Conclusion: Our findings suggest that metformin can effectively up-regulate Treg cells as well as increase Th17 cells in a short time and can reduce the usage of prednisone.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertension predicts poor long-term renal outcomes for patients with lupus nephritis (LN) [1, 2]. We sought to characterize relationships between blood pressure and proteinuria using data from randomized clinical trials.

Methods: We analyzed patient-level data from LUNAR (NCT00282347) [3] and BELONG (NCT00626197) [4], which compared rituximab [3] or ocrelizumab [4] vs. placebo in addition to background therapy for the treatment of LN. Complete renal response (CRR) was defined for LUNAR as urine protein/creatinine (UPCR) levels below 0.5, creatinine levels $\leq 115\%$ of baseline, and inactive urinary sediment. CRR for BELONG was defined as UPCR < 0.5 and creatinine $\leq 125\%$ of baseline. Data from baseline and 1 year visits were analyzed. Logistic regression was used to estimate the association between change in BP and CRR while adjusting for baseline proteinuria and estimated glomerular filtration rate (eGFR). Linear regression was used to estimate the association between change in BP and change in proteinuria while adjusting for race, treatment received, and baseline eGFR.

Results: Each 10 mmHg increase in baseline systolic BP had an odds ratio (OR) of 0.8 for CRR at 1 year (95% CI 0.74, 0.97). This association did not remain significant after adjusting for baseline proteinuria and eGFR (OR 0.9, 95% CI 0.79, 1.05). Baseline systolic and diastolic BP had a weak correlation with baseline UPCR ($r=0.2$, $p<0.01$ for both). Change in systolic and diastolic BP from baseline to 1 year was associated with improvement in proteinuria at 1 year in adjusted regression: each 10 mmHg decrease in systolic BP was associated with a 0.45 g/g (CI 0.3, 0.6, $p<0.01$) improvement in

Figure 1. Change in systolic blood pressure versus change in proteinuria from baseline to one year after adjustment for race, treatment received, and baseline eGFR

proteinuria at 1 year; each 10 mmHg decrease in diastolic BP was associated with a 0.44 g/g (CI 0.2, 0.65, $p<0.01$) improvement in proteinuria. These results were consistent when studies were analyzed separately.

Conclusion: Baseline systolic BP was associated with the probability of CRR at 1 year in univariate analysis. However, this association was explained by baseline proteinuria and eGFR. Changes in systolic or diastolic BP were significantly associated with decreases in proteinuria at 1 year. Further characterization of the relative contributions of BP, disease severity, and immunosuppression are warranted.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The clinical coexistence of Systemic Lupus Erythematosus (SLE) and Sjögren's Syndrome (SS) was recognized in 1959. The prevalence of SS among patients with SLE varies considerably among the published studies (10-30%). There is still controversy as to whether or not SLE patients with overlapping SS have a distinct and significantly milder lupus. To address the clinical and serologic features of SLE and differences from SLE that occurs in overlap with SS.

Methods: This is a multicenter, descriptive, cross-sectional study of 3575 patients from the Spanish Society for Rheumatology Lupus Registry (RELESSER). Unselected SLE patients from 45 Rheumatology Departments across Spain were evaluated for the presence of overlapping SS using the American-European consensus criteria. Cumulative clinical data were collected at the moment of the last assessment. Clinical and laboratory parameters in SLE patients with SS (SLEwSS) were compared with those in SLE patients without SS (SLEwoSS).

Results: SS was identified in 516 SLE patients (14.4%). Compared with the SLEwoSS group, patients with SLEwSS were significantly older, had a higher frequency of mucocutaneous manifestations, Raynaud's phenomenon, peripheral neuropathy, anti-Ro/SSA, anti-La/SSB, neoplasia, and older age at death, but had a significantly lower frequency of renal involvement, thrombocytopenia, anti-DNA, anti-β2-GPI IgM and complement consumption. Both groups displayed a clinically similar presentation of lymphadenopathy, systemic vasculitis, serositis, damage accrual, mortality, musculoskeletal and CNS manifestations.

Conclusion: SLEwSS appears to constitute a subgroup of SLE patients with distinct clinical and serologic features, in whom SS is expressed as an overlapping entity. A particular cluster of clinical variables, namely, mucocutaneous manifestations, Raynaud's phenomenon, peripheral neuropathy, renal involvement and thrombocytopenia, was found to be

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset SLE (cSLE) is a severe lifelong multisystem autoimmune disease. Long-term outcome data are limited. Here, we report for the first time on the development of disease manifestations and damage over time in adults with cSLE and their health-related quality of life (HRQOL).

Methods: All patients underwent a single study visit comprising a structured history and physical examination. Disease activity (SLEDAI-2K), damage (SLICC-Damage Index (SDI)) and HRQOL (SF-36) were determined. Medical records were retrieved.

Results: In total, 111 cSLE patients were included, median disease duration 20 years, 91% female and 72% white. Disease activity was low (median SLEDAI 4), with 68% of patients using prednisone and/or disease-modifying anti-rheumatic drugs. The vast majority of new cSLE-related manifestations developed within 2 years of diagnosis. Damage like myocardial infarctions started occurring after 5 years. Most patients (62%) had damage, predominantly in the musculoskeletal, neuropsychiatric and renal systems. Cerebrovascular accidents, renal transplants, replacement arthroplasties and myocardial infarctions, developed at young age (median age 20, 24, 34 and 39 years respectively). Multivariate logistic regression showed that damage accrual was associated with disease duration (OR=1.15; p<0.001), antiphospholipid-antibody positivity (OR=0.56; p=0.026), and hypertension (OR=3.21; p=0.043). Current HCQ-monotherapy was associated with an SDI-score of 0 (OR=0.16; p=0.009). HRQOL was impaired compared to the Dutch population. Presence of damage reduced HRQOL in only one domain. High disease activity (SLEDAI ≥8) and changes in physical appearance strongly reduced HRQOL (4/8 and 7/8 domains).

Conclusion: The majority of adults with cSLE in this large cohort developed significant damage at young age and have impaired HRQOL without achieving drug free remission, illustrating the great impact of cSLE on future life.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is treated with glucocorticoids, anti-malarials, immunosuppressive medications, and, more recently, biologics (specifically, belimumab and rituximab). While belimumab had positive results in trials, the rituximab trials were negative. With expanding therapeutic options, it is important to understand the current utilization patterns among patients with SLE, as this knowledge can inform policy, formulary planning and future needs. Little is known about the population level trends in the use of these agents, particularly during the early-years of the disease. We described the trends in medication use during the first five years after SLE diagnosis.

Methods: Using a large administrative database of commercially insured and Medicare Advantage beneficiaries across the U.S. (OptumLabs Data Warehouse) from 2006-2016, we identified newly diagnosed patients with SLE (ascertained using three ICD-9/10 codes separated by ≥ 30 days). Patients had at least two years of enrollment prior to SLE diagnosis and were followed for a maximum of five years after diagnosis or until disenrollment, whichever happened first. Follow up was calculated using the person-years method. For every year after diagnosis, we estimated the proportion of patients who filled prescriptions for the drugs of interest (figure).

Results: We identified 10,274 patients with newly diagnosed SLE, of whom 4227 had ≥ 5 years of follow up. Mean age at diagnosis (SD) was 45.7 (12.1) years, 89% were female, 62% were White, 17% Black, 12% Hispanic, 4% Asian, and 5% other/unknown race. Anti-malarials were the most frequently used drugs, filled at least once by 61% of patients during the first year after diagnosis, and decreased to 50% at five years after diagnosis. Prednisone was the second most frequently used drug, used by 47% of patients during the first year of the disease and 35% at 5 years after diagnosis. Methylprednisolone and other steroids were used by 20% or more patients consistently during the 5 years of follow up. Methotrexate was used by 12% of the patients during the first year, and was most common immunosuppressive drug prescribed. Azathioprine and mycophenolate mofetil were each used by 8% of the patients. Rituximab was used by 1% and belimumab by 2% of patients consistently during the five years of follow up. Overall there was a progressive decline in the use of most medications. By year five, 35% of the SLE patients did not fill prescriptions for any of the drugs of interest.

Conclusion: During the first five years after SLE diagnosis, there was a progressive decline in the use of all immunosuppressive medications. Five years after diagnosis, a high proportion of patients with SLE continue receiving glucocorticoids. Is unclear if these observations are due to lower disease activity over time, medication intolerance, increased noncompliance or combination thereof.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids, anti-malarials and conventional immunosuppressive agents have been the mainstay of therapy for systemic lupus erythematosus (SLE) and lupus nephritis (LN); more recently biologic agents have been introduced for their treatment. We evaluated utilization trends in SLE and LN therapy over the past decade.

Methods: Using 2006-2016 data from a large administrative database of commercially insured and Medicare Advantage beneficiaries, we identified patients with SLE and a subset of patients with LN based on validated claims-based algorithms. Included patients had at least one year of enrollment in the cohort. We estimated the annual age- and sex- standardized proportion of patients who filled prescriptions for at least one of the drugs of interest (Table).

Results: A total of 30,787 patients with prevalent SLE were identified, of whom 5,267 had LN. Mean age (SD) was 49.3 (14.1) years for SLE and 51.9 (17.2) years for LN. Ninety percent were female, 61.0% White, 17.4% Black, 11.2% Hispanic, 3.0% Asian and 7.0% other/unknown. Use and time trends of therapeutic agents for 2006-2016 are included in the table. Anti-malarials were the most frequently used drug class for both SLE and LN, with some temporal change over the course of the study; 50.1% in 2006 to 47.5% in 2016 for SLE, and 38.8% in 2006 to 45.1% in 2016 for LN. Prednisone was the second most frequently used drug, decreasing from 40.0% in 2006 to 34.7% in 2016; use of methylprednisolone and other systemic glucocorticoids increased during that time period. Methotrexate was the most commonly used nonbiologic immunosuppressive drug in SLE (8.0%), while MMF was most frequently prescribed in LN (15.0%), both of which remained stable during the study period. Cyclophosphamide use declined over the last decade for both SLE (1.2% to 0.3% in 2016) and LN (4.2% to 1.3% in 2016). Belimumab was the most commonly used biologic for SLE with a slight uptrend since approval. Rituximab use increased in SLE and was the most commonly used biologic for LN. At any point in time ~24% of the patients were not receiving any of the medications of interest.

Conclusion: Over the past decade, a substantial proportion of patients with SLE and LN continued to receive glucocorticoids. Although the use of prednisone declined, the use of methylprednisolone and other glucocorticoids increased concurrently. The proportion of patients receiving nonbiologic immunosuppressants remained relatively stable for both SLE and LN, however there was a progressive decline in the use of cyclophosphamide. Since 2011 the proportion of patients receiving rituximab is higher than for cyclophosphamide. The increasing use of biologics for SLE and LN, particularly rituximab, which is not currently approved for SLE, highlights the need to clarify their therapeutic role in these diseases.

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity is one of the major predictors of damage accrual and mortality in systemic lupus erythematosus (SLE). Glucocorticoid use, especially in high dose, could underestimate the inflammatory status in SLE patients. Based on that, a modification of the SLEDAI accounting for glucocorticoid dose has been proposed, the SLEDAI glucocorticoid index (SGI)¹. The aim of this study is to evaluate the impact of SGI and Mex-SLEDAI GI (M-SGI) as predictors of damage and mortality.

Methods: Patients from a multinational, multiethnic Latin American cohort were included in these analyses. SGI was calculated based on the impact of glucocorticoids proposed by the Toronto Cohort¹. The same value for the impact of glucocorticoid was used for developing an M-SGI. Damage accrual was evaluated using the SLICC/ACR damage index (SDI). To evaluate the impact of SGI and M-SGI on the first increase on damage and on mortality, Cox regression models were performed, adjusting for gender, age at diagnosis, ethnicity, medical coverage, place of residence, educational level, SDI at baseline and antimalarial, glucocorticoid and immunosuppressive drugs use before baseline. Similar models were applied for the SLEDAI and the Mex-SLEDAI. All confounders were evaluated at or before baseline, and disease activity indices were evaluated as a time-dependent variable.

Results: One thousand three-hundred and twenty-one patients were included, median (25th-75th) age at diagnosis was 27.0 (20.0-37.0) years, 582 (44.1%) were Mestizo, 532(40.3%) Caucasian, and 207 (15.7%) other. Median SLEDAI was 4 (0-12), Mex-SLEDAI was 3 (0-6), SGI was 7 (4-12) and M-SGI was 5 (2-9). Median follow-up was 4.3 (2.1-5.9) years. During follow up, sixty-nine patients (5.2%) died and 323 (24.5%) accrued new damage. The median values for the disease activity indices as a function of damage and mortality are depicted in Table 1. The corresponding hazard ratios are depicted in Table 2.

Conclusion: SGI and M-SGI predicted new damage and mortality in SLE patients independently of other well-known risk factors. However, their impact seems to be similar to those of the original versions of these instruments.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM **Hydroxychloroquine and Risk of Thrombosis in Patients with Systemic Lupus Erythematosus: A Systematic Review and Meta-analysis**

Authors: Sankhyan P, Boonpheng B, Cook CT

Background/Purpose: Over the course of the past few years hydroxychloroquine (HCQ) has been demonstrated to have a significant role in the symptom management of systemic lupus erythematosus (SLE) especially in milder forms of the disease. Several studies have also shown its benefit in prevention of thrombosis in SLE patients, yet the evidence remains unclear. We undertook this meta-analysis to assess the risk of vascular thrombosis on SLE patients on hydroxychloroquine.

Methods: A systematic review was performed on the studies obtained from the databases of MEDLINE, EMBASE and Cochrane, from inception through January 2018 to extract studies that demonstrated an odds ratio of thrombosis in SLE patients (with or without anti-phospholipid antibodies) who were treated with HCQ compared to those not treated with HCQ. Effect estimates from the individual study were extracted and combined using random-effect, generic inverse variance method of DerSimonian and Laird.

Results: 11 observational studies with a total of 14,066 SLE patients were enrolled. Compared with the patients not on HCQ, HCQ exposure was associated with significantly decreased risk of vascular thrombosis with a pooled odds ratio of 0.51 (95% CI 0.38-0.69, $p < 0.001$). However, the result may be limited by publication bias as assessed by funnel plot.

Conclusion: HCQ use is associated with 49% lower risk of vascular thrombosis compared to non-HCQ use in patients with SLE, as derived from our meta-analysis.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The risk-benefit of *Pneumocystis jiroveci* pneumonia (PCP) prophylaxis in systemic lupus erythematosus (SLE) is not well defined and there are no SLE-specific guidelines. On the one hand, the risk of PCP is relatively low.^{1,2} On the other hand, high frequency of trimethoprim-sulfamethoxazole (TMP-SMX) related adverse effects have been reported.³ Prophylaxis initiation is highly variable among providers, based on 2008 survey data.⁴ As a result, it is unknown whether the decision to initiate PCP prophylaxis is guided by patient-specific characteristics. Therefore, the objective of this study was to ascertain the rates of PCP prophylaxis and factors associated with prophylaxis initiation among SLE patients receiving immunosuppression.

Methods: Using electronic medical record, we identified new SLE as having: 1) ≥ 2 SLE ICD codes within 1-6 months of each other between 1/1/2006 and 12/31/2017, 2) no visits with SLE codes or SLE-related prescriptions within one year prior, and 3) ≥ 1 immunosuppressive prescriptions after the first SLE visit. Records of patients with the word “pneumocystis” were reviewed to identify PCP cases. Patient-specific characteristics were compared between patients who had received a prescription for PCP prophylaxis (TMP-SMX, atovaquone, or dapsone) within 14 days of starting immunosuppression (besides corticosteroids), and those who did not.

Results: Of the 693 patients who met inclusion criteria, there was 1 confirmed (by quantitative PCR in bronchoalveolar lavage) and 1 probable PCP case; 111(16%) were started on PCP prophylaxis (Table). Compared to patients not on prophylaxis, patients on PCP prophylaxis had a higher frequency of renal disease (15% vs. 7%, $p=0.002$) and congestive heart failure (5% vs. 2%, $p=0.04$). They were more likely to be on hydroxychloroquine (70% vs. 48%, $p<0.001$), and had a longer median duration between the first SLE visit and initiation of immunosuppression (3.5 vs. 11.5 months, $p<0.001$). There were no differences between groups in patient demographics, comorbidities, or cell counts at SLE onset.

Conclusion: Over a 12-year period at our tertiary care center, the use of PCP prophylaxis in SLE patients on immunosuppression was relatively low (16%), and the incidence of PCP among patients not on prophylaxis was rare (0.34%). Prophylaxis was significantly more likely to be initiated in SLE patients with cardiac or renal disease. Additional secondary analyses of duration and choice of PCP prophylaxis, as well as compliance and adverse effects that could have affected the number of patients on prophylaxis are ongoing. These results will guide establishment of evidence-based guidelines on the use of PCP prophylaxis for SLE patients.

Association of Hydroxychloroquine Use and Incident Atrial Fibrillation in Systemic Lupus Erythematosus: A Retrospective Study

Alisha Gupta¹, Aditya Joshi¹, Mary Chester-Wasko² and Tarun S. Sharma³, ¹Internal Medicine, Allegheny General Hospital, Pittsburgh, PA, ²Allegheny Health Network, Pittsburgh, PA, ³Rheumatology, Lupus Center of Excellence, Allegheny Health Network, Pittsburgh, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a derivative of quinidine, a class 1a anti-arrhythmic agent used to prevent ventricular arrhythmias and recurrent atrial fibrillation (AFib). AFib occurs more commonly in patients with systemic lupus erythematosus (SLE) compared to the general population. HCQ is a cornerstone treatment in SLE. This study examines the association of HCQ use and AFib or ventricular arrhythmias in SLE.

Methods: A retrospective cohort of adult SLE (ICD 10: M32) patients at a tertiary academic rheumatology practice from Dec 1,2014 to May 30,2017 excluding patients with prevalent AFib was constructed. Patients were categorized as HCQ users versus non-users. Primary outcome was incident AFib adjudicated by electronic health record (EHR) review and EKG confirmation. AFib events occurring in the first year of observation were considered prevalent AFib to allow for a run-in period and exclude prevalent cases more reliably. Secondary outcome was incident ventricular arrhythmias- a composite of ventricular tachycardia (VT), ventricular fibrillation (VF), torsades, and sudden cardiac death (SCD) adjudicated similarly. Multivariate regression analysis was performed to estimate the association between HCQ exposure and development of incident AFib, after adjusting for relevant confounders, including demographics (age, sex, ethnicity), AFib-related co-morbidities (BMI, smoking, alcohol use, chronic obstructive pulmonary disease, obstructive sleep apnea, hypertension, coronary artery disease, heart failure, diabetes, cerebrovascular accident and transient ischemic attack, peripheral vascular disease, thyroid disorder, chronic kidney disease and liver dysfunction), anti-arrhythmic medication use (beta-blockers, calcium channel blockers, flecainide, digoxin, amiodarone), and autoimmune serologies. Sub-group analysis was performed on patients age >65yrs (given higher risk of AFib).

Results: Our study included 1646 patients with SLE including 754 HCQ users. During the observation period, 5 AFib events occurred in HCQ users and 18 in non-users. Unadjusted odds ratio (OR) was calculated at 0.22 (95% CI 0.08-0.60, p=0.003), and multivariable logistic regression analysis showed an OR of 0.33 (95% CI 0.12-0.91, p=0.03) for incident AFib. Six incident ventricular arrhythmia events (2 VT, 3 torsades, 1 SCD) occurred in HCQ users and 3 (2 VT, 1 SCD) occurred in non-users with OR of 2.49 (95% CI 0.62-9.9, p=0.2). In the age>65 yrs sub-group analysis, OR was 0.4 (95% CI 0.13-1.25, p=0.11).

Table 1: Risk of incident atrial fibrillation according to hydroxychloroquine use in systemic lupus erythematosus

Variable	HCQ users (N=934)	HCQ non- users (n=754)
Age (yrs)	52.2±14.0	56.3±14.7
Female sex	867 (93%)	693 (92%)
Caucasian	777 (83.1%)	615 (81.6%)
BMI (kg/m2)	28.8±7.6	29.5±8.2
Smoking (ever)	372 (39.8%)	336 (44.6%)
Alcohol user	402 (43%)	302 (40%)
Anti-arrhythmic medication use	121 (12.9%)	129 (17.1%)
HTN	244 (26%)	265 (35.1%)
COPD	2 (0.2%)	3 (0.4%)
OSA	19 (2%)	37 (4.9%)
CAD	44 (4.7%)	65 (8.6%)
Heart failure	45 (4.8%)	70 (9.3%)
Diabetes	60 (6.4%)	105 (13.9%)
CVA/TIA	10 (1.1%)	19 (2.5%)
Thyroid disorder	5 (0.5%)	6 (0.8%)
Liver dysfunction	31 (3.3%)	25 (3.3%)
CKD	62 (6.6%)	77 (10.2%)
PVD	20 (2.1%)	32 (4.2%)

Table . (Cont'd)

Variable	HCQ users (N=934)	HCQ non- users (n=754)
AFib	5 (0.5%)	18 (2.4%)
Unadjusted Odds Ratio	0.22 (95% CI 0.08-0.60, p=0.003)	
Adjusted Odds Ratio	0.33 (95% CI 0.12-0.91, p=0.03)	

Conclusion: In this exploratory study, HCQ use was associated with a 67% reduced risk of incident AFib in SLE. In light of the cardiovascular risk benefits of HCQ and its close relation to anti-arrhythmic medication quinidine, if our preliminary results are confirmed in larger studies, our findings may be used as rationale for a randomized study of HCQ's protective role against AFib in high-risk patients with SLE.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune diseases, including systemic lupus erythematosus (SLE), are associated with dysregulated T cell and B cell responses. AMG 570 is a bispecific molecule targeting T cell and B cell activity through inhibition of the inducible costimulator ligand (ICOSL) and the B cell activating factor (BAFF). We hypothesize that targeting both ICOSL and BAFF will be more effective than single target inhibition in SLE and other autoimmune diseases.

We investigated if targeting ICOSL and BAFF has superior efficacy to single target inhibition in mouse arthritis and lupus models. We also investigated the safety, tolerability, pharmacokinetics, and pharmacodynamics of AMG 570 in healthy subjects after single subcutaneous doses.

Methods: A murine surrogate ICOSL/BAFF bispecific along with single or combination inhibition was evaluated in the mouse collagen induced arthritis (CIA) and NZB/NZW lupus models. AMG 570 binding affinity to human and cyno ICOSL/BAFF was tested by Kinexa A. An ongoing, first-in-human study has enrolled healthy adult subjects into 6 escalating single-dose cohorts. Eight participants were enrolled into each cohort and randomized 3:1 to receive AMG 570 or placebo. The primary endpoint of the study was treatment-emergent adverse events (AEs). Secondary endpoints included pharmacokinetics and pharmacodynamics.

Results: ICOSL and BAFF dual inhibition was more effective than single inhibition in ameliorating arthritis incidence and severity in the mouse CIA model as well as reducing anti-dsDNA IgG, delaying proteinuria and improving survival in the NZB/NZW lupus model. Based on high affinity to ICOSL and BAFF, AMG 570 was selected for investigation in a single ascending dose study in healthy subjects. As of an ad hoc interim analysis following six cohorts, 48 healthy participants received one dose of investigational product (AMG 570 or placebo). Overall, 73 mild to moderate AEs were reported. The most common AEs were upper respiratory tract infection and injection site erythema. No drug-related serious AEs or fatal AEs were reported thus far. AMG 570 demonstrated nonlinear pharmacokinetics consistent with cell surface ICOSL binding. At the highest dose tested, AMG 570 achieved >90% mean ICOSL receptor occupancy on circulating B cells 8 days after dosing. AMG 570 led to a reduction in circulating naïve B cells and an increase in circulating memory B cells.

Conclusion: Dual inhibition of ICOSL and BAFF is more efficacious than single target inhibition in mouse disease models. In healthy subjects to date, single doses of AMG 570 have been safe, well-tolerated and demonstrated pharmacodynamic activity consistent with inhibition of both ICOSL and BAFF.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease involving many organs and systems. Evidences show that vitamin D plays an important role in the pathogenesis and progression of SLE. Vitamin D deficiency is highly prevalent in SLE patients due to photoprotection, renal insufficiency and use of different medication. But a causal relationship between vitamin D serum concentration and disease activity in SLE patient could not be established.

To evaluate the prevalence of vitamin D deficiency in patient with SLE and to investigate the association between vitamin D serum concentrations and disease activity, fatigue and quality of life and autoantibodies levels in SLE patients.

Methods: We included a total number of 92 patients diagnosed with SLE according to the American College of Rheumatology (ACR) classification criteria. We assessed disease activity according to SLEDAI and organs damage according to SLICC criteria. All patients completed the quality of life questionnaires Health Assessment Questionnaire (HAQ) and EuroQol. Serum vitamin D levels were measured by standardized immunochemical assay from blood samples.

Results: We analyzed 92 patients, 85 (92,4%) women and 7 (7,6%) men. 43 (46,7%) patients had lower level of vitamin D than the standard given by the laboratory (< 50 nmol/l), the mean was $38,3 \pm 11,2$ nmol/l.

On contrary to some recent studies we did not find any statistically significant differences in the quality of life, fatigue, and disease activity between two groups with low and normal vitamin D levels. Conversely, in low vitamin D group, milder fatigue, better quality of life and lower anti-dsDNA antibody levels were found. Only when we compared a group of 35 patients with an initially low level of vitamin D ($39,7 \pm 9,8$) after supplementing it to standardize its level ($67,3 \pm 15,7$), we found improvements in quality of life, functional ability of patients, fatigue reduction, and decreased SLE activity in these patients according to SLEDAI.

Conclusion: We demonstrated a very high frequency of vitamin D deficiency and insufficiency among patients with SLE. But we didn't establish a causal relationship between vitamin D serum concentration and disease activity in SLE patients. On the other hand, we demonstrated a trend of fatigue and disease activity reduction with vitamin D supplementation in these patients. The limitation of our observation was mainly small sample size of patients and although we included patients with established diagnosis of SLE who are on the long treatment including glucocorticoids and other immunosuppressive drugs.

This study was supported by the Research Project No. 0002372801 of the Czech Ministry of Health.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Preventing organ damage is a major challenge in Systemic Lupus Erythematosus (SLE). To evaluate factors associated with development of steroid-related and unrelated damage in an inception cohort of early diagnosed SLE patients.

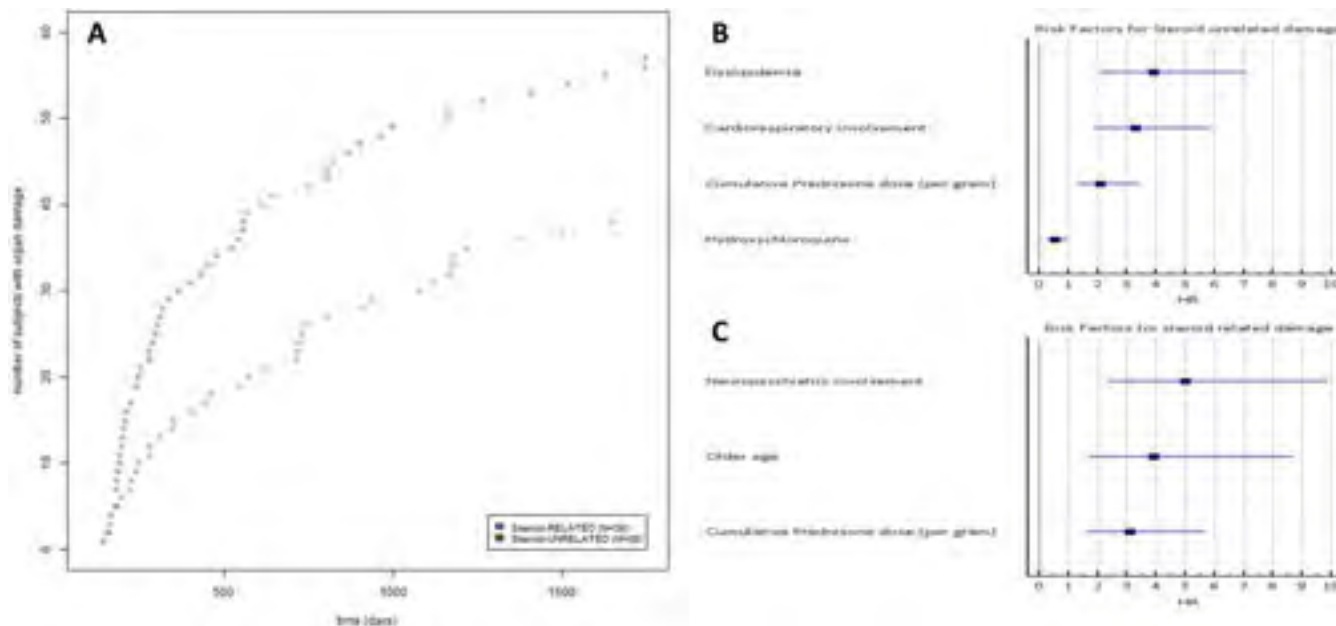

Methods: The Early Lupus Project encompasses 9 Italian centers recruiting consecutive patients diagnosed within 12 months of SLE (1). At enrolment and then every 6 months a panel of data (including demographic, comorbidities, serologic, clinic by BILAG2004 domains, ECLAM, HRQoL by visual analogic scale and treatment) was recorded. Using univariate analysis, we assessed the contribution of covariates collected at baseline in development of steroid-related and not-related damage categorized according to previous definition (2) and assessed by the SLICC/ACR Damage Index (SDI from 0 to ≥ 1). Forward-Backward Cox-regression models were fitted with covariates with $p < 0.05$ to identify factors independently associated with increased risk of damage development.

Results: Overall, 279 patients were enrolled in the Early Lupus Project inception cohort up to the 31st of December 2017; 230 patients (89.6% Caucasians, 13.4% males) were eligible for this study having SDI=0 at enrolment and at least 6 months of follow-up. Age (mean \pm SD) at diagnosis was 36.5 ± 14.4 years, the median interval between diagnosis and recruitment was 1.1 months (interquartile range 0.0-4.8) and median follow-up was 27.4 months (interquartile range 7.2-48.0).

At last follow-up visit 84 patients (36.5%) had an SDI score ≥ 1 (median = 0; interquartile range 0-1); 38 of them (16.5%) developed steroid-related damage and 58 (25.2%) developed steroid-unrelated damage. Figure A shows the kinetics of damage development.

Factors independently associated with increased risk of developing steroid-related damage were baseline neuropsychiatric involvement ($p < 0.001$; HR 5.0 95% CI 2.3-10.6), older age ($p = 0.001$; HR 3.9 95% CI 1.8- 8.7) and cumulative prednisone dose ($p < 0.001$; HR 3.1 per 10 grams; 95% CI 1.6-5.7) were (Figure B). Factors independently associated with increased risk of steroid-unrelated damage accrual were baseline dyslipidemia ($p < 0.001$; HR 3.9 95% CI 2.1-7.1), cardiorespiratory involvement ($p < 0.001$; HR 3.3 95% CI 1.9-5.9), and cumulative prednisone dose ($p < 0.001$; HR 1.0001 per 10 grams; 95% CI 2.1-3.4), whereas hydroxychloroquine reduced the risk of steroid-unrelated damage ($p = 0.041$; HR 0.53; 95% CI 0.29-0.98) (Figure C).

Conclusion: The risk profile for damage development in this early SLE cohort differs for steroid-related and unrelated damage. Addressing modifiable risk factors, adding hydroxychloroquine since the very early stages and treating disease activity to target remission or minimal disease activity, may reduce damage and improve patients outcome.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multisystem autoimmune disease with complex genetic background. Recently, subphenotype in SLE has influenced dialogue on discussing the genetic background, disease course, outcomes and treatment. The objective of this study is to identify phenotype clusters within a SLE cohort patients, and compare the genetic risk score (GRS), clinical manifestations and mortality between clusters.

Methods: This is a single center, descriptive study of from Hanyang BAE lupus Cohort. Patients whose disease duration is less than 5 years were excluded to minimize potential confounding effects of disease duration. Mortality data were derived in connection with data from the Korean National Statistics Office. Patients were grouped into 3 clusters based on SLICC Damage Index (SDI) using K-mean cluster analysis. Clinical characteristics were compared using ANOVA and Tukey's test.

Results: In 1130 analyzed patients, musculoskeletal damage was the most prevalent (20.2%), followed by ocular (11.4%), renal (10.5%) and neuropsychiatric damage (10.2%). Three separate damage clusters were identified, each with significantly different damage manifestations. Cluster 1 (n=824) showed the least damage profile. Cluster 2 (n=195) was represented by the predominance of renal damage (55.4%), with prevalent ocular (58.0%), musculoskeletal (29.2%) damage and diabetes

Table 1. Cluster analysis of 1130 SLE patients

Variable	Damage Cluster			P
	Cluster 1 (n=824)	Cluster 2 (n=195)	Cluster 3 (n=111)	
Female sex	774 (93.9)	169 (86.7)	102 (91.9)	<0.01
Disease duration, years	12.1 ± 5.4	15.0 ± 6.1	14.1 ± 5.8	<0.01
Age at SLE diagnosis	27.9 ± 10.5	27.2 ± 11.3	26.6 ± 10.4	0.40
Adjusted mean SLEDAI	4.0 ± 2.2	5.4 ± 2.9	4.2 ± 2.9	<0.01
SDI score at enrollment	0.2 ± 0.6	0.9 ± 1.2	1.3 ± 1.5	<0.01
SDI score at last follow up	0.5 ± 0.9	2.8 ± 2.1	2.8 ± 1.8	<0.01
Ocular	0	113 (58.0)	16 (14.4)	<0.01
Neuropsychiatric	0	4 (2.1)	111 (100.0)	<0.01
Renal	0	108 (55.4)	11 (9.9)	<0.01
Pulmonary	60 (7.3)	20 (10.3)	19 (17.1)	0.02
Cardiovascular	26 (3.2)	13 (6.7)	3 (2.7)	0.15
Peripheral vascular	27 (3.3)	8 (4.1)	5 (4.5)	0.76
Gastrointestinal	8 (1.0)	3 (1.5)	3 (2.7)	0.45
Musculoskeletal	132 (16.0)	57 (29.2)	39 (35.1)	<0.01
Skin	31 (3.8)	10 (5.1)	7 (6.3)	0.46
Premature gonadal failure	0	5 (2.6)	4 (3.6)	<0.01
Diabetes Mellitus	22 (2.7)	16 (8.2)	6 (5.4)	<0.01
Malignancy	47 (5.7)	7 (3.6)	3 (2.7)	0.13
Weighted GRS	1.56 ± 1.09	1.78 ± 1.00	1.43 ± 1.12	0.04*
Mortality	20 (2.4)	11 (5.6)	16 (14.4)	<0.01

Data were given as mean ± SD or number (%).

SLE, Systemic Lupus Erythematosus, SLEDAI, Systemic Lupus Erythematosus Disease Activity Index, SDI, Systemic Lupus International Collaborating Clinic/American College of Rheumatology Damage Index; GRS, Genetic Risk Score

*Tukey's test showed no differences

mellitus (8.2%). Cluster 3 (n=111) was characterized by neuropsychiatric damage (100%) with musculoskeletal (35.1%) and pulmonary damage (17.1%). Age of onset of SLE and autoantibody positivity were similar among clusters. Cluster 2, represented by prevalent renal and glucocorticoid associated damages, showed higher adjusted mean SLEDAI score (AMS) (Mean ± SD, 6.7 ± 4.8) than other two clusters. Cluster 3 distinguished by neuropsychiatric damage showed the highest mortality among three clusters. However, GRS showed no difference between 3 clusters after Tukey's test.

Conclusion: We identified different patterns of damage manifestations in a large cohort of SLE patients. Renal and neuropsychiatric damage were the two distinct domain of damage that classified patients into 3 clinically meaningful clusters. Patients in cluster 2 (prevalent renal and glucocorticoid associated damage) had the highest AMS. The highest mortality was recognized in cluster with prevalent neuropsychiatric damage. However, GRS showed no difference between clusters. Further studies assessing comprehensive subphenotypes are needed.

Age-Related Metabolic Changes Underlie Pro-Inflammatory Lineage Specification and Contribute to Therapeutic Responsiveness to Mechanistic Target of Rapamycin Blockade in SLE

Zhi-Wei Lai¹, Ryan Kelly² and Andras Perl¹, ¹Medicine, SUNY Upstate Medical University, Syracuse, NY, ²SUNY, Syracuse, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients exhibit T-cell dysfunction which can be reversed by blockade of the mechanistic target of rapamycin (mTOR) with therapeutic efficacy (Nat. Rev. Rheumatol. 12:169-182, 2016; Lancet, 391:1186-1196, 2018). Since mTOR is a key controller of mammalian lifespan (Nature 460:392-395, 2009; Science 326:140-144, 2009), we examined the relationship of immune senescence to rapamycin-responsive pro-inflammatory lineage skewing in SLE.

Methods: 838 immunometabolic parameters were assessed by flow cytometry (Lancet, 391:1186-1196, 2018) in 84 SLE patients (44.3 ± 1.4 years of age; mean \pm SE; range 18-71) having active disease and unresponsive or intolerant to conventional medications, but unexposed to treatment with rapamycin. Disease activity was characterized by SLEDAI (10.1 ± 0.7), BILAG (27.8 ± 1.3), and prednisone use (5.3 ± 1.4). Control samples for biomarker studies were obtained from 84 healthy controls (HC) and matched for patients' age (45.0 ± 1.4 years of age; range 20-63), gender, and ethnicity for each visit. Rapamycin (sirolimus) was started at 2 mg/day with dosage adjusted to tolerance and 6-15 ng/ml through levels in 40 of these SLE patients over 12 months (ClinicalTrials.gov number NCT00779194). The number (n) of patients available for each assay is indicated. Statistical analyses were performed with GraphPad (San Diego, CA); changes at 2-tailed $p < 0.05$ were considered significant for hypothesis testing.

Results: Patients' age did not correlate with SLEDAI, BILAG, or prednisone dosage. Aging occurred with increased mitochondrial transmembrane potential or mitochondrial hyperpolarization (MHP) and increased mitochondrial mass in all T cells, increased CD4/CD8 ratio, depletion of CD45RA⁺ naïve and expansion of CD45RO⁺ memory CD8⁺ T cells both in SLE and HC subjects. Expression of CD98 and activation of mTOR complex 1 (mTORC1) in CD4⁺ T cells was enhanced and CD4⁺CD25⁺FoxP3⁺ Tregs were expanded of HCs only, while mTORC1 activity was selectively increased in CD8 T cells and CD4⁺CD8⁻CD3⁺ double-negative (DN) CD27⁺CD197⁻ T cells and CD8⁺CD62L⁻CD197⁻ effector-memory T cells were only expanded in SLE patients with aging. Rapamycin expanded CD4⁺CD45RO⁺ memory T cells, CD8⁺CD62L⁻CD197⁻ effector-memory T cells, and CD8⁺FoxP3⁺ Tregs irrespective of age, while it preferentially reduced nitric oxide production, MHP, and mitochondrial mass in DN T cells, expanded CD4⁺FoxP3⁺ Tregs, IFN γ -producing CD4⁺ and CD8⁺ T cells, and CD19⁺ B cells in younger SLE patients (37.0 ± 2.7 years of age; n=14). Rapamycin preferentially reduced the production of IL-4 and IL-17 by DN and CD8⁺ T cells in older SLE patients (57.6 ± 1.5 years of age; n=14).

Conclusion: Age-related metabolic changes underlie pro-inflammatory lineage specification and may contribute to clinical efficacy of mTOR blockade in SLE.

SLE Patients with No Organ Damage Might Benefit More from Belimumab Treatment

Ioannis Parodis^{1,2}, Sharzad Emamikia^{1,2}, Alvaro Gomez¹ and Katerina Chatzidionysiou^{2,3}, ¹Division of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, ²Rheumatology, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, ³Division of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), organ damage is associated with unfavourable disease courses and premature mortality. We aimed at investigating the impact of organ damage on belimumab treatment efficacy.

Methods: We included 1684 patients with SLE from the BLISS-52 (n=865) and BLISS-76 (n=819) trials. Data were accessed through a data sharing agreement with GSK. Organ damage was assessed using the SLICC/ACR Damage Index (SDI). Disease activity was assessed using the SLEDAI-2K. We evaluated baseline SDI scores as predictors of treatment outcome using logistic regression with SLE responder index (SRI) response at week 52 as the dependent variable. Adjustments for potential confounding factors were performed as appropriate.

Results: When all patients were considered, high baseline SDI scores were associated with a lower chance of attaining SRI response (OR: 0.88, 95% CI: 0.81-0.95; P=0.002). In multivariate analysis, a high baseline SDI score was an independent predictor of non-response, as was long disease duration, whereas high baseline disease activity and high baseline prednisone dose independently predicted SRI response (Figure). We observed the same association between high baseline SDI scores and non-response at week 52 in patients who received belimumab (1 mg/kg or 10 mg/kg; n=1122) (OR: 0.88, 95% CI: 0.79-0.97; P=0.007). High SDI scores independently reduced the probability of response, and high baseline disease activity and prednisone dose independently predicted SRI attainment. Interestingly, disease duration was no longer an independent predictor of treatment outcome (Figure). In patients who received standard of care therapy only (n=562), baseline SDI score were not found to impact the treatment outcome (OR: 0.88; 95% CI: 0.76-1.02; P=0.091).

Conclusion: Previous observations of baseline organ damage reducing belimumab efficacy (1) were corroborated. This impact of organ damage on treatment efficacy was not seen in the placebo group, lending support for a treatment-specific effect. The data suggest that belimumab may be expected to be more efficacious in SLE patients with no organ damage established prior to treatment initiation, irrespective of disease duration and activity grade.

A Systematic Review Examining the Association between Organ Damage and Health-Related Quality of Life in Systemic Lupus Erythematosus

Edward R. Hammond¹, Dora H. Lin², Irene B. Murimi², Henk Nab³, Hong Kan², Oluwadamilola Onasanya², Jonothan Tierce², Xia Wang¹, Barnabas Desta¹ and G. Caleb Alexander², ¹AstraZeneca, Gaithersburg, MD, ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, ³AstraZeneca, Cambridge, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE-related organ damage is associated with increased morbidity. The comorbidity burden of SLE can involve various organ systems and may include pain, fatigue, difficulty in performing daily life activities, and reduced physical and emotional well-being, all of which contribute to high rates of disability. We conducted a systematic literature review to assess the association between SLE-related organ damage and health-related quality of life (HRQOL).

Methods: Systematic search of PubMed, EMBASE, Cochrane Library, and Latin American and Caribbean Health Sciences Literature bibliography (Jan 2000–Feb 2017) to identify studies in which the association between organ damage (measured by SLICC/ACR Damage Index [SDI]) and HRQOL was evaluated in adults with SLE.

Results: Of 10,420 articles screened, 20 studies (3 prospective cohort and 17 cross-sectional) were included in the analysis. For HRQOL, the 36-item Short-Form Health Survey (SF-36: Physical and Mental Component Summaries [PCS and MCS]) was used in 15 studies; the Fatigue Severity Scale (FSS) in 2 studies; the EuroQOL 5D in 2 studies; and the LupusQOL, Multidimensional Fatigue Inventory, Quality of Life Questionnaire of the European Foundation for Osteoporosis, and WHO Quality of Life Scale (WHOQOL-BREF) in 1 study each. HRQOL was assessed using the SF-36 in the 3 prospective studies; in 2 of these, SDI was modeled as a binary variable. For patients without baseline organ damage, any damage accrued over 2 years was associated with a 5.5-fold increased risk of reduced HRQOL (SF-36 overall relative risk [RR]: 5.5 [95% CI: 1.1–26.6; $p=0.03$]). Similar trends were observed for PCS (RR: 2.5 [95% CI: 0.6–10.0; $p=0.19$]) and MCS (RR: 4.6 [95% CI: 0.9–22.8; $p=0.06$]). Any damage at baseline was associated with 67% reduced odds of achieving minimum clinically important improvement in SF-36 PCS (odds ratio: 0.33 [95% CI: 0.13–0.85; $p=0.02$]; no association was noted for MCS. When SDI was modeled as a continuous variable, increasing organ damage was associated with reduced SF-36 PCS compared with no damage [regression coefficients: (SDI=0); SDI 1: -2.64, $p<0.001$; SDI 2: -2.86, $p=0.003$; SDI 3: -5.94, $p<0.001$; SDI 4: -6.35, $p<0.001$; and SDI 5+: -8.11, $p<0.001$]. In cross-sectional evaluations, increasing organ damage correlated modestly with reduced HRQOL (SF-36 correlation coefficient: -0.12 to -0.30; SF-36 regression coefficient: -0.011 to -4.65; LupusQOL correlation coefficient: -0.31, $p<0.01$; and WHOQOL-BREF regression coefficient: -0.06, $p=0.57$). Increasing fatigue was weakly correlated with organ damage (FSS correlation coefficient: 0.04 to 0.15).

Conclusion: In most studies analyzed, organ damage was associated with reduced HRQOL. Heterogeneity in HRQOL instruments and methodology was observed across studies. Improving construct validity of instruments and consistent evaluation will enable a more accurate estimation of the burden of SLE and enhance efforts to improve HRQOL in SLE.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We conducted an integrated analysis of pooled safety data from all 17 atacicept clinical studies to date, across multiple indications, to further define atacicept's safety profile.

Methods: Analyses were based on 3 pooled datasets: Double-blind placebo (PBO)-controlled set (DBPC-S n=1,568; key endpoint: treatment-emergent AEs [TEAEs]); SLE set (SLE-S n=761; key endpoint: IgG change and serious infection rates); full analysis set (FA-S n=1,845; key endpoint: exposure-adjusted mortality).

Results: Of 1,568 patients in the DBPC-S, 30.8% received PBO, and 8.2%, 24.5% and 36.5% received atacicept 25, 75 and 150 mg, respectively. Overall, baseline characteristics were balanced across treatment arms. Treatment exposure was similar with PBO and atacicept 75 mg and 150 mg (278.3, 225.0 and 286.7 patient-years, respectively), but was lower with atacicept 25 mg (51.5 patient-years). Exposure-adjusted TEAE rates were generally higher with atacicept vs placebo, with no consistent association between atacicept dose and cardiac arrhythmias, serious and severe infections or injection site reactions (Table). Serious infection and serious TEAE rates were similar between atacicept and PBO. TEAE-related discontinuation rates were higher with atacicept versus placebo (16.1 vs 10.9/100 patient-years). In the SLE-S, there was no association between reduced IgG levels and increased infection rates. Across all studies (FA-S), 11 patients died during treatment (10 atacicept [0.5%], 1 PBO [0.1%]; see Table for infection-related deaths in the DBPC-S). Exposure-adjusted mortality rates/100 patient-years (95% CI) were 3.60 (0.90–14.38), 0.34 (0.05–2.43), 1.18 (0.49–2.82) for atacicept 25, 75 and 150 mg, and 0.44 (0.06–3.12) with PBO.

Conclusion: Results from this pooled analysis clarify the benefit-risk relationship for atacicept, which is being further evaluated in additional clinical studies in IgA nephropathy and SLE.

Table. Exposure-adjusted TEAE rates by dose (DBPC-S)

	PBO n=483	Atacicept				Total, n=1,568
		25 mg, n=129	75 mg, n=384	150 mg, n=572	All, n=1,085

Glucocorticoids Withdrawal in Systemic Lupus Erythematosus: Are Remission and Low Disease Activity Reliable Starting Points for Stopping Therapy? a Real-Life Experience

Viola Signorini, Chiara Tani, Elena Elefante, Chiara Stagnaro, Linda Carli and Marta Mosca, Rheumatology Unit, University of Pisa, Pisa, Italy

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GC) are a cornerstone of the treatment of Systemic Lupus Erythematosus (SLE); however, a significant organ damage is associated with long-term GC use in SLE. GC withdrawal is therefore a target in SLE management.

The aims of our study were to evaluate the proportion of patients GC-free in a prospective cohort over a period of 6 years, to evaluate the main characteristics of patients at GC withdrawal with respect to the available definitions of remission and low disease activity (LDAS), to evaluate the occurrence of flares after GC withdrawal.

Methods: This is a retrospective study of prospectively collected data from a monocentric longitudinal cohort of patients with SLE (revised ACR criteria) followed from 2012 to 2017. Patients GC-free at last visit in 2017 were identified and compared with patients on GC at last visit. Patients GC free at the cohort entry (n= 35) or patients with incomplete follow-up (n=45) were excluded from this analysis. Disease activity was evaluated with the SELENA-SLEDAI index, while organ damage with the SLICC/DI. Definitions of remission according to the European consensus criteria (DORIS) and of LDAS according to the Asian Pacific Lupus Consortium definition and LDAS were applied at GC withdrawal.

Results: A total of 188 patients were included; characteristics of GC-free (n=69) and on GC patients (n=119) at last observation are reported in table 1.

Among GC-free patients, disease activity at the moment of GC discontinuation was low (median SLEDAI: 1.2, IQR 0-2) and 12.2% of patients were serologically active; 77,8% had at least one organ damage. 49.2 % of patients were in complete remission on treatment (cRONT), 42.9% in clinical remission on treatment (clRONT) and 6.35% were in LLDAS.

Nine disease flares (14%) were recorded after GC withdrawal (6 cutaneous \pm articular, 3 renal) after a median time of 1 year (min 6 months- max 3 years). By comparing the pre-GC stopping and the post GC stopping periods for each patients we didn't observed a significant increase in the number of flares (p=n.s.); the patients who flared didn't show a significant difference neither of SLEDAI, nor complement values at the stop of GC. Being in remission or in LDAS was not associated with a different risk in disease flare (OR: 0.6; p=n.s)

	GC free (n=69)	on GC (n=119)	p
Age (IQR)	46 (36,53)	44 (35,45)	0.97
Disease duration	15,5 (7-23)	15 (9-22)	0.8
SLICC LAST median (IQR)	0 (0-1)	1 (0-2)	0.007
SLEDAI LAST median (IQR)	2 (0-2)	2 (0-4)	0.01
Therapy with HCQ	56/69 (%)	96/120 (%)	0.8
Therapy with immunosuppressants	30/69 (%)	56/120 (%)	0.6

Conclusion: This analysis shows that GC withdrawal is feasible in a significant proportion of patients on remission or low disease activity; in these patients GC withdrawal is not associated with an increased risk of disease flare and probably it would spare damage accrual.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with fluctuating levels of disease activity. Control of disease activity is associated with better outcomes and the ability to self-manage one's health is an important skill towards this goal. We describe patient's activation towards health self-management in a population of lupus patients and the factors associated with lower health self-management.

Methods: Patients from the Canadian Network for Improved Outcomes in SLE (CaNIOS) centers participating in the MyLupusGuide™ randomized clinical trial were studied at baseline for their health self-management skills. The study is conducted online after patients receive a written invitation to participate, provide consent, and register online. The Patient Activation Measure (PAM) is a validated self-reported tool designed to measure an individual's level of confidence, beliefs, knowledge, and skills about managing one's health. PAM can be used as a continuous score or be divided into four levels with the first two levels indicating insufficient or low activation. We used the PAM as our outcome of interest and compared it to other self-reported data on demographics and psychosocial variables using several validated self-reported instruments (Table 1). Descriptive statistics were performed and univariate linear regressions using mixed model with random effect for site were used for continuous and categorical variables.

Results: Baseline data collection for MyLupusGuide™ trial was available for analysis on 539 patients from ten centers. Their baseline characteristics are reported in Table 1 with mean (sd) age = 50 (14), female = 91%, Caucasian = 74%. The mean PAM score was moderate at 61.2 (13.5) with a proportion of 16, 20, 42 and 22% in PAM levels 1 to 4 respectively, indicating insufficient and low activation towards health self-management in 36% of patients. Variables associated with lower PAM scores (Table 1) included shorter disease duration, higher disease activity, lower physical and mental health status, depressive symptoms, less distraction and instrumental coping and more emotional coping, lower lupus self-efficacy and less social support. Categorical variables associated with lower PAM were being work disabled and less medication adherence.

Table 1: Baseline demographic, disease and psychosocial characteristics of 539 SLE patients and their association with activation towards health self-management.

Abstract Number: 2681

Lupus Primary Care Management Practices

Karin Tse and R. Paola Daly, Lupus Foundation of America, Washington, DC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to the systemic nature of lupus, individuals may interact with a diverse healthcare team when experiencing lupus symptoms and before receiving a diagnosis. This study describes the management practices of various physicians who may care for patients presenting with lupus with a focus on primary care physicians (PCPs) to highlight areas of opportunity to reduce time to diagnosis and care.

Methods: An online survey was administered to 910 physicians in September 2016 using a provider list from the Lupus Foundation of America and a commercial web panel of physicians. Data collection included physicians' perceptions, attitudes and reported behaviors related to the path to diagnosis and treatment of people with lupus. Descriptive analyses were conducted using chi-square and Kruskal Wallis tests for post-hoc comparisons.

Results: Respondent characteristics are described in Figure 1. Figure 2 summarizes referral and management practices among different provider types, notably with higher proportions of dermatologists and PCPs often diagnosing or treating lupus patients. Rheumatologists were excluded from analyses as they are the primary healthcare providers for people with lupus. All provider groups differed significantly from one another in management practice, with PCPs being more likely than pediatricians and OB/GYNs to manage lupus patients on their own before referring patients out. Providers classified as having minimal or no experience with lupus were also asked to identify earliest actions they would take during an appointment if a patient presented with lupus symptoms. 86.2% of PCPs with minimal experience (n=119) would order bloodwork as their first action, which was a higher percentage than all other provider types. Only 13.8% of these PCPs reported that referring to a specialist would be their first action, ranking last after ordering bloodwork, asking a patient to track symptoms and following up, or directly treating the symptoms.

Conclusion: PCPs frequently care for patients presenting with lupus who may or may not yet be diagnosed. These analyses highlight the tendency of PCPs to delay referrals when caring for these patients. Further studies should be conducted to examine whether this management preference exists among larger groups of PCPs and explore potential barriers for referring to specialists.

Disclosure: The Lupus Foundation of America received funding from UCB Pharma to support study data collection.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Streptococcal infections can cause rheumatic fever sharing clinical presentations similar to SLE. Whether oral commensal streptococci could induce cross-reactive and pathogenic antibodies remained unknown. So we aimed to search for novel biomarkers in SLE through cross-reactive antibody repertoire screening, and we investigated to find specific antibodies presented in the serum of lupus patients.

Methods: The streptococcal L7/L12 ribosomal protein(RP-L7/L12) was identified through serum antibody-screening assay in SLE patient with higher disease activity followed by a proteomic approach. Recombinant RP-L7/L12 was purified and serum antibody levels were detected by ELISA quantitatively. The biomarkers of kidney impairment associated with SLE such as UPCR(urine protein to creatinine ratio), serum complement component 3(C3) and Anti-dsDNA were test serially too.

Results: A total of 25 lupus patients were enrolled from Jan, 2016 to May, 2018, with diagnosis of systemic lupus erythematosus according to The Systemic Lupus International Collaborating Clinics (SLICC) 2012 criteria, were to receive rituximab (500 mg) on days 1, 15, 168 (Week 24), and 182. The primary end point was UPCR result at day 336 (Week 48). Patients (N=14/25, 56%) respond to rituximab therapy (decrease of UPCR compared to baseline UPCR (baseline mean: 1.97 ± 2.84 mg/mg; Day 336 (Week 48) Mean: 0.44 ± 0.58), and the overall improvement of UPCR is significant ($p=0.01$ (Wilcoxon signed-rank test)); The concomitant increase of C3 (70.9 ± 28.1 mg/dL; Week 48: 85.19 ± 23.54 mg/dL, $p=0.004$), decreasing Anti-dsDNA (192.11 ± 203.48 ; Week 48: 107.30 ± 101.19 WHO units/mL, $p=0.0025$), and steroid sparing effect (prednisolone equivalent: 15.70 ± 9.47 mg/day; Week 48 mean: 10.20 ± 6.08 , $p=0.0032$) were also noted. The mean SELENA-SLEDAI scores (systemic lupus erythematosus disease activity index SELENA modification) was higher in the response group. Higher anti-RP L7/L12 antibody titres (0.72 ± 0.35 (SLE-glomerulonephritis (GN)) vs 0.52 ± 0.33 ($p=0.09$)) in patients with SLE is associated with higher rate of GN (proteinuria ≥ 0.5 gm/day.) An average 76.0% decrease of anti-RP-L7/L12 titre after a 24-week interval were detected in patients of SLE (N=15) receiving rituximab. Another three patients with SLE had two-fold increase in anti-RP-L7/L12 after rituximab, probably indicative of disease flare. The Pearson correlation coefficient was calculated between the dynamics of anti-RP-L7/L12(baseline/12/24-week) and the dynamics of UPCR change, a moderate positive correlation was observed ($R^2=0.3367$.)

Conclusion: Higher streptococcal anti-RP L7/L12 antibody in SLE is associated with higher rate of glomerulonephritis. The novel antibody against commensal bacterial antigen is predictive of the response of rituximab in SLE. Further identification of human cross-reactive antigens were underway.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-2 (IL-2) is crucial for the growth and survival of regulatory T cells (Treg), and thus for the control of autoimmunity. In previous studies we revealed the significance of an acquired IL-2 deficiency and related Treg defects in the pathogenesis of systemic lupus erythematosus (SLE). Here, we report the cellular responses to low-dose IL-2 therapy observed during an open-label, uncontrolled, dose escalation, phase 1/2a single-center clinical trial in patients with active SLE (EudraCT-Number: 2013-001599-40; DRKS-ID: DRKS00004858).

Methods: Twelve patients with active and refractory SLE (SLEDAI ≥ 6) were treated at our site with a low-dose IL-2 regimen consisting of four separate treatment cycles each with daily subcutaneous injections of recombinant human IL-2 (aldesleukin) at single daily doses of 0.75, 1.5 or 3.0 million IU for five consecutive days. Cells from peripheral blood were analyzed by flow cytometry at every study visit before and one day after each treatment cycle.

Results: All 12 treated patients showed highly significant cycle- and dose-dependent increases in the percentage of FoxP3+CD127^{lo} Treg, of CD25^{hi} cells among Treg and in the mean fluorescence intensity (MFI) of CD25 in Treg. In parallel, absolute numbers of CD25^{hi} Treg and of FoxP3+CD127^{lo} Treg in the peripheral blood increased significantly in a cycle-dependent fashion. By contrast, we observed only minor increases in the proportions and absolute numbers of CD25^{hi} cells among CD3+CD4+FoxP3⁻ conventional T cells (Tcon) and in the MFI of CD25 in Tcon. Moreover, there were no relevant changes in the absolute numbers of CD3+CD8⁺ T cells, of CD3+CD56⁺ NK T cells and of CD3-CD56⁺ NK cells. In addition, we noted robust and dose-dependent increases in the frequencies of Treg expressing the proliferation marker Ki67. Although significant increases in the proportions of Ki67⁺ Tcon were also apparent at the end of each treatment cycle, the calculated ratio between Ki67⁺Treg and Ki67⁺ Tcon continuously increased and was significantly higher at the end of the treatment phase, indicating a partial restoration of the homeostatic Treg/Tcon balance and suggesting a preferential targeting of the Treg population by low-dose IL-2 therapy.

Conclusion: Low-dose IL-2 therapy is capable to selectively expand and target the Treg population in patients with active SLE. This study also provides novel insights into the pharmacodynamics and immunological effects of low-dose IL-2 therapy.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Type I interferon has been identified as one of the central mediators in the pathogenesis of SLE, such that patients are characterized by activation of this pathway with an elevated signature of type I IFN-inducible genes in the blood. Anifrolumab, an IFNAR1-specific human monoclonal antibody developed to block the type I interferon pathway, is under evaluation in Ph3 clinical trials of patients with moderate-to-severe SLE. To understand how anifrolumab modifies disease-relevant biological pathways, we explored gene expression changes in blood in SLE patients enrolled in a Ph2 trial of anifrolumab.

Methods: Gene expression was profiled on blood samples from moderate-to-severe adult SLE patients a Phase 2b clinical study at baseline, 169, and 365 days post-treatment (NCT01438489; n=301) with Affymetrix HGU133+2 arrays. The ratios of day 169 levels to baseline and day 365 to baseline were calculated for 70 cell type- and cytokine pathway-specific gene signatures. Then the 300 and 1000 mg doses were compared independently with placebo with a t-test. Statistical tests were adjusted for multiplicity using false discovery rate.

Results: Type I IFN ($p<0.0001$, FC>2.5), TLR7 ($p<0.0001$, FC>1.6), and MHC class I ($p<0.05$, FC>1.4) gene expression pathways were most suppressed at day 169 post treatment with anifrolumab compared to placebo in both the 300 and 1000 mg patient cohorts. At day 365 post treatment, type I IFN ($p<0.0001$, FC>2.5) and OX40 ($p<0.0001$, FC>1.8) gene expression pathways were most suppressed by anifrolumab compared to placebo. The suppression due to 1000 mg dose was no different from the 300 mg dose. The median suppression level of the type I IFN pathway was >75% at both time points and both dose levels compared to >15%, >20%, and >8% for TLR7, MHC class I, and OX40 gene expression pathways, respectively. Following anifrolumab treatment, expression of PECAM-1, which can reduce both T cell

and B cell activation, was significantly increased at days 169 and 365 (FC=1.51, $p < 0.0001$ and FC=1.47, $p < 0.0001$, respectively).

Conclusion: Type I IFN, TLR7, MHC class I and OX40 gene expression pathways were suppressed with anifrolumab. Both TLR7 and OX40 induce type I IFN signaling and HLA class I is known to be upregulated by IFNs. These results help to explain the efficacy of anifrolumab in SLE, support selection of the 300 mg dose in Ph3 trials, and highlight the potential of anifrolumab to impact autoimmune diseases more broadly.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anifrolumab is a fully human monoclonal antibody that binds to the type I interferon (IFN) receptor. Its efficacy and safety in the treatment of patients with moderate-to-severe systemic lupus erythematosus (SLE) is being evaluated in Phase III clinical trials. Patients with a high IFN-inducible gene signature (IFNGS) respond better to anifrolumab than those with a low IFNGS.¹ AstraZeneca and QIAGEN have developed an *in vitro*, reverse transcriptase polymerase chain reaction (RT-PCR)-based diagnostic test for type I IFN-inducible gene expression (IFIGx) that enables the detection of expression of 4 IFN-inducible genes (*IF127*, *IF114*, *IF114L*, and *RSAD2*) relative to 3 housekeeping genes. The efficacy of anifrolumab will be evaluated in patients with high and low IFNGS. In the present study, we conducted analytical validation of the *therascreen*[®] IFIGx RGQ RT-PCR kit (IFIGx kit) for use in clinical trials, as well as to potentially support future regulatory submissions.

Methods: Measurements were performed on mRNA extracted from whole blood from adults with SLE. Patients were identified as “type I IFNGS test-high” or “type I IFNGS test-low” based on a generated score. Analytical validation comprised 6 studies that measured lot interchangeability, linearity, repeatability, reproducibility, cross contamination, and system verification.

Results: Reproducibility and repeatability were >96% and 100%, respectively, with linearity of score observed at $\pm 10\%$ defined input concentration. No cross contamination in reverse transcription or PCR steps was observed. Results of all studies validated the IFIGx kit (Table).

Conclusion: The analytical validation of the *therascreen*[®] IFIGx RGQ RT-PCR kit demonstrates this is a robust, reproducible diagnostic test for type I IFNGS. The IFIGx kit was shown to be valuable in a prior anifrolumab study,¹ and clinical utility is being further established in the anifrolumab Phase III study to potentially support regulatory filings.

Table: Summary of Analytical Validation of Anifrolumab IFIGx Test

Study	Description	Results
Lot interchangeability	<ul style="list-style-type: none"> Verification that scores and assay Ct values were robust when different lots of kit components were used Acceptance criterion: <0.58 Ct 	<u>Lot interchangeability verified</u> Largest observed change=0.16 Ct
Linearity	Verification—using linear and quadratic regression analyses—that mRNA input concentration (10 ng/μL) is in the assay's linear range	<u>Linearity verified</u> No change in score over the concentration range on either side of 10 ng/μL=0.0043 Ct
Repeatability	Verification of Dx result repeatability when the same operator tested 60 random samples using the same kit lot and instrument	<u>Repeatability verified</u> Observed repeatability=100%
Reproducibility	<ul style="list-style-type: none"> Verification of Dx result reproducibility when multiple operators tested 48 random samples using multiple kit lots and instruments at different sites For verification, overall rate of correct calls must be ≥95% 	<u>Reproducibility verified</u> Overall rate=99.7% After 6 samples with values close to the cut-off were added for further confirmation, overall rate=96.5%
Cross contamination	Investigation of inter- and intra-run cross contamination	<u>No cross contamination</u> No cross contamination found in reverse transcription or PCR steps
System verification	Verification of functionality and utility of the IFIGx software and IFIGx assay package	<u>System verification confirmed</u> Software flags produced as expected

Ct, cycle threshold (PCR cycle at which fluorescence rises above background level); Dx, diagnostic; IFIGx, interferon-inducible gene expression; PCR, polymerase chain reaction; mRNA, messenger ribonucleic acid.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a most important predictor of morbidity and mortality in patients with systemic lupus erythematosus (SLE). Histopathology samples from patients with LN can demonstrate injury to nearly any cell type, including the mesangial, endothelial, podocyte, tubulointerstitial and vascular involvement associated with different pathogeneses, clinical presentations, therapeutic responses, and outcomes in LN patients. Podocytes are epithelial cells that provide the glomerular filtration barrier with foot processes and slit diaphragms. The morphological change with diffuse effacement of the foot processes is correlated with proteinuria in patients with LN. It has also been shown that in patients with nephrotic LN, foot process effacement estimated by the foot process width (FPW) was more extensive than in patients with non-nephrotic LN. We evaluated the possible association between podocyte injury and clinical features in LN.

Methods: We studied 73 patients with LN who underwent a renal biopsy at our hospital or a community hospital in 1993–2016. We collected the data of clinico-pathological parameters and assessed the FPW for evaluating podocyte effacement. We retrospectively analyzed the complete renal remission (CR) rate at 6 and 12 months after induction therapy and determined the predictive factors for CR. Univariate and multivariable competing risks regression analyses were used to determine the predictive factors of CR. Decision tree models predicting CR were built with the Classification and Regression Trees (CART) algorithm.

Results: At 6 and 12 months after induction therapy, 34 patients (46.6%) and 47 patients (64.3%) achieved CR, respectively. The multivariate analysis revealed that female gender (OR 5.288, 95% CI: 1.197–37.29, $p=0.0267$) and FPW (OR 0.999, 95% CI: 0.997–0.999, $p=0.0150$) for predicting CR at 6 months and lymphocyte counts (OR 1.002, 95% CI: 1.001–1.003, $p=0.0028$) and FPW (OR 0.998, 95% CI: 0.996–0.999, $p=0.0027$) for predicting CR at 12 months were significant. The median FPW was 1088 nm (IQR 895–1465 nm) in the total group of 73 patients. The degree of foot process effacement was significantly different among the various types of LN ($p=0.0007$): 701 nm (IQR 546–902 nm) in class I, 817 nm (IQR 685–1056 nm) in class II, 921 nm (IQR 711–1145 nm) in pure class III, 1294 nm (IQR 1086–1804 nm) in pure class IV, 1283 nm (IQR 899–1484 nm) in pure class V, and 1421 nm (IQR 887–1976 nm) in the combined group (class III + V and IV + V). We found that there was a moderate correlation between the individual FPW value and the amount of proteinuria ($r=0.3554$, $p=0.00022$). There was also a significant correlation between the individual FPW and serum albumin ($r= -0.4757$, $p<0.0001$) and between the individual FPW and the index of activity (0–24) ($r=0.4908$, $p<0.0001$). The cut-off point determined by the CART algorithm showed that FPW <908.3 nm provide the best performance to predict patients who achieve CR at 12 months.

Conclusion: We found that the lymphocyte count and/or the foot process width are prognostic markers for the achievement of a CR at 6 and 12 months after induction therapy for lupus nephritis. The pathological role of the FPW is still unknown, but it may reflect the degree of podocyte function.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment benefit is demonstrated by evidence that interventions have positive impacts on how patients feel, function, and/or survive (FDA Guidance, 21CFR314.510). The ACR CRISS, a composite endpoint for trials in systemic sclerosis (SSc), uses a weighted score combining outcome assessments that directly measure how patients feel and function [HAQ-DI and patient (PGA) global assessment] with outcome assessments that are indirect measures of patient symptoms/function [FVC, modified Rodnan skin score (mRSS), and physician global assessments (MDGA)]. Understanding the relationship and magnitude of effects on these indirect assessments would provide confidence that each component of CRISS would reliably predict an effect on direct measures of patient benefit. Our objective was to provide data to support evaluation of CRISS using patient-reported outcome (PRO) anchors - HAQ-DI and PGA.

Methods: We evaluated 2 cohorts: an early diffuse cutaneous SSc (dcSSc) cohort that was used for development of ACR CRISS (1) and a phase 2 trial of TCZ vs. placebo in dcSSc [faSScinate trial (2)]. Using the early dcSSc cohort, we assessed the effect size (ES) at the patient-level for non-PRO variables (mRSS, MDGA, and FVC%) in those we defined as “responders” who met minimal clinically important differences (MCID) estimates for HAQ-DI (defined as an improvement of ≥ 0.22) and PGA improvement of ≥ 1.0 (range 0-10). We interpreted ES using Cohen’s criteria: < 0.20 = negligible, 0.20 - 0.49 = small, 0.50 - 0.79 = medium, >0.80 = large (3). We assessed whether ES in patients who met the responder criteria in HAQ-DI and PGA in the faSScinate trial was associated with larger improvements in the ACR CRISS scores at week 24 and 48.

Results: In the dcSSc cohort, the ES was of greater magnitude for responders vs. non-responders (Table), except for HAQ-DI and FVC% when using PGA as an anchor. In the faSScinate trial, statistically significant improvements in the median ACR CRISS scores were seen in those who attained MCID vs. patients who did not (Table).

Conclusion: In a dcSSc cohort, generally patients who achieved MCID in HAQ-DI and PGA are associated with larger magnitude of improvement in ACR CRISS non-PRO variables. Limitations of the analysis are: 1. HAQ-DI and PGA are part of the ACR CRISS score, and 2. Assessing the relationships in an observational cohort. Ongoing trials should confirm the relationships between non-PRO variables (mRSS, MDGA, and FVC%) vs. PRO anchors.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Endothelial cell dysfunction and/or injury are considered critical early events in the pathogenesis of vasculopathy in patients with systemic sclerosis (SSc). Hyperuricemia is known to induce endothelial dysfunction and vascular inflammation; however, the link between uric acid and SSc vasculopathy has not been well established. We investigated whether increased serum uric acid levels (SUA) are associated with the digital ulcers (DUs) in patients with SSc.

Methods: In this cross-sectional study, we consecutively recruited 71 women with SSc and 103 age- and sex-matched healthy subjects at a university-affiliated rheumatology center, and SUA levels were measured in all study subjects. All patients with SSc fulfilled the preliminary classification criteria established by the American College of Rheumatology for SSc. Active DUs were defined as a loss of epithelialization and tissues involving the epidermis, dermis, subcutaneous tissue, and bone. DUs included both, active and healed lesions.

Results : The mean (\pm standard deviation) SUA levels in patients with SSc were significantly higher than those in controls (4.5 ± 1 vs. 4.2 ± 0.9 mg/dL, respectively, $p=0.027$). Patients with SSc showed a significantly lower body mass index (BMI) than healthy subjects (21.8 ± 2.8 vs. 23.3 ± 3.5 kg/m², respectively, $p=0.005$) whereas no statistically significant intergroup difference was observed in the estimated glomerular filtration rate (eGFR). Among patients with SSc, 22 (31%) had DUs (active DUs: 8, healed DUs: 14). Patients with SSc presenting with DUs showed significantly higher SUA levels than those

without DUs (5 ± 1 vs. 4.3 ± 0.9 mg/dL, respectively, $p=0.008$). In multivariable logistic regression models adjusting for confounders including BMI and eGFR, increased SUA levels were observed to be independently associated with a higher risk for the presence of DUs as shown in Table 1 (OR 2.3, 95% CI 1.16–4.57, $p=0.018$). Additionally, the modified Rodnan skin score and the disease duration showed a significant association with DUs (OR 1.14, 95% CI 1.03–1.27, $p=0.013$; and OR 1.01, 95% CI 1–1.02, $p=0.023$, respectively).

Table 1. Association between serum uric acid level and digital ulcers ever in patients with systemic sclerosis evaluated by logistic regression models

Variables	Univariable model		Multivariable model	
	Crude OR (95% CI)	p-value	*Adjusted OR (95% CI)	p-value
SUA level, mg/dL	2.19 (1.23-3.92)	0.008	2.3 (1.16-4.57)	0.018
MRSS	1.14 (1.04-1.25)	0.004	1.14 (1.03-1.27)	0.013
Disease duration, months	1.01 (1-1.02)	0.02	1.01 (1-1.02)	0.023
ILD	3.27 (1.1-9.78)	0.034	-	-
eGFR, mL/min/1.73m ²	1.01(0.98-1.03)	0.508	-	-
BMI, kg/m ²	0.97 (0.81-1.16)	0.72	-	-
PAH	0.51 (0.1-2.6)	0.424		
Anti-centromere antibody	0.38 (0.1-1.51)	0.169		
Anti-Scl70 antibody	0.65 (0.21-1.95)	0.437		
Diffuse SSc (ref. limited SSc)	1.33 (0.49-3.66)	0.576		

* Estimated using backward multivariable logistic regression models including SUA levels, MRSS, disease duration, ILD, eGFR and BMI.

Conclusion: Our data revealed that elevated SUA levels are associated with a higher risk for DUs in patients with SSc regardless of confounding factors, thereby suggesting the potential role of hyperuricemia in the pathogenesis of SSc vasculopathy.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Microangiopathy predominates in the pathophysiology of Systemic Sclerosis (SSc). However, large vessel involvement leading to higher risk for cardiovascular disease in SSc remains unclear. Nailfold videocapillaroscopy (NVC) is an established method for the assessment of the microvasculature, aiding in distinguishing different types of structural vascular abnormalities. Until recently, NVC was used in the diagnosis of SSc as well as in the assessment and follow-up of peripheral digital vasculopathy however recent data indicates a possible association with macrovascular involvement namely atherosclerosis and coronary artery disease. The aim of this study was the investigation of the relation between microvascular and macrovascular involvement in the setting of SSc.

Methods: Consecutive patients with established SSc treated in the Scleroderma Clinic of State Hospital Unit from September 2016 until June 2017 were enrolled in our study. We conducted NVC to evaluate microcirculation. The number of capillaries/mm² and capillaroscopic index CSURI were measured. Findings were also classified to the three scleroderma patterns (early, active, and late). Cardiovascular risk was assessed using the European SCORE, while the following vascular markers were measured: carotid intima-media thickness (IMT), Augmentation Index (AIx) of the aorta, aortic pulse wave velocity (PWV) and central systolic and diastolic blood pressure. The correlation between microvascular and macro-vascular parameters was examined.

Results: Thirty-seven (1 man) SSc individuals were studied. Among the atherosclerotic morphological and functional parameters assessed, a significant correlation was observed between aortic AIx and the average number of capillaries/mm² ($r = -0.34, p = 0.047$) and between AIx and the capillary index CSURI ($r = 0.35, p = 0.044$). In addition, lower AIx values were recorded in the “early” scleroderma pattern compared to the “active” and “late” pattern [20.5 ± 11.4 vs $34.1 \pm 11.5\%$, $p = 0.02$ (early vs. active) and 20.5 ± 11.4 vs $33.4 \pm 8.8\%$, $p = 0.05$ (early vs late)]. No statistically significant associations were demonstrated between abnormalities of nailfold capillaries and IMT, PWV or SCORE in our population.

Conclusion: The extent of microangiopathy is related to the degree of arterial stiffness assessed by AIx suggesting a potential link between micro- and macrovascular disease in SSc.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin fibrosis is a hallmark of systemic sclerosis (SSc). There are no widely accepted biomarkers of skin involvement in this condition. Several serum or plasma markers have been studied in patients with SSc - monocyte chemoattractant protein-1 (MCP-1), chemokine (C-X-C motif) ligand 8 (CXCL8), interleukin-13 (IL-13), and some more recognized such as - platelet derived growth factor (PDGF), transforming growth factor-beta 1 (TGF-beta 1), epidermal growth factor (EGF) and basic fibroblast growth factor (bFGF). The aim of this study was to assess several circulating biomarkers which may be relevant to the fibrosing process and further to correlate the obtained data with clinical indicators specific for SSc skin involvement.

Methods: 59 SSc patients (M/F 9/50; mean age 52.1 years, mean disease duration 6.7 years, 36 patients with limited cutaneous SSc and 23 with diffuse cutaneous SSc. As a control group 36 healthy individuals matched to sex and age were examined. Serum concentrations of bFGF, granulocyte-colony stimulating factor (G-CSF), granulocyte-macrophage-colony stimulating factor (GM-CSF), MCP-1, PDGF, IL-8 and IL-13 were analysed using commercial multiplex kit. The following clinical examinations were performed: modified Rodnan skin score (mRSS), Hand Mobility in Scleroderma Test (assessing hand function) (HAMIS), Cochin Hand Function Scale (hand function) (CHFS), Delta Finger-to-Palm Distance (extension-flexion) (dFTP), Inter-lip Distance (inter-lip), Inter-incisor Distance (inter-incisor), and Mouth Handicap in Systemic Sclerosis Scale (mouth opening) (MHISS). For statistical evaluation Spearman's correlation coefficient was used.

Results: When compared with healthy controls serum concentrations of bFGF ($p<0.001$), G-CSF ($p<0.0001$), GM-CSF ($p<0.0001$), MCP-1 ($p<0.0001$), IL-8 ($p<0.0001$), and IL-13 ($p<0.001$) were significantly elevated in SSc cohort. PDGF levels were increased in SSc patients with only a lower significance ($p<0.01$). bFGF, G-CSF, MCP-1 and IL-8 levels correlated significantly ($p<0.05$) with mRSS and HAMIS. GM-CSF levels correlated with mRSS and HAMIS and there was only a trend for negative correlation with inter-incisor. There was no correlation of IL-13 and PDGF levels with the evaluated clinical data.

Conclusion: Our results have shown that G-CSF, GM-CSF and IL-8 play a substantial role in SSc fibrosing process. Potential biomarkers as bFGF, G-CSF, MCP-1 and IL-8 correlated with a few clinical indices of SSc skin involvement.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiogenic pathways are likely to contribute to pathogenesis of both vasculopathy and fibrosis in Systemic sclerosis (SSc). The angiogenic actions of Angiopoietins (pro-angiogenic Ang1 and divergent Ang2) through competitive Tie2 binding could be attractive biomarkers in SSc. We report the association between Ang1, Ang2 and Tie2 with objective assessments of peripheral vasculopathy and cutaneous fibrosis in SSc.

Methods: Fifty-one SSc patients (2013 ACR/EULAR criteria) and fifteen healthy controls (HC) underwent functional assessment of post-occlusive digital vascular responses using Laser Speckle Contrast Imaging (LSCI), morphological

Functional assessment by Laser Speckle Contrast Imaging (LSCI) is reflected in a reperfusion gradient of the distal fingers following an occlusive challenge. High Frequency Ultrasound (HFUS) Vascularity index was assessed over the distal phalanx of the middle finger. Inter-capillary distance was manually calculated from Nailfold capillaroscopy (NC) images. HFUS assessment of dermal thickness, Echogenicity and Shear wave Elastography (SWE) were recorded over the proximal phalanx of the middle finger. In SSc, Ang2 demonstrated a negative correlation with the post-occlusive reperfusion gradient on LSCI and positively with inter-capillary distance (the latter of borderline significance ($p = 0.05$)). Ang2 also positively correlated with Echogenicity and SWE. Ang1 demonstrated a weak positive correlation with Echogenicity.

capillary assessment using nailfold capillaroscopy (NC) and High Frequency Ultrasound (HFUS) assessment of cutaneous fibrosis and digital vasculopathy. Modified Rodnan Skin Score (mRSS) and Raynaud's Condition Score were assessed in SSc. Plasma Ang 1, Ang 2 and Tie2 levels were measured using ELISA.

Results: Ang2 was significantly increased in SSc compared to HC (Figure 1). There was no significant difference in Ang1 or soluble Tie2, however Ang1/2 ratio was significantly reduced in SSc compared to HC (median 4.4 versus 6.2, $p = 0.018$). In SSc, Ang2 demonstrated a weak negative correlation with the post-occlusive reperfusion gradient on LSCI and a weak positive correlation with inter-capillary distance (Table 1), suggesting an association between impaired functional and structural microangiopathy and increased Ang2. Ang2 progressively increased with progressive NC qualitative classification (early, active and late, Figure 2). Interestingly, Ang2 also correlated weakly with Echogenicity and Shear wave Elastography on HFUS, suggesting an association with skin fibrosis. Ang1 had a weak positive correlation with Echogenicity only suggesting that as the oedematous phase of SSc skin disease resolves, Ang1 increases. The lack of significant correlation between Ang1 and Elastography suggests there is no clear association with fibrosis (Table 1).

Conclusion: Our findings suggest that Ang2 may reflect anti-angiogenic and pro-fibrotic mechanisms in SSc. Further study is warranted to explore the relative expression of Angiopoietins in well phenotyped SSc patients and evaluate their role as novel biomarkers.

High Frequency Ultrasound As a Novel Approach to Quantifying the Digital Microangiopathy of Systemic Sclerosis

Victoria Flower^{1,2}, Shaney Barratt^{3,4}, Darren Hart⁵, Amanda MacKenzie², Jacqueline Shipley⁵, Stephen Ward² and John Pauling^{1,2}, ¹Department of Rheumatology, Royal National Hospital for Rheumatic Diseases, Royal United Hospitals NHS Foundation Trusts, Bath, United Kingdom, ²Centre for Therapeutic Innovations & Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom, ³North Bristol NHS Trust, Bristol, United Kingdom, ⁴Academic Respiratory Unit, School of Clinical Sciences, University of Bristol, Bristol, United Kingdom, ⁵Clinical Measurement Department, Royal National Hospital for Rheumatic Diseases, Royal United Hospitals NHS Foundation Trusts, Bath, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Background/Purpose: Structural and functional vascular abnormalities occur in Systemic Sclerosis (SSc). We report on the use of High Frequency Ultrasound (HFUS) with Superb Microvascular Imaging (cSMI) as a novel approach to assessing digital vasculopathy in SSc.

Methods: Fifty-three SSc (2013 ACR/EULAR criteria) and fifteen healthy controls (HC) underwent assessment of the distal middle finger using a novel Doppler cSMI modality, able to detect low velocity microvascular flow and simultaneously minimise motion artefact. HFUS cSMI was used to measure Vascularity Indices (VIs) at 3 regions of interest (Dorsovascular [DVVI], Nailfold [NVI] and Fingertip [FVI]). Morphological assessment of capillaries was undertaken using nailfold capillaroscopy (NC). Functional post-occlusive microvascular responses were assessed using Laser Speckle

Figure 1. Vascularity Indices (VIs) on High Frequency Ultrasound (HFUS) at the distal middle finger are significantly reduced in SSc compared to healthy controls (Mann-Whitney U). Box plots demonstrate inter-quartile range and median (horizontal line). Whiskers demonstrate minimum and maximum values. Order from left-right: Dorsovascular VI (grey), Nailfold VI (spot) and Fingertip VI (striped). Significance $p < 0.01$ illustrated by ** compared to healthy controls.

Figure 2. High Frequency Ultrasound (HFUS) Vascularity Indices (VIs) at the distal middle finger are reduced in SSc with Early, Active and Late NC changes. Significance $p < 0.05$ illustrated by *, $p < 0.01$ by ** (Kruskal-Wallis). Box plots demonstrate inter-quartile range and median (horizontal line). Whiskers demonstrate minimum and maximum values. Order from left-right: Dorsovascular VI (grey), Nailfold VI (spot) and Fingertip VI (striped).

Laser Speckle Contrast Imaging Parameter	Dorsovolar VI	Nailfold VI	Fingertip VI
Median Baseline Fingertip Perfusion (Mean of Digits 2-5, n=52)	+0.376 **	+0.393 **	+0.638 **
Percentage change in Post-Occlusive Fingertip Flux (n=40)	-0.339 *	-0.266	-0.465 **

Table 1. Spearman's Rank Correlation Coefficient (r_s) demonstrating weak-moderate correlations between Vascularity Indices (VIs) and LSCI parameters in SSc group with the exception of Nailfold VI and percentage change in post-occlusive fingertip flux, which approached significance ($p=0.065$). Significance $p<0.05$ illustrated by*, $p<0.01$ by**

Contrast Imaging (LSCI). The Raynaud's Condition Score (RCS) diary was collected as a patient-reported measure of Raynaud's phenomenon severity.

Results: All 3 VIs were significantly reduced in SSc compared to HC (Figure 1). The DVVI and FVI were also significantly reduced in SSc with a history of digital ulcers (DU) versus without, (40120 versus 110443, $p=0.015$ and 51955 versus 195408, $p=0.006$ respectively). All 3 VIs in the SSc group correlated with baseline fingertip perfusion on LSCI (strongest association seen with FVI, Table 1). The association was particularly strong in limited SSc (Spearman's r_s +0.703, $p<0.001$). There was a significant reduction in DVVI and FVI of SSc patients with each of early, active and late NC patterns compared to HC, as well as NVI with an active pattern (Figure 2). No significant differences were identified between SSc NC classifications. No correlations were seen with RCS.

Conclusion: Our findings suggest a role for HFUS in the assessment of digital vascular abnormalities in SSc with the advantages of quick quantifiable data capture over broad regions of interest. The relationship with DU history suggests a potential future role as a vascular biomarker and prognostic factor in SSc.

What Is the Effect of Cyclophosphamide Iv Pulse Therapy in Patients with Diffuse Cutaneous Systemic Sclerosis on Skin Involvement: An Observational Study

Brigit Kersten, Nathan den Broeder, Frank van den Hoogen, Els van den Ende and Madelon Vonk, Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic sclerosis who have proximal skin involvement are classified as diffuse cutaneous systemic sclerosis (DcSSc). Patients with progressive skin involvement have worse prognosis. Treatment options consist among others of cyclophosphamide iv pulse therapy (iv CYC). Recent studies show significant improvement of skin thickening in patients treated with cyclophosphamide orally, but the effect of iv CYC on skin involvement remains unclear. Our aim is to examine the extent of skin involvement during 12 monthly iv CYC in DcSSc and to identify factors that predict response to therapy.

Methods: Patients with DcSSc receiving iv CYC between 2004 and 2016 were included. Skin involvement was assessed with the modified Rodnan Skin score (mRSS) at baseline, six, 12, 24 and 36 months by the same rheumatologist. Data of baseline and at least one follow-up measurement were included. Missing mRSS data were imputed using multiple imputation by chained equation. Patients were classified as responders if the mRSS decreased at least 5 points and 25% from baseline at month 12. A prediction model for response at 12 months was created using backwards logistic regression considering baseline variables and response at six months as possible predictors.

Results: A total of 91 patients were included (Table 1). The mean improvement of mRSS over time was -4.05 (95% CI - 5.53 to -2.55) (Figure 1). 43% of patients had a response according to the criteria. In univariate prediction models, baseline mRSS (OR 1.06, $p=0.024$), response at six months (OR: 37.45, $P<0.001$) and completed treatment (yes/no) (OR: 4.108, $p=0.033$), were significant predictors of response at 12 months. For the last variable it should be mentioned that some patients who did not achieve a response at month 6 did not continue iv CYC for that reason.

Figure 1. mRSS course of all patients during iv CYC

Conclusion: This study shows that only 43% of treated DcSSc patients experienced clinically important improvement of skin involvement following iv CYC. Response at month six is the best predictor for response on month 12. This could imply that at this time point, counseling about other available treatment options, should be considered in those patients.

Performance of Anti-Scl-70 Antibody Testing By Multiple-Bead, Enzyme-Linked Immunosorbent Assay, and Immunodiffusion in a University Setting

Kate Homer¹, Jeffery Warren², Dmitry Karayev³, Puja P. Khanna⁴, Amber Young⁵, Vivek Nagaraja⁵, Allan L. Metzger⁶ and Dinesh Khanna⁵, ¹Department of Internal Medicine, Rheumatology Division, Scleroderma Program, University of Michigan, Ann Arbor, MI, ²Department of Pathology, University of Michigan, Ann Arbor, MI, ³RDL Reference Laboratory, Santa Monica, CA, ⁴University of Michigan, Ann Arbor, MI, ⁵Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ⁶RDL Reference Laboratory, Los Angeles, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The gold standard for anti-Scl-70 antibody testing in systemic sclerosis (SSc) uses immunodiffusion (ID) techniques, but enzyme-linked immunosorbent assay (ELISA) and multi-bead technology are often used to save time and cost. There is concern that using this methodology results in an increase in false positive results. Our aim was to assess the performance of the multi-bead, ELISA, and ID testing methods.

Methods: We conducted a retrospective study of patients whose extractable nuclear antigen-10 (ENA-10) autoantibody panel tested positive for the anti-Scl-70 antibody by multi-bead technology during a one-year period. All samples positive by multi-bead were sent to a reference laboratory to be reflexed for ELISA, and all anti-Scl-70 antibodies positive by ELISA were further tested by ID. Clinical data was reviewed by a rheumatologist and assessed for presence of SSc, internal organ involvement, and other connective tissue disease (CTD).

Results: Approximately 9500 extractable nuclear antigen-10 (ENA-10) panels were ordered by physicians at our institution between August 2016 and August 2017. Of these, 129 patients were positive for the anti-Scl-70 antibody by multi-bead assay, 51 were positive by ELISA, and 21 were positive by ID. On chart review of the patients who were positive by multi-bead assay, 33 (25.6%) had SSc and 9 (7.0%) had diffuse cutaneous SSc (dcSSc). Twenty-four (18.6%) had other CTDs, with 72 (55.8%) presenting with no evidence of CTD (Table). Of the 51 patients who were positive by multi-bead and ELISA, 23 (45.1%) had a diagnosis of SSc and 8 (15.7%) had dcSSc. Eight (15.7%) were diagnosed with other CTDs. For the 21 patients who were positive by multi-bead, ELISA and ID, 19 (90.5%) were diagnosed with SSc and 8 (38.1%) had dcSSc. We found that 25.6% of patients positive by multi-bead, 45.1% positive by ELISA, and 90.5% positive by ELISA and ID had SSc.

Conclusion: Multi-bead assays have a high rate of false positive results for the anti-Scl-70 antibody in patients without clinical evidence of SSc. A stepwise approach of confirmation of positive multi-bead results using both ELISA and ID greatly improves the predictive value of antibody testing for the diagnosis of SSc.

Table: Relative frequency of anti-Scl-70 antibody in patients diagnosed with systemic sclerosis, diffuse cutaneous systemic sclerosis and other connective tissue diseases

	Total n (%)	SSc n (%)	Diffuse Cutaneous SSc n (%)	Other CTDs n (%)
Anti-Scl-70 positive by multi-bead	129 (100)	33 (25.6)	9 (7.0)	24 (18.6)
Anti-Scl-70 Negative by ELISA	78 (60.5)	10 (12.8)	1 (1.3)	16 (20.5)
Anti-Scl-70 Positive by multi-bead + ELISA	51 (39.5)	23 (45.1)	8 (15.7)	8 (15.7)
Anti-Scl-70 Negative by ID (positive by multi-bead + ELISA)	30 (58.8)	4 (13.3)	0 (0)	6 (20.0)
Anti-Scl-70 Positive by multi-bead, ELISA and ID	21 (41.2)	19 (90.5)	8 (38.1)	1 (4.8)

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early diffuse cutaneous systemic sclerosis (dcSSc) carries a high morbidity and mortality, predominantly due to internal organ involvement. The purpose of this study was to investigate the time to event of new

Figure: Cumulative Progressive Skin Fibrosis, Internal Organ Involvement and All-Cause Mortality Event Percentages with Confidence Intervals*

*Shading represents confidence intervals.

onset of visceral organ involvement and all-cause mortality in early dcSSc participants in an ongoing US multicenter registry(Prospective Registry of Early Systemic Sclerosis [PRESS]).

Methods: Inclusion criteria include a diagnosis of dcSSc and a disease duration of ≤ 2 years calculated from the date of onset of first non-Raynaud's phenomenon symptom. Organ involvement was defined as new involvement or worsening during follow up visits— 1) absolute increase in mRSS of ≥ 4 units or 20%, 2) an absolute decline of FVC % of $\geq 10\%$; 3) PH on RHC; 4) LVEF of $\leq 45\%$ on echo; 5) scleroderma renal crisis; or 6) all-cause mortality. We reported number of participants experiencing organ involvement during the course of the study via frequency tables and characterized the distribution of events through plots of the cumulative proportion of participants experiencing each event by time. Confidence intervals in the cumulative proportion plots were derived via bootstrap method.

Results: The cohort consisted of 239 participants from 11 US SSc centers at baseline with median follow-up of 414 days (IQR=112-922 days). The baseline mean age for the cohort was 50.1 years, disease duration was 1.3 years, HAQ-DI score was 0.82, 71.1% were female, and 76.2% were white. In this cohort, 199 (83.3%) were treated with immunomodulatory therapies during the course of the study (82.0% during the first year) including 63.2% on mycophenolate mofetil, 20.9% on methotrexate, 5.0% on cyclophosphamide, 3.3% on D-penicillamine, 16.3% on hydroxychloroquine, and 2.1% on azathioprine(percentage is greater than 82.0% as some participants were on multiple therapies at a single time-point and/or during the study). Survival function plots showed that 75 of 231 (32.5%) participants showed progressive skin fibrosis, 27 of 192 (14.1%) showed $\geq 10\%$ worsening of FVC%, 4 of 199(2.0%) showed LVEF of $\leq 45\%$, 12 of 239 (5.0%) had new onset scleroderma renal crisis, 5 of 239 (2.1 %) had PH on RHC, and 14 of 239 (5.9%) died during the course of the study (Figure); 11 of the 14 deaths were considered to be related to SSc.

Conclusion: Despite immunomodulatory therapy, a high proportion of early dcSSc patients experience worsening of mRSS and lung function and mortality within 2 years of dcSSc diagnosis. There are ongoing vascular-predominant complications over the course of the disease, consistent with published literature [1]. This data supports an ongoing need to identify novel therapies for dcSSc.

Increased Mortality in Black and Asian Patients with Systemic Sclerosis in Northern California

Melody Chung¹, Makdine Dontsi², Debbie Postlethwaite², Sumana Kesh³, Lisa Zaba⁴ and Lorinda Chung^{5,6}, ¹Internal Medicine Residency, Kaiser Permanente Santa Clara, Santa Clara, CA, ²Division of Research, Kaiser Permanente Northern California, Oakland, CA, ³Department of Internal Medicine, Kaiser Permanente Santa Clara, Santa Clara, CA, ⁴Department of Dermatology, Kaiser Permanente Santa Clara, Santa Clara, CA, ⁵Division of Immunology and Rheumatology, Stanford University School of Medicine, Stanford, CA, ⁶VA Palo Alto Health Care System, Palo Alto, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies indicate that black patients with systemic sclerosis (SSc) demonstrate a distinct phenotypic profile, with more severe disease, heightened mortality, and poorer prognosis compared to whites. Limited studies have evaluated disease severity and mortality in Asian Americans. Our aim was to compare disease manifestations and survival across race/ethnicity in SSc patients from Northern California, with a focus on Asians.

Methods: A retrospective study was conducted among Kaiser Permanente Northern California adults with a diagnosis of SSc by a rheumatologist from 2007-2017, confirmed by chart review to fulfill 2013 ACR-EULAR classification criteria. Self-reported race/ethnicity was categorized as: white, Asian, Hispanic, and black. Other racial subgroups were excluded from this study. Disease manifestations and all-cause mortality were compared between the race/ethnic groups with whites as the reference. Chi-square, Fisher exact tests, and multest were used for categorical variables. Kaplan-Meier and multivariate Cox regression analyses were used to estimate the probability of survival by race/ethnicity for incident cases, and to assess if race/ethnicity was a significant factor associated with death correcting for age. $P < 0.05$ was considered statistically significant.

Results: 1055 SSc patients were included with 665 incident and 390 prevalent cases. Most patients had limited cutaneous SSc ($n=937$, 89%) with only 11% categorized as diffuse ($n=118$). 89% were female, with mean age 56.5 ± 14.6 years, and mean disease duration 5.0 ± 3.2 years from date of diagnosis. The racial/ethnic distribution was 54% white ($n=569$), 23% Hispanic ($n=241$), 14% Asian ($n=152$), and 9% black ($n=93$). Although Hispanics did not display any significant differences in clinical features from whites, Asians had a lower frequency of calcinosis (32% vs. 16%, $p < 0.001$) and telangiectasias (75% vs. 53%, $p < 0.001$); blacks had a higher frequency of interstitial lung disease (38% vs. 57%, $p = 0.016$), but a lower frequency of telangiectasias (75% vs. 53%, $p < 0.001$) and Raynaud phenomenon (98% vs. 91%, $p = 0.036$). 9-year overall survival rates for whites, Hispanics, Asians, and blacks were 72.0%, 68.6%, 50.1%, and 48.6%, respectively (log-rank $p < 0.01$) (Figure 1). Pairwise comparisons demonstrated increased mortality in Asians compared to non-Asians ($p = 0.008$). On multivariate analysis, Asians and blacks had increased mortality compared to whites even after controlling for age (HR 2.2, CI 1.4-3.5, $p < 0.001$; HR 2.3, CI 1.3-4.0, $p < 0.001$, respectively), but not Hispanics (HR 1.1, CI 0.7-1.8, $p = 0.6$).

Conclusion: Survival in patients with SSc from Northern California differs by race. Asians and blacks had more than 2-fold increased risk of death compared with whites.

Elevated Serum Interleukin-34 Levels Are Correlated with Interstitial Lung Disease in Systemic Sclerosis

Hiraku Suga¹, Ai Kuzumi¹, Yoshihide Asano¹, Ayumi Yoshizaki¹ and Shinichi Sato², ¹Department of Dermatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, ²The University of Tokyo, Department of Dermatology, Tokyo, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin (IL)-34 is a hematopoietic cytokine, which promotes survival, proliferation, and differentiation of monocytes and macrophages. We investigated serum IL-34 levels in patients with systemic sclerosis (SSc).

Methods: The numbers of subjects enrolled in this study were as follows; 43 diffuse cutaneous SSc (dcSSc) patients, 15 limited cutaneous SSc (lcSSc) patients, and 20 healthy controls.

Results: Serum IL-34 levels in dcSSc patients were 10.97 ± 1.42 pg/mL (mean \pm s.e.m), which was significantly higher than lcSSc (5.16 ± 1.16 pg/mL) and healthy controls (3.81 ± 0.77 pg/mL). SSc patients with increased serum IL-34 levels suffered from interstitial lung disease (ILD) more frequently than those with normal levels. When we checked the correlations between serum IL-34 levels and ILD markers, serum IL-34 levels negatively correlated with the percentage of predicted vital capacity ($r = -0.32$, $P < 0.01$), while they positively correlated with ground-glass opacity score ($r = 0.49$, $P < 0.01$) and fibrosis score ($r = 0.31$, $P < 0.05$) on chest computed tomography. Serum IL-34 levels also positively correlated with serum KL-6 levels ($r = 0.33$, $P < 0.01$) and surfactant protein D levels ($r = 0.46$, $P < 0.01$). There was no association between serum IL-34 levels and the presence of anti-topoisomerase I, anti-centromere, or anti-polymerase III antibody.

Conclusion: Increased serum IL-34 levels were associated with greater frequency and severity of ILD in SSc patients, suggesting that serum IL-34 levels could be a useful serologic marker for SSc-associated ILD.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Kidney injury in mixed connective tissue disease (MCTD) is an uncommon manifestation. Prevalence has been reported to be <4% in some cohorts. The frequency of renal involvement in Hispanic patients with MCTD is not known. We aimed to describe the prevalence, clinical characteristics and outcomes of renal involvement in Mexican patients with MCTD.

Methods: We conducted a retrospective single-center study. We included patients with a diagnosis of MCTD according to the Alarcón-Segovia criteria who regularly attended to a referral center in Mexico City (2003-2017) and we identified those with renal involvement defined as proteinuria >500 mg/d with or without active sediment, creatinine elevation 50% above baseline or development of glomerular filtration rate (GFR) <60 ml/min, with no other known cause. We collected demographics, clinical manifestations, follow-up time, treatment, outcomes and damage (SLICC/ACR-DI), renal function, serological and histological variables.

Results: One hundred and thirty one patients with MCTD were followed at our center. We identified 14 patients with renal involvement with a prevalence of 10.7%. Among those patients, 13 were women (92.8%); mean age at onset of renal involvement was 44 ± 8 years. Most frequent manifestations were Raynaud's phenomenon in 13 (92.8%) patients, arthritis in 12 (85.7%), puffy hands in 12 (85.7%), sclerodactyly in 8 (77.1%), sicca syndrome in 8 (77.1%) and myositis in 7 (50%). Median time elapsed from MCTD diagnosis to renal involvement was 83 (2-365) months. In 3 patients, renal involvement was present at MCTD onset. Seven (50%) patients had other signs of MCTD activity at the time of renal involvement onset. Four (28.5%) patients presented with sub-nephrotic proteinuria, 3 (21.4%) with nephrotic range proteinuria and kidney injury, 2 (14.3%) with sub-nephrotic proteinuria and kidney injury, 2 (14.3%) with nephrotic range proteinuria, 1 only with nephrotic range proteinuria and 1 (7.1%) with end-stage renal disease. Microscopic hematuria was present in 9

(64.3%) patients and leukocyturia in 6 (42.8%). Renal biopsy was performed in 8 (57%) patients; pathological diagnoses were: crescentic and necrotizing glomerulonephritis (GN) (2 patients; one of these patients developed positive ANCA antibodies), membranous GN (2), GN ISN/RPS 2003 class III + V (1), GN ISN/RPS 2003 class IV and vasculopathy (1), minimal mesangial GN (1) and chronic tubulointerstitial nephritis with vasculopathy (1). Ten (71.4%) patients achieved either total or partial remission at a median follow up of 82 (1-367) months. Only one patients required dialysis. At last follow up the median SLICC/ACR-DI was 1.5 (0-4) points. Two patients died.

Conclusion: In our cohort of MCTD patients, prevalence of renal involvement was low, although higher than the one reported in other populations. Clinical presentation and pathological diagnoses were diverse. Renal biopsy was helpful, since glomerulonephritis, vasculopathy and overlap with ANCA associated vasculitis were found in several patients; these options should be considered in the differential diagnoses of MCTD patients with renal involvement.

Abstract Number: 2699

Using ICD-10 Codes to Identify Patients with Systemic Sclerosis in the Electronic Health Record

Lia Jamian¹, Leslie Crofford² and April Barnado², ¹Medicine, Vanderbilt University Medical Center, Nashville, TN, ²Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pragmatic research in rare diseases is difficult, largely limited by small sample size and single center cohort studies. The electronic health record (EHR) can serve as a powerful tool to study rare diseases, such as systemic sclerosis (SSc), allowing researchers to collect a large cohort of patients across the healthcare system. To assemble these patients, algorithms are needed to identify these patients accurately. We have previously developed and validated algorithms to identify SSc subjects in the EHR using ICD-9 billing codes, laboratory data, and keywords. With the widespread implementation of ICD-10 billing codes, we sought to develop algorithms using ICD-10 codes, as well as other clinical data to identify SSc patients in the EHR.

Methods: We analyzed data from a de-identified version of Vanderbilt's EHR that contains over 2.8 million subjects with longitudinal clinical data. We identified 1899 potential SSc patients with at least one count of the SSc ICD-9 (710.1) or ICD-10 (M34*) codes. Of these potential subjects, we randomly selected 200 as a training set for chart review to identify true case status. A subject was defined as a case if diagnosed with SSc by a Vanderbilt or external rheumatologist, dermatologist, or pulmonologist (specialist). We selected the following algorithm components based on clinical knowledge and available data: SSc ICD-10 codes, positive anti-nuclear antibody (ANA) (titer $\geq 1:80$), and a keyword of Raynaud's phenomenon (RP) in notes. Positive predictive values (PPVs) and sensitivities were calculated for ICD-10 codes, as well as combinations of the above algorithm components. Subjects with an unclear diagnosis by a specialist (n = 24) or missing clinic notes (n = 20) were excluded from the analysis.

Results: Table 1 provides the PPVs and sensitivities of the algorithms. PPVs were higher for algorithms using ICD-10 codes compared to those using the ICD-9 code. Algorithms that used only ICD-10 codes without other clinical data performed well, with PPVs ranging from 94 to 96%. When adding a positive ANA or RP keyword to ICD-10 codes, PPVs increased to 100%. The algorithm with the highest combined PPV of 100% and sensitivity of 78% was ≥ 2 counts of the SSc ICD-10 codes and a positive ANA or RP keyword.

Conclusion: Overall, the PPVs for algorithms using ICD-10 codes were higher compared to PPVs for ICD-9 codes. While adding clinical data to algorithms only using ICD-9 codes was needed to improve those algorithms' PPVs, this was not needed for algorithms using ICD-10 codes. Therefore, using only ICD-10 codes without the addition of clinical data can serve as an efficient and effective way to identify SSc subjects accurately in the EHR.

Table 1.

Algorithm	Positive Predictive Value	Sensitivity
ICD-9 codes only		
≥ 1 count of the ICD-9 code (710.1)	50%	N/A
≥ 2 counts	68%	85%
≥ 3 counts	82%	77%
≥ 4 counts	90%	67%
ICD-10 codes only^a		
≥ 1 count of the ICD-10 codes	88%	85%
≥ 2 counts	96%	76%
≥ 3 counts	95%	53%
≥ 4 counts	94%	44%
ICD-10 codes AND ANA positive^b		
≥ 1 count of the ICD-10 codes AND ANA	94%	67%
≥ 2 counts AND ANA	100%	75%
≥ 3 counts AND ANA	100%	55%
≥ 4 counts AND ANA	100%	45%
ICD-10 codes AND Raynaud's (RP) keyword		
≥ 1 count of the ICD-10 codes AND RP	96%	83%
≥ 2 counts AND RP	100%	77%
≥ 3 counts AND RP	100%	57%
≥ 4 counts AND RP	100%	47%
ICD-10 codes, RP, ANA positive		
≥ 1 count of the ICD-10 codes AND ANA OR RP	95%	83%
≥ 2 counts AND ANA OR RP	100%	78%
≥ 3 counts AND ANA OR RP	100%	57%
≥ 4 counts AND ANA OR RP	100%	43%
≥ 1 count AND ANA AND RP	94%	68%
≥ 2 counts AND ANA AND RP	100%	61%
≥ 3 counts AND ANA AND RP	100%	43%
≥ 4 counts AND ANA AND RP	100%	35%

^a ICD-10 codes used included M34 grouping.

^b Anti-nuclear antibody (ANA) positive was defined as $\geq 1:80$.

Rescuing Standard Analyses of Immunosuppressive Rescue Therapy in Randomized Controlled Trials: Alternative Approaches in a Scleroderma Clinical Trial

Cathie Spino¹, Robert A. Parker² and Dinesh Khanna³, ¹Biostatistics, University of Michigan, Ann Arbor, MI, ²Medicine-Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Placebo-controlled clinical trials are the gold standard to provide the highest-quality evidence of treatment efficacy; however, in early SSc, requiring participants to take long-term placebo raises feasibility and ethical concerns. Studies may allow immunosuppressive rescue therapy when a participant's condition worsens. Statistically, adjusting for rescue therapy to derive appropriate conclusions about treatment efficacy is complicated. We applied several analytic approaches to address rescue therapy in a recently-completed trial.

Methods: ASSET was a multicenter double-blind, randomized placebo (PBO)-controlled trial of abatacept (ABA; NCT02161406). Eligible participants were randomized 1:1 to 12 months ABA or matching PBO, stratified by duration of dcSSc (≤ 18 vs >18 to ≤ 36 months). After 6 months of treatment, investigators were given a choice to add rescue therapy for worsening signs or symptoms.

Our primary analytic strategy for treatment comparisons for the primary (change from baseline to month 12 in mRSS) and secondary endpoints was based on the ITT principle for inclusion of participants, but to eliminate data after the onset of rescue therapy using linear mixed models. We also applied the “standard” approach of performing a strict ITT analysis and including all observations (i.e., including post-rescue therapy values). In addition to censoring, we used two models to

Table: Least Square Means (Standard Error) and P-values from Linear Mixed Model Analyses of Change from Baseline to Month 12 in Modified Rodan Skin Score (mRSS) for Various Approaches to Rescue Therapy

Model 4: Method to Address Rescue Therapy	Abatacept (N=44)	Placebo (N=44)	Treatment Difference (ABA-PBO)	p-value
#1: Values Censored after Initiation of Rescue Therapy – No Rescue Therapy Covariate [1]	-6.24 (1.143)	-4.49 (1.144)	-1.75 (1.611)	0.2794
#2: No Values Censored after Initiation of Rescue Therapy – No Rescue Therapy Covariate [1]	-6.64 (1.098)	-4.22 (1.039)	-2.42 (1.502)	0.1088
#3: Values Censored after Initiation of Rescue Therapy – Rescue Therapy Covariates [2]	-5.58 (1.317)	-3.48 (1.003)	-2.11 (1.634)	0.1983

mRSS scores have a range from 0 to 51, with higher score indicating greater severity of SSc.

[1] Estimates and p-values are from a linear mixed model with treatment group, month (3, 6, 9 and 12), treatment group x month interaction, duration of dSSC (≤18 vs >18 to ≤36 months), and baseline mRSS as fixed effects and participant as a random effect.

[2] Estimates and p-values are from a linear mixed model with treatment group, month (3, 6, 9 and 12), treatment group x month interaction, escape therapy, treatment group x escape therapy interaction, duration of dSSC (≤18 vs >18 to ≤36 months), baseline mRSS as fixed effects except for escape therapy and participant as random effect(s).

deal with rescue therapy – inclusion and exclusion of terms for rescue therapy and treatment group X rescue therapy interaction.

Results: 44 ABA and 44 PBO were randomized. 7 (16%) ABA and 16 (36%) PBO participants began rescue therapy (p=0.03). By eliminating observations after the start of rescue therapy and not incorporating rescue therapy into the model, the smallest mean treatment difference occurred (see Table, #1). As might be expected with twice as many PBO participants starting rescue therapy, the largest mean treatment difference occurred when all observations were included in the analysis and rescue therapy was not incorporated into the model (See Table, #2). Censoring observations after the start of rescue therapy and incorporating rescue therapy as a covariate resulted in an intermediate estimate. No statistically significant treatment differences were observed from any model.

Conclusion: Although there was differential use of rescue therapy in our study, several simple approaches to handling rescue therapy resulted in comparable conclusions, providing confidence in our results. More sophisticated analytic methods, such as jointly modeling the primary endpoint and the probability of rescue therapy, may be useful, as well as consideration of the choice of estimand during the design of the trial which will help focus analytic efforts.

Botulinum Toxin in the Management of Raynaud's Phenomenon

Daniel Ennis^{1,2}, Zareen Ahmad³, Keshini Devakandan¹, Melanie A Anderson⁴ and Sindhu Johnson¹, ¹Toronto Scleroderma Program, Mount Sinai Hospital, Toronto Western Hospital, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, ON, Canada, ²Rheumatology, University of British Columbia, Vancouver, BC, Canada, ³Toronto Scleroderma Program, Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, ⁴University Health Network Library Services, Toronto General Hospital, Toronto, ON, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The objectives of this study were to evaluate the effectiveness and safety of botulinum toxin injection in Raynaud's phenomenon.

Methods: Medline and Embase databases were search to identify eligible studies. Studies reporting use of botulinum toxin, effectiveness measures and safety outcomes were included.

Results: A total of 421 patients with Raynaud's were identified of which 324 (77%) were determined to have a secondary cause. A total of 202 subjects had systemic sclerosis (SSc) (33% limited SSc, 22% diffuse SSc, and 45% unknown subtype). Botulinum toxin A doses ranged from 10-200 units, administered with similar frequency to the palm (n=272) and digits

(n=253). The mean duration of benefit was 6.28 months with a range of 1 month to 8.6 years. There were no attributable deaths reported with botulinum toxin use. The most common adverse event was intrinsic muscle weakness (32 total events, frequency of 7.6%), and pain in 2 subjects. Only a single subject experienced persistent muscle weakness and atrophy. Benefit was consistently demonstrated across a heterogeneous group of objective and subjective outcomes.

Conclusion: Botulinum toxin injection for the management of refractory primary and secondary Raynaud's phenomenon, using various doses and injection techniques, was demonstrated to be generally safe. Effectiveness of this treatment is suggested by the consistently positive, although heterogeneous, objective and subjective outcomes. These findings support the ongoing study of botulinum toxin for the management of refractory Raynaud's phenomenon.

Incidence, Prevalence, Mortality and Comparison of the ACR/EULAR 2013 Classification Criteria with 1980 Criteria in Physician Diagnosed Systemic Sclerosis: Results from a Population Based Cohort (1980-2016)

Avneek Singh Sandhu¹, Cynthia S. Crowson², Philippe R. Bauer³, Eric L. Matteson⁴ and Ashima Makol¹, ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, ⁴Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a complex and heterogeneous chronic inflammatory disease characterized by widespread fibrosis of the skin and visceral organs, microvascular injury and evidence of immune system activation. We aimed to determine the incidence, prevalence and mortality of physician diagnosed SSc in a population-based cohort and to evaluate the performance of the ACR/EULAR 2013 Classification criteria vs. 1980 ACR criteria in classifying patients with SSc.

Methods: Medical records of patients with a diagnosis or suspicion of SSc in a geographically well-defined area from Jan 1, 1980 to Dec 31, 2016 were reviewed to identify incident cases of SSc (defined by physician diagnosis). Prevalent cases of

SSc on Jan 1, 2015 were also identified. Incidence and prevalence rates were age and sex adjusted to the 2010 US white population. Survival rates were compared with expected rates in the general population. Fulfillment of the 1980 and 2013 classification criteria was ascertained.

Results: 79 incident cases of SSc (90% female, 87% Caucasians, mean age at diagnosis 55.8 +/- 16 y) from 1980-2016 and 49 prevalent cases on Jan 1, 2015 were identified. . The overall age- and sex-adjusted annual incidence for 1980-2016 was 2.7 (95% C.I. 2.1- 3.3) per 100,000 population (age-adjusted incidence was 4.6 (95% CI: 3.5-5.7) per 100,000 for females and 0.6 (95% CI: 0.2-1.1) per 100,000 for males), with no change in incidence over time. The age-and sex-adjusted prevalence on January 1, 2015 was 47.4 (95% CI: 34.1 -60.7) per 100,000 population. 64 of 79 (81%) patients fulfilled the 2013 classification criteria, while only 48% fulfilled the 1980 criteria. All but 1 patient that fulfilled the 1980 criteria also fulfilled the 2013 criteria. At SSc diagnosis, 74 (94%) patients had Raynaud's, 13/44 (30%) had abnormal nail fold capillaries, 16/33 (48%) had digital ulcers/pitting scars, 43 (54%) had sclerodactyly, 39 (49%) had telangiectasias, 8 (10%) had pulmonary hypertension, and 7 (9%) had interstitial lung disease. 66 patients had limited cutaneous SSc, 11 had diffuse cutaneous SSc and only 2 had Sine scleroderma. 39 patients had a positive autoantibody for SSc : ACA in 29, anti-Scl-70 in 8 and anti RNA-polymerase III in 2. Mortality among SSc patients was significantly higher in comparison to the general population (standardized mortality ratio, 2.24; 95% C.I., 1.52-3.18; Figure).

Conclusion: The average incidence of SSc in this population-based cohort was 2.7 per 100,000 population with no evidence of a change in incidence over the 36 year period of study. The new 2013 classification criteria perform significantly better than the 1980 criteria, but failed to classify 19% of patients in this cohort. Overall survival of patients with SSc is worse than the general population with no evidence of improved survival over time, indicating an unmet need for early diagnosis and more aggressive management.

Delay in Initiation of Therapy Predicts Worse Outcomes in Scleroderma Renal Crisis

Aditi Patel¹, Kinjal Banerjee² and Soumya Chatterjee³, ¹Internal Medicine, Cleveland Clinic, Cleveland, OH, ²Cleveland Clinic, Cleveland, OH, ³Rheumatic and Immunologic Disease, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a rare complication of patients with systemic sclerosis (SSc). ACE inhibitors (ACEI) favorably alter the natural history of this condition. However, clinicians are wary of initiating this therapy because of a rising serum creatinine. There is paucity of data on the association between the time of initiation of therapy and long-term outcomes. We evaluated the effect and timing of treatment on long term outcomes in patients with SRC.

Methods: We screened 393 adult patients with SSc (fulfilling 2013 ACR/EULAR criteria) in our institution from 2004 to 2/2018 of which 25 satisfied the diagnosis of SRC, as defined by Steen et al¹. Data on patient demographics, clinical presentation, serology, time to initiation of therapy, and type of therapy were evaluated. We evaluated the following outcomes: mortality, need for dialysis and partial or complete renal recovery. Follow up was censored on May 11th, 2018. Continuous variables were expressed as mean \pm SD. Discrete variables were expressed as mean (%) and compared with chi-squared tests. Kaplan-Meier curves were used to describe long term survival estimates. A two-tailed p-value of less than 0.05 was considered significant for all statistical testing.

Results: Our cohort included 25 patients with SRC of which one patient was normotensive; 63% were females and mean ages at diagnoses of SSc and SRC were 54 \pm 14.1 years and 58 \pm 11.2 years respectively; 96% of the patients were treated with ACEI including 16% who were already on one. Baseline characteristics, clinical features, and disease course of patients with SRC are shown in Table 1. At one year, mortality was 41.2%; 52% (13/25) required dialysis. Of which one patient was able to discontinue dialysis after 25 days. Dialysis requirement was significantly higher in those who were started on ACEI > 48 hours after onset of clinical manifestations (78.6% vs 16.7%, p= 0.018). Kaplan-Meier survival estimates at 5 years follow up are shown in Figure 1.

Table 1: Baseline characteristics, clinical features, laboratory abnormalities, and disease course of patients with SRC.

Age at diagnosis of SSC, in years	54.0 ± 14.1
Age at diagnosis of SRC, in years	58.48 ± 11.2
Gender	
<i>Female</i>	16 (64%)
<i>Male</i>	9 (36%)
Race	
<i>Caucasian</i>	20 (80%)
<i>African American</i>	5 (20%)
Serology	
<i>Anti-RNA polymerase III Ab</i>	13 (52%)
<i>Anti-Scl 70</i>	6 (24%)
<i>None of the above</i>	6 (24%)
Symptoms	
<i>Headaches</i>	10 (40%)
<i>Seizures</i>	0 (0%)
<i>Oliguria</i>	14 (56%)
Manifestations	
<i>Hypertension</i>	24 (96%)
<i>Acute kidney injury</i>	25 (100%)
<i>MAHA</i>	11 (44%)
<i>Thrombocytopenia</i>	9 (36%)
<i>Pericardial effusion</i>	8 (32%)
<i>Myocarditis</i>	1 (4%)
<i>Encephalopathy</i>	2 (8%)
Urine Microscopy	
<i>RBC's in urine microscopy</i>	19 (76%)
<i>Proteinuria</i>	22 (88%)
<i>Clear</i>	2 (8%)
Peak Creatinine	5.73±2.81
Number of antihypertensive meds	
<i>ACEI</i>	24 (96%)
<i>ARB</i>	4 (16%)
<i>CCBs</i>	19 (76%)
<i>Beta-blockers</i>	10 (40%)
<i>Vasodilators</i>	5 (20%)
Choice of ACE inhibitor	
<i>Lisinopril</i>	23 (92%)
<i>Enalapril</i>	5 (20%)
<i>Captopril</i>	1 (4%)
Approved maximum dose of ACEI received	13 (52%)
Pre-existing ACEI use	4 (16%)
Use of preceding or concomitant glucocorticoids	8 (32%)
TMA features on renal biopsy	8 (88%, n=9)

Data presented as Mean ± SD or N (column %). ARB, Angiotensin receptor blocker,

CCB, Calcium channel blocker. MAHA, Microangiopathic hemolytic anemia. TMA, Thrombotic microangiopathy

Conclusion: Early (≤ 48 hours) initiation of ACEI in patients with SRC significantly reduces need for dialysis. However, irrespective of the timing of initiation of therapy, the long-term mortality of patients with SRC remains high.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In a systematic literature review and meta-analysis, to determine maternal and fetal outcomes in pregnant SSc women and to analyse the effect of pregnancy on SSc disease activity.

Methods: A systematic literature search was performed in four different databases: PubMed, Cochran, EMBASE and Web of Science for articles published between 1950 and 1st February 2018. All articles reporting on SSc and pregnancy were analysed. Review articles were examined for further references. Reviewers double extracted articles (with a third reviewer resolving differences) to: (1) obtain agreement on > 95% of pre-defined critical outcomes (eg pregnancy outcome, fetal death etc) and >90% of the other variables; (2) maintain quality assurance; (3) screen and extract data. Descriptive analysis described the results. Comparisons of SSc pregnancies to healthy controls used a Chi-square test.

Results: 458 publications were identified. 16 studies met the inclusion criteria and were included in the meta-analysis 1,403 pregnancies in the SSc group were compared to 12,196,221 healthy control pregnancies. In SSc pregnancies, there were

significantly more miscarriages (15.7% vs 11.3%, $p=0.007$), stillbirths, (4.5% vs 0.3%, $p<0.001$), preterm births (12.9% vs 3.9%, $p<0.001$) and fetuses with intra-uterine growth retardation (IUGR) (5.5% vs 1.7%, $p<0.001$), compared to controls. There were no differences (all $p<0.05$) in the percent infant deaths (2.5% vs 1.9%), infant malformations (2.2% vs 1.7%) and low birth weight neonates (11.8% vs 9.4%) between the two groups. In SSc, pre-eclampsia (4.4% vs 1.1, $p<0.00$) and gestational hypertension (17.8% vs 8.4%, <0.001) occurred more frequently, compared to controls. In additions, there were significantly more Caesarean deliveries in SSc pregnancies (39% vs 31%, $p<0.001$). No increases in maternal mortality or eclampsia rates were observed in SSc patients versus controls. Regarding the effect of pregnancy on SSc disease activity, one or more disease manifestations worsened or appeared during pregnancy in 44/307 (14.3%). In additional in 32/306 (10.5%) pregnancies, SSc manifestations worsened or appeared during the 6-months post-partum period. In two cases this worsening led to maternal death.

Conclusion: Despite our rigorous inclusion/exclusion criteria resulting in selecting only 16 articles out of 458 publications, and despite the limited data available, our SLR and meta-analysis in SSc pregnancies demonstrated an increased frequency of miscarriages, stillbirths, IUGR and pre-term labour versus healthy control pregnancies. SSc patients were more prone to develop pre-eclampsia and gestational hypertension, but not eclampsia. Notably, maternal mortality was not increased in SSc pregnancies, nor did pregnancy lead to worsening disease in most cases. Further analysis is planned to identify the predictors for adverse fetal and maternal outcomes and for disease progression in SSc pregnancies.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Extracorporeal shock wave therapy (ESWT) at low energy has been shown to be effective for digital ulcers in systemic sclerosis (SSc) in our study reported at ACR last year. However, studies to confirm treatment protocols with the most therapeutic effect have not been satisfactorily performed. We aimed to determine the optimal treatment period by comparing the number of cutaneous ulcers before and after treatment.

Methods: The study enrolled 60 patients with SSc and refractory digital ulcers. Of these, 30 were treated with ESWT and 30 received conventional treatment. ESWT treatment was performed once a week for 8 weeks and the results were observed for 4 additional weeks. The total number of ulcers and the number of large ulcers (defined as having a diameter ≥ 5 mm) were evaluated. During the treatment period, outcomes were assessed every week for 8 weeks and then evaluated during a 4-week observation period, after treatment completion. The visual analog scale (VAS) for pain as a patient-reported outcome (PRO) was also evaluated.

Results: The ulcers decreased by 78.34% in the ESWT group and 20.94% in the conventional treatment group at 8 weeks, and the difference was significant ($p=0.0001$). However, the ulcers decreased by 71.85% in the ESWT group and 53.75% in the conventional treatment group at 12 weeks (observation period). No further improvement was seen following the

treatment period in the ESWT group, and the difference in efficacy from the conventional treatment group decreased during the observation period. Large ulcers alone decreased by 84.21% in the ESWT group and 52.78% in the conventional treatment group at 8 weeks, and the difference was not significant. However, the improvement in VAS pain scores at 8 weeks was 43.96% in the ESWT group and -16.60% in the conventional treatment group ($p=0.0817$). The pain VAS scores did not decrease significantly probably because of insufficient improvement in large ulcers.

Conclusion: ESWT treatment was discontinued at 8 weeks, but some ulcers remained. Persistence of large ulcers had a significant influence on VAS pain scores. Treatment protocols may require continued ESWT until ulcer disappearance, especially for large ulcers.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To date, there is lack of a uniform definition of systemic sclerosis related skin ulcer (SSc-skin ulcer) for use in clinical trials. Our group previously published a consensus driven definition of SSc-skin ulcer under the patronage of WSF(1) . The definition was based on a systematic literature review followed by a nominal group technique to establish consensus among SSc experts. Face validity and feasibility were demonstrated. However, further validation of the WSF skin ulcer definition is needed.

Aim: to establish the sensitivity and specificity of the proposed WSF clinical definition of SSc-skin ulcers and evaluate Its reliability among investigators.

Step I: To determine the ability to discriminate between SSc-Skin ulcers, SSc non-ulcer lesions and non SSc lesions.

Step II: To examine the inter-rater and Intra-rater reliability of the WSF definition among investigators.

Methods: Four hundred images {200 SSc skin lesions (ulcers and non-ulcers), 200 non-SSc skin lesions} were evaluated by two highly qualified SSc experts and their scoring were considered the gold standard scores.

Step I: 10 investigators with different levels of expertise in SSc were included to utilize the definition indiscrimination between SSc-skin ulcers from other lesions (SSc non-ulcers and non-SSc lesions) as compared to gold standard. Each investigator scored 40 images.

Step II: A total of 45 images were sent to each of the 10 investigators. Twenty (20) images per investigator evaluated in step I, were examined again for intra-investigator reliability. Twenty-five (25) images (the same images examined across the 10 investigators) were used to examine inter-investigator reliability.

Results: Step I:

- For discriminating SSc-skin ulcers from SSc non-ulcer lesions: sensitivity was 78% and specificity was 94 %
- For discriminating SSc-ulcers from non SSc-ulcer lesions: sensitivity was 78% and specificity was 100%

Step II:

Intra-rater reliability using ICC was 0.99, with kappa agreement of 0.89 (excellent)

Inter-rater reliability using Fleiss Kappa was 0.346 (only fair, given a range of 0-1.0).

Discussion: As is the case for mRSS, repeated training sessions prior to starting a clinical trial may decrease variability among investigators .

Conclusion: Discrimination among a group of rheumatologists with varying SSc experience for differentiating between SS-ulcers, SSc-non-ulcers and non-SSc lesions was very good(sensitivity) to excellent (specificity)

As for other clinical SSc measures (e.g. mRSS), it will be necessary in clinical trials to have the same investigator examining a given patient over time, as inter-rater reliability is not sufficient.

Ref: Y Suliman et al., Defining Skin Ulcers in Systemic Sclerosis: Systematic Literature Review and Proposed World Scleroderma Foundation (WSF) Definition. *JSRD* Vol 2, Issue 2.

World Scleroderma Foundation(WSF) skin ulcer definition:

1. Loss of epidermal covering with a break in the basement membrane (which separates dermis from the epidermis). It appears clinically as visible blood vessels, fibrin, granulation tissue and/or underlying deeper structures (e.g. muscle, ligament, fat), or as it would appear on debridement.
 2. This excludes: Scar, Abrasion, Incision, Laceration, Fissure, Infected ulcer, ulcer with underlying calcinosis, and gangrenous ulcers

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is the most acute and life-threatening complication of scleroderma characterized by sudden increase in blood pressure and worsening kidney function. Historically, development of SRC was almost always fatal. With the use of angiotensin-converting enzyme inhibitors (ACEI), one-year survival has improved up to 76%; however, SRC remains a poor prognostic marker for long-term survival. Dialysis dependency after an episode of SRC portends a worse long-term prognosis. Here we report on our 15 years of experience with SRC at our institution with a focus on identifying characteristics that predicted initiation of dialysis or death.

Methods: We undertook a retrospective single-center chart review of patients aged 18-80 years old that developed SRC between the years 2002-2016. Baseline characteristics such as age, gender, race, comorbidities and exposures were noted. Outcome data was collected at time of admission, 6 months and 12 months. Patients with the diagnosis of scleroderma and acute kidney injury for any other reason other than SRC were excluded.

Results: In the 15-year period, we identified 34 patients with an episode of SRC (table 1). Of these patients, 16 developed poor outcome (death or dialysis) during their hospital admission. Exposure to steroids within one month of admission was

similar in both groups; however, poor outcome was more common in those with exposure to ≥ 40 mg prednisone ($p=0.007$). This trend continued at the 6 and 12-month follow-up.

Conclusion: Exposure to steroids is known to be a risk factor for the development of SRC. Use of higher dosages of steroids may also be associated with worse outcomes in patients with SRC.

Table 1. Results are reported as proportions or means \pm standard deviation or ranges

	Death or Dialysis (n=16)	Recovered (n=18)	p-value

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Standard treatment for the diverse aspects of diffuse cutaneous systemic sclerosis (dcSSc) is not yet well defined although experts have described therapeutic algorithms. The Prospective Registry of Early Systemic Sclerosis (PRESS) is longitudinal cohort of patients with early dcSSc at 11 US centers enrolling since 2012. In this study we describe the medical treatments utilized by PRESS investigators throughout the duration of the study and their changes over time.

Methods: Adult patients with a diagnosis of dcSSc and early disease as defined as <2 years since the onset of the first non-Raynaud's symptom are included. Associations of treatment choices with demographic factors and organ involvement were assessed using logistic regression and Fisher's exact test.

Results: As of May 2018, baseline data were available on 239 patients with characteristics listed in table 1. Follow-up data was available on 168 (70.3%). The median follow-up time was 12 months.

During the study period, 68.4% were noted to have Interstitial lung disease (ILD). At baseline, 60.3% of patients were on an immunosuppressive agent, the majority of whom were taking MMF (37.2%). During follow-up, MMF was the most commonly prescribed immunosuppressive and was taken by 151 patients (63.2%) followed by MTX by 50 (20.9%), and HCQ by 39 (16.3%). Seventy-four (31.1%) of patients used prednisone at baseline but its use waned over time. Forty

(16.7%) patients remained off immunosuppressive therapy throughout the course of follow-up. The use of these drugs over time is shown in table 2.

Immunosuppressive choice was noted to be associated with specific demographic factors. Patients disabled due to scleroderma at the baseline visit were less likely to have previously received MMF, odds ratio (OR) 0.27 (0.07 - 0.96), $p = 0.044$, and patients with RA overlap were more likely to have received MMF, OR 3.26 (1.06 - 10.06), $p = 0.040$. Use of MMF at baseline was not associated with more severe Modified Rodnan Skin Score (MRSS). MTX use at baseline was more common in patients with higher MRSS scores, but this trend lost significance when looked at over the first year. Looking at medication use through one year of follow up, patients were more likely to be prescribed MMF if they had ILD defined at baseline ($p=0.043$) and less likely to receive MTX ($p=0.034$). Prednisone use was more common in those patients with overlapping RA or polymyositis.

Conclusion: Most patients enrolled in the PRESS registry are treated with immunosuppressive agents, most commonly MMF or MTX. Treatment choice varies with disease manifestations and severity.

Baseline characteristic	N=239 patients
Swollen hands or sclerodactyly, n (%)	239 (100.0%)

Conversion of Normal Mean Pulmonary Arterial Pressure to Pulmonary Hypertension in Systemic Sclerosis – a Longitudinal Observational Study

Amber Young¹, Scott H. Visovatti², Tom Cascino², Nektarios Vasilottos³, Vallerie McLaughlin² and Dinesh Khanna¹,
¹Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ²Division of Cardiology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, ³Department of Internal Medicine, University of Michigan, Ann Arbor, MI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary hypertension (PH) is one of the leading causes of mortality in patients with systemic sclerosis (SSc). Active screening detects PH earlier and may improve survival in SSc patients. Our objective was to evaluate the development of PH in high risk SSc patients over time who initially had a negative right heart catheterization (RHC).

Methods: Subjects with a diagnosis of SSc based on the 2013 ACR/EULAR criteria who did not have a prior diagnosis of PH who underwent a resting RHC due to increased risk based on 2013 recommendations for screening and detection of connective tissue disease-PAH¹, which includes DETECT, were included in this prospective observational cohort. Those subjects who did not have a diagnosis of PH according to resting baseline RHC with mean pulmonary artery pressure (mPAP) < 25mmHg underwent subsequent screening resting RHC approximately 24 months later, or earlier if they developed new symptoms and/or change in non-invasive testing parameters.

Results: Sixty-seven subjects with SSc who underwent baseline resting RHC were included. Ninety-percent of subjects were female, 82% were Caucasian, 12% were African American, 66% had limited cutaneous SSc, and 34% had diffuse cutaneous SSc. Mean (SD) age was 61.4 (9.6) years, SSc disease duration was 13.2 (11.4) years, FVC% predicted was 79.9 (20.3), DLCO% predicted was 57.7 (18.4), and FVC/DLCO was 1.5 (0.6). At baseline RHC, 24% had normal mPAP (\leq 20mmHg), 34% had borderline mPAP (BoPAP, 21-24 mmHg), and 42% had PH (\geq 25mmHg) (Figure 1). No patients with normal mPAP or BoPAP were treated with PAH specific therapies. Eleven subjects, 2 with normal mPAP and 9 with BoPAP, underwent repeat RHC; 3 subjects with BoPAP progressed to PH, 3 subjects with BoPAP decreased to normal mPAP, 3 subjects remained BoPAP, 1 subject with normal mPAP progressed to BoPAP and 1 subject with normal mPAP remained at normal mPAP (Figure 2).

Conclusion: Use of 2013 recommendations resulted in identification of a high proportion of subjects with normal mPAP or BoPAP. Approximately 1/3 of patients with BoPAP progress to PH after 2 years, which is different than previously reported^{2,3}. This may be due to universal PAH screening of SSc patients at our center on annual basis.

Physical Activity Trackers Work Well As a Monitor of Physical Activity in Systemic Sclerosis

Amber Young¹, Elizabeth A. Jackson² and Dinesh Khanna¹, ¹Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ²Division of Cardiovascular Disease, Division of Cardiovascular Disease, University of Alabama, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients have reduced physical function, exercise capacity and health related quality of life (HRQOL). The objective of this study was to assess the feasibility and test-retest reliability of physical activity trackers as a measure of physical activity in patients with SSc.

Methods: SSc subjects, based on 2013 ACR/EULAR classification criteria, 18 to 79 years old without large joint contractures or use of mobility devices, and with access to a smartphone or computer were eligible; if subjects had pulmonary hypertension (PH) and/or interstitial lung disease (ILD), medications were stable for 3 months prior to enrollment. Subjects received a Fitbit Zip® physical activity tracker to wear daily during awake hours and performed their

Figure 1. Average Weekly Step Counts

Figure 2. Step Counts are Stable Over Time for Individual Subjects

everyday activities; no step goals were provided. Patient reported outcomes (PROs) were provided at baseline and follow up visit.

Results: Twenty subjects have been recruited; 75% were female, 90% were Caucasian, 50% had diffuse cutaneous SSc, 40% had limited cutaneous systemic sclerosis, 10% had sine scleroderma, 35% had ILD, 10% had PH, mean (SD) age was 49 (11.7) years old and SSc disease duration was 5.3 (3.6) years. PROMIS-29 mean (SD) values at baseline (N=19) were as follows: physical function 47.2 (7.9), social roles 53.3 (8.4), anxiety 49.5 (9.7), depression, 47.3 (8.8), fatigue 50.0 (9.4), sleep disturbance 49.7 (7.3), pain interference 51.7 (7.7), and pain intensity 2.6 (2.4). Two subjects withdrew after enrollment and did not use the tracker. Mean (SD) study duration for the remaining 18 subjects was 177.7 (89.2) days and mean (SD) daily step counts during the first week were 5710.8(3212.4) steps (Figure 1). Mixed effects model to assess test-retest reliability of weekly step counts for each subject indicated step counts were stable over time (Figure 2). PROMIS-29, UCSD SOBQ, SHAQ, and mMRC PROs did not indicate a statistically significant difference from baseline to follow up (data not shown, $p > 0.05$). On comparison of subjects without ILD and/or PH (N=13) to those with ILD and/or PH (N=7), mean (SD) daily steps counts were numerically higher in those without ILD and/or PH (6523 vs 4925, $p = 0.29$) but there were statistically significant differences for PROMIS-29 physical function (50.18 vs 41.5, $p = 0.047$), mMRC grade (0.33 vs 1.33, $p = 0.018$), and VAS breathing problems (0.5 vs 2.17, $p = 0.035$).

Conclusion: Physical activity trackers show acceptable feasibility and test-retest reliability for use in SSc. Future studies will evaluate change in HRQOL with use of step count goal interventions.

Comparison of Gastric Antral Vascular Ectasia Associated with Systemic Sclerosis with That Associated with Other Diseases: Are There Differences?

Rabeea Mirza¹, Yuxuan Jin², Donald F. Kirby³ and Soumya Chatterjee^{1,4}, ¹Rheumatic and Immunologic Disease, Cleveland Clinic, Cleveland, OH, ²Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, ³Digestive Disease and Surgery Institute, Cleveland Clinic, Cleveland, OH, ⁴Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Background/Purpose: Gastric antral vascular ectasia (GAVE) is a pathologic angioectasia with a characteristic endoscopic appearance. Rugal folds with dilated blood vessels radiate from the antrum and converge at the pylorus resembling watermelon stripes, supporting the name watermelon stomach. It can cause anemia and significant morbidity, hence needs surveillance. GAVE has been associated with cirrhosis of liver, autoimmune diseases (e.g. systemic sclerosis (SSc), rheumatoid arthritis, primary biliary cholangitis), ESRD, hypertension, heart failure, hypothyroidism, chronic pulmonary disease and hematopoietic stem cell transplantation. Prevalence of SSc associated GAVE is highly variable ranging from 1% to 76%. Prevalence of GAVE in other associated diseases and its long term outcomes are still unknown. We aimed to compare the differences in GAVE in SSc with that in other diseases.

Methods: We conducted a retrospective chart review of patients with GAVE at a single referral center. We evaluated patients diagnosed with GAVE between 2012 - 2017; 145 GAVE patients were initially identified. We selected 37 consecutive SSc and 37 consecutive non SSc patients from the GAVE database. Outcomes were defined by number of transfusions, number of recurrences of GAVE bleeding diagnosed endoscopically (low <5 or high ≥ 5), and death. Groups were compared using ANOVA and Kruskal Wallis tests for continuous variables and Pearson's chi square tests or Fisher's exact tests for categorical variables. Also, comparisons were made using linear regression to adjust for covariates.

Results:

Table 1.

Factor	Total (N=74)	Non- scleroderma (N=37)	Scleroderma (N=37)	p-value
Age of onset	62.4±12.6	66.8±12.6	57.9±11.0	0.002^a
Gender				0.006^c
Male	23(31.1)	17(45.9)	6(16.2)	
Female	51(68.9)	20(54.1)	31(83.8)	
Ethnicity				0.99 ^d
African American	2(2.7)	2(5.4)	0(0.0)	
Caucasians	71(95.9)	35(94.6)	36(97.3)	
Asian	1(1.4)	0(0.0)	1(2.7)	
Disease Frequency				
Limited SSc		-	23 (31.5)	
Diffuse SSc		-	14 (19.2)	
Chronic pulmonary disease		20(27.4)	-	
ESRD		7(9.6)	-	
Hypertension		36(49.3)	-	
Heart failure		19(26.0)	-	
Cirrhosis of liver		19(26.0)	-	
Primary biliary cholangitis		0(0.0)	-	
Rheumatoid arthritis		2(2.70)	-	
Hypothyroidism		19(26.0)	-	
HSCT		1(1.4)	-	

Statistics presented as Mean ± SD or N (column %).

p-values: a = ANOVA, c = Pearson's chi-square test, d = Fisher's Exact test.

HSCT = hematopoietic stem cell transplantation

ESRD = end stage renal disease

Table 2. Outcome of GAVE

Factor	Total (N=74)	Non-scleroderma (N=37)	Scleroderma (N=37)	p-value
Number of transfusions ^a	2.0 (0.00,25.0)	5.0 (0.00,25.0)	0.00 (0.00, 18.0)	<0.001^b
Number of recurrences of GAVE/GI bleed*				0.43 ^c
Low (<5)	49(70.0)	23(65.7)	26(74.3)	
High (>=5)	21(30.0)	12(34.3)	9(25.7)	

^aβ= Number of transfusions was not significant when adjusted for hemoglobin before transfusion, using multiple regression model

*Data not available for all subjects. Missing values: Number of recurrences of GAVE/GI bleed = 4. Statistics presented as Median (min, max) or N (column %).

P-values: b=Kruskal-Wallis test, c=Pearson's chi-square test

Clinical manifestations associated with GAVE in SSc and non-SSc groups respectively, were telangiectasias (29.7% vs 0%), melena (37.8% vs 86.5%), hematemesis (5.4% vs 8.1%), fatigue (86.5% vs 81.1%), dyspnea (19.4% vs 24.3%) and lightheadedness (2.8% vs 8.1%).

Patients were followed for a median of 5 years. When adjusted for pre-transfusion hemoglobin, difference in transfusion requirements was not statistically significant between the two groups. There was no difference in use of NSAIDs and anticoagulants between the two groups. There was also no difference in number of recurrences of GAVE. Two patients with cirrhosis of liver died.

Conclusion: Our study demonstrates that SSc patients with GAVE were significantly younger than those with non-SSc GAVE, and were mostly females. There was little difference in the presentation, severity and outcome of GAVE between the two groups. In future, further studies with larger cohorts of GAVE patients may be helpful in understanding its natural history and outcomes in specific diseases with which it is associated.

Evaluation of Longitudinal Outcomes in Scleroderma Patients with Negative Immunofluorescent Anti-Nuclear Antibodies

Mayce Haj-Ali¹, Derek Jones², Sean McNish³, Sarah Stupp³, Marissa Mangini³ and Victoria Shanmugam⁴, ¹Department of Medicine, The George Washington University School of Medicine and Health Sciences, Washington, DC, ²The George Washington University, Washington, DC, ³The George Washington University School of Medicine and Health Sciences, Washington, DC, ⁴Rheumatology, The George Washington University, Washington, DC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by inflammation, fibrosis, and vasculopathy. Historical data indicates approximately 90% of patients with SSc test positive for anti-nuclear antibodies using immunofluorescence (IF-ANA) as well as for scleroderma specific extractable nuclear antibodies such as topoisomerase (Scl-70), centromere, THTO, U3RNP, U1RNP and RNA Polymerase III. However, a small subset of scleroderma patients test negative for anti-nuclear antibodies. The purpose of this study was to investigate whether scleroderma patients with negative IF-ANA had different characteristics when compared to scleroderma patients with positive IF-ANA.

Methods: This study was IRB approved and all patients consented to be included in the study. At the time of data lock, 68 patients fulfilled diagnostic criteria for systemic sclerosis. Data was collected on patient demographics, autoantibody profile, clinical findings, internal organ involvement, modified Rodnan Skin Score (mRSS) and Medsger Severity Scale. IF-

ANA testing was performed using the Hep-2 cell line through Laboratory Corporation of America (LabCorp, Burlington, NC).

Results: Of the 68 patients, 54 had positive IF-ANA and 14 had negative IF-ANA. There was no significant difference in age, sex, race or scleroderma subtype (sine, limited, diffuse, or localized) between the IF-ANA positive and negative groups. There was no significant difference in mRSS at baseline between the IF-ANA positive and negative groups. However, patients in the IF-ANA negative group had a significantly lower mRSS at follow-up ($p=0.02$). This significant improvement was driven both by patients treated with immunosuppression and a small number of patients who were found to have underlying malignancy and whose scleroderma went into remission with treatment of the malignancy. Notably however, the IF-ANA negative group was also more likely to have positive U3RNP ($p=0.009$) indicating that this antibody may be missed using IF-ANA.

Conclusion: Scleroderma patients with negative IF-ANA testing appeared to have milder progression of mRSS with therapy at follow-up indicating that this subgroup of patients may have a relatively better prognosis. Additionally, this study found that U3RNP antibody was more commonly seen in the IF-ANA negative subgroup indicating that this antibody subtype may be missed using commercially available IF-ANA testing. This is an important finding since scleroderma patients with U3RNP are at higher risk for life threatening complications of scleroderma, including pulmonary hypertension and pulmonary fibrosis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of mortality in SSc. Immunosuppression is used to treat ILD, but little is known about its benefits in mild ILD or late SSc, as these patients were excluded from randomized trials. Our aim was to determine if, in SSc patients with incident ILD, the effectiveness of immunosuppression was differential according to ILD severity and SSc duration.

Methods: We studied all SSc patients with incident ILD, using data from the Canadian Scleroderma Research Group registry (> 98% met 2013 ACR/EULAR classification criteria for SSc). The primary exposure was time dependent ever/never exposure to methotrexate, cyclophosphamide, mycophenolate, azathioprine and/or cyclosporin A. The primary outcome was progression-free survival, with clinically meaningful progression defined as >10% decline in forced vital capacity (FVC), or >5% to <10% decline in FVC and >15% decline in diffusion capacity of lung for carbon monoxide (DLCO) (OMERACT CTD-ILD 2015). Using ILD diagnosis as time zero, time to progression or death was compared between exposed and unexposed subjects. A marginal structural Cox model with inverse probability of treatment weights and multiple imputation was used to account for potential confounding and for missing data, respectively. Weights were constructed using age at baseline, sex, race, disease subtype (diffuse vs limited), and autoantibodies. Mild ILD was defined as FVC>80% predicted, and late SSc duration was defined as >7 years since first non-Raynaud. Our final model also adjusted for age, sex, race, disease subtype, and autoantibodies. Interaction terms were examined to determine if immunosuppression effectiveness differed in mild vs moderate/severe ILD, or in late vs early SSc. Subjects were censored at the visit when the outcome (death or progression) was first recorded, lost to follow-up or at last study visit.

Results: There were 204 SSc patients with incident ILD; 67 were exposed to immunosuppression at time zero or during follow up and 134 remained unexposed throughout follow-up (Table 1). In our models, subjects exposed to immunosuppression tended to have a lower estimated risk of progression or death versus unexposed subjects: weighted

hazard ratio(HR) 0.65 (95% CI 0.34, 1.25). We were unable to detect a differential effect of immunosuppression according to ILD severity or SSc duration (p=0.24 and p=0.85 for interaction terms, respectively).

Conclusion: We were unable to detect a differential effect of immunosuppression according to ILD severity or SSc duration; this may be due to lack of power. A larger sample would be required to resolve this uncertainty and answer the important clinical question of whether SSc patients perceived to be at increased risk of progressive ILD, even if mild or later in the disease course, benefit from immunosuppression.

Table 1. Baseline characteristics of the cohort, stratified by exposure status

	Never-exposed to treatments (N=134)		Ever-exposed to treatments (N=67)	
	Mean (SD) or N (%)	Missing (%)	Mean (SD) or N (%)	Missing (%)

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA are detected in 0-11.7% (1) of patients with systemic sclerosis (SSc) and only a minority of these patients will develop an overlap syndrome with ANCA associated vasculitis (AAV). The clinical significance of ANCA in SSc patients without AAV is unknown. The aim of this study was to determine the prevalence of ANCA in a large SSc cohort and the association between ANCA positivity and SSc clinical characteristics, autoantibodies and mortality.

Methods: The cohort comprised patients who fulfilled 2013 ACR/EULAR criteria for SSc, enrolled in a multicentre prospective cohort study across 13 centres. ANCA positive (ANCA+) was defined as the presence of at least one of p-ANCA, c-ANCA, atypical ANCA, MPO or PR3. Univariable and multivariable associations of ANCA were determined using Chi-square and logistic regression. The effect of ANCA status on mortality was studied using Kaplan Meier survival analysis.

Results: Of 1303 patients who fulfilled inclusion criteria, 116 (8.9%) were ANCA+. Median follow-up was 3.5 years (IQR 2.7). Mean \pm SD age at recruitment was 57.7 \pm 12.5 years and 25.2% had diffuse SSc. Of the ANCA+ group, 2 (1.7%) had AAV, 13 (11.2%) were MPO+ and 18 (15.5%) were PR3+. Gender and disease subtype did not significantly differ between the ANCA+ and ANCA- groups. The ANCA+ group had a higher prevalence of Asian patients (12.9% vs 3.7%, p=0.001), interstitial lung disease (ILD) (44.8% vs 21.8%, p<0.001), malignancy (26.7% vs 18.6%, p=0.04), synovitis (54.3% vs 38.2%, p=0.001), overlap syndrome with Sjogren's (4.3% vs 1.6%, p=0.04), and overlap features with another connective tissue disease (12.1% vs 5.2%, p=0.003). Pulmonary embolism (PE) was more common among ANCA+ patients (8.6% vs

3.0%, $p=0.002$) even after adjusting for antiphospholipid antibodies. ANCA+ patients had a higher prevalence of anti-Scl70 (25.0% vs 12.8%, $p<0.001$) and anti-Ro (11.2% vs 6.2%, $p=0.04$). ILD remained significantly associated with ANCA in multivariable analysis adjusting for anti-Scl70 (OR 2.6, 95% CI 1.7-4.0, $p<0.001$). Use of azathioprine (13.8% vs 7.5%, $p=0.017$) and calcium channel antagonists (75% vs 64%, $p=0.018$) was more common in the ANCA+ group. The PR3+ group was more likely than PR3- to have anti-Scl70 (44.4% vs 13.4%, $p<0.001$), ILD (50% vs 23.4%, $p=0.009$), PE (16.7% vs 3.3%, $p=0.022$) and to use mycophenolate (22.2% vs 7.6%, $p=0.046$). The MPO+ group was more likely than MPO- to have anti-Scl70 (38.5% vs 13.6% $p=0.006$), overlap syndrome with rheumatoid arthritis (15.4% vs 1.9%, $p=0.028$) and to use cyclophosphamide (30.8% vs 8.8%, $p=0.023$). ANCA+ patients had higher mortality than ANCA- patients ($p=0.006$).

Conclusion: In SSc, ANCA identifies a high risk group, with greater prevalence of ILD and PE, and poorer overall survival. ANCA+ SSc patients require close monitoring for complications.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Background/Purpose: Involvement of the skin and musculoskeletal system is associated with impaired quality of life in patients with systemic sclerosis (SSc). Data on efficacy of non-pharmacological care in SSc is limited due to the heterogeneity in studied interventions/outcomes. The aim of our study was to minimize the limitations of available studies and to determine the effect of intensive physical-occupational therapy on hand/face function and on the quality of life in cohorts with a substantial number of SSc patients.

Methods: All patients were non-selectively consecutively recruited into an intervention (IG) and control (CG) group. They fulfilled the ACR/EULAR 2013 criteria for SSc, and had skin involvement of the hands and face. Patients from both groups received educational material for home exercises, but only the IG underwent a six-month intervention with a subsequent six-month follow-up period. All patients were evaluated by a physician and physiotherapist blinded to intervention at 0, 3, 6 and 12 months. Patients also filled out patient reported outcomes/questionnaires and provided blood for routine laboratory analysis and biobanking. Data analysis was performed between groups and within the group.

Results: In total 25 patients were included in the IG and 30 into the CG. Compared to the observed statistically significant deterioration in CG, we found a statistically significant improvement in IG in objectively assessed function and strength of hand, distance between incisors and lips and also subjectively assessed functional ability (SHAQ). During the follow-up period there was a significant deterioration or stagnation of the achieved results in the IG. Only numerical improvements in IG compared to numerical deterioration in CG, but not statistically significant, were observed, during the intervention period, in subjectively evaluated parameters (hand/face function (CHFS/MHISS), functional ability (HAQ), and some domains of (SF-36).

Conclusion: Our program led to a significant improvement in the observed parameters that were clinically relevant in a substantial proportion of patients with SSc (in the IG) and prevented the natural course of progressive deterioration in hand/face function (observed in the CG).

Acknowledgments: The project was supported by AZV-16-33574A, MHCR 023728 and SVV for FTVS UK 2019-260466.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ischemic complications such as digital ulcers (DU) are a common complication in systemic sclerosis (SSc) patients. The aim of this study was to combine clinical characteristics and imaging methods to a composite predictive score.

Methods: Seventy-nine SSc patients received clinical examination and their patient history was taken. Furthermore, we performed nailfold capillaroscopy (NC), colour Doppler ultrasonography (CDUS) and fluorescence optical imaging (FOI) of the hands at baseline. Newly developed digital ulcers over a period of approximately 12 months were registered. We used criteria with significant ($p < 0.5$) OR values above 3.5 in regard to the development of these new DU to create the score (CIP-DUS, clinical features, imaging, patient history – digital ulcer score).

Results: Twenty-nine percent of the patients developed new DU during follow-up (48.1% diffuse SSc, 18.4% limited SSc). The following criteria were used: SSc diffuse subtype (OR 4.127, $p = 0.0087$), modified Rodnan skin score > 8 (OR 9.429 [95% CI: 3.0-29.2], $p < 0.0001$), pulmonary arterial hypertension (OR 6.854 [95% CI: 1.6-9.7], $p = 0.0088$), present digital ulcers or pitting scars at baseline (OR 15.71 [95% CI: 3.3-74.3], $p < 0.0001$), history of digital ulcer or pitting scars (OR 36.15 [95% CI: 2.1-626.9], $p < 0.0001$), NC pattern (OR 18.6 [95% CI: 1.1-326.4], $p = 0.0035$), reduced capillary density ($< 7/\text{mm}$) in digit III of the right hand in NC (OR 9.0 [95% CI: 1.1-73.6], $p = 0.0266$), missing initial enhancement in FOI in digit III of the right hand (OR 3.857 [95% CI: 1.2-12.8], $p = 0.0323$), percentage of pathologic (i.e. narrowed or occluded) vessels $> 35\%$ in CDUS (OR 4.286 [95% CI: 1.5-12.4], $p = 0.0099$). Criteria with greater OR should impact the score to a higher degree so we appointed three points to dichotomous criteria with OR > 10 , two points for criteria with OR between 5-10, and one point for criteria with OR < 5 . Regarding the NC pattern, 3 points were given to patients with late pattern, 2 points for active and 1 point for early pattern. Best results were found for a cut-off of > 10 points with obtained sensitivity levels of 95% and specificity levels of 74% in regard to new DU (AUC = 0.8687, $p < 0.0001$). In the absence of CDUS and FOI data, specificity levels dropped slightly to 72% with unchanged sensitivity values of 95%.

Conclusion: A new score was introduced with the aim to predict digital ulcers. If applied correctly and with the new imaging techniques proposed, 95% of patients at risk of digital ulcers throughout 12 months could be identified.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although overall survival of patients with systemic necrotizing vasculitides (SNVs) has improved markedly over the last 20 years, infectious complications remain a major cause of morbidity and mortality. This study aimed to identify factors predicting severe infections in SNV patients and assess the impact of the different therapeutic regimens.

Methods: Data were pooled from 5 randomized-controlled trials conducted by the FVSG—CHUSPAN1, CHUSPAN2, WEGENT, CORTAGE, MAINRITSAN—that enrolled 733 patients between 1993 and 2012. Those trials evaluated therapeutic strategies to treat polyarteritis nodosa (PAN), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and/or eosinophilic granulomatosis with polyangiitis (EGPA). The primary endpoint of this study was the occurrence of severe infection, defined as a severe adverse event, requiring hospitalization, intravenous antibiotics and/or resulting in death. Univariate and multivariate analyses were computed to identify associations between baseline characteristics and 2- and 5-year severe infection rates.

Results: SNV diagnoses were: 238 (32.5%) MPA, 224 (30.6%) GPA, 186 (25.4%) EGPA and 85 (11.6%) PAN. Baseline characteristics were: mean \pm SD age 58 ± 12 years, 55% men, 61% with pulmonary involvement, 55% with nervous system involvement, Five Factor Score = 0 for 59%, glomerular filtration rate <60 ml/min in 35%. Induction therapies were glucocorticoids alone (15%), glucocorticoids & azathioprine (16%) or glucocorticoids & cyclophosphamide (69%). Maintenance regimens were azathioprine for 28% of the patients, methotrexate for 9%, rituximab for 8% or none for 55%. After median follow-up of 5.2 (IQR 3–9.7) years, 148 (20.2%) patients experienced ≥ 1 severe infection(s). Median inclusion-to-severe-infection interval was 14.9 (4.3–51.7) months. Among all severe infections 48% were bronchopulmonary and 57% were bacterial. Patients with ≥ 1 severe infection(s) had a higher risk of death (22% vs 8%; $P<0.001$). At 2 years, patients with ≥ 1 severe infection(s) were older, had more frequent pulmonary involvement, nervous system involvement and FFS >0 , and were more likely to have received cyclophosphamide for induction. Multivariate analyses retained pulmonary [OR 2.11 (1.18–3.77); $P=0.01$] and nervous system involvements [OR 1.82 (1.01–3.30), $P=0.048$] as independent predictors of severe infection. At 5-years, baseline characteristics were the same for patients with ≥ 1 severe infection(s) but they had more likely received rituximab for maintenance therapy. Multivariate analyses retained pulmonary involvement [OR 1.71 (1.10–2.65); $P=0.02$] and age [OR 1.19 (1.02–1.38) per 10 years, $P=0.02$] as independent predictors of severe infection.

Conclusion: Severe infections, frequent adverse events in SNV patients, mostly occurred >1 year post-inclusion, and substantially impacted mortality. Age and pulmonary involvement were independent predictors of severe infection. Patients who had taken cyclophosphamide or rituximab had more severe infections than other regimens.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2017, the multicenter European Vasculitis Study Group (EUVAS) evaluated the diagnostic accuracy of a wide spectrum of detection tests of MPO and PR3-ANCA (*Ann Rheum Dis* 2017;76:647). The study reported a high diagnostic performance of PR3-ANCA and MPO-ANCA by antigen-specific immunoassay to discriminate ANCA-associated vasculitis (AAV) from disease controls. They concluded that dual indirect immunofluorescence (IIF) / antigen-specific immunoassay testing of each sample is not necessary for maximal diagnostic accuracy and proposed that the current international consensus on ANCA testing for AAV needs revision. However, the AAV patients of the EUVAS study were predominantly PR3-ANCA positive. The epidemiological manifestations of AAV differ geographically. We aimed to compare various ANCA detection methods in predominantly MPO ANCA-associated vasculitis cohort.

Methods: Stored sera (obtained at the time of diagnosis) from 162 patients with newly diagnosed and untreated AAV, including microscopic polyangiitis (MPA; $n = 115$), granulomatosis with polyangiitis (GPA; $n = 32$), and eosinophilic granulomatosis with polyangiitis (EGPA; $n = 7$), from 124 disease controls, and from 50 unmatched healthy controls were tested for the presence of perinuclear and cytoplasmic pattern ANCA (P-ANCA and C-ANCA, respectively) by standard IIF, and for the presence of MPO-ANCA and PR3-ANCA by 4 different antigen-specific immunoassays: an enzyme-linked immunosorbent assay (ELISA), a chemiluminescent enzyme immunoassay (CLEIA), a third-generation fluorescent enzyme immunoassay (FEIA), and a latex agglutination turbidimetry (LA). Patients with AAV were defined and classified according to the European Medicines Agency algorithm. Patients in whom inflammatory bowel disease and/or autoimmune liver disease was considered were excluded. Sensitivities and specificities for AAV diagnoses and concordance of each AAV tests were evaluated.

Results: P-ANCA and MPO-ANCA was detected in 82% and 61–82% of the AAV patients, respectively. C-ANCA and PR3-ANCA was detected in 8% and 6–11% of the AAV patients, respectively. When P and C-ANCA or MPO and PR3-ANCA were combined, the sensitivities and specificities for AAV diagnoses were 90% and 94% with the IIF, 82% and 98% with the ELISA, 89% and 95% with the CLIA, 88% and 97% with the FEIA, and 65% and 91% with the LA, respectively. K coefficients between P-ANCA and MPO-ANCA (by the ELISA, CLIA, FEIA, and LA) were 0.87, 0.96, 0.93, and 0.64, respectively. K coefficients between C-ANCA and PR3-ANCA (by the ELISA, CLIA, FEIA, and LA) were 0.54, 0.59, 0.58, and 0.48, respectively. Screening for ANCA with the CLIA and FEIA and confirming by IIF strategy increased the diagnostic accuracy only minimally (from 0.92 to 0.93 with CLIA/IIF and from 0.93 to 0.94 with FEIA/IIF).

Conclusion: The present study demonstrated a high diagnostic performance by antigen-specific immunoassays to discriminate AAV from controls in predominantly MPO-ANCA-associated vasculitis cohort. Consequently, increase in overall performance by dual IIF/antigen-specific immunoassay testing of each sample in such cohort is minimal.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluation of infection risk in ANCA-associated vasculitis (AAV) has been limited to small, selected populations and/or serious episodes. In this large study, we aimed to track the risk of all infections in AAV and compare it to the general population.

Methods: A longitudinal matched-cohort study was developed using Scottish administrative health-data registries. Uniquely, these resources provide over 97% population coverage and offer the capacity to link microbiological laboratory data from all levels of health care in Scotland. AAV patients fulfilling European Medicines Agency criteria were identified by clinicians across Scotland. Each was matched with up to 5 general population controls by age (± 2 years), sex and geography. Both cohorts were followed from the date of AAV diagnosis (same day assigned for matched controls) until death or 02/28/17, whichever came first. Data on all infections were retrieved from the Electronic Communication of Surveillance in Scotland Database. Descriptive statistics were used to compare infection types in both cohorts. Incidence rate ratios (IRR) and 95% confidence intervals (CI) were computed using multilevel Poisson regression.

Results: A total of 379 AAV patients (51.7% male; median age: 61.6 years) and 1859 general population controls were followed for a median of 3.5 years. During follow-up, AAV patients and controls developed 1127 and 1256 infections, respectively (55.7% of AAV, 15.8% of controls; IRR 6.7, 95% CI 5.2-8.6, $p < 0.0001$). Over 60 infection types were identified in AAV patients in whom *Escherichia coli* was the most commonly observed infection (15.8% vs 5.2%, $p < 0.001$). However, compared to the general population, AAV patients were at greatest risk of contracting Rhinovirus (IRR 9.5, 95% CI 3.5-25.8, $p < 0.0001$), Mycobacterium (IRR 9.5, 95% CI 2.5-34.1, $p < 0.0001$), Enterobacter (IRR 8.8, 95% CI 3.0-25.7, $p < 0.0001$), and Citrobacter (IRR 6.4, 95% CI 2.0-20.4, $p < 0.0001$), respectively. Interestingly, the highest rates of infections in AAV were observed during the first two years of AAV diagnosis ($p < 0.0001$, Figure 1). Although this risk decreased over time, AAV patients continued to be at a higher risk of infection than controls.

Conclusion: To our knowledge, this is the first and the most comprehensive study to analyse both the risk and type of infections using laboratory records and to track infection risk over time in AAV. Our findings indicate that AAV patients face a high risk of infections, especially in the first two years after AAV diagnosis. This risk reduces with time, but remains significantly greater than that in the general population even after eight years of follow-up.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is a systemic vasculitis with multi-organ involvement which can lead to frequent hospitalizations. Our study is to investigate characteristics and predictors of 30-day hospital readmission in GPA

Methods: We used data from the National Readmission Database (NRD) for the year 2014. Diagnoses were identified by ICD-9 diagnosis code. Non-elective hospital admissions from January to November with a diagnosis of GPA (ICD-9 code 446.4) were included. Readmission was defined as hospital admissions within 30 days of discharge of a prior hospitalization. We studied characteristics of readmissions and non-readmissions. Mixed-effects multivariable logistic regression controlling for clustering of hospitals was performed to investigate the independent predictors for readmissions. To represent the national hospitalization data, analyses were accounted for the complex survey design and stratification of the data per NRD database sets.

Results: A total of 9,119 hospital admissions with a diagnosis of GPA were identified in the year 2014. There were 2,173 readmissions within 30 days (23.8%). The top five primary diagnoses for readmissions were GPA (10.2%), sepsis (8.3%), pneumonia (5.8%), acute respiratory failure (2.6%) and acute kidney injury (AKI, 2.5%). Compared with non-readmissions, GPA readmissions were less likely to have private insurance (19% vs 26%, $p < 0.001$), more likely to have acute in-hospital events including acute respiratory failure (20% vs 18%, $p = 0.021$), sepsis (17% vs 15%, $p = 0.009$) and acute decompensated heart failure (10% vs 6%, $p < 0.001$), more likely to have chronic comorbidities including congestive heart failure (28% vs 20%, $p < 0.001$) and chronic kidney disease (62% vs 48%, $p < 0.001$), more likely to have higher hospital length of stay (8.0 vs 7.2 days, $p = 0.019$) and less likely to discharge home (50% vs 61%, $p < 0.001$) (Table 1). For GPA admissions, those who were readmitted within 30 days after discharge were more likely to be younger (OR = 0.99, $p < 0.001$), with higher Charlson Comorbidity Index (OR = 1.12, $p = 0.044$), have congestive heart failure (OR = 1.75, $p = 0.001$), develop AKI in the hospital (OR = 1.39, $p = 0.006$) and discharge to home health care (OR = 1.29, $p = 0.041$), and less likely to have private insurance (OR = 0.50, $p < 0.001$) (Table 2).

Conclusion: There is a major burden of 30-day readmission among GPA patients. Predictors of readmissions include younger age, public insurance status, higher Charlson Comorbidity Index, heart and kidney complications and unfavorable discharge dispositions.

Venous Thromboembolism in ANCA Associated Vasculitis. a Population-Based Cohort Study from Southern Sweden

Matina Liapi¹, David Jayne², Marten Segelmark³ and Aladdin Mohammad⁴, ¹Medicine, Blekinge Hospital, Karlskrona, Sweden, ²Department of Medicine, University of Cambridge, Cambridge, United Kingdom, ³Clinical Sciences, Nephrology, Lund University, Lund, Sweden, ⁴Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To estimate the rate and predictors of venous thromboembolic events (VTEs) in a population-based cohort of patients with ANCA- associated vasculitis (AAV).

Methods: 322 patients (47% women) diagnosed with AAV between 1997 and 2016 from a well-defined population in southern Sweden, were included in this study. The diagnosis of AAV and VTEs were ascertained by review of medical records. Radiological investigations, clinical notes, laboratory results and prescriptions of anticoagulation therapies were reviewed to identify patients with VTEs. Demographics, clinical and laboratory data were collected from time of AAV diagnosis until death or end of follow-up, September 2017. Birmingham Vasculitis Activity Score (BVAS) was used to assess AAV disease activity. Organ damage was assessed by vasculitis damage index (VDI). VTEs occurred within 3 months prior to AAV diagnosis and any time after that were considered as AAV-related VTEs.

Results: 55 patients (17%) developed a total of 63 VTEs of which 31 cases were deep vein thrombosis, 21 pulmonary embolisms and 11 other VTEs (5 retinal vein thrombosis, 1 sinus thrombosis, 1 subclavian vein thrombosis, 2 cases of jugular vein thrombosis, 1 right ventricle thrombosis, 1 olecranon bursa vein thrombosis). Of all patients with VTEs, 45 (82%) developed AAV-related VTE resulting in an incidence rate of 2.4/100 person-years (95% CI 1.7-3.1) during 1906 person-year of follow-up. The incidence rate of AAV-related VTEs during first year from diagnosis of AAV was estimated to 10.9/100 person-year (95% CI 6.8-14.9), decreased to 6.2 at 2-years ($p=0.07$), 3.9 at 5-years ($p<0.001$) and 2.8 at 10 years from diagnosis of AAV ($p<0.001$). The incidence rate of VTEs /100 person-year in patients with positive MPO-ANCA was 3.3 (95% CI 2-4.7) vs. 2.1 (95% CI 1.2-3.0) in patients with PR3-ANCA, $p=0.1$. Patients who developed any VTE were older at diagnosis and had higher BVAS score, were more likely to be MPO-ANCA positive and had higher VDI at 12 months after diagnosis of AAV (Table 1).

Conclusion: Higher age at diagnosis of the vasculitis, MPO positivity and high disease activity were associated with VTEs. The incidence rate of AAV-related VTEs was higher early at disease onset compared to the whole period of follow-up.

Table 1. VTEs in 322 patients with ANCA Associated Vasculitis

	All patients (n=322)	VTEs (n=55)	No VTEs (n=267)	P-value

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the incidence rates, predictors and outcome of severe infections in ANCA associated vasculitis (AAV).

Methods: We conducted a population-based cohort study in Southern Sweden with 326 incident cases of AAV diagnosed between 1997 and 2016. Clinical diagnosis of vasculitis was confirmed by case record review and patients were classified according to the European Medicine Agency algorithm. Demographics, clinical, laboratory and treatment data was collected from time of diagnosis and follow-up. All events of severe infection (required hospitalization or treated by intravenous antibiotics) were identified. Vasculitis disease activity was evaluated using the Birmingham Vasculitis Activity Score (BVAS) and the extent of organ damage was assessed using the vasculitis damage index (VDI). Estimated glomerular filtration rate (eGFR) was calculated using the MDRD formula. Patients were followed from time of diagnosis of AAV to death or end of study, December 2017

Results: Data on 221 patients (96 women) was collated and are presented in this report. In total 89 (40%) patients experienced at least one severe infection during the follow-up, 25 (11%) suffered two infections and 10 (5%) suffered 3 severe infections or more. Table 1 summarizes demographics, clinical and laboratory data in this study. Compared to those who did not suffer severe infection, patients with severe infection were older at diagnosis, had higher serum creatinine, lower eGFR, were more likely to have MPO-ANCA positivity, had higher BVAS at disease onset and higher VDI after 12 months (Table 1). Age and BVAS at diagnosis were the only factors that independently predicted severe infection. The incidence rate of severe infection was higher during the first year after diagnosis compared to that during the whole follow-up time (38.6/100 year vs. 10.4/100, $p<0.001$). An association between steroid exposure and serious infection could not be demonstrated. Severe infection was associated with worse prognosis in terms of renal and patient's survival (Table 1)

Conclusion: In this cohort the incidence rate of severe infection is comparable to earlier published data in AAV. Severe infection in ANCA associated vasculitis is still a major clinical problem and is associated with high age, increased disease activity at diagnosis, renal disease and MPO-ANCA positivity. The rate of severe infection is higher early in the disease course. Severe infection is associated with a worse prognosis.

Table 1. Severe infections in 221 patients with ANCA associated vasculitis

	All patients (n=221)	Severe infection (n=89)	No severe infection (n=132)	P-value
Age at diagnosis, mean \pm SD, years.	64,5 \pm 17,1	70,2 \pm 14	60,8 \pm 18	<0.001

Patient Experience in ANCA-Associated Vasculitis Evolves over Time from Diagnosis and Both Benefits and Adverse Impacts Are Felt with Current Therapy

Peter Rutherford¹, Dieter Goette¹, James O`Donoghue² and Xierong Liu², ¹Medical Affairs, Vifor Pharma, Zurich, Switzerland, ²Elma Research, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) leads to both acute illness and a long-term condition in which the disease remits and relapses. Therapy is often complex and associated with toxicity in its own right. Relatively little is known about the patient experience in AAV and how that evolves over time, but it is important when considering new therapeutic options. This study aimed to examine patient experiences and views around AAV and its treatment.

Methods: Qualitative research was performed using one-on-one interviews with 33 AAV patients (11 male) from 4 European countries. 20 patients had granulomatosis with polyangiitis, 12 had microscopic polyangiitis, and 1 had eosinophilic granulomatosis with polyangiitis. AAV duration (median 3.5 years, range 1-32) and patient age (3 under 40 years old, 25 aged 40-80 years, and 5 over 70 years) allowed rich insight into the patient journey from diagnosis through follow up.

Results: Thematic analysis of the interview transcripts by a single experienced researcher was performed to examine issues along the patient journey from diagnosis to treatment. Key findings were: (1) Suboptimal referral – patients report a long journey to diagnosis leading to long lasting psychological damage, worsened with treatment burden following diagnosis. (2) Recognition - patient experience is worse with sudden onset or misdiagnosis. Patients express concern over low empathy and understanding of their needs by professionals. (3) Knowledge gaps – patients want to understand their future, duration of therapy, and when they can expect to return to normality. (4) Measuring response –patients have a low awareness of how their response is assessed clinically and categories of response or scales used by clinicians. Patients refer to “feeling better” and going home as being important to them. (5) Decision making – they had a low involvement in treatment decisions particularly over glucocorticoids (GCs) and immunosuppression. (6) Unmet needs – while they are grateful for the efficiency of GCs, they feel major side effects which impair their quality of life, satisfaction and functional status with evolving symptomatic problems over their journey as GC dose changes. These findings were consistent across the 4 countries with only minor differences driven by variations in healthcare system and organization.

Conclusion: Patient experience in AAV is challenging both before and after diagnosis, and once treatment begins with evolution over time. Physicians need to consider AAV patients’ needs at diagnosis, when assessing response to treatment,

and when changing treatment. GCs are a particular problem for patients and there is a need for new therapies which reduce the significant treatment burden.

Variable Response to Induction Therapy and Significant Burden of Treatment Adverse Events over the First 12 Months in Incident ANCA-Associated Vasculitis (AAV) Patients – a Study of Routine Clinical Practice in the EU

Peter Rutherford¹, Dieter Goette¹, Melinda Stamm² and Xierong Liu², ¹Medical Affairs, Vifor Pharma, Zurich, Switzerland, ²Elma Research, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Aims of therapy in incident AAV patients include ensuring rapid diagnosis, assessment of comorbidity, disease activity, and vasculitis damage before commencing treatment with a combination of high dose glucocorticoids (GC) with rituximab (RTX) or cyclophosphamide (CYC). It is believed to be important to achieve control of the vasculitis as soon as possible but also to avoid acute treatment-related morbidity as well as prevention of long term GC damage. This study aimed to examine clinical outcomes and adverse events in incident AAV patients in routine clinical practice in the EU.

Methods: This was a retrospective clinical review of 929 incident AAV (granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA)) patients from 4 European countries (399 physicians) who were diagnosed between 2014-17. Clinical data were reviewed at baseline, and at 1, 3, 6 and 12 months following commencement of induction therapy.

Results: 54% of patients had GPA, 46% MPA and mean age was 56.8 years (SD 14.2) with 53.7% male. Birmingham vasculitis activity score (BVAS) was used in only 12% of cases, but physicians reported 12% as mild/localized, 54% as moderate systemic and 34% as severe, life threatening. Comorbidities were common, with hypertension (44.9%), diabetes (18.1%), COPD/asthma (15.1%) and coronary arterial disease (10%) among the most frequently reported. Only 32.2% reported no comorbidities. Induction therapy varied with 59% receiving CYC, 24% RTX whilst 83% received GCs. As BVAS was not assessed in routine practice, clinical response was assessed as full (no vasculitis activity and GC taper on track), partial (reduction in vasculitis activity and major organ damage arrested) and no response (no improvement in vasculitis). Response rate varied and therapy-related adverse events were common.

	1 month	3 months	6 months	12 months
Full response %	18	43	61	59
At least one AE %	45	42	35	30
Infection %	27	28	23	20
Still receiving GC %	82	79	67	53

Full response at 1 month was associated with good 12-month outcomes (81% full response) whereas a partial response at 1 month (56%) was associated with less favourable outcomes (58% full response at 12 months). Over the first 12 months of therapy, 6% of patients relapsed and required additional Treatment.

Conclusion: Incident AAV patients frequently have comorbidity at diagnosis and vasculitis was rarely assessed using BVAS. Response to remission therapy was variable but early response is associated with a better response rate at 12 months. Therapy-related adverse events and infections are common, especially in the first 3 months. There is an unmet medical need for better response rates and reduction in toxicity of existing therapy.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Microscopic polyangiitis (MPA) is a systemic ANCA-associated small-vessel necrotizing vasculitis characterized by general symptoms, and visceral manifestations, including rapidly progressive glomerulonephritis and alveolar hemorrhage. The main characteristics and long-term outcomes of a nationwide patient cohort are described.

Methods: French Vasculitis Study Group's cohort patients with MPA, satisfying Chapel Hill criteria, were studied retrospectively. Their characteristics at diagnosis, 2009 Five Factor Score (FFS) and Birmingham Vasculitis Activity Score (BVAS) were collected. For the earliest recruits, ANCA tests were not available. MPA diagnoses were reassessed, taking follow-up into account. Patients' overall (OS) and relapse-free survival (RFS) were analyzed using log-rank tests and multivariable Cox proportional hazards models.

Results: Patients (n=382) were diagnosed between 1966 and 2017 (30 [8%] before 1990, 101 [26%] 1990–2000, 152 [40%] 2000–2010 and 99 [26%] after 2010), and followed-up for (mean \pm SD) 5.5 ± 4.6 yr. At diagnosis, mean \pm SD age was 61.1 ± 15.1 yr, with 182 (48%) >65 yr old. Main clinical manifestations included fever >38°C (45%); weight loss (57%); arthralgias (45%); myalgias (40%); purpura (19%); mononeuritis multiplex (33%). Creatinine levels rose >30% in 154 (40%) patients, with mean \pm SD creatininemia at 215 ± 223 μ mol/L, and creatininemia >150 μ mol/L for 158 (41%) patients. Alveolar hemorrhage occurred in 59 (16%; with massive hemorrhage and/or hemoglobin <9 g/dL in 17 (4.5%)) patients, cardiomyopathy in 22 (6%) and severe gastrointestinal signs (bleeding, perforation, pancreatitis) in 15 (4%). IF ANCA test results were available for 350 patients and ELISA for 345; 276 (80%) patients were anti-MPO-ANCA+ and 13 (3.7%) anti-PR3+. FFSs were 0 for 110 (29%) patients, 1 for 181 (47%), ≥ 2 for 91 (24%). Median BVAS was 17.3. Glucocorticoids alone were induction for 92 patients (24%); 280 also took an immunosuppressant, including rituximab for 43 (11%). After a mean \pm SD of 3.0 ± 2.9 yr, 133 (35%) patients had relapsed. Respective 5-year OS and RFS were 86.9% and 60.5%. Over the last 40 yr, OS increased from 63% before 1990 to 94% after 2010 (P for trend <0.001), but not RFS. FFS ≥ 1 and an increased BVAS were associated with death ($P < 0.0001$ and <0.0001, respectively). Multivariable analyses (hazard ratio; 95% confidence interval) retained age >65 yr (4.6; 2.7–7.8), the need for assisted ventilation (3.9; 1.3–11.5), creatininemia >150 μ mol/L (2.6; 1.6–4.2) and mononeuritis multiplex (1.9; 1.1–3.2) as independent risk factors for death; and cardiomyopathy (1.8; 1.0–3.0), severe gastrointestinal manifestations (2.1; 1.1–3.8) and mononeuritis multiplex (1.7; 1.3–2.3) as factors associated with poor relapse-free survival. Immunosuppressant use for induction therapy did not modify those results.

Conclusion: This retrospective study provides useful information on the characteristics and outcomes of a large cohort of MPA patients. OS improved over decades. However, data collection before ANCA discovery and evolution of therapeutic strategies may represent a study limitation.

Severe Infections in Systemic Necrotizing Vasculitis: Incidence and Risk Factors

Claudia Elizabeth Pena¹, Ana Carolina Costi², Lucila Garcia³, Mariana Pera⁴ and Mercedes Garcia¹, ¹Rheumatology, HIGA General San Martin La Plata, La Plata, Argentina, ²Rheumatology Section, HIGA General San Martin La Plata, La Plata, Argentina, ³HIGA General San Martin La Plata, La Plata, Argentina, ⁴HIGA General San Martin La Plata, La Plata, Argentina

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infections in patients with systemic necrotizing vasculitis represent one of the main causes of mortality. Risk factors of infection such as corticosteroid use, intensity of immunosuppressive therapy, age, presence of leucopenia, lymphopenia, associated organic involvement, and dialysis dependence have been identified. Objective: To determine the incidence of infection in patients diagnosed with: Polyangiitis with Granulomatosis (GPA), Eosinophilic Polyangiitis with Granulomatosis (EGPA), Microscopic Polyangiitis (PAM) and Panarteritis Nodosa (PAN), b) clinical characteristics and associated risks factors

Methods: Retrospective study. Data source: clinical records of patients diagnosed with ANCA associated vasculitis and PAN, evaluated in a center of rheumatology (2000-2016). Variables: Demographic data, clinical manifestations, laboratory data, infectious events serious (requiring hospitalization or prolonged antibiotic/antiviral treatment, recurrences of herpes zoster virus or opportunistic infections), sites of infection, isolated microorganisms, mortality related to the infectious event.

Results: 80 patients, 61.25% women. Mean age at diagnosis: 49.2 years (range 18-77). Types of vasculitis: 41.2% GPA, 18.7% EPGA, 26.25% PAM, 3.73% PAN not associated with HBV and 10% ANCA-associated vasculitis that did not met classification criteria. Systemic involvement (68%), pulmonary (59%), renal (58%) and otorhinolaryngology (43.6%) were the most frequent. 36 infectious events were recorded in 28 patients. Follow-up time: Median 22 m (IQR 6-64). Incidence of infection: 38.4%, with a median of 3 m (IQR 1-18 m) from diagnosis of vasculitis. Low respiratory infections (40.7%), sepsis (39.3%), and urinary tract infections (15%) were the most common. 25% of these patients presented a second infectious event, being low respiratory tract the most frequent site (47%). Two patients had a 3rd event (soft tissue infection, septic shock). Bacterial etiology was the most prevalent (45%), being the microorganisms most frequently isolated: *Klebsiella pneumoniae* (25%), *Acinetobacter* spp (19%), *E. coli* and polymicrobial (12.5% respectively). Overall mortality was 17.5% (14/80) and related infectious event: 50% (n=7). 71.4% of patients were in the induction phase of treatment. Immunosuppressants used prior to infectious event: cyclophosphamide (48.1%), azathioprine (11.1%), methotrexate (7.4%), mofetil mycophenolate (3.7%), none (22.2%). Corticosteroids ≥ 30 mg/d were observed in 35.7% patients, ranging from 7.5-30 mg/d (10.7%), and ≤ 7.5 mg/d in 35.7%. Presence of leukopenia (26%), lymphopenia (44%), hypoalbuminemia (24%), renal insufficiency (63%) and dialysis dependency (37%) were identified in patients with infectious events. Renal involvement (p 0.01) and dialysis dependence (p 0.001) were significantly associated with infection.

Conclusion: The incidence of infection was 38.4%. Lower airway infections, septicemia and urinary tract infections were the most commonly implicated sites. Most infections occurred in the induction phases of the disease. Dialysis dependence and presence of renal involvement were significantly associated with this complication.

Prevalence of Clinical and Subclinical Ophthalmologic Manifestations in Association with Systemic Symptoms, Disease Activity and Damage in Patients with Granulomatosis with Polyangiitis

Andrea Hinojosa-Azaola¹, Annette García-Castro² and Alejandra Juárez-Flores³, ¹Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ²Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ³Ophthalmology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ophthalmologic involvement in Granulomatosis with Polyangiitis (GPA) is present in 50-60% of the patients and can affect any part of the ocular globe and the orbit. We aimed to describe clinical and subclinical ophthalmologic manifestations, association with systemic symptoms, disease activity and damage in patients with GPA.

Methods: Cross-sectional study including patients with GPA diagnosis (ACR 1990 classification criteria and/or 2012 Chapel Hill Consensus definitions). All patients underwent rheumatologic and ophthalmologic evaluation. Information regarding demographics, comorbidities, clinical variables, ophthalmologic symptoms, serologic markers, radiographic studies, disease activity and damage was retrieved. Descriptive statistics, correlation and univariable logistic regression analyses, Student t, Mann-Whitney U, chi square and Fisher's exact tests were performed.

Results: Fifty patients were included, 60% female, age 56 years (24-82), disease duration 72.5 months (0-469). Nineteen patients (38%) had ophthalmic manifestations at GPA diagnosis; being scleritis/episcleritis the most frequent (18%), while 27 (54%) presented them during follow-up, with repeated scleritis/episcleritis and lacrimal gland involvement being the most frequent. Concomitant ophthalmic and sinus involvement was present in 12 (24%). Radiologic abnormalities were observed in 35 (76%), being sinusitis the most frequent (Table 1). BVAS/GPA was 1 (0-17) and VDI 5.5 (0-11), with ocular and ENT damage being present in 58% and 70%, respectively. Forty three patients (86%) presented at least one ophthalmologic symptom, being epiphora and blurred vision the most frequent (40%). At least one clinical abnormality was found in 31 (62%). Scleromalacia (27%) and conjunctival hyperemia (26%) were the most frequent findings (Table 2). Association between radiographic granulomas and clinical proptosis ($r=0.69$, $p=0.001$), and between extraconal fat herniation and episcleritis ($r=0.69$, $p=0.0001$) was found. Ophthalmic involvement at diagnosis was associated with concomitant ophthalmic and sinus involvement at follow-up (OR 4.72, 95% CI 1.17-19.01, $p=0.01$). Ophthalmic involvement at follow-up was associated with age at GPA diagnosis (OR 0.94, 95% CI 0.90-0.99, $p=0.03$), VDI (OR 1.29, 95% CI 1.03-1.61, $p=0.02$), and ENT damage (OR 5.27, 95% CI 1.37-20.13, $p=0.01$).

Conclusion: In GPA, clinical and subclinical ophthalmic involvement is frequent at diagnosis and follow-up, it is associated with concomitant sinus involvement and has impact on ocular and ENT damage.

Table 1.

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A draft classification criteria of GPA was proposed at ACR meeting in San Diego in 2017. The present criteria is a modification of ACR/EULAR provisional 2017 classification criteria for GPA presented at ACR Washington meeting in 2016. This has been a result of data driven DCVAS study. The purpose of the present study was to validate the recently proposed draft classification criteria of GPA in a real life cohort of ANCA associated vasculitis (AAV).

Methods: The draft GPA criteria was applied to patients diagnosed to have AAV according to European Medicines Agency (EMA) algorithm. The level of agreement between the draft GPA criteria and EMA algorithm was assessed using Cohen's kappa. The level of agreement between the ACR/EULAR provisional 2017 classification criteria for GPA and EMA algorithm was also assessed using Cohen's kappa. Sensitivity and specificity of the draft GPA criteria and the ACR/EULAR provisional 2017 classification criteria for GPA was calculated taking EMA algorithm as gold standard.

Results: 224 patients with mean age of 41.7 ± 15.0 years were included. Female: male ratio was 1.3:1. ANCA by IIF was done in all patients and was positive in 171 (cANCA -125, pANCA -46). PR3/MPO ELISA was available in 125 patients (PR3-93, MPO- 32). Using EMA algorithm EGPA was diagnosed in 6, GPA in 187 and MPA in 31. With ACR 1990 criteria, GPA was diagnosed in 137 patients while with draft GPA criteria 136 were classified as GPA. Draft GPA criteria had fair agreement with EMA (kappa-0.23, sensitivity-66% and specificity-70%) than ACR criteria (kappa 0.1, sensitivity -64% and specificity-45%). ACR/EULAR provisional 2017 classification criteria for GPA also had a fair agreement with EMA (kappa 0.26, sensitivity -69.5% and specificity-70.2%). Eleven of thirty one MPA patients were reclassified as GPA by draft GPA criteria. 5 patients who were classified as GPA by EMA and ACR/EULAR provisional 2017 classification criteria for GPA were excluded by the new criteria. All of them were MPO positive and had pulmonary nodules and paranasal sinus involvement.

Conclusion: Within the limits of a retrospective design, the study showed fair agreement of draft GPA criteria with EMA algorithm. The specificity of the new criteria compared to EMA algorithm is low, likely due to the stress given to PR3/cANCA positivity.

Table 1. Reclassification of various AAV patients (EMA and ACR 1990) by draft GPA criteria

ANCA associated vasculitis	No. of patients (n=224, %)	Reclassified as GPA by ACR/EULAR 2018 criteria
ACR 1990 GPA	137(61.1)	89
EMA GPA	187(83.4)	125
EMA MPA	31(13.8)	11
EMA EGPA	6(2.6)	0

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM **Increased Risk of Cerebrovascular Accident among Patients with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis: A Systematic Review and Meta-analysis of Cohort Studies**

Abstract

Background/Purpose: An increased risk of cardiovascular disease, including cerebrovascular accident (CVA), among patients with chronic inflammatory immune-mediated disorders is well-recognized, especially among patients with rheumatoid arthritis and systemic lupus erythematosus. Patients with anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) may be at an increased risk of CVA as well although the data are still inconclusive as most studies addressing this association were small in size. The current systematic review and meta-analysis was conducted with the aims to identify all relevant studies and summarize their results together.

Methods: Two investigators independently searched for published studies indexed in MEDLINE and EMBASE database from inception to April 2018 using the search strategy that included the terms for anti-neutrophil cytoplasmic antibody-associated vasculitis and cerebrovascular accident. Eligible studies were cohort studies (either retrospective or prospective) that compared the risk of incident CVA between patients with AAV and individuals without AAV. They must also report the relative risk or hazard ratio with 95% confidence intervals (CI) of this comparison. Point estimates and standard errors from each study were extracted and combined together using the random effect, generic inverse variance technique of DerSimonian and Laird. Evaluation for publication bias was conducted using funnel plot.

Results: Of 1,132 retrieved articles, a total of 5 studies fulfilled the inclusion criteria and were included in this meta-analysis. The risk of incident CVA among patients with AAV was significantly higher than individuals without AAV with the pooled risk ratio of 1.49 (95% CI, 1.06–2.10). The statistical heterogeneity was insignificant with an I^2 of 11%. The forest plot of this meta-analysis is shown as figure 1. The funnel plot (figure 2) of this study was relatively symmetric and did not suggest the presence of publication although the interpretation was limited by the relatively low number of included studies.

Conclusion:: A significantly increased risk of cerebrovascular accident among patients with anti-neutrophil cytoplasmic antibody-associated vasculitis was observed in this study.

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcopenia, characterized by progressive loss of both muscle mass and muscle strength, has been associated with poor outcomes in various diseases. Muscle weakness is a major public health concern because it predicts future all-cause mortality and is associated with falls, disability, cardiovascular mortality and morbidity. However, its impact on systemic necrotizing vasculitides (SNVs) had never been characterized. We aimed to assess the frequency, associated factors and prognostic impact of sarcopenia in SNVs.

Methods: Patients with ANCA-associated vasculitides (AAVs) or polyarteritis nodosa (PAN) seen in our department were successively included in a longitudinal study assessing musculoskeletal parameters, cardiovascular complications and other sequelae (OSTEOVAS cohort). At inclusion, dual x-ray absorptiometry assessment skeletal muscle mass index (SMI) was obtained, and muscle strength was evaluated by handgrip strength measured with a handheld dynamometer. Handgrip strength is a simple method to assess muscle function in routine practice. Patients were prospectively followed and outcomes were recorded. Cumulative relapse, bone fracture, cardiovascular event, adverse event and mortality rates were analyzed.

Results: One hundred and twenty SNV patients were included (54 men, mean±SD age 53 ± 18 years, median SNV duration 54 months). Median follow-up was 42 months. At inclusion, 28 (23%) patients had low handgrip strength (<30 kg for men and <20 kg for women), but none exhibited low skeletal muscle mass index (<7.23 kg/m² for men and <5.67 kg/m² for women). At that time, low handgrip strength was significantly associated with: age ($P<0.0001$), type of vasculitis ($P=0.011$), Vasculitis Damage Index ($P=0.01$), prior falls ($P=0.0002$), osteoporosis ($P=0.036$), low serum albumin ($P=0.003$) and prealbumin ($P=0.0007$), high C-reactive protein ($P=0.001$), and low femoral neck bone-mineral density ($P=0.0002$), as were high Framingham risk score ($P=0.008$) and high fracture risk ($P=0.002$). During follow-up, 12 (10%) patients suffered bone fractures and 31 (26%) had vasculitis treatment-related severe adverse events. Low handgrip strength was associated (hazard ratio [95% CI]) with higher cumulative incident bone fracture rate (4.25 [1.37–13.2]; $P=0.012$) and severe adverse events (2.80 [1.35–5.81]); $P=0.006$) but not relapses or cardiovascular events.

Conclusion: Handgrip strength assessed in patients with AAVs and PAN was associated with nutritional status and comorbidities, eg bone disease, and predicted the risk of bone fracture and serious adverse events during follow-up. In contrast, the utility of skeletal muscle mass index assessment in this population remains uncertain.

Clinical Characteristics and Outcomes of ANCA-Vasculitides Associated Renal Disease in a Multi-Ethnic Population from a County Hospital

Shilpa Arora¹, Ambrish Athavale² and Peter Hart², ¹Medicine, John H Jr Stroger Hospital of Cook County, Chicago, IL, ²John H Jr Stroger Hospital of Cook County, Chicago, IL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides include granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and renal-limited vasculitis (RLV). We aimed to study the clinical features and renal outcomes of ANCA vasculitides patients in a county hospital.

Methods: 37 consecutive patients with biopsy proven glomerulonephritis related to ANCA vasculitides were included to participate in the study. IRB approval was taken. Patients with minimum follow up of 6 months were considered to be eligible. Data was collected through retrospective medical chart reviews including on demographics, ANCA type and titers, other organ involvement, kidney biopsy findings, treatment received, baseline and follow up at creatinine at 6 months, and outcomes with respect to renal function, and death. Chi-square and t-tests were done to study correlates of crescentic glomerulonephritis, progression to ESRD and mortality.

Results: Mean (SD) age was 54 years (14) with 21 female and 16 male patients. Almost half of the patients (17/37; 46%) were of Hispanic origin (Table 1). Clinical diagnosis was MPA in 16/37 (43%) patients while 10/37 (27%) had GPA, and rest 11/37 (30%) had RLV. Serology was positive for pANCA in 22/37 (59.5%) patients and rest were cANCA positive (12/37; 32.4%). 36/37 (97.3%) patients had hematuria on their urinalysis with 12/37 (32%) having nephrotic range proteinuria (>3.5 g). 27/37 (73%) patients had crescents on kidney biopsy. Pulmonary involvement was seen in over 50% patients (19/37) with diffuse alveolar hemorrhage in 8/37 (21%). Most patients were treated with cyclophosphamide (35/37; 94.6%) with only 8/37 (21%) and 6/37 (16%) being treated with plasmapheresis and rituximab, respectively. Mean (95% CI) baseline and 6 month follow up creatinine were 4.93 (3.65 – 6.22) and 2.82 (1.95 – 3.69), respectively. Median (IQR) follow up was 22 (12-53) months. 10 out of 37 patients (27%) progressed to ESRD and needed dialysis. Mean time (SD) to progression to ESRD was 9.05 (5.08) months. Gender, ethnicity, ANCA type and titers did not predict crescentic glomerulonephritis on kidney biopsy. Crescentic glomerulonephritis did not predict progression to ESRD but correlated with mortality (P value 0.002). Degree of fibrosis on renal biopsy also did not correlate with progression to ESRD but predicted mortality (P value 0.03).

Conclusion: Crescentic glomerulonephritis was more common in this multi-ethnic population. Crescentic glomerulonephritis and degree of fibrosis on kidney biopsy did not predict progression to ESRD but correlated with mortality.

Table 1: Clinical characteristics and outcomes of ANCA related vasculitides associated renal disease

Age	54.40 ± 14.22 (Mean ± SD)
Gender	
Female	21/37 (56.8%)

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Among many other organs and systems, ANCA-associated vasculitis (AAV) may also affect nervous system in up to more than half of patients, resulting in various central nervous system (CNS) disturbances and/or involvement of cranial or peripheral nerves. In the present study, we focused on pure peripheral neuropathy and aimed to compare the frequency of this problem between patients having microscopic polyangiitis (MPA) with those having granulomatosis with polyangiitis (GPA).

Methods: Medical charts of 48 patients with MPA and 58 patients with GPA, fulfilling relevant European Medicines Agency (EMA) classification algorithm, and being followed up by Ege University Hospital Rheumatology Department between 1997 and 2017 were retrospectively analyzed. Presence or absence of symptoms suggesting peripheral sensorial and/or motor neuropathy and electromyography (EMG) results were noted. Additional co-morbidities which may cause neuropathy such as diabetes mellitus were also noted. Patients with CNS problems and/or cranial nerve(s) involvement were

Table: Demographic and disease characteristics of patients with GPA and MPA

	GPA (n=58)	MPA (n=48)	P
Age at disease onset (years, mean ± SD)	46±12	63±10.8	0.001
Gender			
• Female (n, %)	73; 39.7	30; 62.5	0.019
• Male (n, %)	35; 60.3	18; 37.5	
Diabetes mellitus (n, %)	7; 12	18; 20.8	0.22
Mean follow up duration (months, mean ± SD)	61.5±48.9	42.5±39.6	0.045
Types of involvement			
• Renal involvement (n, %)	30; 65.5	36; 75	0.29
• Pulmonary involvement (n, %)	41; 71.7	38; 81.3	0.20
• Cutaneous findings (n, %)	15; 26.3	7; 14.6	0.14
• Musculoskeletal (n, %)	23; 39.7	21; 43.8	0.67
• Peripheral neuropathy (n, %)	7; 12.1	18; 37.5	0.002
ANCA positivity			
• c-ANCA (n, %)	45; 77.6	3; 6.3	<0.001
• p-ANCA (n, %)	9; 15.5	40; 96.8	<0.001

excluded. Descriptive analyses were given using mean \pm standard deviation (SD) for continuous variables and numbers (percentages) for categorical variables. Chi-square test was used to analyze differences between categorical data, while Mann-Whitney U tests were applied to test statistical differences between continuous data.

Results: Demographic features, mean follow up durations, types of clinical involvements, and ANCA status of the patients are given in Table. Patients with MPA were notable with being more frequently women and having older age of disease onset. Frequency of peripheral neuropathy in MPA (37.5%) was significantly higher than in GPA (12.1%). Peripheral neuropathy was in the form of axonal sensorimotor type in all patients, except for two cases with MPA having pure motor neuropathy. The frequency of diabetes in both groups was not statistically different. On the other hand, comparison of all patients with and without peripheral neuropathy showed that peripheral neuropathy group had older age of disease onset (60.88 ± 13.6 versus 51.7 ± 13.73 years, $p: 0.04$) and had more frequent musculoskeletal symptoms (39.7% versus 33.3%, $p: 0.02$).

Conclusion: Our data show that peripheral neuropathy is more frequent in patients with MPA compared to GPA. In literature, there are controversial reports about whether neuropathy is more frequent in GPA or in MPA. This may be due to genetic differences, as well as inclusion or exclusion of cases with central nervous system involvement and/or cranial neuropathy. Future studies with larger series will probably clarify this issue.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) is a systemic inflammatory disorder frequently associated with significant disability and morbidity, which may lead to end-stage renal disease (ESRD) or death. The purpose of our study was to examine disease characteristics and outcomes in an urban African-American (AA) cohort with AAV and compare them with a matched Caucasian (CA) cohort with AAV.

Methods: A detailed electronic chart review of patients with positive anti-neutrophil cytoplasmic antibody testing was performed to identify patients with AAV using the 2012 Revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides. Patients with isolated renal disease were included if they demonstrated biopsy evidence of necrotizing pauci-immune glomerulonephritis with P-ANCA/MPO or C-ANCA/PR-3 positivity at the time of diagnosis. African-American AAV patients were matched 1:2 to CA patients with AAV by gender and age within 5 years.

Results: 21 AA patients with AAV were identified, of which fourteen (66.7%) were female, with a mean age at diagnosis of 61 years. Microscopic polyangiitis occurred more commonly in AA patients than CA patients (38% vs. 14%), while granulomatosis with polyangiitis was more common in CA patients (76% vs. 47%). AA patients had more severe disease at the time of diagnosis, with increased need on admission for ICU care (50% vs. 23%, $p=0.04$), mechanical ventilation (40% vs. 10%, $p=0.007$), hemodialysis (52% vs. 19% $p=0.007$), with lower hemoglobin (mean 7.0 vs. 10.0, $p=0.001$), and higher serum creatinine (mean 6.1 vs. 2.7, $p=0.001$). Although the likelihood of receiving high dose pulse steroid therapy at diagnosis was not significantly different between groups, the mean dose of prednisone initiated at disease diagnosis in AA patients was significantly lower (143 mg vs. 455 mg, $p=0.004$), while the concomitant use of steroid-sparing immunosuppressive agents for induction therapy did not differ significantly between groups. There was a significant increase in the incidence of ESRD in AA patients when compared to CA patients (62% vs. 19%, $p=0.001$) without significant differences in the prevalence or severity of hypertension and diabetes at the time of diagnosis between groups. Death occurred in 33% of the AA patients and 21% of CA patients during follow up.

Conclusion: In an urban cohort, AA patients with AAV were more likely to present with severe disease requiring ICU care, mechanical ventilation, and hemodialysis compared to Caucasian patients with AAV. Despite similar rates and severity of diabetes and hypertension in these populations, African-American patients were significantly more likely to develop ESRD. There are many factors that could influence these outcomes, including other comorbid conditions, genetics, differences in treatment and response to immunosuppressive therapies, environmental factors, and limited access to care because of socioeconomic factors. Further study is needed to better understand factors that influence AAV severity and course in this population in order to improve long-term outcomes and survival.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Elderly patients with ANCA associated vasculitides (AAV) seem to have clinical differences compared to younger patients. The aim of this study is to compare clinical and laboratory characteristics, survival and mortality rates of patients with AAV with respect to age at diagnosis.

Methods: Medical records of patients with microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA) or eosinophilic granulomatosis with polyangiitis (EGPA), classified according to the European Medicine Agency classification algorithm and followed up by Ege University Hospital Rheumatology Department between 1997 and 2017 were retrospectively analyzed. Patients were divided into two groups based upon age at disease onset: <65 years (Group 1) and ≥65 years (Group 2). Gender, age at diagnosis, time to diagnosis, follow up time, involved organs/systems, pattern of ANCA positivity, type of AAV and number of deaths were noted. Chi-square test, two-way t test, Cox regression analysis and Kaplan-Meier method were used to compare the groups.

Results: In our cohort, 87 patients <65 years and 30 patients ≥65 years were enrolled. Demographic, clinical and laboratory characteristics of those patients are given in Table. There were no differences in gender and smoking status

Table. Demographic, clinical and laboratory characteristics of patients with AAV

	Group 1 AAV <65 years (n=87)	Group 2 AAV ≥65 years (n=30)	p value
Female, n (%)	46 (52.9)	13 (43.3)	0.36
Age at diagnosis onset, mean±SD	53.46±11.5	73.37±5.59	<0.001
Follow-up, months, mean±SD	64.6±49.1	22.9±23.6	<0.001

Type of AAV, n (%)			
MPA	24 (27.6)	24 (80)	<0.001
GPA	57 (65.5)	1 (3.3)	
EGPA	6 (6.9)	5 (16.7)	
ANCA positivity, n (%)			
p-ANCA	34 (39.5)	26 (86.7)	<0.001
c-ANCA	45 (52.3)	5 (16.7)	0.002
Initial involvement			
Constitutional	64 (73.6)	23 (76.7)	0.73
Renal	59 (67.8)	17 (56.7)	0.27
Pulmonary	62 (71.3)	25 (83.3)	0.19
Upper airway	33 (37.9)	1 (3.3)	<0.001
Skin	20 (23)	6 (20)	0.71
Neuropathy	17 (19.5)	14 (46.7)	0.004
Joint	33 (37.9)	17 (56.7)	0.04
Mortality, n (%)	6 (6.9)	7 (23.3)	0.01

between the groups, but the rates of malignancy, hypertension and hyperlipidemia were higher in Group 2. Upper airway involvement was more frequent in Group 1, peripheral neuropathy was more frequent in Group 2. These findings were probably due to more frequent occurrence of GPA in Group 1 and MPA in Group 2.

As expected, mortality rate was higher in Group 2 (Table). The mean survival time was 221 ± 7.47 months for Group 1, and 65 ± 8.14 months for Group 2. One-year, 2-years, 5-years and 10-years survival rates were 96%, 96%, 91%, and 91% in Group 1, respectively. On the other hand, one-year, 2-years and 5-years survival rates were 81%, 70% and 70% for group 2, respectively. Ten-years survival rates could not be calculated for Group 2. One death(1/6) in Group 1 and six deaths (6/7) in Group 2 were due to opportunistic infections.

Being diagnosed at the age of 65 years or over increased the mortality by 48.7 times compared to being diagnosed before the age of 65 years (%95 CI: 6.37-372.09, $p < 0.001$). We also found out that each increase of one year at the age of diagnosis resulted in an increment in the mortality 1.1 times (%95 CI: 1.03-1.18, $p: 0.003$). When age factor is removed, type of AAV, basal serum creatinine level and having GFR < 50 ml/min per 1.73 m^2 did not affect the mortality significantly.

Conclusion: In our study, the age at diagnosis was established to be the most significant factor on mortality of AAV. We found out that basal serum creatinine level and GFR did not affect the mortality critically, when adjusted by age. Because of the high mortality rate, more attention should be paid to the management of AAV patients diagnosed at advanced age.

Identifying ANCA-Associated Vasculitis Cases in Electronic Health Records Using Natural Language Processing

Zachary Wallace¹, John H. Stone² and Hyon K. Choi³, ¹Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ²Rheumatology (Medicine), Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Epidemiologic studies of ANCA-associated vasculitis (AAV) using large data sets are often limited by the lack of validated definitions of AAV cases that can be applied on a large scale. A prior study developed algorithms using billing codes, prescription records, and ANCA pattern (not antigen specificity) to classify patients into traditional clinical phenotypes (e.g., granulomatosis with polyangiitis, GPA) with PPV ranging from 81% to 100%. We sought to determine whether a user-friendly natural language processing (NLP) tool could improve the performance of AAV case-finding algorithms in an electronic health record (EHR) database.

Methods: Using EHR data on 2 million patients from a large, multi-center healthcare system that includes Massachusetts General Hospital (MGH) and Brigham and Women's Hospital (BWH), we evaluated the performance of algorithms that incorporated billing codes, ANCA antigen specificity test results, and/or NLP to identify patients with AAV. Unstructured data (e.g., pathology reports, clinical notes) were searched using NLP for key words and phrases suggestive of AAV. The NLP program eliminates reports where the search phrase is near a term that may negate a diagnosis of AAV (e.g., "the patient does not have ANCA-associated vasculitis"). To assess the performance (Positive Predictive Value, PPV) of each algorithm, a cohort of patients with and without AAV was identified from a population of 35,623 patients. We then evaluated the performance of each algorithm in randomly assembled cohorts of patients evaluated in rheumatology and nephrology clinics.

Results: The general AAV cohort used for primary validation was established from the entire population and included 207 patients, the majority of whom had AAV (N=161, 78%). This cohort included 25 patients (12.1%) with positive ANCA test results but without AAV. An algorithm solely using billing codes had a PPV of 79% (73%-84%), 18% (5%-40%), and 4% (0%-14%) for identifying cases of AAV in the entire EHR, a rheumatology clinic cohort, and nephrology clinic cohort, respectively (Table 1). An algorithm that required an NLP reference to AAV, a billing code associated with AAV, and a positive PR3- or MPO-ANCA test result led to a PPV of 95% (88%-98%), 100%, and 100%, respectively.

Conclusion: In our study, the use of NLP substantially improved the PPV of algorithms meant to identify cases of AAV. In the context of increasingly large data sources that include both structured (e.g., billing codes, test results) and unstructured data (e.g., clinical notes), NLP can improve the ability to accurately (PPV > 90%) classify patients with AAV. Furthermore, as ANCA type is increasingly viewed as a superior approach to differentiating AAV subtypes compared with clinical phenotypes (e.g., GPA), an algorithm such as ours that incorporate ANCA types can be useful for future epidemiologic studies in AAV using EHRs.

Table 1: Algorithm Performance in 207 Patients Selected based on ICD-9 Codes for ANCA-Associated Vasculitis

	Total Possible AAV Cases Identified by Algorithm in EHR	Positive Predictive Value (95% CI)
1. ICD-9 code	20,557	79% (73%-84%)
2. ICD-9 and ANCA-positive	1,951	88% (82%-92%)
3. NLP and ANCA-positive	898	92% (87%-98%)
4. NLP or ICD-9 and ANCA-positive	2,065	87% (80%-91%)
5. NLP and ICD-9 and ANCA-positive	775	95% (88%-98%)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis of ANCA-associated vasculitis (AAV) and the classification of granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) is based on clinical and histologic characteristics. The value of renal and non-renal biopsies for classification of AAV is of great interest for the diagnostic work-up. We aimed to evaluate specific histopathologic features of organ biopsies and their contribution to the diagnosis of vasculitis and to the classification of specific AAV subgroups according to ACR criteria and to the preliminary 2017 DCVAS criteria.

Methods: Retrospective, single-center cohort study in patients with GPA, EGPA and MPA, who have received at least one organ biopsy. Characteristic histopathologic features were analyzed. Diagnosis of vasculitis and classification to subgroups were analyzed with and without consideration of histologic features.

Results: 306 patients (GPA 154, MPA 58, EGPA 94, mean age at diagnosis 55.2±16.5 years, 48% males) diagnosed between 1990-2017, were included. 451 biopsies (168 renal biopsies, 283 non-renal biopsies) were taken at active stage of AAV at initial diagnosis (n=415) or during disease-flair (n=36). 222 patients (72.5%) were ANCA positive (150 cANCA+, 72 pANCA+). In kidney biopsies, glomerulonephritis was described in 78.6%, unspecific inflammation in 26.8% and normal tissue in 1.2%. In non-renal biopsies, vasculitis, granuloma, tissue eosinophilia, unspecific inflammation or normal tissue were reported in GPA 32.9 / 29.4 / 21.2 / 71.8 / 9.4%, MPA 27.3 / 9.1 / 27.3 / 90.9 / 9.1% and EGPA 20.2 / 10.1 / 67.4 / 73.0 / 20.2%; p<0.0001. According to the ANCA status, the distribution was 31.1 / 25.2 / 28.3 / 68.9 / 10.7% in ANCA+ patients and 20.8 / 11.1 / 62.5 / 79.2 / 19.4% in ANCA- patients (p<0.0001). Biopsy results were decisive for diagnosis of vasculitis in 2% of GPA, none of MPA and 8% of EGPA patients. Fulfillment of 1990 ACR criteria depended on inclusion of histology in 6.6% of GPA and 35.5% of EGPA. For the preliminary 2017 DCVAS criteria, histology was decisive in 2% of GPA, 0% of MPA and 21% of EGPA.

Conclusion: Histologic proof of vasculitis contributes to diagnosis of AAV. The diagnostic value is most prominent for renal biopsies. While classification to EGPA according ACR criteria depends on histology in almost one third of patients,

it is critical for GPA in only a few patients. The relevance of biopsy for the preliminary 2017 DCVAS criteria is clearly diminished, remaining most prominent for EGPA.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Overall survival has been markedly improved during the last decades in systemic vasculitis. In contrast, the use of immunosuppressive agents led to an increased risk of infectious complications, ranging from common to opportunistic infections (OI). While the former have been well described, data on the latter are scarce. This study aimed to describe characteristics of patients having OI during systemic vasculitis.

Methods: We conducted a retrospective, observational, multicenter study, including patients with medium and small-sized vessel vasculitis according to Chapel Hill definitions and presenting with OI. Clinico-biological findings and therapies were recorded at diagnosis and follow-up of vasculitis and diagnosis of OI.

Results: A total of 108 patients (men 51%, mean age at infection 59.3±15.4 years), experiencing 132 OI between 1985 and 2018, were included. Twenty-five (19%) patients had multiple OI. Vasculitis diagnoses were: ANCA-associated vasculitis (AAV) in 86 (80%) patients, i.e. granulomatosis with polyangiitis in 51, microscopic polyangiitis in 18 and eosinophilic granulomatosis with polyangiitis in 17, polyarteritis nodosa in 10 (9%), and immune complex vasculitis in 12 (11%). Comorbidities included chronic kidney failure with eGFR <60 ml/min/1.73m² in 33 (31%), chronic respiratory disease in 22 (20%) and diabetes in 14 (13%). Before OI, 30 (28%) patients experienced 31 common infections. Treatments received before OI were glucocorticoids in 106 (99%) patients, cyclophosphamide in 75 (73%) with a median cumulative dose of 7.2 g (IQR 3.6-18), rituximab in 31 (32%), and both drugs in 14 (13%). Median interval from diagnosis of vasculitis to OI was 11 (3-62) months.

Opportunistic infections were: invasive fungal infections in 75 (including pneumocystis in 40, invasive aspergillosis in 19, severe candidiasis in 12, cryptococcosis in 4, mucormycosis in 1), viral infections in 30 (including cytomegalovirus in 24), bacterial infections in 24 (including tuberculosis in 12, atypical mycobacteria in 5, nocardiosis in 7), and parasitic infections in 3. OI were disseminated in 24 (18%) cases, and organ-limited in 108 (82%), the latter involving the lungs in 87 (81%).

At diagnosis of OI, patients were under glucocorticoids in 75%, at a median dose of 20 mg/day (5-50). Lymphopenia <1000/mm³ was noted in 34%, with a median CD4 T cell count of 226/mm³(143-578), respectively, and hypogammaglobulinemia <6 g/L in 31%. Only 5 patients with pneumocystis infection had prophylaxis.

OI required hospitalization in intensive care unit in 24 (18%) and led to death in 19 (14%). Among all death (n=37), OI were the leading cause of death (51%).

Twelve OI (9%) were diagnosed concomitantly to a vasculitis flare, and OI led to a modification of immunosuppressive therapy in 42% of cases, mainly through a decrease of immunosuppression.

Conclusion: Opportunistic infections mainly occur during AAV, especially granulomatosis with polyangiitis receiving high doses of glucocorticoids. Pneumocystis was the most frequent infection, followed by cytomegalovirus infection and invasive aspergillus. Prognosis was severe, with high number of patients requiring ICU and/or dying.

Session Title: Vasculitis – ANCA-Associated Poster II

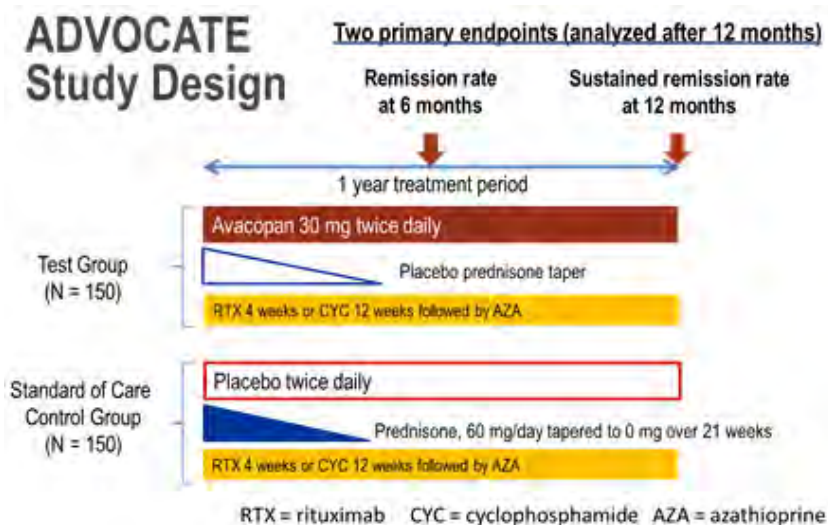

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM **A Randomized Phase 3 Trial Evaluating the Safety and Efficacy of Avacopan in Patients with New or Relapsing Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis**

Peter A. Merkel¹, David Jayne², Thomas J. Schall³, Pirow Bekker³, Jan Hillson³

1. University of Pennsylvania, Philadelphia PA, USA; 2. University of Cambridge, Cambridge UK; 3. ChemoCentryx Inc., Mountain View CA, USA

Background/Purpose: Anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) is a potentially life-threatening systemic autoimmune disease characterized by relapses and remissions. Treatment to induce remission usually includes high-dose glucocorticoids in combination with rituximab (RTX) or cyclophosphamide (CYC), followed by less intensive treatment to prevent relapse. The overall burden of disease remains high, with progressive organ system damage and morbidity attributable to therapy. High-dose glucocorticoids are associated with increased risk of infection, metabolic syndrome, bone loss, and an overall negative impact on health-related quality of life (HRQoL). There is a need for less toxic treatment alternatives for AAV. Avacopan (previously CCX168) is a novel, orally bioavailable, highly-selective

antagonist of the human C5a receptor that has demonstrated promising efficacy and a favorable safety profile when administered for 12 weeks in Phase 2 studies of patients with active AAV (NCT0136388 and NCT0222155).

Methods: The ongoing ADVOCATE trial (NCT02994927) is a double-blind, parallel-arm, active-comparator randomized trial comparing avacopan vs. high-dose glucocorticoids in patients (age ≥ 12 years) with AAV, when co-administered with either 1) RTX OR 2) CYC followed by azathioprine or mycophenolate mofetil, for up to 1 year (**Figure**). The choice of RTX vs CYC is based on investigator judgement. Patients are stratified by: i) intended use of RTX vs CYC, ii) ANCA type (PR3-ANCA vs MPO-ANCA), and iii) newly-diagnosed vs relapsing disease.

The primary trial endpoints are 1) the proportion of patients in remission at week 26 based on BVAS=0 (Birmingham Vasculitis Activity Score) and not taking glucocorticoids; and 2) the proportion of patients who sustain remission from week 26 through week 52. HRQoL will also be assessed in patients through 52 weeks which will add to the understanding of the patient experience in AAV. Other endpoints include adverse events, requirement for rescue medication, markers of renal disease, the Glucocorticoid Toxicity Index, and the Vasculitis Damage Index.

Results: Planned enrollment is ~300 patients from 230 sites in 20 countries, and is expected to be completed in mid-2018. Details of the study design, outcome measures, and baseline patient data will be presented.

Conclusion: The ADVOCATE trial is unique in seeking to advance a nearly glucocorticoid-free induction regimen for AAV and has the potential to have a substantial impact on the approach to treatment of this rare disease.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The glucocorticoid toxicity index (GTI) (Miloslavsky et al. Ann Rheum Dis 2017) is useful to assess impact on morbidity associated with these drugs. It consists of two components, a compound and a specific index. This last includes serious clinical adverse effects.

Our objective was to assess the incidence of the items included in the specific index of the GTI in patients with Giant Cell Arteritis (GCA), Granulomatosis with Polyangiitis (GPA) and Microscopic Polyangiitis (MPA).

Methods: Clinical records of incident cases of GCA, GPA, MPA were scanned for serious adverse effects associated with GC treatment defined in the specific index of GTI over the first two years of treatment. The GC cumulative dose was calculated at 6 months, 1 year, and 2 years of treatment.

Incidence density of serious adverse effects was compared in patients with GCA (all fulfilling ACR criteria) and ANCA associated vasculitis (GPA and MPA, all fulfilling Chapel Hill criteria). Logistic regression multivariate analysis was performed to evaluate the association between total cumulative GC dose and severe adverse effects, adjusted by confounders.

Results: 130 patients were included (92 ACG, 18 GPA, 20 MPA), 80% of whom were women, with a median age at diagnosis of 77 years (ICR 72-81).

Cumulative GC doses at 6 months, 1 and 2 years of treatment were significantly higher in ANCA vasculitis. 97,4 % (IC 95% 82,9-99,6) of patients with ANCA vasculitis used immunosuppressors associated with GC at treatment start vs 14,1% (IC 95 8,3-22,9) of patients with GCA ($p<0,001$). Immunosuppressors usage in patients with GCA did not conduct to a lower cumulative GC dose at 2 years of treatment. 15 patients with ANCA vasculitis (39,5%, IC 95%: 25,1-55,9) and 36 with GCA (39,1%, IC 95%29,6-49,6) presented some serious adverse effect included in the GTI ($p=0,97$).

The adverse effect incidence density was 22,2/100 patients-year for ANCA and 19,9/100 patients-year for GCA (p=0,73). Severe infections were more frequent in patients with ANCA vasculitis than in GCA [13,2% (IC 95%: 5,4-28,4) vs 2,2% (IC 95%: 0,5-8,4), p=0,01]. Mortality was 28,9 % (IC 95%: 16,6-45,5) for ANCA vasculitis vs 3,3% (IC 95%: 1-9,8) for GCA (p<0,001). Having a severe adverse effect or a serious infection was not associated with the GC cumulative dose, the initial GC dose, GC pulses, cyclophosphamide use, and diagnosis in the multivariate analysis. The greater cumulative GC dose was associated with having ANCA vasculitis diagnosis (p=0,019) and having received GC pulses (p<0,001) in the linear regression analysis.

Conclusion: Incidence of GC related adverse effects at 2 years of treatment was similar in ANCA associated vasculitis and GCA. Presenting a serious adverse effect was not associated with the total cumulative or initial GC dose, or having received GC pulses. Serious infection rate was greater in ANCA vasculitis with no relation to the GC dose.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a heterogeneous group of small-vessel vasculitides that typically affects the kidneys, respiratory tract, and other organ systems. The onset of AAV may occur at any age, although literature suggests that this is more common in older populations. We aim to characterize the clinical and laboratory

	Age < 18		18 < Age < 35		35 ≤ Age < 65		Age ≥ 65	
	MPO	PR3	MPO	PR3	MPO	PR3	MPO	PR3
Total Number	7	6	4	14	36	31	26	17
Female	6	4	3	6	20	14	18	7

Arthritis	3	0	0	1	1	3	1	0

manifestations of AAV based on age of onset in pediatric and adult patients younger than 35 years, compared to other age groups.

Methods: We performed a retrospective chart review of all patients with positive MPO or PR3 lab results by ELISA and a diagnosis of vasculitis from 2000 to 2017. Patients were classified into four groups according to age and divided into two groups each depending on MPO or PR3 serotypes. These features were compared to one another through descriptive statistics, as noted in the included table.

Results: 141 patients were identified based on the inclusion criteria, of which 31 were below the age of 35. The majority of patients were white females. Upper respiratory tract involvement and arthritis were much more common in the pediatric and adults younger than 35. PR3 was also more frequent in this group as well. Renal and lower respiratory involvement were comparable between the age groups.

Conclusion: Onset of AAV in young adulthood has distinct characteristics that more closely resemble pediatric AAV than compared to their older counterparts. Prior literature demonstrates a much higher percentage of extrarenal, extra-respiratory involvement in the pediatric population, which is consistent in our sample as well. Further analysis on clinical presentation, prognosis and treatment outcomes are forthcoming.

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Concentrations of many circulating proteins are elevated during severe, active ANCA-associated vasculitis (AAV). Finding biomarkers associated with milder disease, a more clinically relevant need, has proved challenging. In addition, some biomarkers may be directly affected by glucocorticoids.

Methods: 30 patients with AAV participating in a longitudinal cohort were studied. Serum samples from 2 visits were used for this study: i) a visit during active disease and when off prednisone; and ii) a visit approximately 3 months later when in clinical remission and on prednisone. A proteomic approach (SOMAscan, SomaLogic, Boulder, CO, USA) was used to assess more than 1000 circulating proteins simultaneously. Using Wilcoxon signed rank tests, a randomly selected sub-cohort of 15 patients was analyzed first, and markers significant at $p < 0.01$ were then analyzed in the remaining sub-cohort of 15 patients, with $p < 0.05$ regarded as validation. WebGestalt was used to test for enrichment in components of functional pathways.

Results: The cohort included 23 patients with GPA, 5 with EGPA, and 2 with MPA. Mean age was 52, and 18 were female. Thirteen were taking a non-steroid immunosuppressive drug at the time of flare, and 21 afterward. Disease activity was relatively low: physician global assessment of severity on a 0-10 scale had a mean of 3.2 (median 3, range 1-7), and only 7 patients had a “major” manifestation by BVAS/WG. Fourteen proteins were validated as associated with active disease (**Table 1**). Few of these markers have been previously identified in vasculitis, and only one (thrombospondin, TSP) in AAV. Four markers (CCL3/Mip-1a, CCL15/Mip-5, TNFRSF9/4-1BB, prolactin) are associated with the KEGG pathway Cytokine-cytokine receptor interaction.

Conclusion: In a cohort of patients with active but relatively mild AAV, 14 serum proteins were associated with significant change after successful treatment with prednisone. Thirteen of these markers have not been reported in AAV. These proteins, all of which are measurable by commercial immunoassays, are candidates for further study in real-world cohorts of partially-treated patients with AAV with mildly active disease.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vasculitic neuropathy (VN) is a major complication of systemic vasculitis and contributes to morbidity, functional limitation, and health care utilization in affected patients. Patient reported outcomes (PRO) in patients with VN is limited. Our aim was to compare long term PRO for neuropathic symptoms in patients with VN undergoing induction treatment with rituximab(RTX) or cyclophosphamide (CYC).

Methods: The medical record was screened by keywords for patient charts that included vasculitis and neuropathy. Diagnosis of granulomatosis with polyangiitis, microscopic polyangiitis, eosinophilic granulomatosis with polyangiitis, or isolated VN was confirmed per ACR classification criteria or 2012 Revised International Chapel Hill Consensus Nomenclature. VN diagnosis was confirmed independently by a neurologist reviewing clinical presentation, EMG findings,

CAP-PRI, chronic acquired polyneuropathy patient reported index, VAS, visual analog scale, ODSS, Overall Disability Sum Score, UL, upper extremity, LL, lower extremity.

and nerve biopsy. Patient with neuropathy secondary to other etiologies were excluded. Data including treatment regimen, affected limb, Birmingham Vasculitis Activity Score (BVAS), and duration of follow up was collected. Patients were invited to participate in a survey utilizing validated, neuropathy-specific PRO. Outcomes of interest were Chronic Acquired Polyneuropathy-Patient Reported Index score (CAP-PRI), a visual analog scale of self-perceived improvement in symptoms (VAS), and Overall Disability Sum Score (ODSS). Comparisons between treatment groups were performed with ANOVA, Kruskal-Wallis test, Pearson's chi-square test, or Fisher's exact test as appropriate. Multiple regressions were performed to control for disease duration, BVAS, and affected limb.

Results: Sixty-four patients with VN were sent PRO surveys. Survey response rate was 64% (n=41, 25% RTX, 75% CYC). Baseline patient characteristics, clinical features, and specific vasculitis diagnoses are listed in Table 1. No significant differences between treatment groups were seen in CAP-PRI (p=0.16) or VAS (p=0.13) (Table 2). There was no difference between treatment groups for ODSS (p=0.17) in patients with only lower extremity involvement. In patients with both upper and lower extremity involvement, patients treated with RTX had higher disability by ODSS at follow up (p=0.039), though small sample size limits interpretability. Multivariable analyses did not reveal significant differences in CAP-PRI, VAS, or ODSS in the two treatment groups after adjustment.

Conclusion: Overall, no significant differences in PRO were found in patients with VN treated with RTX compared to CYC. Prospective studies could help validate these findings.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell depletion by rituximab (RTX) is effective treatment for ANCA-associated vasculitis (AAV). However, the phenotype of peripheral B cells and the selection criteria for RTX in AAV remain unclear. We assessed the correlation between B cell phenotype and clinical outcome of RTX therapy in AAV patients.

Methods: All AAV patients who were introduced to remission induction therapy were registered for immunophenotyping-analysis using multi-colour flow cytometry. Phenotypic characterization of the circulating T cells and B cells were defined by 8-color flow cytometric analysis for “Human Immunology Project” termed by NIH/FOCIS in 58 AAV patients (18 GPA and 40 MPA). Based on the judgement by physicians who do not know the result of immunophenotyping-analysis, the patients were considered suitable to receive immunosuppressive drugs (conventional immune suppressants group; n=28) or RTX (RTX group; n=30). All patients also received high dose glucocorticoids (GC). We assessed the phenotype of circulating T cells and B cells, the correlation between these lymphocytes and clinical findings in active AAV and evaluated the efficacy and safety outcomes at 6 months after treatment. Definition of clinical improvement was a reduction of 50% or more in BVAS in vital organs without relapse.

Results: The proportions of naïve CD4⁺ T cells was higher, while that of central memory CD4⁺ T cells was lower, in AAV patients than healthy control (HC). Higher proportions of IgD⁺CD27⁺ B cells and lower proportions of IgM memory B cells, were found in AAV patients compared with HC. The proportion of IgD⁺CD27⁺ or class-switched memory B cells was increased in 23 out of 58 patients (40%) compared with HC. The rate of improvement in BVAS negatively correlated with the proportion of naïve B cells and positively correlated with that of IgD⁺CD27⁺ B cells. There was no correlation between the proportion of CD4⁺ T cell-phenotype and the rate of improvement. Twenty nine out of 30 patients (97%) in RTX group achieved clinical improvement. Among 28 patients in conventional immune suppressants group (including 20 intravenous cyclophosphamide and 8 azathioprine), 23 patients (82%) achieved clinical improvement. There was no significant difference in the rate of improvement, relapses, serious adverse events between the two treatment groups. The rate of clinical improvement in patients with excessive B cell differentiation was significantly lower than in patients without excessive B cell differentiation. In the patients with excessive B cell differentiation, the rates of survival, improvement in BVAS and GC reduction were significantly higher in RTX group than in conventional immune suppressants group at 6 months after treatment.

Conclusion: The presence of excessive B cell differentiation was associated with treatment resistance. However, in the patients with excessive B cell differentiation, RTX was effective and showed rapid effect of GC tapering and higher survival rate compared to conventional immune suppressants. The results suggested that multi-color flow cytometry might be useful for the selection of RTX therapy in AAV patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant-cell arteritis (GCA) is the most common primary large-vessel vasculitis affecting patients over 50 yr. Despite frequent and severe adverse events (AEs), glucocorticoids (GCs) are the reference treatment.¹ In 2003, Proven et al reported GC-related AEs in 86% of their patients.² Efficacy of immunosuppressants, specifically methotrexate, is modest. Although tocilizumab is emerging as an alternative agent, the long-term benefit of IL6 blockade is unknown. Moreover, application of the most recent recommendations on GC-induced osteoporosis or vaccinations might change the GC-associated risks and, thus, the risk/benefit balance needs to be updated. We evaluated the GC-induced frequencies of AEs in a French cohort of GCA patients.

Methods: This retrospective study was conducted in 2 French hospitals. GCA was diagnosed between May 2009 and March 2018, based on ACR criteria or the diagnostic criteria used in the GIACTA trial. GC-associated AEs and prophylaxis against infection, osteoporosis and gastrointestinal bleeding were recorded at each outpatient consultation.

Results: The cohort comprised 89 women and 27 men; median age 73 [IQR 67–79] years. The median number of ACR criteria met/patient was 3 [IQR 3–4]. Temporal artery biopsies were positive for 63% and 34% had imaging-revealed aortitis. All took GCs for a median duration of 22 [IQR 18–32] months, with tapering to 5 mg/day achieved after 10 [IQR 8–14] months. At the end of follow-up, 36 patients (31%) were still taking GCs. Among the other 69% who had stopped GCs after 21.5 [IQR 18–28] months, 13 relapsed. Median follow-up was 29 [IQR 19.5–47] months (369 patient/years). Patients were also taking bisphosphonates (79%), calcium (79%), vitamin D (87%) and/or proton-pump inhibitors (51%) and 36% had been vaccinated against pneumococci and/or flu. AEs occurred in 66 (57%) patients, including bone fractures in 22%, diabetes mellitus onset in 1%, gastrointestinal bleeding in 1%, hypertension in 10%, infections in 10%, and cataract(s) in 7%. Thirty-seven (32%) patients received GC-sparing therapy: methotrexate for 32, tocilizumab for 10 and azathioprine for 1; those agents were mainly initiated at the time of relapses/flares (49%).

Conclusion: GC-related AEs were less frequent in this cohort of GCA patients than Proven's cohort, perhaps explained by measures taken to prevent them or our study's retrospective design. Although alternative options to GC are important, the exact place of new therapies should also take into account better prevention of GC-related AEs.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: At least 2 biological therapies [tocilizumab (TCZ) and abatacept (ABA)] have been proven to be effective in the management of Giant cell arteritis (GCA) in randomized controlled trials. Nevertheless, their use as steroid sparing agents might need further investigation.

Methods: We included GCA patients who were treated with TCZ, both intravenous (IV) and subcutaneous (SC), and/or ABA SC (8 mg/kg/month, 162mg/week, and 125 mg/week respectively). Complete response to the treatment was defined as

a clinical and serological remission after 12 months of therapy; partial response as clinical or serological remission after 12 months.

Results: This study included 33 GCA patients [mean age 74, females 63%, mean follow-up 44±34 months]. *Figure 1* resumes the characteristics of the GCA patients included in the study. Twenty-eight patients out of 33 (85%) received one biologic agent. Five patients (15%) needed a therapeutic switch (one patient from TCZ to ABA, and 4 patients from ABA to TCZ). Patients were treated as follow: 9 with TCZ IV, 11 with TCZ SC, and 18 with ABA. Among the TCZ IV group, all patients experienced a response (57% complete response, and 43% partial response). Among the TCZ SC group, 83% experienced a response (67% complete response, and 16% partial response). Among the ABA group, 86% experienced a response (36% complete response and 50% partial response). After 12 months of therapy, 100% of patients in TCZ groups, both IV and SC, and 64% of ABA group were treated with low doses of oral prednisone (≤ 7.5 mg/day) as maintenance. We noticed a significant reduction of inflammatory parameters [C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)] after 12 months of therapy with TCZ [TCZ IV group: mean baseline CRP (mg/dl) 1.9 ± 2.3 , mean CRP after 12 months of therapy 0.3 ± 0.2 ; mean baseline ESR (mm/h) 58.1 ± 25.6 , mean ESR after 12 months 9.5 ± 4.2 ; TCZ SC group: mean baseline CRP 4.5 ± 3.8 , mean CRP after 12 months 0.2 ± 0.2 ; mean baseline ESR 51.9 ± 27 , mean ESR after 12 months 6.5 ± 6]. When compared to standard GC regimen, in patients treated with TCZ, both IV and SC, we estimated a median steroid-sparing effect quantifiable in 30 mg/daily in the first month and an overall steroid-sparing effect of 15 mg/daily when assessed in 12 months.

Eco-color-doppler positivity	30/31	97
GC therapy		
Previous methylprednisolone pulses (n)	7	21.2
Oral prednisone (n)	33	100
Dose of oral prednisone (mg/day) (mean, SD)	49.7 ± 15.1	
Previous immunosuppressive therapies		
Methotrexate (n)	11	33.3
Mean dose (mg/week) (mean, SD)	15.6 ± 1.7	
Mycophenolate (n)	6	18.1
Mean dose (g/day) (mean, SD)	2.2 ± 0.4	

Conclusion: This study confirms the efficacy of biological therapies in the management of CGA. Besides, in our experience TCZ allowed a significant reduction of GCs use, especially in the first month of therapy, when compared to standard GCs-based regimens.

Tocilizumab Monotherapy for Large Vessel Vasculitis: Results of 104-Week Treatment of a Prospective, Single-Center, Open Study

Shuntaro Saito, Ayumi Okuyama, Yusuke Okada, Akiko Shibata, Ryota Sakai, Kentaro Chino, Takahiko Kurasawa, Tsuneo Kondo, Hirofumi Takei and Koichi Amano, Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the efficacy and safety of tocilizumab (TCZ) monotherapy for Large Vessel Vasculitis (LVV), including Takayasu arteritis (TAK) and Giant cell arteritis (GCA).

Methods: Twelve LVV patients (4 TAK patients and 8 GCA patients) who had been newly diagnosed at our hospital from January 2013 to May 2016 were enrolled in a prospective, open-label study. TCZ (8mg/kg) was administered intravenously every 2 weeks for the first 2 months and every 4 weeks for the next 10 months (total 15 times) without any corticosteroid (CS) or immunosuppressants (IS). Patients were followed for another 1 year after last TCZ administration without any treatment. The efficacy was assessed by clinical symptoms (fever, headache, fatigue, etc.) and CRP level. Complete and partial response (CR and PR) was defined as disappearance or improvement of all clinical symptoms due to vasculitis and normalization of CRP ($<0.3\text{mg/dl}$). Poor clinical response was defined as patients who did not satisfy the criteria of CR/PR. Relapse of the disease was defined as the worsening or recurrence of clinical symptoms, increase of CRP attributable to activity of vasculitis, or initiation of CS and/or IS.

Results: The mean age was 58.9 y/o, the mean disease duration was 3.4 months, mean CRP was 6.0 mg/dl at the diagnosis of the LVV. Efficacy of the TCZ monotherapy in active LVV was assessed in 11 patients, since 1 TAK patient chose not to participate in the study at week 2. Although 1 GCA patient had TCZ withdrawal due to heart failure at week 24, there were no other serious adverse events. LOCF (Last Observation Carried Forward) method was utilized to fill the missing data. Relapse after TCZ cessation was assessed in 10 patients who completed week 52. CR and PR rate were 73%/18% at

week 24, and were maintained at week 52. Relapse occurred in 4 out of 10 patients (40%), although 60% completed week 104 after TCZ cessation. Response and relapses at each visit are summarized in figure 1.

Conclusion: This is the first study to show the effectiveness of merely IL-6 signal blockade in LVV patients, which could help us to understand the crucial role of IL-6 in the pathogenesis of LVV. TCZ monotherapy showed high response rate as an induction therapy for newly diagnosed LVV patients, and some of the patients did not require maintenance therapy after TCZ cessation. TCZ monotherapy might be an acceptable strategy as induction therapy for active LVV patients.

Leflunomide and Methotrexate in Treatment of Giant Cell Arteritis: Comparison of Efficacy, Safety and Drug Survival

Stig Tengesdal and Geirmund Myklebust, Department of Rheumatology, Hospital of Southern Norway, Kristiansand, Norway

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) and leflunomide (LEF) are used as adjunct immunosuppressants and corticosteroid sparing agents in treatment of Giant Cell Arteritis (GCA), but the efficacy is poorly investigated. The aim of this study was to compare efficacy, safety and drug survival between MTX and LEF in the treatment of GCA.

Methods: During 2007-2017 all patients diagnosed with GCA at the Department of Rheumatology were included in a hospital-based retrospective study. All patients receiving MTX and/or LEF due to insufficiency and/or adverse effects of treatment with Prednisolone were identified. Duration of treatment, causes of discontinuation and changes in Prednisolone dose, Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were registered. Concomitant myalgia and/or polymyalgia rheumatica (PMR) and large vessel involvement (LVI) (involvement of aorta and its primary and secondary branches) were noted. Remission was defined as doctor's opinion of clinical remission and a Prednisolone dose ≤ 5 mg/day. Baseline Prednisolone dose and CRP values were unevenly distributed between the groups. Therefore the effect in patients with a Prednisolone dose >7.5 mg at start of treatment were analyzed separately, interpreted as a group of patients with higher disease activity. Student-t test was used to compare means and Chi-square test to compare categorical variables. All statistical analyses were performed using the SPSS statistical package version 23.

Results: 216 patients (70.4% women) were included (mean age 72.9 at time of diagnosis). Twenty-seven and 24 patients started treatment with LEF and MTX, respectively. During the treatment-period, the observed mean reduction in Prednisolone dose, ESR and CRP did not differ significantly. No significant difference between LEF and MTX in treatment duration to achieve remission/still on treatment was found ($p=0.19$). For patients with higher disease activity (Prednisolone >7.5 mg), this difference was significant favoring LEF ($p=0.02$). In the same group, a non-significant difference was found in the time to discontinuation due to adverse effects ($p=0.13$). There were no differences in the number of adverse effects in the treatment groups, most of them mild and well known.

Conclusion: To our knowledge this is the first study to compare LEF and MTX in the treatment of GCA. Patients treated with LEF achieved remission earlier than MTX, and this difference was significant in patients with higher disease activity ($p=0.02$). We found no difference in tolerability and reduction in ESR and CRP after 6 months of treatment between the groups.

Disclosure: S. Tengesdal, None; G. Myklebust, None.

FIGURE 1: Patients with Prednisolone dose >7.5mg at start of treatment of LEF (n=7) or MTX (n=7). Treatment duration in weeks (mean, 95%CI) for achieving remission or still on treatment (censored). LEF: 48.4 (22.4 – 76.4); MTX: 104.9 (64.0 – 145.7).

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel vasculitis which can involve the aorta and/or its major branches. Tocilizumab (TCZ) seems to be effective in giant cell arteritis (GCA) (1-4). Our aim was to assess if the clinical and analytical improvement yielded in patients with GCA treated with TCZ is accompanied by a reduction of the vascular inflammation evaluated by PET/CT.

Methods: Study of 36 patients who had a baseline and follow-up PET/CT from a multicenter series of 134 patients with GCA in treatment with TCZ. The evolution of the vascular involvement objectified by PET/CT was assessed. In addition, clinical efficacy, analytical improvement (acute phase reactants) and the reduction of corticosteroid dose was studied.

Results: The 36 patients (28 women and 8 men) had a mean age of 69.8±8.6 years. After TCZ onset, a rapid and maintained clinical improvement was observed (TABLE). In addition, during the first twenty-four months of follow-up, C-reactive protein decreased from 2.4 [0.9-6.8] to 0.1 [0.0-0.5] mg / dL and the erythrocyte sedimentation rate from 41.5 [16.7-58.5] to 4 [2-12.5] mm/1st hour. On the other hand, the levels of haemoglobin experienced an increase from 12.3 [11.3-13.0] to 13.3 [13.0-13.9] g/dL. The median dose of prednisone decreased from 12.5 [9.4-26.2] to 0.0 [0.0-0.0] mg/day. However, the decrease in F18-fluorodeoxyglucose uptake in the PET/CT study was not as evident, reaching a complete improvement in PET/CT uptake in 7 (20%) patients at 24 months of follow-up.

Conclusion: Although TCZ seems to be an important therapeutic agent in the treatment of GCA, achieving a rapid and sustained clinical and analytical improvement, the decrease in vessel inflammation assessed by F18-fluorodeoxyglucose uptake seems to take a slower course.

	Baseline	Month 6	Month 12	Month 18	Month 24

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is an inflammatory disease characterized by pain and stiffness of the neck, shoulder and pelvic girdles. It can also be accompanied by other non-specific symptoms such as inflammatory low back pain, diffuse lower limb pain and constitutional syndrome. ¹⁸F-FDG PET /CT has been proposed as a promising tool for characterizing the anatomical affection of PMR but it remains unknown if there is a correlation between clinical symptoms and ¹⁸F-FDG uptake.

Objectives: Our aim was to assess if the localization of pain of patients with PMR correlates with ¹⁸F-FDG uptake in the corresponding region.

Methods: Study of 75 patients with PMR and their respective PET/CT scans from a referral center. PMR was diagnosed according to 2012 EULAR/ACR criteria. All PET/CT images were evaluated qualitatively by two experienced nuclear medicine physician.

TABLE

Clinical manifestation/location of FDG uptake	F FDG uptake		P
	Positive, n/N (%)	Negative, n/N (%)	
Shoulder girdle pain (n=40)			
Shoulder	27/45 (60.0)	13/30 (43.3)	0.16
Sternoclavicular joints	22/33 (66.7)	18/42 (42.9)	0.04
Cervical interspinous bursae	6/9 (66.7)	34/66(51.5)	0.49
Neck pain (n=12)			
Shoulder	8/45 (17.8)	4/30 (13.3)	0.61
Cervical interspinous bursae	2/9 (22.2)	10/66 (15.5)	0.63
Pelvic girdle pain (n=42)			
Hips	23/32 (71.8)	19/43 (44.2)	0.02
Lumbar interspinous bursae	18/29 (62.1)	24/30 (80.0)	0.40
Subtrochanteric bursae	11/20 (55.0)	31/55 (56.4)	0.92
Isochial tuberosities	10/19 (52.6)	32/58 (55.2)	0.73
Pubic symphysis	3/4 (75.0)	32/71 (45.1)	0.63
Inflammatory low back pain (n=20)			
Hips	10/32 (31.3)	10/43 (23.3)	0.44
Lumbar interspinous bursae	10/29 (34.5)	10/46 (21.7)	0.22
Isochial tuberosities	3/19 (15.8)	17/56 (30.4)	0.26
Subtrochanteric bursae	7/20 (35.0)	13/55 (23.6)	0.33
Pubic symphysis	3/4 (75.0)	17/71 (23.9)	0.06
Diffuse lower limb pain (n=35)			
Knees	16/33 (48.5)	19/42 (45.2)	0.78
Subtrochanteric bursae	8/20 (40.0)	27/55 (49.1)	0.49
Isochial tuberosities	9/19 (47.4)	26/56 (46.4)	0.94
Hips	15/32 (46.9)	20/43 (46.5)	0.98

Results: We evaluated 75 patients (27 men/48 women); mean age \pm SD of 68.2 \pm 0.7 years. A PET/CT was performed in all of them. Pattern of F-FDG uptake in patients with different clinical manifestations are summarized in the **TABLE**. Twenty-two out of thirty-three patients (66.7%) with ^{18}F -FDG uptake in sternoclavicular joints had shoulder girdle pain. Twenty-three patients of thirty-two patients (71.8%) with ^{18}F -FDG uptake in hips had pelvic girdle pain. The remaining localizations of ^{18}F -FDG uptake in PET/CT scans did not show significant correlations with clinical symptoms.

Conclusion: In patients with PMR, clinical manifestations do not always correlate with the anatomic allocation of ^{18}F -FDG uptake. Only, the presence of shoulder girdle pain seems to correlate with ^{18}F -FDG uptake in sternoclavicular joints and pelvic girdle pain with ^{18}F -FDG uptake in hips.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a frequent inflammatory condition in patients over 50 years old. Nearly 60% of patients experience relapses of the symptoms during steroids tapering and steroids dependency is frequent. There is a need to find other therapeutic options to avoid the risks of long term steroid treatment. Methotrexate (MTX) use in PMR has been studied with contradictory results regarding reduction of relapses. Our objective was to evaluate the efficacy of MTX to reduce relapses and recurrences in patients with PMR.

Methods: This is an observational longitudinal cohort study. We included 94 consecutive patients with PMR fulfilling EULAR/ACR 2012 criteria. Clinical symptoms, laboratory results, treatment received and disease course information were extracted from the medical records.

Patients were assigned to 3 groups according to the treatment prescribed by the treating physician. Group 1: treated with steroids alone, group 2: treated with steroids initially and MTX following a relapse or recurrence and group 3: treated with steroids and MTX from diagnosis.

Definitions:

- Relapse: recurrence of symptoms and an increase of erythrocyte sedimentation rate (ESR) or C reactive protein (CRP) in patients still receiving steroids.
 - Remission: time of discontinuing prednisone.
 - Recurrence: recurrence of the original symptoms and an increase of ESR or CRP after discontinuing prednisone.
- We studied predictors of relapse in the total population. To evaluate MTX effect, patients from group 2 were analyzed comparing outcomes during the first period with corticosteroids alone with the second period with steroids and MTX.

Results: Ninety four patients were included, 77.6% women, mean age 75.6 years old (SD 8.1). The median time of follow up was 21.3 months (IQR 11.7-56.2).

Patients were assigned to one of 3 groups according to their treatment: 53 (56.4%) were treated only with steroids (group 1), 33 (35.1%) received initially steroids and later on MTX (group 2) and 8 (8.5 %) had steroids and MTX from diagnosis (group 3). Table 1 shows a comparison between groups.

We found a tendency of ESR to predict relapses (p 0.07) in the total population.

In group 2, we identified 35 relapses during the period of treatment with steroids alone and only 8 relapses during the period of combined treatment (p 0.0001). MTX reduced the dose of corticosteroids used and reduced the time to remission in this group of patients (Table 2).

Table 1

	GROUP 1	GROUP 2	GROUP 3
N	53	33	8
One relapse, n (%)	12 (22.6)	28 (84.8)	4 (50)
More than 1 relapse, n (%)	3 (5.6)	11 (33.3)	2 (25)
Time to the first relapse, months, median (IQR)	9.2 (6.7-10.7)	8.6 (6-14.9)	21.5 (9.6-92.8)
Remission, n (%)	20 (37.7)	14 (42.4)	3 (37.5)
Time to remission, m (IQR)	12.9 (11.8-21.6)	21.2 (15-25.2)	13.3 (12.4-99.8)
Duration of remission, m (SD)	1.8 (0-15.2)	6.6 (2.8-17.6)	19.5 (4.4-40.5)

Total dose of steroids, g, mean (SD)	3.7 (4.8)	5.6 (3.3)	12 (14.6)

Table 2

	pre MTX	post MTX	p
Relapses, n	35	8	0.0001
Time to first relapse, months, median (ICR)	13.2 (6.4-16.8)	9.2 (6.2-17.4)	0.12
Time free of relapse, months, median (ICR)	8.6 (5.3-14.9)	7.5 (4.6-17.4)	0.25
Dose of steroids at first relapse, mg/day, mean (SD)	5.1 (2.3)	3 (1.5)	0.02
Remission, n	7	9	0.73
Time to remission, months, median (ICR)	22.9 (18.1-30.1)	8.7 (7-12.2)	0.01
Duration of remission, months, mean (SD)	14.7 (17.4)	13.9(20.9)	0.53
Recurrences, n	7	4	0.36

Conclusion: The use of MTX in PMR patients who already had a relapse reduces the number of future relapses and reduced the time to achieve remission. Starting MTX allowed a reduction of corticosteroids dose.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adding tocilizumab (TCZ) to tapered prednisone treatment for patients (pts) with giant cell arteritis (GCA) leads to improved rates of sustained glucocorticoid-free remission.¹ It is not known, however, whether the glucocorticoid dose at initiation of TCZ affects disease control. We investigated sustained remission and disease flare according to baseline (BL) prednisone doses in pts with GCA treated with TCZ or placebo (PBO) and scheduled prednisone tapering in the GiACTA trial.¹

Methods: Pts received TCZ-weekly or-every-other-week + 26-week prednisone taper (TCZ-QW [n=100] or TCZ-Q2W [n=49]) or placebo + 26-week or 52-week prednisone taper (PBO+26 [n=50] or PBO+52[n=51]) for 52 weeks.¹ Flare was defined as recurrence of GCA signs/symptoms and/or ESR ≥ 30 mm/h attributable to GCA requiring increased prednisone

Figure 1. Sustained remission at week 52 according to BL prednisone dose

¹Percentages based on number of patients receiving BL dose

²Percentages based on total number of patients in each treatment group at BL

Figure 2. Kaplan-Meier analysis of time to first GCA flare according to high or low BL prednisone dose.

Randomization was stratified by baseline prednisone dose (>30 mg/day and ≤30 mg/day).

Patients never in remission were censored at day 1 and patients who withdrew from the study before week 52 were censored from the time of withdrawal.

	Baseline dose >30 mg/day				Baseline dose ≤30 mg/day			
	PBO+26	PBO+52	TCZ-QW	TCZ-Q2W	PBO+26	PBO+52	TCZ-QW	TCZ-Q2W
Pts who flared, n (%)	14 (60.9)	15 (60.0)	10 (20.8)	6 (24.0)	20 (74.1)	10 (38.5)	13 (26.0)	7 (29.2)

dose. Sustained remission was defined as absence of flare, normalization of CRP (<1 mg/dL), and adherence to the protocol-defined prednisone taper to week 52. All pts received prednisone during screening at a dose selected by the investigator before entry to the trial at BL. In this post hoc analysis, sustained remission rates were assessed according to BL prednisone dose and time to first flare was assessed according to protocol-defined BL prednisone dose stratification factors (>30 mg/day or ≤30 mg/day). All analyses are descriptive.

Results: Sustained remission was achieved by higher proportions of pts in the TCZ groups than the PBO groups across the range of BL prednisone doses (Figure 1). Figure 2 shows Kaplan-Meier analysis of time to flare. Among pts with high BL prednisone doses (>30 mg/day), TCZ-treated pts had longer time to flare than pts in the PBO groups. Pts with low BL prednisone doses (≤30 mg/day) had separation between the TCZ groups and the PBO+26 group from week 12, with longer time to flare in the TCZ and PBO+52 groups than in the PBO+26 group. In the PBO+26 group, pts with low BL prednisone doses flared earlier than pts with high BL doses, but there was no apparent difference in time to flare between high and low BL prednisone dose for the TCZ groups.

Conclusion: Pts with GCA treated with TCZ and prednisone tapering could achieve sustained remission across a range of BL prednisone doses. Fewer pts in the TCZ groups than the PBO groups had GCA flares. Time to flare was similar for pts treated with TCZ regardless of starting prednisone dose. *Reference:* 1. Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) has showed efficacy in randomized clinical trials in Giant cell arteritis (GCA).Data were of selected patients including many GCA of recent onset. In addition, TCZ route (IV or SC) and

concomitant corticosteroid dose were not established. To assess the efficacy and safety of TCZ in an unselected largest series of GCA in clinical practice.

Methods: Retrospective, open label multicenter study on 134 patients from 40 national referral centers with GCA in treatment with TCZ due to lack of efficacy and/or unacceptable adverse events of previous therapy.

Results: 134 (101 women) patients; mean age, 73.0±8.8 years. Before TCZ and besides steroids, 98 (73.1%) patients also received immunosuppressive agents. The median [IQR] time from GCA diagnosis was 13.5 [5.0-33.5] months. After 1 month of TCZ, 93.9% showed clinical improvement. It was observed a decrease in: a) CRP from 1.7 [0.4-3.2] to 0.11 [0.05-0.5] mg/dL ($p<0.0001$), b) ESR from 33[14.5-61] to 6 [2-12] mm/1st hour ($p<0.0001$), c) anemia from 16.4% to 3.8% ($p<0.0001$). This improvement was maintained reaching prolonged remission at 55.5%, 70.4%, 69.2% and 90% at 6, 12, 18 and 24 months respectively. Improvement in ^{18}F -FDG uptake in PET-TAC occurred slower, and complete resolution was observed in 0%, 14.3%, 18.7% and 19.5% cases at 6, 12, 18 and 24 months respectively. The most relevant side-effects were serious infections (10.6/100 patients-year), associated to higher doses of prednisone during the first three months of TCZ.

Conclusion: TCZ leads to a rapid and maintained improvement in refractory GCA, regardless TCZ route, GCA duration and prednisone dose. Serious infections were higher than in clinical trials. With TCZ a maximum dose of prednisone of 15 mg with rapid reduction is advisable.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis with a predisposition for the cranial branches of the external carotid artery. However, aorta and / or its main branches may also be involved (1-4). In a series of patients with GCA who presented extracranial vessel involvement, our aim was to assess a) the vascular territories most frequently affected and b) correlation of a major extension of extracranial vascular involvement with a more severe clinical and analytical features.

Methods: Multicenter study of 68 patients with GCA who presented a compromise of extracranial vessels confirmed by PET/CT. Visual analysis of vascular uptake was performed on supra-aortic trunks (SAT), aortic arch (AA), thoracic aorta (TA), abdominal aorta (AA), iliac arteries (IA), lower limb arteries (LLA), and upper limb arteries (ULA).

Results: We evaluated 68 patients with GCA (51w/17m) with a mean age of 68.0±8.3 years. The vascular territories affected were: TA (n=58, 85.29%), SAT (n=38, 55.88%), AA (n=28, 41.18%), AA (n=18, 26.47%), LLA (n=17, 25%), IA (n=13, 19.12%) and ULA (n=6, 8.82%). We considered 3 groups according to the number of vascular territories affected: a) 1 or 2 territories, b) 3 or 4 territories and c) 5 or more territories and made a comparative study between these groups. In patients with 35 vascular territories affected, we observed a higher baseline ESR, and the most frequent systemic manifestations were polymyalgia rheumatica and constitutional symptoms with statistical significance (TABLE). Distribution of categorical variables was compared by the Pearson Chi-squared test. Quantitative variables were analyzed using the ANOVA test.

Conclusion: In patients with GCA the involvement of TA is very frequent, followed by the SAT and the AA. Regarding the laboratory findings, patients with higher levels of ESR presented a major extension of extracranial vascular involvement, as well as presenting PMR and/or constitutional symptoms was also related to more affection of extracranial territories.

	Number of vascular territories affected			p

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:: Giant cell arteritis (GCA) can be refractory to corticosteroid therapy (1-3). Tocilizumab (TCZ) has been approved in the treatment of GCA. There are no studies comparing the efficacy and safety when using TCZ as monotherapy or in combination with conventional immunosuppressive drugs in GCA. Our aim was to compare efficacy and safety of TCZ combined or in monotherapy in GCA.

Methods: Multicenter study on 134 patients with refractory GCA who received TCZ therapy as monotherapy or combined with conventional immunosuppressants. Large vessel involvement was considered when the aorta and/or its major branches were involved and when disclosed by imaging techniques such as ¹⁸F-FDG PET-CT scan, MRI-A, CT-A, or helical CT-scan. Prolonged remission was defined by the absence of clinical symptoms and signs and normalization of the acute phase reactants for at least 6 months. Relapse was defined as the recurrence of signs or symptoms of GCA and/or ESR>20 mm/h in men or >25 mm/h in women, and/or serum CRP >0.5 mg/dL related to GCA, both before and after starting TCZ therapy. A serious infection was considered to be present when a life-threatening, fatal, or required hospitalization infection occurred, intravenous antibiotics were necessary, or the process lead to persistent or significant disability. We also compared a subgroup of 36 patients, that had a baseline and follow-up PET/CT, to evaluate evolution of the vascular involvement.

Results: We evaluated 134 patients (101 w/33m); mean age, 73.0±8.8 years. TCZ was prescribed as monotherapy in 82 (62.2%) and combined with conventional immunosuppressants in 52 (38.8%) patients: MTX(n=48), AZA (n=3), and LFN (n=1). A comparative study between both groups is summarized in **TABLE**. Patients who received combined TCZ were younger and had a higher C-reactive protein (CRP) and a higher presence of aortitis in imaging techniques. When TCZ was started, prolonged remission was reached with combined therapy (statistical significance at 12 and 24 months). The corticosteroids sparing effect was similar in both groups. Side effects were similar in both groups too. There were no statistical significance regarding aortitis evolution.

Conclusion: Patients receiving combined conventional immunosuppressants with TCZ in the clinical practice study showed a higher prolonged remission. The incidence of serious infections and/or relevant adverse events was not affected according to the treatment. As well as the corticoid-sparing effect was achieved in the same way in both groups.

TABLE 1

	TCZ IN MONOTHERAPY (n=82)	TCZ COMBINED (n=52)	p

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis with a special predilection for extracranial branches of the external carotid artery. Among its most fearsome complications is visual affection. Tocilizumab (TCZ) is a monoclonal antibody directed against the interleukin 6 receptor that has shown utility in the treatment of GCA. Our aim was to assess the evolution of visual clinic in patients with GCA treated with TCZ.

Methods: Retrospective multicenter study on 20 GCA patients with visual involvement in treatment with TCZ. The efficacy of this drug on visual symptoms was evaluated.

Results: We assessed 20 patients (14 women and 6 men) with a mean age \pm SD of 73.7 ± 10.1 years with GCA and visual symptoms. In total there were 23 affected eyes. The symptoms reported were: unilateral blindness (n = 6), unilateral blurred vision (n = 6), unilateral amaurosis fugax (n = 3), unilateral hemianopsia (n = 2), bilateral blindness (n = 1), bilateral blurred vision (n = 1), bilateral hemianopsia (n = 1). Before starting treatment with TCZ, all patients had received high doses of prednisone, with a mean \pm SD dose of 54.2 ± 13.8 mg / day (range of doses: 40-80 mg / day). In addition, 9 of them also received intravenous corticosteroid boluses. In addition, 13 patients received traditional immunosuppressants: methotrexate (MTX) (n= 12), cyclophosphamide (n = 2), leflunomide (n = 1) and azathioprine (n = 1). Regardless of corticosteroids, TCZ was administered as monotherapy in 14 patients, while in 6 it was administered in combination with MTX. The TABLE shows the evolution of the visual affection of these patients. Throughout a median follow-up [RIC] of 9 [4-18] months, none of the 7 patients who had a blindness regained vision. The 2 patients who presented unilateral hemianopsia recovered vision. The patient with bilateral hemianopsia and the patient with bilateral blurred vision experienced a partial improvement. The remaining patients achieved a complete recovery.

Conclusion: Although TCZ seems to be also useful in the treatment of visual manifestations of ACG, once blindness is established, it does not seem to be effective.

	Month 1 n=20	Month 3 n=14	Month 6 n=10	Month 12 n=5
Visual improvement after starting TCZ, n (%)				
Complete improvement	6 (30)	5 (35.7)	5 (50)	1 (25)
Partial improvement	2 (10)	3 (21.4)	0 (0)	0 (0)
No improvement	12 (60)	6 (42.8)	5 (50)	5 (50)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: GiACTA study is a randomized, phase III controlled clinical trial of tocilizumab (TCZ) in giant cell arteritis (GCA) (1,2). Our aim was to compare GiACTA trial data from those of a national multicenter series of 134 patients with GCA from the clinical practice.

Methods: In the GiACTA study the diagnosis of GCA was established by the ACR modified criteria, in our clinical practice series it was established by ACR criteria, positive biopsy of temporal artery and/or presence of imaging techniques consistent with LVV in patients with cranial symptoms of GCA. In the GiACTA trial TCZ was given subcutaneously (162 mg every 1 or 2 weeks) while in the clinical practice study TCZ was used at standard IV dose (8 mg/kg/month) and subcutaneously (162 mg/week). Quantitative variables were expressed as mean±SD and they were compared by the Student's t-test. Dichotomous variables were expressed as percentages and compared using the chi-square test.

Results: We did a comparative study between GiACTA trial (overall n=251 and only relapsing n=132) and our clinical practice series (overall n=134). At TCZ onset, in the clinical practice series (n=134) there were a significantly greater (TABLE): a) mean age at ACG diagnosis, b) polymyalgia rheumatica and visual affection frequency, c) ESR and CRP, and d) previous conventional immunosuppressants (mainly MTX). There was also a non-statistically significant difference, in terms of achieving sustained remission and developing severe infections. The mean dose of prednisone at the TCZ onset was lower in patients from the clinical practice.

Conclusion: Patients receiving TCZ in the clinical practice study have several baseline clinical and laboratory differences when compared to those included in the GiACTA trial. Patients of clinical practice were older, with a longer evolution time of disease. At TCZ onset were more symptomatic and had elevated levels of ESR and CRP, as well as, they had received more previous immunosuppressant agents.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ), an anti-interleukin-6 receptor (IL-6R) monoclonal antibody, was recently approved for the treatment of patients with giant cell arteritis (GCA) based on results of a double-blind randomized controlled trial (RCT) in GCA patients given 162 mg TCZ every week (QW) or every other week (Q2W) by subcutaneous (SC) route (GiACTA trial¹). Another RCT of 8 mg/kg TCZ given intravenously (IV) every 4 weeks (Q4W) also showed positive outcomes in GCA patients.² The double-blind part of each study lasted approximately 1 year. All 3 regimens (SC 162 mg QW, SC 162 mg Q2W, IV 8 mg/kg Q4W) yielded positive outcomes for sustained remission of GCA. However, a higher benefit was noted in some key secondary efficacy outcomes with the QW versus the Q2W SC regimen.¹ The present analysis investigated the pharmacokinetics (PK) of TCZ in GCA patients and assessed the impact of the exposure differential from the 3 regimens on pharmacodynamic (PD) markers.

Methods: TCZ levels and PD biomarkers (soluble IL-6R [sIL-6R], IL-6, erythrocyte sedimentation rate [ESR], and C-reactive protein [CRP]) were measured using validated assays at regular intervals throughout the dosing period from all patients in each trial. PK and PD outcomes were compared to facilitate understanding of the dose exposure-response relationships.

Results: At week 52, mean trough steady state exposure (C_{trough}), a key PK driver of TCZ efficacy, was highest for SC 162 mg QW, then IV 8 mg/kg Q4W, and finally SC Q2W (Figure). At week 52, sIL-6R levels were similar for the SC QW and IV regimens but lower for the SC Q2W regimen (Figure), possibly demonstrating a higher level of target engagement from the SC QW and IV regimens compared with the Q2W regimen. IL-6 levels increased versus baseline after TCZ administration for all 3 regimens, reflecting displacement of bound, endogenous IL-6 from its receptor, consistent with the mechanism of action of TCZ. ESR levels decreased to a similar extent in response to TCZ administration with all 3 regimens. Change from baseline in CRP was comparable between both SC regimens (~79-93% reduction from baseline from the QW and Q2W regimens, respectively). Quantitative changes in CRP values are not available for the IV study.

Conclusion: Comparison of C_{trough} after 52 weeks of dosing with TCZ from the 8 mg/kg IV regimen with that obtained from 2 SC regimens showed that exposures from the IV regimen were within the range of exposures of the SC QW and Q2W regimens. Comparison of PD outcomes showed that all 3 regimens had comparable results, except for lower levels of sIL-6R (a mechanistic marker reflecting serum concentration and target engagement) from the SC Q2W regimen. Comparability of PD results is consistent with similar efficacy outcomes in the SC and IV trials. *References:* 1. Stone JH et al. *N Engl J Med* 2017;377:317-328. 2. Tocilizumab Interruption in Patients with Giant Cell Arteritis Achieving the Clinical Remission: Interim Analysis of an Open-Label, 18-Month, Pilot Study

Carlotta Nannini¹, Laura Niccoli², Emanuele Antonio Maria Cassarà², Olga Kaloudi², Stelvio Sestini³ and Fabrizio Cantini², ¹Prato Hospital, Prato, Italy, ²Rheumatology, Prato Hospital, Prato, Italy, ³Radiology, Prato Hospital, Prato, Italy

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The efficacy of tocilizumab (TCZ), an anti-IL-6 targeted monoclonal antibody, in patients with refractory GCA has been demonstrated. The purpose of this study was to investigate the persistence of clinical remission after TCZ interruption. We also evaluated the role of acute-phase reactants and ¹⁸F-Fluorodeoxyglucose Positron Emission Tomography (¹⁸F-FDG –PET) in predicting the relapse and remission, and the occurrence of adverse event (AEs).

Methods: All refractory GCA patients with involvement of aorta and its thoracic branches received prednisone (PDN) 50 mg/day and intravenous TCZ (TCZiv) 8 mg/Kg/monthly or subcutaneous TCZ (TCZsc) 162 mg/weekly. PDN was tapered and withdrawn at month 2.

At month 6, in patients achieving a stable remission, TCZ was bimonthly tapered as follows: TCZiv 2 mg/Kg, and TCZsc 1 injection every 2, 3 and 4 weeks until month 12. In responders both treatments were interrupted at month 12.

Remission was assessed at months 6, 12, and 18 by the evaluation of GCA symptoms and signs, patient global health assessment by visual analogue scale 1 to 10 (VAS), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP). ¹⁸F-FDG –PET was performed at baseline, month 6, and 2 months after TCZ withdrawn. A Standardized Uptake Value normalized for liver uptake (nSUVmax) ≤ 1 was assumed as normal.

Anova test and Person test were used to measure the difference between groups and for correlations respectively. :

Results: 15 patients were enrolled, 12 females and 3 males, mean age at diagnosis was 69.8 years (± 7.70 SD). Seven patients were treated with TCZiv and 8 patients with TCZsc. After 2 months of TCZ therapy all patients stopped CS, and after 6 months of TCZ treatment all patients were in clinical (VAS mean value 2.01 ± 0.76 SD), laboratory (ESR $9 \text{ mm/h} \pm 6.66$ SD; CRP $0.29 \text{ mg/dl} \pm 0.27$ SD) remission. 11 patients completed the 12-month scheduled follow-up. Of these, 7 maintained the drug-free remission that persisted over a median follow up of 12 months afterward. After 2 months from TCZ discontinuation, in the 7 remitting patients SUVmax and nSUVmax were significantly reduced as compared with baseline, while no differences resulted with ¹⁸F-FDG –PET values at month 6. (table 1). A correlation between nSUVmax and VAS and CRP was found (Pearson 0.9: $p = 0.0005$ and 0.59 $p = 0.006$, respectively). Four patients reactivated after two months of TCZ discontinuation with median VAS 7.9, median ESR 50, median CRP 1.66. Two patients had stable disease with every other week TCZsc and 2 patients with monthly TCZsc. None of the patients required CS. No AEs were recorded. The remaining 4 patients with incomplete follow up, were in remission with no flares after 8,10, and 12 months of treatment.

	Baseline	Month 6	P value	Pre TCZ	After 2 months from TCZ discont.	P value	Month 6	After 2 months of TCZ discont.	P Value
SUVmax mean (\pm SD)	3.3 (0.36)	2.13 (0.42)	0.0005	3.3 (0.36)	1.9 (0.24)	0.0005	2.13 (0.42)	1.9 (0.24)	0.43
nSUVmax mean (\pm SD)	1.49 (0.26)	0.85 (0.19)	0.0005	1.49 (0.26)	0.77 (0.15)	0.0005	0.85 (0.19)	0.77 (0.15)	0.76

Conclusion: Drug-free remission maintenance after TCZ discontinuation seems to be a proposable strategy in GCA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity in large vessel vasculitis (LVV) is traditionally assessed by clinical and serologic (ESR, CRP) parameters. Imaging assessment, including ¹⁸F-fluorodeoxyglucose-positron emission tomography (FDG-PET), may be useful to monitor LVV. The study objective was to determine the impact of tocilizumab, infliximab and methotrexate (MTX) on disease activity in LVV as assessed by clinical, serologic, and imaging-based parameters.

Methods: Patients with GCA or TAK were recruited into a prospective, observational cohort involving ≥ 2 FDG-PET/CT scans at 6-month intervals. Clinical assessment [physician global assessment (PGA, range 0-10)], serologic assessment (CRP-mg/L, ESR-mm/hr), and imaging assessment [PET Vascular Activity Score (PETVAS)] was determined at each visit. PETVAS is a global summary score of arterial FDG uptake assessed qualitatively relative to liver activity in 9 vascular beds, ranging from 0 to 27 with higher scores indicating more vascular inflammation. Clinical and imaging assessments were performed blinded to each other. Wilcoxon signed rank test was used to compare changes in PGA, CRP, ESR, and PETVAS between interval visits in response to treatments.

Results: Fourteen subjects with GCA were treated with tocilizumab. Prior to treatment, every patient had clinical and PET scan activity. There was significant reduction in PGA (2.5 vs 0, $p < 0.01$), CRP (6.8 vs 0.5, $p < 0.01$), ESR (22.5 vs 4.5, $p < 0.01$), and PETVAS (25.0 vs 22.0, $p = 0.01$). PETVAS improved in 5 of 7 patients with GCA treated with tocilizumab. Despite significant improvement in PETVAS, only 2 of 14 patients (14%) had normalization of PET activity after treatment with tocilizumab. In contrast, clinical remission after tocilizumab occurred in most of these patients ($n = 10$; 71%). Most of the subjects were on glucocorticoids (GCs) and there was significant reduction the daily GC dose ($p = 0.01$) at follow up.

Six subjects with TAK were treated with infliximab. All of them had clinically active disease and active PET scan at baseline. There was significant improvement in PGA (5.5 vs 2, $p = 0.03$); however, four of six patients (67%) continued to have clinically active disease at follow up. All six patients had an improvement in PETVAS (21.0 vs 14.5, $p = 0.03$). However, four of the six patients continued to have active vasculitis by PET at follow-up despite treatment and there was no significant change in CRP (24.9 vs 4.9, $p = 0.31$) or ESR (32.5 vs 18.5, $p = 0.13$). Daily GC dose was similar at baseline and follow up ($p = 0.5$).

Treatment with MTX was studied in 12 patients (TAK=3, GCA=9). Variable response to MTX was observed without significant change in PGA (3 vs 0, $p = 0.09$), CPR (5.8 vs 3.5, $p = 0.18$), ESR (31 vs 19.5, $p = 0.33$), or PETVAS (24 vs 18, $p = 0.31$).

Conclusion: Imaging and clinical assessment of disease activity significantly improved but rarely normalized in response to tocilizumab in GCA and TNF inhibitors in TAK. In contrast, methotrexate did not consistently improve clinical or imaging-based assessments of disease activity in LVV. These findings support a need to study the value of FDG-PET as a surrogate outcome measure of vascular activity in randomized clinical trials in LVV.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously, the GiACTA study demonstrated the superiority of subcutaneous (SC) tocilizumab (TCZ) plus prednisone vs prednisone alone in achieving sustained glucocorticoid (GC)-free remission in patients with giant cell arteritis (GCA)¹. We aimed to evaluate the effectiveness and safety of SC and intravenous TCZ in real-world clinical practice.

Methods: We performed a retrospective analysis of GCA patients treated with TCZ at a single center (MGH) between 2010-2018. Time to disease relapse, number of relapses, prednisone use, and adverse events (AE) before and after TCZ

Figure 1. Time to disease relapse before (A) and after (B) TCZ initiation

Table 1. Patient baseline characteristics and treatments

Age, mean (SD)	69.4 (8.4)
Female sex, n (%)	43 (71.7)
Caucasian ethnicity, n (%)	53 (88.3)
Clinical manifestations at disease onset	
Headache, n (%)	47 (78.3)
Scalp tenderness, n (%)	28 (46.3)
Joint claudication, n (%)	31 (51.7)
Amblyopia/tears, n (%)	11 (18.3)
Transient blurry vision, n (%)	18 (30.0)
Permanent vision loss, n (%)	9 (15.0)
Isotopia, n (%)	2 (3.3)
PMR symptoms, n (%)	32 (53.3)
ESR (mm/hr), mean (SD)	72.8 (33.6)
CRP (mg/L), mean (SD)	78.9 (72.6)
Positive FA biopsy, n (%)	30 (49.3)
Prednisone dose (mg/day) at disease onset, mean (SD)	54 (18.6)
Use of other immunosuppressants before TCZ initiation, n (%) ^a	15 (25)
Duration of disease before TCZ initiation (years), median (IQR)	0.6 (0.2-1.8)
Prednisone dose (mg/day) at TCZ initiation, mean (SD)	30 (18.3)
Received TCZ IV, n (%) ^b	22 (37.3)
Received TCZ SC, n (%) ^b	43 (72.6)
Duration of TCZ treatment (years), median (SD)	0.9 (1.0)
Duration of TCZ treatment (years), median (IQR)	0.5 (0.3-1.4)

CRP = C-reactive protein; ESR = erythrocyte sedimentation rate; IV = intravenous; PMR = polymyalgia rheumatica; SC = subcutaneous; SD = standard deviation; TCZ = tocilizumab.

^a Other immunosuppressants include methotrexate, cyclophosphamide, azathioprine, mycophenolate mofetil, sirolimus, tacrolimus, cyclosporine, and rituximab.

^b No patients received both IV and SC.

Table 2. Clinical outcomes and adverse events

	Off TCZ (N = 60)	On TCZ (N = 60)
Patients with ≥ 1 relapse	47 (78.3)	10 (16.7)
1 relapse	21 (35.0)	6 (10.0)
2 relapses	10 (16.7)	2 (3.3)
3 relapses	8 (10.0)	2 (3.3)
≥ 4 relapses	10 (16.7)	0
Time to relapse (years), median (IQR)	0.51 (0.26-0.75)	2.14 (0.56-2.63)
Patients with ≥ 1 AE, n (%)	34 (56.7)	33 (55.0)
AEs attributed to GC*	50 / 66 (75.8%)	42 / 78 (53.8%)
AEs attributed to TCZ*	NA	28 / 78 (35.9%)
Patients with ≥ 1 SAE, n (%)	9 (15.0)	7 (11.7)
SAEs attributed to GC	5 / 11 (45.5%)	4 / 9 (44.4%)
SAEs attributed to TCZ	NA	3 / 9 (33.3%)

AE = adverse event; GC = glucocorticoids; IQR = interquartile range; NA = not applicable; SAE = serious AE; TCZ = tocilizumab.
* Multiple occurrences of AEs are included. Denominators are all AEs or SAEs.

initiation were assessed. Disease relapse was defined as the re-appearance of clinical manifestations of GCA (e.g., cranial symptoms) that required treatment modification.

Results: A total of 60 GCA patients were included in the analysis. **Table 1** depicts the baseline characteristics and the treatments received by this cohort. The median (IQR) disease duration before TCZ use was 0.6 (0.2-1.6) years. Fifty-eight patients (96.7%) received concomitant prednisone (mean [SD] dose: 30 [18.3] mg daily) at the time of TCZ initiation. Patients received TCZ for a median (IQR) period of 0.5(0.3-1.4) years. While not on TCZ treatment, 47 patients (78.3%) had ≥1 relapse (median [IQR] time to flare 0.5 [0.3-0.8] years). On TCZ, 10 patients (16.7%) had ≥1 relapse (median [IQR] time to flare 2.1 [0.6-2.3] years) (**Table 2, Figure 1**). Twenty-four patients (41.4%) successfully tapered off prednisone during TCZ treatment. The incidence of AEs and serious AEs (SAE) was similar before and after TCZ initiation (**Table 2**). During TCZ treatment, however, 42 out of 78 AEs were considered related or possibly related to prednisone. An AE led to TCZ discontinuation in 5 patients. No deaths occurred during the study period.

Conclusion: In this retrospective analysis, TCZ improved clinical outcomes in patients with GCA as indicated by a reduced incidence of relapses and by the ability to discontinue prednisone. The occurrence of AEs and SAEs (many due to GC) did not differ substantially while patients were on or off TCZ. These real-world findings support the previously reported efficacy and safety profile of TCZ in patients with GCA.

High-Dose Prednisone Use up to 42 Days Prior to Temporal Artery Biopsy (TAB) Did Not Reduce Yield of Positive Biopsy in the Veterans Health Administration (VHA) Database Cohort

Sarah H. Chung¹, Meredith B. Morcos¹ and Bernard Ng^{1,2}, ¹Division of Rheumatology, University of Washington, Seattle, WA, ²Rheumatology, VA Puget Sound Healthcare System, Seattle, WA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Temporal artery biopsy (TAB) currently remains the gold-standard confirmatory test for the diagnosis of giant cell arteritis (GCA); positive TAB justifies long-term steroid use and/or immunosuppression. High-dose glucocorticoids are often briskly initiated when GCA is clinically suspected, even before TAB is obtained, to avoid ischemic complications. Historically, this has raised concern over the effect of glucocorticoids on TAB yield. This study aimed to determine if the duration of prednisone use, dosed at 30 mg or more daily, prior to TAB influenced TAB result in subjects with suspected GCA.

Methods: Subjects with a procedure code for TAB between 1999-2017 were queried through the VHA national database. TAB result (positive or negative, presence of granuloma/giant cells) was reviewed manually; indeterminate results (i.e. inconclusive, healed arteritis) were categorized as negative. Prescription data regarding prednisone dosage and dispense date were also extracted for each subject. Days of prednisone use (≥ 30 mg daily) before TAB were categorized as follows: 0-14, >14-28, >28-42, >42, and prednisone started after TAB. Abnormal ESR and CRP values within 180 days before TAB to 14 days after TAB, as well as age, gender, TAB laterality, and TAB length were also extracted. Logistic regression models were run using Stata.

Results: 3,057 biopsies were reviewed, 306 (10%) of which were deemed positive per pathology report. Prednisone use ≥ 30 mg daily was identified among 2,012 subjects. Of these, 1,474 (73.3%) initiated prednisone within 14 days prior to TAB. The duration of prednisone use before TAB, as a continuous variable, was not influenced by age, TAB length, TAB laterality, or abnormal ESR or CRP values by linear regression. Male gender had a significant negative correlation with prednisone initiation prior to TAB (coefficient -2.97, CI -5.6 to -0.4, $p < 0.05$). After adjustment for gender, there was no association between positive TAB and time of prednisone initiation up to 42 days prior to TAB. Furthermore, prednisone administration up to 42 days prior to TAB did not influence the presence of granulomatous inflammation. Interestingly, positive TAB was significantly associated with prednisone dosed after TAB date, suggesting that a positive TAB prompted the provider to initiate treatment. Additionally, there was no significant correlation between a positive TAB and abnormal ESR or CRP values within 180 days pre- and 14 days post-TAB after correcting for pre-TAB prednisone exposure.

Conclusion: This is the largest retrospective study to date showing that prednisone ≥ 30 mg daily initiated up to 42 days prior to a TAB did not influence biopsy yield. This study also demonstrated that abnormal ESR or CRP values prior to TAB were not associated with positive TAB even after corrections for pre-TAB prednisone usage, suggesting that these inflammatory markers may not be independently helpful in the diagnosis of GCA.

Abstract Number: 2762

A Longer or Bilateral Temporal Artery Biopsy (TAB) Is More Likely to Yield a Positive Result for Giant Cell Arteritis (GCA) in the Veterans Health Administration (VHA) Database Cohort

Sarah H. Chung¹, Meredith B. Morcos¹ and Bernard Ng^{1,2}, ¹Division of Rheumatology, University of Washington, Seattle, WA, ²Rheumatology, VA Puget Sound Healthcare System, Seattle, WA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: TAB is currently considered the gold standard for the diagnosis of GCA. However, it is suspected that the sensitivity of TAB is limited by the segmental nature of the artery involvement in this condition. Expert opinion for obtaining TAB recommends an initial unilateral approach with an attempt to obtain at least 10-20 mm of artery, followed by the pursuit of the contralateral side if initial biopsy is negative and clinical suspicion remains high. Several smaller retrospective studies have not reached a consensus with regards to the optimal length of TAB. This study aimed to determine if length of TAB or initial bilateral TAB impacted the yield of positive TAB result in the national VHA cohort.

Methods: Subjects with a procedure code for TAB between 1999-2017 were queried through the VHA national database. TAB reports (positive, negative) were reviewed manually; indeterminate results (i.e. inconclusive, healed arteritis) were categorized as negative. The following data was extracted: 1) post-fixation TAB length 2) whether bilateral TAB was performed in one sitting 3) age at TAB 4) gender. TAB length categories were organized as follows: ≤ 10 mm, 10 to ≤ 15 mm, 15 to ≤ 20 mm, 20 to ≤ 25 mm, 25 to ≤ 30 mm, and ≥ 30 mm. Multivariate analyses and logistic regression models were run using Stata.

Results: A total of 3,057 biopsies were reviewed; 306 (10%) were deemed positive per pathology report. The likelihood of a positive TAB significantly correlated with TAB length greater than 30 mm (OR 1.65, CI 1.06-2.57, $p < 0.05$ when compared to a reference category ≤ 10 mm) as well as with bilateral biopsy in one sitting (OR 2.05, CI 1.43-2.94, $p < 0.01$), suggesting higher yield with longer or initial bilateral biopsies. The likelihood of a positive TAB was incrementally higher with longer biopsies. Positive TAB also significantly correlated with age greater than 70 years (OR 1.9 in the age 61-70 group, CI 1.0-3.7, $p = 0.07$; OR 4.2 in the age 71-80 group, CI 2.2-8.3, $p < 0.01$; OR 6.0 in the age ≥ 80 group, CI 3.1-11.6,

p<0.01 when compared to a reference category aged 51-60 years). Neither gender or age influenced TAB length or the likelihood that bilateral TAB was performed.

Conclusion: This is the largest retrospective study to date examining the relationship between TAB length and yield. Longer length of biopsy (≥ 30 mm) was more likely to yield a positive TAB. Additionally, initial bilateral TAB was twice as likely to yield a positive result compared with unilateral TAB. These observations may be explained by “skip lesions” that can lead to false-negative results with shorter TAB. Overall, these findings suggest that higher yield of TAB might be achieved with longer or initial bilateral biopsies.

Utility of Serum Free Light Chains, Antiphospholipid Antibodies, and Cytokines in Giant Cell Arteritis

Matthew J. Koster¹, Melissa Snyder², Michel Villatoro-Villar¹, Cynthia S. Crowson³, Tanaz A. Kermani⁴ and Kenneth J. Warrington⁵, ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Mayo Clinic, Rochester, MN, ³Department of Health Sciences Research, Mayo Clinic, Rochester, MN, ⁴Medicine, Division of Rheumatology, David Geffen School of Medicine, UCLA, Los Angeles, CA, ⁵Rheumatology, Division of Rheumatology, Mayo Clinic College of Medicine, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the utility of serum free light chains (FLC), antiphospholipid antibodies (APL), and cytokines in the evaluation of patients with biopsy-proven giant cell arteritis (GCA).

Methods: We conducted a cross-sectional study of 75 patients with biopsy-proven GCA. Sera were evaluated for the presence and quantity of the following biomarkers: serum FLC [kappa, lambda], anticardiolipin antibodies (ACL; IgM/IgG), beta-2 glycoprotein antibodies (β 2GP; IgM/IgG), *antiphosphatidylserine*-prothrombin antibodies (PS-PT; IgM/IgG), and 20 circulating cytokines (GCSF, GMCSF, IFN γ , IL-1b, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12p40, IL-12p70, IL-13, IL-17, MCP-1, TNF α , TNF β and VEGF). Quantification of serum FLC was obtained by nephelometric assay. ACL, β 2GP, and PS-PT antibody levels were determined via enzyme-linked immunosorbent assay. Cytokines were measured with a fluorescent microsphere-based assay. Rank sum test was used to compare biomarker levels between patients with active and inactive GCA, patients with and without large vessel vasculitis (LVV), patients with and without visual ischemia. Associations between biomarker levels and ESR/CRP were examined using Spearman correlation methods.

Results: The study included 60 (80%) women and 15 (20%) men. Mean age at inclusion was 75.0 ± 7.3 years. Clinically active disease was present in 28 (37%) and 47 (63%) were clinically inactive at time of sera collection. LVV was identified radiographically in 29 (39%) and visual ischemia occurred in 19 (25%). At time of sera collection, no significant difference in prednisone dose was observed between the evaluated groups. APL were infrequently detected: 13 ACL IgM weak(+); 1 ACL IgM(+); 6 ACL IgG weak(+); 1 β 2GP IgM(+); 3 β 2GP IgG weak(+); 5 PS-PT IgM(+); 2 PS-PT IgG(+). No significant differences between the presence and the level of APL were observed between the evaluated groups. Elevated kappa FLC levels were present in 35 (74%), elevated lambda in 4 (5%), and elevated kappa/lambda ratios in 14 (19%). There was no difference between serum FLC or kappa/lambda ratios between comparison groups. Serum FLC and APL had weak to moderate correlation with ESR/CRP.

Cytokine levels of IL-6, IL-8, and VEGF were significantly higher in active patients compared to inactive patients (p<0.05). No differences between APL, serum FLC, or cytokines were observed between patients with and without LVV. Patients with visual ischemia had significantly higher cytokine levels of GCSF, GMCSF, IFN γ , IL-10, IL-12p70, IL-13, IL-1b, IL-2, IL-4, IL-5, IL-6, TNF α compared to those without visual ischemia. The highest correlations (r_s) among individual cytokines with ESR/CRP were observed with IL-6 (0.42), IL-7 (0.42), IL-8 (0.46), and IL-17 (0.43).

Conclusion: In this study, APL and serum FLC were not useful in determining the level of disease activity or differentiating between patients with or without LVV or visual ischemia. A distinct cytokine profile was observed in patients with visual ischemia compared to those without. Prospective studies are needed to determine the role of these cytokines as biomarkers of visual ischemic complications in patients with GCA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is an immune-mediated, primary systemic vasculitis that affects large and medium-sized arteries. GCA may cause vision loss in up to 20% and requires long term glucocorticoids (GCs). There are currently few data available in France on the epidemiology, patients' (pts) characteristics, diagnosis and management of GCA in a real-world setting. The objectives of this study were to address these questions using Health insurance claims data.

Methods: This retrospective cohort study used the EGB (*Echantillon Généraliste des Bénéficiaires*) database, a 1% random and representative sample of the French national Health insurance system. The EGB database contains anonymous demographic and comprehensive medical data on conditions with long-term disease (LTD) status, hospitalizations and reimbursement claims for medications dispensed in the community. The study used data collected between Jan 1, 2007 and Dec 31, 2015. Inclusion criteria were: 1) age ≥ 50 years; 2) hospitalization for GCA or LTD status for GCA (ICD-10 codes: M31.5/6); and 3) ≥ 4 drug dispensing of oral GCs within 6 months around the index date. The index date was defined as the date of 1st occurrence of GCA code and cases were considered as incident if the GCA code first occurred after ≥ 2 years of follow-up. Demographics, co-morbidities, diagnostic tests and therapies were analysed. A treatment sequence was defined as the start of a new drug or the resumption of the same drug after a stop ≥ 3 months. Prevalence and annual incidence were calculated by using the people recorded in the database as denominator.

Results: Among the 752717 people recorded in the EGB, 241 pts fulfilled our criteria. Prevalence was 150/100000 people ≥ 50 years-old. Around 24 pts were newly diagnosed/year with an annual incidence of 7-10/100000 people ≥ 50 years-old. 72% of the 241 pts were females, mean age was 77.5 (± 8.9) and mean follow-up 3.7 (± 2.6) years. In the 12 months before index date, 74.3% of the pts had ≥ 1 proxy for hypertension, 39.4% for depression/insomnia and 33.6% for osteoporosis. After index date, temporal artery biopsy (TAB) was performed in 43.2%, high-resolution Doppler ultrasound of the temporal arteries in 35.3% and 18FDG-PET in 11.6%. Among the 235 pts (97.5%) who had ≥ 1 drug dispensing of oral GCs, 198 pts (84.3%) used only GCs while 37 (15.7%) also received 1 to 3 adjunctive agents. Mean 1st GCs sequence duration was 17.2 months (± 16.5) in 96.6%. 95 pts (40.4%) had a 2nd sequence, i.e. resume GCs and or start a new drug for a duration of 6.7 months (± 8.1) for GCS alone or 12.2 months (± 8.8) for GCs + adjunctive drug. The most commonly prescribed adjunctive agent was MTX (12.0%). Use of other adjunctive drugs was marginal: hydroxychloroquine 7 pts, azathioprine 4, cyclophosphamide 1, infliximab 1, adalimumab 2 and etanercept 1 pt.

Conclusion: These real-world data indicate an incidence of GCA in France of 7-10/100,000 people ≥ 50 years-old and underline that most patients with GCA are treated with GCs alone whereas adjunctive agents, mainly methotrexate, are given to 15% of patients. The utilization of TAB in only half of the patients might reflect a shift towards increasing use of imaging techniques to diagnose GCA.

Thyroid Artery Involvement Detected By Colour-Doppler Ultrasonography in an Incipient, Single Centre Giant Cell Arteritis Cohort

Rok Jese, Ziga Rotar, Matija Tomsic and Alojzija Hočevar, Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The inflammation of thyroid arteries (ThA) is not commonly considered and investigated in giant cell arteritis (GCA). We aimed to estimate the frequency of ThA involvement as detected by Colour Doppler Sonography (CDS).

Methods: We conducted a prospective single center study between 1 October 2013 and 30 March 2018. The CDS of superior and inferior ThA was performed in all newly diagnosed, treatment naive GCA patients, in addition to the routinely evaluated temporal, facial, occipital and large supra-aortic arteries. The superior and inferior ThA were identified at their respective anatomical locations in close proximity to the thyroid gland and examined using the standard Doppler settings for temporal arteries. Arteries were evaluated in two planes for the highly specific *halo* sign. Laboratory thyroid function tests consisted of TSH, T3 and T4 measurements at the time of GCA diagnosis (prior to any steroid therapy). Characteristics of GCA cases with inflamed ThA were explored and compared to the GCA group without ThA involvement.

Results: During the 54 months we performed the CDS of the multiple arteries in 153 consecutive GCA patients (median age 75.2 (IQR 66.5–80.0) years, 63% female). We observed the halo sign on either superior or inferior ThA in 16 (10.5%) cases. All patients but one (15/16) with ThA involvement also had CDS signs of temporal artery involvement and 2/16 patients (12.5%) had CDS signs of large supra-aortic artery involvement.

Constitutional symptoms were reported significantly more often by the patients with ThA involvement (100% vs. 73%, $p=0.013$); specifically, fever was significantly more frequent (44% vs. 19%, $p=0.047$). No significant correlation was found between ThA involvement and other clinical or demographic characteristics, including headache, jaw claudication and visual disturbances.

Local symptoms consistent with thyroid gland pathology were reported by 4/16 patients (25%) with ThA involvement. Laboratory signs of thyroid dysfunction were found in 3/16 patients (19%) with ThA involvement (2 latent hyperthyroidism, 1 latent hypothyroidism); none of these patients had any previous history of thyroid disease. Previous history of thyroid disease was noted in 19 (12%) out of all GCA patients (13 hypothyroidism, 1 hyperthyroidism, 2 euthyrotic goiter; 3 patients had thyroid surgery because of either goiter or suspected malignancy). Two of those patients also had CDS signs of ThA involvement, yet their thyroid function tests were normal at the time of GCA diagnosis.

Conclusion: In our incipient GCA cohort, a tenth of all patients had ultrasonographic signs of ThA involvement. GCA patients with ThA involvement had a higher prevalence of constitutional symptoms than those without ThA inflammation.

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether there is a seasonal peak onset of giant cell arteritis (GCA). We examined the seasonal variability of GCA in a geographically-defined population.

Methods: In a geographically defined population, we retrospectively identified all incident cases of GCA between January 1, 1950, and December 31, 2009. Detailed review of all individual medical records was performed. All included patients met the 1990 ACR criteria for classification of GCA. Seasonal variation was compared using quasi-Poisson regression models to account for overdispersion.

Results: The cohort included 248 cases of incident GCA (79% female; mean age 75.6 years). Overall, patients in this cohort were more likely to have incident GCA in the summer season with age- and sex-adjusted incidence rates (per 100,000 population) of 5.5 for summer compared with 4.7 for winter, 3.9 for spring and 4.3 for autumn, but this difference did not reach statistical significance ($p=0.19$). However, subgroup analysis by decade revealed that incidence of GCA was significantly highest ($p=0.018$) in the summer season and lowest in the spring during 1995-2009 with an age-adjusted and sex-adjusted incidence rate per year 100,000 of 6.8 compared with winter (4.9), spring (2.7) and autumn (5.0) [Figure].

Figure. GCA incidence rates by season and decade (1950-79 open circles, 1980-94 squares, 1995-09 filled circles) among Olmsted County, Minnesota residents in 1950-2009

Conclusion: Incident GCA is more common in the summer season and least common in the spring. This pattern is more pronounced in recent years. Further research needs to be done in order to understand whether these findings provide insights regarding the etiology of GCA.

Herpes Zoster As a Risk Factor for Polymyalgia Rheumatica: A Population-Based Study

Shafay Raheel¹, Cynthia S. Crowson² and Eric L. Matteson³, ¹St. Joseph's Hospital, Chicago, IL, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of varicella zoster virus (VZV) signal in the temporal arteries of patients with giant cell arteritis has suggested a possible role of VZV in triggering the immunopathology of GCA. This calls into question whether VZV may also play a role in the development of polymyalgia rheumatic (PMR). We aimed to determine whether herpes zoster (HZ) infection is a risk factor for PMR.

Methods: All incident cases of PMR in a geographically-defined area diagnosed between 1990 and 2014 were identified. For each patient with PMR, a non-PMR control subject matched on age and sex was randomly selected from the same underlying population. Each control was assigned an index date corresponding to the PMR incident date of the matched case. The medical records of all patients with codes for HZ were reviewed to confirm the incident date and diagnosis.

Results: The study included 541 patients with PMR and 541 subjects without PMR. The average age at PMR incidence (index date for the non-PMR cohort) was 74 years, and 349 (65%) subjects were female in each cohort. Prior to index date, 61 (11%) patients with PMR and 62 (11%) non-PMR patients had HZ infection ($p=0.92$).

Conclusion: Herpes zoster infection was not associated with an increased risk of PMR. Further work is needed to determine the etiology of PMR.

Disclosure: S. Raheel, None; C. S. Crowson, None; E. L. Matteson, None.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Patients with giant-cell arteritis (GCA) and polymyalgia rheumatica (PMR) are treated with high cumulative glucocorticoid (GC) dose during their disease course. We sought to determine the accrual of comorbidity as well as survival in patients with GCA and PMR.

Methods: We conducted a retrospective follow-up study of an inception cohort of patients diagnosed with GCA and PMR according to ACR criteria and persistently followed at our rheumatology clinic from January 1990 until March 2018. Disease manifestations, time duration of GC dose tapering and discontinuation as well as calculated cumulative GC dose were determined. Baseline and last encounter age-adjusted Charlson Comorbidity Index (CCI) and Rheumatic Disease Comorbidity Index (RDCI) as well as the increment (Δ) of CCI and RDCI at the last study encounter were scored. Mortality rate and cause were recorded.

Results: The cohort consisted of 69 patients (24 GCA and 45 PMR, 68.1% female). Mean age at diagnosis was 71.38 ± 5.58 years and 74.53 ± 9.67 for GCA and PMR, respectively. The mean daily initial prednisone dose for GCA was 61.25 ± 11.91 mg and for PMR 18.11 ± 7.85 mg ($p < 0.001$), and prednisone cumulative dose was $13,382.19 \pm 6189.21$ mg and $6,610.36 \pm 4,755.55$ mg for GCA and PMR, respectively ($p < 0.001$). Systemic symptoms such as fever and weight loss as well as ESR at diagnosis were comparable in GCA and PMR. Time duration until achieving 50% and 25% of the initial prednisone dose was longer for patients with PMR vs. GCA (3.87 ± 2.22 months vs. 3.02 ± 1.15 months, $p = 0.049$ and $p = 0.03$, respectively), however, the disease duration until achieving daily prednisone dose of 7.5 mg and 5 mg was longer in the GCA group (9.88 ± 3.08 months vs. 4.4 ± 2.4 months, $p < 0.001$, and 12.85 ± 6.35 months vs. 7.28 ± 7.48 months, $p = 0.005$, respectively). Nevertheless, the time duration to discontinuation of prednisone and prednisone-free survival did not differ among GCA and PMR patients, as well as the time duration to the first disease flare. Disease remission rate for the entire cohort was 28.9% for a follow-up period of 7.5 ± 3.9 years (range: 2.4 – 16.9 years). The CCI and RDCI scores for GCA at diagnosis and at the last study encounter did not differ between GCA and PMR groups. Interestingly, initial prednisone dose, time to achieving 50% and 25% of initial prednisone dose, time to daily prednisone dose of 7.5mg and 5mg as well as time to prednisone discontinuation and prednisone-free survival did not differ when comparing $\Delta CCI \geq 1$ and $RDCI \geq 1$ with $\Delta CCI = 0$ and $RDCI = 0$, respectively. Mortality rate did not differ between GCA and PMR groups: 5-, 10-, and 15-years survival were 62.5% and 71.1%, 25% and 24.4%, and 8.33% and 4.44%, respectively. Comorbidity was associated with higher mortality rate: CCI and RDCI at diagnosis (HR 1.9, CI 95% 1.3-2.6, $p = 0.0002$ and HR 1.7, CI 95% 1.2-2.2, $p = 0.004$, respectively) and at last study encounter (HR 1.4, CI 95% 1.3-2.6, $p = 0.0002$ and HR 1.5, CI 95% 1.04-2.1, $p = 0.03$, respectively).

Conclusion: Despite significant higher cumulative dose of prednisone for patients with GCA compared to patients with PMR, comorbidity scores and mortality rate are comparable. Our results emphasize the unmet need for novel steroid-sparing drugs in PMR as well as in GCA.

A Single Center Experience of Temporal Artery Biopsies Performed in 30 African American Patients

Ammar Haikal¹, Garth Fraga², Jason Springer¹ and Mehrdad Maz³, ¹Department of Internal Medicine, The University of Kansas Medical Center, Division of Allergy, Clinical Immunology & Rheumatology, Kansas City, KS, ²The University of Kansas Medical Center, Department of Pathology and Laboratory Medicine, Kansas City, KS, ³Allergy, Clinical Immunology, and Rheumatology, Division of Allergy, Clinical Immunology and Rheumatology, Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a systemic vasculitis of large and medium-sized arteries mostly reported in Caucasians (CCs) over 50y.o. There is limited data in the literature on the incidence of GCA in patients of African descent. Here, we view the incidence of GCA based on temporal artery (TA) biopsies in a comparatively large cohort of African-American (AA) patients.

Methods: This is a retrospective chart review of patients (pts) who underwent TA biopsies (TABs) for suspicion of GCA between 1/1/1997 and 1/31/2018 at a tertiary medical center in USA. Cases were identified by searching the pathology database at our institution. Terms used in the search included temporal artery, temporal arteritis, giant cell arteritis, and borderline arteritis. Self-reported demographics were obtained from the charts. Glass slides from 2 AA pts with a positive pathology report for GCA were reviewed by a pathologist to confirm positivity based on histopathologic features for GCA. Comparisons were made with Fisher Exact Test, using two-tailed test with < 0.05 considered significant.

Results: 200 pts with TABs were identified (Table 1). Of these 30/200 (15%) were AA with a total of 33 TABs (3 bilateral). The median age of diagnosis was 66.5 (range 45-90), and 23/30 (75.66%) were female. Although 2/30 (6.7%) were originally reported as positive for GCA, upon review by the pathologist, one was consistent with small vessel vasculitis with fibrinoid necrosis, and the other did not have histopathologic features of GCA. In contrast, 25/155 (16%) CC pts had positive TABs with a median age of 76 (range 56 - 87) and 98/155 (63.22%) were female. The remaining 15/200 pts were of other ethnicities of whom 2 had positive TABs. GCA was less frequent in AAs than CCs based on TAB ($P=0.0163$). Only 3 AAs were seen by a rheumatologist before biopsy as most of the biopsies of AA pts were requested by ophthalmologists, neurologists and primary care physicians. Reasons for biopsy referral among AAs were headache; 24/26 (92%), Scalp tenderness; 9/17 (53%), jaw claudication; 3/13 (23%), and vision loss; 6/21 (28.6%). 14/25 (56%) AA pts had ESR > 50 mm/hr, and 19/22 (86.4%) met 3/5 ACR classification criteria for GCA.

Conclusion: This is one of the largest reported case series in the literature of TA biopsies (TABs) performed in patients of African descent in a single institution in North America. Pathological features of GCA were not present in any TABs in this cohort of 30 African-American (AA) pts. Our data correlates with the clinical observation that GCA usually presents in Caucasians and is rare in AAs. The suspicion and diagnosis of GCA should be made with caution in AA pts. Awareness of this among other specialists and primary care physicians may reduce the need for performing unnecessary TABs.

TABLE 1

Ethnicity	Number of patients with Temporal artery biopsy (total 200)	Median Age at biopsy (range)	Female Gender (F)/total (%)	Biopsy consistent with GCA N/(%)	P-Value by Fisher Test (compared to Caucasians)
Caucasians	155	76 (56 - 87)	98/155 (63.22%)	25/155 (16%)	REF
African-Americans	30	66.5 (45 - 90)	23/30 (75.66%)	0/30 (0%)	0.0163

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The effects of metabolic syndrome on vasculature are complex, and studies exploring the role of metabolic syndrome (including diabetes mellitus, obesity, hypertension, and hyperlipidemia) in the development and progression of giant cell arteritis (GCA) have been inconclusive. The objective of this retrospective study was to investigate how preexisting metabolic syndrome disorders impact the disease course, and if those with one or more disorders would require higher total cumulative steroid dose to achieve remission.

Methods: We identified GCA patients based on electronic medical record review using appropriate ICD-10 diagnosis codes. 51% of patients met ACR criteria for GCA. Selection criteria included time frame of 2008 – 2018, and actively being followed at our rheumatology clinics. We collected demographic, clinical, laboratory, imaging and histopathologic data for patients at the time of diagnosis through chart review. We used descriptive statistics for patient characteristics, and used regression analysis to investigate potential associations between metabolic syndrome disorders and total cumulative steroid treatment. Stepwise regression was used to determine the optimal regression model. We evaluated for potential confounding factors including age, gender, race and methotrexate (MTX) use.

Results: Our study population (n =35) was predominantly Caucasian (67%) and female (74%) with mean age at diagnosis of 62.4 ± 12.8 years. Metabolic syndrome was prevalent at or prior to the time of diagnosis in our group: 60% had hypertension, 23% had diabetes, 43% had hyperlipidemia and 43% were obese. Only two patients did not have any metabolic syndrome disorders. All patients received prednisone since their diagnosis, and 40% received MTX during their disease course. The mean total prednisone dose was 6780 ± 6457 mg. Regression analysis of individual metabolic disorders showed only significant association between hypertension and prednisone dosage, where on average, those with hypertension received 5986 mg less total prednisone ($t = -2.249$, $p = 0.033$). This result was not altered when accounting for age of onset, gender and race ($t = -2.180$, $p = 0.040$). However, when accounting for MTX use in subgroup analysis, the association between hypertension and total prednisone was no longer significant ($t = -1.380$, $p = 0.217$ with MTX; and $t = -1.198$, $p = 0.256$ without MTX). Stepwise regression of hypertension, age, gender, race and MTX use yielded a model including only hypertension and MTX. Stepwise regression including all metabolic syndrome diseases and potential confounders yielded a model including diabetes, obesity, hyperlipidemia, hypertension and MTX, where hypertension was the only variable significantly associated with prednisone dose ($t = -2.550$, $p = 0.021$).

Conclusion: Although a small cohort, our study population was similar in distribution when compared to larger cohorts studied previously. Contrary to our hypothesis, there were no metabolic disorders that were associated with significantly higher doses of cumulative prednisone dose. Further studies with larger study populations are needed to elucidate the complex interactions between metabolic syndrome and GCA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis affecting individuals over 50 years of age. Multiple epidemiological studies have determined increased risk of cardiovascular diseases (CVD) in GCA. There are no guidelines to assess CV risk in GCA. The study objective was to review current practice of monitoring CV risk in GCA by rheumatologists in a single center academic rheumatology practice.

Methods: Retrospective chart review of patients diagnosed with GCA was conducted. Data included demographics, comorbid conditions including CVD, obesity, diabetes mellitus (DM), hypertension (HTN), hyperlipidemia (HLD), tobacco use, and physician intervention for CV risk reduction which was defined as measuring lipid profile (LP), use of antiplatelet agent, smoking cessation counseling, lifestyle modification counseling defined as education on healthy diet, exercise, and weight loss. LP measurement was either done at rheumatologists' office or documented as done outside by primary care physician or cardiologist. We used backward elimination logistic regression to assess associations between the likelihood of physician intervention for CV risk reduction, with respect to age, gender, presence or absence of CV risk factors (BMI, tobacco use, DM, HTN, HLD), and prior CVD. HLD was defined as per American College of Cardiology 2013 guidelines.

Results: 148 patients with GCA were seen from 2008 - 2017. The majority of patients were female (111, 75%) with median age of 75 (range 51-93) years. Prevalence of HTN, HLD, CVD, and DM was 72% (n=106), 53% (n=79), 34% (n=50), and 21% (N=31), respectively. Few patients were active smokers (13, 9%) but many were overweight/obese (93, 64%). LP was assessed at least once in only 18% (n=26) patients, and 43% (n=63) were taking a statin. 67% (n=99) patients were on antiplatelet or anticoagulation (AC) therapy. Lifestyle modification counseling was documented in 45% (n=67) patients. Smoking cessation was discussed in 31% smokers. Among the patients with prior CVD, 82% (n=41) were on antiplatelet/AC; 14% (n=7) had LP assessed; and lifestyle modification counseling was documented in 36% (n=18). Male gender and high BMI were associated with higher likelihood of lifestyle modification counseling, (OR 3.4; 95% CI 1.2-10.2) and (OR 1.16; CI 1.1-1.3), respectively. Measuring LP was more common in men (OR 5.2; 95% CI 1.4-19.5) and in subjects with HLD (OR 32.1; 95% CI 6.0-172.1).

Conclusion: This single center study identified potential areas of improvement in the monitoring of CV risk in patients with GCA. Assessment of lipid profile, lifestyle modification counseling, and smoking cessation were infrequently performed or documented in patients with GCA. The likelihood of physician intervention for CV risk reduction was associated with presence of traditional CV risk factors rather than consideration of GCA as a strong independent risk for CVD. Developing guidelines to monitor CV risk in GCA will be useful for clinicians and may help to reduce CV morbidity and mortality in this population.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Cardiovascular risk in systemic vasculitis may be higher than in normal population, but there is scarce data. Ethnic component plays a role on certain components of the disease and prevalence data on cardiovascular events vary worldwide. Our objective was to compare incidence rates of cardiovascular events (CVE) in patients with giant cell arteritis (GCA) with matched controls from a university hospital-based health management organization (HMO).

Methods: All GCA patients (fulfilling ACR 1990 criteria) diagnosed after the year 2000 from the HMO and age and sex matched controls (1:2) were included. The follow-up period began at the index date, defined as the date of GCA diagnosis for GCA patients and the date of the first medical claim at the HMO for the non-GCA patients. Patients with history of cardiovascular events before diagnosis of GCA and controls with CVE before its correspondent case date of diagnosis were excluded. Subjects were then followed until they voluntarily left the HMO, a CVE occurred, the end of study (May 1st 2018), or death. Electronic medical records were manually reviewed and demographic, clinical and treatment data were collected. Incidence rates per 1000 person-years (PY) of each CVE after index dates were calculated and compared between groups. A multivariate cox regression analysis was performed to identify factors associated with CVE.

Results: 105 GCA patients and 210 controls were included and contributed 1276.9 and 1735.3 PY of follow up respectively. Patients' characteristics are shown in table 1. Use of aspirin and diabetes were more frequent in GCA than in controls. Overall CVE incidence rate was similar between groups: 18.0 per 1000 PY in GCA patients (95% CI 12.3-25.4) and 14.4 per 1000 PY in controls (95% CI 9.9-20.6), $p=0.22$. Development of a thoracic aneurism was significantly more common in GCA patients (6.6 per 1000 PY, 95% CI 3.3-12.7, versus 2.3 per 1000 PY, 95% CI 0.9-6.1, $p=0.04$). Other CVE occurred at similar rates in both groups. In the multivariate cox regression analysis, after adjusting for traditional risk factors, a diagnosis of GCA was not associated with more cardiovascular events and only male sex was associated with an increased CV risk (OR 2.04, 95% CI 1.06-3.95, $p=0.03$). Treatment with statins was protective (OR 0.38, 95% CI 0.18-0.80, $p=0.01$).

Conclusion: As previously described, we found an increased risk of thoracic aneurism in GCA patients in comparison with matched controls. Other CVE were similar across groups.

	GCA patients(n=105)	Controls(n=210)	p
Age, years, media (SD)	75.5 (11.4)	73.4 (8.9)	0.08

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant-cell arteritis (GCA) is the most common vasculitis. Specialists have formulated recommendations on how to manage a patient with a possible diagnosis of GCA. However, general practitioners' (GPs) and internal medicine or rheumatology specialists' practices may differ from those recommendations.

Methods: We conducted an opinion survey to determine how they would hypothetically diagnose and manage a suspected case of GCA in France, based on 2 very short "case-vignette" clinical case descriptions, each representing a situation more-or-less typical of GCA, followed by multiple- or single-choice questions. Questionnaires were emailed via the French doctors' Medical Association, and French societies of internal medicine (SNFMI) and rheumatology (SFR).

Results: Between November 2016 and March 2018, 967 GPs and 485 specialists returned their completed questionnaires. Respectively, >46% and 96%, reported having had a confirmed GCA case in consultation. Hypothetical responses, expressed as the % of cases, are how these doctors think they would react to the described cases. Among GPs, 49.1% would systematically refer the patient to a specialist. GPs would initially diagnose 32.1% and prescribe glucocorticoids (GCs), for the most typical GCA case ($P<0.05$), without any visual complications ($P<0.05$). GPs with a prior suspected-GCA case would start GCs more often ($P<0.05$). GPs would start GCs for 40.6%, at 1 mg/kg/day for 66.4% of them, and set up a temporal artery biopsy (TAB), within a mean of 7–15 days for 78.8%, and imaging studies for 10.2%, mainly TA-color duplex ultrasonography (TA-CDU) for 77.5%. GPs would prescribe antiplatelet drugs for 17.8%. Internal medicine and rheumatology specialists would order a TAB for 80.6%, within a mean of 4–7 days, and imaging investigations for 16.2%, mainly TA-CDU (68.8%) or PET scan (43.9%). Among specialists starting GCs, the preferred dose would be 0.7 mg/kg/day for 46.9%. Specialists would prescribe antiplatelet drugs to 51.7%. Among GPs and specialists who would start GCs, TABs would be ordered for similar percentages of cases, but specialists did so earlier ($P<0.05$). GPs and specialists prescribed GCs based only on clinical findings for 14.1% and 8.7%, respectively. GPs would not order a TAB, considering it too complicated to set up, for 67%. Specialists used imaging more often to diagnose GCA ($P<0.05$). Finally, GPs would prescribe significantly higher GC doses ($P<0.05$).

Conclusion: Based on survey findings for 2 hypothetical cases, nearly a third of GCA cases would be managed by GPs alone. GPs and specialists would prefer TAB as the diagnostic test and TA-CDU as the imaging modality, and neither group would seek confirmation for 14.1% or 8.7%, respectively. Daily GC doses and antiplatelet-drug prescriptions would differ between GPs and specialists.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials have shown the efficacy of Methotrexate (MTX) in giant cell arteritis (GCA) but it is necessary to corroborate these results in real life. The purpose of our study was to assess the incidence and the risk of ischemic relapses in GCA patients treated with and without MTX in clinical practice.

Methods: We performed a retrospective longitudinal observational study. Patients: all GCA patients diagnosed between January 1991 and September 2013 and followed at the Rheumatology department of Hospital Clínico San Carlos until loss of follow up or September 2014. Main outcome: relapses by ischemic event (RIE) defined by the presence of this three circumstances after having achieved an improvement: 1) *clinically:* mandibular claudication, visual manifestations (blurred vision, diplopia, transient or permanent loss of vision), cerebrovascular accident, ischemic heart disease or claudication of limbs, 2) *laboratory test:* increase in the erythrocyte sedimentation rate (ESR) and 3) *treatment:* need to increase corticosteroids (at least 10 mg over the previous dose). Independent variable: exposure to MTX over time. Secondary variables: sociodemographic, clinical and treatment. Statistical analysis: RIE rates were assessed by survival techniques, expressing the incidence per 100 patients-year with their 95% confidence interval [CI]. The influence of MTX on the REI was analysed by multivariate Cox regression models. Results were expressed as Hazard ratios (HR) with their respective CI.

Results: 168 patients were included with a follow-up of 675.6 patients-year. 80.4% were women (mean age: 76.8±7 years). The most prevalent comorbidities were arterial hypertension (64%), dyslipidaemia (34%) and cardiovascular disease (30%). The most common clinical GCA symptoms at diagnosis were headache (87.4%), systemic involvement (55%) and polymyalgia rheumatica (49.7%). At baseline, ESR was 78 ± 30.9 mmHg and the haemoglobin level was 12.06 ± 1.58 mg/dL. 46.4% patients had a positive biopsy and 64% received MTX (mean dose: 10 mg) during follow-up. The mean initial dose of corticosteroids was 50.7 ± 15.5 mg. There were 21 RIE in 20 patients with a frequency of 12.5% and the median time to first RIE was 1.1 [0.4-5.1] years. The main cause of RIE was visual manifestations (61.9%). The incidence of RIE was 3.1 [2.0-4.8], being 1.92 [0.8-4.6] in patients exposed to MTX and 3.8 [2.4-6.3] in those without MTX. The incidence of REI in women was 3.4 [2.2-5.5] and in men was 1.9 [0.6-6]. In the multivariate analysis after adjusting by age, sex, disease activity and calendar time, exposure to MTX (HR 0.3 [0.1-0.9]; p = 0.048) had less risk of RIE compared to no exposure to MTX.

Conclusion: In our cohort, the frequency of REI was 12.5% and the incidence 3.1 per 100 patients-year with a median time to first REI of 1.1 years. The main cause of REI was visual manifestations. In patients with MTX, the incidence of REI was half that of patients without MTX (1.92 vs 3.84). With the results observed in this study, we can consider that the use of MTX decreases the risk of developing REI.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been demonstrated to correlate with disease activity and predict treatment response in rheumatic diseases including rheumatoid arthritis and SLE. Are liable and readily accessible biomarker that fulfils these roles has not been identified in polymyalgia

rheumatica (PMR). This study evaluated the relationship between NLR and PLR, and disease activity and glucocorticoid resistance in PMR.

Methods: Data for disease activity (as measured by the PMR-Activity Score [PMR-AS]), prednisolone dose and full blood count was obtained from the Melbourne Predictors of Relapse in PMR (MPR-PMR) study: a prospective observational cohort comprising 37 patients (35 steroid naïve) with newly diagnosed PMR (2012 EULAR/ACR Classification Criteria) treated with a standardised weaning course of prednisolone (British Society of Rheumatology Guideline) for the duration of follow-up (46 weeks) or until the addition of a steroid-sparing agent was indicated. Prior ethics approval was received from Austin Health Research Ethics Committee and the trial registered with the Australian and New Zealand Clinical Trials Registry (trial identification ACTRN1261400696695). Glucocorticoid resistance was defined as non-response to initial prednisolone dose (15mg/day) or initial response followed by flare (as defined by PMR-AS ≥ 9.35 or $\Delta \geq 6.6$) upon weaning prednisolone to 5mg/day. Univariable linear regression analysis of the relationship between PMR-AS (baseline and mean) and NLR and PLR was performed, with comparison of glucocorticoid-resistant patients to glucocorticoid-responders undertaken using logistic regression on baseline NLR. All statistical analysis was performed using R version 3.5.0.

Results: Complete data was available for 33/37 patients (89.2%). Mean age was 69.2 ± 7.53 years, 54% were male and 97% Caucasian. Median ESR was 46 (29 – 65) and CRP 40.2 (19 – 64.4) at diagnosis, whilst median PMR-AS was high at 68.7 (49.7 – 98). A statistically significant relationship was identified between PMR-AS and both NLR ($p = 0.025$) and PLR ($p = 0.005$) at baseline. PLR correlated with mean PMR-AS during follow-up ($p = 0.033$), whilst there was a trend towards significance in the relationship between NLR and mean PMR-AS ($p = 0.054$). In evaluating treatment response, baseline NLR was found to predict glucocorticoid resistance ($p = 0.042$).

Figure 1: Relationship between PMR-AS and NLR and PLR.

Conclusion: Baseline NLR can predict glucocorticoid resistance in newly diagnosed patients with PMR. Both NLR and PLR may also be useful biomarkers of disease activity in PMR.

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To evaluate if interleukin-6 (IL-6) expression in the temporal artery biopsy (TAB) specimens may differentiate patients with giant cell arteritis (GCA) from those without.

Methods: 63 consecutive formalin-fixed, paraffin-embedded (FFPE) TABs performed between 2009 and 2012 from 32 patients with transmural biopsy-proven GCA, 8 patients with biopsy-negative GCA and 23 controls were retrieved. Demographic, clinical, and laboratory data at presentation and at each follow-up visit were collected. A pathologist reviewed all TABs. Immunohistochemistry was performed on 4µm FFPE tissue sections with a 1:400 dilution of rabbit polyclonal anti-human IL-6 antibody (NOVUS Biologicals Littleton, Co.) for 60' at 37°. Slides of TAB specimens were independently assessed by five readers. IL-6 expression was graded as 0 (absent), 1 (mild), 2 (moderate) and 3 (marked). Inter-reader differences were resolved by consensus. Anti-IL6 staining was considered positive if staining was grade 2 or 3, since grade 1 was faint, sometimes difficult to differentiate from background, and showed the least degree of agreement between Readers.

Results: TAB specimens from patients with biopsy-proven GCA, biopsy-negative GCA and controls were positive for anti-IL-6 staining in 59%, 13% and 48% of cases, respectively, the difference between biopsy-proven and biopsy-negative GCA patients being significant ($p = 0.04$). In non-inflamed TABs, IL-6 was mainly expressed by mesenchymal cells in media and intima layers, while in inflamed TABs IL-6 was mainly expressed by mononuclear inflammatory infiltrating cells. IL-6 grade 2-3 expression was observed in all 6 patients with visual loss compared to 25 (43.9%) of 57 patients without ($p = 0.011$). Blindness was recorded in 2 patients with biopsy-proven GCA and 4 controls (all with a final diagnosis of non-arteritic ischemic optic neuropathy). No associations were found between IL-6 expression and demographic characteristics, GCA signs/symptoms, laboratory and histopathological TAB findings. However, there was a statistical trend ($p = 0.055$) of increased frequency of the halo sign at temporal artery CDS in patients with IL-6 expression grade 2-3 compared to those with IL-6 expression grade 0-1. No significant differences for the expression of IL-6 were observed between patients with and without PMR (5/8 - 62.5% - versus 6/15 - 40% -, $p = 0.400$) and between patients with isolated PMR and those with TAB positive GCA (62.5% vs 59%, $p = 1.000$).

Conclusion: Our study provides evidence that IL-6 expression does not increase the sensitivity of TAB in patients with morphologically uninflamed arteries. A search for further markers that may increase the sensitivity of TAB is warranted.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is an inflammatory disease of large vessels requiring long-term treatment with glucocorticoids. The immunopathology is characterized by vessel infiltrating innate and adaptive immune cells. In GCA, only limited data on dynamics in blood cell populations before, during and after treatment are available. Moreover, it is unknown whether patients that reached treatment-free remission are truly cured or are still suffering from ongoing subclinical vasculitis. This analysis aims to document effects of short and long-term glucocorticoid treatment on leukocyte subsets in this elderly population and may provide clues on the immunopathology of GCA.

Methods: Newly-diagnosed GCA patients (not yet on treatment, $n=41$) were prospectively studied for a median of 914 days. Absolute numbers of leukocyte subpopulations and other standard lab parameters were measured at fixed time points. Values were compared with age-matched healthy controls ($n=52$). Treatment free remission was defined as absence of symptoms without immunomodulatory treatment for at least 6 months.

Results: Platelet counts and inflammatory markers CRP and ESR were significantly increased in newly-diagnosed GCA patients compared to healthy controls. Monocyte and neutrophil counts were, while NK-cells were decreased. CRP and ESR, correlated with monocyte counts, only.

During short-term treatment (up to 3 months), most cell populations decreased but neutrophils and B-cells increased compared to baseline GCA.

After 12 months of treatment, T-cells, NK-cells and neutrophils returned to baseline GCA levels, while B-cells and monocytes were decreased. When compared to healthy controls monocytes and neutrophils were significantly increased after 12 months of treatment while B-cells, CD4+ T-cells and NK-cells were decreased.

In samples of GCA patients in treatment-free remission, innate immune cells did not normalize to healthy control levels. Monocytes and neutrophils remained significantly increased, whereas NK-cells remained decreased.

Conclusion: In GCA, innate rather than adaptive immune cells show major fluctuations before and during treatment. These fluctuations in innate immune cells persisted even in treatment-free remission. Whether this reflects development of a new immune balance or an ongoing subclinical vasculitis remains to be investigated.

Figure 1. Changes in cell populations counts in GCA patients. Counts at baseline (n=41), during short-term (n=69) and long-term treatment (n=100) were expressed as median fold-change compared to healthy controls (n=52). †: significant differences between healthy controls and baseline, ×: significant differences between healthy controls and short-term treatment samples, #: significant differences between healthy controls and long-term treatment samples (Mann-Whitney U test $P < 0.05$).

High Prevalence of Vascular Surgery and Autoimmune Comorbidity in Takayasu Arteritis

Tsuyoshi Shirai¹, Tomoyuki Muto², Yuko Shirota¹, Hiroshi Fujii¹, Tomonori Ishii³ and Hideo Harigae¹, ¹Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, ²Tohoku University Graduate School of Medicine, Sendai, Japan, ³Clinical Research, Innovation and Education Center, Tohoku University Hospital, Sendai, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Large vessel vasculitis (LVV) is the arteritis in aorta and its major branches, and classified into Takayasu arteritis (TAK) and giant cell arteritis (GCA). Some patients with aortic valve regurgitation (AR) or aortic

aneurism need vascular surgery, and TAK patients sometimes manifest comorbidities including ulcerative colitis and other autoimmune diseases. However, their prevalence and clinical characteristics are poorly identified. The aim of this study is to determine the prevalence and clinical characteristics of patients who possessed complications or comorbidities of LVV.

Methods: 144 patients who were diagnosed as either TAK (n=132) or GCA (n=12) according to JCS or ACR classification criteria in Tohoku University during 2008-2017 were enrolled to this study. The prevalence and clinical characteristics of patients who received surgery or were complicated by other autoimmune disorders were retrospectively evaluated.

Results: Vascular surgeries were performed in 38 TAK patients (28.8 %) (Aortic valve replacement (AVR), 15; aortic root substitution, 8; other valve replacement, 4; coronary artery graft, 6; percutaneous transluminal angioplasty of renal artery, 5). The proportion of type V lesion was higher in patients who received surgery (43 %) compared to total population (31 %). Difference in vascular type was more evident in patients with AR and AVR. Type IIa accounted for 36 % of patients with AR and 52% of patients who received AVR, while it accounted 25 % in total population. 46.8 % of vascular surgeries were performed within a year after diagnosis (Figure 1), and the age was negatively correlated with C-reactive protein levels in such patients ($p=0.008$, $r=0.35$). These data revealed that there existed a group in which patients manifested rapidly progressive course. Surprisingly, autoimmune comorbidities were observed in 38.6 % of TAK patients and included inflammatory bowel diseases (IBD, 12 cases), thyroid diseases (9), hearing loss (5), rheumatoid arthritis (4), interstitial pneumonia (3), sternoclavicular joint arthritis (3), osteomyelitis (2), uveitis (2), and spondyloarthropathy (SpA, 2). More than half of comorbidities were diseases in which tumor necrosis factor (TNF)-inhibitor was effective. Most of these comorbidities preceded TAK for about a few years.

Conclusion: 28.8 % of TAK patients received vascular surgeries, and half of them manifested rapidly progressive course. Particularly, type V lesion in young, type IIa lesion with AR, male, and complication of AR in the older are at high risk for vascular surgery. 38.6 % of TAK patients possessed autoimmune comorbidities, half of which can be complicated in SpA as well. This suggests similar pathomechanisms among TAK and SpA-related diseases and effectiveness of TNF inhibitors.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Aortic valve (AV) surgery is often performed for aortic regurgitation (AR) in patients with Takayasu arteritis (TA). However, data on the long-term outcomes, including survival and cardiac and cerebrovascular outcome, are lacking. This study aimed to characterize the long-term outcomes and prognostic factors of TA patients who underwent surgery for AR.

Methods: Medical records of patients with TA who underwent surgery for moderate to severe AR between January 1995 and December 2015 were reviewed. Poor outcomes were defined as all-cause death and major adverse cardiac and cerebrovascular events (MACCE) including life-threatening aortic aneurysm. Overall survival (OS) was presented with the Kaplan-Meier method and risk factors for poor outcome were analyzed with multivariate Cox analysis.

Results: Total 35 patients with TA with AR underwent AV surgery. The mean age of the patients (male 5, female 30) was 47.2 ± 13 years and the mean follow-up duration was 107.9 ± 85.7 months (median, 97 months; interquartile range, 44-150). Inflammatory values (ESR 36.9 ± 30.6 mm/h, CRP 3.4 ± 4.9 mg/dL) were elevated and 25 of total 35 patients (71%) received perioperative steroid therapy. The 5-year OS rate of the patients was 85.4% and the 5-year MACCE free survival rate was 73.9% (OS rate; 68.1%, MACCE free survival; 46.6% at 10-year). Eighteen of 35 patients (51.4%) had a poor outcome during follow-up. Re-operation was needed in eleven patients (11/35, 31.4%) and stroke occurred in three patients (3/35, 8.6%). Hata angiographic classification type V (6/17 [35.3%] vs 10/18 [55.6%], $p = 0.036$) and coronary disease (0/17 [0%] vs 4/18 [22.2%], $p = 0.030$) were significantly more frequent in patients with poor outcome. Multivariate analysis revealed that coronary disease (hazard ratio [HR], 4.665; 95% confidence interval [CI], 1.252-17.385; $p = 0.022$), diagnosis of TA before the age of 40 (HR, 3.909; 95% CI, 1.221-12.517; $p = 0.022$) were significantly associated with development of poor outcomes (Table 1).

Conclusion: In patients with TA with surgery for AR, poor cardiovascular outcome was frequently observed during follow-up period. It was associated with concomitant coronary artery disease, and TA diagnosis before the age of 40.

Table 1. Multivariate analysis of predictive factors of poor outcomes in patients with Takayasu arteritis with surgery for aortic regurgitation.

Variables	HR	95% CI	p-value

Abstract Number: 2780

Insufficient Use of Corticosteroids Results in Higher Relapse in Takayasu Arteritis

Tomoyuki Muto¹, Tsuyoshi Shirai², Hiroshi Fujii¹, Tomonori Ishii³ and Hideo Harigae³, ¹Tohoku University Graduate School of Medicine, Sendai, Japan, ²Medicine, Stanford University School of Medicine, Stanford, CA, ³Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TAK) is the chronic granulomatous inflammation of the aorta, its major branches. Although Corticosteroids, such as prednisolone (PSL), and immunosuppressants are key drugs for the treatment of TAK, relapse is frequent when treatment is tapered and there is limited evidence concerning optimal dose for PSL as initial treatment. The aim of this study is to reveal the correlation between PSL dose and relapse in TAK.

Methods: One hundred and five patients with TAK satisfying the criteria of Japanese Circulation Society and American College of Rheumatology in our institution during 1990 to 2015 were enrolled. Clinical characteristics and outcome of

patients with TAK were retrospectively evaluated. The relapse free period was assessed according to the difference in initial treatments.

Results: Among 105 patients with TAK, relapse was observed in 58 patients (55.2 %) during a median 56 months follow-up. Male gender and younger age of onset were significantly associated with relapse. Although PSL \leq 30 mg/day was preferably prescribed for patients with lower inflammatory markers as monotherapy compared to PSL \geq 40 mg/day (87.2 % vs 51.8 %), a significantly higher relapse rate was observed in PSL \leq 30 mg/day group (hazard ratio 1.69, $p=0.048$). Furthermore, the relapse free period was improved in patients treated with a PSL dose \geq 50 mg/day compared to those with a PSL dose 40 mg /day. In addition, combination therapy with immunosuppressants improved the relapse free period compared with PSL monotherapy in the short term (relapse free rate; 82.4 vs 55.6 % at 12 months).

Conclusion: The lower-dose PSL monotherapy resulted in a higher relapse rate compared to the higher-dose PSL, even when disease activity was low. Furthermore, combination therapy could improve the relapse free period at least in the short term. These results indicate that higher doses of PSL or combination therapy with immunosuppressive drugs are desirable strategies for remission induction in TAK, because it has the potential to decrease the relapse rate and suppress further vascular damage in patients with TAK.

Long Term Follow-up Results of Takayasu Arteritis Cohort: A Tertiary-Single Center Study

Sema Kaymaz Tahra¹, Fatma Alibaz-Oner¹ and Haner Direskeneli², ¹Rheumatology, Marmara University School of Medicine, Istanbul, Turkey, ²Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the clinical characteristics and long term follow-up outcomes of patients with Takayasu's arteritis (TAK) in a tertiary referral center.

Methods: In this retrospective study, 107 (F/M: 96/11) patients fulfilling ACR 1990 criteria for Takayasu Arteritis and referred to our center between 2004 and 2017 were investigated. All clinical and demographic data during first diagnosis and longitudinal followup were abstracted from medical records. Relapse was defined according to the physician's global assessment (PGA).

Results: The median age was 30 (14-67) years at symptom onset and 33(14-68) years at diagnosis. Median follow-up duration was 72 (6-264) months. According to Hata Angiographic Classification, Type 5 (51.8%) and Type 1(38.8%) were the most common patterns with the most frequently affected vessel subclavian artery (82.2%) . At diagnosis 0.5-1 mg/kg/day corticosteroid treatment was started in 94.6% patients and a steroid-sparing immunosuppressive(IS) agent in 96.3% of the patients. An initial pulse steroid (1 g/day) therapy was chosen for 8 patients. Before diagnosis 24% patients had a history of are vascularization procedure. After IS treatments, 24% of the patients were undergone a new revascularization procedure. During follow-up, biologic agents were chosen for 13.8% of the patients (5 infliximab and certolizumab each, 2 adalimumab and 2 tocilizumab). Remission was observed in 84% of the patients. At least one relapse was occurred in 43% and > 1 relapse in %14 patients. At the last visit 26% were determined to have an active disease. A > 4 mg of methylprednisolone dose was required in only 8.4% (Image 1) . Mortality rate was 3.7% (4 patients).

TADS	3.2±3.1

*methylprednisolone **Vasculitis damage index ***Takayasu arteritis damage score

Conclusion: We have defined the long-term follow-up results of our Takayasu's arteritis cohort. Comparing with European and Asia series published recently, requirement for a surgical intervention was lower under immunosuppressive treatments in our series. However, disease activity and relapse rate were still high under conventional ISs, suggesting a need for better therapeutic options.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) and Temporal arteritis (TA) is characterized by chronic granulomatous inflammation in medium and large-sized vessels. It affects 20 in 100,000 people aged 50 and older in the United States. Temporal artery biopsy (TAB) is a common diagnostic tool. Patients are often on anticoagulation (AC) therapy for other comorbidities. In current clinical practice, there are no guidelines on AC use perioperatively for TAB. Our study aimed at examining whether AC therapy was held prior to TAB as well as potential complications post-biopsy in our hospital.

Methods: The study is a retrospective chart review and was approved by the Stony Brook University Institutional Review Board. Electronic Medical Records (EMRs) were searched using ICD 9 and 10 codes for GCA among hospitalized patients between January 2013 and December 2016. Relevant data was collected, including demographics, AC usage and potential TAB related complications, such as ecchymosis, hematoma, infection, wound dehiscence, and facial nerve injury. TAB was performed by General or Vascular Surgeons in our hospital and documented by standard procedure in the EMRs. In most cases, ultrasound was used to map out temporal artery, lidocaine was administered locally, and a segment of temporal artery was obtained. Descriptive statistics and chi-square/Fisher exact tests were used for the data analysis.

Results: Forty-six patients were included in this study due to high clinical suspicion for GCA. The mean age of the patients was 72.8 years, females accounted for 67.4% of patients, and 76.7% were Caucasian. Twenty-seven of 46 patients underwent TAB, of whom 20 patients were on AC therapy prior to procedure. All but one patient continued AC prior to TAB. Of the 20 patients with TAB, surgical data was available in 16 patients. Thirteen patients did not experience complications and only 3 patients reported incision site pain, minor bleeding, or small ecchymosis. There was no significant difference in TAB-associated complications between the two groups. Aspirin dosing was 81 mg, except one patient on 325 mg, and clopidogrel dosing was 75 mg daily. Perioperative use of AC medications and TAB-associated complications are shown in Table 1 and 2.

Conclusion: This study indicates that patients who continued AC prior to TAB developed minimal TAB-associated complications. Our data seems to support the view that there may be inadequate evidence to recommend holding anticoagulation prior to TAB. A prospective study of a large sample size is needed to confirm the results.

¹ report with date if it occurs; ² record every 3-6 months; acute changes need to be recorded whenever they occur (e.g. new medication, imaging finding, osteoporotic fracture); ³ record every 6-12 months; acute changes need to be recorded whenever they occur (e.g. new medication, imaging finding, osteoporotic fracture); ⁴⁻¹⁰ other detailed information given (not specified in this abstract)

Background/Purpose: Giant cell arteritis (GCA) represents the most common form of primary systemic vasculitis, and is frequently associated with comorbidities related either to the disease itself or induced by its treatment. Systematically collected data on disease course, treatment and outcomes of GCA remain scarce. This EULAR Task Force therefore established a core set of data items which can easily be collected by clinicians, in order to facilitate collaborative research into the course and outcomes of GCA.

Methods: A multidisciplinary EULAR task force group of 20 experts including rheumatologists, internists, epidemiologists and patient representatives was assembled. A compilation of items describing GCA status and disease course was compiled to be discussed by three breakout groups during a one-day meeting. The results were presented to all members of the task force and further discussed. Final consensus was achieved by means of several rounds of email discussions after the meeting.

Results: Out of the original compilation, 95 parameters were considered relevant. Potential items were subdivided into the following categories: General, demographics, GCA-related signs and symptoms, other medical conditions, and treatment. Suitable instruments and assessment intervals were proposed for documentation of each item. In the next round of discussions the selection was reduced to a minimum core set of 70 parameters to facilitate implementation of the recommendations in both clinical care and clinical research. The following table represents an excerpt of the set of selected items. This is still a tentative listing since the final voting process on the choice of items is currently ongoing.

Conclusion: The recommended core set of parameters is intended to guarantee comparability of relevant items from different GCA registries and databases for the dual purposes of facilitating clinical research and improving clinical care.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis Poster III: Immunosuppressive Therapy in Giant Cell Arteritis and Polymyalgia Rheumatica

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant Cell Arteritis (GCA) is the most common systemic vasculitis in patient over 50 years of age. It is a medical emergency as it may lead to ischemic complications, including permanent visual loss in 20 % of untreated patients. Early diagnosis enabling a rapid initiation of treatment is of critical importance. Positive Temporal Artery Biopsy (TAB) is still the gold standard test. However, a negative TAB does not rule out the disease. Encephalic high-field MRI, temporal arteries ultrasonography (US) or fluorescein and indocyanine green angiogram (FA) have been widely studied as diagnostic tests. However, there is currently no consensus nor clearly identified algorithm for their use in a current practice, either alone or in combination. Our objective was to develop a new multimodal imaging algorithm based on a combination of encephalic high-field (3T) MRI, ultrasonography (US) and retinal angiogram (fluorescein (FA) and indocyaninegreen (ICGA)) , to improve the diagnosis of GCA

Methods: All patients referred for suspected GCA at our center from December 2014 to October 2017 were prospectively included in this study. The study was approved by an official external Ethical Review Board. Patient's informed consent was obtained upon inclusion.

For each patient, encephalic 3T MRI, cervical and temporal arteries US and retinal angiogram (RA) were performed. Subsequently, a TAB was performed.

TAB-positive patients were considered cases of GCA ; TAB-negative patients files were reviewed by two experts in internal medicine to determine whether they were or not cases of GCA based on ACR criteria.

Diagnostic accuracy of the combination of MRI, US and RA was statistically evaluated, first separately for each imaging modality, then using a multimodal classification tree.

Results: Forty five patients were included. GCA was diagnosed in 25 patients, TAB was positive in 19 patients. Thirty one patients presented a partial vision loss. MRI was positive in 24/44 patients, negative in 16/44 patients and uncertain in 4/44 cases. No patients with negative MRI had GCA. When MRI was positive, 23/24 patients had GCA. If MRI was uncertain and both US and RA were negative, final diagnosis was no GCA ; if either US and/or RA was positive, final diagnosis was GCA. We propose the following algorithm, with a positive predictive value of 96.2 % and a negative predictive value of 100%.

Conclusion: We propose an algorithm that is highly predictive for GCA diagnosis and can be a valuable tool in suspected cases of GCA.

When GCA is suspected, we suggest to perform 3T encephalic MRI first and if uncertain, to add US and RA.

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Both the IL-12 and IL-23 pathways have been linked to SLE pathogenesis. The anti-IL-12/23p40 monoclonal antibody ustekinumab (UST), which is approved for psoriasis, PsA, and Crohn's disease, was evaluated in patients with active SLE. We previously reported greater improvement with UST vs PBO in several SLE disease measures through wk24.¹ Results through 1 year are reported here.

Methods: We conducted a phase 2, PBO-controlled study in 102 patients with seropositive SLE, defined by SLICC criteria and active disease (SLEDAI score ≥ 6 and ≥ 1 BILAG A and/or ≥ 2 BILAG B scores). Patients were randomized (3:2) to UST (6 mg/kg single IV loading dose, then 90 mg SC q8w beginning at wk8) or PBO, added to standard care. At wk24, PBO patients crossed over to UST (90 mg SCq8w). The primary endpoint was the proportion of patients achieving SLE response index (SRI)-4 response at wk24. Modified intention-to-treat (mITT) analyses across SLE disease activity measures were performed to evaluate for maintenance of response with UST between wk24 and wk48. Safety was assessed through wk56.

Results: SRI-4 response rate was significantly greater ($p=0.0057$) in the UST group (61.7%) vs PBO group (33.3%) in the wk24 primary endpoint analysis and was sustained at 1 year (63.3%) in the UST group (Table 1). Rates of SLEDAI-2K (65% at wk24 vs 66.7% at 1 year), PGA (67.9% at wk24 vs 75% at 1 year), and active joint (86.5% at wk24 vs 86.5% at 1 year) responses were also sustained from wk24 to 1 year in the UST group (Table 1). CLASI response rate plateaued by wk28 (53.1% at wk24 vs 67.7% at wk28) and was maintained through 1 year in the UST group (68.6%) (Table 1). Among PBO patients who crossed over to UST at wk24 ($n=33$), 54.5% achieved an SRI-4 response at 1 year. Of UST-exposed patients, 81.7% had ≥ 1 TEAE, 15.1% had ≥ 1 SAE, and 7.5% had ≥ 1 serious infection through 1 year (Table 2). No deaths, malignancies, opportunistic infections, or tuberculosis cases were observed. Safety events were consistent with the known UST safety profile.

Conclusion: UST provided sustained clinical benefit in global and organ-specific SLE activity measures through 1 year, with a safety profile consistent with other indications. Thus, UST may be an effective therapy for SLE.

Reference: vanVollenhoven R, Hahn BH, Tsokos GC, et al. Efficacy and safety of ustekinumab, an interleukin 12/23 inhibitor, in patients with active systemic lupus erythematosus: results of a phase 2, randomized, placebo-controlled study [abstract]. *Arthritis Rheumatol.* 2017 ; 69 (Suppl 10).

Table 1. Efficacy results at 24 weeks and 1 year in patients initially randomized to UST

	UST	
	Week 24	Week 48
Randomized patients (mITT)	60	60
SRI-4 response ^a , n/randomized (%)	37/60 (61.7)	38/60 (63.3)
Improvement from baseline in SLEDAI-2K score ^b , n/randomized (%)	39/60 (65.0)	40/60 (66.7)
$\geq 30\%$ improvement from baseline in PGA, n/evaluable ^c (%)	38/56 (67.9)	39/52 (75.0)
$\geq 50\%$ improvement from baseline in the number of joints with pain and signs of inflammation, n/evaluable ^d (%)	32/37 (86.5)	32/37 (86.5)
$\geq 50\%$ improvement from baseline CLASI activity score, n/evaluable ^e (%)	17/32 (53.1)	24/35 (68.6)

a SRI-4 response was defined as a ≥ 4 -point reduction in SLEDAI-2K total score, no new BILAG A and no more than 1 new BILAG B domain score, and no worsening ($<10\%$ increase) from baseline in the PGA of disease activity score

b SLEDAI-2K response defined as ≥ 4 -point improvement from baseline score

c Values for patients meeting treatment failure criteria are set to missing from the point of treatment failure forward

d Patient subpopulation (67% of total population) with ≥ 4 joints with pain and signs of inflammation at baseline

e Patient subpopulation (60% of total population) with CLASI activity score of ≥ 4 at baseline

CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; mITT, modified intention-to-treat; PBO, placebo; PGA, Physician Global Assessment; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; SRI-4, SLE Responder Index-4; UST, ustekinumab; wk, week.

Table 2. Safety results at 24 weeks and 1 year

	Placebo-controlled period through Week 24		Exposed to UST through 1 year	
	PBO	UST	Randomized to UST	All UST (UST + PBO-UST)
Treated patients	42	60	60	93
Patients with ≥ 1 TEAE	29 (69.0)	47 (78.3)	54 (90.0)	76 (81.7)
Patients with ≥ 1 SAE	4 (9.5)	5 (8.3)	10 (16.7)	14 (15.1)
Patients with ≥ 1 infection ^a	21 (50.0)	29 (48.3)	40 (66.7)	56 (60.2)
Patients with ≥ 1 serious infection ^a	0 (0)	2 (3.3)	6 (10.0)	7 (7.5)
Patients with ≥ 1 DCAE	4 (9.5)	4 (6.7)	5 (8.3)	6 (6.5)

All data are presented as n (%).

a Based on infection system organ class

DCAE, adverse event leading to discontinuation; PBO, placebo; PBO-UST, patients who crossed over from PBO to UST at wk24; SAE, serious adverse event; TEAE, treatment-emergent adverse event; UST, ustekinumab; wk, week.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: The adoption of treat to target approaches for Systemic Lupus Erythematosus (SLE) requires the definition of a target state validated for improved patient outcomes. The Lupus Low Disease Activity State (LLDAS) has been shown in multiple retrospective and cross-sectional studies to have face, content, construct and criterion validity and be associated with better quality of life. We report on a multinational prospective study undertaken to determine whether LLDAS attainment is associated with protection from flare and damage accrual.

Methods: A prospective multicenter cohort study was undertaken in 13 centres between 2013-2017. Patients with SLE (ACR or SLICC criteria) were recruited, SLEDAI-2k, SELENA flare index, PGA, and medication data collected at every visit, and damage (SLICC-ACR damage index (SDI)) collected annually. Time-dependent Cox proportional hazards models were used to assess the association of LLDAS at any time point, as well as the effect of the proportion of time spent in LLDAS, with disease flare and damage accrual (increase in SDI).

Results: 1735 patients (93% female, 77.7% anti-dsDNA positive, mean baseline SLEDAI-2k 4.3 ± 4.4) were followed for (mean \pm SD) 2.2 ± 0.9 years, totalling 12,534 visits (mean interval 0.34 ± 0.17 y). LLDAS was achieved in 54.6% of observed visits. Attainment of LLDAS at any timepoint was highly significantly protective against subsequent flare and damage accrual (Table 1).

Table 1. Association of LLDAS with subsequent flare and damage accrual

Outcome	Time-dependent proportional hazards model (independent variable: in LLDAS (Yes/No))		
	HR	95% CI	p value
Flare (any) at subsequent visits	0.65	0.56 – 0.76	<0.001
Flare (mild-moderate) at subsequent visits	0.74	0.63 – 0.87	<0.001
Flare (severe) at subsequent visits	0.41	0.34 – 0.51	<0.001
Damage accrual (Increase in SDI ≥ 1)	0.55	0.43 – 0.70	<0.001

Similarly, patients who spent $\geq 50\%$ of their observed time in LLDAS had a two-fold reduction in risk of flare and damage accrual (flare: HR 0.49, 95% CI 0.42-0.58, $p < 0.001$; damage accrual HR 0.53, 95% CI 0.41-0.68, $p < 0.001$), compared to those with $< 50\%$ of observed time in LLDAS.

Conclusion: In this large prospective multicenter study, we demonstrate that LLDAS attainment provides significant protection against disease flares and damage accrual. Our findings support the use of LLDAS as a treatment target for SLE, and as an outcome measure for clinical trials and treat-to-target strategies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: The association between human leukocyte antigen (HLA) class I alleles and psoriatic disease indicates a potential role for the innate immune system in disease pathogenesis. HLA class I educates NK cells through interactions with killer cell Immunoglobulin receptors (KIRs) and by supplying peptides that bind HLA-E to form ligands for the more conserved CD94/NKG2A NK receptors. The peptides corresponding to residues –22 to –14 of the leader sequence of HLA-A, HLA-B, and HLA-C specifically bind to the binding site of HLA-E. In ~80% of HLA-B allotypes, methionine at position –21M (21M) is replaced by threonine. Methionine –21 delivers functional peptides, whereas threonine at this position (–21T) does not. This functional dimorphism divides the human population into three groups: –21M/M, M/T, and T/T, with decreased order of potency of the NK CD94/NKG2A+ receptor. We aimed to determine whether the distribution of the M and T haplotypes differed between patients with PsA, PsC and healthy controls.

Methods: Two sets of cohorts were included in this study: (a) A discovery cohort of 664 PsA patients, 1155 PsC patients and 3118 controls. Class I HLA alleles were imputed using SNP2HLA. Logistic regressions were used to obtain the association p values by PLINK. We performed three association analyses between HLA B -21 amino acid polymorphisms and different phenotypes: 1) PsC vs. controls; 2) PsA vs. controls; 3) PsA vs. PsC. Population stratification and sex were controlled by including the top seven principal components and sex as covariates in logistic regression. (b) A replication cohort of 1177 PsA patients, 659 PsC patients and 1096 controls with self reported European ethnicity from a large well-phenotyped single centre cohort. HLA typing was done by sequence specific oligonucleotide (SSO) probes using the reverse line blot technique with ambiguous results resolved using sequence specific primers (PCR-SSP). Association analyses as with the Discovery cohort were repeated. All analyses were conditioned on HLA-B*27.

Results: PsC patients within our discovery cohort had a significantly lower prevalence of -21M compared to controls as well as those with PsA (Table 1). The results of the replication study showed similar results (Table 2).

Conclusion: The study provides indications for a potential role of NK cells in PsA pathogenesis, as well as provides a genetic marker that differentiates PsA from PsC.

Table 1. Results of the association study in the discovery cohort.

Comparisons	Freq of -21M in affected	Freq -21M in controls	OR (95% CI)	P value	P value (adjusted)
PsC vs. Controls	0.285	0.331	0.78 (0.70, 0.87)	4.262e-05	4.411e-06
PsA vs. Controls	0.337	0.331	1.04 (0.92, 1.18)	0.671	0.546
PsA vs. PsC	0.337	0.285	1.36 (1.17, 1.58)	0.001	6.692e-05

The Effects of Plasma Exchange and Reduced-Dose Glucocorticoids during Remission-Induction for Treatment of Severe ANCA-Associated Vasculitis

Michael Walsh¹, Peter A. Merkel² and David Jayne³, ¹Nephrology, McMaster University, Hamilton, ON, Canada, ²Division of Rheumatology, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, ³Department of Medicine, University of Cambridge, Cambridge, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: It is uncertain whether plasma exchange improves clinical outcomes in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. Also uncertain is whether, compared to standard therapy with high-dose oral glucocorticoids, a lower-dose glucocorticoid regimen reduces the risk of infection without increasing the risk of end-stage renal disease or death. The PEXIVAS clinical trial addressed both of these questions.

Methods: PEXIVAS was a 2-by-2 factorial, randomized, controlled trial to separately evaluate plasma exchange and two different regimens of oral glucocorticoids in patients with new or relapsing severe ANCA-associated vasculitis, including lung hemorrhage and/or glomerulonephritis (eGFR <50 ml/min/1.73 m²). Participants were randomly assigned to 7 treatments of plasma exchange or no plasma exchange. Participants were also randomly assigned to either a standard-dose oral glucocorticoid regimen or a reduced-dose oral glucocorticoid regimen (<60% of the standard regimen by 6 months). All patients received immunosuppression with either cyclophosphamide or rituximab. Patients were followed for up to 7 years for the primary composite outcome of death from any cause or end-stage renal disease.

Results: The trial recruited 704 participants from 98 sites in 15 countries: 397 (56%) men; 289 (41%) PR3-ANCA, 209 (59%) MPO-ANCA; 691 (98%) with renal involvement; 191 (27%) with alveolar hemorrhage. 109 (15%) patients received rituximab and 595 (85%) received cyclophosphamide.

Among 704 participants, the primary outcome occurred in 28% of patients allocated to plasma exchange compared to 31% in the no plasma exchange group (hazard ratio 0.86, 95% confidence interval [CI] 0.65 to 1.13; p=0.27). The primary outcome occurred in 28% of patients in the reduced glucocorticoid group and 26% in the standard glucocorticoid group (absolute risk difference 2.3%, 90% CI -3.4% to 8.0%; met non-inferiority hypothesis). Serious infections in the first year occurred less often in the reduced glucocorticoid group compared to the standard group (incidence rate ratio 0.70, 95% CI 0.52 to 0.94; p=0.02). The results were similar for both the plasma exchange and glucocorticoid interventions when the individual outcomes of end-stage renal disease or death were analyzed separately.

Conclusion: Plasma exchange does not reduce the risk of end-stage renal disease or death in patients with ANCA-associated vasculitis. Compared to a standard dose, reduced glucocorticoids did not substantially increase the risk of death or end-stage renal disease and resulted in fewer serious infections. The primary results of PEXIVAS, regarding both the use of plasma exchange and dosing of glucocorticoids, will have immediate and substantial impact on the standard of care for patients with ANCA-associated vasculitis.

Efficacy of Apremilast for Oral Ulcers Associated with Active Behcet's Syndrome over 28 Weeks: Results from a Phase III Study

Gulen Hatemi¹, Alfred Mahr², Yoshiaki Ishigatsubo³, Yeong Wook Song⁴, Melike Melikoglu⁵, Sue Cheng⁶, Shannon McCue⁶, Maria Paris⁶, Mindy Chen⁶ and Yusuf Yazici⁷, ¹Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey, ²Hospital Saint-Louis, University Paris Diderot, Paris, France, ³Yokohama City University Graduate School of Medicine, Yokohama, Japan, ⁴Rheumatology, Seoul National University Hospital, Seoul, Korea, Republic of (South), ⁵Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, ⁶Celgene Corporation, Summit, NJ, ⁷New York University School of Medicine, New York, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Behcet's syndrome is a chronic, relapsing, multi-system inflammatory disorder characterized by recurrent oral ulcers (OU), which can be disabling and substantially impact quality of life. In a phase III study (RELIEF), apremilast (APR) reduced the number and pain of OU in patients with active Behcet's syndrome over 12 weeks.

Methods: In this phase III, multicenter, placebo (PBO)-controlled study, adult patients with active Behcet's syndrome (defined by ≥ 3 OU at randomization or ≥ 2 OU at screening and at randomization without active major organ involvement) were randomized (1:1) to PBO or APR 30 mg BID for 12 weeks. All patients then received APR treatment through Week 64. The primary endpoint was area under the curve (AUC_{Wk0-12}) for total number of OU over 12 weeks, which reflects the

number of OU over time and accounts for the recurring-remitting course of OU. The current analysis assessed APR efficacy in the treatment of OU for up to 28 weeks.

Results: A total of 207 patients were randomized and received ≥ 1 dose of study medication (PBO: n=103; APR: n=104). At baseline (BL), mean OU counts were 4.2 (APR) and 3.9 (PBO) and mean visual analog scale pain scores were 61.2 (APR) and 60.8 (PBO). The primary endpoint of AUC_{Wk0-12} was achieved; a statistically significantly lower AUC_{Wk0-12} was observed for APR vs. PBO (129.54 vs. 222.14; $P < 0.0001$, multiple imputation). APR treatment resulted in a significantly lower number of OU ($P \leq 0.0015$, multiple imputation) and reduction in OU pain ($P \leq 0.0035$, mixed-effects model for repeated measures) compared with PBO at every visit from Week 1 through Week 12. APR efficacy was sustained with continued treatment through 28 weeks. At Week 28, 62% of patients achieved complete response of OU, with a 70% relative reduction in OU pain from BL. Patients initially randomized to PBO and switched to APR at Week 12 showed comparable benefits (Figures). At Week 28, 59.0% of patients achieved complete remission of OU, with a 68% relative reduction in OU pain from BL. The incidence of any adverse event (AE) was comparable between APR and PBO during the PBO-controlled period (78.8% and 71.8%, respectively). The most common AEs were diarrhea, nausea, headache, and upper respiratory tract infection; most AEs were mild or moderate in severity. No new safety concerns were identified with up to 28 weeks of APR treatment.

Conclusion: APR demonstrated efficacy in the treatment of OU in patients with active Behcet's syndrome. Benefits were sustained for up to 28 weeks with continued treatment. APR was generally well tolerated and safety was consistent with the known safety profile of apremilast.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ACR Abstract: Plenary Session III

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is the first described type of monogenic vasculitis. Patients usually present in childhood, but age of onset, disease severity, and organ involvement of DADA2-associated vasculitis is highly variable and clinical features overlap with the typical features of polyarteritis nodosa (PAN). This study aimed to test the prevalence of DADA2 in patients with presumed idiopathic PAN.

Methods: Patients (n=117) with idiopathic PAN, all of whom tested negative for hepatitis B virus infection, were screened for mutations in *ADA2* (formerly known as *CECRI*). DNA was extracted from whole blood by standard methods. Standard PCR amplification and Sanger sequencing was performed for the 9 coding exons of the *ADA2* gene. To further assess the pathogenicity of identified variants on a functional level, *ADA2* activity was determined using the adenosine deaminase assay kit from Diazyme.

Results: Eight of 117 patients (6.8%) were identified as having rare missense variants in *ADA2* with a minor allele frequency of < 0.005. Four patients (3.4%) were homozygous or compound heterozygous for variants in *ADA2*. Of the 7 distinct variants present in these 4 patients, G47A, G47W, R169Q, E328K, F355L, and G383S had previously been reported as causative for DADA2. The remaining variant, P106S, is a rare variant predicted to be damaging to protein function by the PROVEAN algorithm. Four additional patients were carriers for the monoallelic variants R34W, T65M, M309I, and V349I. R34W was reported in DADA2 before, while the 3 remaining variants are of unknown clinical significance.

Serum samples were available on patients with the G383S/G383S and E328K/F355L genotypes and measurements showed markedly reduced *ADA2* enzyme activity, comparable to levels seen in patients with DADA2. *ADA2* activity in the serum of 2 of the monoallelic carriers was not reduced, confirming the non-pathogenicity of T65M and V349I. The median age at diagnosis for the 4 patients with biallelic *ADA2* mutations was considerably younger (median 23.0 years, range 17.4-24.4) than for the 4 patients with heterozygous *ADA2* variants (median 42.0 years, range 16.5-59.0) or the other 109 patients in the cohort (median 47.0 years, range 33.3-56.7) (p=0.04). There were no marked differences in the types of clinical manifestations between patients with or without *ADA2* mutations, including neurologic disease.

Conclusion: This is the first study to report biallelic pathogenic variants in *ADA2* in patients with adult-onset, HBV-negative PAN, and demonstrates that DADA2 accounts for a subset of patients with idiopathic PAN. Given the potential efficacy of TNF-inhibitors in DADA2, that anti-TNF treatment is not the conventional therapy in PAN, and the consequences for other family members, these findings suggest that *ADA2* testing should be considered in patients with HBV-negative idiopathic PAN, especially in patients with an early onset of this potentially life-threatening disease.

Session Date: Tuesday, October 23, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are present in two-thirds of patients with rheumatoid arthritis (RA), and target proteins that have been post-translationally modified by the calcium-dependent peptidylarginine deiminase (PAD) family of enzymes. In addition, anti-PAD4 autoantibodies are found in about 30% of RA patients and are correlated with disease severity. Anti-PAD4 autoantibodies are thought to enhance the calcium (Ca^{++}) sensitivity of PAD4, thereby increasing its activity at sub-optimal Ca^{++} concentrations present in the synovial tissues. In this study, we aim to identify, isolate, and functionally characterize anti-PAD4 monoclonal antibodies (mAbs) derived from RA patients' plasmablasts to investigate their pathophysiological role in disease.

Methods: We sequenced the paired heavy and light chain immunoglobulin genes of individual plasma blasts from RA patients' blood using DNA cell barcode-enabled sequencing. We recombinantly expressed 72 mAbs representing clonal families identified in the plasmablast antibody repertoires of 6 RA patients, and evaluated their capacity to bind PAD4 by ELISA and immunoprecipitation/Western blotting (IP/WB) assays. We further evaluated the effects of anti-PAD4 mAbs and Ca^{++} concentration on PAD4 enzymatic activity by co-incubating each mAb with recombinant PAD4 and the substrate histone H3. We extended these experiments to assays using freshly isolated human neutrophils.

Results: 7/72 (9.7%) recombinant mAbs recognized PAD4 by ELISA and/or IP/WB. Most of the anti-PAD4 mAbs (5 of 7) belonged to clonal families that included additional ACPA members, and 2 anti-PAD4 mAbs were polyreactive against multiple citrullinated antigens. When the anti-PAD4 mAbs and related clonal family members were tested for their effects on PAD4 activity, we found that the majority enhanced enzymatic activity, resulting in increased citrullination of H3 (citH3), both in the recombinant PAD4 and neutrophil *in vitro* assays. Interestingly, in the latter assay, increased citrullinated H3 was observed both at 0.5 (suboptimal) and 2 (optimal) mM Ca⁺⁺. We also observed that combinations of anti-PAD4 mAbs were more effective at enhancing enzyme activity, suggesting additive or synergistic effects of anti-PAD4 mAbs on potentiating PAD4 activity.

Conclusion: We identified affinity-matured and class-switched RA blood plasmablast clonal families that encode PAD4-reactive antibodies, suggesting that they arise from antigen- and T-cell-driven mechanisms. Most of the anti-PAD4 mAbs identified enhanced PAD4 activity *in vitro*, particularly at sub-optimal Ca⁺⁺ concentrations. Experiments to characterize the specific binding epitopes of anti-PAD4 mAbs and to evaluate their pathogenic effects *in vivo* are ongoing.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a severe systemic autoimmune disease characterized by immune-complexes (ICx) which cause inflammation and damage. Effective targeting of autoantibody secreting cells could be key to reset autoimmunity. Functionally, SLE-specific ICx are important triggers of neutrophil extracellular trap (NET) formation. A consortium was formed to study B-cell targeted therapies, including RTX, Bortezomib (BTZ) or combination of RTX + Belimumab (BLM). The present study aimed to investigate the effects of these therapies on relevant autoantibody levels and excessive NET formation.

Methods: This study involved three cohorts of severe SLE patients that were eligible to experimental treatment with RTX (n=16), BTZ (n=12) or RTX+BLM (n=16). A cross-sectional cohort of 35 SLE patients served as a control cohort. A panel of SLE relevant autoantibodies against dsDNA, histones, nucleosomes and C1q were measured by ELISA. NET formation was quantified by a novel highly-sensitive assay using 3D confocal microscopy (Kraaij et al. 2016).

Results: Comparing three regimens, RTX+BLM resulted in the strongest significant reduction on anti-dsDNA, anti-Histone and anti-Nucleosomes antibodies compared to a smaller decrease by RTX and BTZ. Interestingly, RTX+BLM specifically decreased anti-C1q antibodies, which were not targeted by RTX or BTZ. ICx-mediated NET formation was only significantly decreased with a median of 75% [53 – 85%] after RTX+BLM (p=0.0002). Successful seroconversion of autoantibodies associated with decreased NET formation (p=0.02). The latter phenomenon was further corroborated in an independent cohort of SLE patients, where excessive NET formation associated with the presence of three or more autoantibody specificities (p=0.02), and specifically with the presence of anti-C1q antibodies (p=0.03).

Conclusion: In this reverse, translational study of B-cell targeted therapies, we demonstrate that anti-C1q autoantibodies were derived from Blys-dependent proliferating plasma blasts because they were only susceptible to RTX+BLM therapy. Moreover, therapeutically narrowing of the autoantibody repertoire decreased immune-complex mediated NET formation.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: The presence of anti-citrullinated protein antibodies (ACPA) is a hallmark of rheumatoid arthritis (RA). ACPAs specifically recognize citrullinated epitopes, a result of a post-translational modification catalyzed by peptidyl arginine deiminases (PAD). Based on the unique feature of the periodontal bacteria *Porphyromonas gingivalis* (*Pg*) to express *P*-PAD it has been suggested that ACPA-positive RA may be precipitated in the gum mucosa. To address this hypothesis, we have investigated the antibody response against a citrullinated peptide derived from *P*-PAD (CPP3) in patients with RA, patients with chronic periodontitis (PD), and in controls. In addition, we have cloned B cells from gingival tissue of a patient suffering from both PD and RA and generated monoclonal antibodies (mAbs) with an aim to demonstrate that citrulline-specific B cells, previously detected only in RA joints and circulation, may also reside in gingival tissue.

Methods: Gingival tissue-derived single CD19+B cells from an ACPA-positive RA patient with PD were sorted by flow cytometry. Immunoglobulin variable region genes were sequenced and expressed to generate recombinant mAbs. CPP3-reactivity was analysed by ELISA in serum samples from 66 PD patients, 63 periodontally healthy controls (non-PD), 200 RA patients, and 120 systemically healthy controls (non-RA), as well as in 55 mAbs. Differences in antibody levels were examined using Mann-Whitney *U* test for independent groups.

Results: Anti-CPP3 antibody levels were low in non-PD controls, while 65% of PD patients showed elevated levels ($p<0.0001$). Significantly increased antibody levels were also detected in 50% of ACPA-positive RA, 20% of ACPA-negative RA, and in 37% of non-RA controls ($p<0.0001$). Notably, this antibody response was citrulline-specific, as the antibody response against the arginine-containing control peptide RPP3 was significantly lower in all subsets ($p<0.0001$). Among 55 mAbs from gingival tissue, 14 (25%) unique clones were CPP3-reactive, of which 4 showed cross-reactivity with RPP3. Interestingly, 4 out of 14 (29%) CPP3-reactive clones also bound citrullinated peptides derived from human α -enolase, filaggrin and histone4, demonstrating cross-reactivity between a bacterial epitope and human epitopes on a monoclonal level.

Conclusion: This study shows that a substantial proportion of systemically healthy individuals possess ACPAs directed against *Pg*, and these ACPAs also bind epitopes on human proteins. Based on our data, we propose that the ACPA response may be triggered by *Pg*, via an antibody response against CPP3, which cross-reacts with human citrullinated proteins by mechanisms of molecular mimicry.

Peptidylarginine Deiminases Are Required for Normal Immunoglobulin G Half-Life

Mandar Bawadekar¹ and Miriam A. Shelef^{1,2}, ¹Department of Medicine, Division of Rheumatology, University of Wisconsin - Madison, Madison, WI, ²William S. Middleton Memorial Veterans Hospital, Madison, WI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Antibodies are a cornerstone of immunity and pathologic in autoimmunity. Immunoglobulin G (IgG) can undergo multiple different post-translation modifications, some of which can alter IgG half-life, but citrullination has not been evaluated in this context. Citrullination, the post-translational conversion of arginines to citrullines, as well as the citrullinating enzymes peptidylarginine deiminase (PAD) 2 and 4, are increased in inflammation and rheumatoid arthritis. Further, citrullinated IgG has been detected in human rheumatoid arthritis and both PAD2 and PAD4 are required for normal IgG levels in a murine model of rheumatoid arthritis. However, the role of these PADs in a normal antibody response and IgG half-life is unknown. The purpose of this study is to determine if PAD2 or PAD4 is required for a normal IgG response to a T cell dependent immunization and normal IgG half-life.

Methods: Wild-type mice, PAD2^{-/-} mice, PAD4^{-/-} mice, wild-type mice treated daily with the pan-PAD inhibitor Cl-amidine, and wild-type mice treated with vehicle control were immunized and then boosted at day 42 with 4-hydroxy-3-nitrophenylacetyl conjugated to keyhole limpet hemocyanin (NP-KLH) precipitated in alum to generate a T cell dependent immune response against NP. Serum from multiple time points was subjected to enzyme-linked immunosorbent assay (ELISA) to detect anti-NP IgG. To assess IgG half-life, serum from NP-KLH immunized mice was transferred to naïve mice. Serum was collected from recipients and the loss of NP-specific IgG quantified by ELISA over time. Similar studies were performed with transferred purified IgG from NP-KLH immunized PAD2^{-/-} and PAD2^{+/-} mice after *in vitro* citrullination with PAD2. The Fc portion of IgG was purified and citrullination assessed by anti-modified citrulline (AMC) western blot.

Results: PAD2^{-/-}, PAD4^{-/-}, and Cl-amidine treated wild-type mice have reduced IgG titers in response to NP-KLH compared to untreated or vehicle control-treated wild-type mice. NP-specific IgG titers fall faster in recipients of serum from PAD2^{-/-}, PAD4^{-/-}, and Cl-amidine treated mice than recipients of serum from untreated or vehicle control-treated wild-type mice, with a more pronounced effect with serum from PAD2^{-/-} donors compared to wild-type than PAD4^{-/-} donors compared to wild-type. IgG is citrullinated in healthy mice and citrullination of the Fc portion of IgG is reduced as detected by AMC blot in PAD2^{-/-}, but not PAD4^{-/-} mice. *In vitro* citrullination rescues the half-life of IgG from PAD2^{-/-} mice.

Conclusion: IgG is citrullinated and PAD enzymes, especially PAD2, are required for normal IgG levels in response to immunization as well as normal IgG half-life in mice. These findings have implications for immunity, for monoclonal antibody based therapies in rheumatoid arthritis, and for both the longevity and specificity of rheumatoid autoimmune antibodies, which bind to citrullinated proteins and IgG.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: IL-23 is currently a target for several forms of autoimmune diseases, yet its role in promoting pathogenic autoantibody development is less clear. IL-23 was required for pathogenic autoantibody production in Fas

deficient B6-Fas^{lpr/lpr} mice. In contrast, in the type II collagen immunized DBA/1 mice, IL-23 did not promote germinal center (GC) formation and IgG anti-CII autoantibody generation. The purposes of this study are to: (i) determine if IL-23 is required for GC and pathogenic autoantibody development; and (ii) determine if IL-23 acts on follicular T-helper cells (Tfh) or GC B cells to induce autoantibody formation in BXD2 mice.

Methods: Sera autoantibody levels were assessed by ELISA in B6, BXD2, and BXD2-*p19*^{-/-} mice. GC development was determined by FACS (GL-7⁺ Fas⁺) and immunostaining and confocal imaging (PNA⁺). IL-23R expression was measured by FACS and quantitative real-time PCR. GC program genes and plasma cell program genes expression were measured by quantitative real-time PCR. Exogenous IL-23 was administered to mice using an IL-23 expressing adenovirus (AdIL-23, 2x10⁹ pfu).

Results: There was significantly increased total IgM and IgM anti-DNA and RF but decreased total IgG autoantibodies in BXD2-*p19*^{-/-} mice compared to BXD2 mice. Surprisingly, the size and number of GC were increased in BXD2-*p19*^{-/-} mice, compared to IL-23 competent BXD2 mice. *Il23r* expression was higher in Tfh cells compared to non Tfh cells and *Il23r* was undetectable in GC B cells. Moreover, administration of AdIL-23 into B6 mice induced significantly increased expression of IL-23R in Tfh cells but not in GC B cells. Despite the lack of IL-23R expression in GC B cells, the low titers of autoantibodies in BXD2-*p19*^{-/-} mice was associated with a significantly diminished expression of activation-induced cytidine deaminase (AID or *Aicda*) in GC B cells of BXD2-*p19*^{-/-} mice compared to BXD2 mice. However, *p19* deficiency did not suppress the expression of other canonical GC program genes, *Bach2* and *Pax5*.

Conclusion: Our data suggest that IL-23 is required for GC B-cell AID induction and thereby pathogenic autoantibody class-switch recombination. Furthermore, IL-23 acts through a novel population of IL-23R⁺ responding Tfh cells to promote IgG pathogenic autoantibody production in the BXD2 mouse model of lupus.

Session Date: Tuesday, October 23, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Age-associated B cells (ABCs) are a novel B cell subset, which expands with age in non-autoimmune mice but accumulates prematurely in autoimmune-prone strains. ABCs exhibit unique phenotypic and functional characteristics. In addition to classical B cell markers ABCs also express markers such as CD11c and CD11b. ABC differentiation depends on the transcription factor T-bet and is promoted by TLR7 stimulation. While ABCs have been proposed to play a key role in the development of autoimmune diseases and in the sex bias observed in these disorders the molecular mechanisms driving ABC formation and function are poorly understood. The SWEF proteins constitute a small family of proteins that includes SWAP-70 and its homolog DEF6, a recently identified risk variant for human SLE. The lack of SWEF proteins leads to the spontaneous development of a lupus-like syndrome, which, similarly to human SLE, preferentially occurs in female mice. We have recently shown that ABC formation is enhanced in SWEF-deficient mice (double knock-out, DKO mice) and is controlled by IL-21 and IRF5. Here we have investigated whether sex-specific differences control the accumulation and/or function of ABCs in SWEF-deficient mice.

Methods: We have evaluated the accumulation of ABCs and their ability to produce autoantibodies in male and female DKO mice. We have also generated male Yaa-DKO mice, which carry a duplication of the TLR7 gene on the Y chromosome, to assess the effects of TLR7 dysregulation on the sex-bias observed in SWEF-deficient mice. T_{FH} cells, ABCs, Germinal center B cells (GCBs), and plasma cells (PCs), were analyzed in the spleens of WT females, WT males, DKO females, DKO males, Yaa-B6 males and Yaa-DKO male mice by FACS. To monitor the severity of the lupus phenotype,

autoantibody levels were tested by ELISAs. Finally, ABCs from all genotypes were FACS-sorted and stimulated *in vitro* with a TLR7 ligand and autoantibody production in the culture supernatant was tested by ELISA.

Results: As compared to WT mice, ABCs accumulate to a similar extent in male and female SWEF-deficient mice. FACS-sorted ABCs from male mice, however, produced much lower titers of anti-dsDNA IgG_{2c} compared to ABCs from DKO female mice upon TLR7 stimulation. Yaa-DKO male mice exhibited a greater expansion of ABCs than male or female DKOs and a marked accumulation of other immune cells including T_{FH} cells, GCBs, and PCs. Yaa-DKO mice had significantly higher autoantibody titers and a shortened lifespan. Interestingly, *in vitro* stimulation of ABCs from Yaa-DKO male mice with a TLR7 ligand resulted in greatly increased autoantibody production compared to male DKOs.

Conclusion: While ABCs accumulate in a similar manner in female and male SWEF-deficient mice, they exhibit a differential ability to produce autoantibodies upon TLR7 stimulation. The functional capability of the SWEF-deficient ABCs is affected by the Yaa translocation. The enhanced autoantibody producing capability of ABCs from Yaa-DKO male mice is accompanied by increased titers of autoantibodies and a shortened lifespan. Thus TLR7 dysregulation alters the sex-bias exhibited by SWEF-deficient ABCs.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: T cells play a major role in the pathogenesis of Rheumatoid Arthritis (RA). These cells are regulated by signals provided via the T cell receptor (TCR) complex as well as by a set of co-receptors, which can propagate either stimulatory or inhibitory signals. CD28, a co-stimulatory receptor, and PD-1, a co-inhibitory receptor, are two essential T cell co-receptors whose ligands belong to the B7 family, but have opposing functions. Interestingly, both co-receptors play a role in the pathogenesis of RA and recent studies have shown that CD28 is targeted directly by PD-1. Accordingly, understanding the interplay between CD28 and PD-1 in the context of RA may provide novel approaches to better understand or treat autoimmunity. We hypothesize that PD-1 regulates CD28 function by dephosphorylating specific motifs in the tail of CD28 resulting in impaired downstream T cell function.

Methods: Genetically modified T cell lines were used to study the contribution of different versions of CD28 to TCR signaling. Western blotting and cytokine levels were used to measure the role of CD28 on T cell function. The inhibitory effect of the PD-1 was examined by plating T cells on PD-1 ligand coated surfaces. Mass spectrometry was used to uncover additional proteins that regulate the interaction between PD-1 and CD28. To translate our finding to RA, blood and synovial fluid were collected from active RA patients (disease activity score (DAS)>5.1) to analyze expression of PD-1, CD28 and other signaling mediators. Peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were analyzed by flow cytometry.

Results: We discovered that signaling downstream of PD-1 dephosphorylates tyrosine 173 of CD28 and that this event was absolutely required for the ability of PD-1 to inhibit interleukin 2 (IL-2) secretion. Mass spectrometry results identified SAP, a hematopoietic-restricted adaptor protein found to be associated with autoimmunity, as a regulator of the functional interaction between PD-1 and CD28. SAP co-localized and physically interacted with CD28 to counter PD-1 mediated dephosphorylation. More specifically, SAP bound to tyrosine 173, but not to tyrosine 190 of the cytoplasmic tail CD28, and by doing so blocked the ability of PD-1 to dephosphorylate this site. Additionally, serine at position 171 of CD28 was required to stabilize the interaction between SAP and CD28. Finally, we also learned that SAP levels were elevated in synovial fluid and peripheral blood RA T cells, concordant with PD-1 levels and DAS.

Conclusion: Our results demonstrate that SAP binds to phosphorylated CD28 at tyrosine 173 to interfere with PD-1 activity. It has been suggested that RA T cells are in a state of dysfunction with limited ability to regulate IL-2 production. Our finding of elevated SAP levels in these cells provides a mechanistic explanation for these observations whereby SAP interferes with PD-1 signaling by shielding phosphorylated CD28 and leading to persistent activation in acute disease

followed by dysfunction in chronic disease. Therefore, SAP has potential to be utilized as a biomarker for RA disease activity. Manipulation of the PD-1/CD28 axis may prove to be a promising therapeutic target in autoimmunity.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: In healthy individuals with arthralgia and RA-specific autoantibodies (so called *at-risk* individuals) the presence of expanded B-cell receptor (BCR) clones in peripheral blood (PB) accurately predicts who will develop arthritis in the short term¹. Following up on these observations, we investigated in the same cohort of *at-risk* individuals whether the T-cell receptor beta (TCR β) repertoire characteristics in PB and synovial tissue (ST) might also predict imminent onset of arthritis.

Methods: Next-Generation Sequencing of the TCR β repertoire was performed on 20 randomly selected individuals with elevated IgM-RF and/or ACPA levels. Ten individuals did not develop RA during at least 3 years of follow-up, and 10 individuals did. Peripheral blood and synovial tissue samples were analysed during the *at-risk* phase and, for individuals that developed RA, again after RA onset. T-cell clones were identified by their unique TCR β sequence².

Results: In the *at-risk* phase, the synovium is already characterized by expanded TCR β clones, both in *at-risk* individuals that will and will not develop arthritis later. These clones persist in the tissue during onset of arthritis. A higher impact of the dominant TCR β clones in the synovial tissue in the *at-risk* phase was associated with longer time to arthritis ($p=0.02$).

Conclusion: Expanded T-cell clones are present in the synovium of *at-risk* individuals regardless of future development of RA. The expanded clones are maintained after onset of clinical disease. Combined with literature data, these observations show that T cell clones are already expanded in ST very early in disease, and suggest an overall regulatory role. Further studies are needed to characterize these clones.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: The predominant salivary gland (SG) T cell types contributing to disease in Sjögren's syndrome (SS) are unclear. This study assessed the frequency and number of SG CD3⁺ T cell subtypes for association with SS disease features and compared the SG CD4⁺ T cell transcriptome of primary SS subjects to that of sicca controls not meeting criteria for SS.

Methods: CD3⁺ T cells from SG biopsy tissue of subjects with primary SS and non-SS sicca were evaluated for proportion (n=51 SS, n=69 non-SS) and number/mg biopsy tissue (n=34 SS, n=56 non-SS) of T cell subsets defined by CD3, CD4, CD8 and CD45RA using flow cytometry. Proportions of memory CD4⁺ T cells were evaluated for correlation with clinical and oral disease parameters. Sorted salivary gland memory CD4⁺ T cells from a subset of focus score positive SS cases (n=17) and focus score negative non-SS subjects (n=15) were evaluated for global gene expression by microarray. Differentially expressed genes were assessed using the limma R package, and bioinformatics analyses were performed using Ingenuity Pathways Analysis and Gene Set Enrichment Analysis.

Results: Proportions of CD4⁺CD45RA⁺ T cells (mean \pm SEM pSS: 33.2% \pm 2.0, non-SS: 21.9% \pm 1.2, p<0.0001) but not those of other CD3⁺ T cell subsets were increased in SS cases compared to non-SS sicca subjects. Proportions of SG CD4⁺ memory T cells positively correlated with SG focus score (r=0.47, p<0.0001), morphologic area of SG fibrosis (r=0.35, p=0.006), and van Bijsterveld corneal damage score (r=0.37, p<0.0001), with relationships remaining after age correction. Differentially expressed (DE) genes in SS cases versus non-SS sicca subjects were enriched for T follicular helper (Tfh), interferon, T cell homeostasis, resistance to apoptosis, atypical lymphoid trafficking and elevated inflammatory response pathways, but not Th17 profile. Predicted upstream drivers of the DE genes included CXCL13, CD40/CD40 ligand and Bcl6, while predicted decreased effects included FoxP3, Fas, STAT6 and mTOR.

Conclusion: Proportion and number of SG memory CD4⁺ T cells selectively associate with key SS disease features, and SG memory CD4⁺ T cells are enriched for a predominant Tfh-like cell profile.

Adenosine 2a Receptor Signals Act to Limit Autoimmune Arthritis By Inhibiting Pathogenic Germinal Center T Follicular Helper (GC-Tfh) Cells

Shirdi Schmiel and **Daniel L. Mueller**, Medicine/Rheumatic and Autoimmune Diseases, University of Minnesota Medical School, Minneapolis, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: CD4 germinal center (GC)-T follicular helper (Tfh) cells are important in the pathogenesis of autoimmune arthritis. Previous studies have shown that adenosine 2a receptor (A2aR, *Adora2a*) signaling can divert CD4 T cells away from the GC-Tfh cell lineage during the primary response to foreign antigens. Therefore, we examined the effects of A2aR signaling on CD4 T cells during the recognition of a self-antigen using a mouse model of autoimmune arthritis.

Methods: Wildtype and *Adora2a*-deficient KRN TCR-transgenic CD4 T cells specific for glucose-6-phosphate isomerase (GPI)/I-A^{g7} self-peptide were transferred into immunodeficient *Tcr α ^{-/-}* I-A^{g7}-expressing mice to induce arthritis, and then recipients were treated with either the selective A2aR agonist CGS-21680 (CGS) or PBS vehicle alone. Severity of disease, autoantibody titers, KRN T cell numbers and phenotype, and GPI-specific isotype class-switched plasmablasts were tracked.

Results: CGS treatment inhibited arthritis development and KRN Bcl6^{hi} CXCR5^{hi} GC-Tfh cell differentiation, blocked the appearance of high affinity GPI-specific and IgG1 isotype class-switched polyclonal plasmablasts, and led to a reduction in anti-GPI IgG1 titers. Additionally, therapeutic administration of CGS after the onset of arthritis blocked further disease progression in association with reduced KRN GC-Tfh cell numbers and anti-GPI IgG1 titers. The therapeutic effects of CGS treatment were lost when the *Adora2a* gene was deleted only from the KRNT cells.

Conclusion: Strong A2aR signaling diverts autoreactive CD4 T cell differentiation away from the GC-Tfh lineage, thus reducing help for the differentiation of dangerous autoreactive B cells that promote arthritis. Therefore, our data suggest that the A2aR and its downstream signaling pathways in CD4 T cells may be promising therapeutic targets to interfere with autoreactive GC-Tfh cell differentiation.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: A plethora of evidence from genome-wide association studies and relevant animal models implicates a pivotal role of T cells in the pathogenesis of rheumatoid arthritis (RA). CD8⁺ T cells comprise ~40% of all T cells infiltrating the rheumatoid synovium, and the number of activated CD8⁺ T cells in synovial fluids (SF) and peripheral blood (PB) of RA is associated with disease activity. Production of cytotoxic molecules such as granzyme B and perforin in CD8⁺ T cells is more pronounced in patients with RA than in healthy controls (HC).

Apart from their cytotoxicity, CD8⁺ T cells have recently gained attention as an IL-21-producing cell population. In mice a novel subset of IL-21-producing CD8⁺ T cells, like follicular helper CD4⁺ T cells (Tfh), is induced by IL-6 from naïve CD8⁺ T cells and capable of supporting B cell differentiation into Ab-producing cells. However, little is known about a role of human IL-21-producing CD8⁺ T cells, particularly in autoimmune diseases. Here, we have investigated a generation mechanism of IL-21-producing CD8⁺ T cells in humans, and also determined a role of this novel subset in patients with RA.

Methods: CD8⁺ T cells in PB and SF from HC and patients with RA with or without CD3/28 stimulation were subject to the analysis of IL-21 expression at both mRNA and protein levels. To clarify a generation mechanism of IL-21-producing CD8⁺ T cells in humans, naïve (CD45RA+CCR7+) CD8⁺ T cells were highly purified using a flow cytometry and tested for their differentiation into IL-21-producing CD8⁺ T cells in the presence of multiple combination of cytokines along with CD3/28 stimulation. Moreover, using a flow cytometry we thoroughly analyzed the phenotype of a IL-21-producing CD8⁺ T cell subset in HCPB and RAPB as well as RASF. To determine whether IL-21-producing CD8⁺ T cells exert B-cell-helper functions, these cells were co-cultured with memory B cells.

Results: CD3/28 stimulation induced IL-21 production in whole CD8⁺ T cells from HC, and central memory (CD45RA-CCR7+), but not naïve and terminal effector, CD8⁺ T cells were a main producer of IL-21. Among several cytokines extrapolated from studies of CD4⁺ T cell subsets, IL-12 was the most potent cytokine to generate IL-21-producing CD8⁺ T cells from naïve CD8⁺ T cells. IFN- γ , IL-6 and IL-21 were also able to do so, albeit to a lesser extent. The surface phenotype of IL-21-producing CD8⁺ T cells was CD28+CD69+CD95+PD-1+, and these cells also had potential to produce IFN- γ , but not IL-17. Central memory CD8⁺ T cells stimulated with CD3/28 facilitated the differentiation from memory B cells (CD27+CD38-) to plasmablasts (CD27^{high}CD38^{high}) via up-regulation of expression of blimp-1 transcription factors. Compared with HCPB, central memory CD8⁺ T cells were pronounced in RAPB, and this trend was further prominent in RASF. Moreover, RASF enriched CD69+, CD95+ and PD-1+ CD8⁺ T cells than PB from HC and RA. Central memory CD8⁺ T cells in PB and SF from RA most significantly produced IL-21 among CD8⁺ T cell subsets.

Conclusion: Together, these findings suggest that IL-21-producing central memory CD8⁺ T cells are a novel subset that plays a pivotal role in the pathogenesis of RA by exerting B-cell-helper functions.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Previously thought to involve primarily the microvasculature, systemic sclerosis (SSc) has been increasingly linked to macrovascular disease. Cardiovascular and cerebrovascular disease are responsible for 20-30% of mortality in SSc, but few studies have shown an independent association between SSc and stroke. In this study, we assessed whether SSc was an independent risk factor for ischemic stroke.

Methods: Using national VA (Veterans Affairs) electronic health record data, we conducted a retrospective cohort study comparing veterans with SSc (defined as ≥ 1 ICD-9 code) to a matched cohort without SSc. We matched subjects 2:1 on date of birth, sex, race, VA facility, observable time, and baseline smoking status. We collected data from October 1999 to September 2014. Follow-up began after the first ICD code for SSc (710.1) among cases, and a matched index date among controls. We excluded subjects with prior ischemic stroke. Subjects were censored after their first diagnosis of ischemic stroke, death, or last encounter, whichever came first.

Baseline comorbidities (hypertension, diabetes, atrial fibrillation, non-cerebrovascular atherosclerotic disease) were assessed prior to the index date using ICD codes. Use of oral glucocorticoids, aspirin and NSAIDs was identified by a filled prescription or provider-recorded non-VA medication in the 12 months before the index date. Medicare enrollment was used as a proxy for non-VA care, defined as enrollment for ≥ 1 year during follow-up. We generated a Kaplan-Meier plot to compare stroke-free survival between groups. We used an adjusted Cox regression model accounting for matching to generate hazard ratios (HRs) for ischemic stroke.

Results: SSc patients had more cardiovascular risk factors, medication use, and Medicare enrollment (Table). Mean follow-up time was 5.1 years for SSc subjects and 5.2 years for non-SSc subjects. We found a significantly increased risk of stroke among SSc patients (12.0/1000 patient-years vs. 8.8/1000 patient-years, unadjusted HR 1.40 (95% CI 1.20 to 1.64); see Figure). After adjustment for baseline cardiovascular risk factors, medications and Medicare enrollment, the HR remained significant (1.29 (95% CI 1.09 to 1.53)).

Conclusion: SSc is associated with a higher risk of ischemic stroke compared to non-SSc patients in the US veteran population, independent of traditional cardiovascular comorbidities and baseline medications. This is the largest study to date of cerebrovascular disease in SSc. Patients with SSc represent a population likely to benefit from targeted stroke screening or prevention therapies.

Figure: Kaplan-Meier estimates of cumulative incidence of ischemic stroke in veterans with SSc compared to matched controls

Table: Baseline characteristics of individuals with SSc and matched controls in a national Veterans Affairs population

Variable	SSc N=4714	Non-SSc N=9428	p-value
Age (mean years \pm SD)	61.1 \pm 12.9	61.2 \pm 13.1	0.48

Abstract Number: 2803

48-Year Trends in Systemic Sclerosis Mortality in the United States, 1968-2015: Steady Decrease for 15 Years after 33 Years of Continuous Increase

Eric Yen, Devanshu Singh and **Ram R. Singh**, UCLA, Los Angeles, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: A comprehensive evaluation of long-term trends in systemic sclerosis (SSc) mortality is important to understand the influence of recent advances in SSc management and to identify groups at the highest risk of death. Our objective is to identify secular trends in SSc mortality, and trends in SSc mortality relative to mortality from all other causes (non-SSc).

Methods: We used national mortality and census database to calculate age-standardized mortality rate (ASMR) for SSc and non-SSc causes, ratio of SSc-ASMR to non-SSc-ASMR, and proportions of SSc and non-SSc deaths by age groups for each year from 1968 through 2015. We performed joinpoint trend analysis to estimate annual percent change (APC) and average APC (AAPC) for the above measures for the total population and by sex, race, and age.

Results: From 1968 to 2015, there were 46,798 SSc deaths and 106,058,839 non-SSc deaths. The ASMR for SSc was 2.7 (95% CI, 2.4-2.9) per million persons in 1968 and 3.2 (95% CI, 3.0-3.4) per million persons in 2015. Joinpoint trend

analysis showed that SSc-ASMR increased at an APC of 1.0% between 1968 and 1987, and continued to increase at a higher APC (2.2%) from 1987 to 2001, before decreasing starting in 2001 (APC, -2.6%; 95% CI, -2.2% to -3.1%; 2001-2015). In contrast to this rise-and-decline trend in SSc-ASMR, the non-SSc-ASMR continuously decreased throughout the study period. The resulting SSc-ASMR:non-SSc-ASMR ratio was 111.6% higher in 2015 than in 1968. Men with SSc died at younger ages than did women with SSc. However, women had greater annual increases in SSc-ASMR than did men from 1968 to 2000. Black persons had higher SSc-ASMRs and died at younger ages than did white persons. However, over the entire study period, the SSc-ASMR decreased in black persons (AAPC, -0.4%, 95% CI, -0.7% to -0.0%) while it increased in white persons (AAPC, 0.4%, 95% CI, 0.1% to 0.6%). Persons aged ≥ 65 years had the steepest increases in SSc-ASMRs (AAPC, 2.0%; 95% CI, 1.8% to 2.2%; cumulative, 187.0%), whereas those aged ≤ 44 years had the largest decrease (AAPC, -1.9%; 95% CI, -0.2.5% to -1.2%; cumulative -60.0%) over the 48-year period. Consistently, the proportions of SSc deaths significantly decreased in ≤ 44 and 45-54 year age groups, but increased at a higher APC in ≥ 65 year old decedents.

Conclusion: After continuously increasing for 33-years (1968-2000), SSc mortality decreased during 2001-2015. The most improvement in SSc mortality was seen in younger age groups. However, the improvement in SSc mortality has not kept up with the improvement in non-SSc mortality. Racial and sex disparities persist in SSc mortality. Men and black persons with SSc die at younger ages.

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: To utilize electronic health records (EHR) to study SLE, phenotypic algorithms are needed to accurately identify these patients. We aimed to generate an EHR algorithm for SLE using machine learning, which allows the data to inform algorithmic features, with the primary goal of optimizing the positive predictive value (PPV). We also aimed to compare this algorithm with the performance of published rule-based algorithms (Barnado et al. *Arthritis Care Res* 2017) that pre-specify combinations of ICD-9 codes, medications and laboratory tests in our EHR.

Methods: We randomly selected 400 subjects with ≥ 1 SLE ICD-9 code (710.0) from a large, academic medical system EHR, and two rheumatologists identified gold standard cases of definite and probable SLE. Subjects meeting 1997 ACR or 2012 SLICC Classification Criteria for SLE were classified as definite SLE; those with partial, usually 3 criteria, considered to have likely SLE by the treating rheumatologist and reviewers were defined as probable SLE. We divided subjects into a training set (N=200) and validation set (N=200). We extracted codified and narrative concepts using natural language processing (NLP) from the training set and generated algorithms using penalized logistic regression (LASSO) to classify subjects with definite or definite/probable SLE. Algorithms were applied to the validation set using the original case definition and validated externally at the institution where the rule-based algorithms were developed (N=175) using a more liberal definition of specialist-reported SLE diagnosis. We also applied published rule-based algorithms to our training set to assess portability.

Results: In the combined training and validation cohorts (N=200 each), 29% had definite SLE and 41% had definite/probable SLE. Using machine learning methods, our codified data algorithm had a PPV of 90% for definite SLE at 97% specificity and 64% sensitivity (**Table 1**). For definite/probable SLE, the PPV was 92% at 97% specificity and 47% sensitivity. Models with NLP data performed similarly. In the external cohort validation, the codified definite/probable SLE

algorithm had 95% PPV, 98% specificity, and 13% sensitivity. The PPVs of rule-based algorithms were <50% for definite SLE and ≤65% for definite/probable SLE in our EHR (Table 1).

Conclusion: Our final machine learning SLE phenotype algorithms performed well in our EHR and had high PPV but lower sensitivity when externally validated in a cohort that did not require ACR/SLICC criteria to define cases. Rule-based SLE phenotype algorithms did not perform as well in our EHR likely because of these differences in case definitions and variations in clinical practice, medication use, laboratory tests, billing and documentation across EHRs. Unique EHR characteristics, case definitions, and research goals must be considered when applying algorithms to identify SLE patients in EHRs.

Table 1: Algorithm performance characteristics

	Definite SLE*			Definite/Probable SLE		
	Sensitivity (%)	Specificity (%)	PPV (%)	Sensitivity (%)	Specificity (%)	PPV (%)
Machine-learning codified algorithms**	64	97	90	47	97	92
Machine learning codified/ natural language processing algorithms	46	97	87	41	97	90
Top-performing rule-based algorithm 1*** ≥3 ICD-9 codes for SLE, ANA ≥1:40, ever DMARD use, and ever steroid use	58	72	47	53	75	63
Top-performing rule-based algorithm 2*** ≥3 ICD-9 codes for SLE and ever antimalarial use	86	60	46	84	69	65

* In the definite SLE algorithms, probable cases were considered non-SLE.

** Definite SLE algorithm includes the coded variables chronic renal failure, rheumatoid arthritis, sicca syndrome, SLE, unspecified connective tissue disease, anti-dsDNA laboratory test, complement laboratory test, and anti-TNF/biologic DMARDs (etanercept, adalimumab, infliximab, abatacept, tofacitinib, tocilizumab, certolizumab, golimumab, secukinumab, and ustekinumab). Definite/probable SLE algorithm includes the coded variables chronic renal failure, SLE, anti-dsDNA, complement, and antimalarial medication.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: High intake of antioxidants, fruits/vegetables, nuts and legumes and low intake of sodium, sweetened beverages, and red/processed meats may reduce inflammatory biomarkers and decrease risk of chronic inflammatory diseases. Current knowledge remains scarce regarding the association of diet and SLE risk. We prospectively evaluated four dietary quality scores and risk of SLE and its subtypes, dsDNA positive (+) versus negative (-) SLE. We hypothesized that SLE risk would be inversely associated with adherence to healthier dietary quality scores (including the Alternative Healthy Eating Index [AHEI-2010], Alternative Mediterranean Diet Score [aMed], and Dietary Approach to Hypertension [DASH]) and positively associated with an inflammatory dietary pattern, measured by the validated Empirical Dietary Inflammatory Pattern [EDIP]).

Methods: We included 79,569 female nurses in NHS (1984-2012) and 93,553 in NHSII (1991-2013). Lifestyle, environmental, and medical data were collected on baseline and biennial questionnaires. Incident SLE was confirmed by medical record review. Dietary data were obtained from validated food frequency questionnaires at baseline and approximately every 4 years in follow-up. Four dietary scores, (AHEI-2010, aMed, DASH, and EDIP), were calculated and women were classified according to dietary score use in tertiles. Time-varying Cox regression models estimated

Table. Hazard Ratios for Risk of Incident SLE according to Four Dietary Quality Scores (in Tertiles) among Women in Nurses' Health Study (NHS, 1984-2012) and Nurses' Health Study II (NHSII, 1991-2012)

Tertile 2	64/133765	1.02 (0.71-1.45)	31/132808	1.08 (0.65-1.81)		33/133044	0.83 (0.57-1.21)	
Tertile 3	59/133107	0.88 (0.59-1.31)	29/134303	0.98 (0.57-1.67)	0.97	30/133177	0.74 (0.44-1.24)	0.20
Alternate Healthy Eating Index (AHEI-2010): 11 food/nutrients: vegetables, fruits, whole grains, nuts/legumes, sugar-sweetened beverages, red/processed meat, trans-fat % of energy, long-chain omega-3 fats, polyunsaturated fat, sodium and alcohol (each scored 1 to 10). Higher tertiles = healthier.								
Alternative Mediterranean Diet Score (aMed): 9 components: vegetables (excluding potatoes), fruits, nuts, red/legumes, legume, fish, ratio of monounsaturated to saturated fat, red and processed meats, and alcohol. Higher tertiles = healthier.								
Dietary Approach to Hypertension (DASH): 8 components: high intake of fruits, vegetables, nuts and legumes; low-fat dairy products; and whole grains and low intake of sodium, sweetened beverages, and red and processed meats. Higher tertiles = healthier.								
Empirical Dietary Inflammatory Pattern (EDIP): weighted scores including pro- or anti-inflammatory food groups associated with plasma inflammatory biomarker levels (CRP, IL-6, and sTNF-R2). Higher tertiles = increased inflammation = less healthy.								
¹ Multivariable (MV)-adjusted hazard ratios (HR) from time-varying Cox proportional hazards model, adjusted for age, cohort, total energy intake, race, education, household income, smoking, body mass index, oral contraceptive use, age at menarche, menopausal status and postmenopausal hormone use. ² p for trend linear trend across categories of dietary scores, testing median value of each category as contrast.								

multivariable-adjusted hazard ratios (HRs [95% confidence intervals]) of SLE risk, adjusting for potential confounders, overall and by dsDNA subtype, in association with cumulative average dietary scores in tertiles through the 2-year cycle prior to diagnosis.

Results: We identified 184 incident SLE cases (89 dsDNA+ and 95 dsDNA-) from 1984 to 2013. SLE risk was not significantly different among women with dietary patterns in the highest tertile of each dietary score (vs. lowest tertile; AHEI-2010: HR 0.90 [95% CI 0.62-1.31], aMed:HR 0.89 [95% CI 0.61-1.29], DASH: HR 1.20 [95% CI 0.84-1.72], EDIP: HR 0.86[95% CI 0.59-1.25]). No significant trends across tertiles of dietary patterns were observed and no risk was demonstrated for dsDNA+ or dsDNA- SLE subtype with any dietary score (Table).

Conclusion: No association was demonstrated between long-term adherence to the AHEI-2010, aMed, DASH, or EDIP scores with SLE risk overall or by dsDNA subtype among women. These studies make a large effect of dietary pattern upon the risk of developing SLE among women unlikely.

Childhood Physical and Sexual Abuse and Risk of Systemic Lupus Erythematosus Among African American Women

Medha Barbhaya¹, Yvette Cozier², Nelsy Castro-Webb², Sara K. Tedeschi³, Cianna Leatherwood⁴, Lynn Rosenberg² and Karen Costenbader⁴, ¹Rheumatology, Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, ²Slone Epidemiology Center, Boston University, Boston, MA, ³Division of Rheumatology, Immunology and Allergy, Brigham & Women's Hospital, Harvard Medical School, Boston, MA, ⁴Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: We and others have previously reported that post-traumatic stress disorder (PTSD) is associated with increased risk of developing SLE. We aimed to investigate the relationship between physical and sexual abuse as a child and future risk of developing SLE among African American women.

Methods: We examined whether there was an association between self-reported physical and sexual abuse in childhood and SLE risk in a large nationwide prospective cohort of African American women, the Black Women's Health Study (59,000 women enrolled in 1995 and followed through 2017). Nine childhood abuse questions (from Conflict Tactics Scale, Straus MA, 1979 and Pregnancy Abuse Assessment Screen, McFarlane J, 1992) were asked on the 2005 questionnaire. Types of physical and sexual child abuse were described and response categories were, never, 1-3 times or ≥ 4 times (for questions not answered, we considered responses to be 'never'). Covariate data, mainly concerning childhood exposures, were obtained from baseline and biennial questionnaires. Incident SLE was identified by self-report and verified by medical record review for 1997 Updated ACR Criteria. We used Cox regression models to estimate HRs and 95% CIs for SLE risk related to several types of past physical and sexual abuse, adjusting for potential confounders.

Table. Hazard Ratios for SLE in Relation to Childhood Physical and Sexual Abuse among 36,153 Participants in the Black Women's Health Study without SLE at Cohort Enrollment in 1995

≥4 times	14	39396	2.34	1.32	4.15	2.36	1.32	4.19
*Adjusting for started alcohol consumption age ≤ 14, passive smoking exposure at ages 0-10, BMI at age 18, area-level socioeconomic status, first oral contraceptive use at age ≤14 years, parental education level, age at menarche.								

Results: Of the 36,153 women who answered the child abuse questions, mean age at study baseline was 39.2 years (10.6 SD), 14% were current smokers, and mean BMI was 27.9 (6.6 SD). During 670,841 person-years of follow-up, we identified 102 incident SLE cases with self-reported data on childhood physical and sexual abuse. Compared to women who denied any abuse, those who reported frequent severe abuse, including being choked, burned, physically attacked, having genitals exposed to them or having sexual relations, all occurring ≥ 4 times, experienced increased risk of SLE as an adult (HRs 2.3-3.7)(Table).

Conclusion: Childhood physical and sexual abuse, in particular severe and frequent abuse, were associated with increased risk of developing SLE among adult African American women. While these results are based on small numbers and there is a potential for recall bias, they are thought-provoking and need to be pursued and verified. The biologic mechanisms underlying this association are not well understood, but could involve dysregulation of the hypothalamic-pituitary axis and stress hormones in PTSD, or stimulation of inflammatory cytokines.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Prior studies demonstrated associations between post-traumatic stress disorder and increased risk of incident SLE and between childhood trauma and increased risk of hospitalization for autoimmune disease during adulthood. Severe stressors may alter immune function and result in increased inflammation and cytokine release, thereby increasing risk of SLE. We examined if childhood abuse is associated with increased risk of incident SLE.

Methods: Data are from the Nurses' Health Study II, a longitudinal cohort of female U.S.-based nurses enrolled in 1989 followed with biennial questionnaires. To measure childhood physical and emotional maltreatment, we used the Physical and Emotional Abuse Subscale of the Childhood Trauma Questionnaire (CTQ), for sexual abuse, the Sexual Maltreatment Scale of the Parent-Child Conflict Tactics Scales (CTS-SA), and for childhood physical assault, the Physical Assault Scale of the Conflict Tactics Scales (CTS-PA), all administered in 2001 with 75% response rate (68,505/91,268). Higher scores indicate more frequent abuse. We defined incident SLE through 2015 by self-report, confirmed by medical record review with ≥ 4 SLE ACR criteria. We excluded 1,071 women with missing childhood abuse exposure data or with self-reported, unconfirmed connective tissue disease. Multivariable Cox regression models evaluated the association (hazard ratio [HR] and 95% CI) between childhood abuse and incident SLE. We examined whether biennially assessed risk factors (e.g. smoking, BMI, alcohol use, oral contraceptive use) and potential confounders (e.g. age, race, median household income, parental education) accounted for increased SLE risk among those with vs. without childhood abuse exposure.

Results: Among 67,434 women, with a mean age of 34.6 (SD 4.8) in 1989, with >24 years of follow-up, there were 93 incident SLE cases. In age and race-adjusted models, exposure to the highest vs. lowest physical and emotional maltreatment was associated with >2-fold greater risk of SLE (HR 2.21 (95% CI 1.29-3.80)). Exposure to moderate and high levels of physical assault was associated with 1.70 (95% CI 1.08-2.68) times higher risk of SLE vs. no exposure. We did not find statistically significant associations between sexual abuse and SLE risk. After additionally accounting for potential lifestyle, reproductive and socioeconomic factors in separate models, HRs were only slightly attenuated (**Table**).

Conclusion: In this longitudinal cohort, we observed significantly increased risk of incident SLE among women who experienced childhood physical and emotional abuse compared with women who had not. Our findings suggest that exposure to extreme childhood stress and adversity may contribute to SLE development. Further studies are needed to investigate the role of timing and of the socioenvironmental context of abuse exposures and potential underlying mechanisms.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: BMD is a strong predictor of fracture risk in untreated patients. Recent evidence suggests that BMD achieved during treatment also reflects fracture risk; thus, T-scores are being considered as a target to guide osteoporosis treatment. In the Active-Controlled Fracture Study in Postmenopausal Women with Osteoporosis at High Risk trial (ARCH [NCT01631214]), romosozumab (Romo), an investigational bone-forming agent with a dual effect of increasing bone formation and decreasing bone resorption, followed by alendronate (ALN) had greater efficacy in fracture risk reduction and BMD gains vs ALN alone (Saag NEJM 2017). Of note, a cardiovascular imbalance was observed with Romo in ARCH and a comprehensive assessment of these data is ongoing. Here we explored the relationship between T-scores achieved on-study after 1 year with Romo or ALN and subsequent fracture risk.

Methods: Postmenopausal women with osteoporosis and prior fragility fracture were randomized 1:1 to receive Romo 210mg SC QM or ALN 70mg PO QW for 12 months, followed by open-label (OL) ALN 70mg PO QW for ≥ 12 months, with an event-driven primary analysis. We examined change from baseline in BMD and T-scores at 12 months and the relationship between total hip T-scores at month 12 and subsequent nonvertebral (NVT) fracture rates. We also compared fractures in the OL period, including new vertebral (VT) fractures in year 2 (based on month 24 spine radiographs) and clinical, NVT, and hip fractures between arms in the full OL period.

Results: ARCH enrolled 4093 patients (2046 Romo, 2047 ALN); mean baseline T-scores were -2.96 at the lumbar spine and -2.80 at the total hip. 3465 patients (1739 Romo, 1726 ALN) received ≥ 1 OL ALN dose in the OL period (median 1.9 years follow-up). Mean total hip BMD increased by 6.2% for Romo and 2.8% for ALN in the first year, with increases in T-score of 0.31 and 0.15, respectively. At month 12, the achieved total hip T-score was associated with the 1-year NVT fracture rate observed in the OL period (Figure) and the relationship was independent of the drug received in the first year. During the OL period, when all patients were on ALN, patients who received Romo first had a 75% lower relative risk of new VT fracture ($P < 0.001$), and had reductions in clinical (32%, $P = 0.001$), NVT (19%, $P = 0.120$), and hip (40%, $P = 0.041$) fractures vs patients who received ALN first.

Conclusion: Higher absolute total hip T-scores achieved on therapy at month 12 resulted in subsequent lower fracture risk regardless of the treatment received, with ongoing benefits from building a BMD foundation. These data support the concept of a T-score target to improve outcomes in osteoporosis treatment.

Figure: Month 12 total hip T-score and nonvertebral fracture rate during the open-label period

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Table. Ratio of Fractures Prevented per Bone Safety Event Observed in Long-term FREEDOM Extension Subjects Using the Virtual Twin Method

	Exposure-adjusted subject incidence per 100,000 subject-years				
	Clinical fractures N = 2343 Exp = 16295	Major osteoporotic fractures ^a N = 2343 Exp = 15772	Vertebral fractures N = 2416 ^a Exp = 18385	Non-vertebral fractures N = 2343 Exp = 16451	Hip fractures N = 2343 Exp = 19742
Long-term	1777	1525	981	1520	148
Ratio ^b	3160	2689	1874	2904	281
Ratio ^c	0.86	0.57	0.48	0.53	0.58
Fractures prevented	1603	1174	478	1388	148
Ratio of fractures prevented per AE observed ^d	AFF (5) ^e ONJ (35) ^f	280.8 33.5	186.8 21.8	274.2 38.9	19.6 4.2

Based on long-term denosumab subjects. All results are based on 5000 bootstrap samples.

N = number of long-term subjects who had fracture-outcome data. Exp = a exposure time in subject-years (estimated the time from FREEDOM baseline to the onset of first event) (for subjects who had a fracture event) or end of study or last assessment date, whichever was greater (for subjects who did not have a fracture event).

^a Major osteoporotic fractures were defined as clinical spine, forearm, hip, or shoulder fracture.

^b 227 long-term subjects had missing vertebral fracture outcome data during FREEDOM and/or its Extension.

^c Calculated as (long-term rate) / (virtual twin rate).

^d Calculated as (virtual twin rate – long-term rate) / AE rate.

^e The number in parenthesis indicates the AE-related incidence rate per 100,000 subject-years in long-term subjects.

^f There were 2 mild, 5 moderate, and no severe cases of ONJ in the long-term group.

AE, Adverse event; AFF, atypical femoral fracture; ONJ, osteonecrosis of the jaw.

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Osteoporosis is a chronic disease, yet skeletal safety events—atypical femoral fracture (AFF) and osteonecrosis of the jaw (ONJ)—remain a concern with long-term treatment. Ten years of denosumab therapy in postmenopausal women with osteoporosis has demonstrated sustained and low vertebral and non vertebral fracture rates, with low adverse event rates (*Bone Lancet Diabetes Endocrinol* 2017). Here, we generated a denosumab skeletal benefit/risk ratio derived from observed data and model-based estimates from the FREEDOM trial and its Extension.

Methods: Exposure-adjusted subject incidence per 100,000 subject-years of clinical, major osteoporotic, vertebral, nonvertebral, and hip fractures was calculated for long-term subjects randomized to denosumab in the 3-year FREEDOM trial and enrolled in the 7-year Extension (follow-up time on denosumab 3 to 10 years). Due to the lack of a long-term placebo group, fracture rates in a hypothetical cohort of 10-year placebo controls (virtual twins; Vittinghoff *Stat Med* 2010) were estimated: A regression model was generated using data from subjects randomized to PBO during FREEDOM and then enrolled in the Extension; a virtual twin with identical baseline characteristics to each long-term subject was derived; and fracture rates were then predicted for the untreated virtual twin group using the regression model. The number of fractures prevented per 100,000 subject-years was calculated as (virtual twin rate – long-term rate). AFF and ONJ incidences on denosumab were based on observed cases in the long-term group during the Extension; the virtual twin group was assumed to have no AFF or ONJ in the absence of treatment. A skeletal benefit/risk ratio was calculated from fractures prevented per AFF or ONJ observed.

Results: This analysis included 2343 subjects. The estimated number of clinical fractures prevented was 1403 per 100,000 subject-years (Table). There was 1 case of AFF and 7 ONJ (mild and moderate), corresponding to rates of 5 (AFF) and 35 (ONJ) per 100,000 subject-years. Hence, there were 281 and 40 clinical fractures prevented per AFF and ONJ observed, respectively. The skeletal benefit/risk ratio for other fracture endpoints is shown below (Table).

Conclusion: As long-term placebo-controlled fracture outcome studies in postmenopausal osteoporosis are not ethical, the virtual twin model provides a reasonable estimate of untreated fracture rates. Using this model, long-term denosumab therapy has a highly favorable benefit/risk profile when comparing fractures prevented per skeletal adverse event observed.

Fracture and Bone Mineral Density Response By Baseline Risk in Patients Treated with Abaloparatide Followed By Alendronate

Benjamin Leder¹, Carol Zapalowski², Ming-Yi Hu³ and Gary Hattersley², ¹Endocrine, Harvard Medical School, Boston, MA, ²Radius Health, Inc., Waltham, MA, ³Biometrics, Radius Health, Inc., Waltham, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Abaloparatide (ABL) is an anabolic PTHrP analog approved to treat postmenopausal women with osteoporosis at high risk of fracture. In the ACTIVE Phase 3 study of postmenopausal osteoporotic women, 18 months of ABL significantly increased bone mineral density (BMD) and reduced the risk of vertebral, nonvertebral, clinical, and major osteoporotic fractures versus placebo (PBO) irrespective of baseline risk factors. In ACTIVEExtend, women assigned to receive ABL or PBO in ACTIVE were offered enrollment in an extension study during which both groups received open-label alendronate (ALN) 70 mg weekly for 24 months. In this analysis, we assess whether fracture risk reduction and BMD gains were consistent across multiple subgroups categorized by baseline risk.

Methods: A total of 1,139 patients (558, ABL/ALN and 581, PBO/ALN) were enrolled in ACTIVEExtend (18 months of ABL or PBO followed by 1 month for re-consent, followed by 24 months of ALN treatment for a total of 43 months). Risk factor subgroups were prospectively defined by BMD T-score of the lumbar spine, total hip, and femoral neck (≤ -2.5 vs > -2.5 ; ≤ -3.0 vs > -3.0); nonvertebral fracture history (yes/no); prevalent vertebral fracture at baseline of ACTIVE (yes/no); and age (< 65 vs 65 to < 75 vs ≥ 75 years) at baseline. Treatment effects in subgroups were assessed by forest plots

and statistical tests for interactions using relative risk ratios for new vertebral fractures (Breslow-Day test), hazard ratios for nonvertebral fractures (Cox proportional hazards model), and least-squares mean differences in percent change for BMD (ANCOVA).

Results: Patients in ACTIVEExtend were well balanced for baseline characteristics including age, lumbar spine BMD, total hip BMD, femoral neck BMD, vertebral fracture, and prior nonvertebral fracture. The relative risk reductions for new vertebral, non-vertebral, clinical, and major osteoporotic fractures were greater in the ABL/ALN group compared with the PBO/ALN group for all subgroups analyzed. There was no evidence of meaningful interaction between treatment assignment and any baseline risk variable. Additionally, BMD gains at 43 months for total hip, femoral neck, and lumbar spine were greater in the ABL/ALN group versus the PBO/ALN group among all subgroups analyzed without any meaningful interaction between treatment assignment and any baseline risk variable.

Conclusion: These results suggest that the improved efficacy of 18 months of ABL followed by 24 months of ALN versus 18 months of PBO followed by 24 months of ALN is unaffected by baseline risk. Fracture risk reductions and BMD increases were consistent among all prespecified patient risk subgroups.

Harvey³, Chad Deal⁴, Felicia Cosman⁵ and Michael McClung⁶, ¹Medicine, University of Pittsburgh, Pittsburgh, PA, ²Radius Health, Inc., Waltham, MA, ³MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, ⁴Cleveland Clinic, Shaker Heights, OH, ⁵Columbia University College of Physicians and Surgeons, New York, NY, ⁶Oregon Osteoporosis Center, Portland, OR

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: The risk of fracture increases with increasing age. Thus, it is important to understand efficacy and safety of osteoporosis treatments in elderly patients. In the ACTIVE phase 3 study, 18 months (M) of abaloparatide (ABL) treatment significantly increased bone mineral density (BMD) and reduced the risk of new vertebral, nonvertebral, clinical, and major osteoporotic fractures vs placebo (PBO). Women receiving ABL or PBO in ACTIVE were offered enrollment in the ACTIVEExtend extension study in which both groups received 24M open-label alendronate (ALN) 70 mg weekly for a total of 43M (18M ABL or PBO, 1M for reconsent, and 24M ALN). The objective of this post hoc analysis was to evaluate efficacy and safety of ABL followed by ALN (ABL/ALN) vs PBO/ALN in the subgroup of patients aged ≥ 80 years in ACTIVEExtend.

Methods: ACTIVEExtend enrolled postmenopausal women with osteoporosis between the ages of 50 and 85; 558 were from the original ABL group and 581 from the PBO group of the ACTIVE study. Pre-specified endpoints, including BMD, new vertebral, nonvertebral, clinical, and major osteoporotic fractures, were assessed over the 43M period. Nonvertebral fracture endpoints were assessed using the Kaplan-Meier (KM) method, proportional hazard model, and logrank test.

Results: A total of 56 ACTIVEExtend patients (29 ABL/ALN; 27 PBO/ALN) were aged ≥ 80 years at ACTIVE baseline. Mean age was 81.8 years in both groups. Mean percent changes from baseline in total hip, femoral neck, and lumbar spine BMD were all significantly greater with ABL/ALN vs PBO/ALN at all timepoints assessed, except for total hip at M6. At M43, BMD mean percent change from baseline was 5.3% ABL/ALN vs 3.1% PBO/ALN ($P=0.024$) at the total hip, 4.6% ABL/ALN vs 3.1% PBO/ALN ($P=0.044$) at the femoral neck, and 17.2% ABL/ALN vs 8.6% PBO/ALN ($P<0.0001$) at the lumbar spine. Fracture rates were very low in both groups in this small subset of women (new vertebral: 0 ABL/ALN, 1 PBO/ALN; nonvertebral: 1 ABL/ALN, 2 PBO/ALN). Adverse event rates were similar between treatment arms with 78.6% and 81.5% of patients in the ABL/ALN and PBO/ALN groups, respectively reporting ≥ 1 treatment-emergent adverse event.

Conclusion: In conclusion, significant BMD gains were maintained through 43M with ABL/ALN vs PBO/ALN. This post hoc analysis suggests that an ABL/ALN treatment was effective in an elderly subgroup of ACTIVEExtend, with a safety profile similar across treatment arms.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Atypical femoral fractures (AFF) are low energy femoral fractures and subtrochanteric/diaphyseal localization that have been related to long-term bisphosphonate therapy. Patients with AFF exhibit cortical thickening in femoral shaft, suggesting that AFF may occur due to cortical stress. Analysis of cortical bone microarchitecture, biomechanical properties of bone and bone remodeling in AFF are poorly explored in the literature. Our aim is to evaluate patients with AFF including: 1) cortical bone microarchitecture and bone stiffness by high resolution peripheral quantitative computed tomography (HR-pQCT) and 2) cortical microarchitecture and parameters of bone remodeling by bone histomorphometry of iliac crest.

Methods: Eighteen patients with AFF by the American Society of Bone Mineral Research. Cortical bone parameters (cortical volumetric bone mineral density: Ct.vBMD, mgHA/cm³; and cortical thickness: Ct.Th, mm) and bone stiffness (S, kN/mm) were studied at tibia and distal radius by HR-pQCT and compared to healthy controls matched for sex and age. Cortical thickness (Ct.Th, µm) and bone remodeling (bone formation rate: BFR/BS, µm³/µm²/day) were assessment (Osteomeasure software®) and compared with healthy individuals matched for sex and age.

Results: The mean age of the patients was 64.9±13.3 years old, 94.4% women and 72.2% Caucasian. Seventeen used bisphosphonates (5.8±2.7 years) and 83.3% alendronate at the time of fracture. One patient was on denosumab, but had received bisphosphonate for 6 years. Presence of rheumatic disease was observed in 50% of the patients, most of them with rheumatoid arthritis and 44.4% of the patients used oral glucocorticoid. All fractures were diaphyseal, of which 16 (88.8%) were complete and 4 (22.2%) were bilateral. HR-pQCT (n=12) at tibia showed decreased/normal Ct.vBMD in 83.3% and decreased/normal Ct.Th in 91.6% of the patients. Similar findings were observed at distal radius. Seventy-five percent of the patients had decreased S at tibia and 58.3% at radius. At tibia, S was positively correlated with Ct.Th (r = 0.783, p = 0.001) and Ct.vBMD (r = 0.573, p = 0.004). At radio, S was positively correlated with Ct.Th (r = 0.720, p = 0.007). Bone histomorphometry (n=6) exhibited Ct.Th decreased in 66.6% and normal in 33.3% of the cases. All patients had suppressed bone remodeling.

Conclusion: Our data suggest that AFF patients maintain bone fragility observed in peripheral sites (tibia and radius) and in the iliac crest. Impairment of cortical microarchitecture associated with decreased bone stiffness and suppression of bone remodeling would explain bone fragility in these patients. Our data warn that the cortical bone should be contemplated in the treatment of AFF.

Risk of Venous Thromboembolism with Selective Estrogen Receptor Modulators for Postmenopausal Osteoporosis: A Meta-Analysis of Randomized Trials

Rashmi Dhital¹, Dilli Poudel², Bidhya Timilsina³, Theresa Lynn³, Colin Peters³, Oreoluwa Oladiran³, Prem Parajuli³, Prakash Paudel⁴ and Anthony Donato³, ¹Reading Hospital-Tower Health System, West Reading, PA, ²Internal Medicine, Reading Hospital-Tower Health System, WEST READING, PA, ³Reading Hospital, West Reading, PA, ⁴Internal Medicine, Berkshire Medical Center, Pittsfield, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Selective Estrogen Receptor Modulators (SERMs) are one of the available treatment options for postmenopausal osteoporosis. Since Raloxifene was first introduced on 1997 for post-menopausal osteoporosis, studies have shown increased risk of venous thromboembolism (VTE). However, some more recent studies have reported no significant increase in risk. Lasofoxifene and Bazedoxifene (approved for postmenopausal osteoporosis in the US by FDA on 2005 and 2013, respectively) are relatively newer SERMs that are generally well-tolerated and have similar efficacy while also reducing coronary heart disease and stroke risk, making them desirable options for postmenopausal women. However, studies have variable results when it comes to VTE risk with these novel SERMs. The aim of this study was to perform a quantitative meta-analysis of randomized controlled trials(RCTs) to assess the risk of VTE with SERMs.

Methods: Relevant trials were identified through electronic searches of PubMed, EMBASE, Cochrane library and Google Scholar as well as from references of the included studies. Only RCTs comparing SERMs with placebo were included. Data from the trials pertinent to VTE as an adverse event were extracted. A subgroup analyses was performed to identify if any difference existed between Raloxifene and other newer SERMs.

Results: In 11 RCTs involving 39,920, the risk of VTE with any SERM was significantly increased [odds ratio (OR) 1.7, 95 % CI 1.37-2.12, $p < 0.001$, $I^2 = 0\%$] compared to placebo (Fig-1). On a subgroup analysis, this risk was even higher with newer SERMs [OR 2.0, 95 % CI 1.33-2.98, $p < 0.001$, $I^2 = 0\%$](Fig-2). The risk of VTE with Raloxifene was higher than placebo but lower compared to other SERMs [OR 1.58, 95 % CI 1.22-2.05, $p < 0.001$, $I^2 = 0\%$](Fig-2).

Conclusion: The risk of VTE seems to be elevated with any of the SERMs. Even though the newer SERMs have been reported to have better cardiovascular risk profiles (reduction in heart disease and stroke) compared to Raloxifene, the risk of VTE seems to be similar or may be even higher in these agents.

Methotrexate Use and the Risk for Cardiovascular Disease Among Rheumatoid Patients Initiating Biologic Disease-Modifying Anti-Rheumatic Drugs

Fenglong Xie¹, Lang Chen¹, Emily Levitan², Paul M. Muntner² and Jeffrey R. Curtis¹, ¹University of Alabama at Birmingham, Birmingham, AL, ²Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Methotrexate(MTX) has been associated with reduced risk for cardiovascular disease (CVD) in several studies conducted among rheumatoid arthritis (RA) patients never exposed to biologic disease-modifying antirheumatic drugs (bDMARDs). Effect of concomitant MTX use on CVD risk among RA patients initiating bDMARDs remains unknown.

Methods: A retrospective cohort study was conducted using 2006-2015 Medicare claims data for RA patients. Follow up started at initiation (index date) and ended at earliest of 1) end of exposure of the specific bDMARDs agent (days of supply + 90 day extension), 2) switched to other bDMARDs or tofacitinib, 3) CVD event, 4) death date, 5) loss of Medicare coverage, 6) end of study (September 30, 2015). MTX use was defined as 1) concomitant MTX use, with prescription for MTX within 120 days after index date and 2) time varying MTX, defined as prescription date to prescription date plus days of supply without extension. For sensitivity analysis, a 90-day extension was added to days of supply. The primary outcome was

composite of incident MI, incident stroke and fatal CVD. Fatal CVD were identified by a claims based algorithm with PPV $\geq 80\%$. Incidence rates (IR) and 95% confidence intervals (CI) were calculated using Poisson regression. Overall association between MTX use and risk of CVD were assessed using Cox regression. Given that the interactions between MTX and background bDMARDs was significant, we performed contrast (MTX Yes vs. No) to examine the association between MTX and risk for CVD for each underlying bDMARDs in one model. A subgroup analysis limited the cohort to RA patients with previous exposure to MTX was conducted to ensure consistency of findings.

Results: A total of 88,255 DMARDs initiations (64,218 patients) were included in this study. The average age at initiation was 64.6 (12.3) years, 84.0% were female, 68.2% were non-Hispanic white. The crude IRs for CVD were 13.1 (95% CI: 12.2-14.0) and 18.7 (95% CI: 17.6-19.9) events per 1,000 person years (PY) for RA patients with and without concomitant MTX respectively. The crude IRs for CVD were 12.1 (95% CI: 11.1-13.2) and 17.9 (95% CI: 16.9-18.8) events per 1,000 PY for RA patients with and without time varying MTX respectively. IRs for individual bDMARDs are shown in figure. P-value for interaction between concomitant MTX and background bDMARDs was 0.0189 and p-value for interaction between time varying MTX and background bDMARDs was 0.0030. The contrast HRs for concomitant MTX ranged from 0.61 (0.37, 1.01) for golimumab initiators to 0.97 (0.74, 1.26) for adalimumab initiators (Figure). The contrast HRs for time varying MTX ranged from 0.58 (0.35, 0.96) for certolizumab initiators to 0.90 (0.68, 1.18) for adalimumab initiators. Results were robust in sensitivity and subgroup analyses.

Conclusion: Our observational study suggests an overall 23% reduction of CVD risk associated with concomitant MTX use. The effect sizes vary among background bDMARDs.

IRs are per 100 patient-years of exposure. ATE, arterial thrombotic event; BARI, budesonide; CI, confidence interval; DVT/PE, deep vein thrombosis and/or pulmonary embolism; IR, incidence rate; MACE, major adverse cardiovascular event (composite of myocardial infarction, stroke, and cardiovascular death); PBO, placebo; NA, pneumotest arthritis, vs, versus.

Background/Purpose: Baricitinib (BARI), a selective inhibitor of Janus kinases, is approved in >40 countries for the treatment of active rheumatoid arthritis (RA) in adults. Patients (pts) with RA have increased cardiovascular (CV) risk, including for arterial and venous occlusive events. This analysis provides an update to CV safety in pts treated with BARI for up to 6 years.

Methods: Data were pooled from 8 Phase 1-3 studies, including a long-term extension study (LTE) up to April 1, 2017, and analyzed in 3 sets: 1) All BARI RA (all pts exposed to any BARI dose); 2) Placebo (PBO)-controlled (6 studies comparing BARI 4-mg once daily [QD] to PBO, 0-24 weeks); and 3) Extended 2- vs 4-mg (4 studies with BARI 2- and 4-mg QD, including LTE data). Major adverse cardiovascular events (MACE) were adjudicated in Phase 3 by a blinded, independent panel. Study database preferred term searches identified arterial thrombotic events (ATE; adjudicated where applicable) and events of deep vein thrombosis and/or pulmonary embolism (DVT/PE; analyzed without adjudication). Risk factors were analyzed between pts with and without events in the All BARI RA set using Cox regression. Incidence rates (IRs) are per 100 pt-years (PY) of exposure.

Results: 3492 pts were exposed to BARI (7860 PY; median 933 days; max 2230 days), 2723 (78.0%) for ≥ 1 year; 1788 (51.2%) for ≥ 2.5 years. For ATE and MACE, the frequency of reported events and IR were low, comparable across treatments and analysis sets, and did not increase with prolonged exposure (Table 1). For DVT/PE, events (n=6) were reported for BARI 4-mg but not PBO during the 24-week PBO-controlled period. This imbalance was not replicated during 24 weeks after switch to BARI 4-mg from PBO (N=928, 1 event) or active comparator (N=451, 0 events). At longer exposure, DVT/PEIRs were comparable between BARI 2- and 4-mg doses (Table 1). Within the All BARI RA set, IRs were stable over time (Fig 1; overall IR 0.53), the frequency of permanent discontinuation following a DVT/PE event was low (n=5; 0.1%; IR=0.06), and factors (age, BMI, COX-2 inhibitor use, and prior history of DVT/PE) were identified that may contribute to increased risk of DVT/PE (Fig 2).

Conclusion: MACE and ATE IRs were low and did not increase with prolonged exposure. For DVT/PE, IRs were similar between BARI doses and in line with published rates in RA.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Small noncoding RNAs (sRNAs), such as microRNAs (miRNAs), regulate gene expression and can be used as biomarkers of disease. Patients with rheumatoid arthritis (RA) have accelerated atherosclerosis leading to excess cardiovascular morbidity and mortality. Traditional risk factors used in the general population for risk stratification are inadequate in RA. Our objective was to develop a microRNA panel which predicts presence of coronary artery atherosclerosis in patients with RA.

Methods: Plasma sRNA sequencing was performed on samples from 161 patients with RA whose Agatston scores for coronary artery calcium were previously assessed by electron beam computed tomography. The TIGER pipeline was used

Figure 1. Random forest analysis for predictors of coronary atherosclerosis in patients with RA.

to quantify miRNAs. Random forest analysis including plasma miRNA expression by sRNA sequencing, age, race, sex, Framingham risk score, and high-sensitivity CRP was used to determine which covariates best differentiated between those with and without coronary calcium. The top 15 miRNAs based on random forest analysis were chosen. Logistic regression and area under the receiver operating characteristic curve analyses were used to assess the miRNA panel for prediction of the presence of coronary calcium.

Results: Age and Framingham risk score were the strongest predictors of coronary atherosclerosis (Figure 1); however, the AUC for predicting atherosclerosis was the same for age alone and for age plus Framingham risk score (AUC=0.80 (95% CI 0.73, 0.87), $P<0.001$). The addition of the top 15 miRNAs based on random forest analysis resulted in an improved ability to predict atherosclerosis (AUC=0.85 (95% CI 0.79, 0.91), $P<0.001$)(Figure 2).

Conclusion: A set of 15 plasma miRNAs improved coronary atherosclerosis prediction capacity beyond use of traditional risk factors. Further validation is necessary to confirm these findings and the use of the panel for prediction of coronary events in RA.

Cardiovascular Disease Risk with Biologics and Tofacitinib Compared to Conventional Synthetic Dmards in Patients with Rheumatoid Arthritis

Gulsen Ozen¹, Sofia Pedro² and Kaleb Michaud^{1,2}, ¹Rheumatology, University of Nebraska Medical Center, Omaha, NE, ²FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

Background/Purpose: Cardiovascular disease (CVD) represents the leading cause of death in RA, accounting for ~50% of excess mortality. Disease activity, strongly linked to CVD, has been significantly improved by biologic (b) and targeted-synthetic DMARDs in RA. However, the influence of these agents targeting different inflammatory pathways on the CVD risk in RA is not yet clear. We examined the comparative effects of bDMARDs and tofacitinib against conventional synthetic (cs) DMARDs on incident CVD in RA patients.

Methods: RA patients with ≥ 1 year participation in FORWARD, The National Databank for Rheumatic Diseases, from 1998 through 2017 were assessed for incident CVD (myocardial infarction, stroke and heart failure validated from hospital/death records). DMARDs were categorized into 7 mutually exclusive groups: (1) csDMARDs-referent (2) TNFi(3) Abatacept (4) Rituximab (5) Tocilizumab (6) Anakinra (7) Tofacitinib. For glucocorticoids (GC), a weighted cumulative exposure (WCE) model which combines information about duration, intensity, and timing of exposure into a summary measure was used. Event rates were calculated and compared across bDMARDs using Cox proportional hazards with adjustment for sociodemographics, comorbidities, and RA severity measures.

Results: 1,561 CV events were identified in 17,363 RA patients (mean [SD] age 63[13] years, disease duration 18[13] years) during a median (IQR) 4.1(1.8-8.2) years of followup. TNFi and non-TNFi bDMARDs users had significantly higher disease activity, disability, and comorbidity scores than csDMARD users. The incidence rate (95% CI) of CVD for the entire cohort was 1.78 (1.69-1.87)per 1,000 patient-years. Incidence rates in each DMARD group are shown in the *Table*. The adjusted model showed a significant CVD risk reduction with TNFi (HR 0.79 [0.69-0.92])and abatacept (HR 0.53 [0.30-0.92]) compared to csDMARDs whereas GC as WCE was associated with significant risk increase (HR 1.15 [1.11-1.20]). Other bDMARDs and tofacitinib were not significant (Figure). In analysis of individual TNFi, although all TNFi tended to be associated with decreased CV risk, only the risk with infliximab(HR 0.81 [0.67-0.98]) and etanercept (HR 0.78 [0.64-.95]) reached statistical significance.

Conclusion: TNFi, notably infliximab and etanercept, and abatacept were associated with decreased risk of CVD and GC with increased risk. Despite reported similar efficacies of bDMARDs in RA, the difference in CV benefits may be due to drug-specific mechanisms directly influencing the atherosclerosis or metabolic changes.

Table. Crude incidence rates and risk of cardiovascular disease in rheumatoid arthritis by treatment

	No. of events/exposure	Patient-years	Incidence rate (95% CI)*	Unadjusted HR (95% CI)	Adjusted HR _l (95% CI)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00 PM

Background/Purpose: Galectin-3 has emerged as a promising novel biomarker of cardiovascular fibrosis, that can improve cardiovascular risk stratification in high-risk populations. Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by excess cardiovascular risk. We investigated for the first time whether galectin-3 correlates with robust markers of subclinical atherosclerosis, arterial stiffness and myocardial function in patients with RA.

Methods: Serum levels of galectin-3 were determined by enzyme-linked immunosorbent assay (ELISA) in RA and non-RA individuals. Carotid-femoral pulse wave velocity (PWV) was estimated as the gold-standard measure of arterial stiffness with applanation tonometry. Subclinical atherosclerosis was evaluated by measurement of carotid intima-media thickness (cIMT) from carotid ultrasound. Indices of myocardial blood flow (cardiac output, stroke volume), contractility (acceleration index, velocity index) and afterload (systemic vascular resistance) were non-invasively assessed with impedance cardiography, which offers continuous, beat-by-beat measurements of central hemodynamics. Cardiovascular risk was estimated from the Framingham Heart Study.

Results: A total of 124 participants with a mean age of 59.6±11.6 years were studied, of whom 85 were RA patients and 39 controls. Mean DAS score was 3.6±1.2, median disease duration was 10 (5–18) years, and median erythrocyte sedimentation rate was 20 (10–30) mm/hr. Serum galectin-3 was significantly higher in RA patients, compared to the control group [17.7 (9.8 – 33.5) vs 9.1 (6.0 – 12.0) ng/dl, p<0.001]. However, galectin-3 did not significantly differ when the subgroup of patients without cardiovascular comorbidities (n=38) were separately compared to controls [10.7 (6.4–20.3) vs 9.1 (6.0–12.0) ng/dl, p=ns].

In the univariate analysis, galectin-3 significantly correlated with both PWV (r=0.341, p=0.002) and cIMT (r=0.312, p=0.004) among RA patients. An inverse association was found between galectin-3 and stroke volume (r=–0.279, p=0.010), which was even stronger with cardiac output (r=–0.409, p<0.001). Galectin-3 strongly correlated with systemic vascular resistance (r=0.364, p=0.001) and both acceleration index (r=–0.317, p=0.003) and velocity index (r=–0.395, p<0.001). A positive association was observed between galectin-3 and the estimated 10-year cardiovascular risk from the Framingham Heart Study (r=0.379, p=0.001). On the contrary, no associations were found between galectin-3 and disease-related parameters, including inflammation and disease activity. Multivariate analysis revealed an independent association between galectin-3 and cardiac output (beta=–0.274, p=0.039).

Conclusion: In a relatively well-controlled cohort of RA patients presenting with low-grade systemic inflammation and long-standing disease, serum galectin-3 strongly correlated with markers of cardiac performance and the estimated 10-year cardiovascular risk. By contrast, galectin-3 was not related to inflammation and disease activity in these patients.

Alcohol Consumption and the Risk of Coronary Heart Disease and Mortality in Patients with Rheumatoid Arthritis

Isaac Smith¹, Jie Wei², Yuqing Zhang³, Hyon K. Choi² and Marcy Bolster¹, ¹Massachusetts General Hospital, Boston, MA, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of premature cardiovascular events and mortality. Prospective general population studies have shown moderate alcohol consumption is associated with a 25-40% reduced risk of all-cause mortality and coronary heart disease (CHD). Alcohol use has been discouraged in RA patients taking methotrexate (MTX) due to potential liver toxicity. However, a recent population-based study found moderate alcohol consumption (0-14 UK units or 0-8US drinks per week) was not associated with a higher risk of hepatotoxicity. The aim of this study is to examine the effect of alcohol intake on all-cause mortality and CHD events among RA patients taking disease-modifying anti-rheumatic drugs (DMARDs), including those taking MTX.

Methods: A prospective cohort study (1995-2017) was conducted using electronic medical records from The Health Improvement Network (THIN) database, representative of the general United Kingdom (UK) population. Our study population consisted of RA patients taking MTX or other DMARDs. Alcohol exposure was defined as first recorded alcohol use following RA diagnosis and divided into 5 categories: non-drinkers, 1-7 units/week (mild), 8-14 units/week (moderate), 15-21 units/week (moderate-high) and >21 units/week (high), where 1 UK unit = 8g alcohol. We created Cox-proportional hazard models using age as the time-scale and calculated hazard ratios (HR) for the relation of alcohol consumption to all-cause mortality and CHD events, adjusting for age, sex, body mass index (BMI), smoking status, and Townsend deprivation index.

Results: Of 43214 patients with RA (women: 70%, mean age: 60.2 years), 9102 deaths and 2013 CHD events occurred over 350612 person-years (mean follow-up = 8 years). Alcohol use was associated with a decreased risk of all-cause mortality in RA patients taking MTX, particularly with mild to moderate use. When the analysis was restricted to other DMARDs, the results did not change materially (Table). Alcohol consumption was also associated with a decreased risk of CHD events in both groups, most prominently with moderate-high to high use (Table).

Conclusion: In this prospective cohort study, mild to moderate alcohol use is associated with decreased risk of all-cause mortality among RA patients taking MTX and patients taking other DMARDs. Alcohol consumption is also associated with a decreased risk of CHD events in both groups. Given these results, the prior recommendation for avoiding alcohol use in RA patients taking MTX warrants reconsideration.

Table. Relation of Alcohol Consumption to All-Cause Mortality and CHD Events in Patients with RA

Alcohol Intake (Units/Week)†	N	Events	Event Rate (Per 1000 Person-Years)	Unadjusted HR (95% CI)	Adjusted HR‡ (95% CI)

Session Title: Rheumatoid Arthritis – Treatments IV: Strategy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Infliximab (IFX), a TNF inhibitor, is one of the most widely used biological disease-modifying antirheumatic drugs. Recent studies indicated that baseline levels of serum TNF- α could be considered as a key indicator for optimal dosing of IFX for treatment of rheumatoid arthritis (RA) to achieve the clinical response and its sustained remission. The Remission induction by Raising the dose of Remicade in RA (RRRR) study (trial registry no; UMIN000005113) was designed to evaluate the clinical remission after 54 weeks of “programmed” treatment, whose dose

of IFX for each patient was determined by the baseline serum TNF- α . The sustained remission rate after 1-year discontinuation of IFX was compared to standard treatment of IFX at week 106.

Methods: RRRR study was a randomized, active controlled, multicenter phase 4 study. IFX-naïve RA patients who showed an inadequate response to MTX were randomized 1:1 to the programmed treatment strategy (programmed group) and the standard treatment strategy (standard group).

Patients in programmed group received 3 mg/kg IFX at week 0, 2, and 6. After 14 weeks, a dose of IFX was kept or raised based on baseline levels of serum TNF- α (3 mg/kg for TNF- α < 0.55 pg/mL; 6 mg/kg for 0.55 pg/mL- <1.65 pg/mL; 10mg/kg for 1.65 pg/mL or greater) every 8 weeks until week 54 after enrollment. Patients in standard group received 3mg/kg of IFX from week 0 to 54. If patients showed a simplified disease activity index (SDAI) \leq 3.3 at week 54, they discontinued IFX. The primary endpoint was the proportion of patients who kept discontinuation of IFX at week 106 (1-year sustained discontinuation rate).

Results: From April 2011 to September 2013, 405 patients were enrolled and 337 patients who completed IFX treatment at week 0, 2, and 6 were randomized to the programmed group (n = 170) and the standard group (n = 167). The patient characteristics in intention-to treat population were similar between groups (Table 1). One hundred and seventeen patients (68.8%) in the programmed group and 112 patients (67.1%) in the standard group completed the 54 weeks IFX treatment after enrollment. At week 54, 39.4% (67/170) in the programmed group and 32.3% (54/167) in the standard group could attain the remission defined by SDAI ($p = 0.176$) and withdrew IFX treatment.

At week 106, the 1-year sustained discontinuation rate of the programmed group and standard group was 23.5% (40/170) and 21.6% (36/167), respectively (2.2% difference, 95% confidence interval = -6.6 to 11.0%; $p = 0.631$). No difference was observed in severe infections and other severe adverse events between groups.

Conclusion: Programmed treatment strategy using different dose of IFX based on the baseline levels of serum TNF- α tended to increase the remission rate at week 54, but did not increase the sustained remission rate after 1-year discontinuation of IFX treatment at week 106.

Table 1. Patients characteristics

	Standard group (N = 167)	Programmed group (N = 170)
Age, years, median (range)	59 (20 to 83)	58 (20 to 81)
Female, n (%)	136 (81.4)	129 (75.9)
Duration of disease, > 3 years, n (%)	69 (41.3)	71 (41.8)
Baseline SDAI, mean (SD)	27.0 (13.1)	28.2 (14.1)
Tender/painful joint count, mean (SD)	7.7 (6.4)	8.7 (6.4)
Swollen joint count, mean (SD)	7.4 (5.2)	7.4 (4.9)
Patients' global assessment VAS, mean (SD)	49.8 (19.1)	50.7 (25.1)
Physicians' global assessment VAS, mean (SD)	49.0 (19.1)	48.6 (22.4)
CRP, mg/dL, median (range)	0.91 (0.0 to 15.1)	1.0 (0.0 to 20.7)
Baseline DAS28 CRP, mean (SD)	4.1 (1.0)	4.2 (1.0)
Baseline TNF- α , < 0.55 pg/dL, n (%)	55 (32.9)	51 (30.0)
Baseline TNF- α , 0.55 to < 1.65 pg/dL, n (%)	61 (36.5)	68 (40.0)
Baseline TNF- α , > 1.65 pg/dL, n (%)	51 (30.5)	51 (30.0)
HAQ-DI score, mean (SD)	1.0 (0.8)	1.0 (0.8)
mTSS, median (range)	8.25 (0 to 318)	8 (0 to 403)
RF, IU/ml, median (range)	45.2 (0 to 2301)	59 (0 to 2050)
Dose of MTX, mg/w, mean (SD)	10.8 (3.2)	11.5 (3.3)

SD, standard deviation; SDAI, simplified disease activity index; VAS, visual analog scale; CRP, C-reactive protein; DAS28, disease activity score 28; HAQ-DI, health assessment questionnaire disability index; mTSS, modified total sharp score; RF, rheumatoid factor;

Session Title: Rheumatoid Arthritis – Treatments IV: Strategy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Dose tapering and discontinuation of biological therapy in rheumatoid arthritis patients in routine care – 2-year outcomes and predictors

Background/Purpose: A cohort of routine care rheumatoid arthritis (RA) patients in sustained remission had biological disease-modifying anti-rheumatic drugs (bDMARDs) tapered according to a treatment guideline. We studied: 1) the proportion of patients whose bDMARD could be successfully tapered or discontinued; 2) unwanted consequences of tapering/discontinuation; 3) potential baseline predictors of successful tapering and discontinuation.

Methods: One-hundred-and-forty-three patients with sustained disease activity score (DAS28-CRP) ≤ 2.6 and no radiographic progression the previous year were included. bDMARD was reduced to 2/3 of standard dose at baseline, 1/2 after 16 weeks, and discontinued after 32 weeks. Patients who flared (defined as either DAS28-CRP ≥ 2.6 and Δ DAS28-CRP ≥ 1.2 from baseline, or erosive progression on X-ray and/or MRI) stopped tapering and were escalated to the previous dose level.

Results: One-hundred-and-forty-one patients completed 2-year follow-up. At 2 years, 87 patients (62%) had successfully tapered bDMARDs, with 26(18%) receiving 2/3 of standard dose, 39(28%) 1/2 dose and 22(16%) having discontinued; and 54 patients (38%) were receiving full dose. Δ DAS28-CRP_{0-2yrs} was 0.1 ((-0.2)-0.4) (median(interquartile range)) and mean Δ Total-Sharp-Score_{0-2yrs} was 0.01(1.15)(mean(SD)). Radiographic progression was observed in 9 patients (7%). Successful tapering was independently predicted by: ≤ 1 previous bDMARD, male gender, low baseline MRI combined inflammation score or combined damage score (Figure). Negative IgM-rheumatoid factor predicted successful discontinuation. The “heat-map” for predicted probabilities for successful tapering based on logistic regression model including the 4 baseline variables are shown in Figure 2.

Conclusion: By implementing a clinical guideline, 62% of RA patients in sustained remission in routine care were successfully tapered, including 16% successfully discontinued at 2-years. Radiographic progression was rare. Maximum one bDMARDs, male gender, and low baseline MRI combined inflammation and combined damage scores were independent predictors for successful tapering.

Figure 1: Observed association between potential predictors and the proportion of patients with successful tapering (i.e. less than full dose) versus full dose at year 2

A (male gender):

MRI combined inflammation score	≤ 1 bDMARD	> 1 bDMARD	MRI combined damage score
≤ 3	86 %	64 %	≤ 2
	74 %	73 %	3-12
	64 %	66 %	≥ 13
4-12	74 %	57 %	≤ 2
	71 %	60 %	3-12
	67 %	52 %	≥ 13
≥ 13	83 %	55 %	≤ 2
	71 %	47 %	3-12
	65 %	54 %	≥ 13

B (female gender):

MRI combined inflammation score	≤ 1 bDMARD	> 1 bDMARD	MRI combined damage score
≤ 3	86 %	64 %	≤ 2
	78 %	46 %	3-12
	73 %	40 %	≥ 13
4-12	64 %	71 %	≤ 2
	47 %	71 %	3-12
	41 %	71 %	≥ 13
≥ 13	63 %	59 %	≤ 2
	45 %	71 %	3-12
	30 %	71 %	≥ 13

Figure 2: Predicted probability (%) for successful tapering of bDMARDs for male gender (A) and female gender (B). Red, yellow and green shows probabilities of 0-39%, 40-69% and 70-100%, respectively.

Session Title: Rheumatoid Arthritis – Treatments IV: Strategy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: In rheumatoid arthritis (RA), biologics are more efficient in combination with methotrexate (MTX) than in monotherapy. When MTX cannot be used, others csDMARD can be proposed in combination with biologics. However, the effectiveness of other csDMARD compared to MTX in combination with bDMARD is not clear. The aim of our study was to assess currently available literature on the association of csDMARD with biologics, compared with MTX.

Methods: We systematically searched literature (via Pubmed, Embase and abstracts from ACR and EULAR congresses) for studies that compare effectiveness, retention rate and safety of MTX versus other csDMARD (leflunomide [LEF] or all non-MTX csDMARD) as concomitant therapy with rituximab (RTX), TNF inhibitors (TNFi), abatacept, tocilizumab and JAK inhibitor (JAKi). A meta-analysis was performed with RevMan software using an inverse variance approach with fixed or random effects models, depending on the presence of heterogeneity. Data were extracted by one investigator and independently checked by another.

Results: From 3842 articles, the literature search revealed 144 articles and abstracts of potential interest, and further examination resulted in 8 studies fulfilling required criteria for RTX and 10 for TNFi. All of these studies were cohort studies. For tocilizumab, JAKi and abatacept, there were not enough studies to conduct meta-analysis. For patients receiving RTX, who had similar baseline characteristics in the two groups, those treated with LEF had a higher EULAR good response rate than those treated with MTX (n=3250, 5 studies, RR=1.46 (95% confidence interval [95% CI] 1.25;1.70), $P=0\%$, $p<0.001$). The variation of DAS28 at 6 months also tended to be higher in patients treated with LEF (-0.18 [-0.38;0.01], n=1449, 2 studies, $P=0\%$, $p=0.07$). The risk of adverse events also tended to be lower in patients treated with LEF (n=2718, 4 studies, RR=0.73 [0.52;1.03]; $P=0\%$, $p=0.07$).

Regarding patients receiving TNFi, those receiving MTX had a higher EULAR good or moderate response rate than those treated with other csDMARDs (n=1859, 3 studies, RR=0.88 [0.81;0.96]; $P=0\%$, $p=0.004$). The change in DAS28 at 6 months was also higher in patients treated by MTX than other csDMARD (-0.28 [-0.51;-0.05]; $P=0\%$, $p=0.02$). The risk ratio of discontinuing therapy due to adverse events at 6 months and the risk ratio of serious adverse events were similar between MTX and other csDMARD.

Conclusion: LEF or other csDMARD are safe and efficient for people who are intolerant to MTX to combine with biologics. Whereas MTX appears to be superior than other csDMARD in combination with TNFi, LEF might be superior than MTX in combination with RTX. Randomized controlled trials should be conducted to confirm this result.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments IV: Strategy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Tumour necrosis factor inhibitors (TNFi) are highly effective treatments for active Rheumatoid Arthritis (RA). However, up to 40% of patients either fail to respond adequately to TNFi or lose response over time. Options available include treatment with a 2nd TNFi or switching to a biological therapy with a different target such as Tocilizumab (TCZ) or Rituximab (RTX).

Objectives: To compare the effectiveness of a 2nd TNFi, TCZ or RTX, measured by stratified persistency rates, in RA patients with previous discontinuation of their 1st TNFi; to compare the response rates of TNFi, TCZ or RTX at 6 months, 1 and 2 years; to clarify the frequency and reasons for treatment discontinuation.

Methods: Non-interventional prospective study of RA patients exposed to a 2nd TNFi, TCZ or RTX treatment after previous TNFi discontinuation using real-world data from the Reuma.pt database. Patient and disease baseline characteristics, disease activity at follow-up (6 and 12 months and every year thereafter), discontinuation date and reason were collected and compared according to biologic class. Persistency of RTX, TCZ and TNFi were estimated using Kaplan-Meier analysis, from initiation of each therapy until discontinuation/ switch or last follow-up visit.

Results: 643 patients were included, 88.8% females, with a mean age of 59.4 (\pm 12.8) years. After 1st TNFi discontinuation, 390 (60.7%) patients initiated a 2nd TNFi, 147 (22.9%) TCZ and 106 (16.5%) RTX. There were no significant differences in patient and disease characteristics among the 3 groups, except for extra-articular manifestations, higher in RTX group ($p=0.013$), education ($p=0.002$) and current full-time employment ($p<0.001$), both lower in RTX patients. At baseline, TNFi group included more patients treated with concomitant methotrexate ($p=0.002$) and a higher swollen joint count-28 ($p=0.010$). However, the disease activity according to DAS28, CDAI and SDAI were similar between the different therapy groups. The persistency rates according to Kaplan-Meier survival curve were significantly greater (log rank test, $p<0.001$) among patients who initiated TCZ or RTX. The multivariate analysis showed a lower risk of discontinuation for TCZ (HR 0.39, 95% CI 0.23-0.64, $p<0.001$) and RTX (HR 0.42, 95% CI 0.25-0.72, $p=0.001$) and a significant risk for discontinuation for smoking (HR 2.43, 95% CI 1.50-3.95, $p<0.001$) and higher HAQ at baseline (HR 1.51, 95% CI 1.14-2.00, $p=0.004$), adjusted for gender, disease duration and comorbidities. The proportion of patients with a EULAR good response at 6 months ($p<0.001$), 1 ($p<0.001$) and 2 years ($p=0.021$) were, respectively, 23.7%, 28.0%, 31.4% for TNFi, 51.7%, 54.4%, 55.9% for TCZ and 27.5%, 23.1%, 25.6% for RTX. The main reason for discontinuation was inefficacy for TNFi and RTX and adverse events for TCZ ($p<0.001$).

Conclusion: Our findings showed a significantly higher drug persistence for RTX and TCZ compared with 2nd TNFi and a similar persistence among RTX and TCZ, in patients with previous TNFi discontinuation. These data corroborate the notion that switching to a biologic with a different mechanism of action might be more effective after TNFi discontinuation.

NB: Patients were seen 3-monthly. If they remain in remission, they proceed to the next taper unless there is a significant clinical reason not to taper at the time of assessment (as per standard care).

* Order of cs-DMARD therapy tapered if on dual/triple therapy

Flare Definition	csDMARD (n=66) Hydroxychloroquine n=13, Sulfasalazine n=8, Methotrexate n=45, (On monotherapy n=41, Combination therapy n=23)	bDMARD (n=32) Etanercept n=17, Adalimumab /Infliximab/ Certolizumab/Golimumab n=15
Physician Judgement (Increase in therapy +/- prescription of corticosteroid):	47% flare Higher total PD (p=0.005) RF positive (p=0.010) Higher total GS (p=0.012) ACPA positive (p=0.041)	50% flare Reduced Treg (p<0.0001)
DAS28 flare (increase in 3vDAS28 >1.2)	24% flare RF positive (p=0.007) Higher total PD (p=0.018)	29% flare Reduced Treg (p=0.001)
Loss of remission (3vDAS28 >2.6)	38% flare Higher TJC28 (p<0.0001) Higher total PD (p=0.003) Higher CRP (p=0.006) RF positive (p=0.009)	44% flare Reduced Treg (p=0.001) Increased IRC (p=0.008)
Loss of LDA (3vDAS28 >3.2)	27% flare Higher TJC28 (p<0.0001) Higher CRP (p=0.01)	37% flare Reduced Treg (0.004) Increased IRC (p=0.006) RF positive (p=0.014)
Loss of Boolean remission* (TJC, SJC & CRP all >1)	52% flare Longer disease duration (p=0.005) Higher CRP (p=0.002)	70% flare No associations
* Considering only patients who were in Boolean remission at baseline: 46 for csDMARDs and 10 for bDMARDs. Patient global health assessment omitted due to missing data. Abbreviations: Rheumatoid Factor (RF), Anti-citrullinated protein antibodies (ACPA), Power Doppler Synovitis (PDS), Grey Scale Synovial Hypertrophy (GS), Tender/Swollen Joint Counts (TJC28/SJC28), Age-corrected T-regulatory cells (Treg), Inflammatory Related Cells (IRC).		

heterogeneity in terms of flare rate according to the definitions used (Table 1). Tapering of b-DMARDs was associated with higher flare rate (29-70%) compared to cs-DMARDs (24-52%). Demographics were not associated with flare by any definition (except longer disease duration for cs-DMARD patients who lost Boolean remission status). Clinical (notably seropositivity) and US measures were associated with flare for cs-DMARDs. Reduced Treg and higher IRCs at baseline were associated with flare in patients tapering b-DMARDs.

Conclusion: The flare rate varied with the definition used and was more common when tapering b-DMARDs compared to cs-DMARDs. Flare was predicted in the latter patients by clinical and US (including seropositivity) findings, whereas T-cell abnormalities predicted flare in b-DMARD patients. These results will help formulate further tapering strategies.

Table 1. Rate of flare according to different definitions and associations with baseline characteristics

Session Title: Rheumatoid Arthritis – Treatments IV: Strategy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Rituximab (Rtx) induces transient depletion of B cells. Previous data showed that Rtx is particularly effective on autoimmune diseases in which auto-antibodies (auto-Ab) are produced, such as rheumatoid arthritis (RA). It is hypothesized that plasma cells expressing CD20 could be targets of Rtx. Therefore, the immunogenicity related to the use of Infliximab (Ifx) or Adalimumab (Ada) could be cleared by Rtx.

The study aims were i) to analyze the persistence of anti-drug antibodies (ADA) after switching to a 2nd drug (TNFi, Rtx or Tocilizumab-Tcz-) after 24 months of follow-up and ii) to evaluate whether the reduction of ADA level is influenced by the mechanism of action of the second biological therapy (BT).

Methods: Dataset from a prospective cohort including all patients with RA starting BT in a tertiary hospital was used. For this study, data from 40 patients who failed to Infliximab (Ifx) (68%) or Adalimumab (Ada) (32%) related to ADA detection and then switched to a 2nd TNFi (Ifx, Ada, Etanercept or Certolizumab) or to Rtx or to Tcz were analyzed. Additionally, patients should have two determinations of ADA levels: one at the end of the first BT and at least another one at 6, 12 or 24 months after switching BT. ADA levels were determined by bridging ELISA. The proportion of patients with ADA negative levels at 6, 12 and 24 months was determined. Median ADA survival time (mst) performed by Kaplan-Meier curves was determined. The relative reduction (in median) of ADA levels at 6, 12 and 24 months respect to baseline was compared between the switching to different BT.

Results: Out of 40 ADA positive patients with RA, 26 (65%) switched to a 2nd TNFi, 9 (23%) to Rtx and 5 (13%) to Tcz. Patients' characteristics are shown in Table 1.

The percentage of patients with undetectable ADA levels was higher in the group of patients switching to Rtx or Tcz compared with patients switching to a 2nd TNFi (29% and 33% vs 8% at 12 months; 33% and 25% vs 8% at 24 months, respectively).

Moreover, undetectable ADA levels appears earlier in patients switching to Rtx (mst=12) than in patients switching to TNFi or Tcz (mst=24 in both BT).

The relative ADA reduction was higher in patients switching to Rtx than in patients switching to TNFi or Tcz. Reduction of median ADA levels at 6, 12 and 24 months were as follows: 80%, 75% and 92%, respectively for TNFi; 97%, 98% and 98% for Rtx and 25%, 84% and 67% for Tcz.

Conclusion: Despite discontinuing TNFi, ADA titers remain positive in a high proportion of patients with RA after 24 months of treatment with a second biologic. However, in patients receiving Rtx, ADA levels appear to decrease earlier and more patients became ADA negative than patients receiving TNFi or Tcz. This effect could be explained by the intrinsic action mechanism of Rtx on plasmatic CD20+ cells.

Table I: Demographics characteristics of the 40 patients according to the second biologic.

Switch to:	TNFi (n=26)	Rtx (n=9)	Tcz (n=5)	p
Women, n(%)	24 (92%)	6 (67%)	5 (100%)	0.08

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

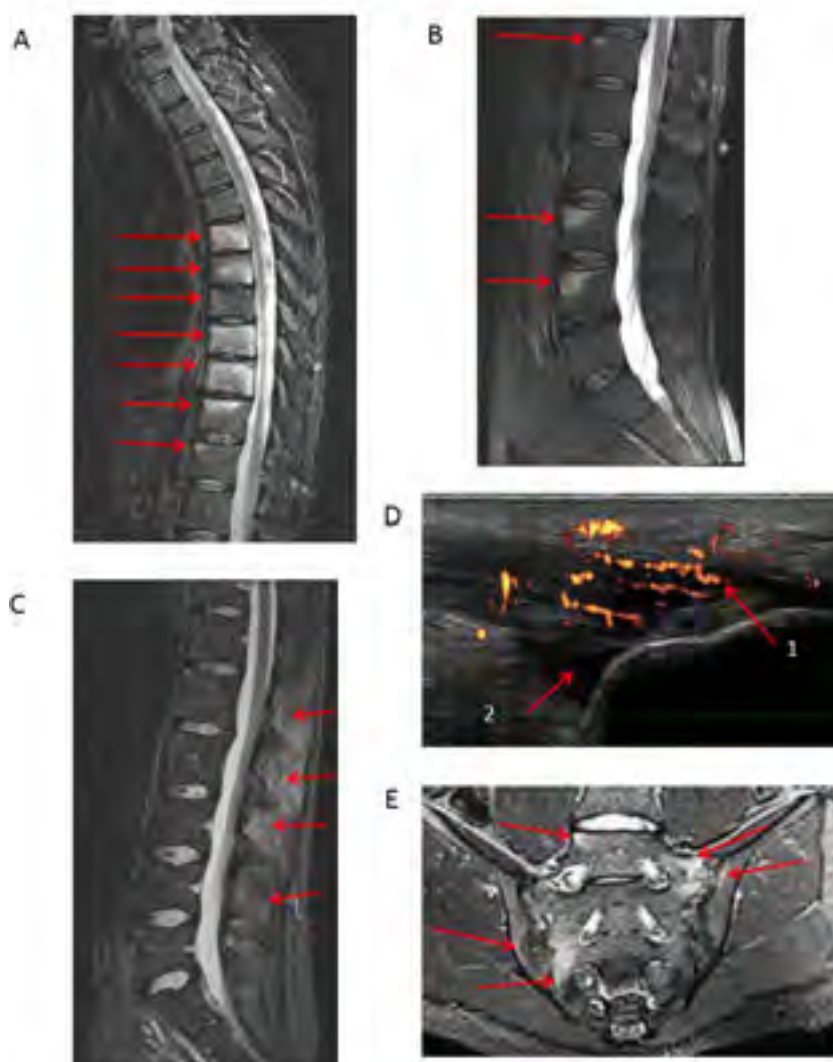

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Vedolizumab therapy for inflammatory bowel disease (IBD) has been associated with mild spondyloarthritis (SpA) related features including sacroiliitis and synovitis. Herein, we report a series of cases demonstrating the emergence of severe SpA associated enthesitis/osteitis following successful IBD therapy with vedolizumab.

Methods: We evaluated 11 vedolizumab treated patients with IBD across 7 centres that developed severe active SpA and/or enthesopathy with the aim of characterising the vedolizumab associated SpA or enthesal flares. Imaging features demonstrating particularly severe disease were recorded.

Results: De novo SpA developed in 9 of 11 patients and flare of known SpA in 2 patients with 4 cases requiring hospitalisation due to disease severity. Available data showed that 1/7 cases were HLA-B27 positive. The median time from vedolizumab initiation to flare was 12 weeks with IBD well controlled in 7/10 (no data 1 case) at flare. Severe SpA

Legend:
 Y= yes, N= no, NA= not available, cpg= cigarettes per day, EAMs= extra-articular manifestations, Y= non-radiographic, Y= positive, N= negative, o= once daily, w= once weekly, PaC= psoriasis, BASDAI= Bath Ankylosing Spondylitis Disease Activity Index, CD= Crohn's disease, UC= ulcerative colitis, CC= Crohn's disease, MR= magnetic resonance imaging, ILL= inflammatory bowel disease, BM= bone marrow oedema, PO= Power Doppler, XR= X-ray, TNF= tumour necrosis factor inhibitor, ADA= adalimumab, CDP= certolizumab pegol, CYS= cyclosporine, GLM= golimumab, IFX= infliximab, MZ= mesalazine, MTX= methotrexate, Tac= tacrolimus, TDP= tofacitinib, VED= vedolizumab, ZOL= zoledronic acid.

enthesitis/osteitis was evident on magnetic resonance imaging (MRI) or ultrasound (figure 1) including acute sacroiliitis (n=5), extensive vertebral osteitis (n=1), peri-facetal oedema (n=1), and isolated peripheral enthesitis (n=3). Due to arthritis severity, vedolizumab was discontinued in 9 of 11 cases and a change in therapy including alternative anti-TNF was initiated. Patient characteristics and outcomes are outlined in table 1.

Conclusion: Severe SpA, predominantly HLA-B27 negative, with osteitis/enthesitis, may occur under successful vedolizumab treatment for IBD. These cases pose the question why in the face of quiescent gut disease do patients develop a severe SpA/ enthesitis? The binding of α 4 β 7 to adhesion molecules to MADCAM-1/ VCAM-1 for T cell transportation into mucosal vascular tissue, may not be dependent for disease at enthesal or joint tissue and would

therefore not hinder adaptive T cell responses at these locations. This proposed model of pathogenesis offers an explanation for these severe SpA flares (figure 2). As we anticipate increasing use of $\alpha 4\beta 7$ inhibition, awareness of this paradoxical reaction and specific phenotype amongst rheumatologists and gastroenterologists alike, can facilitate combined management decisions for effective treatment of IBD and SpA or enthesitis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Systemic inflammation contributes to the excess risk of cardiovascular disease (CVD) in PsA. We had demonstrated that achieving sustained minimal disease activity (sMDA) was associated with protective effect on subclinical atherosclerosis and arterial stiffness¹. Yet, it is unclear if remission or stable low disease activity over time is sufficient to diminish the CV harmful effects of systemic inflammation.

Methods: We conducted a post hoc analysis of the PsA MDA vascular study¹. 101 PsA patients without overt CVD were recruited in this 2-year prospective study. All patients received protocolized treatment aiming at MDA. High-resolution ultrasound for subclinical atherosclerosis and arterial stiffness were assessed annually. Carotid plaque progression was defined as increased number or region harboring plaque. 4 definitions of remission/inactive disease were used: MDA and very low disease activity (VLDA)² defined as 5 & 7 MDA cut points are met. Disease Activity Index for Psoriatic Arthritis remission (DAPSA-rem) and low disease activity (DAPSA-LDA) were defined as DAPSA \leq 4 and \leq 14. Sustained disease control was defined as achieving these targets at each consecutive visit from month 12 till month 24.

Results: 90 PsA patients [male: 52 (58%); age: 50 \pm 11] who completed follow up were included in this analysis. Significant improvement in disease activity was observed (MDA: 15 [17%] at baseline vs 62[69%] at 2-year, $p<0.001$; DAPSA 19 [13,32] at baseline: vs 7 [4,14] at 2 year, $p<0.001$). 46%, 4%, 44% and 4% of subjects achieved sMDA) sustained VLDA (sVLDA), sustained DAPSA-LDA and sustained DAPSA-rem respectively. 34 (38%) had plaque progression. The rate of plaque progression was significantly lower in sMDA group when compared to those who did not. Achieving MDA was also associated with less progression in mean intima-media thickness (IMT) and augmentation index (AIx) (Fig 1). Using multivariate analysis, achieving sMDA had protective effect on plaque progression, less increase in total plaque area (TPA), mean IMT and AIX after adjusting baseline covariates (Table 1). No significant association between progression of vascular parameters and other treatment targets was observed.

Conclusion: Achievement of sMDA was associated with protective effect in subclinical atherosclerosis and arterial stiffness progression but not sDAPSA-LDA. Multidimensional domain of disease control is preferable for minimizing CV risk in PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: It is estimated that between 5 and 10% of patients with spondyloarthritis (SpA) are associated with inflammatory bowel disease (IBD).

The **purpose** of our study was to assess the usefulness of the determination of FC for the diagnosis of IBD in patients diagnosed with SpA without suggestive manifestations or previous diagnosis of IBD.

Methods: Unicentric, observational cross-sectional study with prospective clinical data collection. We included patients consecutively selected in a Rheumatology Clinic diagnosed of SpA who fulfilled ASAS criteria and who did not present digestive symptoms suggestive of IBD (chronic diarrhea, rectal bleeding, perianal disease, chronic abdominal pain - persistent or recurrent-). Demographic, clinical and analytical data of SpA (uveitis, HLAB27, acute phase reactants), treatments and FC were collected, establishing as a pathological FC cut-off point >50 mg/Kg. For patients on NSAIDs, suspension was recommended two weeks prior to collection of stool samples. Patients with a positive FC test underwent ileocolonoscopy. Biopsies (between 4 and 12) of colon and terminal ileum were taken for pathological study. A descriptive analysis of the collected variables and a comparative analysis of the baseline characteristics for the groups

(CF>50mg/Kg and <50mg/KG) were carried out. Qualitative data were compared using the chi-square test and Fisher's exact test, for quantitative data between two groups, a Student's t test was used for independent data as a parametric test and the Mann-Whitney U test as a non-parametric test. The statistical significance considered was $p<0.05$.

Results: Ninety nine patients were included. 50% men, average age 46+11 years. BASDAI of 3.7+2.5. 79% were HLAB27 positive, 31% had high ESR levels (>20mm/h) and 9% had elevated CRP (>10mg/L). 49 patients (49.5%) had high FC levels, with mean levels of 276mg/kg (range 52-3,038). Ileocolonoscopy was performed in 47 of these patients, with alterations in 12 (25.5%), of which 4 (8.5%) were classified histologically as IBD type Crohn's disease. Among patients with FC >50 mg/kg, a greater number of cases of IBD were identified (28.6%) in the subgroup of patients with high CRP, as compared with patients with normal CRP (5.9%) ($p=0.045$). The subgroup of patients with high ESR also presented a prevalence higher (14.3%) than patients with normal ESR (6.9%) ($p=0.393$). Patients with a history of uveitis also had a higher prevalence of IBD (25% vs 5.7%; $p=0.090$). There were no significant differences in relation to HLAB27 nor in relation to the history of psoriasis. No statistically significant differences were found in the mean FC levels between patients with high FC who were diagnosed with IBD and those who did not (328mg/kg vs 296mg/kg).

Conclusion: In our study, the group of patients with FC>50 mg/Kg presented an IBD prevalence of 8.5%, suggesting the usefulness of this biomarker in the screening of IBD among patients with SpA. The diagnosis of IBD was found to be associated with high FC levels, CRP>10 mg/L, high ESR or a history of uveitis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: The response to TNF-blockers in axial spondyloarthritis (AxSpA) is at least partially influenced by HLA-B27 through a still poorly understood mechanism. Given that HLA-B27 regulates the gut microbiota composition in rats, we seek to evaluate the predictive value of the gut microbiota composition in AxSpA patients at baseline on their subsequent responsiveness to TNF-blockers.

Methods: 58 patients were recruited according to the following criteria: active disease despite NSAIDs intake; no history of inflammatory bowel disease; no antibiotics intake within 3 months prior recruitment. Bacterial 16S rRNA gene sequencing region was performed on stools samples before and after TNF-blocker treatment. Diversity metrics and custom LefSe were used to explore the relationship between the composition of the intestinal microbiota and the efficacy of TNF-blockers.

Results: A lower alpha diversity at baseline was unexpectedly associated with better treatment response, HLA-B27 genotype and smoking behavior. Meanwhile, beta diversity was associated with smoking behavior and HLA-B27 genotype before and after treatment. Beta diversity at baseline was associated with the BASDAI index after treatment, and the response to the treatment. These results indicate a potential regulatory role for the gut microbiota on the underlying mechanisms involved in the response to TNF-blockers. Moreover, a LefSe-like approach identified 6 bacterial species as potential biomarkers for the treatment response, despite the absence of global changes (beta diversity) in the microbiota composition following a 3-month TNF-blocker intake.

Conclusion: The baseline composition of the gut microbiota from AxSpA patients could be associated with treatment efficacy. Further functional studies will be conducted to assess which of the aforementioned bacteria could be used as predictors of the treatment efficacy and potentially as probiotics promoting treatment efficacy among non-responders patients.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: To identify synovial tissue (ST) biomarkers differentially expressed in Psoriatic Arthritis (PsA) and seronegative Rheumatoid Arthritis (Ab^{neg} RA) and test their predictive value of therapeutic response.

Methods: 34 PsA patients [12 DMARDs naive and 22 no-responder to Methotrexate (MTX-IR)] with peripheral joint involvement and 55 Ab^{neg} RA (27 DMARDs naive and 28 MTX-IR) underwent US-guided ST biopsy and immunohistochemistry (IHC) for CD68⁺, CD3⁺, CD20⁺, CD21⁺, CD117⁺ and CD138⁺ cells. After study entry, each DMARD naive patient started MTX therapy and was followed in an outpatient setting for at least 6 months to define the achievement of Minimal Disease Activity (PsA) and DAS-remission (Ab^{neg} RA) status respectively. Each IR-MTX patient was treated according to EULAR recommendations.

Results: At study entry, there were no significant differences in terms of demographic and clinical characteristics of enrolled PsA and Ab^{neg} RA cohorts. IHC analysis revealed that naive PsA patients had lower IHC scores of lining and sublining CD20⁺ than Ab^{neg} RA patients (p=0.002 and p=0.05 respectively), whereas no significant differences were found in terms of lining and sublining CD68⁺, CD21⁺ and CD3⁺ cells among the two cohorts. Moreover, regardless to the therapeutic scheme, PsA patients showed higher IHC score of lining and sublining CD117⁺ cells (p<0.001 for both) compared to Ab^{neg} RA patients. Conversely, Ab^{neg} RA patients showed higher IHC score of lining and sublining CD138⁺ cells, despite the therapeutic scheme (p=0.04 and p=0.01 for naive and MTX-IR respectively). Analysing the response rate to the therapeutic scheme, naive PsA patients reaching MDA status at 6 months follow-up, showed, at study entry, lower IHC score of sublining CD3⁺ cells compared to PsA patients not reaching this outcome (p=0.03), conversely, naive Ab^{neg} RA patients reaching DAS-remission status at 6 months follow-up, showed, at study entry, lower IHC score of sublining CD68⁺ cells compared to Ab^{neg} RA patients not reaching this outcome (p<0.001).

Conclusion: CD117⁺ and CD138⁺ cells are differentially distributed among PsA and Ab^{neg} RA. Histological analysis of ST may help to solve the clinical overlap between the two diseases and provides prognostic data about the therapy success.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Treatment with TNFi in early stages of peripheral Spondyloarthritis (pSpA) results in higher rates of clinical remission, compared to treatment in more longstanding disease. When remission is reached, the recently updated T2T-recommendations suggest tapering of treatment. In the CRESPA-trial pSpA patients were treated with golimumab monotherapy; we demonstrated that – after reaching sustained remission – discontinuation of golimumab led to biological-free remission in 53% of patients; conversely 47% experienced a disease flare. It is currently unknown if concomitant administration of DMARDs could lead to higher rates of biological-free remission. The objective is to explore - in pSpA patients in clinical remission - the possibility that co-medication with methotrexate would allow discontinuation of the TNFi.

Methods: The CRESPA-trial included patients with active pSpA and symptom duration <12 weeks; the primary study results have been reported previously (reference). In the CRESPA-Extension protocol, patients were included that either did not reach remission (but had substantial improvement with golimumab treatment), or that experienced recurrence of arthritis, enthesitis or dactylitis within 1 year after discontinuation of golimumab. These patients received additional open-label golimumab 50 mg SC every 4 weeks for 2 years. At week 104, patients were offered an additional 12 weeks of golimumab treatment, but now in combination with methotrexate 15mg weekly. At week 116, patients in clinical remission continued methotrexate, but discontinued golimumab. Patients were prospectively followed to assess the rate of sustained biological-free clinical remission. In case of relapse of arthritis, enthesitis or dactylitis under methotrexate monotherapy, golimumab was restarted.

Results: Currently, twenty three of the original 60 pSpA patients included in the CRESPA-trial, completed the 2-year CRESPA-Extension protocol; of these, 21 (91%) were in clinical remission at week 104 when methotrexate was added. The mean follow-up period after completion of the extension part, was 80 ± 28 w. 5 patients (24%) are still in sustained remission (n=5) under methotrexate monotherapy whereas in 16 patients (76%), golimumab needed to be re-installed because of relapse of disease activity (n=14) or development of adverse events related to methotrexate (n=2). Recurrence of disease was characterized by development of arthritis in all patients with a median of 4 tender and 3 swollen joints. In 50% (n=7) of the cases, concomitant dactylitis was present. 64% (9/14) were having concomitant psoriasis which was mild since all had a BSA < 5%. The mean time for recurrence was 28,6 weeks. Restarting golimumab treatment promptly restored clinical remission in all patients within 12 weeks.

Conclusion: In patients with pSpA in clinical remission after 2 years of golimumab monotherapy, concomitant administration of methotrexate before discontinuation of the TNFi, did not significantly raise the percentage of patients in biological-free remission. In 76% of patients, golimumab had to be restarted, underscoring the overall weak efficacy of methotrexate in pSpA.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disorder characterized by disturbed cellular and humoral immune responses. Dysregulations of intrinsic or adaptive immune system as well as

Figure 1: Multiple subpopulations of lymphocytes decreased in peripheral blood of SLE patients with infection. Absolute numbers of peripheral lymphocytes subpopulations were analyzed by flow cytometry. Data were presented as mean \pm SD and statistical analysis was determined by one-way ANOVA. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$. (a) shows that SLE patients ($n = 495$) have lower levels of T, B, NK, CD4+T and CD8+T cells in PB compared with that of health controls. The numbers of PB lymphocytes in the infected groups ($n = 162$) was also much lower than those in non-infected patients ($n = 333$). (b) show the comparison of numbers of CD4+T cell subsets among different groups. Patients with SLE has lower levels of Th1 cells, Th2 cells, Th17 cells as well as Treg cells compared with those in health donors ($n = 132$), especially the infected groups.

Figure 2: Multiple subpopulations of peripheral lymphocytes of SLE patients were significantly upregulated after low-dose IL-2 treatment ($n = 54$). Absolute numbers of lymphocyte subpopulations in peripheral blood were analyzed by flow cytometry. (a-f) Changes in the numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Treg cells. Comparison between amounts of cells at baseline and after the treatment. Data were presented as mean \pm SD. And data were calculated and compared by paired-sample t -test. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$.

immunosuppressive medications predispose SLE patients to infection. This study aimed to investigate the alterations and their clinical significance of the absolute numbers of lymphocyte subpopulations in SLE patients with different infection and to restore the immunologic balances by low-dose IL-2.

Methods: Total 333 patients with SLE without recent infection, 163 patients suffering infection, and age- and sex-matched 132 healthy individuals were recruited. Of these patients, 54 were received a five-day course of low-dose IL-2 administration at a dose of 0.5 million IU per day. Lymphocyte subpopulations were analyzed by flow cytometry before and after the treatment.

Results: Patients with SLE had a lower level of lymphocyte subpopulations in peripheral blood such as T, B, NK, CD4+T, CD8+ T, Th1, Th2, Th17 and Treg cells, and the reduction in these cells was more obvious in SLE patients with infection

($P < 0.05$ to $P < 0.01$). Low-dose IL-2 effectively expanded T ($P < 0.001$), B ($P < 0.001$), CD4+T ($P < 0.01$), CD8+T ($P < 0.001$), Th1 ($P < 0.01$), Th17 ($P < 0.1$) and Treg cells ($P < 0.01$) of SLE patients, these cells were comparable to that of health controls after the IL-2 treatment.

Conclusion: Patients with SLE had fewer cells in various lymphocyte subsets than healthy controls. The absolute cell numbers in these subsets were reduced more dramatically in SLE patients with infection than those without infection, suggesting that the low absolute numbers of these cells may be used as indicators of high infection risk in SLE patients and low-dose IL-2 may enhance the ability to resistant infection in SLE patients by restoring the decreased number of lymphocyte subpopulations.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: We showed previously that complement activation - cell-bound complement activation products (CB-CAPS) or multi-analyte assay panel (MAP) - is a sensitive and specific biomarker for the diagnosis of systemic lupus erythematosus (SLE). We report here the frequency of positive CB-CAPS and MAP in subjects with diseases in the lupus

Figure. Frequency of positive of CB-CAPS (elevated EC4d and/or BC4d), MAP, anti-dsDNA antibody (measured by ELISA and confirmed by immunofluorescence with the Crithidia lucillae assay), and low complement (low C3 and/or C4), in SLE, pSLE (all patients and divided based on whether they fulfilled or not SLICC criteria), SjS, and other diseases.

CB-CAPS values were not available for 3 patients (2 SLE and 1 SjS) and MAP scores could not be calculated for 3 patients (1 SLE, 1 pSLE, and 1 SjS).

* Difference between elevated CB-CAPS and low complement and in all pSLE (n=92), pSLE SLICC (n=35), pSLE non SLICC (n=57) were statistically significant ($p < 0.0001$, $p < 0.05$, $p < 0.05$, respectively).

Figure. Frequency of positive of CB-CAPS (elevated EC4d and/or BC4d), MAP, anti-dsDNA antibody (measured by ELISA and confirmed by immunofluorescence with the *Crithidia Luciliae* assay), and low complement (low C3 and/or C4), in SLE, pSLE (all patients and divided based on whether they fulfilled or not SLICC criteria), SjS, and other diseases. CB-CAPS values were not available for 3 patients (2 SLE and 1 SjS) and MAP scores could not be calculated for 3 patients (1 SLE, 1 pSLE, and 1 SjS). * Difference between elevated CB-CAPS and low complement and in all pSLE (n=92), pSLE SLICC (n=35), pSLE non SLICC (n=57) were statistically significant ($p<0.0001$, $p<0.05$, $p<0.05$, respectively).

Demographic characteristics of patients enrolled in the study.

pSLE SLICC: pSLE patients fulfilling SLICC criteria; pSLE not SLICC: pSLE patients not fulfilling SLICC criteria; n: number of patients in each group; yr: year; ANA positivity rate (by immunofluorescence [IFA] and/or ELISA) on the day of the visit

	Male (n)	Female (%)	Years since Dx	Comorbidity (%)	African American (%)	Asian (%)	Hispanic (%)	ANA (IFA or ELISA) (%)
SLE	53	38	9.6	24%	38%	8%	21%	98%
pSLE	92	43	8.5	41%	16%	2%	27%	92%
pSLE SLICC	35	42	8.8	54%	28%	2%	27%	97%
pSLE non SLICC	57	43	8.4	35%	14%	7%	24%	90%
SjS	50	54	8.5	38%	28%	14%	13%	98%
Other	51	11	10.5	62%	18%	0%	22%	78%

spectrum (SLE, probable SLE [pSLE], primary Sjogren's syndrome [SjS]) and other rheumatic diseases compared to low plasma complement levels and anti-dsDNA positivity.

Methods: SLE patients fulfilled ACR and SLICC classification criteria. pSLE were enrolled if the investigator had a high suspicion of lupus and fulfilled only 3 ACR criteria (including anti-nuclear antibodies [ANA]); fulfillment of SLICC criteria was not required. Diagnosis of SjS was based on modified ACR criteria and on expert opinion for other diseases. CB-CAPS (complement split product C4d bound to erythrocytes [EC4d] and B-cells [BC4d]) were measured by quantitative flow cytometry. Serum complement proteins (C3 and C4) and autoantibodies were measured by turbidimetry and ELISA, respectively. Anti-dsDNA positivity was confirmed by immunofluorescence with *Crithidia Luciliae*. MAP was evaluated as previously described (Putterman et al., Lupus Science & Medicine, 2014). Statistical comparisons were done by Chi-square analysis.

Results: The study included 53 SLE; 92 pSLE, 35 (38%) of whom fulfilled SLICC criteria; 50 SjS; and 51 other diseases including rheumatoid arthritis (n=31), juvenile idiopathic arthritis (n=3), psoriatic arthritis (n=10), ankylosing spondylitis (n=1), dermatomyositis (n=4), and scleroderma (n=2). Patient characteristics are reported in the Table. A higher percentage of pSLE (fulfilling or not SLICC criteria) were CB-CAPS and MAP positive compared to anti-dsDNA positive or having low plasma complement levels, indicating higher sensitivity of CB-CAPS and MAP than standard markers, not only in SLE, but also in pSLE. Frequency of positive MAP was 27% in SjS, supporting other studies that suggest that complement may be activated in some SjS patients. Positive CB-CAPS or MAP were infrequent in other rheumatic diseases (Figure).

Conclusion: This study demonstrates that CB-CAPS and MAP are positive more frequently than standard immunological markers (eg, soluble complement proteins and anti-dsDNA antibodies) to better identify patients with definite SLE and probable SLE. CB-CAPS were statistically significantly better than low C3/C4 as markers of complement activation and represent new biomarkers for the diagnosis of lupus spectrum disorders.

The Presence of Anti-Rituximab Antibodies Predicts Infusion-Related Reactions in Patients with Systemic Lupus Erythematosus

Chris Wincup¹, Madhvi Menon¹, Edward Smith², David A. Isenberg¹, Elizabeth Jury³ and Claudia Mauri⁴, ¹University College London, London, United Kingdom, ²Centre for Rheumatology Research, University College London, London, United Kingdom, ³Division of Medicine, Centre for Rheumatology Research, University College London, London, United Kingdom, ⁴Division of Medicine, Centre for Rheumatology Research, University College London, University College London, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Rituximab is a genetically engineered chimeric anti-CD20 monoclonal antibody that is commonly used in the treatment of severe and refractory SLE. Although generally well tolerated, infusion-related reactions do occur and can be severe / life threatening. At present it is not possible to predict which patients are at risk of developing these reactions. A major limitation to biologic therapy is the formation of anti-drug antibodies (ADA). To date, ADA to rituximab have not previously been studied in detail.

In this study, we assessed the prevalence of ADA to rituximab in patients receiving treatment for SLE and how this related to therapeutic efficacy and prediction of infusion reactions.

Methods: We assessed for the presence of rituximab ADA using a Meso Scale Discovery Platform in 57 patients with SLE attending University College London Hospital (UCLH), UK. A subgroup of 42 patients were followed up longitudinally for up to 8 years following the first dose of rituximab. Clinical parameters including BILAG, complement C3 levels, dsDNA titres, lymphocyte count and CD19 positive B-cells were recorded. A retrospective review of patient records was undertaken to assess for the occurrence of infusion-related reactions. Mann Whitney U test was used to compare differences between ADA positive (+ve) and ADA negative (-ve) groups. Paired t-tests were used to assess for changes in variables both immediately before and six months after treatment. P-value of <0.05 was considered statistically significant.

Results: Of the 57 patients recruited, 88% were female (50/57) with a mean age of 38.9 years old. Mean disease duration was 102 months. ADA to rituximab were detected in 37% of patients (21/57). Those who developed ADA were significantly younger than ADA -ve patients (mean age 31.9; $p<0.001$) although no difference in disease duration between the two groups was observed ($p=0.37$). Males were also more likely to develop ADA than females ($p=0.04$). Patients receiving rituximab for the treatment of nephritis were more prone to develop ADA ($p=0.03$).

Following retreatment with rituximab, all ADA +ve patients developed infusion-related reactions. No reactions were seen in those who were ADA -ve. There was no difference in the efficacy of B cell-depletion between ADA +ve and ADA -ve patients (as measured by CD19 +ve B-cell count at six months; $p=0.93$). C3 levels showed statistically significant improvements in both groups six months post-treatment. A significant improvement in dsDNA titres was seen in those who were ADA -ve ($p=0.008$). However, there was no statistically significant improved in dsDNA titres in those who were ADA +ve at six months ($p=0.96$).

Conclusion: We have detailed ADA to rituximab in a cohort of SLE patients who have undergone B-cell depletion therapy for the first time. Younger patients, males and those receiving treatment for nephritis were at increased risk of developing ADA. In patients who were ADA +ve there was no significant improvement in dsDNA levels at six months post-treatment. We found that the presence of these antibodies prior to retreatment predicted infusion-related reactions in all cases. In future, routine screening for rituximab ADA will help predict those at risk of subsequent infusion-related reactions.

Association between Changes in Gene Signature Expression and Disease Activity in Systemic Lupus Erythematosus

Michelle Petri¹, Wei Fu¹, Ann Ranger², Normand Allaire², Patrick Cullen³ and Laurence S Magder⁴, ¹Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ²Biogen Idec, Cambridge, MA, ³Biogen Idec, Cambridge, MD, ⁴Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: We assessed the stability of BAFF, interferon, plasma cell and LDG neutrophil gene expression signatures over time, and whether changes in gene expression coincided with changes in SLE disease activity.

Methods: 243 patients with SLE were evaluated for disease activity, serological parameters and peripheral blood gene signatures in clinic visits that occurred between 2009 and 2012. 143 SLE patients contributed two visits, 40 patients contributed three visits and 60 patients contributed four or more visits. Levels of the BAFF gene transcript, plasma cell signature, Interferon (IFN) signature and the low density granulocytes (LDG)-associated neutrophil gene signature were assessed in PAX-gene-preserved peripheral blood by global microarray. For multi-gene signatures, the geometric mean of component expression was calculated. The stability of repeated measures of gene expression was quantified using intra-class correlation coefficients (ICC). SLE disease activity was measured using the Physicians Global Assessment (PGA) and the SELENA-SLEDAI index and its components. Using a mixed effects regression model we assessed: 1) the association between a patient's average gene signature expression over time and disease activity, and 2) the association between a patient's changes in gene expression over time and changes in disease activity.

Results: Gene expression signatures showed more within-person stability than systolic blood pressure. The IFN signature exhibited the most stability. Patients with high levels of BAFF and IFN transcripts tended to have significantly higher levels of musculoskeletal disease, skin disease, anti-dsDNA, and ESR, and lower levels of complement. However, changes in BAFF or IFN gene signatures were not associated with changes in disease activity. The same associations were seen between the LDG gene signature and disease activity. However, when LDG increased, complement tended to increase. Patients with high levels of plasma cell gene signature tended to have higher levels of anti-dsDNA and lower levels of complement. However, unlike the other gene signatures, changes in plasma cell gene signature significantly coincided with changes in anti-dsDNA and complement.

Conclusion: The gene expression signatures were relatively stable within patients over time. BAFF and IFN gene expression were markers of patients with generally higher disease activity, but changes in these gene signatures did not coincide with changes in disease activity. The plasma cell gene signature expression tracked with the traditional SLE serologic markers of anti-dsDNA and complement.

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Interferon alpha ($IFN\alpha$) is an inflammatory cytokine implicated in the development and persistence of autoimmunity. Although $IFN\alpha$ expression is increased in a subgroup of SLE patients its role in other connective tissue diseases (CTDs) is less clear. We aimed to characterise the $IFN\alpha$ signature across CTDs using 3 methods and determine whether in this mixed cohort we could identify common associations with clinical and laboratory features.

Methods: Patients with at least 1 CTD clinical feature and at least 1 autoantibody were recruited. Detailed clinical assessment was conducted and whole blood collected for RNA analysis and plasma for $IFN\alpha$ protein measurement by single molecule assay (SIMOA).

Interferon-stimulated gene (ISG) and nucleic acid receptors (NAR) expression was measured in whole blood using RT-qPCR. The ISG score was calculated as the mean expression of 6 ISGs (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) relative to HPRT1 and 18s. The ISG score was classed as positive (ISG+) or negative (ISG-) using the mean +2 SD of healthy controls. 6 NARs were measured: DDX58, MB21D1, TMEM173, TLR3, TLR7 and TLR9. Expression of 30 ISGs was also explored using the NanoString customer designed code sets in a subgroup of patients.

Results: We recruited 164 patients covering 6 diseases; SLE, Sjogren's syndrome (SS), undifferentiated and mixed CTD (UCTD, MCTD), inflammatory myopathy (IIM) and systemic sclerosis (SSc). 63/164 (38%) of patients were ISG+ (figure). NanoString (27 patients) and was strongly correlated with the IFN score ($r=0.96$). Similarly 39/93 (41%) had plasma $IFN\alpha$ protein levels $<10\text{fg/ml}$ (correlation for the 2 methods, $r=0.83$, $p<0.001$).

There were no differences in mucocutaneous or internal organ involvement between ISG+ and ISG- patients. ISG+ patients had increased prevalence of rheumatoid factor, anti-Sm and -chromatin antibodies after adjusting for disease type.

ISG+ patients had increased frequency of ever having a haematological disorder (as per the ACR SLE criteria) and in models adjusted for disease type, lower lymphocyte and neutrophil counts.

Expression of TLR7, TLR9, DDX58, MB21D1 and TMEM173 (but not TLR3) was increased in CTD compared to HC (all $p<0.001$). Only DDX58 was positively associated with the ISG score ($r=0.6556$) and was increased in patients who were anti-ENA or anti-chromatin positive. Anti-Ro was associated with reduced expression of all NARs (except DDX58); this association remained after adjustment for age, gender, disease group and ISG score.

Conclusion: $IFN\alpha$ is increased in a subgroup of CTD patients but more strongly associates with haematological abnormalities than any disease subtype. Increased NAR expression does not correlate with increased $IFN\alpha$ suggesting that the drivers of $IFN\alpha$ may be multifactorial. The identification of this high- IFN subset of patients within a CTD cohort supports a pathology-based approach to treatment.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical III: Translational Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Mycophenolate mofetil (MMF) is a commonly used medication to treat major organ involvement in SLE, specifically in patients with lupus nephritis. The safety and effectiveness of MMF therapy in SLE is well-known and determined by clinical response, but the systemic impact of MMF treatment on immune cellular subsets, cell activation and soluble mediator pathways in SLE remain ill-defined.

Methods: PBMCs and plasma samples from SLE patients not taking MMF (n=10) and SLE patients taking MMF (n=5) were studied. Subjects were matched by gender, ethnicity, age \pm 5 years, medication use, and disease activity by SELENA-SLEDAI, and fulfilled the American College of Rheumatology (ACR) criteria for SLE classification. Using single cell proteomics by mass cytometry, PBMCs were clustered using 33 markers and cell heterogeneity was visualized using viSNE in Cytobank. Plasma cytokine levels were assessed by 51-plex xMAP assays and ELISAs. Flow cytometry was utilized to assess STAT3 phosphorylation and apoptosis of healthy control PBMCs(n=6) following treatment with IL-6 and MMF *in vitro*.

Results: Patients taking MMF had significant reductions in total numbers of transitional B cells (p=0.0077), plasmablasts (p=0.0480) and T cells (p=0.0486), specifically CD4⁺ Th17-type cells (p=0.0260) and CD4⁺ Treg-type cells (p=0.0469), compared to SLE patients not taking this medication. In addition, activation both of dendritic cells(p=0.0080) and B cells (p=0.04), specifically naïve (p=0.0127) and memory B cells (p=0.04), were reduced in patients taking MMF compared to non-MMF patients. MMF patients also had reduced levels of activated CD4⁺ T cells(p=0.0483). Plasma soluble mediators were decreased in MMF treated SLE patients including chemokines (MIG/CXCL9 and SDF-1a/CXCL12)and growth

Figure 1. Downregulation of STAT-3 associated and B cell pathways distinguish MMF-treated SLE patients from non-MMF treated patients. A radar plot using the group median of the variable converted to Z-scores show significant differences between off-MMF SLE patients (blue) and On-MMF SLE patients (red). Cytokines, chemokines, and significant cell numbers and frequencies were grouped according to STAT-associated pathways, cell lineage or functional properties.

Hydroxychloroquine	3 (4)	2 (7)	0 (0)
Cyclosporine	2 (3)	0 (0)	1 (4)

Reported as frequency (%) unless otherwise noted.

factors (VEGF-A and PDGF-BB) compared to non-MMF patients ($P < 0.05$). Cytokines, chemokines and significant cell populations grouped by STAT-pathways, cell lineage and functional properties revealed significant modifications associated with the STAT3 and B cell pathways (Figure 1). Healthy PBMCs treated with IL-6 and MMF identified a significant downregulation of pSTAT3 following MMF addition ($p = 0.0313$), but no alterations in pSTAT5 or caspase3/7 levels were observed following a 3 hour incubation.

Conclusion: Our results indicate that MMF suppressed STAT3 phosphorylation in response to IL-6 with associated decreases in antigen presentation, lymphocyte activation, and pro-inflammatory soluble mediators of SLE patients. Together these data suggest immunologic changes in the STAT3 pathway are critical for driving MMF disease remission in SLE patients.

Comorbid Vasculitis Among Patients in a National Primary Immunodeficiency Database

Kevin Byram¹, Leonard H. Calabrese² and James Fernandez¹, ¹Cleveland Clinic Foundation, Cleveland, OH, ²Rheumatic & Immunologic Disease and Infectious Disease, Cleveland Clinic Foundation, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Vasculitis has been reported in patients with various forms of primary immunodeficiency (PID) in case reports in the literature. The goal of this study is to evaluate the frequency of vasculitis in a large national database of patients with primary immunodeficiency.

Methods: The United States Immunodeficiency Network(USIDNET) is a large national consortium organized to collect registry data on patients with primary immune deficiencies. The USIDNET database was queried for patient records with a documented history of vasculitis. Data regarding demographics, type of vasculitis diagnosis, specific PID diagnosis, immunologic laboratory results and immunomodulatory treatment was abstracted from the records and descriptive statistics are presented. Focused analyses were also performed for patients with common variable immune deficiency (CVID) and Wiskott-Aldrich syndrome (WAS).

Results: As of March 12, 2018 data were available on 4,888 patients and 76 patients (1.6%) with vasculitis were identified. CVID (n=29, [38%]) and WAS (n=20, [26%]) were the most common PID associated with vasculitis (Table 1). Table 2 describes the results for the total PID cohort, as well as CVID and WAS sub-populations. Overall, 76% of patients were Caucasian, and 46% of patients were female. Central nervous system (CNS) vasculitis was the most common specific vasculitis syndrome identified among patients with PID in the USIDNet Registry (n=11, [14 %]). Glucocorticoids were the most frequent immunomodulatory therapy reported in all populations studied and occurred in more than half of cases (59-69%). In the CVID cohort, 29 cases of vasculitis were identified, with CNS vasculitis being the most common (n=5, [17%]). About half of cases of vasculitis were reported to be present before or at the diagnosis of the PID (n=37, [49%]) and CVID (n=14, [48%]). Henoch-Schonlein Purpura was the most common vasculitis (n=6, [30]) associated with WAS, with most cases (75%) being present before or at diagnosis of WAS.

Conclusion: Vasculitis is an uncommon complication of PID but can be encountered in a variety of syndromes, and was most frequently associated with CVID and WAS in the USIDNet Registry. Vasculitis complicating PID can represent a challenging confounder and mimic of serious infections. Clinicians caring for patients with PID need to be aware that vasculitis may be a rare autoimmune manifestation associated with PID especially those with CNS involvement.

MicroRNA Expression in the Vasculitic Skin Lesions of Adult Patients with IgA Vasculitis

Alojzija Hočevar¹, Matija Tomšič², Jože Pižem³, Luka Bolha³, Snezna Sodin Semrl⁴ and Damjan Glavač³, ¹Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, ²University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia, ³Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, ⁴University of Primorska, Faculty of Mathematics, Natural Science and Information Technology, Koper, Slovenia

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: IgA vasculitis (IgAV) represents a common systemic vasculitis in paediatric and adult population. Our current knowledge of disease pathogenesis is still very limited and information on miRNAs expression in IgAV is lacking. The aim of our study was to determine the expression of five miRNAs (miRNA-146a-5p, miRNA-148-3p, miRNA-155-5p, miRNA-223-3p and let-7b) in the affected skin of adult IgAV patients.

Methods: The study included 65 skin samples from consecutive, untreated IgAV patients (61.5% male, median age 67.6 years, range 29–91), and 20 samples of normal skin from healthy volunteers. Total RNA was isolated from tissue sections of formalin-fixed, paraffin-embedded samples. Expression of miRNAs was measured using qRT-PCR. To present relative miRNA expression, the $\Delta\Delta CT$ method was used. Skin miRNAs expression was correlated to clinical characteristics of adult IgAV patients.

Results: We found significantly higher levels of miRNA-155-5p, miRNA-223-3p and let-7b in the affected skin compared to controls (18.6-fold, 6.4-fold and 7.9-fold higher respectively). Contrary, the miRNA 148-3p expression was significantly lower (2.2-fold). The expression of the miRNA-146-5p was near normal levels. Patients with necrotic skin lesions had significantly higher miRNA-223 tissue expression than those with non-necrotic purpura ($p=0.029$). Gastrointestinal tract involvement inversely correlated with the expression of miRNA-155-5p ($p=0.004$) and/or miRNA-146a-5p ($p=0.041$) in affected skin. No significant association between renal involvement or its severity, and skin expression of the investigated miRNAs was found. Patients with elevated serum IgA had a borderline upregulated skin expression of miRNA 223-3p ($p=0.053$).

Conclusion: An altered expression of miRNA-148b-3p, miRNA-155-5p, miRNA-223-3p and let-7b was found in vasculitic skin lesions in IgAV. The study revealed potential associations between the selected miRNA expression patterns and specific disease manifestations. Aberrantly expressed miRNAs could represent a biomarker in adult IgAV.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Giant cell arteritis (GCA) is a systemic vasculitis of large- and medium-sized arteries, diagnosed either with a temporal artery biopsy (TAB) histology or by imaging techniques. MicroRNAs (miRNAs), the small non-coding RNAs, regulate gene expression post-transcriptionally and contribute to the pathogenesis of autoimmune diseases, including GCA (1). We aimed to explore whether miRNA expression in TABs of treatment-naïve GCA patients is deregulated and could separate TAB-positive GCA from TAB-negative or non-GCA patients.

Methods: Total RNA was isolated from TABs of 24 patients, suspected of having GCA at disease presentation. These patients comprised 3 groups: GCA patients with transmural artery inflammation (TAB-positive; $n=12$), GCA patients without inflammation (TAB-negative, $n=6$), and patients in whom GCA was finally refuted (non-GCA, $n=6$). Occlusion of lumen of temporal arteries in GCA patients was also recorded. The expression of selected miRNAs (based on literature search), including miR-155, -146-a, -146-b, -299, -17-3p, -181-b, -125-b and -29-b was measured with TaqMan qPCR using specific single TaqMan miRNA assays and normalization to the levels of the small nucleolar RNA (RNU48).

Results: While confirming significantly higher median (IQR) of miR-155 expression in TAB-positive GCA patients (0.118 (0.096)) as compared to TAB-negative GCA patients (0.017 (0.051); $p<0.01$) and non-GCA patients (0.029 (0.083); $p<0.05$) (1), our study also shows significantly lower miR-17-3p expression in TAB-positive (0.002 (0.001)) vs. TAB-negative (0.003 (0.001); $p<0.05$) GCA patients. MiR-125-b expression was significantly up-regulated in TAB-positive (0.410 (0.358); $p<0.05$)

and TAB-negative (0.910 (0.573); $p<0.001$) GCA patients as compared to non-GCA patients (0.029 (0.024)). There was no difference observed between the three groups of patients for miR-146-a, -146-b, -299, -181-b and -29-b. GCA patients with occlusion of lumen of temporal arteries had significantly higher expression of miR-155 (0.113 (0.102) vs 0.036 (0.09); $p<0.05$), -146-b (1.029 (0.1) vs 0.305 (0.574); $p<0.01$) and -299 (0.004 (0.006) vs 0.001 (0.002); $p<0.01$) as compared to patients without lumen occlusion.

Conclusion: Our study reports for the first time that miR-125-b could be useful as a biomarker for distinguishing non-GCA patients from TAB-negative GCA patients. MiR-125-b could potentially be involved in tissue remodelling, since it was found to regulate matrix metalloproteinases-2 and -9. This could aid, in the future, to identify patients with atypical GCA presentation, without signs of inflammation in TABs.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Apremilast, an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in a global, phase III, multicenter, randomized, double-blind, placebo-controlled study in patients with Behcet's syndrome and active oral ulcers previously treated with ≥ 1 non-biologic therapy. A subgroup analysis was performed for Japanese patients in this study. We

Outcomes at Week 12 in the Japanese Subgroup			
	Adjusted Treatment Difference (or 95% CI)	APR vs. PBO (LS Mean, Median Time or %)	P Value
AUC for the number of OU from baseline through Week 12	-137.5	115.9 vs. 253.3	0.0166
Proportion of patients achieving complete response	32.8%	57.9% vs. 25.0%	0.0426
Maintenance of complete response*	47.4%	47.4% vs. 0.0%	0.0066
Time to OU resolution	160.3 (d)	Median time in weeks: 2.1 vs. NA†	0.0081
BSAS	-10.9	-10.5 vs. 0.5	0.0316
OU pain VAS (0-100 mm), change from baseline	-17.0	-30.3 vs. -13.3	0.1273
BDCAF, change from baseline			
BDCAI	-0.8	-0.8 vs. 0.0	0.3507
Patient's Perception of Disease Activity	-1.2	-1.4 vs. -0.2	0.0210
Discian's Dyedol Perception of Disease Activity	-1.2	-1.5 vs. -0.3	0.0248
BDQOL, change from baseline	-1.8	-1.2 vs. 0.6	0.1545

*Patients achieving OU resolution by Week 6 who remained OU-free for 46 additional weeks.

†NA, as $\geq 50\%$ of patients with complete OU resolution (median) was not achieved in the placebo group.

BDCAF=Behcet's Disease Current Activity Index; BDQOL=Behcet's Disease Quality of Life.

assessed the efficacy and safety of apremilast compared with placebo over 12 weeks in the subgroup of Japanese patients with Behcet's syndrome in the study.

Methods: In the global study, 207 patients with Behcet's syndrome were randomized (1:1) to apremilast 30 mg BID (n=104) or placebo (n=103) for 12 weeks, followed by a 52-week active-treatment phase. Patients were stratified by region (Japan and "Other"). Patients had active Behcet's syndrome, with ≥ 3 oral ulcers at randomization or ≥ 2 oral ulcers at screening and randomization without major organ involvement. The primary endpoint was the area under the curve (AUC_{Wk0-12}) for the total number of oral ulcers over 12 weeks. Additional endpoints included the assessments of oral ulcers, including pain, overall disease activity (Behcet's Syndrome Activity Score [BSAS] and Behcet's Disease Current Activity Form [BDCAF]), and quality of life (QoL) at Week 12. The primary and secondary variables in the Japanese subset analysis were pre-specified without adjustment for multiplicity. Nominal *P* values are presented.

Results: A total of 39 patients were included in the Japanese subgroup (placebo: n=20; apremilast: n=19). The subgroup analysis showed that the AUC_{Wk0-12} for oral ulcers was significantly lower in the apremilast group compared with the placebo group over 12 weeks (Table), which is consistent with the findings of the overall study population (129.5 vs. 222.1; $P<0.0001$). Similarly, as observed in the overall population, significantly greater improvements were shown in complete response rate of oral ulcers and maintenance of complete response of oral ulcers, time to oral ulcer resolution, and BSAS at Week 12 in the apremilast group. Numerical improvements were observed in oral ulcer pain, BDCAF, and QoL at Week 12 in the apremilast group; unlike the overall population, significance was not achieved, likely due to the limitation of the small sample size. Treatment-emergent adverse events (AEs) were comparable between the apremilast (73.7%) and placebo (75.0%) treatment groups. One serious AE (migraine) was reported with apremilast treatment. No AEs led to discontinuation.

Conclusion: The Japanese subgroup analysis showed that apremilast reduced the number of oral ulcers and overall disease activity and had favorable effects on oral ulcer pain and QoL in patients with Behcet's syndrome and active oral ulcers over 12 weeks. The safety profile was consistent with the known safety profile of apremilast, and results were consistent with findings in the overall study population.

Does Leflunomide Have a Role in Giant Cell Arteritis?

Alojzija Hočevar¹, Rok Jese¹, Ziga Rotar¹ and Matija Tomšič², ¹Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, ²University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Glucocorticoids have been the mainstay treatment of giant cell arteritis (GCA) for decades. Recently, tocilizumab has been proven to be an effective alternative to glucocorticoid. However, not all GCA patients are eligible for biologics. We aimed to evaluate the role of leflunomide as a steroid sparing agent in GCA.

Methods: This open label study included newly diagnosed GCA patients followed at least 48 weeks at a single secondary/tertiary rheumatology centre. At the time of diagnosis patients received glucocorticoid, in line with the EULAR recommendations. At week 12 of follow up (FU), leflunomide 10 mg qd was recommended as an adjunctive therapy to all patients without known contraindications. The final decision to start the leflunomide was patient dependent. At week 48 we planned to stop glucocorticoid in leflunomide group. The number of relapses, a cumulative glucocorticoid dose during follow-up and treatment related adverse events (AE) were recorded and compared between glucocorticoid-only and leflunomide groups.

Results: Seventy-six patients (65.8% female, median (IQR) age 73.7 (66.1–78.8) years) were followed for a median (IQR) 96 (86–96) weeks. Thirty out of 76 patients (39.5%) received leflunomide at week 12 (leflunomide group), the others continued treatment with glucocorticoid (glucocorticoid-only group). During the first 48 weeks of FU, 22 patients relapsed,

4 in leflunomide group (13.3%) and 18 (39.1%) in glucocorticoid-only group. The difference was statistically significant ($p=0.02$; NNT 3.9 (95% CI 2.2-17.4)). Furthermore, 17/30 patients (56.7%) in the leflunomide group managed to stop glucocorticoid at week 48 (with one relapse (5.9%) shortly afterwards). The cumulative glucocorticoid dose at the last visit was lower in the leflunomide group than in the glucocorticoid only group (4,390 (4,132–5,558) mg, vs. 5,340 (4,652–5,792) mg, $p=0.01$). The patients tolerated leflunomide relatively well. Eight out of 30 patients (26.7%) discontinued leflunomide (one due to ineffectiveness and seven due to AE).

Conclusion: Our findings indicate the steroid sparing effect of leflunomide in GCA.

Session Date: Tuesday, October 23, 2018

Session Title: Vasculitis II: Novel Diagnostics and Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: LEF could be the favourable DMARD for PMR/GCA due to inhibitory activity on dendritic cells and IL-6. Previous case series have shown efficacy of LEF in PMR and GCA(1). Higher risk of adverse events due to CS use and disease activity is most associated in patients with relapsing/refractory disease. In current biologic era, LEF could be an efficacious and cost-effective treatment alongside with low dose of CS(2).

Methods: We conducted a retrospective cohort study to evaluate the efficacy and safety profile of LEF in 40 patients with GCA and 23 with PMR. Information was collected from our database of all patients with known GCA and PMR.

	GCA group	PMR Group
Sample size	40	23
Mean age (years)	75.7	67
F:M ratio	28:12	19:4
Investigations for Diagnosis		
US Only	9	N/A
Temporal artery biopsy only	4	N/A
PET only	10	7
Temporal artery biopsy & US	2	N/A
Temporal artery biopsy & PET	4	N/A
US & PET	9	N/A
US & PET & Temporal artery biopsy	2	N/A
Median CRP at diagnosis (mg/dL and interquartile range)	52.5 (19.5-85.5)	25 (12.5-37.5)
Pre LEF treatment		
Median prednisolone dose(mg/day and interquartile range)	16.5 (7.875-24.875)	10 (5-15)
Median CRP values (mg/dL and interquartile range)	10 (4-16)	18 (15-21)
Post LEF treatment		
Median prednisolone dose(mg/day and interquartile range)	5 (0.5-9.5)	N/A
Median CRP values (mg/dL and interquartile range)	4 (2.25-5.75)	4 (2-6)
Reason for LEF		
Relapsing disease	17	16
Steroid sparing agent	33	20
Maintain remission post biologic treatment	2	N/A
Median leflunomide treatment (months)		
	36 (30-42)	33 (21-45)
No of patients used other DMARD before LEF		
	3	2

Demographics, baseline characteristics, prednisolone dose, CRP values, disease and treatment duration with LEF and side effects were reviewed.

Results: Baseline characteristics, investigations, CRP, median treatment duration of CS and LEF are summarised in Image 001. A Wilcoxon signed rank test was used. For 30 GCA and 16 PMR patients (10 and 7 CRP missing respectively, excluded from analysis), median decrease of CRP on initiation and 6 months post LEF treatment was statistically significant ($z=48.5$, $p<0.01$ and $z=7.5$, $p=0.13$ respectively). The median reduction in prednisolone dose from initiation to 6 months was also statistically significant ($z=44.5$, $p<0.000$). Median time to reduce Prednisolone to $<5\text{mg/day}$ was 5.5 months (achieved in 17/23) in the PMR group and 6.5 months for the GCA group (achieved in 9/16) since starting on LEF. Hypertension, hair thinning, rash, gastrointestinal disturbances, liver function test abnormalities and infections were reported in 15 patients in the GCA group. Rash, nausea, weight loss and gastrointestinal disturbances were reported in 7 patients in the PMR group. LEF was discontinued in 7/40 patients in GCA group; 3 due to side effects, 1 due to diagnosis of lymphoma, 1 due to pneumonia which required short admission to the hospital, 2 due to flare which required steroids dose increase despite leflunomide and 1 due to peripheral neuropathy. LEF was discontinued in 7/23 in PMR group due to side effects. One death reported in a patient who was started on LEF 3 months earlier; cause is unknown. In 3/63 patients LEF was discontinued as they sustained remission.

Conclusion: LEF seems to be effective as a CS sparing agent in patients with GCA and PMR. Randomized controlled trials are warranted to confirm the usefulness of leflunomide in the therapy of GCA/PMR.

Session Date: Tuesday, October 23, 2018

Session Title: ARHP II: Clinical Aspects and Outcomes Research

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: The Arthritis Foundation's Walk With Ease (WWE) is an evidence-based 6 week community-based walking program for adults with arthritis delivered in instructor-led or self-directed format. It has been shown to improve physical function, pain, stiffness and fatigue. WWE is also a Centers for Disease Control and Prevention-recommended physical activity (PA) program. In recent years, WWE has been scaled-up and expanded to communities across the United States (US), yet is little known outside North America. This study aimed to examine the relevance, acceptability and feasibility of WWE in a United Kingdom (UK) context, where walking for pleasure and transport is culturally embedded.

Methods: This 4 phase study was carried out in collaboration with community and patient partners: 1) Cultural adaptation; 2) WWE program; 3) Qualitative enquiry; 4) Future planning. Recruitment was primarily via invitation letter to persons registered in selected Aberdeen primary care practices. Eligible (≥ 18 years, doctor diagnosed arthritis (confirmed or self-report), and self-reported joint symptoms in last 30 days, $\text{BMI} \geq 25 \text{ kg/m}^2$, and $<150 \text{ min/week}$ of moderate/vigorous PA) and consented participants were randomised into 2 groups: WWE program or usual care. Descriptive statistics explored physical performance measures (PPM), symptoms and beliefs using physical performance assessment and survey data

collected at baseline and post-6 week program. Participants' experiences of WWE were explored via video ethnography and narrative interviews, and analysed thematically.

Results: Of 149 participants, the majority were women (70%) aged 60 years (76%). OA was most prevalent (66%), followed by back pain (54%) and RA (13%); most also had at least 1 non-arthritis condition (79%). Among participants, 97 received the WWE program: 52 chose instructor-led; 45 chose self-directed. Follow-up was 80.4% at 6-weeks; 82.5% at 18-weeks. Average walk attendance across 5 walking groups was 63% (11.5/18 walks). Nearly all (99%) would recommend WWE to family or friends and 81% reported they were satisfied with the program. At 6 weeks, about half reported being at least moderately better in physical health (47%) and emotional well-being (53%). Within both WWE formats, statistically significant differences representing improvement were observed at 6 weeks from baseline for PPM, symptoms and beliefs (table). Qualitatively, participants described liking and using the WWE guidebook but wanted a foldable exercise leaflet and expanded online resources. Positive experiences were reported, with emergent themes of improved motivation, mental health and social well-being.

Conclusion: Findings indicate that WWE is a relevant and acceptable walking program in a UK context. Wider implementation of this evidence-based program may benefit the physical health and well-being of people with arthritis.

Session Date: Tuesday, October 23, 2018

Session Title: ARHP II: Clinical Aspects and Outcomes Research

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Background

Obesity has been traditionally considered to protect the skeleton against osteoporosis and fracture. Recently, body fat, specifically visceral adipose tissue (VAT), has been associated with lower bone mineral density (BMD) and increased risk for some types of fractures. Chinese visceral adiposity index (CVAI) is a validated index for the evaluation of visceral fat dysfunction in Asians and strongly correlated with insulin resistance (IR) and was found to predict metabolic syndrome (MS), hypertension and diabetes better than body mass index (BMI) and waist circumference (WC). Spinal cortical and trabecular bone mineral density (BMD) were found to be inversely correlated with visceral adipose area measured by computed tomography even after adjusting for BMI. Whether CVAI correlates with bone microstructure in early rheumatoid arthritis (ERA) has not been assessed.

Purpose: 1) To compare CVAI between ERA patients and controls; 2) To assess the relationship between CVAI and the bone microstructure detected by high-resolution peripheral quantitative computed tomography (HR-pQCT) in patients with ERA.

Methods: In this study, 104 female ERA patients treated with a tight-control protocol using csDMARDs were prospectively followed for 1 year. 30 female healthy controls were also recruited. All the 104 female ERA patients were scanned by HR-pQCT of the distal radius and tibia at baseline and one-year. CVAI was calculated by the following formula: $CVAI = -187.32 + 1.71 \times \text{age} + 4.23 \times \text{BMI} + 1.12 \times \text{WC (cm)} + 39.76 \times \text{Log10 TG} - 11.66 \times \text{HDL-C}$. The female ERA patients were sub-grouped according to the median CVAI value (65.73) (low CVAI and high CVAI groups).

Results: After adjusting for age and BMI, the CVAI in the ERA group was significantly higher than the control group (55.10 ± 32.02 versus 41.11 ± 20.89 , $p=0.010$). ESR level at baseline in the high CVAI group was statistically higher than the low CVAI group (73.63 ± 34.49 versus 55.52 ± 27.52 , $p=0.038$). Cortical volumetric BMD (vBMD) in the distal radius and tibia at baseline were significantly lower in the high CVAI group compared to the low CVAI group (all $p<0.01$). Linear regression models indicated that CVAI at baseline was an independent negative predictor of distal radius cortical vBMD at Month 12 ($B=-1.033$, $p=0.022$, 95% CI: $-1.914 \sim -0.153$) and tibia cortical vBMD at Month 12 ($B=-0.828$, $p=0.003$, 95% CI: $-1.366 \sim -0.290$). In addition, CVAI at baseline was an independent predictor of the decreased trabecular vBMD in tibia ($B=0.040$, $p=0.001$, 95% CI: $0.018 \sim 0.063$) and decreased trabecular vBMD in distal radius ($B=0.233$, $p=0.008$, 95% CI: $0.063 \sim 0.403$).

Conclusion: CVAI is an independent predictor of bone loss in female patients with ERA. CVAI may have an important role in the changed trabecular density. These associations may be mediated by a chronic inflammatory state.

Foot and Lower Limb Characteristics in People with SLE: A Comparison with Age- and Sex-Matched Healthy Control Participants

Sarah Stewart¹, Ashok Aiyer², Nicola Dalbeth³ and Keith Rome⁴, ¹School of Podiatry, Auckland University of Technology, Auckland, New Zealand, ²School of Podiatry, The Auckland University of Technology, Auckland, New Zealand, ³University of Auckland, Auckland, New Zealand, ⁴School of Clinical Science, Health & Rehabilitation Research Institute, AUT University, Auckland, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ARHP II: Clinical Aspects and Outcomes Research

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: People with SLE report joint pain and swelling, impaired circulation, cutaneous lesions and foot deformity. Foot- and lower-limb-related functional impairment has also been described in SLE. However, objectively assessed measures of foot function, including muscle strength and gait characteristics have not been evaluated in people with SLE. This study aimed to identify foot and lower limb characteristics in people with SLE compared to age- and sex-matched controls.

Methods: The study included 54 people with SLE (all fulfilling the 1997 ACR classification criteria) and 56 age- and sex-matched healthy control participants (mean (SD) age: 52 (14) SLE vs 48 (14) controls, 93% females in both groups), who attended a study visit designed to comprehensively assess foot function. Assessment of patient-reported foot and lower limb pain and disability was measured using: Manchester Foot Pain & Disability Index; Lower Limb Task Questionnaire; and 100 mm foot pain VAS. Isometric muscle force for ankle plantar flexion, dorsiflexion, inversion and eversion was assessed using dynamometry; foot joint motion was assessed using goniometry; foot type was assessed using the Foot Posture Index (FPI); foot problems were assessed using the Foot Problem Score (FPS); neurological evaluation included vibration perception thresholds (VPT) and presence of protective sensation. Temperature and Ankle Brachial Index (ABI) were also assessed. Dynamic function was assessed using plantar pressure and spatiotemporal gait analysis. Data were analysed using regression models.

Results: Participants with SLE had a mean (SD) disease duration of 15 (12) years and a SLEDAI-2K score of 13 (10). Differences in foot characteristics are presented in the Table. Participants with SLE reported greater foot and lower limb pain and disability in all questionnaires. Compared to control participants, those with SLE had significantly reduced muscle strength for ankle plantar flexion, dorsiflexion, inversion, and eversion. Participants with SLE had higher FPI (3.6 vs 5.4, $P = 0.007$) and FPS (11 vs 16, $P = 0.001$), VPT (8.9 vs 13.2, $P = 0.001$) and prevalence of abnormal ABI (odds ratio (95% CI) 3.13 (1.03, 9.49), $P = 0.044$). No differences were observed between groups for joint motion, protective sensation, or temperature. Participants with SLE exhibited higher pressure time integrals for all regions of the plantar foot and walked significantly slower with reduced step length and greater swing and stance times compared to control participants.

Conclusion: People with SLE report a wide-range of foot complaints related to pain, disability and activity limitation. People with SLE also exhibit objective evidence of foot and ankle disease, including reduced foot and ankle muscle strength, and altered plantar pressure and gait patterns when compared to matched controls.

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Title:

Association between Serum Uric Acid Level and Coronary Artery Disease :

Background/Purpose: Previous studies have shown an unclear relationship between serum uric acid (SUA) and coronary artery disease (CAD). We attempt to clarify this relationship using the largest public US dataset available; the National Health and Nutrition Examination Survey (NHANES).

Methods: NHANES data from 2003 to 2014 was selected based on an affirmative response to the questions: 1. "Ever told you had angina/angina pectoris", 2. "Ever told you had heart attack", and 3. "Ever told you had coronary heart disease". The resulting data set was analyzed for uric acid levels (cut-off >6.0 mg/dL in females and >7.0 mg/dL in males), and CAD risk factors. Proportional analyses as well as univariate and multiple logistic regression models were used to evaluate the associations between SUA levels and CAD.

Results: 36,267 survey participants (Mean age 49.35 yrs.) from 2003 to 2014 were included in the study. There were 20,201 (51.7%) females and 18,863 (48.3%) males. A total of 2,797 (7.2%) had CAD; 39% of these were female and 61% were male. Univariate analyses showed a significant association between high SUA levels (OR 1.4; 95% CI 1.3 - 1.6), hypertension (OR 1.1; 95% CI 1 - 1.2), and renal dysfunction (OR 2.0; 95% CI 1.8 - 2.3). The relationship between SUA and CAD was reaffirmed in our multiple regression models (p-value <0.001) after adjusting for age, sex, race, smoking, diabetes, blood pressure and cholesterol.

Conclusion: Our study showed that there is a significant association between SUA levels and CAD in the NHANES population. This suggests that including SUA in risk models may improve risk stratification for CAD. Further prospective studies are needed to confirm this association and clarify the mechanisms behind it.

Racial Disparities in Utilization of Knee Replacement: Data from the Osteoarthritis Initiative

Jie Wei^{1,2}, Chao Zeng^{1,3}, Uyen-Sa D.T. Nguyen⁴, Hyon K. Choi¹ and Yuqing Zhang⁵, ¹Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ²Department of Health Management Center, Xiangya Hospital, Changsha, China, ³Department of Orthopedics, Xiangya Hospital, Changsha, China, ⁴Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester, MA, ⁵Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ARHP II: Clinical Aspects and Outcomes Research

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: While risk of knee osteoarthritis (OA) is higher among black than white individuals, the rate of knee replacement—an effective treatment for end-stage OA among blacks is lower than among whites. Identifying mechanisms of racial disparity in utilization of knee replacement would help toward development of innovative programs or

interventions to reduce disparities and improve OA care in blacks. We compared the risk of knee replacement between black and white individuals and assessed the extent of which the difference in risk of knee replacement was accounted for by several potential mediators.

Methods: Data on race, age, sex, education, family income, and health insurance at baseline examination as well as incident knee replacement during the follow-up were obtained among participants in the Osteoarthritis Initiative, which is a multicenter prospective cohort study of participants with or at high risk of knee OA. First, we compared the risk of knee replacement between blacks and whites using generalized estimating equations, adjusting for age and sex. Then, we estimated the indirect effect of race on the risk of knee replacement mediated through education, income and health insurance using marginal structural model.

Results: Of 4,057 participants (8,114 knees) in the OAI, 3,368 (83.0%) were white (mean age: 61.5 years; women: 54.9%, \geq college education: 87.6%, income < \$50,000/year: 33.3%, and health insurance coverage: 89.6%) and 689 (17.0%) were black (mean age: 58.9 years; women: 68.5%, \geq college education: 73.4%, income < \$50,000/year: 61.8%, and health insurance coverage: 85.5%). During the follow-up period, 341 (10.1%) whites and 43 (6.2%) blacks have knee replacement therapy. Compared with whites an age-sex-adjusted odds ratio (OR) of knee replacement for blacks was 0.63 (95% Confidence Interval [CI]: 0.45-0.88). In the multiple mediation analysis, the natural direct effect of race on knee replacement was 0.71 (95% CI: 0.49-1.04), and the natural indirect effect through income and health insurance were 0.93 (95% CI: 0.87-1.00) and 0.97 (95% CI: 0.95-0.99), with each of these mediators explaining 20.6% and 9.6% of risk of knee replacement between two racial groups, respectively. (see **Table 1**).

Conclusion: Blacks were less likely to have knee replacement than whites, indicating racial disparities in the utilization of knee replacement. Such a disparity was partially attributed to the difference in income and health insurance between two racial groups. Future studies evaluating how perception and willingness on knee replacement mediate the effect of race on knee replacement are warranted.

Table 1 Results of Multiple Mediation-analysis of the Association between Race (black versus white) and Utilization of Knee Replacement

Black versus white	OR* (95% CI)	Proportion Mediated (%)	P value
Total Effect	0.63 (0.45, 0.88)	-	<0.01
Direct Effect	0.71 (0.49, 1.04)	-	0.09
Indirect Effect through Education	1.00 (0.95, 1.06)	0	1.00

Risk of Obstructive Sleep Apnea in Rheumatoid Arthritis

Patricia Katz¹, Sofia Pedro² and Kaleb Michaud^{2,3}, ¹University of California San Francisco, San Francisco, CA, ²FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, ³Rheumatology, University of Nebraska Medical Center, Omaha, NE

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: ARHP II: Clinical Aspects and Outcomes Research

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30 PM-4:00 PM

Background/Purpose: Self-reported sleep disturbances (SDs) are common in RA. Most studies of sleep in RA have focused on SDs in general. Obstructive sleep apnea (OSA) is one specific type of SD, which has well characterized negative health effects and for which treatment is available. We examined the frequency OSA symptoms, risk, diagnosis, and treatment, and factors associated with OSA risk.

Methods: Data were from Forward – The National Data bank for Rheumatic Diseases, for which participants complete questionnaires every 6 months. RA diagnoses were physician-reported. In one questionnaire, items about the presence of symptoms, physician diagnoses (MD-DX), and treatment of OSA were included. Risk of OSA was assessed using a validated questionnaire with positive predictive value of ~85%¹. Items included snoring, daytime sleepiness, observations of

apnea episodes by others, presence/treatment of hypertension (Table 1). Presence of ≥ 2 of these symptoms plus age > 50 or BMI > 35 indicates high risk for OSA. Use of continuous positive air pressure (CPAP) devices were also assessed. Frequencies of OSA symptoms, risk, diagnosis, and treatment were tabulated. Multivariate logistic regression analyses identified independent predictors of high risk of OSA. Potential predictors included age, sex, smoking, low income, chronic obstructive pulmonary disease (COPD), other comorbid conditions, obesity, disease duration, self-reported RA disease activity (RA Disease Activity Index, RADAI), medications, and pain.

Results: Subject characteristics and prevalence of OSA symptoms are shown in Table 1 (n = 2623). 16% reported MD-DX OSA and an additional 8% were at high risk of OSA, compared to OSA prevalence of $\sim 2\text{--}4\%$ in the general population. 9% used CPAP (58% of MD-DXOSA; 34% of those at high risk for OSA). Independent predictors of OSA risk were obesity, smoking, more comorbid conditions, and RADAI (Table 2).

Conclusion: OSA was more common in RA than in the population, with only 2/3 of those at high risk reporting an OSA diagnosis. Half of those with a diagnosis reported treatment. Some predictors of OSA were similar to predictors in the population (age, obesity), but disease activity was also associated with OSA. Self-reported sleep problems are associated with poor RA disease outcomes. In other conditions, OSA is linked to heightened inflammation, so it could be a cause of increased RA disease activity. Further research is needed to tease out disease-specific causes and effects of OSA and other sleep disturbances in RA.

Human Toll-like Receptor 8 Adversely Affects Placental Development and Pregnancy Outcomes in a Mouse Model of Systemic Lupus Erythematosus

Naomi I. Maria¹, Shani Martinez¹ and Anne Davidson², ¹Center for Autoimmunity, Musculoskeletal & Hematopoietic Diseases, Feinstein Institute for Medical Research, Manhasset, NY, ²Center for Autoimmunity, Musculoskeletal & Hematopoietic Diseases, Feinstein Institute for Medical Research, Manhasset, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Innate Immunity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) predominantly affects women of childbearing age and is associated with adverse pregnancy outcomes including pre-eclampsia, intrauterine fetal growth restriction (IUGR), placental abnormalities and maternal and fetal mortality, particularly during active disease or in the presence of antiphospholipid antibodies (aPL). Pro-inflammatory factors rather than thrombosis are now thought to be the main contributor to placental and fetal damage in women with APS. Pathogenic mechanisms that damage the fetal-maternal unit and cause abnormal placental development, however, remain poorly understood. The endosomal RNA sensor Toll-like receptor 8 (TLR8) that is predominantly expressed in macrophages and neutrophils was recently hypothesized to play a role in antiphospholipid syndrome (APS) and aPL antibody-induced placental and fetal damage. The role of TLR8 in systemic autoimmunity remains elusive as TLR8 function differs from mouse to man with respect to recognition of RNA. We are currently studying the functional consequences of one or two copies of human (huTLR8) in murine SLE, and hypothesize that the presence of huTLR8 and aPLs will adversely affect pregnancy outcomes in SLE.

Methods: Sle1 mice expressing huTLR8 as a BAC transgene (huTLR8tg) were generated and followed clinically. HuTLR8 DNA copy number and mRNA expression was confirmed by qDigital and qRT-PCR respectively. Pregnancies were closely followed and terminal C-sections were performed in pregnant females with dead pups or exhibiting signs of dystocia or prolonged end-stage pregnancy. Pup and placental weight was assessed. Placental tissues were histologically characterized by H&E and immunohistochemical staining for neutrophil GR1-Ly6 and the granular protein Myeloperoxidase (MPO) to distinguish intact from netting neutrophils. Additionally, placental tissue was stored for further mRNA and microRNA analysis. Auto-antibody status in serum from pregnant females was assessed.

Results: Female huTLR8tg Sle1 mice manifested splenomegaly [mean 0.323g, n=16] compared to their non-huTLR8 counterparts [mean 0.123g, n=18] (p=0.0013) and developed anti-cardiolipin antibodies at a younger age than their wild type controls. We observed 26/55=47% loss of litters due to fetal resorption/dystocia resulting in fetal and maternal death, compared with 0% in n=20 Sle1 controls. Pup weights were significantly lower (p<0.0001) for stuck/dead pups [median 1.212g, n=31] compared to normal pups [median 1.649g, n=55]. Abnormal placental morphology was observed, with dense tissue structure, defective vasculature and increased GR1-Ly6 neutrophil infiltration. An increase in netting neutrophils was identified by MPO as decondensed non-intact nuclei.

Conclusion: We observed 47% loss of litters in huTLR8tg Sle1 pregnancies due to fetal resorption/dystocia resulting in both fetal and maternal death. This was due to placental developmental abnormalities, including vascular remodeling and inflammation in the presence of aPLs. Here we identify a potential new model to study adverse pregnancy complications in SLE and APS and further define the mechanistic role of TLR8 in promoting pregnancy loss.

NF-Kappa b Signaling in the Myeloid Cell Lineage Drives the Pathogenesis of Immune-Mediated Nephritis

Samantha Chalmers¹, Sayra Garcia¹, Justine Shum¹, Leal Herlitz² and Chaim Putterman³, ¹Albert Einstein College of Medicine, Bronx, NY, ²Cleveland Clinic, Cleveland, OH, ³Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Innate Immunity**Session Type:** ACR Concurrent Abstract Session**Session Time:** 4:30 PM-6:00 PM

Background/Purpose: Immune-mediated glomerulonephritis is a serious end organ pathology that commonly affects patients with systemic lupus erythematosus (SLE). Nephrotoxic serum nephritis, induced by passive transfer of preformed nephrotoxic antibodies, is a mouse model commonly used to study lupus nephritis (LN). We and others have previously shown that macrophages are important in the pathogenesis of LN. To further delineate critical nephritis-associated pathways, in this study we assessed the importance of NF- κ B signaling in the myeloid cell lineage in the pathogenesis of LN.

Methods: Using flox-cre technology, we created a novel B6 mouse strain with genetic deficiency in RelA (aka p65) restricted to myeloid cells (RelA *flox/flox* LyzM *cre/cre* B6; KO mice), thus facilitating the study of the role of classical NF- κ B signaling in myeloid cells in the context of immune mediated nephritis. Lupus like nephritis was induced at 9-10 weeks of age in both the KO mice and age-matched wildtype control B6 mice (WT mice). Mice were immunized on day 0 with rabbit IgG emulsified in complete Freund's adjuvant, and 5 days later were given the nephrotoxic serum (containing rabbit antibodies which target murine glomerular antigens) by intravenous injection. Mice were then serially assessed for the development of nephritis.

Results: By day 13, myeloid cell RelA KO mice (n=14) injected with nephrotoxic serum had significantly attenuated proteinuria (mean protein: creatinine ratio KO=3.1 \pm 2.2 vs. WT=29.0 \pm 9.0, p<0.05) and lower serum BUN levels (mean KO= 46.0 \pm 5.7 mg/dL vs. WT 69.9 \pm 6.2 mg/dL, p<0.01) compared to control injected WT mice (n=16). Inhibiting myeloid NF- κ B signaling also decreased inflammatory modulators within the kidneys. We found significant decreases in expression of IL-1 α , IFN γ , and IL-6 in kidneys from KO mice, but higher IL-10 expression. We also found a significant reduction of macrophages accumulating in the kidney by immunofluorescent staining, a finding confirmed by flow cytometry. Specifically, flow cytometric analysis revealed decreased numbers of classically activated macrophages infiltrating the kidneys of KO mice. Kidney IgG and C3 deposition, however, was not different between KO and WT mice. Additionally, the two strains had no differences in their antibody response to the initial immunization (in both total IgG concentration and concentrations of different isotypes), indicating that any differences in disease severity were not because deficient myeloid NF- κ B signaling interfered with disease induction. Analysis of renal histopathology is pending.

Conclusion: Our studies indicate that macrophage NF- κ B signaling is instrumental in the contribution of this cell type to the pathogenesis of nephritis induced by pathogenic antibodies. These results suggest that while approaches which decrease macrophage numbers can be effective in LN, more targeted treatments directed at modulating macrophage signaling and/or function could be beneficial, at least in early stages of the disease.

Abstract Number: 2852

Excessive Formation of Neutrophil Extracellular Traps: Different Role in the Pathogenesis of ANCA-Associated Vasculitis and Systemic Lupus Erythematosus

Laura van Dam¹, Tineke Kraaij¹, Sylvia W.A. Kamerling¹, Hans U. Scherer², Ton Rabelink¹, Cees van Kooten¹ and Y.K. Onno Teng¹, ¹Nephrology, Leiden University Medical Center, Leiden, Netherlands, ²Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Innate Immunity**Session Type:** ACR Concurrent Abstract Session**Session Time:** 4:30 PM-6:00 PM

Background/Purpose: ANCA-associated vasculitis (AAV) and systemic lupus erythematosus (SLE) both cause glomerulonephritis with pauci-immune and full-house immunofluorescence patterns, respectively. Although AAV and SLE are clinically divergent autoimmune diseases, neutrophil extracellular traps (NETs) are postulated to be involved in both diseases. NETs are immunogenic, extracellular DNA structures harbouring relevant AAV- and SLE-autoantigens. The aim of this study was to dissect AAV- and SLE-induced NET formation and study their pathogenic role in the pathophysiology of these autoimmune diseases.

Methods: Ex vivo NET formation was quantified by a novel, highly-sensitive NET-quantification assay using 3D-confocal microscopy for 82 AAV patients, 56 SLE patients and 10 healthy controls (HC). Morphology and kinetics of AAV- and SLE-induced NET formation was studied through live-cell imaging. Qualitative characteristics of NETs were investigated by immunofluorescence microscopy that detected co-localisation of NET-related proteins, including citrullinated histone-3 (CitH3) and high mobility group box-1 (HMGB1). Also, the presence of IgG, IgM or IgA autoantibodies on AAV- and SLE-induced NETs was studied through immunofluorescence. Autoantibodies as trigger of NET formation were investigated by depleting serum from IgG and NET inhibition assays were performed using peptidylarginine deiminase-4 (PAD4) and NADPH inhibitors.

Results: Ex vivo NET formation was higher for AAV compared to SLE, which was triggered by immune complexes (ICx) in SLE but not in AAV. In AAV, lytic NET formation was induced involving NADPH oxidase and PAD enzymes resulting in a lytic expulsion of citrullinated NETs within a timeframe of hours. In SLE, non-lytic NET formation with clustering of NET-ting neutrophils is induced within minutes. SLE-induced NETs have immunogenic properties including enrichment for HMGB1, oxidized mtDNA and immune complex formation which was not the case for AAV-induced NETs.

Conclusion: This study demonstrates that excessive NET formation in AAV is intrinsically different to NET formation in SLE, identifying suicidal NET formation and vital NET formation, respectively, which closely associated with the respective, typical features of “pauci-immune”, histone-mediated crescentic glomerulonephritis in AAV and immune-complex mediated “full-house” lupus nephritis in SLE.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Innate Immunity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Photosensitivity, or skin sensitivity to ultraviolet radiation (UVR), is a feature of lupus erythematosus (LE) and other autoimmune conditions. Photosensitive lesions can be disfiguring and photosensitivity can be associated with flares of systemic disease. Increased UVR-induced keratinocyte apoptosis is thought to play a role in the pathogenesis, but factors that regulate keratinocyte apoptosis in photosensitivity are poorly understood. Langerhans cells (LCs), mononuclear phagocytes positioned primarily in the epidermis, can have regulatory roles. As LCs are closely associated with keratinocytes, we hypothesized that LCs can limit UVR-induced keratinocyte apoptosis and skin injury.

Methods: We exposed mice to UVR at a minimal erythema dosage and 24 hours and 5 days later, harvested ear skin for immunohistochemistry to measure activated caspase 3, for flow cytometry to enumerate monocyte infiltration, for histology to measure epidermal thickness, and for toluidine blue dye assays to measure epidermal permeability. Primary mouse and

human keratinocyte cultures were exposed to UVR in the presence or absence of LCs and keratinocyte apoptosis was measured. Skin sections from healthy controls and SLE patients were stained for immunofluorescence analysis of LC numbers and epidermal markers.

Results: Here, we identify a Langerhans cell (LC)-keratinocyte axis that limits UVR-induced keratinocyte apoptosis and skin injury via keratinocyte epidermal growth factor receptor (EGFR) stimulation. We show that absence of LCs in Langerin-DTA mice leads to photosensitivity and that, in vitro, mouse and human LCs can directly protect keratinocytes from UVR-induced apoptosis. LCs express EGFR ligands and ADAM17, the metalloprotease that activates EGFR ligands. Deletion of ADAM17 from LCs leads to photosensitivity and UVR induces LC ADAM17 activation and generation of soluble active EGFR ligands, suggesting that LCs protect by providing activated EGFR ligands to keratinocytes. Photosensitive systemic LE (SLE) models and human SLE skin show reduced epidermal EGFR phosphorylation and LC defects, and topical EGFR ligand reduces photosensitivity.

Conclusion: Together, our data establish a direct tissue-protective function for LCs, reveal a mechanistic basis for photosensitivity, and suggest EGFR stimulation as a treatment for photosensitivity in LE and potentially other autoimmune conditions.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Innate Immunity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: To study the mechanism that leads to bone inflammation in a 4-year old patient of mixed Puerto Rican and African-American background who presented with sterile osteomyelitis (Majeed syndrome), that is caused by two novel compound heterozygous *LPIN2* mutations.

Methods: Targeted genetic analysis for known autoinflammatory genes was performed that revealed Majeed syndrome and functional studies (stimulation assays and immune-histochemistry) on patient's monocytes, monocyte-derived M1 (MDM1) and M2 (MDM2) macrophages (culture with GM-CSF or M-CSF respectively for 5 days) from the Majeed patient, patients with NOMID (n=3) and DIRA (n=4), and healthy controls (n=4) were conducted to assess IL-1 production and the production of other inflammatory cytokines and chemokines.

Results: The patient has a novel splice site mutation on one allele of *LPIN2*, that leads to a loss of exon 10 and 11, and a novel 16.0 Kb deletion on the other allele deleting exons 7-18 including a conserved residue that confers phosphatase activity. Treatment with IL-1 blocking treatment led to complete clinical remission. Functional studies from monocytes and MDM1 macrophages show increased LPS+ATP induced IL-1 production and increased upregulation of gasdermin D with increased cell death in MDM1s from the Majeed pt. similar to NOMID patients but higher than controls. In contrast, the Majeed pt's MDM2 produced lower amounts of IL-10 than MDM2 from HC, NOMID and DIRA patients. However, unstimulated Majeed pt's MDM2 spontaneously produced high levels of IL-8 and CCL2/MCP1 and LPS and ATP stimulated MDM2 macrophages from the Majeed pt. produced significantly higher levels of IL-6, TNF, IL-8 and other chemokines compared to MDM2s from healthy controls and NOMID patients. MDM2 from DIRA patients were more inflammatory than NOMID and HC but less than the Majeed pt's MDM2s. Studies evaluating the effect of the *LPIN2* mutations on osteoclast function are ongoing.

Conclusion: We report two novel loss-of-function mutations in *LPIN2*, in an American pt. of mixed racial background. The increase in caspase-1 activity and gasdermin D levels in the Majeed pt. are consistent with increased inflammasome activation in monocytes and MDM1s. However, the differentiation of Majeed monocytes into inflammatory MDM2 macrophages that express high levels of TNF, IL-6, IL-8 and chemokines known to activate osteoclasts distinguish the Majeed syndrome pt. from pts with GOF mutations in *NLRP3* (causing cryopyrinopathies) and suggest a possible mechanism of sterile osteomyelitis by causing an inflammatory local bone environment that may prevent bone healing.

Session Date: Tuesday, October 23, 2018

Session Title: Innate Immunity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Deficiency of the Interleukin-1 receptor antagonist (DIRA) is an autoinflammatory disease of infancy characterized by severe systemic inflammation with bone and skin involvement. This is a report of a novel variant in the *IL1RN*-gene associated with late onset and atypical phenotype of DIRA.

Methods: A 3 year-old Caucasian boy presented with recurrent monthly episodes of fever and fatigue, associated with lymphadenopathy, pericarditis, pleuritis, pancreatitis, and arthritis involving sacroiliac, hip, knee and ankle joints in the absence of skin involvement. Symptoms had started at age one and progressed over time to life-threatening episodes requiring intensive care. Throughout, ESR, CRP, SAA, S100A8/9, leukocytes, and platelets were highly elevated. Treatment with colchicine and steroids improved symptoms; however, did not prevent flares. Genetic testing did not identify known pathogenic variants of immune deficiencies and AIDs including DITRA.

Results: Whole exome sequencing detected a novel homozygous stop variant c.62C>G; p.Ser21* in the *ILRN* gene (NM_173842.2). Mother, father and brother were heterozygous for the same variant. In addition, three variants of unknown significance were identified in the patient's *PCGF5*, *CPA1* and *SPTA1* genes. Functional studies revealed marginally low secretion of IL-1RA from unstimulated leucocytes and after stimulation with IL-1 β and LPS, confirming the disease-causing nature of the variant. IL-1 inhibition with anakinra at 2 mg/kg/d was started resulting in complete resolution of clinical symptoms, inflammatory markers and signs of inflammation on MRI. Intolerance to daily sc injections prompted a switch to canakinumab at 4 mg/kg/4 weeks. However, canakinumab did not prevent significant disease flares including new bone inflammation. Re-start of anakinra resulted in recapture of disease control.

Conclusion: This is the first report of the novel c.62C>G; p.Ser21* variant in the *IL1RN*-gene resulting in late onset DIRA with prominent systemic and bone/joint inflammation. DIRA should be considered in older children even in the absence of skin disease.

Session Date: Tuesday, October 23, 2018

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Routine measurement of RA disease activity and adjustment of drug therapy to attain remission or low disease activity is recommended by the ACR and EULAR. However, it is unclear whether this occurs in real-world settings. We identified longitudinal RA treatment changes stratified by disease activity categories and the methods used to measure it.

Methods: Using the ACR's national EHR-based RISE registry, we identified adult RA patients who had ≥ 1 rheumatologist visit (indexvisit) with a disease activity measure available (e.g. RAPID3, CDAI) in 2016. We assessed disease activity measurement(s) used for each patient and calculated the proportion of patients with moderate/high disease activity (M/HDA) at the index visit. We evaluated treatment and disease activity changes at the follow-up visit occurring month 7-12 after index. Results were stratified based on available measurement tool and patients' baseline RA medications. Subgroup analyses were conducted for patients with 'persistent' M/HDA (at both the index visit and the visit immediately prior), for patients with past (ever) biologic use, for patients with seropositive RA, and for those with past methotrexate use.

Results: Among 457,950 patients included in the 2016 RISE registry, we identified 50,996 eligible RA patients. Mean age was 62.4 (SD:13.7); 76.7% were women; 52.8% had Medicare insurance and 25.3% had concurrent glucocorticoid use. Most (85%) were evaluated with only one RA measurement at the index visit. RAPID3 was most commonly used (79%), followed by CDAI (34%) and DAS 28 ESR/CRP (3%). A total of 7,467 (14.6%) patients had both RAPID3 and CDAI measured at the index visit. For patients with M/HDA and RA medication at the index visit and who had a follow-up visit occurring 7-12 months after index (n=2,336 for RAPID3, n=904 for CDAI), changes in treatment is shown (Figure). Irrespective of baseline RA medication, RA treatment change did not exceed 65% of the patients. For the subgroup of patients with persistent M/HDA by RAPID3 (n=1,241) or CDAI (n=497), the proportion of treatment switching was consistent with the main analysis. Patients with any history of biologic exposure had a similar pattern in therapy change (<10% different). The treatment pattern for seropositive patients and with a history of methotrexate was also similar to the main analysis.

Conclusion: Irrespective of the measurement tool used (RAPID3 or CDAI), past biologic use, or persistent M/HDA, almost half of RA patients in the ACR RISE registry with M/HDA did not change their current therapy over the next year. To optimize RA therapies in accordance with treat-to-target principles, more effective intervention is needed to encourage treatment change and improve patient outcomes.

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The Veterans Affairs (VA) Rheumatoid Arthritis (RA) (VARA) registry is an observational cohort study of US Veterans with RA at 11 VA Medical Centers. VARA investigators capture clinical and laboratory disease activity measures (DAMs) during clinic visits via standardized templates in the electronic health record (EHR). Six clinical (tender/swollen joints, patient/provider global, MD-HAQ, pain) and 2 laboratory (ESR, CRP) DAMs are extracted post-visit using natural language processing (NLP). An audit and reporting system was developed to identify and report incomplete DAM collection and provide a method for entering missing data, when available. We report the impact of this system on the quantity and quality of DAMs collected.

Changes in Collection of Disease Activity Measures (DAMs) before and after the Implementation (IMP) of an Audit, Reporting, and Feedback System in the VARA Registry.

Patients and Notes	Pre-IMP	Post-IMP		Increase (%)
Unique patients	861	1,017		156 (18.1%)
Total Notes	1,182	1,423		241 (20.3%)
Disease Activity Measure (DAMs)		Feedback and Correction		
		Before	After	
Total DAMs	5,882	7,283	7,585	1,903 (33.5%)
Number Clinical DAMs per note	4.8	5.1	5.4	0.6 (11.7%)
Notes with 6 Clinical DAMs	865 (56.3%)*	1,000 (70.8%)‡	1,051 (75.1%)‡	396 (33.5%)
Notes with 4 DAMs for DAS28	806 (68.1%)*	944 (66.8%)‡	984 (69.7%)‡	138 (22.2%)
Notes with 6 clinical and 2 lab DAMs	595 (50.4%)*	778 (55.1%)‡	820 (58%)‡	225 (37.8%)

* Percent of total notes during the pre-implementation period.

‡ Percent of total notes during the post-implementation period.

‡ Percent change from pre-implementation baseline to post-implementation after corrective.

VARA registry goal is to collect the following Disease Activity Measures (DAMs) at each visit.

Six Clinical DAMs

Joint Tender Count of 28 joints
Joint Swelling Count of 28 joints
Patient Global Assessment of Disease Activity
Physician Global Assessment of Disease Activity
Medical Health Assessment Questionnaire
Patient Pain Score

Two Laboratory DAMs

Westergren Erythrocyte Sedimentation Rate
C-Reactive Protein

Composite DAM

Disease Activity Score for 28 joint count (DAS28)

Methods: After March 2017, VARA site investigators were provided monthly reports of incomplete / missing DAMs for the prior month. Review of clinic notes was used to identify data that was not captured by NLP because of modification of EHR templates or data entry errors. Updated and/or corrected data were entered into the EHR via note addendums and then automatically re-extracted by NLP to complete the capture of DAM data. DAMs collection from October 1, 2016 to March 31, 2017 (pre-implementation – Pre-IMP) was compared to collection from October 1, 2017 to March 31, 2018 (post-implementation –Post-IMP) before and after investigators received monthly reports.

Results: During the pre-IMP period, there were 1,182 notes with DAMs collected on 861 unique patients compared to 1,423 notes on 1,017 unique patients in the post-IMP period--an increase of 156 (18%) unique patients and 241 (20%) notes. The quantity of DAMs collected increased from 5,682 to 7,585, a 34% increase. During this timeframe enrollment in the VARA registry increased by only 4%. The quality of DAMs collected was measured by completeness of notes containing DAMs which also increased with corrections, as demonstrated by an increase in the average number of DAMs collected per note rising from 4.8 to 5.4 and proportion of notes achieving the goal of 6 clinical DAMs increasing from 56% to 75%. There were 170 notes identified with deficiencies and with monthly feedback 302 DAMs that were original missing added to the database. Similar quantity and quality/completeness improvements were seen in notes with all clinical and laboratory DAMs and the ability to calculate DAS28 (see Table).

Conclusion: An audit, reporting, and efficient data collection system improved both the quantity and quality of DAMs collected in this national observational study. The improvement in the collection of DAMs in RA patients will further enhance the feasibility of conducting epidemiologic and outcomes studies of RA and provide higher quality longitudinal data to enhance the care of RA patients via expanded use of HER.

Patterson¹, Michael Evans², Ishita Aggarwal³, Zara Izadi⁴, Milena Gianfrancesco⁵, Gabriela Schmajuk⁶ and Jinoos Yazdany⁷, ¹Division of Rheumatology, University of California, San Francisco, San Francisco, CA, ²University of California - San Francisco, San Francisco, CA, ³Medicine, Santa Clara Valley Medical Center, San Jose, CA, ⁴Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, ⁵Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, ⁶San Francisco VA Medical Center, San Francisco, CA, ⁷University of California, San Francisco, San Francisco, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Treatment with biologic disease-modifying antirheumatic drugs (DMARDs) and tofacitinib confer increased risk of life-threatening infections, including reactivation of latent tuberculosis infection (LTBI), hepatitis B virus (HBV), and hepatitis C virus(HCV). We aimed to assess gaps in patient safety measures such as LTBI and hepatitis screening prior to drug initiation among patients treated with biologic DMARDs or tofacitinib in a large health system across multiple specialties.

Methods: We analyzed electronic health record (EHR) data from a university center, including diagnosis codes, problem lists, medications, laboratories, procedures, clinical notes, and scanned documents. Patients included all new users of a biologic DMARD (abatacept, adalimumab, anakinra, canakinumab, certolizumab, etanercept, golimumab, infliximab, secukinumab, tocilizumab, or ustekinumab) or tofacitinib between 7/1/13 and 10/1/17. We assessed screening for each infection: LTBI (fulfilled via tuberculin skin test, interferon gamma release assay, or prior treatment for TB); HBV (hepatitis B surface antigen); and HCV (Hepatitis C antibody) from 12 months preceding through 60 days after medication initiation. Next, we calculated performance on a composite safety measure that required screening for all 3 infections. We then liberalized the screening window to include any time prior to medication initiation. Multivariable logistic regression was used to assess differences in screening across prescribing specialties, adjusting for race, sex, age, and comorbidities.

Results: We included 1,029 patients; mean age was 39.5(SD 19.5), mean Charlson score 1.1 (SD 2.1), and 64% were White, 13% Hispanic, 12% Asian, 4% African American, and 22% other/not reported. Rheumatology was the most common prescribing specialty (Table) and the most common drugs prescribed were adalimumab (32%), etanercept (24%), infliximab (19%), and ustekinumab (9%). Overall, 62% of patients were screened for LTBI, 42% for HBV, 33% for HCV, and only 26% for all 3 infections within 12 months preceding through 60 days after initiation of an eligible drug. When we assessed screening at any time before drug initiation, the proportions screened were: 68% for LTBI, 55% for HBV, 46% for HCV, and 36% for all 3. Screening patterns differed by treating specialty (p<0.0001) (Table).

Conclusion: Screening for LTBI and hepatitis B and C among patients initiating biologic DMARDs or tofacitinib in a large health system is suboptimal. More robust safety protocols are needed across specialties to ensure adequate screening and prevent adverse drug events in this high-risk population.

Performance on Composite Patient Safety Measure (Screening for LTBI, Hepatitis B, and Hepatitis C), by Treating Specialty			
	N (%)	Unadjusted Performance*	Adjusted Performance** (95% CI)
All clinics	1,029	26.0%	n/a
Rheumatology	265 (25.8%)	32.8%	31.7% (25.9, 37.5)
Dermatology	277 (22.1%)	35.2%	35.8% (29.2, 42.3)
Gastroenterology	211 (20.5%)	21.3%	21.9% (16.2, 27.6)
Pediatrics subspecialties	160 (15.6%)	1.3%	1.5% (0.0, 3.6)
Oncology	10 (1.0%)	20.0%	14.8% (0.0, 34.9)
Other specialties	156 (15.2%)	33.3%	30.7% (23.1, 38.4)

* Proportion of patients who completed screening for LTBI, HBV, and HCV within 12 months before or 60 days after starting a new biologic DMARD or tofacitinib.

** Adjusted proportions calculated based on multivariate logistic regression adjusted for age, race, sex, and Charlson comorbidity score.

Session Date: Tuesday, October 23, 2018

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Rheumatoid arthritis (RA) patients have around 50% increased risk of cardiovascular disease (CVD). Both traditional and RA-specific cardiovascular(CV) risk factors contribute to the excess risk. Although RA is an independent risk factor for CVD, management of traditional CV risk factors is inadequate in this population. In order to improve risk factor management, we implemented a best practice alert (BPA) in the electronic health record (EHR) to prompt referral to preventive cardiology. We then investigated the impact of preventive cardiology on CV risk factor assessment and management in RA patients compared to usual care.

Methods: This retrospective cohort included adult RA subjects without CVD who were seen by a board-certified rheumatologist from 2009-2015 and exposed to the BPA, which prompted referral to preventive cardiology. The date that the BPA triggered was the baseline date. The main analysis included intervention subjects (referred and attended cardiology) and primary control subjects (referred but did not attend). A secondary analysis combined additional control subjects (not referred at all) with the primary control group. The primary outcome was CV risk factor assessment, defined as 4 of 5 traditional risk factors measured within one year. The secondary outcome was risk factor management, including starting or adjusting cardiac medications and providing lifestyle management counseling.

Results: 1,979 RA subjects (mean \pm standard deviation age: 56 \pm 14 years, 80% female, 74% white) were included. Overall, 266 (13%) subjects were referred to preventive cardiology; 145 (55%) subjects attended at least one preventive cardiology appointment (intervention), and 121 (45%) subjects were referred but did not attend (primary control). The

Figure 1. CV risk factor assessment one year prior to and one year after referral to preventive cardiology. Risk factor assessment is defined as at least 4 of 5 risk factors measured, including blood pressure, lipid panel, glucose, BMI, and smoking status.

remaining 1,713 subjects (not referred at all) were included in the combined control group (n=1834). One-third of subjects had risk factor assessment in the year prior to baseline. In the year after baseline, risk factor assessment occurred in 133 (92%) intervention vs. 35 (29%) primary control subjects ($p < 0.0001$; Figure 1). The intervention group had higher frequency of lipid-lowering medication management (intervention 36% vs. primary control 12%, $p < 0.0001$) and lifestyle management counseling (intervention 46% vs. 3% primary control, $p < 0.0001$). Additionally, the intervention group experienced significant decreases in total cholesterol (-14.6 ± 32.2 mg/dl, $p = 0.03$) and low-density lipoprotein (-13.8 ± 23.8 mg/dl, $p = 0.002$) at one year. Results were similar using the combined control group.

Conclusion: RA patients who attended preventive cardiology visits prompted by an EMR-based technology had increased CV risk factor assessment, pharmacologic and lifestyle management, and improved lipid profiles compared to usual care.

Session Date: Tuesday, October 23, 2018

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00 PM

Background/Purpose: Although national quality measures promote the measurement of disease activity (DA) in RA, the burden of DA in a population-based sample of RA patients is unknown. We used the ACR's RISE registry to assess variation in DA and methods of DA measurement nationwide.

Figure 1. Proportion of RA patients in RISE with disease activity in the remission or low categories on their most recent assessment, by practice, between July 2016 - June 2017

Figure 2. Proportion of RA patients in RISE with disease activity in remission or low categories, by state, between July 2016 - June 2017. Colors reflect adjusted proportions from a logistic regression model that controlled for measurement tool only. States in white did not have any patients included in this analysis.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, reducing the selection bias present in single-insurer claims databases. As of June 2017, RISE held validated data from 663 providers in 110 practices, representing ~19% of the U.S. clinical rheumatology workforce. Patients in this study had 2 RA codes ≥ 30 days apart and ≥ 1 RA DA score recorded from July 2016- June 2017 by a practice with ≥ 20 RA patients. DA scores from validated instruments (CDAI, DAS, PASII, or RAPID3) were categorized using accepted cut-points. We calculated 1) the proportion of patients in remission, low, moderate, or high DA on their most recent assessment, overall and aggregated by practice or state; and 2) proportion with ≥ 2 DA scores ≥ 90 days apart with all assessments in remission/low DA. We then tested whether DA was associated with the measurement tool used using a chi square test and generated adjusted state-level proportions of patients in remission/low DA on the most recent assessment using logistic regression.

Results: We included 56,850 patients from 71 practices; 77% were female, 65% white, with mean age 61 ± 13 . Overall, 21% of patients were in remission and 24%, 29%, and 26% had low, moderate, and high DA, respectively. The proportion of patients in a given practice in remission/low DA ranged from 0-99% (Figure 1). Of the 35,573 patients with ≥ 2 DA scores, 27% were consistently in remission/low DA. RAPID3 was the most used tool (54%), followed by CDAI (42%), DAS (2%), and PASII (2%); RAPID3 scores were more likely to be moderate/high DA compared to CDAI scores ($p < 0.001$). State-level variation was significant, even after adjusting for measurement tool ($p < 0.001$, Figure 2).

Conclusion: Less than half of RA patients across the U.S. have DA in remission or low categories on their most recent assessment, with large differences across practices and states. Although some of this variation can be explained by the tool used to assess DA, additional factors such as underlying patient characteristics or preferences, availability and affordability of medications, or differences in treatments or treatment intensity should also be explored.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Clinical Laboratory Telephone Communication Outreach to Rheumatology Patients Improves Guideline-Concordant Timeliness of Monitoring of Conventional and Biologic Disease-Modifying Anti-Rheumatic Drugs (DMARDs)

Tyson Hagen¹, Bharati Bhardwaja², David Silverman³, Susan Shetterly⁴ and Marsha Raebel⁵, ¹Rheumatology, Kaiser Permanente Colorado, Lafayette, CO, ²Pharmacy, Kaiser Permanente Colorado, Lafayette, CO, ³Kaiser Permanente Colorado, La Fayette, CO, ⁴Institute for health Research, Kaiser Permanente Colorado, Aurora, CO, ⁵Institute for Health Research, Kaiser Permanente Colorado, Aurora, CO

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The American College of Rheumatology has published guidelines for laboratory monitoring of conventional DMARDs (cDMARDs). At Kaiser Permanente Colorado (KPCO), although most patients eventually complete recommended monitoring, we found a test utilization gap in timeliness to monitoring. The purpose of this work was to develop a laboratory-led intervention to improve timeliness of test completion. Here we describe the direct-to-patient interactive voice response (IVR) outreach we developed and present healthcare system results of this work.

Methods: KPCO is an integrated healthcare delivery system with about 600,000 members in the Denver-Boulder area. The KPCO Virtual Data Warehouse (VDW) was used to identify patients and to extract all data. cDMARDs included were: methotrexate (MTX), leflunomide (LEF), sulfasalazine (SZA), and azathioprine (AZA). Biologic DMARDs(bDMARDs) included were: tocilizumab (TCZ), tofacitinib (TOF), adalimumab (ADA), certolizumab pegol (CER), etanercept (ETN), golimumab (GOL), infliximab (IFX) and rituximab (RTX). We identified members aged ≥ 18 receiving cDMARD/bDMARD therapy from a rheumatologist. Patients were eligible for outreach if they were due (within 3 days) or overdue for testing based on their most recent dates of alanine aminotransferase (ALT), aspartate aminotransferase (AST), creatinine (Cr), and/or complete blood count (CBC) testing. Whether patients were due/overdue was defined as: 1) MTX, LEF, SZA, AZA: ALT, AST, Cr and CBC every 4 weeks if < 3 months therapy; every 12 weeks if ≥ 3 months therapy. 2) TCZ, TOF: ALT, AST, Cr, and CBC every 6 weeks if < 3 months therapy; every 12 weeks if ≥ 3 months therapy. 3) ADA, CER, ETN, GOL, IFX: CBC every 6 months. 4) RTX: CBC every 3 months. An interactive voice response (IVR) system was employed in outreach. This system sends texts to text-enabled phones and calls to phones that are not text-enabled. The messages state in part: "You are due for a lab test to continue taking your medicine safely. Go to any Kaiser lab within the next week. No appt is needed..." System outcomes analysis was descriptive.

Results: The cohort included 3737 patients, 2365 (63.3%) of whom were taking MTX. Overall, the % of patients due for testing dropped after the intervention began and remained below baseline (Figure). For example, among patients taking MTX during the baseline period, 37% had ≥ 1 ALT testing gap > 100 days (12 weeks + 16 days "grace" period). Comparable proportions of patients had AST, CBC, or Cr testing gaps. During the intervention period, 27% of patients

taking MTX had ≥ 1 ALT testing gap >100 days. Patient and clinician feedback is positive. The outreach requires minimal maintenance.

Conclusion: Automated telephone communication outreach to remind rheumatology patients to obtain ordered laboratory testing improves the timeliness of cDMARD and bDMARD monitoring, is liked by patients, and is efficient.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: We aimed to quantify the magnitude of biologic effect on sacroiliitis in juvenile SpA by comparing the change in the Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint inflammation score (SIS) over time in TNF inhibitor (TNFi)-exposed versus TNFi-naïve patients.

Methods: This retrospective multi-center cohort study included 34 children with SpA. Children were included if they met ESSG SpA or ILAR juvenile arthritis criteria for enthesitis-related arthritis and had at least 2 pelvic MRI studies separated by at least 12 weeks between 2005 and 2018. Images were de-identified, randomized and reviewed independently by 3 radiologists and assigned a SPARCC SIS, with mean score used for analysis. The SIS divides the joint into quadrants and scores presence, depth, and intensity of bone marrow edema on STIR MRI (total score 0-72). We used a recency-weighted cumulative exposure model to quantify TNFi exposure in which higher weights were given to more recent exposure relative to the imaging date. The cumulative exposure scores were applied to a linear mixed-effects regression to test the association of TNFi exposure and change in SIS over time, adjusted for baseline SIS score. Kruskal-Wallis and chi-squared tests were used to assess relationships between clinical findings and SIS scores, as appropriate. Spearman's correlation was used to test association of change in clinical factors with the outcome.

Results: Baseline clinical features are in Table 1. The median time between images was 22 months (IQR 13-34.1). Ten (29%) children received a TNFi prior to baseline imaging, with a median exposure of 10 mos (IQR 3.9-24.4). Of the 26 patients (76%) with TNFi exposure between images, median exposure was 15.6 months (IQR 9-25.8). The mean SIS change score was 6.9 (SD 16.4; range -36 to 47). Patients with baseline SIS >1 had higher physician global assessments

Table 1: Subject characteristics at baseline imaging	All subjects (n=34)	TNFi exposure (n=26)	TNFi naïve (n=8)
	N (%)		
Age, years (median, IQR)	13.1 (10.2-15.3)	13.1 (10.2-15.3)	13.6 (10.8-15.2)
Sex, male	18 (52.94)	13 (50.0)	5 (62.5)
Race, Caucasian	27 (79.41)	21 (80.77)	6 (75.0)
HLA-B27 positive	17 (50)	15 (57.69)	2 (25.0)
Hip arthritis	6 (17.65)	5 (19.23)	1 (12.5)
Lower back pain	23 (67.65)	16 (61.54)	7 (87.5)
Morning stiffness (>15 minutes)	14 (42.42)	10 (40.0)	4 (50.0)
Disease duration, months (median, IQR)	13.8 (5.1-34.6)	14.7 (5.1-32.7)	12.4 (4.9-47.9)
Active joint count (mean, SD)	0.79 (1.98)	0.5 (1.65)	1.63 (2.77)
Tender entheses (mean, SD)	2.5 (3.23)	2.31 (3.28)	3.13 (3.18)
Physician global (0-10; mean, SD)	2.60 (1.82)	2.7 (1.57)	2.29 (2.61)
Patient global (0-10; mean, SD)	4.13 (2.81)	4.26 (2.72)	3.67 (3.33)
SIS baseline (median, IQR)	0 (0-19)	0.5 (0-21)	0 (0-7)
SIS baseline* (median, IQR)	15 (1-28)	19 (1-28)	7 (0-24.5)

*Excludes patients who experienced no change

($p=0.02$), fewer tender entheses ($p=0.02$), and shorter disease duration ($p=0.05$). Cumulative TNFi exposure was significantly associated with a decrease in SIS over time ($b=-0.02$, $p=0.01$). Of those with progression in SIS from 0 to >0 ($n=4$), two were exposed to a TNFi, but were off therapy for at least six months preceding the second MRI. There was no significant correlation between change in pain score and SIS ($p=0.09$).

Conclusion: Biologics have a quantifiable effect in reducing inflammation at the sacroiliac joints in children with SpA. Future studies should evaluate the rate of change in SIS in response to biologics to help guide appropriate timing for follow-up imaging in both clinical practice and efficacy studies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Background/Purpose: Canakinumab (CAN), a selective, human anti-interleukin (IL)-1 β has demonstrated efficacy and safety in patients (pts) with colchicine-resistant familial Mediterranean fever(crFMF), hyper-IgD syndrome (HIDS)/ mevalonate kinase deficiency (MKD), and tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) in epochs 2 and 3 (E2 and E3) of the CLUSTER study(NCT02059291).^{1,2}Here, we evaluated the long-term maintenance of optimal control of disease activity (median of no or 1 flare and no up-titration) on every 4 weeks (q4w) and every 8 weeks (q8w) regimens of CAN and safety in pts with crFMF, HIDS/MKD and TRAPS through epoch 4 (E4) of the CLUSTER study.

Methods: The study comprised 4 epochs (E1–E4). The study design for E2 and E3 have been reported previously.¹ After lead-in E1, E2, a 16-weeks (wk) randomized, double-blind, placebo (PBO)-controlled epoch, assessed the ability of CAN 150/300mg q4w to induce complete response (absence of flares). E3, a 24 wk open-label randomized withdrawal epoch, assessed whether responders to either doses in E2 could maintain clinical efficacy on PBO or a prolonged dosing interval (150/300mg q8w). Pts who did not maintain clinical response on PBO or q8w were up-titrated to 150/300mgq4w. E4, a 72-wk, open-label epoch, assessed the long-term maintenance of efficacy and safety in pts on q4w and q8w dose regimens. Safety assessments included adverse events (AEs) and serious AEs.

Results: At the end of E4 (Wk 112), the proportion of pts who maintained optimal control of disease activity following treatment with 150/300mg q4w or q8w in all 3 cohorts are shown in Figure 1. More HIDS/MKD pts required up-titration to maximum dose (300mg q4w). The majority of pts in all 3 cohorts had Physician Global Assessment <2 (no or minimal disease activity) and a median of 1 or no new flare (crFMF: 96.6%, HIDS/MKD:83.3%, TRAPS: 94.3%). In all 3 cohorts, the median SAA levels decreased rapidly from baseline and remained suppressed through E4 (crFMF: 618 to 21 mg/L, HIDS/MKD: 2061 to 16mg/L and TRAPS: 243 to 12 mg/L). The most frequent AEs in E4, were infections and infestations (crFMF, 70.0%; HIDS/MKD, 86.4%; TRAPS, 81.1%) followed by gastrointestinal disorders (crFMF, 40.0%; HIDS/MKD, 65.2%; TRAPS, 50.9%). No deaths were reported in this study. No new or unexpected safety issues were reported over 112 weeks (E1-E4) of CAN treatment.

Conclusion: CLUSTER study demonstrated that long-term treatment (up to Week 112) with canakinumab 150/300 mg, with up-titrations to q4 w was necessary maintained optimal control of disease activity in crFMF, HIDS/MKD, and TRAPS patients. Majority of patients particularly in the HIDS/MKD cohort remained on the 150/300mg q4w at the end of Epoch 4. No new or unexpected safety issues were reported over 112 weeks of CAN treatment.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Efficacy and safety of intravenous (IV) tocilizumab (TCZ) were shown in patients (pts) with systemic JIA (sJIA) in the phase 3 TENDER study.¹ This multicenter, open-label, phase 1b study investigated dosing regimens of subcutaneous (SC) TCZ in pts with sJIA relative to data from TENDER to identify the optimal SC regimen and ensure that C_{trough} from SC regimens was equivalent to or higher than that from the IV regimen.

Methods: Pharmacokinetics (PK), pharmacodynamics (PD), and safety of TCZ SC were investigated in pts aged 1-17 years with sJIA and inadequate response to glucocorticoids; efficacy was an exploratory objective. Pts could be TCZ naive or could switch from TCZ IV to TCZ SC. Interim analysis was conducted after 24 pts had received TCZ SC for 14 weeks. TCZ SC was administered for 52 weeks according to body weight (BW): <30 kg received 162 mg every 10 days (Q10D) before interim analysis or 162 mg every 2 weeks (Q2W) after interim analysis; ≥30 kg received 162 mg every week (QW).

Results: In total, 51 pts were enrolled; 25 weighed <30 kg and 26 weighed ≥30 kg. Twenty-six pts (51%) were TCZ naive and 25 (49%) switched from TCZ IV. Interim analysis revealed higher than desired exposure in the <30 kg group, so dosing frequency was reduced from Q10D to Q2W. Median and range steady state C_{min} were similar in both BW groups (Table). More than 95% (49/51) of pts treated with TCZ SC had model-computed steady state C_{min} higher than the 5th percentile achieved with TCZ IV. Median and range AUC_{2weeks} were similar in both BW groups (Table). Changes in IL-6, CRP, and ESR were similar for both BW groups. Almost all pts had ≥1 adverse event (AE; n = 50; 98.0%). Injection site reactions (ISRs) occurred in 21 pts (41.2%); most were mild, and none led to treatment interruption or withdrawal. The AE rate was 1200.3/100 pt-years (PY) (909.3/100 PY, excluding ISRs). The most common AEs were viral upper respiratory tract infection (13; 25.5%), neutropenia (13; 25.5%), and cough (12; 23.5%). Nine serious AEs occurred in 7 pts (13.7%; 19.3/100 PY); 5 were infections, all in the <30 kg group. Two deaths occurred, both in the <30 kg group. Median Juvenile Arthritis Disease Activity Score-71 improved from baseline to week 52 for TCZ-naive pts (<30 kg, -13.9; ≥30 kg, -12.4) and was maintained or improved further for pts who switched from TCZ IV (<30 kg, -0.7; ≥30 kg -0.2). At week 52, 29/43 pts (67.4%) had inactive disease (JADAS-71 <1.0).

Table

	TCZ SC		TCZ IV	
	<30 kg TCZ 162 mg Q2W n = 25	≥30 kg TCZ 162 mg QW n = 26	<30 kg TCZ 12 mg/kg Q2W n = 46	≥30 kg TCZ 8 mg/kg Q2W n = 43
Model-computed steady state PK parameters, median (range)				
$C_{min,ss}$ µg/mL	64.2 (16.6-135.9)	72.4 (19.5-157.8)	65.9 (19.0-135.5)	70.7 (5.3-126.6)
$C_{max,ss}$ µg/mL	126.6 (51.7-265.8)	89.8 (26.4-190.2)	274.4 (148.8-444.0)	253.0 (119.6-404.3)
$AUC_{2weeks,ss}$ µg/mL×day	1298 (539-2792)	1154 (334-2370)	1734 (840-2712)	1631 (526-2779)

Conclusion: A PK-based strategy was successful in bridging TCZ SC to TCZ IV in pts with sJIA. Dosing regimens of 162 mg Q2W in pts <30 kg and 162 mg QW in pts ≥30 kg provided adequate exposure to support efficacy comparable to that of TCZ IV. Except for ISRs, safety results were consistent with the known safety profile of TCZ in sJIA. *Reference:* 1. De Benedetti F et al. *N Engl J Med.* 2012;367:2385-2395. Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Treatment with canakinumab (CAN), a selective, human anti-IL-1 β monoclonal antibody, has shown sustained therapeutic effect along with corticosteroid dose reduction/discontinuation in patients with systemic juvenile idiopathic arthritis (SJIA), in a long-term extension study (NCT00891046).¹ Herein, we report the efficacy and safety results from a study evaluating 2 different CAN tapering regimens in SJIA patients who were in clinical remission (NCT02296424).

Methods: This Phase 3b/4 study had two parts. In Part I, 182 patients with inactive disease from the extension study¹ (cohort 1) and CAN-naïve patients (cohort 2) with active disease were administered subcutaneous CAN 4 mg/kg q4w. Per protocol titration off corticosteroids and/or methotrexate was attempted during Part I. Eligible patients (inactive disease for 24 consecutive weeks and being corticosteroid- and methotrexate-free for at least 4 weeks) advanced to Part II. Patients were randomized to either a 3-step CAN dose reduction regimen (2mg/kg/q4w, followed by tapering to 1 mg/kg/q4w and then discontinuation) or dose interval prolongation regimen (4mg/kg q8w, followed by tapering to 4 mg/kg/q12w and then discontinuation); patients advanced to the next tapering step if inactive disease was maintained for 24 weeks. The primary objective was to evaluate if at least 40% of patients were able to maintain inactive disease status for at least 24 consecutive weeks on either 2mg/kg q4w or 4mg/kg q8w.

Results: In Part II, a total of 75 patients were randomized to a dose reduction (n=38) or dose interval prolongation (n=37) CAN tapering regimen. The proportion of patients who maintained inactive disease for 24 consecutive weeks exceeded the predefined threshold of 40% for Step 1 of: the reduced CAN dose (71%; 2 mg/kg q4w) and prolonged dose interval (84%; 4 mg/kg q8w) treatment arms. A total of 68% (26/38) and 79% (30/37) of the dose reduction and interval prolongation arms, respectively were successful in Step 2, while only 33% (25/75) of patients successfully discontinued CAN and maintained inactive disease for 24 consecutive weeks. Adverse events (AEs) and serious AEs observed within the 2 treatment cohorts and across Parts I and II were similar without any specific pattern or relationship to patients' disease status at baseline or treatment regimen. The most frequent AEs were common infections such as nasopharyngitis, upper respiratory tract infection, and pharyngitis followed by SJIA-related events such as rash, pyrexia and arthralgia. Clinical laboratory abnormalities were consistent with expected findings in patients with active SJIA and the known safety profile of CAN.

Conclusion: SJIA patients who are able to maintain inactive disease status on CAN monotherapy can successfully taper CAN by either reducing the dose or prolonging the dosing interval. However, only a minority of patients successfully

discontinued CAN treatment for 24 weeks. The safety profile for both CAN titration regimens was similar and consistent with other CAN SJIA studies; no new signals were identified.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Biologics are a main treatment option for children and young people with juvenile idiopathic arthritis (JIA) who do not respond or are intolerant to methotrexate. Unfortunately, for some children on biologics, disease control will remain elusive and they will continue to have active disease despite usage of multiple biologics; biologic refractory disease. The aim of this analysis was to quantify biologic refractory JIA and identify clinical characteristics, measured at start of first biologic, associated with biologic refractory disease.

Methods: Patients with JIA starting a first biologic, from 1st January 2010 to 31st January 2016, in two UK cohort studies were included; the British Society for Paediatric and Adolescent Rheumatology Etanercept Cohort Study (BSPAR-ETN) and the Biologics for Children with Rheumatic Diseases (BCRD) study. Data were collected at baseline, six months, one year, then annually on patient characteristics and anti-rheumatic therapy. The total number of unique biologics a patient had received was calculated. Patients were classified as refractory on the date they commenced their third biologic. Follow-up was censored at last study follow-up, 31st January 2018, or death, whichever came first. Switching patterns for biologics were described in the biologic refractory patients. Cox-regression analysis identified baseline clinical factors associated with biologic refractory disease. Multiple imputation of missing baseline data was used.

Results: There were 620 patients starting a first biologic, the majority starting tumour necrosis factor inhibitor (TNFi; 88%); 67% female, median age 11 years, median disease duration 2 years, across all ILAR categories, with a majority of patients having either polyarticular rheumatoid factor (RF) negative (32%), or extended oligoarticular JIA (20%). Overall, 39 (6.3%) patients became biologic refractory over a median of 2.9 years of follow-up; median time to third biologic was 2.5 years. The most common treatment pathways for these patients were three TNFi (26%), or two TNFi followed by either tocilizumab (28%) rituximab (12%) or abatacept (8%). The reasons given for discontinuing first and second biologic among biologic refractory patients included: 33% repeated ineffectiveness, 3% repeated adverse events, 15% ineffectiveness followed by an adverse event, 10% an adverse event followed by ineffectiveness, whilst 28% a mixture of other reasons. In the univariable analysis, patients with worse pain at the start of their first biologic were at increased risk of biologic refractory disease.

Conclusion: In this real-world cohort of children and young people with JIA, approximately 6% had received at least three different biologic therapies, here defined as biologic refractory JIA. Higher pain scores at the start of first biologic predicted refractory disease. Further understanding of why some patients are refractory to biologic therapies is vital to enable patient specific treatment pathways, accurate prognosis discussions and cost effectiveness analysis for service provisions.

Session Title: Pediatric Rheumatology – Clinical II: Treatment Update

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Belimumab (BEL) is approved in adults with active systemic lupus erythematosus (SLE). There are no approved biologic therapies for pediatric patients with childhood-onset SLE (cSLE). This Phase 2, multicenter, randomized, double-blind trial (NCT01649765) evaluated the efficacy, safety, and pharmacokinetics (PK) of intravenous (IV) BEL vs placebo (PBO), plus standard therapy (SoC), in cSLE. <

Figure. Primary and major secondary endpoints at Week 52

*At least 50% improvement in 2 of 5 core response variables, with no more than 1 of the remaining worsening by more than 30%; †At least 30% improvement in 3 of 5 core response variables, with no more than 1 of the remaining worsening by more than 30%; *Weeks 44-52

CI, confidence interval; OR, odds ratio

Table. Change from baseline cSLE core response variables at Week 52

	Placebo (N=40)	Belimumab (N=53)
Median [range] % change ParentGA	-21.61 (-95, 800)	-53.85 (-100, 900)
n	38	47
Mean \pm SE % change PGA	-48.80 \pm 8.648	-56.53 \pm 6.089
n	40	53
Mean \pm SE % change SELENA-SLEDAI	-38.0 \pm 6.33	-43.3 \pm 6.05
n	39	53
Median [range] % change Pediatric (physical functioning)	12.5 (-53, 575)	10.3 (-100, 280)
n	40	53
Median [range] % change 24-hour proteinuria	7.092 (-91.548, 570.149)	-2.128 (-85.073, 1681.884)
n	40	53

Pediatric quality of life; PGA, physician global; SE, standard error; SELENA-SLEDAI, Safety of Estrogens in Lupus National Assessment of Disease Activity Index

Methods: Patients with cSLE aged 5–17 years were randomized to BEL 10mg/kg IV or PBO every 4 weeks, plus SoC. The primary endpoint was SLE Responder Index 4 (SRI4) at Week (Wk) 52. Major secondary endpoints were: proportion of patients achieving the Pediatric Rheumatology International Trials Organization/ACR (PRINTO/ACR) cSLE Evaluation criteria for improvement using two definitions at Wk 52; cSLE core response variables at Wk 52 (Table); and sustained SRI4 and Parent Global Assessment (ParentGA) responses (Wks 44–52). Other secondary endpoints included time to first severe flare (modified SELENA-SLEDAI Flare Index). Safety and PK were assessed. The study was not powered for statistical testing.

Results: 93 patients comprised the intent-to-treat population (BEL, 53; PBO, 40). Mean (SD) baseline SELENA-SLEDAI was 10.4 (3.63) for PBO and 10.3 (3.34) for BEL; 17 (42.5%) PBO and 22 (41.5%) BEL patients were anti-dsDNA positive and had low complement. At Wk 52 there were numerically more SRI4 and PRINTO/ACR responders in BEL vs PBO (Figure). Numerically more BEL patients had sustained SRI4 and ParentGA responses at Wks 44–52 vs PBO (Figure). Changes in cSLE core response variables are shown in the Table. Severe flares were 62% less frequent with BEL vs PBO (hazard ratio 0.38 [95% CI 0.18, 0.82]); median (IQR) time to first severe flare was 159.5 (47.5, 314.5) vs 82.0 (57.0, 228.0) days for BEL vs PBO. Overall incidence of adverse events (AEs) was similar between groups. 9/53 (17%) BEL patients experienced ≥ 1 SAE vs 14/40 (35%) PBO patients. 1/53 [1.9%] BEL patients experienced depression/suicide/self-injury vs 4/40 [10%] PBO patients. One PBO patient died of acute pancreatitis. At Wk 52 the geometric mean (95% CI) BEL trough concentration was 44.96 (27.52, 73.43) $\mu\text{g/mL}$ for patients aged 5–11 years, and 59.71 (46.41, 76.81) $\mu\text{g/mL}$ for patients aged 12–17 years.

Conclusion: The benefit/risk profile and PK of BEL IV plus SoC in cSLE are generally consistent with those in adult BEL study populations. The 10 mg/kg IV dose used in adults may be an appropriate dose in cSLE.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Tender joints may be caused by non-inflammatory pathologies but are still included in composite scores like CDAI. The present objective was to explore the impact of tender joints by use of Tender-Swollen Joint Difference(TSJD) assessing patients with predominantly tender (TSJD>0) in comparison to predominantly swollen (TSJD≤0) joints.

Methods: Rheumatoid arthritis (RA) patients assessed by US in a Nordic study of tocilizumab sc to csDMARDs non-responders (1) were included. Clinical(28 tender/swollen joint count (TJC/SJC)), patient reported outcomes, laboratory tests and US examination (36 joints and 4 tendons, scored according to the Norwegian US atlas (2)) were performed at baseline (BL), 4, 12 and 24 weeks. CDAI and EULAR/ACR Boolean remission and sum score grey scale (GS) and power Doppler(PD) were calculated, with PD sum score=0 as US remission. Associations were explored by Spearman's rank correlation and differences between TSJD>0 vs ≤0 by Mann-Whitney test.

Results: 110 patients (83% female, mean (SD) age 55.6 (12.1) years and RA duration 8.7 (9.5) years, 81% anti-CCP positive) were assessed. All variables decreased significantly ($p<0.001$) (table). Number of patients with TSJD>0 decreased during follow-up (64% to 39%). During the study, TJC had low correlation coefficients (range) with SJC (0.24-0.47), examiner's assessment (0.19-0.48) and sum score GS (0.13-0.25)/PD (0.00-0.22). There were no differences in CDAI for patients with TSJD>0 vs ≤0 at BL, but at 4,12 and 24 weeks patients with TSJD>0 had higher CDAI levels ($p\leq 0.002$), but lower GS sum scores at BL, 4 and 26 weeks($p=0.026-0.002$) and lower PD scores at BL and 24 weeks ($p\leq 0.009$). The figure illustrates mean levels of CDAI and GS levels during follow-up dependent on TSJD group. CDAI/Boolean remission in patients with TSJD>0 vs ≤0 was 0%/0% vs 45.2%/33.3% at 12 weeks and 8.1%/5.4% vs 50.8%/40.7% at 24 weeks, while PD remission at 12 and 24 weeks was found in 41.8-70.7% independent of TSJD.

Conclusion: In patients with established RA, TJC had low association with objective signs of inflammation, and patients with predominantly tender joints seldom reached composite score remission despite PD remission. These findings question the dominant role of tender joints in assessment of inflammatory activity.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Quantitative disease activity measures are required to implement a treat-to-target algorithm for the treatment of rheumatoid arthritis (RA). Available measures based on patient-derived data have the advantage of ease of use and have been shown to correlate with physician-derived data. While data support the conclusion that the concept of treat-to-target is beneficial to patient outcomes, there is a paucity of data that show that the utilization of any specific disease activity measure improves outcomes. The purpose of this study was to test the hypothesis of whether the addition of the RAPID3 (Routine Assessment Of Patient Index Data 3) patient-reported outcome (PRO) data improves outcomes in RA. Disease activity as measured by DAS28 as well as patient-centric outcomes, including patient reported well-being, patient satisfaction and medication compliance, were measured.

Methods: The intervention design was a single blind, randomized controlled trial of US Veterans with RA. The intervention was to provide PRO data to rheumatologists treating patients in an outpatient setting. PRO data were not provided to physicians for control subjects. All participating physicians attended a lecture series providing education about treat-to-target strategies in RA. Baseline inclusion criteria were patients older than 18 who have had rheumatoid arthritis according to the 1987 ACR revised criteria for RA, and had been seen at least one time previously with diagnosis of RA. Subjects had at least moderate disease activity (DAS28-CRP > 3.2). Trial duration was 12 months. The primary outcome was a change in DAS28. Secondary outcomes included patient satisfaction, percent with minimal clinically important improvement (MCII) in patient global, medication compliance, DAS28, and frequency of achievement of remission criteria (DAS28-CRP < 2.3).

Results: The study enrolled 141 subjects with PRO data provided to the treating physician for 71 subjects. Average subject age was 57, 88% were male, and average DAS28 score at entry was 4.01. The average duration of disease was 4.8 years. There were no significant differences in these measures between intervention and control subjects. Data for the primary outcome was available for 108 patients. The DAS28 score decreased to 3.63 ± 0.41 in the intervention group and 3.60 ± 0.43 in the control group. DAS28 remission criteria were met in 4 or 5.6% of intervention subjects and 6 or 8.6% of control subjects. There was a trend to improvement in the MCII for patient global scores in the intervention group.

Conclusion: In this population of US Veterans with relatively advanced RA, the provision of RAPID3 data to rheumatologists who were well-versed in the treat-to-target approach to RA did not significantly improve outcomes.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Treatment guidelines recommend using disease activity measures (DAMs) to guide RA therapy, but DAM use in real-world treatment decisions is not defined. We compared frequency of major therapeutic change (MTC) across disease activity categories for 3 DAMs (Disease Activity Score with 28 joints [DAS28], Clinical Disease Activity Index [CDAI], Routine Assessment of Patient Index Data 3 [RAPID3]); explored ability of DAMs to discriminate between patients with/without MTC; and identified DAM thresholds to optimize discriminant ability.

Methods: US Veterans enrolled in Veterans Administration RA registry (VARA) had: visit with complete set of DAMs (index date); 2 additional visits ≥ 60 days apart during 18-month pre-index period; clinical data available 18 months before through 30 days after index date were eligible. MTC was assessed 1 week before through 30 days after index, defined as: initiation of synthetic or biologic disease-modifying antirheumatic drug (sDMARD, bDMARD); DMARD dose escalation $\geq 25\%$; prednisone use (new agent or after 90-day gap); prednisone dose increased 25%; and/or corticosteroid injection in ≥ 2 joints. Sensitivity and specificity for disease category to predict MTC was calculated for each DAM. Youden's Index (sensitivity + specificity – 1) was used to determine thresholds at which providers were likely to initiate MTC. Receiver operating characteristic (ROC) curves were used to assess discrimination thresholds.

Results: For 1,776 patients (12,094 visits), 89% were male, mean RA disease duration was 13.4 years (95% confidence interval[CI]: 12.8, 13.9), and mean age of 63.4 years (95% CI 62.9, 63.9). Positive associations between disease activity level and MTC proportion were observed (Table 1). Most MTCs occurred with sDMARDs (Table 2). Empiric thresholds (highest Youden Indices)(95% CI) were DAS28: 4.02 (3.70, 4.36); CDAI: 12.9 (10.6, 15.1); RAPID3: 3.81(3.32, 4.30) (Figure).

Conclusion: Decision points for MTC per Youden Index thresholds were higher than moderate disease activity definitions, suggesting disease activity stratification is not aligned with physician practice. MTC based on DAS28 and CDAI were driven by changes in sDMARDs. Physician-driven DAMs (DAS28, CDAI) had better discriminant abilities than patient-driven RAPID3.

Table 1 Frequency of MTC Stratified by DAM Category

	Visits with MTC, n/N (%)		
	DAS28	CDAI	RAPID3
High disease activity	890/1,986 (44.8%)	1,115/2,504 (44.5%)	1,849/5,596 (33.1%)
Moderate disease activity	1,342/4,853 (27.7%)	1,094/3,998 (27.4%)	792/3,802 (20.8%)
Low disease activity	381/2,059 (18.5%)	664/4,141 (16.0%)	258/1,513 (17.1%)
Remission	464/3,196 (14.5%)	204/1,451 (14.1%)	178/1,184 (15.0%)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: We have previously reported an evaluation of 941 US Veterans in the Veterans Affairs (VA) Rheumatoid Arthritis (RA) (VARA) registry that 559 (59%) did not have a major therapeutic change (MTC) in RA therapy despite elevated DAS28>3.2. Medical chart notes found that a comprehensive provider judgment (CPJ) of acceptable/low disease activity was a leading factor in the decision to not change therapy despite elevated disease activity by DAS28. This study investigates the utility of CPJ and DAS28 to predict MTC in patients with moderate (DAS28=3.2 to 5.1) and severe (DAS28>5.1)RA and compares types of MTC to determine whether specific changes varied according to the DAS28 and/or CPJ.

Methods: US Veterans in the VARA registry with 1) moderate/severe disease activity (DAS28≥3.2) on index day 2) 18 months of VA data prior to the index date and 3) 90 day observation after index date were eligible for review. A MTC was defined as 1) re-initiation of prior DMARD and/or prednisone (Pred) after ≥90 day gap in therapy, 2) initiation of new DMARD and/or Pred, 3) escalation of current DMARDs and/or Pred and/or 4) 2 joint injections within either 7 days before to 90 days after the index date. There were 403 patients from 9 VARA registry sites meeting the above criteria randomly selected for chart review. A CPJ was made by the chart reviewer (JS) blinded to DAS28 who categorized CPJ as mild or moderate/severe on the basis of text notes by the provider using these terms or similar comments on disease state. The MTC decisions were then stratified by the corresponding CPJ and DAS28 levels to investigate their association with MTC. Specific MTC actions were classified as joint injection, gaps in therapy with re-initiation of same DMARD for Pred, or initiation new DMARD or Pred/escalation of current DMARD or Pred.

Results: The 403 patients evaluated were age 65±10 years, RA disease duration 14±11 years, 85% male, 81% seropositive for rheumatoid factor, and 64% positive for a CCP. The proportion of patients with high CPJ with MTC was 124/195 (63.5%) and similar to MTC in patients with high DAS28 46/72 (64.8%) The interaction of CPJ and DAS28 on MTC suggests CPJ may have a higher association with MTC than DAS 28 (Figure). When evaluating the specific types of MTC that occurred in the groups stratified by both CPJ and DAS28 there were no evident differences in the types of changes that were instituted (Table).

Conclusion: Less than half of patients (45.5%) studied received a MTC despite having moderate to severe RA by DAS28. High disease activity by either CPJ or DAS28 were associated with MTC. In patients with moderate DAS28, a high CPJ was associated with a greater tendency to have a MTC. The specific actions involved in the MTC did not vary significantly with CPJ or DAS28 levels. Both CPJ and the DAS28 appear to be important in the decision to make a MTC in RA patients with moderate/severe disease activity by DAS28.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The identification of risk factors associated with flares in RA is challenging because of the use of different composite disease activity scores and a lack of consistency in the definition of a flare. The Clinical Disease Activity Index (CDAI) is a composite disease activity score that incorporates both a patient and evaluator global assessment (PGA and EGA, respectively). We hypothesized that predictors of flares would vary based on the contribution of clinically important worsening of PGA or EGA to the CDAI and identified predictors of RA flare.

Methods: We utilized data from the Veterans Affairs RA (VARA) registry- a longitudinal multicenter cohort of US veterans who fulfill the 1987 American College of Rheumatology (ACR) criteria for the classification of RA. Only patients with low disease activity (LDA) defined by CDAI score (≤ 10) were included in analyses. A CDAI flare was defined as an increase in CDAI to ≥ 10 and change in CDAI of ≥ 2 . PGA and EGA LDA flares were defined as an increase to >10 and a change ≥ 10 mm in the PGA or EGA. We used multivariable logistic regression incorporating generalized estimating equations to evaluate for independent predictors of flare by the next visit. Covariates tested included age, sex, race, disease duration, smoking status, common comorbidities, sustained low activity, serostatus, current medications, recent medication changes, inflammatory markers, function status (MD-HAQ), and length of interval between visits.

Results: Data from 1,582 observations with LDA were included [mean age 63 (± 11), 90% male, 82% Caucasian, 81% rheumatoid factor (RF) positive]. Predictors of subsequent CDAI flare, EGA flare and PGA flare are outlined in Table 1. Factors associated with subsequent CDAI flare (N=437) included higher tender joint count, swollen joint, and MD-HAQ score. CDAI flare was less likely among those with sustained CDAI LDA at the prior visit. EGA flare (N=505) was associated with the presence of RF, black ethnicity, elevated CRP, and greater TJC. EGA flare was less likely among patients using methotrexate, a sustained LDA by CDAI and higher patient global score. The strongest predictors of PGA flare (N=542) were a greater MD-HAQ score, black ethnicity, and RF positivity.

Conclusion: Sustained LDA is a strongly associated with a reduced risk of subsequent CDAI flare and EGA flare but not PGA flare. Predictors of increase in both PGA and EGA included black ethnicity and RF positivity. However, while the TJC and CRP predicted EGA flare, the MD-HAQ was the strongest predictor of PGA flare. Understanding the factors that influence evaluator and patient perception of disease flare is important, as this may have implications for treatment decisions.

Table 1: Factors associated with subsequent CDAI, EGA or PGA flare from low disease activity.*p<0.05, **p<0.01, ***p<0.001, ns – non-significant

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The incidence of fibromyalgia is highest in the first 12 months after RA diagnosis, ¹indicating that this period may represent a critical window during which acute inflammatory pain transitions to chronic non-inflammatory pain. With this study we aimed to describe the evolution of pain characteristics during the first 12 months after RA diagnosis and to identify predictors of remaining pain and widespread pain distribution (“fibromyalgic RA”) at 12 months.

Methods: Data were obtained from early RA patients in the Canadian Early Arthritis Cohort (CATCH), a prospective inception cohort. The primary outcomes were: 1) remaining pain above the Patient Acceptable Symptom State (PASS), defined as a score >4 on a pain intensity numerical rating scale (NRS, range 0-10), and 2) widespread pain distribution (or “fibromyalgic RA”), defined by tender joint count (TJC28) – swollen joint count (SJC28) ≥ 7.^{2,3} Descriptive statistics were

used to summarize distributions of remaining pain and widespread pain over 12 months. Univariate and multivariable logistic regression models were used to identify predictors of remaining pain and widespread pain distribution at 12 months.

Results: 1,270 patients were included, with mean (SD) age of 53.9 (14.5), symptom duration of 5.8 (3.0) months and baseline DAS28 of 5.0 (1.4). The percentage of patients with remaining pain decreased from 64% at baseline to 24% at 12 months, and the percentage of patients with a wide spread pain distribution decreased from 9% to 5%. The strongest predictors of 12-month remaining pain were sleep problems (highest quartile OR 2.2, 95% CI 1.2-3.9), pain intensity > 4/10 (OR 2.1, 95% CI 1.3-3.4), and higher HAQ-Disability Index (DI) score (OR 1.5, 95% CI 1.1-2.0). The strongest predictors of 12-month adjusted pain distribution were higher HAQ-DI score (OR 1.8, 95% CI 1.1-3.1) and higher number of comorbidities (OR 1.2, 95% CI 1.0-1.5). Baseline non-MTX, conventional synthetic DMARD (csDMARD) was associated with lower likelihood of widespread pain (OR 0.5, 95% CI 0.3-0.8).

Conclusion: Despite improvements in pain during the first year after RA diagnosis, 24% continued to report remaining pain above the PASS, and 5% reported widespread pain at 12 months. Baseline measures of sleep, pain intensity and disability were the strongest predictors of 12-month remaining pain. Disability and comorbidities were the strongest predictors of widespread pain distribution. Inflammatory markers were not associated with 12-month remaining pain or pain distribution.

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Intention-to-treat (ITT) principle is recommended to analyze randomized controlled trials (RCTs). It entails analyzing all subjects per the assigned group at randomization to avoid treatment effect estimation bias. Missing outcome data in RCTs can compromise results¹ and its wrong handling may cause bias. Single imputation methods e.g.

“last observation carried forward (LOCF)” have unrealistic assumptions and discount the uncertainty of imputation². Sensitivity analyses are recommended to assess robustness of such assumptions². We studied RCTs of rheumatoid arthritis (RA) for ITT use, missing outcome data handling, and sensitivity analysis usage. Trends between 2006 and 2016 were analyzed.

Methods: MEDLINE and Cochrane Central Register of Controlled Trials database were searched to identify parallel-design, non-phase-1, English language, original RA RCTs of drug therapy with clinical primary outcome(s) published in 2006 and 2016. The study RCTs were assessed by two reviewers. ITT analysis was defined when all randomized subjects were included in the final analysis for the primary outcome(s). A modified ITT (mITT) allowed exclusion of one or more of the following: those found non-eligible after randomization, those who never received study intervention, and those without baseline or any post-baseline assessment³. All other exclusions were classified as inadequate.

Results: 80 RCTs, 36 from 2006 and 44 from 2016, were eligible (Table 1). 48/69 (69.5%) RCTs had > 10% and 17/69 (24.6) had >20% missing data. RCTs doing ITT or mITT analyses enrolled more subjects ($p < .001$) but had similar completion rates ($p = .734$). Missing data of >10% was more in comparator arm vs. experimental intervention arm [16 (25.4%) vs. 3 (4.8%)]. RCTs performing ITT analyzed 100% subjects. Median (IQR) % analyzed for mITT RCTs was 98.8 (97.5-99.5) and inadequate analysis RCTs was 88.6 (81.7-92.1). LOCF was the most used imputation method. Utilization of ITT or mITT analysis from 2006 to 2016 was similar [23/34 (67.6%) vs 25/42 (59.5%), $p = .465$]. Only 42.9% and 57.1% RCTs reporting ITT analysis actually performed one in 2006 and 2016 respectively. Sensitivity analysis use between 2006 and 2016 was similarly low [6/36 (16.7%) vs 9/44 (20.5%), $p = .666$]. Only one 2006 RCT used the preferred imputation methods. Missing mechanisms and comparison of completers and dropouts were given by one RCT each.

Baseline observation carried forward, N (%)	4 (5.0)	2 (5.6)	2 (4.5)	
Performed sensitivity analysis	(n = 80)	(n = 36)	(n = 44)	.666
N (%)	15 (18.8)	6 (16.7)	9 (20.5)	

* N = 73, 4 RCTs excluded as safety was primary outcome and 3 as strategy trials with no a priori declared experimental intervention; **N = 76, 4 RCTs excluded as safety was primary outcome; ***One RCT had no missing data. **Conclusion**

Missing data is common and most RCTs have >10 % missing data. While most patients are in the final analysis, many RCTs apply ITT principle incorrectly, utilize inappropriate single imputation methods and do not specify missing data handling methods. Sensitivity analyses and mechanism of missingness reporting is very low. No significant changes were seen from 2006 to 2016.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Among patients with rheumatoid arthritis (RA) who have an inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), the addition of a biologic DMARD (bDMARD), is recommended. If treatment with a first bDMARD fails, patients may move to subsequent bDMARD lines of therapy (LOT), either cycling to a bDMARD with the same mode of action (MOA) or switching to a targeted therapy (bDMARD or janus kinase inhibitor) with a different MOA. The objective of this study was to evaluate LOT among RA patients receiving bDMARDs in the US.

Methods: Data were taken from the MarketScan Commercial claims database between Jan 01, 2011 and Sep 30, 2015. Patients were included if they had: ≥ 1 inpatient or ≥ 2 outpatient claims at least 30 days apart for RA; ≥ 1 bDMARD (tumor necrosis factor inhibitor [TNFi] or non-TNFi [date of first bDMARD initiation was the index date]); and 12 months continuous medical and prescription insurance coverage prior to the index date. The bDMARD at the index date was defined as LOT1 and could be used as either monotherapy or in combination with a csDMARD. Patients were considered to have a new LOT (e.g. LOT2, LOT3) when a prescription or administration for a different RA therapy was filled, or the patient resumed the same therapy after a gap of >90 days. Counts and percentages were reported for categorical variables. Means (SD) were reported for continuous variables. Kaplan-Meier (KM) analysis was used to analyze time to discontinuation of each LOT.

Results: 17,525 RA patients were included in the analysis: mean (SD) age 50.9 (9.6) years; 79.0% women; mean (SD) number of LOT 1.8 (1.1); and median follow-up 27 months. The most commonly used medications for LOT1 were etanercept (36.6%) and adalimumab (31.4%). Across all LOT and individual medications, the mean proportion of days covered in the 12 months post-index was 0.63. Approximately half of patients (54.5%) had 1 LOT; 25.8% had 2 LOT; 11.7% had 3 LOT; 8% had ≥ 4 LOT. In patients who started with a TNFi on the index date, 20.6% had ≥ 3 LOT, and in patients who had a non-TNFi on the index date, 15.2% had ≥ 3 LOT. Among patients who had a non-TNFi on the index date, 75.6% and 75.6% of patients who moved to LOT 2 and 3, respectively, had subsequent non-TNFi's. Among patients who had a TNFi on the index date, 76.0% and 51.5% of patients who moved to LOT2 and 3, respectively, had subsequent TNFi's. Overall, the use of concomitant methotrexate was greater (47.8%) in LOT1 than in LOT2 (38.4%) or LOT3 (35.4%). KM estimates showed that patients spent the longest time on LOT1 (mean: 726.9 days), followed by LOT2 and LOT3 (mean: 567.6 days and 487.2 days, respectively).

Conclusion: In this study, the longest duration of treatment occurred for LOT1, and shortened with each subsequent LOT. These results suggest frequent cycling occurs within the non-TNFi and TNFi categories. Future research is needed to understand the duration of LOT by non-TNFi and TNFi agents and the impact on patient outcomes.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Rheumatoid arthritis (RA) patients who fail to respond to methotrexate (MTX) can be subjected to an addition of biologic disease-modifying antirheumatic drug(bDMARD). Currently there are 4 modes of action of bDMARDs: inhibitors of tumor-necrosis-factor alpha (TNFi), of interleukin-6 (anti-IL-6), lymphocyte co-stimulation (anti-CTLA4) and B-cell directed therapy (anti-CD20). All bDMARDs show similar response rates at 6 months treatment, while differences in response between patients may relate to variable level of immunomodulation by each drug.

The a pathogenic and highly prevalent Torque Teno Virus (TTV) is a potential novel candidate for functional monitoring of immune response. TTV in peripheral blood has been shown to mirror the immunocompetence of its host in patients with HIV, malignancies and solid organ transplantation.

Here we explore levels of TTV replication in patients receiving bDMARDs, and their association with clinical response to therapy.

Methods: The BIOBIO Study is a multicenter randomized open-label trial, including RA patients with insufficient response to MTX. Patients were randomized to either TNFi (infliximab, INF); anti-IL-6 (tocilizumab, TCZ); CTLA4-Ig (abatacept, ABA) or anti-CD20 (rituximab, RTX) in addition to MTX. Serum samples were collected at baseline and 3 months. RT-PCR was used to quantify TTV within these serum samples.

Figure: A: Boxplots of TTV levels at 3 months, shown separately for SDAIS responders and non-responders. B: Rates of SDAI response at 6 months separately shown by tertiles of TTV at 3 months (JTV: lowest TTV tertile; MTTV: middle TTV tertile; HTTV: highest TTV tertile)

Results: TTV was measured in 95 RA patients randomized to INF (n=23), TCZ (n=22), ABA (n=27) or RTX (n=23); 77% were female, 72% were ACPA and 51% RF positive and 2/3 showed high disease activity. Median TTV at baseline was 4.3×10^4 c/ml (IQR: 7.4×10^3 , 1.3×10^5) with no difference between the 4 treatment groups. After 3 months of treatment patients showed increase in TTV levels compared to baseline (INF: p=0.018; ABA: p=0.071; RTX: p≤0.001). There was no change in TTV for TCZ, and therefore omitted from further analyses on the association between TTV and treatment response.

TTV at 3 months after treatment was higher in patients achieving a SDAI85 response at month 6 (p=0.007; Figure 1A). Receiver operating characteristics outlined an area under the curve of 0.756 for prediction of SDAI85 at month 6 after treatment by TTV at month 3 (p≤0.001). A TTV level of 5.6×10^5 c/ml at month 3 shows a 67% specificity, 81% sensitivity, relating to a +likelihood ratio of 2.6 (95% CI: 1.6-4.1) for SDAI85 prediction at month 6. Patients in the top tertiles of month 3 TTV had greater changes in SDAI (p=0.043), CDAI (p=0.022) and DAS28 (p=0.022) and higher SDAI85 response rates at month 6 (OR=5.85, CI: 1.4-24.5; p=0.016; Figure 1B). No patient below a TTV value of 2.7×10^4 c/ml showed SDAI85 treatment response.

Conclusion: Our data suggest that TTV level in the peripheral blood corresponds to and predicts clinical response to bDMARDs for RA, except for TCZ. Future prospective trials have to clarify the potential of TTV tailored bDMARD dosing.

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: RA patients who are intolerant or have an inadequate response to conventional synthetic DMARDs (csDMARDs) can be treated with a biologic DMARD (bDMARD). Tumor necrosis factor inhibitors (TNFi) are often used first-line but non-TNFi bDMARDs are also used. Data comparing the effectiveness of TNFi and non-TNFi following csDMARDs are limited; we therefore sought to compare the real-world effectiveness of TNFi and non-TNFi agents in bDMARD-naïve patients.

Methods: Demographic, clinical, disease characteristic, and patient-reported outcomes (PROs) were collected for patients enrolled in a large US registry (Corrona) from Jan 1, 2001 to Jan 20, 2018 with diagnosis of RA, ≥18 years at diagnosis, initiating (mono- or combination therapy) with a TNFi or non-TNFi bDMARD, and with follow-up 6–15 months after initiation. Non-TNFi and TNFi patients were propensity score matched (PSM) on a 1:4 basis by age, RA duration, cardiovascular and hypertension history, prior cancer, private insurance, Medicare, marital status, smoking status, work status, ACR functional class, and concomitant csDMARDs; variables with >10% missing data were omitted. The PSM used no replacement matching. Baseline characteristics after PSM were compared using two-sample *t*-tests (continuous) and Chi-squared tests (categorical). Outcomes were assessed after 12 months of therapy; for patients switching therapy last-visit outcomes were carried forward. Random effect linear (continuous) and random effect logistic (binary) regression were used to compare outcomes at 12 months between matched populations further adjusted by baseline value, concomitant csDMARD, and prednisone use. A number of outcome covariates were assessed as potential effect modifiers using interaction terms in multivariable mixed models.

Results: Of the bDMARD-naïve patients, 4186 initiated a TNFi and 630 a non-TNFi. After PSM, 2372 TNFi and 593 non-TNFi patients were included. Respectively, mean (SD) age was 61.0 (12.9) vs 62.3 (12.8) years (*P* = 0.03); 76.8% vs 79.8% female (*P* = 0.12); mean (SD) duration of RA 8.2 (9.3) vs 8.7 (9.5) years (*P* = 0.24); RF positive 70.2% vs 70.4% (*P* = 0.95);

Table 1. Comparison of efficacy and PRO outcomes at 12 months follow-up in the PSM TNFi and non-TNFi initiators

	TNFi patients (n = 2372)	Non-TNFi patients (n = 593)	Comparison (TNFi vs non-TNFi) ²	P-value

Smolen³ and Daniel Aletaha⁴, ¹Department of Internal Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria, ²Department for Emergency Medicine, Medical University of Vienna, Vienna, Austria, ³Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria, ⁴Medical University of Vienna, Vienna, Austria

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Phase 3 (P3) clinical trials are the mainstay of drug development in all areas of medicine, including rheumatology, allowing to determine safety and efficacy of new drugs on their way to approval. Historically, efficacy results of P3 trials have often been disappointing with respect to the expectations set by phase 2 (P2) trials. It is unclear whether these observations are reflection of a true bias or merely a play of chance. We therefore systematically compared efficacy of P2 versus P3 trials in RA.

Methods: We performed a systematic review of all disease modifying anti-rheumatic drugs (DMARDs) tested in P2 trials in rheumatoid arthritis (RA) over the last 20 years for which also P3 trials exist. We searched Medline, EMBASE, and the Cochrane Library to identify all randomized controlled double-blind trials investigating biological (b) and targeted synthetic DMARDs in RA. The criteria for inclusion in the analyses were defined as follows: (i) treatment arms in P2 and P3 used the same treatment regimen; (ii) the same RA population was studied (DMARD naïve; conventional DMARD insufficient responders (IR); bDMARD IR). The treatment regimen was regarded the same when a DMARD was used at the same dose, interval and route in P2 and P3. Multilevel mixed model logistic regression was used to determine a summary estimate for comparison of P2 versus P3 results on the outcomes of American College of Rheumatology (ACR) 20, ACR50, and ACR70 responses (in separate models). Results are expressed as Odds Ratio (OR) and 95% confidence intervals (95% CI).

Results: In total 1290 abstracts were screened of which 133 were regarded as potentially relevant, with 34 trials (16 agents, 25 regimens, 8855 patients) finally included in the analysis. Summary estimates revealed that outcomes of P2 trials were systematically over estimating the subsequent P3 results for ACR20 (OR: 1.45; 95% CI: 1.12-1.88; p=0.010), ACR50 (OR: 1.45; 95% CI: 1.09-1.93; p=0.017) and ACR70 (OR: 1.51; 95% CI: 1.02-2.25; p=0.043). Figure 1 shows ORs (95% CI) for ACR70 responses, which represent the most relevant clinical outcome in RA.

Conclusion: Our results reveal that Phase 2 clinical trials over estimate the treatment effects when compared with subsequent Phase 3 trials in RA. The identification of this systematic bias towards overestimation of efficacy by Phase 2

studies has implications for considerations of clinical investigators, sponsors, and regulatory agencies during the development and licencing process of new compounds, as well as potential ethical implications. Investigation of determinants of Phase 2 overestimation is currently ongoing.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: TNF- α inhibitors are among the most widely used biological-DMARDs in rheumatoid arthritis (RA). Means to predict response would allow for a more effective, targeted approach to therapy. Th17-related cytokines synergise with TNF- α to intensify joint inflammation. Evidence suggests poor response to TNF- α inhibitors reflects a TNF- α -independent, Th17-driven process. Our aim was to assess plasma concentrations of a panel of Th17-related cytokines to identify predictors of response to TNF- α inhibitors.

Methods: Ninety-three patients with RA as defined by ACR criteria were seen prior to and 4-6 months after commencing etanercept or adalimumab. Plasma concentrations of Th17-related cytokines (IL-1 β , IL-4, IL-6, IL-10, IL-17A, IL-17F, IL-21, IL-22, IL-23, IL-25, IL-31, IL-33, sCD40L, IFN- γ , TNF- α) were measured at baseline. DAS28-CRP with 4 variables (DAS28) was calculated and EULAR cut-off for low disease activity was used to group patients into poor (DAS28 >3.2) and good (DAS28 \leq 3.2) responders at follow up. IL17-IL23-pathway cytokines (IL-17A, IL-17F, IL-22, IL-23, IL-1b and IFN- γ) were grouped to form a pro-inflammatory cumulative score (presence of 0 to 6 cytokines), while anti-inflammatory cytokines, IL-4, IL-10 and IL-25, were grouped to form an anti-inflammatory cumulative score (presence of 0 to 3 cytokines). Multivariate logistic regression was used to identify predictors of response, and odds ratios (OR) and 95% confidence intervals (CI) were calculated.

Results: Patients with IL-23 present at baseline were more likely to be poor-responders [14/20 (70%) of IL-23⁺ patients versus 31/73 (42.5%) of IL-23⁻ patients; p<0.05]. Multivariate analysis suggests that presence of IL-23 predicts poor response following treatment with anti-TNF- α [OR (95% CI) for 6.55 (1.82-23.63), p<0.01], while presence of IL-25 predicts good response [OR (95% CI) = 4.50 (1.53-13.19), p<0.01]. These associations were independent of baseline DAS28. The remaining individual cytokines tested were not associated with response to anti-TNF- α therapy. Pro-inflammatory and anti-inflammatory cumulative scores were not associated with response to anti-TNF- α therapy in univariate analysis. However the anti-inflammatory score was associated with reduced risk of poor response in a multivariate model, including baseline DAS28 and the pro-inflammatory score [OR (95% CI) = 0.54 (0.30-0.97), p<0.05], suggesting the association was dependent on confounding effects of these variables.

Conclusion: IL-23, which promotes pathogenic activity of Th17 cells, may be a useful predictor of poor outcome following anti-TNF- α therapy. IL-25 which downregulates pathogenic activity of Th17 cells may be useful alongside IL-23 to predict a favourable outcome. A cytokine expression profile including IL-25 and additional anti-inflammatory cytokines, IL-4 and IL-10, may indicate increased likelihood of response.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Thymic stromal lymphopoietin (TSLP) has been demonstrated to be involved in B-cell lymphoproliferation and lymphoma mainly by tissue studies on salivary glands (SG) biopsies of patients with primary Sjögren's syndrome (pSS) (1). The aim of this work is to study serum TSLP as a possible novel biomarker in pSS.

Methods: Ninety-one antiSSA-positive pSS patients (females n=86, 94.5%; mean age 57.2 years, range 25-80), fulfilling the 2016 ACR-EULAR classification criteria, were studied by ELISA for the expression of serum TSLP, in comparison with 80 matched healthy blood donors (HBDs) and with 21 patients with non-autoimmune sicca syndrome (nSS). pSS patients were then stratified according to the degree of lympho proliferation (2) in available SG biopsies as follows: fully benign (fbSS), myoepithelial sialadenitis (MESA) and B-cell MALT lymphoma (NHL), and the difference in serum TSLP levels was evaluated between these three subgroups.

In addition, prospective serum samples, collected at the time of MESA diagnosis and also later at the time of NHL development, were studied in 3 pSS cases.

All the pSS patients were naïve to immunosuppressants, biotechnological drugs, chemotherapies and were not receiving steroids at the time of sample collection.

The most relevant clinical features of pSS linked to lymphoproliferation (i.e. persistent parotid swelling and mixed cryoglobulinemia), the presence of ectopic germinal centres (GCs) in SG, and the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) were also collected.

Results: Serum TSLP resulted significantly increased in pSS (mean 47.19 pg/mL, range 0-324.89) compared to nSS (mean 2.74 pg/mL, range 0-15.9) ($p<0.0001$) and to HBDs controls (mean 0.59 pg/mL, range 0-11.09: very low detectable levels only in 4/80) ($p<0.0001$). The significance was the same ($p<0.0001$) also after excluding NHL pSS patients.

Serum TSLP showed a progressive, significant increase from fbSS (n=65; mean 26.54 pg/mL; range 0-75.11) to MESA (n=14; mean 69.72 pg/mL; range 20.62-140.8) (MESA vs fbSS $p<0.0001$) and finally to NHL (n=12; mean 151.96 pg/mL; range 58.16-324.89) (NHL vs fbSS $p<0.0001$; NHL vs MESA $p=0.009$).

In prospective sera, TSLP levels increased in all the 3 pSS patients from MESA to NHL, from 3.76 times to 70.46 times (mean of serum TSLP increase: 30 times).

Benign pSS patients with persistent parotid swelling, mixed cryoglobulinemia and with GCs in SG biopsy showed significantly ($p<0.05$) higher TSLP serum levels compared to pSS patients without these features.

A significant correlation between higher TSLP serum levels and increasing ESSDAI was finally found ($R^2=0.51$; $p<0.0001$).

Conclusion: Serum TSLP could represent a novel biomarker of pSS-related lymphoproliferation. The validation of present results is currently ongoing in independent pSS cohorts belonging to the EU Project Harmonic SS consortium (3).

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: To evaluate the influence of the main immunological markers on the disease phenotype at diagnosis in a large international cohort of patients with primary Sjögren's syndrome (SjS).

Methods: The Big Data Sjögren Project Consortium is an international, multicentre registry created in 2014. As a first step, baseline clinical information from leading centres on clinical research in SjS of the 5 continents was collected. The centres shared a harmonized data architecture and conducted cooperative online efforts in order to refine collected data under the coordination of a big data statistical team. Inclusion criteria were the fulfilment of the 2002 classification criteria. Immunological tests were carried out using standard commercial assays.

Results: By January 2018, the participant centres had included 10,500 valid patients from 23 countries. The cohort included 9,806 (93%) women and 694 (7%) men, with a mean age at diagnosis of primary SjS of 53 years, mainly White (78%) and included from European countries (71%). The frequency of positive immunological markers at diagnosis was 79.3% for ANA, 73.2% for anti-Ro, 48.6% for RF, 45.1% for anti-La, 13.4% for low C3 levels, 14.5% for low C4 levels and 7.3% for cryoglobulins. Positive autoantibodies (ANA, Ro, La) correlated with a positive result in salivary gland biopsy, while hypocomplementemia and especially cryoglobulinaemia correlated with systemic activity (mean ESSDAI score of 17.7 for cryoglobulins, 11.3 for low C3 and 9.2 for low C4, in comparison with 3.8 for negative markers). The immunological markers with a great number of statistically-significant associations ($p < 0.001$) in the organ-by-organ ESSDAI evaluation were cryoglobulins (9 domains), low C3 (8 domains), anti-La (7 domains) and low C4 (6 domains).

Conclusion: we confirm the strong influence of immunological markers on the phenotype of primary SjS at diagnosis in the largest multi-ethnic international cohort ever analysed, with a greater influence for cryoglobulinaemic-related markers in comparison with Ro/La autoantibodies and ANA. Immunological patterns play a central role in the phenotypic expression of the disease already at the time of diagnosis, and may guide physicians to design a specific personalized management during the follow-up of patients with primary SjS.

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Classical connective tissue diseases, such as SLE and RA have well documented progression of disease and damage accrual. However, the natural history of Sjögren's syndrome (SS) has been less well documented, particularly in research settings where comprehensive multidisciplinary assessments can be performed at more than one time point. The objective of the present study was to re-evaluate past participants in the OMRF Sjögren's research clinic (SRC) with the same protocol that was used for their initial research classification with the goal of documenting changes in their disease.

Methods: Questionnaires assessing health changes and willingness to be re-evaluated were mailed to 800 SRC participants. Twenty respondents (17 SS and 3 incomplete SS [iSS] both by AECG and ACR-EULAR criteria) participated in this pilot study in which all procedures performed in their initial evaluation were repeated.

Results: 356 (45%) questionnaires were answered (161 SS and 195 iSS). Subjectively, respondents reported equal or better status of ocular and oral symptoms but significantly worse fatigue and arthralgias ($p < 0.001$) with no differences between SS and iSS. The 20 re-evaluated patients returned after an average of 5.4 years (range 2-9). Thirteen (65%) retained the initial disease classification, but 6 subjects (30%) went from SS to iSS and 1 (5.0%) from iSS to SS. It is noteworthy that this subject only met SS criteria by AECG and not by ACR-EULAR because his serology was anti-La (+) only with negative biopsy. Furthermore, only 2 subjects had a net increase in the number of criteria, while 18 had the same number ($n=8$) or fewer ($n=10$). There were no consistent patterns of change in the objective measures of lacrimal and salivary gland function: 5 subjects became Schirmer's (+) and 1 reversed to (-); the opposite was the case for the ocular staining, with 5 becoming (-) and 1 becoming (+). The only unchanged results in all the recalls were the anti-Ro/anti-La status. The most intriguing results were the changes in the minor salivary gland biopsy; 4 (20%) subjects went from positive to negative biopsy resulting in a change in classification from SS to iSS in 3 cases. Moreover, the focus score was lower in the second biopsy of 10 (50%) cases, 4 (20%) had a higher score and the remaining 6 (30%) were unchanged. The morphology of the salivary gland tissue of these reversed cases showed extensive fibrosis, fatty infiltration and atrophy of the gland, precluding the lymphocytic infiltrates from meeting the definition of being surrounded by normal tissue. Further supporting the notion of worsening gland architecture, final focus score trended to inversely correlate with WUSF ($r = -0.4$; $p = 0.089$). Complement levels and hypergammaglobulinemia did not predict stability or worsening of SS.

Conclusion: Re-evaluated patients showed little disease progression but steady presence of autoantibodies. Detrimental changes in salivary gland morphology were observed in later biopsies, even when classified as "negative" using current criteria. These results suggest that significant tissue destruction in long standing disease may lead to false negative biopsy results in spite of progressive glandular dysfunction.

Abstract Number: 2883

Testing for Anti-Microbial Antibodies with Cross-Reactivity to Human Tissue in Autoimmune Diseases

Peilin Zhang, Lawrence Minardi, J. Todd Kuenstner and Stephen Zekan, PZM Diagnostics, LLC, Charleston, WV

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

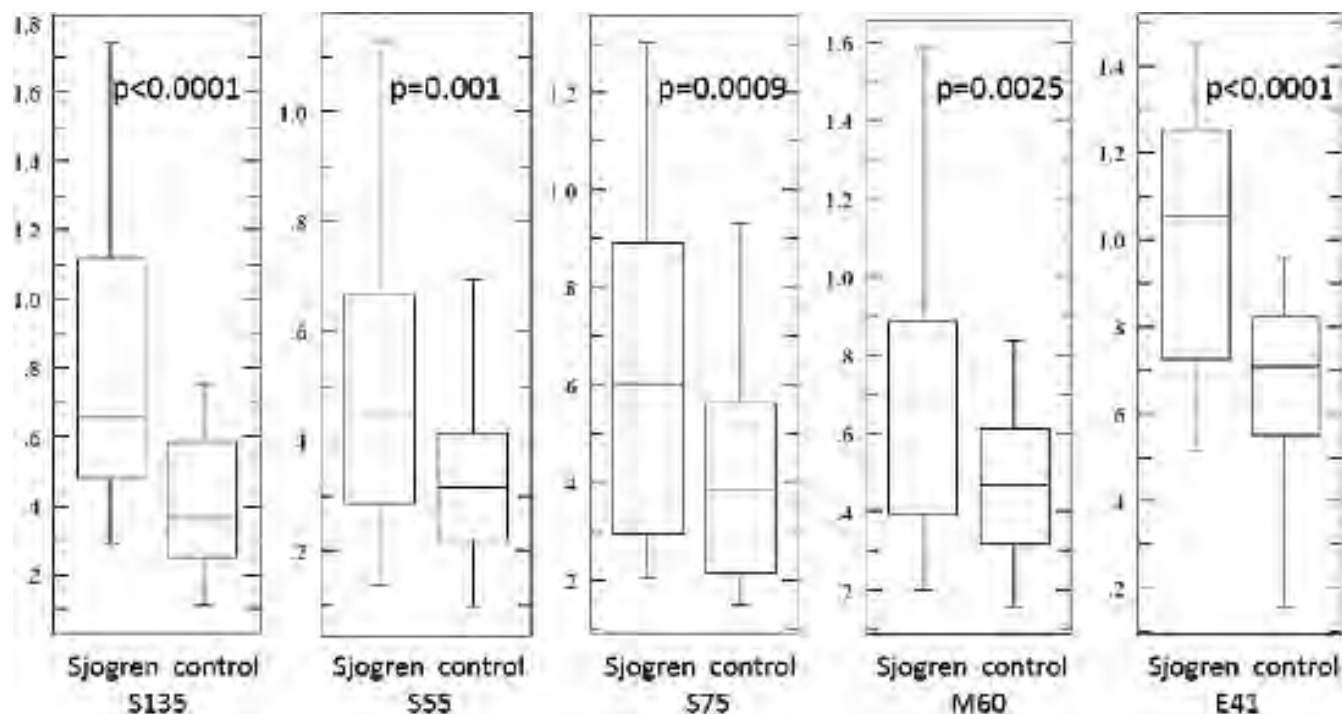

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Autoantibodies are defining features of autoimmune diseases. How and why the autoantibodies are produced and how these autoantibodies relate to pathogenesis is poorly understood. Current study is to examine the role of anti-microbial antibodies in patients with Sjögren's syndrome and Crohn's disease.

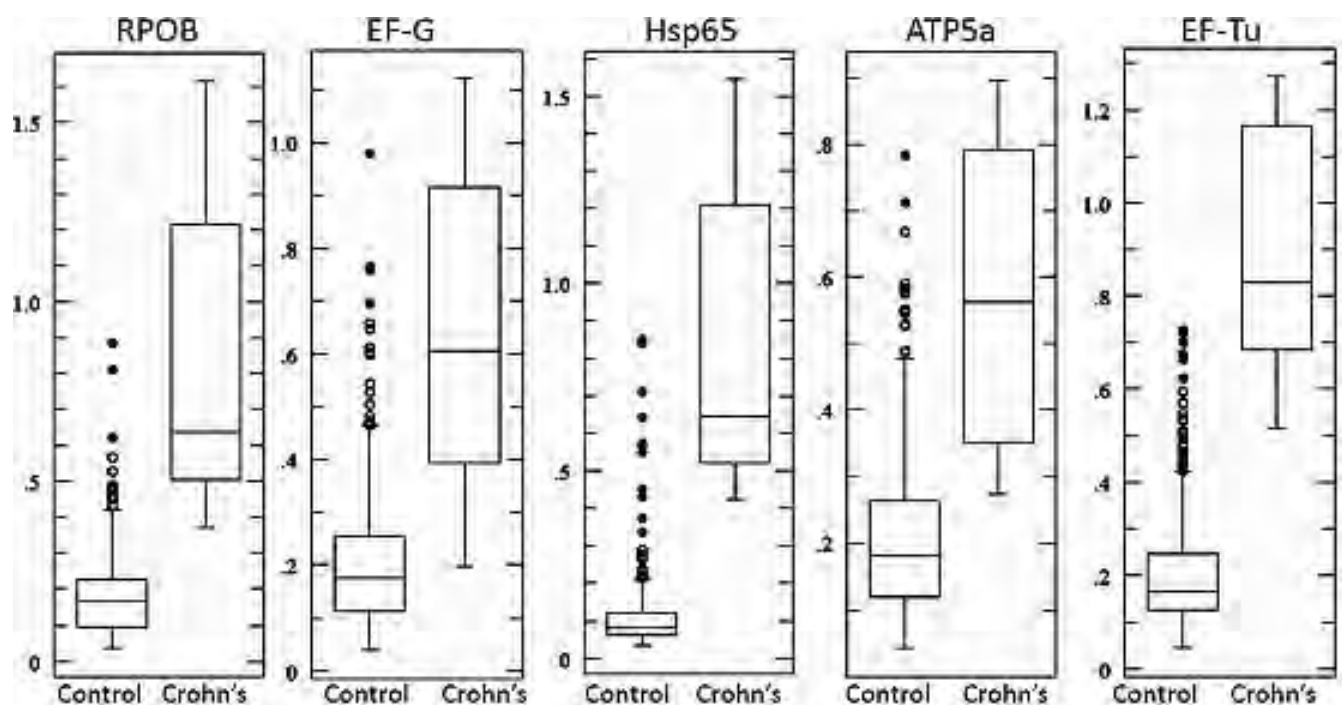

Methods: We have discovered a panel of serology biomarkers against microbial antigens through Western blot analysis, mass spectrometry, immunohistochemistry and ELISA assays.

Results: We have discovered a novel panel of anti-microbial antibodies from the blood of patients with Sjögren's syndrome and Crohn's disease, and these antimicrobial antibodies are significantly elevated in the patients in comparison to the

healthy controls. The anti-microbial antibodies are directed to RPOB (S135) from *S. aureus*, EF-G (S75) from *S. aureus/pseudintermedius*, Hsp65 (M60) from *Mycobacterium*, ATP5a (S55) from *S. aureus* and EF-Tu (E41) from *E. coli*. These bacteria are commensal commonly present on the surface of human body, in the gut, and environment. Specific monoclonal and polyclonal antibodies against these microbial proteins can cross-react to the normal human tissues by immunohistochemistry. We have tested 23 patients with Sjogren's and 45 patients with Crohn's disease for the blood levels

Patients N=23, All negative 4, one or more positive 19, positive predictive value 83%
Control N=31, All positive 0, one or more positive 6, negative predictive value 81%

Normal blood donor samples (n=288)
Crohn's (n=45) $p < 0.0001$ (t-test)

of these anti-microbial antibodies below in comparison to 288 normal controls. We also found these anti-microbial antibodies are elevated in patients with systemic lupus erythematosus, multiple sclerosis, rheumatoid arthritis and Lyme disease.

Conclusion: The defining features of autoantibodies in autoimmune diseases may in fact be anti-microbial antibodies with cross-reactivity to human tissues. The presence of anti-microbial antibodies with cross-reactivity to human tissue may provide a basis of pathogenesis in autoimmune disease through molecular mimicry and offer new direction of research in disease mechanisms and therapeutics for a spectrum of autoimmune diseases.

Correlation between Salivary Gland Ultrasonography, Minor Salivary Gland Histopathology and Sialometry: Towards a Composite Assessment of Salivary Gland Involvement in Primary Sjögren's Syndrome

Chiara Baldini¹, Nicoletta Luciano¹, Francesco Ferro¹, Antonella Cecchetti², Valentina Donati³, Marta Mosca¹ and Stefano Bombardieri¹, ¹Rheumatology Unit, University of Pisa, Pisa, Italy, ²IFC, CNR, Pisa, Italy, ³Pathology Unit, University of Pisa, Pisa, Italy

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease that specifically involves salivary glands. Several complementary tools including salivary gland ultrasonography (SGUS), histology and saliva collection have been proposed to estimate glandular inflammation and dysfunction. Few studies have explored the association between SGUS, salivary gland histology and saliva production. Moreover, it has to be elucidated whether an integrated composite evaluation of salivary gland involvement, based on the combination of these different tools, may improve patients' stratification and management. Aims of this study were: 1) to analyze the correlation between SGUS, saliva production and gland histology, and 2) to assess the prevalence of different subsets of glandular involvement in pSS defined on the basis of the combination of SGUS, histology and sialometry.

Methods: Newly diagnosed pSS patients were consecutively enrolled. Subjects underwent a complete rheumatologic evaluation, SGUS, minor salivary gland biopsy and sialometry (USFR). SGUS was performed by the same operator who graded the echostructure of each gland on a 5-point scale (0–4), defining as pathological a SGUS score ≥ 2 . Histology evaluation included the assessment of the focus score (FS) and the reporting of the number of germinal centre (GC)-like structures.

Results: We included 90 newly diagnosed pSS patients. Out of them: 51 presented abnormal findings at SGUS and 39 had a normal SGUS. SGUS score correlated better with FS ($r=0.642$, $p=0.001$) and GCs ($r=0.492$, $p=0.001$) than with USFR ($r=-0.361$, $p=0.003$). When SGUS findings were combined with histology and USFR we distinguished four major patterns of salivary involvement. The most common subset was represented by patients (26/90 (29%)) with abnormal SGUS, preserved USFR and a high FS. In addition, 21/90 (23%) pSS patients presented abnormal SGUS findings, reduced USFR and a high FS; 17/90 (19%) patients had normal SGUS, preserved USFR and a low FS, and 17/90 (19%) had normal SGUS, preserved USFR and a high FS. Nine patients presented characteristics intermediate between the mentioned subsets. Patients included in the first two groups presented a higher frequency of anti-Ro/SSA, Rheumatoid factor, hypergammaglobulinemia and salivary gland swelling. Patients with lower USFR presented a reduced size in their submandibular glands at SGUS examination.

Conclusion: This study suggest that an integrated evaluation of salivary gland involvement may allow to better define the relationship between tissue inflammation/damage and functional dysfunction. This composite approach may be useful in pSS phenotyping as a prerequisite towards personalized interventions.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by immune cell infiltration in the salivary glands resulting in ocular and oral dryness. Abnormalities in both B and T follicular helper (Tfh) cells associated with ectopic germinal center formation in the salivary gland has been described in pSS. However, the diversity of Tfh cells and relationship between B and T cell subsets has not been fully elucidated. In this study, we examined the expression of ICOS and PD-1, two critical immune co-regulatory molecules for T follicular helper function, on memory T cells in both CXCR5⁺ (Tfh) and CXCR5⁻ (Tph) populations in pSS compared to HC, SLE and RA. We evaluated changes in peripheral blood B and T cell populations in pSS compared to other diseases and healthy controls.

Methods: pSS, SLE and RA patients, along with age and gender matched HC were recruited at University of Rochester. pSS (n=40), SLE (n=19) and RA (n=20) were classified based on ACR criteria. PBMCs were isolated by Ficoll-Hypaque and the frequencies of B and T subpopulations measured by multi-parameter flow cytometry. The mean \pm SEM was calculated for each cell population and statistical analysis was done by t-test. Correlation analysis was done by Pearson method, $p < 0.05$ was considered significant.

Results: pSS and SLE had significantly higher frequency of both CXCR5⁺PD-1⁺ICOS⁺ (PD-1⁺ICOS⁺ Tfh) and CXCR5⁺PD-1^{hi}ICOS⁺ (ICOS⁺ Tph) than HC, while RA and SLE had higher percent of CXCR5⁺PD-1^{hi} (Tph) than HC. Further evaluation of Tfh subsets (based on CXCR3 and CCR6), revealed higher frequency of PD-1⁺ICOS⁺ Tfh1 and PD-1⁺ICOS⁺ Tfh2 in pSS and SLE compared to HC. In addition, we evaluated PD-1⁺ICOS⁻ Tfh populations that have been shown to have B cell helper functions. PD-1⁺ICOS⁻ Tfh1 and PD-1⁺ICOS⁻ Tfh2 were expanded in pSS and RA compared to HC, while RA patients also showed expansion of PD-1⁺ICOS⁻ Tfh17. Characterization of B cells in pSS patients revealed significant contractions of switched memory (SM), un-switched memory (USM) and double negative memory (DN) B cell compared to HC. In contrast, the fraction of activated memory B cells (CD95⁺ or CD21⁺) was significantly higher in pSS compared to HC. Additionally, the frequency of activated CD27⁺ memory B cell were positively correlated with frequency of PD-1⁺ICOS⁺ Tfh and ICOS⁺ Tph. The frequency of ICOSL⁺ B cells was positively associated with the frequency of PD-1⁺ICOS⁻ Tfh17 ($r=0.362$, $p=0.024$), a putative B cell helper Tfh subset. We are currently evaluating transcriptomic and proteomic data from these patients to correlate with flow cytometry data and to further elucidate the interaction between the B cell and T cell compartment in pSS.

Conclusion: Our data highlight the significant abnormalities in the peripheral Tfh and B cell compartment in pSS and the critical role of Tfh-B cell interactions. The association between ICOSL⁺ memory B cells and ICOS⁺ T cells suggests their potential interaction in germinal center-like structures in salivary glands.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Secukinumab (SEC), a fully human monoclonal antibody that selectively neutralizes IL-17A, provided significant and sustained improvement in the signs and symptoms of active PsA, with sustained resolution of enthesitis in Phase 3 FUTURE 2 and FUTURE 3 studies.^{1,2} This *post-hoc* analysis evaluated the effect of SEC on resolution of enthesitis count (EC; defined by Leeds Enthesitis Index) in PsA patients (pts) using pooled data from FUTURE 2 and FUTURE 3 studies.

Methods: Study designs have been reported previously.^{1,2} The results are reported only for SEC 300 and 150 mg (approved doses). Pts with baseline (BL) enthesitis (BLE) or without BLE (No BLE) were included. Evaluation through Week (Wk) 104 included: time to first resolution of enthesitis (i.e. EC = 0); shift analysis of BL EC (1 or 2 or 3–6) to full resolution (FR) and partial resolution (PR; reduction of EC) at Wks 24 and 104; and number of new enthesitis sites developed in pts with No BLE. Individual status over time with respect to resolution of EC was also determined by heat map analysis using last observation carried forward. Data are as observed in the overall population; time to first resolution of enthesitis was analyzed in the overall population and by prior use of tumor necrosis factor inhibitor (TNFi-naïve and – inadequate responders [IR]).

Results: A total of 466 pts had BLE with a mean EC of 3.1±1.6, and 246 pts had no BLE. Median days to resolution of EC in BLE pts for SEC 300, 150 mg and PBO groups were 57, 85 and 167 in overall population; 57, 85 and 120 in TNFi-naïve pts; and 92, 82 and 169 in TNFi-IR pts, respectively. In pts with BL EC = 1 or 2, 72%/61% (SEC 300 mg), 71%/66% (SEC 150 mg) and 45%/44% (PBO), respectively, achieved FR at Wk 24, with FR in SEC groups sustained or increased to 77%/81% (SEC300 mg) and 75%/88% (SEC 150 mg) at Wk 104. In BL EC = 3–6, 81% (SEC 300mg), 73% (SEC 150 mg) and 71% (PBO) of pts achieved FR and PR at Wk 24, with an increase of FR and PR to 88% (in both SEC 300 and 150 mg) at Wk 104 (Figure). A total of 89% of pts with No BLE did not develop enthesitis by Wk 104. Heat map analysis showed that SEC-treated pts at individual level had more resolution of EC than PBO pts at Wk 24.

Conclusion: Time to resolution of enthesitis was earlier with SEC than PBO in the overall population, with faster resolution observed in TNFi-naïve than TNFi-IR pts. Majority of SEC-treated pts with BL EC = 1 or 2 had FR by Wk 24, with further improvement by Wk 104. In pts with BL EC = 3–6, greater improvement was observed with SEC 300 mg vs PBO in the proportion of pts with FR and PR of enthesitis at Wk 24; further improvements were observed in both SEC groups at Wk 104.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Pain remains a common and debilitating symptom in arthritis, despite good options to treat inflammation. In axial spondyloarthritis (axSpA), data on chronic pain remain scarce.

Objective: To assess self-reported and observed aspects of pain in subgroups of axial spondyloarthritis (axSpA), and to investigate associations between these pain aspects and different health outcome measures.

Methods: A cross-sectional study of patients with axSpA (ankylosing spondylitis (AS) and undifferentiated spondyloarthritis (USpA, based on ICD 10 codes)), consecutively enrolled in the SPARTAKUS cohort (n=226). Of 197 patients, for whom all relevant information was available, 173 patients fulfilled the ASAS axSpA criteria, and 115 the modified New York criteria. We investigated self-reported pain (intensity, duration, and distribution) and categorized patients into chronic widespread pain, chronic regional pain and no chronic pain. In addition, pain sensitivity (pain threshold, pain tolerance

and temporal summation of pain), was assessed by computerized cuff pressure algometry (CPA). Comparisons between AS and USpA and between women and men were performed using Student's t-test or Chi-squared test. Associations of pain sensitivity measures and different health outcome measures, adjusted for age and sex, were analyzed by multivariate linear regression.

Results: All assessed pain measures, except for number of pain regions, were similar in AS and USpA. Almost 50% of the axSpA patients, reported chronic widespread pain (AS 42%, USpA 53%), which was more pronounced in women (60% vs. 34% for men, $p<0.001$). For pain sensitivity measures, women had lower pain tolerance as compared to men (AS ($p=0.03$), USpA ($p=0.01$)), while pain threshold was lower only for women with USpA ($p<0.01$) (Table). Furthermore, irrespective of diagnosis subgroup, lower pain tolerance was associated with higher disease activity, more fatigue and less spinal mobility.

Conclusion: In this population-based, cross-sectional study of established axial spondyloarthritis, chronic widespread pain was common, affecting 50% of the patients. A clear sex difference was found, with women reporting worse measures for both self-reported pain and pain sensitivity. Overall, lower pain tolerance was associated with worse disease activity, fatigue and spinal mobility. CPA shows promising results regarding assessment of pain sensitivity and provides additional information in pain evaluation in AxSpA.

Table Comparisons of clinical characteristics and pain variables for AS and USpA and by women and men

Variables	AS				USpA				AS vs. USpA p-value
	All n = 110	Women n = 36	Men n = 74	p-value	All n = 116	Women n = 79	Men n = 37	p-value

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), the use of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), such as methotrexate (MTX) and sulfasalazine (SSZ), as well as the body mass index (BMI) have been associated with circulating TNFi levels. Recently, BMI has also been associated with TNFi clinical response but csDMARDs have not shown any significant clinical improvement for axial manifestations [1]. However, no study has assessed in the same population the influence of both factors -csDMARDs and BMI- on drug serum levels and clinical response.

To investigate the influence of csDMARD and BMI on circulating drug levels and clinical response to TNFi therapy in axSpA patients

Methods: A 1-year follow-up prospective observational study with two cohorts (Madrid and Amsterdam) including 180 axSpA patients treated with standard doses of infliximab (41%) or adalimumab (59%). Laboratory and clinical parameters were collected every 6 months. Patients were stratified by BMI: normal-weight (18.5-24.9 kg/m²) and overweight-obesity (>25.0 kg/m²). TNFi trough levels were measured by capture ELISA [2]. Clinical response to TNFi was defined as ΔBASDAI≥2. The association between concomitant csDMARDs and BMI with drug levels and clinical response to TNFi at 1 year was analysed through multivariate log-regression models (odds ratio and 95% CI). The presence of significant interactions between covariates was tested and all models were adjusted for age, gender, HLA-B27, disease duration, TNFi-type (for drug levels) and baseline BASDAI and CRP (for clinical response)

Results: Seventy-nine out of 180 patients (44%) received concomitant csDMARDs (MTX 14%, SSZ 20% and MTX+SSZ 10%), 78 (43%) patients were normal-weight and 102 (57%) overweight-obese. Mean (SD) age and disease duration was 47 (13) and 11 (9) years respectively, 59% were males, 73% HLA-B27+ and 78% had r-axSpA. Concomitant csDMARDs (OR: 3.82; IC 95%: 1.06-13.84) and being overweight-obese (OR: 18.38; IC 95%: 2.24-150.63) were independently associated with serum TNFi drug presence. Furthermore, a significant interaction between csDMARDs and BMI with clinical response was found. While the use of concomitant csDMARD contributed positively to achieve clinical response in overweight-obese patients (OR: 7.86; IC 95%: 2.39-25.78), no association was found for normal-weight patients (OR: 1.10; 0.33-3.58). Additionally, sensitivity analysis using remission status and ASDAS were performed and showed results along the same line

Conclusion: In patients with axSpA, TNFi drug persistence is positively influenced by the use of concomitant csDMARDs and especially by being normal-weight. However, TNFi clinical response is associated with the use of concomitant csDMARDs only in overweight-obese, but not in normal-weight patients. Based on this, the use of concomitant csDMARDs in patients with axSpA could be beneficial in overweight patients

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: GO-VIBRANT is a Phase 3 trial of intravenous (IV) golimumab (GLM), an anti-tumor necrosis factor alpha (TNF α) monoclonal antibody, in adult patients (pts) w/ active psoriatic arthritis (PsA). To assess whether changes in Clinical Disease Activity Index (CDAI), Disease Activity in Psoriatic Arthritis (DAPSA) score, Minimal Disease Activity (MDA), & Very Low Disease Activity (VLDA) disease activity measures correlate w/ X-ray progression.

Methods: In this multicenter, randomized, double-blind, placebo (PBO)-controlled trial, 480-bonaïve PsA pts w/ active disease (≥ 5 swollen & ≥ 5 tender joints, C-reactive protein ≥ 0.6 mg/dL, active plaque psoriasis or documented history, & despite treatment w/ csDMARDs &/or NSAIDs) received IV GLM 2 mg/kg (N=241) at Wks 0 & 4 then q8 wks or PBO (N=239) at Wks 0, 4, 12, & 20 w/ crossover to GLM at Wk24. In this post-hoc analysis, disease activity measures CDAI, DAPSA score, MDA, & VLDA were associated w/ X-ray progression from baseline to Wk24 & baseline to Wk52. Total modified van der Heijde-Sharp (vdH-S) score was used to assess X-rays at Wks 0, 24, & 52. Imputation rules were applied for all variables using last observation carried forward for partially missing data & non-responder imputation for completely missing data.

Results: Changes in all disease activity measures appeared to be correlated w/ X-ray progression (Table). GLM-treated pts had less X-ray progression regardless of disease activity measure used. GLM-treated pts in remission or in low disease activity (LDA) tended to have less X-ray progression at Wk52 vs pts in moderate or high disease activity categories (mean change in CDAI: remission -1.06, low activity -0.81, moderate activity 0.20, high activity 1.11). Irrespective of level of disease activity, GLM-treated pts from Wk0-52 tended to have less X-ray progression vs PBO-treated pts who switched to GLM at Wk24 (mean change in CDAI 0-52 wk GLM vs PBO: remission -1.06 vs 1.52, low activity -0.81 vs 1.21, moderate activity 0.20 vs 1.32, high activity 1.11 vs 1.75). GLM-treated pts w/ DAPSA scores ≤ 28 at Wk0-52 tended to have less X-ray progression (mean change -0.74) vs pts w/ scores > 28 (mean change 0.41). Pts treated w/ GLM who despite not achieving MDA or VLDA by Wk52 also tended to have far less X-ray progression vs PBO pts (mean change MDA PBO 1.50 vs GLM 0.03; $p < 0.0011$ & mean change VLDA PBO 1.45 vs. -0.30; $p < 0.0001$).

Conclusion: In this analysis, all disease activity measures generally correlated w/ X-ray progression from baseline to Wk24 & baseline to Wk52. Higher disease activity was associated w/ increased X-ray progression. GLM-treated pts not achieving MDA & VLDA at Wk52 tended to have less X-ray progression vs PBO \rightarrow GLM pts. GLM's ability to inhibit X-ray progression, despite pts not being in clinical remission or LDA, illustrates an example of "disconnect" between clinical outcomes & X-ray findings seen in other studies.

Table. Mean change from baseline (SD) in total modified vdH-S score stratified by CDAI, DAPSA, MDA, & VLDA in PsA pts from GO-VIBRANT

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00PM

Background/Purpose: Although recent treatment guideline of axial spondyloarthritis (axSpA) by the European League Against Rheumatism (EULAR) recommended that tapering of tumor necrosis factor inhibitor (TNFi) can be considered if a patient is in sustained remission, its efficacy compared to standard TNFi treatment has not been thoroughly investigated. Furthermore, whether the tapering strategy would affect the probability of achieving the optimal treatment target as recommended by 'Treat-to-Target' strategy is also unknown.

Methods: This was a nationwide, prospective cohort study including 776 axSpA patients in South Korea who had been receiving TNFi for at least 1 year with a 3-year follow-up. The effect of the tapering strategy on longitudinal disease activity was analyzed) by comparison of two groups according to patient's mean dose quotient (DQ) of TNFi during the observation (individual level) and 2) by comparison of 1-year intervals stratified by corresponding DQ (time level). The primary outcome was achieving Ankylosing Spondylitis Disease Activity Score (ASDAS) in active disease (ASDAS-CRP less than 1.3) in 1-year interval. The relationship between the dosing strategy and the primary outcome was analyzed using generalized estimating equations (GEE).

Results: A total of 776 patients, with an observation period of 1576 person-years were analyzed. Patients' mean (SD) age was 37.8 (12.5) years and 605 (78.0%) of them were male. HLA-B27 was positive in 644 (92.0%) patients. Overall, 454 patients had maintained the standard dose of TNFi during the follow up (control group), and 322 patients were exposed to at least one episode of tapering (tapering group).

Mean (SD) ASDAS-CRP at baseline in the control and tapering groups were 3.6 (1.0) and 3.6 (1.1), respectively. ASDAS inactive disease was achieved in 665 (42.3%) intervals and the probability of achieving the target was not changed according to the follow-up periods. At the individual level, longitudinal changes in ASDAS-CRP in both groups were comparable during the observation period (beta = 0.05 [95% confidence interval-0.11 to 0.20]). This result was consistent at the time level; a 1-year interval with reduced DQ showed comparable odds for achieving the treatment target in corresponding intervals (adjusted OR 1.09 [0.89 to 1.33]). However, after further stratification of reduced DQs based on

Figure. Forest plot indicating the probability for achieving the inactive disease (ASDAS < 1.3) analyzed using multivariable generalized estimating equation (GEE). DQ, Dose quotient of TNFi (maximum 1).

the intervals with DQ less than 0.5, those with DQ less than 0.5 were associated with decreased odds for achieving the optimal target (adjusted OR 0.43 [0.22 to 0.85]) (Figure). Meanwhile, drug survival between the two groups was comparable.

Conclusion: Tapering (but not by less than 0.5 of DQ) of TNFi showed a comparable efficacy to standard-dose TNFi treatment in achieving the optimal target in axSpA patients who had received TNFi for more than a year.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: ABASDAI ≥ 4 has often been required to start TNF inhibitors (TNFi) therapy in patients with axial SpA (axSpA). However, this cut-off of high disease activity (HDA) is largely arbitrary. Unlike BASDAI, the Ankylosing Spondylitis Disease Activity Score (ASDAS) incorporates objective measures (e.g. CRP) and has a validated definition of HDA (≥ 2.1). It has thus been suggested that ASDAS could also be used to guide treatment decisions, but evidence to support this is still scarce.

Our objective was to compare the impact of applying the ASDAS and BASDAI definitions of HDA in selecting patients for TNFi-treatment in daily clinical practice.

Table 1. TNFi response criteria across subgroups according to BASDAI/ASDAS category ('efficacy population')

Variables	Overall (N= 296) *	ASDAS ≥ 2.1		ASDAS < 2.1		p-value **

* AxSpA patients treated with TNFi, with complete 6 months of follow-up and data for BASDAI/ASDAS at every time point. ** Comparison between subgroups according to BASDAI/ASDAS category for disease activity (NCR) for categorical variables and Fisher's exact test for categorical variables. ASDAS: Assessment of Spondyloarthritis International Society; BASDAI: Bath ankylosing spondylitis disease activity index; ASAS: Ankylosing Spondylitis Disease Activity Score; ASAS20: ASAS clinical remission; ASAS40: ASAS clinical remission; ASAS PR: ASAS partial remission; BASDAI50: BASDAI clinical remission; ASDAS CR: ASDAS clinical remission; ASDAS MI: ASDAS moderate improvement; ASDAS ID: ASDAS severe improvement.

Methods: Patients from Reuma.pt (Rheumatic Diseases Portuguese Register), with diagnosis of axSpA according to their rheumatologists (both treated and not treated with their first TNFi), with complete baseline BASDAI and ASDAS data and complete 6-month of follow-up (i.e. baseline, 3 and 6 months visits available) were included. Four subgroups [cross-tabulation between ASDAS (≥ 2.1) and BASDAI (≥ 4) definitions of HDA], were compared according to baseline demographic and clinical characteristics in the 'eligible population' (i.e. irrespective of TNFi-treatment). In addition, for patients starting TNFi and with complete follow-up BASDAI/ASDAS data ('efficacy population'), the subgroups were also compared according to different response criteria (Table 1), at 3 and 6 months.

Results: In total, 466 patients were included (59% males and 66% HLA-B27 positive). The large majority (n=382; 82%) fulfilled the definition of HDA according to both BASDAI and ASDAS at baseline (i.e. ASDAS ≥ 2.1 and BASDAI ≥ 4). The frequency of ASDAS ≥ 2.1 , if BASDAI < 4 , was much higher than the opposite condition (i.e. ASDAS < 2.1 , if BASDAI ≥ 4) (70% vs 0.5%). Compared to patients fulfilling both definitions, those who were ASDAS ≥ 2.1 only were more likely to be male (82.5% vs 54%), HLA-B27 positive (79% vs 54%), to show higher levels of CRP (2.6 (SD 2.5) vs 2.2 (2.8) mg/dL) and lower BASFI (3.1 (2.6) vs 5.6 (2.3)). In the 'efficacy population' (n=296), better responses were observed among patients with ASDAS ≥ 2.1 only, especially for the most 'stringent' outcomes [e.g. ASDAS inactive disease (ASDAS ID): 59% and 50%, at 3 and 6 months, respectively], compared to patients fulfilling both definitions (ASDAS ID: 26% and 25% at 3 and 6 months, respectively) (Table 1).

Conclusion: Our results show that the ASDAS-HDA definition (ASDAS ≥ 2.1) is more inclusive than the BASDAI-HDA definition (≥ 4) in selecting axSpA patients for TNFi treatment. Importantly, the additionally 'captured' patients respond better and have higher likelihood of predictors thereof. These results support the use of ASDAS ≥ 2.1 as a selection criterion for treatment decisions.

Safety and Immune Response of a Live Attenuated Herpes Zoster Vaccine in Patients with Systemic Lupus Erythematosus (SLE): A Randomized Placebo-Controlled Trial

Chi Chiu Mok¹, Kwok Hung Chan², Ling Yin Ho³ and Patrick Chiu Yat Woo², ¹Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, ²Microbiology, University of Hong Kong, Hong Kong, Hong Kong, ³Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: To evaluate the safety and immune response of a live attenuated herpes zoster (HZ) vaccine in patients with SLE by a randomized placebo-control trial (RCT).

Methods: Adult patients (age > 18 years) who fulfilled ≥ 4 ACR criteria for SLE and had a SLEDAI score < 6 with stable immunosuppressive treatment in the preceding 6 months were recruited. Exclusion criteria were: active infection, lymphocyte count $< 500/\text{mm}^3$, reduced IgG/A/M level, a history of malignancies, and current treatment with high-dose immunosuppression (eg. prednisone $> 15\text{mg/day}$, azathioprine $> 100\text{mg/day}$, mycophenolate mofetil $> 500\text{mg/day}$, cyclophosphamide and biological agents etc.). Participants were randomly assigned to either HZ vaccine (@Zostavax) or placebo given subcutaneously. Anti-VZV IgG reactivity was measured by a two-step enzyme linked fluorescence assay (VIDAS [Biomérieux]). An index value was computed and higher values reflect increased anti-VZV titers. Cell-mediated response to HZ was assessed by a specific VZV-stimulated IFN γ release ELISPOT assay. Disease activity of SLE was assessed by the SLEDAI. Unsolicited adverse events (AEs) at week 6 were compared between the two groups.

Results: 90 SLE patients were recruited (age 45.6 ± 14.1 years; 93% women): 45 assigned to vaccine and 45 to placebo. Baseline clinical characteristics and SLEDAI scores (1.58 ± 1.8 vs 1.64 ± 1.7 ; $p=0.86$) of the vaccine and placebo groups of

patients were similar. Proportion of patients who were using various immunosuppressive agents, and the baseline lymphocyte count, serum creatinine and IgG/A/M levels were also similar in the two groups. The baseline VZV IgG index value was 3.28 ± 1.19 and 3.45 ± 1.07 in the vaccine and control group of patients, respectively ($p=0.48$). The paired VZV IgG titer at week 6 was significantly higher in the vaccine than control group, even after adjustment for baseline value (4.16 ± 1.26 vs 3.32 ± 1.01 ; $p<0.001$), clinical characteristics, SLEDAI and other risk factors for HZ infection. The increase in VZV IgG antibody was significantly higher in the vaccinated than control patients ($+59.8\%$ vs -2.1% ; $p=0.01$). In 10 patients (5 vaccine; 5 placebo) who had undergone ELISPOT assay so far (the work is ongoing), the number of IFN γ -secreting CD4+ T cell colonies dropped from 32.8 ± 17 to 28.4 ± 12 in the placebo-treated patients but increased from 29.6 ± 4.5 to 55.0 ± 11.4 in vaccinated patients from week 0 to week 6. Twenty-one and 6 unsolicited AEs were reported in the vaccinated and control patients, respectively. Significantly more vaccinated patients reported pain and erythema at the injection site than controls (31% vs 7% ; $P<0.01$), and in all cases, symptoms were mild and self-limiting. Other AEs were minor and did not differ between the two groups. Two vaccinated patients (4.4%) had mild flare of skin/joint disease, and one control patients (2.2%) had mildly increase in proteinuria between week 0 and 6. No patients had evidence of HZ infection 6 weeks after vaccination.

Conclusion: In patients with stable SLE who were not receiving intensive immunosuppression, vaccination with the live attenuated HZ vaccine provoked an expected cell-mediated and humoral response. The HZ vaccine was well tolerated.

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Renal vascular involvement is an important prognostic marker of lupus nephritis (LN). Among patients with various vascular changes, individuals with thrombotic micro angiopathy (TMA) present with severe clinical manifestations and have a high mortality.

We sought to assess renal outcomes and response to anti-thrombotic treatments in addition to conventional immunosuppression in patients with biopsy proven LN and TMA.

Methods: Clinical and renal histopathological data for 97 patients with biopsy-proven LN and TMA were retrospectively analysed. Antibody profiles, induction and maintenance therapies for LN, and anti-thrombotic treatments were collected. TMA lesions were classified into acute and chronic (Figure 1). A complete renal response (CR) was defined as proteinuria <0.5 g/24h and normal or near-normal (within 10% of normal GFR if previously abnormal) GFR. Partial Response (PR)

Acute TMA features	Chronic TMA features
•Endothelial swelling with partial or complete occlusion of lumina;	•Capillary wall thickening with double contours;
• Microthrombi, focal or global;	•Organizing capillary thrombi;
fragmented RBC on glomerular subendothelial space and/or mesangial areas;	•Glomerular ischemic collapse with afferent arteriolar occlusion;
•Mesangiolysis, focal, segmental/global;	•Segmental/global glomerulosclerosis
•Glomerular congestion with efferent arteriolar occlusion	

was defined as a $\geq 50\%$ reduction in proteinuria to subnephrotic levels and normal or near-normal GFR. Renal outcomes were assed at one year post biopsy.

Results: The mean age was 38.9 ± 15.2 years (range, 13–69 years). The study included 85 females (87.6%) and 12 males (12.4%). The clinical presentations were nephrotic syndrome, nephritic syndrome, and asymptomatic urinary abnormalities in 38(39.2%), 20 (20.6%), 39 (40.2%) patients, respectively. Nine patients were classified Class III (9.3%, including 2 as Class III + V), 82 as Class IV(84.5%, 10 as Class IV-segmental(IV-S) (10.3%) and 72 as Class IV-global (IV-G)(74.2%), including 4 as Class IV-G + V) and 6 as Class V (6.2%). Forty-two(43%)patients presented with acute and 55 (57%) with features of chronic TMA. All patients had received treatment with standard immunosuppressants (55% mycophenolate, 39% cyclophosphamide, 6% other regimen) and steroids.

At 12 months, CR was observed in 37 patients (38.1%), PR in 22 (22.6%) and no response in 38 (39.1%). Sixty-one patients (62.9%) were antiphospholipid positive (aPL) and 37 (38.1%) received anticoagulation with vitamin-K antagonist (VKA) and/or heparins. Presence of aPLs(OR, 2.4; 95% confidence interval-CI-, 1.2–7.3; $p = 0.03$), anti-DNA positivity (OR, 12.8; 95% CI 3.0–71.3; $p = 0.002$), and chronic features of TMA (OR, 3.0; 95% CI 1.2–17.5; $p = 0.04$) were all found to be associated with no response. When limiting the analysis to a PL positive patients, after adjusting for type of immunosuppressant therapy and LN class on biopsy, variables that were significantly associated with CR+PR were features of acute TMA rather than chronic (OR, 8.62;95% CI 1.4–97.1; $p = 0.03$) and the use of VKA/heparins(OR, 2.1; 95% CI, 1.02–16.2; $P = 0.046$)

Conclusion: In patients with concomitant LN and TMA, the presence of aPL and chronic features of TMA were associated with poorer renal outcomes. In patients with aPL, the use of anticoagulation appeared protective and warrants further investigation as a therapeutic tool, especially in the setting of acute TMA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Psychosis, one of the rarer neuropsychiatric (NP) events in lupus patients, features in both the ACR and Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE. Our objective was to determine, in a multi-ethnic/racial, prospective SLE inception cohort, the frequency, attribution, clinical and autoantibody associations with lupus psychosis and the outcome as assessed by physicians and patients.

Methods: A prospective study of new onset SLE patients was performed by an international network of 32 academic centers in 11 countries. Patients were evaluated at enrollment and annually for up to 17 years. Data were collected at each assessment on 19 NP events including psychosis, as per the ACR case definitions for NPSLE. Pre-defined decision rules were used to attribute the events to SLE and non-SLE causes. Demographic features, medications, SLE disease activity index-2000 (SLEDAI-2K), SLICC/ACR damage index (SDI) and SF-36 mental (MCS) and physical (PCS) component summary scores were also recorded. Plasma lupus anticoagulant (LAC), serum IgG anti-cardiolipin, anti- β_2 glycoprotein-I, anti-ribosomal P (anti-P) and anti-NR2 glutamate receptor antibodies were measured. Descriptive statistics, time to event analysis and linear regressions were used as appropriate and multivariable models included demographic, clinical and serological variables.

Results: Of 1,826 SLE patients, 88.8% were female, 48.8% Caucasian. The mean \pm SD age was 35.1 \pm 13.3 years, disease duration 5.6 \pm 4.2 months and follow-up 7.4 \pm 4.5 years. There were 31 psychotic events in 28/1,826(1.53%) patients and most patients [(26/28; 93%)] had a single event. In the majority of patients [25/28; (89%)] and events [28/31; (90%)] psychosis was attributed to SLE, usually within 3 years of SLE diagnosis. Concurrent therapies included corticosteroids 23/28 (82.1%) with a mean (SD) prednisone dose of 21.9 (14.9) mg/day, immunosuppressants 17/28 (60.7%), biologics 1/28 (3.6%), antipsychotic drugs 19/28 (67.9%) and antidepressants 11/28 (39.3%). In multivariable analyses, positive associations [hazard ratio and 95% confidence interval [HR (95% CI)] with lupus psychosis were prior SLE NP events [3.59,(1.16, 11.14), male sex [3.0, (1.20, 7.50)], younger age at SLE diagnosis [(per 10 years younger), 1.45 (1.01, 2.07)] and

African ancestry [4.59 (1.79,11.76)]. There was no association with SLE disease activity, organ damage or autoantibodies. Patients with psychosis had significantly lower concurrent SF-36 summary scores compared to patients without NP events (MCS: 38.9±13.3vs. 48.9±10.7;PCS: 38.9±11.0 vs. 44.1±10.9; p<0.001).By physician assessment 80% of psychotic events resolved by the second annual assessment following onset. For these patients there was a concurrent clinically significant improvement in both MCS (45.5±14.1) and PCS scores (43.2±10.9).

Conclusion: Psychosis is an infrequent but important manifestation of NPSLE. It occurs early after SLE onset, is usually mono-phasic and has a significant negative impact on health status. As determined by patient and physician report, the outcome is favorable for most patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Bone health in SLE is adversely affected by vitamin D deficiency, inflammatory cytokines including interferon (IFN)- α , and glucocorticoid use. We tested the hypothesis that vitamin D supplementation would increase bone formation and decrease bone resorption in an SLE clinical trial.

Methods: Vitamin D-deficient SLE subjects had completed a randomized controlled trial (NCT00710021) testing the effect of 2000 IU/d or 4000 IU/d vitamin D supplementation vs. placebo for 12 weeks upon the IFN gene signature. For this analysis, low- and high-dose vitamin D groups were analyzed together. All subjects met 1997 ACR SLE Classification Criteria, had inactive disease (SELENA-SLEDAI ≤ 4), and were taking <20 mg of prednisone daily at baseline. Serum 25 (OH) vitamin D and bone turnover markers (N-terminal propeptide of type 1 collagen [P1NP], a marker of bone formation, and C-telopeptide [CTX], a marker of bone resorption), were assayed in baseline and week 12 blood samples. Change in (Δ) P1NP, CTX, and 25(OH)D were calculated as week 12 minus baseline. Spearman rho estimated the correlation between Δ 25(OH)D and Δ bone turnover markers. We tested the effect of vitamin D supplementation vs. placebo on Δ P1NP and Δ CTX using Wilcoxon rank-sum tests in an intention-to-treat analysis. Subgroup analyses tested the effect of vitamin D among subjects with current glucocorticoid use and with a detectable IFN signature. Secondary analyses excluded bisphosphonate users and tested the effect of achieving vitamin D repletion (≥ 30 ng/mL).

Results: We analyzed 28 subjects randomized to vitamin D and 15 randomized to placebo. Baseline characteristics including P1NP and CTX were similar between groups. Mean age was 39.0 (SD 11.5) years, 93.0% were female, 48.8% Black, 41.8% White, and 39.5% used glucocorticoids at baseline. IFN signature was present in 83.7% at baseline. Sixty-five percent of subjects in the vitamin D group achieved repletion compared to none in the placebo group. Mean increase in 25(OH)D was 17.7 (SD 8.2) ng/mL in the vitamin D group vs. 2.9 (SD 4.9) ng/mL in the placebo group (p <0.01). Changes in 25(OH)D were not significantly correlated with Δ P1NP or Δ CTX. Changes in bone turnover markers were not significantly different in the vitamin D group vs. placebo group in the primary analysis (**Table**). The effect of vitamin D vs. placebo did not differ by glucocorticoid use. An increase in P1NP, suggesting bone formation, was observed in subjects without baseline IFN signature assigned to vitamin D, but this was not significantly different from placebo (p 0.16). Results

from the primary analysis were similar after excluding bisphosphonate users (n=4). Changes in bone turnover markers were not significantly different in those who did vs. did not achieve vitamin D repletion.

Conclusion: Vitamin D supplementation did not affect the 12-week change in bone turnover markers among SLE subjects in this trial.

Table. Effect of vitamin D vs. placebo on 12-week change in bone turnover markers

	ΔP1NP, ng/mL	p value	ΔCTX, ng/mL	p value
Primary analysis (n=43)				
Vitamin D (n=28)	-0.2 (-6.2, 4.7)	0.83	0.01 (-0.04, 0.02)	0.50
Placebo (n=15)	-1.1 (-6.8, 13.0)		-0.04 (-0.07, 0.03)

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Hydroxychloroquine (HCQ) is near-universally recommended for patients with SLE. Use of this medication has previously been associated with a substantial survival benefit among SLE patients. We aimed to determine the potential temporal association between HCQ discontinuation and all-cause and cardiovascular disease (CVD) mortality.

Methods: We conducted a population-based case-control study using an administrative health database including the entire population in the province of British Columbia, Canada (over 5 million individuals). We identified cases with SLE who died, and for each case we identified up to three living controls with SLE matched on age, sex, and SLE disease duration. We used conditional logistic regression to assess the association between current use of HCQ or recent discontinuation of HCQ and the risk of all-cause and cause-specific mortality relative to remote HCQ users. Remote users were defined by a duration greater than 365 days between the last HCQ prescription and the index date (i.e., death date). Recent users had

Table 1. Risk of Death with Current Usage, Non-Usage, and Recent Discontinuation Compared with Remote Usage of Hydroxychloroquine Among Patients with Systemic Lupus Erythematosus

All-Cause Mortality	Cases, N	Controls, N	Crude Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
Remote HCQ Users	72	106	1.0 (reference)	1.0 (reference)
Recent HCQ Discontinuers	65	34	3.03 (1.77-5.17)	3.78 (2.07-6.91)
Current HCQ users	32	156	0.30 (0.18-0.49)	0.35 (0.20-0.59)
HCQ Non-users	121	206	0.83 (0.55-1.24)	0.93 (0.59-1.44)
Cardiovascular Disease Mortality				
Remote HCQ Users	17	28	1.0 (reference)	1.0 (reference)
Recent HCQ Discontinuers	17	11	2.57 (0.96-6.92)	4.63 (1.31-16.42)
Current HCQ users	9	44	0.32 (0.12-0.87)	0.37 (0.11-1.27)
HCQ Non-users	40	59	1.11 (0.51-2.44)	1.15 (0.45-2.99)
Other Cause Mortality				
Remote HCQ Users	35	52	1.0 (reference)	1.0 (reference)
Recent HCQ Discontinuers	33	18	3.17 (1.45-6.93)	3.90 (1.56-9.75)
Current HCQ users	13	72	0.28 (0.14-0.58)	0.32 (0.14-0.71)
HCQ Non-users	37	95	0.89 (0.49-1.64)	1.18 (0.29-2.37)

a duration less than 365 days since the last HCQ prescription and index date. Current users had active HCQ prescriptions spanning the index date. Fully adjusted models included chronic kidney disease, Charlson comorbidity index, glucocorticoids, and cardiovascular medication use assessed at the time of SLE diagnosis.

Results: We identified 290 SLE cases who died and 502 matched controls among 792 individuals with SLE. The mean age at index date was 65.6 years for cases and 64.7 years for controls. The majority were female (87.9% of cases and 91.4% of controls). The mean SLE disease duration was 5.3 years for both groups. Adjusted odd ratios (ORs) for all-cause mortality relative to the remote users were 0.35 (95% CI: 0.20, 0.59) for current users and 3.78 (95% CI: 2.07, 6.91) for subjects who recently discontinued HCQ (**Table 1**). HCQ non-users had the same risk of death as remote users (OR 0.93 [95% CI: 0.59, 1.44]). Similar trends were seen for the risk of mortality due to CVD.

Conclusion: In this general population-based case-control study of SLE mortality, we found a nearly four-fold increased risk of death associated with recent HCQ discontinuation and a substantially increased risk of CVD death. The cause of this association is unknown. This could be partially explained by a direct protective effect of HCQ that is rapidly lost following discontinuation. However, there may also be an indirect association due to selective provider discontinuation or patient non-adherence with HCQ when patients become acutely ill. We also demonstrated a 65% reduced risk of death among current HCQ users compared with remote users. By leveraging remote users as the comparison group, we reduced the potential for confounding by indication. Further studies are needed to explain the temporal relationship between HCQ discontinuation and SLE mortality.

Session Title: Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Hydroxychloroquine (HCQ) retinopathy after 10 years or more of use is more frequent than previously appreciated. This led to new ophthalmology guidelines that changed the recommended dosing from 6.5 mg/kg to 5 mg/kg. However, it is not clear that the lower dose of hydroxychloroquine will have the same efficacy for SLE activity or

the same protective role against cardiovascular risk factors and thrombosis. We asked whether hydroxychloroquine blood levels could help identify those at greater future risk of retinopathy.

Methods: We analyzed data on 477 SLE patients from a clinical cohort who had repeated assessments of HCQ blood concentrations, and were evaluated one or more times for retinopathy (306 single retinopathy exam, 115 two and 58 three or more assessments). The patients were 93% female and 42% Caucasian. Hydroxychloroquine blood levels were performed as previously described. In our analysis, HCQ toxicity was defined dichotomously by a retina expert: all those with a value of “No” or “Possible” were categorized as not having HCQ toxicity, and those who had a “Yes” were categorized as having it. Mean and maximum HCQ blood concentration over all cohort visits prior to the final retinopathy assessment were calculated. Risk of HCQ toxicity was then assessed in tertiles defined by these variables. The duration of hydroxychloroquine use (years in tertiles by distribution) and its association with HCQ toxicity were also examined.

Results: The risk of HCQ toxicity is shown in Table 1.

Table 1. Risk of HCQ retinal toxicity by variable.

Characteristic	No n (%)	Yes n (%)	p	P for Trend
Sex			0.0479	
Female	423 (96.1)	17 (3.9)		
Male	33 (89.2)	4 (10.8)

Normal	0 (0%)	307 (76%)
Total	14	405
Fundal Autofluorescence (FAF)		
Abnormal	16 (76%)	144 (24%)
Normal	5 (24%)	462 (76%)
Total	21	606

OCT Sensitivity = 85%, Specificity = 92%

ERG Sensitivity = 100%; Specificity = 60%

MP1 Sensitivity = 100%; Specificity = 76%

FAF Sensitivity = 76%; Specificity = 76%

Conclusion: Our data show that the risk of HCQ retinopathy increases in men, Caucasians, older patients and with duration (but the frequency was less than in other publications). For the first time, our data show the utility of HCQ blood levels in predicting retinopathy. This would allow clinicians to either decrease dose or increase monitoring in those with high blood levels. Our data also show the need for ophthalmologists with retinopathy expertise to interpret retina testing, as screening tests can be abnormal due to causes other than HCQ retinopathy. Stopping HCQ based on an abnormal test without confirmation from a retinopathy expert could needlessly deprive an SLE patient of an important medication.

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: A novel population of CD4+ T cells with B cell helping capacity has been described in the synovial tissues and peripheral blood of seropositive RA patients with an established disease, and termed ‘peripheral helper’ (Tph) cells (Rao DA et al, Nature 2017). Tph cells are characterized by the lack of CXCR5 together with a bright expression of PD-1 (CD4+CXCR5-PD-1hi T cells). As opposed to CD4+CXCR5+PD-1hi follicular helper T cells (Tfh), Tph cells are not located in lymphoid organs but accumulate in inflamed tissues. Tph cell numbers have not been previously examined in early RA (eRA). Therefore, our objective was to study the frequency of circulating CD3+CD4+CXCR5-PD-1hi Tph cells (cTph), in patients with eRA.

Methods: Peripheral blood was drawn from DMARD-naïve early RA patients (eRA) (2010 ACR criteria) with a disease duration <24 weeks (n=42), and healthy controls (HC) matched for age and gender (n=42). For comparison, blood was also drawn from 66 patients with established RA (disease duration > 2 years), 45 patients with Spondyloarthritis (SpA), and their age and gender-matched HC (one HC per patient). In addition, synovial fluid from 7 patients with established RA and 3 patients with SpA was examined. Established RA patients were receiving low-dose oral methotrexate and were naïve for biological agents. SpA patients were receiving NSAIDs, low-dose oral methotrexate and/or sulphasalazine and were naïve for biologicals. After isolation by Ficoll-Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CXCR5, ICOS and PD-1, and examined by flow cytometry.

Results: The frequency of circulating CXCR5- cells gated for CD4+ T cells was not different among the studied groups. In contrast, eRA patients demonstrated an increased frequency of circulating CD4+CXCR5-PD-1hi Tph and CD4+CXCR5-PD-1hiICOS+ T cells. When examining seropositive (RF+ and/or ACPA+, n=25) and seronegative eRA patients (RF- and ACPA-, n=17) separately, it was evident that the above described alterations were only apparent in seropositive eRA. Likewise, increased cTph numbers were observed in seropositive (n= 47) but not seronegative (n=19) established RA, and not in SpA patients (n=45), which is consistent with data reported by Rao et al. Interestingly, this increased cTph cell frequency was observed only in seropositive RA patients with an active disease (DAS28>2.6, n=24), whereas the numbers of cTph cells in established RA patients who had achieved remission (DAS28<2.6, n=23) were not different from HC. Furthermore, Tph cells were present in the synovial fluid of seropositive RA (n= 4) but not of seronegative RA (n= 3) or SpA (n=3).

Conclusion: Tph cells may play an important role in the pathogenesis of seropositive but not seronegative RA. An increased cTph cell frequency is a marker of active, seropositive RA.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: We previously identified several co-expressed genes associated with achieving sustained drug-free remission (sDFR) following a methotrexate (MTX)-based strategy in early rheumatoid arthritis (RA).¹ The aim of the present analyses was to identify, within the same patients, inflammatory proteins associated with achieving sDFR and to study associated biological pathways and compare these with those previously found in the transcriptomic analyses.

Methods: Data was used from patients participating in the U-Act-Early trial who achieved sDFR (i.e. being drug-free for ≥ 3 months) after therapy with a treat-to-target MTX-based strategy ($n=10$).² When the treatment target, sustained remission (disease activity scores assessing 28 joints (DAS28) < 2.6 and ≤ 4 swollen joints for ≥ 24 weeks), was achieved, therapy was tapered and thereafter discontinued. Controls were patients without a drug-free period during the study ($n=7$). In baseline serum samples, 85 proteins were measured and analysed using multi-analyte profiling. Partial least square discriminant analysis (PLSDA) was used to identify relevant proteins, which were subsequently used for pathway analyses in the Genes Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) databases.

Results: Table 1 shows baseline clinical characteristics; no significant differences were found between those achieving sDFR vs. controls ($p > 0.14$). PLSDA identified 13 proteins, of which pathway analyses yielded 117 significant GO terms and 14 KEGG pathways (Fig. 1). Comparison of the significantly enriched pathways found in the transcriptomic analyses and those in the present study yielded 33 corresponding GO terms, including “janus kinase signal transducer and activator of transcription (JAK-STAT) cascade” ($p \leq 8.97 \times 10^{-3}$) and “positive regulation of tyrosine phosphorylation of STAT protein” ($p \leq 8.37 \times 10^{-3}$), which is important for signal transduction in the JAK-STAT pathway. Additionally, one KEGG pathway (“JAK-STAT signalling pathway”) was also found to be significantly enriched in both transcriptional and proteomic analyses ($p \leq 2.22 \times 10^{-4}$).

Figure 1: Clustered heatmap of the identified proteins. Red colour depicts a negative z-score (i.e. lower concentration) and green colour depicts a positive z-score (i.e. higher concentration). Proteins in the black cluster have on average a lower concentration (i.e. effect estimate ≤ 0) in the sDFR group and those in the grey cluster a higher concentration (i.e. effect estimate > 0).

Table 1: Baseline clinical characteristics		
	sDFR (n=10)	Controls (n=7)
Female gender	8 (80%)	6 (86%)
Age (yrs.)	50 (14)	46 (17)
BMI (kg/m ²)	29 (4)	26 (3)
Caucasian	10 (100%)	7 (100%)
Current smokers	1 (10%)	1 (14%)
Symptom duration (days)	30 (13-40)	31 (20-46)
Seropositive for RF	9 (90%)	5 (71%)
Seropositive for anti-CCP	7 (70%)	6 (86%)
CRP (mg/L)	11 (5-18)	5 (4-12)
ESR (mm/h)	25 (13-47)	16 (13-25)
DAS28 ^a	4.6 (1.2)	4.8 (0.9)
HAQ ^b	0.9 (0.6)	1.0 (0.5)
Sharp/van der Heijde score ^c	0 (0-1)	0 (0-0)
Data presented as mean (standard deviation), median (interquartile range), or n (%). ^a range 0-9.4; 9.4=maximum, ^b range 0-3; 3=maximum, ^c range 0-448; 448=maximum. Anti-CCP=anti-cyclic citrullinated peptide, BMI=body mass index, CRP=c-reactive protein, DAS28=disease activity score assessing 28 joints, ESR=erythrocyte sedimentation rate, HAQ=health assessment questionnaire, RF=rheumatoid factor.		

Conclusion: Biological processes important for effectively reducing inflammation in new-onset RA, treated to target with a MTX-based strategy, were found to be associated with activity of JAK-STAT signalling components. Involvement of this pathway was found both in the analyses of the transcriptome and proteome, demonstrating a specific JAK-STAT profile at baseline affects the immunosuppressive efficacy of MTX.

Engleman Rheumatology Research Center, Department of Medicine, Division of Rheumatology, University of California, San Francisco, San Francisco, CA, ²Pediatrics, Institute for Computational Health Sciences, University of California, San Francisco, San Francisco, CA, ³Orthopedic Surgery, University of California, San Francisco, San Francisco, CA

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The inability to identify relevant arthritogenic CD4 T cells in patients and in murine disease models has limited our understanding of disease initiating events in rheumatoid arthritis (RA). To overcome this limitation, we took advantage of the dynamic expression pattern of Nur77 (*Nr4a1*)—a sensitive and specific marker of TCR signaling that is insensitive to cytokine stimulation—to identify antigen-activated CD4T cells in human RA and the SKG mouse model of autoimmune arthritis.

Figure 1. Frequency of Nur77⁺ antigen-activated CD4 T cells in seropositive RA synovium (left, middle, right) compared to matched RA PBMC (left, middle) and OA synovium (left, right).

Figure 2. Nur77-eGFP marks arthritogenicity of CD4 T cells in SKGNur mice. (a) The 5% highest and 5% lowest Nur77-eGFP sorted CD4⁺CD25⁻ naive T cells were adoptively transferred into SCID recipients. (b) Joint histopathology by H&E. Black arrows indicate normal synovial lining and white arrows indicate synovial proliferation and early joint destruction. (c) Dot plot of blinded histology scores. (d) Frequency of IL-17 producing CD4 T cells from SCID recipient splenocytes.

Methods: We used intracellular flow cytometry to identify T cells that express Nur77 protein in synovial tissue and blood from patients with seropositive RA or osteoarthritis (OA), as well as in the SKG arthritis model. A fluorescent reporter (eGFP) of Nur77 expression was backcrossed into SKG mice (SKGNur) to identify and study arthritogenic T cells in this model. Functional and signaling differences between CD4 T cells that expressed the highest and lowest amounts of eGFP (GFP^{hi} and GFP^{lo}, respectively) were compared using *in vitro* assays, adoptive transfer, and gene expression assays. We searched general public repository databases for available transcriptome data from human RA synovium (13 studies met inclusion criteria comprising over 300 synovial samples) to examine candidate gene expression profiles.

Results: Nur77 expression was specifically enriched in a subset of synovial CD4 T cells from patients with RA (Fig 1). This suggested the presence of antigen-activated T cells in RA synovial tissue. This was confirmed in the SKG mouse. Higher levels of Nur77-eGFP (GFP^{hi}) in SKGNur CD4 T cells marked their autoreactivity and arthritogenic potential and their ability to more readily differentiate into IL-17 producing cells (Fig 2). T cells exhibiting this heightened auto reactivity still had diminished TCR signaling, perhaps due to upregulation of inhibitory receptors. Moreover, the enhanced autoreactivity was associated with upregulation of IL-6 cytokine signaling machinery, but a reduced amount of expression of suppressor of cytokine signaling 3 (SOCS3)—a key negative regulator of IL-6 signaling. As a result, the more autoreactive GFP^{hi} CD4T cell population from SKGNur mice was uniquely hyper-responsive to IL-6. Consistent with findings from SKGNur mice, *SOCS3* expression was similarly downregulated in RA synovium.

Conclusion: This suggests that, despite impaired TCR signaling, autoreactive T cells exposed to chronic antigen stimulation exhibit heightened sensitivity to IL-6 receptor signaling which contributes to their arthritogenicity in SKG mice, and perhaps in patients with RA.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Our group previously demonstrated that anti-citrullinated (cit) protein antibodies (ACPA) in the sputum correlate with remnants of neutrophil extracellular traps (NETs) in RA-free subjects At-Risk for future RA. Sputum neutrophils from these subjects also had increased ex vivo NET formation (NETosis) (*Okamoto ACR 2017*). However, it is unknown what specific features these sputum NETs contain and how they relate to inflammation and ACPA production in the lung. Of note, NETs variably contain cit proteins that can be targets of ACPA. Herein, we explored associations between ACPA and cit-histone H3 (cit-H3) in sputum NETs and local cytokines in the lung.

Methods: In 32 At-Risk subjects without synovitis yet At-Risk for RA because they were first-degree relatives (FDR) of RA patients (N=29) or serum ACPA(+) [N=13, 5/13 also FDRs] and in 16 serum ACPA(-) non-FDR healthy controls, we tested serum and induced sputum for ACPA using anti-cyclic cit peptide (CCP) ELISA (CCP3.1IgG/IgA, Inova). After incubation of sputum plugs for 1 hour without stimulation followed by staining with Hoechst 33342, anti-myeloperoxidase (MPO) and anti-cit-H3, we determined sputum neutrophils that had formed NETs ex vivo by microscopy. Separately, in sputum cell-free supernatant, the level of NET remnants was quantified by sandwich ELISA for the NET-specific protein complex DNA-cit-H3, and the levels of IL-1 β , IL-4, IL-6, IL-8, IL-10, TNF α and IFN γ were measured by Meso Scale Discovery assay.

Results: The% of sputum neutrophils that formed NETs was higher in serum CCP(+) At-Risk but not serum CCP(-) At-Risk subjects compared to controls (Figure 1A). However, the% of sputum neutrophils that formed NETs specifically expressing cit-H3 was higher in all At-Risk subjects (Figure 1B). In all At-Risk subjects, sputum anti-CCP levels significantly correlated with formation of cit-H3 containing NETs (Figure 1C) but not overall sputum NETosis. NET remnants containing DNA-Cit-H3 complexes also significantly correlated with sputum anti-CCP level ($r=0.80$, $p<0.001$). After accounting for multiple comparisons, sputum anti-CCP and DNA-cit-H3 levels significantly correlated with sputum levels of IL-6, IL-8, IL-10 and TNF α (Figure 2).

Conclusion: Sputum neutrophils in At-Risk subjects demonstrate increased cit-H3 expressing NETs that strongly correlate with sputum anti-CCP and multiple cytokines. These findings suggest that cit-H3-expressing NETosis in the lung may play a

Figure 1. Sputum Cit-H3 expressing NETs are elevated in At-Risk subjects and correlate with sputum anti-CCP3.1 levels. The figure depicts the % NETosis in sputum in At-Risk subjects defined as the # of sputum neutrophils that formed NETs ex vivo at 1 hour without stimulation divided by the total # of sputum neutrophils (200 neutrophils counted per subject). Panel B depicts the % NETosis in sputum of At-Risk subjects but is limited to NETs staining positive for citrullinated histone H3 (Cit-H3+). Panel C depicts the correlation between sputum anti-CCP3.1 levels (y-axis) and the % of sputum neutrophils that underwent NETosis expressing Cit-H3 (x-axis) in At-Risk subjects. P-values were calculated using Mann-Whitney U testing (Panels A and B) and Spearman's correlation (Panel C). In all panels, * = Serum CCP3.1(+) At-Risk and ○ = Serum CCP3.1(-) At-Risk

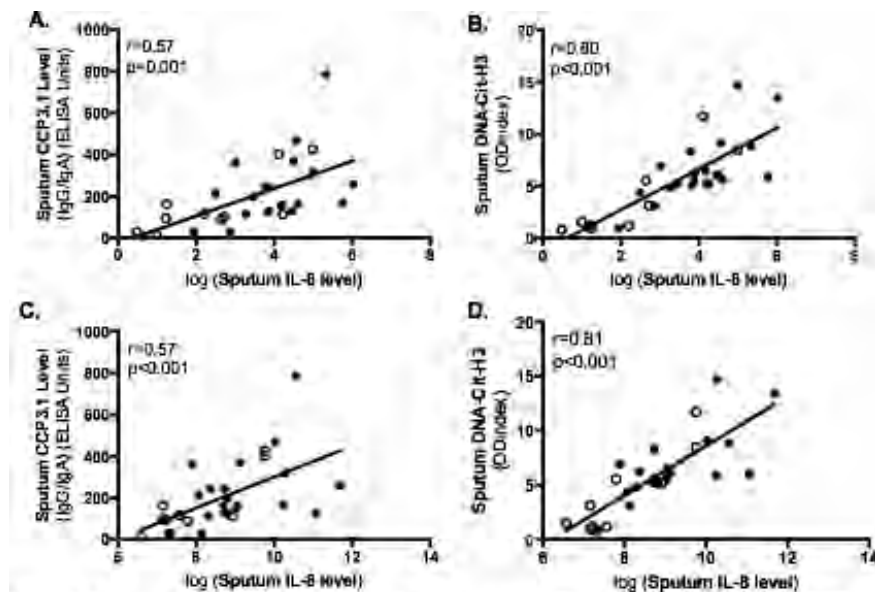

Figure 2. Sputum cytokine levels correlate with sputum anti-CCP3.1 and cit-H3 containing NET remnants in At-Risk subjects. The figure depicts the correlation between sputum anti-CCP3.1 levels and log transformed sputum cytokine levels (IL-6 in Panel A and IL-8 in Panel C) in At-Risk subjects. Similar correlations were demonstrated for TNF α ($r=0.72$, $p<0.001$) and IL-10 ($r=0.52$, $p=0.003$). The figure also depicts the correlation between sputum levels of NET remnants measured by the NET-specific protein complex DNA-citrullinated histone H3 (DNA-Cit-H3) and log transformed sputum cytokine levels (IL-6 in Panel B and IL-8 in Panel D) in At-Risk subjects. Similar correlations were demonstrated for TNF α ($r=0.70$, $p<0.001$) and IL-10 ($r=0.65$, $p<0.001$). R and p values based on Pearson's correlation coefficient. In all panels, \bullet = Serum CCP3.1(+) At-Risk and \circ = Serum CCP3.1(-) At-Risk.

role in the development of ACPA. Additional studies are needed to determine associations with transitions to systemic ACPA and classified RA.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Agonistic antibodies to Peptidylarginine Deiminase 4 (PAD4) are hallmarks of a severe form of rheumatoid arthritis (RA) characterized by the most erosive joint damage and lung disease. PAD4 activation and the production of citrullinated autoantigens targeted in RA is likely a major mechanism by which these antibodies may worsen the disease. However, whether anti-PAD4 antibodies may have other effector functions in RA is unknown. The recent discovery that PAD4 is found on the surface of monocytes drove our interest to define the consequences that anti-PAD4 binding may have on the function of these cells.

Methods: We investigated the consequences of PAD4-activating antibody binding to monocytes using a well-characterized panel of human anti-PAD4 and control monoclonal antibodies (mAbs). Extracellular citrullination of fibrinogen was used to study antibody-mediated PAD4 activation on surface of monocytes. We measured anti-PAD4 antibody surface binding and monocyte activation using flow cytometry, and release of pro-inflammatory cytokines using ELISA at 24 hours. We

assessed differentiation of monocytes into osteoclasts using tartrate resistant acid phosphatase (TRAP) staining and quantitative estimation of acid phosphatase (AP) activity in the presence of a sub-optimal dose of RANKL at 14 days.

Results: PAD4 is expressed on the monocyte surface in an enzymatically active state that can be hyperactivated twofold upon binding by PAD4 antibodies. Flow cytometry studies revealed preferentially binding of PAD4 mAbs to PAD4 present on surface of monocytes where 63% monocytes bound with PAD4 mAbs versus 1.9% binding with control mAbs ($p=0.0087$). Moreover, PAD4 mAbs but not control mAbs induced monocyte activation with upregulation of surface markers such as CD40, CD11c and PDL-1 after 24 hours. Other activation markers such as CD80, CD86 and HLA-DR remained unchanged. Interestingly, monocytes treated with PAD4 mAbs released 100-fold more RA-associated pro-inflammatory cytokines, including IL-6 (1440 pg/ml) and TNF-alpha (94pg/ml), compare to monocytes incubated with control mAbs (14 pg/ml and 0 pg/ml, respectively). At 14 days, we observed larger osteoclast-like cells that were positively stained for TRAP in the presence of PAD4 mAbs compared to control mAbs. This corresponded to a three-fold increase in the amount of AP released by cells cultured with PAD4 mAbs over control mAbs.

Conclusion: Anti-PAD4 autoantibodies can directly interact with monocytes and influence their pathophysiological functions. The pro-inflammatory activation and differentiation into osteoclast-like cells may contribute to the erosive joint disease observed in this severe RA subset.

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Defining the precise CD4+ T cell subsets that are dysregulated in RA patients is critical to deciphering pathogenesis. Here we present Mixed effects modeling of Associations of Single Cells (MASC), a novel reverse single cell association strategy to determine if a cellular subpopulation is associated with case-control status while controlling for technical confounders and biological covariates. We applied MASC to identify T cell populations expanded in rheumatoid arthritis(RA).

Methods: Cryopreserved PBMCs from 26 RA and 26 osteoarthritis patients were analyzed by a 32-marker mass cytometry panel. All RA patients met ACR 2010 Rheumatoid Arthritis classification criteria. We identified 19 CD4+ T cell populations and tested for case-control associations using our novel association testing method, MASC. MASC uses a logistic regression mixed effects model where the cluster membership of each single cell is the dependent variable. The model estimates fixed effects for donor age, sex, and case-control status, and random effects for each donor and technical batch.

Figure 1. MASC identifies an expanded CD27- HLA-DR+ T_{EM} population in RA. (a) MASC odds ratios and association p-values were calculated for each cluster identified by DensVM. Cluster 18 was significantly expanded in RA and was CD27- HLA-DR+. (b) Flow cytometric quantification of the percentage of memory CD4+ T cells with a CD27- HLA-DR+ phenotype in cells from seropositive RA synovial fluid (n=8) and synovial tissue (n=9), compared to blood samples from RA patients and controls. Significance was assessed using one-tailed t-tests and applying a Bonferroni correction for multiple testing. (c) RNA-seq characterization of the expression of key genes in CD27- HLA-DR+ (DR+27-) cells and 6 related CD4+ T cell populations: naive T cells (T_{naive}), regulatory T cells (T_{reg}), central memory T cells (T_{CM}), and three populations of effector memory T cells, CD27+ HLA-DR- (DR-27+), CD27+ HLA-DR+ (DR+27+), and CD27- HLA-DR- (DR-27-). P values are adjusted for multiple testing using the Benjamini-Hochberg procedure.

Results: MASC revealed a significantly expanded population of CD4+ T cells, identified as CD27- HLA-DR+ effector memory cells, in RA patients (OR = 1.7; $p = 1.1 \times 10^{-3}$, **Figure 1A**). These cells comprised ~2% of CD4+ memory T cells in RA samples compared to 0.8% in OA controls. Compared to peripheral blood, synovial fluid and synovial tissue samples from RA patients were significantly enriched for CD27-HLA-DR+ cells, which comprised ~10-15% of synovial CD4+ T cells ($p < 1 \times 10^{-3}$, **Figure 1B**). The abundance of CD4+ CD27^D HLA-DR+ cells decreased in RA patients who responded to immunosuppressive therapy ($p = 0.006$). Considered together, mass cytometry and flow cytometry analyses indicated that CD27- HLA-DR+ cells were significantly associated with RA (meta-analysis $p = 4.8 \times 10^{-5}$). CD27- HLA-DR+ cells express a distinctive effector memory transcriptomic program with Th1- and cytotoxicity-associated features and produce abundant IFN- γ and granzyme A upon stimulation (**Figure 1C**).

Conclusion: MASC is a sensitive and well-calibrated statistical method for analyzing high-dimensional mass cytometry data. We used it in an RA case-control study to identify a novel disease-associated CD4+ T cell population. The expansion of a unique CD27- HLA-DR+ effector memory population in RA periphery may represent disease-driving cells and could be ideal for defining the antigenic repertoire in RA. We propose that MASC is a broadly applicable method to perform association testing with single cell data and can help identify other cellular populations that are critical to rheumatic disease pathogenesis.

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The events that underlie the transition from psoriasis (Ps) to psoriatic arthritis (PsA) are not well understood, although up to 30% of Ps patients develop PsA within 8 to 10 years. A biomarker for subclinical joint inflammation in Ps patients would provide a tool allowing earlier intervention. Ultrasound (US) findings of PsA have been reported in Ps patients without MSK symptoms, but the prevalence of these findings varies in different studies, many without healthy controls. One cellular marker, circulating osteoclast precursors (OCP), is significantly higher in Ps than healthy controls (HC). The purpose of study is to analyze and correlate serum, cellular and imaging biomarkers of arthritis in Ps patients and controls to facilitate early interventions and improve outcomes.

Methods: US studies and serologic assessment for OCP and OCP subsets were performed on Ps patients (dermatologist confirmed) and HC. All US studies were performed on a GE LOGIQ E9 unit, and read by a rheumatologist certified in MSK US (RT). A modification of the PsASon system was used including the four domains: I. Joint: gray scale (GS) synovitis, power Doppler (PD) signal, erosion and osteophytes; II. Tenosynovitis: GS and PD; III. Peritendinitis: GS and PD; IV. Enthesitis: tendon structure, thickness, enthesitis associated bursitis, erosion, calcification or PD signal. US assessment included the bilateral radiocarpal and midcarpal joints, MCP joints, IP joints and PIP joints; 4th and 6th extensor compartments, flexor tendons 2-5 for tenosynovitis, extensor tendons 1-6 for peritendinitis; and bilateral elbow, knee, dorsal and plantar calcaneal entheses. Serum 14-3-3 η levels were assayed by ELISA and blood samples were drawn for OCP quantification from purified monocytes after 8-day cell culture. The OCP were quantitated as #TRAP positive cells per 100,000 monocytes.

Results: 150 patients were screened at the University of Rochester and regional dermatology practices. 78 Ps patients (mean age 49.5; mean BMI 31.9; mean disease duration 20 years; f, n=42; m, n=36) and 25 HC (mean age 43; mean BMI 27.3; f, n=17; m, n=8) were enrolled. No subject had symptoms or physical findings of PsA. Complete OCP data were available for 74 Ps and 20 HC subjects. US assessments were obtained in all HC and 75 Ps subjects. The frequency of OCP in the healthy; PDUS- and PDUS+ groups was 649.4 +/- 947.5; 843.6 +/-1545 and 1514.2. Levels of 14-3-3 η were not elevated in patients or controls.

Ultrasound Scores in Psoriasis and Healthy Controls

	Psoriasis n=75	Control n=25
Total modified PsASon score	9.0 \pm 7.7	2.8 \pm 2.3
Joint synovitis sub score	1.9 \pm 1.1	0.0
Joint PD sub score	2.6 \pm 1.9	0.0
Joint PD + GS sub score	4.5 \pm 1.5	0.0
Enthesis PD sub score	4.2 \pm 2.7	0.24 \pm 0.5
Enthesis erosions sub score	4.0 \pm 1.7	0.0

Conclusion: Imaging abnormalities were noted in almost 50% of Ps patients without MSK symptoms. This was significantly higher than in HC. Findings included synovitis, enthesitis and increased PD signals. The frequency of OCP was significantly higher in Ps patients than controls, and most elevated in patients with US findings. Serum levels of 14-3-3 η were not increased in patients or controls. The combination of US findings and elevated OCP has potential to identify Ps patients at risk for developing PsA.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: EULAR recommendations suggest diagnostic imaging in all GCA suspects. Vascular ultrasound (US) is cheap, readily available and the recommended first line examination in cranial GCA (c-GCA). Hence, US is an attractive first line examination also in large vessel GCA (LV-GCA). However, lower incidence of LV involvement is reported in US studies than in PET studies indicating a lower diagnostic sensitivity of US.

In a prospective study of glucocorticoid-naïve patients suspected of new-onset GCA, we evaluated the diagnostic accuracy of axillary artery US in the diagnosis of LV-GCA using 18F-FDG PET/CT as reference standard.

Methods: Patients suspected of GCA were consecutively considered for inclusion. Inclusion criteria were: 1) age ≥ 50 years; 2) CRP > 15 mg/L or ESR > 40 mm/h; 3) either a) cranial symptoms, b) new-onset claudication c) protracted constitutional symptoms d) polymyalgia rheumatica (PMR) symptoms. Main exclusion criteria were: 1) recent or ongoing glucocorticoid or DMARD treatment; 5) previous diagnosis of GCA or PMR ; 6) large vessel inflammation mimicking LV-GCA. Clinical evaluation and imaging was performed before treatment initiation. The reference diagnosis for LV-GCA was a clinical diagnosis of GCA and a 18F-FDG PET/CT revealing aortic and/or subclavian/axillary artery FDG uptake $>$ liver uptake. Patients not diagnosed with GCA were considered controls. US was performed by experienced sonographers, blinded to PET results. Axillary arteries were assessed for the presence or absence of the 'halo sign' and intima media thickness (IMT) was measured. Sensitivity and specificity of the halo sign in axillary arteries was evaluated. ROC curve analysis was performed to estimate axillary IMT cut off.

Results: 86 patients were included (97 screened). 45 were diagnosed with LV-GCA (with or without concomitant c-GCA), 10 with isolated c-GCA, 21 with PMR and 10 with other diseases. Baseline characteristics of LV-GCA and controls are shown in table 1.

None of the controls had a positive axillary US, whereas 36/45 LV-GCA patients were axillary US positive yielding a specificity of 100% (95% CI: 89-100%) and a sensitivity of 80% (95%CI: 65-90%). Of the 73 PET positive axillary arteries in LV-GCA patients, 53 were axillary US positive (sensitivity 72% (95%CI: 61-83%)). Four PET negative axillary arteries were US positive (specificity 95% (95%CI: 87-99%)). An AUC of 0.86 (95%CI: 0.79-0.92) was obtained by ROC curve analysis of axillary IMT with axillary PET diagnosis as a reference. An IMT cut off value of 0.9 mm revealed a sensitivity of 74% and a specificity of 92%.

Conclusion: In the hands of experienced sonographers, axillary arteries US shows high sensitivity and specificity for the diagnosis of LV-GCA which clearly suggests US as a first line imaging test in LV-GCA suspected patients. Suggested IMT cut off confirms findings of previous studies using different reference standards.

Table 1. Baseline characteristics of the cohort

	LV-GCA	Controls (PMR+others)	PMR	others	LV-GCA vs controls*

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Musculoskeletal ultrasound is increasingly being used as a tool to assess inflammatory burden in rheumatoid arthritis (RA). Ultrasound-based outcome measures include power Doppler (PD) and grey scale synovial hypertrophy and have been assessed on fixed sets of between 5 to 78 joints. Although scanning large numbers of joints maybe feasible in clinical trials, it may not be practical in clinical practice. We therefore evaluated a novel patient-specific method for constructing a longitudinal ultrasound outcome measure in RA patients.

Methods: This was a 24 week, phase IV double blind open label clinical trial of 54 patients at 2 clinical centers with RA by 1987 ACR criteria and moderate to severe disease, treated with IV tocilizumab at initial dose of 4mg/kg. Patients not achieving DAS28-ESR_{3.2} at 12 weeks dose escalated to 8mg/kg. Baseline patient characteristics pluslabs, clinical exam of swollen and tender joints, and PD of 34 joints (bilateral MCP 1-5, PIP 1-5, midline and radioulnar wrist, knee, MTP 2-5) at baseline and at 4, 12, 16, and 24 weeks were collected.

Table 1. Correlation between changes in PDUS / rPDUS scores and changes in DAS score from baseline to 4, 12, 16, and 24 weeks.

	DAS28 Δ0-4wks	DAS28 Δ0-12wks	DAS28 Δ0-16wks	DAS28 Δ0-24wks
PDUS/rPDUS Δ0-4wks	0.32* / 0.16			
PDUS/rPDUS Δ0-12wks		0.55* / 0.46*		
PDUS/rPDUS Δ0-16wks			0.32* / 0.28	
PDUS/rPDUS Δ0-24wks				0.42* / 0.37*

* denotes p < 0.05

Table 2. Proportion of joints that flip from having no PD signal at baseline to having PD signal by follow-up at 4, 12, and 24 weeks.

	4 weeks	12 weeks	24 weeks
All Joints	10.0% (123/1235)	8.1% (95/1171)	5.6% (57/1011)
MCP	13.4% (46/343)	10.0% (33/327)	7.1% (20/283)
PIP	7.9% (33/418)	6.6% (26/396)	5.3% (18/340)
Midline Wrist	25% (4/16)	18.8% (3/16)	14.3% (2/14)
Radioulnar	6.8% (3/44)	12.2% (5/41)	8.3% (3/36)
Knee	8.8% (5/57)	13.0% (7/54)	8.3% (4/48)
MTP	9.0% (32/357)	6.2% (21/337)	3.4% (10/290)

Results: At each visit, PD score (PDUS) was computed as the sum of semi-quantitative PD signal for all joints (0-3 per joint, max 102). A novel patient-specific PD score was calculated from the reduced subset of joints with PD \geq 1 at baseline (rPDUS). Pearson correlation coefficients between 1) changes in PDUS and rPDUS versus changes in DAS, and 2) changes in PDUS versus changes in rPDUS were used to assess each outcome measure's response to therapy from baseline to follow-up periods. The proportion of joints without PD signal at baseline that later developed PD signal ("flipped") was estimated.

54 RA patients with mean age 51.9 ± 15.2 years, 91% female, 61.5% Caucasian, 85% seropositive, mean disease duration 10.0 ± 10 years, 72% on background DMARD at baseline were enrolled. At baseline, 1236 of 1829 joints scanned (67.5%) did not have PD signal. Changes in PDUS and changes in DAS were moderately correlated over intervals 0-4 weeks, 0-12 weeks, 0-16 weeks, and 0-24 weeks. Changes in rPDUS also correlated with changes in DAS, though slightly less so than with PDUS (Table 1). PDUS and rPDUS scores were highly correlated with $r = 0.91$ to 0.97 . The overall proportion of "flipped" joints was 8.1% at 12 weeks and 5.6% at 24 weeks, with greatest variability seen in the midline wrist and MTP (Table 2).

Conclusion: In RA patients starting a biologic, scanning only joints with baseline power Doppler synovitis can substantially reduce the number of joints needing to be scanned at follow-up visits. This gain in feasibility comes at a cost of a small reduction in correlation with validated disease activity measures.

Comparison of the Joints Ultrasonography in the Patients with Rheumatoid Arthritis Treated By Biological Agents and the Corresponding Synovial Histological Findings

Asami Abe¹, Hajime Ishikawa² and Kunihiro Wakaki³, ¹Rheumatology, Niigata Rheumatic Center, Shibata, Japan, ²Department of Rheumatology, Niigata Rheumatic Center, Shibata, Japan, ³Pathology, Niigata Prefectural Shibata Hospital, Shibata, Japan

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Comparison of the joints ultrasonography in the patients with rheumatoid arthritis treated by biological agents and the corresponding synovial histological findings

Background/Purpose: In the treatment of Rheumatoid arthritis (RA), early diagnosis and early treatment with tight control have become increasingly important with the advent of biological therapy. Ultrasonography (US) of the various joints enables the real-time evaluation of synovial hypertrophy, effusion and bone erosion, Power Doppler (PD) ultrasound is able to identify both subclinical synovitis and early erosive disease. The objectives of this study were to investigate whether the image of US at the operated joint reflect synovium histopathology or clinical indicators, and to compare the results in the patient treated by non-biological agent (NonBio) and biological agent (Bio)..

Methods: RA related orthopaedic surgery was performed at 1191 joints including 17 shoulders, 144 knees, 92 elbows, 352 wrists, 333 fingers, 34 ankles and 218 toes during the period between January 2011 and May 2018 at our rheumatic center. Preoperatively, ultrasound evaluations were performed and grade of PD signal was determined at the part with the highest signal. PD signal consists 4 grades from grade 0 to 3. The operations were performed within one week after the ultrasound evaluations. Rooney score of the synovium pathology, DAS28-ESR(4), MMP-3, CRP were investigated. Rooney score represents the histologic features in the synovium of RA. It includes 6 features i.e. synoviocytes hyperplasia, fibrosis, proliferating blood vessels, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, diffuse infiltrates of lymphocytes. They were scored separately on a scale of 1-10. The treatments that the patients received included: biological agents (Bio) (n=351 29%), etanercept (ETN) (n= 96), tocilizumab(TCZ) (n=99), infliximab (IFX) (n=25), adalimumab (ADA)(n=26), certolizumab pegol (CZP)(n=8), golimumab (GLM) (n=49), and abatacept (ABT) (n=47), tofacitinib(TOF) (n=1).

Results: PD signal (0.75}{0.89), DAS28(2.77}{1.13), CRP(0.10}{1.22 mg/dL), MMP-3 (104.6}{108.4 ng/mL) and Rooney score (22.1}{7.7) in the patients treated by Bio were significantly lower than those (1.41}{0.96, 3.67}{1.11, 0.79}{1.32 mg/dL, 145.0}{138.2 ng/dL, 28.5}{9.24) in the patients using NonBio. Rooney score fibrosis (9.57}{1.51) in patients using Bio was

significantly higher than those (8.55}2.45) in patients treated by NonBio. Rooney score synoviocyte hyperplasia (0.91}1.27), three items of lymphocyte (1.59}2.91, 1.38}2.49, 0.86}2.27) in patients treated Bio were lower than those (1.73}1.30, 3.84}3.56, 3.70}3.48, 2.47}2.93) in patients treated by NonBio. TCZ, ADA, ABT and IFX had some significant differences for Rooney score and Rooney item score between the patients treated NonBio.

Conclusion: The activity of RA synovitis at operated site was suppressed in patients treated by Bio. There were some differences in clinical data, histopathological score, PD signal and DAS among Bio.

Disclosure: A. Abe, None; H. Ishikawa, None; K. Wakaki, None.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: To evaluate the agreement between ultrasound (US), whole body magnetic resonance imaging (WBMRI) and clinical assessment of joint inflammation and enthesitis in rheumatoid arthritis (RA) patients, by comparison on joint/entheses level and by evaluating the correlation between composite scores at patient level.

Methods: US, WBMRI and clinical assessment for tender joints (TJ) and swollen joints (SwJ) were performed in 19 RA patients (90% Women, median (range) age 55 (26-73), diseases duration 5.5 (1-42), SwJ(28) 5 (1-13), TJ(28) 7 (2-24) and DAS28-CRP 4.66 (3.48 -6.66))) fulfilling ACR 1987 criteria for RA. The 28 conventional joints, bilateral ankles and MTP 1-5, and the entheses of supraspinatus, gluteus muscles, quadriceps and Achilles tendon were assessed by WBMRI and US.

Figure 1. Correlation between US score (for 28 joints (US28)) & whole body MRI score (for 28 joints (WBMRI28)) for assessing joint inflammation.
* Range of score score=US28 (0-14) and WBMRI28 (0-32)

Spearman correlation=0.72, p=0.003

Joint inflammation by US was graded 0-3 on B-mode and colour Doppler (CD), respectively, and subsequently converted to +/- for both components by defining US synovitis as B mode ≥ 2 or CD ≥ 1 . US finding of enthesitis was defined by presence of CD activity $< 2\text{mm}$ from the cortical insertion, with or without erosions, or enthesophytes/calcifications. For WBMRI, joint inflammation was defined as presence of synovitis and/or osteitis, and enthesitis as presence of soft tissue inflammation and/or osteitis. For both modalities, the max score was 2 for a joint and 1 for an enthesis. To assess the total inflammatory burden, a composite score was established as sum scores for the 28 conventional joints for US (US28) and for 26 joints (WBMRI26) for WBMRI - same 28 joints except elbows (due to poor image quality). The agreement between the clinical joint assessment, US and WBMRI for joint inflammation and enthesitis was calculated with Cohen's kappa (κ). The correlations between US28, WBMRI26 and DAS28-CRP were calculated by Spearman correlation coefficient (ρ).

Results: US28 and WBMRI26 sum scores showed good correlation $\rho = 0.72$ ($p = 0.003$) (Fig. 1), whereas US28 and WBMRI26 did not correlate with DAS28 CRP ($\rho = -0.26$, $p = 0.28$; $\rho = 0.20$, $p = 0.47$ respectively). Moderate-good agreement was found between US and WBMRI in wrists and MCP 1, 2 and 5 ($\kappa = 0.42-0.62$) but poor in other joints ($\kappa \leq 0.37$). Agreement between US and clinical joint tenderness was poor (all $\kappa < 0.31$; except $\kappa = 0.42$ for wrist), but better between US and clinical swelling for shoulders, elbows, MCP1 and PIP5 ($\kappa = 0.42-0.66$) while ≤ 0.36 for other joints. Agreement between WBMRI and clinical joint swelling or tenderness showed $\kappa < 0.35$ in all joints. Enthesitis was rare in RA patients, when defined by positive Doppler signal on US (only 3 cases were detected) and hence poor agreement ($\kappa < 0.1$ at all entheses) was found between US and WBMRI.

Conclusion: WBMRI and US sum scores of joint inflammation showed good correlation in RA patients but the agreement at joint level was variable. The agreement on enthesitis between MRI and US was low, but findings were minimal. No correlation with DAS28 was found for either modality.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Imaging of Rheumatic Diseases II: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Plain radiography of knee osteoarthritis (OA) has inherent diagnostic and prognostic limitations, especially in early disease. Ultrasound (US) examination sheds light on disease activity and inflammatory changes in OA, but there is no uniformity or standard for its routine use in evaluation of OA. Our aim is to identify sonographic features that consistently assess burden of disease and predict future OA progression.

Methods: Knee US was performed on OA patients who were enrolled in a study of biomarkers for radiographic progression. We recorded US images of the more painful knee at baseline and both knees at 24 months. Each set of US images was scored semiquantitatively (0-3) for osteophyte size, degree of damage to the femoral articular cartilage (FAC), severity of synovitis/effusions, and popliteal cyst size, and these scores were combined to calculate a composite score (0-12). Weight-bearing knee radiographs taken at baseline and 24 months were scored for Kellgren-Lawrence (KL) grade. Linear regression of each set of the 5 US scores and the corresponding KL scores (with 0 and 24 month readings combined) were run to assess how well each of the US measures trended with KL readings. A second analysis compared the 5 mean *baseline* ultrasound scores for two groups of patients, those with and without KL worsening at 24 months, to identify sonographic predictors of radiographic progression.

Results: US images were obtained on 591 knees from 199 patients at the two time points. There was a significant association between the KL grades and each of the 5 US scores by regression, most significant for osteophytes ($R^2 = 0.396$) and the composite score ($R^2 = 0.334$), all with p -values < 0.001 (see **Figure 1**). In separate t-test analyses of the radiographic

Figure 1. Four different sonographic features and the composite score correlate with radiographic KL grades in knee OA.

Table 1. Ultrasound predictors of radiographic progression in knee OA

Ultrasound Measure (mean score at baseline)	No Progression Δ KL=0 (n=175)	Progressed Δ KL>0 (n=24)	p-value
Synovitis/effusion (0-3)	0.75	1.77	0.072
Femoral Articular Cartilage Wear (0-3)	1.13	1.33	0.513
Osteophyte Size (0-3)	1.08	1.27	0.542
Popliteal Cyst Size (0-3)	0.27	0.75	0.178
Composite Score (0-12)	3.16	4.25	0.049*

progression over 24 months of the more painful knee, the 24 patients whose KL grade worsened (Δ KL>0) had a higher mean baseline US composite score than those whose KL grade didn't change (Δ KL=0) (4.25 vs. 3.16, $p=0.049$). The 4 sonographic subscores were also higher at baseline in patients who later progressed radiographically, but none reached significance (see **Table 1**).

Conclusion: US can be used to reliably identify structural and inflammatory changes in knee OA – often earlier or better than plain radiography. Our cohort also demonstrates that more robust sonographic pathology predicts which patients' knee OA may be more likely to progress overtime. This may be helpful in selecting patients for trials of disease-modifying medications.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Randomized controlled trials currently report benefits and adverse events (AEs) separately, and therefore do not permit comparisons of patients’ overall experiences on one treatment versus another. The purpose of this study is to develop a Global Patient-Reported Outcome Measure (G-PROM) to quantify and compare the distribution of patients’ overall experiences on medications.

Methods: We invited rheumatoid arthritis (RA) patients who were part of an online community to complete a survey, based on Trajectory Mapping (TM) to generate a hierarchy of AEs. The TM survey establishes a hierarchy by enabling patients to indicate whether an AE is worse, better, or no better or worse than a referent AE. TM allows the construction of “equivalence classes” i.e., groups of AEs judged by patients as having a comparable impact on quality of life. We subsequently conducted a second survey in which participants (who did not participate in the initial TM survey) were asked to indicate their preference for pairs of outcomes, where each outcome include both a specified level of benefit [little or no improvement (ACR20 or less), some improvement (between ACR20 and 50), and major improvement (ACR50 and greater)]and an AE (see Figure 1).

Results: 195 participants completed the initial TM survey. The mean age was 53.5 (11.6), 89% were female, and 56% were college graduates. The initial TM survey generated 11 hierarchies of AEs. The final hierarchy (9 levels of AEs ranging from no AEs to serious AEs resulting in irreversible harm) was chosen based on goodness of fit parameters (see Figure 2). 426 participants with similar demographic characteristics completed the second survey. Ratings revealed that when paired with benefits, AEs clustered into 3 main groups: no, mild or manageable AEs (Levels 1-4), moderate AEs (Levels 5-6), and serious AEs (Levels 7-9). Participants’ ratings generated a 5-level hierarchy of global outcomes illustrated in Figure 3.

Conclusion: After validation, G-PROM will enable randomized controlled trials to report the percentage of patients classified into each level; thus, providing patients and their rheumatologists with a much clearer understanding of the range and likelihood of the total effects of competing treatment options on their quality of life.

Figure 1. Example of Paired Comparison Question

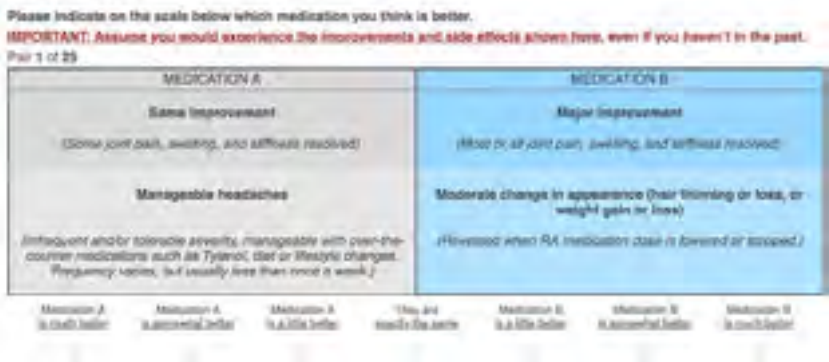

Figure 2. Adverse Events Hierarchy

LEVEL	ADVERSE EVENTS							
1	No AEs							
2	Mild injection site skin reaction or rash							
3	Manageable headaches	Manageable mouth ulcers	Mild infection	Reversible blood test abnormalities	Manageable fatigue	Manageable brainfog/light headedness	Diet-controlled high BP ¹ , DM ² , cholesterol	Mild weight gain, hair loss
4	Manageable depression, anxiety	Manageable stomach pain, diarrhea	Manageable nausea, vomiting	Medication-controlled high BP, DM, cholesterol	Moderate weight gain, hair loss			
5	Cataracts	Curable skin cancer	Severe fatigue	Severe brainfog/light headedness				
6	Severe headaches	Stingies						
7	Serious infection							
8	Serious complication (full recovery)							
9	Serious complication with damage or requiring ongoing treatment							

1. BP = Blood pressure
2. DM = Diabetes mellitus

Figure 3. Global Outcome Hierarchy

LEVEL	GLOBAL OUTCOME		
1 (Best)	Major improvement + No, mild, or manageable AEs		
2	Major improvement + Moderate AEs	Some improvement + No, mild, or manageable AEs	
3	Major improvement + Serious AEs	Some improvement + Moderate AEs	Little or no improvement + No, mild, or manageable AEs
4	Some improvement + Serious AEs	Little or no improvement + Moderate AEs	
5 (Worst)	Little or no improvement + Serious AEs

Mandl⁴, ¹Medicine/Rheumatology, Tufts Medical Center, Boston, MA, ²Hospital for Special Surgery, New York, NY, ³Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, ⁴Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The accurate and efficient serial measurement of patient centered outcomes is a priority in the clinical care of SLE. Patient-Reported Outcomes Measurement Information Systems (PROMIS®) Global Health Short Form (PROMIS10) is a 10-item universal patient reported outcome measure of global physical and mental health with construct validity in SLE. The longitudinal responsiveness (sensitivity to change) of PROMIS10 in SLE patients is unknown. We aimed to evaluate the responsiveness of PROMIS10 in SLE outpatients using patient and physician-derived anchors.

Methods: Adults meeting ACR SLE classification criteria were recruited from an SLE Center of Excellence. Subjects completed PROMIS10 at two visits a minimum of one month apart. SLE disease activity was measured with a patient global assessment of change, a physician global assessment and the physician-derived SELENA-SLEDAI. Responsiveness over time of PROMIS10 scores was evaluated using known-groups validity. Effect sizes of changes in PROMIS global physical health and global mental health scores from baseline to follow up were compared across groups of patients who differed in their patient global assessment of change, physician global assessment, and SELENA-SLEDAI using Kruskal-Wallis tests.

Results: A diverse cohort of 228 SLE patients completed baseline surveys (Table 1), with 190 (83%) completing a follow up survey. Using the patient-based anchor, PROMIS10 demonstrated mild to moderate responsiveness to improvement (effect size 0.29) and worsening (effect sizes -0.27 and -0.54) of health status for both global physical health and global mental health (Table 2). Using the physician global assessment and SELENA-SLEDAI as anchors, there were no statistically significant differences in effect sizes across groups.

Conclusion: PROMIS10 showed responsiveness over time to patient-reported, but not physician-derived changes in lupus health status. These data suggest that PROMIS10 can be used to efficiently measure and monitor important aspects of the patient experience of lupus not captured by physician-derived metrics. Further studies are needed to evaluate the role of PROMIS in optimizing longitudinal disease management in SLE.

Lupus Flare Activity from the Patient Perspective

Winnie Nelson¹, Patricia Katz², R. Paola Daly³, Lauren Topf³, Erin Connolly-Strong⁴ and Michael Reed⁵, ¹Health Economics and Outcomes Research, Mallinckrodt Pharmaceuticals, Bedminster, NJ, ²University of California San Francisco, San Francisco, CA, ³Lupus Foundation of America, Washington, DC, ⁴Mallinckrodt ARD, Inc., Bedminster, NJ, ⁵Vedanta Research, Chapel Hill, NC

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Lupus patients may experience flares in disease activity that require rapid management. This study describes the experience, identification, and management of a flare from the patient perspective.

Methods: An online survey was administered to persons with lupus who responded to outreach from the Lupus Foundation of America or the Research Now survey research service. Data collection included sociodemographic characteristics, flare profile, the Lupus Impact Tracker (LIT), and hospital admissions. The results were summarized with descriptive statistics.

Results: 1503 individuals with self-reported lupus completed the survey from May to October 2017. 77% were Caucasian, 89% were female, mean age was 45 yrs, mean duration of illness was 12 yrs, and 19% reside rurally. 78% had flare activity in the past year. Of these, half reported 4 or more flares, and 66.9% perceived their flares as moderate to severe. The most common flare symptoms (**Figure 1**) were extreme fatigue/exhaustion (87%), aching/increased swelling of the joints (80%), and muscle weakness/pain (73%). Respondents who suffered more flares had worse LIT scores and more hospital admissions during the past year (**Figure 2**). Many respondents (48%) could not predict when a flare would occur but noted that flare triggers were events such as emotional stress, overdoing it, lack of rest, and sunlight exposure. 40.5% engaged the healthcare system, such as doctor, ER, or hospital, when suffering a flare. 54% self-treated flares, most frequently with over-the-counter products and prescription drugs kept on hand. For the most recent flare 34.8% delayed seeking care for 3

Figure 1: Flare symptom frequency among respondents with flare activity in the past 12 months (n=1174)

Figure 2: Flare frequency stratification and corresponding mean results for LIT and number of past year hospital admissions for lupus among respondents with flare activity in the past 12 months (n=1174)

Figure 3: Flare management strategies among respondents with flare activity in the past 12 months (n=1174)

Legends (Stress 7.4%, Acupuncture 5.8%, Diet/Herbs 3.1%, Acupuncture 2.8%, Massage 2.9%, Diet/Herbs 2.8%)

days or longer (24.3% of urban residents, 41.9% of rural); more than half did not receive care within 24 hours (46.1% of urban, 62.2% of rural). **Figure 3** shows various tactics used to manage flares.

Conclusion: Lupus flare burden is high, and flares often resulted in healthcare encounters and medication use. The most common flare symptoms may not be congruent with how clinicians define flares, leading to communication challenges. Patients appear to be receptive to self-treatment, presenting an opportunity to enhance their self-care skills. Findings provide insight into how clinicians and patients can work together to identify and manage flares more effectively.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

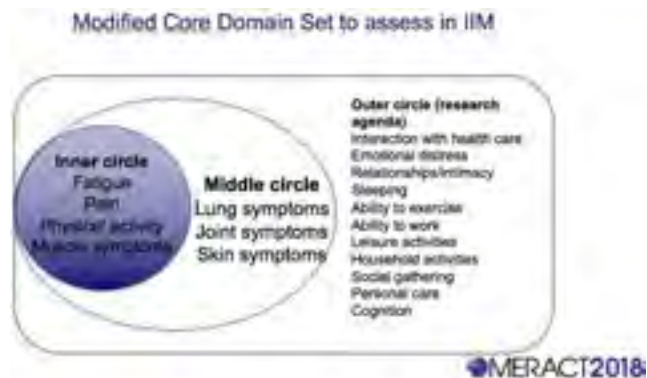

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

A Draft Modified Core Domain Set for Patient-Reported Outcomes (PRO) in Patients with Idiopathic Inflammatory Myopathies (IIM): An OMERACT Report

Background/Purpose: The OMERACT Myositis special interest group (SIG) represents clinicians, patients, and researchers from four continents. Focus groups were conducted including 61 patients on three countries resulting in a list of 26 domains (1). In collaboration with International Myositis Assessment Clinical Study Group (IMACS), our goal was to identify a set of core patient-reported outcomes (PRO) in regards to life impact important to assess in clinical trials and clinical practice in myositis.

Methods: Patients with adult polymyositis, dermatomyositis, antisynthetase syndrome, or immune-mediated necrotizing myopathy (IMNM) in South Korea, Sweden and USA (N=638) responded to the first online modified Delphi in 2016. The second modified Delphi included patients (N=563), healthcare providers (HCP) (N=101), care givers (N=27) and

regulatory agencies (n=xx) from multiple countries in 2017. A third modified Delphi was administered in 2018 including 410 patients, 109 HCP, 22 caregivers.

Results: From this work, four domains were deemed mandatory to measure in all clinical trials for IIM: fatigue, pain, levels of physical activity, and muscle symptoms (Figure 1). Additional optional domains include skin symptoms, lung symptoms, and joint symptoms. Several other domains were deemed important to study with further research efforts including sleeping difficulty, cognitive distress, ability to work, and emotional distress.

Conclusion: A draft set of core PRO has been developed through validated methods based on OMERACT guidelines. Fatigue, pain, levels of physical activity and muscle symptoms were included in the inner circle and should always be used in clinical trials in IIM. We next seek to develop corresponding instruments with each of these domains with future efforts. Reference: Regardt M et al. Patients' experience of myositis and further validation of a patient-reported outcome measure – establishing core domains and expanding patient input on clinical assessment in myositis. Report from OMERACT 12. J Rheumatol 2015;42:2492-5.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: PROMIS (Patient-Reported Outcomes Measurement Information System) measures have not been tested in psoriatic arthritis (PsA). We examined the reliability, validity and responsiveness of the PROMIS Fatigue (PR-FAT) 4-item short form in PsA and developed estimates of the minimally important difference (MID).

Methods: Data were from Forward/National Data Bank for Rheumatic Diseases. Participants complete questionnaires every 6 months. PR-FAT was included in five administrations. Changes were calculated for consecutive questionnaire administrations, yielding four change periods. Cronbach's α tested internal consistency. Construct validity was assessed by examining correlations of PR-FAT with other measures of fatigue and other patient-reported outcomes. Responsiveness was examined using changes in self-rated fatigue, self-rated health and satisfaction with health as anchors, and

standardized response means (SRMs) were calculated. MIDs were estimated using both anchor- and distribution-based methods.¹ Anchor-based analyses used comparisons of overall health to 6 months ago (rated as much better, somewhat better, neither better nor worse, somewhat worse, much worse).² Four sets of analyses were conducted: physician-confirmed PsA only without concomitant osteoarthritis (OA) or rheumatoid arthritis (RA) (n ranged from 60–78 in the 5 administrations) and with RA/OA (n: 102–129), and physician-confirmed PsA plus self-reported PsA without RA/OA (n: 111–148) and with RA/OA (ALL_PsA; n: 192–245).

Results: Findings were similar for all groups, so only results for ALL_PsA are shown. Table 1 shows characteristics of respondents. Cronbach's α was ≥ 0.94 for each administration. Concurrent validity analyses showed high correlations with self-rated fatigue (≥ 0.72), moderate correlations with pain (r: 0.45–0.66) and function (r: 0.34–0.58) and significant differences among self-rated health groups ($p < 0.0001$). In responsiveness analyses, all SRMs were > 0.3 . Estimates of MID are shown in Table 2.

Conclusion: PR-FAT appeared to be reliable and valid in this sample with PsA. SRMs in responsiveness analyses met the criterion generally accepted as adequate (0.3).³ The MID appears to be similar to those reported for other PROMIS scales. This information supports the use PR-FAT in PsA and provides important information to facilitate interpretation of scores.

Can Passively-Collected Phone Behavior Determine Rheumatic Disease Activity?

Kaleb Michaud, Sofia Pedro and Rebecca Schumacher, FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Advances in reality mining combined with the pervasive use of smart phones have shown measurable changes in phone behavior due to changes in health. We sought to determine if passively collected digital measures could predict patient-reported outcome (PRO) measures in patients with rheumatic diseases.

Methods: Participants were a subset of adult smart phone users enrolled in Forward, The National Databank for Rheumatic Diseases during 2013-2015. They used a custom smart phone app that collected daily passive digital measures including GPS-tracked mobility (single path) and mobility radius (circle that included all daily mobility). Users with Android OS phones also provided number and duration of calls and texts. PROs included daily pain and global assessment and weekly HAQ-II and PAS-II. Disease flares were regularly self-reported. Statistics included linear mixed effect models (MRM) with random slope for days for PROs and logistic GEE (for flares). Best models were selected using stepwise. Moving averages (MA) of the prior week were applied to the log-transformed passive data. Possible confounders accounted for included patient demographics, clinic measures, and seasonal factors.

Results: Of the 446 participants, 292 (66%) had rheumatoid arthritis (RA). They were mostly female (91%), of middle age (54 ± 12 yrs) with moderate disability (HAQ-II 0.8 ± 0.6) and comorbid illness (RDCI 2.3 ± 1.7); 44% were treated with biologics. The MA of text length was most strongly and inversely associated with PROs including weekly pain ($\beta = -0.15$, 95%CI -0.26, -0.05). MA of mobility measures were significantly associated with global, HAQ-II, and PAS-II, but not pain. Table 1 shows estimates in RA from the MRM model for passive phone data keeping other variables at mean values. Flare incidence was significantly associated with the MA of mobility radius (OR = 0.92, 95%CI 0.86, 0.98).

Conclusion: Digital measures collected via smart phone may be a less intrusive means to identify worsening in patients with RA and other rheumatic diseases. Additional studies should confirm and expand these findings.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The Juvenile Arthritis Disease Activity Score (JADAS) and its clinical version excluding the acute phase reactant (cJADAS) were developed for measuring disease activity in children with juvenile idiopathic arthritis (JIA). Cutoffs for the state of remission, low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) are necessary to interpret the scores. Aiming to obtain cutoffs suitable for any clinical setting, new values were recently developed for JADAS10 and cJADAS10 in oligoarthritis and polyarthritis, based on a large multinational dataset (Consolaro A, et al. *Arthritis Rheumatol.* 2017; 69s10). Aim of the study is to externally validate the new cutoffs for JADAS10 and cJADAS10 disease activity states.

Methods: Four JIA patients dataset were considered: 1) 4397 oligoarthritis and polyarthritis patients from the EPOCA study; 2) 148 oligoarthritis patients from the TRIMECA trial; 3) 172 polyarthritis patients from the Abatacept trial, 4) 113 patients first starting methotrexate from a monocentric retrospective cohort (Swart et al, *Ann Rheum Dis.* 2018;77:336-342). Face validity was assessed in dataset 1) by plotting the proportion of patients in remission and LDA against the values of the 6 parameters in the ACR JIA core set. Discriminative ability was assessed in datasets 2) and 3) by comparing the percentage of patients below the cutoff values in the different ACR pediatric categories of response. In dataset 1) we compared in each disease activity state, the level of pain (0-10 VAS), functional ability impairment, and number of restricted joints and the frequency of patients satisfied with disease outcome, starting a new medication for JIA, and having morning stiffness. Predictive ability was assessed in dataset 4) by calculating sensitivity and specificity of the cutoffs for remission and LDA after 3 months for treatment response after 12 months.

Results: Only most relevant results are described. JADAS10 and cJADAS10 cutoffs for remission allowed up to 1 active joint for polyarthritis and 0 for oligoarthritis. In dataset 2), 42% and 63% of patients achieving an ACRp70 response met the JADAS10 cutoffs for remission and LDA, respectively. In dataset 3), these percentages were 48% and 82%, respectively. In dataset 1), the median level of pain was 0, 1.5, 3, and 5.5 for polyarthritis patients in cJADAS10 remission, LDA, MDA, and HDA, respectively (Kruskal-Wallis $p < 0.001$). The frequency of satisfaction with disease outcome was 94%, 76%, 56%, and 24% for oligoarthritis patients in cJADAS10 remission, LDA, MDA, and HDA, respectively (Chi2 test $p < 0.001$). In dataset 4), 100% and 71% of patients with oligoarthritis classified as non-responders after 12 months had JADAS levels after 3 months above the cutoffs for remission and LDA, respectively. For polyarthritis, 90% and 80% of non-responders had JADAS levels after 3 months above the cutoffs for remission and LDA, respectively.

Conclusion: New JADAS cutoffs showed good face and content validity; achievement of remission and LDA defined by the cutoffs predicted the response to therapy. Cutoffs were developed and validated in a large multinational dataset and they are ready for use in clinical trials and routine practice.

Multiplex Serum Biomarker Analysis before and during Therapy with Canakinumab in Patients with Systemic Juvenile Idiopathic Arthritis

Tanja Hinze¹, Christoph Kessel¹, Claas Hinze¹, Julia Seibert², Hermann Gram² and Dirk Foell³, ¹Department of Pediatric Rheumatology and Immunology, University of Muenster, Muenster, Germany, ²Novartis, Basel, Switzerland, ³Pediatric Rheumatology and Immunology, University of Muenster, Muenster, Germany

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Canakinumab (CAN), a monoclonal anti-interleukin (IL)-1 β antibody, is approved for the treatment of systemic juvenile idiopathic arthritis (SJIA). CAN-treated patients with SJIA showed a high treatment response rate in an open-label long-term extension study. However, little is known about the correlation of various serum biomarkers in patients with different treatment outcomes.

Methods: Serum samples from 54 patients treated with CAN in the open-label long-term extension study were studied in a 14-plex bead array assay (Luminex) at different time points during the clinical trial, including days 1 (prior to first administration of CAN), 3 and 15, and months 1, 3, 6, 12, 18 and 24. Treatment outcomes included (1) a modified pediatric American College of Rheumatology (pACR) 90 response within 15 days of treatment with CAN and (2) an pACR100 response or clinical inactive disease within 15 days plus no disease flare or macrophage activation syndrome (MAS) during the study (=sustained complete response). Biomarker data, multiple clinical parameters and treatment outcomes were analysed using rank correlation, two-group comparisons via non-parametric testing (Mann-Whitney U test), receiver operating characteristic (ROC) analysis and hierarchical clustering.

Results: Twenty-six of 54 patients (49%) reached a modified pACR90 response within 15 days. Within a median follow-up of 23 months (range 0.5-32 months), 12 of 54 (22%) patients had a sustained complete response and 5 (9%) had developed MAS. Several biomarkers were moderately to strongly associated with each other prior to initiation of CAN therapy (Spearman rank correlation coefficient highest for interferon (IFN)- γ and IL-18: 0.90). Biomarkers did not correlate significantly with age, duration of disease or active joint count. Several biomarkers (IL-1 β , IL-18, IL-6 and S100A12) were markedly elevated when compared to healthy controls and decreased during CAN therapy. There were significant differences in day 1 CXCL9 levels between patients exhibiting an pACR90 response by day 15 (responders: median 296 pg/ml, non-responders: 709 pg/ml, $p < 0.01$). Further, day 1 levels of CXCL9, IL-7 and IL-18 as well as the CXCL9:IFN- γ ratio differed between sustained complete responders and those without sustained complete response (CXCL9 median: 278 pg/ml vs. 566 pg/ml; IL-7: 12.3 pg/ml vs. 7.4 pg/ml; IL-18: 1700 pg/ml vs. 556 pg/ml; CXCL9:IFN- γ ratio: 0.12 vs. 0.50). As determined via ROC analysis, these markers had moderate accuracy in predicting a sustained complete response (area under the curve: for CXCL9 0.72, CXCL9:IFN- γ ratio 0.79, IL-18 0.73, IL-7 0.83). Several clusters were apparent but not clearly related to clinical outcomes.

Conclusion: Several serum biomarkers measured prior to and shortly after initiation of CAN therapy in patients with SJIA showed an association with treatment response. Lower CXCL9 serum concentrations, a lower CXCL9:IFN- γ ratio, and higher IL-18 and IL-7 serum concentrations measured before CAN therapy were moderately associated with a better treatment response.

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Physical activity (PA) is an important component of health, and is essential for optimal growth and development. Children with juvenile idiopathic arthritis (JIA) are reported to have lower PA levels than healthy peers, but most reported studies are cross-sectional and have included small patient numbers. The LEAP study is a large prospective study of children and youth with JIA, conducted at 12 centres in Canada, that aims to describe the trajectory of PA and its relationship to disease factors, quality of life, inflammation, and bone and muscle function. Here we report baseline PA at the time of LEAP study entry, and its association with these factors in children with JIA compared to healthy peers.

Methods: All patients with definite JIA (ILAR criteria) enrolled in the LEAP study between 2012-2015 who completed baseline visits were included. Patients had either newly diagnosed JIA (enrolled within 6 months of diagnosis), or previously diagnosed JIA (enrolled > 2yrs after diagnosis). The Physical Activity Questionnaire (PAQ) was the primary outcome. This 7 day self report tool is scored from 1 (very low PA) to 5 (high PA). We compared the PAQ for JIA patients to standard population normative values. The clinician completed demographic and clinical data, including a physician global assessment of disease activity (PGDA; VAS 0-100), while patient/parent-report outcomes included the Juvenile Arthritis Quality of Life Questionnaire (JAQQ), and the Childhood Health Assessment Questionnaire (CHAQ). Descriptive statistics and tests of association were performed using STATA.

Results: Of the 573 patients included (69% female, mean age 12.1 \pm 2.6 yr), 166 had newly diagnosed JIA and 407 had previously diagnosed JIA (median disease duration 0.3 and 5.8 yr respectively). The mean PAQ score was lower overall for children with JIA (mean 2.61, SD 0.75) compared to a healthy population (mean 2.75, SD 0.6) ($p < 0.001$). Newly diagnosed JIA patients had a lower PAQ score (median 2.54, IQR 2.4, 2.6) than those with longer disease duration (median 2.64, IQR 2.5, 2.7) ($p = 0.003$). PAQ score varied significantly ($p = 0.0059$) by JIA disease subtype, with lowest scores in patients with RF + polyarthritis (PAQ 2.15, IQR 1.9, 2.39) and enthesitis related arthritis (PAQ 2.48, IQR 2.29, 2.67); children with systemic JIA, oligoarticular persistent, psoriatic and undifferentiated subtypes had mean PAQ scores higher than 2.65. Variables associated with lower PAQ score included older age, higher number of active joints, and worse PGDA, JAQQ and CHAQ scores. Self-reported pain and gender were not associated with the PAQ score.

Conclusion: This large pan-Canadian study confirms that children with JIA have lower PA levels than healthy peers. PA is lower at diagnosis and in early disease compared to later in disease, and children with RF+ polyarthritis and ERA have lower PA levels. Children and youth with higher disease activity report lower PA, lower functional status and lower health related quality of life.

An Epidemic: Severe Lung Disease in Patients with Systemic Juvenile Idiopathic Arthritis, Risk Factors and Predictors

Shima Yasin¹, Christopher Towe^{2,3}, Ndate Fall⁴, Alexei Grom^{3,4} and Grant Schultert^{1,5}, ¹Rheumatology, Divisions of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ²Pulmonology, Division of Pulmonology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ³Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH, ⁴Division of Rheumatology, Divisions of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ⁵Pediatrics, Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

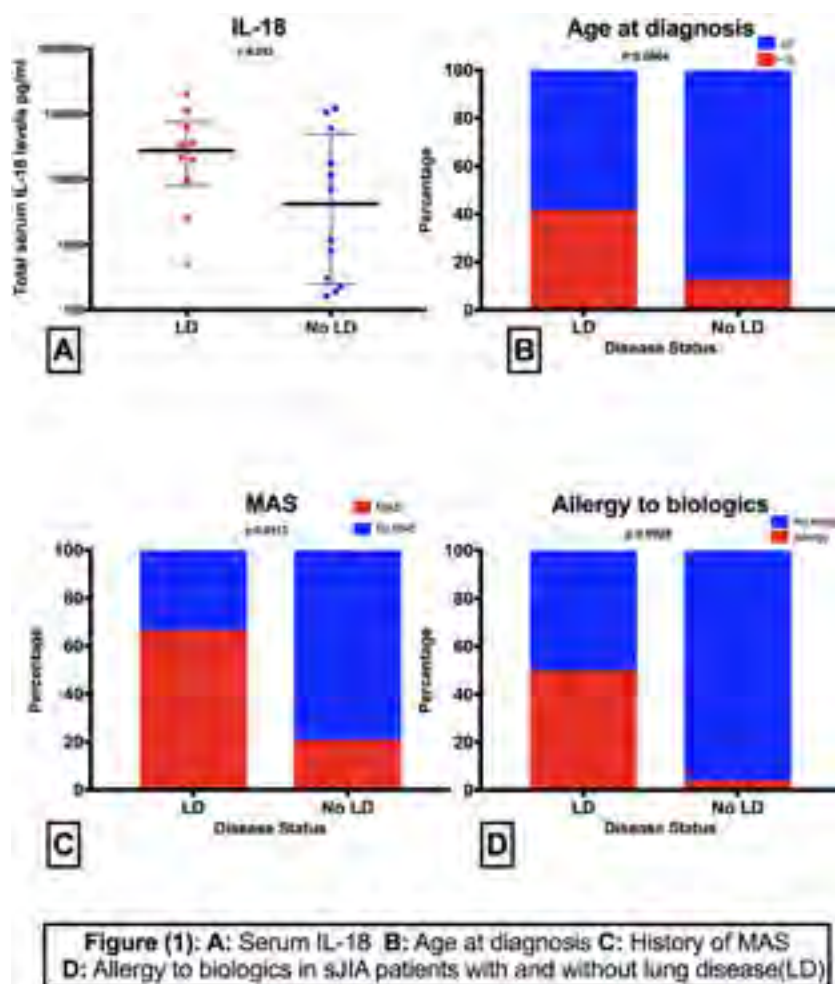

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: There is growing awareness of severe and often fatal chronic lung disease in patients with systemic juvenile idiopathic arthritis(sJIA). However, clinical features and risk factors for sJIA- associated lung disease are poorly characterized.

Objectives: 1- Describe clinical characteristics and immunological findings in patients with sJIA- associated lung disease.
2- Determine risk factors and predictors of lung disease in sJIA patients.

Methods: This study was approved by CCHMC Institutional Review Board, and informed consent was obtained from all patients. Clinical data was abstracted from medical records. We matched 12 sJIA patients with chronic with lung disease to

24 controls without lung disease using current age and gender (1:2) in a case-control design. We used Fischer exact and T-test for comparisons.

Results: Since 2010, we evaluated 12 patients (including second opinion) with sJIA-associated lung disease. Nearly half (5/12) were evaluated over the last year. In the last 5 years 74 patients with sJIA have had their primary rheumatology care at CCHMC. Of those patients, 6 developed lung disease, indicating both increased detection and an incidence as high as 8%.

In our cohort, 83% of patients with lung disease (10/12) were diagnosed with sJIA before age 5 (42% before age 2). Median age at diagnosis was 2.5 years (IQR: 0.75-4.25). When compared to controls, lung disease patients were diagnosed with sJIA at younger age, many before age 2 (OR: 5, $p=0.08$) (Figure 1-B). In the majority (75%) lung disease symptoms started within 1 year of diagnosis with mean time from sJIA onset to lung disease diagnosis of (1.65 ± 1.26). Interestingly, all patients with lung disease presented with prominent systemic features and two-thirds (66.6%) have history of macrophage activation syndrome (MAS). Compared to controls, lung disease patients were significantly more likely to have had MAS with OR of 7.6 ($p=0.0113$) (Figure 1-C). They also had markedly elevated IL-18 levels (Median 27,612.0, IQR: 9746-63,417). IL-18 levels were higher than those in patients with active sJIA without lung disease (Median 7194 IQR: 907-60,260 ($p:0.032$)), but when compared to age-matched controls it did not achieve significance ($P:0.093$) (Figure 1-A).

Moreover, significantly more patients with lung disease (6 patients) developed allergic/anaphylactic reaction to one of the cytokine-targeted biologics (mostly tocilizumab) with an OR of 23 ($p:0.0028$) (Figure 1-D).

Conclusion: Severe lung disease is increasingly recognized in children with sJIA, particularly in those presenting at younger age, with prominent systemic features, history of MAS, or allergy to biologics. These patients also tend to have ongoing chronic inflammation with highly elevated IL-18 levels. Early screening and expedited work up of this fatal complication is prudent especially in patients with before mentioned risk factors.

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Interferons (IFNs) seem to play an important role in the pathogenesis of juvenile dermatomyositis (JDM). We previously reported that expression of both type I and type II IFN related genes is increased in muscle biopsies of JDM patients and correlates with histological and clinical features of the disease. Interferon regulated genes (IRGs) have also been reported to be upregulated in peripheral blood of JDM patients and could represent valuable biomarkers of disease activity. The aim of this study was to investigate expression of IRGs (measured as type I IFN score), as well as serum levels of two type I and type II IFN induced chemokines (CXCL9, CXCL10) in peripheral blood of JDM patients and to assess their correlations with clinical and laboratory findings.

Methods: We collected 125 blood samples from 28 JDM patients at different time points during follow-up. We measured expression of IRGs (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) by quantitative PCR (qPCR) and calculated the type I IFN score; serum levels of CXCL9 and CXCL10 were analyzed by ELISA. At each visit, the following clinical data were recorded: physician's global assessment of disease activity VAS (Visual Analogue Scale), cutaneous VAS, Cutaneous Assessment Tool (CAT) activity score, Childhood Myositis Assessment Score (CMAS), serum levels of creatine phosphokinase (CK, IU/l), antinuclear antibody (ANA) status, presence of myositis specific or myositis associated antibodies (MSA/MAA), prednisone (or equivalent) dose (mg/kg/daily) ongoing immunosuppressive medications.

Results: Type I IFN score was significantly higher in patients with features of active disease (physician's global VAS >0.2, CAT activity score ≥ 1 , CK >150 IU/l). CXCL10 levels were significantly higher in patients with features of active muscle disease (CMAS <46, CK >150 IU/l) whereas CXCL9 levels were significantly higher only in patients with abnormal CK levels. In a multilevel mixed effect approach, type I IFN score was significantly associated with physician's global VAS, cutaneous VAS, CAT activity score, CMAS and CK levels; CXCL9 showed no significant association with the evaluated clinical features; CXCL10 levels were significantly associated with CK levels and CMAS. Including time from disease onset to sampling did not change the results. Immunosuppressive medications negatively modulated expression of IRGs and IFN induced chemokines.

Conclusion: Our findings indicate that expression of IRGs, measured as type I IFN score, and serum levels of CXCL10 reflect specific features of disease activity in JDM, further supporting their role as valuable disease biomarkers.

The Performance of the Newly Proposed EULAR/Acr Classification Criteria in Juvenile-Onset Systemic Lupus Erythematosus

Sezgin Sahin¹, Sule Bektas¹, Amra Adrovic¹, Oya Koker², Kenan Barut¹ and **Ozgur Kasapcopur³**, ¹Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey, ²Istanbul University, Istanbul Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey, ³Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: To avoid misclassifications, a new set of classification criteria have been developed by the collaboration of the EULAR/ACR and the draft was presented at the 2017 ACR/ARHP Annual Meeting. To compare the sensitivity and specificity of the new EULAR/ACR criteria with those of the 1997 ACR criteria and 2012 SLICC criteria in juvenile-onset SLE patients.

Methods: Juvenile SLE patients initially were evaluated by ACR-1997, SLICC-2012 and EULAR/ACR classification criteria at baseline. The diagnostic sensitivity of the three sets of classification criteria were further tested within 1 year of diagnosis and at last patient visit, longitudinally. Subjects with a clinical diagnosis other than SLE for at least 1 year-period, consecutively enrolled as controls.

Results: A total of 104 juvenile-onset SLE patients were enrolled for the sensitivity performance of classification criteria at diagnosis and 104 controls (69 juvenile idiopathic arthritis, 9 juvenile systemic sclerosis, 5 juvenile dermatomyositis, 1 mixed connective tissue disease, 15 vasculitis and 5 other diseases) for specificity at their last visit. Since the follow-up period was less than 1 year, 12 SLE subjects excluded after baseline evaluation. Finally, 92 SLE subjects were eligible for sensitivity evaluation within 1 year of diagnosis and at last visit. The median age of the SLE patients at diagnosis of clinician was 13.0 years (range 3.1–17.9 years, interquartile range (IQR) 11.1–16.5 years) with median disease duration of 5.0 years (IQR 3.0-8.0 years). The female-to-male ratio was 4.7:1. The newly developed EULAR/ACR classification criteria were more sensitive than SLICC-2012 and ACR-1997 at diagnosis (93.3% versus 91.3% and 85.6%, respectively), and at first year (95.7% versus 94.6% and 90.2%, respectively ($p > 0.05$)). At last visit the sensitivity of the new set of criteria and SLICC-2012 were same (97.8 %), but higher compared to ACR-1997 criteria (95.7%). Specificity of the EULAR/ACR criteria (86.5%, $n=90$) were found to be higher than SLICC-2012 (81.7%, $n=85$). Compared to SLICC-2012, an additional 5 subjects among 104 controls without SLE succeeded to get rid of misclassification as SLE by the newly developed criteria. However, the performance of the new EULAR/ACR criteria in diagnostic specificity (86.5%), could not reach the level of ACR-1997 criteria (89.4%).

Conclusion: Juvenile-onset systemic lupus erythematosus was classified by the newly proposed EULAR/ACR criteria with higher sensitivity compared with SLICC-2012 and ACR-1997 at disease onset and within one year of diagnosis. However, last visit assessment demonstrated equal sensitivity between new EULAR/ACR criteria and SLICC-2012. Although the difference was not significant, the new set of criteria seems to be capable of recruiting more children with juvenile SLE to clinical trials. The performance of the newly developed criteria seems more successful in specificity compared to the

SLICC-2012. Application of the newly developed EULAR/ACR criteria to the juvenile-onset SLE patients resulted in higher sensitivity and specificity compared to SLICC-2012.

Session Date: Wednesday, October 24, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Osteitis condensans ilii (OCI) is regarded to as a non-inflammatory disorder induced by mechanical stress and mechanical instability of the sacroiliac joints (SIJ). OCI is being increasingly recognized as an important differential diagnosis for axial spondyloarthritis (axSpA), due to onset at young age, possible inflammatory character of back pain and recently described presence of subchondral bone marrow edema on magnetic resonance imaging (MRI) of the SIJ. The objective of the study was to compare active and chronic inflammatory lesions of the SIJ as detected by MRI in patients with OCI and axSpA.

Methods: Using medical database search we identified n=103 patients aged ≥ 18 years who were diagnosed with OCI upon presentation with chronic back pain and suspicion of axSpA. A total of 27 patients had evaluable MRIs of the SIJ in STIR and T1-weighted sequences that were used for the current study. These patients were matched according to the back pain duration to 27 patients with definite axSpA. MRIs were scored in a blinded fashion according to the Berlin scoring system for osteitis, fatty metaplasia, erosions, sclerosis and ankylosis independently by 3 trained and calibrated readers. In addition, the preferential localization of lesions (ventral, mid, or dorsal part of the SIJ) was recorded.

Results: There were no differences either in the osteitis score or in the proportion of patients with presence of osteitis on MRI of the SIJ between OCI and axSpA patients (table). The fatty metaplasia score was significantly lower in OCI as compared to axSpA, although the difference in the prevalence of the fatty lesions did not reach the level of statistical significance. There was a non-significant trend towards a higher sclerosis score in OCI patients. Importantly, there was a highly significant difference in the erosion score and in the prevalence of erosions: only 2 (7.4%) OCI vs. 18 (66.7%)

Table 1. MRI findings in the sacroiliac joints in patients with osteitis condensans ilii (OCI) and with axial spondyloarthritis (axSpA).

MRI findings		OCI	axSpA	p-value ^{***}
		N=27	N=27	
Osteitis	Osteitis score (0-24), mean \pm SD	3.8 \pm 2.3	4.4 \pm 4.1	0.89
	Osteitis present*, n (%)	25 (90.2%)	23 (85.2%)	0.351
Fatty metaplasia	Fatty metaplasia score (0-24), mean \pm SD	2.0 \pm 2.3	4.5 \pm 6.7	0.001
	Fatty metaplasia present*, n (%)	14 (51.9%)	20 (74.1%)	0.158
Erosions	Erosions score (0-6), mean \pm SD	0.2 \pm 0.4	3.0 \pm 2.3	<0.001
	Erosions present*, n (%)	2 (7.4%)	18 (66.7%)	<0.001
Ankylosis	Ankylosis score (0-2), mean \pm SD	0	0.3 \pm 0.7	0.040
	Ankylosis present*, n (%)	0 (0%)	4 (14.8%)	0.111
Sclerosis	Sclerosis score (0-2), mean \pm SD	1.4 \pm 0.6	1.0 \pm 0.8	0.055
	Sclerosis present*, n (%)	24 (88.9%)	19 (70.4%)	0.175

The absolute lesion scores represent mean values of 3 readers.

* Score ≥ 1 in the opinion of at least two readers.

** Mann-Whitney U-test for the scale variable or Fisher's exact test for the categorical variables.

axSpA patients had at least one erosion (table 1). Importantly, none of the OCI patients had high-grade (>5 erosions) erosive changes.

There were substantial differences concerning localization of the lesions: in OCI, ventral localization was recorded in 96% of the cases for osteitis, in 100% for fatty metaplasia, and in 96% for sclerosis, while in axSpA, osteitis was preferentially localized in the ventral part only in 29% of the cases, fatty metaplasia in 25%, sclerosis in 29% ($p<0.001$ for all comparisons vs. OCI). Ankylosis and erosions were localized in the mid part in almost all cases.

Conclusion: MRI of sacroiliac joints in OCI is characterized by preferential ventral localization of lesions (osteitis, fatty metaplasia, and sclerosis), absence of ankylosis and absence of extended erosive changes. Such a findings constellation should be taken into account as suggestive of OCI for the differential diagnosis of axSpA in clinical practice.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Axial inflammation is a key feature in axial spondyloarthritis(axSpA). An (overall) definition of bone marrow oedema (BMO) on the MRI of the SIJ(MRI-SIJ) has been proposed by ASAS (i.e. considering all 8 anatomical quadrants (Q) of both SIJ together). This study aims to investigate how BMO evolves over time at the quadrant level by comparing several patterns of inflammation and their possible impact on clinical and structural outcomes.

Figure. Graphical representation of examples (of the multiple possible combinations) of presentation of BMO throughout time (baseline, 2 and 5 years) across 8 SIJ quadrants and combined into four patterns. **Persistent BMO:** Constant BMO, in at least one quadrant (e.g. 1-1-1, and no fluctuating pattern in the remaining quadrants). **Fluctuating BMO:** Fluctuating BMO at any of the 8 quadrants (e.g. 1-0-1 or 0-1-0 across observations), regardless of the pattern of BMO in the remaining quadrants; **Other:** Other pattern of BMO (not included in the previous) (e.g. 1-1-0 in one quadrant); **No BMO:** No BMO at any observation (0-0-0, in all quadrants).

Table. Clinical and imaging features at 5 years comparing the different BMO change patterns* (n=136)

	Persistent BMO (n= 14; 10.3%)	Fluctuating BMO (n=17; 12.5%)	Other pattern of BMO (n=42; 30.9%)	No BMO (n= 63;46.3%)	p-value§
ASDAS-CRP	2.0 (0.9)	1.5 (0.9)	2.0 (0.9)	2.0 (0.9)	0.18
CRP mg/L	6.4 (6.0)	4.6 (5.7)	3.8 (4.7)	3.2 (2.6)	0.03
BASFI (0-10)	2.0 (1.6)	1.2 (1.7)	1.9 (2.0)	2.3 (2.2)	0.27
BASMI (0-10)	2.5 (1.4)	1.9 (0.5)	2.3 (0.9)	2.4 (0.8)	0.31
ASQoL (0-18)	6 (4.6)	4.4 (4.5)	6.3 (5.3)	7.4 (5.2)	0.17
mNYC (%)	6 (46)	6 (35)	10 (24)	5 (9)	<0.05
mNYC continuous (0-8)	3.4 (2.6)	2.4 (2.0)	1.9 (1.9)	1.0 (1.4)	<0.01
mSASSS (0-72)	4.9 (11.5)	0.2 (0.5)	1.0 (2.5)	1.0 (3.1)	0.33
N Syndesmophytes	1.7 (3.8)	0 (0)	0.2 (1.0)	0.3 (1.0)	0.05
SPARCC SU (0-72)	8.5 (5.8)	6.3 (7.5)	2.4 (4.1)	0.1 (0.3)	<0.01
MRI-SIJ ≥ 5 fatty lesions or erosions (%)	7 (50)	8 (47)	12 (29)	3 (5)	<0.01

*Detailed in Figure. Mean (SD) or n (%). §For categorical variables chi2 was used; for continuous Kruskal-Wallis H test was used.

Methods: Patients from the DESIR cohort (early axSpA according to the rheumatologist) with MRI-SIJ available at baseline, 2 and 5 years were included. Each image was scored by 3 trained central readers blinded to chronological order. BMO was considered positive if detected (by $\geq 2/3$ readers) in $\geq 1/6$ slices in each of the 8 quadrants and per timepoint. Four different patterns of BMO throughout time were defined (persistent same Q BMO, persistent fluctuating Q BMO, other pattern of BMO and no BMO) considering all 8 quadrants (Figure). The four groups were compared in terms of clinical and imaging outcomes at 5 years.

Results: In total 136 patients were included (age 34 (SD 9) years, 50% male, and 63% HLA-B27 positive). The ‘No BMO’ pattern was the most frequent (n=63; 46%). The fluctuating pattern was seen in 17 patients (13%) and the ‘persistent BMO’ in 14 patients (10%). ‘Other patterns of BMO’ (not fitting any of the previous) were seen in 42 patients (31%). Considering the increasing sequence of local inflammation as ‘no BMO’, ‘other patterns of BMO’, ‘fluctuating BMO’ and ‘persistent BMO’, a gradient could be found in several outcomes, namely: higher likelihood to be mNYC positive (9%, 24%, 35% and 46%, respectively); higher CRP (3.2, 3.8, 4.6 and 6.4 mg/L), higher SPARCC-SIJ scores (0.1, 2.4, 6.3 and 8.5), and a higher frequency of SIJ structural changes (≥ 5 fatty lesions or erosions: 5%, 29%, 47% and 50%) at 5 years (Table). Bone formation was especially observed in the persistent BMO group. No differences in treatment were found across the groups.

Conclusion: Only 10% of the patients showed persistent inflammation in the same Q over a 5-year period and 12.5% fluctuating inflammation in different Qs. A gradient of higher structural damage and systemic inflammation was found in patients with increasing cumulative local inflammation at the quadrant level of the SIJ.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Spinal radiographic progression has been investigated in patients with r-axSpA, but not yet as thoroughly in early axSpA. We aimed to analyse the progression of spinal radiographic damage in patients with early axSpA.

Methods: Five-year spinal radiographs from patients with early axSpA from the DESIR cohort were scored by 3 readers (average) according to the mSASSS (0-72). Change scores for all available intervals were calculated. The development of new syndesmophytes (2 out of 3 readers) was calculated as a net change: number of patients with positive change minus number of patients with negative change divided by total number of patients. Two- and 5-year mSASSS progression and development of new syndesmophytes were assessed in subgroups defined at baseline according to the ASAS axSpA criteria and its arms, mNYC and also to the presence of syndesmophytes.

Results: In total, 549 patients (mean age 34 (SD 9) years, 46% males, 63% fulfilling ASAS axSpA criteria, baseline mSASSS0.5(1.5)) were included. Thirty-eight patients (7%) showed syndesmophytes at baseline, 42% of which were ASAS axSpA criteria negative. Mean mSASSS progression was 0.2(0.9) at 2 years and 0.4(1.8) at 5 years. 18% of the patients fulfilling the ASAS axSpA criteria showed a 5-year positive mSASSS change (>0), compared to 30% in those not fulfilling the criteria (Figure). 26% of the patients fulfilling the imaging arm had a positive change: highest positive change in MRI-mNYC+ (34%), followed by MRI+mNYC+ (27%) and lastly MRI+mNYC- (23%). Mean mSASSS progression was highest in the mNYC+MRI+ group (1.3(4.0)). Eleven percent of the patients fulfilling only the clinical arm of the ASAS criteria had a positive change in mSASSS at 5 years, mean change of 0.1(0.7). Patients with baseline syndesmophytes (across all subgroups) had the highest progression: 2.7(5.0) mSASSS-units. At 5 years, 7% of all patients had a net change of any new syndesmophyte; this was 6% for ASAS+, 9% for ASAS-, 10% for the imaging arm (18% for mNYC+MRI+) and 3% for patients fulfilling the clinical arm only. Seventeen percent of the mNYC+ patients had a net change in new syndesmophytes as well as 42% of the patients with baseline syndesmophytes.

Conclusion: Spinal radiographic progression, though limited in early axSpA, can be captured already at 2 years of follow-up. Inflammation and damage in the SIJ are associated with a higher radiographic progression. The presence of baseline syndesmophytes strongly predicts the development of further structural damage already early in the disease.

Figure: Five-year mSASSS radiographic progression categories according to the subgroups of the ASAS criteria, arms of the ASAS criteria and fulfillment of mNYC at baseline.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Fatty lesions (FL), similar to bone marrow edema (BME) and sclerosis (SCL), are characteristic findings in MRI examinations of patients with ankylosing spondylitis (AS) and degenerative disc disease (DDD). It has recently been shown that FL are associated with syndesmophyte formation in AS. The anatomic correlate of FL has not been studied to date. Current assumptions are solely based on non-invasive data. Here we examine the cellular composition of FL in the edges of vertebral bodies of patients with AS or DDD by histology.

Methods: Patients with AS or DDD undergoing planned kyphosis correction surgery by spinal osteotomy (in AS) or surgery to correct spinal stenosis (in DDD) were included into this biopsy study. The spinal surgeon (HB) took all biopsies mainly in the area close to the vertebral edge in many of which FL had been seen by MRI (Fig. 1a for AS and 1b for DDD). Biopsies were decalcified, embedded in paraffin, cut and stained by hematoxylin and eosin. The marrow composition was analyzed and the cellularity graded (%surface area) by two different investigators blinded to patients' diagnosis. Four different marrow compositions could be differentiated: (i) fat, (ii) fibrosis, (iii) inflammation and (iv) hematopoiesis (normal).

Results: A total of 60 biopsies mostly obtained from the lower thoracic spine and the lumbar spine of 21 AS patients (mean age 51.7 years, mean disease duration 24.6 years) and of the lumbar spine in 18 DDD patients (mean age 60.1 years) were available. On the patient level, the histological appearance of MRI-FL was different between the groups: fat marrow was present in biopsies of 19 AS (90%) but in only 5 DDD (28%) patients. Inflammatory marrow changes, resembling mononuclear infiltrates, were found in 8 AS (38.1%) and 14 DDD (77.8%) patients at areas with concomitant FL and BME on MRI, while marrow fibrosis was seen in 6 AS (28.6%) and 4 DDD (22.2%) patients at areas with concomitant FL and SCL on MRI.

In the semiquantitative histopathological analysis, the mean distribution (\pm standard deviation) of the various bone marrow tissue types in the biopsies differed between the AS vs. DD in a similar way, with 43% (\pm 26.3%) vs. 16% (\pm 30.3%) for fatty marrow, 11% (\pm 15.5%) vs. 55% (\pm 42%) for inflammatory marrow and 9% (\pm 16.1%) vs. 13% (\pm 27.8%) for fibrotic marrow, respectively.

Conclusion: The presence of FL on MRI corresponds to fat deposition in the bone marrow of patients with advanced AS. These data show that the MRI change termed “fatty lesion” is indeed based on the deposition of fat in the vertebral bone marrow in AS. Since vertebral bone marrow is physiologically harboring hematopoiesis, AS seems to lead to a change in the bone marrow microenvironment with local disruption of hematopoiesis and replacement by fat. The link between fat and new bone formation should be studied in earlier disease stages.

Session Date: Wednesday, October 24, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: MRI of the sacroiliac joint (SIJ) is emerging as an important prognostic tool for assessment of patients presenting with axSpA. A major challenge in the evaluation of early SpA is establishing the diagnosis and this requires prospective follow up to determine which cases have developed axSpA with more certainty. We aimed to assess the baseline distribution and prognostic capacity of MRI lesions in the SIJ of patients diagnosed with axSpA after 2 years follow up in the ECHOSPA cohort.

Methods: Consecutive outpatients with age <50 years and symptoms >3 months suggestive of SpA (inflammatory back pain [IBP], peripheral arthritis or inflammatory arthralgia (IA), enthesitis or dactylitis, uveitis with HLA-B27 positivity, a family history of SpA) were enrolled. The diagnosis of SpA was ascertained by an expert committee, blind to MRI evaluation, after at least 2 years of follow-up. MRI scans from 223 cases were available for evaluation by 2 readers and an adjudicator who assessed MRI lesions in the SIJ according to updated consensus definitions from the ASAS-MRI group. These were recorded in an ASAS consensus-derived eCRF that comprises global assessment (active and/or structural lesion typical of axSpA present/absent) and detailed scoring of individual lesions (SPARCC SIJ inflammation, SPARCC SIJ structural). Clinical, lab, and imaging variables associated with the diagnosis of axSpA at 2 years were first identified by univariate regression. A base model of all clinical/lab variables associated with axSpA was included as a group in multivariate logistic regression models that tested the independent association with MRI lesions.

Results: Mean age of the 223 cases was 39.6 (10.5) years, mean symptom duration was 2.5 (4.1) years, 49.5% were HLA-B27+ and 63.7% were female. Primary inclusion criterion was IBP in 53%, IA in 27%, ED in 9%, B27+U in 8% and Fam in 4%. At 2 years follow up, 165(74%) were deemed to have axSpA. In group comparisons (Table) and univariate regression, both active and structural MRI lesions were associated with diagnosis of axSpA at 2 years ($p=0.03$, $p=0.01$, respectively). Age, B27, and psoriasis were the clinical variables associated with diagnosis of axSpA at 2 years in univariate analysis (all $p<0.0001$) and were included together with gender in multivariate analyses. Active and structural lesions typical of axSpA and SPARCC BME score ≥ 2 were each independently associated with diagnosis of axSpA at 2 years (OR (95%CI)- 6.8(1.4-34.1)($p=0.02$); 17.9(2.2-146.6) ($p=0.007$); 4.9(1.3-18.4) ($p=0.02$). With all variables simultaneously added to the model, only structural lesions were significantly associated.

Conclusion: Assessment of both active and structural lesions on MRI may help determine which patients have axSpA with higher diagnostic certainty over time.

Table. Distribution of MRI lesions at baseline according to diagnosis of axSpA after 2 years.

MRI Lesion	AxSpA n=165 (74.0%)	NOT SpA n=58 (26.0%)	P value
Active lesion typical for axSpA	26 (16.0%)	2 (3.6%)	0.019
Active lesion typical for axSpA (confidence ≥ 3 , 0-4 scale)	18 (11.9%)	1 (1.8%)	0.027
ASAS MRI positivity	24 (14.6%)	1 (1.7%)	0.006
ASAS MRI positivity (confidence ≥ 3 , 0-4 scale)	17 (10.8%)	1 (1.7%)	0.048
Structural lesion typical for axSpA	32 (19.6%)	1 (1.8%)	0.0004
Structural lesions typical for axSpA (confidence ≥ 3 , 0-4 scale)	27 (17.3%)	0 (0%)	0.0002
Active AND structural lesion typical for axSpA	19 (11.7%)	0 (0%)	0.004
Active OR structural lesion typical for axSpA	39 (23.9%)	3 (5.4%)	0.001
Only active lesion typical of axSpA	7 (4.3%)	2 (3.6%)	1.0
Only structural lesion typical of axSpA	13 (8.0%)	1 (1.8%)	0.12

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Defining what constitutes a definite MRI lesion in the SIJ typical of axSpA has been hampered by lack of international consensus for standardized lesion descriptions and definitions. The ASAS MRI group has generated updated consensus lesion definitions (ASAS_MRI_defⁿ) for the spectrum of MRI lesions in the SIJ and these have been applied to the assessment of MRI images from the ASAS Classification Cohort (ASAS-CC) by 7 experts in MRI interpretation from the ASAS-MRI group. We aimed to determine optimal quantitative SPARCC cut-offs for specific MRI lesions for a definite MRI lesion typical of axSpA, the external reference being majority reader decision as to the presence of an active or structural lesion typical of axSpA.

Methods: ASAS_MRI_defⁿ were recorded in an eCRF that comprises global assessment (active or structural lesion typical of axSpA present/absent), links to reference images, and detailed scoring of lesions per SIJ quadrant (SPARCC SIJ inflammation, SPARCC SIJ structural). MRI images were available from 278 of the 495 cases that had MRI performed in the ASAS-CC. Detailed SPARCC scoring data was based only on assessment of images in DICOM format (n=175). We calculated sensitivity and specificity for varying numbers of SIJ quadrants with bone marrow edema (BME), erosion, and fatty lesions where a majority of readers ($\geq 4/7$) agreed as to the presence of an active or structural lesion typical of axSpA.

Results: BME was the most frequent lesion (SPARCCBME score, mean (SD) =14.4(15.5) in cases where a majority of readers agreed there was an active lesion typical of axSpA. For majority agreement as to the presence of a structural lesion typical of axSpA, the most frequent lesions were fatty lesion, and erosion (mean (SD) SPARCC score per case of 8.6(9.1) and 8.2(5.7), respectively). Other structural lesions were much less frequent. Optimal SPARCC cut-offs that focus on specificity ($\geq 95\%$) were BME ≥ 3 for defining an active lesion, and fatty lesion ≥ 3 and erosion ≥ 2 for defining a structural lesion (Table).

Conclusion: The ASAS MRI specific lesion definitions perform well when judged against the expert opinion of ASAS-MRI readers. In particular, the optimal cut-off for an erosion lesion, as defined by ASAS, has similar performance to the optimal cut-off for BME.

Table. Sensitivities and specificities of cut-offs for SIJ lesion scores (number of SIJ quadrants) according to presence of definite active or structural lesion typical for axSpA ($\geq 4/7$ readers in agreement)

	Sensitivity (95% CI)	Specificity (95% CI)
Majority agree active lesions indicative of axSpA present		
BME Score ≥ 2	80.0 (65.4 - 90.4)	93.9 (88.2 - 97.3)
BME Score ≥ 3	77.8 (62.9 - 88.8)	99.2 (95.8 - 100.0)
Majority agree structural lesions indicative of axSpA present		
Fatty lesion (any) ≥ 2	63.2 (46.0 - 78.2)	90.5 (83.7 - 95.2)
Fatty lesion (any) ≥ 3	55.3 (38.3 - 71.4)	94.8 (89.1 - 98.1)
Erosion Score ≥ 2	84.2 (68.7 - 94.0)	96.6 (91.4 - 99.1)
Erosion Score ≥ 3	79.0 (62.7 - 90.4)	99.1 (95.3 - 100.0)
Majority agree active OR structural lesions indicative of axSpA present		
BME Score ≥ 2	70.4 (56.4 - 82.0)	95.0 (89.5 - 98.2)
BME Score ≥ 3	66.7 (52.5 - 78.9)	100.0 (97.0 - 100.0)
Fatty lesion ≥ 2	50.0 (36.1 - 63.9)	93.4 (87.4 - 97.1)

Table . (Cont'd)

	Sensitivity (95% CI)	Specificity (95% CI)
Fatty lesion ≥ 3	40.7 (27.6 - 55.0)	95.9 (90.6 - 98.6)
Erosion Score ≥ 2	63.0 (48.7 - 75.7)	98.4 (94.2 - 99.8)
Erosion Score ≥ 3	57.4 (43.2 - 70.8)	100.0 (97.0 - 100)

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Correct classification of patients with systemic lupus erythematosus (SLE) is critical for clinical trials and clinical and translational science. The ACR 1997 criteria were criticized for their suboptimal sensitivity. The Systemic Lupus International Cooperating Clinics (SLICC) 2012 criteria increased sensitivity, but at the price of reduced specificity. This and further advances in the field led to the current four phase SLE criteria project. Following an item generation phase and item reduction via a Delphi and a nominal group exercise (1), the provisional criteria were derived from a multicriteria decision analysis exercise (2). These criteria were hence simplified and validated in a large international cohort.

Methods: A large international cohort of 2,321 patients was collected from 23 SLE expert centers, contributing up to 100 patients with SLE and with non-SLE, each. Diagnoses were verified by 3 independent reviewers for 1,193 SLE and 1,059 non-SLE patients. 501 randomly selected SLE and 500 non-SLE patients formed the derivation cohort. All other patients with confirmed SLE or non-SLE diagnosis formed the validation cohort. Sensitivity and specificity were compared to the ACR 1997 and the SLICC 2012 criteria.

Results: The criteria were fine-tuned and simplified, using ANA of $\geq 1:80$ as entry criterion and a classification threshold of 10. Items can only be counted for classification if there is no more likely cause, and at least one clinical item must be present.

Renal	Class III/IV nephritis	10	Class II/V nephritis	8	Proteinuria ≥ 0.5 g/day	4
Specific antibodies	Anti-Sm or Anti-dsDNA	6				
Muco-cutaneous	ACLE	6	SCLE or DLE	4	Alopecia or oral ulcers	2
Serosa	Acute pericarditis	6	Effusion	5		
Musculo-skeletal	Arthritis	6				
CNS	Seizures	5	Psychosis	3	Delirium	2
Blood	Autoimmune hemolysis or thrombocytopenia	4	Leukopenia	3		
Complement	Low C3 and C4	4	Low C3 or C4	3		
Anti-phospholipid	Anti-Cardiolipin or anti- $\beta 2$ -GPI or lupus anticoagulant	2				
Constitutional	Fever	2				

Sensitivity was close to the SLICC 2012 criteria, specificity maintained at the level of the ACR 1997 criteria. This performance was independently confirmed in the validation cohort.

	ACR 1997 criteria	SLICC criteria	New criteria
Derivation			
Sensitivity	84.63	96.81	98.00
Specificity	95.20	90.00	96.40
Validation			
Sensitivity	82.76	96.70	96.12
Specificity	93.38	83.62	93.38

Conclusion: The novel set of criteria reached the goal of improved sensitivity close to the SLICC 2012 criteria, while maintaining the specificity of the ACR criteria.

Funding note: This project is jointly supported by the ACR and EULAR, but the final criteria have not yet been reviewed or approved by either organization.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Outcome measures that combine control of SLE activity and prednisone reduction are clinically relevant. A clinical goal in SLE is to reduce risk of long-term organ damage. We assessed whether two recently proposed disease activity outcomes were predictive of future damage.

Methods: For each month of follow-up in a large SLE cohort, we determined whether the patient was in Clinical Remission (as defined by the DORIS working group) or lupus low disease activity state (LLDAS) (as defined by Franklyn et al). Clinical Remission was defined as a PGA<0.5, clinical SLEDAI=0 and no prednisone or immunosuppressants. Clinical Remission on Treatment allowed for prednisone≤5mg/day and immunosuppressant use. LLDAS was defined as a SLEDAI ≤4, PGA ≤1.0, no major organ activity, and no new activity. LLDAS on treatment allowed for prednisone use ≤7.5 mg/d and immunosuppressants. Damage was defined using the SLICC/ACR Damage index.

Results: There were 81,118 person-months observed among 2,026 patients (92% female, 53% Caucasian, 39% African-American). Table 1 shows the rates of damage, per person month, in subgroups defined by Remission or LLDAS.

Table 1. Rates of new damage, in subgroups defined by past levels of disease activity

LLDAS on Treatment	-	-	-	-	-
None	7,656	117	1.53	1.0 (Ref)	-
Not none, but < 25%	10,555	134	1.27	0.83 (0.65,1.06)	0.14
25% to 50%	12,686	129	1.02	0.66 (0.51,0.85)	0.0013
50% to 75%	18,151	133	0.73	0.48 (0.37,0.61)	0.001
75%+	13,141	82	0.62	0.40 (0.30,0.54)	<0.0001

Damage rates were relatively low when LLDAS was achieved at least 50% of the time. These rates were similar to those experienced by patients who met a more stringent treatment restriction with Remission on Treatment at least 50% of the time.

Conclusion: Percent time in LLDAS had a clear dose response for rate ratios of organ damage. The equivalence of LLDAS and DORIS remission on treatment is welcome news, as LLDAS on treatment > 50% of the time is an easier goal to achieve (3 times more person-months observed in our cohort) and more realistic as a clinical trial outcome.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The Definitions of Remission in SLE (DORIS) group has proposed multiple definitions of remission, but these are infrequently attained and have not previously been evaluated in relation to protection from damage accrual in a prospective study. In contrast, the Lupus Low Disease Activity State (LLDAS) is potentially more attainable, and has been shown to be associated with improved patient outcomes. The objective of this study was to compare the attainability and effect of LLDAS and remission on outcomes in a prospective multicenter study.

Methods: A prospective multinational cohort study was undertaken in 13 centres between 2013-2017. Time dependent Cox proportional hazards models were used to compare LLDAS and DORIS definitions of remission in terms of impact on disease flares and damage accrual. All eight DORIS remission definitions include a clinical SLEDAI-2K of 0, and PGA (0-3) <0.5, whilst varying in allowing for serological activity, prednisolone and immunosuppressants.

Results: 1735 SLE patients (meeting ACR or SLICC criteria) were recruited, and followed for (mean \pm SD) 2.2 ± 0.9 years, totalling 12,534 visits. LLDAS was achieved in 6922 visits (54.6%). In contrast, remission was achieved in 140 (1.1%) to 1952 (15.4%) visits depending on definition. LLDAS attainment at any visit was associated with significantly reduced subsequent flare (HR 0.65, 95%CI 0.56-0.76, $p < 0.001$) and damage accrual (HR 0.55, 95%CI 0.43-0.70, $p < 0.001$). In contrast, considering every visit, only the least stringent remission definition (allowing serology, prednisolone ≤ 5 mg, and immunosuppression) could be demonstrated to be associated with significantly reduced subsequent damage accrual (HR 0.58, 95%CI 0.39-0.88, $p 0.01$). Only remission definitions including serological remission were significantly associated with reduction in subsequent flares. Using a cut off of $\geq 50\%$ of observed time meeting a given definition, LLDAS resulted in a two-fold reduction in risk of flare and damage accrual (HR 0.49, 95%CI 0.42-0.58, $p < 0.001$; HR 0.53, 95% CI 0.41-0.68, $p < 0.001$, respectively), while only the least stringent remission definition, or the related definition excluding serology (13.6% visits), were significantly protective against damage (HR 0.59, 95% CI 0.42-0.83, $p 0.003$; HR 0.69, 95% CI 0.48-0.99, $p 0.05$, respectively). When attained for $\geq 50\%$ of observed time, all but one remission definition was significantly associated with reduced flares.

Conclusion: In this first-ever prospective study, LLDAS was markedly more attainable than any remission definition, whilst still conferring significant protection against flares and damage accrual. Among the remission definitions only the least stringent could be shown to be associated with significant reduction in damage accrual, likely reflecting a low frequency of remission attainment overall, and normal serology was required for protection from subsequent flare. LLDAS is a valid treatment target for SLE which is more achievable than remission.

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Missing data due to drop-out and loss to follow-up is a common problem in SLE trials. The usual approaches for handling this issue include analyzing only subjects with complete data (complete case analysis; CC), last observation carried forward (LOCF), or imputing non-responses for missing outcomes (non-responder imputation; NRI). However, the validity of these methods depends on strong assumptions about the missing data mechanism. Multiple imputation (MI) is a flexible model-based technique that accounts for uncertainty in the imputation process by generating several possible values for the missing data, resulting in multiple complete data sets. These are analyzed separately and results are combined. MI is being used more widely in different disease settings but has not been applied to analyze the primary outcome in a SLE trial. We explored the use of MI to address missing data in the composite outcome, SLE Responder Index (SRI)-5, using data from patients assigned to standard of care (SoC) in a 52-week trial.

Methods: Data on 279 SLE patients randomized to SoC for 52 weeks who were receiving mycophenolate mofetil (MMF), azathioprine, or methotrexate at entry were obtained from the Lupus Foundation of America-Collective Data Analysis Initiative database. Multiple imputation using chained equations was applied to handle missing data in an analysis to evaluate differences in SRI-5 response rates at 52-weeks between patients treated with MMF versus other immunosuppressants (non-MMF). Three different imputation models were considered that included various combinations of longitudinal measures of disease activity (both composite and individual measures) and patient characteristics to impute the missing outcomes. Results were compared to estimates from the CC, LOCF, and NRI methods.

Results: Missing data rates were 32% in the MMF and 23% in the non-MMF groups. As expected, the NRI missing data approach yielded the lowest response rates (Table 1). The smallest and least significant estimates of between group differences were observed with LOCF. The precision of the estimated difference, as measured by the width of the confidence interval, was lowest with the CC method because of the reduced sample size. Group differences were magnified with all three MI models compared to results of other methods. Imputing SRI-5 directly (MI-1) versus the individual components (MI-2) yielded nearly identical results.

Conclusion: Given the limitations of conventional approaches for handling missing data, the MI method should also be considered in SLE trials. However, results can vary depending on the imputation model that is used, and the assumptions required for validity of this and other missing data methods must be justified. Sensitivity analysis using different approaches is important to demonstrate robustness of results especially when missing data rates are non-negligible.

Table 1. SRI-5 Response Rates on SoC at 52 weeks by Immunosuppressant Use

Missing Data Approach	Non-MMF	MMF	Difference	95% CI	P-value
CC	46.8%	29.3%	17.5%	1.7% to 33.3%	0.043
LOCF	40.6%	30.0%	10.6%	-2.7% to 23.9%	0.13
NRI	36.1%	20.0%	16.1%	4.1% to 28.0%	0.019
MI-1	47.6%	28.5%	19.1%	4.6% to 33.5%	0.010
MI-2*	46.0%	27.0%	19.0%	4.3% to 33.6%	0.011
MI-3	47.6%	29.7%	17.9%	3.1% to 32.7%	0.018

*MI-2: Imputed data sets: MI-1: Imputation model includes MMF status, race, baseline values of SLEDAI, PGA, BILAG score, protein/creatinine ratio, anti-dsDNA, SRI-5 at 12, 24, 36, 44, 52 weeks; MI-2: Imputation model same as MI-1 but separately imputing components of SRI-5 (SLEDAI, BILAG, PGA); MI-3: Imputation model includes MMF, SRI-5 at all time points.

Systemic Lupus Erythematosus Biomarkers Identified Using Multi-Omic and Artificial Intelligence Analysis through Interrogative Biology

Eric Grund¹, Lixia Zhang¹, Leonardo Rodrigues¹, Viatcheslav Akmaev¹, Rangaprasad Sarangarajan¹, Michael Kiebish¹, Niven Narain¹ and Gary S. Gilkeson², ¹BERG, LLC, Framingham, MA, ²Department of Medicine, Medical University of South Carolina, Charleston, SC

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Biomarkers for use in developing treatments and diagnostics for Systemic Lupus Erythematosus (SLE) are a large unmet need. The wide differential in patient progression and outcome for SLE calls for the identification of informative biomarkers for use in patient stratification and determining course of treatment. In this study we used Berg Interrogative Biology®, a platform technology integrating multi-omic (metabolomics, lipidomics and proteomics) and artificial intelligence (bAIcis®) technologies to discover serum and urine based candidate markers of lupus.

Methods: This study was conducted using retrospectively collected and clinically annotated serum and urine samples from 166 patients (90 African American and 71 Caucasian). Medical data included demographic data, ACR classification criteria, SLICC-damage index, SLEDAI disease activity scores, lab data, and medication information. Omics data for Mass Spectrometry included serum proteomics, metabolomics and lipidomics, and urine proteomics and metabolomics. As part of Berg Interrogative Biology® technology, all clinical and omics datasets were processed and fully integrated in a harmonized dataset. The multi-omic/clinic dataset was analyzed by Berg Artificial Intelligence technology (bAIcis®) that uses data-driven methods to identify panels of Lupus candidate biomarkers, each with a target area under the ROC curve (AUC) of 0.8 with the minimal combination of up to 6 biomarkers. Biomarker panels were analyzed separately for each biomatrix. bAIcis® provided (1) a summary table with individual AUC, panel AUC, panel power, and number of samples participated; (2) a panel ROC curve; and (3) a diagnostic table with statistics: sensitivity, specificity, positive predicted value (PPV), negative predicted value (NPV), and odds ratio.

Results: Biomarker panels in serum and urine were discovered for lupus vs non-lupus (2 biomarkers in serum with AUC 0.836 and 5 in urine with AUC 0.805), renal disease vs no renal disease (2 biomarkers in serum with AUC 0.848 and 2 in urine with AUC 0.844), scleroderma vs. non-scleroderma (2 biomarkers in serum with AUC 0.826 and 2 in urine with AUC 0.705), scleroderma vs. lupus (5 biomarkers in serum with AUC 0.831 and 3 in urine with AUC 0.771), SLICC stage <2 vs >=2 (4 biomarkers in serum with AUC 0.829 and 2 in urine with AUC 0.77), SLEDAI score <6 vs >=6 (2 biomarkers in serum with AUC 0.809 and 2 in urine with AUC 0.641), ANA (1 biomarkers in serum with AUC 0.604 and 2 in urine with AUC 0.73), and drug efficacy for Mycophenolate (2 biomarkers in serum with AUC 0.847 and 1 in urine with AUC 0.933).

Conclusion: Biomarker panels with AUC > 0.8 and power > 0.8 will be pursued in further prospective clinical study with a larger subject number. The urine and serum biomarker panels for lupus vs no lupus, renal disease vs no renal disease, scleroderma vs no scleroderma, scleroderma vs lupus, SLICC stage, and drug efficacy for Mycophenolate are fit for further validation. Integrating multi-omic analysis with artificial intelligence identified several biomarker panels that meet numerous unmet needs for the identification and clinical stratification of Systemic Lupus Erythematosus.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Punch biopsy, the standard diagnostic and monitoring procedure for patients with cutaneous lupus erythematosus (CLE), impedes patient recruitment and follow up due to risk of infection, discomfort and cosmetic scarring. This study assessed the feasibility of an adhesive tape device from Dermtech, Inc to collect RNA from affected and unaffected skin and its potential to detect gene expression differences between groups.

Methods: Subjects with active discoid lupus erythematosus (DLE; n=9), subacute CLE (SCLE; n=1), atopic dermatitis (AD; n=3) and healthy volunteers (HV; n=10) were enrolled. Skin tape samples from affected (A) and unaffected (U) skin were collected from all subjects. Gene expression was quantified by qPCR on the OpenArray platform. Candidate genes (n=94) were grouped by differential expression using consensus K-means and hierarchical clustering. Distinct gene clusters were assigned to canonical pathways using tools in Ingenuity Pathway Analysis (Invitrogen) software.

Results: Using an unbiased clustering algorithm, genes amplified from skin RNA collected by tape were segregated into 6 clusters. Two of 6 clusters resulted in differential expression between both CLE-A vs HV, and CLE-A vs CLE-U, as follows: (Cluster 1) composed largely of type I interferon (IFN-I) signaling genes (n=18 genes, fold change 23 and 7, p<0.001 and p=0.002, respectively) and (Cluster 2) containing genes involved in cytotoxic T lymphocyte and natural killer (NK) cell-mediated apoptosis, communication between innate and adaptive immune cells, and cytokines and chemokines in viral infection (n=22 genes, fold change 5 and 3, p<0.001 and p=0.007).

Conclusion: RNA from the skin surface distinguishes CLE-A from HV skin and CLE-A from CLE-U skin with robust fold changes in genes implicated in CLE pathogenesis including IFN-I signaling and cytotoxic T lymphocyte and NK cell-mediated apoptosis. This non-invasive technique offers promise for the diagnosis, stratification and follow up of patients with CLE.

Session Information

Session Date: Wednesday, October 24, 2018

Background/Purpose: Studies have shown that myocardial involvement may occur in systemic sclerosis (SSc) and lead to cardiac failure. We showed previously that cardiac magnetic resonance imaging (CMRI) with T1 mapping sequences could detect myocardial microscopic fibrosis in 50% of SSc patients, especially in those with diffuse cutaneous forms. However, no prospective data is yet available to analyze the prognostic impact of MMF on cardiac outcome in SSc patients.

Methods: We conducted a single-center prospective study of consecutive patients with SSc fulfilling the ACR/EULAR criteria. CMRI with T1 mapping and multi-b value diffusion-weighted sequences were performed in all patients. T1 mapping sequences assess collagen myocardial infiltration, defining microscopic fibrosis. Myocardial microscopic fibrosis was defined on T1 mapping sequences by a value greater than 1250 ms. Patients were prospectively followed-up for the occurrence of cardiovascular (CV) events and decline in left ventricular ejection fraction (LVEF) assessed by cardiac ultrasonography.

Results: Forty patients, 35 women and 5 men, mean age 54.7 ± 14.6 years, were included. At inclusion, patients had diffuse cutaneous forms in 19 cases, limited cutaneous forms in 16 cases, and SSc sine scleroderma in 5 cases. Median time from disease diagnosis to CMRI was 77 months (1-302). Myocardial microscopic fibrosis was found in 21(53%) SSc patients.

After a median follow-up of 38.2 months (IQR 19.4-41.0), 10 (25%) patients experienced CV events: hospitalization for heart rhythm disorder in 7 cases, for heart failure in 2 cases (leading to death in one case) and unstable angina in one case.

Presence of myocardial microscopic fibrosis on CMRI at inclusion was significantly associated with a poorer CV event-free survival ($P=0.02$). Hazard ratio (95% confidence interval) for incident CV events in patients with myocardial microscopic fibrosis compared to those without was 4.47 (1.27-15.8) (Fig. A).

In contrast, no difference in the decline of LVEF over time was noted between patients with and without myocardial microscopic fibrosis (from 62.0 ± 3.2 and $62.9 \pm 4.7\%$ at inclusion to 59.0 ± 10.8 and $59.4 \pm 5.3\%$ at 36 months, respectively) (Fig. B).

Conclusion: This study shows a significant association between myocardial microscopic fibrosis assessed by T1 mapping sequences on cardiac MRI and cardiovascular events in systemic sclerosis, but no impact on LVEF decline over time. The prognostic impact of myocardial microscopic fibrosis should be evaluated in larger studies, especially in patients with diffuse cutaneous forms.

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: The Le Roy *et al.* classification of SSc into limited and diffuse cutaneous subtype remains the most commonly used. Nevertheless, autoantibodies are much better predictors of organ involvement. Although more sophisticated approaches exist, a simple classification, using antibodies and skin subset is relevant to clinical practice and could help risk stratification.

Methods: Initially subjects were divided into 12 groups, based on skin subset and autoantibodies - ACA, anti-Scl-70 antibodies, anti-RNA polymerase antibodies (ARA), anti-U3RNP antibodies, anti-PmScl antibodies and a group with other antibodies, including rarer specificities, ANA+ ENA- and ANA negative patients.

Kaplan-Meier (KM) estimation of survival and cumulative incidence of organ complications were calculated for each subgroup. Subgroups were ranked in terms of endpoint estimates and those showing similar ranking in multiple endpoints, were merged.

Results: The cohort consisted of 1025 SSc patients. Mean age at disease onset was 47 years and 16% were male. Diffuse cutaneous (dc)SSc was diagnosed in 35% of the subjects. Antibody characteristics included ACA in 31%, Scl-70 in 22%, ARA in 11%, U3RNP in 5% and PmScl in 4% of the subjects. For the whole cohort, at 20 years from onset, estimated survival was 60%, incidence of significant pulmonary fibrosis (PF) was 44%, pulmonary hypertension (PH) 25%, scleroderma renal crisis (SRC) 7% and cardiac SSc 6%.

The final classification included 7 subgroups. Group 1 (29%) consisted of ACA+ lcSSc patients. This was the subgroup with the highest survival (72%), the lowest incidence of PF (13%) and SRC (no cases) at 20 years from onset. The incidence of PH was similar to the average for the whole cohort.

Group 2 (11%) consisted of all ARA+ subjects and it had the highest incidence of SRC (32% at 20 years), while other organ complications and survival were similar to the cohort average.

Group 3 (11%) included Scl-70+ lcSSc patients and although incidence of PF in this group was the second highest (69% at 20 years), other complications were rare. The group had the lowest incidence of PH (6%) and the second lowest incidence of SRC (3%) at 20 years.

On the other hand, Scl-70+ dcSSc patients (group 4, 11%), had a very poor prognosis with the highest incidence of PF (91%), cardiac scleroderma (14%) and the worst survival (41%) at 20 years.

Group 5 included all U3RNP+ patients (5%). Although survival in this group was not bad (70% at 20 years), this group had the highest PH incidence (40%) and the second highest incidence of cardiac SSc (11%) at 20 years.

Groups 6 and 7 (22% and 11% respectively) included lcSSc and dcSSc patients with other antibody specificities. Group 6 had low overall risk of SRC and cardiac SSc, while other outcomes were similar to the cohort average. Conversely, group 7 had poor prognosis, with the second lowest survival (42% at 20 years) and above average rates of organ disease, particularly PF and SRC.

Conclusion: We propose a simple classification scheme, combining autoantibody specificity and extent of skin involvement, which is easy to apply in a clinical setting and distinguishes well between patient groups at risk of serious complications.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in Systemic Sclerosis (SSc) but its pathogenesis is not fully understood. Esophageal disease is common in SSc and micro-aspiration of both acid and non-acid gastroesophageal reflux could be involved in the pathogenesis of ILD. Esophagogastroduodenoscopy (EGD) is an essential tool to evaluate disease severity of upper gastrointestinal tract involvement in SSc. The objective of the present study is to assess the role of EGD in predicting pulmonary functional deterioration in SSc patients.

Methods: One hundred and fifty patients with SSc and suspected esophageal involvement underwent EGD. Pulmonary function tests were performed at baseline and after a 36-months follow-up. Patients were characterized for disease phenotype, BMI, smoking exposure and medication history. A significant ILD progression was defined as a relative decline $\geq 10\%$ of FVC or a concomitant decline $\geq 5\%$ of FVC and $\geq 15\%$ of DLCO.

Results: One hundred and thirty-six patients (90.5%) were female with a mean age of 55.6 ± 13.8 years and 12.1% were active smokers. Fifty patients (33.3%) had a diffuse cutaneous disease; 37.4% and 40.8% were positive for anti-centromere and anti-Scl70 antibodies respectively. The mean disease duration from the first non-Raynaud symptom was 5.9 ± 6.7 years. Sixty-one patients (40.8%) showed EGD signs of reflux esophagitis. Among them, 31.3% had an erosive form (9.5% grade A, 15.6% grade B, 4.8% grade C and 1.4% grade D according to Los Angeles classification). At the baseline, 23.1% of the patients had a $FVC \leq 80\%$ and 45.6% had a $DLCO \leq 50\%$. Patients with erosive esophagitis did not differ in terms of sex, age, duration and disease variant, positivity for anti-centromere, skin score values, FVC and DLCO at baseline compared to patients without erosions, but had a lower prevalence of anti-Scl70 (28.3 vs 52.5%, $p=0.005$) and active smoking (20.0 vs 8.4%, $p=0.05$). At follow-up, patients with esophageal erosions showed a greater relative decrease in FVC ($3.4\% \pm 9.3\%$ vs $1.7\% \pm 12.0\%$; $p=0.013$) without significant differences in the DLCO change. Overall, 11.0% of patients presented pulmonary disease progression. The presence of esophageal erosions was associated with a significantly greater risk of lung disease progression (OR 5.3, 95% CI 1.7-16.8, $p=0.004$) after paired correction for sex, age, duration of disease, auto-antibodies, skin involvement variant, baseline FVC and DLCO, smoke exposure and therapy with immunosuppressants, proton pump inhibitors, prokinetics, antiplatelet agents and prostanoids.

Conclusion: SSc patients with erosive esophagitis present a higher risk of progression of interstitial lung disease. This evidence supports a role of micro-aspiration of gastric contents in the development of inflammation and fibrosis of the airways.

Session Title: Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Vinculin is a cytoskeletal protein that plays a major role in cell-cell and cell-extracellular matrix adhesion thus regulating cell growth, migration and function of enteric nerves, smooth muscles as well as endothelial cells. Antibodies directed against vinculin protein have been identified as biomarker in irritable bowel syndrome (IBS). Recently, vinculin was identified as one of the targets of anti-endothelial antibodies in serum of SSc patients.

Aim: To evaluate serum anti-vinculin antibodies (aVin-abs) in two phenotypically different SSc patient cohorts (vascular and gastrointestinal-enriched groups).

Methods: Controls and SSc subjects recruited from two SSc centers (University of California, Los Angeles [UCLA], USA and the University of Leeds, UK. Subjects were assessed as two groups:

Group I (gastrointestinal [GI] enriched group) included 83 SSc patients (pts), where 55 pts were noted to have a gastrointestinal (GI) Visual analogue scale [GI-VAS] > 40/ 100 whereby GI-VAS was a component of SSc Health Assessment Questionnaire. Group II (vascular-enriched group) included 72 SSc pts, of whom n=17 had digital ulcers, and n=23 had known pulmonary artery hypertension. SSc serum samples as well as 50 age and sex matched controls were evaluated in one laboratory, where aVin-abs were tested by ELISA and results reported as OD. Clinical data were obtained by chart review for statistical correlations.

Results: Features and demographics of recruited SSc subjects supported the group assignments (Table 1). Among all SSc patients, aVin-abs were significantly higher in SSc groups than in controls (1.4 ± 0.9 compared to 0.6 ± 0.6 in control [p-value=0.002] in Group I) and, (1.0 ± 1.0 in SSc versus 0.6 ± 0.6 in control [p-value =0.01] in Group II). Group I (GI-enriched) patients were then dichotomized based on aVin-abs cutoff level (used in IBS study [high>1.7 or low< 1.7]). Using this cutoff, BMI was significantly lower in SSc pts with high levels of abs ($19.9 \pm 4.1 \text{ kg/m}^2$) versus low levels (21.9 ± 4.7) (p=0.05). Significantly higher GI-VAS was recorded in SSc pts with high aVin-abs (6 [range 2-9]) in comparison to SSc pts with low (2 [range 1-9]) (p-value=0.0001). In group II, we examined predictors of higher aVin-abs in group II (vascular -enriched): BMI and PAH were significant predictors of higher anti-vinculin (p<0.005 and 0.04, respectively

Conclusion: This is one of the first studies to report an association between autoimmunity to vinculin in patients with SSc-GI involvement. This suggests that higher aVin-abs are associated with greater severity of GI involvement with consequent decreased BMI. In addition, we report that aVin-abs also appear associated with vasculopathy such as pulmonary artery hypertension.

	Group I	Group II
Age mean (SD)	57.4 (12.64)	56.36 (13.83)
Sex: females	69 (83%)	58(82.85%)
Diffuse subtype	24 (29%)	(32) 48.48%
BMI Mean (SD)	26.16 (5.71)	24.3 (4.25)
GI-VAS	3 (1-9)	2.2 (0-9)
PAH	5(6%)	23 (31%)
Current skin ulcers	30(36%),	17 (25%)
FVC mean (\pm SD)	98.3 ± 25.2	79.8 ± 26.1

Evaluation of American College of Rheumatology Provisional Composite Response Index in Systemic Sclerosis (ACR CRISS) in a Phase 3 Randomized Controlled Trial

Dinesh Khanna¹, Celia J. F. Lin², Helen Spotswood³, Jeffrey Siegel², Angelika Jahreis², Christopher P. Denton⁴ and Daniel E. Furst⁵, ¹Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ²Genentech, Inc., South San Francisco, CA, ³Roche Products Ltd., Welwyn Garden City, United Kingdom, ⁴University College London, London, United Kingdom, ⁵University of California Los Angeles, Los Angeles, CA

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: Treatment with the IL-6 receptor inhibitor tocilizumab (TCZ) in early progressive systemic sclerosis (SSc; focuSSc trial; NCT02453256) resulted in numeric improvements in skin sclerosis and clinically meaningful forced vital capacity(FVC) results at week 48 (data on file). The combined response index for SSc (ACRCRISS), a composite

outcome measure for trials in SSc,¹ is a 2-step process that assigns a probability of improvement for each patient (pt) ranging from 0 [no improvement] to 1 [marked improvement]. Step 1 assesses clinically meaningful decline in cardio-pulmonary-renal involvement with a probability of 0. For remaining pts, the probability of improvement examines change from baseline in 5 variables: modified Rodnan skin score, FVC%, pt and physician global assessments (PtGA, MDGA), and HAQ-DI. CRIS distinguished between TCZ and placebo (PBO) in the faSScinate trial.² We prospectively assessed the performance of ACR CRIS, an exploratory outcome in focuSSced, at week 48; this is the first time ACR CRIS has been prospectively evaluated in a phase 3 trial in SSc.

Methods: Pts ≥18 years of age with active SSc were randomly assigned 1:1 to TCZ 162 mg or PBO subcutaneously every week for 48 weeks. Step 1 for ACR CRIS was captured prospectively with blinded review of adverse events (AEs) and serious AEs between medical monitors and the lead investigator. Step 2 was calculated as defined.¹ The van Elteren test was used to assess whether differences existed between TCZ and PBO groups in the ACR CRIS score in its continuous form. The analysis included all pts who received study treatment, stratified by baseline IL-6 levels (<10; ≥10 pg/mL) with no imputation for missing data.

Results: In total, 210 pts (104 TCZ, 106 PBO) received study treatment; 13 pts in the PBO group and 6 in the TCZ group met the predefined definition of worsening cardio-pulmonary-renal involvement (step 1) and were given a score of 0. Using the ACR CRIS as a continuous measure, scores favored TCZ over PBO at week 48: median(IQR), 0.89 (0.09-1.00) vs 0.25 (0.00-0.99) ($p = 0.023$; Figure). In the binary form of CRIS, 51% of pts in the TCZ group vs 37% in the PBO group achieved the cutoff of ≥0.60 at week 48 (difference, 13.9; 95% CI, 1.0-26.8; $p = 0.035$).

Conclusion: In analysis of patient-level data from the focuSSced trial, more pts had cardio-pulmonary-renal involvement in the PBO group than in the TCZ group (captured by step 1). Additionally, step 2 CRIS score distinguished TCZ from PBO. The focuSSced study validates the ACR CRIS end point for the first time in an independent prospective clinical trial and highlights the importance of step 1 as an indicator of reduced organ progression during 48 weeks of treatment. **References:** 1. Mecoli^{3,4} and Zsuzsanna McMahan⁵, ¹Department of Internal Medicine, Johns Hopkins Bayview, Baltimore, MD, ²Medical and Rheumatology, Johns Hopkins University, Baltimore, MD, ³Internal Medicine/Rheumatology, Johns Hopkins University, Baltimore, MD, ⁴Rheumatology, Johns Hopkins University, Baltimore, MD, ⁵Department of Internal Medicine, Johns Hopkins University School of Medicine, Baltimore, MD

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: Although up to 90% of scleroderma (SSc) patients are affected by gastrointestinal (GI) dysmotility, clinical features of patients with severe lower gastrointestinal involvement are not well-defined. We sought to identify such features by studying a large cohort of SSc patients.

Methods: We performed a retrospective analysis of patients seen during a 15-year period between 2002-2017 at The Johns Hopkins Scleroderma Center. All patients had data prospectively collected in a longitudinal database if they met 2013 ACR/EULAR criteria for systemic sclerosis, 1980 American College of Rheumatology (ACR) criteria or had at least three of five features of CREST syndrome. Lower gastrointestinal involvement was defined as ever having a Medsger's GI severity score of a 3, which is characterized by malabsorption syndrome and/or recurrent episodes of pseudo-obstruction. Clinical and serologic characteristics of these patients were compared to those who received grades of 0, 1, or 2 throughout follow-up.

Results: There were 193 patients with SSc who received a grade of 3 in GI severity during follow-up, and 3,577 patients who did not. In univariable analyses, lower GI involvement was significantly associated with older age at the time of severe bowel disease onset (58 vs. 53 years, $p < 0.001$), diffuse cutaneous disease (47% vs. 37%; $p = 0.006$), history of tendon friction rubs (24% vs. 16%; $p = 0.003$), myopathy (31% vs. 17%; $p < 0.001$), cancer (22% vs. 16%; $p = 0.027$), and death (44% vs. 34%; $p = 0.006$). Such patients were also more likely to have ever had a lower FVC (66% vs. 70%, $p = 0.01$) and DLCO (56 vs. 61%, $p = 0.02$) and to have received opioids (44% vs. 27%; $p < 0.001$), and prednisone (42% vs. 32%; $p = 0.005$). A positive association with anti-U3RNP antibodies trended towards significance (7% vs. 4%; $p = 0.06$). Autoantibodies to RNA polymerase 3 (RNAPol3) were inversely associated with severe lower bowel involvement (11% vs. 18%; $p = 0.02$). In multivariable analyses (adjusted for significant variables from the univariable analysis) age (OR 1.03; 95%CI 1.02-1.05), diffuse cutaneous disease (OR 1.76; 95%CI 1.16-2.67), myopathy (OR 1.56; 95%CI 1.06-2.30), and opioid use (OR 2.31; 95%CI 1.64-3.25) remained significantly associated with severe lower bowel disease in SSc. Anti-RNA pol3 antibodies were protective of this complication (OR 0.39; 95%CI 0.22-0.68).

Conclusion: We report extra-intestinal clinical features of SSc patients with lower GI involvement in a large cohort. Our results demonstrate that older age, diffuse skin disease, and myopathy are associated with developing lower GI involvement. The prescription of opioids may be a modifiable risk factor for the development of severe lower GI involvement in patients with SSc.

Complementary Practices As Alternatives to Pain: Effectiveness of a Pain Management Program for Patients in an Orthopedic Clinic

Maggie Wimmer, Robyn Wiesel, Berenice Adams, Mikhaila Goldman, Titilayo Ologhobo, Yu Sun, Mavis Seehaus, Sandra Goldsmith and Laura Robbins, Hospital for Special Surgery, New York, NY

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: In 2018, according to the National Institute of Health, opioid misuse and addiction is a major public health issue. Approximately 70% of individuals who use opioids on a long-term basis have musculoskeletal disorders, such as low back pain, spondylosis and osteoarthritis. Additionally, one-third of patients with Rheumatoid Arthritis are prescribed an opioid to treat their condition, while one in ten use opioids chronically during their disease course. Over the last 25 years, there has been an increase in physicians prescribing opioids for chronic pain, while there is limited availability of alternatives for identifying, managing, and treating pain. To address this epidemic, Hospital for Special Surgery (HSS) implemented a Pain and Stress Management (PSM) program to improve knowledge and implementation of complementary practices as alternatives to medications.

Methods: In 2017, the PSM program was piloted to patients at the HSS Ambulatory Care Center (ACC), a low income, diverse community living with chronic musculoskeletal conditions. Reaching 122 participants, this included weekly

meditation conference calls and monthly workshops with a social work-led debrief session. Participants engaged in mindful breathing techniques and meditation practices to cope with chronic pain and stress. Knowledge, self-management and program acceptability were evaluated using post surveys. As a follow-up to the survey, qualitative data was collected to obtain additional information on program effectiveness (i.e., how often participants use the learned techniques and how the techniques have helped participants cope with their pain and stress).

Results: The program was highly rated by 98% of participants. Most participants showed increase in knowledge of complementary alternative treatments (95%) and ability to apply the techniques learned to manage their pain and stress (95%). One out of three participants reported using the mindful breathing techniques 5 or more times a week in place of medication. Debrief sessions revealed that after using the techniques, participants experienced improved daily function, calmness, improved self-efficacy and state of mind, reduced pain and stress, and were less reliant on pain medication to manage their condition.

Conclusion: Results indicate that alternative approaches are effective in reducing pain and stress, and improving self-management and general well-being. Based on the success of the PSM program in the orthopedic clinic, we are expanding the program to patients of the HSS rheumatology clinic, who also rely on opioid use to cope with chronic pain, to help this population increase their knowledge and awareness of alternative approaches to manage their debilitating condition.

Reach and Effectiveness of a Health Communications Campaign Promoting Self Management Education: Results of a Pilot Test of the Learn More. Feel Better. Campaign

Teresa Brady¹, Meghan Lewis², Carla Cartwright², Anne Hvizdak³ and Sara Lasker⁴, ¹Clarity Consulting and Communications, Atlanta, GA, ²Porter Novelli, Atlanta, GA, ³Bureau of Aging and Disability Resources, Wisconsin Department of Health Services, Madison, WI, ⁴Healthy & Hygge, Madison, WI

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: *Learn More. Feel Better.* (LMFB) is a multi-modal marketing campaign to promote self-management education (SME) as a chronic disease management strategy. The campaign targets adults ages 45-75 with chronic conditions including arthritis. Campaign strategies include paid and earned media, and local partner activity; all promote the same call-to-action to visit www.cdc.gov/LearnMoreFeelBetter to learn more about SME.

CDC pilot-tested the LMFB campaign in January-August, 2017, in one designated market area (DMA) (a midwestern five county area including a midsize urban area). Implementation included paid ads (print, radio, billboard, digital, and physician waiting/exam rooms), earned media (news stories/blog posts resulting from media outreach), and local partner promotion (in-person events, web and social media). Two campaign tactics (digital advertising via Google ads, and physician waiting/exam rooms ads) ran continuously. The remaining strategies and tactics were conducted intermittently (e.g., the magazine ad ran in February, June, and July; billboards ran 4 weeks in March-April).

The purposes of this observational study are to assess: 1) effectiveness of LMFB in motivating people to visit the LMFB website, 2) effectiveness of the website in retaining visitors' interest, and 3) lessons learned to guide future campaign implementation.

Methods: Campaign effectiveness was defined as the number of visits to the LMFB website homepage, as calculated by Site Catalyst, a web analytics software program. To put this into perspective, this number was compared to number of visits to select CDC webpages from the target DMA for the same time period.

Effectiveness of the website in retaining interest was assessed by examining the number of people who left the homepage without visiting additional pages, also calculated by Site Catalyst. Patterns of impressions and website visits were examined to identify lessons learned.

Results: The 7 month LMFB pilot-test resulted in more than 31 million impressions; with approximately 80% from paid media, 11% from earned media, and 9% from partners' promotion.

The pilot-test generated 26,851 visits to the LMFB homepage; 58% from the targeted DMA, a total of 85% from the state. Other CDC websites had less than 1% of their visits from the target DMA during the pilot-test period. Visits to the

homepage peaked in periods where ads were running in multiple channels; the impact of digital ads is easiest to track, but ads in traditional media (print, radio, billboard) contribute to impressions and message repetition that leads to action.

Only 17% of homepage visits resulted in visitors viewing another page on the website. :

Conclusion: LMFB pilot-test was successful in driving traffic to the LMFB website; nearly 60% came from the targeted DMA. The additional visits from the state are likely due to spread of LMFB materials since the only 15% of visits were from outside the state. Paid media was an essential part of this pilot-test and use of multiple channels increased effectiveness. However, the LMFB homepage was less successful in enticing visitors to visit additional pages on the site, suggesting further improvements to the homepage are necessary.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: People who increase their physical activity (PA) (e.g., in an intervention) typically return to a less active lifestyle within 3-6 months. Yet, the health benefits of a more active lifestyle require lasting behavior change. In people with osteoarthritis (PWOA), increasing PA can reduce chronic joint pain. The present study examined social support for PA from a committed romantic partner as a facilitator of lasting PA change. We sought to clarify types of partner support associated with short- and long-term PA increases in insufficiently active PWOA.

Methods: Participants included people with hip/knee OA who self-reported <120 minutes of moderate-to-vigorous PA (MVPA) per week and their partner (N=116 couples). Couples attended a group class on OA, PA, and working together to help PWOA become more active. After class they were instructed to complete the Active Living Everyday Workbook (12 chapters, 1 per week) and to read a study booklet on social support for PA. Partners could try to increase their PA, but that was not a focus of the study. Participants independently completed a pre-class baseline assessment and follow-up assessments at 3-, 6-, and 12-months post-class. At each assessment, they wore an accelerometer and completed questionnaires, including 2 validated measures of partner support for PA. Partners reported support they provided to their PWOA, and PWOAs reported support they received from their partner. PWOAs' accelerometer-assessed MVPA at each assessment was categorized as: 0=minimal (<45 min/week), 1=insufficient (45 to <60 min/week), 2=borderline (60 to <150 min/week), or 3=exceeding recommendations (≥150 min/week).

Results: Factor analysis of our data suggested 2 main ways partners could support PA: (1) enacted informational, instrumental, and emotional support for PA (general support) and (2) doing PA with the PWOA (collaborative support). We conducted ordinal logistic regressions predicting PWOAs' level of MVPA at 3-, 6-, and 12-months, adjusting for their baseline MVPA and demographic and medical characteristics. Support variables evaluated in the models included PWOA-reported general and collaborative support received and partner-reported general and collaborative support provided. In models predicting MVPA at all assessments, PWOAs' baseline MVPA significantly predicted their MVPA at follow-up assessments (p 's <.001). At 3 months, there were no associations between the support variables and PWOAs' level of MVPA. PWOAs with a higher level of MVPA at 6 months had partners who reported providing more collaborative support at baseline (p =.04). PWOAs with a higher level of MVPA at 12 months reported receiving greater general partner support for PA at the 6- and 12-month follow-ups (p 's=.03-.04) and they tended to have more partner-reported collaborative support for PA at baseline and at the 12-month follow-up (p 's .07-.09).

Conclusion: Findings suggest that partner support for PA may play a more critical role in maintenance than in initiation of PA over the course of a year, especially with respect to PWOAs' reports that partners had recently provided them with general support for PA. We will discuss implications for interventions.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: An estimated 54 million US adults have arthritis, and more than half are not receiving the recommended physical activity (MMWR, 2018). Walk With Ease (WWE) is one of five evidence-based programs shown to improve physical activity and self-management in patients with arthritis (Callahan, 2011). However, WWE is not widely used in non-urban communities. The objectives of this study were to 1) implement WWE in a community YMCA fitness center, 2) examine physical function and self-reported health outcomes in patients with arthritis, and 3) examine the feasibility and sustainability of implementing WWE.

Methods: Brochures, flyers, and electronic health record referrals from a YMCA and one health system were used to recruit adults who self-identified with arthritis and met the program requirements of being able to stay on their feet for 10 minutes. A physical therapist and two Arthritis Foundation trained YMCA staff members conducted a total of six, 6-week sessions, meeting 3 days/wk between Aug 2016 and Dec 2018. Walking speed measurements and 2-minute step counts were performed at baseline and 6-week follow-up. Pre/post-surveys were distributed to all registered participants, including those who did not complete the program. Survey items (n=25) included a 10-point visual analogue scale for arthritis pain, mood, fatigue, and global health, a validated multi-dimensional health assessment questionnaire (MD-HAQ) and a weekly exercise plan. Results were compared using paired t-tests.

Results: Of 35 registered participants, 31 attended WWE (range 2-10 participants per session). Participants were predominately 65 years or older (78%), female (77%) and Caucasian (100%). All had pre- or post-data, while only 21 (67%) had paired data. In paired data, normal and fast walking speed increased an average of 0.53 ft/s (p=0.02) and 0.67 ft/s (p=0.01), respectively. 2-minute step count increased an average of 48.5 steps (p<0.01). MD-HAQ and pain scores improved an average of 2.84 (p<0.01) and 1.43 (p=0.01). Global health scores improved an average of 1.43 (p<0.01). Most participants (87%) reported plans to continue to exercise 2-3x/wk. Average program costs to YMCA (\$208/participant) were comparable to a comprehensive physical therapy visit. Limitations include a small, single-center cohort with low diversity and inconsistent completion among participants.

Conclusion: Our pilot study showed that WWE improves physical function and self-reported health outcomes in patients with arthritis. In addition, WWE appears to be a feasible, sustainable, and cost effective program within non-urban community partners. Given observed improvements, health professionals should continue to emphasize the importance of physical activity, including community referrals. Future studies should examine how to increase provider referral of patients with arthritis to improve patient outcomes.

Table 1. Results of pre- and post-outcome measures

Outcomes	Pre, mean	Post, mean	Significance, p value
Normal walk speed (ft/s)	3.84	4.55	0.02

Session Date: Wednesday, October 24, 2018

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: There is evidence that education programs are effective (e.g. improved disease activity and quality of life) for patients with arthritis, but little is known about the impact of education interventions in axial spondyloarthritis (axSpA). The purpose of this study was to determine the impact of an e-Learning education program on patients' disease knowledge and self-efficacy, as well as to determine the predictors associated with better self-management.

Methods: The Toronto Western Hospital Spondyloarthritis Program developed an interactive, e-Learning education program for axSpA^{1,2}. Patients were randomly allocated to either the intervention (e-Learning with usual care) or control (usual care) group. All patients completed the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Knowledge (AS-Q) questionnaire, and the Stanford Exercise and Chronic Disease Self-Efficacy (CDSE) scales at baseline, first follow-up (FU1), and at second follow-up (FU2) 6-12 months after FU1. A linear-based generalized estimating equation for continuous data was used to explore the associations between covariates including group, baseline sociodemographic characteristics (including risk factors for poor disease outcomes) and a main effect for time.

Results: 44 AS and 10 non-radiographic axSpA patients (n = 54) were included in the analyses. Of these, 23 received the intervention and 31 proceeded with usual care. 85.2% had completed college or university and the median number of education sources (i.e. # sources accessed such as internet, pamphlets, physician) prior to the study was 3 (IQR = [2,3]). The mean age was 41.9 years (12.9 SD) and 81.5% were HLA-B27+ with a mean of 17.8 (10.8 SD) years of symptoms. There was a significant increase in disease knowledge over time (p = 0.043) but no group differences for the above outcomes. Three or more education sources were significant (p = 0.014) predictors for an increase in AS-Q in the control group. Allocation to the e-Learning group was a predictor of more confidence in getting help (p = 0.015) from family and friends as per the CDSE. Female gender (p = 0.05) was a predictor of greater confidence in managing disease overall, and symptoms >10 years predicted more confidence in managing both disease (p = 0.018) and depression (p = 0.014).

Conclusion: The e-Learning module shows promising efficacy in improving knowledge, health literacy behaviours, and also serves to benefit individuals with limited access to specialized, tertiary care. There is a need for trials to assess more effective education outcomes and future studies should include characteristics and risk factors (e.g. gender, previous education sources, symptom duration) that were shown to be meaningful in this analysis.

Session Title: ARHP III: Interventions and Self-Management

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00 AM-10:30 AM

Background/Purpose: African Americans (AAs) bear a disproportionate burden of osteoarthritis (OA), with greater pain and disability compared with Non-Hispanic Whites. Pain coping skills training (PCST) is a promising intervention to reduce racial disparities in OA-related pain and other outcomes, but there has been little study of PCST among AAs. This project engaged AAs with OA and other stakeholders (caregivers, clinicians) to culturally tailor a PCST program for AAs, then evaluated the PCST program in a multi-site randomized controlled trial.

Methods: 248 AAs (51% male, mean age = 29 years) with knee OA were randomized with equal allocation to PCST and wait list (WL) control groups. The PCST program involved 11 telephone-based sessions over 12 weeks, delivered by a counselor. Outcomes were assessed at baseline, 12 weeks and 36 weeks and included the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale (primary outcome), WOMAC total score (pain, stiffness and function), Coping Strategies Questionnaire (CSQ) – Total Coping Attempts, Pain Catastrophizing Scale (PCS), PROMIS Pain Interference Scale, Patient Health Questionnaire (PHQ-8, depressive symptoms), and Arthritis Self-Efficacy Scale. Linear mixed models were fit for all outcomes with unstructured covariance to account for repeated measurements. All models included stratification variables (enrollment site and gender).

Results: At 12-week follow-up, the PCST group improved (decreased) in WOMAC pain score more than the WL group, but the difference was not statistically significant (Table 1). At 12-week follow-up there were significant differences, in favor of the PCST group, for CSQ Total Coping Attempts, PCS, and Arthritis Self Efficacy ($p < 0.01$). At 36 weeks, WOMAC pain scores were significantly improved in the PCST group compared with the WL group ($p < 0.05$, Table 1). CSQ Total Coping Attempts and Arthritis Self Efficacy scores were also significantly improved at 36 weeks in the PCST group, compared with the WL group ($p < 0.01$).

Conclusion: The culturally tailored PCST program resulted in improved pain severity, particularly at longer-term follow-up, and pain coping among AAs with knee OA. Other studies also suggest that effects of PCST interventions may be more robust after patients have had more opportunity to practice and incorporate skills. Dissemination of this PCST program may help to reduce racial disparities in pain.

Table 1 Mean Differences in Study Outcomes Between PCST and WL Control Groups

Outcome	Time Point	WL Control (N=124) Mean (95% CI)	PCST (N=124) Mean (95% CI)	Treatment Difference: PCST-WL Mean (95% CI)	p-value

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Pathologic T cell-B cell interactions and production of autoantibodies are hallmark features of SLE. T follicular helper (Tfh) cells are generally considered the principal T cell population capable of helping B cells. However, distinct T cell populations can augment B cell responses in chronically inflamed peripheral tissues. We recently described a dramatically expanded population of T peripheral helper (Tph) cells that promotes B cell responses in synovium of patients with seropositive RA. Here we evaluate the frequency, phenotype, and clinical associations of Tph cells in the circulation of patients with lupus.

Methods: Mass cytometry data from the Accelerating Medicines Partnership RA/SLE Network were used to quantify cell populations in PBMCs from 27 lupus nephritis patients, 27RA patients, and 25 non-inflammatory controls. Frequencies of Tph cells (PD-1^{hi}CXCR5⁻ CD4⁺ T cells), Tfh cells (PD-1^{hi} CXCR5⁺CD4⁺ T cells), and CD21^{low} CD19⁺ B cells were quantified by standardized gating, and associations with SLEDAI and dsDNA titers were assessed. For *in vitro* T cell-B cell co-cultures, sorted Tph cells, Tfh cells, or control T cell populations from SLE patients were co-cultured with memory B cells and stimulated with SEB + LPS, and CD38^{hi} CD27⁺ plasmablasts were quantified at day 5.

Results: We first confirmed that Tph cells (PD-1^{hi} CXCR5⁻ CD4⁺ T cells) from SLE patients possess B cell helper function, as we previously observed in RA. Tph cells sorted from blood from 5 different lupus patients strongly induced B cell differentiation into CD38^{hi} CD27⁺ plasmablasts *in vitro* (Figure 1A). By mass cytometry, Tph cells are markedly expanded in the circulation of SLE patients compared to non-inflammatory controls (4.3-fold increase, p<0.0001, Figure 1B). Tfh cells are also increased in the SLE patients compared to controls (1.9-fold); however, the magnitude of the increase in Tph cells in SLE patients well exceeds that of Tfh cells. Tph cell frequency is higher in lupus nephritis

Figure 1: Expanded Tph cells in SLE patients. A) Plasmablast differentiation induced *in vitro* by PD-1-high CXCR5-neg Tph cells or other T cell populations sorted from PBMCs of SLE patients (n=5 donors). B) Proportion of Tph cells among memory CD4+ T cells in PBMC from SLE, RA, and control patients by mass cytometry. C) Correlation between circulating Tph cells and CD21-low B cells in SLE patients (red) or including all patients (black). Spearman statistics.

patients with dsDNA titers >50 ($p=0.017$) and with SELENA-SLEDAI > 10 ($p=0.046$) compared to patients with lower disease activity measures. Similar associations with disease activity were not observed for Tfh cells. Expression of surface receptors on Tph cells from SLE and RA patients was similar. A strong positive correlation emerged between the frequencies of Tph cells and CD21^{low} B cells, an activated B cell population highly expanded in SLE (Spearman $r=0.56$, $p=0.0026$, Figure 1C). In contrast, no correlation was seen between Tfh cells and CD21^{low} B cells in SLE patients.

Conclusion: Tph cells are markedly expanded in the circulation of patients with SLE and demonstrate robust B cell helper function. The strong and specific positive correlation between Tph cell and CD21^{low} B cell frequencies suggests that these cells may act coordinately in the pathologic autoimmune response in SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Autoreactive T-B cell interactions in lymphoid tissue have been thought to play a crucial role in the autoantibody production in systemic lupus erythematosus (SLE). These CD4⁺ T cells are known as follicular helper (T_{FH}) cells expressing CXCR5, a chemokine receptor promoting cell migration to B cell follicles. Recently, a new population of ‘peripheral helper’ T (T_{PH}) cells that help B cell responses has been discovered in synovium of patients with rheumatoid arthritis. Like T_{FH} cells, T_{PH} cells express ICOS and PD-1, but these cells lack CXCR5. Here we assessed whether T_{PH} cells are involved in the pathogenesis of SLE.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from SLE patients and age- and sex-matched healthy individuals as controls. The patients fulfilled the 1997 ACR criteria. A total of 65 patients provided blood samples (57 women and 8 men). The median age of patients was 41 years (range, 21-52), and the median SLEDAI score was 4 (range 0-31). The majority of patients (n=54) were taking medications such as glucocorticoids, hydroxychloroquine, tacrolimus, cyclosporine, azathioprine, mizoribine, and mycophenolate mofetil. Isolated PBMCs were stained with antibodies against CD3, CD4, CD45RA, CXCR5, PD-1, ICOS, CD19, CD20, CD27, CD38, CD180, IgD, and HLA-DR,

and were analyzed by flow cytometry. T_{PH} were defined as PD-1^{hi}CXCR5⁺CD45RA⁺CD4⁺CD3⁺ cells. Frequency and activated status of T_{PH} cells were compared with those of other immune cells including B cell subsets, clinical data (anti-DNA antibody titers, serum complement levels, and lymphocyte counts) and SLEDAI. IL-21-producing capacity of T_{PH} upon stimulation with phorbol 12-myristate 13-acetate (PMA) and ionomycin was analyzed with intracellular staining.

Results: The proportions of T_{PH} cells as well as activated T_{PH} cells were increased in SLE patients than healthy controls. The frequency of T_{PH} cells positively correlated with SLEDAI and anti-DNA antibody titers, and negatively correlated with serum complement levels. Activated T_{PH} cells were also associated with SLEDAI, anti-DNA antibody titers, serum complement levels, and lymphocyte counts. We did not observe differences in relative frequencies of T_{PH} cells in SLE patients regardless of treatment. As previously reported, the frequency of plasmablasts was increased in SLE patients and correlated with disease activity. The frequency of activated T_{PH} cells were correlated with that of plasmablasts and activated switched memory B cells. Lupus T_{PH} cells had the capacity to produce IL-21, a pivotal cytokine for B cell and plasma cell differentiation.

Conclusion: Our data demonstrate that the increased frequency and activated status of T_{PH} cells are associated with the disease activity as well as enhanced B cell responses in SLE. CD4⁺ICOS⁺PD-1⁺ cells and plasma cells were reported to be present in the nephritic kidneys and associated with active disease in SLE. Because T_{PH} cells also express ICOS and PD-1, the interaction of T_{PH} cells with B cells may occur in the lupus kidneys and contribute to the autoantibody production in the peripheral tissue in SLE.

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: The cell-types and pathways driving lupus nephritis (LN) are incompletely understood. The Accelerating Medicine Partnership lupus network Pathway Exploration and Analysis in Renal disease (AMP-PEARL) consortium sequenced RNA from ~2,900 single cells from LN kidney biopsies from 24 patients and discovered 21 immune cell types, including 5 myeloid subsets. This study provided unprecedented molecular information, but lacked *in situ* immune cell spatial context and was underpowered for associations with clinical outcomes. We investigated the *in situ* organization of the immune landscape to determine whether it drives clinical outcomes. Because myeloid cells link innate and adaptive immunity, we hypothesized that their *in situ* organization reflects the physical configuration of larger immune cell networks that promote kidney remodeling and clinical outcomes.

Methods: We assembled a new cohort of 30 LN patients presenting with Class III or IV disease of varying severity who had their 1st kidney biopsies (naïve to potent immune-modulators). To dissect the *in situ* organization of the 5 new myeloid subsets (3 monocyte phenotypes, 1 dendritic cell, and 1 resident macrophage), we converted single cell RNA-sequencing signatures into molecular stains based on highly expressed myeloid subset-specific discriminatory genes with known biological functions. We then stained clinical samples from our cohort for multiplex fluorescent imaging and quantification across tissue sections.

Results: We validated the 5 new myeloid subsets and find they are similarly organized across class III and IV tissue: one monocyte subset (alternatively activated) is excluded from glomeruli but present in the interstitial space; two other monocyte subsets (inflammatory and phagocytic) are present in glomerular and interstitial space and enriched inside tubular urinary space. We also find that DCs are enriched in interstitial over glomerular space.

Conclusion: By converting single cell RNA sequencing information into molecular stains, we developed a novel approach to validate *in situ* the 5 newly identified myeloid subsets and mapped each to anatomic niches in class III and IV tissue, suggesting molecular organizing principles drive *in situ* cellular configurations. We are also mapping myeloid subsets in class V LN, histopathological lesions, and examining their connectivity to larger immune cell networks by quantifying the composition of neighboring immune cells (T, B, NK cells) to identify the rules of *in situ* immune cell organization. We will examine our findings with clinical outcomes, possibly laying the groundwork for disease re-classification based on the immune response and highlighting cell-types and intercellular connections for follow up studies. We anticipate that this approach can be applied to other cell and tissue types.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disorder with a heterogeneous clinical presentation and periods of waxing and waning disease. Heterogeneity in SLE is influenced by genetic and non-genetic susceptibility found in different ethnicities that drive disease expression and severity. The immune pathways that contribute to heightened disease activity in lupus and immune variation by race are critical to understanding SLE disease mechanisms and outcomes.

Methods: Peripheral whole blood samples of European or African American healthy controls (n=18) and SLE patients with either high (SLEDAI \geq 4) (n=20) or low (SLEDAI<4) (n=20) disease activity were stimulated for 4 minutes with either interferon- α (IFN α), PMA and ionomycin, or Toll-like receptor (TLR) ligands for either TLR4, TLR7/8 or TLR9 for phospho-protein analysis. Phenotype and phospho-protein analysis was assessed by CyTOF and cell heterogeneity was analyzed using t-SNE and manual gating. All SLE patients met ACR classification criteria.

Results: European American SLE patients with high disease activity were differentiated from patients with low disease activity by reduced frequencies of peripheral B cells, specifically naïve B cells (CD27-IgD+CD24^{lo}) (p=0.0101) and double negative B cells (CD27-IgD-) (p=0.0220), while African American patients with high disease activity had elevated frequencies of memory B cells (CD27+IgD-CD38+) (p<0.05) compared to patients with low disease activity. Several cell

subsets had increased expression of activation markers during high disease activity including B cells ($p=0.0350$) and plasmacytoid dendritic cells (pDCs) ($p=0.0435$) in European Americans (Figure 1A), and neutrophils ($p<0.05$), pDCs ($p=0.005$), CD8+ T Cells ($p=0.0003$) and NKT cells ($p=0.0033$) in African Americans (Figure 1B). Following whole blood stimulation with IFN α , African American high disease activity patients were distinguished by reduced ability to activate pSTAT5 in almost all major cell populations ($p<0.05$), and pSTAT3 in monocytes ($p=0.0157$), granulocytes ($p=0.01$) and B cells ($p=0.0409$) compared to low disease activity patients and controls, possibly due to higher basal levels of activation. Further, granulocytes and all antigen presenting cells had reduced activation or unchanged levels of pCREB, p-p38, pCREB and Syk following TLR7/8 stimulation in African American high versus low disease activity patients ($p<0.05$). European American high disease activity SLE patients were distinguished by increased signaling in B cells and dendritic cells following TLR4 and TLR7/8 stimulation, specifically in p-p38, pERK1/2, and pCREB ($p<0.05$).

Conclusion: Our results support a model where race influences heightened SLE disease activity mechanisms with dysregulation in B cell signaling and other antigen presenting cells following TLR7/8 and Type I IFN pathway activation.

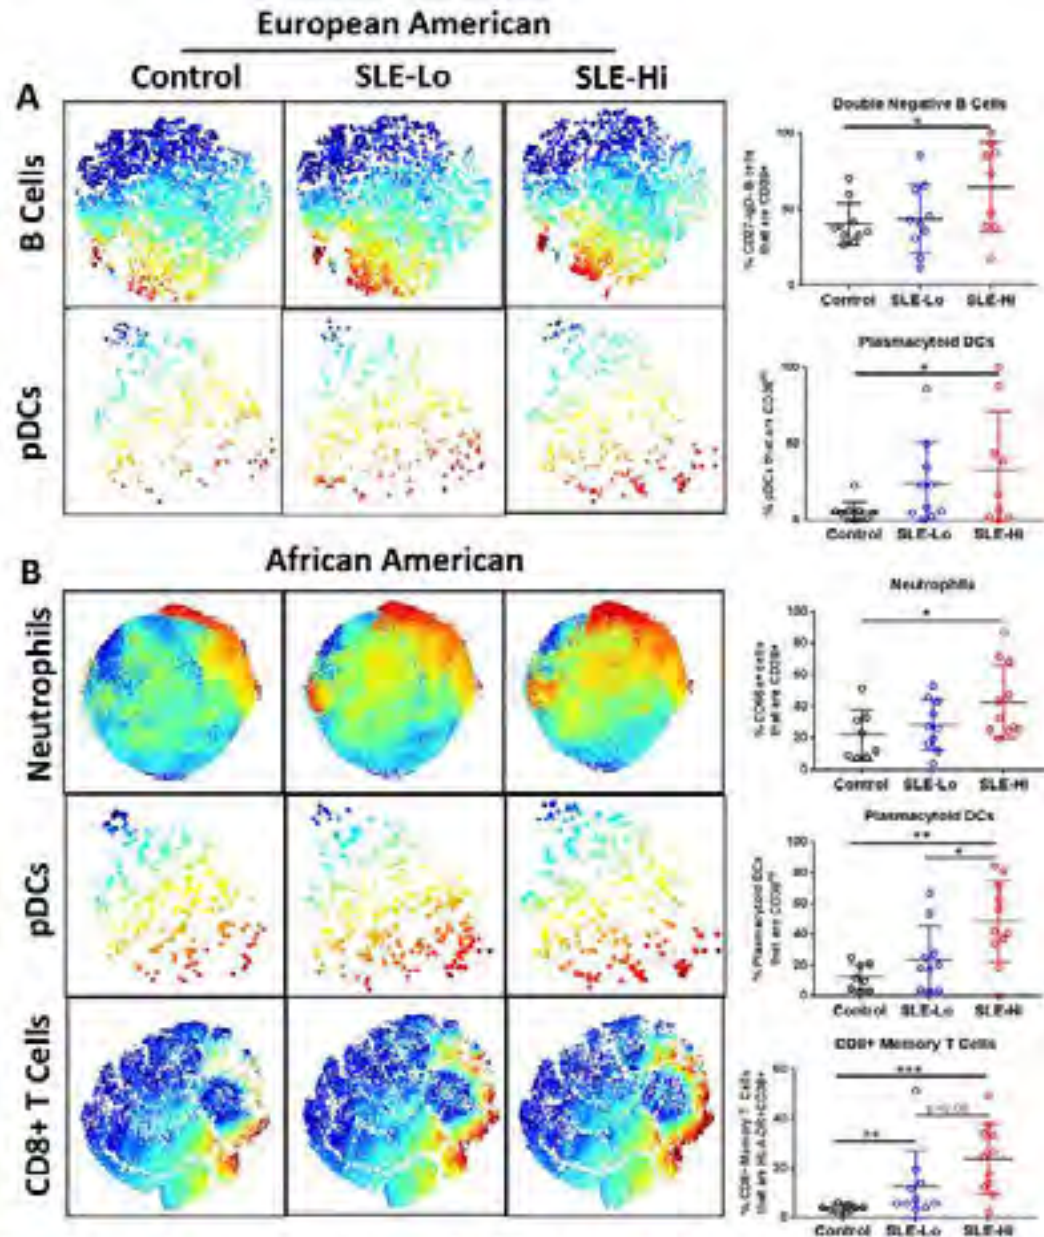

Figure 1. Cell activation markers are increased in SLE patients with high disease activity. All cell subsets as determined by gating in visNE were assessed for frequencies of activation, inhibitory and chemokine receptors. Concatenated files of controls and SLE patients were used to create visNE dot plots individually colored by channel using ArcSinh-5 transformed expression values. visNE of visNE plots was used for representation of specific populations showing CD38 expression in European Americans (A) B cells and pDCs, and African Americans (B) neutrophils, pDCs and CD8+ T Cells. Significant differences in cell surface marker expression are also shown using bar graphs. Median \pm interquartile range shown * $p<0.05$, ** $p<0.01$, and *** $p<0.001$.

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Renal histology remains a primary tool for classification and treatment decisions in lupus nephritis (LN). Single-cell RNA-seq (scRNA-seq) analysis may provide mechanistic insights into the genesis; more precisely categorize different pathologic subtypes; and better inform treatment decisions and prognosis. Here we characterized single-cell transcriptome profiles of the renal cellular landscape using scRNA-seq.

Methods: ScRNA-seq was performed on ~2 mg cryostored kidney tissue collected from clinically indicated renal biopsies in 9 SLE patients and 2 healthy transplant donors. A droplet-based 10X Chromium platform (10X Genomics) was used to capture single cells in emulsion followed by cDNA synthesis. The cDNA library was sequenced on Illumina HiSeq 2500. Cell-barcode and unique molecular identifiers (UMIs) were tagged in read1, an adapter was trimmed from 5' of read2 and poly(A) sequences of length 6 or more were removed. The resulting reads were aligned to the human (hg38) reference genome and a single cell gene expression matrix was generated. Using a graph-based method embedded in the Seurat package, cell clustering analysis was performed. Cells with > 25% mitochondrial content were considered poor quality and filtered out as were any cells with < 100 genes detected.

Results: We obtained 16,192 and 3,104 high-quality scRNA-seq profiles from 9 LN patients (class I, II, IV/V and IV) and 2 donor controls respectively. Graph-based clustering analysis revealed several cell clusters as visualized by *t-distributed stochastic neighbor embedding (t-SNE)*. Differential gene expression analysis along with expression of established lineage markers revealed these clusters as loop of Henle (LH), proximal convoluted tubule (PCT), distal convoluted tubule (DCT), intercalated cells (IC), mesangial cells (MC), podocytes (PC), T cells (TC), macrophages (MAC), B cells (B cell), plasmablasts (PB), endothelial cells (EC) and fibroblasts (FB). Differential gene expression analysis revealed elevated levels of interferon response genes such as *IFI6*, *IFITM1*, *IFITM3* and *ISG15* in CD, DCT and EC of LN samples. In addition, *WFDC2*, recently described as an LN biomarker, was upregulated in CD and DCT of LN samples. PCT in the LN samples revealed increased expression of *COL4A1*, *COL4A2* and *COL18A1* genes whose proteins form the structural component of the basement membrane. FB detected in the LN samples expressed *COL1A1*, *COL1A2*, and *COL3A1* as the most abundant collagen genes.

Conclusion: ScRNA-seq derived from excess and limited cryostored renal biopsy tissue in LN can be used to generate a cellular atlas invaluable to the study of heterogeneity in disease. These data provide important insights into potential pathogenic mechanisms, particularly with regard to tissue fibrosis so highly relevant to the ultimate renal prognosis.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: We previously reported that treatment with ustekinumab (UST), an anti-IL-12/23 p40 neutralizing monoclonal antibody, improved global and organ-specific measures of disease activity in a randomized, placebo (PBO)-controlled study of patients with active SLE (NCT02349061)¹. Type I interferon (IFN-I) and type II IFN (IFN-g) are elevated in a subset of SLE patients. The comparative effects of IFN-I and IFN-g in SLE remain uncertain, although targeting IFN-I (anifrolumab) has demonstrated clinical efficacy, whereas a preliminary study with anti-IFN-g mAb (AMG811) failed to establish benefit^{2,3}. Given the potential importance of the IFN-I and IFN-g pathways in SLE pathogenesis, we studied the effects of UST treatment on both IFN-I and IFN-g in patients with active SLE.

Methods: We conducted a phase 2, PBO-controlled study in 102 adults with seropositive SLE by SLICC criteria and active disease (baseline SLEDAI score ≥ 6 and ≥ 1 BILAG A and/or ≥ 2 BILAG B scores) despite standard-of-care therapy¹. Gene expression analysis using a previously published 21 gene IFN-I gene signature (IGS)⁴ was performed by microarray analysis using whole blood PAXgene RNA samples. Analysis of serum protein levels of IFN-g and IFN- α was performed using MSD (IFN-g) and Quanterix (IFN- α) platforms.

Results: Serum levels of IFN-g and IFN- α and the IGS were significantly elevated at baseline versus healthy controls ($p < 0.0001$). Approximately 67% of the SLE patients were IGS high at baseline. At 4 weeks, patients who received UST, but not PBO, exhibited decreased IFN-g protein levels ($p = 0.0032$). Despite non-significant differences at baseline, there was a trend toward greater reduction in IFN-g levels in UST-treated patients who achieved an SRI-4 response at wk24 compared to non-responders. There was no decrease in IFN- α protein levels or the IGS after treatment with either UST or PBO. Whereas the proportion of patients achieving an SRI-4 response at wk24 was numerically greater in the IGS low patients (81.8% UST vs. 54.5% PBO) versus the IGS high (48.6% UST vs. 20% PBO) population, the magnitude of the treatment effect (UST vs. PBO) was similar in both subsets (IGS low effect size = 27.3% vs. IGS high effect size = 28.6%).

Conclusion: In this SLE trial population which had significant upregulation of IFN-I protein and IGS at baseline, clinical response to UST was not associated with IFN-I reduction. In contrast, a significant decrease in IFN-g protein levels was associated with UST treatment. These findings suggest that a broad population of SLE patients may respond to UST regardless of baseline IFN status. Moreover, an effect of UST treatment on TH1 responses manifested by IFN-g levels in SLE patients was suggested, a finding that will be tested in a phase 3 trial.

Major NSAID Toxicity: Derivation and Internal Validation of a Simple Clinical Risk Score

Daniel Solomon¹, Ming Shao², Katherine E Wolski³, Steven E Nissen⁴, M. Elaine Husni⁵ and Nina Paynter⁶, ¹Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ²Cleveland Clinic Foundation, Cleveland, OH, ³Cardiovascular Medicine, Cleveland Clinic, Cleveland, OH, ⁴Cardiovascular Medicine, Chair, Cleveland Clinic, Cleveland, OH, ⁵Orthopedic and Rheumatologic Institute, Cleveland Clinic, Cleveland, OH, ⁶Medicine, Harvard University, Boston, MA

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Epidemiology and Public Health IV: Determinants and Consequences of Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: NSAIDs and Coxibs represent one of the most commonly prescribed drugs by rheumatologists and are used regularly by >10 million Americans. While most patients enjoy analgesic benefits with these medications, some experience major toxicities. Improving the risk-benefit ratio requires a more precise understanding of the risks for an individual patient. The goal of this research was to derive and validate a risk score for major NSAID toxicity.

Methods: The TRIPOD recommendations were followed for conducting this research, such that patients recruited during the first 4 years (n = 15,196) of enrollment in the PRECISION trial were used to derive a risk score and patients enrolled in last 5 years (n= 8,757) were used for validation. Participants were censored at 1 year, patient termination of study NSAID or time of first major toxicity. The major NSAID toxicity outcomes included cardiovascular (CV) event, clinically significant gastrointestinal event, significant renal events, or death. Variables significantly associated (p<0.1) with major toxicity after adjustment for baseline age and gender were candidates for inclusion in the final Cox proportional hazards regression model. Discrimination of the model was assessed with the c-index and calibration was assessed by examining the slope from the observed to expected risk plots. After derived models were found to have similar model fit statistics in the validation set, the cohorts were combined, allowing calculation of a risk score for the 1-year probability of major NSAID toxicity. Three risk categories were created: very low (<1%), moderate (1 to <4%) and high (4+%); agreement was assessed between predicted and observed risk.

Results: In the derivation cohort, statistically significant variables included age (HR1.03 per year), male sex (HR 1.51), history of CVD (HR 1.94), history of hypertension (HR1.29), history of diabetes (HR 1.42), aspirin use (HR 1.37), tobacco use (HR 1.55), statin use (HR 1.43), elevated serum creatinine (HR 2.83), hematocrit \geq 43% (HR 1.05), and RA (vs OA; HR 1.79). Harrell's c-index was 0.66 in the validation cohort and the model was well calibrated for the risk of major NSAID toxicity (calibration slope 0.75 for observed to predicted probabilities of outcomes). In the total population (n = 23,953), 1,389 (5.8%) had predicted 1 year risk <1%, 15,979 (66.7%) had predicted 1 year risk 1-4%, and 6,367(26.6%) had predicted 1 year risk >4%. Calibration in the combined cohort is demonstrated in the survival probability plot (see Figure).

Conclusion: We have derived and internally validated a risk score using data from the PRECISION trial to predict the 1 year risk of major NSAID toxicity for patients with osteoarthritis or rheumatoid arthritis on chronic NSAIDs. Elements of the score are easy to obtain and, if found to be externally valid, could help clinicians and patients determine risk-benefits of chronic NSAID use.

Disappearance of Autoantibodies in RA: Does It Occur with Current Treatment Strategies? a Long-Term Follow-up Study in Patients That Achieved DMARD-Free Sustained Remission

Debbie M. Boeters¹, Leonie E. Burgers¹, René E.M. Toes¹ and Annette H.M. van der Helm-van Mil^{1,2}, ¹Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, ²Department of Rheumatology, Erasmus Medical Center, Rotterdam, Netherlands

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Epidemiology and Public Health IV: Determinants and Consequences of Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Disease modifying antirheumatic drug (DMARD)-free sustained remission, the sustained absence of arthritis after cessation of all DMARD-therapy, is increasingly achievable with current treatment strategies. It is a proxy of cure of RA and also signifies normalisation of functional status. Absence of ACPA is an important predictor. Nonetheless, $\leq 10\%$ of ACPA positive patients currently achieves this outcome. It has recently been suggested that immunological remission, defined as disappearance of ACPA and RF, is a proxy of cure. (Schett G, *ARD*, 2016) We performed a long-term observational study in ACPA and/or RF positive patients to determine if these autoantibodies disappear in patients who achieve DMARD-free sustained remission, thus after having developed the best possible clinical outcome.

Methods: Of 1587 RA patients (970 RF and/or ACPA positive) included in the Leiden Early Arthritis Clinic, 339 (21%) achieved DMARD-free sustained remission. Of these, 117(35%) were ACPA and/or RF positive at diagnosis and were studied. In addition 22 autoantibody positive RA patients who experienced a late flare after having been in DMARD-free remission for 2.4 years were studied. As control, 50 autoantibody positive RA patients who were unable to stop DMARD therapy, were evaluated. DMARD-free sustained remission was achieved after a median follow-up of 4.5 years. Median total follow-up was 13 years. ACPA and RF levels were determined in serial samples, at least at baseline and at and/or after achieving DMARD-free remission.

Results: 12.8% of ACPA positive RA patients who achieved DMARD-free sustained remission, had converted to ACPA-negativity at achieving remission (Figure). However within RA patients with a late flare or with persistent disease and similar follow-up duration this occurred in 8.3% and 5.7%, respectively ($p=0.56$). For RF similar results were observed. RF positive RA patients who achieved DMARD-free sustained remission had seroconversion to RF-negativity in 19.7%, whereas this also occurred in 14.6% of RF positive RA patients with persistent disease. Evaluating the estimated slope of serially measured levels revealed that the RF levels decreased significantly more in patients that achieved DMARD-free

sustained remission compared to those that did not ($p<0.001$). Within ACPA-positive patients however, there was no enhanced decrease in ACPA levels ($p=0.66$).

Conclusion: DMARD-free sustained remission is achieved in 12% of RA patients that were autoantibody positive at diagnosis. Only a minority had converted to seronegativity when DMARD-free sustained remission was achieved; this proportion was not different from that in patients with persistent disease. The finding that ACPA remains present in RA patients with sustained absence of arthritis and normalized function after DMARD-cessation suggests that immunological remission, defined as disappearance of ACPA, probably should not be a treatment target.

Healthcare utilization			
Number of outpatient visit	6.2 (±4.0)	5.3 (±3.9)	1.01 (0.99, 1.03)
Number of rheumatologist visit	2.0 (±2.3)	1.3 (±1.8)	1.15 (1.11, 1.19)
Inpatient visit	6.2	4.7	1.38 (1.04, 1.83)
Emergency department	12.9	12.2	0.85 (0.71, 1.01)

*Adjusted for demographics, comorbidities, medication use, vaccination, and healthcare utilization; some variables are not shown here.

Figure. Geographic distribution of proportion of triple therapy in the US from 2003 to 2014

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Epidemiology and Public Health IV: Determinants and Consequences of Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: While efficacy of triple therapy [methotrexate (MTX), sulfasalazine(HCO), and sulfasalazine(SSZ)] and TNF inhibitor (TNFi) plus MTX was similar in a previous clinical trial, use of triple therapy is infrequent in the US. We aimed to examine geographical and clinical factors associated with the two treatment strategies for RA.

Methods: We used Truven Market Scan data (2003-2014) to conduct a cohort study among RA patients ≥ 18 years old with MTX prescription. Triple therapy was defined as adding on both HCO and SSZ, and TNFi therapy was defined as adding a TNFi to MTX. Index date was the first dispensing date of the last drug to complete triple therapy, or TNFi. Exclusion criteria included malignancy, renal dialysis, HIV, nursing home stay, or hospitalized infection, and any prior use of study drugs except MTX 180 days before the index date. We assessed geographic patterns and baseline covariate including demographics, comorbidities, medications, and health care utilizations associated with starting TNFi or triple therapy using multivariable logistic regression.

Results: We identified a total of 46,693 patients (45,305 (97.0%) TNFi plus MTX and 1,388 (3.0%) triple therapy initiators). Females were more likely to receive TNFi therapy (OR, 95% CI = 1.17, 1.04-1.33, Table). We noted a significant geographical pattern with regard to initiation of triple therapy (Figure). Patients were most likely to receive triple therapy in Midwest (Table, Figure). Specifically, Nebraska had the highest rate of receiving triple therapy, followed by its adjacent states. We did not find any association between underlying cardiovascular diseases and either of two treatment groups. However, obese patients were 42% more likely to be started on triple therapy. Baseline psoriasis and inflammatory bowel disease increased odds of receiving TNFi (OR, 95% CI = 4.88, 3.05-7.80 and 3.57, 1.14-11.14). Generally, TNFi initiators used more medications and had rheumatologist or inpatient visit more frequently than those on triple therapy.

Conclusion: In this large nationwide cohort of RA patients, triple therapy use was infrequent. Geographical and certain clinical factors such as coexisting psoriasis or inflammatory bowel disease, use of bisphosphonates, proton pump inhibitors, frequency of rheumatologists visit, and inpatient visit were associated with choosing TNFi versus triple therapy.

Risk of Neurological Adverse Events during Tumour Necrosis Factor Inhibitor Treatment for Arthritis: A Population-Based Cohort Study from Danbio and the Danish National Patient Registry

Lene Dreyer¹, Tine Iskov Kopp², Rikke Kart Jacobsen³, Melinda Magyari², Else Helene Ibfelt³, Henning Locht⁴, Finn Thorup Sellebjerg², Dorte Vendelbo Jensen⁵ and René Cordtz⁶, ¹Departments of Rheumatology and Clinical Medicine, Aalborg University Hospital and Aalborg University, 9000 Aalborg, Denmark, ²Danish Multiple Sclerosis Center, Department of Neurology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, ³Center for Clinical Research and Prevention, Bispebjerg and Frederiksberg Hospital, Frederiksberg, Denmark, ⁴Department of Rheumatology, Frederiksberg Hospital, Copenhagen, Denmark, Copenhagen, Denmark, ⁵The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark, ⁶Center for Rheumatology and Spine Diseases, Gentofte-Rigshospitalet, Hellerup, Denmark

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Epidemiology and Public Health IV: Determinants and Consequences of Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Tumor necrosis factor alpha inhibitors (TNFi) have successfully been used for the treatment of immune-mediated inflammatory disorders including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) since 1998. However, several case reports and series have indicated that different neurological disorders including multiple sclerosis (MS), inflammatory neuropathies, demyelinating diseases and optic neuritis may be a serious, although rare, adverse event following TNFi treatment. A field of complexity as some studies show that RA is protective of MS and vice versa. We investigate the association between new-onset neurological events following TNFi-treatment in arthritis patients compared to non-TNFi-treated arthritis patients.

Methods: 41,026 patients registered in DANBIO between January 1, 2000 and January 20, 2017 were identified with a diagnosis of either RA, AS or PsA. Complete follow-up on mortality, emigration and newly diagnosed neurological diseases suspected to be associated with use of TNFi until May 10, 2017 was obtained by linkage to the Danish National Patient Registry and the Civil Registration System. A cox proportional hazard model was used to examine the association between use of TNFi and risk of a neurological event.

Results: The DANBIO arthritis cohort experienced 223,861 person-years of observation. 98 patients were diagnosed with demyelinating disease or inflammatory neuropathy during follow-up, with 49 contacts among ever TNFi-treated patients and 49 contacts among non-TNFi-treated patients corresponding to a Hazard Ratio (HR) of 1.52 (95% Confidence Interval (CI): 0.96-2.42) adjusted (adj) for age, gender and year of inclusion. TNFi treatment among RA patients was not associated with an increased risk of a neurological event ($HR_{adj}=1.19$, 95% CI: 0.65-2.18), whereas PsA and AS patients had an increased risk of having a neurological event following TNFi treatment ($HR_{adj}=2.61$, 95% CI: 1.11-6.13). In on-drug models the HR_{adj} for neurologic events in RA was 0.95 (95% CI: 0.49-1.83) and 2.43 (95% CI: 1.01-5.83) in PsA/AS.

Conclusion: The use of TNFi for the treatment of arthritis may be associated with increased risk of having a demyelinating disease or inflammatory neuropathy among patients with PsA or AS. Since these events are rare, larger multicenter studies are warranted to further characterize the risk.

Changing Trends and Prescribing Patterns in Opioid-Treated Primary Care Patients with Non-Cancer Pain over a 10-Year Period

Meghna Jani, Belay Birlie Yimer, Therese Sheppard, Mark Lunt and William G Dixon, Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom

Session Information

Session Date: Wednesday, October 24, 2018

Background/Purpose: The opioid epidemic in the U.S. has led to similar concerns about prescribed opioids in the U.K. In new users, the rate of escalation to more potent opioids is likely to contribute to long-term prescriptions, which in turn may be associated with opioid dependency, addiction and overdose. The scale of such escalation however is unclear in the U.K. We sought to: (i) describe trends of prescribed opioids for non-cancer pain in the UK primary care setting over a 10-year period (ii) assess the sequential transition of opioid strength from index date over a 2-year period. **Methods:** We conducted a retrospective observational study from 1/1/2006 to 31/12/2015 using Clinical Practice Research Datalink (CPRD). New users of opioids, >18 years without cancer in the 2 years prior to index date were identified. The number of prescriptions for each drug were calculated by each calendar year accounting for the number of eligible patients registered in CPRD for that year. Sunburst plots were created to evaluate the sequential transition of opioids over time. A 4-state hidden Markov model was used to estimate the transition probability for individuals escalating to more potent opioids over a 2 year period. States were defined as (i) no drug (ii) weak opioid (codeine, dihydrocodeine) (iii) moderate opioid (tramadol) (iii) strong opioid (all others).

Results: 968,797 opioid users were included: mean age (SD) was 55(18) years; 59% being female. New users of opioids were most commonly prescribed codeine (n=685,823; 71.0%), followed by dihydrocodeine(n=166,906; 17.2%), tramadol (n=85,840, 8.8%) with 194,373 (20.1%) strong opioid prescriptions. The rate of prescribing strong opioids/10,000 population increased 12 fold from 2006-2013 (Figure 1). Transitions between opioid strength are demonstrated in Figure 2. Of new users prescribed weak opioids as their first prescription, 5.2% transitioned to moderate opioids, 4.1% to strong opioids over 2 years. Transition probability of moving from weak to strong opioid at a given time point over 2 years was 0.001, whilst staying on a strong opioid (if first prescription) was 0.97.

Conclusion: Strong opioid prescribing increased till 2013-14 gradually decreasing following UK initiatives to improve monitoring and use of controlled drugs. Although less potent codeine prescriptions made up the majority of first prescriptions, the transition probability of staying on a strong opioid at 2 years remained high if prescribed first as a new user.

Figure 1:Trends in strong opioid utilisation in CPRD by individual opioids

Figure 2: Opioid pathway over 2-year period from index date (excluding repeated prescriptions)

Socioeconomic Differences in Opioid Use By People with Inflammatory Arthritis

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Epidemiology and Public Health IV: Determinants and Consequences of Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Internationally, prescription opioid use is often higher among patients of lower socioeconomic status (SES). In addition, despite improved treatments for inflammatory arthritis, opioid use remains high among patients with inflammatory rheumatic diseases. The aim of this study was to determine the effect of lower SES on opioid use in people with inflammatory arthritis.

Methods: The Australian Rheumatology Association Database (ARAD) is an observational database that collects outcome data for people with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and juvenile idiopathic arthritis (JIA). Participants complete semi-annual then annual questionnaires, which includes demographic and social details, self-reported medical history and medication use, and quality of life scales. We used the baseline questionnaire to examine opioid use between 2006 and 2016. Opioids classified were aspirin/codeine, paracetamol/codeine, dextropropoxyphene, oxycodone, oxycontin, morphine and tramadol. As a measure of SES, participants were assigned an Australian Bureau of Statistics (ABS) Socio-Economic Indexes for Areas (SEIFA) score (Index of Advantage/Disadvantage) based on their postcode (SEIFA 1= lowest quintile, SEIFA 5= highest quintile).

Results: 34.0% of 4,429 ARAD participants were taking opioids at baseline. Use was significantly more prevalent in lower SES participants (SEIFA 1: 47.4%, SEIFA 5: 36.6% (OR 1.56; 95%CI 1.22-2.00)). When other significant factors were considered in a multivariable model (including HAQ score (OR 1.85; 95%CI 1.64-2.09), currently smoking (OR 1.35; 95%CI 1.08-1.68) and being permanently unable to work (OR 1.66; 95%CI 1.26-2.19)), lower SES was still more prevalent but not significantly (OR 1.08; 95%CI 0.83-1.42). The prevalence of baseline opioid use between 2006 and 2016 did not change significantly. The prevalence of use in the SEIFA 1 participants remained higher than SEIFA 5 throughout this time period ($p < 0.05$). Although the most commonly used opioid was paracetamol/codeine, the more potent opioids (oxycodone and morphine) were associated with higher use in lower SES.

Conclusion: Although opioid use was more prevalent in the lower SES group, the strongest predictor of use was a high HAQ score, indicating more disability. Current smokers and those permanently unable to work were also more likely to take opioids. Higher use in lower SES groups has been evident over time and has not altered. Future research into the reasons for this difference may include further exploration of factors predictive of cessation and prescriber characteristics.

Session Date: Wednesday, October 24, 2018

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Lupus nephritis (LN), seen in up to 60% of individuals with SLE, progresses to end stage renal failure in 10-30% of patients within 15 years of diagnosis. Few studies have evaluated performance on LN quality measures. Using measures from the SLE quality indicators project and 2012 ACR guidelines for monitoring and treating LN, we evaluated quality of care for LN across multiple clinical sites for patients enrolled in the multi-ethnic, population-based cohort of the California Lupus Epidemiology Study (CLUES).

Table 1: Description of quality measures and pass rates for each measure			
Quality Measure	Description	Eligible, n	Pass, n (%)
Screening measures (denominator population: prevalent SLE, no history of nephritis)			
1) Lupus nephritis labs	Urinalysis, urine protein/creatinine ratio, creatinine every 6 months in year prior to CLUES visit	129	53 (41.1)
2) SLE activity serologies	C3 or C4, and anti-DNA levels every 6 months in year prior to CLUES visit	129	48 (37.2)
3) Blood pressure	Blood pressure recorded every 6 months in year prior to CLUES visit	129	109 (84.5)
Diagnosis of lupus nephritis (denominator population: suspected LN defined by ACR criteria: i.e. increasing creatinine without alternative cause, proteinuria more than 1gm/24 hours, or proteinuria more than 0.5gm/24 hours plus hematuria, or proteinuria more than 0.5gm/24 hours with cellular casts)			
4) Renal Biopsy	Within 1 year of suspected LN unless contraindicated	89	58 (65.2)
Timely and appropriate treatment (denominator population: incident or relapsed LN)			
5) Initiation of immunosuppressant (mycophenolate, cyclophosphamide, azathioprine, cyclosporine, tacrolimus, rituximab)	Within 30 days of LN diagnosis	94	80 (85.1)
6) Initiation of anti-malarial treatment	Within 1 year of LN diagnosis	91	81 (89.0)
7) Initiation of ACE inhibitor or ARB	Within 1 year of LN diagnosis	93	75 (80.7)
8) Blood pressure target	≥140/90 within 1 year of diagnosis	94	71 (75.5)

Notes on eligibility:

4) Renal biopsy: 5 patients excluded from denominator because 3 patients had APLS on anticoagulation, 1 patient had ITP with intracerebral hemorrhage, 1 patient had prolonged coagulation studies.

6) Anti-malarial: 3 patients excluded from denominator because of allergy or intolerance to anti-malarial agent (1 patient with alopecia).

7) ACE inhibitor or ARB: 1 patient excluded from denominator because of renal failure presentation

Methods: Participants were recruited from 2015 to 2017. Data were collected during in-person clinical study visits and from a comprehensive medical record review. The primary outcome was performance on LN screening measures in those without prevalent LN, and for diagnosis and treatment measures in those with LN (Table 1). Covariates were

Based on GEE with an observation for each patient for each eligible quality measure.				
Models adjusted for all models shown, plus age, disease duration, and years with current provider, which were not associated with overall pass rates in any model.				
*p<0.05				

sociodemographics (age, gender, race/ethnicity, education, household income), clinical measures (disease duration and lupus severity index), and practice characteristics (provider setting and number of years with current provider). An overall pass rate was calculated, defined as the percentage of measures passed for which a patient was eligible; that is, among those eligible for a specific intervention, what percentage received it. Generalized estimating equations (GEE) with a logit function were used to estimate the probability of passing any one measure, with and without adjustment for covariates.

Results: Patients were followed in 25 clinical sites (2 academic, 1 staff model HMO with 6 practices and 17 community rheumatology practices). Performance on quality measures for 223 patients was evaluated, 94 of whom had LN. Overall pass rates were 54.4% for patients without LN and 78.3% for those with LN (Table 2). After adjustment in patients without LN, women and those with a higher lupus severity index had significantly higher pass rates, as did patients seen in academic settings. In patients with LN, patients with less educational attainment and those cared for in academic settings had significantly higher performance.

Conclusion: Across 25 diverse health settings, the largest gaps in care were for LN screening measures, with lower performance in community settings (vs academic) and for men. Across settings, performance was higher and more consistent for LN treatment quality measures, suggesting that once patients develop kidney disease, care is more standardized. Identification of these gaps in care can be used to target LN quality improvement initiatives.

Session Information

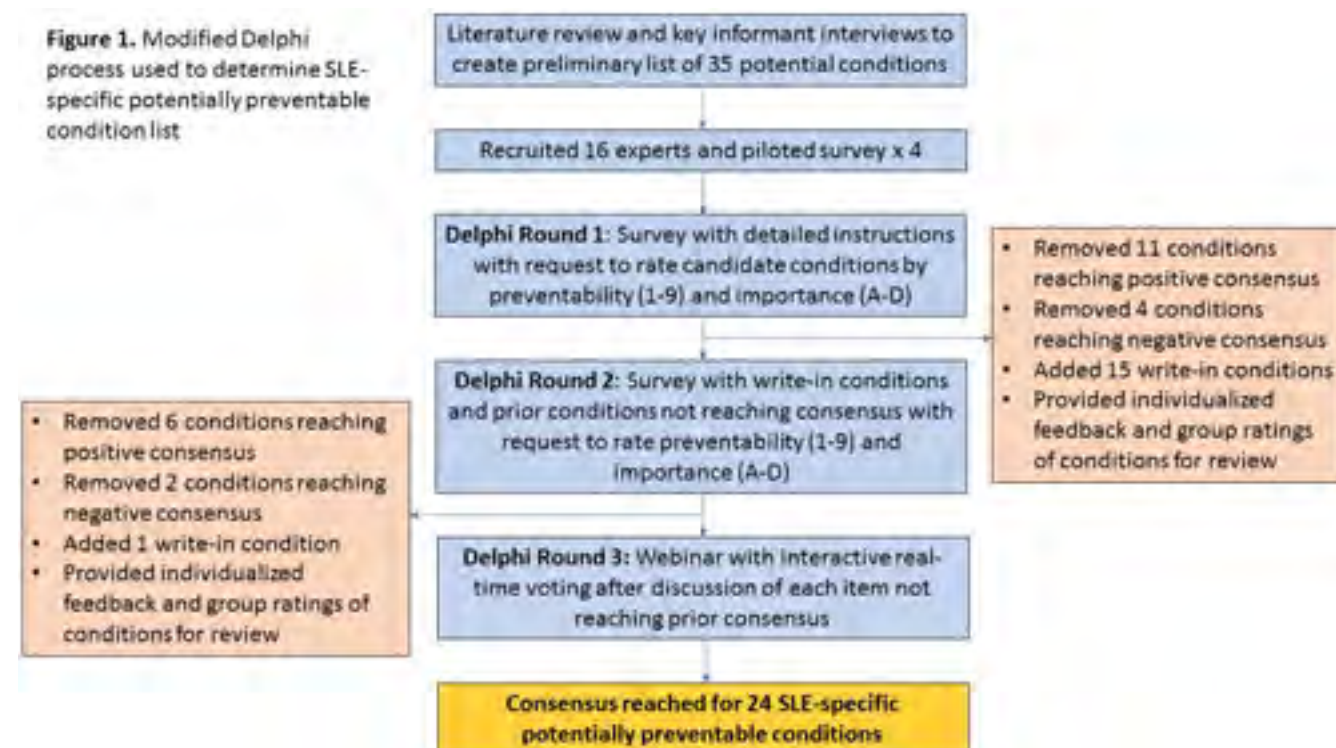

Session Date: Wednesday, October 24, 2018

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: The U.S. Agency for Healthcare Research and Quality developed a set of general ambulatory care-sensitive conditions that may result acute care use (hospitalizations and emergency department visits), potentially preventable if high quality, timely ambulatory care was provided. We aimed to update and extend this work to develop a list of conditions specific to patients with SLE that may result in acute care use and could be potentially prevented, or their complications minimized, if timely, effective ambulatory rheumatology care had been received.

Methods: We performed a literature review and conducted key informant interviews to inform the selection of SLE-specific potentially preventable conditions. We then used a modified Delphi method to further refine the list. We assembled a panel of 16 nationally-recognized experts across the U.S. including adult (7) and pediatric (2) rheumatologists/researchers, a neurologist, an obstetrician/gynecologist, a cardiologist, two nephrologists, an infectious disease specialist and a dermatologist/rheumatologist with expertise in the SLE patient care and research. Panelists independently completed two web-based survey rounds in which they were asked to rate both the preventability (1(preventable)-9 (not preventable)) and importance on a population scale (A(extremely important)-D (not important)) of each condition, and to provide comments and additional conditions for consideration. Analysis was guided by the RAND-UCLA Appropriateness Method. Consensus was determined by median scores ≤ 3 , < 3 extreme responses in the contrary direction, and $\geq 65\%$ with high [A or B] importance ratings. A final webinar was used to adjudicate conditions that did not reach prior consensus.

Results: Thirty-five potential conditions were initially considered (Figure 1). The response rate was 100% for both survey rounds and 14/16 panelists participated in the webinar process. 11 conditions met consensus criteria from round one, 6 from round two and 7 from the final round. Included conditions fell into 3 broad categories: medication-related toxicities (12 conditions), vaccine-preventable illnesses (5), or SLE-related complications (7) (Table).

Conclusion: SLE-specific potentially preventable adverse conditions include a diverse set of infectious, medication-related and SLE disease-related complications. This set of conditions will allow for identification of high risk SLE patients and facilitate targeted interventions with the goal of reducing preventable acute care use and adverse outcomes.

Table. Final set of SLE-specific potentially preventable conditions meeting consensus criteria as potentially preventable and important on a population level among patients with known SLE+

SLE-Specific Potentially Preventable Conditions	Preventability Rating 1 (definitely preventable) - 9 (not preventable)	Importance Rating*N (%)

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Early diagnosis, treatment and ongoing care are critical to optimize RA outcomes. The purpose of the study was to evaluate key elements of RA quality of care using 4 Arthritis Alliance of Canada performance measures (PMs) in Alberta, Canada: PM1) Waiting times for rheumatologist consultation for RA; PM2) Percentage of RA patients with at least one visit to a rheumatologist in the first year of diagnosis; PM3)Percentage of RA patients dispensed a disease modifying anti-rheumatic drug(DMARD); PM4) Time to DMARD initiation.

Methods: All prevalent RA cases 16 years and older between 2002/03 and 2016/17 in AB were defined using 2 or more physician billing codes at least 8 weeks apart and within a 2-year period, or 1 or more hospitalization codes for RA in health administrative data. PMs were estimated through linked datasets for fiscal years 2012-2015. PM1: The wait time in days (d) between referral and first appointment were calculated through linkage with central rheumatology triage databases in two sites. PM2: The percentage of incident RA cases with at least one visit to a rheumatologist within one year of their first RA code. PM3: The percentage of prevalent RA patients dispensed a DMARD (including conventional DMARDs, biologic agents and small molecule inhibitors) was calculated through linkage to a pharmacy database. PM4: Time from RA referral to DMARD dispensation was reported in the calendar year of RA incidence.

Fiscal Year	PM1: Waiting time for rheumatology consultation (Site 1) ¹			PM1: Waiting time for rheumatology consultation (Site 2) ²			PM2: % of RA patients with at least 1 visit to a rheumatologist ³ within the first year of diagnosis in Alberta		PM3: % of RA patients dispensed a DMARD (includes biologic and small molecule inhibitors)		PM4: Time in DMARD therapy from referral in new onset RA at or after rheumatologist appointment (Site 1)		PM4: Time in DMARD therapy from referral in new onset RA at or after rheumatologist appointment (Site 2)	
	Total incident RA	Median Waiting time (d) (Q1, Q3)	% meeting 28d benchmark	Total incident RA cases	Median Waiting time (d) (Q1, Q3)	% meeting 28d benchmark	Total incident RA cases	% meeting PM2	Total prevalent RA cases	% meeting PM3	Total incident RA cases	Median (Q1, Q3) days to DMARD	Total incident RA cases	Median (Q1, Q3) days to DMARD
2012	224	217.5 (119.5, 275.5)	0%	147	50 (28, 83)	25%	2730	55%	35113	41%	42	126.3 (49, 305)	42	73.3 (45, 135)
2013	306	89.5 (30, 221)	34%	137	53 (35, 91)	21%	2800	57%	37016	41%	216	30 (13, 268)	77	106 (52, 145)
2014	421	79 (23, 204)	20%	153	62 (27, 88)	20%	2977	60%	38806	41%	247	75 (26, 197)	67	84 (44, 230)
2015	335	128 (49, 245)	17%	154	42 (20, 88)	37%	2710	63%	40541	42%	138	165 (59, 354)	167	90 (76, 125)

RA case definition from the Public Health Agency of Canada's National Chronic Disease Surveillance System: RA cases aged more than 16 years old from linked hospitalization (Discharge Abstract Database (DAD)) and physician billing (administrative) databases using a validated case definition: 1. Hospitalization of 2 weeks (at least 6 weeks apart) within 2 years, with ICD-9-CM codes of 71.4A, or ICD-10-CA codes of M05.X, M06.X. Exclusion: applied subsequent to qualifying for other types of inflammatory arthritis.

¹Central triage waiting times in Site 1 includes waiting times to 20 rheumatologists

²Central triage in Site 2 includes waiting times to 12 rheumatologists

³As there is no rheumatologist identifier that is consistently used in the administrative database, interviews with some 10% of claims for RA were conducted to this PM and this was extrapolated for the entire province of Alberta (includes physicians not participating in central intake either Site 1 or Site 2)

Results: The PMs are reported in Table 1 by year and by site where appropriate based on available data sources needed to calculate some measures. Median wait times for rheumatology consultation (PM1) were longer in Site 1 than in Site 2 with between 9-28% meeting the 28-day benchmark in Site 1 and 21-37% in Site 2. Between 2012-2015 the percentage of RA incident cases seen by a rheumatologist within 1 year of onset (PM2) increased from 55 to 63%; however, during this time period the percentage of patients dispensed DMARD therapy (PM3) remained sub-optimal at approximately 40%. Median time to DMARD from referral also suboptimal (PM4).

Conclusion: RA patients in Alberta continue to experience long waiting times to care and treatment with up to 37% of suspected RA cases not seeing a rheumatologist within 1 year of onset. Furthermore, only 40% of RA patients are on DMARD therapy. Further research is warranted to evaluate predictors of adherence to the PMs and to determine the impact on patient outcomes.

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Healthcare transition is the “purposeful, planned movement of adolescents and young adults with chronic physical and medical conditions from child-centered to adult-oriented health care systems.” The American College of Physicians has partnered with national organizations, including the ACR, to develop guidelines and tools to promote a smooth transition to adult care. We aim to assess current transition practices and beliefs among North American pediatric rheumatology providers and to identify differences from a 2010 provider survey published by Chira et al.

Methods: In April 2018, Childhood Arthritis and Rheumatology Research Alliance (CARRA) members received a 25-item online survey about healthcare transition. *Got Transition's* Current Assessment of Health Care Transition Activities for Transitioning Youth to Adult Health Care Providers was used to measure clinical transition processes on a scale of 1 (basic) to 4 (comprehensive). Bivariate data analysis was used to compare 2010 and 2018 survey findings.

Results: Over half of CARRA members completed the 2018 survey. Participants included pediatric rheumatologists (74%), adult- and pediatric-trained rheumatologists (4%), pediatric rheumatology fellows (18%), and other (4%), including emeritus faculty and mid-level providers. Most belonged to university-affiliated practices (87%) in the U.S. (91%). Providers aim to transfer patients at age 18 (23%) or 21 (33%), but the actual age of transfer is often 21 or older (56%). The most common target age to begin transition planning was 15-17 (49%). Few providers use the ACR transition tools (31%) or have a dedicated transition clinic (23%). Only 17% have a transition policy in place; 63% do not consistently address healthcare transition. Transition outcomes of interest included an adult rheumatology visit within 6 months of the last pediatric visit (80%), adherence to medications and plan of care (78%), continuous insurance coverage (78%), and

patient-reported gaps in access to care (76%). When compared to the 2010 survey, improvement was noted in 3 of 12 transition barriers: availability of adult primary care providers, availability of adult rheumatologists, and transition knowledge and skills of pediatric staff ($p < 0.001$). However, more providers cited the close bond among adolescents, parents and pediatric providers as a barrier (Figure 1).

Conclusion: This survey of pediatric rheumatology providers demonstrates some improvement in transition barriers since 2010, though most practices still maintain minimal support for patients and providers around healthcare transition. Further research is needed to understand how to effectively facilitate transition to adult care for young adults with childhood-onset rheumatic diseases.

Diagnostic Accuracy of Gout in Electronic Health Records and the Role of Rheumatology Electronic Consults

Juliana Chang¹ and Maida Wong², ¹Internal Medicine, University of California, Irvine, School of Medicine, Orange, CA, ²Rheumatology, Tibor Rubin VA Medical Center, Orange, CA

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Gout is the most prevalent inflammatory arthritis globally. Despite treatment advances, it still has a significant effect on quality of life and healthcare costs. Studies using administrative coding as a marker of accurate diagnoses have shown inconsistencies due to diagnostic criteria differences or gout misdiagnosis. Although gout can be solely managed by primary care physicians (PCPs), complex cases often require rheumatology consultation. The wait time for an initial rheumatology clinic visit ranges from 38 days to 47 weeks. However, electronic consults (e-consults) allow for swift two-way communication between PCPs and rheumatologists (pre-consult exchange) to facilitate coordination of care among providers.

Objectives: To determine the accuracy of gout diagnosis based on the International Classification of Diseases, ninth (ICD 9) and tenth (ICD 10) revision and the differences in gout outcomes depending on PCP management, e-consult or rheumatology clinic visits at the VA Medical Center in Long Beach, CA.

Methods: A retrospective cohort study of 81 e-consult patients was created with a control group of 176 patients from 2009-2014. In the e-consult group, 58 patients were ICD 9 or 10 coded for gout and 23 were not; in the control group, 116 were ICD 9 or 10 coded for gout and 60 were not. A blinded abstractor determined the accuracy of gout coding based on chart review and EULAR criteria.

Additionally, a second sample of 163 gout patients from 2009-2014 was identified and stratified to 3 modes of management: PCP only (48), e-consult (48), and rheumatology clinic visit (67). Data was reviewed for 24 months following initial gout diagnosis or e-consult. Management was evaluated based on frequency of flares and related ED visits, creatinine clearance, and serum uric acid levels (sUA).

Results: The sensitivity and specificity of ICD coding for accurate diagnosis of gout was 94% and 79% in the control (positive PPV and negative predictive values NPV were 88% and 90%). For e-consult patients, the sensitivity and specificity of accurate diagnosis coding was 100% and 70% (PPV 83%, NPV 100%). E-consult patients were more accurately diagnosed with gout by PCPs than in the control group ($p=0.03$).

Of e-consults, 77% were resolved electronically and 23% were converted to rheumatology clinic visits. The mean wait time for e-consult recommendations was 2.1 days. The mean clinic visit wait after pre-consult exchange was 22.9 days compared to an average of 43.1 days for direct rheumatology clinic consults. Both e-consult and rheumatology clinic patients had more gout flares and related ED visits at baseline; however, at 12 months, both groups had significantly fewer gout-related ED visits, decreased sUA, and improved creatinine clearance.

Conclusion: VA databases are an accurate source of gout patients based on ICD 9 and 10 coding. When viewing e-consults, rheumatologists can rely on accurate PCP gout diagnoses, confidently answer clinical questions, and triage to clinic more quickly. E-consult serves as an effective alternative in managing gout with shorter wait times for recommendations and appointments. Therefore, complex gout management can be enhanced by e-consults to decrease gaps in care and optimize healthcare resources.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Juvenile idiopathic arthritis (JIA), the most common pediatric rheumatologic diagnosis, influences many aspects of a child's life. Although there is no known cure, disease control is often achievable. Early recognition and treatment leads to better disease control that is crucial to prevent chronic pain, irreversible joint damage, and future disability. Clinically Inactive Disease (CID) has been defined and is the accepted outcome measure. In our large pediatric quaternary referral hospital, the number of JIA patients achieving CID was 11% whereas it is reported up to 40% in other centers nationally. Here, we report improvement from 11% to 37% CID within two years by implementing a quality improvement project.

Methods: A key driver diagram (KDD) was used to identify barriers to achieving CID and to develop optimal disease management strategies. The most effective interventions were initially centered around educating parents and patients on disease management, pre-visit planning and provider data entry of disease activity criteria. The physician global assessment

(PGA), a subjective score with interprovider variability, was identified as one of the top barriers to inactive disease. In efforts to standardization, PGA scoring exercises were conducted. In addition, providers reviewed currently active patient cases in population management to provide inputs to optimize therapy. These exercises helped standardize disease activity level scoring by allowing providers to challenge each other regarding optimal care of patients. Transparency in provider level feedback surrounding PGA scores and the percentage of patients with inactive disease was shared quarterly with providers. We had multiple other interventions as summarized in KDD (Figure 1).

Results: During the baseline period (Jan 2015-May 2016), only 11% of patients at our center met criteria for CID. After initial interventions, 20% of patients were considered inactive as of June 2016 (p-value <0.001). As population management and PGA exercises took effect, another shift in data occurred in January 2017, resulting in 25% of patients having no disease activity (p-value<0.001). The team has five data point reaching goal, ready for another shift in data (Figure2).

Conclusion: A dedicated QI project, focusing on multiple interventions, improved the disease activity level of patients with JIA. It is expected that as the team continues with these exercises and proceeds with next steps, the percentage of patients with inactive disease will continue to rise.

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Many recent studies have shown an association between gout and increased cardiovascular risk, however the mechanism by which this occurs is unclear. Dual-Energy Computed Tomography (DECT) is a new technology that has been used to detect subclinical monosodium urate (MSU) deposition in the joints of patients with gout. In this study, we investigated whether DECT could also detect MSU deposition in the vasculature of patients with gout.

Methods: Fourteen tophaceous gout patients and ten non-tophaceous patients were recruited from a single-center urban academic hospital. All patients underwent DECT scans of the neck and chest using a Siemens Somatom Force CT scanner, and images were processed with SyngoVia imaging software to identify MSU deposits. An automated volume assessment program was used to calculate the volume of urate deposits in the vasculature of patients.

Results: The range of uric acid deposition within patients' vasculature varied widely, from 0 mm³ to over 450 mm³, but the majority of study participants (88%) were found to have evidence of MSU deposition in their vasculature. Due to the large volume of these deposits, we did not feel that this was consistent with artifact. The average MSU deposition volumes were 109.4 mm³ for the tophaceous patients and 116.5 mm³ for the non-tophaceous patients, but this difference was not statistically significant ($p = 0.84$).

Conclusion: DECT is able to detect the presence of MSU deposition in the vasculature of patients with both tophaceous and non-tophaceous gout. Whether or not this results in cardiovascular inflammation remain to be determined. Future directions include using PET/MRI to evaluate for local inflammation at the site of MSU deposits in the vasculature.

Figure1: This patient's aortic arch has about 20 mm² of uric acid in this slide alone, seen in green.

Figure 2: This patient has multiple discrete spots of MSU crystallization (green), lining his ascending thoracic aorta and in the interior of his coronary artery.

Figure 3: To confirm the calibration of the DECT scanner, we tested three bladder stone samples whose UA composition ranged from 50-80%; the remainder being calcium oxalate. Scans and analysis confirmed that the scanner is able to pick up MSU (green) and differentiate it from calcium derivatives (purple).

Session Date: Wednesday, October 24, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Emerging evidence indicates that macrophage activation is critically supported by glucose metabolic shifts. Although macrophages are key contributors to inflammation, little is known about the role of glucose metabolism in the pathogenesis of inflammatory gouty arthritis. Thus, we evaluated glucose metabolism in the murine air-pouch model of acute gouty inflammation.

Methods: Mice (N=6 in each group) were injected with PBS or 3-bromopyruvate (BrPa; 7.5 mg/kg) 1 hour before MSU injection to assess the effect of glycolysis inhibition *in vivo*. After 6 hours injection of monosodium urate (MSU) crystals (3 mg/ml) in the air pouch, both the air pouch lavage and peripheral blood were collected. The infiltrating leukocytes obtained from the lavage after centrifugation and peripheral blood mononuclear cells (PBMCs) isolated from the blood were subjected to quantitative RT-PCR for expression of glycolysis-related genes Glut1 and LDHa, and NLRP3 inflammasome-related genes IL-1 β and NLRP3. Production of IL-1 β , CXCL1 and IL-6 were quantified from supernatant of the lavage by ELISA analysis. The air-pouch tissues were also collected and fixed, and subsequently H&E staining was performed. For *ex vivo* studies, thioglycolate-elicited peritoneal macrophages were collected and stimulated with LPS (100 ng/ml for four hours) and MSU (0.2 mg/ml overnight) with and without pretreatment of 2-deoxy-glucose (2DG, 10mM), another glycolysis inhibitor, for one hour. Expression of glycolysis-related genes and cytokine production were assessed from the cells and conditioned media, respectively, using the methods mentioned above.

Results: MSU crystals promoted glycolysis in both infiltrating leukocytes and PBMCs, evidenced by increased expression of Glut1 and LDHa. This was associated with upregulation of gene expression of IL-1 β and NLRP3 in both PBMC and air-pouch elicited cells. BrPa significantly lowered numbers of infiltrating leukocytes ($3.26 \pm 0.79 \times 10^6$ vs $0.74 \pm 0.1 \times 10^6$, $p < 0.01$, in the MSU group after PBS or BrPa respectively) and the amount of proinflammatory cytokines CXCL1 (2379 ± 620 vs 992 ± 255 pg/ml, $p < 0.05$), IL-1 β (429.6 ± 140.7 vs 103.3 ± 12 pg/ml, $p = 0.02$), and IL-6 (2111 ± 418 vs 865 ± 236 pg/ml) in the air pouch. It also markedly reduced leukocyte infiltration in the air pouch lining in response to MSU crystals (3 ± 0.66 vs 1 ± 0.57 , $p = 0.012$ in PBS or BrPa-treated mice respectively). Treatment with 2-DG in peritoneal macrophages significantly inhibited gene expression of Glut 1, hexokinase 2 (HK2), and LDHa, and production of CXCL1, IL-1 β , IL-6, and TNF after LPS and/or MSU stimulation.

Conclusion: Glycolytic inhibition could attenuate MSU crystal-induced inflammatory response. Targeting metabolic dysfunction could be a novel treatment strategy for acute gouty arthritis.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Uric monosodium urate (MSU) depositions are detected by ultrasound (US), and US is included in the ACR/EULAR classification criteria for gout. OMERACT definitions for US elementary lesions in gout include the double contour sign (DC) (deposits of crystals on the surface of cartilage), tophus (larger hypo-echoic aggregation of crystals, usually well delineated), aggregates (small hyper-echoic deposits) and erosions. MSU depositions have some predilection sites, but only a few small studies have explored the decrease of depositions during treatment. The present purpose was to explore by US the longitudinal development of MSU depositions during a treat-to-target approach with urate lowering therapy (ULT) in patients with gout.

Methods: In a prospective observational study, patients with crystal-proven gout were included after a recent gout flare and if increased serum urate levels (>360 $\mu\text{mol/L}$ / >6 mg/dl). In a treat-to-target approach using ULT and increasing drug doses with monthly follow-up until treatment target was met (<360 $\mu\text{mol/L}$, or <300 $\mu\text{mol/L}$ if clinical tophi). An extensive US assessment was performed (GE E9 machine, grey scale 15MHz) at baseline and after 3, 6 and 12 months to detect MSU depositions (DC, tophi and aggregates) with bilateral assessment of radiocarpal joint, MCP 2, insertion of triceps and quadriceps, proximal and distal patellar and the Achilles tendon, cartilage of distal femur (maximal flexed knee) and the talar cartilage and MTP 1 joint. The degree of elementary lesions was semi quantitatively scored 0-3 (0=none, 1=possible, 2=certain, 3=major deposits). Total sum scores of DC, tophi and aggregates separately as well as all lesions were calculated for each visit. Changes from baseline were explored by paired samples T-test.

Results: 161 patients were included at baseline (93.3% men, mean (SD) age 57.0 (14.1) years, disease duration 8.0 (7.7) years). The mean (SD) serum urate level decreased from 487 (82) $\mu\text{mol/L}$ at baseline to 312 (52) $\mu\text{mol/L}$ at 12 months ($p<0.001$). Sum scores of deposits decreased over 12 months (table, $*=p<0.05$, $**=p<0.001$), and the numeric decrease was largest for DC (figure). In addition, the percentage of patients with no detected lesion increased most for DC (baseline to 12 months; DC: 8 to 53%, tophi: 8 to 16% and aggregates 1 to 3%).

Conclusion: During a treat-to-target approach with ULT all forms of deposits decreased, and most extensively for DC. This study shows that reduction of the uric load in gout during treat-to-target ULT may be visualised by US, and that DC may be the lesion most sensitive to change.

	Baseline (n=161) Mean (SD)	3 months (n=124) Mean (SD)	6 months (n=115) Mean (SD)	12 months (n=88) Mean (SD)
Double Contour sum score	4.2 (3.4)	3.1 (2.8)**	2.3 (2.7)**	1.2 (1.9)**
Tophi sum score	6.5 (6.6)	6.3 (5.7)	5.4 (6.1)**	4.2 (5.3)**
Aggregates sum score	9.1 (5.3)	8.8 (4.9)*	7.9 (5.2)**	6.7 (4.9)**
Double Contour, tophi and aggregates sum score	19.8 (13.6)	18.1 (12.0)**	15.6 (12.8)**	12.1 (10.9)**

Session Date: Wednesday, October 24, 2018

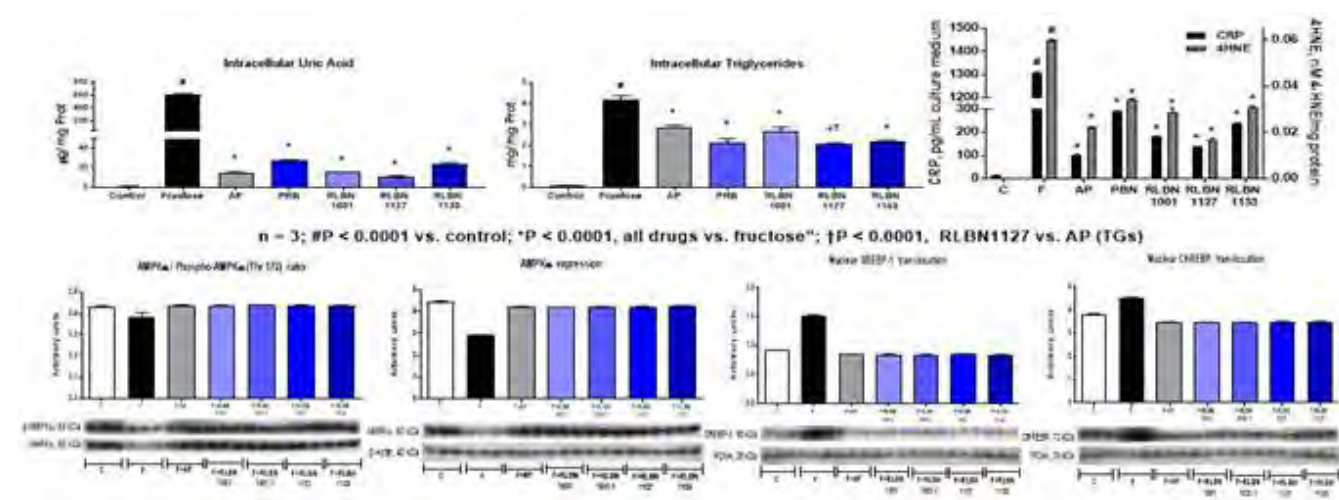

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Dietary fructose promotes an increase in uric acid (UA) that may lead to gout. UA itself promotes lipogenesis and inflammation in both gout as well as other diseases, such as atherosclerosis, metabolic syndrome and NASH. *In vivo*, these effects can be blocked by hypouricemic drugs, but only in models with elevated UA. *In vitro* incubation with fructose also models lipogenic and inflammatory activities in hepatocytes. We discovered a prototype drug that markedly reduced serum UA in human subjects (frequently to $< 1.0 \text{ mg/dL}$), and we developed potent bifunctional derivatives that inhibit xanthine oxidase (XO) and URAT1 (and uricase). We evaluated fructose-induced increases in intracellular (IC) UA and triglycerides in HepG2 cells, explored mechanisms and metabolic consequences, and their modulation by both mono- and bi-functional hypouricemic drugs.

Methods: Control HepG2 cells were cultured in DMEM w/low glucose w/o phenol red for 48-72 h and changed every 24 h. Test cells were cultured with added fructose (25mM), plus new or standard drugs (RLBN1001, RLBN11127, RLBN1133, allopurinol [AP], and probenecid [PBN]) (100mM). IC and extracellular (EC) UA and triglycerides (TGs) were measured by enzymatic kits (Sekisui). Lipid content was confirmed by Oil Red O and colorimetry (Cayman). Micro-CRP and 4-hydroxynonenal (4HNE) were assessed by ELISA and colorimetry, respectively (Cayman). Experiments were conducted three times, each in triplicate. Expression of prolipogenic enzymes and inflammatory mediators were evaluated by WB.

Results: Fructose sharply increased IC UA, which was significantly suppressed by AP and RLBN1127 (95% and > 98%, respectively; see figure). Increased UA was accompanied by an increase in IC TGs with confirmed steatosis at 48 hours. While all hypouricemic drugs reduced IC TGs, RLBN1127 was significantly superior to AP in blocking TG production ($P < 0.0001$). All drugs reduced over-expression of fatty acid synthase, acetyl CoA carboxylase and ATP citrate lyase (data not shown). All drugs normalized fructose-related increases in nuclear translocation of SREBP-1 and ChREBP, and significantly reduced increases in 4HNE and CRP (graphic). Lastly, these drugs significantly increased and restored fructose-induced reductions in total expression and activity of AMP Kinase.

Conclusion: Suppression of fructose-induced increases in UA with hypouricemic drugs significantly reduced TGs and markers of lipid peroxidation and inflammation in hepatocytes. These agents acted via AMPK activation, a constitutive *in vivo* suppressor of lipogenesis and inflammation, which limits urate crystal-induced NF- κ B activation and IL-1 β release. These results suggest that bifunctional activity may confer advantages over monofunctional drugs. RLBN1127 is a clinical candidate for treatment of biomarker-targeted patients with inflammatory disease, particularly gout and NASH.

Session Date: Wednesday, October 24, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Gout is characterized by deposition of monosodium urate (MSU) crystals in articular joints, where they activate macrophages inducing NLRP3 inflammasome activation and bioactive IL-1 β release. However, it is not fully understood how the initiation of gouty inflammation takes place. Intake of meat and seafood is associated with frequency and intensity of gout flares. Choline is a vitamin-like essential nutrient, mainly found in meat and seafood. Choline transporter CTL1, and Choline Kinase (ChoK α), enzyme that converts choline into phosphocholine, are highly expressed in macrophages and fibroblast like synoviocytes in inflamed joints. Here we study whether choline uptake and phosphorylation contribute to NLRP3 inflammasome activation and gouty inflammation.

Methods: Wild type or AMPK α 1 knockout primary bone marrow derived macrophages (BMDM) were cultured in L929 media for 7 days. shCtrl, shCTL1 and shChoK α were generated by lentiviral infection. Choline and phosphocholine were measured by ¹HMRs. Choline deficiency was studied using media without or with 3.54 μ M choline. ChoK α inhibitor RSM932A was used at 5 μ M and colchicine at 10nM. BMDM were treated with 100ng/ml LPS for 4h and 400mg/ml MSU for 3h. IL-1 β was measured by ELISA. Protein levels were examined by immunoblot, and mRNA expression by QPCR. Mitophagy was defined by p62, LC3 or DRP1 recruitment to mitochondria by confocal microscopy (CM). MSU crystals-induced peritonitis was induced by 3mg/ml MSU crystals i.p. injection (n=4 mice/group). For synovium-like air pouch model, 2.5mg/Kg ChoK α inhibitor MN58b or PBS was injected 24h before adding 3mg/ml MSU crystals into the air pouch (n=6 mice/group). Cells from pouch fluids were counted; pouch tissue stained for F4/80, CTL1 and ChoK α and visualized by CM.

Results: LPS increased 6 fold CTL1 expression, and boosted intracellular choline by 238% (p<0.01) and phosphocholine by 559% (p<0.001). Choline deficiency reduced MSU-induced IL-1 β release by 60% (p<0.001), shCTL1 by 57% (p<0.05), and shChoK α by 89% (p<0.05) and ChoK α inhibition via RSM932A by 71% (p<0.005). Impaired choline uptake or ChoK α activity promoted AMPK activation and DRP1, LC3 and p62 recruitment to mitochondria. AMPK deletion blocked choline deficiency effect on IL-1 β release. Of note, treatment with colchicine, previously defined to inhibit NLRP3 inflammasome activity and activate AMPK, also reduced CTL1 (90%) and ChoK α levels (85%). *In vivo*, after MSU crystal injection, cells collected from peritoneal cavity strongly expressed both CTL1 (p<0.05) and ChoK α (p<0.01). F4/80 positive myeloid cells recruited into the air pouch also expressed ChoK α and CTL1. Last, treatment with ChoK α inhibitor MN58b reduced MSU crystal-induced leukocyte recruitment by 47% (p<0.05) and IL-1 β release by 66% (p<0.01).

Conclusion: Our results show that Choline, which is mainly sourced from diet, contributes to gouty inflammation. MSU crystal-induced activation of myeloid cells causes overexpression of genes involved in choline uptake and metabolism, and this is prevented by Colchicine treatment. Targeting choline transporter CTL1 or ChoK α , and limiting dietary choline, could be novel therapeutic anti-inflammatory approaches for gouty arthritis.

Stamp³, ¹University of Auckland, Auckland, New Zealand, ²Auckland District Health Board, Auckland, New Zealand, ³University of Otago, Christchurch, New Zealand, ⁴University of Otago, Christchurch, Christchurch, New Zealand, ⁵Department of Medicine, University of Auckland, Auckland, New Zealand

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic Science and Imaging

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Bone erosion is a frequent complication of severe gout. Computed tomography (CT) is considered the gold standard for measurement of bone erosion. CT studies have demonstrated a close relationship between monosodium urate (MSU) crystals and bone erosion, suggesting that dissolution of MSU crystals with urate-lowering therapy may influence the progression of bone erosion in gout. The aim of this study was to examine whether serum urate lowering can prevent progression of bone erosion detected by CT in people with gout.

Methods: We conducted an imaging sub-study of a two-year randomized clinical trial of intensive vs. conventional allopurinol dosing in people with gout on allopurinol with serum urate (SU) \geq 6mg/dL. The intensive treatment group had

immediate escalation of allopurinol dose to achieve SU <6mg/dL. The control group had no change in their allopurinol dose in Year 1, and then had allopurinol dose escalation to achieve SU <6mg/dL. Participants at one of the two study sites were invited into an imaging sub-study, which included CT scans of both feet, and plain radiographs (XR) of the hands and feet at the baseline, Year 1 and Year 2 visits. CT scans were scored by two radiologists using a validated CT bone erosion scoring system for gout (erosion at seven bones/foot according to the RAMRIS method). XR were scored for erosion and joint space narrowing by a radiologist and rheumatologist using a gout-modified Sharp van der Heijde score. All scorers were blinded to treatment allocation, serum urate, and each other's scores. The pre-specified primary endpoint was change from baseline in CT erosion score, measure at Years 1 and 2. Data were log_e transformed and analyzed using ANCOVA with baseline score as a covariate.

Results: Data were available for 88 participants (46 control, 42 dose escalation) at Year 1 and 82 (44 control, 38 dose escalation) at Year 2. No difference between groups was observed for CT bone erosion scores from baseline to Year 1 (P=0.16). However, differences between randomization groups were observed from baseline to Year 2 (P=0.015). Over the two year study period, the rate of progression in CT erosion score was higher in the control group compared with the dose escalation group (percentage change (SEM) 7.5 (1.7) for the control group and 1.4 (1.8) for the dose escalation group) (Figure). No differences between groups were observed in XR erosion scores or joint space narrowing scores over the observation period.

Conclusion: This is the first randomized controlled trial to demonstrate that progression of bone erosion can be prevented using a treat to serum urate target strategy. These findings support the concept that reduction of serum urate to sub-saturation levels can influence structural damage in gout.

Figure. Change in CT erosion scores according to randomization group. Data are shown as percentage change in CT erosion scores (SEM).

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Idiopathic retroperitoneal fibrosis (IRF) is a rare disease characterized by abdominal periaortic fibro-inflammatory tissue. The aim of this study was to evaluate the prognostic value of fibrosis FDG uptake using FDG/PET CT in patients with IRF

Methods: In this monocentric retrospective cohort study, all patients admitted for IRF from January 2009 to December 2017 underwent a FDG/PET CT at diagnosis and during follow up. Metabolic activity assessed by fibrosis FDG uptake was measured by generating a volume of interest to calculate the maximal standardized uptake value (SUVmax). Complete remission was defined by the disappearance of initial symptoms associated with normal CRP, increased/stabilization of eGFR and decreased/stabilization of the retroperitoneal mass on CT-scan. The primary outcome was IRF relapse rate during follow-up

Results: FDG/PETCT was performed at diagnosis, 3.1 [1-8.7] months (i.e. 1st evaluation) and 10.4 [4.9-17.5] months (i.e. 2nd evaluation) after IRF diagnosis in 23 patients (54.7 [36.9-89] years, 73.9% of men). FDG fibrosis uptake was seen in 23 (100%; SUVmax 6.5 [3.8-11.9]), 16 (69.6%; SUVmax 3.65 [2.1-5.4]) and 12 (52.2%; SUVmax 3.75 [2.7-7.8]) patients at diagnosis, 1st and 2nd evaluation, respectively. All but one patient had received steroids at IRF diagnosis and 21 (91.3%) were incomplete remission at both 1st and 2nd evaluation. During a median follow-up period of 38.7 [3-107] months, 6 (26.1%) patients suffered IRF relapse that occurred 15.7 [9.2-42.8] months after diagnosis. Univariate analysis showed that CRP level at diagnosis, complete remission at 1st and 2nd evaluation and fibrosis FDG uptake at 2nd evaluation were associated with IRF relapse. In the multivariable analysis, only fibrosis FDG uptake at 2nd evaluation (p=0.046) was associated with IRF relapse. Sensitivity, specificity, negative predictive value and positive predictive value of fibrosis FDG uptake at 2nd evaluation to predict IRF relapse were respectively 100%, 60%, 100% and 50%. Eventually, patients with fibrosis FDG uptake at 2nd evaluation had a higher recurrence rate during followup (p=0.047)

Conclusion: In IRF, fibrosis FDG uptake during follow up is associated with clinical outcome. FDG/PET CT may help to better stratify the risk of relapse in IRF and target immunosuppressive therapy

Characteristic of patients

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Despite a low incidence of hypogammaglobulinemia (HG) in clinical trials using rituximab (RTX), HG occurs in follow-up of patients with autoimmune disease.

Immunoglobulin replacement therapy (IRT) has been used to reduce infection rates but there is a paucity of data on its efficacy and impact on longer-term outcomes.

We examined the characteristics of patients with RTX associated HG in autoimmune disease, and their long-term outcomes with and without IRT.

Methods: Patients attending a Vasculitis and Lupus clinic, who received RTX for autoimmune disease between 2004 and 2012, with an immunoglobulin G (IgG) <7 g/L on at least 2 occasions were included in this retrospective case note review. Patients were categorized into nadir IgG subgroups of <3 g/L, 3 to <5 g/L and 5 to <7 g/L. Categorical variables are summarised as proportions, and continuous variables as mean \pm standard deviation or median [interquartile range (IQR)]. Differences between nadir IgG subgroups were assessed by Chi squared tests and trends across subgroups confirmed by Somer's D tests. Continuous variables were compared using analysis of variance (ANOVA), Kruskal-Wallis and Wilcoxon sign ranked tests as appropriate. Analyses were performed in SPSS.

Results: Of 142 patients, 101 (71.1%) had ANCA associated vasculitis, 18 (12.7%) systemic lupus erythematosus and 23 (16.2%) other diagnoses. Most received RTX for relapsing (69.3%) or refractory (25.0%) disease. Mean follow-up was 97.2 months from first RTX.

Progressive HG was observed. Median time to IgG <5 g/L was 22.5 months [IQR 3.0 to 61.5] and to IgG <3 g/L was 24.5 months [IQR 4.0 to 80.75].

Mycophenolate use prior to RTX and prednisolone use following RTX were associated with a lower nadir of IgG (Table 1). These associations were confirmed by Somer's D tests.

IRT was commenced in 29 patients, the majority (65.5%) with IgG <3 g/L. It was well tolerated, with 2 discontinuing due to adverse effects. IRT was withdrawn without excess recurrent infections in 5 patients.

IRT was associated with a reduction in annual infection rates (Table 2). Severe infections (requiring intravenous antibiotics or hospital admission) were uncommon, with no change with the use of IRT.

Conclusion: RTX associated HG is progressively identified with longer term follow-up. Although annual infection rates were low, in patients with recurrent infection, use of IRT was associated with a reduction in infection burden.

Table 1

	All (n = 142)	nadir IgG 5 – 7 g/L (n = 40)	nadir IgG 3 – 5 g/L (n = 66)	nadir IgG < 3 g/L (n = 36)	p

Multicentric Reticulohistiocytosis (1980-2017): A Rare Disease, Commonly Associated with Malignancy and Autoimmunity

Avneek Singh Sandhu¹, Cynthia S. Crowson², David Wetter³, Gavin McKenzie⁴ and Ashima Makol¹, ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Dermatology, Mayo Clinic, Rochester, MN, ⁴Radiology, Mayo Clinic, Rochester, MN

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Multicentric reticulohistiocytosis (MRH) is a systemic disease characterized by papulo-nodular skin eruptions and progressive, deforming arthritis. We aimed to examine the clinical correlates and outcomes of MRH seen at our center, and study the association with malignancy and autoimmunity.

Methods: A retrospective cohort of MRH patients treated at our institution from 01/01/1980 to 04/30/2017 was assembled. Demographics, clinical features, laboratory tests, imaging findings, histopathology (HP), treatments and outcomes were abstracted. Auto immune (AI) disorders and malignancies before and after MRH diagnosis were collected.

Results: We identified 24 patients with MRH (58% female, 75% Caucasian, mean age at diagnosis 52y) with median follow up of 2.3 y. All patients had confirmed diagnosis by HP (23 skin, 7 synovial) and had cutaneous & articular involvement. Nodular skin lesions were noted in 96% patients (periungual area & dorsal hand in 87%, periarticular 61%, face 54%, arms 42%, back 29%, neck 21%, legs 21%, ears 12%, scalp 12%) and mucosal nodules in 30% patients. 92% patients had arthralgia, 88% had joint swelling, and 54% had synovitis. Frequency of joint involvement was upper extremity (UE) PIP(29%)> UE DIPs, MCPs, wrist>MTPs, Toes>Knees>Elbows. Radiographic erosions were noted in 67% patients. Constitutional symptoms included fatigue(15),unintentional weight loss(10),lymphadenopathy(4) and pruritis (11).Systemic features included dysphagia(5),photosensitivity(4), dry eyes(3), and serositis(3). Several patients had positive serologies: ANA(8),RF(5), CCP(3), SSA(3), SSB(2), dsDNA(1). A third of patients had concomitant AI disorders(RA[3],

SS[1], chronic focal granulomatous nephritis[1], JIA[1], psoriasis[1], myasthenia gravis and ITP[1]) and 1/3rd had malignancy (melanoma{3}, basal cell carcinoma[2], and 1 each with ovarian carcinoma, squamous cell carcinoma lung, peritoneal adenocarcinoma, and endometrial carcinoma). Most patients were treated with systemic CS(15) and DMARDs (13): MTX(8), CYC(10), chlorambucil(2) and CSA(1). Biologics (infliximab, etanercept, adalimumab) were used in 4 patients. 2 patients had complete resolution of symptoms, while majority showed only partial improvement. 10 patients developed joint deformities involving: wrist(4), MCP(4), PIP(7), DIP(4), MTP(3), and knee(2). None had arthritis mutilans. 75% were alive at last follow up.

Conclusion: To our knowledge, this is the largest series of MRH patients from a single institution, highlighting the rarity of the condition, and an unmet need for treatment options that can allow sustained disease remission. We emphasize the need for HP to distinguish it from mimicking rheumatic conditions and initiating early aggressive treatment to potentially prevent deforming arthritis. A high vigilance for malignancy and other AI diseases is necessary.

Clinical Features and Pulmonary Function Test Findings Associated with Large Airway Disease in Relapsing Polychondritis

Background/Purpose: Relapsing polychondritis (RP) is a systemic disease that can lead to fatal end-organ damage, including subglottic stenosis (SGS) and tracheobronchomalacia (TBM). The study objective was to evaluate the clinical disease features and pulmonary function test (PFT) findings associated with SGS and TBM.

Methods: Patients 18 years and older were selected from a prospective observational cohort of RP. All patients met McAdams or Damiani's diagnostic criteria and underwent dynamic expiratory phase CT imaging of the thorax, direct laryngoscopy, and PFTs. SGS was defined by pathological narrowing of the subglottis visualized by direct laryngoscopy. TBM was defined as antero-posterior and/or lateral flattening of the tracheal wall during expiration on dynamic CT. Percentage of tracheal collapse during mid-expiration was measured by a single radiologist. Airtrapping was defined as an area of low attenuation compared to the remainder of the lung parenchyma on expiratory CT images. Lung volumes and diffusion capacity were assessed for all patients. Differences were assessed by Fisher's exact test or Kruskal-Wallis test. Median values are presented.

Results: A total of 46 patients were included. 9 patients (20%) had SGS, 19 patients (41%) had TBM, and 4 patients (8%) had both (Table). Patients with SGS were predominantly female (100% vs 83, $p=0.07$) and younger at symptom onset (33 vs 40 years, $p=0.04$). There was no gender or age differences in patients with TBM compared to those without (84% vs 89% female, $p=0.68$; 43 vs 44 years, $p=0.94$). No clinical symptoms were significantly associated with SGS. Patients with TBM had significantly more wheezing (68% vs 23%, $p<0.01$), a prior diagnosis of asthma (79% vs 22%, $p<0.01$), and hearing loss (47% vs 19%, $p=0.05$). Patients with TBM had more respiratory symptoms such as choking sensation (84% vs 66%, $p=0.37$) and pleuritic chest pain (32% vs 15%, $p=0.27$) but these differences were not statistically significant. The median tracheal collapse in patients with TBM as compared with patients without was 71% vs 19% ($p<0.001$). Patients with air trapping on dynamic CT scan had significantly worse tracheal collapse (58% vs 24%, $p<0.01$). There were no significant associations between PFT results and SGS status. Total lung capacity was significantly higher in patients with TBM (102% vs 92%, $p=0.03$), but no other PFT parameters were associated with TBM.

Conclusion: SGS and TBM are relatively common in RP, and specific clinical features and PFT findings are associated with airway damage. Female gender and younger age at symptom onset are associated with SGS. Wheezing, hearing loss, air trapping, and increased total lung capacity are associated with TBM. These findings may help identify subsets of patients with RP who are likely to have large-airway involvement.

	With SGS (n = 9)	Without SGS (n = 36)	P-value	With TBM (n = 19)	Without TBM (n = 25)	P-value
Sex (Female, %)	9 (100%)	30 (83%)	0.07	16 (84%)	24 (89%)	0.68
Age at symptom onset (Years \pm SD)	33 (17-36)	40 (30-46)	0.04	43 (36-57)	44 (36-50)	0.94

Session Date: Wednesday, October 24, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Interstitial lung disease (ILD) is one of the most serious complications associated with rheumatic systemic diseases. Patients with ILD have increased mortality and limited treatment options. Lung transplant has been recognized as an option for patients with end-stage ILD associated with rheumatic systemic diseases (RSD-ILD). However, rheumatic diseases are still sometimes considered a contraindication for lung transplant because of concerns for worse outcomes.

Our aims were to: a) assess long-term post-transplant survival in patients with RSD-ILD and b) compare post post-transplantsurvival of patients with RSD-ILD to patients with idiopathic pulmonary fibrosis (IPF).

Methods: Single center study in a referral center for lung transplant of all patients who underwent lung transplantation for RSD-ILD between 1998 and 2017. This cohort was compared with patients with IPF (group-matched for age, transplant year and basiliximab induction). Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test.

Results: We studied 26 patients with RSD-ILD matched to 26 patients with IPF. The underlying diseases of patients with RSD-ILD were: Rheumatoid arthritis (n=8), Scleroderma (n=6), Sjögren syndrome (n=4), ANCA-vasculitis (n=3), Anti synthetase syndrome (n=2), Takayasu arteritis (n=1), Dermatomyositis (n=1), Systemic lupus erythematosus (n=1). The comparative study of baseline characteristics between both groups is shown in the TABLE. Cumulative survival rates at 5 years post-transplant did no differ significantly between RSD-ILD and IPF [42.4% vs 65.8% (p=0.075)] (FIGURE 1).

Conclusion: Patients undergoing lung transplantation for RSD-ILD had similar long term post-transplant survival as those with IPF. These data support that lung transplantation should be considered in patients with end-stage ILD associated with rheumatic diseases.

Session Date: Wednesday, October 24, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: The most devastating complication of Familial Mediterranean Fever is secondary AA amyloidosis and is still a problem in many cases. Efforts have been paid to prevent AA amyloidosis or to control an already formed Amyloidosis in order to prevent organ function loss, particularly renal insufficiency. There are emerging therapies in FMF related amyloidosis. Here is aimed to evaluate the role of anti-IL-1 regimens, Anakinra and Canakinumab regarding their efficacy and safety in FMF related amyloidosis.

Table 1-a: The parameters of renal functions and acute phase reactants in patients with initial Creatinine level below 1.5 mg/dL (Group 1)

	Anakinra(n= 19)			Canakinumab (n=10)		
	Before treatment	After treatment	p	Before treatment	After treatment	p
Creatinine (mg/dl)	0,9 ± 0,28	0,9 ± 0,44	<0,01	1,35 ± 1,57	1,78 ± 1,93	=0,01
GFR (ml/min)	90,3 ± 27,72	96,15 ± 38,58	<0,01	85,7 ± 40,6	80,8 ± 51,61	<0,01
Proteinuria (mg/day)	2686 ± 3257	2328 ± 4458	<0,01	6000 ± 5550	3730 ± 5030	<0,01
CRP (0-5 mg/L)	16 ± 14	4,47 ± 7,19	<0,01	8,1 ± 10,52	3,7 ± 4,3	=0,02
Sedimentation	43,5 ± 31,3	19,3 ± 26,4	<0,01	51,22 ± 33,54	17,1 ± 31,2	<0,01

Table 1-b: The parameters of renal functions and acute phase reactants in patients with initial Creatinine level above 1.5 mg/dL (Group 2)

	Anakinra(n= 13)			Canakinumab (n=9)		
	Before treatment	After treatment	p	Before treatment	After treatment	p
Creatinine (mg/dl)	3,3 ± 2,4	3,4 ± 2,4	<0,01	3,1 ± 2,4	3,2 ± 2,5	<0,01
GFR (ml/min)	30 ± 24,1	24,4 ± 21,4	<0,01	30 ± 22	27,5 ± 20,7	<0,01
Proteinuria (mg/day)	5482 ± 8040	3651 ± 4635	=0,01	7670 ± 7600	7585 ± 6830	=0,01
CRP (0-5 mg/L)	24,3 ± 13,9	6,4 ± 10	<0,01	23,44 ± 40,52	20,52 ± 29,31	=0,05
Sedimentation	56,8 ± 35,1	31,3 ± 17,8	<0,01	51,22 ± 33,54	34,55 ± 27,19	<0,01

Methods: In this single center study, 44 patients diagnosed with FMF and had a histologically proven diagnosis of amyloidosis, were exposed to anakinra or canakinumab. Patients who used anakinra less than one month and canakinumab less than 2 injections were not included in this review. For all patients recruited in this review, the indication for anti-IL-1 therapies was FMF-related amyloidosis and ongoing inflammation despite adequate colchicine treatment. Patients were questioned with regards to FMF related characteristics, comorbidities. MEFV gene status, laboratory measures, side events and therapy outcomes were tested and followed.

Results: Among 44 patients, 40 were initially treated with anakinra and 4 with canakinumab. Among 40 patients treated with anakinra initially, anakinra was switched to canakinumab due to allergic reactions or insufficient response in 15 patients. There are 16 patients still being treated with anakinra and 10 with canakinumab. In order to evaluate the efficacy of anti-IL-1 agents, the patients were divided into two groups with regards to their initial renal function. Patients with initial Creatinine level below 1.5 mg/dL when an anti-IL-1 drug was initiated were reviewed as Group 1 and the patients who initially had chronic renal insufficiency and Creatinine level above 1.5 mg/dL were defined as Group 2. The analysis of clinical outcome was then performed as summarized in Table 1-a and Table 1-b. The decrease in proteinuria is more modest ($p=0.01$) in Group 2 in comparison with Group 1 ($p<0.01$). At the time of this review 8 patients were still on hemodialysis. Three patients had renal transplantation.

Conclusion: In cases with FMF related AA amyloidosis, there is a need for sufficient inflammatory control. We suggest that anti-IL-1 therapies are effective and tolerable in amyloidosis. These agents are particularly effective when administered in initial stages of renal disease and the effect is less pronounced in case of an already formed renal insufficiency. The anti-IL-1 agents are generally well tolerated and the related side effects were mostly reversible.

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Immune checkpoint inhibitors (ICI) are a major breakthrough in cancer treatment providing frequent durable responses and improving overall survival. Blocking immune checkpoints (Programmed cell Death 1 (PD-1)/PD-ligand 1 or Cytotoxic T Lymphocyte-Associated Protein 4 (CTLA-4)) to restore antitumor immune response may also induce immune-related adverse events (irAEs) targeting a large spectrum of organs including cardiac and skeletal muscle tissue. The overall mortality related to irAE is less than 2% with myocarditis being fatal in ~40-50% of cases. Myocarditis is associated with myositis in at least 25% of cases.

To date, only few cases of myositis have been reported. With the increased rate of ICI use, improvement in recognition, description, and management of muscular irAEs are required.

Methods: Data were collected from the VigiBase (<http://www.vigiaccess.org/>), the World Health Organization database of individual safety case reports (Uppsala, Sweden). Cases were identified using the High Level Term “Muscle infections and inflammations” of the Medical Dictionary for Regulatory Activities terms and at least one of seven following ICIs (Nivolumab, Pembrolizumab, Ipilimumab, Tremelimumab, Avelumab, Durvalumab, and Atezolizumab).

Results: Through March 2018, 180 myositis patients were identified (71 years [29-90]). They had most often been treated for melanoma (31.1%) or pulmonary cancer (30.6%) and 85% had received monotherapy, usually anti-PD1. The median time of myositis onset was 26 days [18-39] after the initial exposure to ICIs (data available in 61 patients). Amongst all myositis patients, 16.1% (n=29) also presented with myocarditis, 15.6% (n=28) with myasthenia gravis-like symptoms (oculomotor disorders and/or ptosis), 3.3% (n=6) with both and 13.9% with other concurrent irAEs including hepatitis (n=14), colitis (n=3), thyroiditis (n=3), nephritis (n=3), and hypophysitis (n=2). ICI-associated myositis caused significant morbidity and mortality, with fatalities occurring in 21.2% of patients. Moreover, 49.4% of patients with myositis had severe complications such as prolonged hospitalization, a life-threatening event, or a disabling effect. The mortality rate was significantly associated with combination therapy compared to monotherapy (38.5% vs. 18.1% p=0.02) and was higher in patients with concomitant myocarditis (51.7%) compared to those without myocarditis (14.9%, p<0.0001).

Conclusion: ICI-associated myositis occurs early during therapy and is most often reported with combination regimens. ICI-associated myositis has a unique clinical presentation including ocular signs and concomitant myocarditis. Systematic screening for myocarditis might be crucial in patients with ICI-associated myositis, due to the frequent overlap between these conditions and the high mortality of ICI-myocarditis.

Lenabasum, a Cannabinoid Type 2 Receptor Agonist, Reduces T-Cell Population and Downregulates Type 1 and 2 Interferon Activities in Lesional Dermatomyositis Skin

Nithin Reddy^{1,2}, Majid Zeidi^{1,2}, Barbara White³ and Victoria P. Werth^{1,2}, ¹University of Pennsylvania, Philadelphia, PA, ²Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, ³Corbus Pharmaceuticals, Inc., Norwood, MA

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 (CB2) agonist that activates resolution of innate immune responses. CB2 is a G-protein coupled receptor found primarily on activated immune cells. Lenabasum has improved skin inflammation and fibrosis in systemic sclerosis patients. In-vitro, it has shown to affect T-cell activity, alter Th1 and Th2 cytokine production, and decrease type I interferon activity. We sought to characterize the in vivo effect of lenabasum on inflammatory cells and cytokines thought to be involved in the disease pathogenesis of dermatomyositis (DM).

Methods: 22 adult patients with refractory, skin-predominant DM on stable standard-of-care treatments were recruited for a double-blind, placebo-controlled, randomized trial. 86% percent of subjects were on stable immunosuppressive medications. Lenabasum was initially administered orally at a dose of 20 mg a day for 4 weeks, which was subsequently raised to 20 mg twice a day for an additional 8 weeks. In a subset of subjects, lesional skin biopsies were collected at baseline and at Week 12. Immunohistochemical staining of CD4, IFN-beta, IFN-gamma, IL-4, IL-31 and IL-31 RA and QRT-PCR for Type I IFN, IFN-gamma, and IL-4 were performed on RNA extracted from the tissue samples. Sections were analyzed using the Nikon Eclipse 80i microscope. The percentage of the dermis with positive staining was quantified using NIS Elements Software. Comparisons of percent area of protein staining in the dermis and mRNA levels of various cytokines between lenabasum and placebo groups were performed using the Wilcoxon signed-rank test.

Results: There was strong co-localization of CB2 with Th1 CD4+ T cells in baseline biopsies. CD4+ area in the skin biopsies from lenabasum-treated subjects were significantly decreased at Week 12 compared to the placebo group (p<0.05). There were significant reductions in type I IFN signature, IFN-beta protein staining, and IFN-gamma mRNA and protein staining at Week 12 in subjects on lenabasum compared to those on placebo (p<0.05 for all). IL-31 protein (p<0.01) was reduced at Week 12 in subjects who received lenabasum compared to those taking placebo, but IL-31 mRNA expression and IL-31RA+ protein staining did not change. There were no changes in IL-4 protein or mRNA expression.

Conclusion: Lenabasum reduces Type 1 and 2 interferon levels as well as T cell inflammation in dermatomyositis. These effects have the potential to inhibit underlying disease pathways in DM and thus contribute to any clinical benefit of lenabasum in DM.

Abstract Number: 2978

Performance of the 2017 European League Against Rheumatism / American College of Rheumatology (EULAR/ACR) Classification Criteria for Adult Idiopathic Inflammatory Myopathies (IIM) in an Australian Cohort

Queenie Luu¹, Jessica Day^{2,3}, Alix Hall⁴, Vidya Limaye^{2,5} and Gabor Major^{6,7}, ¹Rheumatology, Bone and Joint Institute, John Hunter Hospital, New Lambton Heights, Australia, ²Rheumatology, The Royal Adelaide Hospital, Adelaide, Australia, ³School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia, ⁴Hunter Medical Research Institute, New Lambton Heights, Australia, ⁵Discipline of Medicine, University of Adelaide, South Australia, Adelaide, Australia, ⁶Rheumatology, Bone and Joint Institute, John Hunter Hospital, Newcastle, Australia, ⁷University of Newcastle, Newcastle, Australia, Newcastle, Australia

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: EULAR/ACR recently approved classification criteria for idiopathic inflammatory myopathies (IIM) with 93% sensitivity and 88% specificity. An acknowledged limitation of the study is the absence of controls/comparators in the external validation cohort, prompting the authors to call for further validation studies in different populations. We sought to 1) evaluate the performance of the criteria in an Australian cohort of adult patients with suspected IIM; 2) determine the level of agreement between the EULAR/ACR criteria and traditional criteria (Bohan and Peter, and Targoff); 3) determine the optimal cut-point for Australian patients; 4) assess the effect of including MRI of the musculature or an extended panel of antibodies, as additional ‘risk factors’; 5) assess the effect of extending “endomysial infiltration of mononuclear cells surrounding but not invading myofibres” to include invasion of myofibres.

Methods: Data were collected retrospectively on all consecutive patients referred for muscle biopsy to two large tertiary teaching hospitals. Area under the receiver operator curve (AUC) was calculated to assess the overall performance of the EULAR/ACR criteria. The Youden method was used to determine the optimal cut point. Patients were scored for ‘risk of IMM’ according to the EULAR/ACR criteria and dichotomized into probable/definite and negative/possible groups. The predictive accuracy of the EULAR/ACR criteria was assessed by evaluating the sensitivity and specificity.

Results: Eighty seven of 204 patients had IIM. Overall, the EULAR/ACR criteria had an outstanding level of discrimination (AUC=0.90). Application of the criteria in this cohort however, showed lower sensitivity (71% vs. 93%) but comparable specificity (89% vs. 88%). The optimal cut point of 5.23 (sensitivity 91%, specificity 75%) for this sample was lower than the EULAR/ACR cut point of 6.7. The EULAR/ACR criteria had a moderate agreement with Bohan and Peter (kappa=0.45, 95%CI=0.28, 0.62, p<0.001) and Targoff (kappa=0.40, 95%CI=0.23, 0.57, p<0.001). Inclusion of MRI of the musculature (AUC=0.86, 95%CI=0.79, 0.93), or non-Jo1 myositis specific antibodies (AUC=0.84, 95%CI=0.77, 0.91) improved the ability of the model to identify IIM compared with the EULAR/ACR criteria alone (AUC=0.80, 95% CI=0.75, 0.86). Furthermore, extending the criteria so that endomysial infiltration of mononuclear cells included invasion of myofibres, resulted in a model with a comparable level of accuracy to the original criteria (both AUCs=0.90). However, the sensitivity was slightly improved (75% vs. 71%) while the specificity remained the same (89% vs. 89%).

Conclusion: The EULAR/ACR criteria had an outstanding discrimination between IIM and non-IIM. Application of the criteria to an Australian cohort has shown comparable specificity but lower sensitivity, and lower optimal cut-point than reported. There is moderate agreement with traditional criteria. Addition of MRI of the musculature, or non-Jo1 myositis specific antibodies, improved the ability of the model to identify IIM. Extending the criteria so that endomysial infiltration of mononuclear cells included invasion of myofibres may improve sensitivity.

Innovative Approaches for the Assessment of Interstitial Lung Disease in Idiopathic Inflammatory Myopathies: Ultrasound Evaluation of Pleural Irregularities and Semiquantitative and Quantitative Analysis of Lung CT

Simone Barsotti^{1,2}, Chiara Romei³, Elisa Cioffi⁴, Claudia Roncella⁵, Elisabetta Perrone³, Alessandra Tripoli¹, Marta Mosca¹, Fabio Falaschi³ and Rossella Neri⁶, ¹Rheumatology Unit, University of Pisa, Pisa, Italy, ²Department of Medical Biotechnologies, University of Siena, Siena, Italy, ³Pisa University Hospital, II Radiology Unit, Pisa, Italy, ⁴Rheumatology Unit, Rheumatology Unit, University of Pisa, Pisa, Italy, ⁵Pisa University Hospital, I Radiology Unit, Pisa, Italy, ⁶Rheumatology Unit, University of Pisa, PISA, Italy

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Interstitial Lung Disease (ILD) in patients with Idiopathic Inflammatory Myopathies (IIM) is associated to high mortality and morbidity. The study of pleural irregularities (PI) with lung ultrasound (US) and quantitative automated scoring of high resolution computed tomography (HRCT) have been recently proposed as a method for assessing the ILD. Purpose of our study is to compare the US assessment of PI and HRCT semi-quantitative and quantitative analysis of ILD.

Methods: Forty-five IIM patients (30 F, 15M, mean age 64 ± 12), 44 diagnosed according to Bohan and Peter (23 PM, 22 DM) and 1 IBM according to Griggs criteria, with a disease duration of 54 ± 86 months, were enrolled. Lung US was performed in 53 anterior and posterior intercostal spaces with 8-18 MHz linear probe, assigning a PI score ranging from 0 to 2 (0 (no PI), 1 (mild PI - 3-5mm), 2 (severe PI > 5 mm) and calculating the total PI score (PIS). In a subset of patients to assess reliability and reproducibility of the PIS, the lung ultrasounds were also repeated by the same operator after two days and by a second operator.

HRCTs were assessed by an expert radiologist to obtain a semiquantitative score - Warrick score (WS) and 26 HRCTs were also evaluated with a quantitative analysis by a volumetric texture and local volumetric histogram feature-based analysis software (CALIPER). With CALIPER were quantified lung involvement as a percent of interstitial lung abnormalities (ILD%): a combination of percent of areas of ground glass, reticulation and honeycombing. Analysis of the vascular involvement was obtained as percent of pulmonary vessel volume (PVRV %).

Results: PI were present in all patients with a mean PIS of 25 ± 14 . At HRCT, the semiquantitative analysis of CT data, identified ILD in 32 patients with a mean WS of 7.2 ± 7.0 . CALIPER software quantified a mean ILD% of 2.90 ± 5.72 and a mean PVRV% of 2.56 ± 1.29 .

A good correlation was identified between PIS and WS ($r=0.716$ $p<0.001$) and with PIS and ILD% and PVRV% ($r=0.559$ $p=0.003$ and $r=0.615$ $p<0.001$ respectively). Additionally, a good correlation was identified among WS and ILD% and PVRV% ($r=0.693$ $p<0.001$ and $r=0.651$ $p<0.001$ respectively).

The PIS score was repeatable (inter-reader reliability: $\alpha=0.916$) and reproducible (intra-reader reliability: $\alpha=0.945$).

Conclusion: The evaluation of ILD with innovative techniques may allow a more precise grading of ILD in IIM patients. Our study suggests a possible role for both PI and CALIPER in the evaluation of ILD in clinical practice and for RCTs, as PI US may be useful for the initial screening of ILD and the automatic software CALIPER could make ILD assessment easier and more reproducible.

Calcineurin Inhibitor for the Treatment of Myositis-Associated Interstitial Lung Disease: Comparison between Cyclosporine and Tacrolimus

Takahisa Gono¹, Kenichi Masui², Naoshi Nishina³, Shinji Sato⁴ and Masataka Kuwana¹, ¹Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, ²Department of Anesthesiology, Show University Hospital, Tokyo, Japan, ³Division of Rheumatology, Department of Internal Medicine, Keio University

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Treatment options for myositis-associated interstitial lung disease (ILD) include corticosteroids (CS) in combination with or without cyclophosphamide (CY), calcineurin inhibitors (CNIs) such as cyclosporine (CyA) and tacrolimus (TAC), mycophenolate mofetil, and/or rituximab. However, efficacy of individual treatment regimens has never been compared in randomized clinical trials, and treatment decision is made based on expertise of physicians. We have recently launched the multicenter retrospective cohort of Japanese Patients with Myositis-associated ILD (JAMI), which involved 497 incident cases of adult myositis-associated ILD from 44 institutions across Japan. By taking advantage of our large-scale cohort database, we investigated the efficacy of CNIs in myositis-associated ILD.

Methods: A total of 491 patients with adult-onset PM/DM were selected from the JAMI database. Clinical characteristics and survival rates were compared between the patient groups, followed by additional comparisons using propensity score matching method. Survival rates were calculated by the Kaplan-Meier method.

Results: The mean age at disease onset was 56, 67% were female, and median disease duration was 2 months. In a crude analysis, cumulative survival rate was significantly lower in 402 patients treated with regimens including CNI than in 89 patients treated with regimens without CNI ($P = 0.03$; Figure 1A). Clinical characteristics associated with CNI use included positive anti-MDA5, shorter disease duration, higher levels of CRP and ferritin, lower oxygen saturation, and more intensive immunosuppressive regimens. After matching patients for background using propensity score, there was a trend toward a better survival rate in patients treated with CNI than in those without (Figure 1B). When we further examined efficacy between 201 patients treated with CyA and 187 patients with TAC, treatment with TAC was associated with a better survival rate, compared with CyA treatment, in a crude analysis ($P = 0.02$). After matching patients for background using propensity score, the survival rates were similar between patients treated with CyA and TAC. The patients treated with CNIs were further divided into 4 subgroups according to main components contributing to the propensity score, including anti-MDA5, CRP, ferritin, and disease duration at diagnosis, there was no difference of survival rates between CyA-treated and TAC-treated patients in each subgroup (Figure 2).

Figure 1. Overall survival rates between CNI subset and non-CNI subset

Conclusion: Our results suggest potential efficacy of CNI, either CyA or TAC, in combination with CS-based regimens for broad spectrum of myositis-associated ILD.

Figure 2. Overall survival rates of each subgroup after matching clinical background between CyA subset and TAC subset.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: We recently made the fundamental observation that mitochondrial extrusion is instrumental in mediating inflammation, autoimmunity and organ damage in lupus. Mitochondrial stress and mitochondrial autoantibodies have been reported in adult dermatomyositis (DM). However, the role of mitochondrial extrusion in juvenile DM is not known. One debilitating manifestation of chronic JDM is calcinosis, the formation of calcium deposits in soft tissue. Calcification may occur intracellularly in organelles, including mitochondria, but the role of mitochondrial calcification in JDM has not been investigated. In the current study, we investigated the role of mitochondrial calcification and extrusion in JDM pathogenesis, as well as the clinical utility of mitochondrial biomarkers.

Methods: Anti-mitochondrial autoantibodies, as well as cell-free mtDNA levels were analyzed in healthy children (HC, n=20), pediatric lupus (n=10), polymyositis (n=7), JDM patients (n=66), and RNP+ myositis (9), by a state-of-the-art flow cytometry technique as well as an in-house qPCR assay. In the Juvenile Myositis (JM) population, 74% were female, with a mean age of 11.3 years. The association of mitochondrial markers with clinical parameters was tested, including disease activity scores (DAS) for skin, muscle and total, the presence of calcinosis as well as Myositis Specific Antibodies (MSA). Electron microscopy of muscle surrounding calcifications was performed.

Results: As determined by electron microscopy, JDM children had evidence of mitochondrial calcification in affected muscle biopsies. Though phagocytosed by tissue-resident macrophages, the engulfed calcified mitochondria were not

degraded, but remained in intracellular vesicles. Consistent with an important role of calcinosis in impaired mitochondrial extrusion and clearance, JM children with calcinosis had increased levels of cell-free mtDNA as compared to JM children without calcinosis and healthy children ($p<0.05$). Unexpectedly, levels of mtDNA were inversely correlated with DAS ($r=-0.32$, $p=0.007$) and the macrophage-derived inflammatory marker neopterin ($r=-0.44$, $p=0.0003$). Further, mitochondrial autoantibodies were elevated in JDM patients as compared to healthy individuals (40% vs 6%, $p<0.001$), with the highest frequency found in JDM children with p155/p140 (57%) and MDA5 (75%) MSA. For RNP+ myositis, the frequency was 42%. In JDM patients with no Myositis Associated Antibodies, only 18% of the children had anti-mitochondrial antibodies. Levels of anti-mitochondrial antibodies were associated with calcinosis ($p<0.05$), C4 levels ($r=-0.63$, $p=0.002$) and a bioassay for immune complexes ($r=0.38$, $p=0.002$). Children with SLE had increased anti-mitochondrial antibodies (90%, $p<0.0001$) as well as mtDNA ($p<0.05$).

Conclusion: Our results demonstrate a clear contribution of mitochondria in JDM pathogenesis and suggest mitochondrial calcification and subsequent extrusion and autoimmunity a novel, and potentially therapeutically targetable pathway. Further, mitochondrial biomarkers may offer clinical utility in monitoring disease activity and severity in Juvenile Myositis.

Normal Mortality of the Cobra Early Rheumatoid Arthritis Trial Cohort after 23 Years Follow up

Pomme Poppelaars¹, Lilian van Tuyl² and Maarten Boers^{1,3}, ¹Rheumatology, Amsterdam Rheumatology and immunology Center | VU University Medical Center, Amsterdam, Netherlands, ²Amsterdam Rheumatology and immunology Center | VU University Medical Center, Amsterdam, Netherlands, ³Epidemiology & Biostatistics, Epidemiology & Biostatistics | VU University Medical Center, Netherlands, Amsterdam, Netherlands

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

ACR abstract

Background/Purpose: Mortality in patients with rheumatoid arthritis (RA) is higher than in the general population. In most studies this becomes apparent only after more than a decade of follow up. The COBRA (COmbinatie therapie Bij Reumatoïde Artritis) trial showed long-term effectiveness of combination therapy of early RA without undue harm [1]. After 11 years of follow up, patients with COBRA treatment had numerically lower mortality compared to patients with sulphasalazine (SSZ) monotherapy [2]. We now present mortality in the COBRA trial cohort after 23 years compared to the general population and explore early predictive factors.

Methods: In the COBRA trial, patients with early RA (median disease duration, 4 months) were treated with SSZ monotherapy ($n=79$) or a combination of SSZ, low-dose methotrexate and initially high, step-down prednisolone (COBRA, $n=76$). We investigated mortality in the COBRA cohort through the Dutch state registry for mortality (Centrum van Familiegeschiedenis). We compared the mortality in this cohort to a reference sample of the general population in the Netherlands matched for age and gender (Statistics Netherlands). The Standardized Mortality Ratio (SMR) compared the trial groups with the general population. We explored the following early predictive factors for mortality through forward stepwise Cox regression: smoking, treatment, disease duration (according to 3 definitions), disease activity score (DAS-44) and 16-week change; Health assessment questionnaire; rheumatoid factor (ACPA not available at that time); Sharp van der Heijde damage score and change at 28 and 56 weeks; HLA-DR1-4.

Results: Follow up was nearly complete (154/155 patients). Duration of follow up was mean 23 (inpatients alive, range 22-24) years. In total 44 patients died (28%, SMR = 0.80[95%CI: 0.59-1.06]); 20 of 75 COBRA patients (27%, SMR 0.75; [0.47-1.14]) and 24 of 79 SSZ patients (30%, SMR 0.85 [0.56-1.25]); the difference in mortality was not significant ($p=0.61$). In the general population reference sample ($n=154$) 55 people (36%) died. The positive trend for COBRA over SSZ decreased over time(Figure). 5 factors were significantly associated with increased mortality hazard: damage progression at 28 weeks; high HAQ score; and absence of HLA-DR 2 or 3. Disease duration from start of complaints showed a nonlinear pattern.

Conclusion: This is the first early RA (trial) cohort to show mortality similar to the general population after 23 years of follow up. In fact, mortality was numerically lower than expected. Some (but not all) predictive factors for disease severity

were apparent. Our study confirms that early, intensive treatment of RA (that can include glucocorticoids) has long-term benefits, and strongly suggests these benefits include normalization of mortality.

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: To analyze the evolution of baseline demographic, clinical, serological and genetic characteristics of patients with incident RA over 20 years.

Methods: Since July 1998, the Early Undifferentiated Poly Arthritis (EUPA) cohort recruits consecutive adults with recent-onset immune-mediated synovitis affecting at least 3 joints. Baseline characteristics were compared in three subgroups of patients fulfilling RA criteria according to date of inclusion (1998-2004;2005-2010; 2011-2017). Anti-cyclic citrullinated

peptide (CCP2) antibodies and RF were measured using commercial assays, while anti-Sa were measured with an in-house assay or a commercial assay calibrated with it (ArthritisRheum;2009;60:698-707). Human Leucocyte Antigen (HLA)-DR alleles were determined using sequence-specific primer PCR. False discovery rate correction was used to adjust p-values for multiple comparisons.

Results: 739 patients were included: 247 in 1998-2004; 263 in 2005-2010; 229 in 2011-2017. We observed a decrease in current smokers over time: 22.4, 18.6, 12.3%, respectively ($p=0.04$). Symptom duration increased (2.8, 3.5, 4.1 months; $p<0.001$). Markers of inflammation decreased (ESR (mm/h): 36, 26, 24, $p=0.01$; CRP (mg/L): 15.0, 11, 8.9, $p=0.002$), as did disease activity (DAS28-CRP: 5.5, 5.1, 5.0, $p=0.01$), and patient overall assessment of disease activity (PGA) (59.0, 56.5, 49.0 mm, $p=0.02$); without a parallel decrease in joint counts (SJC: 11, 11, 12 NS) or an increase in corticosteroid or DMARD use before inclusion (33.6, 50.2, 36.7%, $p=0.002$, 26.7, 39.5, 28.8%, $p=0.01$, respectively).

RF positivity decreased (47.8, 36.9, 36.7%, $p=0.03$), but positivity remained stable for anti-Sa (22.9, 18.0, 22.5% NS) and anti-CCP2 (40.8, 35, 35.4% NS), although the mean titers of anti-CCP2 significantly decreased (3.5, 3.2 and 1.0 IU/ml, $p<0.001$). The proportion of Shared epitope (SE) positive patients decreased significantly (51.0, 42, 35.2%; $p=0.04$), while the DERA epitope remained stable.

Relative to anti-CCP negatives, the proportion of SE (62.2 vs 33.8%, $RR=2.01$, $p<0.001$) and current smokers (21.8 vs 15.5%, $RR=1.28$, $p=0.04$) were higher among anti-CCP2+ patients, and remained stable in anti-CCP2+ patients over time (64.9, 61.8, 54.3%, NS; 25.3, 20.9, 18.8% NS respectively). SE positivity and current smoking decreased in anti-CCP2-

Corticosteroid		247 83 (33.6)	263 112 (50.2)	229 84 (36.7)	0.0016

patients (41.7, 30.3, 22.6%, $p=0.02$; 20.6, 17.2, 8.6%, $p=0.02$).

Conclusion: In this cohort of recent onset RA recruited over 20 years, we observed a constant drift towards less inflammatory RF-negative arthritis at baseline. Decreasing smoking rates paralleled lower levels but not lower incidence of positive CCP. The increasing proportion of SE negative patients in this RA cohort with a relatively stable incidence over 20 years suggest the implication of as yet unidentified environmental arthritis-inducing factors acting on this aging population.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Implementation of RA guidelines have improved remission outcomes in RA; nevertheless 45% of early RA participants do not achieve remission in the first year. Moreover, fewer women reached remission than men. Our goal was to identify and compare predictors of persistent disease activity (LDA/MDA/HAD) in the first year of RA treatment in men and women.

Methods: Sample included adults in CATCH (Canadian Early Arthritis Cohort) from 2007-16 with active disease at baseline and ≥ 12 m F/U. Standardized visits included clinical assessments, questionnaires, and lab tests. Logistic regression with backwards election was used to identify predictors of failing to achieve remission (DAS28 <2.6) by 12 months among baseline sociodemographic and RA characteristics and patient reported outcomes.

Results: The sample included 1628 adults with 2010 or 1987 ACR/EULAR criteria for RA, who were mostly female (72%) with a mean (SD) age of 55 (15), with 2 (2) comorbidities, and symptom duration of 6 (3) months. At enrollment, all had active disease (DAS28MDA (42%); HDA (53%)), almost all most were initially treated with csDMARDs and 75% with MTX. 44% of women and 36% of men did not reach remission by 12 months. Among women, multivariable results showed obesity more than doubled the likelihood of not achieving remission; other key predictors were minority status, lower education, and higher TJC and fatigue scores at baseline (Table). In men, current smoking was associated with a 3.5 greater odds of not achieving remission in the first year; other predictors included older age, and higher pain. Not using MTX increased the likelihood of not achieving remission in women by 28% and men by 45%. Longer symptom duration and higher ESR were associated with not achieving remission in all. Factors not related to persistent disease activity included family history of RA, RF/ACPA status, erosions, SJC, HAQ and depressive symptoms at baseline.

Conclusion: In this large pan-Canadian cohort of early RA patients receiving guideline-based arthritis care, obesity in women and current smoking in men were the strongest predictors of not achieving remission in the first 12 months followed by non-use of MTX, higher baseline inflammation and longer symptom duration. Additional poor prognostic indicators in women included minority status, lower education, and higher fatigue, whereas older age and greater pain were associated with persistent disease activity in men. Smoking cessation in men and weight reduction in women, and optimizing MTX use may facilitate rapid reduction of inflammation, an essential goal of treatment in early RA.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Treat-to-target (T2T) has become a key element in the management of rheumatoid arthritis (RA). Several different measures exist to define the preferred treatment target of remission. The objective of the present study was to compare treatment response and achievement of remission during the first 6 months after initiating first disease modifying anti-rheumatic drug (DMARD) therapy in two early RA-cohorts applying different T2T strategies.

Methods: We included 231 patients from the ARCTIC trial (inclusion period 2010-2013) and 434 patients from the observational NOR-VEAC study (inclusion period 2010-2016). Both studies applied a T2T strategy. In ARCTIC the treatment target was deep remission defined as Disease Activity Score (DAS) <1.6 with no swollen joints (44 joints), and

in half the patients, in addition no power-Doppler ultrasound activity. Patients were followed with visits at 1, 2, 3, 4 and 6 months and a fixed T2T escalation protocol. In NOR-VEAC the treatment target was sustained DAS28 remission (<2.6) and treatment was guided by current EULAR treatment recommendations for RA. All patients attended visits at 3 and 6 months, and extra monthly visits could be scheduled if needed. In the present study, included patients fulfilled the 2010 ACR/EULAR criteria for RA, were DMARD-naïve and started treatment with methotrexate (MTX). We used the Simplified Disease Activity Index (SDAI) 50/70/85% response criteria to assess improvement in disease activity from baseline to 3 months. Pearson's chi-squared test was used to compare achievement of SDAI response at 3 months and proportions in remission according to the ACR/EULAR Boolean-criteria, SDAI (≤ 3.3) and DAS28 at 6 months.

Results: At inclusion patients in ARCTIC were significantly younger, had higher disease activity and more were ACPA positive than in NOR-VEAC (age (SD) 51.5 (13.7) vs. 54.4 (13.7) years, $p=0.01$; SDAI 24.9 (13.1) vs. 21.0 (14.2), $p<0.001$; ACPA positivity 82% vs. 69%, $p<0.001$). The median baseline dose of MTX was similar in the two cohorts (15 mg), however at 3 and 6 months the median dose was higher in ARCTIC. More patients in NOR-VEAC had changed DMARD regimen at 3 months (9.2% vs. 0.9%, $p<0.001$) and 6 months (21.3% vs. 19.2%, $p=0.04$). At 3 months, SDAI improvement levels were significantly higher in ARCTIC than in NOR-VEAC (table). Median (25-75% percentile) time to first SDAI remission was 3.0 (1.2-8.1) months in ARCTIC and 6.4 (3.4-12.1) in NOR-VEAC ($p<0.001$). At 6 months, 38% of patients in ARCTIC vs. 30% in NOR-VEAC had reached ACR/EULAR Boolean-based remission, whereas 45% vs. 34% had reached SDAI remission.

Conclusion: In a tight control T2T cohort aiming for deep remission we observed greater improvement in disease activity the first 3 months, shorter time to first remission and a higher proportion of patients in remission according to the ACR/EULAR Boolean-criteria or SDAI at 6 months than in a real-life T2T cohort targeting DAS28 remission.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Modifiable lifestyle factors such as inactivity and obesity contribute to cognitive decline in the general population, but little is known about how these factors may contribute in the setting of a chronic inflammatory condition such as Rheumatoid Arthritis(RA). We studied the clinical and functional risk factors related to a decrease in perceived cognition function in patients with longstanding RA.

Methods: We collected data on joint exams, serologies and detailed clinical, psychological, exercise and functional outcomes over 10 years in a prospective academic RA cohort. Self-reported memory, concentration and word-finding difficulties were assessed yearly by questionnaire and graded from “never” to “often”. A repeated measures logistic regression model using pairs of years examined the role of exercise (defined as those meeting the Dept. of HHS physical activity guidelines of 75 minutes of vigorous or 115 minutes of moderate aerobic activity per week), Body Mass Index (BMI), sleep and depression (MHI-5) in the first year (T0) to the progression of cognitive complaints described as “often” 1 year later (T1). Regression models also adjusted for other clinical and demographic variables including DAS-CRP3 score, DMARD and corticosteroid use.

Results: Of 1219 RA subjects, 127 (10.4%) described either poor memory, poor concentration or word finding difficulties as affecting them “often” at the first study visit. Only the perception of memory difficulties increased over time ($R^2=0.64$, test for trend, $p=0.006$). RA patients, (mean age. 56.5 years, 82% female, 58% with a college education) were less likely to develop word finding difficulties and impaired concentration if they met the Dept. of HHS physical activity recommendations ($p<0.0001$; $p=0.0002$, respectively). Concentration worsened among those RA patients who were female ($p=0.03$), had a higher DAS28-CRP3 score ($p=0.04$), and higher MHI-5 depression scores ($p=0.05$); RA patients taking an anti-TNF therapy were less likely to develop worsened memory complaints ($p=0.0004$). Sleep, BMI, fatigue and medication use, such as methotrexate or corticosteroids, were not independently associated with a worsening of any of the cognitive complaints, adjusting for other covariates.

Conclusion: Clinical factors such as lower disease activity and anti-TNF use reduced the likelihood of worsened memory and concentration over time. However, meeting the Dept. of HHS guidelines for physical activity was protective against an increase in concentration and word retrieval difficulties. Our study suggests potential modifiable risk factors for the prevention of cognitive dysfunction in RA.

5 years follow-up and to correlate the Sharp score index with different indices of clinical remission observed during the first year.

Methods: This was a retrospective analysis of mean (95% CI) change from baseline (BL) to 5 years Sharp/Van der Heijde (SVdH) scoring according to DAS28, SDAI, CDAI and ACR/EULAR Boolean remission scores for pts at Month 3, 6 and 12. Newly pathological joint defined by a SVdH score of 0 at BL and a score greater than or equal to 1 at follow up were analyzed as a secondary objective. 133 ERA pts naïve to DMARDs therapies were analyzed (100 women and 33 men) with a mean age (49.9 +/- 13.3), mean DAS 28-CRP (4.89 +/- 1.3), mean HAQ (1.25 +/- 0.67), mean SDAI (28.4 +/- 15.5), mean CDAI (25.8 +/- 14.8) and mean SVdH (6 +/- 14). Differences were statistically tested using t tests.

Results: ERA ps were divided in 2 groups : “Xrays Stable” if the delta of SVdH score was ≤10 (n=90) or “Xrays Progressive” if the delta of SVdH score was >10 (n=43). As expected, number of pts with ACPA and BL erosion was higher in the Xrays Progressive group. No significant BL characteristics differences were observed for DAS28CRP, CDAI, SDAI, HAQ, smoking status, swollen joint count or CRP. % of pts reaching DAS28CRP, SDAI, CDAI and Boolean remission rates observed at 6 months were statistically significant different between groups (fig). Boolean remission was the most stringent test with a statistical difference observed also at month 3 (specificity 90.5%, sensitivity 32.2%). There was no significant difference in clinical responses between subgroups of pts who developed new pathological joints and those who did not.

Conclusion: These results demonstrate that remission is an important therapeutic goal to protect joint damage in ERA. All remission criteria were able to predict the radiological prevention. The identification of a new pathologic joint is not associated with lack of response.

Characteristics and Outcomes in a Prospective Cohort of Patients with Aortitis Diagnosed Following Surgical Resection

Hart Goldhar¹, Mohamed Abdelrazek² and Nataliya Milman³, ¹Medicine, University of Ottawa, Ottawa, ON, Canada, ²Medical Imaging, University of Ottawa, Ottawa, ON, Canada, ³University of Ottawa Department of Medicine, University of Ottawa Division of Rheumatology, Ottawa, ON, Canada

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Aortitis, characterized by inflammation of the aorta, is broadly divided into infectious and non-infectious aortitis (NIA); the latter group consists of a number of inflammatory conditions (most commonly giant cell arteritis [GCA] and rheumatoid arthritis [RA]) and idiopathic aortitis (IA), when an underlying inflammatory cause cannot be identified. Retrospective data depicts a high rate of development of subsequent vascular complications in NIA, but corresponding prospective studies are lacking.

Methods: We analyzed patients enrolled in a prospective observational cohort of patients with histologic aortitis, who were diagnosed at The Ottawa Hospital between 2013-2017 following surgical repair of thoracic aortic aneurysms or dissections. Upon referral, triggered by a positive histopathologic specimen, patients were assessed for evidence of inflammatory or infectious disease and presence of additional vascular lesions. Consenting patients with NIA were followed prospectively with periodic clinical assessments and laboratory and radiographic studies. Aortic outcomes during follow-up included 'significant events', defined as new thoracic or abdominal aortic aneurysms, dissection/rupture, or need for further surgery, as well as aortic branch ectasias, aneurysms, and stenosis. Fisher's exact and the Mann-Whitney tests were used for significance calculations.

Results: Sixteen patients were included; 9 had IA and 7 had secondary aortitis (SA), specifically GCA (5) and RA (2). IA patients were more likely to have smoked (100% vs. 43%, $p=0.02$), and had more associated arch or descending aortic aneurysms on pre-operative baseline imaging compared to SA (6 vs. 0, $p=0.01$). At median 3.6-years of follow-up, 8 patients had 13 significant aortic events (9 and 4 events in 5 IA and 3 SA patients, respectively) (Table 1). The incidence of aortic dissection or second intervention, and the average annual rate of growth of descending aortic aneurysms, was higher in the first year post-surgery, compared to subsequent years. Immunosuppressive therapy did not seem to affect the outcomes, while elevated inflammatory markers during follow-up seemed to correlate with accumulation of severe aortic damage. No IA patients were diagnosed with a defined inflammatory condition at follow-up.

Conclusion: This is the first reported prospective study in patients with surgically diagnosed aortitis. Within the statistical limitations of a small cohort, we report a high incidence of aortic complications, especially in the early post-surgical period, and unaltered by immunosuppression. Studies of larger sample size and longer follow-up will be needed to corroborate these findings.

Table 1 Cumulative number of patients with (and total number of) aortic events over entire duration of follow-up.

Event	IA (N=9)	SA (N=7)	Total (N=16)	Events By Year (1 st /2 nd /subsequent)
Median follow-up, years	4.1	3.2	3.6	
New thoracic aortic aneurysm	3 (3)	2 (2)	5 (5)	1/2/2002
New abdominal aortic aneurysm	1 (1)	0	1 (1)	0 / 0 / 1
New branch ectasia/aneurysm	2 (2)	2 (2)	4 (4)	2/1/2001
New stenosis or occlusion	3 (3)	0	3 (3)	3 / 0 / 0
Aortic dissection/rupture	2 (2)	1 (1)	3 (3)	3 / 0 / 0
Further surgical aortic intervention	2 (3)	1 (1)	3 (4)	3/1/2000
Significant aortic events*	5 (9)	3 (4)	8 (13)	8/3/2002

* 'Significant aortic events' is a composite outcome that includes new aneurysms, dissection/rupture, or further interventions.

Cardiac Involvement in Systemic Vasculitis: A Retrospective Pathological Study

Olena Zimba¹ and Mykola Bahrii², ¹Department of Internal Medicine N2, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine, ²Department of Pathology and Forensic Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: Even though clinically significant heart involvement is rare, cardiovascular complications are leading causes of death in systemic vasculitis (SV). The comprehensive analysis of histopathologic findings is needed to elucidate the driving mechanisms of increased cardiovascular risk in SV. The purpose of this study was to investigate the variation of cardiac pathological findings in autopsy cases of Takayasu arteritis (TAK), polyarteritis nodosa (PAN) and granulomatosis with polyangiitis (GPA).

Methods: Microscopic examinations of the heart were performed in 108 autopsy cases of SV over a period of 15 years, of which 37 were PAN, 60 – TA and 11 – GPA.

Results: The destructive-productive vasculitis affecting myocardial, epicardial medium and small-sized arteries was observed in 81.1% cases of PAN. The most common acute change was panarteritis with intramural, and perivascular lymphocytes, and macrophages infiltrates. The most remarkable lesions in coronary arteries were nodules visible to the naked eye along coronary arteries (30%). In cases of chronic course of PAN, intimal hyperplasia due to proliferation of endothelial cells has been identified. In 5 (16.7%) cases, luminal occlusion due to intimal proliferation, fibrosis and thrombus formation led to the myocardial infarction. The pathological manifestation of cardiac involvement in PAN included the left ventricular hypertrophy due to renovascular arterial hypertension in 26 cases (70.3%). Interstitial myocarditis was observed in 4 cases (10.8%).

The pathological changes in coronary vessels have been found in all cases of GPA. The destructive-productive vasculitis affecting intramyocardial small arteries, arterioles, and capillaries was the most common. The acute stage has been characterized by abnormalities of the vessel wall from mucoid swelling to fibrinoid necrosis. The chronic lesions were characterized by intimal hyperplasia, fibrosis, hyalinosis of the vessels with their luminal narrowing. The most common lesion of myocardial interstitial matrix was extravascular granulomatous inflammation.

Our data show high frequency (76.7%) of pathological changes of coronary arteries in TAK such as intimal hyperplasia, granulomatous arteritis, and coronary atherosclerosis. Intimal hyperplasia consists of areas of musculo-fibrous proliferation or multi-layer scleral hyaline plaques. This pillow-like thickening of the intima around of the coronary orifices leads to their luminal narrowing. The coronary orifices were the site most commonly affected by TAK. Luminal narrowing of coronary arteries with coronary flow reduction led to subsequent fatal myocardial infarction in 15 cases (25%). Coronary atherosclerosis of varying severity was observed in 35 cases (58, 3%). The most common location of atherosclerotic deposits was regions of the pillow-like thickening of the intima around of the coronary orifices.

Conclusion: Our data suggest that cardiac involvement is common in SV with a wide range of acute and chronic changes and can be potentially life-threatening.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Cardiovascular (CV) risk in chronic inflammatory diseases is increased. Polymyalgia Rheumatica (PMR) is an inflammatory condition that might have a prolonged course. Our objective was to compare incidence rates of cardiovascular events (CVE) in patients with PMR with matched controls from a university hospital-based health management organization (HMO).

Methods: PMR patients (fulfilling ACR 2012 criteria) diagnosed after the year 2000 from the HMO were identified and matched (1:2) by date of birth and sex with controls from the same HMO. Those PMR patients with CVE before PMR diagnosis were excluded. Controls with CVE before its correspondent case date of diagnosis were also excluded. Patients were followed until they voluntarily left the HMO, a CVE occurred, the end of study (May 1st 2018), or death. Electronic

medical records were manually reviewed and demographic, clinical and treatment data were collected. Incidence rates per 1000 person-years (PY) of each CVE were calculated and compared between groups. A multivariate cox regression analysis was performed to identify factors associated with CVE.

Results: 868 PMR patients and 1736 controls were included and contributed 10865.2 and 12654.6 PY of follow up respectively. Patients' characteristics are shown in table 1. PMR patients were 682 females (78.7, 95% CI 75.8-81.3) with a mean age at diagnosis of 75.2 years (SD 7.9). Overall CVE incidence rate was lower in PMR patients than controls: 10.3 per 1000 PY (95% CI 8.6-12.2) versus 14.8 per 1000 PY (95% CI 12.8-16.8) respectively, $p = 0.001$. Cardiovascular death was also less frequent in PMR patients than in controls: 0.6 per 1000 PY (95% CI 0.2-1.2) versus 1.9 per 1000 PY (95% CI 1.2-2.8) respectively, $p=0.02$. When analyzing each CVE, stroke and abdominal aneurism incidence rates were higher in controls than PMR (table 1) while other CVE were similar across groups. In the multivariate cox regression analysis, men (OR 2.2, 95% CI 1.7-2.8, $p < 0.001$) and arterial hypertension (OR 1.5, 95% CI 1.1-1.9, $p 0.003$) were associated with an increased CV risk, while a PMR diagnosis was protective (OR 0.4, 95% CI 0.3-0.5).

Conclusion: Despite having more traditional cardiovascular risk factors and having been followed longer than controls, CVE were more frequent in the control group than in PMR patients. This may be due to a closer medical follow-up.

	PMR patients(n= 868)	PMR controls(n= 1736)	p

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: To investigate the cancer risk in patients with biopsy-proven giant cell arteritis (GCA).

Methods: The study population consisted of 830 patients (74 % women) with biopsy-proven GCA diagnosed between 1997 and 2010. The mean age at diagnosis of GCA was 76.3 years, 77.2 years for men and 75.8 for women. The cohort was cross-linked with data from the Swedish Cancer Registry. The patients were followed from GCA diagnosis until death or

December 31, 2013. All malignancies that occurred throughout the observation time were identified. Malignancies were divided into two groups; those preceding the date of the GCA diagnosis and those subsequently diagnosed. As a measure of relative risk, the age- and sex standardized incidence ratios (SIR) were calculated compared to the background population, i.e. the ratio of the incidence of observed cancer cases after the diagnosis of GCA to that of the expected number, based on cancer rates in the background population. SIRs were calculated for all types of cancer combined and for site-specific cancers.

Results: 107 patients (13%) were diagnosed with a total of 133 malignancies after the onset of GCA. Malignancies in the same organ/system were excluded, and thus 118 malignancies were included in SIR calculation. The overall risk for cancer after the GCA diagnosis was not increased with a SIR 0.98 (95% CI 0.81 – 1.17). However, there was an increased risk for myeloid leukemia SIR 2.31 (95% CI 1.06 – 4.39) and a reduced risk for breast cancer SIR 0.33 (95% CI 0.12 – 0.72) and upper gastrointestinal (GI) tract cancer SIR 0.16 (95% 0.004- 0.91). Rates of other site-specific cancers, e.g. cancer of the skin, lower GI tract, prostate or respiratory system, were not different from the expected (Table 1).

Conclusion: The overall risk for cancer in GCA patients was not increased compared to the background population. However, we found an increased risk for leukemia and a decreased risk for breast and upper gastrointestinal tract cancer. Possible explanations for these findings include effects of inflammation on tumor genesis and differences in other exposures that contribute to cancer risk. For example, some traditional risk factors for breast cancer, such as obesity, diabetes and late menopause, have been reported to be reduced in patients with GCA.

Table 1 Site-specific and total standardized incidence ratio of cancer in 830 patients with biopsy-proven GCA

Malignancy type	Observed, n	Expected, n	SIR	95% CI
Upper GI tract	1	6.1	0.16	0.00-0.91

Are Specific Vascular Symptoms in Takayasu's Arteritis Reflective of Vascular Inflammation, Vascular Damage, or Both?

Despina Michailidou¹, Joel S. Rosenblum¹, Mark A. Ahlman², Jamie Marco³ and Peter C. Grayson⁴, ¹NIAMS, National Institute of Arthritis, Musculoskeletal and Skin Disease ^{NIAMS}, Bethesda, MD, ²Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, ³Radiology and Imaging Sciences National Institutes of Health, Bethesda, MD, ⁴National Institute of Arthritis, Musculoskeletal and Skin Disease, National Institutes of Health, Bethesda, MD

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Patients with Takayasu's arteritis (TAK) can experience symptoms due to vascular inflammation or vascular damage. The study objective was to investigate whether specific vascular symptoms are more closely associated with vascular disease activity measured by ^{18}F -fluorodeoxyglucosepositron emission tomography (FDG-PET) or vascular damage assessed by magnetic resonance angiography (MRA).

Methods: Patients with TAK were recruited into a prospective observational cohort. Participants underwent clinical assessment and standardized imaging assessment (FDG-PET and MRA) within a 24-hour period, blinded to each other. Vascular disease activity was defined as arterial FDG uptake > liver by visual assessment. Vascular damage was defined as either stenosis, occlusion, or aneurysm in specific arterial territories on MRA. Clinical symptoms present on the day of evaluation (carotidynia; frontal headache; arm claudication) were compared to imaging findings in corresponding arterial territories. Generalized symptoms (headache; dizziness; history of CNS event defined as TIA/stroke or syncope) were studied in association with the number of affected neck vessels by MRA. Performance characteristics were calculated and the association between clinical symptoms and imaging features was assessed by Fisher's exact test.

Results: 51 participants contributed data from 92 study visits. For FDG-PET, the sensitivity (SN) of specific clinical symptoms ranged from 16% to 33% and specificity (SP) from 74% to 98%. For MRA the SN of the same symptoms ranged from 6% to 71% and SP from 79% to 100%. Details of specific associations are shown in the Table. Carotidynia was significantly associated with carotid activity by FDG-PET ($p<0.01$) but not carotid damage by MRA($p=0.18$). Frontal headache was significantly associated with both carotid activity by FDG-PET ($p<0.01$) and carotid damage by MRA ($p=0.04$). Arm claudication was significantly associated with subclavian damage by MRA($p<0.01$) but not subclavian activity by FDG-PET ($p=0.47$). Headache ($p=0.02$) and history of CNS events ($p<0.01$) was significantly associated with damage to ≥ 2 neck arteries, and dizziness ($p<0.01$) was associated with damage to ≥ 3 neck arteries.

Conclusion: Absence of clinical symptoms does not rule out vascular abnormalities by FDG-PET or MRA, but presence of symptoms is often associated with imaging abnormalities. Certain features are more closely associated with FDG-PET activity while others are more closely linked to vascular damage. Complaints of headache, dizziness, and CNS events are associated with the burden of vascular pathology in the neck arteries. These findings have direct clinical implications and may inform the development of disease activity indices in TAK.

Table. Association of Clinical Symptoms with Imaging Findings in Takayasu's Arteritis

Symptom	Arterial territory	Image Study	TN	TP	FN	FP	P value	Sensitivity (95% CI)	Specificity (95% CI)
Carotidynia	L carotid artery	FDG-PET	122	8	17	5	<0.01	32% (15-54%)	96% (91-99%)
	R carotid artery	MRA	66	12	82	4	0.18	13% (7-21%)	94% (86-98%)

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Vasculitis III: Clinical Subtypes and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Behcet's Syndrome (BS) is a vasculitic process which is characterized by recurrent oral and genital aphthous ulcerations, ocular, vascular, neurological, and gastrointestinal involvement. Although the exact pathogenic mechanism for vascular lesions in BS patients is still unclear, endothelial dysfunction may be important in the development of these lesions. Endothelial dysfunction is accepted as the initial lesion in atherogenesis and recent studies have shown that the increase in carotid intima media thickness (cIMT) is significantly associated with endothelial dysfunction. In this study, it was aimed to determine the frequency of subclinical atherosclerosis (ATS) according to vascular involvement in BS patients.

Methods: A hundred patients with BS and 30 healthy controls (HC) were included in this study. Participants with a history of cardiovascular (CV) events, type 1 or 2 diabetes mellitus, chronic kidney disease, and malignancy were excluded. Bilateral cIMTs were evaluated by using B-mode ultrasonography (US) in BS patients and compared with those in controls. Subclinical atherosclerosis was defined by CIMENT \geq 0.9 mm or \geq 1 carotid plaque which accepted as US positive group.

Results: The demographic characteristics, cardiovascular risk factors and US findings of patients with BS and HC are listed in table1. cIMT in BS patients was higher compared to HC (0.78 ± 0.21 mm versus 0.69 ± 0.13 mm; $p=0.006$). Thirty two (32%) BS patients, and two (6,7%) HC had subclinical atherosclerosis (BS versus HC: $p=0.006$). cIMT in BS patients with vascular involvement was higher than nonvascular group (0.83 ± 0.21 versus 0.75 ± 0.21 ; $p=0.072$). Comparison of disease characteristics and traditional CV risk factors of US positive and US negative BS patients are shown in Table 2. In regression analysis, older age and having vascular disease were independently associated with subclinical ATS (Table 3).

Conclusion: This study showed that cIMT measurements were higher in BS patients than HC and also significantly higher in BS patients with vascular group than nonvascular group. Vascular involvement in BS patients is an independent risk factor for the development of ATS. Therefore, BS patients with vascular involvement should be carefully monitored for the development of CV disease.

Costs Associated with Non-Medical Switching from Originator to Biosimilar Etanercept in Patients with Rheumatoid Arthritis in the UK

Kateryna Onishchenko¹, Stamatia Theodora Alexopoulos¹, Cinzia Curiale² and Miriam Tarallo², ¹Consulting at McCann Health, London, United Kingdom, ²Pfizer, Rome, Italy

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: To estimate the cost impact of non-medical switching from originator etanercept (ETN) to biosimilar ETN in patients with rheumatoid arthritis (RA) in the UK.

Methods: A cohort-based decision tree model was developed with a 1-year time horizon. The model population included patients with stable RA who responded to originator ETN treatment and had no change in treatment in the prior 6 months. Patients could undergo a non-medical switch to an ETN biosimilar (first switch) and then switch again if required (second switch) after 3-6 months. Data on the proportion of patients switching therapies, baseline healthcare resource use (including visits to rheumatologists, nurses, medical imaging, blood tests, hospitalization and emergency room visits), and impact of switching on resource use was sourced from a survey of 150 rheumatologists from EU5 markets. The average impact of switching (based on mean values for change in resource utilization due to switching) was calculated as per-patient costs, with low- and high-impact scenarios (based on lower and upper values of the 95% confidence intervals for change in resource utilization due to switching) also modelled as sensitivity analyses. Cost data were sourced from published UK sources.

Results: The model assumed that 5000 patients were treated with originator ETN, with 1259 (25.2%) switching to a biosimilar. Of those, 875 (69.5%) switched to SB4 and 384 (30.5%) to GP2015. After 3 months, 26.3% of patients who switched treatments did so again: 8.3% back to originator ETN, 3.8% to the other ETN biosimilar, and 14.2% to another biologic (abatacept [ABA], adalimumab or tocilizumab). Annual per-patient cost of continuous originator ETN treatment (drug and other healthcare costs) was £12,742. Originator ETN was more expensive than SB4 or GP2015 (annual per-patient costs of £9295 vs £8528 and £8365, respectively). Across all 3 impact scenarios, switching was more costly than continuous originator ETN (Figure). All switching treatment chains had higher overall annual per-patient costs than continuous originator ETN treatment. Switching from originator ETN to GP2015 or SB4 resulted in the lowest impact of

switching vs. continuous originator ETN (mean [low scenario, high scenario] values of £1120 [£110, £2131] and £1283 [£272, £2293], respectively). The highest impact of switching occurred following a second switch to ABA. Cost impact of the ETN→GP2015→ABA treatment chain vs. continuous originator ETN was £10,189 [£6244, £14,134], and for the ETN→SB4→ABA treatment chain was £10,230 [£6285, £14,174].

Conclusion: Non-medical switching can result in increased costs to the healthcare payer because of increased healthcare resource use following switching.

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00 AM-12:30 PM

Background/Purpose: To quantify the healthcare expenditures associated with oral glucocorticoids-related-adverse events (OGCs-AEs), among patients in the US with giant cell arteritis (GCA) using claims data from MarketScan[®] Commercial and Medicare Supplemental Databases.

Methods: Patients age ≥50 years with GCA and at least one OGC prescription fill, during 1/1/2009-6/30/2014 (first OGC claim after GCA diagnosis date = index date) were selected. Cumulative dose of OGCs was measured during the 1-year post-index period. Patients were stratified in four cohorts (>0 to ≤2,607 mg, >2,607 to ≤4,800 mg, >4,800 to ≤7,200 mg, >7,200 mg) based on the distribution of OGC exposure. Incidence of potential AEs and AE-related direct healthcare costs (2016 USD) were also assessed during the 1-year post-index period. A generalized linear model with log link and gamma distribution was used to evaluate the association between the log of cumulative dose of OGCs and AE-related direct healthcare costs, adjusting for baseline characteristics.

Results: The 1,602 GCA patients (mean age 73, 69% females) had mean cumulative OGC dose post-index of 5,806 mg (median=4,800 mg), with most exposure occurring in the first 6 months. The proportion of patients with any potential OGCs-AEs was 36.5% overall (n=584) and increased as cumulative dose increased (30.7%-45.3% across quartiles). Unadjusted mean AE costs for patients with an AE was \$12,818 (median=\$1,844). In the multivariable model, increasing OGC dose was associated with increasing AE-related healthcare costs (cost ratio=1.38 [95% CI 1.16-1.64] per 1 unit

increase in log (cumulative OGC dose), $p < 0.001$). Mean (median) predicted AE costs for the dosing quartiles were: \$4,389 (\$2,749) for >0 to $\leq 2,607$ mg, \$5,176 (\$3,009) for $>2,607$ to $\leq 4,800$ mg, \$5,576 (\$3,633) for $>4,800$ to $\leq 7,200$ mg, \$6,609 (\$4,447) for $>7,200$ mg.

Conclusion: Rates of OGCs-AEs tended to increase with an increase in cumulative OGC dose, which resulted in increased healthcare costs. These results highlight the need for efficacious therapies that reduce the exposure and potential risks associated with OGCs.

Clarke⁵, ¹Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ²AstraZeneca, Gaithersburg, MD, ³Truven Health Analytics an IBM Company, Ann Arbor, MI, ⁴University of California, San Francisco, San Francisco, CA, ⁵Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Estimates of the economic burden of SLE within economically disadvantaged populations in the US are limited. The purpose of this study is to provide an assessment of the economic burden of SLE in a Medicaid cohort, with an emphasis on disease severity as measured by treatment indicative of moderate-to-severe SLE.

Figure 1: Mean unadjusted total costs, total and by type of service, and multivariable-adjusted total costs during 12-month follow-up period compared between Medicaid-insured moderate-to-severe and mild SLE patients. Generalized linear modeling with log link and gamma error distribution estimated total healthcare costs adjusting for differences in age, sex, race, health plan type, and mean Charlson Comorbidity Index (CCI). *p-value < 0.05 **p-value < 0.001.

Methods: SLE patients ages 18-64 years treated with antimalarials, immunosuppressants, biologics (belimumab, abatacept, or rituximab), or systemic glucocorticoids from 1/1/2010 through 12/31/2014 were identified from administrative claims in

the MarketScan[®] Medicaid Multi-state database. The first prescription fill date was the index date. Patients were required to have at ≥ 1 inpatient claim or 2 non-diagnostic outpatient claims >30 days apart for SLE during the 12 months prior to the index. If the patient had only outpatient claims, ≥ 1 SLE diagnoses must have been made by a rheumatologist or nephrologist. Patients were categorized according to their SLE treatment during a 6-month exposure period starting on the index as follows: 1) mild SLE: either antimalarial monotherapy or low-dose oral glucocorticoid (≤ 5 mg/day) monotherapy or 2) moderate-to-severe SLE: any immunosuppressive or combinations of SLE medications other than either antimalarial or low-dose oral glucocorticoid monotherapy. All-cause healthcare utilization and costs were evaluated during the 12 months following the initial exposure period (in 2016US dollars). Generalized linear modeling with log link and gamma error distribution estimated total costs and total costs excluding outpatient pharmacy costs during follow-up, adjusting for demographic and clinical characteristics.

Results: 802 treated SLE patients were identified (91.3% female; 56.1% black). Based on patients' SLE treatment, 74.8% were classified as having moderate-to-severe SLE. Patients with moderate-to-severe disease were significantly younger than those with mild disease (mean age [SD]: 41.4 years[12.4] vs. 46.5 years [9.9]; $p<0.001$) and were more likely to have lupus nephritis (34.2% vs. 18.1%; $p<0.001$). Mean unadjusted total costs and by type of service, and multivariable-adjusted total costs are shown in Figure 1. Over half of the total costs were derived from the inpatient setting. The mean multivariable-adjusted total costs incurred over 12 months of follow-up were \$66,935 among moderate-to-severe patients and \$53,329 among mild patients ($p=0.04$); mean multivariable-adjusted total costs excluding pharmacy costs were \$56,050 among moderate-to-severe patients and \$44,932 among mild patients ($p=0.06$).

Conclusion: Approximately $\frac{3}{4}$ of SLE patients within this Medicaid cohort received treatment indicative of moderate-to-severe SLE indicating a substantial burden of disease. Healthcare costs were high for all patients, and the greatest proportion of cost was due to inpatient admissions.

Session Date: Wednesday, October 24, 2018

Session Title: Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Prescription drugs are the third largest category of healthcare spending in the US. Four of the top five costliest drugs are biologics used for the treatment of RA. Financial relationships between physicians and pharmaceutical companies may affect prescribing. We examined the costs of drugs prescribed by rheumatologists to U.S. Medicare beneficiaries and assessed the relationship between pharmaceutical industry payments to physicians and prescribing behavior.

Methods: Three databases, Medicare part B, Medicare part D, and Open Payments were queried for non-research payments to rheumatologists between 2013-2015. Prescription drugs responsible for 80% of the total expenditure were identified for analysis (table). Prednisone was included for comparison. We calculated the mean annual drug cost per beneficiary per year; the percentage of rheumatologists who received any payments; and the median annual payment per physician per drug per year. Payments were categorized as Type 1 (intended for “key opinion leadership”) and Type 2 (intended for physicians who receive information from these experts including food and beverages, or educational materials). The relationship between industry payments and prescription drug expenditure was examined using Spearman rank correlation methods.

Medication	Number of Rheumatologist Prescribers	Average Annual Medication Cost (\$)	Average Annual Cost per Beneficiary ¹ (\$)	% MD with any Sunshine payment	% with payments type 1 ²	Per-Physician Median (IQR) Annual Payments, \$	Correlation Total Payments, Rho	Type 1 Payments, ⁴ Rho
rACTH	156	\$1,519,864	\$29,955	96.2	32.7	138 (\$7 - 2,367)	0.43	0.52
Adalimumab	3875	\$19,979,396	\$21,491	56.5	10.7	114 (\$2 - 266)	0.23	0.16

Infliximab	1346	\$59,054,316	\$15,940	62.9	7.1	91 (\$2 - 70)	0.21	0.14
Golimumab	1123	\$6,215,740	\$15,476	88.4	0.1	86 (\$9 - 185)	0.19	0.17
Rituximab	490	\$108,285,620	\$15,172	72.9	5.9	99 (\$5 - 180)	0.19	0.14
Certolizumab	1037	\$11,309,336	\$13,941	70.0	11.6	79 (\$6 - 176)	0.26	0.14
Absorcept	1948	\$24,619,321	\$13,445	19.2	3.6	57 (\$1 - 123)	0.27	0.11
Toriparatide	1596	\$5,124,564	\$8,378	50.3	2.6	18 (\$9 - 46)	0.33	0.19
Denosumab	1675	\$9,064,445	\$1,297	62.1	1.0	86 (\$4 - 168)	0.18	0.09
HCQ ³	4672	\$2,381,281	\$62	-	-	-	-	-
Methotrexate ³	4735	\$13,695,960	\$358	22.4	1.3	9 (\$3 - 20)	0.22	0.06
Prednisone ³	4785	\$5,777,821	\$43	37.0	0.9	10 (\$3 - 29)	0.25	0.09

rACTH, repository corticotropin; HCQ, Hydroxychloroquine
¹ Defined as total drug cost divided by number of beneficiaries for the subset with available beneficiary costs (i.e., physicians with ≥10 beneficiaries per year)
² There were no payments associated with hydroxychloroquine
³ Brand versions associated with payments (Ravot, Ocremap, and Ravotop). No payments were associated with generics
⁴ Type payments—Speaker fees, consulting fees, honorariums, travel costs and non-research grants

Results: We identified 4,932 rheumatologists who prescribed any drug(s) to Medicare beneficiaries. Etanercept and adalimumab were the most commonly prescribed non-generic drugs while repository corticotropin (rACTH) was the least prescribed. Based on the mean annual medication costs, etanercept (\$741 million), adalimumab (\$620 million) and infliximab (\$539 million) had the highest expenditures. The annual cost of rACTH was \$82 million, or \$230,000 per beneficiary per year. Prednisone, the most commonly prescribed drug overall, had yearly mean annual cost of \$16 million. In general, biologic costs ranged between \$14,000 and \$21,000 per beneficiary per year, with the exception of denosumab which was much less costly. Drugs with the lowest annual cost per beneficiary were prednisone (\$42), methotrexate (\$358) and hydroxychloroquine (\$362). The correlation between total payments and total prescription costs per physician were low (rho<0.3), except for rACTH (rho=0.45; 95% confidence interval [CI]: 0.31, 0.57). The correlations between type 1 payments and total prescription costs were generally weaker (rho<0.2), except for rACTH (rho=0.52; 95% CI: 0.39, 0.62).

Conclusion: Payments by the pharmaceutical industry to rheumatologists are weakly associated with Medicare prescription costs. However, rACTH has a disproportionate cost relative to the number of prescribers and there was strong association between pharmaceutical payments and prescription costs related to rACTH. This finding is particularly important given the paucity of evidence and lack of clear indications for the use of rACTH.

Session Title: Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: SLE patients frequently experience pain. Opioid use for the management of chronic pain has been associated with increased morbidity, mortality, and healthcare resource utilization. We investigated the prevalence and factors associated with opioid use among MILES Cohort participants to identify opportunities to improve quality of care in SLE.

Methods: Data were derived from structured interviews at baseline visit of MILES, a longitudinal, population-based cohort of 462 SLE participants and 192 controls matched across sex, age, race and geography in southeastern Michigan. Detailed information on opioid use including prescribed frequency (scheduled or as needed) and duration were obtained. For the 30 SLE participants who reported more than one opioid use, opioid with longest duration was included in the analyses. We used multivariable logistic regression to evaluate factors associated with opioid use among SLE participants. Variables determined *a priori* to be important, or with p-values <0.1 in univariate analysis, were included in multivariable models (see Table).

Figure: Duration of opioid use for the 8% of controls and 31% of SLE participants on opioids

Table: Factors associated with opioid use among SLE participants

Variables	OR (95% CI)	p-value
Age	1.00 (0.98-1.03)	0.643
Female	1.04 (0.34-3.25)	0.940
Race		
Black	Reference

Other	0.37 (0.04-3.84)	0.410
Insurance		
Medicaid	Reference	
Medicare	0.92 (0.40-2.09)	0.835
Private	0.66 (0.29-1.51)	0.327
Income	0.91 (0.61-1.38)	0.669
Access to Healthcare		
Transportation difficulty to access healthcare	0.71 (0.32-1.61)	0.436
Mental healthcare within 12 months	1.36 (0.65-2.82)	0.400
At least one ED visit in preceding 12 months	2.44 (1.25-4.76)	0.009†
At least one admissions in preceding 12 months	1.32 (0.65-2.68)	0.438
Duration of SLE	1.02 (0.98-1.05)	0.349
Pain		
Visual analog scale pain score	1.50 (1.28-1.75)	<0.01†
Pain catastrophizing score	1.00 (0.96-1.04)	0.861

†statistically significant p-value<0.05

Results: All 654 participants completed the MILES Cohort baseline visit; average age 53.4 (SD 12.8), 584 (89%) female, 288 (44%) black and 159 (24%) with Medicaid insurance. Only 15 controls (8%) reported opioid use compared to 143 among SLE participants (31%) ($p<0.001$). One in three controls were prescribed scheduled opioids, whereas half of the SLE participants on opioids were given scheduled prescriptions. SLE participants on average reported 6 years of opioid use (SD 7 years) compared to 3 years among controls (SD 2 years) ($p=0.140$). Moreover, 34% of SLE participants on opioids reported opioid usage ≥ 5 years, whereas only 7% of controls on opioids had usage ≥ 5 years ($p=0.037$) (see Figure). In multivariable analysis, among SLE participants, those with higher pain score [OR 1.50(95% CI 1.28-1.75)] and at least one ED visit in the preceding 12 months [2.43 (1.25-4.74)] were more likely to be on opioids (see Table).

Conclusion: One in three SLE participants reported opioid use, and a third of those have opioid usage ≥ 5 years. Higher pain score and having at least one ED visit were significantly associated with opioid use. Studies have shown patients who frequent the ED are more likely to be prescribed opioids for pain. Moreover, opioid prescription in the ED has been found to increase the risk of long-term opioid therapy and associated morbidity and mortality. Further study is warranted to improve pain management and reduce opioid use in SLE participants, particularly for those who frequent the ED, to improve quality of care.

Session Information

Session Date: Wednesday, October 24, 2018

Session Title: Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) patients who are anti-citrullinated peptide antibody (ACPA) positive are prone to more severe structural damage, radiographic progression and inferior response to therapy. It's known that ACPA positive patients are associated with additional cost as compared to ACPA negative. It's unclear however if the incremental cost associated with ACPA-positive RA varies by the care pathway they follow. The study objective was to evaluate the incremental costs associated with ACPA-positivity in different groups of RA management pathways.

Methods: A retrospective cohort study was conducted in RA patients identified using electronic medical records from the Kaiser Permanente Southern California health plan. Between 01/01/2007 and 12/31/2015, we identified patients aged ≥ 18 years who had ≥ 2 RA diagnoses within a 12-month period, a disease-modifying antirheumatic drug (DMARD) prescription and laboratory test for ACPA. Patients were followed for two years post diagnosis. Latent class analysis (LCA) method was applied to identify ≥ 2 heterogeneous RA management patterns. RA-specific healthcare utilization during the first-year follow-up was used to identify the latent classes. During the second year of follow-up, we estimated total RA-specific expenditures associated with hospital stays; outpatient visits; office visits; pharmacy; laboratory and radiology utilization. A generalized linear model, evaluating the difference in expenditure between ACPA positive vs negative patients was specified with an effect modification term for latent class and adjusting for socio-demographics and comorbidities.

Results: We identified 2842 incident RA patients, mean age 56 years and majority female 76%. LCA indicated five latent classes representing mutually exclusive pathways of patient management and care (Table 1). Adjusted total RA-specific expenditure ranged from \$1167 in class one to \$21008 in class five for ACPA-positive patients (Table 2). The difference between ACPA positive and negative patients in the least severe class (Class 1) was statistically non-significant difference of \$214. However, in class two and above, this difference was statistically significant and progressively increasing. In patients characterized by high disease activity and high progression (Class 5) the expenditure difference was 27-fold higher (\$5708) as compared to Class 1 (Table 2).

Conclusion: Across the 5 distinct care pathways identified by LCA, based on the management and care of RA patients, the magnitude of the incremental cost associated with ACPA-positivity varied.

Table 1 Distribution of Markers of Latent Classes

New Cardiovascular Events in Patients with Gout Treated with Xanthine-Oxidase Inhibitors: An Inception Cohort Analysis

Neus Quilis¹, Laura Ranieri², Jose Sanchez-Paya² and Mariano Andrés², ¹Hospital Universitario del Vinalopó, Elche, Spain, ²Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: The recent CARES trial findings have contributed to the controversy around the development of cardiovascular (CV) events in gouty patients using febuxostat (FBX). In those with prior CV disease, FBX showed an increased CV mortality risk over allopurinol (ALLO), leading to the issue of an FDA warning. Whether this also applies to individuals without prior established CV disease is unknown. We aimed to assess the risk of new CV events in gout patients after the prescription of xanthine-oxidase inhibitors (XOI) in clinical practice.

Methods: Inception cohort (Jan'14-Dec'17), enrolling patients with crystal-proven gout in whom XOI (ALLO or FBX) were initiated and had at least 6 months of follow-up. The primary outcome were new CV events [CV death; coronary heart disease (CHD); congestive heart failure (CHF); stroke; peripheral artery disease (PAP)] after XOI initiation. Comparison between ALLO and FBX was performed using Kaplan-Meier plots and log-rank test. To adjust for confounders, Cox regression models were built, for the whole sample and stratified by the pre-existence CV disease. Covariates were selected if associated with the outcome or if they showed a different distribution between XOI groups.

Results: 256 patients were analyzed, 213 treated with ALLO and 43 with FBX. 69 cases (27.0%) had established CV disease. 22 new CV events occurred in a median of 9.5 months (IQR 4.5-19.3): 13 CHF cases, 5 CHD, 2 strokes, and 2 PAP, leading to 7 CV deaths. 16 events occurred in patients with a prior CV (23.2%), six in those with no prior CV events (3.2%). Regarding XOI treatment, 13 events happened with ALLO (6.1%) and 9 with FBX (20.9%). Use of colchicine at the time of the event was comparable. A higher incidence of new CV events in those treated with FBX was seen ($p < 0.001$, Kaplan-Meier plot). The simple Cox regression model confirmed a higher risk with FBX compared to ALLO (table), which persisted after adjustment. After stratification by prior CV disease, a significant CV risk with FBX was only detected in those with prior CV disease.

Conclusion: After adjustment for confounders, an excess risk of CV events is confirmed in patients with gout and prior CV disease treated with FBX. Whether this phenomenon relates to FBX itself needs further clarification.

*covariates: age, gender, hypertension, diabetes, dyslipidemia, smoking, established CV disease, baseline GFR, overweight, baseline SU, tophi, oligo/polyarthritis at presentation.

Paik¹, Jemima Albayda², Eleni Tiniakou³, Andrew Koenig⁴ and Lisa Christopher-Stine⁵, ¹Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ²Johns Hopkins University School of Medicine, Baltimore, MD, ³Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ⁴Pfizer Inc, Collegeville, PA, ⁵Medicine, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: Dermatomyositis (DM) is an idiopathic inflammatory myopathy that primarily affects the muscle and skin. In refractory disease, it is common to fail 2 or more steroid sparing agents or high dose steroids. This open-label, 12-week proof-of-concept study was conducted to evaluate the efficacy and safety of tofacitinib, a JAK inhibitor, in active, treatment refractory DM.

Methods: 10 subjects were enrolled at one center. Tofacitinib was given as 11mg XR daily. Subjects were washed out of any steroid sparing agent and not allowed more than 20 mg of prednisone daily prior to study entry. The primary outcome was the proportion of subjects meeting the definition of improvement (DOI) at 12 weeks, defined by the International Myositis Assessment and Clinical Studies (IMACS) as improvement of $\geq 20\%$ in 3 of 6 core set measures (CSM) with no more than 2 worsening by $\geq 25\%$ [which cannot include the manual muscle testing (MMT)]. The secondary outcome measures were the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI), steroid-sparing effect of tofacitinib, safety, and tolerability.

Results: 9 subjects were analyzed because the last subject has not yet completed the study. All subjects failed at least 2 steroid sparing agents or high dose steroids. All 9 subjects met the primary outcome DOI at 12 weeks, with 5 of 9 (56%) demonstrating moderate improvement and 4 of 9 (44.4%) having minimal improvement based on the Total Improvement Score (TIS) of the Myositis Response Criteria. The median TIS was 40 [IQR 32.5, 47.5] indicative of at least moderate improvement. The secondary outcome of the mean change in CDASI activity score from baseline to 12 weeks was statistically significant (28 ± 15.4 (baseline) vs. 9.5 ± 8.5 (12 weeks), $p=0.0005$) with clear trend in improvement (Figure 1). Chemokine data on CXCL-9/10 also showed a trend toward improvement with treatment but did not show a

statistically significant change from baseline (CXCL9, $p=0.09$; CXCL10, $p=0.06$) (Figure 2). Myositis autoantibody titers did not show any change in titer after treatment. Six subjects were positive for anti-TIF-1 gamma and 5 of 6 (83%) were moderate responders. Four of 9 (44.4%) were on prednisone 20mg/daily at entry and 3 of 4 (75%) were able to completely taper off all steroids. Tofacitinib was well tolerated without any serious adverse events.

Conclusion: Tofacitinib demonstrated evidence of strong clinical efficacy as measured by a validated myositis response criteria with a corresponding decrease in chemokine levels. A randomized controlled trial should be considered to further assess efficacy in dermatomyositis.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: A previous Phase 2a study of SM04690, a small molecule, intra-articular (IA), Wnt pathway inhibitor, demonstrated positive effects on knee OA pain, physical function, and medial joint space width (mJSW) at 52 weeks in key subgroups compared to placebo¹. A 24 week Phase 2b study was performed to refine patient reported outcome (PRO) measures, target population, dose, and further evaluate safety. PRO results for weeks 12 and 24 are presented here.

Methods: Subjects had ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2-3, Pain NRS ≥ 4 and ≤ 8 in target knee and < 4 in contralateral knee. A single IA injection of 2 mL SM04690 (0.03, 0.07, 0.15 or 0.23 mg), vehicle placebo (PBO), or sham (dry needle only) was given in the target knee at baseline. PRO endpoints included change from baseline compared with PBO in weekly average of daily OA target knee pain by numerical rating scale diary (NRS, [0-10]), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain [0-100], WOMAC Physical Function [0-100], and Patient Global Assessment (PTGA) (VAS [0-100]). This study was not formally powered, and sample size was based upon accepted dose-finding convention.

Results: 695 subjects (mean age 59.0 [± 8.5] years, BMI 29.0 [± 4.0] kg/m², female 58.4%, KL3 57.3%) were enrolled and dosed; 635 (91.4%) completed the study. No meaningful differences in incidence of adverse events were seen among treatment groups or between treatment and control groups.

In the full analysis set population (randomized, dosed subjects), significant improvements from baseline were observed in pain NRS for 0.07 mg (Week 12 [$P=0.001$], Week 24 [$P=0.031$]) and 0.23 mg (Week 12 [$P=0.012$], Week 24 [$P=0.022$]) SM04690 dose groups (**Figure**). Similar improvements were observed in WOMAC Pain for 0.07 mg (Week 12 [$P=0.04$]) and 0.23 mg (Week 12 [$P=0.003$], Week 24 [$P=0.031$]) dose groups. For WOMAC Physical Function, improvements were observed for 0.07 mg (Week 12 [$p=0.021$]) and 0.23 mg (Week 12 [$p=0.006$], Week 24 [$P=0.017$]) dose groups. PTGA improvements were observed for 0.07 mg (Week 12 [$P=0.031$]), and 0.23 mg (Week 12 [$P=0.010$], Week 24 [$P=0.033$]) dose groups.

Conclusion: SM04690, in development as a potential disease modifying OA drug, showed in this Phase 2b study statistically significant improvements from baseline in 0.07 mg and 0.23 mg SM04690 dose groups compared with PBO for Pain NRS, WOMAC Pain, WOMAC Physical Function and PTGA. These data further define outcome measures, target population, and dose for SM04690 as a potential treatment for knee OA. Ref: Yazici Y, et al. *Arthritis Rheumatol.* 2017; 69 (suppl 10). Actual observations over time and ladder plots depicting mean improvement ($\pm 95\%$ CI) of SM04690 compared with placebo adjusted for baseline for Pain NRS

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: PePRS is a Phase IIa international, multicenter, open-label single arm study of rituximab in pediatric patients with newly diagnosed or relapsing GPA or MPA. We report safety and exploratory efficacy data for the initial 6-month remission induction phase and for the long-term follow-up of all patients through ≥ 18 months.

Methods: Patients aged ≥ 2 to ≤ 18 years with recurrence or new onset of potentially organ- or life-threatening disease were included. Patients with severe disease requiring mechanical ventilation due to alveolar hemorrhage, requirement for plasmapheresis, or hemodialysis at screening were excluded. Three doses of pulsed intravenous (IV) methylprednisolone were administered during the screening period followed by four weekly IV rituximab infusions of 375 mg/m^2 body surface area and concomitant oral glucocorticoid taper. After the 6-month remission induction phase, patients received standard of care treatment (including additional rituximab infusions if required) for disease control. Visits occurred at 1, 2, 4 and 6 months during the remission-induction phase and every 3 months thereafter for a minimum of 18 months. The pediatric vasculitis activity score (PVAS) was used for exploratory efficacy assessments. Remission was defined as a PVAS of 0 and oral prednisone or prednisolone equivalent dose of $\leq 0.2 \text{ mg/kg/day}$ (max 10 mg/day).

Results: Of the 25 patients enrolled from 11 centers, 19 (76%) had GPA and 6 (24%) had MPA. The majority were female (20 patients [80%]), white (17 patients [68%]) and the median age was 14 years (range: 6-17 years). Most patients (18/25) had new-onset disease. Median baseline PVAS was 8 (IQR 5-15). The median duration of follow-up was 24 months (range: 16-54 months). All 25 patients completed the first 4 rituximab infusions and the 6-month remission induction phase; 24 of 25 completed ≥ 18 months of follow-up. All patients experienced ≥ 1 adverse event (AE) during the first 6 months, with infusion-related reactions (IRRs) being the most common AE (Table). IRRs occurred in 32% of patients with the first infusion and were less frequent thereafter. Overall, infections occurred in 68% of patients (with upper respiratory tract infection being the most frequent [16% of patients]). Ten serious AEs (SAEs) occurred in 7 patients during the 6-month remission induction phase, including 1 IRR. Over the entire study, 27 SAEs occurred in 12 patients, and no deaths were reported. Exploratory efficacy assessment showed that 56% of patients achieved remission by month 6; 100% of patients achieved remission by month 18. The median duration of remission during the study was 56 (IQR, 38-83) weeks.

Table. Common Adverse Events Reported in $\geq 10\%$ of Patients During Remission Induction Phase	
Adverse event	Number of patients (% of patients with ≥ 1 AE)
Infusion-related reaction	15 (60%)
Headache	4 (16%)
Nausea	4 (16%)
Upper respiratory tract infection	4 (16%)
Abdominal pain (upper)	3 (12%)
Constipation	3 (12%)
Arthralgia	3 (12%)
Back pain	3 (12%)
Cough	3 (12%)
Epistaxis	3 (12%)

AE, adverse event.

Conclusion: In this first global clinical trial of rituximab in pediatric patients with GPA/MPA, rituximab was well tolerated with an overall safety profile comparable to rituximab-treated adults with GPA/MPA. No new safety signals were observed. PVAS remission was achieved in 100% of patients by 18 months.

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: We previously reported abnormal cardiac MRI (CMR)-determined aortic stiffness in patients with early, treatment-naïve RA^{1,2}. We now report on whether this vascular stiffness is modifiable with RA DMARD therapy, and explore whether TNFi confers additional advantage over MTX csDMARD +/- subsequent escalation to TNFi.

Methods: A sub-grp of patients without CVD from an early (symptoms<1 yr), DMARD-naïve, RA (ACR/EULAR criteria) RCT³ with DAS28_{ESR}≥3.2 were recruited for 3.0T CMR to determine aortic distensibility (AD) at baseline, yrs 1 and 2 at a dedicated cardiology-CMR unit. Patients were randomised to first-line etanercept (ETN)+MTX (grp 1) or MTX/treat-to-target escalation to triple csDMARD, and switch to ETN+MTX at week 24 if failed to achieve clinical remission (grp 2; non-escalated subgroup 2a). At week 48, ETN was stopped, standard of care treatment maintained with observation up to week 96. AD values were natural log (ln) transformed prior to analysis; results are expressed as ratios between groups. Patients with DAS28_{ESR}≥2.6 at wk 48 defined non-responders. Change in AD value from baseline was evaluated in combined grps 1 and 2; between group, and within group (response states) change in AD at 1 and 2 years was compared adjusting for baseline DAS28_{ESR}.

Results: Eighty early RA patients of mean(SD) age 49.4(13.08) and systolic BP 123(16) were recruited. Median(IQR) ESR, CRP and mean(SD) DAS28 were 31(31)mm/hr, 8(23)mg/L and 5.6(1.5) respectively. 66(85%) and 59(76%) patients were ACPA and RF positive respectively. 17(21%) were current smokers.

Table 1 details the analyses, confirming significant reduction in mean AD from baseline to year 1 [3.59 (3.14,4.11) vs 2.99 (2.66,3.36) respectively; p<0.01]. This was maintained at year 2 [3.55(33.09,4.09) vs 2.99(2.66,3.36); p=0.04]. There appeared to be no numerical difference in change at years 1 (and 2, data not shown) when comparing grp 1 vs grp 2, all responders vs non-responders and grp 1 responders vs non-responders (all adjusted for baseline AD, age, sex). To clarify this apparent absence of effect of disease activity as represented by response status, correlation analyses between AUC disease activity and AD at year 1 in the combined grps 1&2, and between grps 1 & 2 also did not identify an association.

Table 1

Comparison		Ratio (95% CI), <i>P</i> value				
		Geometric mean AD (unadjusted)		Unadjusted	Adjusted for baseline AD	Adjusted for baseline AD, age, sex (\pm baseline DAS28ESR as applicable)
Combined Group 1 & 2 Baseline		2.99 (2.66,3.36)		1.20 (1.08,1.33), <i>p</i> <0.01	na	na
1 year		3.59 (3.14,4.11)				
Group 1 (all n=40)	Group 2 (all n=41)	3.74	3.44	0.91 (0.70,1.21), <i>p</i> =0.54	0.92 (0.76, 1.14) <i>p</i> =0.48	0.92 (0.76, 1.14) <i>p</i> =0.49
Group 1 & 2 non-responders (n=46)	Group 1 & 2 responders (n=35)	3.60	3.58	0.99 (0.76,1.30), <i>p</i> =0.97	0.97 (0.79,1.20) <i>p</i> =0.81	0.97 (0.78, 1.21) <i>p</i> =0.79
Group 1 non-responders (n=20)	Group 1 responders (n=20)	3.66	3.83	1.04 (0.71,1.53), <i>p</i> =0.82	1.00 (0.75, 1.34) <i>p</i> =0.98	1.00 (0.75, 1.36) <i>p</i> =0.96
Group 1 responders (n=20)	Group 2a responders (n=10)	3.83	2.75	0.72 (0.44,1.16), <i>p</i> =0.17	0.82 (0.60, 1.13), <i>p</i> =0.21	0.84 (0.60, 1.18) <i>p</i> =0.30
AUC DAS28						
Group 1 & 2 ^				1.07(0.79,1.44), <i>p</i> =0.65	1.03(0.82,1.3) <i>p</i> =0.78	1.05(0.83,1.33) <i>p</i> =0.69*
Group 1 (all n=40)	Group 2 (all n=41)	3.75	3.44	0.92(0.7,1.21), <i>p</i> =0.53	0.93(0.75,1.15) <i>p</i> =0.48	0.92(0.73,1.14) <i>p</i> =0.42*

^ Coefficients presented per 100 unit increase in AUC

* Adjusted for baseline AD, age, sex and AUC disease activity

Planned exploratory comparison of grp 1 ETN responders and grp 2a responders (no ETN exposure) suggested a 16% difference (0.84 (0.60, 1.18), *p*=0.30).

Conclusion: This first longitudinal CMR treatment-naïve ERA RCT cohort demonstrates vascular function abnormalities are modifiable (reduced) upon introduction of RA DMARD therapy. Treatment strategy rather than disease activity appeared to influence AD change; if confirmed in a larger trial this would suggest ETN+MTX confers a greater benefit over standard initial MTX/csDMARD.

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: Filgotinib (FIL), an oral, selective, Janus Kinase 1 (JAK1) inhibitor was effective in phase 2 studies of active RA in patients (pts) with insufficient response to MTX, warranting further evaluation in phase 3.

Methods: In this global, phase 3 study (ClinicalTrials.gov Identifier: NCT02873936), pts with moderately-to-severely active RA and an inadequate response or intolerance to 1 or more prior biologic DMARDs (bDMARDs), were randomized 1:1:1 to once daily FIL 200 mg, 100 mg, or placebo (PBO) for 24 weeks; pts were required to continue stable conventional synthetic DMARDs. The primary endpoint was the proportion of subjects who achieved an ACR20 response at Week (Wk) 12.

Results: Baseline characteristics of the 448 pts randomized and treated with the study drug (FIL 200 mg, n=147; FIL 100 mg, n=153; and PBO, n=148) included: 80.4% female; 23.4% ≥ 3 prior bDMARDs; 56 yrs mean age; 12.4 yrs RA disease duration; 27 of 68 tender joint count; 17 of 66 swollen joint count; and 5.9 DAS28(CRP). At Wk 12, an ACR20 response was achieved by more pts receiving FIL 200 mg or 100 mg than PBO (66.0, 57.5 and 31.1%, respectively; both $p < 0.001$) (Table 1). The reduction from baseline in HAQ-Disability Index (HAQ-DI) at Wk 12 was greater in the FIL 200 mg and 100 mg groups compared to the PBO group (-0.55 and -0.48 vs -0.23, respectively; both $p < 0.001$). Other key secondary endpoints, including SF-36 and FACIT-Fatigue, were also met at both FIL doses (Table 1). Adverse event (AE) rates were similar for FIL 200 mg, FIL 100 mg and PBO groups (69.4% and 63.4% vs 67.6%, respectively) as were rates of serious AEs (4.1%, 5.2% and 3.4%, respectively) (Table 2). There were 4 cases of uncomplicated herpes zoster (2 in each FIL group). There was one non-serious AE of retinal vein occlusion in the FIL 200 mg group; no other venous thrombotic events were reported. Two adjudicated MACE were reported: subarachnoid hemorrhage in the PBO group and myocardial ischemia in the FIL 100 mg group. There were no cases of opportunistic infection/active TB, malignancy, GI perforation or death.

Conclusion: In this phase 3 study of pts with highly active RA and prior inadequate response/intolerance to bDMARDs, treatment with FIL over a 24-week period was associated with significant improvement in the signs and symptoms of RA, with a safety profile consistent with Phase 2 data. FIL may provide a novel treatment option for pts who continue to have active RA despite prior biologic therapies.

This study was sponsored by Gilead Sciences, Inc.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: The CD40L/CD40 co-stimulatory pathway is important for T-cell-dependent antibody production and plays a central role in RA and other autoimmune diseases. VIB4920 (formerly MEDI4920) is an Fc-deficient CD40L antagonist which demonstrated acceptable safety and dose-dependent inhibition of TDAR in a Phase 1a study.

Methods: This Phase 1b, randomized, double-blind, placebo-controlled, multiple-ascending dose study enrolled 57 pts with active RA, defined as 28-joint Disease Activity Score–C-reactive protein [DAS28CRP] ≥ 3.2 ; and ≥ 4 tender and swollen

joints. Pts were positive for RF and/or anti-citrullinated peptide antibodies and previously had inadequate response to ≥ 1 DMARDs and/or anti-TNF therapy. Pts were treated with IV VIB4920 (75, 500, 1000 or 1,500 mg) or PBO every other week for 12 weeks. Key endpoints were safety, tolerability, pharmacokinetic parameters, anti-drug antibodies (ADAs), change in DAS28–CRP and biomarkers of disease activity (RF, CRP, Vectra-DA) at Day 85.

Results: Table 1 summarizes the main baseline demographic and clinical characteristics. Treatment emergent AEs were equally distributed among groups; no thrombotic events or coagulation abnormalities were noted. One grade 4 SAE of encephalitis was reported in the 1500mg VIB4920 dose group. This was considered unrelated to VIB4920. The patient subsequently was diagnosed with metastatic melanoma of the brain after recurrence of similar symptoms. ADAs were observed in over 30% of pts with the lower doses, but no ADAs were observed in the 1000 and 1500 mg dose groups. A significant dose response was demonstrated for the change from baseline in DAS28CRP at Day 85 ($P < 0.001$). A clinically important difference in DAS28CRP improvement versus placebo was observed in the 1000 and 1500 mg VIB4920 groups using mixed model for repeated measures (Figure and Table 1). Low disease activity or DAS28 remission was achieved in 50% of the 1,000 mg and 75% of the 1,500 mg dose groups compared to 13.4% in the PBO group at Day 85. There was a dose dependent decrease from baseline in RF and CRP levels and in Vectra-DA scores (Table) with the greatest effect in the two highest doses.

Baseline characteristics	PBO N=15	VIB 4920			
		75 mg N=8	500 mg N=10	1,000 mg N=12	1,500 mg N=12
Age, yrs, mean (SD)	58.3 (8.0)	57.9 (7.4)	53.7 (9.8)	52.1 (11.5)	50.9 (8.6)
Years since diagnosis, mean (min, max)	11.1 (1.1, 39.8)	12.8 (1.6, 28.5)	9.3 (2.2, 19.9)	12.6 (0.5, 44.0)	8.5 (1.2, 23.2)
DAS-28-CRP, mean (SD)	5.7 (1.18)	5.4 (0.85)	5.0 (0.98)	5.5 (0.56)	5.0 (0.58)
Swollen Joint counts, mean (SD)	10.0 (4.2)	9.5 (5.3)	7.1 (2.5)	8.8 (2.7)	6.6 (1.0)
Tender joint count, mean (SD)	16.9 (7.1)	19.3 (7.4)	11.5 (4.9)	16.2 (5.2)	11.5 (5.7)
RF/ACPA positive (%)	86.7/100	87.5/75	70.0/100	83.3/100	91.7/100
Key efficacy endpoints at Day 85					
DAS-28 adjusted mean change from BL (SE) (n)	-1.0 (0.3) (14)	0.1 (0.4) (6)	-1.2 (0.3) (10)	-2.2 (0.3) (12)	-2.3 (0.3) (12)
Low disease activity: (DAS28-CRP 2.6 to < 3.2) (%)	1 (6.7%)	0	1 (10.0)	2 (16.7)	4 (33.3)
Remission (DAS28-CRP < 2.6); (%)	1 (6.7)	0	2 (20.0)	4 (33.3)	5 (41.7)
Patient global assessment, adjusted mean change from BL (SE) (n)	-4.7 (5.8) (14)	1.8 (8.6) (6)	-11.8 (6.9) (10)	-24.0 (6.3) (12)	-25.6 (6.3) (12)
RF adjusted geometric mean reduction from BL; % (n)	6.5 (14)	0.1 (6)	39.1 (10)	48.2 (12)	51.3 (12)
Vectra-DA score adjusted mean change from BL (SE) (n)	2.1 (2.9) (14)	-0.3 (4.3) (6)	-0.1 (3.4) (10)	-8.2 (3.1) (12)	-12.2 (3.1) (12)
CRP adjusted geometric mean reduction from BL; % (n)	-14.6 (14)	15.2 (6)	-17.6 (10)	49.4 (12)	62.9 (12)

Conclusion: In this proof of concept study VIB4920 significantly decreased disease activity at Day85 achieving at least low level of disease activity in 50%-70% of patients in the two higher doses. Dose dependent decrease in RF levels and the Vectra DA score provides supportive evidence that VIB4920 effectively blocks the CD40/CD40L pathway. Combined with an acceptable safety profile these data support further development of VIB4920 for autoimmune diseases.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: Clinical application of biomarkers to predict response to therapy is the next frontier in RA. Despite the key role of IL-6 in RA, the utility of IL-6 to predict prognosis or treatment response in RA is limited. Post-hoc analyses of MOBILITY (NCT01061736) and MONARCH (NCT02332590) studies investigated if serum baseline IL-6 level was associated with radiographic and clinical responses to sarilumab versus comparator treatment.

Methods: Baseline IL-6 levels were measured using a validated assay in 1193 patients (pts) randomized to sarilumab (SC 150 or 200 mg q2w) +MTX or placebo (PBO) +MTX, and 300 randomized to sarilumab 200 mg or adalimumab 40 mg q2w. Efficacy was compared between and within treatment groups according to baseline IL-6 tertile using linear and logistic regression.

Results: All low tertile pts had normal IL-6 levels (<12.5 pg/mL) and >85% of high tertile pts had IL-6 levels $\geq 3 \times$ ULN. At baseline, pts in the high tertile had more joint damage, greater disease activity, and elevated levels of CRP vs the low tertile pts (nominal $P < 0.05$; Tables). In the MOBILITY PBO+MTX group, pts in the high tertile developed more joint damage than pts in the low tertile (mean \pm SD mTSS progression 4.67 ± 9.80 vs 1.51 ± 5.25 [Figure]; odds ratio 3.3; 95% CI 1.9, 5.6). Clinical and radiographic efficacy (sarilumab+MTX vs PBO+MTX) in MOBILITY improved with increasing baseline IL-6 tertile (Table 1). In MONARCH, sarilumab efficacy vs adalimumab was greater in the high vs low tertile (Table 2) – ACR20/70 for sarilumab vs adalimumab: 89%/30% vs 52%/4% [high tertile] and 64%/18% vs 58%/18% [low tertile]. Data show that high IL-6 is better than high CRP at predicting efficacy outcomes. The incidence of treatment emergent adverse events was similar across IL-6 tertiles.

Conclusion: Across clinical and radiographic endpoints, pts with elevated baseline IL-6 levels had greater response to sarilumab compared with MTX or adalimumab than pts with normal IL-6 levels. Prospective validation is warranted to confirm these data.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: A potentially increased risk of venous thromboembolism (VTE) was noted in pre-marketing trials of baricitinib, which is a Janus kinase inhibitor (JAK-I). This led the FDA to restrict approval of baricitinib to only the low dose (2mg) for treatment of rheumatoid arthritis (RA). It remains unknown whether the risk of VTE is attributable to JAK-inhibition and extends to tofacitinib, which is increasingly used in RA since its approval in 2012.

Methods: We conducted a new-user cohort study using administrative claims data from the Truven Marketscan (2012-2016) and Medicare (parts A, B, and D, 2012-2015) databases to evaluate the risk of VTE with tofacitinib versus tumor necrosis factor (TNF)-inhibitors in RA patients. RA patients ≥ 18 years were identified during a 180-day baseline period of continuous insurance enrollment prior to a cohort entry date marked by treatment initiation with tofacitinib or a TNF inhibitor (adalimumab, certolizumab, etanercept, golimumab, or infliximab) without use of any biologics or tofacitinib any time prior. Patients were followed for the outcome of VTE, defined as a composite of pulmonary embolism or deep vein thrombosis diagnosis in inpatient claims, on as treated basis. A propensity score (PS) based fine-stratification weighting approach was used to account for 60 confounding variables. A weighted Cox proportional hazards model provided hazard ratio (HR) and 95% confidence intervals (CI). HRs were pooled across databases with inverse variance meta-analytic methods.

Results: A total of 34,074 and 17,086 RA patients were identified with a mean age of 50 and 71 years from Truven and Medicare, respectively; of whom 5.6% and 5.8% were tofacitinib initiators. A greater proportion of tofacitinib initiators had used ≥ 3 non-biologic disease modifying agents and glucocorticoids at baseline, indicating more active or longer duration RA in this group. PS-adjustment provided excellent balance on all 60 covariates. The incidence rates (IRs)/100 person-years were 0.60 and 0.34 in Truven and 1.12 and 0.92 in Medicare for tofacitinib and TNF-Is, respectively (**Table 1**). PS-adjusted HRs showed no significant differences in the risk of VTE between tofacitinib and TNF-Is in either database. The pooled HR was 1.33 with 95% CI ranging from 0.78 to 2.24.

Conclusion: We observed a numerically higher, but statistically non-significant, risk of VTE for tofacitinib versus TNF-Is in RA patients. The absolute rates of VTE in routine care RA patients were low and comparable to those observed in pre-marketing trials of baricitinib and tofacitinib. Although residual confounding is possible and the precision of estimates was limited due to a small event count, these results are helpful in ruling out the possibility of a large increase in the risk of VTE with tofacitinib and provide preliminary evidence regarding the safety of this JAK inhibitor agent with respect to VTE risk.

Table: Absolute and relative risk of venous thromboembolism incidence in rheumatoid arthritis patients initiating tofacitinib or tumor necrosis factor inhibitors (TNF-Is)

Data source	Exposure group	Sample size	Events	Total person years of follow-up	Incidence rates/100 person years (95% CI)	Unadjusted hazard ratio (95% CI)	PS-adjusted hazard ratio (95% CI)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: Primary Sjogren's syndrome (pSS) is a systemic, progressive autoimmune disease characterized by secretory gland dysfunction which lacks effective therapy. Clinical trials in patients with pSS using leflunomide (LEF) or hydroxychloroquine (HCQ) previously effectively inhibited B cell hyperactivity, but induced only modest insignificant effects on clinical parameters. LEF and HCQ have complementary inhibitory properties on different immune cells, including B cells, T cells and pDCs. In vitro LEF and HCQ additively inhibit T and B cell activation as well as CXCL13 production. To study the potentially additive clinical effects of these drugs we conducted a randomized, double-blind, placebo-controlled, mono-center proof of concept study to evaluate the efficacy, safety and tolerability of LEF/HCQ therapy in patients with pSS (REPURpSS-I study).

Methods: Clinically active (ESSDAI \geq 5) pSS patients (n=29) were randomized to receive LEF 20mg daily and HCQ 400 mg twice daily or placebo/placebo (2:1) for 24 weeks. Primary and secondary endpoints were changes in ESSDAI and stimulated whole saliva (SWS) flow at 24 weeks, respectively. Other outcomes assessed were Patient Reported Indexes (ESSPRI), Multi-dimensional Fatigue Inventory (MFI), Physician's and Patient's Global Assessments, SF-36, and various circulating mediators. Outcomes also included safety assessments.

Results: Twenty-nine patients were enrolled: 8 patients received placebo and 21 received LEF/HCQ combination therapy (mean baseline ESSDAI scores of 11.5 and 11.8, respectively). Overall, LEF/HCQ was safe and well-tolerated. There was a single serious AE requiring de-blinding (pancreatitis at week 16 in the placebo cohort). The ESSDAI score at 24 weeks

significantly improved in the LEF/HCQ group ($p=0.044$, $n=9$ responders with ESSDAI decrease ≥ 3) compared to baseline, in contrast to those receiving placebo ($p=0.818$, 1 responder). As anticipated, lymphopenia and elevated CK levels were significantly higher in the LEF/HCQ group. When calculating ESSDAI scores without these, stronger decreases in the LEF/HCQ group ($p=0.000$) compared to placebo ($p=0.940$) were observed. In this case eleven patients in the LEF/HCQ group displayed a decline in ESSDAI of ≥ 3 (average decrease 6.64 points), whereas this was not observed in the placebo group. Oral dryness showed significant improvement (SWS from 823 to 1366 $\mu\text{l}/5$ minutes, $p=0.04$) in the LEF/HCQ treated group as compared to decline in the placebo group (SWS from 1125 to 815 $\mu\text{l}/5\text{min}$, $p=0.169$). Significant improvements in other measures such as ESSPRI, ESSPRI pain, ESSPRI fatigue, Physician's Global Assessment, and Patient's Global Assessment were also observed in the LEF/HCQ group (all at least $p<0.05$) but not in those receiving placebo. Serum IgG, IgM rheumatoid factor ($p<0.0001$ and 0.001 resp.) and CXCL13 decreased, whereas C3 and C4 increased ($p=0.016$ and $p=0.003$) in the LEF/HCQ group, but not in the placebo-treated patients.

Conclusion: This pilot RCT suggests clinical efficacy for LEF/HCQ combination therapy in almost half of the patients with primary Sjögren's syndrome. Larger RCT's are needed to confirm the observed effects and to identify potential biomarkers for response.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) and tumor necrosis factor inhibitors (TNFi) such as etanercept (ETN) are often prescribed for psoriatic arthritis (PsA) either alone or in combination, but fundamental gaps in knowledge about their optimal use remain. This study examined the efficacy of MTX monotherapy relative to ETN monotherapy and the value of adding MTX to ETN in key clinical domains of PsA, including progressive joint damage.

Methods: This phase 3, randomized controlled, double-blind international study enrolled patients with active PsA based on Classification Criteria for Psoriatic Arthritis (CASPAR). They were naïve to biologic drugs with no prior MTX for PsA. A total of 851 patients were randomized to 3 groups for 48 weeks: ETN 50 mg plus MTX 20 mg weekly (Combo; $N = 283$); ETN 50 mg plus oral placebo weekly (ETN-mono; $N = 284$); or MTX 20 mg plus injectable placebo weekly (MTX-mono; $N = 284$). The primary endpoint was the American College of Rheumatology (ACR)20 response at week 24. The key secondary endpoint was Minimal Disease Activity (MDA) response at week 24. The study was powered to detect a treatment difference in ACR20 and MDA at week 24 between the Combo and the MTX-mono arms and between the ETN-mono and MTX-mono arms, tested in a Bonferroni-based gatekeeping chain procedure. Additional endpoints included other measures of inflammatory arthritis, radiographic progression, severity of non-articular disease manifestations, and patient-reported outcomes.

Results: Baseline characteristics were well balanced in the 3 study arms. Mean (SD) age was 48.4 (13.1) years, most patients were white, and median PsA duration was 0.6 years (mean [SD] 3.2 [6.3] years). From weeks 4 to 24, the MTX-containing arms maintained a mean MTX dose >18.8 mg. ACR20 and MDA response rates at week 24 were significantly greater for ETN-mono vs MTX-mono (ACR20: 60.9% vs 50.7% [$P=0.029$]; MDA: 35.9% vs 22.9% [$P=0.005$]) and for Combo vs MTX-mono (ACR20: 65.0% vs 50.7% [$P=0.005$]; MDA: 35.7% vs 22.9% [$P=0.005$]). At week 48, the Combo and ETN-mono arms showed less radiographic progression compared with the MTX-mono arm (Table). Other secondary outcomes are

shown in the Table. Overall, the Combo and ETN-mono arms had similar results, with some differences in skin outcomes. Aside from GI events, adverse event rates were similar in the 3 study arms. No new safety signals were seen.

Conclusion: This is the first head-to-head comparison of MTX and a TNFi to address fundamental questions in the treatment of PsA. ETN monotherapy or ETN in combination with MTX showed greater efficacy compared with MTX monotherapy. Addition of MTX to ETN did not appear to improve efficacy compared with ETN alone. These results support the use of ETN as monotherapy for PsA.

Acknowledgment: Linda Rice at Amgen Inc. and Julia Gage (on behalf of Amgen Inc.) assisted in abstract drafting. The study sponsor was Amgen Inc.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: TNF inhibitors (TNFi) are recommended for patients with axial SpA (axSpA) who do not respond to or tolerate NSAIDs. Some patients are inadequate responders or intolerant to TNFi and this axSpA population has not been exclusively studied in a clinical trial. In COAST-W (NCT02696798), we investigated the efficacy and safety of ixekizumab, a high-affinity monoclonal antibody that selectively targets IL-17A, in patients with active radiographic axSpA (r-axSpA) with prior inadequate response (IR) or intolerance to 1 or 2 TNFi.

Methods: In this randomized, double-blind, placebo-controlled, Phase 3 trial, adult patients with IR/intolerance to 1 or 2 TNFi and an established diagnosis of r-axSpA (patients fulfilling ASAS classification criteria for axSpA, with radiographic sacroiliitis centrally defined by modified New York criteria) were recruited and randomized 1:1:1 to placebo (PBO) or 80-mg subcutaneous ixekizumab every 2 (IXEQ2W) or 4 (IXEQ4W) weeks, with either 80-mg or 160-mg starting dose (assigned 1:1). The primary endpoint was ASAS40 response rate at Week 16. Secondary outcomes and safety were also assessed. Categorical outcomes were analyzed by logistic regression with non-responder imputation. Continuous outcomes were analyzed by mixed-effects model of repeated measures except MRI SPARCC scores (analysis of covariance using observed case without imputation).

Results: In total, 316 patients were randomized to PBO (N=104), IXEQ2W (N=98), or IXEQ4W (N=114). All patients possessed very active (mean BASDAI: 7.4±1.3) and longstanding disease (median duration of symptoms = 16.7 years); 90% had a prior IR and 10% were intolerant to TNFi. At Week 16, significantly higher proportions of IXEQ2W (N=30 [30.6%]; p=0.003) or IXEQ4W (N=29 [25.4%]; p=0.017) patients achieved ASAS40 versus PBO (N=13 [12.5%]), with statistically significant differences as early as Week 1 for both treatment regimens. Significant improvements were observed for disease activity, function, quality of life, spinal MRI inflammation, and high sensitivity CRP (Table 1). The majority of treatment emergent adverse events (AE) were mild/moderate (Table 2). Serious AEs were consistent across arms. One death was reported (IXEQ2W) due to suicide, which was not attributable to study drug per the blinded principal investigator.

Conclusion: Both ixekizumab treatment regimens yielded rapid and significant improvements in the signs and symptoms of r-axSpA at Week 16 in patients with previous IR or intolerance to 1 or 2 TNFi, compared to PBO.

Biologics, ankylosing spondylitis (AS) and axial spondyloarthritis

Methods: Pts were initially randomized to receive intravenous (IV) SEC 10 mg/kg at baseline, Weeks (Wks) 2 and 4, followed by subcutaneous (SC) SEC 150 mg (IV→150 mg) or 75 mg (IV→75 mg) every 4 wks thereafter or matched placebo (PBO). Based on ASAS20 response at Wk 16, PBO pts were re-randomized to secukinumab 150 or 75 mg SC at Wk 16 (non-responders) or Wk 24 (responders). After the 2-year core trial, 274 pts entered the 3-year extension study. Detailed study design has been reported previously¹. Dose escalation from SEC 75 mg to 150 mg was allowed following a protocol amendment. Assessments at Wk 260 included ASAS20, ASAS40, ASAS5/6 and other efficacy outcomes (reported as observed). Clinical efficacy including dose escalation results are reported for all pts who entered the extension trial (i.e.

Efficacy endpoints	SEC Groups Including PBO Switchers		Dose Escalated Group

N for ASAS20 and ASAS40 was 112, 126 and 75 for SEC 150 mg, SEC 75 mg, and dose escalated group, respectively (all including PBO switchers). N for ASAS PR and BASDAI50 was 132, 128 and 75 for SEC 150 mg, SEC 75 mg, and dose escalated group, respectively (all including PBO switchers).

N, total number of randomized patients; M, number of evaluable patients; n, number of responders; ASDAS, Assessment of Spondyleritis Disease Activity Index; SF-36, Short-Form 36; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BAF1, Bath Ankylosing Spondylitis Functional Index; BASMI, Bath Ankylosing Spondylitis Mobility Index; CRP, C-reactive protein; PBO, placebo; SD, standard deviation; SEC, secukinumab; SF-36 PCS, short-form 36 physical component summary.

Re-escalation is defined as the last assessment done on or before the patient administered the escalated dose.

All values are confidence intervals unless noted with both one and a two-sided confidence intervals. Data available are included in this analysis.

including placebo-switchers); former is based on randomized dose whereas latter is based on treatment dose. Safety is reported as exposure adjusted incidence rate (EAIR)/100 pt-years for all pts (n = 360) who received ≥ 1 dose of study treatment.

Results: A total of 84.4% (108/128) and 83.6% (122/146) of all the pts (i.e. including PBO switchers) who received SEC 150 mg and 75 mg, respectively, completed 260 wks of treatment. Improvements in ASAS20, ASAS40, BASDAI50, and other efficacy outcomes were sustained through Wk 260 (Table). A total of 82 pts on SEC 75 mg (56.2% of total 75 mg population) had dose escalated to 150 mg after Week 168; ASAS40, ASAS PR, ASAS 5/6, and BASDAI50 responses were improved in pts whose dose was escalated from SEC 75 mg to 150 mg (Table). Across the entire treatment period (SEC exposure [mean \pm SD]: 206.6 \pm 90.17 weeks), SEC was well tolerated with a safety profile consistent over the course of the study. EAIRs of selected adverse events of interest were 0.1, 0.6, 1.8 and 0.5 per 100 pt-years for ulcerative colitis, Crohn's disease, uveitis and malignant/unspecified tumors, respectively.

Conclusion: Secukinumab provided sustained efficacy across multiple domains of AS including signs and symptoms, physical function, and objective markers of inflammation through 5 years. Efficacy improved in pts who had dose escalation from 75 mg to 150 mg. Secukinumab was well tolerated over long-term use with no new safety signals identified and a safety profile consistent with previous reports.¹

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Poster Session

Session Time: 09:00AM-11:00AM

Background/Purpose: XmAb5871 is a humanized anti-CD19 antibody Fc-engineered for increased affinity to FcγRIIb. Co-ligation of CD19 and FcγRIIb inhibits B lineage cells key to SLE pathogenesis. This Phase 2 study was designed to

minimize background medications and placebo responses to improve interpretation of a small trial in a complex, heterogenous disease.

Methods: SLE patients were enrolled with moderate to severe, non-organ threatening disease, which was ameliorated during screening with ≥ 160 mg of IM Depo-Medrol. Improvement was required before randomization, defined by SLEDAI decrease ≥ 4 points or ≥ 1 grade decrease in ≥ 1 BILAG A or B score. All immunosuppressive drugs were withdrawn except antimalarials or up to 10 mg/day prednisone or equivalent. Subjects were randomized to IV XmAb5871 (5 mg/kg) or placebo and given Depo-Medrol 80 mg IM on Days 1 and 15. Study treatments were every 14 days for up to 16 doses until Day 225 or loss of improvement (LOI), defined as SLEDAI increase of ≥ 4 points OR new BILAG A or B, with investigator agreement of significance. At LOI, patients could receive standard of care and withdraw. The primary endpoint was the proportion of subjects with no LOI by Day 225 in the efficacy evaluable group, defined as those who completed Day 225, had LOI, or discontinued due to a drug-related adverse event. Those who dropped out for other reasons were excluded from this analysis.

Results: 104 patients (99 female) were randomized. Median age was 44.5 years (20-65). XmAb5871-treated subjects stayed in the study longer receiving more infusions than the placebo group – 6.9 months vs 3.6 months and 15 vs 8.5, respectively. Six XmAb-treated patients were withdrawn for infusion-related events. 10 patients terminated from the placebo arm vs 2 from the XmAb5871-treated arm with exclusion from the efficacy evaluable population. These exclusions led to higher placebo response rates compared to the ITT population.

Table 1: Primary and Secondary Endpoints: Maintenance of Improvement

	Efficacy Evaluable Population			Intent to Treat Population		
	XmAb5871	Placebo	p value	XmAb5871	Placebo	p value
% Response at Day 225	42	28.6	0.181	40.4	23.1	0.06
% Response at Day 169	58	40.5	0.11	57.7	34.6	0.02

¹ Primary Endpoint

The most common AEs in XmAb5871-treated patients were transient, infusion-related gastrointestinal side effects during the 1st or 2nd infusion. There were 8 SAEs in 7 XmAb-treated subjects, 5 in 4 placebo patients, no opportunistic infections, and no deaths. Major organ flares: Placebo: 2 nephritis, 1 enteritis, 1 systemic flare; XmAb5871: 1 pneumonitis. All were treated and stabilized. Infection rate was low compared to other SLE trials; one pneumonia occurred in an XmAb5871-treated patient.

Conclusion: XmAb5871 was well-tolerated, infection rate was low, flares were similar to other lupus trials. Preliminary data from this small trial supports further evaluation of XmAb5871 in SLE.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: The diagnostic accuracy of PET/CT against temporal artery biopsy (TAB) in patients suspected of having GCA has not been well studied. PET/CT has traditionally been used to image the aorta and primary branches, but newer generation scanners can also detect inflammation in the smaller temporal (TA), occipital (OA), maxillary (MA) and vertebral arteries (VA). We assessed the accuracy of a newer generation PET/CT time-of-flight scanner for GCA.

Methods: 64 newly suspected GCA patients were enrolled over 20 months. All underwent PET/CT from the vertex to diaphragm within 72 hours of starting corticosteroids and before TAB. Two PET experienced nuclear medicine physicians

Figure: Axial PET/CT head from a biopsy positive GCA patient showing increased FDG tracer uptake in the maxillary and right superficial temporal arteries consistent with active arteritis

Table: PET/CT compared with a) temporal artery biopsy and b) clinical diagnosis for GCA

a) PET/CT compared with temporal artery biopsy (TAB) for GCA			
Patients			Performance
	TAB +	TAB -	Total
PET/CT +	11	7	18
PET/CT -	1	39	40
Total	12	46	58
			Sensitivity: 92% Specificity: 85% PPV: 61% NPV: 98%
b) PET/CT compared with clinical diagnosis for GCA			
Patients			Performance
	Clinical +	Clinical -	Total
PET/CT +	15	4	19
PET/CT -	8	39	45
Total	21	43	64
			Sensitivity: 71% Specificity: 91% PPV: 79% NPV: 87%

PPV: Positive predictive value. NPV: Negative predictive value

blinded to clinical and biopsy data independently reported scans as globally positive or negative for GCA. They also rated the grade that tracer (FDG) uptake exceeded background blood pool for 18 artery segments and the maximum grade per patient (0 = none, 1 = minimal/equivocal, 2 = moderate, 3 = very marked). Discordant results were resolved by consensus. The clinical diagnosis was made at the six-month mark by consensus between the PET/CT blinded treating clinician and blinded external reviewers.

Results: 58/64 (91%) patients underwent TAB and 12/58 (21%) biopsies were positive for GCA. 21/64 (33%) had a clinical diagnosis of GCA and 42 (66%) met the 1990 ACR criteria for GCA. Compared with TAB, global GCA assessment by PET/CT had sensitivity (Sn) 92%, specificity (Sp) 85%, positive predictive value (PPV) 61% and negative predictive value (NPV) 98%. Interobserver reliability was good ($\kappa = 0.65$). Compared with clinical diagnosis, PET/CT had Sn 71% and Sp 91%. 2/7 PET/CT 'false positive' cases had GCA consistent disease flares when corticosteroids were weaned. Defining an uptake grade cut-off 1+ in any vessel as a positive scan gave Sn 100% and Sp 46% against TAB while a cut-off 2+ gave Sn 83% and Sp 83%. Four (33%) TAB positive patients had grade 2+ uptake localized to the TA, OA, MA or VA arteries and may have been missed on older generation scans.

Conclusion: This PET/CT protocol had good diagnostic accuracy. The high NPV of 98% indicates that it could be used as a first-line test to rule out GCA.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: TPX-100, a peptide derived from Matrix Extracellular Phosphoglycoprotein (MEPE), has been shown to induce articular cartilage regeneration after cartilage injury in animal models. A previously-reported Phase 2 double-blind, randomized, 12-month clinical trial in subjects with bilateral mild-to-moderate patellofemoral (PF) OA showed knees treated with TPX-100 (one IA injection/week for 4 weeks) had statistically significant and clinically meaningful improvements in knee function at 6 and 12 months compared with placebo-exposed knees. No between-knee differences in patellar cartilage morphology were seen; however, only 14% of knees had PF cartilage changes within limits of detection on follow-up MRIs, limiting comparative power. We now report a post-hoc clinical “responder” analysis, using pre-specified criteria for functional improvement (Roos 2003). Because nearly $\frac{3}{4}$ of subjects had bilateral tibiofemoral (TF) OA as well as PF OA, we analyzed TF cartilage thickness/volume changes in responders versus non-responders.

Methods: Adult men and women with MRI-confirmed bilateral (ICRS 2-3) PF OA were enrolled at 18 U.S. sites. Among subjects enrolled (n=118), one knee was randomly assigned to receive IA TPX-100 via 4 weekly injections (20-200 mg/injection), while the contralateral knee received identical placebo injections. The use of the contralateral knee as an internal control was designed to lessen bias due to inter-subject variation (e.g. age, sex, BMI, genetic factors, and activity levels). Knee-specific patient-reported outcomes (PROs) included the Knee Osteoarthritis Outcome Scores (KOOS) and WOMAC scores for each knee. Baseline, 6- and 12-month MRIs were read centrally, blind to treatment assignment. This analysis, while post hoc, was conducted based on pre-defined criteria for clinically-important differences derived from the literature. The database was locked prior to the present analysis.

Results: As reported previously, TPX-100 was safe and well tolerated. Overall analgesic use, including NSAIDs, declined by 68%. Efficacy analyses were based, per protocol, on subjects who received 4 weekly IA injections of 200 mg TPX-100 or placebo in each knee and who had at least one MRI after baseline (n=93 subjects/186 knees). Among TPX-100-treated knees, 61/93 (66%) met pre-defined responder criteria, with significantly more TPX-100-treated knees than placebo-exposed knees showing functional improvement at 6 or 12 months or both ($p \leq 0.02$). Among these subjects, 68 (73%) also had MRI-confirmed bilateral TF OA (ICRS 2-4), and 44/68 (65%) of TPX-100-treated knees met responder criteria at 6 or 12 months or both. TPX-100 responder knees also had significant increases in TF cartilage thickness compared with baseline ($p \leq 0.003$).

Conclusion: In clinical trials of disease-modifying OA drug (DMOAD) candidates, a frustrating discordance has been noted between structural (cartilage) change and measures of patient benefit, reflected in the FDA's new draft guidance document (August 2018). The present analysis represents, to our knowledge, the first time that clinically meaningful functional benefit has been linked with MRI-confirmed knee cartilage thickness increases.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: IL-17F shares structural homology and overlapping biologic function with IL-17A. *In vitro* studies demonstrate that IL-17F has biologic effector function that can modulate inflammation. Early clinical data support dual neutralization of IL-17A and IL-17F as a novel targeting approach in psoriasis, PsA and AS. We report interim results from a Phase 2b study (NCT02969525) assessing the dose response, long-term efficacy and safety of bimekizumab (BKZ), a mAb that potently and selectively neutralizes both IL-17A and IL-17F, over 48 weeks in patients with active PsA.

Interim results were presented at the meeting. Values at Week 12, 24 and 48. *Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). **Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). ***Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). †Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). ‡Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). §Indicates significant difference versus placebo (performed using Fisher's exact test or chi-square test, as appropriate). LD, loading dose; MDA, mean disease activity; PASI, Psoriasis Area and Severity Index.

Methods: 206 patients with active PsA, $\geq 3/76$ swollen joint count and $\geq 3/78$ tender joint count and fulfilling the CASPAR (score ≥ 3) criteria, were randomized (1:1:1:1) to receive subcutaneous BKZ 16 mg, 160 mg, 160 mg with 320 mg loading dose (160 mg [LD]), 320 mg, or placebo (PBO) Q4W, for 12 weeks (double-blind period). After Week 12, patients receiving PBO or BKZ 16 mg were re-randomized (1:1) to receive BKZ 160 mg or 320 mg; all other patients continued on their previous dose (dose-blind period). The primary endpoint was ACR50 response at Week 12.

Results: 203/206 and 189/206 patients completed the double- and dose-blind periods, respectively. Overall, demographics and baseline disease characteristics were balanced across groups. 19% of patients had prior exposure to TNF inhibitors. There was a statistically significant ($p < 0.05$) dose-response at Week 12 for ACR50 response rates. At Week 12, significantly more patients receiving BKZ versus PBO achieved ACR50 (primary endpoint: 16–160 mg [LD] doses), ACR20 and PASI90 (in those patients with baseline BSA $\geq 3\%$; 160–320 mg doses) (table). ACR20/50/70, PASI75/90, MDA and resolution of enthesitis response rates increased up to Week 24 in those continuing on their initial BKZ dose; responses were maintained through the study and were similar across the three highest dose groups at Week 48. In addition, rapid improvements were observed across all response criteria in patients re-allocated to BKZ 160 or 320 mg (table). There was no apparent relationship between dose and TEAEs. Serious AEs were reported by 9/206 (4.4%) patients up to Week 48 (8/206 [3.9%] receiving BKZ). The most common TEAE up to Week 48 was nasopharyngitis 25/206 [12.1%]. Oral candidiasis was reported at Week 48 by 10/206 (4.9%) patients (all cases during BKZ treatment). No deaths, or cases of IBD or MACE were reported.

Conclusion: BKZ provided substantial improvements in both musculoskeletal and skin outcomes; response rates continued to increase after Week 12 (primary analysis) and were sustained from Week 24 to 48, with a safety profile consistent with previous BKZ studies. These data provide further support that neutralizing IL-17F in addition to IL-17A with BKZ is a promising therapeutic approach in patients with active PsA.

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: Guidelines recommend low-dose, short-duration glucocorticoid (GC) treatment for RA,^{1,2} but long-term use, especially at prednisone-equivalent doses >5 mg/d, should be avoided.² Many patients (pts) with early and established RA receive long-term GCs, often ≥ 5 mg/d.³ SEMIRA (Steroid ELiMination In RA) compared GC tapering vs continuation for maintaining disease control in RA pts with chronic GC exposure who were receiving tocilizumab (TCZ).

Methods: Before randomization pts had to receive TCZ +/- conventional synthetic (cs)DMARDs and GC (prednisone-equivalent dose 5-15 mg/d) for ≥ 24 weeks (wks). At randomization pts had to be in at least stable low disease activity (LDA: DAS28-ESR ≤ 3.2) and stable concomitant therapy (prednisone 5 mg/d [GC5mg]) and TCZ +/- csDMARDs) for ≥ 4 wks. Pts were randomized either to continue blinded GC5mg for 24 wks or to undergo blinded taper (G Ctaper, starting at 4 mg/d with 1-mg reduction every 4 wks to 0 mg/d at wks 16-24) while receiving stable TCZ and csDMARD doses. Pts who experienced RA flare received open-label prednisone 5 mg/d rescue therapy for 2 wks and continued blinded treatment. The primary outcome was mean change in DAS28-ESR at wk 24. The key secondary outcome was "treatment

Table. Key efficacy results (intent-to-treat population)		
	TCZ+GC5mg N = 128	TCZ+GCtaper N = 131
Change in DAS28-ESR from baseline to week 24		
Primary end point		
Change from baseline to week 24, LSM (95% CI)	-0.075 (-0.271, 0.121)	0.538 (0.346, 0.729)
Difference between treatment groups: estimate (95% CI), <i>p</i> value for treatment group difference ^a	0.613 (0.346, 0.879) <i>p</i> < 0.001	
Subgroup analyses by baseline stratification factors		
	Difference between treatment groups, LSM (95% CI)	<i>p</i> value for difference between subgroups
TCZ use		
Monotherapy	0.47 (-0.05, 0.99)	<i>p</i> = 0.493
Combination with csDMARD	0.68 (0.36, 1.00)	
Baseline DAS28		
<2	0.57 (0.20, 0.95)	<i>p</i> = 0.862
≥2	0.63 (0.23, 1.02)	
Secondary end points		
Treatment success, n (%)	99 (77.3)	85 (64.9)
Treatment success effect (GCtaper vs GC5mg)		
Odds ratio ^b (95% CI)	0.50 (0.285, 0.889); <i>p</i> = 0.018	
Relative risk ^c (95% CI)	0.833 (0.714, 0.972); <i>p</i> = 0.021	
Patients who experienced ≥1 flare, ^d n (%)	14 (10.9)	34 (26.0)
Time from randomization to first flare, ^d weeks, mean (SD)	12.11 (7.93)	15.64 (7.13)
Patients who discontinued blinded treatment due to insufficient flare control, n	1	0
DAS28-ESR value at time of study treatment withdrawal was imputed for patients who withdrew from treatment prematurely, and DAS28-ESR value at initiation of rescue therapy was imputed for patients who received rescue therapy from week 20 or later.		
^a Least-squares mean from an ANCOVA model including treatment, baseline DAS28-ESR, and baseline stratification factors (weight, region, DMARD use at randomization) as covariates. ^b Logistic regression analysis with treatment and adjusted for the randomization stratification factors. ^c Cochran Mantel-Haenszel test with treatment and randomization stratification factors. ^d Flare defined as DAS28-ESR >3.2 and increase >0.6 units vs baseline		
ANCOVA, analysis of covariance; CI, confidence interval; GC5mg, stable 5-mg glucocorticoid; GCtaper, glucocorticoid taper; LSM, least-squares mean; SD, standard deviation; TCZ, tocilizumab.		

success”— DAS28-ESR ≤ 3.2 at wk 24 **and** no RA flare during 24 wks **and** no adrenal insufficiency requiring replacement therapy.

Results: 259 pts were randomized to GCtaper (n = 131) or GC5mg (n = 128); 114 and 112, respectively, completed 24 wks. Mean baseline DAS28-ESR was 1.9. Mean RA duration was 9.2 years. For the primary end point, the between-arm difference was 0.6 DAS28-ESR units (95% confidence interval: 0.346, 0.879) favoring GC5mg. Results were consistent across key subgroups (Table). The majority of pts in both arms achieved treatment success (65% GCtaper vs 77% GC5mg, with a significant difference; Table). No pts discontinued from the GCtaper arm due to insufficient flare control. Serious adverse events were reported for 5% of GC5mg vs 3% of GCtaper pts with no deaths. There were no cases of symptomatic adrenal insufficiency.

Conclusion: Continued GC 5 mg/d provided better DAS28-ESR control than GC taper in RA pts in LDA or remission. The 0.6 DAS28-ESR unit between-arm difference should be interpreted in the context of approximately two-thirds of tapered pts experiencing treatment success and no tapered pts discontinuing due to lack of flare control. The taper schedule was safe regarding adrenal insufficiency. Together these results suggest that all pts achieving LDA or remission with TCZ who are receiving long-term low-dose GC should be considered for GC tapering, ideally targeting discontinuation.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: Fibromyalgia (FM) is a chronic pain condition associated with pain and fatigue, especially during physical activity. Treatments designed to modulate central pain pathways to reduce activity-induced pain could improve function and quality of life in this population. TENS activates endogenous central inhibitory pathways and decreases central excitability thus we tested if using TENS during physical activity would improve activity-induced and resting pain and fatigue and lessen disease impact.

Methods: Women aged 18-70, meeting ACR 1990 FM criteria with reported pain ≥ 4 of 10 at two pre-randomization visits were randomly assigned to active TENS (n=103), placebo TENS (n=99) and no TENS treatment (n=99). Active TENS was applied on the upper and lower back at a mixed frequency, strong but comfortable intensity, 200µsec pulse duration. Placebo TENS was applied in the same manner as active TENS but delivered electrical current for 45s with a ramp to 0 in the last 15s. The no TENS group wore a non-active TENS unit during testing to blind the outcome assessor. Participants were instructed to use TENS during activity for at least 2h per day. Pain and fatigue during activity (6-minute walk test) and at rest were reported before and during application of TENS on the day of randomization and after one month of home use. Patient-reported outcomes were assessed with the brief pain inventory (BPI), multidimensional assessment of fatigue (MAF), revised FM impact questionnaire (FIQR), and a global rating of change. Using mixed model analyses, we examined the effect of TENS using an intention to treat analysis.

Results: After 1 month of active TENS, the primary outcome of activity-induced pain showed a mean reduction of 1.82 (95% CI: 2.39-1.25) that was significantly greater than placebo TENS (0.85, 95% CI: 1.43-0.27; $p=0.01$) and no TENS (0, 0.56 - +0.41; $p<0.01$). Similarly, activity-induced fatigue showed a mean reduction of 1.53 (2.23-0.83) that was significantly greater than placebo TENS (0.08, 0.79-0.63; $p<0.01$) and no TENS (+0.35, 0.34 - +1.04; $p<0.01$). With active TENS there were also significant improvements in resting pain, BPI interference, and MAF compared to placebo TENS and no TENS (all $p<0.05$). Active TENS improved the FIQR by a mean of 8.48 (12.92-4.04), which was significantly different from no TENS (1.39, 4.40- +1.62; $p<0.001$) but not placebo TENS (3.42, 6.54-0.30; $p=0.07$). The global rating of change indicated that 70% of those in the active TENS group improved compared to 31% in the placebo TENS group and 9% in the no TENS group ($p<0.001$).

Conclusion: Active TENS produced significant improvement in pain, fatigue, and disease impact compared to placebo TENS or no TENS. Most women who received active TENS reported global improvement in their condition. As a safe, inexpensive, home based-treatment, TENS may be included as part of the management strategy for women with FM.

Figure 1: TENS Improves Pain and Fatigue in Women with FM. Compared with placebo TENS and no/mock TENS, active TENS significantly ($*p<0.05$) improved pain and fatigue before (resting) and during (movement) activity when applied acutely in the clinic during V2 and V3 (solid lines). There was evidence of a chronic effect after 1 month (hashed lines) of home use between the two visits and no tolerance to TENS was observed. GMWT=6-minute walk test; STSTS=5 times sit-to-stand.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: ACR Late-breaking Abstract Session

Session Type: Late-Breaking Abstract Session

Session Time: 16:00PM-18:00PM

Background/Purpose: Tanezumab is a humanized mAb that blocks nerve growth factor (NGF) and is in clinical development for chronic pain treatment. Tanezumab administered intravenously has proven efficacy in previous studies of osteoarthritis (OA) pain.

Methods: A randomized, double-blind, placebo-controlled, multicenter, parallel-group, 40-week study (16-week treatment period; 24-week safety follow-up) was conducted to examine the efficacy and safety of subcutaneous (SC) tanezumab administered in two treatment regimens over 16 weeks: fixed-dosing (2.5 mg administered at Baseline and Week 8) and step-up dosing (2.5 mg administered at Baseline and 5 mg at Week 8). This study enrolled OA patients who had not responded to or could not tolerate standard pain treatments. Patients (N = 696) had: OA of the hip or knee based on clinical and radiographic ACR criteria, baseline WOMAC Pain and Physical Function scores of ≥ 5 (11-point numerical rating scale), baseline Patient's Global Assessment of OA (PGA-OA) of "fair," "poor," or "very poor", and a history of insufficient pain relief or intolerance to acetaminophen, NSAIDs, and either tramadol or opioids (or were unwilling to take opioids). Co-primary endpoints were change from Baseline to Week 16 in WOMAC Pain subscale, WOMAC Physical Function subscale, and PGA-OA. Safety assessments included adverse event (AE) reporting, physical and neurological examinations, joint x-rays, electrocardiogram, and laboratory tests.

Results: At Week 16, patients treated with tanezumab 2.5 mg or 2.5/5 mg experienced statistically significant improvement in WOMAC Pain, WOMAC Physical Function, and PGA-OA compared with patients receiving placebo (Table 1). Both tanezumab dosing regimens met the study co-primary endpoints. The most common AEs ($\geq 3\%$ in any treatment group and more frequent in each tanezumab treatment group than in the placebo treatment group) were nasopharyngitis, pain in extremity, and paresthesia. The incidence of serious AEs or withdrawals due to AEs was similar between treatment groups (Table 2). Adjudicated rapidly progressive OA occurred in 1.3% of tanezumab-treated subjects during the 40-week study.

Conclusion: Tanezumab 2.5 mg SC provided significant pain relief and improved both function and PGA-OA versus placebo in OA patients. Increasing the dose to 5 mg at Week 8 was associated with modest additional benefit versus continuation on tanezumab 2.5 mg. This study demonstrates that SC tanezumab may be an effective option for patients who have demonstrated intolerance or incomplete response to standard treatments for OA.

Table 1. Change in Baseline to Week 16 in WOMAC Pain subscale, WOMAC Physical Function subscale, and Patient's Global Assessment of OA.

Abstract Number: PP01

Physician, Patient, Person. Success in Balancing Multiple Roles Takes Support

Brandi Stevens¹ and Katharine Moore², ¹Pediatrics, Riley Hospital for Children at Indiana University, Indianapolis, IN, ²Pediatric Rheumatology, Children's Hospital Colorado, Aurora, CO

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: It was the most important conference of the year, and I could barely walk. With a slow limping gait, there is no hiding it in the midst of nearly 16,000 attendees at the world's largest gathering of rheumatologic experts. How embarrassing, I thought. I'm supposed to be the doctor here, not the patient. Little did I know how much this new eruption of arthritis would define my coming months.

At the same conference, a colleague is making excuses to others for her need to stop and catch her breath so frequently while walking between talks. She's become skilled at hiding that she's in the midst of a flare of hemolytic anemia secondary to systemic lupus erythematosus (SLE).

We are just two of a subset of rheumatology providers living with rheumatologic conditions. This adds a layer of complexity in caring for patients, interacting with colleagues, and providing self-care. Of the 6,400 rheumatology providers identified in the 2015 ACR Workforce report, 1 in 12 women and 1 in 20 men will develop an inflammatory autoimmune rheumatic disease in their lifetime.

As rheumatologists with rheumatic illnesses, life is an uninvited in-depth study on empathy and the reality of living with the illnesses we treat every day. Through failed and escalating treatments, we struggle not only with our daily function and disease, but also with loss of identity, temptation to self-treat, and the fear of loss of privacy and academic reputation. This can lead to feelings of isolation, and of being neither fully patient nor physician. Studies have documented that physicians are hesitant to approach colleagues for treatment of chronic illnesses and struggle to adapt to the patient role compromising their own well-being.

Treatment: My colleague with SLE connected me with other physicians with rheumatic disease through a private Facebook group. In this unique group, our role as providers does not limit our vulnerability to disease. It is a safe space to share worries, frustrations, and occasionally humorous perspectives on having these fickle, chronic diseases.

Maintenance: With support and the opportunity to share, we became less concerned with a loss of identity as physicians. Apprehension about symptoms or medications did not represent a deficiency in our knowledge, but the human experience of living in a changing and problematic body. We experienced as much diversity in our group with acceptance, anger, denial, and coping as when giving a new diagnosis to our own patients. Hearing the experiences of other physicians struggling with rheumatic illness is validating. Gaining the patient role in no way diminishes the ability to be excellent rheumatologists, and being a doctor does not make us less human.

Quality of Life: While autoimmune diseases are unpredictable, we have comfort in knowing that no matter what our illnesses and professional demands require, we have supportive and encouraging peers. Being a part of a group of women who are striving daily to be empowered patient physicians helps to alleviate stress and worries about the future, while also providing confidence in our ability to be successful rheumatologists, despite the struggles we face as patients.

Abstract Number: PP02

Sustained Weight Loss Managed by Multiple Medical Specialists

Lawrence Phillips, Arthritis Foundation, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: A patient who was diagnosed in 1974 with type 1 diabetes and in 2000 with rheumatoid arthritis weighed 366 pounds in 2014. He found he was gasping for breath while doing even simple tasks like walking across the room. He contacted his rheumatologist believing he might be suffering from lung issues related to RA. His rheumatologist referred him to his heart specialist who after performing an examination ultimately referred him to a pulmonologist.

Treatment: The pulmonologist performed diagnostic tests and a complete examination and found no RA related lung issues. However, he did find that the patient was suffering from a fractured sternum emulating from open heart surgery in 2005. With that finding the pulmonologist referred the patient to a thoracic surgeon for repair. The surgeon performed an examination acknowledging the patient's sternum was fractured along the lines of the open-heart surgery. The thoracic surgeon declined to operate unless patient lost at least 100 pounds.

The patient decided to consult his endocrinologist who suggested a routine of prescribed food consumption and education. The patient was also selected for a bariatric surgery program. The patient elected to pursue the strict dietary program offered by his endocrinologist, and over the course of 14 months, he lost 93 pounds. The thoracic surgeon acknowledged the patient's commitment to weight loss and performed the sternum repair in 2015.

Following thoracic surgery, the patient gained 14 pounds, and his rheumatologist suggested he pursue a sustained weight management program. With the oversight of his endocrinologist and rheumatologist, the patient selected a long-term weight management program, and to date, the patient has lost an additional 43 pounds. He now weighs 222 pounds or 9 pounds more than his high school graduation weight. Patient and his rheumatologist have set a weight goal of 200 pounds.

Maintenance: Patient regularly attends meetings tracks his food intake and loves riding his bicycle. He consults with his rheumatologist and endocrinologist about his progress.

Quality of Life: Patient has found his quality of life has been greatly improved. He is using his 5th biologic treatment for RA which has been maintained for the past 4 years thus halting a rapid succession of treatments that failed. Patient has decreased average insulin usage by 63 units per day and has steadily maintained an A1C of less than 6.0 for the past 4 years. The patient reports his quality of life has significantly improved. Patient photographed in 2012 before the start of the weight loss journey. Patient photographed in April 2018.

Abstract Number: PP03

Managing OsteoArthritis Pain with Daily Meditation

Raquel Masco, Patient/Volunteer, Arthritis Foundation, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: Original diagnosis of OsteoArthritis in 2016 by family doctor(family medicine/general practitioner). There had been ongoing pain and symptoms for years. Original medications prescribed were Indomethacin and Ibuprofen (prescription). Subsequent diagnosis of -Inflammatory Polyarthritis -as of 2017. Cymbalta started in Spring 2018. Ibuprofen is still being taken.

Treatment: Began meditation in early 2017. It started as focusing on breathing when pain was really bad and progressed to a daily routine of focused meditation (including real-time and video guided meditation) - not just when pain set in - a regular time set aside to reduce stress, relieve stress and become centered. Physical activity in the form of a daily walk that is also meditative has also helped with the mental aspect of pain relief as well as physical.

Maintenance: Being mindful and deliberate about meditation makes a world of difference. I am able to meditate naturally and on purpose. Taking rest days from the daily walk is important as well. Giving my body time to bounce back and not overdoing is just as important maintaining the daily physical/mental activity.

Quality of Life: The stiffness and decreased mobility was beginning to a toll on my emotional state as normal way of life. Running the nonprofit I began in 2011 was becoming difficult. There were many days of lateness and difficulty walking and providing services for clients. Daily meditation has made it easier to move around early in the morning before work. Being focused helps in better decision-making. This led to changing operations hours to make serving clients feasible and effective. Personal relationships have grown deeper as a result of a clearer mind and the ability to participate in socialization.

My daily walks that are in the evening are great setting for meditation

Meditation in the office is a part of daily meditation. Turning the lights down low and having a guided meditation video and/or music helps set the tone and the atmosphere.

A photo of me participating in a 7-day meditation challenge. We had to get grounded – no shoes– reflect on how we felt taking off barriers in nature.

Abstract Number: PP04

Improved Quality of Life with Patient Engagement in Research

Kelly English¹ and Graham Macdonald², ¹Arthritis Patient Advisory Board, Arthritis Research Canada, Richmond, BC, Canada, ²Occupational Science and Occupational Therapy, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: I am a woman, 60 years old who has lived with difficult-to-treat Rheumatoid Arthritis for 23 years. When first diagnosed with RA, there were constant tests, doctor's appointments, stress management classes, education classes, pain and illness to deal with as well as 2 young boys who needed their mother to be there to enjoy life with them. My best was saved for my boys but could not do the everyday things we had done in the past. We had to sell our house as it was not disability-friendly and there were financial needs relating to my disease. It took a year to diagnose and I had trouble with every med that was given to me; there was little efficacy as well. When biologics came into play, things were a little better for a couple of years, although I experienced constant infections. Then a severe reaction to a TNF receptor left me with neuropathic damage to my right leg that was not able to be reversed. The result is permanent pain on that side. It has affected my balance, gait and concentration.

Treatment: I am a patient fully engaged in several research teams from the point of hearing about a research idea and guiding the direction of research, to lay summaries and dissemination, and every phase of research in between. My 5 years since joining the Arthritis Patient Advisory Board has seen participation in quality of life research projects testing activity monitors, health journals and medicine adherence focus groups. I hoped this would give me a way to improve my life and give me new ideas about my RA. The environment at Arthritis Research Canada is an amazing one. Everyone from the scientific director to the secretaries to the trainees understand my disease and are flexible as well as encouraging. Patient engagement on research is a given here – not an exception to the rule.

Maintenance: See table 1

Table 1

Research Study	Goals	Difference to Me
Health Ethics	Focus group on social media & ethics	Start to my journey. Made me realize how much of new technology I was not using. I.e.: fitness trackers, wellness apps
Answer 2	To help people with decision making around Biologics	Great teaching tool about decision making – helped with video and with testing product. - became aware of other's concerns with meds. -could also check to see some of the available meds before talking to my rd.
Health Journal	To test a health journal testing joint count, depression screening, reporting to rheumatologist.	Since using this I have been more aware of symptoms and have gone back to record my past meds and reactions/side effects.
Fitbit/Fitvizz/ OPERA	Using a fitness tracker, combined with a physio consultation & now being tested as a complete program with Health Journal	This has been a game changer in my health. -Aware of how many active minutes of exercise, how closely or how apart they are, activity every hour. - invested in as I have been in the program throughout the testing/research period, from testing the product to critiquing the almost finished software changes.
Medicine Adherence focus group	Focus group on how people both remember to take and why they don't take medications for RA	Despite reading about this; I had no idea that people had so many reasons not to take and fears around medication - have been extra vigilant about my own meds especially compliant with vitamins
Framework for Patient Engagement in Research	To develop a framework for Patient Engagement in Research that will work not just in the Arthritis field but in any health field	- involved in from the beginning to dissemination. It has been true Patient Engagement in Research and is the project I am most proud to be in - have co-presented the poster at ACR 2017 - have assisted in developing the statements for the framework, wording of research paper, disseminated the information - have seen the process from start to finish which has been most important
<i>PRECISION: Preventing Complications from Inflammatory Skin, Joint and Bowel Conditions</i>	<i>Sit on the consumer core of the panel</i>	-Through PRECISION I have expanded my medical vocabulary. This has enabled me to understand better the posters at ACR and at the Canadian Rheumatology conferences - As part of the consumer core have heard of new discoveries as the team has researched them. -alerted on health problems such as potential COPD in the future - it has given me great hope as research by Dr. Diane Lacaille has shown that the lifespan of people with RA has actually improved over time. These are simply 2 discoveries out of many that have come out of this group

Quality of Life: It has been a long journey getting to where I am now. Results of Being a Patient in Research are:

- a team member on research projects
- an improvement in my fitness level,
- vitamin use isoptimal
- self esteem is higher than ever
- improved communication with my doctors by knowing medical terminology and treatments ahead of my appointments, and by having knowledge of new research findings to share with my rheumatologist and general practitioner from conferences and the research teams
- very supportive community in Arthritis Research Canada's Arthritis Patient Advisory Board
- attended ACR conferences and Canadian Rheumatology Conferences since I have been on the advisory board
- have a vested interest in the health research and pay very close attention to stretching my health knowledge and adherence. I know my quality of life has improved and my doctors acknowledge this.
- Depression has decreased.

My quality of life and the contributions I have made to others' lives is a result of being a Patient Engaged in Research.

Disclosure: K. English, None; G. Macdonald, None.

Abstract Number: PP05

Integrative Approach to Treatment of an Adult with Juvenile Rheumatoid Arthritis

Shannan O'Hara-Levi, Patient, Staten Island, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

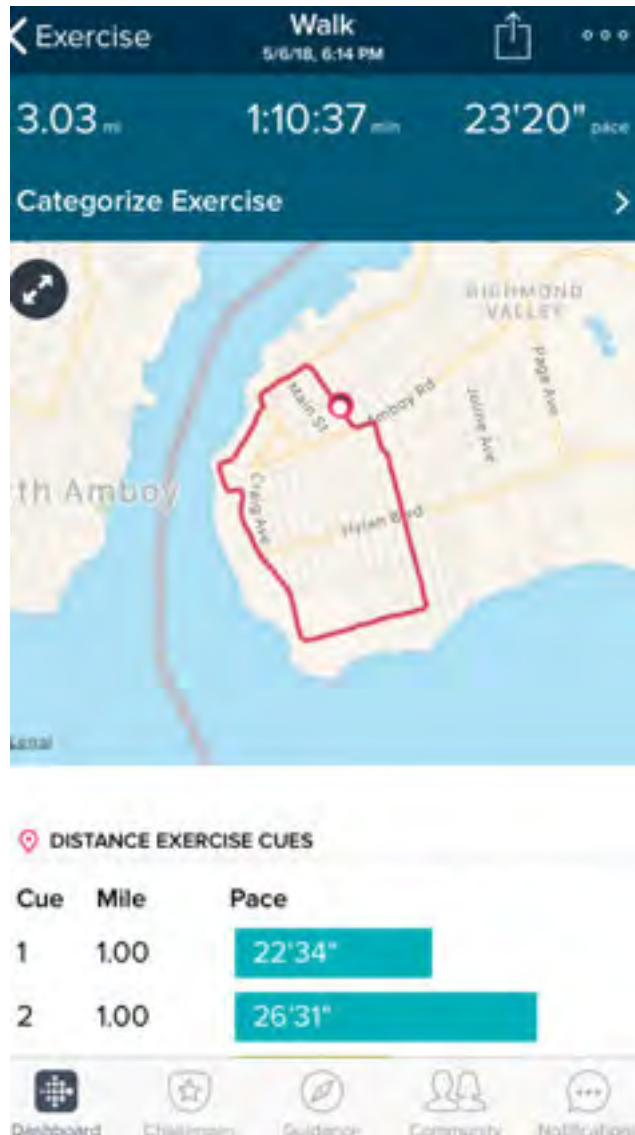

Session Time: 12:00PM-2:00PM

Background/Diagnosis: I was diagnosed in 1987 at age 3 with Polyarticular Juvenile Rheumatoid Arthritis which effected every joint in my body. At time of diagnosis I was expected to be in a wheelchair by age 6. With the help of NSAIDs, prednisone and Gold Injections, this was not the case. Eventually, I began trials of various drug cocktails that included those previously listed with the addition of DMARDs, namely Methotrexate and Plaquenil, and a rotation of various supplements including shark cartilage and vitamins. The ever changing trials of these cocktails continued until my mid-teenage years when biologic medication was introduced. After trying many different biologic medications and having varying results, I was taken off those medications and maintained on prednisone and Methotrexate for the time being. However, disease progression continues resulting in bilateral shoulder replacements in 2018.

Treatment: I have adapted an integrative approach to my treatment plan along with my medical team. This approach includes incorporating vitamin supplements and dietary restrictions under the supervision and recommendation of my rheumatologist and regular walking.

Maintenance: Prior to adding an integrative approach to my treatment, I was trying and most often failing drugs and drug cocktails regularly, which become stressful and disappointing. By adding specific supplements picked out by my doctor, I have guidance as to what is working for my body. In addition, dietary restrictions have improved my health and given me a sense of control over my illness. I use this sense of control to ensure that not only do I take my supplements and eat well; I move my body in one of the few ways it can regularly by walking daily. By ensuring that these integrative approaches are a regular part of my lifestyle, I am able to work better with my medical team as I am able to have some control of these treatments which will hopefully lead to decreased disease progression.

Quality of Life: Due to recent changes in my disease progression, the addition of these integrative approaches has ultimately led me to having a better quality of life. I am able to see these additions of supplements and dietary changes as a privilege instead of an additional burden of this disease because I do have some sort of control here. Walking has given me a boost of self-confidence as I “compete” with friends and family thru an app that tracks my walking. This added bonus is not only fun but keeps me accountable in a positive way. Prior to these changes, I was disappointed in my health and disease progression. Now, I am more confident in having a fun, healthy way of taking control over my health.

Abstract Number: PP06

Learning to Self-Advocate in the Transition from Pediatric to Adult Lupus Care

Denita Perry¹ and Diane Gross², ¹Unaffiliated, Joliet, IL, ²Lupus Research Alliance, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: I was diagnosed with lupus at age 15. I was starting my sophomore year of high school and noticed a rash that the doctor said was eczema, but I knew it was not. I wasn't feeling well, I had pain and my hair was falling out. My mom took me to the hospital and I was diagnosed with lupus. I was hospitalized for a month, I couldn't take care of myself, I needed help to get dressed and eat, I was sore to the touch and I lost 20 pounds. It was information overload. I was 15, I didn't really understand what was going on, I was a dancer and on the track team with 2 college scholarship opportunities. Lupus took that all away from me.

Treatment: After the hospital, I started treatment at a children's health center, began getting better and went into remission.

The problem came when I turned 20 and had to transition to adult care. My new doctor started changing my medications, and I ended up hospitalized several times in one year. I was on methotrexate and folic acid and started having stomach issues. One day I was in so much pain that my doctor said to come to the office. After laying on her office floor she sent me to the emergency room without seeing me.

I never went back to that doctor. A friend of my mother suggested a hospital with a lupus center. I looked online and have been going there ever since.

I learned how to advocate for myself. I had to learn to be an adult. I used to keep things to myself and not share with doctor but learned to speak up.

I now have a good relationship with my doctor. I can call her at any time, it's like she's a second mom. It's worth the 1-2 hours it can take to get downtown.

Maintenance: I have done both physical and occupational therapy for my joints. I have changed how I eat, cutting out junk food. While I can't run like I did before lupus, I do exercise.

I know the signs that a flare is coming on and I get to the doctor sooner.

I learned to explain what I need. Now if I end up in the ER I can advocate for myself.

Quality of Life: I was diagnosed when I was young and very active. At first, I didn't always take my meds. I was embarrassed. My peers didn't understand. Whenever I tried to explain lupus, it was a pity party that I didn't want.

For the 5 years in pediatric care I saw the doctor regularly and had lupus under control. Then in the initial transition to adult care, for about 4 years, I got worse. Now I have a doctor who I can be honest with.

I am in school now and will finish my program this year. I take classes and am able to do easy temp work so I can call in day to day and not go in if I'm not feeling well. I am on disability and work part time to pay for school and my car.

I have potential jobs after graduation that are willing to work with me to accommodate my health issues. The disability office at school has been very helpful.

I was always angry, feeling sad, I didn't know how to feel, had so many emotions at once, I felt confused and lost.

That one fateful trip to the emergency room made me realize I had to take control. I learned to accept the situation, manage it, and make the best of it. I now know how to take care of myself and how to work with my healthcare team.

Disclosure: D. Perry, None; D. Gross, None.

Abstract Number: PP07

Strengthening My Resiliency: How My Interprofessional Healthcare Team and I Improved My Management of Lupus

Cecilia Amoakohene¹, Jorge Sanchez-Guerrero², Murray Urowitz², Dafna D Gladman², Zahi Touma² and Laura Wakani²,

¹Unaffiliated, Toronto, ON, Canada, ²University of Toronto Lupus Research Program, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

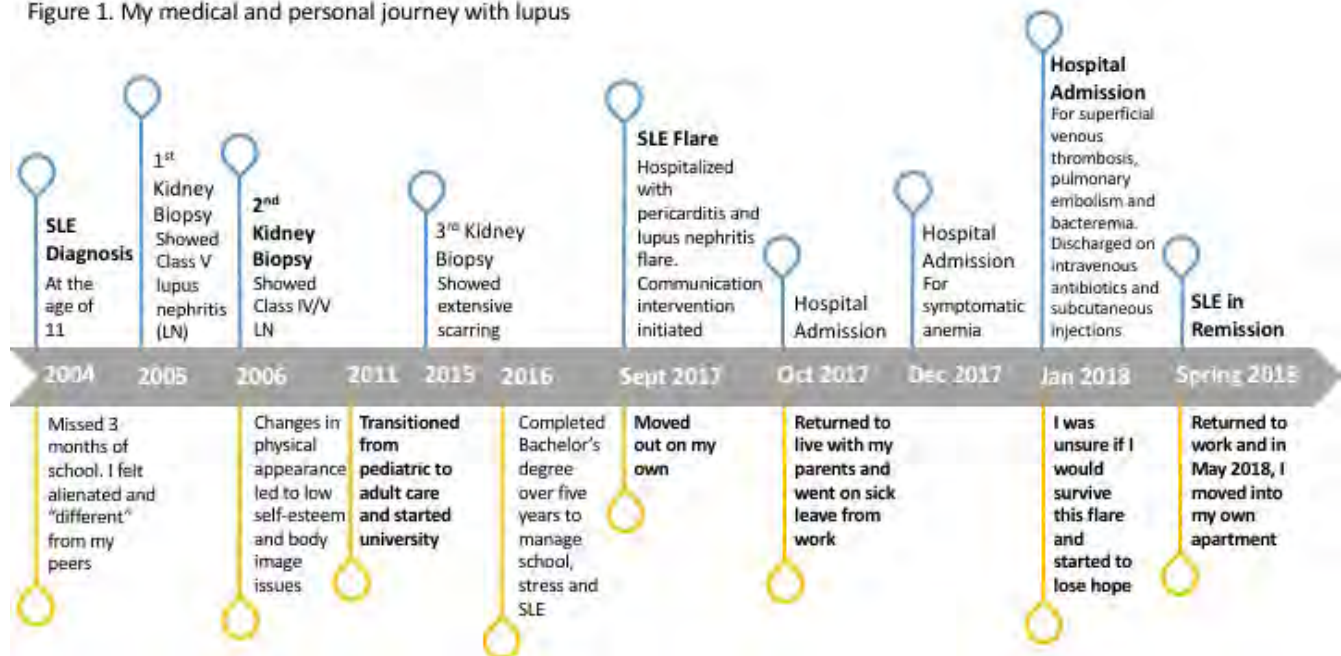

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: I was diagnosed with systemic lupus erythematosus (SLE) at the age of eleven and have experienced multiple SLE flares, hospitalizations, invasive procedures and complex treatment plans. My journey with SLE has at times made me feel isolated, affected my body image and self-esteem. While living with these challenges, I completed a Bachelor's degree and began a career. In 2017, a severe SLE flare left me on sick leave and often unable to perform basic daily tasks due to pain, fatigue and weakness, forcing me to return to live with my parents. My journey with lupus is outlined in Figure 1.

Figure 1. My medical and personal journey with lupus

Treatment: Cecilia's care team recognized the challenges she faced managing her latest SLE flare. As an interprofessional team, a care plan was developed and strategies implemented to promote patient-centered communication and improve disease management. As part of the care plan, regular communications with Cecilia were prompted by her healthcare team after each admission and change in treatment. Communication was predominantly nurse-led, via email, and covered symptoms, medications and side effects, and coping. Open-ended questions engaged Cecilia in identifying and prioritizing symptoms or concerns. Frequency of contact varied according to severity of symptoms or complexity of treatments, and often was weekly. Regular contact provided opportunities to improve symptom management, assistance and encouragement in managing treatments, and facilitated timely access to her rheumatology/nephrology team.

Maintenance: The interventions improved my self-management of SLE, engagement with my healthcare team and my resiliency during a stressful period of my life. Transitioning from pediatric to adult care, I felt I was a patient file, an "interesting case." By recognizing and responding to the challenges I was facing, I felt my healthcare team was invested in my care and thought of me as a person. Prompting me to check-in with myself increased my capacity to alert my team to symptoms or complications, seek urgent medical attention when needed, and manage intravenous antibiotics and subcutaneous injections at home. Increased self-awareness, paired with a receptive team, encouraged my involvement in clinic appointments and treatment decisions, and to seek additional supports, such as online support groups. My symptoms have significantly improved, I am tapering my prednisone dose and have returned to work. This resiliency helped me persevere and led me to where I am today—healthier and happier than I was before this flare began.

Quality of Life: My quality of life has greatly improved since the intervention and recovery from my SLE flare. I am able to perform basic daily tasks again, live on my own, and participate in activities I love, such as exercising. I am more confident about the future knowing I have the support of my healthcare team and the resiliency to live well with lupus.

Disclosure: C. Amoakohene, None; J. Sanchez-Guerrero, None; M. Urowitz, None; D. D. Gladman, None; Z. Touma, None; L. Wakani, None.

Abstract Number: PP08

Communication, Support, and Advocacy Lead to Improved Health and Quality of Life

Christele Felix, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: In 2007 I was diagnosed with Lupus which has since then wreaked havoc on my kidneys, lungs, GI tract, peripheral nervous system, to name a few. Additionally, as is usually the case with Lupus, chronic fatigue and joint pain had a devastating effect on my everyday life. The overall goal for my rheumatologist and I was to prevent further organ damage, and tackle the 2 recurrent symptoms that threatened to affect my quality of life: Fatigue and joint pain. Pinpointing the ways these affected the goals I had for my life took time and communication. It is undeniable that patient's relationship with this/her doctor/health team may positively influence the patient's health and life under the right conditions.

Treatment: My 11 years as a chronic patient have seen many mid-to-long-terms interactions with doctors. My partnership with my rheumatologist continues to positively impact my life every day. Through our visits and communications, my rheumatologist made it a practice to ask about my life outside of Lupus. Aside from my care, she took an active interest in me as a whole person, strongly encouraged my advocacy, and prompted me to join support groups. Her support of my career goals and interests in research fostered a relationship of trust, inspiring me to take a more active participation in my care. She also validated my vision that my patient/advocacy experience would inform the work I would do.

Maintenance: The outcome of this new perspective is that I've taken charge of my health with a new approach, from consistency with my treatment plan to paying greater attention to my diet and exercise; This more comprehensive approach also included better managing my energy and stress levels. The culture among my support group peers is one of encouragement and of accountability. Support from my doctor and the support she encouraged me to receive from my peers push me to pursue my goals, and to speak up for people like us, to fight for better quality of life for people with Lupus. At patient education events, I spend time talking with doctors about doctor-patient relationships and adherence and how doctors can help.

Quality of Life: Chronic patients will greatly benefit from such support and encouragement from their doctors. Patients whose life goals/interests are taken into consideration develop a rapport of trust with their doctor which in turns increases treatment and lifestyle compliance. My doctor's active pursuit of a collaborative team with her patient led to a transformation in the way I do my part. I encourage doctors to consider establishing a personal connection with their patients (common interest, hobby, etc) and asking patients about what is important to them. Additionally, doctors should encourage support groups and self advocacy. This all leads to better treatment compliance, and a more engaged, healthier, and happier patient.

Abstract Number: PP09

Improved Quality of Life and Decreased Symptoms of Lupus with Diet, Exercise, and Functional Medicine

Marisa Zeppieri-Caruana, Lupus Chick, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: Like most people who live with a chronic illness and/or autoimmune disease, my story started long before I realized. Symptoms came and went throughout my life without any answers. I headed to nursing school during college and things really went south after I was hit by a truck as a pedestrian, run over while I was crossing a street. I believe if I could survive that, there isn't much else life can throw at me that could get me down!

At the age of 23, I was diagnosed with Lupus after I suffered a small stroke and had a variety of classic symptoms come out at once. When you are in your twenties, receiving a diagnosis of a disease that has no cure and can be life-threatening is frightening and leaves you with a sense of uncertainty. I had never met anyone else with Lupus and most people were unfamiliar with it.

Over the years, the disease has taught me so much about how strong I truly am. It has also shaped my character and personality. Today I am even more motivated to accomplish my dreams because I know how quickly life can be taken away. I am dedicated, even more, compassionate towards others, and have a deeper focus on the important things in life.

Treatment: Through dietary changes and exercise and complementary therapies, I have been able to decrease certain lupus symptoms, increase energy, and improve my overall quality of life. Working with an allergist and nutritionist helped me determine what I was allergic to, and also how to add anti-inflammatory foods into my diet. Eating cleaner, preparing my own meals, and juicing increase my energy and even improved some of my vitamin and mineral levels in my blood work over the past few years. Adding restorative yoga when I am feeling well has helped me with anxiety and the overall stress of living with a chronic illness. It has also made my body feel stronger and in more control. Last, adding functional medicine supplements and working with a functional medicine doctor as part of my healthcare team, I have been able to increase energy and decrease some inflammation thanks to different herbal compounds and supplements.

Maintenance: Above and beyond my regular treatments for lupus, I am also the founder and editor in chief of "LupusChick", an online nonprofit that has been a tremendous source of hope and support for me and those in our community. Being surrounded by and having contact with a half a million people per month who are living with lupus and other chronic illnesses, who "get it", help me get through the difficult moments, flare-ups, and daily struggles that my medical team sometimes doesn't personally understand.

Quality of Life: All of this in combination with my regular medication, rest, and a positive attitude has made quite a difference in my life.

*AstraZeneca has provided sponsorship to cover the cost of the submission of this poster to the ACR, as well as travel and subsistence for the presenting author. AstraZeneca has had no involvement or input into the content or development of the poster, with the exception of support for layout and design.

Using a Mobile App to Facilitate Patient-Doctor Discussions to Make Informed Decisions Regarding 'Painsomnia'

Shelley Fritz¹, Kristine Carandang² and Dawn Gibson³, ¹ArthritisPower Patient Partner: CreakyJoints/Global Healthy Living Foundation, Tampa, FL, ²Chan Division of Occupational Science & Occupational Therapy, University of Southern California, Los Angeles, CA, ³Founder #SpoonieChat; CreakyJoints/Global Healthy Living Foundation Patient Partner, Upper Nyack, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: As a patient with AS, Dawn founded #SpoonieChat to provide a space on twitter for people living with chronic diseases to support each other. One common theme in #SpoonieChat is the relationship between pain and sleep. 'Painsomnia' is a patient-generated term that addresses this cycle of pain and insomnia.

A follower of #SpoonieChat who experiences painsomnia is Shelley. Shelley was diagnosed with RA in 2012, following symptoms of symmetrical joint pain in hands and toes; fatigue, and malaise. After treatments including methotrexate, Plaquenil, and 5+ biologics, Shelley has made significant lifestyle changes and is currently on Rituximab. In addition to monthly blood work and physician exams, changes in Shelley's treatment are based on her own data gathered by weekly symptom tracking.

To understand patients' adaptations to manage painsomnia we used collective knowledge generated from #SpoonieChat with Shelley's unique experiences as an individual patient recorded through patient reported outcomes measures via ArthritisPower.

Treatment: ArthritisPower is a patient-led, patient-generated, app-based research registry for arthritis, bone and inflammatory skin conditions and is free to use for patients like Shelley to track symptoms, to record subtle changes, to see how they are doing over a period of time whether on a new medication and/or in connection to sleep, physical function and other measures.

By tracking pain interference, Shelley has found pain to be interrelated with levels of fatigue, sleep quality, and cognitive issues, thereby negatively impacting her quality of life. Figure 1 shows Shelley's pain interference scores over a six-month period. Shelley identifies the causes of fluctuations by also tracking dates of flares, steroid usage, periods of illness, and restful vacations.

Maintenance: Through this approach, Shelley worked with her rheumatologist to lessen the symptoms and progression of RA. Shelley continues to track these elements through ArthritisPower to look for patterns influenced by medication and maintenance strategies including diet, exercise, decreasing stress, and increasing sleep. This provides the doctor with information beyond blood work, lab tests and swollen joint counts to work with Shelley in managing her condition and treating the things that matter to her to help her live a better quality of life.

Quality of Life: Doctor and patient conversations can be more meaningful when patient experienced data is systematically collected and discussed. Data gathered through ArthritisPower gives patients like Shelley, an organized way to talk with their doctor on each of the indicators of pain and sleep which affect cognitive function, physical function, depression.

The Road Less Traveled– Nontraditional Approaches to Increased Patient Adherence and Positive Outcomes

Carlene Harrison, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: African-American female diagnosed with SLE, Lupus Nephritis, Discoid Lupus, and Raynaud's Phenomenon in 2011. Symptoms included joint pain, edema in the ankles, malar rash, flank pain, frothy urine, and fatigue.

Treatment: Patient was treated with corticosteroids, immunosuppressants, anti-malarials, and topical steroidal ointments. The patient disclosed she wasn't taking her medicine due to external pressure and stress. Remembering discussions about the patient's interest in research and career goals, the doctor brought copies of recent medical journal articles on SLE to a consult. Emphasizing the importance of treatment adherence, the doctor did something that was unheard of, she asked about her school and research focus. Patient opened up, her scientific curiosity and passion shining through. They discussed the effects of each medicine. She continued this approach throughout her time leading the patient's care. Incorporating the patient into the medical decision-making process, she continued printing materials relevant to the patient's care and was a model for collaborative care. This was evident in allowing the patient to choose a medicine to stop when data showed the regimen she was on, was making no meaningful change.

Maintenance: While there is mounting emphasis placed on quality healthcare outcomes, what is often omitted from the conversation is how these results come about. These interactions with this physician were different from many others she had encountered. Asking about the patient's research interests, showed the patient she wasn't viewed as a set of illnesses. She showed she cared; whether she truly cared or instead used this as a means to an end, it helped change the patient's behavior. The additional step of seeking feedback from the patient on the very medical decisions that impacted her life was paramount. It was no longer merely a physician-patient relationship. Although on different academic and career levels, the patient felt the physician viewed her as a colleague of sorts, even if one that required mentoring.

Quality of Life: The change in the doctor's approach to care led to a change in the patient's attitude toward her health and she became more open about her illness and joined local and online support groups. The patient currently mentors newly diagnosed patients, is an advocate for Lupus patients (often meeting with legislators to enact change), and co-manages a patient led healthcare community. The patient is still undergoing treatment for her Lupus and is receiving infusions of a biologic approved for Lupus treatment along with her other medications. She attributes the change in her attitude and lifestyle to the change in her physician's approach. She recently relocated back to the town where that physician is stationed. The physician now leads her medical team. The patient has full trust in the capabilities of the team because of the leadership. The most important take away from this patient's experience is to meet your patients where they are. Take an active interest in their whole lives and not just the symptoms you treat. Patient experience proves in overwhelming numbers, this will lead to better adherence and healthcare outcomes.

Living a Full Life with A.S. Through Adaptations

Gail Wright, Spondylitis Association of America, Buffalo Grove, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: After running a half marathon and 2 5'ks, I had unexplained back/ hip pain that wouldn't resolve. I returned to my PT. After 3 months of low back, hip work I woke up on a Saturday morning with the most intense chest pain I'd ever felt in my life. Moving my arms sent electric shocks throughout my body. I crawled into my PT. He sent me to the emergency clinic. After a chest x-ray and EKG to confirm that I didn't have breast cancer or a heart issue, my primary doc threw a whack of meds at me to get me at least out of the chair. I was very lucky. I was able to see a Rheumatologist within 2 weeks and was quickly diagnosed. Because of what I now know was Costochondritis, I was led to receive my diagnosis.

Treatment: My Rheumatologist quickly started me on a biologic and other supporting medications. I have been through a few different medications to find what works for me. I exercise on a regular basis. I have learned HOW to communicate with my docs. Short, factual sentences. I can stand for 7 minutes. I don't grocery shop anymore because it's too painful. Then, I'm quiet. I trust in my team. I show them that I trust and will follow their direction for care.

Maintenance: I continue to combine medications, exercise and support from friends and family to keep myself living a full life.

Quality of Life: Currently I live an extremely full life. I am able to hike, vacation, exercise, garden, work full time and lead a full social life. I maintain the attitude that there is nothing that I can't do. I to figure out HOW to do it. I love gardening. When I blew L4-L5 into pieces, my husband accepted my pinterest challenge to build a vertical garden. He built a staircase attached to my fence. My vegetable garden went vertical! The vertical garden has changed over time- and more planters have been added to the fence!

When I wanted to continue hiking and enjoying my love of the outdoors, we found a tool called a flip stick. With the flip stick, my husband and I enjoyed an incredible hike through Arches National Park

After my shoulder surgery and carpal tunnel surgeries- every day was leg day. After my lumbar fusions! 2D; you got it- every day was arm day.

As difficult as it is- at one point I was not able to walk more than about 2,000 steps in a day. This did not stop me from enjoying a trip to Las Vegas. Instead, I rented a scooter!

Support Groups and Patient Centred Care; Making a Difference in the Lives of People with Autoimmune and Rheumatic Conditions in Ghana

Paulina Padiki Narh¹, Abdul Aziz A. Adodo Can-Tamakloe¹ and Ida Dzifa Dey², ¹The Rheumatology Initiative tRi, Accra, Ghana, ²Department of Medicine, Rheumatology Unit, School of Medicine and Dentistry, University of Ghana, Accra, Ghana

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Patient Perspectives Poster Session

Session Type: Patient Perspectives Poster Session

Session Time: 12:00PM-2:00PM

Background/Diagnosis: I felt relieved when my diagnosis was confirmed, but upon hearing Lupus and Nephritis and no cure, I felt shattered. I was referred to the only Rheumatology clinic in the country.

The Rheumatology Initiative tRi founded in 2012, is a non-profit organization dedicated to providing education, advocacy and research into the autoimmune rheumatic conditions.

Much has been achieved in reducing mortality of patients with autoimmune conditions worldwide. Unfortunately, for a significant proportion of patients in developing countries like Ghana, poverty limits access to these lifesaving medications and other supportive services that improve survival.

Treatment: tRi established a Patient Assistance Program which provides emergency medical assistance to those with a life altering diagnosis of an autoimmune disease, but are financially challenged and also life skills training as a long-term, empowering solution. Over the past five years, tRi has helped over 158 patients with treatment support. On average these can cost between 100 to 500 dollars a patient.

As a direct beneficiary when I had lupus nephritis in 2014, it was a huge source of relief to not have to worry about what would happen to my kidneys if I delayed treatment, due to challenges funding my induction therapy. I complete the whole course of treatment successfully and have been in remission for the past 2 years.

tRi support group, Rheusolute, focused on young and adolescent persons currently has over 180 members and doubles as source of information and healing interaction outside the consulting room.

Maintenance: As part of ensuring remission, I get daily reminders from tRi to take my maintenance medications, which reduces my tendency for non-compliance.

Knowing there were young people like me in the support group with similar conditions chasing their dreams and aspirations gave me so much comfort and strength, it's like a second home, always ready to listen and advice.

I have graduated from a beneficiary to an administrator who coordinates access to life saving medications for other patients who have an emergency.

It's with a sense of satisfaction that I end each day knowing that I was involved in potentially saving a life just as mine was.

Quality of Life: tRi is currently the only support group and advocate for autoimmune conditions in Ghana. Life with lupus can be very traumatic with high medical costs, flares and several other negatives. Taking daily medications hasn't been easy.

Living with Lupus means life style changes; always having a backup plan since plans can change at any time. Learning to know myself better, engage in less stressful activities, eat healthy and being positive. But, not even the previous fear of death I had persists.

I can now face the future with much hope and I would continue to tame the 'wolf' and take control of my life because lupus does not determine who I am.
