance of apoptotic debris.

Method: To localize the genetic polymorphisms that drive the abnormal phenotypes in B6.NZBc13 mice with the full 29-73cM NZB interval, subcongenic mouse strains (c13(29-51cM), c13(38-73cM) and c13(45-73cM)) were generated. Uptake of apoptotic debris was examined in vivo by injecting CMTMR-labeled apoptotic thymocytes intraperitoneally into 8-12 wk old B6 and congenic mice. Peritoneal exudate cells were isolated 15-60 min post-injection and the proportion of peritoneal macrophages (PMΦ) that had engulfed apoptotic debris was assessed by flow cytometry. To examine clearance of apoptotic debris in germinal centers (GCs), the amount of apoptotic debris associated with tingible-body macrophages (TBMΦ) was quantified by immunofluorescent staining of splenic sections from 6 mo old mice. The splenic cellular profile was also examined by flow cytometry.

Results: Uptake of apoptotic debris by PMΦ was impaired in c13(45-73cM) subcongenic mice in vivo, resulting in a delay in the clearance of apoptotic bodies in the peritoneum compared to control B6 mice. Examination of splenic sections showed large and intact TUNEL+ apoptotic bodies as well as increased numbers of these bodies associated with TBMΦ in GCs of B6.NZBc13 and c13(45-73cM) subcongenic

mice, suggesting a failure to efficiently engulf apoptotic debris. Similar numbers of TBMΦ per GC was observed across all strains, indicating that these differences did not arise from differences in the number of TBMΦ between the mouse strains. Similar to mice with clearance defects in their GCs (Mfge8-/- mice), B6.NZBc13 and c13(45-73cM) mice had an increase in GC size as compared to B6 mice. This was accompanied by a marked increased in the proportion of GC B cells compared to B6 mice.

Conclusion: The results suggest that one of the genetic polymorphisms in B6.NZBc13 mice promotes autoimmunity by impairing clearance of apoptotic debris. Phenotypic profiles from subcongenic mice suggest that the apoptotic debris clearance deficiency maps to the distal interval (51-73cM). Future studies will continue to identify the nature of the clearance defect and potential candidate genes located in this interval.

Sle2c1 Sublocus Synergizes with Lpr Mutation in Contributing to Lupus Development. Zhiwei Xu and Laurence Morel, University of Florida, Gainesville, FL

Purpose: The function of the *Sle2* mouse lupus susceptibility locus and its derived *Sle2c1*sublocus have been previously shown to be associated with a lower threshold of activation of the B cell receptor leading to an accumulation of B1a cells in NZM2410 model. To explore whether these loci had any effects on other immune components, we introduced *lpr* as an amplifier into B6.Sle2 and its subcongenic strains, and analyzed systemically their cellular and functional phenotypes.

Methods: Homozygous B6.Sle2.lpr and *lpr*-carrying subcongenic strains were constituted for this experiment. At age of 4-6 months, both male and female mice were sacrificed, then the size of spleen and lymph nodes was examined and the lymphocyte phenotypes were analyzed systemically. Meanwhile, the infiltrated cell components in kidney were detected by flow cytometry and nephritic pathology scores evaluated. In addition, the IL-2 production in vitro by the activated $CD4^+$ T cells from 2 month-old mice was tested with ELISA method.

Results: It was found that the co-expression of *Sle2* and *lpr* on a C57BL/6 background markedly increased weight of peripheral lymph organs compared with B6.lpr mice, but lymph nodes show more significantly than spleen in augmentation fold. The peripheral lymph organs of B6.Sle2.lpr mice have more T cells, B cells and $CD3^+B220^+CD5^+$ cells than B6.lpr mice. Controversially, B6.Sle2.lpr mice demonstrated significantly decreased $CD4^+Fop3^+$ Treg cells in spleen and lymph nodes in comparison with B6.lpr mice. On other hand, the B6.Sle2.lpr mice had more T cells and macrophages accumulation rather than B cells in kidney, and demonstrated more serious nephritis and a shorter longevity than B6.lpr mice. By comparing the effect of *lpr* mutation on shorter *Sle2a*, *Sle2b* and *Sle2c1* subloci derived from the Sle2 locus, it was discovered that only the B6.Sle2c1.lpr mice had the same pathology changes as the B6.Sle2.lpr mice, which mapped the synergistic interaction with *lpr to Sle2c*1 sublocus. Furthermore, $CD4^+$ T cells from B6.Sle2c1.lpr mice produced less IL-2 than the B6.lpr $CD4^+$ T cells.

Conclusion: With the exception of regulating B cell receptor activation threshold, the *Sle2c1* locus has a potential of decreasing IL-2 production and breaking Treg cell balance, promoting T cell expansion and aggravating lupus development. It needs to be clarified whether there is an intrinsic interrelation of these newly-identified phenotypes of the *Sle2c1* sublocus.

Induction of Antigen-Specific Tolerance by DNA Vaccination Using Sm Autoantigen Combined with IL-10 in a Murine Model of Lupus. Beatriz T. Martín Márquez[1], Minoru Satoh[2], Erika A. Martínez García[1], Jose F. Muñoz Valle[1], Víctor E. Arana Argaez[1], Rogelio Hernandez Pando[3] and Monica Vazquez Del Mercado Espinosa[4], [1]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Universidad de Guadalajara, Guadalajara, Mexico, [2]Dept. of Medicine, Univ. of Florida, Gainesville, FL, [3]Instituto Nacional de las Ciencias Médicas y Nutrición Salvador Zubirán, México D.F., Mexico, [4]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Universidad de Guadalajara, Hospital Civil Juan I. Menchaca, Guadalajara, Mexico

Purpose: Anti-Sm antibodies are specific for systemic lupus erythematosus (SLE) and considered pathognomonic. The mechanisms that regulate anti-Sm antibody production are poorly understood; however, a critical role of TH1 cytokines has been suggested. Thus, induction of antigen-specific tolerance by DNA vaccination of the Sm antigen with immunoregulatory cytokine IL-10 could be a novel approach to control autoantibody production and tissue damage. Induction of antigen-specific tolerance was evaluated by immunization with DNA encoding Sm antigens in combination with IL-10 in pristane-induced murine model of lupus.

Method: DNA vaccines of Sm D1, D2, B´/B, B´/B COOH, IFN-gamma and IL-10 were prepared by direct cloning techniques and purified. Eight groups of 3 month-old female BALB/c mice (13/group) received intramuscular injections of 100 microgram of cocktail mixture of pcDNA™3.1D/V5-His-TOPO® encoding D1, D2, B´/B or B´/B COOH plus IFN-gamma or IL-10 at day 2 and 9. At day 16, mice received an intraperitoneal injection of pristane to induce experimental lupus. Serum samples were collected at day 0 and monthly thereafter. Serum autoantibodies were tested by ELISA (anti-dsDNA, chromatin, U1RNP/Sm, Su/Ago2, ribosomal P peptide) and immunoprecipitation using ^{35}S-methionine labeled K562 cell extract. IgG subclass levels were measured by ELISA. Proteinuria was assessed monthly using Multistix®. Kidney pathology and immune complex deposition were examined at 6 months.

Results: The levels of anti-U1RNP/Sm antibodies in IL-10-Sm D2 vaccinated group were lower than those of IFN-gamma -Sm D2 vaccinated group (P = 0.026 by Mann-Whitney), consistent with the IFN-gamma dependence of anti-U1RNP/Sm autoantibody production as reported. However, the prevalence and levels of other autoantibodies were not different in this pair, indicating an antigen-specific process induced by the vaccination. IgG2a levels in IFN-gamma vaccinated group appeared to be higher than those in IL-10 vaccinated group with the same Sm antigen vaccination, consistent with the IFN-gamma overexpression. Significant proteinuria (> 1.5+) was less common in IL-10 vaccinated group vs. IFN-gamma vaccinated group for the same Sm antigen (Sm D1, 15% vs 42%; Sm D2, 31% vs 54%; B'/B 46% vs 42%; B'/B-COOH, 23% vs 100%, P = 0.0001). These data suggest possible beneficial role of IL-10 in preventing immune complex glomerulonephritis.

Conclusion: DNA vaccination using lupus autoantigens and IL-10 may have a potential as a novel therapy to induce antigen specific tolerance and prevention of kidney damage in experimental lupus.

Allogenic Mesenchymal Stem Cell Transplantation Ameliorates Lupus Mice Via Inhibition of B-Cell Activating Factor (BAFF).

Lingyun Sun[1], Xiaolei Ma[1], Huayong Zhang[1], Zhifeng Gu[1], Richard M. Silver[2] and GS Gilkeson[2], [1]the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Medical University of South Carolina, Charleston, SC

Purpose: B cells play an important role in the pathogenesis of SLE. B-cell activating factor (BAFF) is a member of the TNF superfamily that regulates B-cell survival and autoreactivity. Recent evidence indicates that bone marrow-derived mesenchymal stem cells (BM-MSCs) possess immunosuppressive properties both in vitro and in vivo. We previously demonstrated that transplantation of human MSCs can significantly improve the autoimmune disorders in MRL/lpr mice. This study investigates whether effect and mechanism of murine BM-MSCs transplantation for MRL/lpr mice occurs by inhibiting B cell activation and BAFF expression.

Method: 18-week-old MRL/lpr mice were treated with BM-MSCs derived from BALB/C or saline. The disease-free BALB/C mice were used as negative control. Mice were monitored for 24h proteinuria. Sera were tested for levels of anti-double-stranded DNA (ds-DNA) antibodies, BAFF , IFN-γ, IL-2, IL-4, IL-10 and TGF-β. Mice were sacrificed at 26 weeks of age, and kidneys were subjected to histologic examination. The percentage and number of marginal zone (MZ), T1 and T2 B cells in spleen were detected by flow cytometry.

Results: MSCT prevented disease onset and significantly prolonged survival. The treated mice had significantly less renal damage. Eight weeks after transplantation, the levels of BAFF in serum in treated group decreased significantly than in placebo as well as the levels of serum IFN-γ and IL-10, while the levels of serum TGF-β were increased. Treated mice had significantly smaller spleens than control animals, with fewer MZ, T1, T2 and activated B cells.

Conclusion: Our findings suggest that MSCT can inhibit the excessive activation of B cells in MRL/lpr mice, including T1, T2 and MZ B cells. BAFF production was reduced in MSCs-treated mice in association with the diminished production of anti-dsDNA autoantibodies,

proteinuria, IFN-γ and IL-10. Thus, down-regulation of BAFF may play an important role in the mechanism of action by which MSCT ameliorates lupus progression.

Targeted Inhibition of the Alternative Pathway Ameliorates Progression of Renal Disease in Murine Models of Systemic Lupus Erythematosus. Hideharu Sekine[1], Ting Ting Hsieh Kinser[1], Efrain Martinez[1], Fei Qiao[1], Phil Ruiz[2], GS Gilkeson[1] and Stephen Tomlinson[1], [1]Medical University of South Carolina, Charleston, SC, [2]University of Miami, Miami, FL

Purpose: The complement system appears to play a dual role in the progression of lupus; serving a beneficial role in enhancing the clearance of immune complexes (ICs) and apoptotic cells, while serving a pathogenic role in inducing local inflammation and injury. The alternative pathway has been identified as playing a key role in renal injury, while the classical pathway is known to have an important contributory role in IC clearance. At ACR 2008, we reported on a preliminary study using the alternative pathway specific inhibitor, CR2-fH, for treatment of renal disease in lupus-prone MRL/lpr mice. The data suggested that CR2-fH significantly ameliorated renal disease and, unexpectedly, reduced serum autoAb levels. Here, we report on an expanded study in MRL/lpr mice, and also compared the effects of CR2-fH with CR2-Crry (inhibits all complement pathways) and sCR2 (targeting vehicle only). We also report on the characterization of CR2-fH in female NZB/W F1 mice that spontaneously develop lupus-like nephritis.

Method: Groups of 8 MRL/lpr mice or 10 NZB/W F1 mice (all females) were injected with 0.4mg of CR2-fH protein i.v. twice a week for 8 wks starting from week 15 or 23, respectively (after development of proteinuria/renal disease). Groups were also treated with CR2-Crry (0.25 mg), CR2 alone (0.18 mg) or with saline biweekly. Sera and urine were collected every two weeks, and kidneys were collected for histological evaluation at 23 wks or 32 wks. Levels of serum anti-dsDNA Ab, circulating ICs and urinary albumin excretion were analyzed by ELISA.

Results: CR2-fH and CR2-Crry treatment of MRL/lpr mice resulted in improved survival and significant reductions in albuminuria, glomerular C3 deposition and circulating ICs. Similarly, CR2-fH and CR2-Crry treatment of NZB/W F1 mice resulted in improved survival and reduced glomerular C3 deposition. However, a significant reduction in proteinuria was only seen in the CR2-fH treated group. CR2-fH treatment of MRL/lpr mice, but not CR2-Crry, also resulted in significantly reduced glomerulonephritis and serum anti-dsDNA Abs. Of interest, mice treated with sCR2 alone also showed significantly reduced glomerular C3 deposition, anti-dsDNA antibodies and circulating ICs, although there was no significant reduction in glomerulonephritis or proteinuria, and there was no survival benefit.

Conclusion: These data indicate that targeted inhibition of the alternative complement pathway is an effective treatment for murine lupus, and is more effective than blocking all three complement pathways. In addition to the potential benefit of avoiding systemic complement inhibition by a targeted approach, the data indicate benefits to leaving the classical/lectin pathways intact. The data also indicate that the sCR2 targeting vehicle contributes to therapeutic activity, possibly via modulation of autoimmunity, although it does not reduce organ inflammation.

Amelioration of Lupus Nephritis with Dendritic Cells Using a NF-KappaB Decoy and Histone H3 Peptide in NZB/W F1 Mice. Hitoshi Hasegawa, Atsushi Inoue, Masashi Kohno, Takuya Matsumoto and Masaki Yasukawa, Ehime University Graduate School of Medicine, Toon, Japan

Purpose: The expression of costimulatory molecules on antigen-presenting cells is crucial in determining T-cell immune response and is regulated by nuclear transcriptional factor (NF)-kappa B. The peptide of core histone H3 contains T cell epitopes of NZB/W F1 mice. We investigate the effect of NF-kappaB decoy-treated dendritic cells (DCs) on the lupus nephritis in NZB/W F1 mice reducing the T cell response against Histone H3 peptide.

Method: DCs propagated from bone marrow cells of NZB/W F1 mice were used. Double-stranded NF-kappaB decoys were generated using equimolar amount of single-stranded sense and antisense phosphorothioate-modified ODN containing NF-kappaB binding sites and were added at the initiation of DC culture of mice. Female 10-week-old NZB/W F1 mice were treated with DCs pulsed with Histone H3 peptide, three times. Phenotypical expression of DC was analysed by flowcytometry. Immune stimulatory activity of DCs was examined in T cell proliferation assay. Proteinuria concentration of NZB/W F1 mice was measured weekly to monitor the development of nephritis. Serum levels of anti-DNA antibodies were measured by ELISA. For assessment of lupus nephritis, NZB/W F1 mice were sacrified at 28 weeks of age and evaluated histologically.

Results: NF-kappaB decoys suppressed suface expression of costimulatory molecules, including CD80, CD86 and CD40 of DCs, but the expression of MHC was not affected. NF-kappaB decoy-treated DCs significantly suppressed allostimulatory activity and self-antigen specific T-cell proliferative responce. Administration of NF-kappaB decoy-treated DCs reduced significantly proteinuria, anti-DNA antibodies of 28-week-old NZB/W F1 mice compared with control mice. The pathological change in the control mice included mesangial thickening and hypercellularity evolving into sclerosis. The nephritis score in the NF-kappaB decoy DCs-treated mice was significant lower than that in the control mice. This indicates that NF-kappaB DCs pulsed with Histone H3 peptide may suppress or delay renal inflammation in vivo.

Conclusion: NF-kappaB decoy-treated DCs may promote tolerance induction by reducing the antigen-specific autoimmune response and provide a therapeutic effect to lupus nephritis of NZB/W F1 mice. This strategy may be benefical for the treatment of human autoimmune diseases.

Epigallocatechin-3-Gallate (EGCG) Attenuates Inflammation in MRL/Lpr Mouse Mesangial Cells. Abigail Peairs[1], Lu Gan[2], Liwu Li[2] and Christopher Reilly[1], [1]Virginia College of Osteopathic Medicine, Blacksburg, VA, [2]Virginia Tech, Blacksburg, VA

Background and Purpose: EGCG, a bioactive component of green tea, has been reported to exert anti-inflammatory effects though activation of the metabolic regulator, AMP-activated protein kinase (AMPK). Mesangial cells from MRL/lpr lupus-like mice are hyper-responsive to immune stimulation and overproduce nitric oxide (NO) and other inflammatory mediators when stimulated. In our current studies, we sought to determine the mechanism by which EGCG attenuates immune-induced expression of pro-inflammatory mediators.

Methods: Mesangial cells isolated from MRL/lpr mice were stimulated with LPS/IFN-γ following pretreatment with various concentrations of EGCG with or without various pharmacologic agents including AMPK inhibitors (AraA and 5'-iodotubercidin), the mTOR inhibitor Rapamycin, or the PI3K inhibitor LY294002. Cellular response was determined at various time points by flow cytometry, real-time RT-PCR, ELISA and Western blot.

Results: EGCG increased AMPK activation in a concentration dependent manner and attenuated LPS/IFN-γ induced inflammation (cellular iNOS expression, supernatant NO, and interleukin-6) in MRL/lpr mouse mesangial cells. Interestingly, EGCG attenuated inflammation in the presence of the AMPK inhibitors (AraA and 5'-iodotubercidin) indicating that the anti-inflammatory effects of EGCG are independent of AMPK. Furthermore, we found that EGCG effectively inhibited the immune stimulated PI3K/Akt/mTOR pathway independently of AMPK, by decreasing phosphorylation of Akt, suggesting a novel mechanism for EGCG mediated anti-inflammatory action.

Conclusion: Taken together, these studies show that EGCG attenuated inflammation in MRL/lpr mouse mesangial cells via the PI3K/Akt/mTOR pathway. Akt is a key signaling molecule in the innate immune response, and has been implicated in mesangial cell activation in lupus. Our findings suggest a potential therapeutic role for the use of EGCG to regulate inflammation and control autoimmune disease.

Active Immunization with IFNα Kinoid® Induces Polyclonal Antibodies That Neutralize IFNα From Systemic Lupus Erythematosus Patients. Alexis Mathian[1], Zahir Amoura[1], Estelle Adam[2], Fabien Colaone[2], Marco F.M. Hoekman[3], Pierre Vandepapelière[2], Julien Haroche[1], Jean -Charles Piette[4], Pierre Lebon[5] and Géraldine Grouard-Vogel[2], [1]Pitié-Salpêtrière hospital, Paris, France, [2]NEOVACS SA, Paris, France, [3]Utrecht University, Utrecht, Netherlands, [4]Department of Internal Medicine, Pitié-Salpêtrière Hospital, Paris, France, [5]Department of Virology, Saint-Vincent de Paul Hospital, Paris, France

Purpose: Passive administration of monoclonal antibodies (mAbs) has been shown to be effective for the treatment of autoimmune diseases such as rheumatoid arthritis, but its therapeutic use is limited by the immunogenicity of the antibodies. Additionally, several cytokines such as interferon-alpha (IFNα), the key cytokine implicated in systemic lupus erythematosus (SLE), have different subtypes, which make very difficult and unlikely their neutralization by a single mAb. The Kinoid® immunization process developed by Neovacs is a novel approach that targets cytokines by inducing natural polyclonal antibody response and circumvents the induction of the anti-mAbs response. Kinoids® are heterocomplexes made by conjugating the targeted cytokine to a carrier protein such as the keyhole limpet hemocyanin (KLH).

Method: In the current study, FVB human IFNα2b transgenic mice were immunized with IFNα2b Kinoid (IFN-K) formulated in ISA51 adjuvant (SEPPIC). Control mice were immunized with inactivated IFNα2b emulsified in ISA51. This inactivated IFNα2b control was manufactured the same way as IFN-K but in absence of KLH.

Results: Only mice immunized with IFN-K generated neutralizing antibodies against IFNα2b. Furthermore, these antibodies neutralized all the 13 human IFNα subtypes, as assessed by the compendial Madin Darby bovine kidney-vesicular stomatitis virus infection assay. When the assay was performed with sera from SLE patients as a source of IFNα, the protective IFNα activity was neutralized by these polyclonal antibodies. However, the antibodies induced by IFN-K immunization neutralize neither IFNβ nor IFNγ. *In vitro* stimulation with native human IFNα2b of splenocytes from IFN-K immunized mice did not induce a cellular response, whereas it did with IFN-K and KLH antigens.

Conclusion: Our study shows that in mice tolerant to human IFNα2b:
Active immunization with IFN-K induces polyclonal antibodies that specifically neutralize all subtypes of human IFNα,
Active immunization with IFN-K breaks B-cell but not T-cell tolerance to IFNα thus demonstrating the safety of the product,
Polyclonal antibodies produced by active immunization with IFN-K are able to neutralize human IFNα present in sera from SLE patients,
The IFNα2b-kinoid vaccine is a promising new therapeutic strategy for the treatment of SLE.

Delayed Antigen-Specific Responses and Increased Disease Activity in MRL-Lpr Mice Following Influenza Infection. Judith A. James, Jourdan R. Anderson, Erica V. Edwards and Sherry R. Crowe, Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: Influenza virus infections result in significant morbidity and mortality, especially in individuals with impaired immune systems, such as those with systemic lupus erythematosus. It is unclear, however, whether this increased morbidity is due to intrinsic immune defects or immunosuppressive therapy. To address this question, we utilized the MRL-*lpr* mouse model and examined viral susceptibility, antigen-specific responses, and autoimmune disease activity following intranasal influenza infection.

Method: MRL and MRL-*lpr* mice were inoculated with saline or a sub-lethal dose of a mouse adapted influenza virus at 10 weeks of age. Mice were monitored for two weeks post-infection and morbidity and mortality were recorded. Viral titers from lung were determined by a standard egg assay. To assess the antigen-specific response, intracellular cytokine staining and antigen-specific ELISAs were performed. H&E staining was used to monitor organ pathology and flow cytometry and immunohistochemistry was used to characterize cellular infiltrates. Finally, pre- and post-infection serum autoantibody levels were monitored by ELISAs.

Results: MRL-*lpr* mice had increased morbidity ($p = <0.001$), as measured by weight loss, as compared to MRL. Additionally, MRL-*lpr* mice had significantly increased cellular infiltrates in the lungs ($p = 0.05$). These signs of increased susceptibility were not due to increased viral replication, as there were no differences in viral titers or viral clearance between the strains. MRL-*lpr* mice did mount different T cell cytokine responses compared to MRL. MRL-*lpr* mice made significantly less TNFa and more IFNg both pre- and post- infection ($p < 0.001$). Both groups of mice had high levels of anti-influenza antibodies, but the MRL-*lpr* mice had significantly less antigen-specific antibodies at each time-point ($p < 0.05$). MRL-*lpr* mice also had decreased numbers of influenza-specific $CD8^+$ T cells at the peak of the

immune response ($p < 0.05$). Interestingly, influenza infection of MRL-*lpr* mice also resulted in significant peri-vascular cellular infiltrates in the kidneys ($p < 0.05$), composed primarily of $CD4^+$ T cells. MRL-*lpr* mice also showed a transient but significant increase in the concentration of anti-cardiolipin antibodies ($p = 0.05$) after infection, but no changes in other autoimmune specificities studied.

Conclusion: Lupus-prone mice had increased susceptibility and pathology following influenza infection. Additionally, these mice had decreased antigen-specific humoral and cellular immunity and increased autoimmune disease activity. This model will provide a unique system to dissect the immune-pathogen interaction in an autoimmune disease setting. These data will also provide valuable information on how autoimmunity impacts the immune response to influenza.

Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Pathogenesis, Animal Models and Genetics I

Monday, October 19, 2009, 9:00 AM - 6:00 PM

1052

Fibrocyte Recruitment and Myofibroblast Differentiation After Acute Lung Injury Is Blocked by Selective Inhibition of TGFbeta Signalling in Resident Pulmonary Fibroblasts. Korsa Khan, Rachel Hoyles, Emma Derrett-Smith, Xu Shiwen, David Abraham and Christopher P. Denton, UCL Medical School, London, United Kingdom

Purpose: TGFbeta overactivity is implicated in the development of lung fibrosis and may be a potential therapeutic target in fibrotic disease such as scleroderma (SSc). We have used post-natal deletion of the high affinity type II TGFbeta receptor (TbetaRII) in fibroblasts to test the role of TGFbeta signalling in resident lung fibroblasts in the fibrotic response to lung injury.

Methods: TbetaRII was deleted using a compound Cre-Lox genetic strategy with post-natal administration of tamoxifen over 5 days to activate Cre-recombinase in mice harbouring a conditional allele of TbetaRII to delete the receptor from fibroblasts exclusively. Illumina microarray gene profiling was used to confirm anergy to TGFbeta (2ng/ml) in explanted lung fibroblasts. A bleomycin lung injury model was used to induce lung fibrosis. Multichannel immunofluorescence was used to define the cell populations after lung injury at 7 and 14 days on tissue sections and fibrocytes were defined by co-expression of CD34, Col1 (Collagen I) and alphaSMA. Myofibroblasts were identified by co-expression of Col1 and alphaSMA.

Results: There was almost complete attenuation of lung fibrosis in mice treated with intratracheal bleomycin (Null-B) after deletion of TbetaRII in resident fibroblasts. At 7 days after injury there was evidence of epithelial mesenchymal transdifferentiation (EMT) but the number of fibrocytes and myofibroblasts was substantially reduced. Using high power field counts (hpf) the number of fibrocytes in Null-B lungs at 7 days was decreased compared wildtype littermate controls (WT-B;3.6±2.22 cells/hpf, 26.6±4.96 cells/hpf p=0.007 respectively). At 14 days this reduction was sustained (8.6±2.06 cells/hpf compared with 46.6±4.947 cells /hpf p=0.0007). Furthermore, myofibroblast expression was reduced in 7 day Null-B lungs compared with WT-B (134.2±28.54 cells/hpf compared to 11.4±3.25 cells/hpf, p=0.01). Again, this was maintained at day 14 (72.2±20.73 cells/hpf, 7.6±1.46 cells/hpf p=0.03). Analysis of gene expression defined a cohort of TGFbeta responsive genes that were not upregulated in fibroblasts after deletion of TbetaRII. This included the key profibrotic mediators CTGF and ET-1, raising the possibility that defective induction of these mediators may underlie the altered fibrocyte recruitment and myofibroblast differentiation that we observe (see Table).

Mean (±SEM) Normalised Gene Expression in Lung Fibroblasts

	Wildtype (n=6)			Null (n=3)		
	Basal	**TGFb**	**P value**	**Basal**	**TGFb**	**P value**
CTGF	2282 ±1781	9926 ±2115	0.031	1753 ±951	2027 ±1190	NS

ET-1	401 ±22	838 ±197	0.035	541 ±49	504 ±65	NS

Conclusion: Intact TGFbeta signalling in resident lung fibroblasts is essential for lung fibrosis to develop and our results support a key regulatory role of these cells in determining fibrocyte recruitment and myofibroblast differentiation.

Critical Requirement of RAGE for Development of Lung Fibrosis in An Experimental Model of Systemic Sclerosis. Tracy Delaney, Jennifer Kearley, Ebony Benjamin, Cindy Chen, Gary P. Sims, Daniel Rowe, Phillip Brohawn, Yihong Yao, Jane Connor, Ronald Herbst, Bahija Jallal and Anthony J. Coyle, MedImmune LLC, Gaithersburg, MD

Purpose: Receptor for advanced glycosylated ends (RAGE) is involved in cellular detection of immune complexes containing DNA/RNA, which are associated with autoimmune diseases such as systemic sclerosis (SSc). To determine whether RAGE plays a role in autoimmune-driven fibrosis, mice deficient in RAGE were compared to wild type (WT) in an *in vivo* model of SSc.

Methods: RAGE-/- and WT mice were immunized with 100ug human collagen V on days 0 and 21, and on day 50 lung function was assessed by Flexivent using both pressure/volume (P/V) loops and airway hyperresponsiveness (AHR) to methycholine challenge methods. Lymph nodes were phenotyped by multicolor FACS analysis, and qPCR analysis of lung mRNA was performed by Fluidigm array. Lung RAGE expression and ectopic germinal centers were visualized by immunohistochemistry on frozen tissue sections, and collagen quantified by Sircol assay.

Results: Lung elastance and airway resistance were significantly deviated from controls in immunized WT mice but not RAGE-/- mice. Increased parenchymal collagen, intersititial neutrophils, and alveloar wall thickening were observed in immunized WT but not RAGE-/- animals. Ectopic CD4+/IgG+/PNA+ aggregates present in WT lungs were absent in RAGE-/- lungs, as was overexpression of IL-4, TGFb, IL-13, and MMPs. Immunization-induced B cell expansion in lymph nodes and autoantibody production were unaffected by RAGE deficiency.

Conclusion: Development of lung inflammation and fibrosis, but not expansion of autoreactive B cells, is RAGE-dependent in an experimental murine model of SSc.These data support a key role for RAGE in autoimmune-driven lung fibrosis and suggest a pathogenic role for RAGE-mediated signaling within lung epithelium in this model.

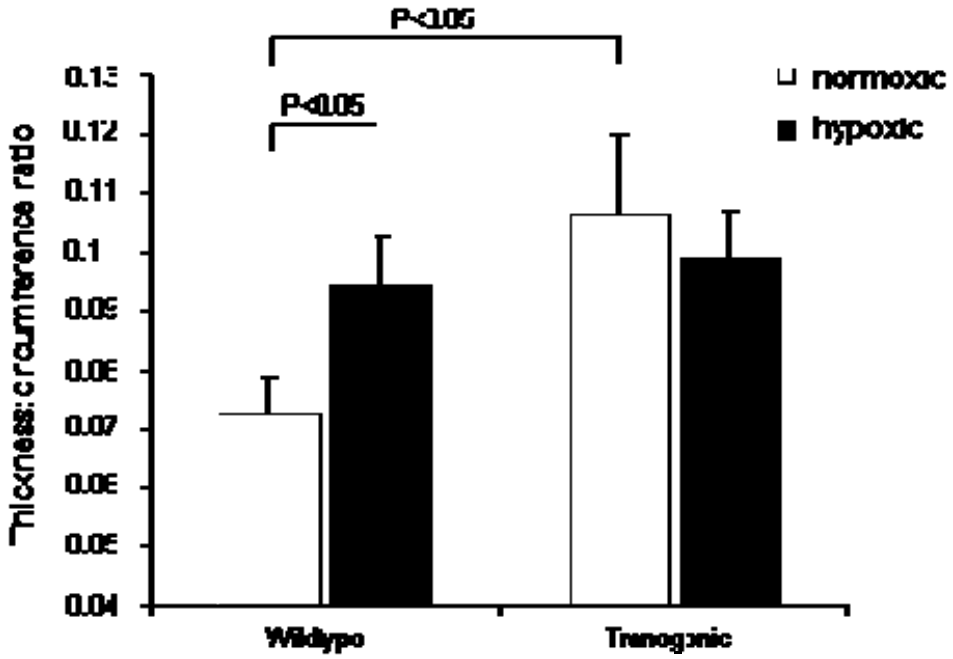
Fibroblast-Specific Activation of TGF-Beta in Transgenic Mice Recapitulates a Histological Phenotype of Hypoxic Pulmonary Hypertension In Vivo. Emma Derrett-Smith[1], Xu Shi-wen[1], Reshma S. Baliga[2], Korsa Khan[1], David Abraham[1] and Christopher P. Denton[1], [1]UCL Medical School, London, United Kingdom, [2]UCL, London, United Kingdom

Purpose: Vascular complications of systemic sclerosis (SSc) are a major cause of mortality and morbidity and are initiated by endothelial injury. The transgenic mouse strain TβRIIΔk-fib expresses a kinase-deficient type II TGF-β receptor linked to a fibroblast-specific promoter leading to balanced ligand-dependent upregulation of TGF-β signalling. We have examined changes in pulmonary vascular structure and signalling in this model of systemic sclerosis and compared responses to hypoxic stress with wildtype control mice.

Methods: Transgenic (n=6) or littermate wildtype mice (n=6) were exposed to hypoxic stress (10% O_2 for 21 days) and pulmonary vascular responses were compared with normoxic transgenic and control animals (n=6 in each group). We evaluated vascular and perivascular architecture by H&E and special stains, and used immunohistochemistry to examine TGF-β and endothelin expression. Vascular smooth

muscle cell (vSMC) proliferation and biochemical phenotype was also studied in vitro by culturing under hypoxic and normoxic conditions, including signalling responses to exogenous TGF-β1 and endothelin-1.

Results: Increased TGF-β1 immunostaining was confirmed in transgenic lung vessels with an associated reduction in endothelin receptor A expression in cultured vSMCs (mean wildtype copy number 2517±1261, mean transgenic copy number 315±73, $p<0.05$). There was no change in these variables between normoxic or hypoxic mouse tissues. As previously reported, in normoxic transgenic mice medial thickness was significantly increased in pulmonary arterial vessels compared with wildtype littermates. After exposure to hypoxia there was significant thickening of the pulmonary vascular smooth muscle cell layer in wildtype mice but no further increase in transgenic vessel wall thickness. These results are summarised in Figure 1. There was increased extracellular matrix deposition and marked perivascular infiltration with mononuclear inflammatory cells in hypoxic transgenic mice compared with hypoxic wildtype littermate animals (mean cell number per high power field in wildtype lung 128.8±21.9, in transgenic lung 176.0±20.3, $p<0.05$).



Conclusion: In this study we confirm that the pulmonary vascular phenotype previously reported in this mouse model of scleroderma recapitulates the histological response of wildtype littermates to hypoxia, an established murine model of pulmonary hypertension. Our results support a role for TGF-β overactivity in the pulmonary vasculopathy of systemic sclerosis.

Insulin-Like Growth Factor-II Promotes Fibrosis in Systemic Sclerosis-Associated Pulmonary Fibrosis Via Both IGF-IR and IR.

Eileen Hsu and Carol A. Feghali-Bostwick, University of Pittsburgh, Pittsburgh, PA

Purpose: Although the cause of systemic sclerosis (SSc) remains unknown, fibrosis is believed to result from the interaction of soluble mediators with fibroblasts. We recently reported increased expression of insulin-like growth factor-II (IGF-II) in vivo in lung tissues of patients with SSc. In addition, IGF-II induces a fibrotic phenotype in vitro in primary lung fibroblasts. Our goal is to examine the mechanisms mediating IGF-II-induced extracellular matrix (ECM) production and fibrosis.

Methods: Primary fibroblasts were cultured from explanted lung tissues of patients with SSc and normal lung donors. Real time PCR was used to measure IGF-II mRNA levels in fibroblasts. Fibroblasts were transfected with sequence-specific siRNA or scrambled RNA control

prior to stimulation with recombinant IGF-II. ECM production was assessed in cell lysates and supernatants by western blot. Insulin-like growth factor-I receptor (IGF-IR) and insulin receptor (IR) were immunoprecipitated, and receptor levels and phosphorylation status were examined by western blot.

Results: IGF-II mRNA was increased 10-fold in primary pulmonary fibroblasts of SSc patients with mild fibrosis compared to normal lung fibroblasts (p=0.053). Fibroblasts from SSc lungs with severe fibrosis had a 64-fold increase in IGF-II mRNA levels (p=0.002). Neutralizing IGF-II activity decreased fibronectin production in a dose-dependent fashion, suggesting that IGF-II acts in an autocrine fashion to promote ECM production. Primary fibroblasts from SSc and normal lungs expressed both IGF-IR and IR. Co-precipitation studies revealed that these receptors exist as IGF-IR/IR heterodimers in primary lung fibroblasts. Both IGF-IR and IR β subunits were phosphorylated within 10 minutes of IGF-II stimulation. IGF-II-dependent ECM production was blocked in the presence of neutralizing anti-IGF-IR and IR antibodies. Further, IGF-II-dependent ECM production was decreased by inhibition of IGF-IR and IR with sequence-specific siRNA.

Conclusion: Our findings implicate IGF-II and its receptors in SSc-associated lung fibrosis. Inhibition of IGF-II decreases ECM production, demonstrating that IGF-II is an important mediator of fibrosis that acts in an autocrine or paracrine fashion. Primary lung fibroblasts expressed both IGF-IR and IR in hybrid forms that were activated by IGF-II. IGF-II-induced ECM production depends on both of these receptors. IGF-II and its receptors may serve as potential therapeutic targets in SSc-related pulmonary fibrosis.

Transforming Growth Factor-ß1 (TGF-ß1) Induction of Endothelial-to-Mesenchymal Transition in Cultured Murine Pulmonary Endothelial Cells: A Novel Mechanism of Systemic Sclerosis Fibroproliferative Vasculopathy? Zhaodong Li and Sergio A. Jimenez, Jefferson Institute of Molecular Medicine, Thomas Jefferson Univ, Philadelphia, PA

Purpose: Tissue fibrosis, most prominent in the skin, lungs, and microvasculature, is the pathological hallmark of systemic sclerosis (SSc). Resident fibroblasts and bone-marrow-derived mesenchymal cells (fibrocytes) are thought to be the main cells involved in the fibrogenic process. However, other mesenchymal cell populations may exist including cells originated from epithelial-to-mesenchymal transition (EMT). The possibility that tissue fibroblasts may also be derived from endothelial cells via a process of endothelial-to-mesenchymal transition (EndoMT) has recently been implicated in cardiac and renal fibrosis. Here we investigated the occurrence of EndoMT in murine lung endothelial cells and examined the role of TGF-β and Endothelin-1 (ET-1) in this process. We also examined the participation of caveolin-1 (Cav-1), a protein involved in TGF-β receptor internalization, on pulmonary endothelial cell transition into myofibroblasts.

Method: Primary mouse pulmonary endothelial cells (PEC) from Wild-type (WT) and Cav-1 knockout mice (Cav-1 KO; provided by Dr. Michael Lisanti, Thomas Jefferson Univ) were isolated by immunomagnetic methods employing sequential anti-CD34 and anti-CD102 antibody selection and cell sorting. The purified PEC were examined by cell morphology and Dil-Ac-LDL uptake assays. The effects of TGF-β1 and ET-1 on EndoMT were tested in cultured PEC from WT and Cav-1 KO mice. EndoMT was assessed by immunofluorescence and Western blot for α-smooth muscle actin (α-SMA) expression. The role of Cav-1 expression was examined in PEC from Cav-1 KO following restoration of Cav-1 function employing cell permeable Cav-1 scaffolding domain peptides.

Results: The results showed that pure PEC populations can be isolated from WT and Cav-1 KO and expanded in culture. TGF-β1 induced significant α-SMA expression in PEC from WT mice. ET-1 alone had no effect, however, it acted synergistically and potentiated TGF-β1 effects. In contrast, bFGF did not cause increased upregulation of α-SMA expression. PEC from Cav-1 KO mice showed very high levels of spontaneous α-SMA expression, which was downregulated by restoration of Cav-1 function.

Conclusion: Murine PEC are capable of undergoing EndoMT *in vitro* in response to TGF-β and ET-1 potentiates these TGF-β effects. Cav-1 deficient PEC display high level of spontaneous EndoMT which is abrogated by restoration of Cav-1 function. These results suggest that a process of EndoMT may participate in the development of tissue fibrosis and proliferative vasculopathy characteristic of the pulmonary involvement in SSc. Further studies are needed to clarify the downstream signaling pathways and the potential role of EndoMT in SSc-associated tissue fibrosis and vasculopathy *in vivo*. Supported by NIH Grant RO1 AR055660.

Distinct Deregulated Pathways Underlie the Molecular Subsets of Scleroderma and Are Recapitulated in Select Animal Models. Jennifer L. Sargent[1], Antonios O. Aliprantis[2], Matthew B. Greenblatt[2], Minghua Wu[3], Giuseppina Alessandra Farina[4], Raphael Lemaire[4], Laurie H. Glimcher[2], Stephen H. Clark[5], John Varga[6], Robert A. Lafyatis[4] and Michael Whitfield[7], [1]Dartmouth Medical School, Hanover, NH, [2]Harvard School of Public Health, Boston, MA, [3]Feinberg School of Medicine, Northwestern University, Chicago, IL, [4]Boston University School of Medicine, Boston, MA, [5]University of Connecticut Health Center, Farmington, CT, [6]Northwestern University Feinberg School of Medicine, Chicago, IL, [7]Hanover, NH

Purpose: Scleroderma (systemic sclerosis; SSc) is a devastating autoimmune disease of unknown etiology. Highly heterogeneous clinical presentation has hindered the understanding of mechanisms of disease pathogenesis. With no clear molecular markers of disease activity and severity, development of appropriate animal models of scleroderma is challenging. Milano et al. analyzed the gene expression in skin biopsies from diffuse and limited SSc patients, morphea and healthy controls (PLoS ONE 2008). Distinct gene expression groups were identified that could be mapped to specific clinical covariates such as increase skin score and ILD.

This study addressed two questions. What are molecular mechanisms and signaling pathways underlie the molecular subsets of scleroderma? And, can the molecular subsets of scleroderma be mapped to commonly used animal models of the disease?

Method: We determined the relative contribution of pro-fibrotic cytokines TGFβ, IL13 and IL4 to gene expression in SSc biopsies. Gene expression signatures associated with responses to TGFβ, IL13 and IL4 were defined in cultured primary adult dermal fibroblasts. Expression of these signatures was then examined in the molecular subsets of SSc.

Genome-wide profiles of skin from Tsk1, Tsk2, cGVHD and bleomycin-induced fibrosis murine models of SSc were analyzed. Mouse and human SSc datasets were merged using distance weighted discrimination, intrinsic genes were selected, and the samples and genes hierarchically clustered. Biological pathways shared by SSc subsets and the animal models were determined using Genomica software.

Results: TGFβ signaling underlies the diffuse-proliferation subset and IL13 and IL4-associated signaling is enriched in the inflammatory subset of scleroderma. Skin from Tsk2 mice shares gene expression features with the diffuse-proliferation subset, including enrichment of a TGFβ-responsive signature. IL13 signaling is required for expression of a disease-associated signature in cGVHD skin and reflects gene expression in skin from inflammatory subset.

Conclusion: We have shown that distinct signaling pathways underlie the diffuse-proliferation and inflammatory subsets of SSc suggesting that patients in these groups may benefit from differential treatment. Having demonstrated similar pathways deregulated in the Tsk2 and cGVHD models, we propose that these models are optimal systems in which to test new therapeutics targeting TGFβ and IL13-signaling pathways.

Efficacy of Aminaftone in a Monocrotaline Rat Model of Pulmonary Hypertension. Alessandro Santaniello[1], Roberto Latini[2], Vanessa Zambelli[2], Lorenzo Beretta[1] and Raffaella Scorza[1], [1]Fondazione IRCCS Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena and University of Milan, Italy, Milan, Italy, [2]Istituto di Ricerca Mario Negri, Milan, Italy

Purpose: Pulmonary arterial hypertension (PAH) is a frequent complication of systemic sclerosis characterized by a progressive increase in pulmonary vascular resistance leading to right ventricular (RV) failure with severe mortality and morbidity. Endothelin-1 (ET-1) is the most relevant factor in the PAH pathogenesis. We recently reported that aminaftone (AMNA) is able to down regulate ET-1 production in endothelial cells. In this work we evaluated whether AMNA may able to contrast negative effects of monocrotaline (MCT)-induced PAH in a rat model

Method: Sixty Male Wistar rats were allocated in 4 different groups:

Control group with no MCT injection (15 rats). Three other groups of rats received MCT by a single subcutaneous injection (60 mg/kg) in a volume of 3 ml/kg and were assigned to receive no treatment (15 rats), AMNA as food admix 30 mg/kg/day (15 rats) or 150 mg/kg/day (15 rats) for 4 weeks. The doses of AMNA were the maximally effective doses based on a dose-range-finding study.

Hemodynamic measurements were performed 4 weeks after MCT injection. The rats were anesthetized by intraperitoneal injection of 60mg/kg of pentobarbital. A catheter was inserted into the right jugular vein for measurement of right ventricular pressure (RVP), using the procedure previously described by Stinger. Measurements were recorded a PowerLab data acquisition system.

Heart, lungs, kidneys, and liver were removed after rats sacrifice and weighed, and the ratio of organ weight to body weight (BW) was calculated. The right ventricle (RV) and the left ventricle plus septum (LV) were separated and weighed; the ratio RV/RV+LV was used as an index of RV hypertrophy.

All data are presented as mean ± standard deviation. Statistical analyses were performed by analysis of variance (ANOVA). The null hypothesis was rejected when $P < 0.05$.

Results: In the different groups the mortality was: 0% (control rats); 25% (only MCT injection); 0% (MCT + AMNA 30 mg/kg/day); 0% (MCT + AMNA 150 mg/kg/day).

RV/RV + LV was only significantly lower in the rats treated with MCT + AMNA 30 mg/kg/day vs rats treated with MCT (0,3 ± 0,03 Vs 0,34 ± 0,02; p<0,05). No significant differences were observed in RVP and in other organ weight between groups.

Conclusion: AMNA ability to reduce ET-1 production suggested a potential beneficial effect in the treatment of PAH. Mortality percentage and RV hypertrophies reduction observed in this experimental session confirm a possible therapeutic role of AMNA in the management of PAH. This evidence might support further research to evaluate whether AMNA may be used in combination with current conventional therapy to ameliorate the prognosis of PAH patients.

The Inflammasome Is Involved in Bleomycin-Induced Dermal Fibrosis and Is Activated in Systemic Sclerosis (SSc) Fibroblasts. Judy Rieger[1], Alina Boesteanu[1], Sihem Sassi-Gaha[1], Carol A. Feghali-Bostwick[2], Peter D. Katsikis[1] and Carol M. Artlett[1], [1]Drexel University College of Medicine, Philadelphia, PA, [2]University of Pittsburgh, Pittsburgh, PA

Purpose: SSc is an autoimmune disease characterized by fibrosis of unknown etiology affecting the skin and visceral organs. The initiating events and development of fibrosis are unknown, however infection or environmental stimuli have been implicated. The newly identified inflammasome mediates the innate immune system and regulates potent proinflammatory cytokines such as IL-1b, IL-18, and IL-33. Inflammasome activation is controlled by an adaptor (ASC) and sensor (NALP3) that activate caspase-1 to cleave IL-1β, IL-18, and IL-33 into their active forms. IL-1β polymorphisms and an increase in protein have been reported in SSc as well as elevated levels of IL-18, directly suggesting the involvement of the inflammasome in SSc pathogenesis. Fibroblasts are able to modulate the innate immune system and contribute to plasma levels of IL-1β, and IL-18. We determined the role of the inflammasome in bleomycin (BLM)-induced dermal fibrosis utilizing NALP3-/- mice and investigated inflammasome activation in fibroblasts isolated from patients with SSc.

Method: Normal human fibroblasts and SSc fibroblasts derived from active lesions of SSc patients were cultured in complete DMEM. Normal fibroblasts were treated with BLM and gene expression for inflammasome transcripts was quantified by RT-PCR, and inflammasome transcripts and protein were measured in SSc fibroblasts. Localized dermal fibrosis was induced by subcutaneous injections of BLM for 28 days in NALP3 -/- and C57Bl/6 mice in one flank. The opposite flank was injected with PBS. Injection sites were harvested, stained with Masson's Trichrome and measured for skin thickness. Fibrosis was assessed as a change in skin thickness in the BLM site versus PBS site of the same mouse. Lung pathology in the mice was also assessed.

Results: In normal human fibroblasts, BLM induced genes involved in the inflammasome; IL-1β by 39% (p=0.045), IL-18 by 30.5% (p=0.02), and NALP3 by 51% (p= 0.02). Compared to normal fibroblasts, SSc fibroblasts were found to express more IL-18 (p<0.0001), IL-33 (p<0.001) and NALP3 (P<0.0001) mRNA and NALP3 protein (p<0.001). In the animal studies, BLM induced an increase in skin thickness of 41% in C57Bl/6 mice (p<0.0001) but in the absence NALP3, fibrosis was completely abolished (p=0.0026). Furthermore, BLM induced increased lung occlusion and collagen deposition in the lung of C57Bl/6 whereas NALP3-/- mice had normal lung architecture.

Conclusion: Using the BLM-induced model of fibrosis we report that the innate immune system participates in fibrosis via inflammasome activation, BLM can upregulate inflammasome specific genes, and furthermore the NALP3/ASC inflammasome is required for the development of dermal fibrosis. Finally, we found that SSc derived fibroblasts have an increased basal expression of NALP3 mRNA and protein. We conclude that the NALP3 inflammasome is an important mediator in the development of dermal fibrosis and may play a role in the pathogenesis of SSc.

VEGF Aggravates Skin Fibrosis in Different Animal Models of Systemic Sclerosis (SSc). Britta Maurer[1], Alfiya Akhmetshina[2], Renate E. Gay[1], Georg Schett[3], Beat A. Michel[1], Michael Detmar[4], Steffen Gay[1], Jörg HW Distler[2] and Oliver Distler[1], [1]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland, [2]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Inst Pharmaceut Sciences, ETH Zurich, Zurich, Switzerland

Purpose: In SSc, the underlying mechanisms that link vasculopathy and fibrosis have yet to be elucidated. Recently, VEGF has been reported to induce migration of normal fibroblasts through PDGF receptor signalling due to receptor homology. Since SSc patients have high tissue and serum levels of VEGF, the aim of our study was to analyze the impact of VEGF on fibrosis in vitro and in inflammatory (bleomycin) and non-inflammatory (TSK1) animal models of SSc.

Method: Homo- (+/+) (n=8) and heterozygous (+/-) (n=9) VEGF transgenic (tg) and wildtype (wt) mice (n=6/9) were treated for 4 weeks with bleomycin or NaCl. Skin sections were analyzed by HE and Masson's trichrome staining and immunohistochemistry. Additionally, VEGF +/-/TSK1 (tight skin mice) (n=6) were generated. Furthermore, SSc and healthy skin fibroblasts (n=4 each) were treated with recombinant VEGF-A (20 ng/ml), and collagen production was measured by quantitative RT-PCR and the Sircol assay.

Results: In SSc skin fibroblasts, VEGF stimulation increased procollagen I and III mRNA by a mean ± SEM 3.4 ± 1.3 and 5.6 ± 3 fold, in healthy skin fibroblasts by 2.5 ± 0.4 and 1.5 ± 0.3 fold ($p<0.05$). Similarly, in the Sircol assay, the supernatants of VEGF stimulated SSc fibroblasts contained more collagen protein than those of unstimulated controls (77 ± 9.4 ng/ml vs. 54 ± 5.7 ng/ml). In VEGF +/- and VEGF +/+ mice treated with bleomycin, skin thickness increased by 2.3 ± 0.07 and 2.3 ± 0.08 fold compared to 1.7 ± 0.02 fold of bleomycin treated wt mice ($p<0.05$). Strikingly, VEGF +/+ mice, but not VEGF+/- mice and controls, spontaneously developed fibrosis even without bleomycin challenge with an increase of skin thickness by 1.8 ± 0.2 fold ($p<0.05$), indicating a dose-dependent in vivo effect of VEGF on skin fibrosis. Masson's trichrome staining showed that skin thickness was caused by extracellular matrix accumulation rather than skin edema. In all VEGF tg mice, inflammatory infiltrates consisting of macrophages and T cells were prominent, which was even more pronounced after bleomycin challenge. In addition, crossing VEGF +/-/ with TSK1 mice as a model for non-inflammatory SSc resulted an increased hypodermal thickness of 694.5 ± 15 µm in VEGF +/-/TSK1 compared to TSK1 and VEGF +/- controls with 456 ± 20.6 µm and 258.3 ± 22.2 µm ($p<0.05$). Most notably, VEGF tg mice displayed an altered vessel morphology with distorted capillaries that resembled the microvascular features of SSc patients.

Conclusion: Our results show that VEGF aggravates fibrosis in vitro and in vivo. Potential mechanisms include direct profibrotic effects via PDGF receptors and indirect profibrotic effects by the induction of inflammation via VEGFR1 signalling on monocytes. Thus, our data suggest VEGF as a novel link between vascular injury, inflammation and onset of fibrosis in SSc.

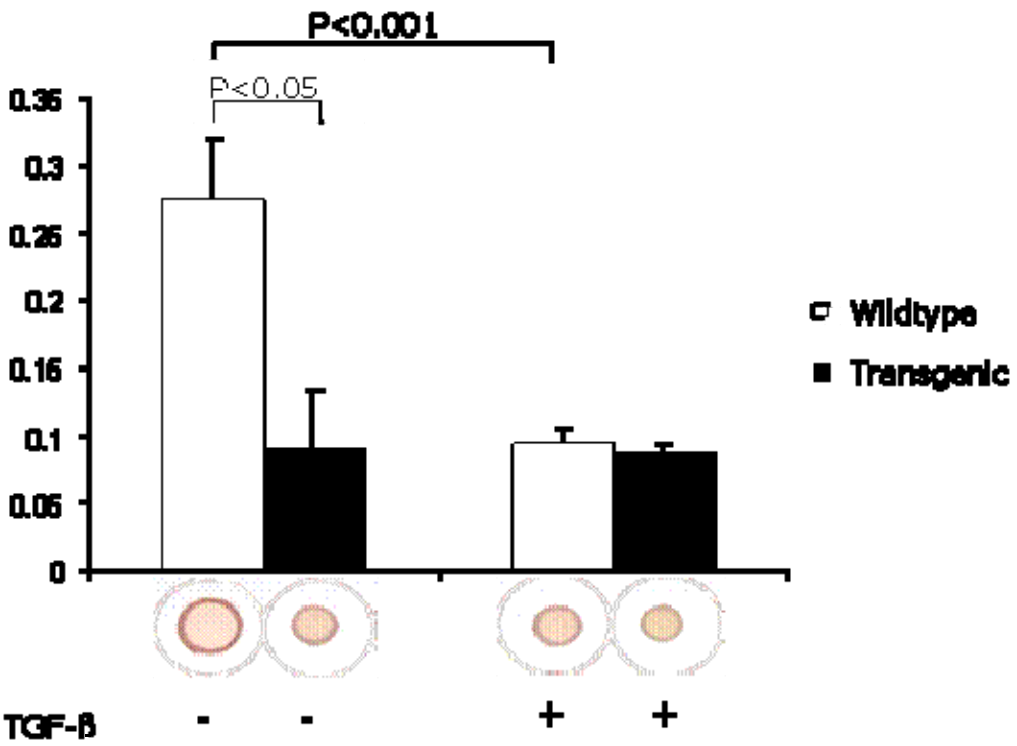
Aortic Smooth Muscle Cells Show a Pro-Fibrotic Phenotype in a TGF-Beta Dependent Mouse Model of Systemic Sclerosis. Emma Derrett-Smith, Audrey Dooley, Korsa Khan, Xu Shi-wen, David Abraham and Christopher P. Denton, UCL Medical School, London, United Kingdom

Purpose: In systemic sclerosis, the large elastic arteries have altered elasticity and compliance. We have examined the large systemic vessels in a mouse model of SSc characterised by ligand-dependent activation of TGF-β signalling in fibroblasts.

Methods: The transgenic mouse strain TβRIIΔk-fib expresses a kinase-deficient type II TGF-β receptor linked to a fibroblast-specific promoter leading to balanced ligand-dependent upregulation of TGF-β signaling. Biological replicate samples from transgenic (n=6) or wildtype littermate control mice (n=6) were compared. Aortic and cardiac tissue were examined by histological, biochemical and isolated organ bath studies. Vascular and perivascular architecture was examined by H&E and special stains including immunostaining for TGF-β1 and pSmad 2/3. Confirmatory aortic smooth muscle cell proliferation, phenotype and functional assays, including signalling responses to exogenous TGF-β and endothelin-1 were performed. Aortic ring contractile responses to direct and receptor-mediated stimulation were assessed.

Results: TGF-β1 and pSmad 2/3 staining were increased in transgenic aortic adventitia, which was increased in diameter with an associated reduction in smooth muscle layer. Non cross-linked collagen content of transgenic thoracic aortic tissue measured by Sircol assay was increased compared to wildtype (mean transgenic collagen content 22.5±1.87 mg/ml, mean wt 12.4±0.45 mg/ml, $P<0.05$). Transgenic aortic smooth muscle cells showed upregulation of TGF-β responsive genes important for cytoskeletal function, such as transgelin (mean transgenic copy number $1.06x10^6±6.6 x10^4$, mean wildtype copy number $7.6x10^5±5.5x10^4$, $P<0.05$) and smoothelin (mean transgenic copy number 11406±1306, mean wildtype copy number 5627±758, $P<0.05$), which were then resistant to further stimulation with exogenous TGF-β1. Consistent with an activated phenotype, transgenic SMC promoted significantly more contraction of free floating type I collagen lattices when compared with wildtype, but there was no further contraction after TGF-β1 stimulation (see Figure 1).



Aortic ring responses to receptor-mediated contraction with endothelin were reduced in the transgenic animals: for instance, mean change in tension from baseline with $1x10^{-9}$ endothelin-1 treatment in wildtype animals (n=3) was 21.4±9.0 mg, compared with -5.7±2.9 in transgenic animals (n=3), $P<0.05$. Bosentan reduced endothelin-mediated contraction in wild-type animals, but had no effect in transgenic animals.

Endothelin receptor A gene expression was reduced in transgenic animals (mean wildtype copy number 2517±1261, mean transgenic copy number 315±73, $p<0.05$).

Conclusion: The histological, biochemical and functional phenotype of this transgenic mouse model of scleroderma offers insight into the altered biomechanical properties previously reported for large elastic arteries in human SSc, and supports a potential role for perturbed TGF-β and endothelin activity in this process.

Tissue Plasminogen Activator (tPA) Restores Normal Fibrinolysis / Coagulation Balance in Kidney and Reverses Clinical Score in Skin in a Murine Graft-Versus-Host Disease Model of Scleroderma: Proof of Concept for Therapeutic Fibrinolysis in Scleroderma.
Timothy Burwell[1], Tracy Delaney[1], Cindy Chen[1], Julie Bakken[1], Isabelle de-Mendez[2], Dominic Corkill[2], Bahija Jallal[1], Jane Connor[1], Anthony J. Coyle[1] and Raphael Lemaire[1], [1]MedImmune LLC, Gaithersburg, MD, [2]MedImmune LLC, Cambridge, United Kingdom

Purpose: Scleroderma is a systemic autoimmune disease that affects skin and internal organs, including kidney and lung. Affected tissues share a common pathogenesis characterized by three key manifestations: fibrosis, inflammation and vasculopathy. Scleroderma vasculopathy features occlusion of small arteries that is due to vasoconstriction, intimal proliferation and thrombosis. Thrombosis results from an imbalance between coagulation and fibrinolysis. Whether thrombosis in scleroderma is primarily due to alteration in fibrinolysis or coagulation remains unclear. In this study, we investigated thrombosis in a murine Graft-versus-Host disease (GVHD) model of human scleroderma exhibiting an occlusive vasculopathy, along with fibrosis and inflammation. We also assessed the therapeutic value of fibrinolysis in that model.

Method: GVHD was induced by injection of spleen cells from donor B10.D2 mice into recipient RAG2-deleted BALB/c mice. Clinical skin score was assessed and proteinuria levels in urine measured by dipstick. Biomarkers of fibrinolysis and coagulation were determined in plasma, skin, kidney, and lung at weeks 2, 4 and 6 post-graft using qPCR, ELISA and IHC. The therapeutic value of augmenting fibrinolysis in the GVHD model was evaluated utilizing tissue Plasminogen Activator (tPA) and evaluating effects on thrombosis, fibrinolysis and coagulation biomarkers, and clinical skin score.

Results: Induction of scleroderma-like GVHD in mice led microthrombi formation in blood vessels of deep dermis. The presence of microthrombi was associated with dramatic increases in expression of key regulators of fibrinolysis (active plasmin, PAI-1, uPA, tPA, uPAR, kallikreins) and coagulation (Factor VII and X) in skin. Murine scleroderma-GVHD caused similar large alterations in fibrinolysis and coagulation pathways in kidney, lung and plasma. Additionally, increase in proteinuria in urine upon GVHD induction was associated with increase in coagulation factors TF and vWF in kidney. Importantly, intra-peritoneal injection of tPA on the third and fourth weeks after initiation of GVHD significantly reduced expression levels of uPA, TF and vWF in kidney and clinical score in skin between 4 and 6 week post-graft.

Conclusion: These data strongly suggest that systemic alterations in both fibrinolysis and coagulation cause thrombosis in murine scleroderma-GVHD, eventually impacting in progression of the pathology. Restoration of normal fibrinolysis/coagulation balance in kidney and reversal of clinical score in skin by tPA demonstrate the therapeutic value of fibrinolysis in murine scleroderma GVHD, and ultimately in human scleroderma.

1063

Platelet Derived Serotonin (5-HT) Plays a Crucial Role for Experimental Fibrosis.
Clara Dees[1], Alfiya Akhmetshina[1], Nicole Busch[1], Jochen Zwerina[1], Michael Bader[2], Georg Schett[3], Oliver Distler[4] and Jörg HW Distler[1], [1]Dept Int Med 3, Univ Erlangen, Erlangen, Germany, [2]Max Delbrück Ctr Mol Med Berlin, Berlin, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Ctr Exp Rheum, Univ Hosp Zurich / Zurich Ctr Integr Hum Physiol (ZIHP), Zurich, Switzerland

Purpose: Systemic sclerosis (SSc) is characterized by progressive vascular disease and organ fibrosis. We have shown previously that 5-hydroxytryptamine (5-HT) exerts pro-fibrotic effects via 5-HT2B receptors. Tryptophanhydroxylase-1 (tph-1) is the rate-limiting enzyme for the synthesis of 5-HT. After synthesis, 5-HT is stored in large amounts within platelets and can be released upon platelet activation. The aim of the present study was to investigate the role of platelet activation and release of 5-HT for fibrosis.

Method: The 5-HT content in lesional skin was analyzed by competitive ELISA. Clopidogrel, an inhibitor of the glycoprotein IIb/IIIa pathway, was used to prevent platelet activation. Depletion of 5-HT from platelets was achieved by knockdown of tph-1. The role of platelet derived 5-HT for fibrosis was evaluated in the mouse model of bleomycin-induced dermal fibrosis, a model for early, inflammatory stages of SSc, and in tight-skin-1 (tsk-1) mice, which serve as a model of later, less inflammatory stages of SSc.

Results: In the mouse model of bleomycin-induced dermal fibrosis, the concentration of 5-HT in lesional skin significantly increased to 5.8 ± 0.5 ng/mg compared to 3.2 ± 0.2 ng/mg in control mice ($p < 0.05$). The levels of 5-HT were also upregulated from 3.5 ± 0.4 ng/mg to 4.8 ± 0.2 ng/mg ($p < 0.05$) in the skin of tsk-1 mice. Treatment with clopidogrel significantly reduced the 5-HT content of the skin in both models. Along with reduced levels of 5-HT, treatment with clopidogrel decreased dermal thickening upon bleomycin-challenge by 61 ± 13 % ($p < 0.05$). Inhibition of platelet activation prevented also hypodermal thickening in tsk-1 mice with a mean reduction of hypodermal thickness by 51 ± 16 % ($p < 0.05$). Moreover, treatment with clopidogrel significantly reduced the number of myofibroblasts in bleomycin treated mice and tsk-1 mice. Selective depletion of 5-HT from platelets by knockdown of tph-1 exerted also potent anti-fibrotic effects and confirmed the results obtained with clopidogrel. Dermal fibrosis was significantly ameliorated in mice lacking tph-1 with a mean reduction in dermal thickening of 61 ± 6 % ($p < 0.05$) and almost complete prevention of myofibroblast differentiation.

Conclusion: We demonstrate increased levels of 5-HT in different animal models of SSc. Inhibition of platelet activation decreased the release of 5-HT and prevented dermal fibrosis in the model of bleomycin-induced fibrosis and in tsk-1 mice. In addition, mice lacking 5-HT in platelets are less sensitive to experimental fibrosis. Thus, platelet activation in affected vessels and subsequent release of the pro-fibrotic mediator 5-HT might provide a novel link between vascular manifestations and tissue fibrosis in SSc.

Fli1 Is a Negative Regulator of Estrogen Receptor α in Dermal Fibroblasts. Tomoyasu Hattori, Yoshihide Asano, Lukasz Stawski and Maria Trojanowska, Medical University of South Carolina, Charleston, SC

Purpose: Fli1, a member of the Ets family of transcripion factors, has been shown to play a pivotal role in the regulation of extracellular matrix genes in dermal fibroblasts. Furthermore, Fli1 has been shown to be persistently down-regulated in fibrotic scleroderma skin. Estrogen has also been shown to positively regulate collagen synthesis in dermal fibroblasts. Estrogen mediates its effects through estrogen receptors (ERs), ERα and ERβ, however the roles of ERs in dermal fibroblasts remain unknown. The goal of this study was to examine a possible interaction between the estrogen and Fli1 pathways focusing on the cross-talk between Fli1 and ERα.

Method: The protein expression of ERα *in vivo* was examined by immunohistochemistry using skin samples taken from 3 $Fli1^{+/-}$ mice (1 male, 2 females). Primary dermal fibroblasts were isolated from $Fli1^{+/-}$ mice (2 females). The level of ERα expression was determined by quantitative reverse transcriptase-PCR and Western blot techniques. $Fli1^{+/+}$ littermates were studied in parallel as controls. Human dermal fibroblast cultures were established from skin biopsies taken from 4 adult young women (range 19-28 years old) in compliance with the Institutional Review Board for Human Studies. Endogenous Fli1 levels were suppressed in human dermal fibroblasts using specific small interfering RNA (siRNA). Human dermal fibroblasts were incubated in serum-free medium for 48 hours followed by 24 hour stimulation with 2ng/ml of human recombinant transforming growth factor (TGF)-β1. The binding of Fli1 to the human ERα promoter was examined by chromatin immunoprecipitation assay (ChIP).

Results: Dermal fibroblasts expressed higher levels of ERα protein in the skin of $Fli1^{+/-}$ mice as compared to the $Fli1^{+/+}$ mice. The proportion of the ERα- positive fibroblasts was 5.7-fold, 4.0-fold and 2.1-fold higher in the individual $Fli1^{+/-}$ mice as compared to control $Fli1^{+/+}$ mice. The expression level of ERα was also higher in cultured mouse fibroblasts obtained from $Fli1^{+/-}$ mice as compared to $Fli1^{+/+}$ mice at both mRNA (3.1-fold) and protein (4.6-fold) levels. Endogenous Fli1 expression was suppressed >80% by specific siRNA in

cultured human dermal fibroblasts. Down-regulation of Fli1 by siRNA resulted in up-regulation of ERα mRNA (1.9-fold) and protein (1.5-fold). Consistent with these observations, TGF-β1 that is known to inactivate repressor function of Fli1, increased the level of ERα protein in human dermal fibroblasts (1.4-fold). Fli1 was found to occupy the Ets binding site within the human ERα promoter *in vivo* by ChIP assay.

Conclusion: This study demonstrates for the first time that Fli1 functions as a suppressor of ERα in dermal fibroblasts, suggesting that estrogen/ERα pathway might contribute to the profibrotic effects induced by activation of the TGF-β/Fli1 signaling. Activation of estrogen/ERα pathway may also potentiate fibrosis in patients with scleroderma.

Bowen[1], Jia Lin[1], Changshou Gao[1], Rob Woods[1], Jodi Karnell[1], Rachel Ettinger[1], Philip Brohawn[1], Yihong Yao[1], Bahija Jallal[2], Ronald Herbst[1] and Anthony J. Coyle[1], [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, Gaithersburg, MD

Purpose: Human cluster of differentiation antigen 278, also called inducible T-cell co-stimulator (ICOS) is a T cell-specific surface antigen selectively expressed by recently activated, memory, and T follicular helper (T_{fh}) T cells. In this study, the function of ICOS in the pathogenesis of a graft-versus-host disease (GvHD) mouse model of scleroderma (SSc) was investigated using a glycoengineered anti-mouse ICOS MAb with enhanced antibody-dependent cellular cytotoxicity (ADCC).

Methods: We have generated a glyco-engineered rat anti-ICOS monoclonal antibody (MAb) directed against the ligand binding domain of murine ICOS as mouse IgG2a. The antibody was produced in a fucosyltransferase 8-deficient Chinese Hamster Ovary (CHO) producer cell line (BioWa Potelligent® Technology), a procedure that generates a homogenously afucosylated antibody (anti-ICOS-aFuc) with enhanced ADCC. The activity of the afucosylated anti-mouse ICOS MAb, was evaluated in a murine GvHD model, which recapitulates key aspects of human SSc, including inflammation, fibrosis, and vasculopathy.

Results: Dosing of the anti-ICOS-aFuc MAb reduced severity and incidence of dermal lesions when compared to isotype control MAb and control syngeneic graft. Mean clinical scores were significantly reduced in anti-ICOS-treated groups compared to isotype control MAb-treated mice, as early as 12 days post-graft (3.4-fold, $p<0.002$), and thereafter up to 4 weeks post graft (8.1-fold, $p<0.0001$). The anti-ICOS-aFuc MAb also prevented the disease-associated accumulation of T_{FH} cells and the associated expansion of germinal center B cells and immunoglobulin secreting B cells. There were no ICOS MAb-related clinical signs or changes in body weight in animals during the study.

Conclusion: The results from this study indicate that ICOS plays an important role in dermal pathology of murine GvHD-SSc, as depletion of $ICOS^+$ T cells reduced the overall clinical disease score. The identification of dysregulated $ICOS^+$ T_{FH} cells in GvHD-SSc underscore their critical function in driving the generation of pathogenic B cells into germinal center B cells in secondary lymphoid tissues and in the differentiation of immunoglobulin secreting B cells in the skin. Importantly, treatment with the anti-mouse ICOS-aFuc MAb resulted in a significant reduction of the clinical signs of disease and represents an innovative therapeutic strategy for the treatment of T helper associated autoimmune GvHD-SSc.

Anti-Inflammatory and Anti-Fibrotic Effect of Angiotensin AT2 Receptors Stimulation or AT1 Receptors Blockade in Scleroderma. Francesca Santi[1], Katja Ströder[2], Franziska Rompe[2], Anja Wieland[2], Metin Artuc[3], Christa Thöne-Reineke[2], Nazzarena Malavolta[1], Claudio Borghi[1], Thomas Unger[2] and Ulrike Muscha Steckelings[2], [1]University of Bologna - Rheumatology Unit, Bologna, Italy, [2]CCR - Centre for cardiovascular research Berlin - Germany, Berlin, Germany, [3]Dermatology Department - La Charité Hospital Berlin, Germany

Purpose: Skin harbours a complete renin-angiotensin-system (RAS). There is evidence for an upregulation of RAS in Scleroderma lesions. Our project aimed at investigating whether pharmacological interference with the RAS (angiotensin AT1 receptor blockade or AT2 receptor stimulation) may be effective in reducing inflammation and fibrosis in a scleroderma murine model.

Method: Female C3/H mice were treated with bleomycin injection (100 µl of a 100 µg/ml solution s.c.) every second day over a period of 4 weeks. Animals were randomised in 4 treatment groups (n=6 each): (i) control group (only vehicle), (ii) Bleomycin; (iii) Bleomycin+ AT1R blocker, Candesartan (0,1 mg/kg bw, s.c. every day); (iv) Bleomycin + AT2R agonist, Compound21 (0,3 mg/kg bw, s.c. every day). Subsequently, tissue samples were collected and analysed for markers of inflammation and fibrosis by real time RT-PCR, Western Blotting and conventional histological staining (HE).

Results: After 4 weeks of Bleomycin injection, histological analysis showed an increased in extracellular matrix primarily within the subdermal layers. This fibrotic reaction was ameliorated both by Compound21 and Candesartan treatment. Histological reduction of fibrosis as a results of Compound21 or Candesartan treatment coincided with a reduced expression of precollagen I&alphaI and TGF&beta as estimated by Western Blot. Furthermore, Bleomycin elicited an increase in IL-6 and MCP-1 mRNA expression, which could be significantly reduced by Compound21 and Candesartan. Experiments in vitro on human fibroblasts both from healthy donors and from scleroderma patients show results similar to our murine model.

Conclusion: Our data indicate that pharmacological interference with the cutaneous RAS by AT1R blockade or by AT2R stimulation could be a potential therapeutic approach to reduce inflammation and fibrosis in scleroderma and, potentially, in other pathological settings with similar pathomechanism.

Autoimmune-Driven Skin Fibrosis: The Critical Requirement for IFNAR1 in An Experimental Model of Systemic Sclerosis. Tracy Delaney[1], Christopher Morehouse[1], Philip Brohawn[2], Yihong Yao[1], Cindy Chen[1], Ricardo Cibotti[1], Jane Connor[1], Ronald Herbst[1], Bahija Jallal[2] and Anthony J. Coyle[1], [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, Gaithersburg, MD

Purpse: Diffuse systemic sclerosis (dSSc) is an autoimmune disorder featuring progressive fibrosis in skin and in visceral organs such as lung and kidney. Type I interferons (IFNs) have been associated with autoimmunity, but their role in dSSc pathogenesis remains unclear. To determine whether Type I IFNs contribute to autoimmune-driven fibrosis, mice deficient in their shared receptor IFNAR1-/- were compared to wild type (WT) in an experimental model of dSSc.

Methods: IFNAR1-/- and WT mice were immunized with human collagen V on days 0 and 21 and monitored by dipstick for signs of proteinuria for an additional 4 weeks. On day 50 animals were assessed for target tissue inflammation, fibrosis, and serum autoantibodies. qPCR analysis of lung, skin, and kidneys was performed by Fluidigm array, and autoantibody titers by ELISA. Fibrosis was evaluated by trichrome staining and Sircol assay.

Results: Human collagen V immunization induced a sustained elevation in proteinuria between day 35 and day 50 in both WT and IFNAR1-/- mice. Inflammation and fibrosis in kidneys and lungs of WT and IFNAR1-/- mice were equivocal by histological analysis on day 50. By contrast, skin inflammation and fibrosis scores were markedly reduced in the immunized IFNAR1-/- group compared to WT; these differences were confirmed by Sircol assay for collagen. Overexpression of pro-inflammatory cytokines, leukocyte surface markers, and pro-fibrosis genes was highly significant in WT SSc skin compared to control skin, whereas little upregulation was detected in IFNAR1-/- SSc skin. Elevated serum titers of autoantibodies against the SSA, SSB, and the a and b subunits of the PDGF receptor were similar in both immunized WT and IFNAR1-/- mice.

Conclusion: Type I IFN signaling through IFNAR1 is required to drive skin fibrosis, but not lung or kidney fibrosis, in experimental dSSc. These data implicate Type I IFNs in an as yet unidentified key pathway that supercedes the production of pathogenic autoantibodies in importance in skin involvement in this model.

Hydrogen Sulfide Attenuates the Development of Skin Fibrosis in Tight-Skin Mice. Eiji Muroi, Ayumi Yoshizaki, Koichi Yanaba, Toshihide Hara, Fumihide Ogawa, Motoi Takenaka, Kazuhiro Shimizu and Shinichi Sato, Nagasaki Univ Schol of Biomed, Nagasaki, Japan

Purpose: Oxidative stress has been suggested to contribute to clinical manifestations associated with systemic sclerosis (SSc), such as vascular damage, fibrosis, and autoantibody production. The generation of oxygen free radicals and reactive nitrogen species is not only due to inflammation processes, but also greatly enhanced by frequent episodes of reperfusion injury (Raynaud phenomenon). This has led to hypothesize that oxidative stress is the pivotal event in the early phase of disease. Therefore, it is likely that antioxidant treatment is useful for treatment of SSc, especially the early phase when oxidative stress is at maximal levels. Hydrogen sulfide (H2S) can neutralize a variety of reactive species and thereby exhibits the cytoprotective (antinecrotic or antiapoptotic) effects. In this study, we assessed the therapeutic effect of H2S on a tight-skin (TSK/+) mouse, a mouse model for human SSc.

Method: One-week-old TSK/+ mice were intraperitoneally injected with NaHS (H2S donor) at 100 μmol/kg each day for 4 weeks. Hypodermal thickness of 5-week-old mice was measured under a light microscope. Serum autoantibody levels were determined by enzyme linked immunosorbent assay. Fibroblasts from TSK/+ mice were cultured with or without NaHS for 24 hours. Skin expression levels of mRNA were determined by real-time reverse transcription polymerase chain reaction.

Results: NaHS treatment significantly reduced hypodermal thickness by 70%. Consistent with this finding, NaHS treatment in TSK/+ mice also decreased skin content of hydroxyproline, a modified amino acid uniquely found at a high percentage in collagen. Since H2S can function as an antioxidant by up-regulating heme oxygenase-1 (HO-1), an anti-inflammatory and cytoprotective molecule, we investigated skin HO-1 expression. The fibrotic skin from TSK/+ mice exhibited reduced HO-1 expression relative to the wild type skin. NaHS treatment significantly increased HO-1 expression in the TSK/+ skin to a similar level of the wild type skin. Furthermore, H2S can inhibit the generation of nitric oxide, which is a cytodestructive molecule in various pathological conditions, through down-regulation of endothelial nitric oxide synthase (eNOS) expression. Consistent with this, NaHS treatment significantly reduced eNOS expression in the TSK/+ skin. Finally, proα2 (I) collagen gene expression by cultured TSK/+ fibroblasts was significantly inhibited by NaHS treatment.

Conclusion: In the current study, NaHS treatment showed remarkable effectiveness in TSK/+ mice, suggesting that oxidative stress is critical for the development of skin fibrosis in TSK/+ mice.

Th17 Polarization in Systemic Sclerosis Is Influenced by Immunosuppressive Treatment Regardless Time of Evolution. Tatiana S. Rodriguez-Reyna, Janette Furuzawa-Carballeda, Javier Cabiedes, Luís Daniel Fajardo-Hermosillo, Mariana Díaz-Zamudio and Luís Llorente, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis and vasculopathy. A key feature of the inflammatory lesions is the presence of T cells. Several studies suggest that the T-cell activity in SSc takes place outside the conventional Th1/Th2 subsets and high levels of IL-17 have been reported. Our aim was to establish the differences in T helper subsets and Tregs between SSc patients with different disease subsets and time of evolution, and contrast groups.

Method: Blood samples from 135 SSc patients were obtained. Clinical evaluation was determined using the Medsger severity scale. SSc patients were classified in: diffuse cutaneous (dc) (n=57) and limited cutaneous (lc) disease (n=78). As contrast groups age- and sex-matched healthy volunteers (n=16), active systemic lupus erythematosus (aSLE) (n=13) and active rheumatoid arthritis (aRA) patients (n=12) were included. Peripheral blood mononuclear cells were analyzed by flow cytometry to determine Th1 ($CD4^+$/IFN-γ^+), Th2 ($CD4^+$/IL-4^+), Th17 ($CD4^+$/IL-17^+) and Treg ($CD4^+$/$CD25^+$/$Foxp3^+$) subsets. Statistical analysis was performed using Mann-Whitney Rank Sum Test, student´s t test, Chi square test and multivariate ANOVA.

Results: Th17 subset was 3 to 5-fold increased in SSc groups vs healthy controls (dc=125±14 cell/mL; lc=82.9±12 cell/mL; control=27±4 cell/mL; p=0.001) and aSLE patients (13.1±3 cell/mL, p=0.001). Th1 cells were increased in SSc vs healthy controls (dc=61.3±12 cell/mL, lc=45.5±6 cell/mL, control=6±3 cell/mL $p \leq 0.001$) and aSLE patients (6±3 cell/mL, $p<0.001$). No differences in Th2 and Treg subpopulations were found between SSc patients and healthy controls; Th2 cells were higher in SSc patients (77.7±9 cell/mL) than in the

aRA (27.8±14 cell/mL; p=0.01 vs lcSSc; p=0.001 vs dcSSc) and aSLE (19.1±7 cell/mL; p=0.004 vs lcSSc; p<0.001 vs dcSSc) groups, and Treg cells were increased in the aRA group (176.4±34 cell/mL) when compared to the others (controls:79±10 cell/mL, p=0.02; dcSSc:92.1±10 cell/mL, p=0.01; lcSSc:83.1±11 cell/mL, p=0.001; aSLE:52.3±12 cell/mL, p=0.001). Interestingly, Th17 and Th2 cells were higher in SSc patients with longer time of evolution of the disease (>8.1 years; median) and also in patients that were not receiving immunosuppressive treatment (prednisone ≥5 mg/day, cyclophosphamide ≥50 mg/day or azathioprine ≥50 mg/day) at the time of the sample. In a multivariate ANOVA that included treatment and time of evolution of the disease, only the treatment remained significant (p=0.04 for the overall model; p=0.02 for the effect of treatment), suggesting that this factor explains the variability amongst subgroups.

Conclusion: Th17 and Th1 subsets are increased in patients with SSc. Immunosuppressive treatment modifies Th17 and Th2 subsets in these patients regardless time of evolution of the disease.

Decreased Expression of Caveolin-1 Contributes to IGFBP-5′s Fibrotic Activity. Yukie Yamaguchi, Hidekata Yasuoka and Carol A. Feghali-Bostwick, University of Pittsburgh, Pittsburgh, PA

Purpose: Caveolae and Caveolin-1 (Cav-1) serve as a platform for membrane trafficking, endocytosis, and signal transduction. Recently, the physiological importance of decreased Cav-1 levels in fibrotic lung and skin of patients with systemic sclerosis (SSc) was reported. We have previously described increased expression of insulin-like growth factor binding protein- 5 (IGFBP-5) in fibrotic disorders such as SSc. IGFBP-5 is a pro-fibrotic factor that induces production of extracellular matrix (ECM) components in vitro, in vivo in lung and skin, and ex vivo in human skin. Although IGFBP-5 is a secreted protein that can translocate to the nucleus, little is known about the role of shuttling and compartmentalization of IGFBP-5 in the development of fibrosis. We therefore sought to examine the localization of IGFBP-5 and the role of Cav-1 in its compartmentalization in primary fibroblasts.

Methods: IGFBP-5 was expressed in primary human and mouse lung fibroblasts. Localization of IGFBP-5 and Cav-1 was evaluated by western blot, immunocytostaining and electron microscopy. Purified FLAG-tagged IGFBP-5 was added to WT and Cav-1 null fibroblasts and its internalization was assessed. In addition, IGFBP-5 re-uptake by cells was examined in WT fibroblasts treated with Caveolae-disrupting agents and small interfering (si)RNA. Cav-1 function was restored in Cav-1 null fibroblasts using Cav-1 scaffolding peptide (CSD). The effect of IGFBP-5 on ECM degradation was also assessed.

Results: IGFBP-5 was detected in all cell fractions and was bound to Cav-1 in lipid rafts. Cav-1 was detected within vesicular structures in the nucleus of IGFBP-5-expressing fibroblasts. Lung fibroblasts from Cav-1 null mice had reduced levels of intracellular IGFBP-5, but increased ECM levels. Internalization of IGFBP-5 was decreased in Cav-1 null fibroblasts and inhibited by both caveolae disruption and Cav-1 siRNA. In addition, restoration of Cav-1 function using CSD dramatically increased IGFBP-5 internalization, indicating that cellular uptake of IGFBP-5 occurs via a caveolin-mediated pathway. Finally, increased deposition of IGFBP-5 in the ECM resulted in excessive ECM deposition likely due to decreased degradation of ECM components such as fibronectin.

Conclusion: Cav-1 mediates the internalization and nuclear translocation of IGFBP-5. Decreased Cav-1 expression in fibrotic diseases leads to increased deposition of IGFBP-5 in the ECM and reduced ECM degradation. Our findings identify decreased internalization of IGFBP-5 and its increased extracellular deposition as novel mechanisms mediating fibrosis.

Profibrotic Wnt Signaling in Human Mesenchymal Cells: Implications for Scleroderma. Jun Wei[1], Ethan Leng[1], Jennifer L. Sargent[2], Michael L. Whitfield[2], Anna Lam[1], Cara Gottardi[1] and John Varga[1], [1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Dartmouth Medical School, Hanover, NH

Purpose: Scleroderma is characterized by fibrosis in the skin and lung. Activated fibroblasts and myofibroblasts are central in pathogenesis. Wnt signaling plays an essential role in development and cell fate determination and its dysregulation is implicated in both rheumatoid arthritis and osteoarthritis. In contrast, the role of Wnt in scleroderma is largely unknown. Here we investigated Wnt expression and signaling in scleroderma.

Method: Expression of Wnt-related genes in scleroderma skin biopsies was examined by DNA microarray analysis and immunohistochemistry. Wnt ligands were used to activate Wnt signaling in cultured dermal fibroblasts. Activation of b-catenin was detected GST-ICAT (Inhibitor of Catenin And Tcf) and Western analysis. Expression of a-smooth muscle actin (a-SMA) and calponin was determined by Western blot, immunofluorescence and real-time qPCR. Cell proliferation was assayed. Adipogenic differentiation of human subcutaneous preadipocytes was evaluated by Oil Red O staining. Localization of b-catenin was examined in bleomycin-induced mouse scleroderma.

Results: DNA microarray analysis revealed elevated skin mRNA expression for Wnt receptors (FZD2) and decreased expression for Wnt antagonists (DKK2, Wif1) in subsets of patients with diffuse cutaneous scleroderma. Immunohistochemistry showed increased cytosolic b-catenin localization in scleroderma skin and lungs, indicating activated Wnt signaling. Ectopic expression of Wnt3a or Wnt10b stimulated fibroblast proliferation and Type I collagen and calponin synthesis, and induced a-SMA expression and myofibroblast differentiation in subcutaneous preadipocytes. In contrast, Wnt3a repressed adipogenic differentiation and expression of the adipocyte markers PPAR-g and FABP4 in subcutaneous preadipocytes.

Conclusion: Activated Wnt signaling in scleroderma lesions may be directly responsible for myofibroblasts differentiation and fibroblast proliferation. Furthermore, Wnt induces adipogenic precursor cell differentiation into fibroblasts. The results suggest that Wnt signaling plays an important novel role in the pathogenesis of scleroderma. Modulating Wnt activity may therefore represent a novel therapeutic approach for the treatment of scleroderma.

Activation of the TGFbeta/c-Abl/PKCdelta/Fli-1 Pathway Is a Major Contributor to SSc Fibrosis. Andreea M. Bujor, Yoshihide Asano, Faye N. Hant and Maria Trojanowska, Medical University of South Carolina, Charleston, SC

Purpose: Scleroderma (SSc) is a connective tissue disease characterized by prominent skin fibrosis. Previous studies have linked PKCδ and Fli1 to SSc pathogenesis and the phosphorylation of Fli1(Thr312) by PKCδ downstream of TGFβ has been shown to inhibit the repressor function of Fli1 on the collagen promoter. Despite this, the upstream signaling events underlying TGFβ induced PKCδ activation remain unknown. Overexpression of c-abl was reported in SSc. Furthermore, in other cells c-abl induced PKCδ tyrosine phosphorylation and nuclear translocation. The aim of this study was to further define the molecular mechanisms that mediate the TGFβ induced Fli1 phosphorylation in dermal fibroblasts.

Methods: Protein expression of collagen type I, c-abl and P-Fli1 (Thr312) was measured in adult SSc fibroblasts from skin biopsies and matched normal controls by western blotting (n=4). Normal dermal fibroblasts were either transduced with an adenovirus overexpressing constitutively active PKCδ (CA-PKCδ) or transiently transfected with a plasmid containing bcr-abl (a constitutively activated form of c-abl) in the presence or absence of TGFβ and Imatinib. Western blot analysis was used to measure the effects on the protein levels of collagen type I and P-Fli1 (Thr312). Quantitative real-time PCR was performed to measure the mRNA levels of COL1A1 and COL1A2.

Results: Data analysis showed significantly increased expression of P-Fli1 (Thr312) in cultured SSc fibroblasts compared to normal controls in all of the pairs tested. The enhanced Fli1 phosphorylation in SSc fibroblasts correlated with an increase in the protein levels of collagen type I and c-abl in these cells. Cells transduced with the CA-PKCδ had a two fold increase in collagen levels. Blockade of c-abl using Imatinib was followed by a 70% down-regulation of the mRNA and protein levels of collagen type I which was consistently rescued by over-expression of CA-PKCδ. The levels of P-Fli1 (Thr312) where significantly increased after 2h of TGFβ addition and pretreatment with Imatinib prevented the TGFβ effect on Fli1 phosphorylation. In agreement with these observations, constitutive activation of c-abl by bcr-abl over-expression was sufficient to induce the phosphorylation of Fli1 on Thr312 to levels similar to those obtained after TGFβ treatment.

Conclusion: This study shows for the first time that Fli1 is constitutively phosphorylated on Thr312 in SSc fibroblasts in culture. Additionally we show that c-abl is required for the TGFβ induced Fli1 phosphorylation in dermal fibroblasts. Our results suggest that the constitutive activation of TGFβ/c-abl/PKCδ/Fli1 pathway in SSc fibroblasts could contribute to fibrosis by inhibiting Fli1 induced repression of collagen promoter. Blockade of the TGFβ/c-abl/PKCδ/Fli1 pathway by Imatinib further clarifies the antifibrotic mechanisms of this molecule and suggests that SSc patients with constitutive activation of this pathway could benefit from Imatinib treatment.

IL-15 Expressed On RA Synovial Fibroblasts (RASFib) Induces Proliferation of CD4+CD25+ Regulatory T Cells (Treg) and Augments Their Suppressive Potency. Y. García-Carmona, M. Benito-Miguel, Alejandro Balsa, C.P. de Ayala, E. Martin-Mola and M. E. Miranda-Carus, Hospital La Paz, Madrid, Spain

Purpose: We previously described that fibroblast-like cells from the synovium of Rheumatoid Arthritis patients (RASFib) constitutively express intracellular and surface IL-15, that induces activation of cocultured T cells. The purpose of the present study was to examine the effect of RASFib IL-15 expression on the function of human CD4+CD25+ Treg cells

Method: RASFib were obtained from synovectomy or arthroplasty specimens of RA patients. Total CD4+ T (TCD4T), CD4+CD25+ T reg and CD4+CD25- Teff cells were isolated from the peripheral blood of 30 healthy controls by Ficoll-Hypaque gradient, followed by magnetical sorting. Purity of the T cell populations was 99% by flow cytometry. Cocultures of RASFib and T cells were established in 96-well plates, in the presence or absence of IL-15 neutralizing agents. The function of Treg cells was assessed using two different approaches: A.The regulatory function of natural proportions of Treg cells was inferred by comparing the proliferative and cytokine responses of aCD3 stimulated total CD4+ versus CD25+ depleted CD4+ T cells, and B. The per cell potency of Treg was assessed in cocultures of isolated CD4+CD25+ Treg with CD4+CD25- Tresp, established at different Treg/Tresp ratios. Proliferation was determined by CFSE dilution and cytokine secretion was measured by ELISA of culture supernatants

Results: RASFib, through their constitutive IL-15 expression, were able to induce the proliferation of human Tregs stimulated through their TCR, and at the same time potentiated their suppressive action on the cytokine secretion of CD4+CD25- responder T cells (Tresp). In parallel, constitutive RASFib IL-15 expression mediated an upregulated response of Tresp cells. Subsequently, total CD4+ T cells, containing natural proportions of Treg and Tresp, secreted an increased amount of pathogenic cytokines when cocultured with RASFib despite the presence of proliferating Treg with superior regulatory potency

Conclusion: RASFib IL-15 exerts a dual action on the equilibrium between Treg and Tresp cells, by potentiating the suppressive effect of Treg while augmenting the pro-inflammatory action of Tresp; the result is a shift of the Treg/Tresp balance towards a pro-inflammatory state. This alteration of the Treg/Tresp equilibrium is not observed in the presence of OASFib or dermal fibroblasts, that do not constitutively express surface IL-15

Characterizing Natural CD4$^+$Foxp3$^+$ Regulatory T Cells by Anatomical Location. Scott M. Lieberman[1] and Laurence A. Turka[2], [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania School of Medicine, Philadelphia, PA

Purpose: Natural $CD4^+Foxp3^+$ regulatory T cells (T_R) are specialized cells which develop in the thymus and function to control naturally occurring autoreactive lymphocytes, thus preventing autoimmunity. Humans and mice with *Foxp3* mutations resulting in defective T_R, develop widespread organ-specific autoimmunity. Studies suggest T_R confer organ-specific tolerance in an antigen-specific manner; however, the exact nature of their cognate antigens is unknown. Recent studies show T_R T cell receptor (TCR) repertoires vary based on anatomical location suggesting compartmentalization based on antigen specificity; however, contributions of non-TCR dependent survival or trafficking signals may play a role. Here we evaluate T_R population homeostasis and trafficking based on anatomical location.

Method: T_R were isolated by fluorescence activated cell sorting (FACS) from mice expressing enhanced green fluorescent protein under control of the Foxp3 promoter (Foxp3-GFP knockin). T_R were isolated from spleen or lymph nodes grouped as follows: skin-draining (axillary, brachial, inguinal, popliteal), cervical, or gut-draining (mesenteric, pancreatic, gastric). For certain analyses, pancreatic/gastric and iliac lymph node groups were included separately. T_R were analyzed for steady state phenotype and proliferation by flow cytometry or were transferred intravenously to nonlymphopenic congenic ($CD45.1^+$) or lymphopenic ($RAG1^{-/-}$) hosts. Each T_R group was isolated from several donors and pooled based on anatomical location of origin before transfer to single recipients. Seven days later, recipient spleen and lymph node groups were isolated and their cellular content analyzed by flow cytometry.

Results: T_R comprise 10-20% of $CD4^+$ T cells within spleen and lymph node groups with small degree of variation. Phenotypically, they demonstrate similar steady state proliferation profiles and T_R surface markers with little anatomical variation. Surprisingly, T_R from each anatomical location, when transferred to nonlymphopenic or lymphopenic hosts, are easily recovered from all anatomical sites with no clear preference associated with anatomical site of origin.

Conclusion: T_R from skin-draining, cervical, or gut-draining lymph nodes or spleen do not vary extensively in phenotype and are able to traffic widely throughout secondary lymphoid organs upon adoptive transfer into nonlymphopenic or lymphopenic hosts. Whether T_R behave in an organ- or antigen-specific manner in this adoptive transfer system remains to be determined and studies of their differential abilities to ameliorate organ-specific autoimmunity are underway.

Regulatory T Cells Directly Suppress B Cells in Systemic Lupus Erythematosus. Noriko Iikuni, Elaine V. Lourenco, B H. Hahn and Antonio La Cava, Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: In systemic lupus erythematosus (SLE), adaptive $CD4^+CD25^+Foxp3^+$ cells (Tregs) suppress T helper (Th) cells that help autoantibody (autoAb)-producing B cells. It is not known whether naturally occurring Tregs can directly suppress B cells in SLE without an intermediate suppression of Th cells. This aspect is important for its implications in the natural course of SLE, because most if not all of the clinical and pathologic effects in SLE associate with a dysregulated production of autoAb.

Method: Lupus Tregs were incubated with B cells in the absence of Th cells, and suppression of B cells was investigated.

Results: Natural Tregs inhibited B-cell activity *in vitro* ($P<0.005$) and *in vivo* ($P<0.04$) in SLE, independently of age, through cell contact-mediated mechanisms that directly suppress autoAb-producing B cells, including those B cells that increase numerically during active disease in SLE patients such as $CD19^+CD27^{high}$ ($P<0.009$) and $CD19^+CD27^-IgD^-$ ($P<0.0007$) B cells. Using blocking antibodies and cells infected with dominant negative receptors, we identified membrane-bound TGFb on Tregs and TGFb receptor II on B cells as key molecules for the direct suppressive activity of Tregs on B cells. **Conclusion:** The dat indicate that one way by which natural Tregs attempt to limit humoral autoimmunity in SLE is by directly targeting autoAb-producing B cells.

Retinoic Acid Accelerates the Maturation of Human CD4+Foxp3+ Regulatory T Cells Induced Ex-Vivo with IL-2 and TGF-ß. Ling Lu, Julie Wang, Song Guo Zheng and David A. Horwitz, USC Keck School of Medicine, Los Angeles, CA

Purpose: Mouse CD4+ cells activated for 1 week ex-vivo with IL-2 and TGF-β are induced to become Foxp3+CD25+ regulatory T cells (iTregs) that are protective in models of SLE. Similar treatment of human CD4+ cells for one week, however, results in only partially differentiated polyclonal iTregs. Repeated re-stimulation was needed for them to become anergic, express membrane-bound TGF-β, and develop suppressive activity. Since retinoic acid (RA) enhances TGF-β induced iTregs in the intestinal immune system, we reasoned that RA might be able to accelerate the differentiation of human CD4 Foxp3+ iTregs.

Method: Naïve human CD4+ cells prepared by negative selection were suboptimally TCR activated for 6 days with anti-CD3/28 coated beads with IL-2, ± TGF-β1 and all-trans retinoic acid (atRA). The cells were then examined by FACS for surface markers characteristic of natural Foxp3+ Tregs, for intracellular cytokine production, for anergy, and for suppressive activity *in vitro* and *in vivo*.

Results: After 6 days of TCR stimulation with IL-2 and TGF-β >50% of CD4+ cells expressed Foxp3, but these cells proliferated robustly upon further stimulation, produced large amounts of IL-2, IFN-γ, and TNF-α, and lacked the ability to markedly suppress the proliferation of CFSE-labeled T cells. The addition of atRA to IL-2 and TGF-β increased Foxp3+ cells to 85%, and enhanced DR and membrane-bound TGF-β expression. Moreover, production of IL-2 and IFN-γ was markedly reduced, as was their proliferative response to restimulation. Remarkably, these cells had strong *in vitro* suppressive activity at a dilution of 1 to 32 and this effect was completely TGF-β dependent. To assess *in vivo* suppressive activity, sublethally irradiated NOD SCID IL-2R γ chain$^{-/-}$ mice were injected IV with human PBMC and additional naïve CD4+ cells. These mice spontaneously produced large amounts of human IgG after 1 week, and succumbed to a xenogenic graft-versus-host disease by two weeks. Substitution of CD4+ cells conditioned with IL-2 and TGF-β instead of naïve CD4+ cells offered minimal protection. However, the addition of CD4+ cells conditioned with IL-2, TGF-β and atRA to PBMC resulted in complete suppression of human IgG production, and significantly enhanced the survival of these mice ($p<0.01$).

Conclusion: These studies suggest that large numbers of potentially therapeutic Foxp3+ iTreg cells can be produced rapidly and expediently from naive T cells of patients with SLE and other chronic immune-mediated diseases. Following transfer back to the donor, the effects of TGF-β should enable these iTreg cells to home to both lymphoid tissues and inflammatory sites and retain their ability to expand. Studies will also be presented to indicate whether the addition of RA to IL-2 and TGF-β has also conferred resistance to proinflammatory cytokines that decrease Treg suppressive effects, and promote their conversion to effector T cells. Studies are also in progress to learn whether the addition of other epigenetic agents to RA can improve even further the generation of Foxp3+ iTregs ex-vivo.

Characteristics of CD8+CD25- Cells Induced to Become Suppressor Cells Ex-Vivo with IL-2 and TGF-β. Xiao H. Zhou[1], Ling Lu[1], Julie Wang[1], Hejian Zou[2], David Brand[3], Huimin Fan[4] and Song Guo Zheng[1], [1]University of Southern California, Los Angeles, CA, [2]Huashan Hospital, Fudan University, Shanghai, China, [3]VA Medical Center, Memphis, Memphis, TN, [4]East Hospital, Tongji University, Shanghai, China

Purpose: CD8+ T cells stimulated with IL-2 and TGF-β can be induced to develop suppressive activity. However, the phenotype and functional characteristics of these polyclonal regulatory T cells (iTreg) have not been well characterized. Here we want to determine characteristics of these cells primed with IL-2 and TGF-β in vitro.

Method: GFP transgenic mouse were used to distinguish expanded thymus-derived Foxp3+CD8+ cells from conventional CD8+CD25-. Splenic GFP-cells from these mice were stimulated with anti-CD3/28 coated beads and IL-2 with or without TGF-β. The phenotypes of regulatory cells were analysis by flow cytometry. Transfer DBA/2 spleen cells (80×106) to F1 (DBA/2×C57BL/6 F1 hybrid) to establish a Lupus-like graft-versus-host disease model for the in vivo suppress function analysis of iTreg.

Results: Following 4-day stimulation, 35% of CD8+ cells become CD25+GFP+ cells in the presence of IL-2 and TGF-β. Granzyme B expression was decreased compared to CD8+ cells activated without TGF-β. These cells were also anergic following restimulation. Although their Foxp3 expression is lower than TGF-β induced CD4+ cells, they displayed similar suppressive activity in cell contact-dependent, non-cytotoxic suppressive activity manner in a standard in vitro assay. Neutralization of TGF-β, IL-10 or IL-10 receptor and the TGF-β receptor□(ALK5) inhibitor was unable to abolish the suppressive activity. Similar to CD4+ iTreg, adoptive transfer of CD8+ iTregs suppressed a chronic GVHD with a lupus-like syndrome. Thus, TCR stimulation with IL-2 and TGF-β can induce CD8+ cells as CD4+ cells to become Foxp3+ Treg cells and both of these subsets have protective effects against pathologic immune-mediated inflammation.

Conclusion: Naïve CD8+CD25- cells polyclonally activated with TGF-β and IL-2 became CD28-CD103+Foxp3+ cells. These cells suppressed T cell proliferation in vitro and co-transfer of these cells markedly blocked the development of GVHD with a lupus-like syndrome. Neutralization of TGF-β or blockade of TGF-β signaling did not abolish the suppressive activity in vitro. These cells did not express granzyme or perforin and lacked cytotoxic activity. The suppressive mechanisms need to be further elucidated. Generation of CD8+ induced Tregs may have considerable therapeutic potential.

1078

Generation of Tregs by Homotypic T Cell Interaction. Katja Thümmler, Andreas Ramming, Jan Leipe, Iryna Prots, Hendrik Schulze-Koops and Alla Skapenko, University of Munich, Munich, Germany

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease driven by constantly activated CD4 effector T cells. Current evidence suggests that an insufficient activity of regulatory T cells is the prerequisite for the development of persistent inflammatory activity in RA. During the disease, activated T cells continuously circulate back and forth from the synovial tissue into the draining lymph nodes, permitting intense interactions with bystander cells (e.g. T cells, B cells, synovial fibroblasts, macrophages, etc.) in the respective tissues. We have recently described that bystander contact between activated effector T cells and resting T cells results in the production of immunoregulatory cytokines, such as IL-10 and IL-4, from the later. Here, we analyzed whether these T cells that were primed by homotypic interaction with activated effector T cells to produce immunomodulatory cytokines exert a regulatory T cell phenotype, thereby representing a potential physiological negative feedback mechanism in inflammation.

Method: Purified CD4 T cells were activated under effector T cell polarizing conditions (e.g. Th1, Th2, Th17) for five days, fixed to prevent further proliferation and effector cytokine release, and cultured with freshly isolated syngeneic CD4 T cells. Phenotype and function of the resulting cells were analyzed by FACS, ELISA, and in functional Treg assays.

Results: T cells that were primed with activated effector cells produced IL-10 (if primed with Th1 or Th17 effectors) or IL-4 (in response to contact with Th2 cells). They expressed CD25 on their surface, however, they were negative for Foxp3 protein and mRNA. Nevertheless and importantly, all primed T cells expressed a potent regulatory capacity in vitro, regardless of the nature of the priming effector T cells that was comparable with that of naturally occurring CD25+ Foxp3+ Tregs. The regulatory effect upon proliferation of CD25- responder T cells was dose dependent and could be abrogated by exogenous IL-2. Spatial separation of primed T cells from responder T cells by a transwell completely prevented the regulatory activity of Th2 cell-primed T cells. In contrast, Th1 cell-primed T cells exerted their regulatory function in part via secretion of IL-10. In vivo, D011.10 CD4 T cells that were primed by activated T cells from Balb/c mice in vitro, were able to suppress expansion of OVA-specific T cells upon antigen challenge in the D011.10 transfer model.

Conclusion: Our data indicate that activated T cells are able to prime resting T cells in a bystander fashion to exert immunoregulatory functions in contact and cytokine-dependent manners. As these T cells are functional in vivo, the data further suggest that homotypic T cell interactions may represent a physiological means to counteract sustained inflammation. Functional failure of this mechanisms may contribute to the pathogenesis of autoimmune diseases, such as RA.

The Adhesion Receptors, ICAM1 and ICAM3 Regulate the Generation of Regulatory T Cells Induced by Homotypic T Cell Interaction. Katja Thümmler, Andreas Ramming, Jan Leipe, Iryna Prots, Hendrik Schulze-Koops and Alla Skapenko, University of Munich, Munich, Germany

Purpose: We have recently described that bystander contact between activated effector T cells and resting T cells results in the generation of regulatory T cells from the later that exert potent immunoregulatory functions in vitro and in vivo. Here, we analyzed the molecular mechanisms involved in the generation of regulatory T cells from resting T cells upon priming with syngeneic activated effector T cells.

Method: CD4 T cells were purified from the peripheral blood from healthy individuals, activated under effector T cell polarizing conditions (e.g. Th1, Th2, Th17) for five days, fixed to prevent further proliferation and effector cytokine release, and cultured with freshly isolated

syngeneic CD4 T cells. The biological activities of receptor/counterreceptor pairs as well as of individual cytokines were neutralized by monocloncal antibodies, and the phenotype and function of the resulting cells were analyzed by FACS, ELISA, and in functional Treg assays.

Results: In response to contact with activated effector T cells (stimulator T cells), resting T cells started to proliferate and to produce IL-10 (if primed with Th1 or Th17 effectors) or IL-4 (in response to contact with Th2 cells). Spatial separation of stimulator from responder T cells by a transwell completely prevented the development of cytokine producing cells. In contrast, neutralization of IL-4 or IFN-γ was without a significant effect on the appearance of cytokine producing T cells. In line, blocking of the major T cell adhesion receptor, LFA-1 prevented proliferation and cytokine production of the responder population. Notably, the interaction between LFA-1 with its individual ligands, ICAM-1, ICAM-2 and ICAM-3 determined the phenotype of the developing T cell. Whereas blocking of ICAM-1 inhibited cell proliferation and production of IFN-γ, but not that of IL-4 and IL-10, neutralization of ICAM-2 had no effect on the outcome of the priming cultures, and inhibition of LFA-1/ICAM-3 interactions prevented the secretion of IL-4.

Conclusion: The data indicate that engaging of LFA-1 is important in the generation of regulatory T cells induced upon priming with activated effector T cells. Moreover, the data also imply that interaction of LFA-1 with individual ICAMs results in the activation of distinct signaling pathways. Our results provide the first evidence of a role of ICAM/LFA-1 interactions in the generation of regulatory T cells.

The Selective Immunoproteasome Inhibitor PR-957 Blocks Production of Inflammatory Cytokines by Polarized Th1 and Th17 Cells without Affecting TGF-β Production by Regulatory T-Cells. Erika Suzuki, Mark Bennett, Shirin Kapur and Christopher J. Kirk, Proteolix, Inc., South San Francisco, CA

Purpose: The immunoproteasome is a unique form of the proteasome predominantly found in cells of the immune system. We have recently described a selective inhibitor of the immunoproteasome, PR-957, that blocks production of interleukin (IL)-6, TNF-α, and IL-23 in human monocytes, interferon-gamma (IFN-γ) production in human T-cells and ameliorates inflammation in mouse models of rheumatoid arthritis (Nature Medicine, *in press* July 2009). PR-957 also blocked the differentiation of mouse T-cells to a T_h17 phenotype. In this study, we investigated the role of the immunoproteasome in human T-cells differentiated to T_h1, T_h17 and T_{reg} phenotypes.

Method: PBMCs and purified CD4+ T cells from normal healthy donors were stimulated for up to 12 days with plate-bound anti-CD3 and anti-CD28 antibodies in the absence or presence of polarizing cytokines. Cells were treated with brief (1 hr) and long (24 hr) exposures to PR-957 at concentrations that selectively inhibit the immunoproteasome. Culture supernatants were analyzed for cytokine levels and cells were analyzed for immunoproteasome activity and gene expression profiling.

Results: Inhibition of the immunoproteasome reduced proliferation (but was not cytotoxic) in T_h17 and T_h1 cells. Proteasome activity recovered after removal of PR-957 with an average $t_{1/2}$ of ~72 hr regardless of stimulation or differentiation conditions. Following PR-957 treatment, IL-17A production by T_h17 cells was reduced by an average of 46% (range: 28%-67%; N=3 different donors) and IFN-γ release by T_h1 cells was decreased by an average of 63% (range: 50%-84%; N=4). In contrast, TGF-β production by T_{reg} cells was unaffected by immunoproteasome inhibition. However, in the absence of polarizing cytokines, treatment of cells with PR-957 increased the production of TGF-β by an average of 82% (range:49%-100%; N=3) relative to untreated cells.

Conclusion: These results demonstrate that PR-957 blocks cytokine release by T_h1 and T_h17 cells, but not by T_{reg} cells. Furthermore, immunoproteasome inhibition in the absence of polarizing cytokines may favor development of a regulatory phenotype in T-cells. Gene expression analysis and functional assays are on-going to further understand the effects of PR-957 on the balance between T_h1, T_h17 and T_{reg} cells as this agent proceeds towards clinical development in rheumatoid arthritis.

CD4+CD25-LAG3+ Regulatory T Cells Suppress a Mouse Model of Colitis. Tomohisa Okamura, Keishi Fujio, Mihoko Shibuya, Shuji Sumitomo, Hirofumi Shoda and Kazuhiko Yamamoto, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Purpose: IL-10-secreting Foxp3-CD4+ T cells have been a focus of active investigation. However, it is difficult to assess the *in vivo* physiological function of IL-10-secreting regulatory T cells because of the lack of specific markers that can reliably differentiate them from the other T cells. LAG-3 is an MHC class II-binding CD4 homolog associated with regulatory activity of CD4+ T cells. We tried to identify IL-10-secreting regulatory T cells (Tregs) using LAG-3 as a marker molecule.

Method: Single cell suspnesion of the spleen and Peyer's patch (PP) of B6 mice were stained with anti-CD45RB, anti-LAG-3, anti-CD4 and anti-CD25. Cells were analyzed by FACS and cDNA was synthesized from sorted cell populations. Gene expressions were analyzed with qunatitative-PCR. Activated CD4+T cells were transduced with retroviral expression vectors. Colitis model of RAG1 deficient B6 mice and TEa TCR transgenic mice were used to examine in vivo suppression of CD4+CD25-LAG3+ cells. DTH model of BALB/c mice were used to examine in vivo suppression of Egr-2 transuced CD4+ cells.

Results: Approximately 2% of CD4+CD25- T cell population consisted of CD4+CD25-LAG3+ T cells in the spleen. Moreover, CD4+CD25-LAG3+ T cells are enriched to about 8% in the PP. They are hypoproliferative upon in vitro antigenic stimulation, and suppress in vivo development of colitis. Gene expression analysis reveals that CD4+CD25-LAG3+ Tregs characteristically express early growth response gene-2 (Egr-2), a key molecule for anergy induction. Retroviral gene transfer of Egr-2 converts naïve CD4+ T cells into IL-10-secreting and LAG-3-expressing phenotype and Egr-2 transduced CD4+ T cells exhibit antigen-specific immunosuppressive capacity in vivo. Unlike Foxp3+ natural Tregs, high affinity interactions with selecting peptide/MHC ligands expressed in the thymus does not induce the development of CD4+CD25-LAG3+ Tregs. In contrast, the number of CD4+CD25-LAG3+ Tregs is influenced by the presence of environmental microbiota.

Conclusion: IL-10-secreting Egr-2+LAG3+CD4+ Tregs can be exploited for the control of peripheral immunity.

Reciprocal Regulation of FOXP3 and IL-17 Expression in Human CD4+ T Cells by 1,25(OH)2 Vitamin D3. Seong Wook Kang[1], Sang-Hyun Kim[2], Won-Woo Lee[2], Kyung-A Hwang[2], Seung-Hyun Lee[2] and Insoo Kang[2], [1]Yale University School of Medicine and Chungnam National University, Daejeon, South Korea, [2]Yale University School of Medicine, New Haven, CT

Purpose: A body of evidence supports the role for regulatory T cells (Treg) and T helper 17 (Th17) cells in developing autoimmunity and inflammatory diseases. While FOXP3+ Tregs are generated in the thymus (nTreg), FOXP3+ Treg can also be induced from non-Treg CD4+ T cells (iTreg). 1,25-dihyroxyvitamin D3 ($1,25(OH)_2VD3$) exerts an inhibitory effect on immune cells and low circulatory levels of 25(OH)VD3 are reported in patients with autoimmune diseases. However, it is unknown whether $1,25(OH)_2VD3$ can directly alter FOXP3 and IL-17 expression in human CD4+ T cells.

Method: Human naïve and memory $CD25^-CD4^+$ T cells were stimulated with anti-CD3/CD28 antibodies in the presence of cytokines and/or $1,25(OH)_2VD3$. The expression of FOXP3 and IL-17 was measured by flow cytometry and RT-PCR. IL-17 in culture supernatants was analyzed by ELISA. In order to measure the inhibitory effect of $1,25(OH)_2VD3$ induced FOXP+ cells, stimulated cells were cocultured with autologous $CD25\text{-}CD4^+$ T cells (target cells). For reporter gene assay, the promoter and enhancers of the *FOXP3* gene were cloned and transfected into human CD4+ T cells using electroporation.

Results: $1,25(OH)_2VD3$ promoted FOXP3 expression by CD25-CD4+ T cells in a dose-dependent manner with TCR triggering and IL-2. This effect was more prominent in memory CD4+ T cells, which could be secondary to higher levels of vitamin D receptor (VDR) expression in these cells compared to naive CD4+ T cells. Also, $1,25(OH)_2VD3$-treated cells had increased *FOXP3* mRNA expression. To determined whether $1,25(OH)_2VD3$-induced FOXP3+CD4+ T cells (VDiTreg) had inhibitory function, we co-cultured $1,25(OH)_2VD3$-treated cells with target CD25-CD4+ T cells. VDiTreg suppressed proliferation of target CD25-CD4+ T cells in a cell number-dependent manner. Such suppression was largely dependent on cell contact and FOXP3 expression as separating the two populations during cell culture or knockdown of *FOXP3* expression in VDiTreg blocked the inhibitory effect of VDiTreg. The direct effect of $1,25(OH)_2VD3$ on the *FOXP3* gene expression was further demonstrated by the reporter gene assay showing an enhanced promoter activity of the *FOXP3* gene in the presence of this vitamin. $1,25(OH)_2VD3$ suppressed IL-17 production from human naïve and memory CD4+ T cells, suggesting a reciprocal regulation of FOXP3 and IL-17 expression by$1,25(OH)_2VD3$.

Conclusion: 1,25$(OH)_2$VD3 promotes FOXP3 expression in CD25-CD4+ T cells, more profoundly in memory cells, with TCR triggering and IL-2 and such cells have potent inhibitory function dependently of FOXP3 and cell contact. Our findings suggest that 1,25$(OH)_2$VD3 regulates immune responses by altering IL-17 production and FOXP3 expression in CD4+ T cells in humans.

Generating Designer Regulatory T Cells for the Treatment of Arthritis. Graham P. Wright[1], Clare A. Notley[1], Michael R. Ehrenstein[1] and Hans J. Stauss[2], [1]University College London, London, United Kingdom, [2]University College London, United Kingdom

Purpose: Regulatory T cells (Tregs) are capable of controlling and suppressing the action of multiple different immune cells. This multi-faceted suppressive ability makes them ideal candidates for the control of autoimmunity. Whilst adoptively transferred polyclonal bulk Tregs are able to suppress immune-pathology in several murine models, the superiority of antigen (Ag)-specific Tregs has been clearly demonstrated using T cell receptor (TCR)-transgenic mice. To date the potential for clinical translation of targeted Ag-specific therapy with Tregs has been hampered by difficulties of isolating rare Ag-specific Tregs from the natural polyclonal T cell repertoire. Furthermore, the initiating Ag is frequently unknown in autoimmune diseases. Here, we explored two separate strategies to generate primary T cells with Ag-specific regulatory activity.

Method: Firstly, TCR gene transfer into purified CD4+CD25+ T cells was used to redirect the specificity of naturally occurring Tregs. Secondly, co-transfer of FoxP3 and TCR genes served to convert conventional CD4+ T cells into antigen-specific regulators.

Results: Both approaches generated T cells that engrafted efficiently and retained TCR and FoxP3 expression when adoptively transferred into recipient mice. Using an established arthritis model, we demonstrate antigen-driven accumulation of the gene modified T cells at the site of joint inflammation, which resulted in a local reduction in the number of inflammatory Th17 cells and a significant decrease in arthritic bone destruction. Importantly, the specificity of the gene-modified Tregs was distinct from that of the arthritis-inducing pathogenic T cells.

Conclusion: The data indicate that adoptive therapy with gene-modified Tregs resulted in local, Ag-specific control of immuno-pathology in the absence of systemic immune suppression. Furthermore, this work highlighted the potential of Tregs to treat immuno-pathology via linked suppression without prior knowledge of the disease causing antigen.

1084

The Neuropeptide npT1 Identified by Microarray Profiling of Developing CD25+ Regulatory T Cells (Tregs) Is Specifically Expressed in Mature Human Tregs. Iryna Prots[1], Alla Skapenko[1], Katja Thümmler[1], Jan Leipe[1], Andreas Ramming[1], Peter E. Lipsky[2] and Hendrik Schulze-Koops[1], [1]University of Munich, Munich, Germany, [2]National Institutes of Health, Bethesda, MD

Purpose: Compromised development and/or function of CD25+ regulatory T cells (Tregs) are hypothesized to be of central importance for the development of autoimmune diseases, such as rheumatoid arthritis (RA). The mechanisms, however, that regulate the generation of peripheral Tregs are largely unknown. To gain insights into Treg differentiation on a molecular level, we investigated gene expression profiles at different stages of peripheral Treg development.

Method: Human peripheral Tregs were generated using a previously described in vitro system from CD4+CD25- naive T cells stimulated in the presence of autologous feeder cells and interleukin (IL)-4. Total RNA was isolated at start and from highly purified CD25+ and CD25- T cells at days 3, 5, 7, and 10 of culture, respectively, and used for DNA microarrays. CD25+ T cells generated in the absence of IL-4 constituted activated effector T cells lacking regulatory capacity and were therefore used to control for Treg-specificity. Differentially expressed transcripts in Tregs and effector T cells versus CD25- T cells were determined at each time point and Treg-specific transcripts were identified based on their differential expression between Tregs and effector T cells at each time point.

Results: A high number of transcripts were differentially expressed in Tregs compared to CD25- T cells at early time points, and markedly reduced numbers of differentially expressed transcripts were found at late time points. In contrast, the number of differentially expressed transcripts in effector T cells versus CD25- T cells was high during the whole culture period. Analysis of biological processes among

identified genes revealed significant over-representation of cell cycle and DNA-metabolic processes in Tregs and effector T cells at early time points and, in effector T cells, over the whole culture period. Of interest, Tregs at late time points were characterized by over-represented immune system and chemotaxis processes. Expression of 93 transcripts was specifically regulated in IL-4-induced Tregs compared to effector T cells at different time points. A neuromediator, npT1, transcript had the highest expression in mature Tregs and the strongest difference between mature Tregs and effector T cells. Expression of npT1 in in vitro generated Tregs was confirmed by RT-PCR in independent experiments. Moreover, npT1 was also expressed by resting and activated natural occurring Tregs purified from the peripheral blood of healthy donors.

Conclusion: Late developing and mature Tregs have less active cellular state compared to effector T cells. The neuropeptide, npT1 is specifically expressed in late developing and functionally mature peripheral and natural occurring Tregs. NpT1 represents a novel Treg-specific gene that links the control of specific autoimmunity with the neurosystem and may constitute an interesting target for novel immunomodulatory treatment strategies.

HLA DRB1*1503: A Predominant Allelic Haplotype in SLE Correlated to Immunoregulatory Gene Expression Affecting Regulatory T Cells. Jeanann Suggs, Vikas Majithia, Julius M. Cruse and Robert E. Lewis, University of Mississippi School of Medicine, Jackson, MS

Purpose: Systemic lupus erythematosus (SLE) is the prototype of systemic autoimmune disease where the role of regulatory T cells (Tregs) is not yet fully characterized. The variability in expression levels of immunoregulatory genes and HLA DRB1 allelic haplotype composition may have effects on CD25+FoxP3+ regulatory T cell population and was evaluated in SLE patients.

Method: SLE patients followed at our institution were grouped according to HLA DRB1 allelic haplotype composition and the resulting subgroups were analyzed for Treg composition using flow cytometry. Expression levels of genes affecting immunoregulatory cells were analyzed and compared with race matched healthy controls.

Results: Molecular HLA typing revealed a prevalence of HLA DRB1*1503 allelic haplotype expression in the lupus patients (~33%). Analysis of the total CD45+CD3+CD4+ T cell population demonstrated an increased proportion of Tregs in the lupus patients compared with healthy controls. Comparison of lupus subgroups by HLA DRB1 allelic haplotype composition demonstrated increased proportions of Treg cells in both the HLA DRB1*1503 and non-HLA DRB1*1503 subgroups compared with healthy controls. Increased proportions of CD25+FoxP3- T cell populations were found in the combined lupus population, as well as each subgroup, compared to healthy controls. Gene expression analysis of the total population and both HLA DRB1 subgroups revealed increased FoxP3 gene expression compared with controls. The combined lupus population had decreased expression of immunoregulatory genes GATA3, TNFSF4, and TNFAIP3, compared with control samples. Decreased expression of GATA3 was only reproduced in the non-HLA DRB1*1503 subgroup comparison to controls. Both the HLA DRB1*1503 and non-DRB1*1503 subgroups revealed decreased TNFSF4 gene expression compared with healthy controls. TNFAIP3 was found to have decreased expression in the non-HLA DRB1*1503 subgroup only when compared with healthy controls. Furthermore, the non-HLA DRB1*1503 subgroup revealed significantly decreased expression of TNFAIP3 compared to the HLA DRB1*1503 subpopulation.

Conclusion: Increased FoxP3 gene expression, the transcription factor required for regulatory T cell differentiation, together with decreased TNFSF4 and GATA3 expression, genes that promote regulatory T cell expansion and Th2 cell expansion, respectively, correlates positively with the paradox of an increased proportion of regulatory T cells in lupus patients. Decreased TNFAIP3 expression, especially in the non-HLA DRB1*1503 subgroup, could signal a reduced suppressive capability of these regulatory T cells in lupus patients, as diminished gene expression has attenuated regulatory T cell functions in mouse models. Results of the present investigation revealed a greatly increased incidence of HLA DRB1*1503 allelic haplotype in African American females within the lupus population studied that was closely correlated with immunoregulatory gene expression affecting CD25+FoxP3+ T cells.

CD98hc Enables Clonal Expansion and Adaptive Immune Responses. Joseph Cantor[1] and Mark H. Ginsberg[2], [1]University of California San Diego, La Jolla, CA, [2]Univ CA SD, La Jolla, CA

Purpose: Lymphocyte clonal expansion facilitates adaptive immunity. We hypothesized that CD98hc, a lymphocyte activation marker, is important for clonal expansion.

Method: We used conditional gene targeting in mice to delete CD98 in B or T cells and tested adaptive immune responses.

Results: Deletion of B cell CD98hc did not affect B cell compartmentalization, but did result in reduced antibody responses. The mechanism of this effect did not involve interference with early signaling from antigen receptors, but instead was due to total suppression of rapid B cell proliferation, and consequent inability to form plasma cells. CD98hc can mediate both integrin signaling and amino acid transport. Reconstitution with CD98hc mutants revealed that its integrin interaction is required and its amino acid transport function is dispensable for B cell proliferation. Deletion of CD98hc in mature T cells reveals a similar role in rapid proliferation of T cells and subsequent effector functions.

Conclusion: These data establish that CD98hc enables clonal expansion and show that this function is performed by support of cell proliferation through interaction with integrins.

Allelic Imbalance of BLK Detected in CD4+ T Cells Suggesting That BLK Acts Via T Cell Pathways in Autoimmune Pathogenesis. Lina M. Olsson[1], Robert R. Graham[2] and Peter K. Gregersen[1], [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Genentech, Inc., South San Francisco, CA

Purpose: The intracellular tyrosine kinase, B-lymphocyte kinase (BLK) is associated with both Rheumatoid Arthritis and Systemic Lupus Erythematosus. Three associated SNP variants in BLK are located in the same haplotype covering the 5'UTR/ promoter region and upstream sequences. Studies in B cell lines show that the RA associated allele of the upstream SNP rs13277113 is associated with a lower mRNA expression of BLK. The SNP marker rs922483 in the 5'UTR of BLK is in high LD with all the associated variants (r^2 = 0.8-0.9). We wished to determine the effect of the Blk risk haplotype on expression in freshly isolated and separated peripheral blood cells.

Method: Transfection experiments suggest that rs922483 is a causative variant for Blk expression differences in B cell lines. Its location in the mature BLK transcript permitted us to use this variant to directly investigate allele specific expression in freshly isolated peripheral blood cells in heterozygous individuals. We separated B cells, $CD4^+$ and $CD8^+$ T cells, granulocytes, monocytes, macrophages and dendritic cells in normal subjects with defined BLK genotype.

Results: Using TaqMan assays, we documented high Blk expression in B cells, with decreased Blk after activation with anti IgM and/or CD40. T cells expressed lower levels of Blk and Blk transcript was extremely low in most other cells types. Using a sensitive pyrosequencing assay for allelic imbalance we have made two unexpected observations. First, both resting and activated B cells showed no evidence of allelic imbalance, in contrast to published reports in B cell lines. Secondly, prominent allelic imbalance was present in $CD4^+$ T cells in 5/6 individuals, with lesser degrees of allelic imbalance in $CD8^+$ T cells. Compared to the DNA reference allele ratio (A/G) of 0.4 ± 0.03, the ratio in $CD4^+$ T cells was lower and ranges between 0.1 and 0.3 in the 5 individuals showing allelic expression differences.

Conclusion: These data suggest that the causative Blk allele may play a role in disease pathogenesis by its action in T cells as opposed to, or in addition to, B cells. The contrasting data in fresh B cells compared with B cell lines suggests that if Blk plays a role in autoimmune pathogenesis in B cells, it may be in particular subsets of B cells. Future studies will investigate the role of Blk alleles in regulating expression in specific B cell subsets.

Evidence for the Involvement of Gamma-Delta TCR+ T-Cells in Systemic Sclerosis. Adaobi I. Nwaneshiudu[1], Weon-Joo Jaung[1], Alexander Tsygankov[1], Emilia Oleszak[1], Allen R. Myers[2] and Chris D. Platsoucas[1], [1]Temple University School of Medicine, Philadelphia, PA, [2]Temple Univ Schl of Medicine, Philadelphia, PA

Purpose: Emerging evidence support a major role for T-cells in the pathogenesis of systemic sclerosis (SSc), a disease characterized by fibrosis, endothelial cell injury and immune dysfunction. The purpose of this study was to investigate whether SSc is an antigen-driven disease, by determining if γδ TCR+ T-cells are clonally expanded in skin biopsies and/or peripheral blood of patients with SSc. Human γδ TCR+ T-cells are a minor subset of T-cells in the peripheral blood but are well represented in epithelial tissues. As with αβ TCR+ T-cells, generation of the γδ TCR diversity is random during T-cell development, resulting in a repertoire of T-cells each with a unique TCR heterodimer. Therefore the probability of finding identical TCR on different T-cells is negligible, except in the context of an antigen-driven clonal expansion.

Method: Total RNA was isolated from homogenates of skin biopsies and PBMC from patients with SSc (n=7), using the Trizol® reagent. After reverse transcription for cDNA synthesis, TCR transcripts of the major subsets of the human γ-chain (i.e. VγI and Vγ9) and δ-chain (i.e. Vδ1 and Vδ2) were amplified in each sample, by gene-specific primers. Subsequently, the transcripts were cloned using the Invitrogen pCR2.1 TOPO® vector, and clones of transcripts, selected randomly, were sequenced. Predicted amino-acid sequences of the transcripts were determined using the ExPasy online software and transcripts were quantified based on the identity of productively-rearranged CDR3 region sequences of the TCR chains.

Results: Comparison of randomly-selected clones of γ- and δ-chain transcripts from each patient, revealed the presence of substantial proportions of identical VγI-chain transcripts (14.3%-37.2% identical; $p<0.05$), and Vγ9 transcripts (24%-83.3%; $p<0.05$) in skin biopsies and/or PBMC of patients with SSc. Likewise, there were multiple identical Vδ1-chain transcripts (25%-50%; $p<0.05$), and Vδ2-chain transcripts (18.1%-80%; $p<0.05$) in the samples analyzed. These results were statistically significant using binomial distribution.

Conclusion: Mulitple identical γ-and δ-chain TCR transcripts were identified in skin biopsies and peripheral blood of patients with SSc, demonstrating the presence of oligoclonal populations of γδ TCR+ T-cells in these patients. These γδ TCR+ T-cells may have undergone proliferation and clonal expansion *in vivo* in response to as yet unidentified antigens.

Increased Expression of the High Affinity IL-7 Receptor Alpha in Inflamed Joints of RA Patients Mediates Immune Activation That Is Blocked by Soluble IL-7R. Joel A.G. van Roon, Sarita A.Y. Hartgring, Marion J.G. Wenting, Kim M.G. Jacobs, Johannes W.J. Bijlsma and Floris P.J.G. Lafeber, University Medical Center Utrecht, Utrecht, Netherlands

Purpose: IL-7, a member of the IL-2 family, is a potent T cell stimulatory cytokine. Increased IL-7 levels are found in several inflammatory diseases including rheumatoid arthritis (RA). IL-7 effects are essentially mediated through the high affinity IL-7receptor-α chain (IL-7Rα) in conjunction with the common-gamma chain (γc). IL-7 stimulates proliferation, survival and differentiation of T cells and induces T-cell dependent monocyte, B cell activation and osteoclast formation. In addition, IL-7 induces TNFα dependent and independent immune activation. Our purpose was to evaluate the expression and the functional ability of the IL-7Rα in patients with RA.

Method: IL-7Rα expression was determined by immunohistochemistry in synovial tissue of patients with RA (n=24), undifferentiated arthritis (n=27), and osteoarthritis (OA, disease control, n=15). In addition, CD3 and IL-7 expression was assessed by IHC. IL-7Rα expression on CD4 T cells, CD19 B cells and CD14 monocyte/macrophages from RA synovial fluid (SF), synovial tissue (ST) and peripheral blood (PB) was determined. Also, the proliferative capacity and FoxP3 expression of IL-7Rα^{bright} and IL-7Rα$^{dim/-}$ T cells was evaluated. Furthermore, the capacity of IL-7Rα blockade to prevent activation of CD4 T cells was studied *in vitro*.

Results: Significantly higher IL-7Rα expression in the synovial tissue of RA and UA as compared to OA patients was found (both $p<0.001$). The IL-7Rα expression significantly correlated with CD3 and IL-7 expression levels in the synovial tissue ($r = 0.769$, $p<0.001$; $r = 0.561$, $p< 0.001$, resp). CD4 T cells from RA synovial fluid and tissue strongly expressed IL-7Rα. T cells from RA ST and SF predominantly expressed the IL-7Rα. In contrast to their circulating counterparts, a substantial percentage of B cells and macrophages from the synovial fluid and tissue also expressed IL-7Rα, although less prominent than T cells.

Interestingly, we found that IL-7Rα^{bright} T cells from blood that did not express FoxP3 were highly proliferating as compared to IL-7Rα$^{dim/-}$ T cells that expressed high levels of FoxP3. Finally, soluble human IL-7Rα inhibited IL-7-induced proliferation and IFNγ production by mononuclear cells from RA patients.

Conclusion: Increased IL-7Rα expression in patients with RA could contribute to synovitis. IL-7 can activate IL-7Rα^{bright} arthritogenic T cells, overriding suppressive effects of IL-7Rα$^{dim/-}$ T cells as we have previously shown for CD25^{+} Tregs. In addition, decreased CD4 T-cell activation was achieved by inhibition of IL7Rα-mediated immune activation by soluble human IL-7Rα, indicating the therapeutic potential of targeting IL-7/IL-7Rα.

T-Cell Receptor (TCR) Threshold Calibration by Homeostatic Cytokines in Rheumatoid Arthritis (RA). Pratima Deshpande, Karnail Singh, Cindy Wang, Cornelia M. Weyand and Jorg J. Goronzy, Lowance Center for Human Immunology and Rheumatology, Atlanta, GA

Purpose: RA patients fail to maintain tolerance and develop autoantibodies to common antigens such as IgG and citrullinated peptides. We and others have proposed that the overriding defect is a failure in TCR calibration. RA T cells respond to stimulation with increased ERK phosphorylation. The increased ERK activity sustains TCR signaling, thereby lowering the TCR activation threshold. The defect includes all T-cell subpopulations suggesting that an exogenous factor is responsible for TCR tuning.

Method: RA patients and controls were compared for phosphorylated STAT3 and STAT5 by FACS. T cells from healthy controls were incubated with IL-1β, TNFα, IL-6, IL-15 or IL-21 overnight, and washed and stimulated by CD3/CD28 crosslinking. Activation-induced ERK phosphorylation, expression of activation markers, and production of IL-2, IL-17 and IFN-g was quantified by FACS. Splenocytes from 3L2 transgenic mice were stimulated with 1 μM agonistic and partially agonistic peptides. PBMC from HLA-DR4 healthy donors were stimulated with 10 μg/ml citrullinated or regular vimentin peptides. Peptide-specific proliferation was assessed by thymidine incorporation.

Results: RA T cells express increased phosphorylated STAT3 and STAT5. T cells from healthy controls were pre-incubated with STAT3 and STAT5 cytokines (IL-6, IL-7, IL-15 and IL-21) or proinflammatory cytokines for 24 hours, and the effect of this preincubation on TCR-induced ERK phosphorylation was assessed. IL-1β and TNFα did not sensitize T cells to respond with increased pERK levels to TCR ligation. In contrast, preincubation with all homeostatic cytokines enhanced ERK responsiveness. Homeostatic cytokines did not directly activate the ERK pathway; the effect was dependent on de novo transcription. Conditioning with homeostatic cytokines had functional consequences. Conditioned T cells responded to CD3/CD28 ligation with increased expression of activation markers CD69, CD25, CD40L, and CD137 and differentiated into effector T cells producing more IL-2, IFNγ, and IL-17. Most importantly, pre-incubation with IL-15 or IL-21 lowered the TCR threshold to respond to low-affinity antigens. Proliferative responses of 3L2 TCR-transgenic splenocytes to partial agonistic peptide were increased, and PBMC from healthy HLA-DR4 donors responded to citrullinated vimentin.

Conclusion: STAT3 and STAT5-dependent homeostatic but not inflammatory cytokines prime T cells to respond with increased ERK phosphorylation, resulting in TCR threshold lowering and improved effector differentiation. This mechanism may be responsible for the autoimmunity observed in lymphopenic mouse models and be relevant for RA patients who have accelerated immune aging, elevated homeostatic cytokines and defects in TCR calibration. We propose that the exposure to homeostatic cytokines breaks T cell tolerance and paves the way to chronic inflammation.

IL-7 Receptor Ligands IL-7 and TSLP Promote Collagen-Induced Arthritis, Associated by Differential T-Cell Activity and Induction of Proinflammatory Mediators. Sarita A.Y. Hartgring[1], Cynthia R. Willis[2], J W. J. Bijlsma[3], Floris P.J.G. Lafeber[1] and Joel A.G. van Roon[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Amgen Inc., Seattle, WA, [3]University Medical Center, Utrecht, Netherlands

Purpose: Increased IL-7 levels are found in RA. IL-7 effects are mediated by heterodimers of the high affinity IL-7 receptor-α chain (IL-7Rα) and the γc chain. IL-7 stimulates T cells and induces T-cell dependent monocyte and B-cell activation. Thymic stromal lymphopoietin (TSLP) shares the IL-7Rα for signaling, but has a distinctive receptor subunit, the TSLP receptor. TSLP acts on dendritic cells, mast cells, and CD4 T cells and plays a key role in Th2-type inflammatory responses. The effects of IL-7 and TSLP administration on collagen-induced arthritis (CIA) and immune activation and tissue destruction were studied.

Method: CIA was initiated by immunizing male DBA/1 mice with chicken type II collagen. Mice were administered PBS as a control, IL-7 or TSLP (10μg on day 21, 23, 25, 27, 29, and 31). Arthritis was determined by visual examination of swelling and redness of the paws (max 4 per paw/16 per mouse). Joint destruction on day 33 was assessed on basis of radiographs and histological examinations of the ankle joints. Proinflammatory mediators were measured by multi-analyte profiling of serum.

Results: IL-7 strongly increased arthritis severity (mean score day 33 vs. PBS; 11.3 ± 0.9 vs. 6.5, $p<0.01$). TSLP also significantly increased arthritis severity (10.1 ± 0.9, $p<0.05$). A significantly higher radiological score of 1.8 was found for the IL-7 group compared to the PBS (score 1.0). By contrast, TSLP did not alter joint destruction compared to PBS group (mean score of 1.1). This was consistent with the histological joint damage; IL-7 treatment significantly increased the intensity of cell infiltrates, bone erosions and cartilage damage, whereasTSLP did not. Absolute numbers of thymocytes were not changed by IL-7 or TSLP treatment as compared to PBS. Total splenic cell numbers, B cells and T cell subsets were also not affected by IL-7 or TSLP. However, IL-7 and TSLP treatment induced differentiation towards memory T cells ($p<0.01$), associated with an increase in percentages IFNγ- and IL-17-producing T cells in the IL-7 group, and increased IL-4-producing T cells in the TSLP group (all $p<0.05$). Both IL-7 and TSLP administration increased the serum concentrations of CD40L, indicative of T cell activity, and T cell chemoattractant MDC (both $p<0.05$).

Conclusion: IL-7R ligands IL-7 and TSLP promote clinical arthritis without expansion of thymic or splenic T cell numbers. Both IL-7R ligands increase differentiation towards proinflammatory T cells, associated with an increase of proinflammatory mediators. Importantly, IL-7 intensifies arthritis severity and joint destruction, accompanied by increased Th1 and Th17 cells, whereas TSLP promotes arthritis and joint destruction to a lesser extent, which is associated with an increase in Th2 cells. This demonstrates the differential regulation of arthritogenic responses by different IL-7R ligands.

Autoimmune Regulator (Aire) Controls T Cell Help During Collagen-Induced Arthritis. Ian K. Campbell[1], Sarah A. Kinkel[2], Francois-Xavier Hubert[3] and Ian Wicks[4], [1]Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, [2]Walter and Eliza Hall Institute of Medical Research and Department of Medical Biology, The University of Melbourne, Parkville, Australia, [3]Walter & Eliza Hall Institute of Medical Research, Australia, [4]Walter & Eliza Hall Institute of Medical Research, Parkville

Purpose: Autoimmune regulator (Aire) is a transcription factor expressed in medullary thymic epithelial cells that regulates central tolerance to peripheral self-antigens. Mutations in Aire occur in patients with autoimmune polyendocrinopathy candidiasis ectodermal dystrophy (APECED or APS-1). We previously showed that Aire-deficient (Aire-/-) mice on the C57BL/6 background have an enhanced susceptibility to collagen-induced arthritis following immunization with chick type II collagen (CII), a model we have shown is CD4 T cell and B cell dependent. The purpose of this study was to evaluate whether Aire-/- mice are also susceptible to autoimmune arthritis following immunization with self type II collagen (mCII).

Methods: Aire-/- and wild-type (WT) mice were given a single injection of mCII in complete Freund's adjuvant. Mice were monitored for clinical signs of arthritis for up to 41 days. Serum anti-mCII levels were determined by ELISA. The T cell response to mCII was evaluated by [3H]-thymidine incorporation and by ELISpot for interferon-γ. Follicular helper (TFH) T cells (CD4+, CXCR5+, PD-1hi) were evaluated by flow cytometry.

Results: A single immunization with mCII in complete Freund's adjuvant induced severe arthritis in 11 out of 12 Aire-/- mice but only mild disease was observed in 2 of 8 WT mice. The clinical signs of arthritis were confirmed by histology. Disease did not develop in Aire-/- mice (n = 4) that were immunized with mCII in incomplete Freund's adjuvant, showing the requirement for innate system signaling at the time of immunization. Anti-mCII antibodies (IgM and IgG) were detected in the Aire-/- but not in WT mouse sera. A conventional CD4 T cell

response to mCII could not be demonstrated for either mouse genotype. The TFH cell population in pooled spleen and draining lymph nodes was not increased in Aire-/- mice.

Conclusion: The data mirror the response we previously reported for Aire-/- mice immunized with chick CII. Reduced central tolerance to CII in Aire-/- mice manifests as increased CD4 T cell help to B cells for cross-reactive autoantibody production and enhanced CIA. Aire and central tolerance help prevent cross-reactive autoimmune responses to CII initiated by environmental stimuli, as well as spontaneous autoimmunity.

Altered Fli1 Regulation and Expression in Lupus T Cells and Effects On T Cell Function. John L. Svenson[1] and Tamara K. Nowling[2], [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC

Background/Purpose: Lupus is a systemic autoimmune disease characterized by increased expression of several inflammatory and transcription factor genes. Mounting evidence indicates strongly that the expression level of the transcription factor gene Fli1 has a significant impact on the pathogenesis of lupus. Currently, little is understood about how Fli1 is regulated in lymphocytes and how its expression affects lymphocyte survival and/or function. To identify mechanisms involved in the transcriptional regulation of Fli1 gene expression in lymphocytes from MRL/lpr lupus mice.

Methods: We first isolated splenic T cells from MRL/lpr lupus prone mice and C57BL/6 non-autoimmune prone mice. Cells were stimulated with PMA and Ionomycin. Total RNA was collected and subjected to real-time PCR to assess effects on Fli1 expression. Next, chromatin immunoprecipitation was used to assess the in vivo binding of Ets factors to the Fli1 promoter in MRL/lpr compared to C57BL/6 T cells. Finally, Flow cytometry was used to assess proliferation when Fli1 levels were reduced or increased in T cells of C57BL/6 mice.

Results: Our results demonstrate that Fli1 expression decreases in stimulated T cells from C57BL/6 non-autoimmune prone mice but not MRL/lpr lupus mice. In vivo binding assays demonstrate that the binding of Ets1, Ets2, Fli1 and Elf1 to the endogenous Fli1 promoter in C57BL/6 T cells is altered in primary T cells from MRL/lpr lupus mice. Finally, proliferation of T cells isolated from C57BL/6 with genetically reduced Fli1 activity is increased in response to immune stimuli whereas over-expressing Fli1 in T cells isolated from C57BL/6 results in decreased proliferation.

Conclusion: These results demonstrate that Fli1 expression fails to become down-regulated in MRL/lpr T cells upon activation, likely due aberrant transcriptional regulation. The failure to become down-regulated likely leads to Fli1 over-expression in T cells and these results demonstrate that Fli1 levels impact the proliferation of T cells. Together, our results provide evidence of how changes in regulatory mechanisms may influence expression, cellular function and the pathogenesis of lupus.

Immune Complex Is Required but Insufficient for Autoimmune Tissue Injury: Essential Role of Effector CD8+ T Cell. Ken Tsumiyama[1], Akira Hashiramoto[2] and Shunichi Shiozawa[2], [1]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Sciences/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Purpose: We previously showed that repeated immunization with a conventional antigen caused systemic autoimmunity in the mice otherwise not prone to spontaneous autoimmune diseases. Overstimulation of CD8+ T cells by repeated immunization with antigen led to development of full-matured MHC class I-restricted, antigen-specific effector cytotoxic T lymphocyte (CTL). This CTL, generated *via* antigen cross-presentation, subsequently caused autoimmune tissue injury (Tsumiyama K, *et al.* Arthritis Rheum. 58 (suppl. 9): S705, 2008). Here we investigate the contribution of immune complex (IC) to the pathogenesis of autoimmune glomerular lesion, and show that IC is required but still insufficient for autoimmune tissue injury. Instead, full-matured effector CD8+ T cell is absolutely required.

Methods: Wild-type (WT) BALB/c mice, β_2-microlobulin (β_2m)-deficient mice, in which both MHC class I and CD8+ T cells were absent, or μMT mice, who produce no antibodies because of the lack of B cells, were repeatedly immunized with ovalbumin (OVA). Splenocytes of WT mice immunized 12x with OVA were adoptively transferred into naïve WT mice. Renal pathology was assessed by detection of proteinuria and histopathological study, and sera were collected to determine anti-OVA antibody and IC using ELISA. IFNγ-producing CD8+ T cell in spleen was detected under flow cytometry.

Results: Two following findings indicate that CD8+ T cell recognizing MHC class I is essentially required for the induction of autoimmune tissue injury: first, transfer of the $CD8^+$ T cells of mice immunized 12x with OVA induced autoimmune glomerular lesion in recipient mice. Notably, IFNγ-producing CD8+ T cell was newly generated in these recipient mice. Second, after repeated immunization 12x with OVA, massive deposition of IC was observed in the glomeruli of both WT and β_2m-deficient mice, whereas proteinuria were minute as compared to WT mice, and glomerulonephritis was never seen in β_2m-deficient mice. On the other hand, neither IC nor OVA was deposited in the glomeruli of μMT mice that lack B cells even after repeated immunization 12x with OVA. In these μMT mice, however, IFNγ-producing CD8+ T cell was increased to the levels similar to WT mice. Thus, while CD8+ T cells of μMT mice were full-matured as with those of WT mice, proteinuria were not increased and renal lesion was absent in these μMT mice, which indicated that IC is also required for generating glomerulonephritis.

Conclusion: We show that IC or immunizing antigen deposited in target organ is required but insufficient for the induction of autoimmune tissue injury. The full-matured CD8+ T cell is essentially required for the generation of autoimmune tissue injury.

T Cell Upregulation of CD80 but Not CD86 Limits Peak Antigen Activated Effector CD8 T Cell Numbers. Irina Puliaeva[1], Roman Puliaev[1], Thomas J. Lang[2] and Charles S. Via[1], [1]Uniformed Svcs Univ Health Sci, Bethesda, MD, [2]Woodstock, MD

Purpose: T cell upregulation of B7 molecules CD80 and CD86 has been shown to limit T cell expansion in immunodeficient hosts however the relative roles of CD80 separate from CD86 on CD4 vs. CD8 T cells in a normal immune system have not been delineated.

Method: To address this question, we used the parent-into-F1 (P->F1) murine model of graft-vs-host disease and transferred T cells deficient in CD80 and/or CD86 into normal, wild type (WT) F1 hosts. Mice were assessed by flow cytometry at selected time points over the first 14 days after transfer for donor T cell engraftment, host cell elimination and in vivo T cell proliferation as measured by bromodeoxyuridine incorporation. Mice were tested individually (n=4-5 mice/group per time point).

Results: CD80 knock out (KO) but not CD86 KO donor cells exhibited a five-fold reduction in the number of donor cells required for complete elimination of host B cells compared to WT donor cells. Kinetic studies comparing CD80 KO to WT donor cells using optimal and sub optimal donor cell doses demonstrated no differences in T cell engraftment prior to day 10 consistent with flow cytometry results demonstrating that maximal donor T cell upregulation of CD80 occurs after day 10. At day 10, CD80 KO->F1 mice exhibited significantly greater donor CD4 and CD8 proliferation, greater day 12 peak donor CD8 T cells and greater day 14 elimination of host cells compared to WT->F1 mice. Despite the greater day 12 peak in CD80 KO donor CD8 T cell engraftment, contraction of CD80 KO T cells nevertheless occurred reflecting CD80-independent downregulatory mechanisms. Mixing of WT and KO donor T cell subsets prior to injection demonstrated that maximal host cell elimination required that CD80 be deficient on both CD4 and CD8 donor T cells.

Conclusion: These results indicate that expression of CD80 but not CD86 on both CD4 and CD8 ag-specific T cells is important in limiting maximal expansion of CD8 CTL effectors as part of a normal immune response. Our results support the therapeutic targeting of CD80 in conditions where stronger CD8 effector responses are desirable.

1096

Placebo-Controlled Study of Rilonacept for Gout Flare Prophylaxis During Initiation of Urate-Lowering Therapy. H. Ralph Schumacher Jr.[1], John S. Sundy[2], Robert Terkeltaub[3], Howard R. Knapp[4], Scott Mellis[5], Yuhwen Soo[5], Shirletta King-Davis[5], Steven P. Weinstein[6] and Allen R. Radin[5], [1]U Penn & VAMC, Philadelphia, PA, [2]Duke Univ Med Ctr, Durham, NC, [3]VAMC/UCSD, San Diego, CA, [4]Billings Clinic Res Ctr, Billings, MT, [5]Regeneron Pharmaceuticals, Tarrytown, NY, [6]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Purpose: The NALP3 inflammasome/ IL-1 pathway has been implicated in crystal-induced inflammatory arthritides. We assessed weekly subcutaneous rilonacept (R) [IL-1 Trap] 160 mg, a soluble IL-1 receptor-Fc fusion protein, compared to placebo (Pbo) (1:1) for prevention of acute gout flares (GF) during the initiation of urate-lowering therapy in hyperuricemic patients with gout.

Method: A US multi-center, randomized, phase 2 study was initiated in adults with intercritical gout, urate ≥ 7.5 mg/dL, and self-reported history of ≥ 2 GFs in the previous year. Sixteen weeks (wk) of double blind study drug treatment was initiated along with allopurinol 300 mg daily (a lower initial dose was used in those with renal dysfunction), which was titrated to a serum urate < 6 mg/dL. Medications other than study drug for GF prophylaxis were not allowed. GFs (those requiring treatment with an anti-inflammatory agent) were confirmed via phone contact with the study site and reported by the patient via interactive voice response diary. GFs were treated with an NSAID or oral glucocorticoid for 5 to 10 days, with study treatments continued. Endpoints included the mean # of GFs (primary), % of patients with 1 or more GFs, and assessments of safety and tolerability during the treatment period.

Results: 83 patients were randomized, 42 to Pbo and 41 to R. Baseline parameters were similar between treatment groups and included: 80M/3F; mean age, 51 years (27-77); tophaceous gout, 10%; mean # of GFs reported in the prior year, 4.5. Fourteen patients (11 on Pbo/3 on R) withdrew prior to wk 16. Urate levels decreased similarly in both groups.

	Week 12 (primary endpoint timepoint)			Week 16 (end of prophylaxis period)		
	Placebo	Rilonacept	P value	Placebo	Rilonacept	P value
mean per patient [total] # GFs	0.79 [33]	0.15 [6]	0.0011	0.93 [39]	0.22 [9]	0.0036
% [# patients] with ≥1 GF	45% [19]	15% [6]	0.0037	48% [20]	22% [9]	0.0209
% [# patients] with >1 GF	21% [9]	0% [0]	0.0024	26% [11]	0% [0]	0.0005

During the first and last 4-wk period of prophylaxis with study drug and the subsequent 6-week post-prophylaxis period, respectively, 14, 6, and 2 GFs and 2, 3 and 2 GFs were reported in the Pbo and R groups, respectively. Reported adverse events (AE) were similar between treatment groups, with the most common categories being infections (26% on Pbo, 15% on R) and musculoskeletal system disorders (21% on Pbo, 15% on R). No deaths or serious infectious AEs were reported.

Conclusion: In this first double blind, Pbo-controlled trial of IL-1 blockade in patients with gout, rilonacept markedly reduced the occurrence of gout flares during initiation of urate-lowering therapy, and demonstrated an acceptable safety profile. The absence of a post-prophylaxis increase in GFs suggests that a 16-wk period of GF prophylaxis may be sufficient in many patients.

Evidence for a Two-Stage Approach to Urate-Lowering Therapy in Patients with Gout. Fernando Perez-Ruiz[1] and Ana M. Herrero-Beites[2], [1]Hospital De Cruces, Barakaldo, Spain, [2]Hospital de Gorliz, Gorliz, Spain

Purpose: Lowering serum urate (Sur) level under the threshold for saturation (<6 mg/dl) is considered to be the target to completely dissolve monosodium urate (MSU) crystal deposits in patients with gout (Pascual E, et al, Ann Rheum Dis 2008). Life-long therapy is recommended to avoid new crystal formation, but there is no evidence to support life-long therapy achieving Sur < 6 mg/dl after depletion of MSU deposition.

Method: A cohort of patients is followed-up after voluntary withdrawal of urate-lowering therapy (initial 98 patients reported in: Perez-Ruiz F, Arthrits Rheum 2006) with the following inclusion criteria: achieving Sur < 6 mg/dl for 5-year or 5-year after the disappearance of the last subcutaneous tophus. Sur control was made at least twice the first year and at least once a year afterwards. Average Sur during follow-up was calculated using a trapezoidal method. Both diagnosis of gout and diagnosis of recurrence were based on MSU crystal observation. Kaplan-Maier analysis for survival function was used stratifying patients on the distribution of Sur into terciles for those over 7.0 mg/dl.

Results: 194 patients. 49 (25.3%) tophaceous, 168 (87.6%) with two or more joints involved were treated a mean of 65±9 months, range 58 to 116 months, achieving mean average Sur levels 4.89±0.84, range 2.80-5.99 mg/dl. Baseline Sur was 8.84±1.29 and 8.67±1.46 mg/dl after withdrawal of ULDs. Mean time on treatment was 65±9 months (range 58-116 months), mean follow-up after ULDs withdrawal was 29 months (range 6 to 124). Recurrence of gout was observed in 73 (37.6%) patients. There were 22 (11.3%) patients showing Sur 6-7 mg/dl after ULDs withdrawal, none of them showing recurrence. Patients with Sur > 7 mg/dl were divided into groups by terciles distribution: 7.01 to 8.22, 8.23 to 9.50, >9.50 mg/dl. Results of the rate of recurrence and estimated median and 95% confidence interval limits of time to recurrence are shown in Table 1. Survival function graphic is shown in Figure 1.

Table 1. Kaplan-Meier analysis for survival for serum urate levels

Serum urate after UDLs withdrawal	N	Events	%			
				Median Estimation (months)	Lower 95% CI limit	Upper 95% CI limit
≤7.0 mg/dl	22	0	0			
7.01-8.22 mg/dl	52	13	25.0	69	44	93
8.22-9.50 mg/dl	53	27	52.9	44	40	48
>9.50 mg/dl	53	33	61.1	24	41	50

Conclusion: After long-term achievement of proper control of serum urate levels far below the saturation threshold (crystal depletion period), subsequent target for proper control of Sur level could be settled just below the saturation threshold (prevention of new crystal formation period).

Patients' and Providers' Views of Gout Management: A Qualitative Study. Leslie R. Harrold[1], Kathleen M. Mazor[2], Sarah J. Velten[2], Ira S. Ockene[1] and Robert A. Yood[3], [1]University of Massachusetts Medical School, Worcester, MA, [2]Meyers Primary Care Institute, Worcester, MA, [3]Fallon Clinic, Worcester, MA

Purpose: Previous research has shown that gout is often not properly managed. We sought to examine patients' and providers' views on the treatment of gout to better understand why management is so challenging.

Method: In-depth telephone interviews were conducted with gout patients (n=26) who initiated treatment with a urate-lowering drug (ULD) in the prior 6 months and with providers who care for gout patients (n=15), mostly primary care physicians. The interviews were audiotaped and transcribed verbatim. Using qualitative methods, results were analyzed and themes were identified. Interviews focused on acute management, chronic management, prevention and improvement strategies.

Results: For treatment of acute gout symptoms, providers viewed the majority of patients as having excellent relief with NSAIDs, colchicine and glucocorticoids. In contrast, some patients felt the medications prescribed were ineffective. For chronic gout therapy, providers felt most patients had a good understanding of the rationale for ULD therapy and that patients responded well. Many patients were unsure of the duration of chronic therapy and some felt ULDs triggered, worsened or had no impact on their disease. Most providers thought medication adherence was relatively good. Some patients reported discontinuing medications. Discontinuations were largely purposeful and due to clinical or financial concerns. Most providers thought their patient education was adequate to teach disease self-management behaviors. Patients requested more information, more time for interactions and greater awareness by their providers of the use of natural remedies.

Table 1. Responses from the patient and provider in-depth interviews.

Themes	Provider's responses	Patients' responses
Chronic medication management		
Education and knowledge	Patients have a good understanding regarding the need for long-term medication use.	They were aware that allopurinol reduces serum uric acid levels, but had unanswered questions regarding gout etiology
Treatments	Allopurinol was prescribed; the dose was adjusted based on symptoms, serum uric acid level and renal function.	Several changed doses during attacks; many patients were unclear of the duration of therapy with allopurinol.
Response to treatment	Patients respond well to therapy.	Several believed allopurinol triggered or worsened their gout.
Prevention and adherence		
Recommendations	Dietary changes were recommended to most patients.	Most reported receiving recommendations on dietary changes to prevent gout.
Follow through on recommendations	Medication adherence is not a problem as the pain of a gout attack is a strong motivator; lifestyle changes more challenging for patients to adhere to.	Most reported incorporating the recommended lifestyle changes; medication nonadherence was due to clinical and financial factors.

Conclusion: There is a striking disconnect between how providers and patients view gout and its management.

Methotrexate as An Alternative for Refractory Calcium Pyrophosphate Arthropathy. Francisca Sivera, Mariano Andres, Juan Miguel Lopez-Gomez, Paloma Vela and Eliseo Pascual, Dpt. Rheumatology, Hospital General Universitario Alicante, Alicante, Spain

Purpose: A series of 5 patients suffering from chronic calcium pyrophosphate dihydrate (CPPD) arthritis and responding poorly to non-steroidal anti-inflammatory drugs (NSAIDs) and colchicine treatments has been reported to respond to methotrexate (MTX) [*Arthritis Rheum* 2007;56:688-921]. We present our experience with the use of MTX in 8 similar patients with CPPD arthropathy.

Method: Retrospectively we identified 8 patients who are currently followed at our clinics after successful treatment with low dose MTX for chronic primary CPPD arthropathy (all diagnosed by crystal identification and all had radiologic chondrocalcinosis). All patients were refractory to NSAIDs and colchicine. Treatment response was evaluated by the physician's opinion (excellent, good, medium, poor or absent response) and the patient's opinion, measured on a 10-cm visual analogue scale (0=no effect; 10=complete resolution of symptoms). Months of follow-up, initial and maximum MTX dose, administration route, the use of colchicine, glucocorticoids or NSAIDs and adverse effects was recorded on all patients.

Results: Four patients presented with persistent polyarthritis, three with persistent oligoarthritis and one patient with frequent recurrent bouts of severe acute monoarthritis ("pseudogout") in ankle, knee and wrist. Median duration of the disease since its diagnosis prior MTX was 32.5 months (range 1-96). In 6/8 patients MTX was administered orally, and subcutaneously in the remaining 2. Seven out of 8 patients received colchicine too. No patients were on NSAIDs or glucocorticoids. MTX efficacy measured by both patient and physician was in general good to excellent (Table). MTX was discontinued in 2 patients due to adverse effects (transient bone marrow aplasia and elevation of liver enzymes).

Results:

Characteristics, efficacy and adverse effects in CPPD arthropathy treated with MTX

Sex/Age (years)	**CPPD presentation**	**MTX maximum dose (mg/wk)**	**Time on MTX (months)**	**Evaluation (physician)**	**Patient opinion**	**Adverse effects**
M/69	Polyarthritis	12.5 or	7	Excellent	8	Leukopenia
F/65	Oligoarthritis	7.5 or	12	Good	7	None
F/59	Polyarthritis	20 or	18	Good	6	None
F/83	Oligoarthritis	10 sc	18	Good	9	None
F/46	Monoarthritis	15 sc	10	Good	8	None
M/76	Polyarthritis	20 sc	12	Excellent	8	None
F/70	Oligoarthritis	15 or	48	Medium	5	Liver enzymes
F/81	Polyarthritis	15 or	9	Good	9	Myelotoxicity & Stomatitis

M: male; F: female; or: orally, sc: subcutaneous.

Conclusion: Our results support the results of the reference and indicate that MTX is an effective treatment for at least some patients with chronic CPPD arthropathy. Additional studies are necessary to determine to what extent and for which patients is MTX effective.

Pegloticase Therapy Does Not Increase Oxidative Stress Status. Michael S. Hershfield[1], L. Jackson Roberts II[2], Nancy J. Ganson[1], Susan J. Kelly[1], John S. Sundy[3], Edna Scarlett[4] and Denise A. Jaggers[5], [1]Duke University Med Ctr, Durham, NC, [2]Vanderbilt University, Nashville, TN, [3]Duke Univ Medical Ctr, Durham, NC, [4]Durham, NC, [5]Durham

Purpose: Pegloticase, a pegylated recombinant mammalian urate oxidase, can rapidly lower plasma urate (PUA) to <2 mg/dL. Since urate is postulated to be an important free radical scavenger, and urate oxidation generates hydrogen peroxide, it has been suggested that pegloticase therapy might increase oxidative stress. To address this concern, we examined plasma concentration of F2-Isoprostanes (IsoP) in a phase 2

trial of pegloticase in 21 patients with refractory gout. IsoP result solely from free radical attack on membrane-associated arachidonic acid, and plasma IsoP is well validated as a biomarker of oxidative stress status.

Method: Plasma IsoP was measured by GC-MS, and PUA by HPLC. The clinical protocol called for 5 infusions of pegloticase (8 mg) at 3 week intervals. PUA and IsoP were assessed at baseline and 2, 48, and 168 h after infusion #1, at 7 d after the final infusion, and at a follow-up visit about 7 weeks later.

Results: At baseline, mean PUA was 10.8 +/- 1.3 mg/dL, and mean plasma IsoP was 69 +/- 40 pg/mL (normal, 35 +/- 6 pg/mL). After pegloticase infusion #1, PUA fell to 7.0 mg/dL within 2 h, and to <1 mg/dL at 48 and 168 h in all 21 subjects. In 15 subjects, mean PUA remained <1 mg/dL at 7 d after the final infusion, and was 6.3 mg/dL at follow-up. In 6 subjects who developed clearing antibodies to pegloticase, mean PUA in the final 2 samples had returned to baseline. Overall, plasma IsoP showed no relationship to PUA ($R^2 = 0.01$). As a change from baseline, mean plasma IsoP (all 21 patients) decreased by 7% by d 7 after infusion #1, and by 12% at 7 d after the last infusion of pegloticase in the 15 persistently hypouricemic patients.

Conclusion: Elevated baseline plasma IsoP suggests that hyperuricemia in refractory gout is associated with high oxidative stress. Sustained hypouricemia induced by IV pegloticase therapy was associated with a slight, but non-significant decrease in plasma IsoP, and over a wide concentration range there was no correlation between plasma urate and IsoP levels. These findings indicate that pegloticase therapy does not increase oxidative stress status, and they raise questions about the importance of urate as a free radical scavenger.

Improvement in Health-Related Quality of Life (HRQOL) in Patients with Treatment Failure Gout (TFG) Treated with Pegloticase Measured by SF-6D Derived Utility. Vibeke Strand[1], N. Lawrence Edwards[2], Herbert S. B. Baraf[3], M. A. Becker[4], John S. Sundy[5], B. Huang[6] and A. Forsythe[7], [1]Stanford University, Portola Valley, CA, [2]Univ of Florida, Gainesville, FL, [3]Arthritis & Rheumatism Associates, P.C., Wheaton, MD, [4]University of Chicago, Chicago, IL, [5]Duke Univ Medical Ctr, Durham, NC, [6]Savient Pharmaceuticals, Inc., East. Brunswick, NJ, [7]Savient Pharmaceuticals, Inc., East Brunswick, NJ

Background: Short Form-6D (SF-6D) is an indirect preference-based measure derived from responses to the Medical Outcomes Survey Short Form 36 (SF-36) to assess quality-adjusted life years (QALYs), ranging from 0.30 to 1.00; higher values indicating better health. New methodologies allow 8 mean SF-36 domain scores to be converted into utility scores (SF-6D) that can be used to calculate QALYs.[1,2]

Purpose: To assess the effectiveness of Pegloticase (PGL) 8 mg q2 wks treatment in patients (pts) with TFG over 6 and 12 months by changes in SF-36 and SF-6D.

Methods: Primary data was collected from 2 replicate phase 3 trials of 6 months duration and open label extension (OLE). PGL 8 mg IV was administered q2 or q4 wks vs placebo (Pbo), followed by PGL q2 or q4 wks or observation in OLE. Patients (N=212 at baseline) completed SF-36 at baseline, and weeks 13, 19, 25, 37 and 49.

Results: At baseline, SF-36 domain scores were 4.4 – 32.3 points lower and SF-6D: 0.646 compared with age and gender matched US norms: 0.759, reflecting the major impact of TFG upon HRQOL. Improvements in SF-6D with q2 wks PGL treatment at Week 25 were large (Table) SF-6D change = 0.084, clinically meaningful, well exceeding the minimum clinically important difference (MCID) for SF-6D of 0.041. SF-36 changes at week 25 were statistically significant in 6 domains, reflected by an increase in PCS of 6.42; ≥MCID in all domains and met or approached A/G norms in 5 domains vs. no improvement reported by subjects receiving PBO. Sustained or further improvements were evident over 49 wks treatment in OLE. Improvements in SF-36 scores were consistent with those reported in patient global, pain and physical function (by HAQ); and resulted in Number Needed to Treat values of 1.2 to 4.5 based on changes ≥MCID in 1, 2, 3 or all 4 patient reported outcomes.

Conclusion: PGL q2 wks therapy resulted in clinically meaningful improvements in SF-36 and SF-6D utilities approaching US A/G norms, reflecting that pharmacodynamic effects of PGL treatment (normalization of uric acid and resolution of tophi) result in disease modification in this TFG population.

Table: PGL q2 wks: SF-36 domain and SF-6D utility scores

Domain	PCS	Physical Function	Role Physical	Bodily Pain	General Health	Vitality	Social Function	Role Emotional	Mental Health	SF-6D
A/G norms	50.0	77.5	76.7	67.5	67.1	58.8	81.8	84.2	75.0	0.759
PGL Baseline	35.16	45.2	47.2	37.4	47.4	47.3	61.9	69.4	68.6	0.646
Pbo Wk 25	22.31	40.0	45.1	35.8	45.5	45.2	63.2	75.4	75.5	0.649
PGL Wk 25	40.44*	59.5*	64.2*	61.8*	56.3*	60.0*	77.4*	79.8	79.3	0.730

Evaluation of Drug-Drug Interaction Potential Between RDEA594, Allopurinol and Febuxostat in Preclinical Species. Xiaoqing Yang, Ryan Dick, Virginia Borges, Nahid Yazdani, Andrea Green, Kimberly Manhard, Barry Quart and Li-Tain Yeh, Ardea Biosciences, San Diego, CA

Purpose: RDEA594 has demonstrated serum uric acid (sUA) lowering effects in humans following dosing of either of RDEA594 or its parent, RDEA806, in over 300 healthy volunteers and patients. The lowering of sUA is directly linked to increased urinary excretion of uric acid, which is believed to result from inhibition of the URAT1 transporter. Allopurinol, its active metabolite oxypurinol, and febuxostat, are xanthine oxidase inhibitors used in the treatment of gout. Because of a different mode of action, RDEA594 could be used in combination with allopurinol or febuxostat for uric acid lowering therapy. Assessment of the drug-drug interaction potential between RDEA594, allopurinol and febuxostat was conducted in monkeys and rats.

Method: In male Cynomolgus monkeys, a two period, one-way crossover study was conducted with oral administration followed by plasma and urine collection. In Period 1, a single dose of either RDEA594 at 25 mg/kg (group 1) or allopurinol at 12 mg/kg (group 2) was administered. After a 7 day wash out, in Period 2, RDEA594 was administered concomitantly with allopurinol (group 1), or allopurinol administered concomitantly with RDEA594 (group 2). In Sprague-Dawley rats, RDEA594 or febuxostat was dosed for 3 days before concomitant administration of the other compound on Day 4. The resulting pharmacokinetics of RDEA594 or febuxostat following co-administration was then compared to rats receiving single dose of either RDEA594 at 30 mg/kg or fexobustat at 10 mg/kg.

Result: RDEA594 had no effect on the plasma PK or urinary excretion of allopurinol and oxypurinol in monkeys. Comparing allopurinol plus RDEA594 versus allopurinol alone, the C_{max} and AUC for allopurinol were 0.55 µg/mL, 1.23 µg*hr/mL and 0.65 µg/mL, 1.61 µg*hr/mL, respectively, with $P > 0.05$, indicating an absence of interaction. The C_{max} and AUC for oxypurinol were 2.1 µg/mL, 15.1 µg*hr/mL and 2.0 µg/mL, 14.0 µg*hr/mL, respectively, with $P > 0.05$. The urinary excretion of Allopurinol and oxypurinol were also found to be unaffected by concomitant RDEA594 administration. Similarly, Allopurinol was found to have no effect on the plasma PK or the urinary excretion of RDEA594. Findings from *in vivo* rat study indicated that RDEA594 had no effect on the plasma PK of febuxostat, and vice versa.

Conclusion: No drug-drug interactions were found between the xanthine oxidase inhibitors allopurinol, oxypurinol, febuxostat and RDEA594. RDEA594 coadministration did not alter plasma PK or urinary excretion of the xanthine oxidase inhibitors, and they did not affect the plasma PK and urinary excretion of RDEA594.

Colchicine Efficacy Assessed by Time to 50% Reduction of Pain Is Comparable in Low Dose and High Dose Regimens: Secondary Analyses of the AGREE Trial. Robert Terkeltaub[1], D. E. Furst[2], Katherine Bennett[3], Karin Kook[3], R. S. Crockett[4] and Matthew W. Davis[5], [1]VA Medical Ctr, San Diego, CA, [2]UCLA, Los Angeles, CA, [3]Salamandra, LLC, Bethesda, [4]D.A.T.A. Inc, Bayou La Batre, AL, [5]United Research Laboratories, Philadelphia, PA

Purpose: Colchicine has been used for centuries for the treatment of gout flares but until recently it has not been studied extensively for safety and efficacy in controlled trials. The randomized, double-blind (DB), placebo-controlled AGREE trial established that low-dose (LD) colchicine is as effective as high-dose (HD) colchicine in achieving flare control with a placebo-like side effect profile. This analysis focuses on the efficacy of colchicine as reflected by time to 50% joint pain reduction. Also investigated was a comparison of pain improvement scores at 24 and 32 hr following administration of study drug.

Methods: Patients (pts) with acute gout flare (ACR criteria) were randomly assigned to HD colchicine (4.8 mg: 1.2 mg initially, then 0.6 mg q1hr ×6), LD colchicine (1.8 mg: 1.2 mg initially, then 0.6 mg at 1 hr), or placebo (PBO) groups. After confirmation of gout flare, pts took study drug or placebo and recorded pain intensity as well as adverse events (AEs) for 72 hr thereafter. Efficacy was defined as ≥2-unit reduction in target joint pain score at 24 hr. Pain improvement scores were analyzed 24 and 32 hrs post first dose.

Results: 575 pts were randomized and 184 received study drug or PBO (52 HD, 74 LD, and 58 PBO). Mean baseline pain scores were 6.8 to 6.9 (0 to 10 scale). Both HD and LD colchicine groups achieved significant reduction (≥2-units) in mean pain scores relative to PBO at 24 and 32 hrs post first dose (see table). There was no statistical difference between colchicine groups in time to 50% joint pain reduction (24.5 hr for HD, 24 hr for LD). Rates of AEs were similar between LD and PBO groups, but greater than PBO in the HD group.

	(%) of Responders			**Treatment Comparisons**		
	Colchicine Dose			**(Odds Ratio and 95% CI)[1]**		
Hours Post First Dose	**High (N = 52)**	**Low (N = 74)**	**Placebo (N = 58)**	**High *vs.* Placebo**	**Low *vs.* Placebo**	**High *vs.* Low**
24	34.6	43.2	17.2	2.54 (1.04, 6.18) p = 0.0368	3.66 (1.61, 8.32) p = 0.0015	0.69 (0.33, 1.45) p = 0.3298
32	38.5	45.9	17.2	3.00 (1.24, 7.24) p = 0.0126	4.08 (1.80, 9.27) p = 0.0005	0.74 (0.36, 1.51) p = 0.4033

[1]p-value comparisons using unstratified Pearson chi-square test.

Conclusion: Unlike NSAIDs used for acute gout, colchicine has no primary analgesic properties. Yet in this first PBO controlled, DB study, colchicine provided significant joint pain relief (without adjunctive analgesic therapy) within 24 hr post-drug administration. Both HD and LD groups achieved significant gout joint pain relief by 24 hr compared to PBO. HD and LD efficacy also was observed 32 hr following initial dose. Despite similar pain relief seen in LD and HD groups, the LD colchicine safety profile was comparable to PBO. These results provide further evidence for the treatment of early acute gout flare with a LD colchicine regimen.

Routine Serum Uric Acid (SUA) Monitoring Predicts Antibody-Mediated Loss of Response and Infusion Reaction Risk During Pegloticase Therapy. Dave Wright[1], John S. Sundy[2] and Theresa Rosario-Jansen[1], [1]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [2]Duke Univ Medical Ctr, Durham, NC

Purpose: To characterize relationship between development of anti-pegloticase antibodies (α-PGL), SUA and IRs during pegloticase therapy.

Methods: Pegloticase is a PEGylated recombinant mammalian uricase developed for treating the signs and symptoms of treatment failure gout. Subjects in 2 replicate randomized, double-blind, placebo-controlled studies received pegloticase 8 mg IV q2wks or q4wks or placebo (pbo). Persistent responders maintained SUA <6.0 mg/dL for ≥6 months; transient responders had initial SUA lowering, but SUA returned to ≥6.0 mg/dL. A validated ELISA was used to measure α-PGL during the 6 month studies. IRs were defined as any adverse event occurring during or within 2 hrs post-infusion. Relationships between α-PGL, SUA and IRs were assessed.

Results: α-PGL were detected in 88% of subjects on pegloticase q2wks and q4wks groups and in 15% pbo. Titers were mostly ≤1:2430 in persistent responders (55 of 65). In transient responders, titers usually exceed 1:2430 (67 of 104). α-PGL recognized the PEG moiety of pegloticase. Isotyping of α-PGL showed that 78% had both IgM and IgG, 20% had IgM only, and 2% had IgG only. Development of α-PGL was associated with loss of SUA response due to accelerated clearance of pegloticase. The presence of α-PGL significantly decreased peak and trough serum pegloticase, but were not directly neutralizing of pegloticase activity assayed *in vitro*. Approximately 80% of transient responders lost the SUA response in the first 5 wks of therapy, and ~90% in the first 8 wks. At the time SUA rose in transient responders, serum pegloticase was no longer detectable and α-PGL were rising, but there was no relationship to α-PGL titer at this time point. IRs occurred in 26% in q2 wk and 40% of q4wk groups. In subjects with IRs, 20/22 and 20/34 in the q2wk and q4wk groups, respectively, had SUA ≥6 mg/dL at the time of IR and high levels of α-PGL (mean titer 1:28,013). Most (71%) IRs occurred after loss of SUA response. In those receiving the recommended q2wk dosage of pegloticase, 91% of IRs would have been avoided if pegloticase treatment had been discontinued when SUA was ≥6 mg/dL.

Conclusion: Development of anti-pegloticase antibodies is associated with loss of SUA response and the majority IRs. Most IRs occurred after loss of SUA response. Therefore, routine SUA monitoring can be used to prospectively identify patients receiving pegloticase who may no longer benefit from treatment and are at greater risk for IRs.

RDEA594, a Novel Uricosuric Agent, Significantly Reduced Serum Urate Levels and Was Well Tolerated in a Phase 2a Pilot Study in Hyperuricemic Gout Patients. Ben Lasko[1], Beth Sheedy[2], Vijay Hingorani[2], Guy Tellier[3], Kimberly Manhard[2], Li-Tain Yeh[2], Jeffrey N. Miner[2], Bradley Kerr[2], Zancong Shen[2] and Barry Quart[2], [1]Manna Research, Toronto, ON, [2]Ardea Biosciences, San Diego, CA, [3]Omnispec Clinical Research, Mirabel, QC

Purpose: RDEA594 is in development for the management of hyperuricemia in gout patients. It is a uricosuric agent that acts through inhibition of the uric acid transporter (URAT1) in the proximal tubule of the kidney. RDEA594 was safe and well tolerated and demonstrated dose-dependent reductions in serum urate (sUA) in over 100 healthy volunteers in Phase I studies of up to 10 days duration. The primary objective of this pilot study was to compare the proportion of patients whose sUA level was <6.0 mg/dL following 2 weeks of continuous treatment with RDEA594 compared to allopurinol and placebo in gout patients

Method: Twenty-one gout patients with hyperuricemia (sUA ≥ 8.0 mg/dL) were enrolled. Patients were randomized in a 2:1:1 ratio to the following treatment groups: RDEA594 200 mg once daily (qd) for 1 week followed by 400 mg qd for 1 week, RDEA594 matching placebo qd for 2 weeks, or open-label allopurinol 300 mg qd for 2 weeks. The study included a 2-week run-in period, a 2-week treatment period, and

a 1 week follow-up period. To reduce the incidence of gout flares, colchicine (0.6 mg qd) was administered to all patients throughout the 5-week study. An immediate release (IR) capsule formulation was administered under fed conditions. Serum urate levels were assessed at baseline, Days 1, 8, 9, 14 and 15, and at the end of the follow-up period. Safety was assessed by adverse events (AEs), clinical laboratory test results, vital signs, 12-lead ECGs, and physical examinations. Drug exposure was assessed by measuring concentrations of RDEA594 in plasma and urine.

Results: Preliminary results suggest that RDEA594 plasma levels in gout patients were generally consistent with those observed in Phase 1 healthy volunteer studies. A large majority of the patients achieved target sUA concentrations of less than 6 mg/dL after the first week of treatment, which was comparable to patients receiving allopurinol and significantly better than placebo. On average, RDEA594-treated patients achieved a 40% reduction in serum urate levels by this early time point. RDEA594 was well tolerated in this study, with no serious adverse events and no premature discontinuations due to adverse events at the time of this assessment

Conclusion: Preliminary results in this pilot study show that RDEA594 lowers sUA and is well tolerated after dosing in gout patients with hyperuricemia

Allopurinol Hypersensitivity Reactions: A Case-Control Study of the Role of Renal Dosing. Miriam S. Silverberg[1], Rajitha Mallela[2], Alan J. Lesse[1], Matthew R. Bonner[1], Alan N. Baer[3] and Carl Li[1], [1]University at Buffalo, Buffalo, NY, [2]University of Rochester, Rochester, NY, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: The use of standard dose allopurinol in patients with impaired renal function has been linked with the development of allopurinol hypersensitivity reactions. In 1984, Hande et al (Am J Med 76:47-56) noted an increased frequency of renal impairment among reported patients with severe allopurinol hypersensitivity reactions and proposed guidelines for the reduction of the dose of allopurinol based on estimated glomerular filtration rate (GFR). The objective of this study was to determine whether allopurinol doses higher than those recommended in these guidelines are associated with an increased frequency of hypersensitivity reactions among gout patients.

Method: We conducted a case-control study among patients with a diagnosis of gout (n= 66) from 10/2004 – 11/2007 in the VA computerized chart system. Cases (n=15) were defined based on the presence of an allopurinol hypersensitivity reaction in the adverse reactions section of the patient's medical record. Controls (n = 51) were patients with gout on allopurinol who had not had an adverse reaction to allopurinol. Each study patient was categorized as to whether or not allopurinol dose was high, low, or appropriate for GFR based on published guidelines. Charts were reviewed for description of allopurinol reactions.

Results: Adverse cutaneous reactions occurred in 13 patients (rash 12, pruritus 1), agranulocytosis in one, and angioedema in one. A higher percentage of cases had allopurinol dosed low or appropriate according to the guidelines compared to controls, although the difference was not statistically significant (66.7 vs 43.1%, p=0.109). More patients in the control group were taking ACE inhibitors (51.0 vs 20.0%, p=0.034). Otherwise there was no significant difference between the 2 groups (Table).

Table (percentage appears in brackets)

	Cases n=15	Controls n=51	p Value
Mean Age (yrs) [95%CI]	72.3 [61.8,86.1]	71.3 [60.4,82.2]	0.425
Caucasian	10 (66.7)	44 (86.3)	0.125
Male gender	15 (100)	50 (98.0)	

Thiazide diuretic	0 (0)	9 (17.6)	0.106
Other diuretic	4 (26.7)	15 (29.4)	1.00
Ampicillin/Amoxicillin	0 (0)	4 (7.8)	0.567
ACE inhibitor	3 (20.0)	26 (51.0)	0.034
ARB	1 (6.7)	3 (5.9)	1.00
Allopurinol dose:			
100 mg	8 (53.3)	22 (43.1)	NS
300 mg	6 (40.0)	29 (56.9)	
other	1 (5.9)	0	
Average creatinine clearance (ml/min) [range]	54.6 [27-75]	63.5 [35-99]	
Dose low or appropriate according to guidelines of Hande et al	10 (66.7)	22 (43.1)	0.109

Conclusion: Our study did not demonstrate a relationship between the development of hypersensitivity reactions and the prescription of allopurinol at doses higher then recommended by the guidelines. Surprisingly, the cases were more likely to be taking allopurinol at appropriate doses or doses lower than recommended by the guidelines, although the difference between cases and controls was not statistically significant. These results are important as adherence to these guidelines may lead to suboptimal control of hyperuricemia and therefore recurrent flares of gout.

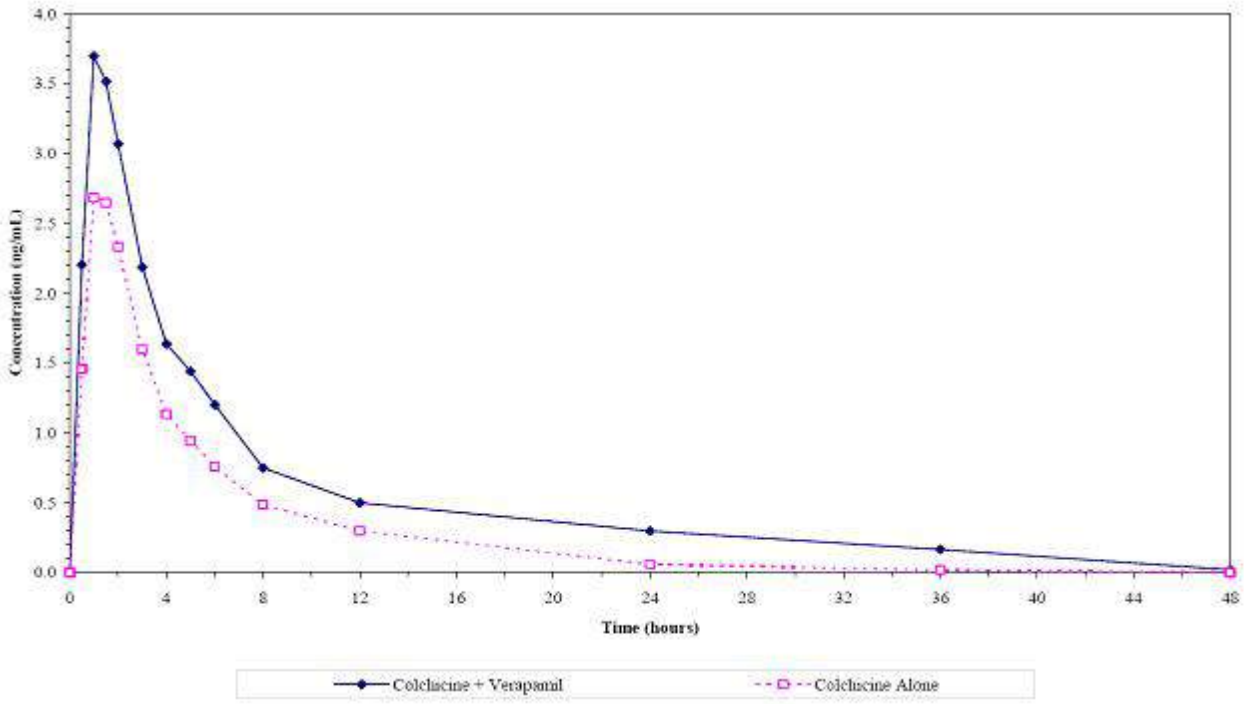
New Dosing Guidelines for Colchicine to Avoid Toxicity When Used with Ca2+ Channel Blockers: The Potent P-Gp/CYP3A4 Inhibitor Verapamil Increases Maximal Concentration of Single-Dose Colchicine by 30% and Exposure by ~100% in Healthy Subjects. Robert Terkeltaub[1], D. E. Furst[2], Karin Kook[3], Jennifer L. DiGiacinto[3] and Matthew W. Davis[4], [1]VA Medical Ctr, San Diego, CA, [2]UCLA, Los Angeles, CA, [3]Salamandra, LLC, Bethesda, [4]United Research Laboratories, Philadelphia, PA

Purpose: Despite the widespread use of colchicine for treatment of acute gout flares, there has been little characterization of colchicine (COL) drug-drug interactions (DDI). Colchicine is a substrate for both the CYP3A4 enzyme and P-glycoprotein (P-gp) transporter. Of particular interest are DDIs involving drugs often used concomitantly with COL that could impact COL metabolism. Currently, 25-50% of gout patients have hypertension. 2.5 billion tablets of verapamil (VER) are prescribed/yr in the USA, principally for hypertension. We previously described the pharmacokinetics (PK) for the calcium channel blocker diltiazem (1.7 billion tablets/yr prescribed) with COL. In that study concomitant diltiazem increased the COL C_{max} value by 31% as well as AUC values by 87% ($AUC_{0-\infty}$). Here, we examined the effects of VER, a potent P-gp/CYP3A4 inhibitor on the PK of single-dose COL.

Methods: In this open-label, 2-period, DDI study, fasting M/F subjects (N=24; 18–45 yrs.) received a single 0.6-mg oral dose of COL on Day 1. Blood samples were taken at various times for PK analysis on Days 2, 3, 4, and 5. On Day 15, following a washout period, subjects received 240 mg VER once daily x5. On Day 19, a second 0.6 mg dose of COL was given. Samples were taken for PK analysis on Days 20, 21, 22, and 23. PK parameters were AUC_{0-t}, $AUC_{0-\infty}$, C_{max}, T_{max}, K_{el}, V_{area}/F, CL/F, and $t_{1/2}$.

Results: Co-administration of VER increases COL concentrations by 30% to a mean maximum of 3.85 ng/mL compared with 2.97 ng/mL with COL alone. COL AUC_{0-t} and $AUC_{0-\infty}$ were 13.1 ng•h/mL and 15.4 ng•h/mL, but increased to 24.6 ng•h/mL and 30.6 ng•h/mL,

respectively, when co-administered with VER. COL T_{max} (1 hr) was unaffected by VER dosing. Total apparent oral clearance decreased from 43.9 L/hr to 21.0 L/hr with co-administration.



Conclusion: Co-administration of VER increases COL C_{max} by 30% and exposure by 99% ($AUC_{0-\infty}$) and reduces its clearance by 52%. This PK profile reflects the DDI observed between COL and VER. Previously, we reported preliminary DDI data for diltiazem and COL comparable to that for VER. Taken together the data suggest COL dosing should be reduced by 50% when administered chronically and concomitantly with either VER or diltiazem. For treatment of acute gout flare, the standard dose of COL should be reduced from 3 to 2 tablets (one-third reduction) for patients on VER or diltiazem.

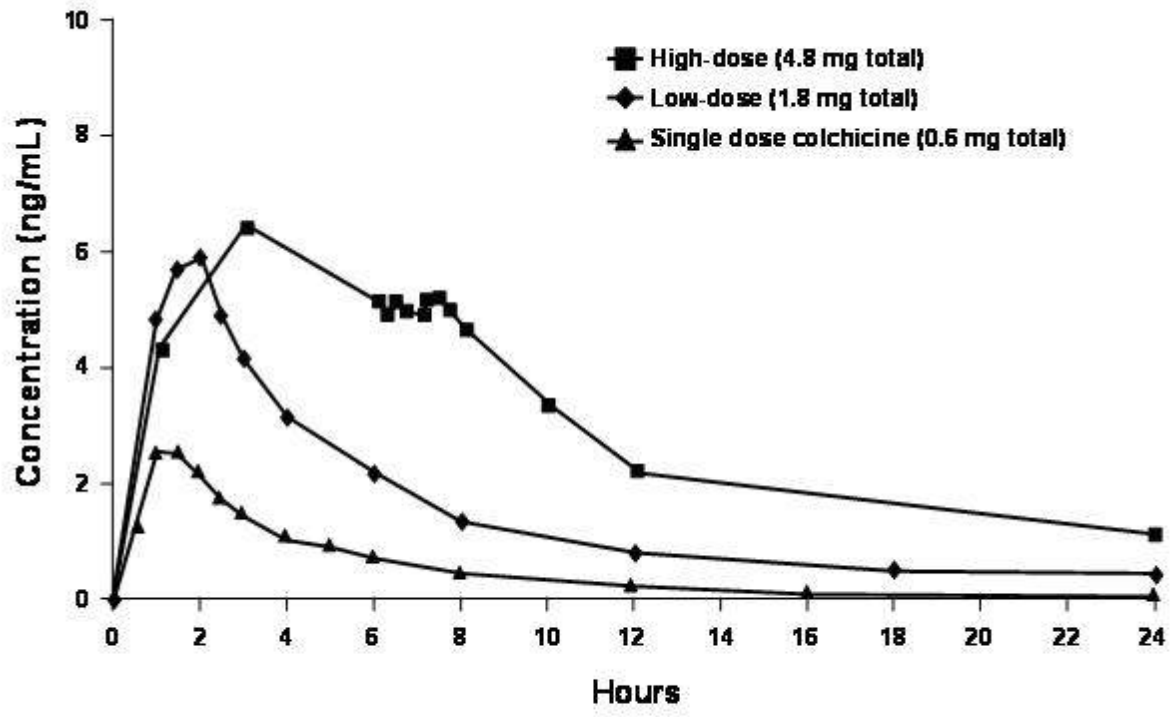
Maximal Plasma Concentrations of Low-Dose Vs High-Dose Colchicine Are Similar but Total Exposure Is Dose Dependent: Implications for Safe Administration of Colchicine to Treat Acute Gout Flare. Robert Terkeltaub[1], D. E. Furst[2], Karin Kook[3], Katherine Bennett[3], Kristin Arnold[4] and Matthew W. Davis[4], [1]VA Medical Ctr, San Diego, CA, [2]UCLA, Los Angeles, CA, [3]Salamandra, LLC, Bethesda, [4]United Research Laboratories, Philadelphia, PA

Purpose: Although colchicine is frequently used for the treatment of gouty attacks, dosing that optimizes its therapeutic index has not been defined. The AGREE trial showed that low-dose colchicine was as effective as high-dose (standard) colchicine (≥50% pain reduction at 24 hrs) but had a better safety profile. Summarized here are the results from pharmacokinetic (PK) studies that evaluated a new oral formulation of colchicine (Colcrys™, Col) as single doses or as low-dose and high-dose regimens.

Methods: A total of 75 healthy male or female subjects were enrolled across 4 phase 1 studies. Plasma samples were collected for PK analyses (LC–MS/MS) following single-dose Col (0.6 mg, fed/fasted), and low-dose (1.2 mg + 0.6 mg after 1 hr) and high-dose (1.2 mg + 0.6 mg x6) Col regimens. PK parameters included $AUC_{0\text{-}t}$, $AUC_{0\text{-}\infty}$, C_{max}, T_{max}, K_{el}, V_{area}/F, CL/F, and $t_{1/2}$. Adverse events (AEs) were assessed and cardiac safety was measured by ECG.

Results: PK of 0.6 mg Col was linear. Food decreased AUC ≈15% but did not affect C_{max} in subjects given 0.6 mg Col. At steady state, mean peak plasma concentration was 3.5 ng/mL ≈1.3 hours post-dose. High-dose and low-dose regimens had similar max blood levels (C_{max}=6.8 and 6.2 ng/mL, respectively). High-dose Col had 2-fold greater total exposure than low-dose, with an $AUC_{0\text{-}\infty}$ of 105 compared with 43.8 ng•h/mL, respectively. There were no clinically relevant changes in PR, QRS, or QTc intervals. The most common AEs were headache, diarrhea, dizziness, nausea, stomach pain, and vomiting. All AEs were mild to moderate in intensity and none resulted in discontinuation from any study.

C_{max} of high-dose and low-dose Col is similar but AUC is dose dependent.



Conclusion: Low-dose Col provides similar max plasma concentrations to high-dose Col (standard dosing). These results suggest that peak colchicine blood levels of ≈6 ng/mL are adequate for pain reduction within the first 24 hrs following gout flare. Additional exposure from high-dose Col may only increase unwanted side effects. For early acute gout flare treatment, low-dose Col (1.2 mg + 0.6 mg after 1 hr) is recommended. The PK profile exhibited by the low-dose regimen should prove to be useful in predicting Col safety and efficacy in patients with compromised clearance or those concomitantly administered CYP3A4 or P-gp inhibitors.

1109

Assessment of a Gout Education Session. Timothy A. Lonesky[1] and L. Brown[2], [1]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [2]Hitchcock Clinic Inc, Lebanon, NH

Purpose: Gout is a growing health problem affecting 7% of men and 3% of women over 65 years of age. There is scant literature about patient understanding of gout or educational programs in management of the disease although there is abundant research about poor or mismanagement with emphasis on patient education repeatedly discussed. Also,both ACR and EULAR list efficacy of educational programs as future research agenda. This study was developed to educate our local gout population about their disease and correct various knowledge gaps with secondary goals of assessing patient characteristics, evaluating an education session with emphasis on the "match-fire" analogy adapted from Dr. Robert Wortmann's article in the Dec issue of Am J Med 1998 via a pre and post session questionairre, and evaluating any correlation between patient characteristics and gout knowledge.

Method: ICD 9 code diagnosis of gout in Department of Rheumatology at DHMC from 2007-2008 were recruited to participate. 374 patients were sent an invitation, inviting them and family members to attend an evening education session at the medical center. 10 sessions were lead by a rheumatology fellow with a powerpoint presentation followed by question and answers. Patients were given a 20 true or false questionairre at the beginning and conclusion of the session.

Results: Responders were 75% male with all of them finishing highschool and 60% attending some college. 42% had gout > 10 years. 58% had care via rheumatologist vs 42% via PCP (with 80% of these via non-physician primary). 64% felt their understanding of gout was "average." 27% knew their current uric acid level with a range of 3-5.4 mg/dL (all under care of rheumatologist and all answered medication questions correctly). The average pre-session correct score on the questionairre was 52% and the average post-session score was 75%. Questions with the greatest improvement in score included gouts relationship to obesity (+40%), dairy products (+59%), vitamin C (67%) along with gout being a "curable" disease with proper medical management (+53% with all patients believing this to be true by the end of the session). Participants thought the sessions were useful with a grading of 8.2 on a visual analogue scale. All participants improved their score but despite intervention, some areas continued with poor performance (<50% of participants correctly answering). These included questions about NSAID and steroid use in chronic gout treatment along with expectations of 300mg of daily allopurinol improving uric acid to < 6mg/dL.

Conclusion: In a highly educated population of gout patients, an intervention to improve knowledge gaps via a interactive educational session was successful however even immediately after a session, based on a true and false questionnaire, some areas of knowledge remained poor. Based on this, the visual aid "match-fire" analogy adaption, may be able to give patients a proper and easily understandable reference to the use of their medications. Future studies need to be done to see which educational interventions will improve gout management.

Gout Management in Primary Care Vs. Rheumatology: Evidence for Suboptimal Treatment. Robert T. Keenan[1], Robert A. Lehman[2], William R. O'Brien[3], Daria B. Crittenden[1], Kristen H. Lee[1] and Michael H. Pillinger[4], [1]NYU-HJD, New York, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]New York University, New York, NY, [4]NYU Langone Medical Center/NYU Hospital for Joint Diseases, New York, NY

Purpose: Primary care physicians (PCPs) manage most gout patients, but several studies suggest that the quality of PCP gout management may differ from that of rheumatologists. To prevent acute gouty attacks, a serum uric acid (UA) of ≤ 6 is the consensus UA lowering target. We compared the achievement of UA ≤ 6 in patients managed by PCPs vs. rheumatologists.

Methods: Gout patients were identified, from among all NY Harbor VAMC patients ages 18-100 (n-33,000) as having any 1 of 7 ICD codes for gout. Gout patients were defined as managed by their PCP if they had not seen a rheumatologist during the study period (7/07-6/09), or treated by a rheumatologist if they had seen a rheumatologist ≥3 times during the interval. Patients with 1-2 rheumatology visits were excluded. Mean serum UA for the two groups were compared using R statistical software (version 2.8.1).

Results: Prevalence of gout in the overall population was 2.5% (34% African-American, 49% White, 8% Hispanic, 2.5% South East Asian, 1% Pacific Islander, 0.5% Native American and 5% unknown). All subjects were male; average age was 72 years. Among 575 patients meeting ICD-9 diagnosis for gout, 474 had been treated for gout only in primary care, whereas 85 had been managed by a rheumatologist. 5.3% in the PCP cohort vs. 14.1% in the rheumatology cohort had a crystal confirmation of their disease. Patients receiving allopurinol achieved UA ≤6 in the rheumatology- but not the PCP-treated group. Among 191 patients prescribed allopurinol in the PCP cohort, 25.7% had no UA measurement during the study period; in contrast, 100% of the 57 rheumatology patients receiving allopurinol had ≥1 UA measurement. Average allopurinol dose in the PCP and rheumatology cohorts were 196 mg and 182 mg, respectively. Among patients with gout and hypertension, 16.7% were prescribed hydrochlorothiazide (HCTZ) in the PCP cohort vs. 11.8% in the rheumatology cohort.

Uric acid outcomes in gout subjects by treatment setting

	PCP	**Rheumatology**	**P-value** α=0.05
Mean UA among all patients	7.85 (7.65,8.01) (n=474)	6.54 (6.12,6.97) (n=85)	<0.0001
Mean UA among patients prescribed allopurinol	6.94 (6.56,7.31) (n=142)	5.94 (5.49,6.39) (n=57)	0.0004
Mean UA among patients prescribed HCTZ	7.85 (7.33,8.37) (n=63)	6.22 (4.84,7.60) (n=10)	0.0218

Conclusion: Our analyses suggest that gout patients cared for by PCPs may be undertreated. Compared with rheumatologists, PCPs are more likely to under dose, and/or inadequately monitor the results of, UA-lowering therapy. PCPs may also be more likely than rheumatologists to eschew crystal diagnosis, and to fail to account for the UA-raising properties of anti-hypertensive diuretics. To ensure proper clinical care, rheumatologists may need to assume a greater role in treating gout patients, and/or better educate PCPs in appropriate gout management.

First Application of Computer-Assisted Analysis of Digital Photographs for Assessing Tophus Response: Phase 3 Studies of Pegloticase in Treatment Failure Gout. A. N. Maroli[1], R. Waltrip[1], M. Alton[1], Herbert S. B. Baraf[2], B. Huang[1], C. Rehrig[1] and R. Ford[3], [1]Savient Pharmaceuticals, Inc., East. Brunswick, NJ, [2]Arthritis & Rheumatism Associates, P.C., Wheaton, MD, [3]RadPharm, Princeton, NJ

Purpose: Based upon anecdotal investigator-generated digital photographs that identified tophus elimination with pegloticase treatment in Phase 2, a standardized photographic and analytic process was developed to assess tophus response in 6-month, double-blind, placebo-controlled Phase 3 studies of pegloticase.

Method: An approach to quantitation of tophus elimination was jointly developed by Savient and RadPharm. This used serial photography and a method of categorizing skin lesions similar to Response Evaluation Criteria in Solid Tumors (RECIST). As RECIST has been used by FDA/EMEA for oncologic drug approvals, the principles of RECIST were used to categorize the response of tophaceous mass lesions to a novel therapy. Specialized software for clinical trials was used to standardize image viewing, measurement, and annotation in an audit-tracked environment for integrity of the central reading process. Method manual and site-based training programs were used to ensure standardization of equipment, image acquisition and quality assurance. Analysis and measurement of tophi were performed by an independent blinded Central Reader (rheumatologist). Investigational sites (n=56: US, Mexico, Canada) were trained using identical equipment and standard view templates for hands and feet. Quality procedures were used to assure that digital media were properly labeled, processed and delivered for image analysis. Assessment was blinded to and independent of any Sponsor or trial site input. From each

subject's baseline views, Central Reader selected target tophi to follow utilizing a "Sequential Locked Read" paradigm; post-baseline photographs were read and compared with baseline image with no knowledge of intervening or future assessments. Calibrated electronic calipers were used to measure the tophus area. Complete response (CR) of an individual target tophus was defined as 100% decrease in area. Overall tophus response per subject was the complete resolution of at least one tophus without appearance of a new tophus or progression of an existing tophus.

Results: Method captured tophus response and was successfully operationalized in a multicenter clinical trial. Treatment with intravenous pegloticase 8 mg q2 weeks led to reduction in tophus burden compared to placebo: 22% of subjects experienced CR of a target within first 3 months (p=0.011) and 45% within 6 months (p=0.002).

Conclusion: Computer-assisted analysis of digital photographs, used for skin lesions in oncology, has been successfully applied to assessment of tophus treatment response in rheumatology. Standardized photographic data recording and computer-aided analysis in a Central Reader paradigm, successfully documented outcomes, with findings consistent with clinical observations.

1112

The Costs of Treatment Failure Gout: A Claims-Based Analysis. E.Q. Wu[1], A.P. Yu[1], A. Guérin[2], D. Latremouille-Viau[3], M. Tsaneva[2] and A. Forsythe[4], [1]Analysis Group, Inc., Boston, MA, [2]Analysis Group, Inc., Montréal, QC, [3]Analysis Group, Inc., Montreal, QC, [4]Savient Pharmaceuticals, Inc.,, East Brunswick

Purpose: Gout is a chronic disease characterized by severe pain and swelling of joints due to deposition of monosodium urate crystals in joints, tendons and surrounding tissues. Patients who are refractory to conventional urate-lowering therapy i.e., unable to reduce SUA below 6.0mg/dL, have higher rates of flares and incidence of tophi which impose a significant disease and economic burden. This study estimated the cost of treatment failure gout from a payer perspective.

Method: As a surrogate to broadly represent the treatment failure gout population, the following metrics were used: in the MarketScan commercial claims database (2003/10-2008/09), patients diagnosed with gout (ICD-9-CM: 274) with ≥3 flares within a 12-month period were selected, with the first flare occurrence date as the index date. A gout flare was defined as an episode with gout diagnosis followed by a claim for NSAIDs, colchicine, corticosteroids, ACTH, or intra-articular aspiration or injection within 7 days, or a diagnosis for joint pain (ICD-9-CM: 719.4) followed by a claim for colchicine within 7 days. Patients were considered if they received allopurinol prescriptions and had tophus diagnoses (ICD-9-CM: 274.8x) by the end of one year. For each gout patient aged ≥ 18, a gout-free control with the same age, sex, and region of residence was selected and was assigned the same index date as his matched counterpart. Included patients needed to have at least 12 months of continuous enrollment following the index date. One year costs were compared between gout and gout-free patients. GLM models with log link and gamma distribution and two-part models were used, and controlled for age, sex, region of residence, and type of insurance. All costs were inflated to 2008 US dollars using the medical care component of the Consumer Price Index. A subgroup analysis among more severe gout patients with ≥6 flares was performed.

Results: A total of 373,186 enrollees received a diagnosis of gout, 679 of which met the criteria of treatment failure gout. The average age was 50 years, and 82% were male. Mean total annual cost was estimated at $17,603 for treatment failure gout patients, compared to $6,891 for the control group. After adjusting for confounding factors, incremental total cost of treatment failure gout was $10,222 (p<0.01), which was largely attributable to higher adjusted outpatient costs ($3,814; p=0.01), inpatient costs ($3,056; p<0.01), and drug costs ($879; p<0.01). A subgroup of 195 gout patients with ≥6 flares had even higher total healthcare costs, with adjusted incremental costs at $22,237 (p<0.01).

Conclusion: Treatment failure gout in patients on conventional urate lowering therapy whose SUA is not normalized presents substantial economic burden to the payers. Patients with more flares incurred even greater costs. This study, however, is limited by the lack of specific diagnostic codes in gout.

Chronic Use of Pegloticase: Safety and Efficacy Update. J. S. Sundy[1], Herbert S. B. Baraf[2], SR Gutierrez-Urena[3], R. A. Yood[4], B. Huang[5], A. N. Maroli[5], R. Waltrip[5], Z. Horowitz[6] and M. A. Becker[7], [1]Duke Univ Medical Ctr, Durham, NC, [2]Arthritis & Rheumatism Associates, P.C., Wheaton, MD, [3]Hospital Civil De Guadelajara, Guadalajara, [4]Fallon Clinic, Worcester, MA, [5]Savient Pharmaceuticals, Inc., East. Brunswick, NJ, [6]Savient Pharmaceuticals Inc, East Brunswick, NJ, [7]University of Chicago, Chicago, IL

Purpose: To assess safety and durability of treatment response to intravenous (IV) pegloticase (PGL) 8mg every 2 weeks (q2wks) or q4wks during an open label extension (OLE) study in subjects with treatment failure gout who completed one of two replicate randomized double-blind, placebo-controlled trials (RCTs).

Method: Subjects completing 6 month Phase 3 RCTs of pegloticase, a PEGylated recombinant mammalian uricase, were eligible for OLE study. Data for first 6 months of OLE are presented. Subjects/investigators chose q2wk or q4wk PGL 8mg dosing schedule without knowledge of RCT group or response. Objectives of the OLE were assessment of safety and maintenance of RCT primary and secondary efficacy outcomes.

Results: 151/212 (71%) of RCT subjects and 151/157 (96%) of RCT completers enrolled in the OLE (82 PGL q2wks, 67 PGL q4wks, 2 observation). Adverse event (AE) patterns were similar between RCT and OLE, with exception of the continued decrease in incidence and frequency of gout flares observed for PGL after the first 3 months of the RCTs. The frequency of infusion reactions (IRs) or serious AE (SAE) IRs in OLE and RCTs were similar.

	PGL regimen (RCT to OLE)					
	q2 to q2 wks	**q2 to q4 wks**	**q4 to q2 wks**	**q4 to q4 wks**	**Pbo to q2wks**	**Pbo to q4wks**
N	34	23	25	28	23	16
IR, n(%)	6(18)	4(17)	7(28)	13(46)	12(52)	12(75)
SAE, n(%)	2(5)	0	1(4)	0	4(17)	3(19)
SAE IRs leading to discontinuation, n(%)	0	0	1(4)	0	2(9)	3(19)
IRs leading to discontinuation, n(%)	1(3)	1(4)	2(8)	2(7)	2(9)	3(19)

Three deaths occurred in the OLE (3/151); none was considered to be related to study drug. Cardiovascular (CV) event pattern and frequency of CV events was not different than that found in the RCT.

Forty-three of 48 subjects whose SUA was consistently <6 mg/dL on PGL in RCTs maintained SUA <6 mg/dL in OLE. While 32 subjects had complete resolution (CR) of at least 1 tophus on PGL in RCT, 20 additional subjects (12 of whom received PGL in the RCT) demonstrated their first CR in the OLE. Tophi progressed in 3 pts in OLE (who received PGL q2wks in RCT and OLE) whose SUA response was transient, but not maintained < 6mg/dL. Reductions in tender or swollen joint counts attained in RCTs continued or were maintained in OLE. Improvements in patient global assessment of disease activity, pain, and disability scores observed in RCTs improved or were maintained in OLE

Conclusion: In subjects with treatment failure gout, chronic pegloticase therapy is well tolerated with no suggestion of increased risk with treatment extending up to 1 year. Efficacy in reduction of SUA concentration and symptomatic endpoints was maintained.

Balance Ability in Polyarticular Juvenile Idiopathic Arthritis. Vanessa Bueno[1], Claudio A. Len[2], Maria T. Terreri[3], Jamil Natour[4] and Maria O. Hilário[2], [1]Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo,, Brazil, [3]Universidade Federal de Sao Paulo, Brazil, [4]Federal University of Sao Paulo, Sao Paulo, Brazil

Purpose: To evaluate balance ability in children and adolescents with poliarticular juvenile idiopathic arthritis (JIA) and its correlation with joint limitation, functional capacity, pain VAS and Berg Balance Scale (BBS) score.

Methods: JIA patients with lower limbs involvement were consecutively selected from our outpatient Pediatric Rheumatology clinic. Inclusion criteria were age between 10 years-old and 16 years-old, minimum height of 130 centimeters and normal visual acuity. The control group comprised "healthy" children and adolescents matched for age and gender. Balance was measured by a Biodex stability System (Inc, Shirley NY). The patients protocol included Childhood Health Assessment Questionnaire (CHAQ), Pediatric Escola Paulista de Medicina - Range of Motion scale (Pediatric EPM-ROM) and a pain VAS. The Biodex test included two adaptation periods with an interval time of one minute each one and three consecutive 20 minutes test in level 8 (lower instability) and 2 (higher stability). We measured anterior-posterior (AP), medial-lateral (ML) and overall dislocation (OD).

Results: JIA group comprised 50 patients (35 girls, mean age 13,5 ± 2,19 years-old) and control group included 50 children and adolescents (35 girls, mean age 13,5 ± 2.18 years-old. In the patients group mean CHAQ score, Pediatric EPM-ROM and pain VAS were 0.83, 0.70 and 3.04, respectively. BBS score was 51 for patients and 55 for controls. We did not observed difference between JIA patients and controls in Biodex test level 8 ($p = 0,907$); in Biodex test level 2 the difference was statistically significant in all 3 variables: AP ($p = 0.007$), ML ($p = 0.004$ and OD ($p = 0.001$) We did not find any correlation among this variables and CHAQ, Pediatric EPM-ROM and pain (Spearman correlation coefficient).

Conclusion: Our polyarticular JIA patients have worse balance ability than healthy children; we must be alert to this problem in our daily routine.

Does the School Dimension Determine Impairment of Health-Related Quality of Life in Patients with Juvenile Idiopathic Arthritis?

Tania M.S. Mendonça[1], C.A. Len[2], Carlos H. M. Silva[1], Rogerio M.C. Pinto[3] and M.O.E. Hilário[4], [1]UNIVERSIDADE FEDERAL DE UBERLANDIA, Uberlandia, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil, [3]Brazil, [4]Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Purpose: To evaluate health-related quality of life (HRQL) of children and adolescents with juvenile idiopathic arthritis according to age group and arthritis subtypes using the Brazilian version of PedsQL™ 4.0

Methods: Patients with JIA and their respective caregivers were recruited in August 2008, from the Pediatric Rheumatology outpatient clinic at the Medical School of the Federal University of Uberlândia (Brazil). These patients were classified according to the ILAR criteria and, with their respective caregivers, answered the Brazilian version of PedsQL™ 4.0 and a sociodemographic evaluation questionnaire. The descriptive statistics characterized the population. The Kruskal-Wallis test was used to compare the medians of the PedsQL™ 4.0 domains scores of the patients and their caregiver, according to the subtypes of arthritis in the 2-4, 5-7, 8-12 and 13-18 year old age groups. Cronbach's alpha coefficient was used to confirm instrument reliability for this population.

Results: 52 children and adolescents with JIA (mean 11 ± 4.02 years) and their caregivers (mean 39.1 ± 9.19 years) participated in the study. The patients were predominantly oligoarticular (46.2%), attending basic education (82.7%), equivalent gender and with a low family income (75%). The Cronbach's alpha coefficient was adequate, with a variation of 0.7 to 0.9 for the PedsQL™ 4.0 domains of the groups evaluated.

Patients aged 8-12 years, of the oligoarticular subtype presented lower scores in the school dimension ($p<0.05$) of the Pedsql™ 4.0. According to the caregivers' perception, the same result was found, but for the polyarticular subtype ($p<0.05$).

Conclusion: JIA impaired the HRQL of patients as detected by the Brazilian version of PedsQL™ 4.0. The disease, therapy and side effects of the medications interfere in attendance at school and in concentration, diminishing the children's motivation in the 8-12 age group and making it difficult for them to adapt at school, independent of arthritis subtype. The family, school and interdisciplinary team should take steps to keep schooling from being more than minimally impaired.

MACTAR, a Patient Perspective Outcome for Polymyositis and Dermatomyositis, Reveals Disease Aspects Not Covered by Traditional Outcomes. Li Alemo Munters[1], R.F. Van Vollenhoven[2] and Helene Alexanderson[1], [1]Rheumatology Unit, Department of Medicine and Department of Physical Therapy, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicin, Karolinska University Hospital, Karolinska Institutet., Stockholm, Sweden

Purpose: The objective of this study was to evaluate patient perspective on disease impact using the MacMaster Toronto Arthritis patient preference questionnaire (MACTAR) and to evaluate measurement properties of the MACTAR for patients with polymyositis (PM) and dermatomyositis (DM) in Sweden.

Method: The MACTAR is a semi-structured interview asking questions on different aspects of disease impact and their importance to the patient to improve. Twenty-eight patients with PM and DM (15 women and 13 men) were included. Eleven patients were diagnosed with PM and 17 with DM and they had a median age of 57 (range 28-74) years. Their median diagnosis duration was 9 (1-32) years; 9 worked full-time, 9 part-time, 7 were retired and 3 patients were on sick-leave. We analyzed measurements recommended by International Myositis Assessment Clinical Study Group (IMACS) and myositis specific outcomes including measures of disease activity (six-item core set), Myositis Damage Index, muscle strength (Manual Muscle Test), muscle endurance (Functional Index 2), activity limitation (Myositis Activities Profile and Health Assessment Questionnaire), participation restriction (Disease impact on well-being on a Visual Analogue Scale) and health related quality of life (SF-36) as well as the MACTAR, which was performed twice.

Results: Sexual activity, walking and social activities constituted the predominating problems selected by patients with chronic PM/DM as important to improve. The majority of activities captured by the MACTAR as important to improve were represented in the International Classification of Functioning Disability and Health (ICF) component Activity/Participation. Moderate to high correlations were revealed between the MACTAR and three domains of health related quality of life (r_s=-0.67- -0.73), a moderate correlation with measurements of activity limitation and participation restriction (r_s= 0. 51-0.60) and lower correlations for disease activity and disease damage. A good to excellent reliability of the MACTAR total score was revealed with weighted Kappa (K_w = 0.68) and intra-class correlation (ICC = 0.83) without signs of systematic variations, $p>0.05$.

Conclusion: The MACTAR identified aspects of disease impact of high importance to the patients not covered by IMACS recommended and myositis specific outcomes. The MACTAR seems to have promising measurement properties assessing patient perspective of activity limitation/ participation restriction and health related quality of life in patients with PM and DM in a Swedish context. The MACTAR might therefore be considered as a patient perspective outcome in clinical trials and other research settings.

Perceived Home Demands of Women with Fibromyalgia: Five-Year Study. Susan T. Reisine V[1], Deborah Dauser[2], Judith A. Fifield[3] and Stephen Walsh[4], [1]Univ of CT Health Center, Farmington, CT, [2]University of Connecticut, Farmington, CT, [3]Univ of Connecticut Health Ctr, Farmington, CT, [4]University of Connecticut, Storrs, CT

Purpose: To assess changes in perceptions about the psychological demands of family work among women with fibromyalgia (FM) and assess the effects of demographic factors, employment, neuroticism, social support, hours of family work, fatigue and pain on perceived demands.

Methods: 287 female FMS patients were recruited from a national sample of rheumatologists. Participants were interviewed by phone at baseline and annually for four years. Data were collected on demographic characteristics, disease duration, pain and fatigue on 100 point visual analogue scales, neuroticism, social support, total number of hours in family work per week and perceived psychological demands of family work (range=7-35). 228 participants remained at the end of the study for a 79% retention rate. A slope for each person with at least two observations (N = 241) for the perceived home demands measure was estimated and then the overall slope was calculated. An unconditional means model was fit using multilevel modeling with SAS PROC MIXED to determine if a multilevel model would provide substantial benefit over a standard fixed effects model. Variables were entered sequentially into the model; non-significant terms were removed from the final model.

Results: At baseline, the mean age of participants was 47.3 (sd=11), had 14.3 (sd=2) yrs education, 90% were White, 50% employed, 63% were married with median household incomes of $40-49,999; mean score on pain was 57 (sd=24); on social support was 59 (sd=8) , on neuroticism was 57.8 (sd=13); on hours of nurturant work per week was 26 (sd=23), and on hours of instrumental work per week was 26 (sd=16), on fatigue score was 75 (sd=22); and on perceived demands was 28.5 (sd=7). The rate of change at study year one was -2.4. The rate of change in the growth slope was 1.4 and there was a deceleration of -.26. By year 5, home demands among women with FM were significantly lower by about 8 points. There was no difference in home demands between those who were employed versus those who were not employed after adjusting for age, race, neuroticism, social support and fatigue. There was a significant within-person association between fatigue and home demands such that those with higher fatigue also had higher perceived home demands and those with lower fatigue levels also had lower perceived home demands. Pain was not significantly associated with perceived demands.

Conclusion: Women with FM perceive high psychological demands from family work; employment does not affect perceived demands; fatigue and perceived demands move together through time, although it is unclear whether fatigue shapes perceptions or demands affect level of fatigue; the significant reduction in perceived demands may reflect a process of adaptation to family demands over time.

A New Plantar Tender Point in Fibromyalgia: A Worthy Candidate for the ACR Classification Criteria? A. Spindler[1], W. Spindler[1], V. Bellomio[1], A. Berman[1], E. Lucero[1], H. Berman[1], R. Sueldo[1], L. Gonzalez[1], M.V Gandur[1], M. Guardia[1], A.L Barbaglia[1], M. Santana[2], C. Waimann[3], K. Kyrmair[3], R. Chaparro del Moral[4], O. Rillo[5] and J. Moreno[6], [1]Hospital Padilla, Tucuman, Argentina, [2]Facultad de Medicina, Tucuman, Argentina, [3]IREP, Buenos Aires, Argentina, [4]Hospital Tornu, Buenos Aires, Argentina, [5]Hospital Tornu, [6]CER, San Juan

Purpose: Fibromyalgia (FM) is a complex, chronic condition which causes widespread pain accompanied by tenderness at 11 or more of 18 predetermined tender point sites, ACR Classification Criteria (1990 FMACRCC). Because 10 of these sites are in the neck and shoulder areas, which are major target areas for rheumatic and musculoskeletal conditions, diagnostic dilemmas often arise. Because of this reason reproducible tender points placed elsewhere would be advantageous in diagnosis of FM. The objective of this study was to assess sensitivity and specificity of a tender point placed infero-medially in the distal third of the longitudinal plantar arch in FM patients and controls

Method: A multicenter study was carried out in consecutive patients with FM (1990 FMACRCC) and concurrent healthy controls matched by sex and age (± 3 years). The proposed site, the accepted ACR sites (pairs) and control sites (pairs) biceps, quadriceps, and external aspect of the foot were evaluated by digital pressure averaging 4 kg/cm^2 exerted by a previous trained rheumatologist. Sensitivity and specificity of the new, the ACR accepted and the control tender points were compared by unpaired t-test and the McNemar test.

Results: There was a total of 55 FM female patients with an average age of 47 ± 9.8 years. Healthy controls comprised 48 females with a similar age distribution (44 ± 11 years). The new plantar site was tender in 48/55 FM patients (87%) vs. 2/48 controls (4%) giving a sensitivity of 87%, specificity of 96%, positive LR of 20.9 (CI 95%=6.2-76.1) and negative LR of 0.13 (CI 95%=0.06-0.25). Some of the ACR tender sites had lower sensitivity and specificity than the new plantar site i.e, occiput was tender in 15% of controls (sensitivity 71%, specificity 85%), trapezius was positive in 33% of controls (sensitivity 87%, specificity 67%) and low cervical was positive in 35% of controls (sensitivity 78%, specificity 65%).Control sites were negative in 34/48 (71%) FM patients with the plantar site positive. The plantar site had good concordance in FM patients with tender sites such as the lateral epicondyle (73%) and the occiput (65%)

Conclusion: Our findings indicate that a tender site located infero-medially in the distal third of the longitudinal plantar arch has a high sensitivity and specificity in patients with FM as defined by the FMACRCC. Furthermore, it had a greater specificity than cephalad sites such as occiput, trapezium and low cervical sites. Further investigations on this novel site appear warranted.

Impact of Chronic Gout On Foot Function: Case-Control Study. Keith Rome[1], David Survepalli[1], Alex Sanders[1], Maria Lobo[2], Fiona M. McQueen[3], Peter McNair[1] and Nicola Dalbeth[4], [1]AUT University, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand, [3]University of Auckland, Auckland, [4]University of Auckland, Auckland, New Zealand

Purpose: Despite the predilection of gout to the foot, the impact of this disease on foot function is currently unknown. The aim of this case-control study was to analyse the impact of chronic gout on foot function and measures of foot disability.

Method: Cases with gout (n=25) were recruited from rheumatology outpatient clinics. All cases had a history of acute gout according to ACR diagnostic criteria (median disease duration 21 years, flare frequency 2.92/year, 44% with tophi). Cases were excluded if they were experiencing an acute gout flare at the time of assessment, had lower limb amputation or diabetes mellitus. Age, sex and BMI-matched control participants (n=25) without arthritis, lower limb amputation or diabetes mellitus were also analysed. Plantar pressures were recorded using an in-shoe system to determine peak pressure and pressure-time integrals under ten regions of the foot. An instrumented walkway was used to capture spatial and temporal gait parameters. Disease impact was measured using the Leeds Foot Impact Scale. To preserve data independence, data from the right foot of each participant were analysed.

Results: Significant differences in all foot measures were observed between cases and controls (Table). In particular, significant differences were present in the pressure-time integrals across all foot regions except under the hallux and lesser toes, with higher pressures over time in the gout group. Gait parameters that included walking speed, cadence and double-support were also impaired in cases with gout. Patient reported scores of disease impact were significantly higher in the cases.

Conclusion: Chronic gout is associated with important changes in load-bearing function across the entire foot, which may contribute to the development of pain and disability in this disease.

Table: Foot function measures (median, IQR)

Variable	Control Group	Gout Group	P
Peak Pressures (kPa)			
Medial Heel	276 (230-362)	259 (190-316)	0.59
Lateral Heel	261 (205-317)	253 (180-292)	0.07

Illness Perception in Patients with Gout. Nicola Dalbeth[1], William J. Taylor[2], Jimmy Chong[1], WingChi Leung[1], Rini Chegudi[1], Anne Horne[1], Fiona M. McQueen[1] and Keith Petrie[1], [1]University of Auckland, Auckland, New Zealand, [2]University of Otago Wellington, Wellington, New Zealand

Purpose: Illness perception is a key determinant of behaviour directed at managing disease. Although low adherence to both dietary advice and pharmacological therapy has been reported in patients with gout, patients' perception of the disease has not been systematically studied. The aim of this study was to examine illness perception in patients with gout.

Methods: 105 patients with gout for less than 10 years were recruited from primary and secondary care settings. Participants completed a gout-specific Brief Illness Perception Questionnaire (B-IPQ), pain visual analogue scale, work instability scale, and medication adherence questionnaire. Serum urate and flare frequency were also recorded.

Results: There was a large variation in patients' perception of the illness and perceived ability to control their symptoms (Table). Generally, patients viewed gout as a chronic condition that was responsive to treatment but not strongly influenced by personal actions. Most patients believed gout was caused by diet or alcohol use and the majority believed they had a good understanding of their illness. Overall gout was seen as having a moderate impact on their life. Patients who reported greater flare frequency and pain had higher B-IPQ consequence, identity, emotional impact scores and lower personal control scores (all $p<0.05$). No relationship was observed between medication adherence and B-IPQ scores. A more negative overall B-IPQ score correlated strongly with work instability ($r=0.598$, $p<0.0001$). Of the clinical features assessed, pain and serum urate were independently associated with negative illness perceptions, accounting for 28% of total variance in multiple linear regression analysis.

Conclusion: Negative illness perception is associated with poorly controlled disease and work disability in patients with gout. Longitudinal studies are now needed to determine the influence of illness perception on outcomes in this disease.

Table: Summary of illness perception measures based on components of the B-IPQ.

Brief Illness Perception Questionnaire	**Mean (SD)**
Consequences (10=severely affects life)	5.30 (3.48)
Timeline (10=will continue forever)	7.19 (3.40)
Personal control (10=extreme amount)	5.40 (3.19)
Treatment control (10=extremely helpful)	7.50 (3.03)
Identity (10= many severe symptoms)	5.85 (3.12)
Concern (10=extremely concerned)	7.14 (3.04)
Understanding (10=very clearly)	7.22 (2.70)
Emotional impact (10=extremely affected)	5.28 (3.58)
Average B-IPQ – questions 3, 4, 7 reversed (α=0.801)	5.15 (2.06)
Most important factor believed to cause gout	**n (%)**
Diet	36 (34)
Alcohol	15 (14)
Medications/therapy	9 (9)
Injury/trauma	6 (6)
Bodily illness	5 (5)
Genetics	5 (5)
Stress/lifestyle	4 (4)
Weight	2 (2)
No response/no idea	19 (18)

Reduced Quality of Life Is Associated with Impaired Functional Capacity and Higher Levels of Fatigue in Patients with Systemic Lupus Erythematosus. Annette M. Oeser, Young-Hee Rho and C. Michael Stein, Vanderbilt University, Nashville, TN

Purpose: Spitzer's Quality of Life Index (QL Index; Spitzer WO et al, J Chronic Dis 1981, 34(12):585-597) is a simple Apgar-like scale that measures the general well- being of patients and is easy to administer. It has been used in patients with cancer, congestive heart failure, and the frail elderly. However, there is no information about its performance in patients with systemic lupus erythematosus (SLE). Thus, we examined the hypothesis that QL Index is significantly associated with disease severity, fatigue, and functional capacity in patients with SLE.

Methods: We studied 162 subjects with SLE and 88 control subjects. Controls were frequency-matched based on age, sex, and race. Demographic and clinical data were obtained from patient interview, medical record review, physical examination, and patient questionnaires, including Spitzer's QL Index, Modified Health Assessment Questionnaire (MHAQ), Fatigue Severity Scale (FSS), and Rheumatology Attitudes Index (RAI), and visual analog scales (VAS) measuring pain, fatigue and disease activity. The QL Index is scored with a high number representing a better quality of life, while MHAQ, FSS, RAI, and the VAS scales are scored in the opposite direction. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured. Disease activity and damage were ascertained by SLEDAI and SLICC, respectively. Differences between patients and controls were determined by Wilcoxon rank sum test for continuous variables. Spearman's rank correlations were used to examine the association between QL Index and the MHAQ, FSS, RAI, pain VAS, fatigue VAS, disease activity VAS, CRP, ESR, SLEDAI and SLICC. Data are presented as median [interquartile range].

Results: QL was significantly lower in patients with SLE (8 [7-10]) than control subjects (10 [10-10]), $p < 0.001$). In SLE the QL Index was inversely correlated with MHAQ (rho= -0.69, $p < 0.001$), RAI (rho=-0.66, $p < 0.001$), fatigue severity scale (rho=-0.72, $p < 0.001$), pain VAS (rho=-0.61, $p < 0.001$), fatigue VAS (rho=-0.55, $p < 0.001$), and disease activity VAS (rho=-0.51, $p < 0.001$). The QL Index was also negatively correlated with CRP (rho=-0.24, $p = 0.002$), SLEDAI (rho=-0.29, $p < 0.001$) and SLICC (rho=-0.25, $p = 0.001$), but not ESR (rho =-0.06, $p=0.47$).

Conclusion: Quality of Life, as measured by the QL Index, is reduced in patients with SLE as compared to controls. This reduction is significantly associated with increased levels of fatigue, impaired functional capacity and markers of disease activity. Spitzer's Quality of Life Index is a simple test that captures components of many symptoms that contribute to decreased quality of life in SLE.

The Interferon Signature Is Not Associated with Depression or Fatigue in Systemic Lupus Erythematosus. Erinn Kellner[1], Pui Lee[1], Yi Li[1], Mark S. Segal[2], Eric S. Sobel[1], Minoru Satoh[1] and Westley H. Reeves[1], [1]University of Florida, Gainesville, FL, [2]Dept. of Medicine, Univ. of Florida, Gainesville, FL

Purpose: Patients with SLE often suffer from depression and fatigue in addition to the physical manifestations of the autoimmune disease. Elevated production of type-I interferons (IFN-I) has been found in lupus patients and recombinant IFN-I therapy is known to trigger a variety of neuropsychiatric side effects including depression and fatigue. This study was conducted to evaluate the relationship between dysregulated IFN-I production and the manifestations of depression or fatigue in lupus patients.

Method: Depression and fatigue in patients with SLE (n = 58) were assessed by Beck's Depression Inventory and the Multidimensional Fatigue Index (MFI), respectively. Anxiety, pain and energy levels were evaluated by visual analog scales. Serum IFN-I levels were assessed using the expression of interferon-stimulated genes (ISGs) in peripheral blood mononuclear cells (quantitative PCR).

Results: Depression and fatigue were reported by more than half of SLE patients in our study but these neuropsychiatric findings were largely unexplained by disease-related factors such as clinical manifestations, complement levels, medication usage, or autoantibody profile. In line with previous findings, elevated ISG expression was present in about two-thirds of SLE patients. However, through both cross-sectional and longitudinal studies analysis we found no significant correlation between ISG expression and the levels of depression or fatigue.

Conclusion: Although recombinant IFN-I (IFN-alpha) therapy is associated with a wide-range of neuropsychiatric side effects including depressive illness, elevation of endogenous IFN-I levels is unlikely to be responsible for the depression and fatigue experienced by lupus patients.

1123

Impact of Physical Activity Program in Systemic Lupus Erythematosus. Marcelo I. Abrahão[1], Rafael Montenegro-Rodrigues[2], Roberta G. Marangoni[3], Stella Peccin[1] and Virginia F.M. Trevisani[1], [1]Federal University of Sao Paulo, Sao Paulo, Brazil, [2]Rodrigues Montenegro, São Paulo, Brazil, [3]Marangoni, São Paulo, Brazil

Purpose: To verify the impact of physical activity in quality of life, and physiological capabilities in patients with Systemic Lupus Erythematosus (SLE).

Method: Sixty-three SLE patients, according to 1997 ACR criteria, not practitioners of physical activity were selected. Their mean age were 42.2± 15.2 years, mean BMI 28.3± 11.1 and mean disease duration of 3.83.8 ± 3.2 years. The patients were randomized and allocated into three groups; cardiovascular training (CT), endurance training (ET) and the control group (CG) to be executed three times a week during 50 minutes for twelve weeks . The group held training CT performed exercise with intensity of 65% to 75% of heart rate reserve. The group held training ET performed 8 exercises of 15 repetitions in a total of 3 series with intensity of 65% to 75% of maximum load. The CG group received orientations about SLE disease .To evaluate the effect of the program for physical activity, muscle strength and aerobic capacity were assessed by a blinded evaluator, using a dynamometer analog (IMF) and 12-minute walk test (T12), respectively, on the first visit and after twelve weeks of the program. The SF36 (Physical Aspect) questionnaire and visual analogue scale for pain, were also assessed on the first visit and twelve weeks afterward. Data analysis: This was ANOVA (analysis of variance) for numerical variables between groups. Chi - square for categorical variables between groups. Test - paired t for each group between the times.

Result: The results are described in the table below

	PA		Pain		IMF		T 12	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post
CG	24.7 ±27.2	29.7±17	6.5±1,5	5.6±2	20.3±7.5	19.7±7.4	936±169	904±187
CT	33.3±34*	49.8±34*	5±2,1	4.6±2	23.9±9.7*	34.5±13.2*	1019±224*	1406±256*
ET	17.3±16*	27.7±15*	6.2±1,4	4.1±1.6*	25.7±10.6*	45.3±15.4*	911±171*	1148±172*

*p<0,05

PA: Physical Aspect

Conclusion: Endurence training showed to be more effective than cardiovascular training in patients with SLE. Physical activity program may be useful for improving quality of life and physiological capabilities future studies will be needed to determine the universal efficacy of this method.

1124

Low Lean Mass: a Major Factor for Low Bone Mass in Pre-Menopausal Women with Systemic Lupus Erythematosus. Luciana P. Costa, Eloisa Bonfa, Valeria F. Caparbo, Eduardo F. Borba, Luciana F. Muniz, Juliane A. Paupitz and Rosa M.R. Pereira, Faculdade de Medicina da USP, São Paulo, Brazil

Purpose: To analyze the frequency of low bone mineral density and risk factors for bone loss in pre-menopausal women with SLE

Method: Ninety-three SLE patients, pre-menopausal women,≤11 years disease duration were evaluated and had the bone mineral density (lumbar spine and femur) analyzed by dual-energy X-ray absorptiometry (DXA). Low bone mass for chronological age was defined if Z-score was ≤ -2 SD. Body composition was also analyzed by DXA. Vertebral fractures were analyzed at entry by VFA (vertebral fracture assessment) using DXA software. Demographic, clinical and laboratorial data related to SLE and risk factors for OP/fractures (personal or familial history of fracture, age, smoking, glucocorticoid dose, physical activity and calcium intake) were obtained from an ongoing electronic database protocol and interview. Laboratory evaluation included calcium, phosphorus, alkaline phosphatase, parathormone and vitamin D. Statistical analysis was performed using Fisher's, *t* Student's tests and logistic regression analysis.

Results: Twenty nine (31.2%) patients presented low bone mass for chronological age (Z-score ≤ -2 SD) in any site evaluated (lumbar spine, femoral neck and total femur). The comparison of SLE patients with Z-score ≤ -2SD (Group 1) with patients with Z-score > -2SD (Group 2) revealed no difference regarding OP/fractures risk, such as age (29.17 ± 5.68 vs. 30.64 ± 8.59 years, p= 0.40), BMI (25.02 ± 5.36 vs. 26.33 ± 5.11 kg/m^2, p= 0.26), percentage of Caucasian (68.9 vs. 67.2%, p= 1.0), current smoking (6% vs. 10%, p=1.0), high physical activity (12.5 vs. 35%, p=0.11), daily calcium intake (518.13 ± 1.3 vs. 572.70 ± 370.89mg, p=0.75) or personal (18.8 vs. 10.8%, p=1.0) or familial history of fractures (6.3 vs. 10.8%, p=0.42). The analysis of disease and treatment factors revealed comparable findings for organ involvements (p>0.05), number of ACR criteria (5.58 ± 1.30 vs. 5.34 ± 1.18, p=0.38), disease duration (3.89 ± 3.04 vs. 3.89 ± 3.18 years, p= 0.99), last SLICC (0.38 ± 0.62 vs. 0.25 ± 0.50, p= 0.29), mean follow-up SLEDAI score (5.54 ± 2.91 vs. 4.97 ± 3.45, p=0.45), maximal glucocorticoid dose (50.35 ± 16.44 vs. 44.39 ± 21.93mg, p= 0.20), cumulative glucocorticoid dose (23.7 ± 9.59 vs. 17.6 ± 15.3g, p=0.28), number of methylprednisolone pulse therapy (1.96 ± 2.59 vs. 2.01 ± 2.85, p= 0.94) or immunossupressor use (93% vs. 84%, p=0.20). Biochemical bone parameters were also alike in both groups: serum calcium, phosphorus, alkaline phosphatase, parathormone and vitamin D (p>0.05). The frequency of vertebral fractures by VFA was low and comparable in Group 1 and 2 (0 vs. 1,6%, p=1.0). Body composition evaluation demonstrated that lean mass was significantly lower in the group with low bone density (37.8 ± 4.9 vs. 41.6 ± 6.2g, OR 1.14, CI 1.04 – 1.26, p 0.007) whereas fat mass (21.5 ± 8.2 vs. 24.3 ± 9.7, p=0.18) and % of fat (34.3 ± 6.5 vs. 34.6 ± 7.1, p=0.84) were similar in both groups.

Conclusion: Low lean mass is a major risk factor for low bone mineral density in pre-menopausal women with SLE reinforcing the relevance of a nutritional and exercise program for these patients.

Measurement and Characteristics of Fatigue in Patients with Inflammatory Arthritis Prior to Anti-TNF Therapy. Patricia Minnock[1], Gabrielle McKee[2], Oliver M. FitzGerald[3], Anne Barbara Mongey[3], Douglas J. Veale[3] and Barry Bresnihan[3], [1]Our Lady's Hospice, Dublin 6, Ireland, [2]Trinity College Dublin, Dublin, Ireland, [3]St Vincent's University Hospital, Dublin, Ireland

Purpose: The unique contribution of fatigue to the assessment of patients with inflammatory arthritis has been demonstrated. The purpose of this study was 1) to compare the performance of two fatigue scales, and 2) to evaluate the relationship between fatigue and the core outcome measures in patients with inflammatory arthritis prescribed anti-TNF therapy.

Methods: Patients with rheumatoid arthritis (RA) and patients with psoriatic arthritis (PsA) prescribed anti-TNF therapy underwent standard clinical assessment of disease activity at baseline. Fatigue was measured using 2 validated scales: 1) the multidimensional assessment of fatigue scales (MAF) and 2) a one dimensional 5-point ordinal scale (OS). The clinical characteristics and the relationship between fatigue and 6 core outcome measures were evaluated across the two diseases.

Results: A total 188 patients were enrolled (RA, 135; PsA, 53). At baseline, the mean ages (SD) were 54.3 (12.8) years in RA, and 45.8 (12.5) in PsA. The mean (SD) MAF levels were 28.3 (11.2) and 26.6 (12.2) in RA and PsA, respectively. The 5-point OS measures of fatigue were as follows: none (RA, 6.3%; PsA, 10.0%), mild (RA, 16.2%; PsA, 17.5%), moderate (RA, 40.5%; PsA, 35.0%), severe (RA, 27.0%; PsA, 30.0 %), very severe (RA, 9.9%; PsA, 7.5%). The table summarises baseline clinical characteristics:

	RA		**PsA**	
	Mean	SD	Mean	SD
SJC28	7	5	5	6
TJC28	9	8	7	6
Pain	5	2	6	2
Patient Global Health	6	2	6	3
CRP	25	43	15	20

HAQ	1.0	0.679	0.653	.573
DAS28-CRP	5.01	1.20	4.49	1.14
Haemoglobin	12.9	1.7	13.4	1.6

Significant correlations ($p<0.01$) between both fatigue scales and the core outcome measures TJC (OS, r= 262; MAF, r= 307), Pain (OS, r= 477; MAF, r= 469), GH (OS, r= 546; MAF, r= 520), HAQ (OS, r= 436; MAF, r= 399), were observed across both disease groups. On multiple regression analysis (backward deletion technique) fatigue in RA was poorly explained by the core set variables (R^2= .324); while in the PsA model (R^2= .543) both HAQ (Beta .505; p=.000) and GH (Beta .364; p=.005) made significant contributions to assessment of fatigue.

Conclusion: This study demonstrated that the single item 5-point ordinal scale performed as well as the MAF with respect to correlations between fatigue and the core outcome measures of disease activity. Furthermore, these findings further confirm the independence of fatigue as an outcome measure in RA, and the association between fatigue and both function and global health in PsA.

Creation of a Short Version of the Valued Life Activities Questionnaire (S-VLA). Patricia Katz[1], Diane D. Allen[1], Afton L. Hassett[2], Tracy Li[3] and R. Maclean[3], [1]UCSF, SF, CA, [2]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Bristol-Myers Squibb, Princeton, NJ

Purpose: Disability in valued life activities (VLAs), defined as the wide range of activities that individuals may perform on a daily basis, has been strongly linked to psychological well-being, satisfaction with function, and quality of life among individuals with rheumatoid arthritis (RA). Need for accommodations (ACCs) in VLAs predicts progression of disability in RA. The current VLA disability questionnaire queries difficulty in 33 activities, with 4 follow-up questions for each activity regarding ACCs. Difficulty is rated on a 5-point scale from no difficulty (0) to unable to perform the activity (4). A scoring method incorporating use of ACCs has been developed. Our objective was to create a short version of the questionnaire, incorporating use of ACCs.

Methods: Data from 2 years' administration of the long form VLA questionnaire (L-VLA) in a longitudinal cohort of individuals with RA were used (n=449, 421). Analyses were first conducted with Year 1 data and then validated with Year 2 data. Item response analyses using ConQuest were performed. Items were deleted based on misfit (weighted mean square statistic <0.75 or >1.34 AND t-statistics <-2 or >+2), logit values that duplicated information provided by other items providing information at similar logit values, and substantive considerations. Psychometric properties of the short version (S-VLA) were compared to those of the L-VLA.

Results: Partial credit and rating scale models were both tested; the partial credit model had fewer item and step misfits (G^2 likelihood ratio = 623.881, $p<.0001$). The scoring range was expanded to 0-5 to account for use of ACCs (0=no difficulty, no ACCs; 1=no difficulty, with ACCs; other difficulty ratings increased by 1 to account for additional category). Deletions were progressive, resulting in a 21-item version, a 14-item version, and 4 12-item versions. A 14-activity version of the VLA questionnaire, with 1 follow-up question for each regarding ACCs, was selected. The S-VLA had 0 misfitting steps; 2 items had potential misfit but were retained for both substantive reasons and to provide logit spread. Correlation between L-VLA and S-VLA scores was .97; correlations of the L-VLA and S-VLA with other measures of functioning and RA impact were similar (Table). Analyses were confirmed in Year 2 data.

	EAP reliability	Cronbach's a	HAQ	Overall rating of RA impact 0-100	RA affects things you NEED to do	RA affects things you LIKE to do
L-VLA	.949	.97	.79	-.54	.74	.65
S-VLA	.932	.94	.83	-.56	.74	.66

Conclusion: A short form of the VLA disability questionnaire has been developed. The S-VLA appears to be reliable and valid, and can provide a brief assessment of disability in a broad range of life activities. Since it includes the broad range of activities, it may be more sensitive to change than other measures of functioning such as the HAQ and may appear more relevant to individuals with RA.

1127

The Accuracy of Self-Administered Rheumatoid Arthritis Activity Compared with Clinician Exam. Marlena Hyer Kern and Peter K. Gregersen, Feinstein Institute for Medical Research, Manhasset, NY

Purpose: The joint exam in Rheumatoid Arthritis (RA) is highly variable between patients and practitioners. This evaluation compares two aspects (presence and severity) of the self report of joint pain to the clinician exam for joint swelling and tenderness.

Method: Questionnaire Data was collected prospectively on patients diagnosed with RA during one-time research visit for the NARAC genetic study of RA. Study subjects (n= 1644) were seen individually by study personnel who performed a 28 count joint assessment of pain and swelling. At the same visit participants also completed the Rheumatoid Arthritis Disease Activity Index (RADAI) – a self administered questionnaire combining information on the presence of pain as well as pain severity in ten joint areas.

The examiners were trained by one board certified rheumatologist with return demonstration and analysis of assessments

Results: Both dichotomous and continuous measures of pain by self report show good correlation with clinician based assessment of joint tenderness and swelling. Continuous pain measures were marginally superior. The Spearman correlation coefficients were computed to determine the degree of correlation between the clinician joint count and both the patient's pain (yes/no – $r=0.484$ $p<0.0001$ $N=1644$) and intensity of pain (0=none, 1=mild, 2=moderate, 3=severe; $r=0.523$ $p<0.0001$ $N=1644$) in ten joint areas.

Conclusion: There was good correlation between the patient self report and the clinician assessment of rheumatoid arthritis disease activity. The data suggest that self report may be a cost effective substitute for clinician based joint assessment when conducting studies of rheumatoid arthritis. Further development of this analysis may permit large scale studies of disease activity in RA, including assessments of response to novel therapies, without the expense of clinician based evaluation Conclusion

A Computer Time Trade-off: A Good Alternative for the Interview Time Trade-off in Rheumatoid Arthritis. Laurien Buitinga[1], Louise Braakman-Jansen[1], Erik Taal[1] and M.A.F.J. van de Laar[2], [1]University of Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente & Universtiy Twente, Enschede

Purpose: The purpose was to evaluate the test-retest reliability of a computer Time Trade-Off (TTO) (an instrument that measures preferences for health states) in patients with Rheumatoid Arthritis (RA), and to compare the computer with the interview TTO regarding feasibility, agreement, and convergent validity.

Method: A cross-over design was used to compare the computer with the interview TTO. Fifty-nine RA patients participated. Thirty patients completed both TTO measures. Twenty-nine other patients completed the computer TTO twice to examine test-retest reliability. Feasibility was measured by comparing actual and experienced time duration of the TTOs and assessing general experience of the patient. Convergent validity was measured by calculating Spearman's correlation between both TTOs. Agreement between both TTOs was measured by using the Bland-Altman analysis.

Results: Both TTOs were feasible. The computer TTO showed high test-retest reliability (ICC=0.88, 95% CI: 0.75 to 0.94), and high convergent validity ($r=0.73$) with the interview TTO. Bland-Altman analysis showed a small mean difference (0.06, SD=0.14) between the computer and interview TTO. Limits of agreement were wide (-0.22 to 0.34).

Conclusion: Feasibility and reliability of the computer TTO were good. Convergent validity of the computer TTO was high when the interview was used as validation standard. Agreement between the interview and computer TTO was good at group level, indicated by the small mean difference in utilities between both methods. The computer TTO is a good alternative for measuring utilities in RA.

Disclosure: L. Buitinga, None; **L. Braakman-Jansen**, None; **E. Taal**, None; **M. A. F. J. van de Laar**, None.

Analysis of Correlated Ordinal Data in a Self-Matched Study with Applications to Knee Pain Severity. Yanyan Zhu[1], Howard Cabral[2], Charles E. McCulloch[3], David T. Felson[4], Michael C. Nevitt[3] and Yuqing Zhang[1], [1]BUSM, Boston, MA, [2]BUSPH, Boston, MA, [3]UCSF, SF, CA, [4]Boston University School of Medicine, Boston, MA

Purpose: In longitudinal studies, pain severity is often measured on an ordinal scale. To minimize confounding from person-level factors we have proposed a self-matched study in which comparisons are made within a knee over time and one knee per person is studied. To date, no statistical method is available to analyze such ordinal data when persons provide data for two knees. We adapted amalgamating conditional logistic regression (ACLR) for self-matched studies and tested 4 modifications to account for the correlation between knees.

Method: We used 4 methods to account for between-knee correlation while applying ACLR: 1. Clustered: treat a person (cluster) as a stratum; 2. Pooled: obtain point estimates assuming independence but calculate proper robust variance estimates; 3. WEE: apply weighted estimating equations (WEE), the weighted version of the estimating equations used in the pooled method. Each knee was weighted by the inverse of the number of knees a person provided; 4. WCR: perform within-cluster resampling (WCR). Each time a knee was randomly selected from each person with replacement. We evaluated the performance of these methods by simulation and applied them to assess effusion in relation to knee pain severity in the Multicenter Osteoarthritis Study (MOST). Both simulated data and real data included 1349 persons. 188 persons had data for both knees, while the remainder contributed a single knee. Of the knees, 119 had observations from 3 time points and the rest had 2. A random-intercept proportional odds model was used in simulation. The simulated data (500 replicates) had a 4-level ordinal outcome variable and two covariates, one continuous from a N(0,1) distribution and the other binary (p=0.2). The regression coefficients were set at b_1=0.5 and b_2=1.0.

Results: The effect estimates from all methods were close to true value with bias less than 1% except for the clustered method, and the average model-based standard errors (SE) were close to the true SE (SD) (Table 1A). When these methods were used on the MOST data, all results suggested that increased severity of effusion was associated with higher severity of knee pain, but the magnitude from clustered method differed from others (Table 1B).

Conclusion: Pooled data, WEE and WCR methods generated very consistent results when the proportion of persons with data for two knees was small (18%). Further studies are required to assess the performance of these approaches when proportion of persons with data for two knees is relatively large.

The Chest Also Has a Spine. Bruce Rothschild[1] and Youssef Masharawi[2], [1]Arthritis Ctr, Baldwin, KS, [2]The Stanley Steyer School of Health Professions, Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel

Purpose: Bone alterations visible on chest x-rays are often overlooked or simply not reported. Radiation exposure concerns and artifacts have compromised use and interpretation of thoracic vertebral x-rays. Standards for recognition of compression fractures have been suggested, but are somewhat arbitrary. This study reports a new diagnostic technique for distinguishing osteoporotic fractures on routine lateral chest x-rays.

Method: The anterior, middle and posterior thoracic vertebral heights were measured on lateral chest x-ray in 3 groups: A control group of 120 individuals with unaffected vertebrae, 44 individuals with osteoporotic fractures and in 28 individuals with Scheuermann's disease. First and second derivatives were obtained of the relationships among the anterior height/posterior height (A/P), anterior height/mid height (A/M) and mid height/posterior height (M/P).

Results: The A/P indices (T6-T10) in all three groups were statistically indistinguishable. The M/P indices (T6-T10) were significantly smaller than the A/M indices in the osteoporosis group. The ratio of A/M to M/P first derivatives at thoracic vertebrae T6-T10 were significantly greater in the osteoporosis group than in the control and Scheuermann's groups ($p<0.05$). The intersection, on the superior aspect of the vertebral body, of the anterior-midpoint line and the posterior-midpoint line created an 'angle of depression' in the osteoporosis group, contrasted with an 'angle of elevation' in the Scheuermann's group.

Conclusion: Direct visualization of the intersection (described mathematically as the second derivative) of the A-M and M-P lines permits recognition of osteoporosis in the standing (weight-loaded) chest x-ray, in contrast to standard unloaded thoracic spine technique. Although most trabecular loss occurs subjacent to endplates, spine density testing focuses on more central vertebral regions. The technique reported herein identifies at least an often overlooked subset of individuals requiring bone-protective intervention.

No Link Between C-Reactive Protein (CRP) and Bone Mineral Density (BMD) in Men, but Menopause Status Modifies the Relation in Women: The Framingham Osteoporosis Study. R.R. McLean[1], X. Zhang[1], E.J. Benjamin[2], L.A. Cupples[3], D.P. Kiel[1] and M.T. Hannan[1], [1]Hebrew SeniorLife & Harv Med Sch, Boston, MA, [2]Framingham Heart Study & Boston Univ, Boston, MA, [3]Biostat Dept, Boston Univ Sch of Pub Hlth, Boston, MA

Purpose: Laboratory studies suggest several pro-inflammatory cytokines influence bone resorption, which may partly mediate bone loss due to estrogen deficiency. Epidemiologic studies have not elucidated the interrelations of inflammatory biomarkers, menopause status and BMD in women, and few have examined men. We determined the cross-sectional association between elevated systemic inflammation, indicated by increased serum CRP concentration, and BMD among men and women in the Framingham Offspring Study. We hypothesized an inverse relation between CRP and BMD, which would be strongest in postmenopausal women not on estrogen.

Method: Fasting blood samples were obtained from 1,291 men and 1,614 women (1998-2001) and CRP (mg/L) was measured using a high-sensitivity assay (interassay CV=5.3%). Using clinical cut points, participants were categorized into CRP groups (<1, 1 to 3, >3 mg/L). Femoral neck BMD (g/cm^2) was measured with a Lunar DPX-L. Women were categorized as premenopausal (n=231), postmenopausal on estrogen (n=498), and postmenopausal not on estrogen (n=893). We used analysis of variance to compare crude mean BMD among CRP groups, separately for men and groups of women. Using analysis of covariance, we further adjusted for age (y), height (in), weight (lbs), physical activity (PASE) and current smoking (y/n).

Results: Mean age was 61 y (range 29-86). Due to a consistent threshold effect at 1 mg/L the upper 2 CRP groups were combined (≥1 mg/L). Crude mean BMD was similar between CRP groups for men and premenopausal women, yet was greater in the ≥1 mg/L group in postmenopausal women. After adjustment the lack of association in men remained, yet premenopausal women with CRP ≥1 mg/L tended to have 3.6% lower BMD (P=0.06). In postmenopausal women not on estrogen the ≥1 mg/L group had 2.3% higher BMD (P=0.04) but the difference was not significant for those on estrogen.

Crude and least-squares adjusted* mean (±SE) femoral neck BMD for CRP groups by sex, menopause status and estrogen use.

		CRP <1 mg/L	CRP ≥1 mg/L	P value
Men		(*n=341*)	(*n=950*)	
	Crude	0.974 (0.007)	0.972 (0.005)	0.82
	Adjusted	0.982 (0.007)	0.970 (0.004)	0.14
Premenopausal women		(*n=86*)	(*n=143*)	
	Crude	0.962 (0.014)	0.970 (0.011)	0.65
	Adjusted	0.985 (0.013)	0.952 (0.010)	0.06
Postmenopausal women on estrogen		(*n=71*)	(*n=426*)	
	Crude	0.866 (0.015)	0.899 (0.006)	0.05
	Adjusted	0.876 (0.014)	0.897 (0.006)	0.18
Postmenopausal women not on estrogen		(*n=206*)	(*n=682*)	
	Crude	0.799 (0.009)	0.838 (0.005)	<0.01
	Adjusted	0.815 (0.008)	0.834 (0.004)	0.04

*Adjusted for age, height, weight, physical activity, smoking

Conclusion: Our findings suggest increased systemic inflammation may be a risk factor for lower BMD among premenopausal women, but not for men or postmenopausal women on estrogen. Elevated inflammation was associated with higher BMD in postmenopausal women not on estrogen, contrary to our hypothesis. Future studies should examine the role of estrogen using biomarkers rather than crude estrogen status categories, and explore comorbidities that could explain our unexpected findings among postmenopausal women.

Efficacy and Safety of Concurrent Training in Systemic Sclerosis. Ana Lucia de Sa Pinto[1], Bruno Gualano[2], Romy B. C. de Souza[1], Vitor S. Painelli[2], Natalia C. Oliveira[1], Guilherme G. Artioli[2] and Fernanda R. Lima[1], [1]School of Medicine - University of Sao Paulo, Sao Paulo, Brazil, [2]School of Physical Education - University of Sao Paulo, SP, Brazil

Purpose: It has been demonstrated that exercise capacity is reduced in systemic sclerosis. Moreover, we recently showed that aerobic training is an effective and safe strategy to improve exercise tolerance, aerobic condition and oxygen saturation in these patients. However, the optimal training model for these patients remains to be determined. Therefore, we aimed to investigate the effects of 12-week concurrent training program in patients with systemic sclerosis.

Method: Nine patients without evidence of pulmonary involvement (pulmonary artery systolic pressure equal to or below 40 mmHg, forced vital capacity measured by spirometry and diffusion lung capacity of carbon monoxide (DLCO) higher than 75% of the predicted value) were engaged in a 12-week aerobic and resistance exercise program. Lower and upper limb dynamic strength (assessed by leg press and bench press one maximum repetition [1RM], respectively); isometric strength (assessed by trunk extension and handgrip test), balance and mobility (assessed by timed-up-and-go test), and muscle function (assessed by timed-stands test); Rodnan score, digital ulcers and Raynaud phenomenon; and inflammation and muscle (creatine kinase [CK] and aldolase) blood markers were assessed at baseline and after the 12-week program.

Results: Exercise training significantly enhanced 1RM leg press (41%) and 1RM bench press (12.9%) as well as trunk extension (23.6%) and handgrip strength (11.1%). Muscle function was also improved (14%, $p = 0.04$) but balance and mobility were not modified. Time-to-exhaustion was increased (46.5%, $p = 0.0004$) and the change in aerobic condition (VO2 peak and ventilatory thresholds) did not reach statistical significance ($p > 0.05$). Rodnan score was also not altered muscle enzyme remained within normal levels (CK: pre 113 ± 87.2 vs. post 122 ± 90.7 UI/l and aldolase: pre 5.23 ± 2.3 vs. post 5.47 ± 2.4 UI/l). No change was observed in digital ulcers and Raynaud phenomenon. There were no cardiac complains or muscle injury.

Conclusion: This is the first study to demonstrate that a 12-week concurrent program is safe and substantially improves muscle strength and function in patients with systemic sclerosis, but does not promote clinical benefits on aerobic condition.

Effectiveness of Sensorimotor Training in Patients with Rheumatoid Arthritis. Kelson NG Silva Sr.[1], Lucas E.P.P Teixeira[1], Aline M. Imoto[1], Marcelo I. Abrahão[1], Alvaro N. Atallah[2], Stella Peccin[1] and Virginia F.M. Trevisani[1], [1]Federal University of Sao Paulo, Sao Paulo, Brazil, [2]Sao Paulo, Brazil

Purpose: The purpose of this study was to evaluate the effectiveness of sensorimotor training at improving functional capacity and pain relieve in patients with rheumatoid arthritis.

Methods: A randomized, controlled assessor blinded trial was conducted with assessments made before and after 04 months. The sample of 102 patients was statistically randomized into two groups: intervention group (balance training + medicine clinical treatment) and control group (only medicine clinical treatment). The duration of the sensorimotor training was 16 weeks with exercise frequency twice a week and duration of each exercise session of 40-50 minutes. The outcomes used were: Health Assessment Questionnaire (HAQ), Timed Up & Go Test (TUGT) and pain visual analogue scale (VAS). For statistical analysis, the team used Mann-Whitney Test to compare both groups (continuous outcomes), paired T-test for comparison between before and after intervention. For all tests an alpha=5% was used, being considered significant $p<0,05$.

Results: The baseline assessment demonstrates the homogeneity of the two groups (age, disease duration, height, weight, gender, HAQ, TUGT and VAS). Ninety-one patients had concluded the research. As observed in Table 1, there were statistically significant difference in the results of the HAQ, TUGT and VAS that it demonstrates improvement of the functional capacity and pain. No improvements were apparent in the control group.

Conclusion: Based on the findings of our study, we conclude that sensorimotor training is effective in improvement of functional capacity and pain relief.

Table 1

Variables	Control Group		Intervention Group		p-value
	Before	After	Before	After	
HAQ	1,30 ± 0,69	1,31 ± 0,72	1,41 ± 0,60	0,70 ± 0,42*†	p < 0,05
TUGT	10,05 ± 4,96	9,45 ± 5,31	9,82 ± 2,84	6,73 ± 1,17*†	p < 0,05
VAS	7,00 ± 2,79	6,35 ± 2,91	7,15 ± 2,12	4,61 ± 2,13*†	p < 0,05

* It indicates significant statistical difference in relation to the group has controlled the same for moment.

† It indicates significant statistical difference in relation to before experiment moment.

1134

Associates of Tolerance to Neuromuscular Electrical Stimulation in Rheumatoid Arthritis. Sara R. Piva[1], Nathan Strudle[1], Gustavo J. M. Almeida[1], M. C. Wasko[2], G. Kelley Fitzgerald[1] and Anthony Delitto[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Purpose: Nearly two-thirds of patients with rheumatoid arthritis (RA) experience muscle weakness and atrophy. Neuromuscular electrical stimulation (NMES) is a viable intervention to treat muscle atrophy and weakness in RA. The therapeutic effect of NMES is dependent on the dose of electrical stimulation. Tolerance is a limiting factor of NMES effectiveness because patients must tolerate high doses of NMES to maximize gains in muscle function. Identifying factors associated with NMES tolerance may guide strategies to improve tolerance to this intervention. This study aimed to identify psychological factors associated with NMES tolerance in subjects with RA

Method: Thirty eight subjects with RA participated in this cross-sectional study, with age 60 ± 11 years, 63% female, BMI 27 ± 6. Measures of social and biomedical characteristics included age, gender, race, marital status, education, height, weight, disease duration, medication, and disability (HAQ). Psychological factors included pain coping strategies, pain acceptance, sense of control over life and environment, anxiety, depression, and the sensory and affective domains of pain. NMES procedure: Subjects sat on an isokinetic dynamometer. The maximum voluntary isometric contraction (MVIC) of the quadriceps femoris muscles strength was determined. Torque output during the MVIC was the reference to determine NMES dose (% of MVIC torque generated during electrically elicited muscle contraction). Then, 15 NMES contractions were administered to the quadriceps muscles (stimulus parameters 75Hz, 450 µsec, on/off time 14/46sec). Intensity of the NMES was increased as tolerated. NMES tolerance was defined as the highest NMES dose tolerated by each subject during the NMES procedure. NMES procedure was repeated during 2 visits to allow adaptation to the electrical stimulation. Analysis: We calculated bivariate correlations between NMES tolerance and all other variables. Variables significantly correlated were selected to build a linear regression model to predict NMES tolerance. The social and biomedical characteristics were first forced into the model. Then, psychological factors were added using a stepwise approach

Results: Bivariate correlations demonstrated that more years of education, less disability, lower anxiety, and higher scores in 2 coping strategies (coping self-statements and ignoring pain sensation) were associated with higher NMES tolerance. After controlling for education and disability, only ignoring pain sensation was a predictor. Education and disability explained 45% of variability in NMES tolerance and ignoring pain sensation explained additional 13%. Regression diagnostics revealed that the assumptions of linear regression models were not violated

Conclusion: RA subjects who ignore pain sensation tolerate higher doses of NMES. These results suggest that incorporating coping strategy techniques to help subjects ignore the sensation of pain will help to increase tolerance to the NMES

1135

Post-Acute Physiotherapy for Primary Total Hip Arthroplasty: A Cochrane Systematic Review. MD Westby[1], S. Carr[1], D. Kennedy[2], V. Brander[3], M. Bell[2], MM Doyle-Waters[4] and C. Backman[5], [1]Mary Pack Arthritis Program, Vancouver, BC, [2]Sunnybrook Health Sciences Centre, Toronto, ON, [3]Northwestern Orthopaedic Institute, Chicago, IL, [4]Centre for Clinical Epidemiology & Evaluation, Vancouver, BC, [5]University of British Columbia, Vancouver, BC

Purpose: To determine the effects of post-acute physical therapy (PT) following primary total hip arthroplasty (THA) for osteoarthritis (OA) on pain, function and health-related quality of life (HRQoL).

Method: Randomized and clinical controlled trials published 1990 - 2008 were identified using electronic and secondary searches (no language restrictions).Included studies involved adults who underwent primary THA for OA and received PT treatment in any setting, after discharge from acute care and initiated within 12 months of surgery. Studies involving revision, hemi- or resurfacing surgery, inflammatory arthritis or recent fracture were excluded. Two reviewers screened papers for inclusion, extracted data using a standardized form and assessed methodological quality using an 11-item scale (van Tulder). Clinical heterogeneity, grades, weighted mean difference (WMD) and 95% confidence intervals for primary outcomes were determined. Effect sizes for trials with small samples and differing baseline values were calculated using mean change values for within and between group differences.

Results: Of 1,538 trials identified, 98 were retained for second level screening, and 8 for full review. Main reasons for exclusion were: timing, type of intervention and lack of THA subgroup data. Trial heterogeneity prevented meta-analysis. Overall quality was low to moderate. Only 3 trials reported adequate randomization, concealed allocation and blinded outcome assessors. While participants (N = 497) were similar across studies, interventions and comparators varied substantially. A ‘silver’ grade was given to all trials. Positive mean post-test values were found for: 1) surgeon-rated function with body weight (BW) supported treadmill walking (WMD 13.60, [7.58, 19.62]) compared to routine inpatient care; 2) Timed Up and Go with unsupervised home exercises (WMD 1.8, [0.15, 3.45]) versus outpatient PT; and 3) Sit-to-Stand test after outpatient resistance training (WMD -4.50, [-7.09, -1.91]) and daily home exercises with electrical stimulation (WMD -3.00, [-5,97, -0.03]) compared to standard care. No between-group differences for pain or HRQoL were found. Positive standardized effect sizes ranged from 0.87 to 1.50 (large effects).

Conclusion: There is limited evidence to support the use of inpatient BW supported treadmill training, outpatient resistance exercises and home-based exercise with and without electrical muscle stimulation for improving surgeon-rated and performance-based function after THA. High quality trials with larger samples and standardized outcome assessment methods are needed, however, to establish specific treatment recommendations for post-acute PT after THA.

1136

Post-Acute Physiotherapy for Primary Total Knee Arthroplasty: A Cochrane Systematic Review. MD Westby[1], D. Kennedy[2], DL Jones[3], A. Jones[4], MM Doyle-Waters[5] and Catherine L. Backman[6], [1]Mary Pack Arthritis Program, Vancouver, BC, [2]Sunnybrook Health Sciences Centre, Toronto, ON, [3]West Virginia University, Morgantown, WV, [4]Federal University of Sao Paulo, São Paulo, Brazil, [5]Centre for Clinical Epidemiology & Evaluation, Vancouver, BC, [6]University of British Columbia, Vancouver, BC

Purpose: To determine the effects of post-acute physical therapy (PT) following primary total knee arthroplasty (TKA) for osteoarthritis (OA) on pain, function and health-related quality of life (HRQoL).

Method: Randomized controlled trials published between 1990 and 2009 were identified using electronic and secondary searches (no language restrictions).

Included studies involved adults who underwent primary TKA for OA and received PT interventions in any setting, after discharge from acute care, and initiated within 12 months of surgery. Studies involving revision, unicompartmental surgery, inflammatory arthritis or recent trauma were excluded. Two reviewers screened papers for inclusion, extracted data using a standardized form and assessed methodological quality using an 11-item scale (van Tulder). Clinical heterogeneity, grades, weighted mean difference (WMD) and 95% confidence intervals were determined for primary outcomes. Effect sizes for trials with small samples and differing baseline values were calculated using mean change values for within and between group differences.

Results: Of 2,534 trials identified, 47 were retained for second level screening, and 7 for full review. Main reasons for exclusion were: timing, type of intervention and lack of TKA subgroup data. Trial heterogeneity prevented meta-analysis. Overall quality ranged from low to high. Six trials reported adequate randomization, concealed allocation and blinded outcome assessors. While participants (N = 779) were similar across studies, interventions and comparators varied substantially.

A 'gold' level grade was given to 3 trials and 'silver' to 4. Positive mean post-test values were found for: 1) pain (WMD -7.60, [-14.15, -1.05]) and the SF-36 Mental Component Summary (WMD -4.00, [-6.84, -1.16]) after out-patient intensive functional rehabilitation compared to standard home therapy; and 2) 3-minute walk test (WMD 24.40, [12.82, 35.98]) after daily electric muscle stimulation versus standard PT. No between-group differences were found for self-reported function, timed stair climb or 6-minute walk test. Positive standardized effect sizes ranged from 0.52 to 1.47 (medium to large).

Conclusion: There is limited evidence to support the use of outpatient functional exercises and electrical muscle stimulation for improving pain, mental health status and walking speed after TKA. High quality trials with larger samples and standardized outcome assessment methods are needed, however, to establish specific treatment recommendations for post-acute PT after TKA.

Disclosure: M. Westby, None; **D. Kennedy**, None; **D. Jones**, None; **A. Jones**, None; **M. Doyle-Waters**, None; **C. L. Backman**, None.

Describing "Usual" Physical Therapy Practice Following Total Knee Replacement in Montgomery County, Pennsylvania. Carol A. Oatis[1], Jl Brennan[1], S. Kushman[1], A. Werner[1] and Patricia D. Franklin[2], [1]Arcadia Univ, Glenside, PA, [2]Univ of MA Med School, Worcester, MA

Purpose: Total knee replacement (TKR) is one of the most common surgeries performed in the United States at an approximate rate of 500,000 per year. Recovery from TKR requires physical therapy, yet research identifying "best" practice following this procedure is lacking. The purpose of this study was to describe "usual" therapy practices following TKR in the acute care (AC), home care or inpatient rehabilitation (HCIR), and outpatient settings (OP).

Methods: 145 physical therapists from 32 randomly selected facilities in Montgomery County, PA were provided with surveys for participation. 7 physical therapists considered "thought leaders" were also included to ensure representation of the full spectrum of care. Chief physical therapists at the selected sites were asked to provide surveys to all physical therapists in their facility who treat patients following TKR. The survey was made available online, using Survey Monkey™, or in hard copy. The survey assessed 105 exercise and therapeutic modalities that may be considered after TKR. "Usual" care was operationally defined as interventions used "always" or "often" by more than 50% of respondents. "Consensus" was defined as agreement exceeding 85%.

Results: 80 surveys were returned at a response rate of 53%. Consensus in all three settings included knee flexor/extensor stretching and strengthening, and gait training on indoor surfaces. Usual care in the three settings included ankle PF stretching. Although some form of strength and flexibility exercises for the hip, knee and ankle were utilized in all three settings, little agreement existed for frequency, intensity or mode of exercise in any setting. For example, active knee extension in standing and standing knee extension with resistance were uncommon in OP (<50%). Stabilization and abdominal exercises were rare in AC and OP (>50% rarely or never do) and variable in HCIR (42% rarely or never do and 11% often or always do). Neuromuscular electrical stimulation was very rare or variable in all settings (36-87% rarely or never do). Ice was usual care in AC but consensus in OP. Heat was usual care in OP. Patellar mobilizations were very uncommon in AC (<15%), variable in HCIR (38% often or always do, 32% rarely or never do) and usual care in OP (84%). OP gait training was usual care but < 32% reported gait training against resistance.

Conclusion: This study describes usual physical therapy intervention following TKR provided in Montgomery County, PA. While agreement exists in the general approach to treatment, wide variability in exercise intensity, frequency, and mode exists. Use of therapeutic

modalities also varies. An understanding of the existing variability in practice may help explain the disparity in patient outcomes, as well as help direct future research to determine "best practice."

Translating Physical Activity Guidelines Into Motivating Language for People with Arthritis. Teresa J.. Brady[1], K. Sammons[2], K. Grulikowski[2], M. Taylor[2] and K. Schermerhorn[2], [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Porter Novelli, Atlanta, GA

Purpose: In October 2008 the Department of Health and Human Services (HHS) released new guidelines recommending that all adults participate in at least 2.5 hours of moderate physical activity each week. The Centers for Disease Control and Prevention's Arthritis Program is revising a health communications campaign designed to promote physical activity (PA) among people with arthritis (PWA). The purpose of this qualitative study was to determine how best to describe the HHS guidelines in terms that motivate PWA to increase their PA.

Methods: 27 mall intercept interviews were conducted in Atlanta, Cleveland, and Houston in February 2009. Inclusion criteria were: self report of doctor diagnosis of arthritis, exercising less than three days/week, some limitations due to arthritis, belief that exercise can reduce arthritis pain, black or white, age 40-70, less than college education and income less than $75,000. Each respondent viewed 3 print ads, each using a different descriptor of the physical activity guideline (2.5 hours/week, 30 minutes 5 days/week, or 150 minutes/week). Order of ads was rotated for each interview. The three descriptors were then displayed together and respondents were asked to identify which would be most likely to motivate them to increase their physical activity. Respondents were also asked to comment on other elements of ads they found motivating.

Results: Sample was 52% female, 55% black, 63% income under $45,000. Despite the fact that most respondents recognized that all 3 descriptors represented the same amount of PA, the majority (78%) found 30 minutes 5 days/week to be the most motivating PA descriptor. Rationale included: time frame fit schedule, 30 minutes would be physically easier to do, smaller amount of time would pass quickly, and concrete schedule eliminated need for any calculations. For the majority, the other descriptors, described as total hours or minutes, appeared too large and unattainable; the need to track and total time was also unappealing.

No racial differences were found, but gender differences did exist. All women preferred the 30 minutes 5 days/week descriptor, 38% of men preferred the 2.5 hour descriptor. A slight majority of these men had some college or trade school. Their rationale was also related to scheduling: these men thought they did not have time to exercise 5 days/week, but could meet the recommendation in 1-2 long sessions, such as a weekend basketball game.

Other concepts in body copy identified as motivating included connecting PA to improved mood, seeing results in 4-6 weeks, describing PA as more than keeping busy, and encouraging a choice of activity.

Conclusion: To motivate PWA to increase their physical activity, the new HHS PA guidelines need to be translated into descriptions that seem attainable for PWA. The majority prefer 30 minutes 5 days/week as the descriptor, although some men prefer to think of the cumulative 2.5 hours/week. Clinician counseling and population based health messages should use terms motivating for PWA.

Engaging Media to Help Shape and Promote Arthritis Management Messages. Teresa J.. Brady[1], K. Sammons[2], L. Ramsey[1] and K. Heumann[2], [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Porter Novelli, Atlanta, GA

Purpose: Media are critical in shaping the public dialogue on health. Understanding media perspectives can help us position health messages to garner both media and public attention. The Centers for disease control and Prevention's Arthritis Program convened a Media Roundtable with leading media opinion leaders to discuss what the media see as drivers and motivators for health behavior change related to general public health issues, and specifically arthritis.

Methods: Three months of media coverage by leading national media vehicles were reviewed to identify priority reporters to invite to the roundtable discussion. The roundtable format included 30 minutes of presentation on the urgent realities of chronic disease generally and arthritis specifically followed by ninety minutes of semi-structured discussion among the reporters and CDC experts. Note-takers captured the discussion and notes were analyzed to identify predominant themes and key insights from the discussion.

Results: Six reporters, representing 4 national print vehicles (Time, Good Housekeeping, Essence, Better Health and Living), one wire service (Health Day) and one Web outlet (WebMD) accepted the invitation to participate.

Key themes that emerged from the discussion included:
Consumer attention gravitates to the "sexy"; arthritis is not seen as sexy. Media see arthritis as "a nuisance to be tolerated"
Positioning arthritis as a threat to "the way you want to lead your life" may allow it to compete with more "sexy" (i.e. scary) conditions
A story needs to be "news"-- but anything that is new to them (such as the existence and benefits of packaged self management programs) is considered news.
prevention is a "tough sell" and at a minimum we will need new and more creative examples of healthy behaviors if we expect to break through the "white noise".
Personal success stories work, particularly in the weight loss and fitness arenas.
Concerns about food and medication safety are driving consumer interest in natural remedies and a "back to basics" trend.
The non-pharmacological arthritis management strategies can be positioned as natural approaches to chronic disease management (i.e. "natural solutions you don't know about").

Conclusion: The media in attendance were quite engaged in the discussion; most asked if another roundtable would be held. Most arthritis messages are not "sexy", but can be positioned as natural solutions to the threat arthritis poses to quality of life. New more creative examples are needed, and personal success stories can be advantageous to promote arthritis management messages.

ARHP Concurrent Abstract Sessions

Cognitive Functioning in Fibromyalgia and Lupus
Monday, October 19, 2009, 7:45 AM - 8:45 AM

1140

Cognitive Impairments in Patients Diagnosed with Fibromyalgia, Systemic Lupus Erythematosus, and Rheumatoid Arthritis. Kati Thieme, Anique Thieme and Richard H. Gracely, University of North Carolina, Chapel Hill, NC

Purpose: To determine the presence of cognitive impairments in fibromyalgia syndrome (FM), systemic lupus erythematosus (SLE), and rheumatoid arthritis (RA) patients, to compare these impairments among there three patient groups and to healthy controls (HCs), and to evaluate the contributions of demographic, physical, pain, stress, affective, and cognitive variables to these impairments.

Method: Thirty-seven FM, 27 SLE, 26 RA patients, and 20 HCs underwent a neuropsychological assessment to evaluate concentration, memory, psychomotor speed, cognitive interference, learning, and recall deficits. Pain intensity, fatigue, and sleep disorders were assessed and adrenocorticotropic hormone (ACTH) were collected.

Results: FM and SLE patients showed significantly more cognitive impairments than RA patients and HCs. FM patients demonstrated significantly greater concentration and SLE patients more memory deficits. There were no significant differences between FM and SLE patients in psychomotor speed and complex attention, however, both groups showed significantly worse cognitive abilities than RA patients on all measures except for psychomotor speed. The combination of impaired sleep quality and increased ACTH-production explained 52.4% of the variance of impaired short-term concentration. Fatigue and non-clinically significant depression explained 72.9% of variance of deficits of recognition memory in patients with SLE.

Conclusion: The results support the presence of significant cognitive deficits in FM and SLE patients compared to RA patients and HCs. The association of cognitive impairments and fatigue in SLE suggests immunological influences, whereas ACTH influenced sleep quality in non-depressed FM patients implicating endocrine influences on neuropsychological functioning.

Subjective Cognitive Complaints and Cognitive Impairment in out-Patients with Systemic Lupus Erythematosus. Janni Lisander Larsen, Asmus Vogel and Soren Jacobsen, Copenhagen University Hospital, Copenhagen, Denmark

Purpose: A considerable proportion of SLE patients have cognitive deficits. The relationship between subjective cognitive complaints and objective cognitive impairment in SLE, is variable. It is suggested that even minor subjective complaints of disturbances in memory and attention can be an indicator of cognitive dysfunction. However, others have not found such an association. The purpose of this study was to investigate the prevalence of cognitive impairment; depression and self reported cognitive complaints in outpatients with SLE. Further, the study aimed to explore the relationship between cognitive impairment, affective status and perceived cognitive difficulties in this group.

Method: 57 female outpatients with SLE, according to the 1997 revised criteria, where included. Median age 41. Median SLEDAI and damage scores were 0 ranging from 0-14 and 0-7, respectively. Cognitive complaints were assessed with the patient administered Perceived Deficits Questionnaire (PDQ). The questionnaire was followed by a comprehensive 1 hour neuropsychological test battery. To assess affective symptoms the Major Depression Inventory was applied. Age and sex adjusted normative data derived from previously sampled data on healthy controls.

Results: 22 of 57 patients (38.5%) where classified as cognitively impaired. The most common cognitive deficits were found in executive functions and attention. A low proportion of the patients reported cognitive problems (17.5%) and even among those subjects who had cognitive impairments the proportion of cognitive complaints remained very low (18%). Cognitive impaiment was not associated with history of neuropsychiatric SLE. In the present study 22.5% had scores indicating possible depression. Self-rated depressive symptoms had a high correlation with subjective complaints whereas only four neuropsychological tests were moderately but significantly correlated with subjective cognitive complaints. When these four variables and the self-rated depression score were entered into a linear regression model only the depression ratings had a significant impact ($p < 0.001$) on the PDQ score.

Conclusion: Cognitive impairments (mostly in mild degree) are common in female outpatients with SLE. The level of subjective cognitive complaints was generally very low and many patients with cognitive deficits did not have more complaints of cognitive dysfunction than healthy controls. Subjective cognitive complaints were strongly correlated to self-rated affective symptoms indicating that affective status, and possibly other factors like personality traits, are more important, for the level of subjective experience of cognitive functions, than actual cognitive performance. In patients with SLE complaints of cognitive problems may indicate impairment or reflect other factors like emotional distress or depression. Importantly, absence of subjective cognitive complaints does not exclude the presence of cognitive problems.

Positive Affect as a Resilience Factor in Fibromyalgia and Other Complex Symptom Disorders. Afton L. Hassett[1], Shantal V. Savage[1], Sarah E. Dihmes[1], Steven Buyske[2] and Naomi Schlesinger[1], [1]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Rutgers University, Piscataway, NJ

Purpose: Patients with fibromyalgia and other complex symptom disorders (CSD) such as chronic Lyme disease and chronic fatigue syndrome frequently present to rheumatology clinics. These conditions are characterized by multiple physical symptoms that are often comorbid with psychiatric disorders. A number of investigations have demonstrated that a subgroup of CSD patients display resiliency – possess protective psychosocial characteristics that result in less disability and greater life satisfaction. Herein, the role of positive affect (PA) was explored for its potential contribution to better outcomes in patients with CSD.

Methods: Sixty individuals with CSD were evaluated using the Composite International Diagnostic Interview for somatic symptoms and self-report questionnaires: Positive and Negative Affect Scale, Health Assessment Questionnaire, Quick Inventory of Depressive Symptomatology, Satisfaction with Life Scale, and Symptoms Checklist. Participants were categorized as having “High PA” (½ standard deviation [SD] above the mean) and “Low PA” (½ SD below the mean). The “Normal PA” group was comprised of participants who scored

within ½ SD from the mean. Differences in positive and negative affect, number of symptoms, disability, depression and life satisfaction were evaluated.

Results: Patients in the High PA group reported significantly fewer symptoms than those in the Normal PA (P = 0.003) or Low PA (P = 0.0001) groups. Further, those with High PA reported less disability and greater life satisfaction than those with Low PA (P = 0.004 and P = 0.001, respectively). Depression was more common in Low PA compared to Normal (P = 0.004) and High PA (P<0.0001). Patients in the High PA group were more likely to be Caucasian and have more years of education than patients in the Normal and Low PA groups. There were no significance differences among PA groups regarding level of negative affect. All significant differences for outcomes remain significant after applying a Bonferroni correction for multiple testing.

Conclusion: A subgroup of patients with complex symptom disorders like fibromyalgia who have high levels of positive affect experience fewer symptoms, less disability, and greater life satisfaction than those with lower levels of positive affect.

Cortisol Awakening Response and Affective Factors in Fibromyalgia. Afton L. Hassett[1], Angela Clow[2], David A. Williams[3] and Daniel Clauw[3], [1]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]University of Westminster, London, England, [3]University of Michigan, Ann Arbor, MI

Purpose: Alterations in hypothalamic-pituitary-adrenal (HPA) axis functioning have been commonly observed in subgroups of patients with fibromyalgia (FM). The cortisol awakening response has been shown to be particularly sensitive to psychological variables. In general, positive affective factors have been associated with lower morning cortisol levels, while negative affective factors have been associated with higher levels. However, the role of affective factors in cortisol awakening response has not been well studied in FM. The objective of this study was to evaluate relationships between positive and negative affective factors and cortisol levels after awakening in patients with FM and healthy controls.

Methods: Composite scores based on data collected over three days were calculated for the initial awakening cortisol sample and for the second sample taken 60 minutes after awakening for 20 patients with FM and 26 healthy controls. The following variables were considered in light of their likely association with affect: Center for Epidemiological Studies–Depression Scale (CES-D); Short Form 36 Health Survey (SF-36) subscales: Mental Health, Role Emotional, and Social Functioning; and the anger and anxiety symptoms from the State-Trait Personality Inventory (STPI).

Results: We found that in the healthy controls, higher morning cortisol levels were related to the negative affective variables depression (CESD; $r = .372$; $p = 0.03$) and anxiety (STPI; $r = .41$; $p = .02$) and inversely related to the positive affective variables SF-36 Role Emotional ($r = -.35$; $p = .05$) and Mental Health ($r = -.41$; $p = .02$) subscales. Conversely, in patients with FM, higher morning cortisol levels were not related to the negative affective variables. Instead, higher morning cortisol scores were related the positive affective variables including: SF-36 Role Emotional subscale ($r = .49$; $p = .02$), SF-36 Mental Health ($r = .48$; $p = .02$) and SF-36 Social Functioning ($r = .45$; $p = .03$). Overall, the relationships between cortisol and affective variables were most prominent at initial awakening and few of these relationships existed in composite cortisol scores evaluated later in the day.

Conclusion: Evaluation of affective variables in morning cortisol levels suggests a paradoxical relationship in FM. Unlike what was observed in the healthy controls, in FM positive affective factors were associated with higher morning cortisol levels, while negative affective factors were not associated with lower morning cortisol levels. We hypothesize that because hypocortisolism is common in FM, perhaps the higher cortisol scores influenced by positive affective factors may be indicative of *better* HPA axis functioning. Future studies should explore this possibility.

Yearly, Standardized, Comprehensive Assessment and Treatment Advice for Patients with Systemic Sclerosis (SSc): Feasibility of a Day Care Program. Annemie JM Schuerwegh[1], Anne A. Schouffoer[1], Liesbeth JJ Beaart- van de Voorde[1], Francisca J. M. Tromp[1], Maarten K. Ninaber[2], Tom WJ Huizinga[1], Zuzana de Jong[1] and Thea PM Vliet Vlieland[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Pulmonology, Leiden University Medical Center, Netherlands

Purpose: The significant morbidity associated with systemic sclerosis (SSc) requires the involvement of various medical specialists and health professionals in many patients. In general, the provision of health care for patients with SSc is characterized by a lack of standardization and co-ordination. The aim of the present study was to test the feasibility of a yearly, standardized, comprehensive assessment program in a day care setting for patients with SSc .

Method: The scleroderma day care program is a yearly recurrent, two day-program for SSc patients referred by non-academic or academic rheumatologists. The program consists of: a) an inventory of the patients problems and needs by means of a questionnaire, to be filled in; b) pulmonary function tests, High Resolution CT thorax, ECG, transthoracal echography of the heart, cardio-pulmonary exercise testing (CPET), 24h rhythm registration and blood analysis; c) clinical history taking and clinical evaluation by a specialized rheumatologist, pulmonologist, cardiologist, and health professionals (occupational therapist, physical therapist and/or social worker) according to the patients needs. Diagnostic outcome parameters are discussed in a multidisciplinary meeting and result into a treatment advice for the referring rheumatologist. Feasibility was evaluated according to the number of patients referred over a period of 3 months, the completion of the planned diagnostic procedures within two working days, the necessary period to report the treatment advice to the referring rheumatologist and the number of treatment advices other than continuation of current therapy.

Results: Over a period of 3 months, 44 patients were referred; twenty patients completed the day care program (n= 10 tertiary referral; n=10 secondary referral). In all patients, the diagnostic tests were completed during the two treatment days. The numbers of patients in whom evaluations by a health professional was requested were for occupational therapy: 12, physiotherapy: 9 and social worker: 5. Treatment advice resulted in further referral to another specialist (n=2 respectively cardiac electrophysiology and endocrinology), analysis of suggestive pulmonary arterial hypertension (n=3), change of supportive medical therapy (n=3) or immunosuppressive therapy (n=4). Health professional advice resulted into further intensive treatment by a peripheral physical therapist (n=9), referral to a psychotherapist (n=1). The required period between the program and reporting the advice to the referring rheumatologist was 3,5 weeks.

Conclusion: These preliminary results of a specialized SSc day care program indicate that a compact diagnostic and advising route is feasible. An outcome evaluation of satisfaction by referring doctors and patients is necessary. Collecting data in a systematic manner will provide more insight into the course of the disease.

Measuring Body Image Avoidance in Patients with Systemic Sclerosis. Lisa R. Jewett[1], Brett D. Thombs[2], Marie Hudson[2], Leslie Heinberg[3], Fredrick M. Wigley[4] and Jennifer A. Haythornthwaite[5], [1]McGill University, Montreal, QC, [2]McGill University and Jewish General Hospital, Montreal, QC, [3]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Clevland, OH, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD

Purpose: Patients with systemic sclerosis, or scleroderma, experience substantial disfigurement, often in visible and socially relevant areas of the body. Social avoidance related to body image distress is a significant problem for individuals with acquired disfigurement from medical illness or injury. However, body image avoidance has never been systematically studied in patients with scleroderma and existing measures are designed for non-disfigured individuals with body image and/or eating concerns. The objective of this study was to compare

the validity and reliability of a general Body Image Avoidance Questionnaire for Acquired Disfigurement (BIAQ-AD; N = 181) with a disease-specific measure for patients with acquired disfigurement from scleroderma (BIAQ-Scleroderma; N = 93).

Method: 203 female patients completed the BIAQ-AD, the BIAQ-Scleroderma, or both between 1997 and 2002. The BIAQ-AD was adapted from the Body Image Avoidance Questionnaire (Rosen et al., 1991) by removing weight and eating-related items, and the BIAQ-Scleroderma included items reflecting scleroderma-specific concerns (e.g., I wear long sleeves to hide skin changes). Confirmatory factor analysis and exploratory factor analysis were performed with MPLUS to determine the factor structure; internal consistency reliability was assessed using Cronbach's alpha; and concurrent validity was assessed by comparing BIAQ-AD and BIAQ-Scleroderma with the Adapted Satisfaction with Appearance Scale (ASWAP), Beck Depression Inventory (BDI) and the McGill Pain Questionnaire Short-Form (MPQ-SF).

Results: A 1-factor model provided the most parsimonious fit for both the BIAQ-AD ($\chi2(21) = 44.25$, CFI = .98, TLI = .99, RMSEA = .08), and the BIAQ-Scleroderma ($\chi2(19) = 53.28$, CFI = .92, TLI = .94, RMSEA = .14). The BIAQ-AD (Cronbach's alpha = 0.87) correlated 0.44 with the ASWAP, 0.72 with the BDI, and 0.25 with the MPQ-SF. The BIAQ-Scleroderma (Cronbach's alpha = 0.83) correlated 0.68 with the ASWAP, 0.59 with the BDI, and 0.27 with the MPQ-SF.

Conclusion: The high correlation of the general measure (BIAQ-AD) with the Beck Depression Inventory suggested it overlapped with general distress substantially more than the scleroderma-specific BIAQ-Scleroderma, which better addressed distress related to body image avoidance. Therefore, the BIAQ-Scleroderma is the preferred tool for assessment of body image avoidance in patients with scleroderma. The development and validation of the BIAQ-Scleroderma is a necessary initial step towards better assessment of body image avoidance in patients with scleroderma, however, further research is needed towards the development and testing of interventions to help these patients function better socially.

The Longitudinal Trajectory of Depressive Symptoms in Systemic Sclerosis. Evan G. Newton, McGill University, Montreal, QC

Purpose: Studies find depression to be consistently elevated in chronic disease samples. A recent systematic review found 36-65% percent of scleroderma patients to have significant depressive symptoms. However, little is known about the course of depression over time among patients with chronic disease. The majority of studies in rheumatoid arthritis find depression to be stable over time. These studies, however, fail to account for patient drop-out and how change in depressive symptoms may reflect change in disease symptoms. When multiple imputation was used to account for missing data, we found that disability increased over time in the CSRG registry, and that much of this change in disability was explained by change in the symptoms of systemic sclerosis. The objective of this study was to determine the course of depressive symptoms in our sample, and to see what symptoms of disease might be related to depressive symptoms over time.

Method: The sample consisted of all patients in the CSRG registry who were assessed annually between 2004 and 2008. At the annual assessments, patients completed a standardized evaluation including a medical history, physical evaluation, of various measures of disease status, and the CES-D. Multiple imputation was used to account for missing data. Mixed-effects models were conducted to model the CES-D trend over time, taking into account symptoms of scleroderma.

Results: 741 patients presented a baseline, with a sample mean on the CES-D of 14.37 (10.4), 59% having limited disease, 41% having diffuse disease. Of the demographic variables, marital status =2.16, 95% CI = 0.18, 4.13) and greater than high schoolβ(unmarried) (=-1.39, 95% CI = -2.78, -0.00) were predictive of CES-Dβeducation (=0.83,βscores. Of the time varying disease covariates, breathlessness (=0.56, 95% CI =β95% CI = 0.60, 1.06) and gastrointestinal symptoms (0.37, 0.75) were the strongest predictors of CES-D scores. Visit number was not predictive of depressive symptoms.

Conclusion: Despite the increase in disability over time, depressive symptoms were stable. This finding suggests that a person with scleroderma may have already taken into account the uncertain future of living with a chronic disease, resulting in significant but stable depressive symptoms in the face of further reductions in physical health.

The Influence of Illness Perceptions On Physical and Mental Health in Scleroderma. S. Arat[1], P. Verschueren[1], E. De Langhe[1], M. Vanthuyne[2], V. Smith[3], K. Van den Heede[4], D. Blockmans[1], F. Houssiau[2], F. De Keyser[3] and R. Westhovens[1], [1]Rheumatology and Internal Medicine, University Hospitals KULeuven, Leuven, Belgium, [2]Université catholique de Louvain, Brussels, Belgium, [3]Ghent University Hospital, Ghent, Belgium, [4]Nursing Competence Center, University Hospitals KULeuven, Belgium

Purpose: To evaluate the contribution of illness perceptions and coping on physical and mental health in a large inception cohort of scleroderma patients.

Method: This is a cross-sectional study in a group of 217 scleroderma patients included in the Belgian Systemic Sclerosis Cohort (BSSC), evaluating patients at entry, month 6 and yearly thereafter. Patients completed the Revised Illness Perception Questionnaire (IPQ-R) as well as a coping questionnaire –COPE. Epidemiological data and disease specific data such as scleroderma subtypes and disease activity (according to the European Scleroderma Study Group) were collected as part of the BSSC registry. Physical and mental health were measured on each follow-up consultation by the Short Form 36 (SF-36). The relationship between illness perceptions and physical/mental health as well as between coping and physical/mental health, was analysed using multivariate linear regression analysis adjusted for age, gender, disease activity and scleroderma subtype.

Results: According to Leroy's classification**,** 49 patients had limited systemic sclerosis (lSSc), 129 limited cutaneous systemic sclerosis (lcSSc) and 39 diffuse cutaneous systemic sclerosis (dcSSc). The total sample consisted of 48 men and 169 women. The median age was 54 years, median disease duration 5 years and median Modified Rodnan Skin Score 4. Having lcSSc and disease activity were significantly ($p<0.05$) associated with physical health (beta standardized coefficients (bsc) respectively 0.182 and -0.119). The perception of "serious consequences" and "strong illness identity" was even more strongly associated with physical health ($p<0.001$) (bsc respectively -0.359 and -0.327). Disease activity was significantly ($p=0.005$) associated with mental health (bsc -0.166). "Strong illness identity" and "higher patients' emotional response to their condition" were associated with lower mental health ($p<0.001$) (bsc respectively -0.292 and -0.279). Coping variables were also associated with physical and mental health but resulted in less significant associations. Coping (in terms of behavioural disengagement, mental disengagement and positive reinterpretation and growth) mediated the link between "illness identity" and mental health. The coping style "substance use" mediated the link between "psychological attributions" and mental health. Coping did not interact in the relation between illness perception variables and physical health.

Conclusion: Illness representations are more significant contributors to physical and mental health than classical disease characteristics and therefore should be taken into account in the daily care of patients with scleroderma.

Efficacy and Safety of Rituximab in Subjects with Active Proliferative Lupus Nephritis (LN): Results From the Randomized, Double-Blind Phase III LUNAR Study. R. Furie[1], R. J. Looney[2], B. Rovin[3], Kevin M. Latinis[4], G. Appel[5], J. Sanchez-Guerrero[6], F.C. Fervenza[7], R. Maciuca[8], P. Brunetta[9], D. Zhang[8] and J. Garg[8], [1]North Shore-LIJ Health System, Lake Success, NY, [2]University of Rochester, Rochester, NY, [3]Ohio State, Columbus, OH, [4]KS Univ Med Ctr, Kansas City, KS, [5]Columbia, New York, NY, [6]Inst Nacional, Mexico City DF, Mexico, [7]Mayo Clinic, Rochester, MN, [8]Genentech, South San Francisco, CA, [9]Genentech, Inc., South San Francisco, CA

Purpose: Small, uncontrolled LN studies have suggested that RTX may be efficacious. The efficacy and safety of RTX compared to placebo (PLA) added on to background therapy of mycophenolate mofetil (MMF) and corticosteroids in pts with proliferative LN was studied.

Methods: Pts with class III/IV LN and urine protein to creatinine ratio (UPCR) >1 were randomized 1:1 to receive RTX (1000mg) or PLA on days 1, 15, 168, and 182. Primary endpoint (EPS) was % pts with complete (CRR) or partial renal responses (PRR) at Wk 52 and was analyzed by a stratified Wilcoxon rank sum test.

Results: 72 pts were randomized to each arm and were similar at baseline (BL). Overall mean age at entry was ~30 yrs, ~90% were female, 28% were Black, 36% Hispanic, 31% White, and 67% had class IV LN. BL mean UPCR was 4.0 ±2.8 and serum creatinine was 1.0 ±0.5 mg/dL Mean daily MMF dose was 2.4±0.63g in PLA and 2.7±0.41g in RTX. There were no statistically significant differences in the primary or clinical secondary EPS. Blacks and Hispanics randomized to RTX had greater responses compared to PLA than Whites, but statistical significance was not achieved. RTX had a greater effect on levels of anti-dsDNA and complement at Wk 52. Peripheral CD19+ B cells were depleted in all RTX pts and maintained in most pts until Wk 52. Serious adverse events (SAEs) and infectious SAEs were similar between groups. Neutropenia (1 vs 4), leukopenia (3 vs 9), and hypotension (3 vs 9) occurred more frequently in RTX. Two deaths (sepsis and pneumonitis) occurred in the RTX group.

Conclusion: To date, LUNAR is the largest randomized, placebo-controlled trial to evaluate RTX as an intervention in LN. Although there were numerically more responders in the RTX group (57% vs 46%), the study did not show a statistically significant difference in primary or clinical secondary EPS. RTX had a significantly greater effect on levels of anti-dsDNA and complement, although the clinical significance of this is unclear. AEs and SAEs were similar in frequency between groups, with no new or unexpected safety signals.

Table: Efficacy EPS and Safety

	PLA (N=72) N (%)	RTX (N=72) N (%)	p-value*
Primary			
CRR PRR	22 (30.6) 11 (15.3)	19 (26.4) 22 (30.6)	0.55
Key Secondary			
Pts with BL UPCR>3 to UPCR<1	53.7	47.4	0.51
% change from BL in anti-dsDNA	50	69	<0.01
Mean Change from BL in C3 (mg/dL)	25.9	37.5	<0.03
Exploratory			
Pts with BILAG Renal Domain Score C at Wk52	28 (38.9)	39 (54.2)	0.07
Overall response (CRR+PRR)	33 (45.8)	41 (56.9)	0.18
Black	9/20 (45)	14/20 (70)	0.20
Hispanic	11/23 (48)	16/29 (55)	0.78
White	13/26 (50)	10/19 (53)	1.00
Pts with new immunosuppressant prior to Wk52	8 (11.1)	1 (1.4)	0.03

Azathioprine Versus Mycophenolate Mofetil for Maintenance Immunosuppression of Proliferative Lupus Nephritis: Results of a Randomized Trial (MAINTAIN). Frederic A. Houssiau[1], David P. D'Cruz[2], Shirish R. Sangle[2], Philippe Remy[3], Carlos Vasconcelos[4], Enrique de Ramon Garrido[5], Inge-Margrethe Gilboe Sr.[6], Isabelle Ravelingien[7], Maria Tektonidou[8], Genevieve Depresseux[1], Loic P. Guillevin[9] and Ricard Cervera[10], [1]Universite catholique Louvain, Brussels, Belgium, [2]Lupus Research Unit, The Rayne Institute, St Thomas' Hospital, London, United Kingdom, [3]Hôpital Henri Mondor, Créteil, France, [4]Unidade de Imunologia Clínica - Hospital Santo António, Oporto, Portugal, [5]Hospital del SAS de Malaga, Malaga, Spain, [6]Rikshospitalet, Oslo, Norway, [7]Onze Lieve Vrouw Ziekenhuis, Aalst, Belgium, [8]University of Athens, Athens, Greece, [9]Hopital Cochin, Paris, France, [10]Autoimmune Diseases. Hospital Clínic, Barcelona, Spain

Purpose: To demonstrate the superiority of mycophenolate mofetil (MMF) over azathioprine (AZA) as maintenance therapy of proliferative lupus nephritis in a randomized investigator-initiated open trial.

Method: 105 (mainly Caucasians) lupus patients from 29 European centers, with WHO Class III, IV, Vc or Vd nephritis and with a 24-hour proteinuria ≥ 0.5 gram were included. The number of patients was calculated to obtain a power of 0.80 with an α level of 0.05, on the basis of an anticipated 35% renal flare rate in the AZA group and a 10% flare rate in the MMF group, this difference being considered as clinically meaningful. All patients received 3 daily intravenous (IV) pulses of 750 mg methylprednisolone, followed by oral glucocorticoids (0.5 mg/kg/d equivalent prednisolone; per protocol tapering), and 6 fortnightly cyclophosphamide IV pulses of 500 mg (Euro-Lupus regimen). Based on randomization performed at baseline, AZA (target dose: 2 mg/kg/d) or MMF (target dose: 2 g/d) was started at week 12 for a total period of 60 months. Time to renal flare was the primary endpoint. Survival curves were derived using the Kaplan-Meier method and statistically tested with the Log rank test. All patients had a theoretical followup of ≥ 3 years. Analyses were by intention-to-treat.

Results: 52 and 53 patients were randomized in the AZA and MMF groups, respectively. Their baseline clinical, biological and pathological characteristics did not differ. After a median (range) followup of 53 (15-65) months, 24 patients had been dropped (mainly for pregnancy wish [n = 10; 2 AZA and 8 MMF, p = 0.05] and toxicity [n = 7; 5 AZA and 2 MMF], NS). A renal flare was observed in 13 AZA patients and 9 MMF patients. Time to renal flare, to severe systemic flare, to benign flare and to renal remission did not statistically differ. Doubling of serum creatinine occured in 4 AZA and 3 MMF patients. Infectious side-effects did not differ between the groups but drug-related hematological cytopenias were statistically more frequent in the AZA group (p = 0.03).

Conclusion: After a median followup of 53 months, MMF was not superior to AZA to prevent renal relapses of lupus nephritis.

A Novel Autoantibody against 200/100 Kd Proteins Is Associated with Necrotizing Myopathy. Lisa Christopher-Stine, Grace Hong, Livia Casciola-Rosen, Andrea M. Corse and Andrew Mammen, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: The inflammatory myopathies are a family of conditions characterized by proximal muscle weakness, elevated serum muscle enzymes, and inflammatory infiltrates on muscle biopsy. However, ~20% of patients with clinical features of myositis do not have a significant degree of inflammation on muscle biopsy. Instead, biopsies from these patients demonstrate numerous degenerating, necrotic, and regenerating myofibers. Necrosis may be seen in patients with muscular dystrophies or toxic exposure as well as in those patients with myositis specific autoantibodies (MSAs). Nevertheless, a substantial proportion of patients with necrotizing myopathies have none of these known associations. We sought to determine novel autoantibody associations in patients with predominately necrotic features in the absence of substantial inflammatory infiltrates on muscle biopsy.

Method: 225 patients in the Johns Hopkins Myositis Cohort had both a muscle biopsy available for review at our institution and banked serum. Biopsies were evaluated for the presence of inflammation, regeneration, degeneration, necrosis, and vacuolar change. Antibody specificities in patient sera were assessed by performing immunoprecipitations from 35S-methionine labeled HeLa cell lysates.

Results: 38 patients in the JHU Myositis Cohort had predominant necrosis on muscle biopsy without histologic findings of perifascicular atrophy or red-rimmed vacuoles. Sera from these patients were screened by immunoprecipitation for the presence of novel autoantibodies. 12 patients had known autoantibody association or other diagnoses [SRP (6), anti-Jo-1(1), 1 anti-PL12 (2), anti-PL-7 (1), profound hypothyroidism(1), and dysferlinopathy(1)]. The remaining 26 patients had no known MSAs or other diagnosis to explain the necrotizing myopathy. A novel autoantibody specificity was found in 16 of these 26 patients (62%). These sera immunoprecipitated a pair of proteins with molecular weights of 100 kDa and 200 kDa. In contrast, control human sera did not precipitate these or other proteins. Only one additional patient with this autoantibody specificity was identified among 197 patients without prominent features of necrosis on muscle biopsy.

Conclusion: We have identified a novel autoantibody specificity which is associated with characteristic muscle biopsy findings and a variable clinical phenotype. Since we have not found instances of sera which precipitated only one of these proteins, we hypothesize that these may be subunits of a protein complex. Our findings show that patients with anti-200/100 represent a distinct subgroup of necrotizing myopathy patients that were previously considered to be “autoantibody negative.” Future studies will be directed towards identifying the autoantigens recognized by these autoantibodies.

Combination Antibiotics as a Treatment for Chronic Chlamydia-Induced Reactive Arthritis. John D. Carter[1], Luis R. Espinoza[2], R.D. Inman[3], K.B. Sneed[1], Louis Ricca[1], Frank B. Vasey[1], Joanne Valeriano[1], J.A. Stanich[4], C. Oszust[4], H.C. Gerard[4] and Alan P. Hudson[4], [1]University of South Florida, Tampa, FL, [2]LSU Medical Center, New Orleans, LA, [3]Toronto Western Hospital, Toronto, ON, [4]Wayne State University, Detroit, MI

Purpose: *Chlamydia trachomatis* (Ct) and *Chlamydophila (Chlamydia) pneumoniae* (Cpn) are known triggers of reactive arthritis (ReA). These chlamydial species exist in a persistent metabolically active infection state in the synovium suggesting that persistent chlamydiae may be susceptible to antimicrobial agents. The goal of this study was to investigate whether a six-month course of combination antibiotics is an effective therapy for patients with chronic *Chlamydia*-induced ReA.

Methods: This study was a 9-month, double-blind, triple-dummy prospective trial assessing a 6-month course of combination antibiotics as a treatment for *Chlamydia*-induced ReA. Eligible patients were age 18 to 70 years, fulfilled a modified European Spondyloarthropathy Study Group (ESSG) Criteria, and had disease duration equal to or longer than 6 months. Subjects had to be polymerase chain reaction (PCR)-positive for Ct or Cpn in order to be randomized to therapy; randomization was performed in a 1:1:1 fashion. Treatment was for 6

months; the 3 groups included doxycycline 100mg twice daily and rifampin 300mg daily, azithromycin 500mg daily x 5 days then twice weekly and rifampin 300mg daily, or matching placebos. The primary efficacy endpoint was to assess the number of responders in the combination antibiotic group vs. placebo at month 6 compared to baseline. Responders were defined as those subjects who improved 20% or more in at least 4 of 6 predefined validated variables without worsening in any one variable.

Results: 80 subjects were screened and 42 were randomized to treatment (27 to combination antibiotics and 15 to placebo). Subjects in each group had similar demographics and baseline characteristics. At month 6, 17/27 subjects (63%) randomized to combination antibiotics were responders compared to 3/15 (20%) on placebo (P-value = 0.01). Secondary efficacy endpoints showed similar results with significant improvement in the modified swollen joint count, tender joint count, physician global assessment (P-values 0.0007, 0.002, and 0.0009, respectively), and a trend with the erythrocyte sedimentation rate (P-value = 0.07) in those patients on combination antibiotics compared to placebo. 6/27 (22%) subjects on combination antibiotics experienced complete resolution of their symptoms whereas 0/15 subjects on placebo achieved this endpoint. There were significantly more subjects who became PCR negative at month 6 in the active therapy group than in the placebo group (P-Value = 0.03). Adverse events (AE's) were mild; there were no significant differences between the groups.

Conclusion: These data suggest that a 6-month course of combination antibiotics are an effective therapy for chronic *Chlamydia*-induced ReA and that chlamydial organisms in a persistent infection state are susceptible to this treatment approach.

This study was supported by grant AR-053646 from the US National Institutes of Health.

Serial Re-Screening in High Risk Patients On Anti-TNF-α Therapy Validate CDC Recommendations for Monitoring TB Risk. D. Cooray[1], R. Moran[1], A. Broumand[1], S. Bagheri[1], J.S. Louie[2], DE Furst[2] and GA Karpouzas[1], [1]Harbor UCLA Med Ctr, Torrance, CA, [2]University of California Los Angeles, Los Angeles, CA

Purpose: *Mycobacterium tuberculosis* (MTB) and non-tuberculous mycobacteria (NTM) have been reported in patients (pts) receiving anti-Tumor Necrosis Factor-α (aTNF) agents, either as a result of reactivation of latent disease (LTB) or as new infections. Pts considered for aTNF therapy should undergo tuberculin skin testing (TST) and/or ex vivo cellular responses to mycobacterial antigens (Quantiferon) and chest x-ray (CXR). Asymptomatic pts with mycobacterial reactivity [TST or Quantiferon positive (+)] and a negative (-) CXR are typically treated with Isoniazid (INH) for 9 mos. In symptomatic pts, CDC suggests obtaining sputum cultures and chest Computed Tomography (CT). We report our extended follow-up of re-screens and subsequent conversion rates in aTNF exposed pts, and propose a comprehensive algorithm for dissemination in all new converters.

Methods: We reviewed 411 pts treated with aTNF agents between 11/1/2000 and 6/16/2009 at a county hospital. Pts were included for analysis if they had received at least one month (mo) of adalimumab (ADA), etanercept (ETN), or loading dose of infliximab (IFX) 3mg/kg at 0,2, and 6 weeks. Screening TST and CXR were obtained and (-) pts were serially re-screened while continuing aTNF therapy. Since this population is considered high risk, induration of ≥ 5mm was considered to be (+) on TST. Those who were asymptomatic with a new (+) TST were tested with cultures and polymerase chain reaction (PCR) assessment of sputum, urine, and stool for MTB or NTM, along with CXR or chest CT.

Results: Of 411 pts exposed to aTNF therapies, 382 received baseline TST and 100 tested (+). Seventeen of 100 TST (+) pts had evidence of old granulomatous disease but were asymptomatic. All 100 pts with TST (+) were given INH for 9 mos. Of the remaining 282 TST (-) pts, 174 had 1 re-screen at least 1 year later, 46 had 2 re-screens, and 10 had at least 3-4 re-screens. Eighteen of 230 (7.8%) rescreened pts developed a (+) TST (induration size 15.05±5.9 mm) while treated with aTNF agent: 3 pts were on ETN (50mg qw), 13 pts on ADA (5 on 40mg qow and 8 on 40mg qw), 2 pts on IFX . All were asymptomatic and had (-) CXR. Two of the 18 converters (11%) had (+) sputum cultures: 1 for MTB and 1 for M.chelonae respectively and were committed to 4 drug regimen for 6 months. Urine, stool cultures and PCR were (-). The remaining 16 pts with TST conversions were treated with INH for 9 mos continued their aTNF and did not develop active TB over a median of 13 months.

Conclusion: Our expanded cohort reveals a high prevalence of LTB on baseline screening as well as TST conversions with 3 aTNF agents at varying time points. Despite the fact that pts may be clinically asymptomatic, we were able to uncover active disease by obtaining cultures

on all pts that seroconvert. We validate the CDC recommendations that all pts on aTNF agents should have yearly TST. If new LTB becomes evident, prompt therapy with INH prevents active infection. Cultures and PCR of sputum, urine, and stool in addition to chest CT may be prudent adjuncts for monitoring.

Angiogenesis, Cell Trafficking, and Cell Retention: The Dynamics of Inflammation

Monday, October 19, 2009, 2:30 PM - 4:00 PM

1154

IL-17 Upregulates Expression of Proangiogenic Mediators, and Vascularity Is Elevated in the IL-17-Induced Arthritis Model. Shiva Shahrara[1], Sarah R. Pickens[1], Michael V. Volin[2], Chiang-Ching Huang[1] and Richard M. Pope[1], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Midwestern University, Downers Grove, IL

Introduction: IL-17 is a proinflammatory cytokine that plays a crucial role in animal models of rheumatoid arthritis (RA). However the role of IL-17 in the angiogenesis of RA has not been determined.

Purpose: These studies were performed to identify the role of IL-17 in mediating proangiogenic factors in cells present in the RA synovial tissue and whether local expression of IL-17 in murine ankles affected vascularity within the joint.

Methods: Microarray studies were performed using synovial tissue (ST) fibroblasts from 6 patients with RA that were treated or untreated with IL-17 for 5h. The data were quantile normalized, and IL-17-activated genes were determined by Student's t test. Expression of the proangiogenic factors was confirmed in RA fibroblasts by real-time RT-PCR. Additionally, human microvascular endothelial cells (HMVECs) were examined for IL-17-induced proangiogenic factors. Finally, ankles harvested from adenovirally expressed IL-17 (Ad-IL-17) or the control group (Ad-CMV) were stained with von Willebrand factor.

Results: IL-17-induced proangiogenic factors identified in RA fibroblasts by microarray analysis included fibroblast growth factor (FGF2), heparin-binding EGF-like growth factor (HBEGF), CXCL1, CXCL5, CXCL8 and CCL2. Employing real-time RT-PCR, we confirmed that IL-17 induced the expression of FGF2, CXCL1, CXCL5 and CCL2 ($p<0.05$) in RA ST fibroblasts. Although not detected in the microarray results, we also demonstrated that 4 to 8h of IL-17 induced the expression of vascular endothelial growth factor (VEGF) by RA fibroblasts ($p<0.05$). We also examined HMVECs for IL-17-induced proangiogenic factors and found that IL-17 markedly increased the expression of VEGF and CXCL1 starting at 2h ($p<0.05$). Given that IL-17 induced proangiogenic factors from RA ST fibroblasts and HMVECs, we asked whether intra-articular injection of IL-17 into mice ankles had any effect on synovial tissue vascularity. The Ad-IL-17 treated group demonstrated significantly greater ankle circumference on days 4 and 10 post injection compared to the Ad-CMV control group. Von Willebrand staining of ankles harvested from day 10 post injection demonstrated that Ad-IL-17 treated mice have significantly ($p<0.05$) increased endothelial staining compared with Ad-CMV control group.

Conclusion: These results suggest that IL-17 mediates angiogenesis in RA by inducing proangiogenic factors from RA ST fibroblasts and HMVECs. Therefore, IL-17 and its downstream proangiogenic factors may be potential targets in RA.

Soluble Junctional Adhesion Molecule-C Promotes Mononuclear Cell Recruitment in Rheumatoid Arthritis. Bradley J. Rabquer[1], Nanditha Teegala[1], Charles A. Lesch[1], M. Asif Amin[1], Jeffrey H. Ruth[1], Matthew K. Shaheen[1], Phillip L. Campbell[1], Beat A. Imhof[2] and Alisa E. Koch[3], [1]University of Michigan, Ann Arbor, MI, [2]Centre Medical Universitaire, Geneva, Switzerland, [3]Veteran's Administration and University of Michigan, Ann Arbor, MI

Purpose: Rheumatoid arthritis (RA) is characterized by synovial hyperplasia, neovascularization, and inflammatory cell infiltration. We have shown that junctional adhesion molecule-C (JAM-C) is overexpressed on endothelial cells (ECs) and fibroblasts in the RA synovium, mediates myeloid cell adhesion to the RA synovium, and that soluble JAM-C (sJAM-C) is elevated in RA synovial fluid (SF) compared to osteoarthritis SF or normal serum. The aim of this study was to determine which cells produce sJAM-C and if sJAM-C is a mononuclear cell (MNC) chemoattractant.

Methods: We performed ELISAs to detect sJAM-C in the culture supernatant of ECs and RA synovial fibroblasts. *In vitro* monocyte (MN) chemotaxis assays were used to determine if sJAM-C is chemotatic for MNs and if sJAM-C contributes to the RA SF chemotatic potential for MNs. The ability of sJAM-C to induce leukocyte migration *in vivo* was assessed using a mouse peritoneal leukocyte recruitment model.

Results: sJAM-C was present in the culture supernatant of human microvascular endothelial cells (HMVECs, n=3 experiments, mean 16 pg/ml), immortalized human microvascular endothelial cells (HMEC-1s, n=4 experiments, 80 pg/ml), and RA synovial fibroblasts (n=7 patients, 78 pg/ml). Stimulation of HMVECs (n=3), HMEC-1s (n=4), or RA synovial fibroblasts (n=7) with tumor necrosis factor-α (TNF-α) resulted in increased sJAM-C production compared to nonstimulated cells (6.9 fold increase, 2.1 fold increase, and 1.4 fold increase, respectively, $p<0.05$). *In vitro*, sJAM-C stimulated MN migration in a dose dependent manner that was significantly greater than PBS from 1 to 250 nM (n=4 experiments, $p<0.05$). In an *in vivo* mouse peritoneal recruitment model, sJAM-C induced significantly more macrophage and lymphocyte migration than PBS (n=10 mice, $p<0.05$). When sJAM-C was depleted from RA SFs, the ability to chemoattract MNs *in vitro* decreased by a mean of 25% (n=3 patients, $p<0.05$)

Conclusion: Our results indicate that: 1) sJAM-C is secreted by ECs and RA synovial fibroblasts, and TNF-α stimulates this secretion; 2) sJAM-C promotes MN migration *in vitro* and MNC migration *in vivo;* and 3) sJAM-C is a significant contributor to the RA SF chemotatic potential for MNs. These results suggest that modulation of sJAM-C may provide a novel route for controlling synovial MNC infiltration in RA.

Macrophage Migration Inhibitory Factor and CD74 Regulate Leukocyte Chemotactic Responses Via Facilitation of MAPK and RhoAGTPase Activation. Leilani Santos, Huapeng Fan, Pam Hall, Julia Gregory, Michael J. Hickey and Eric F. Morand, Monash University, Clayton, Australia

Purpose: Macrophage migration inhibitory factor (MIF) contributes to the pathogenesis of rheumatoid arthritis, lupus, and atherosclerosis, via mechanisms including facilitation of leukocyte recruitment. The mechanisms whereby MIF affects leukocyte recruitment are unknown. We therefore investigated the contribution of MIF, and its receptor CD74, to leukocyte responses to chemokines in vivo and in vitro.

Methods: Intravital microscopy, in vitro migration assays, immunoblotting, confocal microscopy and activated Rho GTPase protein assays were used to examine the role of MIF and CD74 in responses to CXCL1 (KC) and CCL2 (MCP-1), which are classical neutrophil and monocyte chemokines respectively.

Results: Intravital microscopy of muscle postcapillary venules demonstrated that leukocyte rolling and adhesion induced by recombinant MIF were significantly reduced in CD74-/- mice, consistent with CD74 acting as the receptor for MIF-mediated leukocyte recruitment events in vivo. Significant increases in leukocyte adhesion and emigration were observed in vivo in response to injection of CXCL1, and both parameters were significantly reduced in either MIF-/- or CD74-/- mice.

CXCR2 (CXCL1 receptor) expression was intact in MIF-/- neutrophils, but both MIF-/- and CD74-/- neutrophils exhibited reduced chemotactic responses to CXCL1 in in vitro migration assays. CXCL1 induced phosphorylation of p38 but not ERK MAP kinase in WT neutrophils, and this was significantly impaired in both MIF-/- and CD74-/- neutrophils.

Similarly, CCL2-induced leukocyte adhesion and emigration were significantly reduced in both MIF-/- and CD74-/- mice. MIF-/- and CD74-/- macrophages exhibited normal CCR2 expression but reduced CCL2-induced phosphorylation of ERK MAP kinase. MIF signalling through CD74 has been suggested to depend on F-actin stress fiber formation and RhoAGTPase. CCL2-induced F-actin stress fiber formation and RhoAGTPase activity were significantly reduced in both MIF-/- and CD74-/- macrophages.

Conclusion: These data suggest that MIF, through CD74, promotes chemokine-dependent leukocyte recruitment via facilitation of intracellular signal transduction responses. These findings suggest a new mechanism for the actions of MIF, and suggest that MIF inhibition could impact on chemokine-dependent leukocyte recruitment in inflammatory diseases.

IL-17A Upregulates Angiogenesis, Cytoskeletal Rearrangement and Cell Migration in a Chemokine Dependent Manner. Ellen Margaret Moran[1], Jennifer McCormick[1], Mary Connolly[1], Aisling Kennedy[1], Ursula Fearon[2] and Douglas J. Veale[1], [1]Dublin Academic Medical Centre, St.Vincent's University Hospital, Dublin, Ireland, [2]Dublin Academic Medical Centre, St.Vincent's University Hospital, Dublin 4, Ireland

Purpose: IL-17A is a pivotal cytokine implicated in the pathogenesis of RA. The aim of this study was to examine the functional effect of IL-17A on angiogenesis, cytoskeletal architecture and cell migration.

Method: IL-17A, VEGF and Ang1/2 were measured by ELISA in paired serum/synovial fluid (SF) from inflammatory arthritis patients. Synovial α-SMA expression was quantified by immunohistochemistry in the same patients. RA synovial explants, RASFCS and human dermal endothelial cells (HDECs) were stimulated with IL-17A (10-50ng/ml). Angiogenesis was assessed by HDEC Matrigel tubule formation assays. Cytokine and chemokine expression in the culture supernatants was measured using protein arrays and ELISA. RASFC and HDEC actin cytoskeleton integrity, invasion and cell migration was assessed by dual immunofluorescence staining, invasion and wound repair assays. RASFC integrin expression was examined using integrin binding assays.

Results: HDEC tubule formation was upregulated by 270% compared to basal following IL-17A stimulation ($p<0.05$). IL-17A SF levels correlated with VEGF SF ($r2=.747$) and Ang2 SF ($r2=.843$) levels (all $p<0.01$). IL-17A serum levels correlated with aSMA expression ($r2=.451$, $p<0.05$) a marker of blood vessel maturity. GROα, IL-6, IL-8 and MCP-1 production by RA explants and RASFCs was significantly increased by IL-17A stimulation ($p<0.05$). IL-17A induced HDEC and RASFC migration and invasion as visualized by wound repair and invasion assay an effect that was inhibited by the presence of neutralizing antibodies against GROα and MCP-1. IL-17A significantly increased RASFC β1 integrin expression ($p<0.05$) but downregulated αv β3 expression. Examination of the IL-17A amino acid sequence revealed two integrin binding domains. IL-17A induced disassembly of the actin cytoskeleton and loss of FA, showing dramatic filopodia formation compared to unstimulated cells. This effect was blocked by incubation with a pharmacological inhibitor of Rac1 a member of the Rho GTPases family. Rac1 inhibition also blocked IL-17A induced RASFC wound closure.

Conclusion: These data suggest IL-17A expression within the RA joint is associated with angiogenic growth factors and vascular stability. IL-17A upregulates angiogenesis and induced chemokine dependent cell migration. Finally, IL-17A induces cytoskeletal rearrangement possibly via a β1 integrin-Rac1 dependent pathway.

Alterations in the Hypoxic Joint Environment and Blood Vessel Maturity Pre/Post Anti-Tnfα Therapy. Aisling Kennedy, Chin Teck Ng, Monika Biniecka, Jacintha O'Sullivan, Douglas J. Veale and Ursula Fearon, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Purpose: Angiogenesis is an early event in inflammatory arthritis. Persistent mature blood vessels within the synovial tissue following treatment of arthritis may be re-activated to induce a pro-inflammatory response. The aim of this study is to assess blood vessel maturity and stability pre/post anti-TNFα therapy and examine their relationship to *in vivo* tissue oxygen pO_2, disease activity scores and angiogenic growth factor expression.

Method: Twenty IA patients were assessed at baseline and three months post anti-TNFα therapy. Response to treatment was assessed using DAS28 and CRP scores. Using a specialist pO_2 probe (Licox), pO_2 levels in synovial tissue (ST) *in vivo* under direct visualisation at arthroscopy were assessed at baseline and 3 months post therapy. Matched serum, synovial fluid (SF) and ST were collected. Blood vessel (BV) maturity was assessed by dual immuno-fluorescent staining using Factor VIII (endothelial cell marker) and αSMA (pericyte marker). 8 dihydro 2'-deoxyguanosine (8-oxo-dG), a marker of pro-mutagenic lesions, was used to assess oxidative DNA damage *in situ* in ST by IHC. VEGF and Ang2 were measured by ELISA.

Results: Seventy-five % of patients responded to anti-TNFα therapy, which reduced DAS from 4.49 (2.76-6.52) (median (range)) to 3.17 (1.54-4.48) (median (range)) ($p<0.05$). At baseline a significant number of immature vessels (showing no pericyte recruitment, indicating a loss of endothelial/pericyte cell-cell contact) was demonstrated in patients with inflammatory arthritis ($p<0.01$), in contrast to OA and normal tissue where all vessels had acquired pericytes and were mature. A significant reduction in number of synovial blood vessels (Factor VIII) was demonstrated post therapy ($p<0.05$), in contrast to αSMA, where there was no significant change. This resulted in a significant increase in BV maturity in responders ($p<0.01$) suggesting blood vessel stability and quiescence. This was coupled with a decrease in SF VEGF and Ang2. BV nuclear 8-oxo-dG expression was decreased post-therapy with a lower levels demonstrated in responders vs non-responders ($p<0.05$). pO_2 levels in responders increased from 2.4% (median) at baseline to 3.4% (median) with the pO_2 levels in non-responders decreasing from 3.7% to 2.5%. Significant inverse correlations were observed between DAS28-CRP and pO_2 (r-0.36, p=0.009), ΔDAS28 and ΔBV-maturity (r=-0.606, p=0.008), 8-oxo-dG nuclear % and pO_2 (r=-0.391, p=.007). ΔVEGF and ΔAng2 correlated with ΔDAS28 (r=0.39, $p<0.05$ and r=0.4, $p<0.05$ respectively).

Conclusion: Blood vessel maturity, stability and DNA damage are reduced post anti-TNFα therapy and associated with disease activity and *in vivo* pO_2 levels. Blood vessel maturity may perpetuate a hypoxic environment within the synovial tissue, driving oxidative damage and maintaining angiogenic growth factor levels.

Chemokine Receptors CCR7 and CXCR5 and the TNF:TNF Receptor System Are Important for the Retention of CD4+ T Cells From RA Patients in the Synovial Membrane. Manuela Rossol[1], Undine Meusch[1], Anett Schulz[1], Christoph G. Baerwald[2] and Ulf Wagner[2], [1]University of Leipzig, Leipzig, Germany, [2]University Hospital, Leipzig, Germany

Purpose: Infiltration of the synovial membrane with lymphocytes is a hallmark of rheumatoid arthritis (RA). We previously described an in vitro system to study this process. CD4+ T cells from the blood of RA patients invaded tissue sections of RA synovial membrane in higher numbers than CD4+ T cells from healthy controls. Goal of the present study was to analyze underlying mechanisms.

Methods: Using a horizontally oscillating microtome, vital tissue sections of 30-40µm thickness were prepared from synovial tissue of RA patients. The tissue sections were co-cultured with fluorescence-labelled CD4+ T-cells from RA patients. After 24 hours, the tissue sections were vigorously washed and analyzed by inverse fluorescence microscopy.

Results: Both naive and memory CD4+ T cells from RA patients were equally able to infiltrate the synovial tissue sections. Blockade of the chemokine receptors CCR7 or CXCR5 significantly inhibited the retention of RA CD4+ T cells in the synovial membrane. Recovery of the tissue invading CD4+ T cells by enzymatic digestion of the tissue and subsequent FACS analysis of CD4+ T cells revealed the presence of TNF-receptor 1, while non-infiltrating CD4+ T cells from the culture supernatant did not express TNF-receptor 1. In addition, TNF producing CD4+ T cells from synovial tissue which were isolated by immunomagentic separation, did infiltrate the tissue in high numbers, whereas isolated TNF non-producing CD4+ T cells did not. Accordingly, an anti-TNF antibody blocked the tissue infiltration by CD4+ T cells.

Conclusion: Both naive and memory CD4+ T cells of RA patients have the intrinsic capability to migrate and persist in the synovial tissue. The process depends on chemokine receptors and the TNF:TNF receptor system.

ACR Concurrent Abstract Sessions

Anti-Citrullinated Protein Antibodies in Rheumatoid Arthritis

Monday, October 19, 2009, 2:30 PM - 4:00 PM

1160

Moderate to Severe Adult Periodontitis Increases Risk of Rheumatoid Arthritis in Non-Smokers and Is Associated with Elevated ACPA Titers: The ARIC Study. J. A. Molitor[1], A. Alonso[1], M.H. Wener[2], B.S. Michalowicz[3], J. Beck[4], V. H. Gersuk[5], J.H. Buckner[5] and A.R. Folsom[1], [1]Univ of MN, Minneapolis, MN, [2]Univ of WA, Seattle, WA, [3]Univ of MN, Minneapolis, [4]Univ of NC, Chapel Hill, [5]Benaroya Rsch Ini., Seattle, WA

Purpose: Genetic risks for the development of anti-citrullinated peptide antibodies (ACPA) have been established, but the only environmental exposure consistently associated with ACPA+ Rheumatoid Arthritis (RA) risk is tobacco exposure (TE).

Objectives**:** 1. Establish the risk for development of incident (new) RA cases in a large cohort characterized for periodontitis severity and smoking status. 2. Assess ACPA and RF seropositivity of RA cases.

Method: We studied 6616 participants in the Atherosclerosis Risk in Communities (ARIC) study who were examined 4 times during the period 1987-1998 and for whom a detailed periodontal assessment was made in 1996-1998. Periodontitis status (no, mild, moderate or severe disease) was determined using published criteria. Subjects hospitalized with a discharge code of RA in the 9 years before their periodontal exam were designated as having “prevalent” RA; those with a first-time RA discharge code up to 8 years following their periodontal assessment were designated as having “incident” RA. Hazard ratios (HR) were determined using the Cox proportional hazards model adjusting for age, sex, and race. Available sera from 1990-92 and 1996-98 from both the incident and prevalent RA cases were examined with a second-generation ACPA ELISA and ELISA for IgG-RF, IgA-RF, and IgM-RF. HLA- DR4 alleles were determined by quantitative real-time PCR.

Results: Incidence rates of RA in the ARIC cohort were comparable to those in Olmsted County, MN. The HR of developing RA in subjects with moderate to severe periodontitis (n= 27) was 2.6 (95% CI=1.0-6.4, p=0.04), compared to those with no to mild periodontitis (n= 6). Among lifetime non-smokers, the HR was 8.8 (95% CI=1.1-68.9, p=0.04). In adjusted analyses, periodontitis severity was not associated with RA incidence among current and former smokers. ACPA levels were significantly higher in participants with moderate-severe periodontitis than in those with no-mild periodontitis (222.5 U vs. 8.4 U, p=0.04). Of 13 cases with ACPA+ at either sampled visit, 11 were both smokers and had moderate-severe periodontitis (85%, vs 47% predicted, chi-square, P=0.007), indicating a possible interaction between smoking and periodontitis in the production of ACPA. Of 12 DR4+ participants, 6/7 ACPA+ were both smokers and had moderate-severe periodontitis, whereas only 1/5 ACPA-/DR4+ individuals was both a smoker and had moderate-severe periodontitis (p=0.07, Fisher’s exact test).

Conclusion: Moderate to severe periodontitis may be a risk factor for the development of RA in non-smokers. Individuals with moderate to severe periodontitis have higher ACPA titers than those with no or mild periodontitis. There is evidence of an interaction between smoking and periodontitis increasing the likelihood of high-titer ACPA.

The Mechanisms Underlying Arthritogenicity of Human Anti-Citrulline Antibodies. William Brintnell[1], David A. Bell[2] and Ewa Cairns[3], [1]Univ Western Ontario, London, ON, [2]SJHC, London, [3]Univ Western Ontario, London

Purpose: Determine the mechanisms responsible for the arthritogenic effects of human anti-citrulline antibody.

Background: We previously reported that intra-peritoneally (ip) administered affinity purified human RA IgG anti-citrulline antibody (ACA) to FcγRIIb deficient mice induced inflammatory arthritis. This was not seen with human RA IgG devoid of ACA (CCP_2) or serum IgG purified from normal donors.

Methods: Human RA IgG ACA (vs. CCP_2) was affinity purified with a proprietary citrullinated peptide (JED) from ten patients with RA. 45 U of anti-CCP_2 or equal concentration of purified human IgG without anti-CCP_2 activity (4-20 μg of IgG) was administered ip to pre-autoimmune FcγRIIb deficient or wild type B6129SF2/J or DR4 tg mice. The joints were examined by H&E staining. Intra-articular (ia) citrulline was detected by the AMC reagent and C3 deposition by goat $F(ab')_2$ anti-mouse C3 antibody.

Results: Inflammatory arthritis developed and peaked 12 days following ip injection of purified human RA IgG ACA but not equal concentration of RA IgG lacking ACA in the FcγRIIb deficient mice. Control wild type mice or DR4 tg mice did not develop arthritis unless they were also administered ia citrullinated human fibrinogen. The ia deposition of citrulline and C3 was seen in all arthritic mice. Naïve FcγRIIb deficient mice but not wild type mice also had significant deposition of citrulline. Purified ACA lacked C1q binding.

Conclusion: The arthritis in these mice is due to ia binding of affinity purified human RA ACA to ia citrulline leading to complement activation and arthritis. Ia citrulline in FcγRIIb deficient mice may result from the spontaneous apoptotic release of citrulline from synoviocytes while in control wild type and DR4 tg mice citrulline must be administered exogenously. These studies indicate that: 1) human IgG anti-citrulline antibody is arthritogenic and 2) the inflammatory arthritis resulting from anti-citrulline antibody is dependent on ia citrulline release. These studies have important implications for understanding the mechanisms of arthritis induction by ACA in human RA.

Smoking and Anti-CCP Antibodies Predict Rheumatoid Arthritis. Carl Turesson[1], Ulf GB Bergström[1], Lennart Truedsson[2], Olle Melander[3], Tore Saxne[4] and Lennart TH Jacobsson[1], [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Section of MIG, Department of Laboratory Medicine, Lund, Lund University, Lund, Sweden, [3]Section of Medicine, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [4]Section of Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden

Purpose: Previous studies indicate that smoking is a predictor of rheumatoid arthritis (RA) and that anti-CCP antibodies may be detected in individuals who develop RA years before onset. Our purpose was to investigate circulating autoantibodies and their relation to smoking before the onset of RA.

Method: The study design was a nested case-control study. Between 1991 and 1996, subjects (n=30447; 12121 men and 18326 women) from a defined catchment area were included in a community based health survey. Information on life style factors was obtained using a self-administered questionnaire, and blood samples were stored from all participants. From this population, individuals who developed RA *after* inclusion were identified by linking the health survey database to a community based RA register and to local and national patient administrative registers. One control for each case, matched for sex, year of birth and year of screening, who was alive and free of RA when the index person was diagnosed with RA, was selected from the health survey. Anti-CCP antibodies, antibodies to mutated citrullinated vimentin (anti-MCV) and IgM RF were determined by ELISA.

Results: One hundred and seventy two patients (36 men/136 women, mean age at RA diagnosis 63 years, 67 % RF positive at diagnosis or later) were diagnosed with RA after inclusion in the health survey. The median time from inclusion to RA onset was 5 years (range 1-13). Current smoking was a predictor of RA ($p<0.001$). Serum was available from 169 cases and 168 controls. Pre-RA cases were more likely to be anti-CCP positive (>20 U/mL; 21.9 % vs 0.6 %; $p<0.001$), with similar patterns for anti-MCV and IgM RF, and among men and women when studied separately. All three antibodies were detected up to 10 years before disease onset. The median anti-CCP level for positive cases

was 82 U/mL (interquartile range 36-170). Pre-RA cases screened 1-4 years before disease onset were more likely to be anti-CCP positive compared to those included 5 or more years before disease onset (28% vs 17%). There was no major difference in current smoking habits between anti-CCP positive and anti-CCP negative pre-RA individuals (38% vs 36% current smokers), but anti-CCP positive pre-RA cases were more likely to have a history of ever smoking (85% vs 61%; p=0.009). Current smoking was a predictor of RA in analysis restricted to anti-CCP negative subjects (odds ratio 1.88; 95 % CI 1.13-3.12).

Conclusion: Current smoking was not associated with anti-CCP antibodies occurring before the onset of RA, but previous smoking may have played a role in their development. Current smoking predicted RA in the absence of anti-CCP antibodies. This suggests that smoking may influence several distinct mechanisms in the pre-clinical phase of RA.

Citrullinated Fibrinogen Stimulates TNF Release Via TLR-4 and Citrulinated Fibrinogen Immune Complexes Co-Stimulate through TLR-4 and Fc Gamma Receptor. Jeremy Sokolove[1], Xiaoyan Zhao[2] and William Robinson[3], [1]Stanford University Medical Center, Mountain View, CA, [2]Stanford University Medical Center, Palo Alto, CA, [3]Stanford School of Med, Stanford, CA

Purpose: Extravasation of fibrin(ogen) is ubiquitous in RA synovium and inflammation in general. Citrullinated proteins have been demonstrated within the inflamed synovium in RA and other forms of inflammatory arthritis and molecular characterization has consistently identified citrullinated fibrin(ogen) specifically. The presence of anti-citrullinated protein antibodies characterizes RA and has been associated with increased RA severity. The innate immune receptor TLR-4 is critical in murine models of RA and has been implicated in human RA. In addition to it's role in bacterial defense, several studies have demonstrated TLR-4 dependent signaling by damage associated non-microbial molecules including fibrin(ogen). We sought to determine whether citrullinated fibrinogen could stimulate through TLR-4 and whether citrullinated fibrinogen immune complexes could co-stimulate via TLR-4 and the Fc gamma receptor.

Methods: Murine peritoneal macrophages from wild-type or TLR-4 deficient mice or the murine macrophage cell line RAW 264.7 were used for in-vitro stimulation assays. Fibrinogen was citrullinated in-vitro at 37°C using rabbit PAD enzyme in the presence of 10mM CaCl and 5mM DTT. Native fibrinogen was treated identically except for the sham addition of PAD. Macrophages were treated with escalating doses of native fibrinogen (25-500 ug/ml), citrullinated fibrinogen (3.25-100 ug/ml), LPS, or citrullination buffer alone for 16 hours and supernatants subjected to ELISA to determine TNF secretion. Native or citrullinated fibrinogen immune complexes were formed by combination with rabbit anti-human fibrinogen polyclonal antibody and used to stimulate macrophages as above.

Results: Both native and citrullinated fibrinogen caused a dose dependent release of TNF from cultured murine macrophages and this effect was TLR-4 dependent. Citrullinated fibrinogen displayed significantly increased potency over native fibrinogen. Citrullinated fibrinogen immune complexes stimulated TNF release at levels significantly above that seen with citrullinated fibrinogen alone and this was attenuated in TLR-4 deficient macrophages. Further studies in human and animal systems including characterization of signaling pathways responsible for co-stimulation are currently under investigation.

Conclusion: This study demonstrates that citrullination of fibrinogen dramatically increases it's potency on TLR-4 mediated TNF release and that citrullinated fibrinogen immune complexes can co-stimulate through TLR-4 and Fc gamma receptor. Given that citrullinated fibrinogen, as well as several other RA associated autoantigens, are potential TLR-4 agonists, these observations suggest a novel pathogenic mechanism for RA associated autoantibodies in the initiation and propagation of synovial inflammation.

Dosage of the HLA Shared Epitope Alleles in Relationship to Anti-Citrullinated Protein Antibodies and Radiological Damage in Rheumatoid Arthritis. H. Ulrich Scherer[1], Diane van der Woude[2], Silje W. Syversen[3], Michael van der Linden[2], Benedicte A. Lie[4], Tom W.J. Huizinga[2], Désirée M.F.M. van der Heijde[2], Annette H.M. van der Helm-van Mil[2], Tore Kvien[3] and René E.M. Toes[2], [1]Charité University Medicine, Berlin, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Oslo University Hospital, Oslo, Norway

Purpose: HLA shared epitope (SE) alleles are associated with the presence of anti-citrullinated protein antibodies (ACPA), the epitope recognition pattern of ACPA, and with radiological damage in patients with rheumatoid arthritis (RA). The aim of the present study was to elucidate the relationship between the dosage of HLA SE alleles and ACPA fine specificity, and to investigate their independent effects on disease outcome.

Method: Antibodies recognizing five distinct citrullinated antigens were determined by enzyme-linked immunosorbent assay in sera from 150 ACPA-positive RA patients who had been genotyped for HLA SE alleles. Annual radiographs were scored according to the Sharp-van der Heijde method, and the association between ACPA fine specificity and radiological damage after 5 years was investigated by Mann-Whitney U-tests and a linear mixed model. To investigate if there was an ACPA-independent effect of the HLA SE alleles on radiographic damage in RA, the relationship between the dosage of HLA SE alleles, ACPA status and radiological damage was assessed. A second cohort of 238 RA patients with 5- and 10-year radiographic follow-up was used for replication.

Results: HLA SE alleles predisposed in a gene-dose dependent manner to the recognition of certain citrullinated peptides such as vimentin 59-74 (chi-square p-value <0.001) and enolase 5-20 (p=0.006), but not to others such as fibrinogen β 36-52 (p=0.5). None of the ACPA fine specificities studied was associated with progression of radiological joint damage. In both RA cohorts, the initial relationship between HLA SE alleles and radiological damage was no longer present after stratification for ACPA-status, demonstrating that there is no ACPA-independent effect of HLA SE alleles on disease outcome.

Conclusion: Our results indicate that there is no association between the fine specificity of the ACPA response and radiological joint damage. Neither the presence of HLA SE alleles, as a surrogate marker for the constitution of the ACPA response, nor any of the citrullinated epitopes analyzed, was associated with progression of joint damage. These findings are compatible with the hypothesis that HLA SE alleles are instrumental in the priming of naive T cells which subsequently provide help to ACPA-producing B cells.

The Periodontium Contains Citrullinated Proteins, PAD-2 Enzymes and HC Gp-39. W. Nesse, J. Westra, J. E. van der Wal, J. Balsma, F. Abbas, E. Brouwer and A. Vissink, University of Groningen and University Medical Center Groningen, Groningen, Netherlands

Purpose: Periodontitis is a chronic inflammation of the tissues anchoring the teeth within the jaws that is accompanied by loss of this anchoring tissue. Periodontitis is more common among rheumatoid arthritis (RA) patients and vice versa. The severity of RA is related to the severity of periodontitis, and treatment of periodontitis has been shown to lower the erythrocyte sedimentation rate and disease activity score of RA patients.

One hypothesis is that periodontitis might exacerbate or even induce auto-immunity. Anti-Cyclic Citrullinated Protein Antibodies (ACPAs) and human cartilage glycoprotein $39^{263\text{-}275}$/HLA-DRαβ1*0401 complexes (HC gp-39/HLAc), are highly specific for RA and are suspected of being involved in the etiology of RA. ACPAs target citrullinated proteins. Citrullination is catalyzed by Peptidyl Arginine Deiminase (PAD) enzymes. The present study was aimed at establishing the presence of citrullinated proteins, PAD-2 enzymes and HC gp-39/HLAc in periodontal tissue of periodontitis patients and in gingival crevicular fluid (GCF) samples of healthy controls.

Method: Periodontal tissue samples of 15 randomly selected periodontitis patients were stained for the presence of PAD-2 (Abcam, ab16478), citrulline (Chemicon, Ab5612) and HC gp-39/HLAc (Moab 12A, Organon). Synovial tissue samples of RA patients were used as a control for staining of PAD-2, citrulline and HC gp-39/HLAc. GCF samples were obtained from 8 healthy volunteers at sites exhibiting signs of gingival inflammation. They were tested for the presence of citrullinated proteins by Western Blotting (Anti-citrulline modification kit, Millipore). Synovial fluid of RA patients was used as positive control.

Results: Citrullined proteins and HC pg-39 were present in periodontitis tissue of respectively 6 and 7 out of 15 periodontitis patients. PAD-2 presence could not yet be ascertained in periodontitis tissue, possibly due to technical matters. Citrullinated proteins and PAD-2 were present in GCF samples of respectively 4 and 6 out of 8 healthy controls, at sites exhibiting gingival inflammation. Citrullinated proteins were present in synovial fluid of 5 out of 6 RA patients.

Conclusion: This is to our knowledge the first study showing that citrullination occurs *in vivo* in the periodontium, lending support to the hypothesis that periodontitis may exacerbate or even initiate ACPA formation. Furthermore, this study is the first to show that HC gp-

39/HLAc are present in periodontitis tissue. HC gp-39/HLAc presence was (up to now) thought to be highly specific for RA. In "healthy" controls**,** preliminary results also show presence of citrullinated proteins and PAD-2 enzymes in GCF taken from sites exhibiting gingival inflammation. Thus, the periodontium contains citrullinated proteins, PAD-2 enzymes and HC gp-39.

Dysregulation of Wnt/Beta-Catenin Signaling in Ank/Ank Mice Is Associated with Hypertrophic Chondrocyte Differentiation and New Osteoid Deposition in Articular Cartilage: a Novel Insight in a Mouse Model of Joint Ankylosis. F. Las Heras[1], K.P.H. Pritzker[2], H.W. Tsui[3], B. Chiu[3], F.W.L. Tsui[4] and R.D. Inman[4], [1]Mount Sinai Hospital. Institute of Medical Science. University of Toronto, Toronto, ON, [2]Mount Sinai Hospital. University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON, [4]Toronto Western Research Institute. University of Toronto, Toronto, ON

Purpose: The cellular basis of pathologic joint ankylosis remains unresolved. Wnt/β-catenin signaling activation has been associated with chondrocyte hypertrophy in animal models relating to osteoarthritis and joint ankylosis. To address the relation between the Wnt signaling pathway and the ankylosing process seen in *ank/ank* mice, we studied the pathology and β-catenin protein expression in articular chondrocytes from *ank/ank* mice.

Method: *ank/ank* mice and wild-type littermates at ages 8, 12 and 18 weeks (4 animals per time point) were used for this study. Sections from fixed, decalcified, paraffin-embedded knee joints were stained with hematoxylin and eosin. Chondrocyte size was determined using morphometric methods for articular cartilage in predetermined areas of the tibial plateau. Immunohistochemical staining with anti-collagen X, anti-tissue non-specific alkaline phosphatase (TNAP) and anti-β-catenin antibodies were performed on the fixed tissues.

Results: *ank/ank* chondrocytes in uncalcified cartilage were significantly larger than controls, in all age groups studied. *ank* mouse average chondrocyte area was 93.9 $\pm$ 36.0, 92.8 $\pm$ 30.4 and 100.0 $\pm$ 40.4 μm at 8, 12 and 18 weeks of age respectively, compared to an average chondrocyte area of 72.2 $\pm$ 29.2, 70.9 $\pm$ 25.0 and 64.8 $\pm$ 22.9 μm in wild-type mice. Two hypertrophic chondrocyte markers, collagen X and TNAP showed high expression in the articular chondrocytes of *ank/ank* mice. Immunohistochemistry for β-catenin expression revealed intense staining in *ank/ank* articular cartilage, with nuclear translocation. This strong cartilage staining was present in each age group studied. β-catenin was also expressed in *ank/ank* subchondral bone, primarily in osteoblasts and areas of new osteoid deposition. In contrast, β-catenin signal was only present in control mice at 8 weeks, with cytoplasmic but no nuclear staining.

Conclusion: The nuclear localization of b-catenin in the articular hypertrophic chondrocytes of *ank/ank* mice suggests that Wnt/b-catenin signaling plays a central role in these mice in the pathogenesis of joint ankylosis.

Genome-Wide Screening Newly Discovers That the Tnfα- and IL17- Inducible RGS1 Is the Most Highly Differentially Expressed Gene in Undifferentiated Spondyloarthritis (USpA). David T. Y. Yu[1], Yu-ling Wei[2], James C. Wei[3], Feng Huang[4], Ming-Shiou Jan[5], Mark B. Frank[6], Micheal Centola[7] and Jieruo Gu[8], [1]UCLA Med Schl/35-36 Rehab Ctr, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]Chung Shan Med Univ Hospital, Taichung, [4]Chinese PLA General Hospital, Beijing, China, [5]Chung Shan Medical University, Taichung, [6]Oklahoma Med Research Fdn, Oklahoma City, OK, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]3rd Affiliated Sun Yat-Sen Uni, Guangzhou

Purpose: Axial USpA is frequently considered to be an early form of ankylosing spondylitis (AS). Identifying the most highly differentially expressed PBMC gene will be useful in generating new diagnostic test and new experimental approach to pathogenesis of USpA and AS.

Method: Genome-wide microarray analyses followed by Realtime PCR validation of 25 promising candidates were carried out on PBMC from 20 healthy subjects, 21 AS and 28 axial USpA patients. 11 of the validated candidates were assessed again by PCR using a second cohort of 18 USpA, 23 AS, 12 RA, 8 mechanical low back pain patients and 26 healthy control subjects.

Results: Both microarray and PCR assays of the first cohort showed that the number of differentially expressed genes in USpA was > 6X more numerous compared to AS, which was surprisingly much less different from healthy subjects. Proinflammatory IL-1A, IL-1B, IL-6, IL-8 and several chemokines were differentially expressed only in USpA but not in AS. PCR results of the second cohort were in agreement. In both cohorts, RGS1 (regular of G-protein signaling-1) was identified as the most outstanding being 20.9 and 11.1 fold higher in USpA and AS compared to healthy subjects (p=0.000004 and 0.0002 after Bonferroni correction). RGS1 was not enhanced in RA or in those with mechanical low back pain. For distinguishing the combined USpA and AS group, the diagnostic potential was: sensitivity 84.2%, specificity 87.5%, +LR 6.7, PPV 97, NPV53.8. Evaluation of the specificity of RGS1 in the RGS family was carried out by comparing it to other members of the RGS family. PCR of the following common RGS members showed that only RGS1 carried diagnostic value: RGS -2, -3, -4, -5, -8. Next, to identify the responsible variant, we tested for RGS1 using 2 other pairs of primers spanning 2 different segments of the gene. The diagnostic potential was the same with all 3 pairs of primers. They also showed that the RGS1 isoform which was responsible was the Sp1 isoform. Although RGS1 has already been identified as candidate gene for diabetes and celiac disease, how it might cause pathology is unclear. Here, we tested 25 potentially arthritis-causing cytokines/chemokines with a cell line. TNFa and IL17 were discovered to be the strongest inducers of RGS1.

Conclusion: (1) The PBMC of USpA is different from AS in having many more highly expressed genes, including several which are proinflammatory. (2) The TNFa- and IL-17- inducible RGS1 is the most highly differentially expressed gene in USpA. (3) The role of RGS1 in SpA and other RGS1-related diseases is a new area of research.

Spondyloarthritis in HLA-B27 Transgenic Rats Is Prevented by Epididymo-Orchiectomy Even After Onset of Epididymo-Orchitis.

Joel D. Taurog, Nimman Satumtira and Martha L. Dorris, U-Texas SW Med Ctr, Dallas, TX

Purpose: In lines of rats transgenic (TG) for HLA-B27 and human β2m that develop spondyloarthritis (SpA), epididymo-orchitis (EO) develops in nearly all males. In the B27/hβ2m 21-3x283-2 F1 rats (*A&R* 54:1317, 2006), in which only males develop arthritis and spondylitis, EO is evident as scrotal swelling at a median age of 100 d, about 50 and 90 d before the median onset of arthritis and spondylitis, respectively. Here, we asked whether EO is a prerequisite for SpA in these rats.

Method: B27/hβ2m TG 21-3x283-2 F1 males underwent castration (bilateral resection of testis and epididymis), hemicastration (unilateral resection), or sham castration (scrotal incision only) between ages 36 d and 125 d. Castrated rats were given testosterone (T) replacement by either SQ implantation of T pellets or by twice-weekly SQ injections of T-17β-cypionate in sesame oil. Some sham castrated rats were given sesame oil alone. Rats were weighed, bled for serum, and observed for > 300 d for EO (in the sham and hemi- groups), arthritis, and spondylitis. Resected tissue was examined histologically.

Results: The earliest histologic inflammation was in the epididymis after 50 d of age, coinciding with the emergence of mature sperm. Histologic orchitis lagged epididymitis by several wks. The earliest age of arthritis onset was 112 d. As shown in the Table, no arthritis or spondylitis developed in the TG rats castrated before age 92 d (p=0.015 vs. sham castration, p=0.00004 vs. hemicastration), and these rats remained completely healthy. The arthritis that occurred in the rats castrated after 91 d of age had a later onset than in the control groups (p=0.034 compared with all controls). Only one rat of 8 castrated between 92 and 99 d developed arthritis, and this consisted only of dactylitis in a single digit that began at age 296 d. The other 2 rats that developed arthritis were castrated at 115 and 125 d.

Procedure	Age at procedure (d)	Total #	# arthritis	Age onset arthritis (median, d)	Maximum arthritis score (mean ± SD)	# spondylitis
Castration	43-91	18	0	—	—	0

Castration	92-125	11	3	296	2.3 ± 2.3	1
Sham castration	43-91	14	5	152	3.9 ± 2.5	1
Sham castration	92-115	7	5	158	5.4 ± 1.8	5
Hemicastration	36-91	21	13	148	4.8 ± 1.5	6

T pellet implantation resulted in serum T levels that tended to be below normal but were not significantly different from those found in the two control 21-3x283-2 groups. T ester SQ resulted in supraphysiologic serum T levels, but the growth curve was identical to that of the sham castrated rats.

Conclusion: Bilateral resection of testis and epididymis prevented subsequent development of SpA if carried out before the age of onset of arthritis, even if EO was already present. The data suggest that prolonged epididymitis and/or orchitis is an essential precursor of SpA in 21-3x283-2 F1 rats. Loss of physiologic androgen secretion is a formally possible, but much less likely, alternative explanation. The role of HLA-B27 in triggering EO in rats, and the role of genital tract inflammation in human SpA, are worthwhile topics for continued investigation.

Mast Cells Contribute to Synovial Inflammation in Non-Psoriatic and Psoriatic Spondyloarthritis. Troy Noordenbos[1], Nataliya Yeremenko[1], Tineke Cantaert[1], Christine Teitsma[1], Marleen van de Sande[1], Paul P. Tak[2], Juan D. Canete[3] and Dominique Baeten[4], [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [3]Hospital Clinic de Barcelona and IDIBAPS, Barcelona, Spain, [4]Academic Medical Centrum, Amsterdam, Netherlands

Purpose: We recently observed a striking synovial infiltration with cells positive for C-kit, a marker for mast cells and hematopoietic stem cells, in psoriatic arthritis (PsA). As mast cells have potent inflammatory functions, including the production of TNF, we performed a systematic analysis of C-kit positive cells in different forms of chronic inflammatory arthritis.

Method: Synovial tissue biopsies from active rheumatoid arthritis (RA)(n=21), non-psoriatic spondyloarthritis (SpA)(n=16), and PsA (n=23) were stained by immunohistochemistry and double immunofluorescence. Synovial fluid (SF) from RA (n=18), SpA (n=19), and PsA (n=16) was analyzed by ImmunoCap and ELISA. The effect of C-kit inhibition by imatinib mesylate on proinflammatory cytokine production was tested in vitro on fresh SpA synovial biopsies.

Results: C-kit positive mononuclear cells were found in the synovial sublining in all disease groups but were significantly increased in SpA (p=0.010) and PsA (p=0.001) versus RA despite similar levels of global inflammation as reflected by CD3, CD20, and CD68 staining. Double stainings confirmed that C-kit positive cells were not hematopoietic stem cells but mast cells. SF levels of SCF, IL-3, and IL-33, all factors involved in chemotaxis and differentiation of mast cells, as well as sST2, the soluble decoy receptor for IL-33, were similar in all groups. Most C-kit positive mast cells in SpA synovium were degranulated as indicated by double staining with toluidine blue and anti-tryptase and by SF analysis for mast cell products. Interestingly, the synovial infiltration with C-kit positive cells in SpA persisted despite successful treatment with TNF blockers. However, C-kit inhibition in vitro strongly reduced the production (mRNA by qPCR) and secretion (protein by ELISA) of IL-6 and IL-8 by synovial biopsies, suggesting that mast cells contribute to the ongoing inflammatory process.

Conclusion: There is an increased synovial infiltration with and degranulation of C-kit positive mast cells in non-psoriatic and psoriatic SpA. Inhibition of C-kit in vitro leads to a reduction of proinflammatory cytokine production by synovial biopsies. These data suggest a role for mast cells in driving and/or sustaining the synovial inflammation in SpA.

High-Density Genome-Wide Linkage Study in Spondyloarthritis (SpA) Families Identifies Three New Significant Susceptibility Chromosomal Regions. Maxime Breban[1], Félicie Costantino[2], Elena Zinovieva[2], Patrick Nitschke[3], Jean Philippe Jais[3], Emma Walton[2], Roula Said Nahal[1], Ivo Gut[4], Diana Zelenika[4], Gilles Chiocchia[2] and Henri Jean Garchon[2], [1]Ambroise Paré Hospital, Boulogne-Billancourt, France, [2]Institut Cochin, INSERM U567, Paris, France, [3]Université Paris-Descartes, Paris, France, [4]CNG, Evry, France

Purpose: The HLA-B27 allele is the major genetic susceptibility factor for SpA. However, the MHC region accounts for only half of the genetic predisposition to SpA. Previous linkage analyses have identified very few significantly linked non-MHC loci, of which a single locus called SPA2 on 9q31-q34 was replicated. More recent genome-wide association study spotted two highly relevant genes, ERAP1/ARTS1 and IL23R. Nonetheless, a significant fraction of the genetic predisposition to SpA remains to be explained. One major interest of linkage studies using large families is their potential to capture loci with low-prevalence disease alleles. Here, we report on a new genome-wide linkage scan using a large set of multiplex SpA families and a high-density panel of biallelic markers.

Method: 906 subjects from 144 families with multiple cases (range: 2-8 per family), comprising 334 affected-pairs were genotyped using Affymetrix® 250K single-nucleotide polymorphisms (SNPs) array. Genotypes were called using Chiamo. After removal of Mendelian errors, pedigrees were submitted to further cycles of error checking with MERLIN program. Multipoint non-parametric linkage analysis was then conducted with MERLIN using the Kong and Cox statistics and either a linear or an exponential model. Thresholds for significance and suggestiveness of linkage were computed as recommended by Lander and Kruglyak (Nature Genet 1995;11:241). Family-based association analyses of significantly linked regions were done using UNPHASED and FBAT.

Results: Besides the MHC that reached a maximum LOD score of 22.3 ($p < 10^{-10}$), 4 regions displayed significant evidence of linkage (LOD score ≥ 3.65; ≤ 0.05 false-positive region expected by chance): Xqter, 6p11-q11, 13q13 and 9q33 with maximum LOD scores of 5.94, 5.21, 4.38 and 4.06 respectively. Three of these regions are reported here for the first time. In addition, 12 regions were linked at a suggestive level (LOD score ≥ 2.23; ≤ 1 false-positive region expected by chance). Significantly linked regions were not affected by linkage disequilibrium modelling using the rsq option of MERLIN set at 0.1. Using this same data set, we initiated an association analysis of the 6p11-q11 region to pursue the linkage finding and detected 11 SNPs associated with P values ranging from $3x10^{-5}$ to $1x10^{-3}$. None of these SNPs was in linkage disequilibrium with the HLA-B27 allele located some 30 cM away ($D' < 0.1$ and $r^2 < 0.002$). Association analysis of other linked regions is underway. This will be followed by a replication study in independent trios and case-control sets.

Conclusion: In addition to the MHC and SPA2 locus, we identified several new chromosomal regions likely to influence SpA segregation in families. Our study emphasizes the interest of linkage studies using dense marker panels to elucidate the complex genetics of SpA.

HLA Class I and II Associations of Ankylosing Spondylitis. Matthew A. Brown[1], Rui Jin[2], B. Paul Wordsworth[3], Millicent Stone[4], M. M. Ward[5], Michael H. Weisman[6] and John D. Reveille[7], [1]Diamantina Institute of Cancer, Immunology and Metabolic Medicine, Woolloongabba, Queensland, 4102., Australia, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]NDORMS, Univ of Oxford, UK, Oxford, England, [4]University of Toronto, Toronto, ON, [5]NIH/NIAMS, Bethesda, MD, [6]Cedars-Sinai Med Ctr, LA, CA, [7]University of Texas Medical School at Houston, Houston, TX

Purpose: Whilst HLA-B27 is known to be the major MHC gene associated with AS, there is substantial evidence that other MHC genes, including other alleles of HLA-B and non-HLA-B loci, are also AS-associated. Association has been reported with HLA-B60 in many studies, but the subtype of B60 that is primarily involved is not known. Similarly, associations with HLA-DRB1 alleles, particularly HLA-DR1, have been reported in many series. Whether these are direct associations or reflect linkage disequilibrium with other MHC genes is unknown. We sought to investigate the MHC associations in AS in a large ethnically matched case-control cohort.

Method: 1376 Australian, British and North American AS cases of white European descent were typed for HLA-B, - C, -DRB1 and -DQB1 to 4 digit resolution. Control genotypes were available from 3610 controls from the 1958 British Birth Cohort (BC). Case-control comparisons were made by contingency table analysis for individual loci, and relative pre-dispositional effects analysis was performed to analyse the association of non-B27 HLA-B loci.

Results: In addition to association of HLA-B27 with AS, strong association was seen with non-B27 HLA-B alleles, (global association $P=10^{-15}$). This was due to associations with HLA-B38 ($P=2.7x10^{-6}$, OR=2.72), B40 ($P=1.5x10^{-5}$, OR=1.54), and B52 ($P=5.7x10^{-4}$, OR=2.53). These associations were confirmed in comparisons of both the UK and US cases independently, compared with the 1958 BC controls. The HLA-B40 association was mainly due to association of the B*4001 allele (P=0.0033, OR=1.39), with no significant association seen with the other major B40-split, B*4002 (P=0.1). Considering only B27-positive cases and controls, association was seen at HLA-DRB1 ($P=1.9x10^{-3}$) and DQB1 ($P=1.2x10^{-4}$), but not at HLA-C (P=0.3).

Conclusion: This study confirms that non-B27 HLA-B alleles including B38, B40 and B52 are significantly associated with AS. Association was also seen at HLA-DRB1 comparing B27-positive haplotypes, supporting the existence of non-HLA-B MHC associations with AS. Further SNP mapping in this dataset is being performed to refine these MHC associations.

ACR Concurrent Abstract Sessions

Health Services/Epidemiology: Osteoarthritis and Rheumatoid Arthritis

Monday, October 19, 2009, 2:30 PM - 4:00 PM

1172

Has Survival Improved in Patients Recently Diagnosed with Rheumatoid Arthritis? Cynthia S. Crowson, Elena Myasoedova, Eric L. Matteson, Hilal Maradit Kremers, Terry M. Therneau and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: It is known that rheumatoid arthritis (RA) is associated with increased premature mortality, which does not seem to have substantially improved in recent decades. We examined whether survival has improved for patients who developed RA since 1995.

Method: A population-based inception cohort of RA patients who fulfilled 1987 ACR criteria for RA between 1-1-1995 and 1-1-2008 was assembled and followed until death, migration, or 1-1-2009 for vital status. This cohort augmented our previous population-based cohort of RA patients who met criteria for RA between 1-1-1955 and 1-1-1995. Kaplan-Meier methods were used to estimate mortality rates. Cox proportional hazards models were used to compare survival by decade after adjusting for age and sex.

Results: The study population included a total of 1066 RA patients (mean age of 57.0 years, 71% women). Of these, 463 had incident RA in 1995-2007 (66% rheumatoid factor [RF] positive) with a mean follow-up of 6.3 years (total of 2956 person-years) during which 53 patients died. The remaining 603 patients (65% RF positive) had incident RA in 1955-1994 with a mean follow-up of 17.0 years (total of 10241 person-years) during which 419 patients died. In the 1995-2007 period, the 10 year survival was 79.5% (95% confidence interval [CI]: 74.0%, 85.4%). In comparison, the 10 year survival in the 1985-1994 decade was 70.7% (95% CI: 63.6%, 78.6%), which did not differ from the 3 decades prior to 1985 (p=0.87; see Figure). This represents a significant improvement in survival in RA patients diagnosed during the 1995-2007 period compared to the 1985-1994 decade (hazard ratio: 0.67; 95% CI: 0.45, 0.99; p=0.047) adjusting for age and sex. Further adjustment for RF positivity did not alter this difference. There was no evidence that this improvement in survival differed for RF positive compared to RF negative patients (interaction p=0.72).

Conclusion: Our findings suggest that survival in RA patients diagnosed since 1995 has significantly improved as compared to RA patients diagnosed in previous decades. Further study is needed to determine whether this improvement is related to more aggressive treatment strategies, the use of biologics, or other factors.

1173

The Relationship Between Use and Availability of Rheumatology Services. Crystal MacKay, Mayilee Canizares, Aileen Davis and Elizabeth M. Badley, Toronto Western Research Institute, Toronto, ON

Purpose: Access to rheumatology services is an ongoing challenge. Little is known about the patterns of use of rheumatology services and the relationship between use and availability of services. The objective was to examine health care visits to rheumatologists and availability of rheumatology services in a geographically defined region with universal health care coverage.

Method: Administrative data on physician billings from the regional health insurance plan database were used to examine ambulatory (outpatient) physician visits to rheumatologists in 2006/07. Person visit rates (number of people with visits per 100,000 population), visit rates (number of visits per 100,000 population), and age and sex distributions to rheumatologists were calculated. Availability of rheumatology services was examined using data from a survey of rheumatologists (2007). The relationship between rheumatology visits and availability of rheumatologists was examined using Poisson regression.

Results: Person visit rates to rheumatologists per 100,000 population were highest for osteoarthritis (OA) (311.9), followed by rheumatoid arthritis (RA) (305.8), and ill-defined conditions (e.g. pain in the leg) (155.4). Visit rates per 100,000 population were highest for RA (778.9) ill-defined conditions (616.2) and OA (361.3). The mean number of visits to rheumatologists for all arthritis was 2.0. Overall, person visit rates to rheumatologists increased with age for arthritis and related conditions. The female: male ratio was 2.6:1.

There were 1.2 rheumatologists per 100,000 population with geographic variation across the region. Overall, in areas with greater availability of rheumatologists, people with arthritis and related conditions were more likely to visit a rheumatologist ($p=0.01$). There was variation by specific condition. In areas with more availability, people with OA and other arthritis (e.g. soft tissue disorders) were more likely to visit a rheumatologist ($p=0.01$ and <0.0001, respectively). In contrast, visits for RA remained relatively consistent across regions, with no significant association between availability and use of rheumatologic services. This is consistent with results from the rheumatology

survey, in which rheumatologists reported shorter waiting times for likely inflammatory arthritis (mean =3.6 weeks) compared to non-urgent patients (mean=13.4 weeks).

Conclusion: Rheumatologists play a key role in the management of arthritis. While these findings suggest that availability influences utilization of rheumatologic services, it appears that rheumatologists may be prioritizing consultation with patients with inflammatory arthritis and seeing patients with non-inflammatory conditions if capacity is available. New models of care and strategies to enhance access to a full range of rheumatologic services are warranted in areas of low provision.

Disclosure: C. MacKay, None; **M. Canizares**, None; **A. Davis**, None; **E. M. Badley**, None.

1174

HMG-CoA Reductase Inhibitors (statins) Provides Primary Prevention for Rheumatoid Arthritis. Howard Amital[1], Gabriel Chodick[2], Yoav Shalem[2] and Varda Shalev[2], [1]Meir Medical Ctr, Kfar-Saba, Israel, [2]Department of Medical Informatics, Maccabi Healthcare Services,, Tel-Aviv, Israel

Purpose: The beneficial effects of statins on cardiovascular morbidity and mortality are unequivocally established. Recent findings indicate that statins also enhance anti-inflammatory effects in patients with various rheumatic conditions. Recent publications underline the presumptive role statins may have on treatment of rheumatic conditions; nevertheless data dealing with primary prevention of these disorders by statins are absent.

This study evaluated the effect of statin therapy in subjects with no indication of existing clinical or laboratory rheumatoid arthritis (RA) or osteoarthritis (OA)using the database of a one of the largest health maintenance organization (HMO) in Israel.

Method: This retrospective cohort study included all adults that were medically insured by the Maccabi Health services that had at least one dispensed monthly pack of statins between the 1.1.1998 through 31.12.2008. Patients who had precedent diagnosis of RA or OA prior to first purchase of statins (index date), were excluded. Patients that had a laboratory finding compatible with RA or were treated by a either a DMARD or a biological agent were excluded as well. The patients were followed throughout this period for the diagnosis of either RA or OA. These findings were validated by recording consequent relevant medications of laboratory tests.

In this study the population was sorted according to proportion of days covered (PDC) with statins subdivided by quintiles. The lowest quintile of PDC with statins served also as the control group.

Results: The study encompassed 211,627 patients (841,067 patient's years) who were treated. The percentage of females was 50.9% and of males 49.1%. During this period 2,578 new cases of RA were diagnosed (an incidence rate of 3.1 per 1,000 patient's year). During the same period among 193,699 patients (an overall 734,415 patient's years) 17,878 new cases of OA were diagnosed (an incidence rate of 24.3 per 1,000 patient's year). Analysis by quintiles revealed a clear and significant dose dependent decrease of RA incidence according to PDC quintiles (Fig. 1) whereas a significantly milder trend was demonstrated with OA. Patients in the highest PDC quintiles had a 40% decrease in the incidence rate of RA compared to 10% in patients with OA ($p<0.001$). Interestingly, the younger the age of which statin therapy was initiated, the higher the protective value it conferred (hazard ratio of 0.44, 0.56 and 0.62 in subjects who started by the age ranges of 18-55, 56-65 and 66-75 respectively, $p<0.001$).

Conclusion: In a "real life" database of a large HMO in Israel statin therapy may prevent future development of RA. A dose dependent manner was observed between the statin PDC and the prevention rate.

Figure 1 – A histogram demonstrating hazard ratios of the incidence of RA and OA in population without these diagnoses as function of statin proportion of days covered (PDC), $p<0.001$.

Rheumatoid Arthritis Susceptibility Variant at the CCL21 Locus Is Associated with Premature Mortality in Patients with Inflammatory Polyarthritis. T. Farragher[1], D. Plant[1], E. Flynn[1], S. Eyre[1], D. Bunn[2], W. Thomson[1], D. Symmons[1] and A. Barton[1], [1]arc Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Norfolk Arthritis Register, Norwich, United Kingdom

Purpose: Genome-wide association and subsequent replication studies have identified a number of confirmed rheumatoid arthritis (RA) loci in recent years. These findings have largely been established in cohorts with long-standing, severe disease and, as such, the identified variants could be markers of disease severity. RA is associated with premature mortality; indeed, this could be viewed as the ultimate marker of severe disease. Therefore, we aimed to establish whether any of the recently identified RA susceptibility loci are also associated with all-cause or cardiovascular disease (CVD) mortality in patients with inflammatory polyarthritis (IP).

Method: 17 single nucleotide polymorphism (SNPs) were selected for genotyping and tested using Sequenom® MassArray™ iPLEX chemistry in adults with recent onset IP recruited to a primary care-based inception cohort from 1989 to 2005. These SNPs were previously found in more than one well-powered study, to be markers associated with RA susceptibility and consisted of: rs1160542 (*AFF3*), rs2812378 (*CCL21*), rs763361 (*CD226*), rs4810485 (*CD40*), rs3087243 and rs231775 (*CTLA4*), rs6822844 (*IL2/IL21*), rs2104286 (*IL2RA*), rs743777 (*IL2RB*), rs6897932 (*IL7R*), rs1678542 (*KIF5A*), rs7574865 (*STAT4*), rs13207033, rs5029937 and rs6920220 (*OILG3/TNFAIP3*), rs10760130 and rs2900180 (*TRAF1/C5*). Vital status was ascertained from central records. The association of SNP marker allele carriage with mortality risk was assessed using Cox proportional hazard regression models after adjusting by gender. The mortality risks of those SNP marker alleles found to be associated were then stratified by anti-citrullinated protein/peptides antibody (ACPA) at baseline and shared epitope (SE).

Results: All 17 SNPs were successfully genotyped in 2,324 IP subjects. Carriage of 2 copies of the risk allele of rs2812378 mapping to the *CCL21* gene predicted increased all-cause mortality (hazard ratio (HR) 1.40; 95% confidence intervals (CI) 1.04, 1.87), while carriage of one or 2 copies also predicted increased CVD mortality (HR 1.33; 95% CI 1.01, 1.75). Although carriage of the *CCL21* risk allele was associated with mortality in those who were ACPA negative, the highest mortality risk was seen in subjects who had 2 copies of the *CCL21* risk alleles, 2 copies of SE and were ACPA positive (all-cause HR 3.20; 95% CI 1.52, 6.72: CVD HR 3.73; 95% CI 1.30, 10.72). The other 16 SNPs were not associated with increased mortality.

Conclusion: In this large study, we have found that carriage of the *CCL21* risk alleles was also associated with premature mortality in RA, independently of ACPA and SE status. Interestingly, CCL21 and its receptor CCR7 have previously been reported to play a role in the development of atherosclerosis. Therefore, the association between the risk allele at this gene and mortality, particularly CVD, highlights the potential inflammatory processes involved in the increased CVD risk experienced by RA patients.

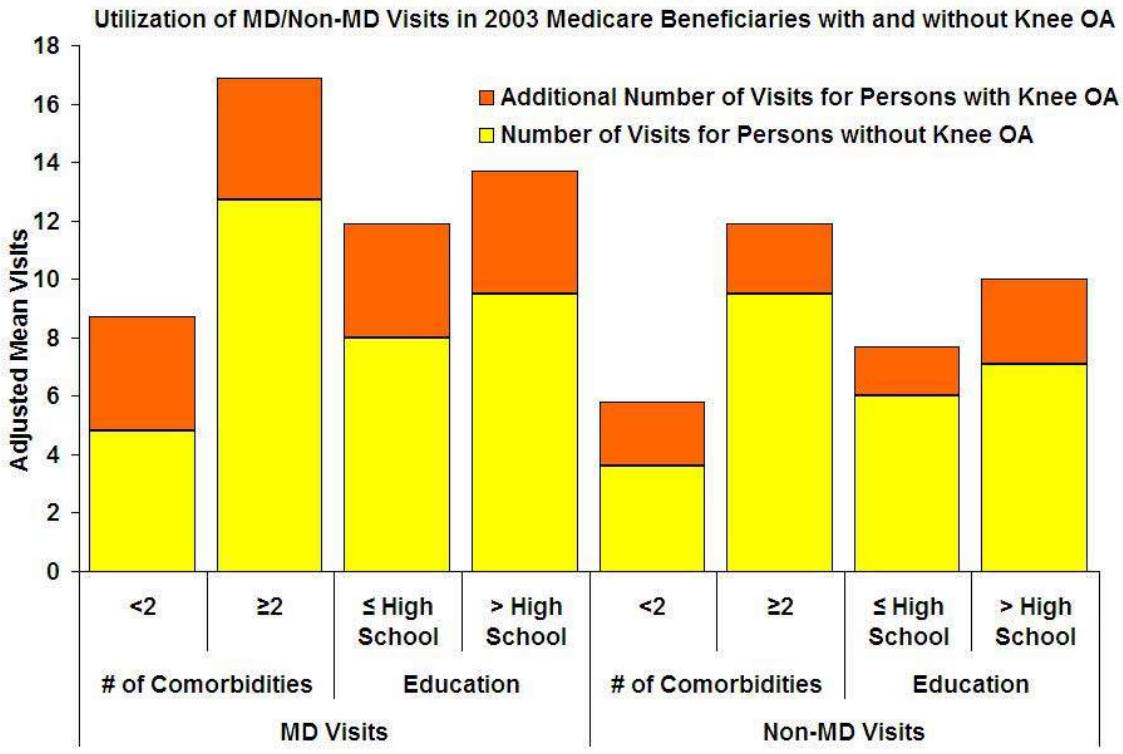
Effect of Knee Osteoarthritis On Outpatient Visits in a Population-Based National Sample. E.A. Wright[1], J.N. Katz[2], M.G. Cisternas[3], C.L. Kessler[1], A.G. Wagenseller[1] and E. Losina[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]MGC Data Services, Carlsbad, CA, [4]Brigham and Women's Hospital, BU School of Public Health and Harvard Medical School, Boston, MA

Purpose: The impact of osteoarthritis (OA) on outpatient health care utilization in population-based samples has been rarely studied. Accurate estimates of resource usage are critical for informed health care policy development.

Method: Using the 2003 Medicare Beneficiary Study (MCBS), we selected a national cohort of persons with primarily knee OA, based on ICD-9 codes (715.x6, 715.x9, 715.x0), and a randomly selected cohort of sex and age-matched OA-free persons. MCBS is a population-based survey of a stratified random sample of Medicare beneficiaries. Subjects completed a detailed questionnaire assessing demographic, socioeconomic and other factors. These data are linked to Medicare claims, which document health services utilization and treated comorbidities. We distinguished two components of outpatient health care utilization: visits to physicians (MD visits) and non-physician providers (non-MD visits, including nurses, physical therapists and laboratory studies). We built multiple regression models accounting for sampling weights to determine whether knee OA independently affected utilization, controlling for comorbidities (<2 vs. ≥2 conditions), obesity (BMI ≥30), functional limitation (difficulty walking), education (≤ vs. > high school), race and working status (full/part-time or not working).



Results: The MCBS cohort included 12,486 Medicare beneficiaries. Of these, 1,410 (11%) met our definition of OA (OA+) and were matched to 2,820 OA free (OA-) individuals. Mean age in both cohorts was 77 years; 70% were female. OA+ and OA- differed significantly

in obesity (OA+: 29%, OA-: 19%), % with ≥ 2 comorbidities (OA+: 65%, OA-: 45%), and functional limitation (OA+: 38%, OA-: 27%). The OA+ cohort had significantly more MD visits (15.6) and non-MD visits (11.4) than the OA- cohort (9.8 and 7.5, respectively). In multivariable regression models controlling for age, sex, comorbidities, obesity, functional status, race, education and working status, knee OA independently predicted increased MD and non-MD visits. In particular, the OA+ cohort had on average 4.1 more MD visits (95% CI: 3.5, 4.8) and 2.6 more non-MD visits (95% CI: 2.1, 3.1) than the OA- cohort. The figure shows the incremental number of visits due to knee OA stratified by education and by number of comorbidities.

Conclusion: This first national, population-based study of health care utilization in OA documents considerable outpatient usage attributable to knee OA, independent of the effects of comorbidity, education and other patient characteristics. These findings should be considered in policy decisions affecting outpatient resource utilization in the elderly.

1177

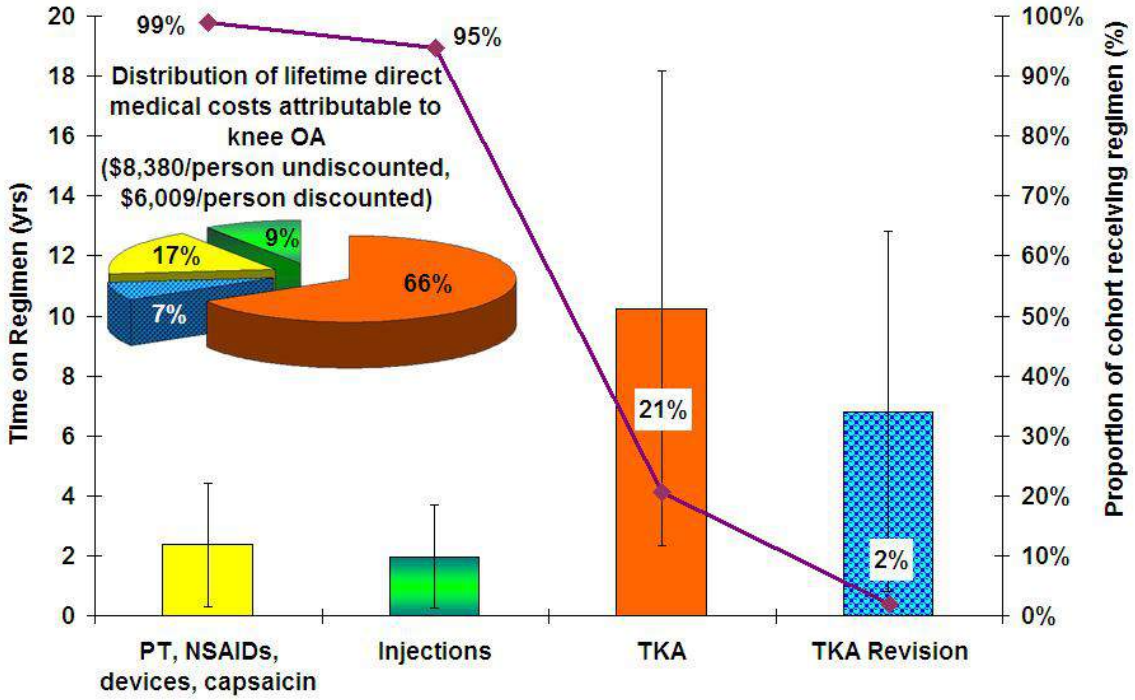
Cost-Effectiveness of ACR Guideline-Based Care and Lifetime Direct Medical Costs Attributable to Knee OA Management in the US. E. Losina[1], N.N. Niu[2], H.L. Holt[3], W.M. Reichmann[3], D.J. Hunter[4], L.G. Suter[5], D.H. Solomon[2], E.H. Yelin[6], J.M. Jordan[7], R.P. Walensky[8], A.D. Paltiel[5] and J.N. Katz[2], [1]Brigham and Women's Hospital, BU School of Public Health and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]New England Baptist Hospital, Boston, MA, [5]Yale University, New Haven, CT, [6]UCSF, San Francisco, CA, [7]University of North Carolina, Chapel Hill, NC, [8]Brigham and Women's Hospital and Massachusetts General Hospital, Boston, MA

Purpose: Knee OA is debilitating and affects >4.5 million US adults. ACR treatment guidelines include pain management, physical therapy (PT), NSAIDS, intra-articular steroid injections and total knee arthroplasty (TKA) for those who reach end-stage disease. There have been no studies estimating cost-effectiveness (C-E) of ACR treatment guidelines or costs attributable to knee OA.

Method: We used a validated computer simulation model of knee OA natural history and management to follow a cohort of newly diagnosed knee OA patients (mean age 60, 54% female, 65% K-L 2, 30% K-L 3, 5% K-L 4) to death. Treatment efficacy and toxicity were derived from published literature; OA progression was derived from Johnston County Osteoarthritis Project and calibrated to published literature. Prevalence of comorbidities and quality of life estimates were derived from NHANES and mortality, from US life tables. Treatment costs were derived from Medicare reimbursement and Red Book (range: $609/yr for PT, NSAIDS, devices and capsaicin to $20,456 for TKA). The cost of background pain control was $551/yr. Costs related to other co-morbidities ranged from $557/yr for 0-1 to $3,603/yr for >3 co-morbidities. We considered four scenarios: 1) no treatment; 2) pain control only; 3) ‘ideal': 100% of patients on ACR-recommended treatment; 4) ‘real': acceptance ranging from 100% for NSAIDS, PT, capsaicin to 30% for TKA and 12% for TKA revision. The C-E of ACR recommended treatment was estimated as the ratio of incremental cost to incremental effectiveness (expressed in quality-adjusted life years, QALYs). Costs (in 2008 $US) are reported as total direct medical costs and costs attributable to knee OA. Both costs and QALYs were discounted at 3%/yr.

Results: Discounted life expectancy of persons with knee OA was 15.6 years (22.2 years, undiscounted) or 11.9 QALYs. Background (unrelated to knee OA) medical costs were $11,862. Pain control increased costs by $7,434 without altering QALYs. ‘Ideal' ACR guideline-based treatment yielded costs of $25,052 and improved QALYs by 0.47, yielding an incremental to ‘no treatment' cost-effectiveness ratio of $28,060/QALY. Figure 1 illustrates average time spent, distribution of cost attributed to and proportion of original cohort on each regimen according to ‘real' scenario.

Figure 1: Distribution of life time direct medical costs, time on regimens and proportion receiving each regimen



Conclusion: ACR guideline-based knee OA care is very cost-effective. Lifetime costs attributable to knee OA represent a relatively small part (24%) of total direct medical costs. Using a conservative estimate of 4.5M affected by knee OA in US, $27 billion will be spent on knee OA related care.

1178

Developing a Cartilage Scoring System for RA Using 3T MRI Scanning. Andrew Clarke[1], Alexandra McHaffie[1], Quentin Reeves[1], Nicola Dalbeth[2], Arista Chand[3], Elizabeth Robinson[3], Megan Williams[1] and Fiona M. McQueen[4], [1]Auckland District Health Board, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Auckland, New Zealand, [4]University of Auckland, Auckland

Purpose: To develop and test an MRI score for quantifying cartilage loss and/or damage at the wrist in RA using a high field 3T system

Method: MRI scans were obtained on a Philips Achieva 3T MRI scanner with a dedicated 8 element phased-array wrist coil in 22 early RA patients (duration less than 2 years), 16 established RA patients (duration 5 - 35 years) and 22 healthy controls. The following turbo spin echo sequences were used: T1 weighted and T2 weighted with fat saturation in the axial and coronal planes and proton density coronals including an ultra high resolution sequence. T1 weighted fat saturation axial and coronal sequences were obtained post intravenous

gadolinium. Eight sites were chosen within the wrist where cartilage could be profiled well including 1) distal radio-ulnar joint, 2) radiolunate joint, 3) radioscaphoid joint, 4) triquetrum-hamate joint, 5) capitate-lunate joint, 6) scaphotrapezoid joint, 7) 2nd metacarpal base-trapezoid joint and 8) 3rd metacarpal base-capitate joint (Figure 1 shows sites 2 - 6 on a coronal view of the wrist). Cartilage was scored using a system based on the Sharp van der Heijde score for XRay joint space narrowing: 0 (normal thickness), 1 (asymmetrical or minimal narrowing to maximum of 25%), 2 (definite narrowing with loss of up to 50% of the normal space), 3 (definite narrowing with loss of 50-99% of the normal space or subluxation, 4 (absence of joint space, presumptive evidence of ankylosis or complete luxation). Scores were obtained independently by 3 musculoskeletal radiologists. Sum scores were assessed for reproducibility. 15 sites at the wrist were also scored for synovitis, bone oedema and erosion using the RAMRIS system as published (1).

Results: Intraclass correlation coefficients (ICCs) for inter-observer reliability for cartilage scoring between the 3 readers was excellent: ICC= 0.91, (95% CI: 0.86, 0.94). For other RAMRIS components ICCs were as follows: bone erosion 0.79, (95% CI: 0.61, 0.88), bone oedema 0.80, (95% CI: 0.50, 0.91) and synovitis 0.63, (95% CI: 0.46, 0.77). Cartilage scores (median, range) were higher in the established RA group (12.5, 0-30) than the early RA group (2.0, 0-7) ($p = < 0.0001$) but early RA cartilage scores did not differ from healthy controls (2.0, 0-10). Cartilage scores correlated with RAMRIS synovitis ($r = 0.52$), bone oedema ($r = 0.63$) and bone erosion scores ($r = 0.66$), $p < 0.0001$ for all.

Conclusion: A scoring system has been devised to allow quantitation of cartilage thinning in the RA wrist, using high field 3TMRI. This has been shown to have excellent inter-reader reliability and should allow the measurement of cartilage loss to be added to other parameters of RA joint damage. Results suggest that cartilage loss may not be an early feature of disease.

Comparison of Diffusion-Weighted and Diffusion Tensor Magnetic Resonance Imaging of Abnormalities in the Muscles of Polymyositis Patients. Jane H. Park[1], Brittany C. Lee[1], Jing Qi[1] and Nancy J. Olsen[2], [1]Vanderbilt Medical School, Nashville, TN, [2]Univ TX Southwestern, Dallas, TX

Purpose: To characterize and compare diffusion abnormalities in areas of inflammation and fat infiltration in the thigh muscles of polymyositis (PM) patients using diffusion-weighted MRI (DWI) and diffusion tensor MRI (DTI).

Methods: Unaffected, inflamed, and fat-infiltrated muscles were identified in 2 PM patients based on T1- and T2-weighted images, STIR images, and T1 and T2 relaxation times. PM 1 showed focal inflammation in the vastus lateralis and adductor magnus. PM 2 with chronic disease had fat infiltration in the vastus lateralis, intermedius, medialis, and also the adductor. Both patients had 3 unaffected hamstring muscles (biceps femoris, semitendinosus, and semimembranosus) with normal imaging characteristics. For DWI, a diffusion-weighted echo planar imaging sequence with 23 different diffusion gradients (b-values) and 4 orientations was used. DTI images were obtained with a diffusion weighted spin-echo echo-planar pulse sequence in 6 directions at b = 600 s/mm^2. DWI data were analyzed for apparent diffusion coefficients (ADC), diffusion (D), and perfusion (D*) using exponential curve fits. For DTI, ADC and eigenvalue (λ_1, λ_2, λ_3) calculations and fiber tracking were performed using PHILIPS software (PRIDE).

Results: ADC values calculated from DWI and DTI images were similar and significantly correlated ($r = 0.925$, $P < 0.001$). Inflamed muscles in PM 1 had higher ADC values compared to unaffected hamstring muscles ($P < 0.05$) (Table 1). Fat-infiltrated muscles in PM 2 showed lower ADC values compared to unaffected muscles ($P < 0.02$). DWI data analyzed with a biexponential curve fit gave D values within the muscle compartment and capillary D* values relative to the X, Y, and Z axes of the magnet. For DTI, λ_2 and λ_3 were higher in inflamed muscles ($P < 0.05$), and λ_1 - λ_3 were lower in fat-infiltrated muscles compared to unaffected muscles ($P < 0.05$). ADC, λ_1, and λ_2 were negatively correlated with the percentage of fat in PM muscles ($P < 0.05$). Tractography showed affected muscles had more erroneous and curved fibers that were significantly shorter than those in unaffected muscles ($P < 0.05$).

Conclusion: DWI and DTI demonstrated similar ADC values with increased motion in inflamed muscles and decreased motion in fat-infiltrated muscles. DWI produced lower, more exact D values within the muscles, higher D* values in capillaries, and designated motion relative to the axes of the magnet. DTI detailed water movement parallel (λ_1) and perpendicular (λ_2, λ_3) to the long axis of the muscle fiber. DTI tractography also showed fiber tracts were shortened with inflammation and fat infiltration. DWI and DTI characterize fluid motion and fiber structure which are important for metabolite transport and fiber strength.

Table 1. DWI and DTI measurements. ADC, D, D* = (x 10^{-3} mm^2/s)

	DTI		**DWI**		
Patient	**Fiber length** (mm)	**ADC**	**ADC**	**Diffusion (D)**	**Perfusion (D*)**
Unaffected (1)	63.4	1.57	1.57	1.27	5.6

Variable X-Ray Beam Angulation Improves Quality of Medial Tibial Plateau Alignment in Fixed-Flexion Knee Radiographs of Osteoarthritis (OA) Patients. Kalyan Alapati[1], Ilana Belitskaya-Levy[2], Mark Schweitzer[3], Nogah Shabshin[4], Jonathan Samuels[1], Steven B. Abramson[5] and Svetlana Krasnokutsky[1], [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU School of Medicine, New York, NY, [3]The University of Ottawa, Ottawa, [4]Chaim Sheba Medical Center, Tel Hashomer, Israel, [5]NYU School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Purpose: To assess whether variability in caudal X-ray beam angulation (CBA) improves alignment of the medial tibial plateau (MTP) versus a fixed 10° CBA, using non-fluoroscopic fixed-flexion knee radiographs.

Methods: 133 subjects with knee OA underwent fixed-flexion AP X-ray examinations as part of a longitudinal study. We performed a cross sectional substudy in which 90 subjects were imaged with a 10° CBA (Method 1) and 43 subjects were imaged using different CBAs (choosing from 5°, 10°, 15°) determined by a trained radiology technician, depending on MTP alignment assessed in real time (Method 2). After reading a blinded training set of radiographs, an experienced radiologist, who was blinded to patients and method used, read the x-rays for MTP alignment quality using a 1-5 scale (1,2=good, 3=acceptable, 4= poor, 5= unacceptable), and for Kellgren-Lawrence (KL) grade.

Results: Method 1 subjects (10° angulation): MTP alignment quality was scored as good or acceptable 62% and 69% of the time for the right and left knees, respectively. Method 2 subjects (variable angulation): Variable angulation resulted in good or acceptable MTP alignment quality on at least one x-ray 86% and 88% of the time for right and left knees, respectively. When CBA was changed, MTP alignment quality changed 84% of the time for the right knee and 77% of the time for the left knee in subjects who had at least 2 radiographs (n=43). The KL grade changed 28% and 46% of the time in the right and left knees, respectively, when MTP alignment quality changed in the same knee. The KL grade changed 38% and 36% of the time in the right and left knees, respectively, when there was no change in MTP alignment quality but there was a change in CBA. A change in CBA resulted in MTP alignment quality change in bilateral knees 66% of the time, of which this change was in the same direction (improved vs worsened) 86% of the time. Using a CBA of 10° resulted in improved (over other angulations) MTP alignment quality 53% and 50% of the time for the right and left knees, respectively. Using a CBA of 10° resulted in worsened MTP alignment 33% and 22% of the time for right and left knees, respectively.

Conclusion: While fixed 10° CBA in fixed-flexion radiographs results in acceptable or good MTP alignment quality the majority of the time, variable CBA improves this frequency in knee OA subjects. Changes in CBA often change the MTP alignment quality, usually in the same direction in both knees, and sometimes change the KL grade. More studies are needed to determine the optimal CBA for non-fluoroscopic fixed-flexion protocols and all radiographic knee OA studies should report the specific techniques used, including CBA.

Bone Marrow Edema Is An Independent Predictor of Progression of MRI Erosions After 3 Years in Patients with Early Rheumatoid Arthritis. Siri Lillegraven[1], Espen A. Haavardsholm[1], Pernille Bøyesen[1], Mikkel Østergaard[2], Till Uhlig[1] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Hvidovre and Gentofte, Denmark

Purpose: The presence of magnetic resonance imaging (MRI) bone marrow edema (BME) in early rheumatoid arthritis (RA) has been shown to be a predictor of erosive disease after one and two years (1;2). We examined predictors of 3-year progression in OMERACT RA MRI (RAMRIS) erosion score.

Methods: 50 RA patients were recruited from a cohort of consecutively enrolled patients with disease duration of less than one year. The patients were examined clinically and with MRI of the dominant wrist (GE Signa 1.5 Tesla MRI scanner, General Electric (GE) Signa, Milwaukee, WI, USA) at 0, 3, 6, 12 and 36 months, and serum was collected at all time points. Patients were treated according to standard clinical practice. MRI erosive progression of at least three RAMRIS units after three years was used as dependent variable in logistic regression analyses. Possible predictors of erosive disease (anti-ccp status, RF-status, ESR, CRP, DAS28, smoking, RAMRIS bone marrow edema, RAMRIS synovitis, tender and swollen joint count, DXR change from 0 to 3 months, MMP3 and YKL40 levels) were tested in univariate models, and variables with $p<0.2$ were included in further multivariate analyses, adjusting for age and gender.

Results: The median baseline age (25th percentil, 75th percentile) was 57.0 (46, 65) years, disease duration was 95 (72, 153) days, 76% were female, 50% were RF positive and 56% were anti-CCP positive. 13 patients (26%) were classified as MRI progressors. In the

univariate analyses, anti-CCP, RF, RAMRIS synovitis, RAMRIS BME and DAS28 were associated with 3-year change in RAMRIS erosions at the p<0.2 level. In the multivariate analysis, using backward elimination, BME was the only independent predictor of progressive erosive disease with an odds ratio of 1.19 (CI 1.03, 1.38, *p*=0.02) per unit BME. RAMRIS BME in patients with or without 3-year progression of erosions is shown in a cumulative probability plot (Figure).

Conclusion: Baseline amount of RAMRIS BME was the only independent predictor of MRI erosive progression after 3 years. These findings further support that presence of BME is an important predictor of long-term progression of bone erosions in RA.

Comparative Study of MRI and Power Doppler Ultrasonography (US) of the Heel in Spondyloarthritis (SpA) Patients with and without Heel Pain and in Controls: The ETERS Study. Marie-Charlotte Lavie[1], Laure Gossec[2], Frédéric Lavie[3], Henri Guerini[1], F. Rannou[4], Christelle Nguyen[4], Xavier Ayral[1], Antoine Feydy[5] and M. Dougados[6], [1]Cochin Hospital Paris France, Paris, France, [2]French Society of Rheumatology Patient Education, Paris, France, [3]Cochin Hospital, Rene Descartes University, Paris, Paris, France, [4]Paris Descartes University, Cochin Hospital, AP-HP; INSERM, Federative Institute on Handicap Research (IFR 25), Paris, France, [5]Paris Descartes University, Cochin Hospital, AP-HP, [6]Hôpital Cochin, Rene Descartes University, Paris, Paris, France

Purpose: Enthesitis of the heel is frequent in spondyloarthritis (SpA). However symptomatic heel pain occurs only in a minority of SpA patients. Magnetic resonance imaging (MRI) and Power Doppler ultrasonography (PDUS) may visualize posterior and inferior inflammatory heel lesions but their utility is debated. To assess the diagnostic capacities of MRI and of PDUS of the heel : a) to distinguish patients with SpA versus controls; and b) to distinguish SpA patients with versus without heel pain.

Method: Cross-sectional, monocenter study. In all, 72 patients (144 heels) were included: definite heels SpA patients according to Amor's criteria (n=96) were divided into 3 groups: (1) heels with no history of pain (n=57), (2) heels with history of pain (n=18), (3) heels with current pain related to enthesitis according to clinical examination and expert opinion (n=21). Patients with degenerative low back pain (48 heels) group (4)) were included as a control group. Bilateral heel MRI (coronal STIR, sagittal STIR and sagittal T1 images) and PDUS were performed by two different senior musculoskeletal radiologists blinded to other data, the same day as clinical evaluation. Imaging analysis was focused on inflammatory signs.

MRI was considered as positive if any of the following signs were observed: Intra or peri Achilles tendon or aponeurosis hypersignal, Achilles tendon thickness > 5.29 mm, retrocalcaneal bursitis, plantar fascia thickness > 4.4 mm, or calcaneus bone edema. PDUS was considered as positive if any of the following signs were observed: Achilles tendon or aponeurosis echostructure abnormality, Achilles tendon thickness > 5.29 mm, plantar fascia thickness > 4.4 mm, retrocalcaneal bursitis, or presence of abnormal Power-Doppler signal.

Results: For the whole population, mean age was 50+/- 18 yrs, and 53% were male. Among SpA patients, 82% were B27+ and 64% had sacro-iliitis (mean symptom duration, 13+/-12 yrs). Inferior bone edema was the only specific abnormality of SpA (18% of SpA heels vs 4 % of controls heels, p=0.020), but with a poor sensitivity. PDUS showed no specific abnormality of SpA, even when using the power Doppler. However, among patients with SpA, painful heels presented more inflammatory abnormalities than painless heels (81% versus 56% in MRI, p=0.045, and 58% versus 17% in PDUS, p=0.008, respectively).

Conclusion: Heel MRI and PDUS show frequent abnormalities (inflammatory lesions) in SpA and more so in painful heels. However, they are also frequently abnormal in controls. Our results suggest that heel MRI and PDUS cannot be used for the diagnosis of SpA. However, PDUS and MRI may be useful for the depiction and assessment of enthesis inflammatory lesions in SpA with heel pain.

Tenosynovitis On Ultrasonography Predicts Erosive Progression On MRI in Early RA Patients: AFollow-up Study. Siri Lillegraven[1], Espen A. Haavardsholm[1], Pernille Bøyesen[1], Hilde B. Hammer[1], Mikkel Østergaard[2], Till Uhlig[1] and Tore K. Kvien[1], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Hvidovre and Gentofte, Denmark

Purpose: It has been shown that the presence of bone marrow edema (BME) on magnetic resonance imaging (MRI) in early rheumatoid arthritis (RA) is a predictor of erosive disease. Less is known about the predictive value of early ultrasonography (US) findings. The main objective of this report was to study US as predictor of progressive erosive disease in early RA.

Methods: 61 RA patients from a cohort of consecutively enrolled RA patients with disease duration < 1 year were examined with US of the dominant wrist, MRI of the dominant wrist (performed on a GE Signa 1.5 Tesla MRI scanner) and clinical examination at 0, 3, 6, 12 and 36 months. All US examinations were performed by the same experienced ultrasonographer (HBH) with an 8-16 MHz linear array transducer (Diasus, Dynamic Imaging, Scotland). The degrees of B-mode synovitis and tenosynovitis were scored as 0=none, 1=minor, 2=moderate and 3= high. All patients were treated according to standard clinical practice. Erosive progression of one or more units on the OMERACT RA MRI (RAMRIS) erosion score after one year was used as dependent variable in logistic regression analyses. Possible predictors of erosive disease were tested in univariate models, and variables with a p-value < 0.2 were used in further model building. Age and sex were included in all models.

Results: The median (25th percentile, 75th percentile) baseline age was 57.0 (45, 65) years, disease duration was 107.5 (76, 190) days, 75% were female and 56 % were anti-CCP positive. In univariate analyses, extensor carpi ulnaris (ECU) tenosynovitis detected with US, total US inflammation score, CRP, RAMRIS synovitis, RAMRIS BME and swollen joint count were associated with 1-year change in RAMRIS erosions at the p<0.2 level. In the logistic regression model, using backward elimination, BME and US-tenosynovitis at the ECU tendon were independent predictors of progressive erosive disease after one year (table). The picture shows a cross-sectional view of B-mode ECU tenosynovitis.

	B	***p*-value**	**OR**	**CI for OR**
US Tenosynovitis at extensor carpi ulnaris	1.44	0.03	4.21	1.18 - 15.0

RAMRIS bone marrow edema	0.32	0.05	1.38	1.00 – 1.90

Conclusion: US tenosynovitis was an independent predictor of erosive progression measured by MRI during the subsequent year. This suggests that US may contribute to prediction of erosive progression in RA.

Natural History of Restricting Back Pain in Community-Living Older Persons. Una E. Makris[1], Liana Fraenkel[2], Leo M. Cooney[1], Linda Leo-Summers[3] and Thomas M. Gill[1], [1]Yale School of Medicine, New Haven, CT, [2]Department of Veterans Affairs, West Haven, CT, [3]Program on Aging, New Haven, CT

Background: Back pain is a common complaint among older persons, with prevalence rates as high as 47% in some groups. Prior research has shown that back pain in older persons is associated with subsequent disability in activities of daily living and mobility. It is also associated with depression, poor self-reported health, and increased utilization of health care resources. Despite the considerable morbidity and costs attributable to back pain, data describing the natural history of this disorder in older persons are sparse.

Purpose: To elucidate the natural history of restricting back pain in community-living older persons over an extended period of time.

Methods: We evaluated the 754 participants (mean age 78.4 years, 64.6% women) of the Yale Precipitating Events Project, a longitudinal study of community-living persons, aged 70+ years, who were all non-disabled in activities of daily living at enrollment. The participants completed monthly assessments of restricting back pain, defined as staying in bed for at least half a day and/or cutting down on one's usual activities due to back pain, for up to 10 years of follow-up. One or more consecutive monthly reports of restricting back pain defined an episode. Descriptive statistics, including the rate, number of episodes per participant, frequency, duration of episode, and time between restricting back pain episodes were calculated.

Results: The overall rate of restricting back pain, based on a median follow-up of 107 months, was 5.1 per 100 person-months. 550 participants (72.9%) had at least one episode of restricting back pain and 413 (54.8%) had multiple episodes. Among the 550 participants with restricting back pain, the median number of episodes was 3 (range: 1-29), and the average (SD) duration of each episode was 1.4 (0.9) months (range: 1-11). Restricting back pain lasting at least 2 months (i.e. persistent) was observed in 238 (31.6%) participants. Of the 2,508 episodes of restricting back pain, 78.5%, 14.0%, 4.4% and 3.0% had a duration of 1, 2, 3, and 4+ months, respectively. Overall, the time between episodes of restricting back pain decreased as the number of episodes increased ($P < .001$); for example, the median number of months (interquartile range) was 9 (4-24) between the 1st and 2nd episodes, 7.5 (3-20) between the 2nd and 3rd episodes, and 5.5 (3-12) between the 3rd and 4th episodes.

Conclusion: Among community-living older persons, restricting back pain is a common disorder that often recurs, although episodes are usually short-lived. Additional research is needed to further characterize the natural history, risk factors and precipitants of restricting back pain, with the ultimate goal of preventing the onset and/or recurrence of this common disorder.

Effectiveness of the Physical Therapy Agents On Lumbar Spondylosis Treatment. Mehmet Zeki Kiralp[1], Engin Cakar[2], Umit Dincer[2] and Oguz Durmus[2], [1]Associate Professor, Istanbul, Turkey, [2]MD, Istanbul, Turkey

Background: Lumbar spondylosis is a common reason of low back pain and disability in elderly people. Therapeutic approaches are range from physical therapies and noninvasive medications to some spinal interventions and surgery. Transcutaneous electrical nerve stimulation (TENS), ultrasound, hot pack and exercises are common physical therapy modalities.

Purpose: The objective of this study was to evaluate the effectiveness of physical therapy agents in lumbar spondylosis in regard to pain, disability, health quality, balance and fall risk.

Method: This was a prospective randomized controlled study. 57 patients who had lumbar spondylosis and radiological stages were 2-3 according to Kellgren Lawrence grading scale were recruited. The patients were randomized to two groups. One group was physical therapy group which the therapy contains therapeutic exercises, ultrasound, TENS, hot pack. The other group was only therapeutic exercise group. The therapy contained 15 sessions (1 session per day, 5 weekdays).

Result: At the end of the study, all of the outcomes of physical therapy group were improved significantly except the medial/lateral index of postural stability test. On the other hand, the only exercises group, only the VAS and Oswestry scores improved. Interrgroup comparisons of the final scores were also showed that physical therapy groups' all of the scores except the mental health score of the SF 12 and medial/lateral stability score (Table 1).

Conclusion:

The combination of the physical therapy agents (ultrasound, TENS, hot pack) with therapeutic exercises in the lumbar spondylosis therapy is an effective approach in regard to pain, disability, health quality, and balance and fall risk.

Modified Phalen's Test as An Aid in Diagnosing Carpal Tunnel Syndrome. Donald M. Loveman[1], Sayeeda Bilkis[2], Shabnam Asgher Ali[3], Abdul Kadir[4] and James A. Eldridge[5], [1]TTUHSC, Odessa, TX, [2]Reeves County Hospital, Pecos, TX, [3]Louisiana State Univ Hlth Sci Ctr, Shreveport, LA, [4]Odessa, TX, [5]University of Texas of the Permian Basin, Odessa, TX

Purpose: Carpal tunnel syndrome (CTS), the most common peripheral entrapment neuropathy, is typically evaluated in the outpatient setting by sensory and motor examination supplemented by two provocative tests, Phalen's Test and Tinnel's Test. A Modified Phalen's Test (MPT) in which sensory testing is performed in the Phalen's position has been thought to be useful, but the MPT, as previously studied, has not been widely used because of its complexity. We developed a simplified technique for performing the MPT. This study is designed to evaluate the usefulness of the MPT as a screening diagnostic tool for CTS in the outpatient setting. The electrodiagnostic study continues to be the gold standard for the diagnosis of CTS.

Method: The MPT combines the traditional Phalen's test with simultaneous objective sensory examination of the hand. The traditional Phalen's test is considered positive if paresthesiae are reproduced during the maneuver. The MPT is positive if a median nerve sensory deficit is demonstrated during the Phalen's maneuver. A positive electrodiagnostic study was used as the gold standard for diagnosing CTS. Chi-square analyses were used to test for equivalency between the MPT and the traditional Phalen's Test, the MPT and electrodiagnostic study, and the traditional Phalen's test and electrodiagnostic study. ROC curve estimations were developed to determine the specificity and the sensitivity of the MPT associated with the electrodiagnostic study results.

Results: Sixty-six hands were included in this study. The results showed a significant Chi-square analysis for the MPT compared with the gold standard with a Chi-square of 41.449 ($p<.001$) and the resultant Phi Coefficient of 0.792 ($p<.001$). When comparing the traditional Phalen's test to the gold standard, the Chi-square analysis resulted in a Chi-square of 15.349 ($p<.001$) with a Phi Coefficient of 0.482 ($p<.001$). The Chi-square results show that the MPT is equivalent to the electrodiagnostic study, and the MPT has an accuracy of 79.2% compared to the accuracy of the traditional Phalen's test of 48.2%. ROC curve estimates for the MPT reported a sensitivity level of approximately 84.4% compared to 50% for the traditional Phalen's test. The standard error of the estimate for sensitivity was lower for the MPT (3.3%) compared to the traditional Phalen's test (5.8%). Therefore the MPT is more sensitive.

Conclusion: The MPT is a highly useful screening diagnostic tool for CTS. The MPT is more accurate than the traditional Phalen's test at predicting a positive result from electrodiagnostic studies. The MPT is more sensitive than the traditional Phalen's test at predicting a positive result from electrodiagnostic studies.

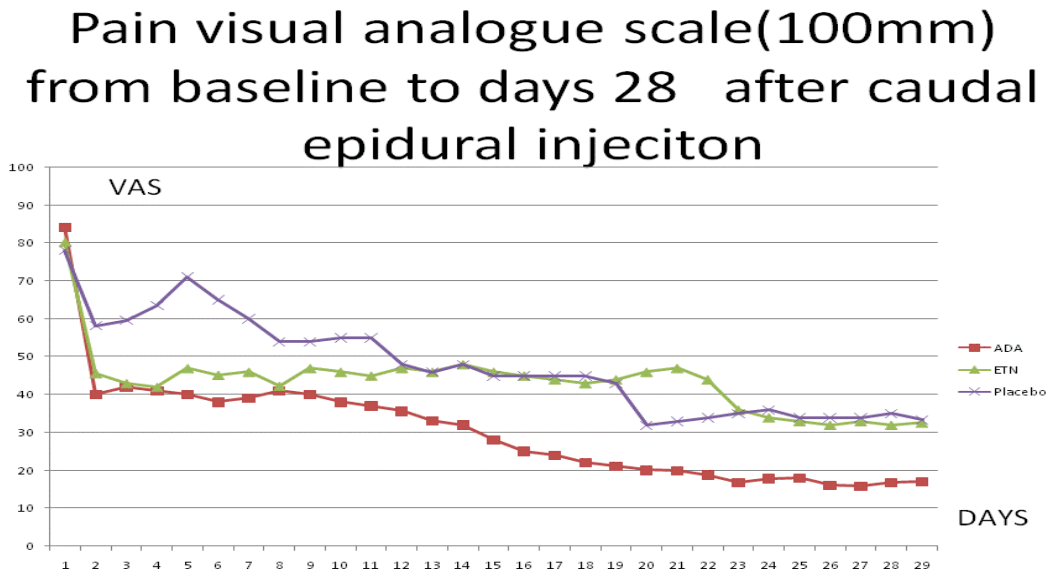
The Efficacy and Safety of Caudal Epidural Injection with the TNF Antagonist, Adalimumab and Eternacept, in Patients with Disc-Herniation-Induced Sciatica- Results of a Randomized, Controlled , 1-Month Follow-up Study. Kensuke Kume[1], Kanzo Amano[2], Amano Kuniki[3], Susumu Yamada[1] and Hideyuki Nagata[1], [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hiroshima, Japan, [3]Chief of Rheumatology, Hiroshima, Japan

Purpose: We determine the efficacy and safety of caudal epidural TNF blockade with adalimumab(ADA) and etanercept (ETN) injection, in patients with disk-herniated sciatica.

Methods: Inclusion criteria were unilateral acute severe sciatic pain with an MRI-confirmed disc herniation concordant with the symptoms and signs of radicular pain. All patients had to be candidates for discectomy, as evaluated bythree independent orthopedic surgeons. Thirty-eight patients were allocated to a single caudal epidural injection guided by fluoroscopy of either 40mg ADA or25 mg ETN or placebo.

Assessments at baseline and various time points(every day after injection) included clinical examination with straight leg raising restriction(SLR), questionnaires related to subjective symptoms(leg and back pain by 100-mm visual analog scale,VAS), number of discectomies ,and adverse events possibly related to treatment. The primary endpoint was a reduction in leg pain from baseline to 1 week, which was analyzed using a repeated-measures analysis (parametoric and non-parametric method).

Results: At 1 day after injection, a significant reduction in pain was observed in three groups. And pain on the VAS for ADA and ETN was a significant decrease than placebo. Pain on the VAS for ADA,ETN and placebo at baseline were mean 82.5(SD 16.5),80.3(SD 19.6)and 78.0(SD18.5)mm respectively, VAS at 1day after injection were mean 40.0(SD11.2),45.6(25.1),and 59.8(SD14.5)mm($p<0.001$),



At 1 month, a significant reduction in pain was observed inthree groups . ADA was significant reduction than both ETN and placebo(Fig 1), and similar efficacy was observed between ETN and placebo at 1 month after injection. Pain on the VAS for ADA,ETN and placebo after injection were mean 18.5(SD 11.5),32.3(SD 19.6)and 32.6(SD22.5)mm respectively. Three patients in ADA, five patients in ETN and 4 patients in placebo required surgery respectively. No adverse effects related to treatment (shock, allergy, infusion reaction, infection and etc.) were encountered within 1 month in all groups.

Conclusion: The results of this randomized study support that caudal epidural injection of ADA or ETN for lumbar radicular pain in patients with disc herniation-induced sciatica is efficacy and safety, is potential to be quick recovery from the pain. Caudal epidural injection of ADA is potential to be a good intervention for lumbar radicular pain in patients with disc herniation-induced sciatica.

Predictors of Successful Long-Term Therapy Outcome in Patients with Chronic Non-Specific Low Back Pain Attending a Multidisciplinary Rehabilitation Programme. Pedro Machado[1] and Jan Gawronski[2], [1]Coimbra University Hospital, Coimbra, Portugal, [2]Royal National Orthopaedic Hospital, Stanmore, United Kingdom

Purpose: Chronic non-specific low back pain (CNSLBP) is common and imposes a huge burden on healthcare systems. Our aim was to identify predictive factors of improved long-term outcome for patients with CNSLBP attending the “Active Back Programme” (ABP).

Methods: The ABP is a 3-week intensive multidisciplinary rehabilitation programme designed to help people with CNSLBP. In this longitudinal study, 521 patients attending the ABP were included; 1-year follow-up data was available for 329 patients (63%). Significant improvements were observed in all the investigated domains (Wilcoxon test and McNemar test, as appropriate). Clinically meaningful improvements (CMI) and active working status were used to dichotomize patients 1 year after the ABP (dependent variable). CMI was defined as a change of at least 30% in the pain score by visual analogue scale (VAS) or in the Oswestry low back pain disability score (ODI) (1), and as a change of at least 3 points in the SF-36 physical component (QLPCS) or the mental component summary score (QLMCS) (2,3). Baseline independent predictors of 1-year CMI were investigated using forward multivariate logistic regression. All baseline variables were categorized and entered in the model as independent variables: gender, age, number of previous courses, time with low back pain, litigation, job status, pain VAS, ODI, QLPCS and QLMCS.

Results: Baseline predictors for CMI after 1 year are presented in table 1.

Table 1: Baseline independent predictors of CMI after 1 year

1 year outcome	Baseline predictors	OR (95% CI)	p-value
CMI in PAIN VAS	Better mental health status	2.1 (1.20-3.63)	0.009
	Better function (lower disability)	2.0 (1.15-3.49)	0.014
	Female gender	1.9 (1.09-3.41)	0.024
CMI in ODI	Lower pain	2.2 (1.20-3.98)	0.010
	Female gender	2.0 (1.05-3.62)	0.034
	Better physical health status	1.8 (1.00-3.22)	0.049
CMI in QLPCS	Better mental health status	2.1 (1.25-3.52)	0.005
	Lower pain	1.9 (1.16-3.28)	0.012
	Female gender	1.9 (1.09-3.16)	0.022
CMI in QLMCS	Better physical health status	2.6 (1.55-4.47)	<0.001
	Female Gender	2.3 (1.31-3.93)	0.004
Job yes, and working	Job yes, and working	49.5 (12.7-193.4)	<0.001
	Job yes, but on sick leave	15.6 (3.7-66.8)	<0.001
	Shorter duration of back pain (3M – 2Y)	5.4 (1.34-21.64)	0.018
	Better physical health status	2.3 (1.21-4.50)	0.011

Pain VAS, ODI, QLPCS and QLMCS were dichotomized at the median before entering the logistic regression model.

Conclusion: A better outcome 1 year after the ABP was independently determined by a better baseline physical and mental health status, lower pain and disability scores, active working status, shorter duration of back pain and female sex. Our study suggests that patients should be referred early to the ABP, before disease status becomes severe and while patients are still active workers.

Development and Validation of a Meniscal Symptom Index for the Diagnosis of Meniscal Tear. N.N. Niu, E. Losina, J. Wright, S.D. Martin, D.H. Solomon and J.N. Katz, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Purpose: Eliciting clinical history is a crucial step in diagnosing meniscal tear (MT). There has been little research on the reliability or the diagnostic value of symptoms clinicians believe are commonly associated with MT. The aims of this study were 1) to test the reliability and discriminant validity of a newly-developed set of expanded descriptions for meniscal symptoms and 2) to develop a Meniscal Symptom Index and test its ability to discriminate patients with meniscal tear from patients with other knee disorders.

Methods: Based on input from clinicians and patients, we developed questions to elicit the presence of 11 symptoms commonly associated with MT (i.e. clicking, locking, catching, etc). These questions were administered in a survey to patients ≥ 18 years seeing orthopedic surgeons forknee pain at a single academic institution. The case definition of MT was determined by medical record documentation of the physician's diagnostic impression, made on the basis of findings from the physical exam, patient history and MRI. Diagnoses of other knee disorders such as osteoarthritis or patellofemoral syndrome were also based on medical record review. The test-retest reliability of the symptoms was assessed by mailing out the same survey to 30 patients 1 week after their visit. Item level discriminant validity for the expanded descriptions was assessed based on the association between presence of each symptom and diagnosis of MT. The Meniscal Symptom Index was calculated as a sum of items associated with MT with likelihood ratios (sensitivity / (1-specificity)) > 1.25, and which were independent predictors of diagnosis of MT in a multivariate logistic regression model that adjusted for other symptoms as well as age and sex.

Results: 250 individuals (mean age 51 ± 13 years, 66% female) completed the survey. Based on medical record review, 100 had MT and 150 did not (119 had either osteoarthritis or patellofemoral syndrome and 31 had ligamentous injuries). Test-retest reliability showed item-level Kappas in the range of 0.52 to 1 for the expanded descriptions. Those symptoms with likelihood ratios > 1.25 and which were independent predictors of MT in logistic regression included: localized pain, clicking, catching, and giving way. The Meniscal Symptom Index consisted of the sum of these 4 items with possible range from 0 (none of these symptoms present) to 4 (all 4 present). Among subjects with none of these symptoms, 11% (95% CI 0 – 24%) had MT, whereas among those with all 4 symptoms, 72% (95% CI 58 – 86%) had MT (Figure).

Conclusion: Preliminary assessment shows a newly-developed Meniscal Symptom Index of 4 symptoms to be reliable and valid in the diagnosis MT.

Does Statin Use Protect against RA or Modify RA Disease Activity at Diagnosis? ME Holmqvist[1], IS Gallais[1], S. Wedrén[1], Lars Klareskog[2], L. Alfredsson[1] and Johan Askling[2], [1]Institute of Environmental Medicine, Stockholm, Sweden, [2]Karolinska University Hospital, Sweden

Background: Among patients with prevalent rheumatoid arthritis (RA), statins have been shown to reduce disease activity. Statin use has also been suggested to protect against RA development. Whether statins actually affect the risk of developing RA, or modulate disease activity at RA diagnosis, needs be confirmed.

Purpose: To assess the effect of statin use on the risk of developing RA and on disease activity measured via disease activity score 28 (DAS28) at RA diagnosis.

Method: To assess the risk of RA, we used 1,973 cases of incident RA and 2,230 randomly selected age-, sex-, and residential area matched population-based controls, all included in the Swedish Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study between 1996 and 2007. All cases fulfilled the ACR criteria for RA. Information on use of medications during the last five years prior to RA was collected through questionnaires. Cases were further classified with regard to the presence or absence of antibodies citrullinated protein antigens (ACPA). To assess disease activity at RA diagnosis, we used 1468 of the EIRA cases who were also included in the Swedish Rheumatology Register, a clinical register used by the treating rheumatologist initially used to follow patients over time, where information on DAS28 at diagnosis was available and classified their RA activity as EULAR low (DAS28<5,1) or high (DAS28>5,1).

Analysis: To assess the risk of RA, we calculated odds ratios (OR) using logistic regression taking the matched study design into account, and adjusted for BMI and smoking. To assess the association between statin use and low DAS28 at baseline, we used unconditional logistic regression and adjusted for sex, age, residential area, smoking history and ischemic heart disease (IHD) history (table).

Results: Use of statins was neither associated with risk of RA (adj OR=1.0, 95% CI0.7-1.5), nor with decreased disease activity at RA diagnosis (adj OR= 1.0, 95% CI 0.5-2.0), Table.

	Total n RA ca/co	**N statin users among ca/co**	**Crude OR* (95% CI)**	**Adjusted OR[#] (95% CI)**
RA overall	1973/2230	59/62	1.1 (0.7-1.5)	1.0 (0.7-1.5)
ACPA positive RA	1144/2230	24/62	0.8 (0.5-1.2)	0.8 (0.5-1.2)
ACPA negative RA	697/2230	26/62	1.3 (0.8-2.0)	1.2 (0.8-2.0)
	Total n Low/high DAS28	**N statin users among low/high DAS28**	**Crude OR* (95% CI)**	**Adjusted OR[¤] (95% CI)**
RA overall	601/867	18/34	0.9(0.5-1.7)	1.0(0.5-1.8)
ACPA positive RA	370/502	7/13	0.8(0.3-2.0)	0.7(0.2-2.1)
ACPA negative RA	188/298	8/17	1.0(0.4-2.4)	1.1(0.4-2.9)

*adjusted for age, sex, residential area [#]crude+ BMI and smoking [¤]crude+ smoking, IHD

Conclusion: In our study of 1,973 cases of incident RA and 2,230 randomly selected controls, use of statins during the five years prior to RA diagnosis was neither associated with an altered risk of developing RA, nor with a decreased DAS28 at RA diagnosis.

Prognostic Value of Patient History, Radiography and Serology On Poor Outcomes in Undifferentiated Inflammatory Arthritis Patients. Maria A. Petre[1], Carly K. Cheng[1], Gilles Boire[2], J. Pope[3], Boulos Haraoui[4], Carol A. Hitchon[5], Shahin Jamal[6], J. Carter Thorne[7], NEAR Researchers and Vivian P. Bykerk[1], [1]Mt Sinai Hospital, Toronto, ON, [2]Centre hospitalier universitaire de Sherbrooke, Sherbrooke, [3]St Joseph Health Care, London, ON, [4]Institut de Rhumatolgie de Montreal, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]St. Michael's Hospital, Toronto, [7]Southlake Regional Health Centre, Newmarket, ON

Purpose: To determine the clinical outcome of undifferentiated inflammatory arthritis (UIA) patients enrolled in 2 Canadian early arthritis cohorts and the prognostic value of patient history, physical exam, serology, and radiography for poor patient outcomes.

Methods: Data from patients (n=643) enrolled since Sept. 2003 were collected from the Toronto/Canadian Early Arthritis Cohorts (TEACH/CATCH). CATCH is a multi-centre observational prospective "real world" cohort of patients with early inflammatory arthritis (EIA). Inclusion criteria: age >16, symptom duration of 6-52 weeks of persistent synovitis, ≥2 effused joints or 1 swollen MCP/ PIP + ≥1 of: + RF, + anti-CCP, AM stiffness >45 minutes, response to NSAIDs, or painful MTP squeeze test. UIA was defined as not meeting 1987 ACR classification criteria for rheumatoid arthritis (RA) or criteria for other rheumatological diagnoses. The proportion of patients developing a classifiable diagnosis over time (survival analysis) and hazard ratios (HR) for the prognostic value of baseline age, gender, smoking status, initial use of DMARDs, RF status, 2nd-5th MTP involvement (including erosions), in the progression of UIA to RA were calculated. The feet were evaluated in this study due to their under-representation in the current ACR criteria for RA diagnosis.

Results: Baseline (BL) characteristics of UIA patients were: mean age 51±15 years, 75% female, median symptom duration 6.1 months, and mean DAS28 3.5±1.9. Of all the patients completing the study to 1 year (n=229), 23.1% were UIA at baseline (n=53). Of those who were UIA at baseline, 64.1% remained UIA at 12 months, while 35.8% developed RA. HRs are given in Table 1.

Conclusion: Early presence of MTP tenderness and erosions predicted which patients will develop RA, not accounting for anti-CCP status. Smoking was not predictive. Further analyses on the role of anti-CCP are planned.

Predictors for progression of UIA to rheumatoid arthritis (RA)

	Hazard Ratio (to RA by ACR Criteria)	Confidence Interval
Age (>65)	0.995	0.961-1.029
Female Gender	1.011	0.339-3.013
Smoking	1.526	0.403-5.777
DMARD	0.919	0.343-2.461
RF	0.147	0.019-1.157
2-5 MTP tenderness	1.111	1.001-1.233
2-5 MTP swelling	0.904	0.801-1.019
Foot erosions	4.428	1.231-15.930

Predictors of HAQ Response After 3 Months of Treatment with Different Strategies in Recent Onset Active RA. L. Dirven[1], J.A.P.M. Ewals[2], T.W.J. Huizinga[1], P.J.S.M. Kerstens[3], A.J. Peeters[4], B.A.C. Dijkmans[5] and C.F. Allaart[1], [1]LUMC, Leiden, Netherlands, [2]Haga hospital, The Hague, Netherlands, [3]JBI, Amsterdam, Netherlands, [4]GDGG, Delft, Netherlands, [5]VUMC, Amsterdam, Netherlands

Background: Early clinical response is a strong predictor of later outcomes in rheumatoid arthritis (RA).

Purpose: To identify predictors of a HAQ score >= 1 after 3 months of treatment in patients with recent-onset RA. The results might help rheumatologists in weighing their first choice treatment.

Method: Data of 497 recent-onset RA patients from the BeSt study, randomized to initial monotherapy or initial combination therapy with prednisone or infliximab, were used. Treatment adjustments were made every 3 months aiming at a disease activity score (DAS) =< 2.4. Predictors for HAQ >= 1 after 3 months of treatment were identified with univariate and multivariate logistic regression analysis. The predicted risk of HAQ >= 1 after 3 months of treatment as well as the number needed to treat to prevent this, were determined per treatment group and for each subpopulation.

Results: At baseline, 76% of the patients had HAQ >= 1 (1.7 ± 0.5) and after 3 months this was 40% (1.5 ± 0.5). Baseline HAQ, visual analogue scale (VAS) pain, body mass index (BMI) and treatment group were significant independent predictors of HAQ >= 1 after 3 months of treatment; presence of rheumatoid factor and/or anti-cyclic citrullinated peptide antibodies and baseline radiological damage were not. Compared to initial monotherapy, both combination therapy groups showed a reduced risk for HAQ >= 1, also in patients with an unfavorable risk profile. With cut-offs of <35% (low risk) and >60% (high risk), 47% of patients treated with initial methrotrexate monotherapy had a high risk for HAQ >= 1 after 3 months, 20% had a low risk and 33% had an intermediate risk. With initial combination therapy the risks were markedly reduced. The number needed to treat with initial monotherapy to prevent one patient from having a HAQ >= 1 after 3 months, ranged from 3-6 and 3-5 for patients with a high or intermediate risk to 6-9 for patients with a low predicted risk.

Conclusion: A high baseline HAQ, high VAS pain and high BMI are independent predictors of worse functional ability after 3 months of treatment, which is in itself a predictor of later outcome. The initial treatment choice determines early functional improvement. Since the number needed to treat is low in all risk profiles, it seems plausible that all patients start with combination therapy as their initial treatment.

Baseline predictor of HAQ		OR (95% CI)
HAQ	< 1.38	*ref*
(tertiles)	1.38- 2.00	2.39 (1.40-4.09)
	> 1.38	4.64 (2.43-8.86)
BMI	< 24	*ref*
(tertiles)	24-27	1.85 (1.07-3.18)
	>27	2.19 (1.22-3.93)
Treatment	mono	*ref*
	combo prednisone	0.27 (0.15-0.48)
	combo infliximab	0.37 (0.22-0.63)
VAS pain	< 40	*ref*
(tertiles)	40-60	2.72 (1.52-4.59)
	> 60	3.67 (1.85-7.27)

1193

Care Gap in Early Inflammatory Arthritis Patients with a High Fracture Risk Identified Using the FRAX® Tool. Vivian P. Bykerk[1], Carly K. Cheng[1], Gilles Boire[2], Janet E. Pope[3], Boulos Haraoui[4], Carol A. Hitchon[5], Shahin Jamal[6], J. Carter Thorne[7], NEAR Researchers and Heather McDonald-Blumer[8], [1]Mt Sinai Hospital, Toronto, ON, [2]CHUS - Sherbrooke University, Sherbrooke, [3]St Joseph Health Care, London, ON, [4]Institut de rhumatologie de Montréal, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]St. Michael's Hospital, Toronto, [7]Southlake Regional Health Centre, Newmarket, ON, [8]Mt Sinai Hospital, Toronto

Purpose: A fracture risk assessment tool (FRAX®; http://shef.ac.uk/FRAX) estimates a 10-year absolute risk of sustaining a hip or other major osteoporotic fracture. FRAX® identifies patients at low (<10%), moderate (10-20%) or high (>20%) risk of fracture using validated clinical risk factors ± bone mineral density (BMD) testing. This study determined the frequency of patients with early inflammatory and rheumatoid arthritis (EIA and ERA) at high risk of major osteoporotic fracture using FRAX® and evaluated the care gap in high risk patients.

Method: 239 patients were enrolled since July 2007 in the Canadian Early Arthritis Cohort (CATCH) study, a multi-centre observational prospective "real world" cohort of patients with EIA. Inclusion Criteria: age >16, symptom duration of 6-52 weeks of persistent synovitis, ≥2 effused joints or 1 swollen MCP or PIP + ≥1 of: positive RF, positive anti-CCP, morning stiffness >45mins, response to NSAIDs, or painful MTP squeeze test. FRAX® was calculated based on ethnicity assuming norms from the United States of America (USA) and United Kingdom (UK), without BMD. History of hip fracture in a parent hip was inconsistently reported in the CATCH standardized questionnaire and assumed to be absent if data were not available.

Results: Baseline characteristics: mean age 52±15 years, 80% female, 79% RA (ACR criteria), median symptom duration 6.1 months, mean DAS28 ESR 4.9±1.5, 16% treated with oral glucocorticoids. Based on USA norms, patients at high risk vs. low risk had a higher mean age ($p<0.011$), higher DAS28 ($p=0.036$), and received more glucocorticoids ($p=0.011$). DAS28 of patients at moderate risk was greater vs. low risk ($p=0.112$). The rate of Ca, Vit D and bisphosphonate use did not increase in low to moderate to high risk groups ($p=0.05$).

Table: FRAX® major osteoporotic fracture risk (n=239)

	Low Risk (<10%)		**Moderate Risk (10-20%)**		**High Risk (>20%)**	
	USA	**UK**	**USA**	**UK**	**USA**	**UK**
N (%)	155 (65%)	175 (73%)	52 (22%)	52 (22%)	32 (13%)	12 (5%)
Age (mean)	44±12	47±13	64±7	66±8	72±8	79±6
Oral glucocorticoids (base)	11.6%	25.7%	21.2%	26.9%	31.3%	75.0%
Received Ca or Vit D	13.6%	14.9%	19.2%	15.4%	15.6%	16.7%
Received a Bisphosphonate	4.5%	4.0%	3.9%	7.7%	9.4%	8.3%
DAS28 ESR (base mean)	4.9±1.5	4.8±1.5	5.3±1.5	5.0±1.5	5.5±1.0	5.3±1.2

Conclusion: FRAX® identified 5-13% of patients at high risk using a conservative analysis, as being older, having higher disease activity and more frequent glucocorticoid use at baseline compared to patients at low risk. Despite awareness that classic risk factors are associated with high risk, a very low proportion of patients are being treated with supplemental Ca, Vit D and bisphosphonates. These data highlight the need to identify and modify fracture risk in patients presenting with EIA/ERA.

1194

Cytokine Response Profiling in Rheumatoid Arthritis: A Correlative Study of Patients with Early or Late Disease Compared to Controls. John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson and Sherine E. Gabriel, Mayo Clinic, Rochester, MN

Purpose: The long-term goal of our research is to identify immunologic signatures that can predict outcomes (i.e., response to therapy) in patients with rheumatoid arthritis (RA). The purpose of this analysis was to develop this concept by identifying *ex vivo* cytokine response profiles that discriminate patients with early or late RA from controls.

Methods: Patients with RA (1987 ACR criteria) and control subjects with no history of rheumatic disease were included. Data on demographic and clinical characteristics, including C-reactive protein (CRP) and the Health Assessment Questionnaire (HAQ), were collected. Fresh peripheral blood mononuclear cells (PBMC) from subjects were stimulated ex vivo under eight stimulation conditions, including: anti-CD3/anti-CD28 (CD3/CD28); cytomegalovirus and Epstein Barr virus (CMV/EBV) lysates; or human heat shock protein 60 (HSP60). The profiles of cytokine release in response to stimulation were determined using multiplex immunoassays with a 17-cytokine panel. For comparison, the cytokine profiles were also analyzed in serum samples. The fold-changes in the cytokine values between the RA and control groups were compared using mixed effects models, adjusting for age, sex, and cytokine plate effects.

Results: The study included 85 patients with RA and 15 controls. Of the patients, 25 had early active disease (mean duration: 0.2 yr; CRP: 40.3 mg/L; HAQ: 1.4), and 60 had established quiescent disease (mean duration: 13.6 yr; CRP: 4.1 mg/L; HAQ: 0.5). Analyses revealed recurring profiles of impaired Th1 and Th2 responsiveness to T cell activation and increased Th17 and myeloid responsiveness to stimulation with toll-like receptor ligands. A 9-cytokine signature was developed that clearly discriminated the patients with early and late RA from controls. Patients with early RA exhibited decreased responsiveness of Th1 (IL-12, MIP-1b, and TNF) and Th2 (IL-10) subsets to CD3/CD28, decreased IL-8 and increased IL-6 responsiveness to CMV/EBV, and increased responsiveness of Th17 (IL-17A) and myeloid subsets (GM-CSF, MCP-1) in response to HSP60 as compared to controls. Patients with late RA appeared to have recovered Th1 responsiveness, and partially recovered Th2, but had persistently increased Th17 and myeloid responsiveness to HSP60 as compared to controls. A similar 9-cytokine profile assessed in patient sera discriminated the early RA group, but not the late RA group, from controls.

Conclusion: Using *ex vivo* cytokine response profiling and multiparametric analyses, we have developed an immunologic signature that discriminates patients with early active as well as established quiescent RA from controls. These data provide a preliminary signature that has the potential to identify patients with persistent disease activity and also to stratify patients on the risk of adverse disease outcomes.

1195

The Season of First Symptoms Influences the Severity in Early Arthritis : Results From the ESPOIR Cohort. Gaël Mouterde[1], Nathalie Rincheval[2], Cedric Lukas[1], RM Flipo[3], Philippe Goupille[4], Jean-Pierre Daures[2] and Bernard Combe[1], [1]Lapeyronie hospital, Montpellier, France, [2]Epidemiology unit, Montpellier, France, [3]Rheumatology,Lille University, Lille, [4]Université François Rabelais de Tours, CNRS, UMR 6239; CHRU de Tours, Tours, France

Purpose: To determine predictors of radiographic progression in an inception cohort of early arthritis patients.

Method: Patients presenting with synovitis of at least 2 joints for 6 weeks to 6 months were included in the multicenter French ESPOIR cohort. Following data were collected at baseline : clinical and biological features of arthritis, IgM Rheumatoid factor (RF) and anti-CCP auto-antibodies (anti-CCP), HLA-DRB1* typing, socio economic factors, comorbidities. Radiographs of hands, wrists, and feet were scored at baseline, 6 and 12 months. A radiographic progression was defined by an increase of at least 1 point of the modified total Sharp score (mTSS) assessed at baseline and after 6 and 12 months.

The sensitivity and specificity of RF and anti-CCP at baseline in discriminating between erosive and non erosive disease at 6 months and one year were determined. Optimal cutoffs for these tests were derived from receiver operating characteristic (ROC) curves using a cost function. Logistic regression was performed to evaluate the association between the radiological progression and baseline variables.

Results: Of the 813 recruited patients, complete data were available for 736 patients : 48±12 years old, females 77%, mean disease duration 103+/-53 days, DAS28 5.11±1.31, HAQ score 0.97±0.68, CRP 21.9±32 mg/l, HLA-DRB1*01 or 04 57.5%. 341 (46.3%) of them were positive for RF and 290 (34.4%) were positive for anti-CCP.

Radiographic progression after six months was associated with the following initial factors : anti-CCP (OR=3.73 [2.04; 6.82], p<0.0001), median ESR (OR=2.52 [1.38; 4.61], p=0.0027), median mTSS (OR=2.18 [1.20; 3.94], p= 0.0105). Surprisingly, the season of first symptoms onset influenced the severity in early arthritis : mTSS after six months was worse if symptoms had occurred in winter (OR=2.82 [1.14;7], p=0.0255 *versus* summer), or in spring (OR=2.83 [1.10;7.37], p=0.0322 *versus* summer). Similarly, mTSS after six months was worse if symptoms had occurred in winter (OR= 2.61 [1.20; 5.71], p=0.0158) or in spring (OR=2.63 [1.13; 6.14], p=0.0025) *versus* autumn as reference season. Morning stiffness protect against radiographic progression in the cohort (OR=0.41 [0.20; 0.86], p= 0.0175).

A progression of the mTSS after one year was associated with anti-CCP (OR=5.38 [3.01; 9.65], p<0.0001) and age (≥50 years old, OR=2.57 [1,46; 4.54], p=0.0011). In univariate analysis, the progression of the mTSS after one year was worse if symptoms had occured in winter or in spring (OR=2.01 [1.22;3.32] and OR=1.68 [1.01;2.80] respectively *versus* summer.

Conclusion: Onset of arthritis symptoms during winter or spring was associated with a more severe radiographic outcome at 6 months in early arthritis patients. One explanation could be as a result of either a vitamin D deficiency or environmental factors, such as winter viruses, influencing protein citrullination.

Scleroderma Pumonary Hypertension Quality Enhancement Research Initiative (QuERI): Use of Diagnostic Tests by Community Rheumatologists. James R. Seibold[1], Alina Dragomir[2], Mary Tan[2], Daniel E. Furst[3], Nicholas Hill[4], Vallerie McLaughlin[5], Richard M. Silver[6], Virginia D. Steen[7] and Anatoly Langer[8], [1]University of Michigan, Ann Arbor, MI, [2]Canadian Heart Research Center, Toronto, ON, [3]UCLA, Los Angeles, CA, [4]Tufts Medical Center, Boston, MA, [5]Cardiology, University of Michigan, Ann Arbor, MI, [6]Medical University of South Carolina, Charleston, SC, [7]Georgetown University Medical Center, Washington, DC, [8]Canadian Heart Research Centre, Toronto, ON

Purpose: Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are the leading causes of death in systemic sclerosis (SSc, scleroderma). Evidence-based standards for diagnosis and classification are available but consensus suggests a “care gap” between published standards and community practice. We utilized a Delphi consensus to develop a diagnostic template judged accessible to the primary care rheumatologist and relevant to early recognition of both PAH and ILD. QuERI offers computer-based feedback to investigators. We report on the initial experience in 207 patients with scleroderma among 27 US rheumatologists including 22 community practice settings (168 patients) and 5 academic referral centers (39 patients).

Methods: Physicians were asked to enroll scleroderma patients (known or newly diagnosed) and provide data on a recommended panel of clinical features and diagnostic tests.

Results: (Median, 25th and 75th percentile): Patients enrolled were 57 years old (49, 66), 90% female. Raynaud phenomenon was present in 87.0%, duration 8 years (4,14). In spite of specific clinical focus on lung, CXR was performed in only 43.0% and was abnormal in 36.0%. V/Q scan was done in only 1% and HRCT in only 37.2%. PFT was performed in 82.6% and showed DLCO <55% predicted in 27.1%, and FVC/DLCO ratio >1.4 in 44.6%. Doppler echocardiogram was done in 85.0% of patients and revealed tricuspid jet of >3 m/sec in 11.1% and estimated RVSP >40 mm Hg in 20.0%. Right heart catheterization was performed in only 4.8% of patients. Practice setting influenced use of testing:

Recommended/Contingent Diagnostic	Community centre	University centre	P value

Tests	(22 centers N=168)	(5 centers N=39)	
PFT's	133 (79.2%)	38 (97.4%)	0.007
DLCO<55% of predicted	28/105 (26.7%)	10/35 (28.6%)	0.83
FVC/DLCO > 1.4	48/104 (46.2%)	14/35 (40.0%)	0.53
Echocardiogram	141 (83.9%)	35 (89.7%)	0.36
VQ lung scan	2 (1.2%)	0	1.0
ECG	17 (10.1%)	6 (15.4%)	0.40
Six minute walk	11 (6.6%)	11 (28.2%)	<.0001
High resolution CT scan	50 (29.8%)	27 (69.2%)	<.0001
Chest x-ray or CT scan	100 (59.5%)	31 (79.5%)	0.02
Right heart catheterization	5 (3.0%)	5 (12.8%)	0.02
Diagnostic criteria of PAH		0	
	4/5		

14 were treated with endothelin receptor antagonists and 8 were receiving chronic PDE-5 inhibitors although only 5 were treated for "PAH indication." ILD was confirmed by PFT and HRCT in 23 (96%) of 24 patients receiving agents of putative benefit including cyclophosphamide (6) and mycophenolate mofetil (18).

Conclusion: This preliminary assessment suggests that certain basic essential diagnostic tests, such as right heart catheterization for PAH, continue to be underutilized. The SSc QuERI offers stricter guidelines, adherence to which could optimize management of these high-risk patients.

Telangiectases in Scleroderma: A Potential Clinical Marker of Pulmonary Arterial Hypertension. Ami A. Shah, Fredrick M. Wigley and Laura K. Hummers, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: Pulmonary arterial hypertension (PAH) is a significant cause of morbidity and mortality among patients with scleroderma. Clinical markers are needed to screen and identify scleroderma patients at risk for PAH since early therapy may result in a survival benefit. Telangiectases, lesions composed of vasodilated post-capillary venules, may be an easily accessible marker of scleroderma vascular disease.

Method: Consecutive subjects with scleroderma were enrolled and scored for the presence of matted, non-stellate telangiectases on the face, hands, arms, chest and abdomen, back, legs, and feet. For each body area, telangiectases were scored as 0 if no telangiectases were present, 1

if there were less than 10 telangiectases, and 2 if 10 or more telangiectases were counted (11 body areas for maximum score of 22). Subjects were grouped into tertiles of total telangiectasia score (0-3, 4-7, 8+). Differences in clinical variables between the 3 groups were assessed by analysis of variance and the Fisher's exact test where appropriate. The correlation between RVSP and telangiectasia score was assessed by Pearson's correlation coefficient. Linear regression analysis was performed to assess the association between RVSP and telangiectasia score, adjusted for age, race, smoking status, scleroderma subtype, disease duration, and autoantibody status. Logistic regression analyses were performed with the presence of PAH by right heart catheterization (RHC) as the dependent variable and telangiectasia score, age, subtype, disease duration, autoantibody status, and diffusing capacity as possible explanatory variables.

Results: One hundred forty seven patients with scleroderma were enrolled. Telangiectasia scores ranged from 0-20, and the mean telangiectasia score was 6.0 (SD 4.5). Fifty-four patients had a telangiectasia score of 0-3 (1st tertile), 50 had a score of 4-7 (2nd tertile), and 43 had a score of 8-20 (3rd tertile). Patients in the second and third tertiles of telangiectasia score were older ($p<0.0001$) and had a longer duration of scleroderma ($p<0.0001$). RVSP and telangiectasia score were positively correlated ($r=0.271$, $p=0.001$). The RVSP increased by 10.9 mmHg for a 10 point increase in telangiectasia score (95% CI 3.6 – 18.3mmHg, $p=0.004$), adjusted for age, race, disease duration, scleroderma subtype, smoking status, and autoantibody status. The relative odds of PAH by RHC was 12.4 for a 10 point increase in telangiectasia score after adjustment (95% CI 1.78 - 85.9, $p=0.01$).

Conclusion: Increased numbers of telangiectases are strongly associated with the presence of pulmonary vascular disease. Telangiectases may be a clinical marker of more widespread aberrant microvascular disease in scleroderma.

Heritability of Systemic Sclerosis: A Population Database Study. Tracy M. Frech and Allen D. Sawitzke, University of Utah Medical Ctr, Salt Lake City, UT

Purpose: Systemic sclerosis (SSc) is a heterogeneous chronic illness characterized by variability in clinical manifestations, internal organ involvement, and outcome, due to a complex interplay of inflammation, fibrosis, and vasculopathy. Despite its unpredictability, almost all patients with SSc have Raynauds phenomenon (RP), and one of the leading causes of mortality in this population is interstitial lung disease (ILD). Genetic predispositions to SSc have been described, but the genetic underpinnings that may predispose to specific disease presentations are unknown. Ideally, an approach to identify patients at highest risk for SSc would concurrently provide insight into its relationship to other autoimmune and fibrotic diseases which can also have RP and/or ILD. This study looks at the familiality and relative risks of SSc, in relation to RP, ILD, systemic lupus erythematous (SLE), Sjogrens (SS), dermatomyositis (DM), rheumatoid arthritis (RA), and unspecified connective tissue disease (UCTD).

Method: A unique genealogic resource, the Utah Population Database (UPDB) was used to examine heritability using records from more than 7.0 million individuals. For this study, diagnosis were defined by ICD-9 codes; SSc (710.1), RP (443), ILD (515), SLE (710.0), SS (710.2), DM (710.3), RA (714), and UCTD (710.9) collected in any of three sources a) death certificates, b) U of U enterprise data warehouse or c) state-wide hospital discharge data. The cases of SSc were mapped to pedigrees of the UPDB for analysis. Measures of risk to relatives of 1st, 2nd and 3rd degree to cases were calculated and for related diagnosis as above. Controls without any of the ICD-9 codes of interest were randomly selected from the UPDB to allow calculation of Familial Standardize Incidence Ratio (FSIR), relative risks (RR), and Population Attributable Risk (PAR). The FSIR computes an individual's familial risk for SSc, accounting for the number of biological relatives, their degree of relatedness to the proband, and their time at risk of detection.

Results: Over 1300 distinct patients statewide with a diagnosis of systemic sclerosis were used to compute PAR and find 30 families with the highest FSIR. First degree relatives have a RR of 3.07. The adjusted PAR, a measure of the familial contribution to risk for SSc, is about 8% (0.04-0.12). The RRs were significant at the 0.05 level for all kinship classes closer than second cousins. The P values given are the probability of a family having some observed number of cases under the null hypothesis of no familial disease aggregation. Excess clustering of fibrotic and autoimmune diagnoses in these families was found.

Conclusion: This data suggests that SSc pedigrees can be identified on a population basis and that these pedigrees include increased numbers of family members with RP, ILD, SLE, SS, DM, RA, and UCTD. It is likely that at least two factors contribute, one to fibrosis and another to a shared predisposition to autoimmunity.

Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS): Two-Year Outcomes for Pre-Pulmonary Arterial Hypertension (PAH). Vivien M. Hsu[1], Hafiz Khan[2], Yijin Wu[3], Elena Schiopu[4], M. Mayes[5], Chris T. Derk[6], Lee S. Shapiro[7], ME. Csuka[8], Aryeh Fischer[9], Dinesh Khanna[10], Robyn T. Domsic[11], Jerry A. Molitor[12], Virginia D. Steen[13] and the PHAROS Investigators, [1]UMDNJ, New Brunswick, NJ, [2]Newark, NJ, [3]Rutgers University, New Brunswick, NJ, [4]Scleroderma program, University of Michigan, Ann Arbor, MI, [5]U.Texas Houston, Houston, TX, [6]Jefferson Medical College, Philadelphia, PA, [7]Albany, NY, [8]Med Coll of Wisconsin, Milwaukee, WI, [9]National Jewish Medical Center, Denver, CO, [10]University of California Los Angeles, Los Angeles, CA, [11]University of Pittsburgh, Pittsburgh, PA, [12]Univ of MN MMC108, Minneapolis, MN, [13]Georgetown University Medical Center, Washington, DC

Background: Pulmonary Arterial Hypertension (PAH) and pulmonary hypertension (PH) secondary to interstitial lung disease are the leading causes of systemic sclerosis (SSc) related deaths. Early detection and treatment should improve morbidity and mortality. PHAROS is a multi-center, prospective, observational study to determine risk factors and outcomes of patients who have definite or are at high risk for PAH/PH

Purpose: This analysis compares the clinical features and preliminary outcomes of the 206 pre-PAH subjects currently enrolled in PHAROS.

Methods: PHAROS defines pre-PAH by one of the following entry criteria: DLCO ≤ 55% predicted, FVC%/DLCO% ratio > 1.6, or echocardiographic (echo) PASP >40 mmHg. Data is collected bi-annually and includes patient generated, clinical and objective data. Right-heart catheterization (RHC) is performed in those suspected to have PH. Definite PH is defined as mean pulmonary artery pressure ≥25 mmHg at rest or ≥30 mmHg with exercise on right heart catheterization.

Results: *206 pre-PAH subjects have been enrolled: 26 (13%) males,* mean age 56.1, (standard deviation 11.5 SD), *m*ean disease duration (from onset of non-Raynaud symptoms) 13.7 years, 73% Caucasians, 18% blacks. Scleroderma antibodies known in 165 patients: 30% anti-centromere, 16% topo-isomerase, and 13% nucleolar ANA pattern. Mean PFT values: DLCO 49.8% predicted (19.5 SD), FVC/DLCO 1.79 (0.59 SD), and FVC 81.9% predicted (18.9 SD). The mean echo PASP was 39.8mm Hg (25.7 SD). 152 participants had additional follow up visits (mean 1.47years, range 0.5 to 3.5) and 110 had repeat studies. 18% patients did not fulfill echo entry criterion on follow up studies.

61 RHCs were performed in this population: 42 had normal RHC and 19 were abnormal. In those normal RHC, the mean echo systolic PAP was 42.6mmHg compared to the mean systolic PAP on RHC of 30.9mmHg ($p<0.001$) In the 19 patients who developed PH after first visit, 13 had PAH (Group I, mPAP>25 at rest or >30mmHg with exercise) and 6 had Group 2 PH (mPAP>25mmHg with a capillary wedge pressure ≥15 mmHg). Definite PAH developed in 3% of pre-PAH patients at 1 year and 16% by 2 years. Only a lower DLCO predicted the future development of PAH, 40% predicted vs 49.7% predicted ($p<0.03$).

Conclusion: 16% of subjects at increased risk for PAH have evolved to PAH at 2 years. A very low DLCO was the best predictor for PAH. Echo PASP were extremely variable over time and did not correlate well with RHC. This ongoing prospective study is a very important resource to elucidate outcomes and risk factors for development of PAH.

Point Prevalence of Pulmonary Hypertensions in Systemic Sclerosis: Results From Two Large Cohorts (of European Caucasian patients) and Meta-Analysis. J. Avouac[1], P. Airo[2], C. Meune[1], L. Beretta[3], P. Dieudé[1], P. Caramaschi[4], S. Cappelli[5], K. Tiev[6], E. Diot[7], A. Vacca[8], Jl Cracowski[9], J. Sibilia[10], A. Kahan[1], M. Matucci-Cerinic[5] and Y. Allanore[1], [1]Rheumatology, Paris, France, [2]Reumatologia, Brescia, Italy, [3]Rheumatology, Milan, Italy, [4]Rheumatology, Verona, Italy, [5]Rheumatology, Florence, Italy, [6]Internal Medicine, Paris, France, [7]Internal Medecine, Tours, France, [8]Rheumatology, Monserrato, Italy, [9]Pharmacology, Grenoble, France, [10]Rheumatology, Strasbourg, France

Purpose: To measure the point prevalence of pulmonary hypertensions (PHs) using the gold-standard method that is the right heart catheterization (RHC) in two large European cohorts of patients with systemic sclerosis (SSc) and to perform a meta-analysis of available data.

Method: A multicenter study was performed in France and Italy to recruit consecutive SSc patients systematically assessed for the existence of PH. Criteria for catheterisation were a systolic pulmonary arterial pressure (sPAP) >40mmHg on echocardiography or DLCO<50% or unexplained dyspnea. A proportion meta-analysis has also been performed including the present study and four published studies using similar definition of PH, identified after a systematic literature research (through electronic databases between 1966 and June 2009).
