Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient Reported Outcome (PRO) measures for Quality of Life (QoL) in patients with lupus are useful supplements to the physician-derived indices of disease activity in estimating disease-impact and true patient-burden. PRO tools in pediatric lupus to date either capture QoL insufficiently or are too time-consuming to be used in routine clinical practice. Lupus Impact Tracker (LIT) is a practical, brief, 10-item, unidimensional, PRO tool, validated in adults, covering the concepts of cognition, lupus medications, physical health, pain/fatigue impact, emotional health, body image, and planning/desires/goals. We propose to determine the psychometric properties of LIT and its correlation with physician derived disease activity in pediatric and young adult patients with lupus.

Methods: This is a prospective, observational, pilot study where patients aged between 12 and 25 years, fulfilling the 1997 ACR classification criteria for SLE, were enrolled. Patients completed LIT alongside 3 consecutive, routine clinical visits. Data were collected on demographics, and clinical and laboratory disease-parameters including disease activity (SLEDAI) and damage (SLICC-ACR) indices.

Intraclass correlation coefficients (ICC) were calculated between serial LIT scores for test-retest reliability. Spearman correlation coefficients were calculated between LIT scores and SLEDAI and Kruskal-Wallis tests for association between LIT scores and SLEDAI-based groups (mild/moderate/severe). Using a Bonferroni type adjustment, a p-value <0.01 was considered significant.

Results: Of 28 patients completing 3 visits, 79% were female, 36% African American, 36% Asian, and 14% Latino. The mean (SD) age at enrollment was 17.25 (2.7) years, with a mean (SD) disease duration of 4.02 (2.79) years. Mean (SD) SLEDAI scores were 4.04 (3.3), 3.61 (2.8), and 4.29 (3.8) for the first, second and third visits. Mean (SD) LIT scores were 31.52 (27.2), 23.66 (23.4), and 24.91 (24.6) for the first, second and third visits. Intra-class correlation (ICC) between LIT scores at visit 1 and visit 2 was 0.696, and between LIT scores at visit 2 and 3 was 0.815, demonstrating moderate to high test-retest reliability. LIT and SLEDAI scores were moderately correlated at visit 3 with Spearman correlation coefficient of 0.69, but only weakly at visits 1 and 2 (0.205 and 0.203 respectively). No significant association was found between LIT and SLEDAI-severity groups (Kruskal Wallis $P=0.28$, 0.20, 0.74 at visits 1, 2 and 3 respectively).

Conclusion: This is the first pediatric study to show LIT as a simple, practical instrument to assess QoL, with moderate to high test-retest reliability. In conformity with some studies in adult lupus, it has only low to moderate correlation with physician derived disease activity. While this can be partly due to inclusion of patients with stable and low SLEDAI scores in this pilot, it also supports that PRO measures are supplementary rather than surrogate to disease activity indices based on clinical and serologic parameters alone. Results of correlation of LIT scores with other validated pediatric PRO measures will be reported next with a larger sample size.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-adherence to medical recommendations in childhood-onset systemic lupus erythematosus (cSLE) is estimated to be between 40-50%. For patients with cSLE, non-adherence results in increased hospitalizations, preventable disease damage, disease flares, and higher health care costs. Currently there are no published data regarding adolescent patients' perspectives on the management of cSLE, including barriers to treatment adherence. The aim of this study was to characterize the adolescent's perspective on the management of cSLE and its impact on their lives.

Methods: Ten adolescents diagnosed with cSLE per ACR SLE classification criteria were recruited from a pediatric rheumatology clinic and cSLE patient registry. Participants' characteristics are summarized in Table 1. Two separate focus groups were conducted and led by trained facilitators to discuss topics around living with cSLE and its management. The sessions were audio-taped, transcribed, and coded for themes by three independent coders.

Results: Focus group transcript analyses revealed seven major themes: 1) Barriers/Facilitators of treatment adherence, 2) Symptoms Impacting Daily Life, 3) Lack of Understanding/Knowledge about cSLE, 4) Impact on personal relationships, 5) Self-care and management, 6) Worry about the Future, and (7) Relationship/communication with healthcare providers. Adherence barriers included the number, taste, timing and side effects of oral medications. Adherence facilitators were desire to avoid being sick/in pain/hospitalized, use of pill boxes, reminder apps, and storage/location of pills. Fatigue, pain, and mood significantly impacted daily life for these adolescents. All adolescents described difficulties at school, including absenteeism related to disease flares and hospitalizations, missed schoolwork, bullying, and/or the general lack of awareness and understanding of cSLE among educators and peers. They emphasized the role of healthcare providers in helping increase schools' awareness and understanding of cSLE. Future worries were quality of life, transition to college, and job opportunities. All adolescents wanted direct communication with, and between, their providers.

Conclusion: While adherence was identified as a significant problem, some adolescents also noted strategies to improve self-management. All adolescents desired increased knowledge/understanding from the public regarding cSLE, especially aimed at school advocacy. Important next steps are to identify modifiable factors, with the long-term goal of developing interventions to improve the overall well-being and self-management for adolescents with cSLE.

Table 1: Participant demographical and disease characteristics

A Better Understanding of Childhood Sjögren Syndrome: Evaluation of the 2016 Acr/EULAR Classification Criteria for Use in Diagnosing Sjögren Syndrome in Children

Matthew Basiaga¹, Sara M. Stern², Jay Mehta³ and Scott Lieberman⁴, ¹University of Washington, Division of Pediatric Rheumatology, Seattle Children's Hospital, Seattle, WA, ²Pediatrics-Rheumatology, University of Utah, Salt Lake City, UT, ³Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, ⁴Pediatrics (Division of Rheumatology), University of Iowa Stead Family Children's Hospital, Iowa City, IA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical presentation of Sjögren syndrome in children differs from adults: dryness symptoms are more common in adults, while parotitis is more common in children. Criteria developed for adult classification have demonstrated low sensitivity when applied to pediatric populations, and no child-specific criteria have been established. The latest adult classification criteria have not yet been evaluated for use in children. Our objective was to evaluate the applicability of these new criteria for use in children.

Methods: Retrospective chart reviews were conducted to collect individual patient level data for children diagnosed with Sjögren syndrome (based on clinical diagnosis at age <18 years). Data including clinical features, laboratory values, imaging studies, and test items in the 2016 ACR/EULAR criteria were collected, and de-identified data were entered into a REDCap database. This study was approved by the Institutional Review Boards or equivalent regulatory bodies at individual affiliate institutions.

Results: To date, 144 children with Sjögren syndrome were included from 11 institutions across 4 countries (data collection is ongoing). This constitutes the largest childhood Sjögren syndrome patient series to date. The majority of children (88%) were female with a mean age of 11.7 years at diagnosis (range 1–17.8 years). Twenty-three children (16%) also had another autoimmune disease (18 with SLE, 4 with uveitis, 1 with subacute cutaneous lupus). Frequency of clinical features were as follows: 54% with parotitis, 54% with dry eyes, 54% with dry mouth, 52% with arthralgias without arthritis, 29% with arthritis, 21% with lymphadenopathy, 18% with cytopenias, 14% with fevers, 13% with cutaneous vasculitis, 10% with weight loss, and <10% each with recurrent vaginitis, myositis, pulmonary, renal, or neurologic manifestations. Only 6 children had testing for all 5 items included in the 2016 ACR/EULAR criteria. Most children (93%) had testing for anti-SSA antibodies, but fewer underwent minor salivary gland (MSG) biopsy (46%), Schirmer testing (40%), ocular surface staining (OSS, 15%), or measurement of unstimulated whole saliva flow (UWSF, 13%). While most children studied

(95.8%) were missing at least one data point, 38 of 144 children (26%) met the 2016 ACR/EULAR classification criteria for Sjögren syndrome. Of these 38 children: 35 (92%) had positive anti-SSA antibodies; 29 (76%) had positive Schirmer test; 22 (58%) had positive MSG biopsy; 4 (11%) had positive UWSF; and 1 (3%) had positive OSS. Of the 106 children not meeting criteria: 70 (66%) had positive anti-SSA antibodies; 10 (9%) had positive MSG biopsy; 8 (8%) had positive Schirmer test; and 4 (4%) had positive UWSF.

Conclusion: Criteria items from the 2016 ACR/EULAR criteria are not routinely assessed in children diagnosed with Sjögren syndrome making formal retrospective assessment of criteria difficult. Prospective study of these criteria along with defining child-specific normal values and adding child-specific criteria items (such as recurrent parotitis) are warranted. Establishing criteria for childhood Sjögren syndrome is a key step toward better understanding and treating this condition.

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Daily oralprednisone has been the main therapy in juvenile dermatomyositis(JDM), and combination therapy with methotrexate (MTX) introduced soon afterdiagnosis has been increasingly used. There have been few randomized studies toprovide evidence for therapeutic choices in JDM. We therefore evaluated effectsof initial therapies on treatment outcomes using propensity score analysis in large North American JDM registry.

Methods: We examined outcomes associated with 3 treatments used in the first3 months after diagnosis in 286 JDM patients: high (≥ 2 mg/kg/d) vs. lowdaily prednisone dose; pulse intravenous methylprednisolone (IVMP) vs. none;MTX vs. none. The 4 outcomes, achievement of half of the initial prednisonedose, prednisone discontinuation, treatment escalation at 12 and 24 months, anddevelopment of calcinosis, were evaluated by Coxproportional hazards and logistic regression. We accounted for differences in useof initial therapies by creating propensity score models that were matched 1:1 for patients with and without each therapy. Differences inthe propensity score model covariates were examined by Chi-square and Wilcoxonrank sum tests. Initial hazard models did not includethe use of other medications, while final models adjusted for duration of othermedications received.

Table1: Cox proportional Hazards modeling of relative hazard of 3 outcomes in the first 12 and 24 months of treatment, by initial pulse intravenous methylprednisolone.

Outcome	Time	IVMP not received (N=75), n (%)	IVMP received (N=75), n (%)	HR (95% CI) initial model	HR (95% CI) final model
Time to half of initial prednisone dose	12 months	26 (37%)	25 (29%)	0.96 (0.56-1.67)	0.75 (0.39-1.43)
	24 months	43 (57%)	41 (51%)	0.93 (0.61-1.43)	0.84 (0.52-1.34)
Time to prednisone discontinuation	24 months	21 (28%)	23 (31%)	1.19 (0.66-2.15)	1.41 (0.76-2.63)
Time to treatment escalation	12 months	30 (40%)	20 (27%)	0.62 (0.35-1.09)	0.48 (0.26-0.88) [#]
	24 months	44 (59%)	29 (39%)	0.58 (0.36-0.93) [#]	0.49 (0.29-0.80) [#]

IVMP received group showed significant difference ($p < 0.05$) compared to IVMP not received group.
Abbreviations: IVMP, intravenous methylprednisolone; HR, Hazard ratio

Table2: Cox proportional Hazards modeling of relative hazard of 3 outcomes in the first 24 months of treatment, by receipt of prednisone and methotrexate in combination in the first 3 months vs. prednisone alone.

Outcome	Time	Prednisone (N=48), n (%)	Prednisone and MTX (N=48), n (%)	HR (95% CI) initial model	HR (95% CI) final model
Time to half of initial prednisone dose	12 months	19 (40%)	16 (33%)	0.83 (0.43–1.61)	0.56 (0.23–1.38)
	24 months	28 (58%)	28 (58%)	0.84 (0.49–1.45)	0.48 (0.23–0.98)[‡]
Time to prednisone discontinuation	24 months	7 (15%)	17 (35%)	2.83 (1.18–6.55)[‡]	2.05 (0.57–7.30)
Time to treatment escalation	12 months	14 (29%)	14 (29%)	1.04 (0.50–2.18)	0.66 (0.22–1.92)
	24 months	19 (40%)	18 (38%)	0.98 (0.51–1.87)	0.50 (0.22–1.10)

[‡] Prednisone and MTX in combination group showed significant difference (P<0.05) compared to Prednisone group.
Abbreviations: MTX, methotrexate; HR, hazard ratio

Results: Of 286 patients, 169 received high dose prednisone, 83 received IVMP, and 90 received MTX in the first 3 months. The propensity score models had good fit, indicated by reduced model AIC values compared to intercept only models, and each of the covariates was balanced between treatment groups within each of the propensity score quartiles. High doses of prednisone had no effect on the likelihood of achieving the 3 treatment outcomes compared to lower doses of prednisone. Patients receiving initial pulse IVMP were less likely to have a treatment escalation at 12 and 24 months compared to those not receiving pulse IVMP (Table 1). Patients receiving prednisone/MTX in combination in the first 3 months were more likely to achieve prednisone discontinuation at 24 months in a model without adjustment for other medications received (Table 2). These 3 initial therapies had no association with the development of calcinosis at ≥ 24 months.

Conclusion: Initial pulse IVMP therapy and prednisone in combination with MTX in the first 3 months of treatment are associated with reduced requirements for future treatment in JDM patients. There was no association of initial prednisone dose with these outcomes. Pulse IVMP and MTX in combination with prednisone are recommended in the early treatment of JDM patients.

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: At present no clear evidence based guidelines exist to standardize the tapering and discontinuation of corticosteroids (CS) in juvenile dermatomyositis (JDM). Aim of our study is to provide evidence-based recommendations for CS tapering/discontinuation through the analysis of the patients in the PRINTO new onset JDM trial, and to identify predictors of clinical remission (CR) and CS discontinuation.

Methods: New onset JDM children were randomized to receive either prednisone (PDN) alone or in combination with methotrexate (MTX) or cyclosporine (CSA). We stratified patients according to CR into two major groups. Group 1 included

those on CR, who could discontinue PDN, with no major therapeutic changes (MTC) (reference group). Group 1 was compared with those who did not achieve CR, without or with MTC (group 2 and 3, respectively). PRINTO/ACR/EULAR JDM core set measures (CSM) and their median changes over time were compared in the 3 groups. A logistic regression model with odds ratios (OR) and 95% confidence intervals (CI) was used to identify predictors of CR with PDN discontinuation.

Results: 139 children were enrolled. The reference Group 1 showed at least a 50% decrease in the CSM already in the first 2 months when compared to the other two groups. The achievement of a PRINTO JDM 50-70-90 response at 2 months (ORs range 4.5-6.9) from treatment start, an age at onset >9 years (OR 4.6) and the combination therapy PDN+MTX (OR 3.6) increase the probability of achieving CR ($p<0.05$). (Table)

Conclusion: This is the first proposal of evidence based specific cut-offs for corticosteroid tapering/discontinuation based on the change in JDM CSM of disease activity.

Table	OR (95% CI)	p [#]
Responder at 2 months:		
Printo-50 (vs. not responder/Printo-20)	5.41 (1.37 - 21.32)	0.0076
Printo-70 (vs. not responder/Printo-20)	6.90 (1.91 - 24.99)	0.0017
Printo-90 (vs. not responder/Printo-20)	4.46 (1.08 - 18.38)	
Age at onset > 8.53 years (≤ 8.53 years)	4.64 (1.69 - 12.71)	
Treatment group: PDN+MTX (vs. PDN / PDN+CSA)	3.63 (1.30 - 10.09)	0.0116
AUC of the model: 0.80

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis is a major complication of JDM and is associated with disability and poor quality of life. There are no known effective treatments for calcinosis; current therapy is based on anecdotal retrospective studies. Our aim was to introduce a systematic evaluation of calcinosis and assess the response to IV Immunoglobulin (IVIG) in combination with IV Methylprednisolone (IVMP) in JDM patients (pts).

Methods: A retrospective review was conducted of 11 pts with probable or definite JDM with calcinosis treated with IVIG and IVMP, added to ongoing immunosuppressive therapy. The evaluation of treatment response was based on change at follow-up in 9 potential body areas with calcinosis (head, upper and lower extremities, chest, back, abdomen, buttocks); total number of calcinosis lesions, their size and consistency; associated signs of inflammation (erythema, warmth, tenderness) in the lesions; and impact on function (limitation of joint range of motion (ROM) and Child Health Assessment Questionnaire (CHAQ) scores).

Results: The median age at baseline was 14 years, median disease duration was 4 years [IQR 3-8] (Table 1). The median duration of IVIG treatment to documented clinical improvement in calcinosis was 16 months [IQR 9-60], with monthly

IVIG dose ranging from 1- 2 gm/kg and IVMP dose ranging from 1mg/kg to 30 mg/kg/dose with IVIG. The median [IQR] number of anatomic areas with calcinosis was 6.0[1.0-7.0] pre- and 8.0 [2.0-8.0] post-treatment, with 4 pts(36%) having fewer anatomic areas involved with calcinosis after treatment, 4 (36%) with additional areas involved and 3 (27%) with no change at follow-up. A decrease in the total number of calcinosis lesions was documented in 6 pts (55%), while 3 (27%) had an increase and 2 (18%) had no change in the number of lesions. Among the 6pts with fewer calcinosis lesions, 3 exhibited a decrease in size of calcinosis while 2 had softening of the lesions. The median [IQR] number of areas with inflammation was 2.0 [1.0-6.0] pre- and 1.0 [0.0-3.0] post-treatment, with improvement in calcinosis-related signs of inflammation noted in 6 pts (55%), while 3 (27%) had increased inflammation and 1 (9%) had no change. Nine of 10 pts with restricted ROM at baseline due to calcinosis demonstrated improved ROM at the final evaluation visit (p=0.001). The median [IQR] number of restricted joints was 3.0 [1.0-5.0] pre- and 2.0 [0.0-2.0] post-treatment (p=0.047). CHAQ scores improved from median of 0.9 [0.19-1.9] pre- to 0.10 [0.0-0.69] post-treatment (p=0.05).

Conclusion: These data suggest that the combination of IVIG and IVMP was effective in improving calcinosis in a subset of JDM pts, as evident in improvement in the extent of calcinosis, associated inflammation, and physical function. This study also highlights the need for objective tools to assess calcinosis to aid in the evaluation of treatment responses.

Table. Eleven JDM Patients with calcinosis treated with IVIG and IVMP

ID	Age (yrs.)	IVIG duration (Mths.)	N. of anatomic areas with calcinosis		Calcinosis lesion number and characteristics		N. of areas with signs of inflammation		N. of restricted joints due to calcinosis		N. of joints with improved ROM Final	CHAQ Score (0-3)		Therapies administered while on IVIG and IVMP
			Initial	Final	Initial	Final	Initial	Final	Initial	Final		Initial	Final

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an unmet need for more objective disease outcome measures in Juvenile Myositis (JM) patients. This pilot study sought to test the reliability, validity and responsiveness of muscle ultrasound (US) modalities as outcome measures in JM subjects.

Methods: This prospective, consecutive observational JM cohort (using Bohan and Peter criteria) had clinical, functional and muscle US data collected at baseline, 3 and 6 months. US modalities assessing muscle consistency and perfusion [i.e. GrayScale with Echogenicity and Muscle Thickness, Power Doppler, 2D Shear wave® Elastography, and Contrast Enhanced US with Lumason® (CEUS)] were performed unilaterally on the proximal vastus lateralis (VL) at each study visit before and after all exercises including functional measure tests. Spearman correlation was utilized to evaluate the relationship of baseline US VL data pre- and post-exercise to International Myositis Assessment and Clinical Studies Group (IMACS) validated Core Set Measures (CSM). Descriptive statistics for VL US longitudinal measurements were performed and graphed to visualize trends. Subjects were characterized as change vs no change, guided by ACR/EULAR myositis response criteria and designated as 'active' or 'inactive' disease (PRINTO definition and physician judgement).

Results: Eleven enrolled subjects included primarily Caucasian females (mean age 10.7 ± 4.2 years) with a mean disease duration of 36 ± 23.7 months. At baseline, several US measures had fair to strong correlations ($r_s \geq 0.30$) with CSM, with most associations being stronger post-exercise (Table 1). Longitudinal assessment confirmed this post-exercise trend with disease status. The 'no change' subjects demonstrate consistent muscle US values over time (reliability) (Fig 1). Patients with initial 'active' disease showed an increase in elastography following exercise, reflecting an increase in muscle stiffness (Fig 1A), and a decrease in degree of perfusion post exercise, measured by Peak Intensity CEUS, over time (Fig 1B).

Figure 1: Descriptive longitudinal of change vs no change patients and median values of US measurements of Elastography, Peak Intensity, and Time to Peak

Table 1. Spearman correlation coefficients of different ultrasound modalities of the vastus lateralis muscle pre/post exercise and the PROMIS SF, Core Set Measures, and functional tests in 11 JM patients¹ at their baseline study visit.

	Core Set Measures							Functional Tests		
	PROMIS SF Pt/Parent	CHAQ SDI	Pt/Parent Global	MDAS	MD Global	CMAS	MMTB	STS	TUG	6MWD

CEUS AUC Pre	.30	.23	.09	.30	.46	.11	-.08	-.34	.61*	-.21
CEUS AUC Post	-.18	-.21	.11	.12	-.46	.08	.08	.04	.10	-.03

Due to low sample size, Spearman's correlation coefficients were interpreted as follows: fair ($\geq 0.3, < 0.5$), moderate ($\geq 0.5, < 0.7$), strong ($\geq 0.7, < 0.9$) or very strong (≥ 0.9) and were considered significant at the .01 level **, the .05 level *, and at the .15 level +. Abbreviations: Pre (Pre exercise), Post (Post exercise), CEUS (Contrast Enhanced Ultrasound), T_p (Time to Peak), I_p (Peak Intensity), AUC (Area Under the Curve), CHAQ (Childhood Health Assessment Questionnaire), Pt (Patient), Patient-Reported Outcome Measurement Information System Mobility Short Form (PROMIS-SF), MDAS (Myositis Disease Activity Scale), CMAS (Childhood Myositis Assessment Scale), MMTB (Manual Muscle Testing B), STS (Sit to Stand), TUG (Time Up and Go), 6MWD (6 Minute Walk Distance)

Additionally, the speed of perfusion on Time to Peak CEUS increased in subjects who clinically improved in their disease status (change group) (Fig1C).

Conclusion: Following exercise in active JM patients, the VL remains stiffer with less capillary enhancement compared to stable patients, likely reflecting residual vasculopathy. In patients showing clinical improvement, speed of perfusion (T_p CEUS) increases over time and may be useful as a future treatment response measure. Further longitudinal analysis is underway with healthy controls to strengthen these findings.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Background/Purpose: The use of physical activity monitors (PAM), which objectively quantify free-living movement, may enhance assessment of disease activity in juvenile myositis (JM) clinical trials and complement traditional core set measures (CSM) of disease activity. We examined the validity, reliability and responsiveness of the average daily step counts (ADSC) obtained from a commercially available PAM, Fitbit® One, as outcome measures in patients with JM.

Methods: JM patients age 3-17 were enrolled from rheumatology clinic. The following evaluations were performed at baseline, 1, 3 and 6 months: a) CSMs including Manual Muscle Testing (MMT), Childhood Health Assessment Questionnaire (CHAQ), MD global disease activity (MD-global), Extra-muscular global disease activity (Ex-Mus global), muscle enzyme, patient/parent global disease activity (pt-global), Childhood Myositis Assessment Scale (CMAS), Disease Activity Score (DAS), b) Patient-Reported Outcome (PRO) Measurement Information System Mobility Short Form (PROMIS-SF), and c) office functional tests: Sit-to-Stand (STS), Timed Up and Go (TUG) and Six Minute Walk Distance (6MWD). Fitbit® One was worn for 7 consecutive days monthly for 6 months, and PAM measures, including ADSC were assessed. Pearson Correlation assessed the relationship between Fitbit® ADSC and current CSMs, PROs and functional tests. Reliability and responsiveness of PAM measures were determined.

Table 1. Pearson correlation analyses of Fitbit® steps in free-living environment with CSMs¹, PROs² and functional tests.

	Average Fitbit Steps		
	Pearson's r	Sig. (2-tailed)	N
Core Set Measures			
MD global	-0.51	0.045*	17
MMT ³	0.54	0.03*	17
Parent/Patient Global Assessment: Disease Activity	-0.48	0.05*	17
Ex-Mus global ⁴	-0.47	0.06	17
CMAS ⁵	0.22	0.40	17
DAS ⁶	-0.36	0.15	17
Functional Tests			
6MWD ⁷	0.18	0.48	17
STS (highest)	0.57	0.04	17
TUG (highest)	0.15	0.56	17

¹Core Set Measures (CSM), ²Patient Reported Outcomes (PRO), ³Manual Muscle Testing (MMT), ⁴Extra-muscular global disease activity (Ex-Mus global), ⁵Childhood Myositis Assessment Scale (CMAS), ⁶Disease Activity Score (DAS), ⁷Six Minute Walk Distance (6MWD), ⁸Sit to Stand (STS), ⁹Timed Up and Go (TUG). *P < 0.05.

Results: A total of 17 JM participants have been enrolled, including 5 active and 12 stable, 76.5% female, 94% White with mean (SD) age of 11.5 years (3.4). As the study is ongoing, this data represents baseline, 1 and 3-month time points. Fitbit® ADSC showed moderate to strong correlation at baseline with key CSMs including MD global, MMT, pt-global, Ex-Mus global, but no to weak correlation with CMAS and functional tests (Table 1). Patients with stable disease at baseline and follow-up (1 and 3 months) showed no significant change in Fitbit® ADSC over time demonstrating strong test-retest reliability, whereas patients with active disease demonstrated Fitbit® ADSC increase longitudinally associated with clinical improvement (Figure 1).

Conclusion: Fitbit® ADSC had moderate to strong correlation with key JM CSMs except CMAS and functional test. ADSC also demonstrate preliminary reliability and responsiveness. Continued analysis of longitudinal data will help to determine the utility of a commercially available PAM as an outcome measure in JDM.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: JDM is an autoimmune systemic vasculopathy characterized by myositis and skin rash. Some myositis specific antibodies (MSAs) are associated with clinical manifestations in JDM, including extensive photosensitive rash and a chronic disease course. Prior research demonstrates a link between UV radiation (UVR) and certain MSAs. However, it is unclear if UVR worsens disease severity in JDM. We investigated the association between UVR and development of calcinosis, which we used as a proxy for severe disease. Understanding the role of UVR in disease severity may help clinicians develop interventions to limit UV exposure and poor outcomes in JDM.

Methods: This was a cross-sectional study of JDM subjects in the U.S. multi-center Childhood Arthritis & Rheumatology Research Alliance (CARRA) registry enrolled from 2010-15. We excluded subjects missing date of symptom onset or zip code. Mean UV index (UVI) in the calendar month prior to symptom onset in each subject's zip code was calculated from daily satellite solar noon measurements. The primary outcome was history of calcinosis. Chi-squared and Kruskal-Wallis tests were used to compare subject characteristics stratified by UV quartiles. Multivariate logistic regression was used with adjustment for sex, race, age, interval to diagnosis, disease duration, and latitude. Race was dichotomized as black or non-black. Interaction between race and UVI was evaluated.

Results: Among subjects (n=522), 11% identified as black and 89% as non-black, of which 79% identified as white. Overall, mean UVI was 4.9 (± 2.6) and 11% had calcinosis. Stratified by UV quartiles, clinical and demographic characteristics were similar. In a multi-variate analysis, there was no significant relationship between mean UVI and calcinosis (see Table 1 for OR's). Black race was associated with a 3-fold greater odds of calcinosis. However, when accounting for a statistically significant interaction between race and UVI, black subjects were less likely to develop calcinosis at the mean UVI. At higher UVI levels, the odds of calcinosis steadily increased in the non-black subjects. Additional statistically significant risk factors for calcinosis in our model included male sex, older age at disease onset, longer disease duration, and delay in diagnosis.

Conclusion: In the CARRA JDM registry, we found that black subjects living in areas with lower UVI, had a 3-fold greater odds of calcinosis compared to non-black subjects. However, non-black subjects living in areas with moderate to high UVI, had increased risk of calcinosis beyond those of black subjects suggesting that lighter skinned individuals with JDM may be more susceptible to UVR and subsequent development of calcinosis. Our data suggests UVR is an important factor associated with calcinosis but also highlights the complex interplay between genes and environment present in autoimmune conditions like JDM.

Table 1: Multivariate logistic regression model of mean UVI as a predictor of Calcinosis

Predictor	Unadjusted OR	95% CI	p-value	Adjusted OR	95% CI	p-value

Correlation between Disease Activity and Hip Score in Patients with Rheumatoid Arthritis after Total Hip Arthroplasty

Hiroki Wakabayashi^{1,2}, Masahiro Hasegawa³ and Akihiro Sudo^{4,5}, ¹Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu City, Mie, Japan, ²Orthopaedic Surgery, Mie University Graduate School of Medicine, Mie, Japan, ³Mie University Graduate School of Medicine, Tsu, Japan, ⁴Department of Orthopaedic surgery, Mie University Graduate School of Medicine, Tsu-city, Japan, ⁵Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu City, Japan

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Disease Activity Score including 28 joints (DAS28), the Simplified Disease Activity Index (SDAI) and the Clinical Disease Activity Index (CDAI) were developed in order to provide a quantifiable measure of rheumatoid arthritis (RA) activity. Although inflamed hip joints greatly impact activities of daily living (ADL) and walking ability, the hip joint was not included in the DAS28, SDAI or CDAI assessments. This study aimed to assess the correlation between a hip score and disease activity in patients with RA after THA.

Methods: We analyzed the effect of RA disease activity on a hip function score in an observational cohort of RA patients after THA. Thirty-three registered RA patients who had undergone THA (44 joints) between 1997 and 2016 and who had been followed for more than 1 year were included. Hip function was recorded and RA disease activity was measured on the same day. The mean age of the patients was 66.8 years (range, 41–84 years). They were followed for a mean of 7.9 years (range, 1–19) after surgery. The Japanese Orthopedic Association (JOA) hip score was used as a clinical outcome measure for hip dysfunction. The JOA hip score accounts for: ‘pain’ (up to 40 points), ‘range of motion’, ‘ability to walk’, and ‘activities of daily living (ADL)’ (each up to 20 points), such that a higher score indicates less pathology. The mean duration of disease following RA diagnosis for this patient group was 22.9 years (range 2–47 years). The RA disease progression was assessed by Steinbrocker radiographic stages, 9 patients (11 THA) were in stage II, 4 patients (7 THA) were in stage III, and 20 patients (26 THA) were in stage IV. More than half of the studied patients had advanced to Steinbrocker radiographic stage IV. RA disease activity were measured using the DAS28, SDAI and CDAI. RA functional assessment was measured using the modified health assessment questionnaire (mHAQ).

Results: The mean JOA score for hip function was 83.8 (range, 39–99) at the final follow-up. The mean DAS28-ESR, DAS28-CRP, SDAI, CDAI and mHAQ measuring RA disease activity levels were 3.87 (range, 0.77–6.04), 2.39 (range, 1.03–5.21), 8.89 (range, 0.23–27.33) and 7.67 (range, 0.1–23.90), respectively, at the final follow-up. There was a significant negative correlation between the JOA hip score and all disease activity assessments observed after THA (DAS-ESR [P = 0.0012]; DAS-CRP [P = 0.0036], SDAI [P = 0.0023], CDAI [P = 0.0016] and mHAQ [P < 0.0001]). There were significant JOA score changes among the parameters of ADL (DAS-ESR [P = 0.0081]; DAS-CRP [P = 0.0245]), SDAI [P = 0.0116] and CDAI [P = 0.0187] and mHAQ [P < 0.0001]) and the ability to walk (DAS-ESR [P = 0.0012], DAS-CRP [P = 0.0011], SDAI [P = 0.0011], CDAI [P = 0.0007] and mHAQ [P < 0.0001]). Thus, ADL and ability to walk are correlated with RA disease activity.

Conclusion: We found significant negative correlations between JOA hip scores and all disease activity assessments in RA patients treated with THA. We conclude that THA may have a positive secondary systemic effect on RA disease activity, and tight control of RA disease activity may improve hip function for RA patients after THA.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Preoperative patient expectations of Total Knee Arthroplasty (TKA) influence postoperative outcomes and satisfaction. Rheumatoid Arthritis (RA) may lower preoperative expectations after TKA compared to patients with knee osteoarthritis (OA). As RA patients undergoing primary TKA have lower expectations, but comparable knee specific clinical outcomes when compared to OA patients we hypothesized that satisfaction would also be comparable.

Methods: A retrospective review of 76 RA patients who underwent primary TKA from 2007-2011 were matched 1:2 with a cohort of 152 OA patients based on age, gender, ASA score, and Charlson Comorbidity Index score. The Hospital for Special Surgery Knee Replacement Expectations Survey (HSS-KRES), Visual Analogue Scale Pain (VAS), Knee injury and Osteoarthritis Outcome Score (KOOS), and the Short Form-12 (SF-12) were compared at baseline and at two years post-op. Minimum Clinically Important Difference (MCID) was calculated for KOOS and SF-12 subdomains.

Results: RA patients had significantly lower preoperative expectations (mean HSS-KRES 68.8 vs 77.7, $p=0.03$), higher VAS pain (66.2 vs 59.8, $p=0.05$), worse KOOS pain, knee symptoms, and activities of daily living limitations at baseline ($p<0.01$). At 2 years, the RA group had larger improvement in VAS pain (-53.7 vs -44.8, $p=0.02$) and these 3 KOOS domains ($p<0.05$), achieving comparable scores to OA patients. RA patients had a significantly higher proportion of patients achieve MCID (11.96) for KOOS symptoms (98.4% vs 77.2%, $p<0.001$). There was no significant difference between satisfaction rates with over 85% of RA and OA patients either somewhat satisfied or very satisfied at 2 years follow-up.

KOOS QOL		91	43.77	26.25	59	51.24	26.02	0.090
SF-12 PCS		129	12.14	10.44	65	11.15	8.85	0.511
SF-12 MCS		129	2.89	9.74	65	2.14	12.50	0.758

Table 2. Comparison of baseline, 2-year and delta expectation scores, pain, and patient reported outcome measures. OA: Osteoarthritis cohort; RA: Rheumatoid Arthritis cohort; N: number of patients; ColPctN: percentage of patients; Std: stand deviation; p-value ¶: obtained using Two-sample t-test

Conclusion: While RA patients had lower baseline expectations compared to OA patients they achieved meaningful improvement in KOOS and SF-12 subdomains and there was no difference in satisfaction compared to OA patients after TKA. These findings may be used for preoperative counseling prior to TKA.

Bone Loss in Different Sites over Time in Patients with Rheumatoid Arthritis

Rachel Tribbick¹, Marco Massarotti², Jemma G Kerns³, Frank Dondelinger¹ and Marwan Bukhari⁴, ¹CHICAS, Lancaster University, Lancaster, United Kingdom, ²Rheumatology, Royal Lancaster Infirmary, University Hospital of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, ³Medical School, Lancaster University, Lancaster, United Kingdom, ⁴Royal Lancaster Infirmary, Lancaster, United Kingdom

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is described as an independent risk factor for osteoporosis and is included in models, including the FRAXTM tool which uses bone mineral density (BMD) as well as demographics to predict fracture risk. Most dual X-ray absorptiometry (DEXA) scans only measure the non-dominant hip. Published data are from existing datasets that are X-sectional and the influence of factors on progression of BMD loss in different sites has not been studied. We aimed to test the hypothesis that bone loss over time is more pronounced in patients with RA, compared to those without.

Methods: We used data from patients referred for DEXA in the North West of England from June 2004 and October 2016. Patients have their FRAXTM risk factors assessed and their BMD measured in both femoral necks, shaft, trochanter and Ward's triangle in addition to L1-L4 in the lumbar spine (LS). Patients attending for multiple scans in this period without a diagnosis of RA were used as a comparator group. A longitudinal mixed-effects model was fitted, with BMD at each site as

the exposure, adjusting for all risk factors for OP in addition to fitting interaction terms for bisphosphonate use in addition to calcium/vitamin D use.

Results: 6941 patients were included, 6169 (88.9%) were females. Of whom 1270 (20.5%) were menopausal. Mean age was 63 years (SD 11.3 years) and 749 patients with RA (named the RA group) had multiple scans and were compared to the 6192 without an RA diagnosis. There is an average of 2.35 scans per patient (SD 0.64 scans), an average of 4.26 years apart (SD 1.88 years). Patients in the RA group had significantly higher average BMD in the lumbar spine than those in the non-RA group. There was no significant difference in the bone mineral density of the femur between the RA and non-RA groups. Conversely, patients in the RA group lost BMD faster in the femur than the non-RA group, but BMD loss in the lumbar spine was not significantly different between groups.

Figure 1. Showing the results of the longitudinal analysis for average BMD (top) and bone loss over time (bottom)

Conclusion: The average BMD in the lumbar spine is higher in the RA group than in the non-RA group, but bone loss appears to be increased in the femur at all sites of measurement. The most likely explanation is increasing OA in the lumbar spine causing slower loss of BMD. This is clinically significant because bone loss in the hip is used as a predictor for fracture and the rapid bone loss seen would necessitate reducing the interval between scans in this group of patients. Limitations of the study include lack of information about length of disease and specific treatments history for the RA patients.

The Electrophysiologic and Sonographic Evaluation of Peripheral Nerves in Rheumatoid Arthritis Patients

Sule Sahin Onat¹, Zuhale Özisler², Ali Orhan², Sibel Ünsal-Delialioglu² and Sumru Ozel², ¹Ankara Physical Medicine and Rehabilitation Training and Research Hospital, Ankara, Turkey, ²Ankara Physical Medicine and Rehabilitation Research and Training Hospital, Ankara, Turkey

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The compression neuropathies due to arthritis, tenosynovitis and deformities in the joints, mononeuritis multiplex are very common in patients with rheumatoid arthritis (RA). No previous study investigated function and morphology of peripheral nerves in patients with RA. This study was aimed to compare the morphology and electrophysiology of median, ulnar and tibial nerves in patients with RA to healthy controls.

Methods: Fifteen female patients (20-60 years) were diagnosed with RA at least 1 year before according to ACR criteria and 12 healthy women (matched for age and body mass index) were enrolled. A total of 30 RA patient extremities and 24 healthy controls were included. Patients with an additional disease (diabetes, hypothyroidism, uremia, Lyme, sarcoidosis, leprosy, Guillain Barre syndrome, neurotoxic drug use, etc.), which may be caused by polyneuropathy, were excluded. Disease activity was assessed by using the clinical disease activity index (CDAI), DN4-neuropathic pain questionnaire, with or without neuropathic pain. The patients and the control group were assessed by three independent researchers. After clinical assessment of the clinician (SUD), the patients were referred to the electrodiagnosis laboratory. Nerve conduction studies (NCS) were performed by the same electrodiagnostician (ZO) who was blinded to clinical findings. The patients who had an electrodiagnostic abnormality were excluded. Patients were referred to ultrasonographic assessment, which was done by a third blinded researcher (SSO). In the electromyography (ENMG) measurement; median (motor and sensory), ulnar (motor and sensory), tibial (motor), and sural (sensory) nerve conduction studies were performed bilaterally.

Results: Sonographic measurements of nerve cross-sectional area of the median nerve at level of wrist, ulnar nerve at wrist and midpoint of forearm, and cubital tunnel and tibial nerve at the level of the both ankle and poplitea were statistically bigger in patient with RA than the control group ($p < 0.05$) (Table 1). Cubital tunnel syndrome (6 in RA patients, 2 in control group; $p < 0.05$) and carpal tunnel syndrome (4 in RA patients, 2 in control group; $p < 0.05$) were observed significantly more in RA patients than control group in ENMG study.

	Patients with RA mean \pm standard deviation	Control group mean \pm standard deviation	p
Median nerve cross sectional area			
Wrist	10.8 \pm 3.8	9.6 \pm 4.2	0.896
Mid forearm	8.2 \pm 2.6	7.1 \pm 3.4	0.231
Elbow	14.4 \pm 4.7	10.3 \pm 4.9	0.828
Ulnar nerve cross sectional area			
Wrist	5.2 \pm 2.7	3.1 \pm 1.3	0.005
Mid forearm	7.2 \pm 3.1	4.3 \pm 1.5	0.001
Elbow	10.6 \pm 3.2	7.9 \pm 3.4	0.016
Tibial nerve cross sectional area			
Ankle	6.1 \pm 3.1	3.9 \pm 1.7	0.044
Poplitea	29.9 \pm 12.1	17.3 \pm 6.4	0.003

Conclusion: In summary, there are morphological changes in the peripheral nerves of RA patients, although their functions are not impaired yet. Therefore, it is important to evaluate the peripheral nerves sonographically in RA patients.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most common autoimmune inflammatory arthritis in adults. Extra-articular manifestations of RA can occur in about 40% of patients, either in the beginning or during the course of their disease. Recent studies have suggested that RA may have an important relation in the development of cognitive and neurological dysfunction. However, the bond between RA and the brain is still uncertain. The purpose of this study was to assess the frequency and the clinical predictors of cognitive impairment in rheumatoid arthritis (RA) patients.

Methods: A cross-sectional and case-control study was performed including consecutive RA patients seen in a rheumatology outpatient clinic of referral tertiary hospital. The control group included 100 healthy subjects. We registered clinical and demographic data including age, sex, level of education, time of disease, time of diagnosis, drugs in use, cardiovascular risk factors and other comorbidities. Functional capacity was assessed using the Health Assessment Questionnaire (HAQ). Neurological appraisal was made with standardized questionnaires: Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA) and the Hospital Anxiety and Depression (HAD). Analysis of the data was performed using chi-square and t-tests and a multivariate analysis (SPSS 22.0). Significance level was set as <0.05.

Results: We included 200 patients (166 were female) with a mean age of 57.4 (\pm 11.4) years; Among these patients, 163 (81.5%) used corticosteroids, 148 (74%) methotrexate, 16 (8%) sulfasalazine, 91 (45.5%) leflunomide, 35 (17.5%) chloroquine and 57 (28.5%) biologic therapy. The mean age of RA diagnosis was 43.0 (\pm 13.6) years. In both univariate and multivariate analysis, compared to the control group, patients with RA presented significant lower MMSE (21.9 \pm 3.9) and MoCA (17.0 \pm 4.4) scores (p <0.05). Adjusting for level of education, just 61 and 50 patients presented normal MMSE and MoCA scores (p <0.01), respectively. Cognitive decline was associated with higher HAQ scores (functional outcome due to RA) and prolonged time of disease (p <0.05). No correlation was found between sex, disease-modifying antirheumatic drugs, rheumatoid factor, C-reactive protein levels and the neurological impairment. The mean HAD score was 17.7 (\pm 7.7) and anxiety and depression were more prevalent in RA patients than in control group (p <0.01).

Conclusion: Patients with rheumatoid arthritis may present with cognitive decline and dementia as extra-articular manifestations of the disease. Neurological impairment is usually disregarded and might be under-diagnosed in RA patients. Future studies are necessary in order to better understand the relationship between RA and the brain.

Rheumatoid Meningitis: Meningeal Biopsy Is Not Essential for Diagnosis

Fawad Aslam¹, Angela Parsons², Marie Grill² and Brent Goodman², ¹Rheumatology, Mayo Clinic, Scottsdale, AZ, ²Department of Neurology, Mayo Clinic, Scottsdale, AZ, 85259, USA., Scottsdale, AZ

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid meningitis (RM) is a rare complication of RA with a high mortality rate if untreated. Traditionally RM has been a diagnosis of exclusion. Although there are no established diagnostic criteria for RM, current clinical practice relies on a meningeal biopsy for diagnosis¹. Previous reports have stressed on the critical importance of a biopsy before rendering a diagnosis of RM². Our study aimed to review the clinical history of RM at our institution and assess the role of meningeal biopsy in RM patients.

Methods: An administrative database search with the key terms “rheumatoid arthritis”, “pachymeningitis”, “leptomeningitis”, “chronic meningitis”, and “meningitis not otherwise specified” was conducted within the Mayo network from 1990-2017 to identify RM patients. Patients were only included if the RA was diagnosed by a rheumatologist and RM was diagnosed both by a rheumatologist and neurologist. A retrospective chart review was undertaken to obtain complete clinical history, testing, imaging, histopathology, treatment and outcome.

Results: Fourteen patients with a diagnosis of RM were identified. Mean age was 67 years and 57% were males. RA disease duration ranged from many years to new onset RA diagnosed concurrently with RM. No patient had seronegative disease. RA disease activity was controlled in 10/11 (91%) of the patients at RM diagnosis. Subcutaneous nodules were present in 4/13 (31%) and erosions in 3/10 (30%) patients. Headache, seizure and hemiparesis were the most common presentations of RM. No patient had cranial neuropathies. Cerebrospinal fluid cell count and protein levels were normal in 3/14 (21%) patients. All patients demonstrated enhancement of the pachymeninges, leptomeninges or both, with 12/14 (86%) having a fronto-parietal predominance on MRI. Comprehensive clinical workup excluded other conditions. Of the 10 patients undergoing biopsy, 10/14 (80%) showed nonspecific findings of inflammation or necrosis and none showed vasculitis or rheumatoid nodules. Infectious organisms and specific histological changes of IgG4 disease were absent. Corticosteroids, rituximab and methotrexate were used for treatment. 10 of the 12 (83%) patients who underwent repeat imaging showed complete or near complete resolution of abnormalities. The four RM patients treated without undergoing a biopsy did similarly well.

Conclusion: RM can present at any time in RA and occurs in well controlled RA. MRI shows fronto-parietal meningeal enhancement. Biopsy is negative for pathognomonic features of RM. Patients with suspected RM without biopsy do equally well with treatment. In contrast to the previous literature, our study shows that clinical evaluation, testing and imaging in RA patients with meningitis, in the absence of atypical features e.g. seronegative disease, is sufficient to diagnose RM without a biopsy. Biopsy should not delay treatment. RM responds well to immunosuppressive treatment.

Self-Reported Depression in Patients with Rheumatoid Arthritis Is Undertreated and Associated with Poorer Clinical Status and Lower Rates of Remission in Routine Care

Isabel Castrejón, Mariam Riad, Jacquelin R. Chua and Theodore Pincus, Division of Rheumatology, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression in patients with rheumatoid arthritis (RA) may be pre-existent, amplified, or newly-developed after onset of RA. Together with other comorbidities, socioeconomic factors, education level or affective factors can influence perception of pain, functional disability, and health status. The prevalence of depression in RA patients has been estimated to be 19% over 5 years and affect remission rates according to a classical composite index (Leblanc-Trudeau, C et al. Rheumatology 2015;54:2205-14). We compared patient self-reported scores included in the Multidimensional Health-Assessment Questionnaire (MDHAQ) and levels of remission according to RAPID3 in patients who reported depression versus no report of depression.

Methods: All patients, regardless diagnoses, complete a MDHAQ at each visit in the waiting area before seeing the rheumatologist at all visits. The 2-page MDHAQ includes physical function (FN) in 10 activities of daily living, three 0-10 visual analogue scales (VAS) for pain (PN), patient global estimate (PATGL), fatigue (FT), RADAI self-report joint count, a review of 60 symptom checklist, three 0 to 3.3 scores for depression, anxiety, and sleep quality, and demographic data. RAPID3 (0-30) is the sum of 0-10 scores from FN, PN, and PATGL; remission corresponds to a RAPID3 value ≤ 3 . Patients with RA (physician ICD9 and ICD10 diagnosis) were classified according to self-report of checking depression as part of a symptoms checklist. A retrospective chart review was conducted to evaluate the percentage of patients with treatment or specialist evaluation for depression. Demographic and clinical characteristics were compared according to self-reported depression status using Student t-test and chi-square test.

Results: Overall 464 RA patients were included in the analysis, of which 118 (25%) self-reported depression in the last month. Only 37 (31%) of all patients reporting depression had evidence in the medical record of treatment and/or specialist evaluation for depression. Mean age (SD) was 55.5 (14.9) and 86% were female, with no difference between depression groups. Patients reporting depression had lower education level (12.5 vs 14.3, $p < 0.001$) and poorer scores for physical function, pain, and patient global leading to higher RAPID3 and lower percentage of patient in remission (12.4 vs 4%, $p < 0.001$) (Table). Depressed patients also reported higher scores for fatigue, number of painful joints, number or symptoms, and more difficulty with sleep, and anxiety (Table).

Table: MDHAQ/RAPID3 patient self-report scores in patients with rheumatoid arthritis according of their depression status. Data are presented as mean (SD) and percentages. Comparisons by Student t-test and chi-square test.

	No self-reported depression N= 346 (75%)	Self-reported depression N= 118 (25%)	p
Demographic variables			
Age, years	55.4 (14.9)	55.8 (15.1)	0.80
Female, %	84%	91%	0.08
Education level, years	14.3 (3.1)	12.5 (3.4)	<0.001
MDHAQ/RAPID3: Patient self-report scores			
Physical function (0-10)	2.4 (2.0)	3.4 (1.9)	<0.001
Pain (0-10)	5.3 (3.0)	6.8 (2.6)	<0.001
Patient global estimate (0-10)	4.9 (3.0)	6.6 (2.7)	<0.001
RAPID3 (0-30)	12.6 (7.2)	16.6 (6.4)	<0.001
% patients in RAPID3 remission	12.4%	4%	<0.001
Fatigue (0-10)	4.2 (3.2)	6.3 (3.0)	<0.001
Self-reported joint pain-RADAI (0-48)	12 (10)	18 (12)	<0.001
Review of Symptoms (0-60)	8 (7)	18 (9)	<0.001
Sleep problems (0-3.3)	1.1 (0.9)	1.9 (0.9)	<0.001
Dealing with depression/feeling blue (0-3.3)	1.1 (0.9)	1.9 (0.9)	<0.001
Dealing with anxiety/being nervous (0-3.3)	0.1 (0.4)	0.7 (0.4)	<0.001

Conclusion: The prevalence of self-reported depression in our RA patients was 25%, with only 31% treated for this condition. RA patients with self-reported depression exhibit higher scores for all MDHAQ patient-reported outcomes,

including to a lower rate of RAPID3 remission. MDHAQ/RAPID3 may be useful to identify patients with depression in busy clinical settings.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies pay a particular attention to catastrophizing. Catastrophizing is a negative cognitive and affective response based on inadequate expression of pain. The objective was to assess catastrophizing level in rheumatoid arthritis (RA) and to determine if there is a link between catastrophizing and physical pain intensity, disease activity, disability, depression and quality of life.

Methods: We performed a systematic review of literature and search the following databases : PUBMED-MEDLINE, COCHRANE and EMBASE until April 2018. All observational, cross-sectional and randomized control studies investigating catastrophizing in patients with rheumatoid arthritis were included. Statistical analysis defined pooled mean catastrophizing level, using the Pain Catastrophizing Scale (PCS) and assessed the association with disease activity (DAS28), pain (Numerical Rating Scale NRS) and quality of life (SF36).

Results: On 1494 articles concerning catastrophizing and rheumatic disorders, 22 articles concerned RA patients. Finally, 7 were selected in the meta-analysis including 601 RA patients (mean age 57.4 years old, 67.7% female, mean pooled DAS 28 = 3.4 and mean pooled VAS = 3.8). Mean pooled catastrophizing level at baseline was 14.7 (sd = 11.4) in RA patients. In one study, a RA sample identified 22% of high catastrophizers (defined by PCS > 30). There is a significantly positive correlation between pain catastrophizing and disease activity in 3 studies (r between 0.22 and 0.39, all p<0.01) (Table). Pain is strongly associated with catastrophizing (r=0.71 (p<0.01) for NRS; r = -0.43 (p<0.01) for SF-36 Bodily Pain). Higher PCS scores were significantly associated with higher levels of distress i.e. lower SF-36 Mental Health score (r= -0.52 (p<0.01)). Moreover catastrophizing is significantly associated with reduced physical function (r=-0.35 (p<0.01) for SF36 Physical Function) (Table).

Conclusion: Catastrophizing is rarely measured but it's a common psychological trait which is clearly associated with disease activity, pain, mental health and physical function. It would be interesting to early detect it in order to adapt pharmacologic and non-pharmacologic treatment.

Table 1 : Correlation coefficient between Pain Catastrophizing Scale(PCS) and variables of interest in RA patients

	DAS 28	Pain	Mental Health	Physical Function
PCS	r = 0.33 (p<0.002) r = 0.39 (p< 0.01) r = 0.22(p<0.01)	r = 0.71 (p<0.01)* r = -0.43 (p<0.01)°	r = -0.52 (p<0.01)	r = -0.35 (p < 0.01)

Results are expressed by correlation coefficient (r) and significance level (p)

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Intact cognitive function is important for executing several tasks on day-to-day basis in people with chronic diseases, including rheumatoid arthritis (RA). A number of studies have reported a high prevalence of cognitive impairment in patients with RA. Chronic systemic inflammation in RA may play an important role in the pathogenesis of cognitive impairment, in addition to the traditional risk factors. Our objective was to investigate the association between disease activity and cognitive impairment in patients with RA.

Methods: All patients who were of Thai nationality, aged of 18 years old or older, diagnosed of RA according to the ACR 1987 revised criteria for the classification of RA or the 2010 Rheumatoid arthritis classification criteria, literate, and had at least a visit of follow-up were included in this study. A total of 464 patients from the RA registry of 2 academic centers, Siriraj and Phramongkutklao hospital were included. Demographics, clinical and laboratory data related to disease activity (Disease activity score 28 or DAS28), functional status (Health assessment questionnaire or HAQ) were collected. Cumulative disease activity of DAS28 was calculated by the sum of serial measurement of DAS28 divided by the total times of clinic visits from first to last measurement. Cognitive function was assessed using the Thai version of the Montreal cognitive assessment (MoCA-T). Subjects were classified as cognitively impaired if they scored less than 25, a cutoff point validated in Thai population. Univariate and multivariate analyses were performed to identify factors associated with cognitive impairment.

Results: Most subjects (85%) were female with the mean age \pm SD of 59.2 ± 11.4 years old and median (range) educational level of 9 (4-14) years. The median duration of follow-up (range) was 5.2 (2.2-5.9) years. They were long-standing RA [median disease duration (range) of 9.9 (5.1-16.6) year], had moderate cumulative disease activity [mean DAS28 \pm SD of 3.5 ± 0.81], and mild functional impairment [median HAQ (range) 0.5 (0.13-1.10)]. Seventy percent was classified as having cognitive impairment. Patients with cognitive impairment significantly impaired in all domains, especially in visuospatial/executive, language, and abstraction. In multiple logistic regression analyses, old age (> 60 years) [RR 3.43, 95% CI 2-5.9, $p < 0.001$], low education (< 6 years) [RR 9.9, 95%CI 4.9-19.9, $p < 0.001$], and high cumulative disease activity (mean DAS28 > 2.6) [RR 2.2, 95%CI 1.04-4.4, $p = 0.038$] were independently associated with cognitive impairment.

Conclusion: Besides traditional risk factors, high cumulative RA disease activity is associated with cognitive impairment. Therefore, treat-to-target aiming at low disease activity or remission may be beneficial for preventing cognitive decline in RA patients.

Multiple logistic regression analysis to identify factor related to cognitive impairment in RA

Factors	RR	95%CI	P-value
Age > 60 years	3.43	2.01 – 5.86	< 0.001
Smoking	1.75	0.75 – 4.09	0.197
Education < 6 years	9.88	4.91 – 19.86	< 0.001
Unemployment	1.11	0.67 – 1.86	0.678

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis(RA) have a modest increased risk of overall cancer and of lymphoma. The purpose of our study was to report trends in the incidence of all site cancers and lymphoma in US Veterans with RA relative to US population-based rates from the Surveillance, Epidemiology, and End Results (SEER) Program.

Methods: In order to identify RA patients in the national VA, we used the following algorithm: ≥ 2 RA diagnostic codes at least 30 days apart, rheumatologist diagnosis of RA, and either a DMARD prescription or positive autoantibody test (RF or anti-CCP) within the VA Corporate Data Warehouse between 1/2001-12/2015; exclusion criteria included patients with diagnostic codes for psoriatic arthritis or ankylosing spondylitis. Diagnoses of all site cancers (includes all cancers -in situ and malignant)were identified from the VA Central Cancer Registry (VACCR) and mortality data from the National Death Index. The study period was divided into three 5-yearintervals: 2001-2005, 2006-2010, and 2011-2015. Person-years of follow-up for RA patients was calculated from the index date (first fulfilling the RA algorithm) to the earliest of death, the development of any cancer (for trendsin all site cancer), or development of lymphoma (for trends in lymphoma), or theend of the study period (12-31-2015). Rates of all site cancer and lymphoma forthese time intervals in 5-year age groups (20-24 through 85+) were obtained from SEER*Stat version 8.3.5. Standardized incidence ratios (SIRs) were calculated for each time period by dividing the observed number of cancers in RA patients to the expected numbers obtained by applying the SEER rates.

Results: We identified 50,870 male US Veteranswho fulfilled our RA algorithm and eligibility criteria. The mean (SD) age was64 (11) years, 80% were white, 13% black, 60% were current or former smokers,65% were RF positive and 62% were anti-CCP positive. Among these patients, 4435all site cancers and 461 lymphomas were observed. Relative to SEER, the highest SIRs were observed in 2001-2005 for both all site cancers (1.8, 95% CI 1.7-1.9)and lymphomas (2.9, 95% CI 2.4-3.5). We observed a decrease in SIRs for bothtypes of cancers in 2006-2010 and then a slight increase in the last time period(Figure 1).

Conclusion: To our knowledge, this is the first study evaluating incidence trends of all site cancers and lymphoma in a national cohort of veteran RA patients. We observed higher rates of both all site cancers and lymphomas, in the veteran RA population compared to the SEER population, but the trend was toward decreasing risk over more recent years compared to a similarly-aged non-RA population.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: During the last 20 years, the treatment in rheumatoid arthritis (RA) has changed. Considering the increasing use of biological immunomodulators to treat chronic inflammatory conditions and the concern that immune modulation may alter cancer risk and progression, it's important to know the tumors incidence in patients with RA. The objective of this study was to analyze the incidence and trend of hospital admissions for solid tumors in patients with RA in Spain during the period between 1999 and 2015.

Methods: This is a retrospective population based study. We have analyzed a national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of RA patients during the period 1999 to 2015. We selected the MBDS for solid tumors (breast, colon, pancreas, prostate, lung, pleura, melanoma, ovary, cervix, uterus, bladder and kidney). Cases were identified by the presence in primary and secondary diagnosis of ICD9 codes. The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence of RA

of 0,5% (0,8% in women and 0,2% in men). Crude and adjusted rates of the solid tumors were calculated, and the trend was analyzed using the Generalized Linear Model (GLM) with the year as the analysis variable.

Results: 338.343 RA hospital admissions were detected in the study period, being 18.401 (5,4%) due to solid tumors. The main clinical-demographic characteristics are shown in the next table.

	Total	Women	Men	<i>P value</i>
N (%)	18.401 (5,4)	8689 (3,8)	9712 (8,6)	<i>P</i> <0,001
Age, mean (SD)	69,98 (11,21)	68,62 (12,3)	71,20 (9,99)	<i>P</i> <0,001
In-hospital exitus n (%)	2455 (13,34)	1035 (11,9)	1420 (14,62)	<i>P</i> <0,001
Charlson Index, mean (SD)	5,72 (2,95)	5,63 (2,95)	5,80 (2,95)	<i>P</i> <0,001
Stay, mean (SD)	10,94 (11,6)	10,76 (11,6)	11,1 (11,77)	<i>P</i> =0,051

The solid tumor adjusted rate during the study period was 647,53/10⁵ inhabitants/yr (366,97/10⁵ in women and 1792,99/10⁵ in men; relative risk men:women =4,8). This rate increased from 305,65/10⁵ in 1999 to 993,19/10⁵ inhabitants/yr in 2015 (814,06/10⁵ in 1999 to 2535,5/10⁵ in 2015 in men and from 181,68/10⁵ in 1999 to 607,71/10⁵ in 2015 in women). The annual age-adjusted rate increased significantly: 7,37% (6,52% in men and 8,02% in women; *p*≤0,001). Figure 1.

Conclusion: There was an increasing incidence of hospital admissions due to solid tumors in RA in Spain during the period 1999-2015. An annual rate increase of 7.37%, is estimated.

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an elevated cardiovascular (CV) disease risk, mostly explained by both an increased prevalence of traditional CV risk factors and the presence of systemic inflammation that accelerates atherosclerosis. There is accumulating evidence that anti-inflammatory treatment for RA reduces this CV risk. A non-invasive tool for detecting arterial wall inflammation in atherosclerosis is 18F-Fluorodeoxyglucose-Positron Emission Tomography/Computed Tomography (18F-FDG-PET/CT). In this study we investigated the effect of anti-inflammatory treatment with methotrexate (MTX) and/or adalimumab on arterial wall inflammation in RA assessed by 18F-FDG-PET/CT.

Methods: 18F-FDG-PET/CT was done in patients with active early RA starting MTX (n=25) and active established RA starting adalimumab (n=24) before and after 6 months of therapy, and in osteoarthritis controls (OA; n=29). 18F-FDG uptake in arterial wall was determined by standardized uptake values (SUV). Volumes of interest covering the arterial segment with the highest 18F-FDG were defined to derive the maximum SUV (SUVmax) in the ascending, descending and abdominal aorta and the aortic arch. Global arterial uptake was estimated using the mean SUVmax of the arterial segments.

Results: Mean age was 65±9 for early RA, 61±7 for established RA and 63±5 years for OA controls. Median disease duration was 2.1 (interquartile range (IQR) 1.3-3.3) weeks for early RA and 6.9 (IQR 1.8-13.9) years for established RA. DAS28 was 4.9±1.0 and 4.4±1.0 at baseline and declined to 3.1±1.3 and 2.8±1.4 after 6 months therapy, respectively. At baseline mean SUVmax was 1.86±0.38 for early RA, 1.68±0.43 for established RA and 1.56±0.41 for OA controls. SUVmax tended to decline more in early RA patients when compared to established RA (1.86±0.38 to 1.79±0.43 (-3.7%) and 1.68±0.43 to 1.63±0.43 (-3.0%), respectively). SUVmax in most arterial segments declined after 6 months of therapy (Table 1). The most prominent decline in SUVmax was in the abdominal aorta in established RA patients (-9.8%).

Conclusion: A decline in global arterial SUV max and in most of arterial segments was found in both early and established RA patients after 6 months of MTX and/or adalimumab, suggesting that anti-inflammatory therapy with either MTX and/or adalimumab decreases arterial wall inflammation and thus CV risk in RA.

Table 1. Arterial 18F-FDG uptake

	OA	Early RA			Established RA		
	Baseline	Baseline	6 months MTX	Δ	Baseline	6 months adalimumab	Δ
SUVmax	1.55±0.44	1.82±0.38	1.77±0.38	-2.7%	1.69±0.61	1.60±0.44	-5.3%
ascending aorta							
SUVmax descending aorta	1.57±0.42	1.93±0.53	1.81±0.47	-6.2%	1.65±0.39	1.71±0.47	+3.6%
SUVmax	1.62±0.43	1.84±0.44	1.81±0.58	-1.6%	1.73±0.61	1.56±0.45	-9.8%
abdominal aorta							
SUVmax	1.51±0.48	1.85±0.48	1.76±0.45	-4.9%	1.66±0.40	1.64±0.59	-1.2%
aortic arch							
Mean SUVmax over 4 segments	1.56±0.42	1.86±0.38	1.79±0.43	-3.7%	1.68±0.43	1.63±0.43	-3.0%

Prevalence and Characteristics of Metabolic Syndrome in Men and Women With Early Rheumatoid Arthritis

B. Kuriya, O. Schieir, M.F. Valois, J.E. Pope, G. Boire, L. Bessette, G. Hazlewood, J.C. Thorne, D. Tin, C. Hitchon, S. Bartlett, E.C. Keystone, V.P. Bykerk and L. Barra, on behalf of CATCH investigators.

Background/Purpose: Metabolic syndrome (MetS) increases the risk of cardiovascular disease (CVD) and is highly prevalent in established RA but data on the prevalence in early RA (ERA) are conflicting. Furthermore, there are limited data on potential differential expression of MetS by sex in RA. Our aim was to estimate the prevalence and characteristics of MetS among men and women with ERA.

Methods: The Canadian Early Arthritis Cohort (CATCH) is a multicenter observational study of ERA patients. Participants (n=1536) with confirmed ERA (symptoms <12 months) and complete baseline data for MetS components were included to estimate the prevalence of MetS according to the 1999 World Health Organization definition, requiring ≥2 of 5

Figure. Prevalence of MetS at baseline by age group and sex.

components (BMI ≥ 30 , or BP $\geq 140/90$, or HDL level ≤ 1.0 mmol/L in women or ≤ 1.0 mmol/L in men, or triglyceride level ≥ 2.0 mmol/L, or random glucose ≥ 6.1 mmol/L). Sex-stratified logistic regression was used to identify clinical, laboratory and treatment variables associated with MetS.

Results: The study sample was 71% female, mean age was 54 (SD 15) years, mean DAS28-ESR at cohort entry was high 5.1 (SD 1.4) and the majority was treated with csDMARDs (87%), at or before, the baseline visit. At baseline, 462 (30%) met criteria for MetS; prevalence was higher in men 180 (41%) than women 282 (26%); $p < 0.0001$. Age and sex stratified prevalence of MetS is shown in the Figure. The most frequent MetS components in men were hypertension (60%), glucose intolerance (39%), obesity (BMI ≥ 30 , 36%) and low HDL (36%); and in women were hypertension (47%), obesity (30%) and glucose intolerance (23%). These components were all significantly higher in men than women ($p < 0.05$). In univariable analysis, MetS was significantly associated with higher mean uric acid, creatinine and alanine aminotransferase levels in women; and higher mean creatinine in men. These associations were no longer significant after adjustment in multivariable logistic regression.

Conclusion: The prevalence and characteristics of MetS were different in male and female ERA patients. Further investigation is needed to determine if different strategies for CVD risk management in men and women with ERA and MetS is required.

Figure. Prevalence of MetS at baseline by age group and sex.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of coronary artery disease (CAD), but the association with heart failure (HF) is less characterized. We aimed to identify factors associated with HF risk among patients with RA.

Table. Characteristics of rheumatoid arthritis patients according to incident heart failure status

	No heart failure N = 8,970 (94.5%)	Incident heart failure N = 522 (5.5%)	P*
Baseline at RA diagnosis			
Age, years	58 (46, 65)	63 (54, 71)	< 0.001
Female	76	73	0.06
White	89	96	0.06
Coronary Artery Disease	2.9	12.3	< 0.001
Atrial Fibrillation	1.2	5.3	< 0.001
Hypertension	64	75	< 0.001
Dyslipidemia	23	30	< 0.001
Chronic Kidney Disease	1.1	2.9	0.001
Diabetes mellitus	11	20	< 0.001
Body mass index, kg/m ²	28 (24, 33)	29 (25, 34)	0.009
Heart rate, bpm	78 (71, 86)	79 (70, 89)	0.08
Pulse pressure, mmHg	50 (40, 60)	55 (48, 68)	< 0.001
Creatinine, mg/dl	0.81 (0.70, 0.98)	0.90 (0.77, 1.12)	< 0.001
Statin	19	23	0.012
Anti-platelet	16	23	< 0.001
Anti-hypertensive	32	59	0.002
Ever Use of Medication			
Non-biologic DMARD	83	67	< 0.001
Anti-TNF	45	28	< 0.001
Antimalarial	42	35	0.11
Other biologic/small molecule DMARD	17	6.9	< 0.001
Systemic Corticosteroid	50	81	< 0.001

Values are percentage or median (25th, 75th percentiles). DMARD = disease-modifying anti-rheumatic drug. TNF = tumor necrosis factor. *Unadjusted.

Methods: Using the Vanderbilt University Medical Center electronic health record, we retrospectively identified 9,492 adult RA patients (median age 56 years, 76% female, 89% white) without prevalent HF at RA diagnosis. RA diagnosis was defined as ≥ 2 RA specific ICD-9 codes (714.0-714.2) that were ≥ 14 days apart and an anti-rheumatic medication prescription. Medication categories were: non-biologic disease modifying anti-rheumatic drug (DMARD) [azathioprine, cyclophosphamide, leflunomide, methotrexate, sulfasalazine]; anti-tumor necrosis factor (TNF) [adalimumab, certolizumab, etanercept, golimumab, infliximab]; antimalarial [chloroquine, hydroxychloroquine, quinacrine]; other biologic/small molecule DMARD [abatacept, anakinra, rituximab, tocilizumab, tofacitinib]; and systemic corticosteroid. Incident HF was defined as ≥ 1 ICD-9 code (428.x or 425.x) with diuretic use within 90 days. The associations between demographic, clinical factors, and medications with the risk of incident HF were quantified with multivariable-adjusted logistic regression.

Results: Over a median 5.0 (range: 0.1 to 27) years of follow-up, a total of 522 RA patients (5.5%) developed incident HF (Table). Increasing age, CAD, a trial fibrillation, as well as higher body mass index, heart rate, pulse pressure, and creatinine at baseline (first RA ICD-9 code) were each associated with greater HF risk (Figure). The risk of HF varied by use of anti-rheumatic medication class before HF. Non-biologic DMARDs, other biologic/small molecule DMARDs, and systemic corticosteroids were associated with lower HF risk, $p \leq 0.001$ for all. Anti-TNF agents and antimalarials were not associated with the risk of HF, $p \geq 0.10$ for both.

Conclusion: RA patients are at risk for HF. Established cardiovascular disease or traditional risk markers are associated with increased risk. Anti-rheumatic medications variably associate with HF risk, with lower risk observed among patients taking non-biologic or other biologic/small molecule DMARDs or systemic corticosteroids.

Increased Concentration of Large Very Low Density Lipoprotein Particles Associates with Progression of Carotid Atherosclerosis in Rheumatoid Arthritis

Ilana Golub¹, Jennifer Wang², Ani Shahbazian¹, John Moriarty¹ and Christina Charles-Schoeman³, ¹University of California, Los Angeles, Los Angeles, CA, ²University of California Los Angeles, Los Angeles, CA, ³Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a marked increase in cardiovascular (CV) morbidity and mortality compared to the general population. Conventional lipid profiles are insufficient to stratify CV risk in this population, and may not capture many of the lipoprotein abnormalities which predispose to atherosclerosis (ATH). Nuclear magnetic resonance (NMR) spectroscopy simultaneously quantifies the number, size, and composition of lipoprotein particles, providing a better understanding of the modifications in each lipoprotein. The current work investigated the relationship of lipoprotein profiles by NMR spectroscopy with progression of carotid ATH in a longitudinal cohort of patients with RA.

Methods: The study population included 119 RA patients who had carotid ultrasounds performed at 2 time points separated by a mean \pm SD of 5.5 ± 1.2 years at a single academic center. The number and type of carotid plaques were assessed, and an ATH score provided by the same radiologist for all scans. Fasting blood was collected for lipoprotein analysis, inflammatory markers, and lipoprotein particle profiles measured by NMR spectroscopy (Liposcience Inc. Raleigh, North Carolina, USA). Traditional cardiovascular risk factors, medication use, and RA disease characteristics were assessed for all patients at baseline and follow-up visits.

Results: In RA patients without baseline carotid ATH, mean large very low density lipoprotein (VLDL) particle concentrations were significantly higher in patients with incident plaque formation over the follow-up period, compared to patients without incident plaque formation ($p < 0.05$). Similar trends were noted in evaluation of all RA patients with plaque progression regardless of baseline ATH status. In multivariate analysis controlling for significant traditional CV risk factors, RA disease characteristics, medication use, and the presence of carotid plaque on baseline ultrasound, large VLDL concentrations remained significantly associated with increased risk of carotid plaque progression measured by ≥ 1 unit increase in carotid ATH score ($p < 0.05$). Similar results were noted when defining ATH progression by ≥ 1 new carotid

plaque from the baseline scan. Triglyceride levels were also significantly associated with plaque progression in univariate analysis, but did not remain significant in multivariate analysis. Mean total, LDL, and HDL cholesterol levels were not associated with carotid ATH progression in this cohort.

Conclusion: The current work suggests a relationship between large VLDL particles and cardiovascular risk in RA patients as assessed by the progression of carotid ATH over 5 year longitudinal follow-up. Further CV outcome studies may be warranted to determine if large VLDL particles are a useful biomarker of CV risk in patients with RA.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular diseases (CVDs) are a worldwide health problem, with an increased risk in Rheumatoid Arthritis (RA) due to its inflammatory context, comorbidities and the use of risk medications as corticosteroids or NSAIDs. The introduction of biological therapies and new therapeutic strategies have emerged in the last decades implying an important change in the management and evolution of RA, and also a greater awareness among rheumatologists about cardiovascular risk. However, the trend of CVDs in RA in Spain is unknown. Our objective was to analyze the incidence and trend of hospital admissions for CVDs in patients with RA in Spain during the period between 1999 and 2015.

Methods: We performed an observational retrospective population study analyzing the Spanish national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA during the period 1999 to 2015. We selected the MBDSs for CVDs, myocardial infarction (MI), ischemic heart disease (IHD), congestive heart failure (CHF), cerebrovascular disease (CeVD) and aortic aneurysm (AA). Cases were identified by the presence in primary and secondary diagnosis of ICD 9 codes. The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence of RA of 0.5% (0.8% in women and 0.2% in men). Crude and adjusted rates of the selected CVDs were calculated, and the trend was analyzed using the Generalized Linear Model (GLM) with the year as the analysis variable. Statistical analysis was made using SPSS statistical package version 20 (SPSS Inc, Chicago, IL).

Results: 338,343 RA hospital admissions were detected in the period, being 207,597 (61.3%) due to CVDs. Table 1 summarizes the data of the six subgroups of CVDs along the seventeen years period. Mean age was similar in all groups. Deaths during admission were greater in CHF and CeVD. AA group presented the lowest diabetes mellitus percentage. Age-adjusted rates during the period for all groups were greater in men than in women: Relative Risk (RR) around 2 in CVD, CHF and CeVD, around 5 in MI and IHD, and 12 in AA. An annual increase in all group rates was found with an estimation of 5-7% in CVD, MI, IHD, CHF and CeVD and 9% in AA. Table 1. Trends data of cardiovascular diseases in Spanish Rheumatoid Arthritis in-patients during 1999-2015 period. Age adjusted rates expressed as rate per 10⁵ inhabitants/year. SD standard deviation. CI 95% confidence interval 95%.

Conclusion: CVDs were the first cause of hospital admissions in Spain in RA patients during the period 1999-2015. Moreover, in that period there was an increasing incidence of hospital admissions due to CVDs in all the studied

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Early atherosclerotic lesions appear as non-calcified plaques (NCP) on a non-invasive coronary artery evaluation by computed tomography angiography (CCTA). Advanced,more vulnerable lesions appear as mixed/ partially calcified plaques (MP) or calcified plaques (CP). We evaluated the role of inflammation, medication exposure and cardiac risk factors (CRFs) on NCP generation and progression in RA patients with a follow-up evaluation of coronary anatomy with CCTA.

Methods: Ninety-nine participants underwent a repeat CCTA assessment within 83±3.6 months. All coronary lesions were counted and characterized as NCP, MP, or CP; prevalence, number, stenotic severity and burden of individual NCP plaques on both baseline and follow-up scans was recorded. Patients were subsequently classified into four groups according to plaque disposition: NCP-negative (no NCP at any time), NCP-positive (NCPpresent at both times), disappearing-NCP (present at baseline, absent at follow-up), or new-NCP (absent at baseline, present at follow-up). A Multinomiallogistic regression model evaluated predictors independently associated with classification of patients into the respective NCP groups compared to the NCP-negative group.

Results: Overall NCP prevalence was lower at follow-up compared to the baseline assessment (26.5% vs. 52.4%, p<0.001, table 1); 21 of 99(21%) patients showed disappearance or development of new NCP lesions. In the NCP-positive group, 68% of the follow-up NCP plaques derived from original NCP lesions, with the vast majority (93%) displaying identical

Table 1. Changes in numbers of all and NCP coronary plaques from baseline scan

NCP-Groups	n	n-total plaques		N (%) NCP plaques		
		baseline	Flu	baseline	Flu	p
NCP-negative	35	26	52	0 (0%)	0 (0%)	-
NCP-positive	43	113	154	74 (62.7%)	62 (40.3%)	0.038
Disappearing NCP	17	43	40	24 (55.8%)	0 (0%)	<0.001
New NCP	4	0	7	0 (0%)	5 (71.4%)	0.048
All	99	187	253	98 (52.4%)	67 (26.5%)	<0.001

Table 2. Predictors of dynamic change of coronary non-calcified plaque in RA.

Group	Predictors	OR (95% CI)	p-value
NCP-negative		Ref	ref
NCP-positive	AUC-CRP	0.94 (0.90-0.99)	0.016
	Statin exposure (years)	1.21 (1.0-1.43)	0.046
Disappearing NCP	AUC-CRP	0.95 (0.90-1.01)	0.11
	Statin exposure (years)	1.26 (1.01-1.58)	0.04
New NCP	AUC-CRP	1.01 (0.67-1.05)	0.63
	Statin exposure (years)	0.97 (0.77-1.19)	0.40

stenotic severity and burden; 29% were incident NCP plaques. Of baseline NCP lesions, 18% receded. In the disappearing group, 75% of the original NCP plaques receded, whereas 16% transitioned to more stable calcified plaques (CP). Patients in the NCP-positive group displayed lower cumulative inflammatory burden [area under the curve for c-reactive protein (AUC-CRP), $p=0.016$] and longer duration of statin exposure compared to the NCP-negative ones (table 2, $p=0.046$). NCP disappearance was mostly predicted by lengthier statin exposure ($p=0.04$).

Conclusion: Lower inflammatory burden and longer statin exposure inhibit NCP growth or progression to more advanced, vulnerable plaques. Lengthier statin exposure may further induce regression of such early atherosclerotic lesions.

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In early atherogenesis inflammation drives and co-localizes with intimal calcification. In chronic, advanced plaques inflammation and calcification are inversely correlated and spatially distinct; advanced calcification is considered a stabilizing physiologic process rendering plaques less prone to rupture. We evaluated the role of inflammation, biologic treatments and cardiac risk factors on the de-novo generation and progression of advanced, calcified coronary plaques (CP) in patients with rheumatoid arthritis (RA).

Methods: Ninety-nine participants with a baseline non-invasive evaluation of coronary anatomy with computed tomography angiography (CCTA) underwent a repeat assessment within 83 ± 3.6 months. Coronary lesions were counted and defined as non-calcified (NCP), mixed (MP) or calcified (CP). The prevalence, number, stenotic severity and burden of individual CP plaques was recorded. Patients were classified into three groups according to plaque disposition: CP-negative (no CP at any time), CP-positive (CP present at both times), and new-CP (absent at baseline, present at follow-up). A Multinomial logistic regression model evaluated predictors independently associated with patient classification into the CP-positive or New-CP groups compared to the CP negative group.

Table 1. Changes in numbers of all and NCP coronary plaques from baseline scan

CP-Groups	n	n-total plaques		N (%) CP plaques		p
		baseline	FU	baseline	FU	
CP-negative	61	56	61	0 (0%)	0 (0%)	-
CP-positive	18	80	105	38 (43.6%)	61 (58.1%)	0.44
New-CP	20	40	76	0 (0%)	45 (59.2%)	<0.001
Disappearing-CP	2	11	11	2 (18.2%)	0 (0%)	0.46
All	99	187	253	37 (19.8%)	106 (41.8%)	<0.001

Table 2. Predictors of dynamic change of coronary non-calcified plaque in RA

Groups	Predictors	OR (95% CI)	p-value, n/
CP-negative	Age	1.36 (1.13-1.62)	<0.001
	Diabetes	8.03 (0.80-809.26)	0.076
	Hyperlipidemia	12.51 (1.45-106.31)	0.022
	Erosions	0.60 (0.13-6.18)	0.62
	AUC-CRP	1.10 (1.03-1.19)	0.008
CP-positive	Biologic exposure (years)	0.78 (0.54-1.14)	0.20
	Age	1.18 (1.07-1.31)	0.001
	Diabetes	0.29 (0.02-4.15)	0.33
	Hyperlipidemia	0.96 (0.28-3.39)	0.93
	Erosions	0.17 (0.04-0.73)	0.017
New-CP	AUC-CRP	1.08 (1.03-1.14)	0.002
	Biologic exposure (years)	1.21 (1.03-1.57)	0.030

Results: CP prevalence was higher at follow-up compared to baseline (42.3% vs. 19.8%, $p<0.001$, table 1); 21 of 99 (21%) patients developed new CP lesions. In the CP-positive group, 43% of the lesions at follow-up were unchanged from baseline, 16% derived from progression of MP, 3% from NCP and 23% were incident CP lesions. In the New-CP group, 73% of lesions were incident CP, 13% derived from NCP and 13% from MP. CP-positive patients were older, with greater baseline hyperlipidemia and higher inflammatory burden [area under the curve for c-reactive protein (AUC-CRP), $p=0.008$] compared to the CP-negative ones (table 2). New CP subjects were older, had greater frequency of baseline erosions, higher inflammatory burden ($p=0.002$) and lengthier biologic exposure ($p=0.015$) vs. the CP-negative group.

Conclusion: Higher inflammatory burden promotes generation, maturation and early calcification of coronary plaques in patients with RA. Higher duration of biologic exposure, through systemic and/ or local inflammatory control, fosters advanced calcification and stabilization of atherosclerotic plaques.

Predictors of Change in Coronary Plaque Burden and Composition in Patients with Rheumatoid Arthritis

George Karpouzas¹, Sarah Ormseth², Elizabeth Hernandez² and Matthew Budoff³, ¹Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, ²Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, ³Cardiology, Harbor-UCLA Medical Center, Torrance, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported higher prevalence, burden and more vulnerable occult coronary plaque composition in patients with rheumatoid arthritis (RA) compared to age and gender-matched non-autoimmune disease controls. We now explore the predictors of change in coronary atherosclerosis burden and plaque composition in RA patients with a follow-up non-invasive interrogation of coronary anatomy.

Methods: One hundred participants with a baseline 64-slice coronary computed tomography angiography (CCTA) for atherosclerosis interrogation, underwent a follow-up assessment in a mean of 83±3.6 months. Plaque load was evaluated with 3 quantitative scores: segment involvement score (SIS) reflected the number of segments with plaque; segment stenosis score (SSS) reported the cumulative stenosis grade conferred by plaque over all evaluable segments and the plaque burden score (PBS) described the cumulative plaque size over all evaluable segments. Plaque composition was defined as non-calcified (NCP), mixed (MP) or calcified (CP). Coronary artery calcium score (CAC) was quantified by the Agatston method. Multivariate linear and logistic regression models evaluated independent determinants of change in total, NCP, MP and CP plaque burden; multinomial logistic regression models compared predictors of individual plaque type burden progression or regression against non-progressors.

Results: Total plaque burden increased in 41%, remained stable in 41% and decreased in 18%. Duration of prednisone exposure in-between studies, and age independently predicted total plaque burden change (all p<0.05). NCP regression was predicted by lower prednisone and higher statin duration exposure, whereas NCP progression was forecasted by longer prednisone and shorter biologic DMARD inter-scan exposure, older age, and higher prevalence of HTN compared to

*p<0.05 **p<0.01 ***p<0.001

non-progressors (all $p < 0.05$). CP-progressors were older, with higher cumulative inflammatory burden [area under the curve for c-reactive protein (AUC-hsCRP)], more obese and with greater prevalence of hypertension, and (all $p < 0.05$) than non-progressors. Finally, CAC increase was independently predicted by older age, hypertension and cumulative inflammatory burden (all $p < 0.05$).

Conclusion: Cardiac risk factors, inflammation and duration of exposure to medications such as prednisone, biologics and statins significantly and differentially impacted coronary plaque burden and composition change over time in RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Atherosclerotic plaque calcification is considered a stabilizing physiologic process; calcified coronary plaques (CP) are less prone to rupture and yield lower risk of cardiovascular events compared to non-calcified (NCP) or the more vulnerable partially calcified, mixed plaques (MP). Interestingly, higher coronary artery calcium score (CACS) and its progression associate with higher event risk in general patients. Likewise, we reported that CACS predicted cardiac events in rheumatoid arthritis (RA) patients independently of risk factors or cardiac risk scores. To address this paradox, we evaluated the contribution of MP burden to CACS as well the influence of change in MP burden on CACS progression in RA patients with a baseline and follow-up evaluation of coronary anatomy with computed tomography angiography (CCTA).

Table 1. Contribution of Mixed and Calcified plaque burden and their change on CACS and its change over time in patients with rheumatoid arthritis

	Model 2				
	SSS-MP change	.314	.010		
Change (Follow-up - Baseline)	SSS-CP change	.538	.000		
	Age	.341	.008		
	Gender	-.053	.53		

Model 1: Unadjusted; Model 2: age and gender adjusted

Beta: standardized coefficient; RW: Relative Weight; Raw RWs indicate the contribution of each predictor in a model for the total variance explained (sum to R^2) after accounting for the effects of intercorrelations among variables; Rescaled RWs represent the % contribution of each predictor to the total explainable variance; 95% CI: 95% Confidence Interval

Methods: Ninety-nine patients underwent a repeat CCTA within 83 ± 3.6 months from baseline. Total number of segments with plaque (segment involvement score-SIS) and cumulative stenosis severity rendered by plaque over all evaluable segments (segment stenosis score-SSS) we computed for all participants. Coronary lesions were defined as non-calcified (NCP), mixed (MP) or calcified (CP). Generalized Linear Models predicted the contribution of MP and CP plaque burden to the baseline and follow-up CACS as well as the influence of change in the burden of the respective lesions on CACS progression.

Results: Mixed and calcified plaque burden (SSS-MP and SSS-CP respectively) strongly correlated with CACS at both baseline ($r_{mp}=0.75$ and $r_{cp}=0.77$, $p<0.001$) and follow-up ($r_{mp}=0.57$ and $r_{cp}=0.68$, $p<0.0001$), whereas non-calcified plaque did not ($r_{ncp}=-0.03$, $p=0.85$ and -0.16 , $p=0.30$ respectively). Both MP and CP burden comparably and significantly contributed to CACS magnitude at both times; MP accounted for 36.5% and 38.5% of explainable variance in CACS while CP accounted for 63.5% and 61.5% of it at baseline and follow-up respectively. Likewise, change in MP and CP burden from baseline to follow-up significantly contributed to and justified 27% and 73% of explainable CACS change variance respectively.

Conclusion: The vulnerable MP and the more stable CP burden and their change significantly and collectively contributed to CACS at any time as well its progression respectively in patients with RA. Therefore, the MP burden and its change epitomize the vulnerability components within the higher baseline and progressing CACS scores yielding higher cardiovascular event risk.

Waist Circumference Based Abdominal Obesity Versus Body Mass Index in Rheumatoid Arthritis: Influence on the Risk of Diabetes and Cardiovascular Disease

Gulsen Ozen¹, Sofia Pedro² and Kaleb Michaud^{1,2}, ¹Rheumatology, University of Nebraska Medical Center, Omaha, NE, ²FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipose tissue deposited around the mesentery is highly associated with insulin resistance and cardiovascular disease (CVD). Compared to BMI, waist circumference (WC) has been shown to be a better marker of adiposity around the abdomen in the general population. However, it is not known if it is similarly associated with CVD and type 2 diabetes (T2D) in RA patients. We sought to determine whether WC is a better T2D and CVD predictor than BMI.

Methods: RA patients with ≥ 1 year participation in FORWARD, National Databank for Rheumatic Diseases without baseline T2D from 1998 through 2017 were assessed for T2D (self-report or initiating of antidiabetic medication) and CV events (myocardial infarction, stroke and heart failure validated from hospital/ death records). WC was measured by the patients according to World Health Organization (WHO) 2008 measurement guideline. $WC \geq 102$ cm in men and ≥ 88 cm in women was considered as abdominal obesity. BMI was categorized according to WHO classification. Cox proportional hazard models with adjustment for sociodemographics, comorbidities, RA severity measures and treatment (DMARDs and glucocorticoids) constructed to estimate T2D and CVD risk. WC and BMI were evaluated in different models. WC and BMI interaction in the same model was also assessed.

Results: The study included 2,177 RA patients (mean [SD] age 66 [12] years) of which 28% were obese ($BMI \geq 30$ kg/m²) and 52% had abdominal obesity. During a median (IQR) 5.9 (2.6-11.1) years of follow-up, 229 incident T2D cases and 94 CV events were observed. The incidence rate (95%CI) of T2D was slightly higher in obese patients than patients with abdominal obesity (33.4 [27.8-40.1] vs. 24.1 [20.6-28.2]); but, CVD incidence (8.6 [6.5-11.1] vs. 8.7 [6.1-12.4]) was similar. In adjusted models both obesity (HR 1.86 [1.33-2.59]) and abdominal obesity (HR 1.59 [1.19-2.13]) were significantly associated with incident T2D, however the risk with obesity was higher than the abdominal obesity. For the CVD, neither BMI based obesity nor WC based abdominal obesity were significantly associated with increased risk (Table). When women and men analyzed separately, abdominal obesity was a more prominent predictor of T2D in women (HR 1.75 [1.25-2.44]) than men (1.05 [0.54-2.06]). In analysis of interaction of BMI and WC in normal weight and overweight patients, abdominal obesity in the presence of normal weight tended to increase the T2D risk.

Conclusion: Both BMI based obesity and WC based abdominal obesity were strong risk factors for T2D in RA patients but BMI predicted T2D better. Neither of them was associated with CVD. Obesity in RA can have a paradoxical effect in RA in terms of mortality which might be areas on why obesity and abdominal obesity were not associated with CVD, the leading cause of death in RA. Regardless, WC measurement in RA might be helpful in particularly nonobese female patients to estimate T2D risk.

Table. Association of waist circumference and body mass index with incident type 2 diabetes and cardiovascular disease in RA patients

	Type 2 Diabetes		Cardiovascular Disease

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Screening and management of hyperlipidemia in rheumatoid arthritis(RA) is suboptimal, despite RA patients' high risk for cardiovascular disease(CVD) mortality. Our purpose was to identify barriers to screening for hyperlipidemia among patients with RA from the viewpoint of primary care physicians (PCPs) and rheumatologists.

Methods: We recruited rheumatologists and PCPs nationally to participate in moderated, structured group teleconference discussions using the nominal group technique. The groups had either only PCPs or only rheumatologists. Participants generated lists of barriers to screening and management for hyperlipidemia in patients with RA, within the same session. Each participant was allowed 6 votes to rank items: 3 votes for the most important item, 2 for the second most important, and 1 to the third most important. Investigators characterized items and totaled the votes as themes and sub-themes.

Results: Twenty-six rheumatologists participated in 1 of 3 groups (group size ranged from 7-11) and 22 PCPs participated in 1 of 3 groups(group size ranged from 4-9). The items generated across the 6 separate groups were categorized into physician-, patient- and system-level barriers. Table 1 lists the barriers for hyperlipidemia screening and Table 2 lists the barriers for management of hyperlipidemia for both rheumatologists and PCPs.

The largest number of barriers for rheumatologists were at the physician level (e.g. 'ownership' of hyperlipidemia screening and management), with 83% of the priority votes for screening and 89% for treatment. Patient-level barriers received the majority of votes among the PCPs groups (44% for screening and 69% for management).

Table 1: Screening for hyperlipidemia: List of themes and sub-themes of barriers for rheumatologists and primary care physician (PCPs) to screen patients with RA, with their respective priority votes

<i>Category</i>	<i>Subcategory</i>	<i>Rheumatologist (% votes)</i>	<i>PCP (% votes)</i>
Physician Level	Total Votes	83.0	42.5
	Lack of time	34.0	1.7
	Conflict regarding ownership of hyperlipidemia screening	25.9	10.8
	Lack of training and knowledge of hyperlipidemia guidelines	17.9	19.2
	Focus only in RA	4.9	--
	Physician prioritization of RA symptomology over preventive measures	--	10.0
	Lack of physician knowledge about RA	--	0.8
Patient Level	Total Votes	7.5	44.2
	Effect of RA and its treatment	2.5	9.2
	Patient prioritization of RA symptomology over preventive measures	2.5	9.2
	Patient expectations	1.9	--
	Patient already on multiple medications	0.6	0.0
	Side effects of RA medications and RA drug interactions	0.0	--
	Comorbidities	0.0	--
	Patient's barriers with transportation	0.0	--
	Multiple blood draws	0.0	8.3
	Side effects of statins and drug interactions with statins	0.0	5.0
	Barriers from the patient	--	0.0
	Poor patient compliance with medical care	0.0	9.2
	Patients' lack of awareness of CVD risk	--	3.3
System Level	Total Votes	9.9	13.4
	Lack of care coordination	6.8	11.7
	Financial barriers (limited insurance coverage, cost of repeating labs)	3.1	--
	Lack of financial incentive for screening	--	1.7

Note: RA = rheumatoid arthritis; CVD = cardiovascular disease; 0% = that sub-theme emerged during the brainstorming session but did not receive votes; "--" = the sub-theme did not emerge in the respective group.

Conclusion: Our data showed that rheumatologists are conflicted about whether management of CVD risk reduction strategies among patients with RA should fall within the role of the rheumatologist or PCP. PCPs are more concerned about the overall effect of RA and its treatment in the context of screening and managing hyperlipidemia. These findings improve our understanding of why RA patients are not consistently screened and treated for hyperlipidemia. To address this gap, there is a need to develop strategies that clarify the specific roles of the PCP and rheumatologist and develop solutions that target key barriers.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Congestive heart failure (CHF) is a major contributor to morbidity and mortality in patients with rheumatoid arthritis (RA). Myocardial disease is typically clinically silent, only manifesting as myocardial dysfunction after an extended preclinical phase. Feature-tracking (FT) cardiac magnetic resonance (CMR) imaging can be used to assess early left ventricular (LV) dysfunction. It is critically important to differentiate between the effects of disease and those of biological treatment on LV regional function, since this distinction may have important implications for long-term management of RA. This study aimed to assess LV regional function in RA patients and to determine the impact of biological treatment using global circumferential and longitudinal strain values, assessed by CMR.

Methods: RA patients and controls without cardiac symptoms were enrolled, and those with no history and/or clinical findings of systemic and pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent non-contrast CMR. Patients with RA were administered non-biologic disease-modifying antirheumatic drugs (nbDMARDs) or biologic DMARDs (bDMARDs). All subjects underwent evaluation of LV regional function, as measured by CMRI. LV global longitudinal peak systolic strain (GLS) is a prognostic indicator of adverse cardiovascular outcomes in various patient populations, and global circumferential peak systolic strain (GCS) is a predictor of CHF in the general population. GLS and GCS were calculated in the 16 LV segments. Group comparisons were made using the Wilcoxon rank sum test, Fisher's exact test, and Steel test where appropriate.

Results: We compared 100 patients with RA (86% women; mean age, 55.3±10.3 years) with 30 healthy controls (100% women; mean age, 55.7±4.5 years). No statistically significant differences in cardiovascular risk (CV) factors were observed in the characteristics between the patients and the healthy controls. GCS was significantly reduced by 27% in the RA group compared to controls (p=0.017). Furthermore, GCS was significantly lower by 17% in the nbDMARD group than in the bDMARD group (p=0.035). GCS in the RA group was associated with the Simplified Disease Activity Index (SDAI) (p=0.05). GCS in the RA group was not associated with CV risk factors or other RA status. GLS in the RA group was significantly reduced by 22% compared to the control group (p=0.027). GLS in the RA group was not associated with CV risk factors or RA status. GLS was lower by 16% in the nbDMARD group than in the bDMARD group (p=0.049). GLS tended to be associated with the SDAI.

Conclusion: This prospective study assessed LV regional dysfunction in RA, using global circumferential and longitudinal strain values on CMR. Subclinical LV regional dysfunction of GCS and GLS was prominent in RA patients without cardiac symptoms. Biologic treatment may normalize LV regional dysfunction, associated with a reduction in disease activity in RA patients.

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and systemic disease with high cardiovascular (CV) risk. Carotid intima-media thickness (CMT) is an independent surrogate marker of subclinical atherosclerosis. Several instruments may underestimate CV risk in RA (1). Objectives: to describe demographic and clinical characteristics, CV risks and carotid ultrasound (US) measurements; to assess the differences among three RA-groups according to CMT and to assess the usefulness of CV risk scores as predictors of higher CMT.

Methods: All patients fulfilled 1987 ACR and/or 2010 ACR/EULAR classification criteria. Subjects between 40-75 years old were included. CV risk was calculated by seven scales. Carotid US was performed by an on-call-certified radiologist and reviewed by two radiologists. Carotid plaque (CP) = CMT ³0.12 cm or a ³50% focal increase of CMT compared to the surrounding normal arterial wall. Three RA-groups were created according to CMT.

Results: One hundred RA-patients were included, demographic data are in figure 1. CMT: 25 had <0.079 cm (group 1), 38 had 0.08-0.09 cm (group 2) and 37 had CMT ³0.09 cm (group 3). Six scores had statistically significant result. The highest sensitivity to detect increased CMT was obtained by SCORE-moderate risk (75.7%) and the highest specificity was 100% with Framingham-lipids-high risk.

Conclusion: CIMT can be used as an independent surrogate marker of subclinical atherosclerosis in RA-patients. Different CV risk scores did not predict the presence of CP.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Screening for cardiovascular (CV) disease in patients with rheumatoid arthritis (RA) remains controversial, however, there is agreement in considering echocardiography as the most immediate and simple approach to obtain reliable markers of right ventricle (RV) performance. (1) When RV systolic function adaptation fails, the RV becomes uncoupled from pulmonary circulation and dilates to preserve flow output at a price of systemic congestion. It has been reported that evaluation of RV functional state by using the relationship between the tricuspid annular plane systolic excursion (TAPSE) and the pulmonary artery systolic pressure (PASP) as a surrogate for the RV length-force, is of clinical prognostic relevance. (2) Objective: Assess RV function by TAPSE/PASP ratio in RA-patients and as compared to controls.

Methods: A case-control study with Hispanic RA-patients aged 40 to 75 years that fulfilled the 2010 ACR/EULAR criteria and matching controls were included. Exclusion criteria: poor acoustic window, prior atherosclerotic CV disease and overlap syndromes. Patients were matched using age, sex and CV comorbidities. Transthoracic echocardiogram was performed by a board-certified cardiologist, and reviewed by two cardiologists. TAPSE was measured as the total displacement of the tricuspid annulus (mm) from end-diastole to end-systole and PASP was estimated using the modified Bernoulli equation, according to ASE's guidelines.

Results: A total of 76 RA-patients and 52 matched controls were included. Demographic and clinical characteristics of both groups are shown in Table 1. As shown in Table 2, the mean TAPSE/PASP ratio was significantly lower in RA-patients than controls (0.89 ± 0.29 vs 1.02 ± 0.28 , $P=0.016$). TAPSE/PASP ratio showed significant correlation with age ($r=-0.24$, $P=0.03$) and null correlation with disease duration ($r=0.2$, $P=0.08$) and DAS 28-CRP ($r=0.05$, $P=0.69$).

Conclusion: TAPSE/PASP was reduced in RA-patients compared to controls. This ratio correlates with RA-patients age. TAPSE/PASP estimated by echocardiography may detect early RV dysfunction in RA. Larger studies are needed to determine the utility of TAPSE/PASP ratio to detect CV disease in Hispanic RA-patients.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the last several years a higher prevalence of heart failure has been described in Rheumatoid arthritis (RA) patients, particularly heart failure with preserved ejection fraction (HFpEF). Elevated left atrial pressure (LAP) may not only be a pathophysiologic substrate of symptoms in patients with HFpEF, it may also be direct prognostic markers.(1) Several studies have emphasized the importance of left atrial function in RA-patients. (2) Objective: to compare the LAP and diastolic left ventricle (LV) filling patterns between RA-patients and controls.

Methods: A case-control study with RA patients aged 40 to 75 years that fulfilled the 2010 ACR/EULAR criteria and matching controls were included. Exclusion criteria: poor acoustic window, prior atherosclerotic cardiovascular (CV) disease and overlap syndromes. Patients were matched using age, sex and CV comorbidities. Transthoracic echocardiogram was performed by a board-certified cardiologist, and reviewed by two cardiologists. LAP was estimated using the Nagueh-formula [$1.24 * (E/E') + 1.9$] and ASE's guidelines were used to define elevated LAP and diastolic LV filling patterns.

Results: A total of 80 RA-patients and 54 matched controls were included. Demographic and clinical characteristics are shown in Table 1. As shown in Table 2, the mean LAP was not significantly higher in RA-patients than controls (12.9 ± 3.6 vs 12.2 ± 2.5 , $P=0.18$). The difference between elevated LAP prevalence was not significant among both groups (8.8% vs 5.6% , $P=0.49$). Abnormal diastolic LV filling pattern was more prevalent in RA-patients compared to controls. LAP showed null correlation with disease duration ($r=0.06$ $P=0.64$) and DAS 28-CRP ($r=0.01$ $P=0.93$).

Conclusion: Left atrial pressure values were not different in Hispanic RA-patients evaluated when compared to controls and did not correlate with disease activity and duration. RA-patients had abnormal relaxation more frequently than controls.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis increases the risk of cardiovascular disease (CVD). Less is known about the direct influence of CVD on RA outcomes, but higher comorbidity burden has been suggested to adversely affect RA treatment response. We tested our hypothesis that CVD risk factors (RFs) alone, in the absence of CVD, are associated with higher disease activity and disability in RA.

Methods: The Ontario Best Practices Research Initiative (OBRI) is a clinical registry of RA patients followed in routine care. RA subjects with complete data to calculate disease activity according to the Disease Activity Score-28 (DAS28), Clinical Disease Activity Index (CDAI), 28 swollen joint count (SJC28) and functional status (Health Assessment Questionnaire Disability Index [HAQ-DI]) at cohort entry were selected. Patients were divided into mutually exclusive groups by baseline CVD status as: (1) no CVD/no CVD RFs; (2) CVD; (3) no CVD but CVD RFs including hypertension (HTN), dyslipidemia (DLP), diabetes (DM), or smoking. We performed separate linear regression analyses, adjusted for baseline clinical and demographic variables, to determine the independent effect of CVD status on disease outcomes at baseline.

Results: Of 2033 patients examined, 54% had no CVD, 5% had CVD and 41% had CVD RFs alone. The most common RF was HTN (23%) followed by current smoking (17%), DM (12%) and DLP (5%). The majority had 1 CVD RF (34%) with decreasing frequency of 2 (8%), 3(2%) or all 4 (0.3%) risk factors. Subjects with CVD or CVD RFs were significantly older, had less education, higher ESR, higher joint counts, higher pain scores and greater number of non-CVD comorbidities. In cross-sectional analyses, having a CVD RF was associated with significantly higher composite disease activity scores (DAS28 and CDAI), and HAQ-DI scores (Table). No association between CVD status and swollen joint count was observed.

Conclusion: Even in the absence of CVD, traditional CVD risk factors are associated with greater RA disease severity and disability. Self-perceived impact of comorbidity (patient global assessment of health) may be driving this relationship. Investigation into the magnitude of effect for the individual CVD RFs, and whether differences in RA treatment patterns by CVD status may mediate this relationship is warranted. This will help determine if CVD RFs are truly poor prognostic markers for RA outcomes.

Table. Multivariable linear regression of disease activity outcomes and functional status at baseline according to CVD status.

	β - coefficient (95% CI); p-value			
	DAS28-ESR	CDAI	SJC-28	HAQ-DI
No CVD / No CVD RFs	Ref	Ref	Ref	Ref
CVD	0.39 (0.03, 0.75); 0.03	2.29 (-0.85, 5.43); 0.15	0.76 (-0.39, 1.92); 0.20	0.15 (-0.19, 0.31); 0.08
CVD RFs / No CVD	0.28 (0.11, 0.44); 0.001	1.70 (0.25, 3.14); 0.02	0.39 (-0.14, 0.92); 0.15	0.20 (0.12, 0.27); <0.0001

Models adjusted for age and gender; furthermore, variables that were significantly associated with both CVD status and disease outcomes were also considered (e.g. education, other comorbidities, annual household income, and health insurance coverage)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease associated with an increased cardiovascular (CV) risk that is already present at the time of diagnosis. However, it is unclear at what point in the period before diagnosis of RA the CV risk increases. Therefore, we assessed CV risk factors and the 10-year risk of CV mortality in a cohort of subjects at risk for RA and analyzed associations with anti-citrullinated protein antibody (ACPA) status and arthritis development.

Methods: In a cohort of 555 consecutive arthralgia patients with positivity for rheumatoid factor (RF) and / or ACPA, demographics, medical history, medication use and comorbidities were assessed. Lipid profile was determined and blood pressure was measured. The 10-year CV risk according to the European Heart SCORE was calculated for patients of whom data were complete.

Results: ACPA positive patients (n=348) were younger (mean age 48.3 vs 51.5, p=0.002), had higher CRP levels (median 2.3 mg/l vs 2.0, p=0.007) and had lower cholesterol (mean level 5.2 mmol/l vs 5.6, p<0.001), HDL (mean level 1.0 mmol/l vs 1.2, p<0.001) and LDL levels (mean level 3.5 mmol/l vs 3.7, p=0.021) than ACPA negative patients. Patients who developed arthritis (n=188) had a higher heart rate (68 beats per minute vs 63, p=0.048) and lower cholesterol (mean level 5.2 vs 5.5, p=0.006), HDL (mean level 1.0 vs 1.1, p=0.003) and ApoB levels (mean level 0.8 g/l vs 0.9, p=0.011) compared to patients who did not develop arthritis. In ACPA positive patients, lower LDL was predictive for the development of arthritis.

The European Heart SCORE was calculated in 144 patients (median 1, IQR 0-2). 43.8% had a low risk (SCORE<1%), 48.7% a medium risk (SCORE 1-<5%) and 7.7% had a high to very high 10-year risk (SCORE ≥ 5%) of cardiovascular mortality. The Heart SCORE was not associated with ACPA status or arthritis development.

Conclusion: Similar lipid abnormalities as known in RA patients with untreated disease were also present in seropositive arthralgia patients at risk for RA. In ACPA positive patients, LDL predicted development of arthritis. However, arthralgia patients who developed arthritis did not have a higher CV risk score than those who did not develop arthritis. Also, despite differences in lipid profile, the CV risk score does not differ between ACPA positive and ACPA negative patients at risk for RA. Overall, differences in lipid profile were too small to have an effect on the 10 year risk of CV mortality as calculated by the European Heart SCORE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients have an elevated risk of cardiovascular (CV) disease unexplained by traditional CV risk factors. Markers of systemic inflammation, including those elevated in RA, are associated with increased plaque vulnerability. Neovascularization of the vasa vasorum (VV) is a key early feature of vulnerable plaque that is also associated with inflammation in the general population. RA-related factors may promote vulnerable plaques with increased VV neovascularization, leading to elevated CV risk. Microbubble contrast-enhanced ultrasound (CU) is a novel technique validated for quantifying VV neovascularization, which is not measured by traditional imaging techniques. Increased carotid adventitial vasa vasorum density (aVVD) indicates increased plaque vulnerability. We use CU to measure and compare aVVD in RA subjects and non-RA control subjects. We further examine correlations of aVVD with biomarkers of inflammation and atherosclerosis.

Methods: We performed a cross-sectional study of RA (n=87) and non-RA control subjects (n=101). All RA patients met 2010 ACR classification criteria. Subjects were assessed for traditional cardiovascular risk factors. Nitrite, CD40L, E-selectin, MMP-9, ICAM-1, VCAM-1, CRP, and ESR were measured in serum. CU was performed along the common carotid arteries bilaterally. CU images were analyzed using Myocardial Contrast Echocardiography 2.9 software. aVVD was quantified as the ratio of mean common carotid artery adventitial to lumen video intensity using maximum of both sides. Demographic data, CV risk factors, and biomarker levels were compared between RA and control subjects using Wilcoxon rank-sum or chi-square tests. Association of aVVD with biomarkers and CV risk factors, stratified by case status, was examined using Pearson and Spearman correlation, respectively, and linear regression models adjusted for number of CV risk factors and age.

Results: RA subjects were older (59.6 ± 12.0 versus 56.1 ± 14.8 years; $p = 0.01$) and had higher number of CV risk factors (40.2% versus 20.6% had ≥ 3 risk factors; $p = 0.003$) compared to controls. aVVD was higher in RA subjects (0.64 ± 0.14 versus 0.61 ± 0.15 ; $p = 0.02$). In RA subjects, MPO was lower (422.8 ± 516.4 versus 604.4 ± 455.1 ng/mL; $p = 0.0002$) and ESR was higher (21 ± 16 versus 16 ± 13 mm/hr; $p = 0.01$). The other biomarkers did not differ significantly between groups. aVVD was correlated with MPO ($r = -0.33$, $p = 0.001$) and CRP ($r = 0.25$, $p = 0.02$) in control subjects, associations which remained significant after adjusting for number of CV risk factors and age. No significant correlations were found between aVVD and biomarkers in RA patients. Number of CV risk factors was not significantly correlated with aVVD in RA and controls.

Conclusion: Using the novel CU technique, we found that aVVD is significantly higher in RA compared to control subjects, suggesting CU may quantify increased plaque vulnerability in RA patients with subclinical atherosclerosis. The differences in correlation of aVVD with biomarkers of atherosclerosis and traditional CV risk factors between RA and control subjects suggests RA-related differences in atherosclerotic progression.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the incidence and risk factors implicated in the development of first cardiovascular event (CVE) in patients with chronic inflammatory rheumatic diseases (CIRD) attending rheumatology clinics after 2.5 years of follow-up.

Methods: Analysis of data after 2.5 years of follow-up in an observational prospective study [CARDiovascular in rheumatology (CARMA) project] that includes a cohort of patients with CIRD [rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA)] and another cohort of matched individuals without CIRD attending outpatient rheumatology clinics from 67 hospitals in Spain. The cumulative incidence per 1000 patients and the incidence density per 1000 patient-months of non-fatal CVE were estimated in both cohorts at 2.5 years from the start of the project. Weibull proportional hazard model was used to calculate the Hazard Ratio (HR) and 95% confidence interval (95% CI) of the risk factors involved in the development of CVD events. Losses to follow-up and their causes were also analyzed.

Results: The total number patient who completed the follow-up visit at 2.5 years was 2,598 (89.2% of those who started the study). Seven patients had died due to CVE and 23 because of non-CVE. The higher number of losses to follow-up was found in the control group (15.81%), because many of them were not periodically follow-up at the outpatient clinics. Cardiovascular cumulative incidence in patients with CIRD 15.30 cases per 1000 patients (95% CI: 12.93-17.67), being higher in AS patients 22.03 (95% CI: 11.01-33.04). The higher risk of developing a first CVE during the 2.5 years of follow-up was in patients with AS (HR: 4.11, 95% CI: 1.07-15.79; p: 0.04), those with older age (HR:1.09; 95% CI: 1.05-1.13, p <0.001), higher systolic blood pressure (HR: 1.02; 95% CI: 1.00-1.04, p = 0, 01) and longer duration of the rheumatic disease (HR: 1.07; 95% CI: 1.03-1.12), p <0.01). In contrast, female gender was a protective factor (HR: 0.43; 95% CI: 0.18-1.00, p = 0.05).

Conclusion: Patients with AS prospectively followed-up at rheumatology outpatient clinics show higher risk of developing a first CVE than those with RA or PsA. Besides traditional CVD risk factors a longer time course of the disease is a risk factor for the development of CVD in patients with CIRD.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Since low serum IGF1 is generally attributed to inflammation and RA severity, we analyze if serum levels of IGF1 is associated with cardiovascular (CV) risk in women with rheumatoid arthritis (RA).

Methods: The risk of developing of CV disease within 10 years was calculated in a cohort of 184 female RA patients (median age 53 years, range 21-71) with no history of CV events, using the Framingham strategy. A 5-year follow-up of new CV events was completed by a structured interview in all the patients. The reported CV events were confirmed through the Swedish National Patient Register. The CV risk and CV event-free survival curves were compared with respect to serum IGF1 levels, where IGF1 levels below the median of the total cohort were considered low.

Results: The RA women with low IGF1 (n=96, median 110 pg/ml) had significantly higher CVR compared to those with normal IGF1 (n=88, median 181 pg/ml) with the predicted risk of 7.2 % and 3.3 %, respectively (p<0.001). In age-adjusted groups, CVR was significantly higher in females ≤50 years with low IGF1 (p<0.001). At 5-year follow up, 12 (6.5%) patients experienced CV event. A Kaplan-Meier analysis showed that the CV events occurred with higher frequency in the patients with low IGF1 at baseline (p=0.029). After 5 years the risk of having experienced a cardiovascular event was 5 times higher in patients with low IGF1 at baseline (RR 4.583; CI95% 1.033-20.34; p=0.027). At baseline the IGF1 low group had high prevalence of hypertension (24% vs. 8.5%, p=0.004) and higher BMI (p=0.008). The atherogenic index (total cholesterol/HDL) (2.8 vs 3.0) and smoking (15% vs. 14%) was similar between the groups. With exception for disease duration, the groups were similar in RA-related CVR factors as seropositivity (91% vs 92%), disease activity measured by DAS28 (median 3.20 vs 2.90), or systemic inflammation measured by serum IL6 and IL1b. The prevalence of treatment with MTX monotherapy was higher in the IGF1low group (56% vs. 39%, p=0.024), while the use of TNFi and other biologics was similar within the groups.

Conclusion: Female patients with RA, IGF1 levels in the normal low range are associated with higher CVR and experienced higher frequency of CV events. This increase in CV disease seems to be independent of the RA-related characteristics.

Cardiovascular Risk Management in Seropositive Rheumatoid Arthritis: What Can We Do Better?

Matthew McElwee¹, Peter Boersma², Hiba Hashmi³ and Anna K. Shmagel¹, ¹Division of Rheumatic and Autoimmune Diseases, University of Minnesota, Minneapolis, MN, ²School of Public Health, University of Minnesota, Minneapolis, MN, ³School of Medicine, University of Minnesota, Minneapolis, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The increased risk of cardiovascular disease (CVD) in rheumatoid arthritis (RA) has been well established. While the reasons for an increased risk of CVD in RA remain unclear, it is imperative to carefully manage cardiovascular risk factors in RA patients. The purpose of this study was to compare CVD risk management in seropositive RA patients compared with non-RA patients in a large healthcare system.

Methods: The study design was a matched retrospective cohort comparing subjects with seropositive RA and non-RA patients drawn from the outpatient population receiving care within the Fairview Health System in Minnesota between 1/1/2005 and 12/31/2015. A cohort of 732 adult subjects with seropositive RA was identified from electronic medical records, and matched with a cohort of 2994 non-RA patients based on age and sex. Demographic characteristics and multiple clinical measures of cardiovascular risk, including BMI, outpatient blood pressure, smoking status, serum lipids and hemoglobin a1c, were ascertained from electronic medical record. Mortality was assessed from medical and state records. Chi-square tests were used for categorical variables and t-tests or Wilcoxon-Mann-Whitney tests for continuous variables. Generalized estimating equation models were used for longitudinal analyses.

Results: The mean age at baseline was 56 years in both RA and non-RA cohorts, and the majority of patients were female (79% RA, 80% non-RA). Participants in the two cohorts were largely white (82% RA, 85% non-RA), and overweight or obese (baseline BMIs of 25 or greater in 69% RA, and 71% non-RA patients). RA patients, on average, lived in zip codes with a lower median household income than non-RA patients (65,100 vs 67,700, $p<0.01$). Patients had a minimum of one year follow up (mean 6 years RA, 5.7 years non-RA). There were more deaths in the RA cohort than non-RA cohort during the follow-up period (15% vs 10%, $p<0.01$). RA patients and non-RA patients, on average, had blood pressure readings, cholesterol and A1C measurements in the normal range, and there was no difference in these parameters between cohorts in longitudinal analyses. Mean systolic blood pressure was 125 and mean diastolic blood pressure was 73 in both RA and non-RA patients. Mean HDL, LDL, Total cholesterol, and A1C were 55 ± 1 , 104 ± 2 , 188 ± 2 , and 6.7 ± 0.1 , respectively, for RA patients and 53 ± 0.4 , 103 ± 1 , 183 ± 1 , and 6.9 ± 0.05 for non-RA patients. However, there was a higher percentage of current smokers among RA patients (24% vs. 14%, $p<0.01$).

Conclusion: While most CVD risk factors were well managed in seropositive RA patients and in non-RA controls, we found an excess of active smoking in RA patients compared with the non-RA cohort, indicating an area of potential practice improvement.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite dramatic change in treatment options in recent years, cardiovascular disease (CVD) mortality has not improved in rheumatoid arthritis (RA) and remains the leading cause of mortality in RA. Rates of screening and treatment for modifiable CVD risk factors in RA remains poor (27-45%). The primary objective was to evaluate baseline cardiovascular risk awareness (CVRA) in patients with RA.

Methods: Consecutive patients at two academic centers with a diagnosis of RA of at least 3 months' duration were enrolled. Patients completed questionnaires on demographics, RA characteristics, active treatment and CVRA. CVRA was measured using the Heart Disease Knowledge Questionnaire (HDKQ; 30 items), and the Heart Disease Fact Questionnaire- RA (HDFQ-RA; 13 items). Descriptives for the study group and total correct response rates (%) were obtained for each tool. We then performed linear regression analysis with demographics (age, gender, ethnicity, and race), disease features (RA medications, RAPID3) and lifestyle (self-reported smoking and sedentary status) as independent variables to assess for correlates of CVRA.

Table 1 Cardiovascular risk awareness (CVRA) in rheumatoid arthritis patients	
Baseline CVRA items with <50% correct response rate	
Heart Disease Knowledge Questionnaire-RA	
	AR (n=167)
Women are less likely to get heart disease after menopause than before.	48.1
Having had rheumatoid arthritis increases the risk of getting heart disease.	58.5
The most important cause of heart attacks is stress.	55.7
Smokers are more likely to die of lung cancer than heart disease.	46.1
The healthiest exercise for the heart involves rapid breathing for a sustained period of time.	43.1
Sudden trouble seeing in one eye is a common symptom of having a heart attack.	37.2
Atrial defibrillation is a procedure where hardened arteries are opened to increase blood flow.	36.5
Margarine with liquid soyflower oil is healthier than margarine with hydrogenated soy oil.	34.7
Men and women experience many of the same symptoms of a heart attack.	40.1
Total Mean	60
Total SD	19
Heart Disease Fact Questionnaire	
	AR (n=167)
Anti-inflammatory medications such as diclofenac or ibuprofen taken by patients with rheumatoid arthritis may increase their chance of heart disease.	28.3
Having lots of inflammation ("flares") of rheumatoid arthritis adds to the increased chance of heart disease.	40.1
Total Mean	75
Total SD	19

Table 2. Predictors of baseline CVRA

HDKQ: Heart Disease Knowledge Questionnaire, HDFQ-RA: Heart Disease Fact Questionnaire Rheumatoid Arthritis

Results: 167 RA patients participated. Mean (SD) age was 57.6±13.8 years; 87% were women. Thirty-seven percent were Caucasian and 40% African American. Forty-three percent were taking NSAIDS routinely, 60% methotrexate, and nearly 50% were on some dose of corticosteroid. Mean (SD) RAPID3 score was 11.8 (7.6). Self-reported CVD risks were: smoking (18%), hypertension(44%), diabetes mellitus (25%), High cholesterol (44%), overweight (46%), sedentary lifestyle (45%) and poorly controlled RA (48%).

Mean (SD) total correct response rates for HDKQ and HDFQ-RA at baseline were 60 (19) and 75 (19). For individual items, the correct response ratio was less than 50 for 9/30 HDKQ, and 2/10 HFFQ-RA items. Of note, participants performed poorly on the two items (role of NSAIDS and active RA) pertaining specifically to RA and increased CVD risk (Table 1). Determinants of poor CVRA on univariate analysis were less education, Hispanic ethnicity and Non-Caucasian Race (Table 2). On multivariate analysis, education was the sole independent predictor of CVRA, after adjusting for race, ethnicity, lifestyle and medication (Table 2).

Conclusion: General and RA specific understanding of CVRA is poor among RA patients. Education (not ethnicity/ race, or RA activity and medications) was the sole independent predictor of CVRA after adjusting for other variables. Interventions to improve CVRA should target those at risk and they need to be aligned to their educational level.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased urinary albumin excretion (UAE) is an early marker of renal microvascular damage that correlates with cardiovascular risk and corresponds to a state of generalized microvascular impairment, even below the threshold values usually considered for microalbuminuria (30-300 mg in a 24h urine sample). However, data regarding prevalence of microalbuminuria are conflicting in patients with rheumatoid arthritis (RA), a disease characterized by excess cardiovascular risk. Moreover, it remains unclear whether it corresponds to a state of generalized microvascular dysfunction in this particular group of patients. We investigated for the first time whether microalbuminuria is associated with other forms of microvascular impairment located in the dermal capillary network, the retinal and the coronary microvasculature.

Methods: 24h urine samples were obtained from RA and non-RA individuals to estimate UAE. Morphological changes in the retinal microvasculature were evaluated from retinal photography. Retinal images were processed with specifically designed computerized software that calculates retinal arteriolar and venular diameters, to obtain central retinal arteriolar equivalent (CRAE) and central retinal venular equivalent (CRVE), as well as their ratio (arteriovenous ratio, AVR). Functional assessment of the coronary artery network was based on measurement of the subendocardial viability index (SEVR), a non-invasive estimate of microvascular coronary perfusion, using radial artery applanation tonometry. Dermal capillary rarefaction was evaluated with nailfold capillaroscopy applied in the distant phalanx of the fingers, using semi automated software that calculates capillary density in the obtained images.

Results: A total of 111 individuals were studied, of whom 74 were RA patients with long-standing disease [9 (4–16.5) years], moderate disease activity (DAS score: 3.6 ± 1.4), and relatively low levels of systemic inflammation, and 37 were matched controls. Patients with RA presented narrower retinal arterioles, shown by decreased CRAE (78.0 ± 8.9 vs 87.4 ± 10.0 μm , $p < 0.001$) and AVR (0.69 ± 0.10 vs 0.78 ± 0.10 , $p < 0.001$); impaired coronary microvascular perfusion, shown by decreased SEVR (140.6 ± 22.3 vs 150.7 ± 21.6 %, $p = 0.038$), and pronounced capillary rarefaction, reflected in a lower number of dermal capillaries per visual field (132.5 ± 28.2 vs 151.2 ± 25.6 , $p = 0.007$), compared to controls. By contrast, neither UAE [5.1 ($2.8 - 10.8$) vs 6.5 ($3.0 - 11.7$) mg/24h] nor prevalence of microalbuminuria (11.0 vs 8.1%) differed between patients and controls ($p = \text{ns}$ for both). In the RA group, UAE was not significantly associated with inflammation or other disease-related parameters, nor with any of the studied microvascular indices of the coronary microcirculation, the retinal microvasculature, and the dermal capillary network.

Conclusion: In our population of RA individuals, microalbuminuria was not associated with morphological and functional alterations in distal microvascular beds. Increased UAE in RA patients might be primarily considered as a manifestation of compromised function of the renal microvasculature, rather than a marker of generalized microvascular dysfunction.

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Effects of Statin-treatment on Coronary Plaques in Patients with Inflammatory Joint Diseases

Background/Purpose: Statins have an established preventive effect on coronary artery disease in the general population. The effect of statins on coronary plaque progression and characteristics in patients with inflammatory joint diseases (IJD) is unknown. Our aim was to evaluate the change in coronary atherosclerosis in long-term statin-treated patients with IJD.

Methods: Sixty-eight patients with IJD and carotid artery plaque(s), underwent coronary computed tomography angiography before and after 4.7 (range 4.0-6.0) years of statin treatment. The treatment target for low density lipoprotein cholesterol (LDL-c) was ≤ 1.8 mmol/L. Changes in coronary artery calcification (CAC) and coronary artery plaque volume (calcified, mixed/soft and total) from baseline to follow-up were assessed using the 17-segment model of the American Heart Association. Linear regression analysis was used to identify predictors of atherosclerotic progression.

Results: Coronary plaques were present in 42% of the patients at baseline and in 51% at follow up. Mean CAC score increased with 173 ± 284 , calcified plaque volume with 39.4 ± 78.3 mm³ and total plaque volume with 22.8 ± 54.6 mm³ ($p < 0.01$, for all) (Figure 1). Mean mixed/soft plaque volume decreased with -10.4 ± 27.5 mm³ ($p < 0.01$). At follow-up, 51% of the patients had obtained LDL-c treatment target. Compared to patients above LDL-c target, patients with an LDL-c ≤ 1.8 mmol/L experienced reduced median progression of both CAC (21 [2-143] vs. 69 [16-423], $p < 0.01$) and total plaque volume (0.08 [-1.0-13.9] vs. 13.0 [0.0-60.8], $p = 0.02$) (Table 1).

Conclusion: We revealed a progression of atherosclerotic plaque volume in statin-treated patients with IJD, mainly due to calcifications. However, soft, unstable plaques were reduced, probably as a result of an alteration in plaque composition from mixed/soft plaques into calcified, stable plaques. Patients with recommended LDL-c levels at follow-up experienced a reduced atherosclerotic progression compared to patients with LDL-c levels above the treatment target. Our results support the importance of treatment to guideline recommended lipid targets in IJD patients.

Cardiometabolic Risk Factors Impact on the Cardioprotective Effect of Apelin on Systolic and Diastolic Function, in Patients with Rheumatoid Arthritis

Sulé Gunter¹, Lebogang Mokotedi², Monica Gomez², Linda Tsang², Aletta Millen³ and Patrick Dessein², ¹Department of Health Sciences, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa, ²Department of Health Sciences, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa, ³Department of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The rheumatoid arthritis (RA) population demonstrate a significantly increased incidence of cardiac events. Cardiac dysfunction in RA may occur as a result of impaired filling during diastole, or as contractile insufficiency (systolic dysfunction). Chronic systemic inflammation may be the underlying cause of cardiac alterations, and also impact significantly on traditional cardiovascular risk profiles. Apelin is an endogenous peptide known for its vasoactive effects, inotropic action and general cardioprotective function. Apelin may prove to be particularly beneficial within the RA population.

This study aimed to determine the association of apelin concentrations with measures of cardiac geometry, systolic and diastolic function, independent of traditional risk factors and inflammation in RA patients.

Methods: 186 RA patients were included, where demographic, anthropometric and RA disease characteristics were recorded. Cardiac structure and function was assessed using two-dimensional directed M-mode echocardiography, Pulsed Doppler, and tissue Doppler imaging. Circulating cytokine concentrations were determined using immunoturbidimetric methods. Apelin-13 concentrations were quantified using a solid-phase sandwich ELISA technique. The association of apelin concentrations with stroke volume, ejection fraction, endocardial and midwall fractional shortening, relative wall thickness, left ventricular mass, mitral inflow (E/A), lateral and septal e', left ventricular filling pressures (E/e'), and left atrial volume index (LAVI) were determined in comprehensively adjusted multivariate and backward regression analyses.

Results: Apelin concentrations were not independently associated with cardiac geometry, diastolic or systolic function ($p > 0.05$) in all patients. Body mass index impacted on apelin-ejection fraction and apelin-fractional shortening relations (interaction $p = 0.02$, for both), and hypertension impacted on apelin-E/A ratio, apelin-stroke volume, apelin-ejection fraction, apelin-endocardial fractional shortening and apelin-midwall fractional shortening relations (interaction $p = 0.03$, $p = 0.01$, $p = 0.02$, $p = 0.01$ and $p = 0.03$, respectively). In stratified analyses, apelin was associated with improved ejection fraction and endocardial fractional shortening in patients with a BMI $\geq 25 \text{ kg/m}^2$, but not in those with a BMI $< 25 \text{ kg/m}^2$. Apelin concentrations were associated with an improved E/A ratio (partial $r = 0.31$; $p = 0.04$), stroke volume (partial $r = 0.29$; $p = 0.03$), ejection fraction (partial $r = 0.39$; $p = 0.01$), endocardial fractional shortening (partial $r = 0.40$; $p = 0.003$) and midwall fractional shortening (partial $r = 0.31$; $p = 0.02$) in hypertensive but not normotensive patients.

Conclusion: Apelin concentrations are associated with improved active relaxation in hypertensive patients only. The inotropic effects of apelin is paradoxically increased in the presence of adverse metabolic risk factors. The vasoactive and cardioprotective effects of apelin may be particularly beneficial in those with adverse cardiometabolic risk profiles.

Marginal Structure Modeling of Association between Disease Activity and Hospitalized Infection Among Patients in a Rheumatoid Arthritis Registry

Huifeng Yun¹, Lang Chen¹, Jason Roy², Jeffrey D. Greenberg³ and Jeffrey R. Curtis¹, ¹University of Alabama at Birmingham, Birmingham, AL, ²University of Pennsylvania, Philadelphia, PA, ³Hopital Hautepierre, Strasbourg, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Background/Purpose: Higher disease activity might be associated with a higher risk of developing infections among patients with rheumatoid arthritis (RA). Since no randomized trial has been conducted using disease activity as the main exposure, this association may be confounded due to the effects of other RA treatments or comorbidities. To examine the association between RA disease activity and hospitalized infection using data from the U.S. Corrona RA registry linked to Medicare claims data for outcome ascertainment. We hypothesized that patients who started in moderate disease activity and subsequently attained low disease activity or remission had lower rates of infection.

Methods: Using CORRONA RA patients with Medicare coverage in 2006-2014, we identified eligible patients who had at least one visit with moderate disease activity based on the clinical disease activity index (CDAI between 10 and 22). Hospitalized infection was assessed in Medicare data. Follow-up started at the second Corrona visit and ended at the earliest date of: hospitalized infection, high disease activity (CDAI >22), loss to follow-up, or 12/31/2014. We calculated the incidence rate of hospitalized infection for patients in remission, low and moderate disease activity and estimated the effect of CDAI on hospitalized infection by controlling for time-dependent confounders using marginal structural models (MSM). Each observation was weighted using stabilized inverse-probability-of-treatment weights (IPTW), truncated at the 1st and 99th percentile.

Results: A total of 1,618 RA patients were eligible for analysis, for which 212 hospitalized infections were identified over mean follow-up of 2.2 years. These patients had mean (SD) age of 69.0 (10.0) years and 77.2% were female. The crude incidence of hospitalized infection was 4.0 per 100 person years for patients in remission, 7.1 for low disease activity and 7.5 for moderate disease activity. Using MSMs, and referent to being in remission, the hazard ratio of hospitalized infection associated with moderate disease activity was 1.19 (95% CI: 0.42-3.42) and for low disease activity was 0.78 (95% CI: 0.37-1.67). Baseline factors that were significantly associated with an increased risk for infection included older age, duration of RA, glucocorticoid use, and history of hospitalized infection.

Conclusion: In rheumatoid arthritis patients, the crude incidence of hospitalized infection was higher for patients in low or moderate disease activity compared to those in remission. However, these differences were greatly attenuated after controlling for confounding using marginal structural models to account for the interplay of disease activity, RA treatments, treatment switching, and other potential confounders.

Table: Events, absolute incidence rate and hazard ratios of hospitalized infection by disease activity

Disease activity	Events	Incidence rate per 100 person years	Unadjusted Hazard Ratio (95% CI) without weight*	Adjusted HR (95% CI) without IPTW weighting**	Unadjusted HR (95% CI) with stabilized weights†	Adjusted HR (95% CI) with stabilized weights†

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of infections particularly respiratory infections. These may be augmented due to RA itself and to immunosuppressive drugs, specially biologic therapy. Vaccination programs are designed to decrease infections. In RA patients underwent to Vaccination program previously to start a new or a change in biologic therapy from October 2011; our aim was to assess the incidence of severe respiratory infections and to determine the underlying basal risk factors for the development of these complications.

Methods: Retrospective study of 401 patients diagnosed with RA who were invited to participate in a protocolled vaccination program from October 2011 to October 2016 in a referral center. The follow-up was made until June 2017 with a minimum follow-up period of 8 months and maximum of 5.5 years. Serious infections were defined as those that required hospitalization or at least one dose of intravenous antibiotic treatment at the emergency room. Information was retrieved from the hospital records. Only 7 patients refused vaccination (2%). Information was not obtained in 4 of the remaining 394 patients. Therefore, these 4 patients were not included in the assessment.

Results: We finally studied 390 patients (307♀/83♂), mean±SD age 61.28±12.9 years that were vaccinated and followed-up. The main features at the time of vaccination were: median diseased duration (4 years), positive rheumatoid factor (56.7%), subcutaneous nodules (4.9%), erosive arthritis (36.9%), pulmonary fibrosis (3.8%), secondary Sjögren syndrome (5.1%), other extraarticular manifestations (14.6%) and rheumatoid vasculitis (5.6%). Most patients had received immunosuppressive drugs before the vaccination program. The most frequently used were systemic corticosteroids (n=228), methotrexate (n=362) and biologic agents (40.3%). During the follow-up, 42 patients (10.7%) had required hospital admissions due to infections, 17 of them were severe respiratory infections (4.35%). The remaining 25 admissions were in the setting of urinary tract infections (n=12), intraabdominal infections (7), skin and soft tissues (12) and articular (1). Also 12 of these patients had zoster herpes. The presence of anti-citrullinated protein antibodies (ACPA) was associated with an increased frequency of admissions due to these infections (TABLE). It was also the case for the presence of a history of biologic therapy prior to vaccination. No association of severe respiratory infection with rheumatoid factor, erosions or pulmonary fibrosis was found.

Conclusion: Vaccinated patients with RA present a low incidence of severe respiratory infections. Positivity for ACPA and the use of biologics prior to vaccination are associated with increased risk of severe respiratory infections in these patients. Therefore, vaccination should be performed prior to the onset of biologic treatment.

TABLE.

Admission for severe respiratory infections	Crude OR (CI 95%)	p	Adjusted OR* (CI 95%)	p
RF positivity	2.13 (0.67 – 6.83)	0.2011	2.26 (0.69-7.84)	0.1799
ACPA positivity	3.73 (1.04-13.43)	0.0441	4.49 (1.2-16.83)	0.0259
Erosions	2 (0.71-5.64)	0.1898	2.16 (0.75-6.25)	0.1573
Rheumatoid vasculitis	1.48 (0.40-5.42)	0.5527	1.38 (0.37-5.22)	0.6336
Pulmonary fibrosis	4.27 (0.87-20.91)	0.2932	2.45 (0.46-13.05)	0.2932
Biologic treatment before vaccination	3.02 (1.01-9.02)	0.0476	2.61 (0.85-8.07)	0.0947

The Lung in an English Cohort of Rheumatoid Arthritis Patients – an Overview of Different Types of Involvement and Treatment

Ana Catarina Duarte¹, Maria José Leandro² and Joanna Porter³, ¹Rheumatology Department, Hospital Garcia de Orta, Almada, Portugal, Almada, Portugal, ²Center for Rheumatology, University College London, London, United Kingdom, London, United Kingdom, ³Department of Respiratory Medicine, University College London, London, United Kingdom, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lung disease is described in 5–20% of pts (pts) with RA and affects parenchyma, pleura, airways and vasculature; drug-induced pulmonary disease also occurs. It is associated with a higher mortality and identification of safe and effective drugs is essential.

Methods: Retrospective analysis of the electronic records from RA cohort followed at University College Hospital. Lung involvement was based on high resolution computed tomography. Demographic data, smoking status, complementary exams at baseline/follow-up and therapies used were analysed. A sub-analysis of pts treated with rituximab (RTX) evaluated response at 12, 24 and 36 months. Declines of 15% in gas transfer from baseline and/or 10% in forced vital capacity were recognized.

Results: From 1129 RA pts, 87 (7.7%) had documented lung involvement. Mean age at last follow-up was 68.3±12 years, 74.7% were female and 85.1% Caucasian. Median diseased uration was 14 (IQR 8-29) years. 54% of pts had erosive disease. RF was positive in 88.1% and ACPA in 87.8%. 23 pts had positive ANAs (25 missing data) and 4 anti-Ro52, 2 anti-Scl70, 2 anti-PL12. Secondary SS occurred in 6.9%, cutaneous rheumatoid nodules in 5.7% and cutaneous vasculitis in 1.1%. 11.5% and 43.7% were current and previous smokers, respectively. Mean interval between articular and pulmonary symptoms was 12.3 years; 2 pts had lung disease as a prior manifestation. Types of lung involvement are shown in table 1. At last follow-up appointment 22 pts were still on MTX and 27 had previously received it. MTX-acute pneumonitis occurred in 2 pts, both in the 1st year of treatment.

Table 1 – Characterization of different types of lung involvement

	Female	Mean age at lung disease diagnosis (mean±SD)	Interval between RA and lung disease diagnosis (median [IQR])	Smoking habits	Positive RF	Positive ACPA
NSIP (n=18)	61.1%	66.3±12.5	1 [0-15]	76.5%	88.9%	88.2%
UIP (n=18)	61.1%	66.8±13	1 [0-13.5]	52.9%	87.5%	94.1%
OP (n=4)	100%	57±7.1	10 [4.25-21]	25%	100%	100%
Isolated bronchiectasis (n=31)	87.1%	63.7±9.3	17 [5.5-24.5]	45.2%	83.3%	78.6%
Obliterative bronchiolitis (n=2)	50%	74.5±3.5	30.5	50%	50%	100%
Panbronchiolitis (n=2)	100%	48.5±15.5	8.5	50%	100%	100%
Rheumatoid nodules (n=4)*	100%	45.8±11.4	6.5 [2.5-15.75]	75%	100%	75%
Pleural effusion (n=3)*	66.7%	41±9.3	13	66.7%	100%	100%

Note – 5 patients had evidence of interstitial lung disease in high resolution computed tomography, but with an unspecified pattern; 1 patient had evidence of small airways disease secondary to RA without any specific pattern

*1 patient had concomitantly pleural effusion and rheumatoid nodules

Legend: NSIP - nonspecific interstitial pneumonia; UIP - usual interstitial pneumonia; OP – organizing pneumonia

Table 2 – Disease outcomes after treatment with rituximab

Time of reevaluation	12 months			24 months			36 months		
ILD pattern	OP	NSIP	UIP	OP	NSIP	UIP	OP	NSIP	UIP
TLCO stable/ improvement	2/2 100%	7/9 77.8%	1/3 33.3%	1/1 100%	5/5 100%	1/2 50%		2/2 100%	1/2 50%
TLCO decline		2/9 22.2%	2/3 66.7%			1/2 50%			1/2 50%
FVC stable/ improvement	2/2 100%	7/9 77.8%	2/3 66.7%	1/1 100%	4/5 80%	1/2 50%		2/3 66.7%	1/2 50%
FVC decline		2/9 22.2%	3/3 100%		3/5 60%	1/2 50%		1/3 33.3%	1/2 50%
HRCT stable/ improvement		3/3 100%	1/3 33.3%		3/3 100%		2/2 100%	2/2 100%	
HRCT worsening			2/3 66.7%			1/1 100%			

Legend: ILD - interstitial lung disease; NSIP - nonspecific interstitial pneumonia; UIP - usual interstitial pneumonia; OP – organizing pneumonia; TLCO - gas transfer; FVC - forced vital capacity; HRCT - high resolution computed tomography

RTX was used in 26 pts (57.8%) with ILD (14 nonspecific interstitial pneumonia-NSIP, 8 usual interstitial pneumonia-UIP, 2 organising pneumonia-OP). The mean number of cycles was 4 (range 1-12). Two pts were concomitantly receiving MMF and 1 AZA. RTX treatment outcomes are shown in table 2.

In the cohort there were 18 (20.7%) deaths. Seven of them were related to ILD (4 UIP, 3 NSIP) and occurred 8.8 years after the ILD diagnosis. Two were due to infection, but none was felt to be directly related to immunosuppressive therapy.

Conclusion: Lung disease occurred in 7.7% of our cohort, with ILD being the commonest presentation (51.7%).

MTX was widely used in pts with lung disease with only 2 cases of acute pneumonitis. Although the number of ILD-pts treated with RTX was small, the drug improved/stabilized the disease in most NSIP and OP pts. UIP pattern was associated with disease progression, despite RTX, and worse outcome.

Analysis of Sequential Development of Pulmonary Lesions in Patients with Rheumatoid Arthritis

Ayae Tanaka¹, Kazuhiro Kurasawa¹, Yuta Takamura¹, Tomoyuki Miyao¹, Ryutaro Yamazaki², Satoko Arai¹, Takayoshi Owada¹, Reika Maezawa¹ and Masahumi Arima¹, ¹Rheumatology, Dokkyo Medical University, Mibu, Tochigi, Japan, ²Rheumatology, Dokkyo Medical University, Mibu, tochigi, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported that there was patterns of coexistence of pulmonary lesions and airway disease (AD) were common abnormalities of patients with pulmonary involvement. However, it remains unknown through what pathways various pulmonary lesions develop. The purpose of this study was to determine the sequential development of pulmonary lesions in RA. For this purpose, we examined the pattern of newly emerging pulmonary lesions and relationship between pre-existing and new lesions.

Methods: A retrospective cohort study. Subjects were consecutive 208 RA patients who started bDMARDs in our department and received HRCT scan before and during the therapy. Based on HR-CT, pulmonary abnormalities were classified 20 lesions such as ground-glass opacity (GGO), reticular pattern, and bronchiolitis. We recorded their existence

Newly-emerging pulmonary lesions and pre-existing lesions

	Newly-emerging lesions										Total
	ground-glass opacity	consolidation	reticular pattern	interlobular septal thickening	curved linear opacity	nodular pattern	small nodular pattern	bronchiolitis	bronchiectasis		
None	1	2	2	1	3	2	1	6	0		42
ground-glass opacity	-	1	0	0	0	1	0	0	0		12
consolidation	1	-	1	0	0	2	1	0	0		16
reticular pattern	5	4	0	0	2	4	1	2	2		41
bronchiolitis	1	1	1	0	0	1	0	1	1		14
bronchiectasis	1	0	0	0	1	1	0	1	1		5
curved linear opacity	1	0	0	0	-	0	0	1	0		14
nodular pattern	1	4	2	1	1	-	0	2	2		30
small nodular pattern	0	1	2	2	0	1		1	0		23
bronchiolitis	1	5	0	0	0	1	1	-	1		34
bronchiectasis	2	2	0	0	2	1	1	0	2		18
low attenuation areas	1	2	0	0	1	2	1	1	1		28
Total	20	15	6	8	9	11	5	11	11		

Red; >50% of newly emerging lesions, Yellow; >=25% and numbers>2. Overlapping pulmonary lesions were frequently found.

and changes during the therapy. Cluster analysis was conducted according to new lesions by Ward method. A checkerboard analysis of pre-existing and new lesions was conducted.

Results: Subjects were 208 RA patients, M/F; 64/144, mean age; 59.2 years old, disease duration; 7.9 years. bDMARDs used for the longest period were TNF inhibitors in 79.8% of the subjects. Pulmonary abnormalities were found in 146 (70.2%) of RA patients (ILD 81, (38.9%); nodular lesions 45, (21.6%); and AD 115, (55.3%)) at the entry. During the observation period (3.26; 2.61 years), new pulmonary lesions were found in 31.3% of patients and the incidence was 10.0/100-person year. New lesions were frequently occurred in patients with pre-existing pulmonary lesions. Cluster analysis of new lesions showed 7 clusters; Cluster 1: nodular lesions developed mainly patients with AD and reticular pattern, Cluster 2; curved linear opacities with/without reticular pattern which occurs in patients without pre-existing diseases or bronchiolitis with nodules, Cluster 3; bronchiectasis developed in patients with bronchiolitis, Cluster 4; consolidation developed in patients with pre-existing pulmonary diseases, particularly AD, Cluster 5; bronchiolitis occurred in patients with bronchiectasis, Cluster 6; no new pulmonary lesions and Cluster 7; GGO developed in patients with AD and fibrotic ILD. Similarly, a checkerboard analysis of pre-existing and new lesions revealed followings (Fig.1); 1) in patients without pre-existing lesions, bronchiolitis or curved linear opacities occurred, 2) patients with bronchiolitis developed bronchiectasis, 3) reticular pattern occurred in patients with AD (bronchiolitis/bronchiectasis), and 4) patients with AD with reticular pattern developed GGO and/or consolidation.

Conclusion: Pulmonary lesions were developed in several patterns, not at random. Pre-existing pulmonary lesion induced new pulmonary lesions. Airway diseases, particularly bronchiolitis, might be an important lesion that induce ILD (and nodular lesions).

The Prevalence and Clinical Characteristics of Rheumatoid Arthritis with Interstitial Lung Disease in the San Joaquin Valley of Central California

Candice Yuvienco¹, Matthew White², Kyle Heber³ and Ratnali Jain², ¹Internal Medicine, Division of Rheumatology, University of California San Francisco, Fresno Medical Education Program, Fresno, CA, ²Internal Medicine, University of California San Francisco - Fresno Medical Education Program, Fresno, CA, ³IM, UCSF Fresno, Fresno, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disease of systemic inflammation primarily involving the small synovial joints. Approximately 1.5 million adults in the United States have RA. Interstitial Lung Disease (ILD) is present in 35% of RA cases, and pulmonary complications are responsible for 10-20% of RA-related deaths. Currently, the burden of RA-ILD in the San Joaquin Valley is unknown. This study aims to enhance understanding of this unique condition and its representation in our community; consequently creating the framework for a database of RA-ILD patients.

Methods: In this retrospective, case-control study medical records from CRMC, ACC and URA during January 2013-May 2017 were reviewed to identify and analyze subjects with both RA and ILD. Statistical analysis using Pearson's Chi Square and Logistic Regression was employed to compare characteristics of subjects with RA-ILD (cases) to those with ILD alone (controls).

Results: 4767 subjects with ILD were identified. 34 of these were diagnosed with RA, giving RA a prevalence of 0.7% within the ILD population. 528 subjects with RA were identified. 34 of these were also diagnosed with ILD giving ILD a prevalence of 6.4% within the RA population. The majority of RA-ILD subjects were Hispanic males. 50% were smokers with an average of 37 pack years. The majority had been prescribed steroids, with an average maintenance dose of 6mg prednisone daily. All were prescribed a non-biologic DMARD, with hydroxychloroquine being the most common; while only 32% were prescribed a biologic DMARD. CCP and RF were tested in 93% of cases, and 75% were positive. There was a significant relation between RA-ILD and ILD alone with regards to CCP positivity [$X^2(2, N=44)=12.37, p=0.002$], RF positivity [$X^2(2, N=46)=10.73, p=0.005$], steroid use [$X^2(1, N=81)=11.15, p=0.01$], biologic DMARD therapy [$X^2(1, N=81)=11.56, p=0.01$], and non-biologic DMARD therapy ($p<0.001$). Subjects with a positive CCP were 52 times more likely to have RA-ILD than CCP negative subjects (OR 52.01; CI 1.83 - 1473.63; $p=0.02$). RF positivity was also strongly

associated with RA-ILD (OR 16.68; CI 1.25 - 223.16; p=0.03). In both groups, restrictive pulmonary disease was most common. The average % DLCO of the RA-ILD group was 43% whereas that of the control group was 91%.

Conclusion: This investigation elucidated significant clinical characteristics and treatment patterns among RA-ILD patients in the Central Valley. The high rate of CCP positivity in patients with RA-ILD may support that CCP is linked to aggressive RA with more frequent extra-articular manifestations. Further research is needed to investigate the risk of RA development in the ILD population with CCP positivity. Our RA-ILD population may have more severe pulmonary disease compared to ILD alone, reflected by a much lower average %DLCO. Future studies should examine the effects of anti-TNF therapy on pulmonary function in RA-ILD. Routine TB and cocci screening and pulmonary function testing in this population may be indicated as a result of this study. Standardized coding for RA-ILD may improve our ability to capture more patients and increase the sample size, which was a limiting factor in this study.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the extra-articular manifestation that most frequently worsens the course of Rheumatoid arthritis (RA) disease. Purpose: To describe the characteristics of RA patients with ILD. To assess the incidence rate of functional respiratory impairment in these patients.

Methods: This is a longitudinal prospective study. A cohort of RA patients diagnosed of ILD since Feb 2007 until Mar 2018 were recruited and followed up until lost of follow-up or end of study (May 2018) in a multidisciplinary team, carried by a pneumologist and a rheumatologist in a Tertiary Hospital in Madrid. The main variable was functional respiratory impairment: decline in percent predicted FVC of $\geq 10\%$ since the previous visit. Pulmonary function was measured at baseline and in follow-up visits every 3-6 months. Covariables: a) sociodemographic, b) clinical (basal comorbidities, ILD type (non specific interstitial pneumonia [NSIP]; usual interstitial pneumonia [UIP], Others); c) pulmonary function tests (FVC%, DLCO%); d) laboratory tests (ESR, rheumatoid factor, anti-CCP); e) therapy (corticoids, disease modifying antirheumatic drugs (DMARDs) such as Azathioprine (AZA), Mycophenolate, Leflunomide (LEF) and Biologic Agents (anti-TNFs, Abatacept, Rituximab). Survival techniques were used to estimate the incidence rate (IR) of functional impairment, expressed per 100 patient-years with their respective confidence interval [95 % CI].

Results: We included 43 patients, 63% were women, with a mean age at ILD diagnosis of 70 ± 9.6 years. The most frequent comorbidities at baseline were: hypertension (65%), peripheral vascular disease (18.6%), and cerebrovascular disease (13.9%). 42% of the patients never smoked. Rheumatoid factor and anti-CCP was positive in 85% and 82% of the patients respectively, and the baseline ESR was 43 ± 26 . 32.5% had NSIP and 63% had UIP. The median values of FVC% were 103[84-111]. During the follow-up, 77% of the patients used corticoids; and regarding DMARDs patients used Mycophenolate (n=4), AZA (n=18), LEF (n=16), TNFs (n=6), RTX (n=20) and ABA (n=5). Functional impairment occurred in 16 patients (37%) with an IR of 17 [11.4-25.3] (141.4 patient-years of follow-up). 50% of the patients achieved functional deterioration at 4.6 years since the diagnosis of ILD. Concerning the ILD types, IR for UIP was 18 [10.6-30.3] and for NSIP 15.7 [8.4-29.2]. The IR in patients taking corticoids was 15.3 [9.8-24.1]; LEF 13.2 [6-29.4]; AZA and Mycophenolate 17.4[8.3-36.6]; RTX 10.9[4-29.2].

Conclusion: Our RA patients were in their seventies and had active disease signs (higher ESR and Rheumatoid Factor positive) at the diagnosis of ILD. The most common radiological pattern was the usual interstitial pneumonia. The pulmonary function was mild at ILD diagnosis, maybe reflecting that our patients are diagnosed early in time. Functional impairment occurred in 37% of patients with an incidence rate of 17% patient-years, being 4.5 years the median time free of impairment. The crude incidence of functional impairment varies among therapies, being 10% for RTX. These results show the complexity of these patients and the need of further multicentric observational studies.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Interstitial lungdisease (ILD) is a common extra-articular manifestation of RA,¹ and treatment-induced ILD is more common in Asia than the rest of the world.²

Methods: We aimed to investigate incidence rates (IR; patients [pts] with events per 100 pt-years [PY]) of ILD events in pts with active RA, receiving tofacitinib 5 or 10 mg twice daily in a post hoc analysis of data pooled from 2 Phase (P)1, 10 P2, 7 P3/4, and 2 long-term extension(LTE) trials (ORAL Sequel LTE main study database locked at time of analysis: March 2017). No pts with pre-existing ILD were included. Potential ILD events were adjudicated by three independent pulmonologists as ‘probable’ (compatible adverse event [AE] with supportive clinical evidence) or ‘possible’ (compatible AE with no supportive clinical evidence). ILD IRs at 6-month intervals and by pt age and region are described. A

Table. Incidence rates (patients with events per 100 patient-years) for interstitial lung disease in tofacitinib Phase 1/2/3/4 and LTE trials						
P1/2/3/4 trials (placebo-controlled cohort)						
	n (%)	Placebo N=1136 PY	IR (95% CI)	n (%)	AB tofacitinib* N=6163 PY	IR (95% CI)

*Includes all patients who advanced to tofacitinib during index studies.
BID, twice daily; CI, confidence interval; IR, incidence rate; LTE, long-term extension; N1, number of patients in subgroup; P, Phase; PY, patient-years of risk period of tofacitinib exposure

descriptive case-matched control (ratio of pts with vs without ILD events 1:5, matched by age and gender) analysis identified potential ILD risk factors.

Results: Out of 7061 pts (PY of exposure = 23,394), 42 (0.6%) had an ILD event; median time to ILD event was 1144 days. The IR for ILD with both doses of tofacitinib treatment was 0.18 (Table; Figure). In a placebo-controlled cohort analysis in tofacitinib P2/3/4 studies, ILD event IRs were numerically lower with tofacitinib vs placebo (Table). IRs were numerically higher in pts aged ≥65 vs <65 years, and in Asian vs non-Asian countries; 95% confidence intervals were wide and overlapped. IRs generally remained stable over time, although the number of events was small in each interval (Figure). There were 17/42 (40.5%) serious AEs of ILD; 35/42 events (83.3%) were mild to moderate in severity. In the case-matched control analysis (case 42 vs control 210), the ILD group had a numerically higher proportion of pts who were Asian (31.0% vs 17.6%), smokers/ex-smokers (50.0% vs 39.5%), RF-positive (89.2% vs 71.0%), anti-CCP antibody positive (54.8% vs 46.7%), had received prior MTX (90.5% vs 79.5%), non-MTX csDMARDs (61.9% vs 55.2%), TNF inhibitors (26.2% vs 18.6%), and concomitant glucocorticoids (71.4% vs 52.9%), and had higher baseline mean ESR (57.0 vs 46.9 mm/hr) and CRP (25.4 vs 15.4 mg/L) vs controls.

Conclusion: Across P1/2/3/4/LTE studies, ILD events following tofacitinib treatment were low, and were associated with known risk factors.

Bronchiectasis in RA Is a Crucial Risk Factor of Hospitalised Pneumonia Associated with bDMARDs As Well As Interstitial Lung Disease

Kyoko Honne¹, Masashi Bando², Makiko Mieno³, Masahiro Iwamoto⁴ and Seiji Minota⁵, ¹Division of Rheumatology and Clinical Immunology, Jichi Medical University, Shimotsuke, Japan, ²division of pulmonary medicine, Department of medicine, Jichi Medical University, Shimotsuke, Japan, ³Center for Information, Jichi Medical University, Shimotsuke, Japan, ⁴Division of Rheumatology and Clinical Immunology, Jichi Medical University, Shimotsuke, Japan, ⁵Department of Internal Medicine, Division of Rheumatology/Clinical Immunology, Jichi Medical University, Shimotsuke, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a risk factor of pneumonia in RA patients treated with biological DMARDs (bDMARDs) [1-4]. Bronchiectasis (BE) is a well-known risk for severe pneumonia in general population[5]. However, BE is not fully examined as a risk for severe pneumonia during bDMARDs-treatment. We investigated types of respiratory diseases in RA patients before treatment with bDMARDs and correlated them to severe pneumonia during the treatment with special attention to ILD and BE.

Methods: This was a retrospective study. RA patients in Jichi Medical University, who satisfied the American Rheumatism Association 1987 criteria, were examined for their lungs by high-resolution computed tomography (CT) before starting bDMARDs and divided into three groups by a rheumatologist and a pulmonologist: normal, BE and ILD group. The patients with other lung diseases were excluded. The patients who had both BE and ILD were put into a group of the main lesion of the two. The log-rank test was used to compare the survival curves from the three groups for the differences in the probabilities of severe pneumonia requiring hospitalization. Hazard ratios (HR) on the risk of severe pneumonia between two of the three groups were determined by Cox proportional hazard model with covariates.

Results: A total of 494 patients were examined by chest CT before treatment with bDMARDs from 2003 to 2013. There were 348 patients in normal, 30 in BE and 49 in ILD group. Sixty-seven patients with the pulmonary lesions other than BE and ILD were excluded. Fourteen patients developed severe pneumonia which required hospitalization; 2 in normal (0.57%), 4 in BE (13%) and 8 in ILD (16%). Eleven and 3 patients developed bacterial and pneumocystis pneumonia, respectively. The log-rank test showed differences between the groups ($p < 0.00001$). The pneumonia-free rate of BE was lower than that of normal group (HR 26.79, 95% CI 5.11-196.32). The pneumonia-free rate of ILD was also lower than that of normal group (HR 30.25, 95% CI 7.27-204.54). No difference was shown for the pneumonia-free rates between BE and ILD.

Conclusion: This study suggested that BE in patients with RA is a risk factor of severe pneumonia during the treatment with bDMARDs to the extent comparable to ILD. The frequency of pneumonia in patients with normal lungs is very low.

Long-Term Follow up of Subclinical Interstitial Lung Disease in Rheumatoid Arthritis

Masaomi Yamasaki, Rheumatology, Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Using of high-resolution computed tomography(HRCT) has increased the early detection of interstitial lung disease(ILD) in asymptomatic and undiagnosed individuals. This study was to identify asymptomatic lung disease and to analyze long-term prognosis of subclinical rheumatoid arthritis-associated ILD(RA-ILD).

Methods: 1502 patients with RA were treated and followed them up for seven years or until development of symptomatic ILD. All patients were performed chest radiological examinations at the initial presentation. The HRCT findings which include (1) ground glass opacity, (2) air-space consolidation, linear opacity including (3) septal line and (4) non-septal line, (5) honeycomb lung, (6) traction bronchiectasis, (7)pleural irregularity, and (8)pleural effusion were scored as the CT scoring system. The extent of involvement of each abnormality was assessed independently for each of the three zones of each lung. The HRCT extent score was represented the sum of the score of each lung. HRCT parameters which included the extension score, ACPA and the clinical features at the initial presentation were retrospectively analyzed.

Results: 92(6.1%) out of 1,502 RA patients had abnormal chest radiological findings which consist with ILD. 5 out of 92 patients had shortness of breath and showed a rapidly progressive ILD (5.4%) at the presentation. The rest of 87 (54 women, 33 men) had subclinical RA-ILD who were either asymptomatic or have symptoms and physiologic abnormalities that are as yet unrecognized as being due to RA-ILD at the presentation. 12(13.8%) out of 87 subclinical RA-ILD patients developed symptomatic RA-ILD after diagnosed RA (28.4+/-16.1 months). There was no difference in the positive rates of anti-CCP2 and HRCT findings at the presentation between stable subclinical RA-ILD and later-developing clinical RA-ILD. However there was a difference in the HRCT finding which showed progression of ground-glass attenuation (HRCT score 2.1+/-0.7 vs. 0.1+/-0.3, $p<0.001$). These 12 cases were treated with immunosuppressant which include tacrolimus, azathioprine and MMF. And all cases showed stable ILD on HRCT after treatment of immunosuppressant.

Conclusion: Subclinical RA-ILD, which is detectable on HRCT, should be considered in RA even in absence of chest symptoms. HRCT finding focused on progression of ground-glass attenuation is a sensitive technique for detection of later-developing clinical RA-ILD in subclinical group.

Progression in Interstitial Lung Disease – Comparison of Rheumatoid Arthritis with Idiopathic Pulmonary Fibrosis

Shirish Dubey¹ and Felix Woodhead², ¹Rheumatology, University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom, ²Respiratory Medicine, Glenfields Hospital, Leicester, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a common autoimmune condition characterised by symmetrical inflammatory small joint polyarthropathy and loss of function. Systemic manifestations of RA are relatively common and thought to occur in upto 40% of patients. Interstitial lung disease (ILD) is a systemic complication of rheumatoid arthritis (RA) and is associated with significant increase in mortality compared to patients who do not have ILD. Idiopathic pulmonary fibrosis (IPF), previously known as cryptogenic fibrosing alveolitis, also has a poor prognosis, with median

survival of 3-5 years from diagnosis in the era before any specific treatments were found³. More recently, there have been new treatment options for these patients with Perfenidone and Nintedanib licensed and NICE approved for treatment of IPF. Although it is believed that the prognosis of rheumatological ILD is better, there are not enough data on progression to able to confidently prognosticate these patients. The purpose of this study was to assess the differences in progression in patients with IPF compared to RAILD.

Methods: The Coventry ILD database was set up in 2011; all patients with ILD were added to this. This study retrospectively looked at the patients who had been entered in this registry. Other forms of ILD like Connective Tissue Disorder related ILD (CTD-ILD) were excluded from this study. Data were anonymised prior to extraction for the study and only data available prior to the use of Perfenidone and Nintedanib were utilised. Statistics were performed using R software which is freely downloadable from the internet.

Results: This study included 185 patients of which 55 had IPF and 37 had RAILD. As this is not a matched study, there are significant differences in the presentations of patients in the different arms. Table 1 illustrates the main differences in the study population. The mean age in the IPF group was 72.4 where as for RAILD the mean age was 65.7 with standard deviation of 9.1 and 9.6 respectively. This difference is statistically significant. FVC values were 84.7% and 95% operated and these differences were statistically significant. TLCO values were much lower in IPF patients with values of 48.2 compared with 61.5 in patients with RAILD. Univariate analysis revealed a number of variants including diagnosis, age, sex, TLCO; but multivariate analysis only showed TLCO as the significant variant. Median follow up was 41 months.

Table 1: Baseline characteristics demonstrating that RA has higher FVC at presentation.

Category	IPF	nonIPF IIP	Rheumatoid	P
Number	49	48	34	
Age	72.4 (9.1)	70.8 (9.6)	65.7 (9.6)	0.006
FEV1	84.1 (17.1)	80.6 (20)	88.9 (17.7)	0.133
FVC	84.7 (20.6)	84 (19.3)	95.0 (18.1)	0.026
Tlco	48.2 (14.6)	52.2 (18.1)	61.5 (17.1)	0.002

Outcome: Median 5 year survival was 48% for IPF and 81% for RAILD. Median 50% survival was 4.5 years for IPF and 9 years for RAILD.

Conclusion: Significant gaps remain in our understanding of the natural course of RAILD and IPF. Our study suggests that the biggest single factor influencing outcome is TLCO at baseline.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lung involvement in rheumatoid arthritis (RA) has been recognized as an important contributor to morbidity and mortality. While interstitial lung disease (ILD) is a well-recognized manifestation more common in seropositive RA, the association between RA and other respiratory outcomes such as chronic obstructive pulmonary disease (COPD) and bronchiectasis are less understood. The purpose of this study was to describe imaging abnormalities in clinically-indicated chest computed tomography (CTs) of patients with RA and compare abnormalities based on serologic status.

Methods: We identified patients within a single-center registry composed of 1,500 RA patients with prospective measures of RA characteristics and detailed clinical data who had clinically-indicated chest CTs. We extracted data by reviewing the

initial clinically-indicated chest CT report occurring after baseline study visit. We described the proportion of patients with imaging findings and impression in the report from the attending radiologist. We further stratified the characteristics by RA serostatus (seropositive as rheumatoid factor and/or anti-cyclic citrullinated peptide positivity; seronegative as both negative). We compared patients with seropositive RA to seronegative RA using t-tests or Wilcoxon rank-sum tests for continuous variables and chi-square tests or Fisher's exact tests for categorical variables.

Results: We analyzed 188 patients with chest CTs performed after study baseline. The mean age was 64.3 years (SD 11.9), 79.8% were female, mean RA duration was 21.4 years (SD 13.3), mean body mass index (BMI) was 27.5 kg/m² (SD 6.3), 60.1% were ever smokers, and 73.4% were seropositive. Most CTs were obtained to rule out respiratory illness (43.1%), followed by malignancy (24.5%). The most common chest CT pattern abnormalities were: pulmonary nodules (38.8%), opacities (24.5%), and pleural effusions/thickening (18.1%). The most common final impressions for the chest CTs were: pulmonary nodules (30.3%), atelectasis (21.3%), and ILD (16.0%). Only 11.7% of chest CTs had completely normal final impressions. There were no statistically significant differences between seropositive and seronegative RA, including ILD (p=1.0), bronchiectasis (p=0.21), and COPD (p=0.78).

Conclusion: A wide variety of chest CT abnormalities were present at high prevalence in both seropositive and seronegative RA patients with few having normal findings. While we found no differences based on serostatus in these clinically-indicated chest CTs, there may be differences in the subclinical natural history of lung disease based on RA serostatus and disease activity. The pathogenesis, clinical manifestations, and outcomes of patients with pulmonary abnormalities warrant further research.

Table. Chest computed tomography (CT) findings in patients with seronegative vs. seropositive rheumatoid arthritis (RA)

	All patients (n = 188)	Seronegative RA (n = 50)	Seropositive RA (n = 138)	p value
Demographics				
Age (Mean, SD), years	64.3 (11.9)	63.6 (13.7)	64.5 (11.2)	0.90
Female (n, %)	150 (79.8)	37 (74.0)	113 (81.9)	0.33

RA-Voice: Evaluating Laryngeal Involvement in Rheumatoid Arthritis Patients

Ana Águeda¹, Luisa Azevedo², Joaquim Vieira², Sandra Augusto², Catarina Ambrósio¹, Inês Cunha¹ and Anabela Barcelos¹, ¹Rheumatology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal, ²Otolaryngology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Laryngeal involvement is not uncommon in connective tissue diseases including Rheumatoid Arthritis (RA). Its prevalence has been estimated between 5% and 70% of patients and, in post mortem series, between 45% and 88% of patients. The crico-arytenoid joint is the most commonly affected site. Dysphonia, cough, dryness symptoms, foreign body sensation and odynophagia are among the symptoms of laryngeal involvement although, quite often, it is asymptomatic.

With this study, the authors aimed to evaluate laryngeal involvement in RA patients and healthy sex and age matched controls and evaluate results within the RA patients group according to disease activity and duration of disease.

Methods: This is a cross-sectional study that evaluated laryngeal involvement in RA. Patients were accessed using video laryngostroboscopy (VLS) and objective changes were recorded using the reflux finding score (RFS). The Reflux Symptom Index (RSI), was used to evaluate laryngopharyngeal symptoms and Vocal cord impairment was accessed using the Voice Handicap Index-10 (VHI-10). Statistical analysis was performed using non-parametric tests, given the small sample size and non-normal distribution of the variables.

Results: We enrolled 48 RA patients, with mean disease duration of 13 years, and 30 healthy sex and age matched controls. Two males were active smokers in each group and, in RA group, 4 males and 3 females were previous smokers. 77.8% of the patients were being treated with Metotrexate, 6.25% were receiving concurrent medication with prednisolone above 7.5 mg daily, 14.58% were also medicated with AINE's on demand and 66.67% used proton pump inhibitors, mostly as a preventive measure.

Compared with controls, RA patients presented higher median values in the RFS ($p < 0.0001$) and RSI ($p = 0.0002$) but differences in the VHI-10 were non-significant.

Within the RA group, there were no significant differences in the RFS, RSI nor VHI-10 when comparing patients with DAS 28 3V above vs below 2.6 at the time of evaluation. However, we found significant differences regarding the RSI when evaluating patients according to duration of disease, with patients with longer disease duration having higher scores (0-5 vs 6-10 years $p = 0.03$; 0-5 vs 11-15 years $p = 0.047$; 0-5 vs >15 years $p = 0.015$).

Even though no differences were found regarding the RFS, patients within the > 15 years of disease duration, presented a higher median score (median scores for: < 5 years = 2.5, 6-10 years = 3, 11-15 years = 4, > 15 years = 7).

Conclusion: We found significant differences between RA patients and healthy controls regarding self-perceived laryngeal symptomatology (RSI) and findings on VLS (RFS), with patients scoring higher.

RA patients with longer disease duration had more symptoms and more alterations on laryngeal examination but there were no significant differences according to disease activity.

Current evidence, as identified in the present study, suggests that laryngeal manifestations in RA patients may be under diagnosed and a multidisciplinary team approach is necessary to improve the overall patient management.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The coexistence of different autoimmune diseases (AID) has been well established in the literature. In our knowledge, there is no study assessing specifically the association between RA and other AID. The aim of our study was to determine the frequency of AID in RA patients and to compare this frequency between patients with and without RA or other rheumatologic AID.

Methods: Multicenter, observational, analytical, retrospective study, including consecutive patients with diagnosis of RA (ACR/EULAR 2010 criteria). Patients with initial diagnosis of primary osteoarthritis (OA) were used as control group.

Results: A total of 1549 patients from 23 centers were included: 831 RA [84% women, mean age 55.2 (\pm 13.6)] and 718 OA [82% women, mean age 67 (\pm 11.1)]. Mean age at RA symptoms onset was 45.5 (\pm 13.4). Most patients (90.5%) were treated with DMARDs and 34.3% with biologic drugs. The frequency of AID in the RA group was 22% (n=183). RA patients showed higher frequency of rheumatologic AID (9.4 vs 3.3%, p <0.001), and lower frequency of non-rheumatologic AID than OA patients (15.3 vs 20.5%, p = 0.007). The most frequent rheumatologic AID was Sjögren's Syndrome (SS), with a higher prevalence in RA patients (87.2 vs 29.2%, p <0.001). There was no difference in the frequency of other pathologies. The frequency of rheumatologic AID in RA patients was higher in those with erosive RA (11 vs 6.8%, p =0.048). No association with gender, age, nodular RA or seropositivity was observed. A lower age at RA diagnosis was associated with lower age at thyroid AID (39 vs 48.2, p =0.0001) and SS diagnosis (41.3 vs 57.1, p < 0.0001). Family history of

AID was higher in RA patients (24.4 vs 13.4%, $p < 0.001$). In the control group, family history of AID was associated with higher frequency of non-rheumatologic AID (36.2 vs 20.9%, $p = 0.005$), mostly thyroid diseases.

Conclusion: The frequency of AID in RA patients was 22%. Rheumatologic AID were more frequent in RA patients, mostly in those with erosive RA, whereas non-rheumatologic AID prevailed in OA patients. Family history of AID, mainly rheumatologic ones, was higher in RA patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In non-diabetic healthy individuals insulin secretion and insulin sensitivity are linked by a negative feedback loop characterized by a hyperbolic function. We aimed to study the association of traditional insulin resistance (IR) factors with insulin secretion and sensitivity, and to determine whether the hyperbolic equilibrium of this relation is preserved in patients with rheumatoid arthritis (RA).

Methods: Cross-sectional study encompassing 361 non-diabetic individuals, 151 RA and 210 controls. Insulin, C-peptide and IR indexes by homeostatic model assessment (HOMA2) were assessed. A multivariable analysis was performed to evaluate the differences in the correlation of traditional IR-related factors with glucose homeostasis molecules, as well as IR indexes between patients and controls. Non-linear regression analysis was used to assess the hyperbolic relation of insulin sensitivity and secretion.

Results: HOMA2-S% was lower in RA patients than in controls after adjusting for traditional IR-related factors and prednisone intake (105 ± 53 vs. 108 ± 75 , $p=0.006$). Insulin (9.8 ± 6.5 vs. 13.0 ± 13.4 U/ml, $p=0.007$) and C-peptide serum levels (1.53 ± 0.77 vs. 3.37 ± 2.94 ng/ml, $p=0.000$) were found to be up-regulated in RA patients. The insulin to C-peptide ratio was lower in RA patients (0.14 ± 0.07 vs. 0.08 ± 0.02 , $p=0.000$) after multivariate adjustment including glucocorticoids. Traditional IR-related factors strongly correlated with glucose, insulin, C-peptide, and IR indexes in both patients and controls. However, Pearson's correlation coefficients were lower in patients. This shows that the variability in glucose homeostasis molecules or IR indexes had a weaker association with traditional IR-related factors in RA patients. Linear relations between glucose homeostasis molecules (glucose, insulin and C-peptide) and HOMA2 indexes showed high values that reached statistical significance. However, the relation of C-peptide with insulin, HOMA2-IR with C-peptide, and the relation of HOMA2-%B with insulin and C-peptide were lower in patients with RA than in controls. Hepatic insulin extraction, as assessed by the insulin:C-peptide molar ratio, was lower in patients after multivariable analysis (0.08 ± 0.02 vs. 0.14 ± 0.07 , $p=0.000$). The association between insulin sensitivity and secretion showed a different hyperbolic relation in patients: the variability explained by the curve (non-linear $r^2=0.690$ vs. $r^2=0.899$, $p=0.000$) and beta coefficients ($-0.87[95\%CI -0.95--0.78]$ vs. $-0.98[95\%CI -1.04--0.92]$ ng/ml, $p=0.034$) were lower in RA.

Conclusion: The traditional factors associated with IR in healthy individuals are less related to IR in RA patients. Insulin sensitivity and secretion yield a different hyperbolic equilibrium in RA.

Association between Inflammation and Changes in Kidney Function in Patients with Early Rheumatoid Arthritis

Ganna Prytkova¹, Dmytro Rekalov² and Daryna Nikitina¹, ¹Rheumatology, Zaporizhzhya Regional Clinical Hospital, Zaporizhzhya, Ukraine, ²Department of Internal Diseases, Zaporizhzhya Regional Clinical Hospital, Zaporizhzhya, Ukraine

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: One of the most severe visceral manifestations of RA is nephropathy. The key symptoms of renal dysfunction (RD) are microalbuminuria (MA), β -2-microglobulinuria (β -2M), reduced renal blood flow (RBF) and decreased glomerular filtration rate (GFR).

The aim of our study was to examine whether tumor necrosis factor- α (TNF α) can induce and maintain decrease RD and whether this is associated with severity of RA.

Methods: The median age of the group of 35 (28 female, 7 male) participants with early eRA was 50.71 ± 2.25 years, with median disease duration 9.21 ± 0.43 months. TNF α was from ELISA Kits, R&D Systems (USA), MA and β -2M were from ORGenTec GmbH (Germany). The ratio of albumin-creatinine (AB/CR) in the morning portion of urine and the glomerular penetration index (GPI), reflecting the average concentration of AB in the glomerular ultrafiltration, were also calculated by formula: $GPI = P \cdot V / GFR$, where P - of excreted AB urine concentration (mg/l); V - minute diuresis (ml / min.). The serum and urine CR concentration was determined by a unified method using the Jaffe color reaction (Popper method).

Results: The severity of tubular damage in early eRA is associated with TNF- α expression, especially in the patients with TNF- α above 250 pg/mL, when MA rates were significantly higher ($\chi^2=12,3$ in $p<0,01$). We identified robust data that patients with high TNF α , the number of reported cases of MA was significantly higher. We evaluated not only the stage but also the nature of the dependence, describing the functional relationship between the numerical variables. We have performed of regression analysis, while the serum range of TNF α was considered as an independent variable and as a dependent variable - index characterizing the severity of RD (index of MA). We identified that in the eRA patients with

high TNF α , the number of reported cases of MA was significantly higher ($\chi^2=12,3$ with $p<0,01$). The obtained dependence showed the dynamics of expression of RD in eRA with a progressive deterioration which did associate with the levels of TNF α expression, and variety of the β -2M urine rates in the interval 200–350 $\mu\text{g/L}$.

Conclusion: In this study we have confirmed, that overexpression of TNF- α is involved in the induction of RD, which is manifested by decrease of GFR and increase of urinary excretion of microproteins. At the same time, the dynamics of MA and β -2M values was reliably determined by the stage of disease activity, which reflects the RA severity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased insulin resistance and impaired β -cell function have been demonstrated in rheumatoid arthritis(RA). The aim of the study was to analyze the association of these metabolic disturbances with glucocorticoid (GC) therapy.

Methods: The study population included 127 non-diabetic subjects: 90 RA pts (mean age 52.4 ± 9.9 yrs, disease duration 9 yrs, range 4-13) and 37 matched controls (mean age 49.0 ± 7.5 yrs). All pts were on disease modifying anti-rheumatic drugs (methotrexate in 93.3%), biologic therapy in 27.8%, and GC in 65.6%, none on GC >10 mg/day (median dose 5 mg/day, range 5-10, during 4 yrs (range 2-6yrs), cumulative GC dose was 9.1 g (5.5-16.4 g). Clinical work-up included determination of the body mass index (BMI), waist circumference (WC), blood pressure (BP), disease activity (mDAS28-SE), inflammation markers, lipids, glucose, specific insulin, and C peptide. The updated-computer Homeostasis Model Assessment was used to calculate insulin resistance (HOMA2-IR) and β -cell function (HOMA2-%B). HOMA2-IR >1 was defined as increased insulin resistance. Lack of compensatory rise of HOMA2-%B implied impaired β -cell function.

Laboratory	RA pts (N=90)	Controls (N=37)	RA pts with GC vs. without GC	Controls vs. RA pts with GC	Controls vs. RA pts without GC
Age (years)	52.4 \pm 9.9	49.0 \pm 7.5	ns	ns	Ns
BMI (kg/m ²)	25.7 \pm 4.3	26.2 \pm 4.3	ns	ns	Ns
Hypertension (%)	28/90 (31.1)	8/37 (21.6)	ns	ns	Ns
Triglycerides (mmol/L)	1.2 (0.8-1.5)	1.0 (0.8-1.4)	ns	ns	Ns
Blood glucose (mmol/L)	4.8 \pm 0.6	4.7 \pm 0.8	ns	ns	Ns
Insulin (pmol/L)	68 (50-103)	55.3 (36-69)	ns	0.003	0.072
C-peptide (pmol/L)	785 (520-1010)	600 (450-880)	ns	0.037	0.217
logHOMA2-IR	1.4 (1.0-2.3)	1.2 (0.8-1.4)	ns	0.003	0.05
HOMA2-IR >1	67/90 (74.4)	20/37 (54.2)	ns	0.026	0.024
HOMA2-%B	148 (116-190)	141 (114-158)	ns	0.140	0.642
DAS 28-SE	4.0 \pm 1.5		ns		
DAS 28-CRP	4.2 \pm 1.5		ns		
Duration of GC therapy (years)	4 (2-6)		ns		
Cumulative dose of GC (g)	9.1 (5.5-16.4)		ns		

Results: Increased insulin resistance ($\log\text{HOMA2-IR}>1$) was detected in 74.4% of RA pts and in 54.2% of controls, $p=0.025$. RA pts had also higher values of $\log\text{HOMA2-IR}$ than controls 1.4 (range 1.0-2.3) vs. 1.2 (range 0.8-1.4); $p=0.008$; which was followed with impaired β cell function: HOMA2-\%B 148 (116-190) vs. 141 (114-158) $p=0.186$. Univariate regression revealed association of $\log\text{HOMA2-IR}$ with all insulin resistance risk factors: age, BMI, WC, BP, and triglycerides, while multivariate analysis demonstrated that beside BMI, and triglycerides, **daily dose of GC was an independent risk factor for $\log\text{HOMA2-IR}$ (β 0.191, 95% CI 0.020-0.361, $p=0.029$)**. On the other hand, statistical difference was not found for duration of GC therapy and cumulative GC dose. Analyzing patients with and without GC therapy statistical difference was not found regarding any parameters of glucose metabolism, as well as all classic insulin resistance risk factors (Table 1). In comparison with controls, higher insulin resistance was found for RA pts with GC therapy, which was not followed with differences in B cell function. Patients without GC therapy also had higher insulin resistance, but the statistical significance was borderline. Both RA groups had significantly higher number of subjects with increased insulin resistance than controls.

Conclusion: There was no significant difference in insulin resistance between RA pts with and without GC therapy. Daily dose has more significant influence than duration of GC therapy and cumulative GC dose but this therapy does not play a principal role in increased insulin resistance in RA pts.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankle involvement is common in Rheumatoid Arthritis (RA). It has been reported that more than 90 % of patients develop ankle symptoms over the course of the disease. In spite of this, it remains a neglected anatomical area since clinical implications of ankle involvement appear to be continuously underestimated. We analyzed the ultrasound (US) features of the Achilles Tendon (AT) and entheses in patients with RA and compared these to healthy athletes. Relations between these findings and clinical and physical therapy parameters were identified.

Methods: Consecutive patients aged ≥ 18 with RA according to ACR/EULAR 2010 criteria were included. We consigned socio-demographic data, disease duration, physical activity and Body Mass Index (BMI). Clinical evaluation relied on the Disease Activity Score 28 (DAS28), Health Assessment Questionnaire (HAQ), Routine Assessment of Patient Index Data 3 (RAPID 3), as well as on a visual analog scale (VAS), and entheses pain. Separately, AT thickness and echogenicity were examined bilaterally with US in 60 ankle regions. US examinations were performed by two experienced rheumatologists. To evaluate AT involvement, we used the Madrid Sonographic Enthesitis Index (MASEI) evaluating elementary lesions: bursitis, calcification, erosion, Power Doppler (PD), thickening of tendon, and structural change. Statistical analysis: Standard descriptive results were expressed as the mean \pm standard deviation (SD). Chi-square Test and Fisher's exact test were used for categorical variables whereas T test for the continuous variables.

Results: A total of 60 ankles from 30 patients with RA and 36 ankles from 18 healthy controls were assessed. The mean (\pm SD) age was 58.3 ± 9.5 years and disease duration were 14.5 ± 5.9 years in RA patients. 30% of patients with RA had foot and ankle pain at visit. The mean (\pm SD) DAS28, HAQ and RAPID3 were 3.46 ± 0.9 , 0.9 ± 0.6 , and 11 ± 6.5 respectively. 26.7% were obese. 30% of RA patients performed physical activity. At least 1 AT lesion was found in US of all RA patients. The most frequent US abnormality in RA patients was tibialis posterior tenosynovitis followed by peroneus longus tenosynovitis. A statistically significant difference was found between RA patients and healthy controls in mean (\pm SD) MASEI (3.56 ± 2.4 vs. 2.33 ± 1.7 , $p=0.01$), and subitem scores such as: structural changes (0.66 ± 0.4 vs. 0.2 ± 0.4 , $p<0.01$), erosion (0.8 ± 1.3 vs. 0.02 ± 0.16 , $p<0.01$) and PD (0.3 ± 0.9 vs. 0.02 ± 0.16 , $p=0.03$).

Conclusion: Achilles tendon involvement is rather frequent in RA patients. The MASEI score was significantly higher in patients with RA compared with athletes.

Prevalence and Relative Factors for Frailty in Patients with RA from a Prospective Observational Study

Masahiro Tada¹, Yutaro Yamada², Koji Mandai³ and Noriaki Hidaka⁴, ¹Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan, ²Orthopedic surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, ³Orthopaedic surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, ⁴Orthopaedic surgery, Osaka City General Hospital, Osaka, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Frailty is defined as degradation of physical and cognition function in elderly adult. The characteristics of frailty include not only physical problems as co-morbidity and disability, but also mental and social problems. It is unclear of relationship between frailty and disease activity of patients with rheumatoid arthritis (RA). We investigated the relative factors about frailty in patients with RA from a prospective observational study.

Methods: 95 from 100 patients entered the CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease Activity in Rheumatoid Arthritis) were investigated by frailty check list (maximal score is 25). According to reported article, frailty was defined from 8 to 25 and pre-frailty was from 4 to 7, and normal was from 0 to 3. We investigated relationship of disease activity in frailty, pre-frailty and normal groups, and analyzed the relative factors for frailty.

Results: The prevalence of frailty, pre-frailty, and normal was 19%, 39% and 42%, respectively. The character of groups indicated at Table 1. Frailty group was the oldest of three groups. Disease activity score 28 erythrocyte sedimentation rate (DAS28ESR) and matrix metalloproteinase 3 (MMP3) of frailty group was higher than those of pre-frailty and normal groups. Whereas, modified health assessment questionnaire (mHAQ) of frailty group was lower than those of pre-frailty and normal groups. Normal was 66.6% and frailty was 6.7% in remission patients. However, Normal was 13.3% and frailty was 46.7% in moderate and high disease activity patients. The prevalence of frailty was increased with disease activity. The relative factors for frailty in patients with RA indicated at Table 2. Age, locomotive syndrome, DAS28ESR, mHAQ, and Steinbroker class were related positively and leg muscle score and grip strength were related negatively by univariate analysis. Steinbroker class (odds ratio: 3.25 95%CI: 1.11-9.51, P=0.031) and mHAQ (odds ratio: 1.29, 95%CI: 1.13-1.46, P<0.001) were independent relative factors by multivariate analysis.

Conclusion: It was revealed that frailty involved disease activity and physical function in patients with RA. Control of disease activity is important to prevent not only disease progression, but also frailty.

Table 1. The character of frailty, pre-frailty, and normal in patients with RA

	Frailty (19%)	Pre-frailty (39%)	Normal (42%)	P value
Age, years	72.5 ± 10.3	68.6 ± 11.3	60.7 ± 16.4	0.01
Leg muscle score	84.9 ± 5.9	86.2 ± 6.4	93.2 ± 9.7	<0.001
Grip, kg	12.6 ± 6.9	17.7 ± 7.1	18.1 ± 6.2	0.013
Locomotive 5 score	11.1 ± 5.8	6.4 ± 4.9	2.6 ± 4.0	<0.001
MMP3, ng/dl	143.7 ± 122.0	95.9 ± 66.0	88.6 ± 52.0	0.033
DAS28ESR	3.62 ± 0.97	3.27 ± 1.02	2.83 ± 0.96	0.015
mHAQ	0.9 ± 0.7	0.4 ± 0.2	0.1 ± 0.1	<0.001
Sarcopenia, %	39	41	18	0.063

Increased Risk of Incident Chronic Kidney Disease Among Patients with Rheumatoid Arthritis: A Systematic Review and Meta-Analysis of Cohort Studies

Patompong Ungprasert¹ and Sukit Raksasuk², ¹Clinical Epidemiology Unit, Department of Research and Development, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, ²Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) may have a higher risk of developing chronic kidney disease (CKD) compared with general population. However, the data on this risk are still limited and not well-characterized. This systematic review and meta-analysis was conducted with the aim to comprehensively investigate the risk of incident CKD among patients with RA by reviewing all available studies.

Methods: A systematic review was performed using MEDLINE and EMBASE database from inception to April 2018 to identify all cohort studies (either retrospective or prospective) that compared the risk of incident CKD in patients with RA versus individuals without RA. Point estimates and standard errors from each study were extracted and combined together using the random effect, generic inverse variance method of DerSimonian and Laird. Visualization of funnel plot was used for evaluation for publication bias.

Results: Of 2,580 retrieved articles, a total of 4 retrospective cohort studies with 1,627,981 participants met the inclusion criteria and were included into the meta-analysis. The risk of incident CKD was significantly increased among patients with RA with the pooled risk ratio of 1.52 (95% CI, 1.28-1.80). The statistical heterogeneity of this study was high with an I^2 of 82%. The forest plot of this systematic review and meta-analysis is shown as figure 1. The funnel plot was relatively symmetric and, thus, did not suggest the presence of publication bias in favor of positive studies (figure 2) although interpretation of the funnel plot was limited by the relatively small number of included studies.

Conclusion: A significantly increased risk of incident CKD among patients with RA compared with individuals without RA was demonstrated in this study.

Type 1 Diabetes in RA: Comparison with Type 2 and Its Association with RA Severity and Treatment

Sofia Pedro¹, Gulsen Ozen² and Kaleb Michaud^{1,2}, ¹FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, ²Rheumatology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: DMARD treatment for Rheumatoid Arthritis (RA) has been shown to improve the glucose control and reduce the incidence of diabetes, usually assumed to be type 2 (T2D) in adults. While rare in adults, type 1 diabetes (T1D) can improve with DMARD treatment. We sought to differentiate the prevalence of T1D from T2D and examine the association of diabetes type with DMARDs, and other factors in patients with RA.

Methods: Participants in Forward, The National Databank for Rheumatic Diseases, during 1999-2018 who reported having diabetes and completed new questions added in 2017 regarding the type of diabetes, age of diagnosis, and treatments. Participants were characterized at the earliest time point available after diabetes diagnosis (baseline): either at enrollment into Forward or at the time of diagnosis during followup. Differences by diabetes type were assessed by statistical tests (Chi², T-test). Logistic generalized estimating equation (GEE) models were used in both univariate and multivariable manner to investigate associations between diabetes type and demographics, clinical measures, and RA treatment. Best models were found by QIC criterion.

Results: Of the included 700 diabetic RA patients, 8.6% (60) were of T1D, while the remaining 640 were T2D (91.4%). The onset age for T1D was 36 years (SD 22) vs 54 years (SD 13) for T2D. The majority of T1D was diagnosed before RA diagnosis (63.3%) whereas T2D was diagnosed mostly after RA diagnosis (71.6%). Patients with T1D tended to be younger, have higher education, lower BMI, worse HAQ, and more likely to smoke than patients with T2D (Table 1). These factors were significant in longitudinal models, although no RA severity measures were associated with diabetes type. Patients with T1D were slightly more likely to receive nonTNFi bDMARDs compared to patients with T2D although this was attenuated in the multivariable model (Table 2).

Conclusion: Surprisingly, the percentage of patients with RA reporting T1D was about double that expected in the population (~4% in the general population¹). These patients were younger and tended toward greater use of non TNFi bDMARDs. Future studies should account for type of diabetes due to important differences in impact of auto-immune diseases by treatments.

Thyroid Function in Early Versus Established Rheumatoid Arthritis

Suad Hannawi¹, Issa Al Salmi² and Haifa Hannawi³, ¹Rheumatology Department. Ministry of Health and Prevention, Asst.Prof, Dubai, United Arab Emirates, ²Prof, Muscat, Oman, ³Research Department. Ministry of Health and Prevention, Asst.Prof, Dubai, United Arab Emirates

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Thyroid dysfunction is common in rheumatoid arthritis (RA). Subclinical hypothyroidism is the first most common, followed by clinical hypothyroidism. Thyroid dysfunction in RA had been found to increase the risk of cardiovascular disease. Subclinical hypothyroidism is defined as increased serum thyroid stimulating hormone (TSH) concentration with normal serum free thyroxine (T4) level. The aim of this study was to compare the thyroid function in early RA patients (of less than one-year duration of RA symptoms) versus established RA patients (of more than or equal to one-year duration of RA symptoms).

Methods: We recruited 35 early RA patients (ERA) and 52 established RA patients attending specialized rheumatology clinic. All the patients had no clinical evidence of thyroid dysfunction. Patients with diabetes, pregnancy, renal and liver impairment were excluded. Fasting Free thyroxine (FT4), Free triiodothyronine (FT3), and thyroid stimulating hormone (TSH) were assessed in all the participants. t-test was used to compare the RA disease characteristics and the thyroid function between early and established RA. P value of <0.05 was considered significant.

Results: Rheumatoid arthritis patients had been recruited through a specialized rheumatology clinic, 35 were with new onset rheumatoid arthritis (early RA; ERA of less than a year of RA symptoms onset) and 52 were with established RA (of more than a year of RA symptoms onset). The mean RA duration was 7.4 ± 2.0 months for ERA and 96 ± 92 months for the established RA group. There were no significant differences in age (45.76 ± 2.45 years for ERA vs. established RA respectively, $p=0.49$), or in gender distribution (31 F and 4 M in ERA vs. 46 F and 6 M in established RA, $p=0.9$) between the two groups.

ERA compared to the established RA group had more active RA as manifested by more swollen 28- joints (5.7 vs 1.7 , respectively, $p=0.001$), more tender 28-joints (17 vs 11 , respectively, $p=0.01$), higher DAS-28-ESR score (5.8 vs 4.5 , respectively, $p=0.0001$), higher DAS 28-CRP score (5.1 vs. 3.9 , respectively, $p=0.001$), and longer morning stiffness duration (in minutes) ($p=0.04$). As well, ERA had lower HDL level (1.4 vs 1.2 , respectively, $p=0.04$). On the other hand, established-RA patients had RA disease onset at an earlier age than the EAR group (36.5 vs 44 years, respectively, $p=0.02$).

While the mean TSH, T3 and T4 were within normal range in both groups, there were significant differences in the mean values between ERA and established RA. TSH was 2.12 ± 1.52 in ERA vs. 5.8 ± 8.3 in established RA (NR: 0.27 - 4.2 mIU/L), $p=0.04$. Mean FT3 was 4.54 ± 0.53 in ERA vs. 3.61 ± 1.13 in the established RA (NR: 4 - 6.8 pmol/L), $p=0.04$. Average FT4 was 17.7 ± 4.77 in ERA vs. 15.3 ± 2.51 in the established RA (NR: 12 - 22 pmol/L), $p=0.01$.

Conclusion: RA patients with more than a year of RA symptoms are at a higher risk of silent autoimmune thyroid disease than their age sex matched RA patients with new onset RA; of less than a year of RA symptoms onset. Regular assessment of thyroid function might be an important part in the routine biochemical and immunological profile screening of RA.

Echocardiographic Abnormalities in Rheumatoid Arthritis Patients Compared to Age, Sex and Traditional Cardiovascular Risk Factors Matched Controls

Suad Hannawi¹, Kashif Naeem², Haifa Hannawi³ and Issa Al Salmi⁴, ¹Rheumatology Department. Ministry of Health and Prevention, Asst.Prof, Dubai, United Arab Emirates, ²Cardiology Department. Ministry of Health and Prevention, Dr, Dubai, United Arab Emirates, ³Research Department. Ministry of Health and Prevention, Asst.Prof, Dubai, United Arab Emirates, ⁴Prof, Muscat, Oman

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of the joints with several extra-articular features. Cardiovascular disease (CVD) mortality accounts for 40-50% of all deaths in RA. Apart from

atherosclerotic heart disease other cardiac abnormalities had been found to be prevalent in RA; including, pericarditis, heart failure, coronary vasculitis and valve disease. Due to scarcity of data regarding cardiac disease in the Middle East population, we studied echocardiographic features in RA patients compared to their age, sex, and traditional CVD risk factors matched controls.

Methods: In a cross-sectional study, we recruited 39 RA patients meeting the 1987 revised criteria of RA and 37 age, sex and traditional CVD risk factors matched controls. Standard trans-thoracic echocardiography examination was carried out by a specialties cardio-sonographer who was blinded to the status of the participants. Left ventricular dimensions, wall geometry, ejection fraction, diastolic parameters, right ventricular size and function, valve structure and function, pericardium, pulmonary pressures and aortic root dimensions were assessed by echocardiography. t-test and chi-2 test were used to compare the echocardiographic findings between the two groups. P value of <0.05 was considered significant.

Results: Thirty-nine RA patients (34 F, 4 M) and 37 controls (32 F, 5 M) were studied. Among RA, 27 (69%) were rheumatoid factor positive. The two groups were similar in terms of age ($p=0.86$), gender ($p=0.71$), and traditional cardiovascular risk factors (hypertension ($p=0.61$), diabetes mellitus ($P=0.51$), hyperlipidemia ($p=0.75$), history of smoking ($p=0.97$), and obesity by body mass index definition ($p=0.77$)).

No significant difference was found between RA and the controls in term of left ventricular ejection fraction, wall geometry, diastolic parameters, right ventricular size and function, valves diseases, pulmonary pressures, pericardium and aortic root dimensions. However, left ventricular end-diastolic diameter (43.11 ± 1.14 vs. 39.35 ± 0.84 mm respectively, $p=0.01$), end-systolic diameter (24.39 ± 0.70 vs. 26.96 ± 0.96 mm, respectively, $p=0.03$) and Left ventricular mass index (79.83 ± 5.11 vs. 63.64 ± 3.15 , respectively, $p=0.01$) were significantly higher in RA patients than in the controls.

Conclusion: Patients with rheumatoid arthritis have higher left ventricular end-diastolic and end-systolic dimensions, and greater left ventricular mass index compared to their age, sex and traditional CVD risk factors-matched controls. As the increase in the left ventricular mass index is a predictor of cardiac sudden death, echocardiography might be a simple non-invasive tool for cardiac risk screening in RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome is a known co-existing autoimmune disease in patients with RA, but its prevalence and impact on RA are poorly understood. The aims of this study were to assess the prevalence of secondary Sjögren's syndrome (sSS) and to compare the baseline characteristics of patients with RA, with and without Sjögren's syndrome, in a national sample of patients with RA.

Methods: We identified adult patients with rheumatologist-diagnosed RA (ARA 1987 or ACR/EULAR 2010 criteria) from a large observational US registry (Corrona RA), with at least one visit assessing the presence of sSS (yes/no) between Apr 22, 2010 and Feb 28, 2018. Patients who had an sSS diagnosis were compared with those who never had a diagnosis. In those without a diagnosis, patients had to be enrolled for at least 12 months to ensure complete data capture. The index date was the date of first capture of sSS diagnosis (sSS patients) or first visit in patients with a negative sSS diagnosis (non-sSS patients). Patients with missing sSS information were excluded. The primary outcome was the unadjusted prevalence of Sjögren's syndrome in patients with RA. Baseline characteristics and the prevalence by RA disease duration were assessed by sSS status.

Results: A total of 24,528 patients met the inclusion criteria, of whom 7870 (32.1%) had a diagnosis of sSS. The unadjusted overall rate for the prevalence of Sjögren's syndrome in patients with RA was 0.30 (95% CI: 0.29, 0.31). Compared with patients without sSS, patients with sSS were more likely to be older, female and seropositive (both cyclic

citrullinated peptide positive and RF+), and had a longer duration of RA, higher disease activity (CDAI score), and a higher incidence of co-morbidities (cardiovascular disease, malignancies and serious infections), erosive disease and subcutaneous nodules at the index date (Table 1). The rate of sSS increased with increasing RA disease duration (Table 2).

Conclusion: This study suggests that patients with sSS and RA have a higher disease burden than those with RA alone. sSS was associated with seropositivity, more severe RA, and a greater incidence of other extra-articular manifestations and co-morbidities. A higher prevalence of sSS was observed as the duration of RA increases. Professional medical writing and editorial assistance was provided by Claire Line, PhD, at Caudex, and was funded by Bristol-Myers Squibb.

Table 1. Baseline Characteristics at Index Date

	Patients with sSS + RA (n=7870)	Patients with RA only (n=16,658)

Abstract Number: 542

Incidence and Prevalence of Interstitial Lung Disease in the US Population and in Patients with RA By Anti-Citrullinated Protein Antibody Status

Evo Alemao¹, Roshini Indrakumar², Aarti Rao² and Ying Bao¹, ¹Bristol-Myers Squibb, Princeton, NJ, ²Mu Sigma, Bangalore, India

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I: Comorbidities

Background/Purpose: Interstitial lung disease (ILD) is recognized as the most common pulmonary extra-articular manifestation of RA. The hazard ratio for 30-year risk of ILD in patients with RA (vs a matched cohort of patients without RA) is 8.96 (95% CI: 4.02, 19.94).¹ A recent meta-analysis concluded that anti-citrullinated protein antibody (ACPA) positivity was associated with an increased risk of lung disease (pooled odds ratio: 2.6).² The objective of this analysis was to evaluate the prevalence and incidence of ILD by ACPA levels in general and in the population with RA.

Methods: Data from July 1, 2002, to September 30, 2017, from administrative claims database Optum[®] Clinformatics[™] Data Mart were used. Patients with ACPA test information were included in the analysis; the date of the test was the index date for the general cohort and first RA diagnosis date was index date for the RA cohort. The RA cohort comprised patients having ≥ 2 claims for RA and an ACPA test. Patients in the general and RA cohorts were divided into groups based on median ACPA titer values. Identification of patients with ILD was based on a published algorithm that included a two-step process: an initial diagnosis code of ILD, then a code for chest X-ray or CT scan on or after the first ILD diagnosis, and a second chest X-ray or CT scan after the first scan. Incidence rates (IRs) and prevalence rates were calculated for both cohorts and by subgroups based on ACPA levels.

Results: A total of 177,728 patients with ACPA information were identified (overall cohort); of those 20,746 (11.7%) and 156,982 (88.3%) were ACPA+ and ACPA-, respectively. A total of 9827 patients with RA had ACPA information (RA cohort); of whom 2927 (29.8%) and 6900 (70.2%) were ACPA+ and ACPA-, respectively. The prevalence of ILD in the overall cohort was 5.3% versus 8.2% in the RA cohort. The ILD IRs were higher in the ACPA+ versus the ACPA- group in the overall cohort (13.3 vs 8.4 per 1000 patient-years) as well as in the RA cohort (12.9 vs 11.7 per 1000 patient-years). In addition, the ILD IRs were greater for patients with higher ACPA titers in the overall cohort (Table 1).

Conclusion: The prevalence of ILD in patients with RA was higher than that in the general population. The ILD prevalence and IRs were higher in ACPA+ patients and increased with ACPA titer in the overall cohort. Further analysis with a larger RA cohort is required to confirm these findings.

Disease Severity Among Bio-Naive RA Patients on Csdmards

Leslie R. Harrold^{1,2}, Jenny Griffith³, Heather J Litman⁴, Hua Feng², Casey A. Schlacher⁵ and Joel Kremer⁶, ¹University of Massachusetts Medical School, Worcester, MA, ²Corrona, LLC, Waltham, MA, ³AbbVie, Inc., North Chicago, IL, ⁴Corrona LLC, Waltham, MA, ⁵AbbVie Inc., North Chicago, IL, ⁶Albany Medical College and the Center for Rheumatology, Albany, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Background/Purpose: Conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) are recommended as the first-line treatment for patients with rheumatoid arthritis (RA). Guidelines recommend escalation of treatment to combinations of csDMARD and/or biologics for those with moderate to high disease activity despite treatment with csDMARDs. We sought to characterize disease burden among RA patients who had been on a csDMARD for at least six months and who had not transitioned to a biologic.

Methods: We identified patients enrolled in the US Corrona RA Registry between 06/01/2014 and 1/30/2018 who had been receiving csDMARD continuously for at least 6 months, remained biologic naïve, were in moderate or high disease activity (Clinical Disease Activity Index [CDAI] >10) and had at least one follow-up visit. Disease activity was assessed in the subset of patients with a 6 month follow-up visit (+/- 3 months) comparing those who achieved remission/low disease activity (CDAI≤10) to those who remained in moderate/high disease activity (CDAI>10) in terms of demographics, lifestyle factors, comorbid conditions and disease characteristics using descriptive statistics.

Results: There were 525 patients who met study inclusion criteria, with a mean age of 65 (SD 13), mean duration of RA of 11 years (SD 11), and mean duration of csDMARD therapy of 397 days (SD 210). In those with a 6 month visit (n=409), more than half (n=219) remained in moderate/high disease activity (54%) at follow up. Those who achieved remission/low disease activity (n=190) were similar to those in moderate/high disease activity (n=219) at their 6 month visit with respect to age, BMI, comorbid conditions (history of serious infection, cardiovascular disease, malignancy), duration of RA and prednisone dosage. Baseline swollen and tender joint counts were higher in those who did not achieve remission/low disease activity; a higher proportion of those reaching remission/low disease activity were college educated or higher (39%) compared with 27% (Table). Over the 6-month period, treatment acceleration occurred in <30% of patients. Dose escalation of the csDMARD, initiation of another csDMARD and initiation of abiotic DMARD occurred in 57 (14%), 33 (8%) and 42 (10%) of the total population of patients respectively.

Conclusion: Substantial numbers of patients on csDMARDs have persistent moderate/high disease activity over 6 months of follow-up. These observations indicate that there is considerable need for a treat to target approach to care to prevent joint damage and physical disability and maximize long-term health-related quality of life.

Table

Characteristics		Remained in Moderate/ High Disease activity N=219	Achieved Remission/ Low Disease Activity N=190	P value

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple therapeutic options with different mechanistic actions are available to treat patients (pts) with RA. However, selecting therapies by the characteristics of pts with RA is not a fully established practice. Recent evidence suggests that anti-citrullinated protein antibodies (ACPA) status is associated with a differential treatment response to abatacept (ABA), but not to TNF inhibitors (TNFi).^{1,2} The objective of this analysis was to generate additional evidence on the association of biologic (b)DMARD treatment (ABA and TNFi) effect by ACPA status.

Methods: Data from two RA registries were used to address the research objective. One of the registries was an RA disease-specific registry and provided data for the treatment effect of initiating TNFi; the other was a product-specific RA registry and provided treatment effect of ABA initiation. Pts were evaluated by a rheumatologist annually in the RA disease-specific registry and every 3 months in the product-specific registry.^{3,4} The disease-specific registry was a single-center registry and the product-specific registry was a multi-center and multi-country registry. Descriptive statistics were used to summarize baseline demographics, disease activity measures and serostatus for both cohorts. Percentage change and mean change in disease activity from baseline to 12 months by ACPA status were assessed for pts with data available at baseline and follow-up.

Results: Data for a total of 797 TNFi and 2350 ABA pts were available and were included in the analysis. The average (SD) age was 54.9 (13.9) years for pts in the TNFi cohort and 57.8 (12.6) years for pts in the ABA cohort. ACPA information was available for 92% of TNFi and 83% of ABA pts; 70% and 67% of pts in the TNFi cohort and the ABA cohort were ACPA+, respectively. ACPA+ pts in both cohorts had longer disease duration (Table 1). ACPA+ ABA pts had a significantly greater mean change in disease activity on CDAI, SDAI and SJC compared with ACPA- ABA pts. Similar reduction in disease activity was not observed between ACPA+ and ACPA- TNFi pts (Table 2).

Conclusion: ACPA status is associated with a differential treatment response to abatacept, but not TNFi. These findings are consistent with other studies reported in the literature and could be due to the different mechanism of action of abatacept and TNFi.^{1,2}

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: After failure of initial methotrexate(MTX) treatment in rheumatoid arthritis (RA) patients, various treatment options can be considered. To date, evidence about the preferred follow-up strategy is sparse. We aimed to compare consecutive DMARD treatment regimes in daily practice in RA patients who failed on initial MTX monotherapy.

Figure 1. Kaplan-Meier curve showing the probability to stop treatment over time. The figure is based on unadjusted data. Blue line = csDMARD(s), red line = csDMARD(s) + glucocorticoid, green line = bDMARD ± csDMARD(s).

Table 1. Adjusted changes in DAS over time for each medication group (in patients=528)*

Maximum follow-up duration	6 months	95% CI	1 year	95% CI
csDMARD(s)	-0.75	-1.11; -0.42	-0.39	-0.66; -0.13
csDMARD(s) + glucocorticoid	-0.96	-1.32; -0.69	-0.40	-0.62; -0.23
bDMARD (± csDMARD(s))	-2.00	-2.65; -1.35	-0.91	-1.32; -0.60

*Results given for a linear mixed model analyses and were adjusted for multiple propensity scores. Missing data were imputed using multiple imputation by chained equations (MICE) due to the proportion of missing data. The actual timing of follow-up visits differed per patient. Parameter estimates represent the unit of change in DAS per year.

Methods: Newly diagnosed RA patients who had failed initial MTX treatment were selected from METEOR, an international, observational registry. Subsequent DMARD treatment regimens were categorized as: 1) csDMARD(s) only (143 patients), 2) csDMARD(s) + glucocorticoid (278 patients) and 3) bDMARD ± csDMARD(s) (89 patients). We selected follow-up visits until switch to yet another treatment strategy occurred or until a maximum follow-up duration of 1 year. Linear mixed model analyses were performed to analyze treatment responses per treatment group (DAS) after a maximum follow-up duration of 6 and 12 months. Differences in time to stop treatment between treatment groups after a maximum follow-up duration of 1 year were estimated using Cox regression. Analyses were adjusted for multiple propensity scores, to correct for confounding by indication.

Results: Median follow-up duration on studied treatment was 6.9 (IQR4.1; 9.4) months for patients receiving csDMARD (s), 7.8 (IQR 5.0; 10.2) months for patients receiving csDMARD(s) + glucocorticoid and 9.0 (IQR 6.2; 10.9)months for patients receiving treatment including a bDMARD.

We found differences in treatment response between the 3 treatment groups, both after 6 months ($p=0.001$) and after 1 year ($p=0.029$). Adjusted treatment effects over time stratified for treatment groups are shown in table 1. Both after 6 months and after 1 year, patients receiving a bDMARD experienced most decrease in DAS per year, followed by patients receiving csDMARD(s) + glucocorticoid and by patients receiving treatment with csDMARD(s) alone. Results of the Cox regression showed that patients receiving treatment including a bDMARD had a lower hazard for discontinuing treatment (i.e. failing or intolerance) compared to patients receiving csDMARD(s) alone [HR (95% CI) 0.38 (0.24; 0.60)], but there were no differences between csDMARD treatment with- or without a glucocorticoid [HR (95% CI) 0.89 (0.66; 1.20), figure 1].

Conclusion: In this analysis of worldwide common practice data, RA patients who had failed initial treatment with MTX monotherapy had a better DAS response and treatment survival after a subsequent switch to a bDMARD containing treatment regimen than to a regimen with csDMARD(s), with or without glucocorticoids.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari) is an oral JAK1/JAK2 inhibitor approved for the treatment of moderately to severely active RA in adults in over 40 countries including European countries, the United States, and Japan. In the 52-week Phase 3 RA-BEAM study, bari 4 mg once daily (QD) showed clinical improvements compared to placebo (PBO) and to adalimumab (ADA) in MTX-inadequate-responder (IR) patients (pts).¹ The objective of this analysis was to assess if pts who receive bari early attain added clinical improvement compared to pts with a delayed start of therapy.

Methods: In RA-BEAM 1305 pts (mean disease duration 8.7 years) were randomized 3:3:2 to PBO, bari-4 mg QD, or ADA 40 mg every 2 weeks. At Week 16 or subsequent visits, IRs (lack of $\geq 20\%$ reduction in tender and swollen joint count) were rescued to open-label bari-4mg. At Week 24 PBO pts were switched to bari-4 mg. Patients initially randomized to bari-4 mg were considered the early start group for this analysis and PBO pts switched at Week 24 or rescued at Week 16 or later were considered delayed start. Change from baseline using mixed model repeated measures and mean scores were assessed for the Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), DAS28-hs CRP, DAS28-ESR, HAQ-DI, and modified total Sharp score (mTSS) to compare the early vs delayed start groups between Weeks 24 and 52.

Results: In the early and delayed start groups, 35 (7.2%) and 128 (26.2%) pts were rescued to bari between Weeks 16 and 24, respectively. The early start group had significantly greater change from baseline up to Week 32 and showed greater and more rapid reduction through the first 4 weeks ($>50\%$ reduction) for CDAI compared to the delayed start group (Figure 1). At Week 24, the delayed start group showed a CDAI reduction similar to the reduction achieved by the early start group between Weeks 4 and 8 giving the early start group a 4 to 5 month advantage in disease improvement compared to the delayed start group. After receiving bari, the delayed start group also showed a rapid improvement in CDAI and caught up to the early start patients by Week 40. Similar results were seen for SDAI, DAS28-ESR, and DAS28-hsCRP. However, the early start pts had significantly greater improvement in HAQ-DI still maintained at Week 40 (Figure 1) and a significant advantage from Weeks 16 to 52 (Figure 2) for mTSS.

Figure 2. Structural outcomes in the early (baricitinib group) and delayed (placebo group) start patients. *P-value ≤ 0.05 , **P-value ≤ 0.01 , ***P-value ≤ 0.001 vs placebo

Conclusion: While overall disease activity improvement was similar, early start of bari treatment provided faster efficacy. A delay of up to 6 months in bari treatment had an impact on HAQ-DI and structural damage progression.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: What is the optimal glucocorticoid (GC) bridging therapy with MTX monotherapy in early arthritis?

Methods: In trial A, early RA and UA (arthritis in ≥ 1 joint(s), < 1 year symptoms) patients were randomised to 3 different treatment arms. Here we used data of arm C where patients were treated with prednisone (15 mg/day, tapered to 0 in 10 weeks) and MTX (25mg/week).

In trial B, RA and UA (arthritis in ≥ 1 joint and ≥ 1 other painful joint) patients were treated with prednisone (60 mg/day, tapered in 7 weeks to 7.5 mg/day, continued to 4 months) and MTX (25 mg/week). We compared changes in DAS and HAQ and percentages with DAS ≤ 2.4 and with DAS < 1.6 at first evaluation (3 months in trial A, 4 months in trial B).

Figure 1A: Observed DAS over time, B: Observed HAQ over time, C: Predicted delta DAS, D: Predicted delta HAQ. All predictors are from multiple imputed models, adjusted for age, gender, body mass index, presence of ACPA, presence of rheumatoid factor, symptom duration, effect over time (in DAS) and baseline DAS (for binary outcomes). DAS, Disease Activity Score; HAQ, Health Assessment Questionnaire.

After multivariate normal imputation we applied generalized estimating equations (GEE) for linear outcomes and logistic regression models for binary outcomes, adjusted for potential baseline confounders (figure 1). Adverse events were compared using binominal probability test.

Results: At baseline, patients in trial A (n=97) were more often APCA positive (77% vs 56%) and less often had UA (2% vs 20%) than in trial B (n=610). Baseline DAS, HAQ and symptom duration were comparable.

At the first evaluation time point (median 3.0 (IQR 2.98-3.2) months in trial A, 4.0 (3.8-4.2) in trial B), DAS and HAQ had decreased significantly less in trial A (DAS β 0.500 (95% CI 0.276; 0.725), and HAQ 0.330 (0.189; 0.470) (figure 1). Fewer patients in trial A achieved DAS<1.6 (29% vs 63%) (adjusted OR 0.215 (95% CI 0.124; 0.373) and DAS \leq 2.4 (56% vs 81% (adjusted OR 0.249 (0.143; 0.435)). Presence of ACPA was positively associated with achieving DAS<1.6 in trial B, but not in trial A. Reported serious adverse events were 23 per 100 patient years in trial A and 8 in trial B (table 1). Table 1. Most frequently reported adverse events, per 100 patient years

	Trial A (n=97)	Trial B (n=610)	p
Malaise	42.9	9.45	0.000
Gastrointestinal symptoms	97.6	48.7	0.004
Hypertension	0.00	9.95	0.091
Hyperglycaemia (>7.8mmol/l)	0.00	8.46	0.130
Infections	46.9	39.8	0.582
Skin rashes	27.3	7.96	0.014
Hair loss	23.4	9.45	0.074
Headache	31.2	8.95	0.008
Depression/feeling sad	31.2	11.9	0.031
Bone marrow depression	15.6	0.00	0.000
High creatinine (above normal)	11.7	0.00	0.001
Liver enzymes (above normal)	35.1	22.4	0.229
Dizziness	3.90	5.47	0.837
Dyspnoea	0.00	3.48	0.432

Conclusion: In early arthritis patients, MTX with prednisone 60 mg/day tapered in 7 weeks to and continued at 7.5 mg/day was associated with better early clinical outcomes and fewer (serious) adverse events although slightly more hypertension and hyperglycaemia than MTX with prednisone 15mg daily tapered to nil in 10 weeks.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Monotherapy with etanercept (ETN) maybe a viable therapeutic option for maintenance of patients with rheumatoidarthritis (RA) who prefer to eliminate potential burdens or side effects of combination therapy. Our objective was to compare persistence of low disease activity (LDA)/remission in patients with RA who were on combination therapy with ETN and a conventional synthetic disease-modifying antirheumatic drug (csDMARD; most commonly methotrexate) who then either discontinued the csDMARD or continued on combination therapy.

Methods: This analysis included RA patients from the Corrona registry during 10/1/2001–8/31/2017. ETN monotherapy (Mono) patients were initially treated with ETN + csDMARD combination therapy, achieved Clinical Disease Activity Index

(CDAI) LDA/remission (score ≤ 10), and discontinued the csDMARD (index visit). The index visit for the comparator combination therapy (Combo) group (patients who continued on combination therapy) was selected as the date that had a similar time interval from the initiation visit as the Mono group. Propensity score (PS) matching (1:2 without replacement) was used to ensure balanced groups and included variables selected a priori (baseline CDAI, RA duration, duration in LDA/remission before index) and variables not originally balanced between the Mono and Combo groups. Cox regression was used to compare persistence in LDA/remission between the groups, overall and at specific timepoints, adjusted for any covariates that remained imbalanced after PS matching. Patients were censored if disease activity increased to moderate or severe, ETN was discontinued, or a csDMARD was reinitiated (in patients in the Mono group).

Results: We identified 182 Mono and 403 Combo patients. After matching, 120 Mono and 207 Combo patients were eligible (45 on Mono had >3 years ETN before index date and could not be matched). After PS matching, characteristics at index visit were similar between groups except prednisone dose (mean [standard deviation] 6.2 [2.6] for Mono, 4.7 [3.4] for Combo; standardized difference 0.488). Models indicated that a substantial proportion of both Mono and Combo groups remained in LDA/remission through 24 months after the index date (Table). The overall persistence in LDA/remission between Mono and Combo groups was not statistically different ($P = 0.057$).

Conclusion: Approximately 3 of 4 patients with RA remained on ETN Mono and maintained LDA/remission for 2 years after csDMARD discontinuation. Although Combo persistence was numerically greater than Mono, the high level of persistence with ETN Mono following achievement of LDA/remission and discontinuation of csDMARD suggests that ETN Mono may be a viable option for patients who cannot adhere to or tolerate csDMARDs. Persistence in LDA/Remission*

Time after index visit	ETN Mono (N = 120)	ETN + csDMARD Combo (N = 207)
6 months	0.88	0.96
12 months	0.77	0.92
18 months	0.75	0.89
24 months	0.75	0.86

* Models were adjusted for sex, race, age group, insurance type, anti-cyclic citrullinated peptide antibody status, and prior csDMARD use.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Targeted immunomodulators (TIMs) have revolutionized the therapy of RA and made low disease activity (LDA) a realistic goal for patients. Given the multiple therapy options available, our goal was to quantify and describe the current state of unmet need by examining the proportion and characteristics of patients with moderate/high disease activity using real world registry data.

Methods: We identified patients in the Corrona RA registry ≥ 18 years old with ≥ 1 -year follow-up from 01/2012 to 06/2017. In a cross-sectional cut, we evaluated the percentage of patients with moderate or high disease activity (Clinical Disease Activity Index [CDAI] > 10) at the last registry visit. Then, we estimated the number of patients on continuous therapy (no interruption in therapy > 30 days) with a TIM ≥ 6 months before the last registry visit. Demographic/disease characteristics and treatment history were described. Patient reported outcomes (PROs) and disease activity in the 12 months before the last visit were assessed. PROs included mHAQ, pain, fatigue, Patient Global Assessment (PtGA), and morning (AM) stiffness duration. Percentages of patients with improvement \geq minimum clinically important difference (MCID) from index visit to last registry visit were estimated.

Results: Of 30,100 patients with ≥ 1 year of follow-up, 10,400 (35%) had CDAI >10 at the last registry visit. Of these 5,090 were on continuous therapy with a TIM ≥ 6 months. In this cohort, mean age was 61 years, 81% were female, 87% were white, mean duration of RA was 14 years, 69% and 58% were seropositive for RF and CCP, respectively. Mean CDAI was 21.2, mean mHAQ was 1.2; 35% of patients had high disease activity (CDAI >22), 88% reported having AM stiffness and in 56% its duration was >1 hr. Approximately 39%, 26%, and 16% of patients were treated with their first, second, and third TIM, respectively; 85% were on the same TIM for ≥ 12 months. Out of 5,090 patients, 3,625 patients had a registry visit within 12 months prior to their most recent visit (index visit). Mean PRO scores at index and last registry visits are shown in **Table 1**; $<25\%$ reported improvements \geq MCID in CDAI or PRO scores (**Table 2**).

Conclusion: For 35% of patients followed in the Corrona RA registry, LDA was not achieved. Half had been on a TIM >6 months. In most of these patients, disease activity remained high and patients had significant pain, fatigue, AM stiffness, and reduced physical function. These data clearly indicate that there is an unmet need for new effective therapies to help patients meet treat-to-target goals.

Table 1. PRO Measures in Patients on TIMs ≥ 6 Months

	Index Visita n=3,625	Last Visit n=5,090
mHAQ, mean \pm SD	1.1 \pm 0.7	1.2 \pm 0.7
Pain VAS, mean \pm SD	47.7 \pm 27.3	53.2 \pm 26.3
Fatigue VAS, mean \pm SD	50.6 \pm 28.3	55.0 \pm 27.8
Duration AM stiffness (min), mean \pm SD	90.3 \pm 170.0	105.0 \pm 202.2
Patients with AM stiffness, n (%)		
None	559 (15.7)	614 (12.2)
<30 min	517 (14.5)	704 (14.0)
30–60 min	636 (17.9)	902 (17.9)
>60 min	1836 (51.5)	2801 (55.5)

^a Registry visit ≥ 12 months before the last visit (9-15-month window was used, if there was >1 visit in the range, the visit closest to 12 months was the index visit).

Table 2. Patients Who Reported Improvement in CDAI or PROs \geq MCIDa From Index Visitb to Last Registry Visit

Outcome, n (%)	On TIM ≥ 6 months n=3,625
CDAI	707 (19.7)
mHAQ	652 (23.5)
Pain	789 (21.9)
Fatigue	612 (22.2)
PtGA	776 (21.5)

^a MCID was defined as change in CDAI >6 for patients starting in moderate disease activity, CDAI >12 for patients starting in high disease activity, decrease of ≥ 0.25 points for mHAQ, and decrease of 10 points for pain, fatigue and PtGA.

^b Registry visit ≥ 12 months before the last visit (9-15-month window was used, if there was >1 visit in the range, the visit closest to 12 months was the index visit).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Discontinuation of biologic medications in rheumatoid arthritis (RA) can be used as a proxy for drug efficacy when direct measures of disease activity are not available. Recent data comparing the discontinuation rates of

different biologics, specifically tumor necrosis factor (TNF) vs. non-TNF, have been mixed. Further, most of the existing data on this topic comes from controlled trials or cohorts of referred patients. Our objective was to determine drug discontinuation rates for TNF and non-TNF biologics and identify predictors and indications for discontinuation in a population based cohort.

Methods: We retrospectively studied 606 patients with incident RA from 1999-2013 in a geographically well-defined population. All patients met the 1987 American College of Rheumatology classification criteria for RA and were followed until July 1, 2016. Discontinuation rates were estimated using cumulative incidence adjusted for the competing risk of death. Cox models were used to examine potential predictors of discontinuation.

Results: 156 patients were treated with at least one biologic medication (mean age at first biologic: 52 years; 71% female; median years from RA diagnosis to first biologic: 1.3; median follow-up: 6.0 years). Cumulative incidence for time to discontinuation for first TNF biologic was 38% at 1 year (95% confidence interval [CI], 30-47%) and 56% at 2 years (95% CI, 48-65%). For first non-TNF biologic, these values were 46% at 1 year (95% CI, 34-62%) and 55% at 2 years (95% CI, 42-71%). The most common reasons for discontinuation of any first biologic were inefficacy (43%), adverse effects (15%), and achievement of therapeutic goal (13%). The frequencies of each reason were similar between TNF and non-TNF treated patients. Potential predictive factors for discontinuation, including age, sex, years from RA diagnosis, rheumatoid factor/anti-citrullinated protein antibody positivity, smoking, and obesity, did not reach statistical significance with the exception of age ≥ 65 years, which was associated with increased risk for discontinuing non-TNF biologics (hazard ratio: 3.06; 95% confidence interval: 1.52-6.16).

Conclusion: Discontinuation rates were similar between TNF and non-TNF biologics. We did not identify any significant predictors of drug discontinuation apart from age in this population.

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate and leflunomide are anchor conventionalsynthetic DMARDs (csDMARDs) for rheumatoid arthritis (RA) treatment. Although methotrexate is the usual recommended concomitantcs DMARD along with biological DMARDs (bDMARDs), leflunomide is an alternative treatment option. Objective of this study was to describe leflunomide survival with concomitant bDMARDs use.

Methods: TReasure is a multicenter,web-based registry of RA and spondyloarthritis patients receiving targeted treatments. As of May 2018, 1401 RA patients were recorded. Age, sex, disease duration, BMI, initial bDMARDs, acute phase reactants, swollen and tender joint counts (28 joints), patient global assessment of disease activity, pain VAS, DAS-28, CDAI, and SDAI were recorded before starting bDMARDs. Patients starting a bDMARD were divided into two groups. Group 1 included patients receiving concomitant leflunomide with or without other csDMARDs combined with leflunomide. Group 2 consisted of patients using other concomitant csDMARDs or combinations that did not include leflunomide. DAS-28 disease state at the last recorded visit was compared. Retention rate of leflunomide was calculated by Kaplan-Meier analysis.

Results: Overall, 1401 patients, 444 of which (31.6%) using leflunomide with their first bDMARD were included. Demographic data and baseline disease activity are given in table 1. Initial bDMARDs in group 1 were anti-TNF drugs 275 (61.9%), abatacept 77 (17.3%), rituximab 59 (13.3%), tofacitinib 20(4.5%), and tocilizumab 13 (2.9%). At the baseline visit leflunomide was combined with hydroxychloroquine [266 (59.9%)],methotrexate [83 (18.7%)], or sulfasalazine [67 (15.1%)]. Median (Q1-Q3)duration of treatment with leflunomide was 28 (7-54) months. DAS-28 activity state at the last visit for group 1 and group 2 were; high in 8.8% vs. 8.5%, moderate in 36.7% vs. 33.3%, low in 20.2% vs. 18.0%, and remission in 34.3% vs. 40.1%respectively (p=0.31). Median (Q1-Q3) DAS-28 score at the last visit was not significantly different between groups [3.05 (2.31-3.96) vs. 2.86 (2.18-3.82), p=0.11]. Five-year survival of bDMARDs with concomitant leflunomide was around 80% (figure 1).

Conclusion: Leflunomide was one of the major concomitant csDMARDs in our RA biological registry. It was combined with both anti-TNF and other biologics. Retention rate of bDMARDs with concomitant leflunomide was satisfactory and disease activity with leflunomide was not significantly different from that with other synthetic DMARDs.

Figure 1. Leflunomide retention rate while using bDMARD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Drug tolerability indicates both the patient's and doctor's satisfaction and useful summary measure of overall treatment effectiveness and toxicity. Although more than 5 years have passed since 7 biologics became available for patients with rheumatoid arthritis (RA) in our country, we still lack reliable evidence in directly compared drug tolerability and discontinuation reasons of 7 biologics in a real-world setting of RA.

Methods: In this 7-center, retrospective study, 4466 biologics treatment courses from 2009 to 2017 (female 82.7%, baseline age 57.6y, Bio naïve 63.6%, disease duration 7.8y, rheumatoid factor positivity 76.3%, anti-cyclic citrullinated peptide

antibody (ACPA) positivity 82.7%, disease activity score assessing 28 joints with CRP 3.9, modified Health Assessment Questionnaire 0.7, methotrexate 8.2 mg/week (limited to 16mg/week in our country), prednisolone 6.5 mg/day, number of each agent; tocilizumab (TCZ) 895, etanercept (ETN) 891, infliximab (IFX) 748, abatacept (ABT) 681, adalimumab (ADA) 558, golimumab (GLM) 464, and certolizumab pegol (CZP) 229) were included. Reasons for discontinuation of each biologic were analyzed and classified into 4 major categories: 1) inefficacy (both primary and secondary); 2) toxic adverse events (infection, skin or systemic reaction, hematologic, pulmonary, renal, cardiovascular complications and malignancies); 3) remission; and 4) nontoxic reasons (patient preference, change in hospital, desire for pregnancy, etc.). The judgment and reasons for discontinuation (only one reason were allowed to cite) depended on the decisions of each attending physician. Drug tolerability at 36 months were evaluate by Kaplan-Meier method for each discontinuation reasons, and adjusted by potent confounding factors (sex / age / ACPA positivity / switched biologics numbers) using a Cox proportional hazards model.

Results: The causes of 7 biologics treatment discontinuation at 36 months were as follows. Drug inefficacy (45.4%), nontoxic reasons (22.4%), toxic adverse events (21.0%), and remission (11.2%). Adjusted cumulative incidence rates of each agent and discontinuous reason at 36 months were as follows. Drug inefficacy (TCZ 22.5%, ABT 26.1%, GLM 32.3%, CZP 33.5%, ETN 37.7%, ADA 38.6%, and IFX 38.7%; Cox P < 0.001), toxic adverse events (CZP 6.2%, ABT 7.4%, ETN 11.1%, TCZ 11.8%, ADA 14.9%, GLM 16.4%, and IFX 17.0%; Cox P = 0.0049), and remission (ETN 3.1%, ABT 4.8%, CZP 5.3%, TCZ 5.8%, GLM 6.8%, ADA 10.2%, and IFX 10.7%; Cox P = 0.0018). Overall adjusted tolerability excluding nontoxic reasons and remission were ABT 68.5%, TCZ 68.3%, CZP 62.3%, GLM 56.5%, ETN 55.4%, ADA 52.2%, and IFX 50.9% (Cox P < 0.001).

Conclusion: TCZ and ABT showed lower inefficacy and higher overall retention, ABT and CZP showed lower toxic adverse events, and ADA and IFX showed higher bio-free induction due to remission compared to other biologics in background-adjusted models. These novel findings may contribute to adequate biologics selection in the clinical practice of RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABA), a selective T-cell co-stimulatory modulator, has shown efficacy similar to TNF inhibitors (TNFi) for RA management in clinical trial settings, but different patient (pt) subtypes have shown a differential response to treatments in real-world and clinical trial settings. Additional data comparing the characteristics and associated clinical responses in pts receiving ABA versus other DMARDs in real-world community practice settings are needed.

Methods: We analyzed data from 24,602 pts with RA exposed to DMARDs from January 1, 2014 to September 30, 2017 in the United Rheumatology Database, which provides electronic medical record data from 120 community-based rheumatology providers. Baseline (BL) differences in demographics, disease activity and laboratory measurements were analyzed descriptively between pts receiving ABA versus TNFi, conventional (c)DMARDs and biologic (b) or targeted synthetic (ts)DMARDs of other mechanisms of action (other b/tsDMARDs) as first- or later-line therapy. Mean changes from BL to Year 1 (using records dated closest to Year 1) in CDAI scores were assessed using multivariate linear regressions adjusting for BL covariates (age, sex, smoking status, BMI, Charlson Comorbidity Index, CDAI score and number of prior treatments). Exposure was treated similarly to an intent-to-treat analysis (first observation carried forward).

Results: At BL, ABA pts (vs all other DMARD pts) had higher low- and high-density lipoprotein levels, and were more likely to have a history of type 1 or 2 diabetes (Table 1). ABA pts also had higher BL disease activity (CDAI; mean [SD]: 20.3 [13.0]) versus other b/tsDMARD (19.9 [13.4]), TNFi (18.1 [13.2]) and cDMARD pts (14.4 [12.4]; Table 1). After adjusting for BL covariates, the reduction in least square mean (LSM) CDAI from BL was greater in ABA pts (−5.6) than other b/tsDMARD pts (−3.4); this difference suggested a trend toward significance (2.2 [95% CI: −0.2, 4.6]; p=0.07). The reduction in LSM CDAI was comparable between ABA and TNFi pts (Table 2).

Conclusion: Pts with RA receiving abatacept (vs other DMARDs) in community practice settings tend to have higher disease activity and a history of diabetes, which have been associated with worse clinical response to treatment. Nonetheless, mean changes in disease activity from BL to Year 1 in pts receiving abatacept versus other b/tsDMARDs were larger in magnitude, although the difference was not statistically significant. Additional analyses with a larger pt population are warranted. Writing support provided by Bu Reinen, PhD (Caudex), funded by Bristol-Myers Squibb.

Table 1. Baseline Characteristics of Patients With RA in the United Rheumatology Database*

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been well known that anti-TNF- α treatment for RA patients is associated with ANA development. We previously reported that ANA development along with ANA levels at base line were associated with poor outcomes of infliximab (IFX)(1). However, no replication studies have been reported. In addition, whether the findings are true to general biologic DMARDs (bDMARDs) is uncertain. Here, we evaluate an association between poor treatment response and ANA development during bDMARDs treatment in RA patients and analyze correlates of ANA development.

Methods: Japanese RA patients treated with (n=657) or without (n=211) bDMARDs (IFX, etanercept ETN, adalimumab ADA, golimumab GLM, certolizumab pegol CZP, tocilizumab TCZ, abatacept ABT) as a first line bDMARD were enrolled from a single center cohort. The study participants were not registered in the previous study (1). ANA was measured by indirect immunofluorescence assays at multiple time points of treatment. We conducted multiple logistic linear regression analysis to assess effects of ANA development on treatment outcomes. We further analyzed correlates of ANA development by using patients with RA who were treated by MTX but not by bDMARDs as controls.

Results: ANA development (≥ 2 times baseline levels) at 3 months and at 6-12 months after bDMARDs initiation were significantly associated with insufficient response within a year (odds ratio (OR)=3.51, p=0.020) and between 12 and 24 months (OR=3.16, p=0.038), respectively. The associations remained significant after conditioning on each bDMARD use (OR=3.16-3.56, p<0.05), indicating the observed association was not limited to IFX use. The use of IFX was a risk for ANA development (OR=6.36, p<0.001), and the use of other TNF- α inhibitors (TNFi) also showed the same trends as IFX use (OR=1.68, p=0.214). On the other hand, the use of non-TNFi bDMARDs was not associated with ANA development (OR=0.792, p=0.675).

Conclusion: ANA development could be a marker of poor treatment response in RA patients undergoing bDMARDs treatment. Undefined common factors among RA patients treated with bDMARDs might influence ANA development and subsequent poor treatment outcome.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to evaluate three year outcomes of patients with elderly-onset RA (EORA) who were treated with a therapeutic strategy targeting low disease activity (LDA), and clinical factors associated with physical dysfunction in patients who achieved LDA.

Methods: Data of 197 MTX-naïve EORA (mean age 74.9) from a prospective, monocentric registry were analyzed. Treatment was adjusted targeting LDA defined by DAS28-ESR or simplified disease activity index (SDAI). Treatment was initiated with non-biologic DMARDs (nbDMARDs), followed by biologic DMARDs such as TNF inhibitors, tocilizumab, or abatacept. Primary outcomes were obtained from SDAI and the HAQ disability index (HAQ-DI). Serious adverse events (SAEs) during three years of observational period were assessed at all visits. Associated factors of physical dysfunction (HAQ-DI >0.5) in patients who achieved SDAI-LDA at week 156 or at dropout were examined using multivariate logistic regression models.

Results: MTX was administered in 167 (85%) of the 197 patients, and dose-dependent adverse drug reactions were observed in 100 patients, and 158 patients received mean 8.5 mg/week of MTX at week 24, and 35% of them received a biologic DMARD with or without MTX at week 52, 36% at week 104, and 33% at week 156. Median dose of 3.5mg/day of prednisolone (PSL) were administered with DMARDs in 17% of the patients at week 156. Adherence to the treat-to-target (T2T) strategy was observed in 81%, 87%, 91% at week 24, 52, and 104 weeks, respectively. At week 56, 104, and 156, SDAI-LDA was achieved in 73%, 82%, and 88% by last observation carried forward analysis, SDAI-remission in 36%, 50%, and 56%, and HAQ-DI ≤0.5 in 68%, 71%, and 72%, respectively. Clinically relevant radiological progression (CRRP: Δ modified total sharp score [mTSS] /year >the smallest detectable change [2.1]) was observed in 28% at week 52. Infection requiring hospitalization occurred in 31 patients during the observational period, extra-articular manifestations in 13, ischemic heart disease in 9, malignancy in 11, and bone fracture in 20. Twenty-nine (15%) of the 197 patients dropped from the study for aging (dementia or sarcopenia) in 11, patient decision in 6, exacerbation of interstitial lung disease in 5, infection in 4, malignancy in 2, and sudden death in 1, and 18 of the 29 patients achieved LDA at dropout. HAQ-DI ≤0.5 was not achieved in 46 of the 173 patients who achieved LDA at week 156 or at dropout. Multivariate analysis showed older age (odds ratio (OR) 1.15, 95% confidence interval (CI) 1.07-1.23), SAEs occurred during the observational period (OR 3.96, 95%CI 1.76-8.92), and higher SDAI (OR 1.16, 95%CI 1.02-1.33) were significantly associated with risk of non-achievement of HAQ-DI ≤0.5 in patients who achieved SDAI-LDA. Comorbidities at baseline, mTSS at baseline, and CRRP at week 52 were not significant. Infection requiring hospitalization, ischemic heart disease, and bone fracture were significant among the SAEs.

Conclusion: The patients with EORA can achieve clinical remission and normal physical function by therapeutic strategy targeting LDA. SAEs under T2T strategy of EORA have great impact on physical dysfunction in patients who achieved treatment goals.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR treat-to-target approach for rheumatoid arthritis (RA) recommends regular assessments of disease activity and adjustment of medication regimen until efficacy goals are met. Given recent advances in pharmacologic therapy, this study assessed recent treatment patterns in RA patients (pts) who had newly initiate da DMARD.

Methods: Adult pts with ≥2 claims for RA, initiating first DMARD between 1/2012–9/2016 (index date; ID) were identified in fully-adjudicated commercial medical and pharmacy health insurance claims, including self-insured, full-risk, and Medicare policies for approximately 40 million lives annually. Those with 12-months continuous enrollment pre- and post-ID and without DMARD claims 12 months pre-ID were selected. Initial utilization of conventional synthetic DMARDs (csDMARDs), TNF inhibitors (TNFi), anti-IL6 pathway antibodies, other biologic DMARDs (bDMARDs), and JAK inhibitors (JAKi), as monotherapy and in combination with csDMARDs, was summarized with descriptive statistics. Median therapy duration was assessed with Kaplan-Meier method. End of treatment was defined as drug discontinuation, switch to a new therapy, or addition of another DMARD.

Results: Among 26,808 identified pts (74.2% female; mean age 51.9±11.0 yrs), 97.7% of pts initiated monotherapy and 2.3% started combination therapies. The most commonly-prescribed monotherapies were csDMARD (91.3%) and TNFi (6.6%). The most commonly-prescribed treatments in combination with csDMARDs included TNFi (88.0%) and other bDMARDs (7.3%). The median duration of csDMARD monotherapy was 230 days. The median treatment duration (combination vs monotherapy) was: 225 vs. 206 days (TNFi), 227 vs. 203 days (anti-IL6), 198 vs. 182 days (other bDMARDs), and 347 vs. 301 days (JAKi). JAKi treatment had the longest therapy duration when combined with csDMARDs (347 days), and other therapies lasted for a median of 182-230 days. As monotherapy, JAKi duration was 301 days, and other therapies lasted for a median of 198-227 days.

Conclusion: Real-world data from US longitudinal healthcare claims showed that in RA pts newly initiating DMARDs, the median duration of therapy was less than a year, suggesting a need for a treatment with improved response durability. Duration of JAKi therapy was longer than median duration of other therapies. Further research is needed to determine the reasons for the longer persistence of JAKi therapy and why persistence is low with RA therapies overall.

Therapy initiated by DMARD naïve patients	N	% within monotherapy and combination therapy subgroups	Median length of therapy (days) ¹	% of subjects still on index therapy at day 360	Mean Age (SD)	Female (N, %)	Mean CCI (SD)
Monotherapy	26182		227	38.3%	51.9 (11.0)	19429 (74.2)	1.3(1.1)
initiating csDMARD	23852	91.1%	230	38.6%	52.0 (10.9)	17730 (74.3)	1.3(1.1)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Co-medication with conventional synthetic DMARDs (csDMARDs) is currently recommended with all targeted therapies (bDMARDs and tsDMARDs) for the management of rheumatoid arthritis (RA). However, targeted DMARDs are often used as monotherapy,

Primarily because of intolerance to methotrexate and other csDMARDs. Our aim was to analyze the impact of combination with csDMARDs on the effectiveness of tofacitinib (TOFA), Tumor Necrosis Factor inhibitors (TNFi) and biologic agents with an alternative mode of action (OMA, abatacepter tocilizumab) in a large cohort of patients with RA.

Methods: In an observational cohort study (SCQM), we included all RA patients initiating a new therapy with TOFA, TNFi, or OMA between August 2013 and March 2018, who had at least one follow-up visit. We analyzed whether the effectiveness of TOFA, TNFi and OMA was modified by concomitant csDMARDs therapy at baseline (COMBI) compared to monotherapy (MONO). The primary outcome was drug maintenance, defined as the time from initiation to discontinuation of treatment. A secondary outcome was low disease activity (LDA) state based on the CDAI at 12 months. We used Kaplan–Meier curves to display drug maintenance and Cox proportional hazard models to analyze the hazard for treatment discontinuation. We adjusted for potential confounders (gender, age, disease duration, seropositivity, BMI, smoking, baseline CDAI number of distinct previous bDMARDs). We applied multiple imputation to account for missing baseline covariate data.

Results: A total of 2503 treatment courses were included, 436 on TOFA, 1244 on TNFi, and 823 on OMA. On average, patients on TNFi were younger, less prior bDMARD and received more COMBI. MTX was by far the most commonly prescribed COMBI with all three targeted therapies (88%-90%). (Table)

In multivariable adjusted models, TOFA maintenance was not different in MONO- compared to COMBI-therapy (Hazard Ratio (HR)_{MONO}: 1.05 (95%CI: 0.77 - 1.45)), nor was OMA maintenance (HR_{MONO}: 1.04 (95%CI: 0.84 - 1.30)). On the contrary, TNFi maintenance was significantly decreased in MONO (HR_{MONO}: 1.28 (95%CI: 1.07 - 1.53)).

Low disease activity (LDA) at 12 months was achieved in 47%, 44% and 40% of patients treated respectively with TOFA, OMA or TNFi. The likelihood of reaching LDA with TOFA or with OMA was not significantly modified by MONO (OR_{MONO}: 1.13 (95%CI: 0.70 - 1.83), OR_{MONO}: 1.04 (95%CI: 0.84 - 1.30), respectively), while the likelihood of LDA was significantly reduced for TNFi in MONO (OR_{MONO}: 0.66 (95% CI: 0.49- 0.89)).

Conclusion: In this 'real world' cohort, combination therapy with csDMARDs did not improve drug-maintenance and effectiveness of TOFA or OMA, whereas TNFi appeared to require comedication for optimal treatment results. Our results suggest that usefulness of concomitant csDMARDs varies according to the type of targeted therapy.

Table – Patient and disease characteristics at treatment initiation

	TOFA (N=436)	TNFi (N=1244)	OMA (N=823)	<i>p</i> value

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound (US) is sensitive for detection of synovitis (assessed by Grey Scale (GS) and power/color Doppler). Presence of Doppler activity is found to predict erosive progression. Clinical disease activity in rheumatoid arthritis (RA) is usually evaluated by Composite Disease Activity Scores (CDAS) like CDAI, SDAI and DAS28. Treatment with subcutaneous tocilizumab (TCZ-SC), an IL-6 inhibitor, causes rapid fall in ESR and CRP. Thus, use of CDAS, which includes ESR or CRP, may not give correct information about the inflammatory activity, while this could potentially be better reflected by use of US. The present purpose was to explore the longitudinal response of TCZ-SC on US synovitis in comparison with CDAS in patients with RA.

Methods: This is a multi-country (Denmark, Finland, Norway, Sweden), open-label, single-arm study (part of TOZURA (1)), enrolling patients (pts) with inadequate response to csDMARDs. Pts received TCZ-SC 162 mg qw for 24 weeks as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (CS) (≤10 mg/day prednisone or equivalent), were allowed. US examination (36 joints and 4 tendons, scored according to the Norwegian US atlas (2)) and clinical (examiner's and patient's global VAS, 28 TJC, 28 SJC and ESR/CRP) were performed at baseline, 4, 12 and 24 weeks. Sum scores of GS/Doppler and CDAS were calculated, and remission by US (defined as sum score Doppler of 0, 1, 2 or 3) and CDAS (including Boolean) was explored.

Results: 110 pts were followed with US assessments (83% female, mean (SD) age 55.6 (12.1) years, RA duration 8.7 (9.5) years, 81% anti-CCP positive and 62% with erosive disease). Already after 4 weeks US, clinical variables and CDAS

decreased significantly ($p < 0.001$), and ESR/CRP reached normal levels (table 1). At 24 weeks, CDAI, SDAI and Boolean remission was found in 34.7%, 33.7% and 27.4%, while DAS28(ESR), being more influenced by low ESR, showed remission in 83.5%. US showed major reduction of synovitis after 24 weeks, where stringent Doppler remission criteria showed remission in more than half of the patients (sum score 0; 53.3%, 1; 65.6%, 2; 75.6% and 3; 78.9%).

Conclusion: The different CDAS showed large discrepancies in number of patients in remission. US detected synovitis was markedly reduced with the initial effect seen already after 4 weeks, and with more than half of the patients achieving absence of Doppler activity after 24 weeks.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SB4, SB2, and SB5 are biosimilars of reference etanercept, infliximab, and adalimumab, respectively. Radiographic data were assessed using the modified Total Sharp Score (mTSS) at week 0 and final week (week 52 for etanercept and adalimumab and week 54 for infliximab) in phase III biosimilar studies.¹⁻³ The purpose of this analysis is to identify baseline demographics and disease characteristics that are associated with radiographic progression (RP) and build a matrix model to show the proportion of patients with RP by the identified baseline factors.

Methods: Patients who had radiographic data were pooled. RP was defined as a change in mTSS > 0 from week 0 to final week. The three baseline factors that had the strongest Pearson's correlation coefficient with the change in mTSS were selected, and univariate logistic regression analysis was performed to assess the association between each baseline factor and predicted probability of patients with RP. Then, multivariate logistic model was fitted to develop a matrix that shows the proportion of patients with RP in each tertile of baseline factors.

Figure 1. Predicted Probability (with 95% Confidence Limits) of Patients with RP Based on SJC28, PGA, and CRP

CRP, C-reactive protein in mg/L; PhGA, physician global assessment; SJC28, 28 swollen joint count; VAS, visual analogue scale

Figure 2. Matrix Model of the Proportion of Patients with RP based on SJC28, CRP and PhGA

Table 1. Baseline Demographics and Disease Characteristics

	Total Number of Patients (n=1371)	p-value of Pearson's Correlation Coefficient with the Change in mTSS
Baseline mTSS	37.9 (36.8)	NA
Age, yr	51.4 (12.0)	0.38
Female, n (%)	1120 (81.7%)	0.24
RA Disease duration, yr	5.9 (4.9)	0.94
MTX dose, mg/week	15.2 (4.4)	0.94
SJC28	11.0 (5.3)	0.0041
PhGA	15.1 (8.3)	0.13
HAQ-DI	1.3 (0.6)	0.03
DAS28 (ESR)	4.3 (0.8)	0.02
SDAI	19.9 (11.8)	0.004
CDAI	28.5 (11.4)	0.009
PhGA, mm	61.9 (23.5)	0.048
Patient global VAS, mm	61.9 (23.6)	0.13
Patient pain VAS, mm	62.0 (23.5)	0.13
CRP, mg/L	13.3 (19.1)	0.033
ESR, mm/h	44.4 (20.4)	0.12
RP positive n (%)	1038 (75.4%)	0.73

NA, Not applicable; this parameter is not applicable.

CRP, C-reactive protein in mg/L; DAS28, disease activity score by 28 joints; ESR, erythrocyte sedimentation rate; SJC28, 28 swollen joint count; HAQ-DI, Health Assessment Questionnaire; MTX, methotrexate; PhGA, physician global assessment; SJC28, 28 swollen joint count; SDAI, Simplified Disease Activity Index; VAS, visual analogue scale; VAS, mm.

Results: A total of 1371 patients had radiographic assessments. The mean change in mTSS was 0.41 and the number of patients who had RP was 376 patients (27.4%). The swollen joint count 28 ([SJC28], p -value = 0.0041), C-reactive protein ([CRP], p -value=0.033), and Physician Global Assessment ([PhGA], p -value = 0.048) had the strongest correlation with RP (Table 1). Predicted probability of patients with RP as a function of SJC28, CRP, and PhGA is displayed in Figure 1. The proportion of patients with RP increased as baseline levels of each factor worsened (Figure 2). The proportion of patients with RP was greatest (37%, 95%CI: 32, 43) in the highest tertile of each category (SJC28 >17, CRP >30, and PhGA >80) and least (12%, 95% CI: 8, 20) in the lowest tertile of each category (SJC28 < 10, CRP <5, and PhGA <50).

Conclusion: A pooled radiographic assessment data showed that baseline SJC28, CRP, and PhGA are associated with RP, and the proportion of patients with RP increases as each baseline factor worsened.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease that requires long-term treatment to improve or maintain disease activity. Tumor necrosis factor inhibitors (TNFi), a class of biologic disease-modifying antirheumatic drugs (bDMARDs), are effective at treating symptoms and inhibiting joint progression. Although treatment changes are not recommended in patients with stable disease, health plans have recently enacted formulary changes with higher copayments that could disrupt patient access to TNFis. Our purpose was to describe impacts of formulary copayment changes on TNFi use among patients with RA using the TNFi etanercept (ETN).

Methods: This retrospective observational cohort analysis used the IBM Watson Health Market Scan Commercial database. The study population included adults (aged 18–64 years) with RA, with 6 months continuous ETN use (no gap ≥ 45 days) during 1/1/2013–12/31/2015 (defined as stable use period), and continuous plan enrollment ≥ 6 months before and ≥ 12 months after index date (first date after a patient's 6-month stable-use period). ETN persistence, bDMARD switching, refill gaps, and treatment effectiveness (using a validated effectiveness algorithm) were described for patients with or without formulary change during 12 months after index. Average ETN copayment was calculated at the drug plan-level. Formulary change was defined as a monthly increase of $> \$40$ to account for copay changes attributable to ETN wholesale acquisition costs between 2014–2015. This amount also corresponded to the 90th percentile of average plan-level changes in ETN copayments in the database, representing an average change in copay by a payer.

Results: A total of 1,970 patients met study inclusion criteria (mean age 50.3 years, standard deviation 9.5; 77.8% female). Of these, 133 (6.8%) patients had a formulary change during follow-up. Overall, most patients (60.3%) persisted on ETN for the 12-month follow-up period; 13.0% switched from a bDMARD, and 26.7% discontinued (gap of ≥ 45 days). Nearly half (48.0%) of all patients were considered effectively treated according to the validated algorithm. Compared to patients without a formulary change, those with a formulary change more likely to switch biologics (19.5% vs 12.6%, $P = 0.021$) and tended to be less likely to be persistent (54.1% vs 60.7%, $P = 0.135$), and less likely to be effectively treated (42.1% vs 48.4%, $P = 0.161$) (Table). Patients with a formulary change also tended to be more likely to discontinue bDMARDs for at least 12 months (10.5% vs 7.9%; $P = 0.293$).

Conclusion: Using a combination of health plan- and patient-level data, this retrospective administrative claims database analysis identified a cohort of stable ETN patients and found a significant association between changing formulary status and switching bDMARD therapy for RA and negative trends for persistence and treatment effectiveness. Treatment Patterns Following Formulary Change

	Mean copay change amount		P-value
	≤ \$40	> \$40

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The U-Act-Early trial was a 2-year multicentre, double-blind, randomized, placebo-controlled trial in early (DMARD-naïve) RA patients treated to the target of remission, with step-up strategies starting with tocilizumab (TCZ), methotrexate (MTX) or their combination (TCZ+MTX)¹, here labelled as TCZ, MTX and TCZ+MTX, respectively. When sustained remission (SR, DAS28 <2.6 AND 28 swollen joint count ≤4 for ≥24 weeks) was achieved, medication was tapered and stopped. During the trial, both TCZ arms showed less progression of joint damage than the MTX arm. Patients were subsequently followed for 3 additional years, during which treatment was open and accordance with usual care. The objective is to evaluate progression of radiographic joint damage and biological (b)DMARD use over 5 years in the TCZ, MTX and TCZ+MTX arms as initiated in the U-Act-Early trial.

Methods: 226 of the 317 patients included in U-Act-Early (79 TCZ, 72 MTX, 75 TCZ+MTX) participated in the follow-up. Radiographs of hands and feet were taken at baseline U-Act-Early, after 2 and 5 years. A professional reader scored the radiographs in chronological order, applying the Sharp vander Heijde (SvdH) method. During follow-up medication data was collected every 3 months for the first year and every 6 months thereafter. We analysed change in total SvdH score and in SvdH erosion and joint space narrowing (JSN) scores over 5 years, and bDMARD use over time. Differences between the arms in median change in radiographic scores over time were tested with the van Elteren test, correcting for baseline DAS28 level (<5.1 or ≥5.1) and centre.

Results: Baseline characteristics at start of U-Act-Early of the patients included in this follow-up were not significantly different from those of all patients included in U-Act-Early, suggesting no selective dropout. The median (interquartile range) changes in total SvdH scores over 5 years were 0 (0-1) for TCZ, 0 (0-2) for MTX and 0 (0-1) for TCZ+MTX

Figure 1 Cumulative probability plot for absolute change in total Sharp van der Heide score over 5 years per strategy arm as randomised in U-Act-Early

Figure 2 Percentages of patients who used at least one biological DMARD at any time-point over 5 years per strategy arm as randomised in U-Act-Early

	TCZ+MTX	TCZ	MTX	P-value ¹
SwH score				
Total	0 (0-1) (-2 to 1)	0 (0-1) (-2 to 30)	0 (0-2) (0 to 35)	TCZ+MTX vs. MTX: 0.41 TCZ vs. MTX: 0.05
Erosions	0 (0-0) (0 to 1)	0 (0-1) (-2 to 17)	0 (0-1) (0 to 35)	TCZ+MTX vs. MTX: 0.62 TCZ vs. MTX: 0.80
Joint space narrowing	0 (0-0) (-2 to 0)	0 (0-0) (-1 to 14)	0 (0-1) (0 to 4)	TCZ+MTX vs. MTX: 0.03 TCZ vs. MTX: 0.11

¹ Van Erchemt had no statistical significance (P=0.28) for TCZ vs MTX and MTX vs TCZ+MTX.

(Figure 1 and Table), with a borderline statistically significant difference for TCZ and MTX ($p=0.05$), but not for TCZ+MTX and MTX ($p=0.41$). No differences were shown for the erosion scores over 5 years (TCZ vs. MTX; $p=0.80$ and TCZ+MTX vs. MTX; $p=0.62$); for JSN scores there was a statistically significant difference for TCZ and MTX ($p=0.03$), but not for TCZ+MTX and MTX ($p=0.11$). During U-Act-Early, bDMARD use decreased in both TCZ arms and increased in the MTX arm, but during follow-up it remained higher in both TCZ arms (Figure 2).

Conclusion: Progression of radiographic joint damage over 5 years was low: >70% of patients had no progression at all, without differences between strategy arms, probably due to convergence of treatment strategies resulting from the treat-to-target principle applied in each arm². Use of bDMARD remained higher in both TCZ arms.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ACR and EULAR recommend bDMARD tapering in patients (pts) with rheumatoid arthritis (RA) who achieved stable clinical remission. Yet, there are limited systematically collected data on objective magnetic resonance imaging (MRI)-assessed levels of musculoskeletal inflammation, especially tenosynovitis, in RA pts in stable clinical remission with previous data derived from a range of cohorts with differing definitions of clinical remission. The purpose of the analysis was to evaluate within the PREDICTRA study the extent of disease control, in particular MRI inflammation, in RA pts in DAS28-based stable clinical remission attained on adalimumab (ADA) at the standard dosing of 40 mg every other week (eow).

Methods: PREDICTRA is a multicenter, randomized, double-blind study generating data on pt and disease characteristics that may predict the clinical course of ADA dose-tapering for RA pts in stable clinical remission. RA pts with DAS28-CRP or -ESR <2.6 for ≥6 months following treatment with originator ADA 40 mg eow for ≥12 months in clinical practice were eligible to enter a 4-week (wk) open-label lead-in study period with continued standard ADA dosing. Pts must have had confirmed DAS28-ESR <2.6 at the beginning and end of the lead-in period and quality-verified MRI of the most affected or, if both equally affected, the dominant hand to be eligible for randomization. Study assessments included multiple measures of disease activity (SJC28 and 68, TJC28 and 68, DAS28, CDAI, SDAI, patient's and physician's global assessment of disease activity), physical function (HAQ-DI, SF-36 PCS), and OMERACT RAMRIS scores for synovitis, tenosynovitis, bone marrow edema and erosions. Data of the randomized pts at the end of the lead-in period are presented.

Results: Of the 149 pts that entered the lead-in period, 122 (82%) were randomized. The randomized pts were 75% female, mean age 59.7±10.3 years, RA duration 12.8±9.8 years, prior ADA exposure 5.1±3.0 years, and DAS28 remission duration 2.2±2.1 years. Most pts received concomitant methotrexate (83.6%; mean dose 13.2 mg weekly) and few received concomitant corticosteroids (9.8%; mean dose 3.2 mg daily). Very low disease activity was observed in terms of clinical measures and MRI inflammation scores (synovitis [3.5±3.13], osteitis [1.0±2.01], tenosynovitis [2.7±2.7]). The mean MRI erosion score was low given the disease duration, and physical function scores were within normal ranges (**Table**).

Conclusion: Pts with long-standing RA randomized to the tapering phase of the PREDICTRA study based on sustained DAS28-based clinical remission on prior standard dose ADA therapy showed very low levels of clinical disease activity and normal physical function. This concurred with low MRI inflammation scores, especially for osteitis and tenosynovitis, the latter pathology being reported for the first time in RA clinical remission pts.

Table: Summary of Patient Characteristics

Patient Characteristic (N=122)	Mean (SD)*
Duration of prior adalimumab, years	5.1 (3.0)
Duration of remission, years	2.2 (2.0)
Concomitant csDMARDs dose, mg	
Methotrexate (weekly)	13.2 (5.5)
Hydroxychloroquine (daily)	228.6 (75.6)
Sulfasalazine (daily)	750.0 (288.7)
Concomitant oral corticosteroids dose, mg (daily)	3.2 (1.7)
Anti-cyclic citrullinated peptide (ACCP), Unit	286.6 (206.4)
ACCP positive, n (%)	63 (52.9)
Rheumatoid factor (RF), KU/L	139.5 (395.4)
RF positive, n (%)	90 (76.3)
C-reactive protein (CRP), mg/L	5.3 (28.0)
Erythrocyte sedimentation rate (ESR), mm/hr	11.4 (8.4)

Table . (Cont'd)

Patient Characteristic (N=122)	Mean (SD)*
Tender joint count (TJC) 68	0.3 (0.6)
Swollen joint count (SJC) 66	0.1 (0.3)
DAS28 (ESR)	1.7 (0.6)
Clinical Disease Activity Index (CDAI)	1.3 (1.4)
Simplified Disease Activity Index (SDAI)	1.8 (3.0)
Patient's Global Assessment of Disease Activity –VAS, 0-100 mm	6.4 (8.9)
Physician's Global Assessment of Disease Activity – VAS, 0-100 mm	3.7 (5.0)
Pain – VAS, 0-100 mm	8.5 (11.5)
HAQ-DI	0.3 (0.4)
SF-36 MCS	54.4 (7.7)
SF-36 PCS	50.1 (7.8)
MRI OMERACT scores	
Synovitis, Range 0-24	3.5 (3.1)
Osteitis, Range 0-75	1.0 (2.0)
Tenosynovitis, Range 0-30	2.7 (2.7)
Erosion, Range 0-250	21.4 (26.9)

* All values are Mean (SD) unless otherwise specified

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with early (disease duration ≤ 24 months [mths]), MTX-naïve RA and poor prognostic factors including anti-citrullinated protein antibody (ACPA) positivity (+), abatacept (ABA) + MTX vs MTX was superior at achieving DAS28 (CRP) < 2.6 at 12 mths.^{1,2} The AVERT-2 trial (clinicaltrials.gov, NCT02504268) further investigates the ability of ABA + MTX to induce validated metrics of remission in pts with ACPA+ early RA (disease duration ≤ 6 mths).

Methods: Pts were randomized (3:2) to double-blind, weekly SC ABA 125 mg + MTX vs MTX for 56 weeks (wks). Key inclusion criteria: age ≥ 18 years; RA diagnosis ≤ 6 mths (ACR/EULAR 2010 criteria); ACPA+; TJC and SJC ≥ 3 ; CRP > 0.3 mg/dL (ULN)/ESR ≥ 28 mm/h; SDAI > 11 ; DMARD naïve. Primary endpoint: proportion of pts in SDAI remission (SDAI ≤ 3.3) at Wk 24 in the first 375 pts randomized (primary analysis population). Hierarchically tested secondary endpoints: DAS28 (CRP) < 2.6 at Wk 24 and SDAI ≤ 3.3 at Wk 52 (primary analysis population), and change from baseline (CfB) in total Sharp/van der Heijde score (SHS; X ray) and Boolean remission at Wk 52 (all randomized pts). Comparisons were made using logistic regression for binary outcomes and rank-based non-parametric analysis of covariance for X ray data.

Results: In the primary analysis population, 225 pts received ABA + MTX and 150 received MTX. Overall, 752 pts were randomized to ABA + MTX (n=451) and MTX (n=301); 63 and 68 discontinued, respectively, by Wk 52. Baseline characteristics were similar across treatment arms in each population (Table 1). The proportion of pts achieving SDAI \leq 3.3 at Wk 24 was 21.3% for ABA + MTX and 16.0% for MTX (primary analysis population; p=0.2359; Table 2). Nominally significant benefits in favor of ABA + MTX were observed for all secondary endpoints including mean CFB in total SHS at Wk 52 in all randomized pts (0.5 vs 2.5; nominal p<0.0001; Table 2). Safety profiles were similar across treatment arms; no new safety signals were identified.

Conclusion: Abatacept + MTX vs MTX in ACPA+, early RA did not meet the primary endpoint of a statistically significant difference in SDAI \leq 3.3 at Wk 24 in the primary analysis population, but did so at Wk 52. Consistent with previous studies,^{1,2} the benefits of abatacept + MTX vs MTX were seen for the composite endpoint of DAS28 (CRP) <2.6 at Wk 24 in the primary analysis population, and for the other secondary endpoints in all randomized pts.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The biomarkers CXCL13 and sICAM1 have been associated with outcomes in patients with RA treated with TCZ. This study evaluated the association of CXCL13 and sICAM1 with disease activity and response to TCZ in early RA and DMARD-IR patients.

Methods: Patient subsets from the FUNCTION (early RA) and LITHE (DMARD-IR) clinical trials were selected based on baseline and Week 24 sample availability; serum CXCL13 and sICAM1 levels were measured. Correlations between CXCL13 and sICAM1 levels and DAS28-ESR at baseline, and between change in CXCL13 and sICAM1 levels and change in DAS28-ESR at Week 24, were determined. Changes in CXCL13 and sICAM1 levels from baseline to Week 24 were compared between treatment arms using Welch *t* test. The effect of treatment, baseline DAS28-ESR and baseline CXCL13 and sICAM1 levels on the likelihood of DAS28-ESR remission and ACR50 response at Week 24 was determined via logistic regression. DAS28-ESR remission and ACR50 rates were compared against CXCL13 and sICAM1 status (high vs low median values) within each trial arm using a Cochran-Mantel-Haenszel test.

Results: Overall, 458 of 872 patients from FUNCTION (TCZ+ MTX, n = 160; TCZ monotherapy [TCZ-mono], n = 157; placebo [PBO] + MTX, n = 141) and 287 of 791 patients from LITHE (TCZ + MTX, n = 137; PBO + MTX, n = 150) were included. In these patient subsets, mean disease duration in FUNCTION was significantly shorter than in LITHE (0.45 vs 8.65 years). At baseline, correlation of serum CXCL13 levels with DAS28-ESR was moderate in the early RA population and weak in the DMARD-IR population (Table). Correlation between baseline serum sICAM1 levels and DAS28-ESR was low in both populations. Serum levels of CXCL13 decreased significantly at Week 24 in all treatment arms in both populations; sICAM1 levels decreased significantly at Week 24 in the TCZ-mono arm in patients with early RA and the TCZ + MTX arms in both populations but not in the PBO + MTX arms. Change in CXCL13 levels correlated moderately with change in DAS28-ESR at Week 24 in both populations (Table). Change in sICAM1 levels correlated moderately with change in DAS28-ESR at Week 24 in the DMARD-IR population but weakly in the early RA population. Although the treatment arm had a significant effect on the likelihood of DAS28-ESR remission and achievement of ACR50, the effect of baseline levels of CXCL13 and sICAM1 were not significant. DAS28-ESR remission and ACR50 response rates at Week 24 within each treatment arm of the early RA and DMARD-IR populations were not significantly different between patients with high vs low baseline CXCL13 and sICAM1 levels.

Conclusion: The association of baseline CXCL13 levels with RA disease activity was stronger in the early RA population than in the DMARD-IR population. Baseline levels of CXCL13 and sICAM1 did not predict response to TCZ at Week 24, suggesting that although these biomarkers are associated with disease activity, they do not predict response to TCZ in all RA populations.

Table. Correlation Between Serum CXCL13 and sICAM1 Levels and DAS28-ESR

	Baseline						Week 24*					
	CXCL13			sICAM1			Δ CXCL13			Δ sICAM1		
	n	r	P value	n	r	P value	n	r	P value	n	r	P value
FUNCTION (early RA)	458	0.36	< 0.0001	458	0.14	0.0029	458	0.33	< 0.0001	458	0.16	0.0005
LITHE (DMARD-IR)	282	0.21	0.0003	282	0.17	0.0040	202	0.33	< 0.0001	202	0.26	0.0002

CXCL13, C-X-C motif chemokine ligand 13; DAS28-ESR, Disease Activity Score in 28 joints per erythrocyte sedimentation rate; DMARD-IR, inadequate response to disease-modifying antirheumatic drugs; RA, rheumatoid arthritis; sICAM1, soluble intercellular adhesion molecule 1.

* Correlation between change in CXCL13 and sICAM1 levels from baseline to Week 24 and change in DAS28-ESR from baseline to Week 24; all patients combined.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is anti-folate activated to MTX polyglutamates (MTXPGs). MTX metabolism includes multiple enzyme-mediated reactions and genetic polymorphisms in these genes are linked to MTX disposition and effects. The objective of this study was to examine the influences of variant in the dihydrofolate reductase gene (DHFR: rs1382539 G/A) on MTX polyglutamation and clinical efficacy in rheumatoid arthritis (RA).

Methods: Two US based cohorts of consented adult RA were analyzed, a first cohort of 187 patients (median age 65 years under median 15mg/weekly MTX) evaluated at a single visit for MTXPG levels (>3 months), and a second cohort consisting of 38 patients (mean age 55 years) enrolled in adose escalation study (starting 7.5 mg/week) for 6 months (206 study visits). RBCMTXPG levels (MTXPG₁ [MTX] up to 5 glutamic residues [MTXPG₅]) were measured using liquid chromatography. MTXPG₃ (the preponderant MTXPG species) was expressed as nmol/L packed RBC; percent long-chain MTXPG₃₋₅ (over total MTXPG₁₋₅) and dose normalized MTXPG₃ levels (polyglutamation rate, nmol/L per mg) were also estimated. Real-time PCR was used to genotype the rs1382539 G/A variant in *DHFR*. Differences in MTXPG accumulation by genotypes were analyzed using Mann-Whitney test. Linear mixed effect with random intercept and fixed slope were used to analyze the impact of the variant on longitudinal changes in MTXPG levels and response (per DAS-28).

Results: In the first cohort, carriers of the rs1382539 A/A genotype (n=15 patients [8%], mean age 64±12 years under 15 mg/week) presented with 15 nmol/L lower MTXPG₃ levels (median 26 nmol/L [IQR: 18-55] vs 41 nmol/L [IQR: 28-60]; p=0.04) than those with G/G or G/A genotypes (total 173 patients mean age 64±12 years under 15 mg/week), respectively. Similarly, 16% lower long-chain MTXPG₃₋₅ (median 36% [IQR 18-48%] vs median 52% [IQR 40-68%]; p<0.01) and 0.8 nmol/L per mg lower MTX polyglutamation rate (median 2.1 nmol/mg MTX [IQR 1.2-3.1] vs 2.9 nmol/mg MTX [IQR 2.0-4.3]; p=0.02; Figure) were measured in carriers of the A/A genotype vs G/G or G/A genotypes, respectively (Figure, panel A). In the second cohort, linear mixed effect models revealed that carriers of the rs1382539 A/A genotype (n=4 patients [10%]) also presented with lower RBC MTXPG₃ levels (estimate=-11±5 nmol/L; p=0.03), lower percent long-chain MTXPG₃₋₅ (estimate=-15±1%; p=0.02) and lower polyglutamation rate (estimate=-0.9±0.4 nmol/mg; p=0.01) than carriers of the G/G or G/A genotype (Figure, panel B). While the rs1382539 variant was not significantly associated with clinical efficacy (p>0.05), lower RBC MTXPG₃ level and percent long-chain MTXPG₃₋₅ levels associated with higher DAS28 in the cohort (p<0.05).

Conclusion: Our data indicate that the rs1382539 G/A variant in DHFR impacts MTX polyglutamation in adultRA, and may indirectly contribute to clinical efficacy in some patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The red blood cell (RBC) Methotrexate (MTX) polyglutamate (MTXPG₃) assay is a helpful therapeutic drug monitoring (TDM) tool in autoimmune rheumatic diseases. Our objective was to transition the RBC MTXPG assay from venous blood to capillary blood collected by fingerstick.

Methods: Adult subjects with Rheumatoid Arthritis (RA) (mean age 62±13 [SD]) treated with low dose weekly MTX therapy (mean dose 17±5 mg/week [SD]) were enrolled from two rheumatology practices in the United States. Clinical staff consented subjects and collected paired specimens: a capillary blood specimen (10µl) collected by fingerstick on volumetric absorptive microsampling device (Neoteryx, Torrance, CA, USA), and a venous blood specimen (10 ml) collected in EDTA containing tubes. Dried capillary blood and venous blood were shipped overnight to a CAP/CLIA accredited clinical laboratory. RBC MTXPG₃ levels from capillary and venous blood were measured using validated liquid chromatography coupled with high sensitivity tandem mass spectrometry. Patient reported outcomes (PROs) comparing venipuncture and fingerstick collection methods were obtained at the time of the visit. RBC MTXPG₃ levels from capillary blood were compared to historical levels estimated from a database of venous blood specimens collected from patients on MTX therapy and assessed for compliance, defective activation to polyglutamates (RBC MTXPG₃ <5nmol/L), or in adequate response to MTX.

Results: In the 106 RA subjects enrolled, mean (SD) RBC MTXPG₃ levels recovered from dried capillary blood and venous blood specimens were similar (30±18 nmol/L vs 33±19 nmol/L, respectively) (R²=0.89; slope=1.10). PROs indicated that the fingerstick collection method was convenient and non-inferior to venipuncture, but only a minority of subjects (37%) were comfortable with self-collection of the capillary blood specimen at home. Following one year of testing, capillary RBC MTXPG₃ (36±20 nmol/L RBC) levels from a population of 679 patients (mean age 58±15 years; n=825 capillary blood specimens) were similar to RBC MTXPG₃ (38±24 nmol/L) levels estimated from the database of patient specimens collected using venipuncture (mean patient age 58±15 years; n=47,935). Potential for poor compliance (RBC MTXPG₃ ≤5 nmol/L RBC) was detected in 7.0% (n=54) and 8.5% (n=4,224) patient specimens collected using the fingerstick and venipuncture based method, respectively (Figure).

Conclusion: Measurement of capillary blood MTXPG₃ levels can be applied to the TDM of MTX in clinical rheumatology practice. PROs suggest that patient training will be required before transitioning from office-based to home-based specimen collection.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmunity against citrullinated peptides is a hallmark of rheumatoid arthritis (RA). Chronic periodontitis (CP) is a known major source of citrullinated peptides. Here, we investigated potential associations between the treatment of CP, the reduction pathogenic periodontal microbes, the autoantibody repertoire and RA disease activity.

Methods: We evaluated ten patients with DAS28_{CRP} ≥ 4.2 for the presence and severity of CP. All patients had active disease and were positive for rheumatoid factor and anti-cyclic citrullinated peptide antibody (ACPA). Each had an inadequate response to at least two conventional and two biological disease modifying anti-rheumatic drugs. Periodontal scaling and root planing (SRP) was performed in conjunction with one week of amoxicillin and metronidazole therapy, if significant CP was indicated by clinical attachment level (CAL) loss ≥ 5mm at ≥ 2 separate sites.

The primary outcome was mean DAS28 improvement >1.2 from baseline to month 3, corresponding to good clinical response. Secondary clinical outcomes included periodontal pocket depth (PD), CAL, and bleeding on probing (BOP). The presence of major periodontal pathogens was assessed by semiquantitative polymerase chain reaction in the subgingival biofilm at baseline, month 3 and 6. Sera were longitudinally tested for antibodies against native and citrullinated peptides from enolase, fibrinogen, vimentin, and tenascin-C.

Results: Eight patients had CP requiring treatment. In these patients, DAS28 improved upon SRP by mean (+/- SD) 0.74 +/- 0.93, p=0.049, thereby failing the predefined significance at a group level. Nevertheless, moderate and transient DAS28 response >0.6 at month three was achieved in three patients, and prolonged good clinical response was observed in a fourth patient at month 3 and 6. The clinical signs of CP improved in parallel, PD by 1.8 +/- 1.5 mm (mean +/- SD), p=0.018, CAL by 0.7 +/- 0.6 mm, p=0.051, and BOP by 36 +/- 24%, p=0.018. Furthermore, the microbial burden was significantly reduced upon SRP in the biofilm for the following bacteria: *P. gingivalis*, *Treponema denticola* and *Tannerella forsythia*, p<0.05 for all. However, the serum concentrations of all tested autoantibodies remained unchanged at group level, and the changes in the microbiota and titers of autoantibodies could not specifically be associated with improvement of arthritis symptoms in individual patients.

Conclusion: Successful treatment of CP reduced the burden of specific microbial species in the periodontal biofilm, and improvement of clinical RA disease activity could be observed in individual patients. This finding could support the hypothesis of RA inflammation being permanently triggered by chronic periodontal infections. However, clinical responses in this small interventional pilot study did not track back to changes in the microbiota or in the antigen specific immune response, suggesting patient improvement is not directly linked to these aspects of disease.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), little is known about the prognostic relevance of the change in autoantibody (ab) levels. Seroconversion was reported to be associated with a better clinical and radiological outcome in MTX-insufficient responders (IRs) treated with abatacept (1). The ROC randomized study (2) offered the opportunity to investigate changes in RF and anti-CCP levels in 1st anti-TNF-IR patients treated either with a 2nd anti-TNF, abatacept, rituximab or tocilizumab.

Objective: To evaluate the effects of bDMARDS on rheumatoid factor (RF) and IgG, A and M anti-CCP ab in RA, and associations between changes in serological status and clinical and radiological responses.

Methods: Ab titres (IgM-RF, IgG, A and M-anti-CCP) were determined by ELISA at baseline and month 6 in respectively 230, 220, 242 and 241 patients enrolled in the ROC randomized trial. The association between changes in ab titers with clinical response was assessed at months 6 and 12. Radiographs of the hands and feet were analyzed at screening and at months 12. The van der Heijde-modified Sharp scoring method was used to assess the mean change from baseline in total Sharp score (TSS) and to determine radiographic progression.

Results: Seroconversion of IgM-RF (patients with IgM-RF present at baseline, and then that became undetectable after treatment) was observed in only 4 patients (2%), of IgG antiCCP in 15 (7%), of IgA in 17 (7%) and of IgM in 16 patients (7%).

No significant difference in the proportion of patients converted to seronegative status was observed between patients treated with a 2nd anti-TNF or with a non-TNF targeted therapy. In the non anti-TNF group, seroconversion of IgA anti-CCP was significantly more frequent in rituximab (24%) than in abatacept (7%) or tocilizumab-treated patients (4%) (p=0.007). Seroconversion of RF was associated with a significantly more frequent remission (75% of patients with a DAS28-ESR<2.6 at month 6 among seroconverted patients vs 22% in patients who remained RF positive, p=0.01). IgA anti-CCP seroconversion was associated with a better therapeutic response (good EULAR response in 59% of seroconverted patients at month 12 vs 25% in patients who remained IgA anti-CCP positive, p=0.004). Seroconversions of IgM and IgG anti-CCP were not associated with any clinical or radiological response.

RF levels decreased irrespectively of the biologic used whereas a significant decrease of anti-CCP isotypes was only observed with rituximab. The decrease of RF was correlated with the decrease of polyclonal B-cell activation markers (total IgG, IgA, IgM, kappa and lambda free light chains of immunoglobulins (FLCs), whereas IgG, IgA, IgM-anti-CCP were not correlated with total IgA, G, M or FLCs. Changes in RF or anti-CCP levels were not associated with clinical or radiographic outcome.

Conclusion: Seroconversion of RF and anti-CCP was infrequent. Seroconversion of RF was significantly associated with a more frequent DAS28-remission and seroconversion of IgA anti-CCP with a better EULAR response.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The combination of methotrexate (MTX), hydroxychloroquine (HCQ) and sulfasalazine (SSZ) has been called Triple Therapy (Triple) and has been compared with a combination of TNF inhibitors and MTX (TNFi + MTX). We sought to examine the use of Triple in a large US registry and compare the clinical and sociodemographic characteristics of the patients starting either therapy to determine if there were clinically relevant differences at initiation.

Methods: All eligible initiations in the Corrona registry from 2001-2017 were considered. Initiation of Triple was defined as initiation of one or more of the three drugs resulting in the first time use of all three drugs. Initiation of TNFi+MTX was defined as the initiation of TNFi resulting in the first time use of TNFi + MTX. Initiations were in patients who were biologic/small molecule naïve. Sociodemographic, clinical and disease characteristics were compared at time of initiation between the therapies. Patients initiating Triple who later initiated TNFi+MTX were not included in the TNFi+MTX cohort. Standardized mean differences (SMDs) were used to compare patients initiating Triple vs TNFi+MTX therapy; |SMDs| >0.15 were considered clinically relevant.

Results: From 2001- 2017, we identified 3452 TNFi+MTX and 226 Triple eligible initiations. Table 1 describes patient characteristics with |SMDs|>0.15. Triple initiators were older, had longer disease duration, were more likely to have Medicare coverage, and more likely to be RF+ or CCP+. Triple initiators had a history of more comorbidities than TNFi+MTX initiators. TNFi +MTX initiators had higher disease activity measures than Triple initiators: CDAI and all its components, patient fatigue and mHAQ. There were larger differences in MD Global and joint counts (|SMDs|>0.30) than Pt Global and Pt Fatigue (|SMDs| < 0.19). At start of therapy patient pain and prednisone, analgesic and NSAID use were not different (|SMDs| <0.15).

Conclusion: Utilization of Triple was not common over a period of 16 years covered by the registry. Pts started on triple were older, had less severe RA and a higher comorbidity burden. These differences are likely to impact response to treatment as it appears that rheumatologists channeled pts with more severe RA to TNFi + MTX, while pts with a h/o comorbidities were more likely to receive Triple.

Abstract Number: 570

Evaluation of CXCL13, sICAM1, MMP-3 and S100A8/A9 As Serum Biomarkers in Patients with Rheumatoid Arthritis Treated with Subcutaneous Tocilizumab

D. James Haddon, Thierry Sornasse, Michael J. Townsend, Jinglan Pei and Margaret Michalska, Genentech, Inc., South San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum levels of C-X-C motif chemokine ligand 13 (CXCL13) and soluble intercellular adhesion molecule-1 (sICAM-1) have been associated with outcomes in patients with rheumatoid arthritis (RA) treated with tocilizumab (TCZ); levels of matrix metalloproteinase-3 (MMP-3) and S100A8/A9 have also been associated with disease activity and joint damage. This study evaluated the association of CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels with disease activity and response to TCZ in patients with RA who achieved low disease activity with 24 weeks of TCZ + methotrexate (MTX) treatment and were subsequently randomized to TCZ monotherapy (mono) or TCZ + MTX in the COMPACT trial (NCT01855789).

Methods: US patients with RA who had an inadequate response to MTX received initial combination therapy of MTX plus TCZ 162 mg subcutaneous for 24 weeks. Patients who achieved Disease Activity Score in 28 joints – erythrocyte sedimentation rate (DAS28-ESR) ≤ 3.2 at Week 24 were randomized 1:1 to receive either TCZ mono or continue TCZ + MTX until Week 52. Randomized patients were included in the present study based on baseline, Week 24 and Week 40 sample availability; serum levels of CXCL13, sICAM-1, MMP-3 and S100A8/A9 were measured by immunoassay. Spearman correlations between CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels and DAS28-ESR at baseline, Week 24 and Week 40 were analyzed. Changes in CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels from baseline to Week 24 (open-label period) were determined using Wilcoxon test. Mean changes in CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels from Week 24 to Week 40 (randomized period) were compared between treatment arms using analysis of covariance.

Results: Of 296 randomized patients, 249 were included (TCZ mono, n = 126; TCZ + MTX, n = 123). Biomarker levels were well balanced across treatment arms at baseline and Week 24 (randomization). At baseline, there were weak to mild correlations between DAS28-ESR and biomarker levels (CXCL13 [r = 0.13, P = 0.0411], sICAM-1 [r = 0.20, P = 0.0015], MMP-3 [r = 0.19, P = 0.0021], S100A8/A9 [r = 0.25, P = 0.0001]). Significant reductions in biomarker levels were observed from baseline to Week 24 (open-label period) in all patients (P < 0.0001). CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels were relatively stable between Week 24 and Week 40 (randomized period), with no significant differences between TCZ mono and TCZ + MTX (Table).

Conclusion: In agreement with previous studies, the association between baseline disease activity and CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels was weak to mild; TCZ + MTX treatment from baseline to Week 24 (open-label period) resulted in significant reductions in all biomarkers. Changes in levels of CXCL13, sICAM-1, MMP-3 and S100A8/A9 from Week 24 to 40 (randomized period) were similar between treatment groups, consistent with the finding of non-inferiority of TCZ mono compared with TCZ + MTX in patients with RA who achieve low disease activity with TCZ + MTX.

Table. Changes in Serum Biomarker Levels from Week 24 to Week 40 (Randomized Period) in Patients Receiving TCZ as Monotherapy or in Combination With MTX

Estimated Mean Change From Week 24 to 40* (95% CI)	TCZ Mono (n = 126)	TCZ + MTX (n = 123)	Difference, TCZ Mono Minus TCZ + MTX (95% CI)
CXCL13 (pg/mL)	−0.02 (−0.05 to 0.01)	−0.04 (−0.07 to −0.00)	0.02 (−0.02 to 0.05)
sICAM-1 (pg/mL)	0.01 (−0.01 to 0.02)	−0.01 (−0.03 to 0.01)	0.01 (−0.01 to 0.03)
MMP-3 (ng/mL)	0.04 (0.01 to 0.08)	0.03 (−0.00 to 0.07)	0.01 (−0.03 to 0.05)
S100A8/A9 (ng/mL)	0.01 (−0.05 to 0.07)	−0.05 (−0.12 to 0.01)	0.06 (−0.01 to 0.13)

ANCOVA, analysis of covariance; CXCL13, C-X-C motif chemokine ligand 13; DAS28-ESR, Disease Activity Score in 28 joints calculated with erythrocyte sedimentation rate; MMP-3, matrix metalloproteinase-3; mono, monotherapy; MTX, methotrexate; q2w, every 2 weeks; qw, once a week; sICAM-1, soluble intercellular adhesion molecule-1; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.

* ANCOVA model for estimated mean included log10 transformed Week 24 biomarker value as a covariate, treatment group and the following randomization stratification factors: DAS28-ESR remission status at Week 24 (< 2.6, ≥ 2.6 to ≤ 3.2), patient TNFi exposure (yes or no), baseline weight-by-dosing group (< 80 kg q2w, 80 to < 100 kg q2w, 80-to < 100 kg qw, ≥ 100 kg qw).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is a nongoing Phase 4 comparator study designed to provide a real-world assessment of intravenous golimumab (GLM) and intravenous infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). The primary objective of AWARE is to assess the incidence of infusion reactions, the concomitant use of methotrexate (MTX) is also reported. The FDA approved label for GLM states that it is indicated for the treatment of patients with moderately to severely active RA in combination with MTX; however prospectively obtained real world evidence based data on the rate of GLM use without MTX has not been reported. Here we compare patient demographics, disease characteristics, response to therapy and discontinuation of GLM treated patients with and without concomitant MTX from an interim analysis (IA) of the AWARE study.

Methods: AWARE is a prospective, noninterventional, observational, multicenter 3-year study conducted in the US. RA pts (1,200 adults) were enrolled at the time of initiating treatment with GLM or IFX. All treatment decisions including MTX utilization are made at the discretion of the treating rheumatologist. Imputations of CDAI data were not performed at this IA. Data shown are mean ± standard deviation.

Results: 678 GLM pts were enrolled; of these 487 (71.8%) were GLM Plus-MTX and 191 (28.2%) were GLM No-MTX. Demographics are shown in the table. Response to therapy was assessed with CDAIs and shown in the figure below.

	GLM Plus-MTX	GLM No-MTX
Number of Patients	487	191
Age (years)	61.7 ± 12.85	58.7 ± 14.55
Sex (% Female)	87.1%	81.7%

Table . (Cont'd)

	GLM Plus-MTX	GLM No-MTX
Disease Duration (yr)	9.0 ± 9.67	9.6 ± 10.74
Baseline CDAI	30.9 ± 14.58	33.2 ± 16.61
Race		
White	86.2%	87.4%
African American	8.6%	8.4%
Other	5.1%	4.2%
Weight (kg)	83.6 ± 24.55	84.0 ± 22.21
BMI (kg/ m ²)	31.0 ± 8.45	30.8 ± 7.89

Overall, 92.6% of GLM Plus-MTX and 91.5% of GLM No-MTX pts had a baseline (BL) categorical CDAI disease activity of moderate or high, and 7.4% of GLM Plus-MTX and 8.5% of GLM No-MTX pts had a BL categorical CDAI disease activity of low or remission. Discontinuation from the study during the period of this IA was similar between the GLM Plus-MTX (173/487; 35.5%) and GLM No-MTX (64/191; 33.5%). 7.9% of GLM No-MTX pts reported leflunomide use.

**CDAI Score Among Patients Treated with
Golimumab IV: Plus-MTX or No-MTX**

Conclusion: At BL 28.2% of pts on GLM did not report concomitant MTX use. The demographics of the GLM Plus-MTX pts did not differ remarkably from GLM No-MTX pts. The reported early response to treatment, assessed by CDAI score after 3 months and 6 months was similar in the GLM Plus-MTX and GLM No-MTX groups. These preliminary IA data suggest that in a real-world rheumatology practice setting, use of GLM with or without concomitant MTX led to similar CDAI scores at 3 and 6 months in RA pts with predominantly moderate to high BL CDAI disease category.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic therapy targeting TNF have consistently demonstrated better efficacy and effectiveness when combined with a conventional synthetic DMARD (csDMARD), most frequently methotrexate. Although pre-clinical protocols have shown the short-term efficacy of tocilizumab (TOCI) in monotherapy in very selected patients suffering from rheumatoid arthritis (RA), little is known on the long-term comparative sustainability of monotherapy (Mono) versus combo therapy (Combo). We evaluate here the comparative sustainability of tocilizumab in patients with rheumatoid arthritis initially treated with or without MTX.

Methods: Data from RHUMADATA® patients with RA prescribed TOCI either as an initial or second biologic was analyzed. Patients were followed until treatment discontinuation, loss to follow-up or April 22nd, 2018. The characteristics of selected patients were tabulated and the TOCI discontinuation rates of patients undergoing initial mono and combo therapy compared using Kaplan-Meier methods and Cox regression models adjusting for potential confounders.

Results: A total of 122 patients with RA received TOCI in first or second intention. Of those, 44(36.1%) and 78(63.9%) initially received mono and combo therapy respectively. Most patients were women (77%), mean age at diagnosis was 45.0 (SD=12.8) years, and the average age at treatment initiation was 54.5 (SD=11.8) years. HAQ and DAS28(4)-CRP at treatment initiation were respectively 1.21 (SD=0.57) and 4.64 (SD=1.01). Forty-nine and 11 percent of patients concomitantly received hydroxychloroquine (HCQ) and sulfasalazine (SSZ) respectively. Age-adjusted Carlson's comorbidity index (ACCI) at baseline was 2.5 (SD=1.1), and 79% were RF-positive and 75% ACPA positive. Significant differences in retention rates between mono and combo TOCI therapy were observed (log-rank p-value =0.0002). Mean retention time for mono and combo-therapy were respectively 2.77(SE=0.41) and 5.13(SE=0.43) years. Use of MTX remains significant (p-value<.0001) after adjusting for gender, age and disease duration at treatment initiation, HAQ, DAS28(4)-CRP, RF and ACPA, ACCI, and concomitant use of HCQ and SSZ.

Conclusion: Combining tocilizumab with MTX significantly improves its sustainability.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In France, tocilizumab (TCZ) subcutaneous (sc) 1st prescription and yearly renewal are restricted to hospital. Monitoring may be done by both office-based or hospital rheumatologists. The objective is to describe 12-month drug retention rate, efficacy and tolerance of TCZ sc in real life in rheumatoid arthritis (RA) patients(pts).

Methods: Prospective, multicentre, observational 18-month study including pts with moderate/severe active RA requiring TCZ sc as prescribed in real life. *Primary endpoint:* drug retention rate of TCZsc at 12 months in pts followed by hospital- and office-based rheumatologists. *Secondary end points:* pts characteristics, concomitant treatments, adherence using the Compliance Questionnaire for Rheumatology (CQR5), efficacy and safety of TCZ sc. *Statistical analysis:* pts with ≥ 1 TCZ injection were analyzed for safety. Pts fulfilling inclusion and non-inclusion criteria were analyzed for efficacy.

Results: 291 pts were recruited, 288 were analysed for safety and 281 for efficacy. At baseline: mean age 56.2 ± 12.5 years, females: 74.4%, at least 1 co-morbidity: 71%, mean RA duration 9.5 ± 9.0 years, RF/ACPA +: 83.5%, erosive RA: 61.2%,

mean DAS28ESR 4.76 ± 1.22 . Past RA treatments included DMARDs in 94.3%, mainly MTX (90.4%), and biologics in 63.3%. TCZ Mono (i.e. without csDMARD) was initiated in 42% and TCZ Combo in 57% of the pts, 84.9% of the latest received MTX (mean dose 17.2 ± 4.4 mg/w). 151 pts completed M12, 26 pts had no M12 visit collected yet. 104 (37.1%) pts withdrew: AE 19.4%, lack of efficacy 11.1%.

At M12, drug retention rate was 63.3% in all pts, 61.8% in Mono, 64.1% in Combo (Fig.1). 2 Mono pts had an ongoing csDMARD, 6 Combo pts had no csDMARD. Total number of TCZ injections was 33.3 ± 23.3 done by pt himself in 53.9%, at home in 92.7%. Adherence to TCZ sc was high in 85.4% of the 82 pts who fulfilled the CQR5. 47.3% used prednisone at 13.1 ± 12.8 mg/day in the Mono and 8.4 ± 4.7 in the Combo group.

At M12, 89% of the pts were followed at hospital, 11% by mixed or office-based rheumatologists. Mean DAS28ESR in all, Mono and Combo were 1.89 ± 1.08 , 1.67 ± 1.03 , 2.05 ± 1.11 respectively. DAS28 remission and LDA were respectively 71.8% in all, 77.1% in Mono, 67.2% in Combo and 16.4% in all, 14.6% in Mono, 18.0% in Combo. No new safety signal was reported. 218 (75.7%) pts had at least one adverse event (AE), 41 (14.2%) had at least one serious AE including 7 serious infections.

Conclusion: In this 12-month interim analysis, drug retention rate was 63.3% in patients receiving TCZ sc in real life, with no difference between Mono and Combo groups. DAS28 remission/LDA was 88.2% in all patients, 91.7% in Mono and 85.2% in Combo. No new safety signal occurred. Final analysis will include remaining missing data.

Fig. 1. Kaplan-Meier curve of the drug retention rate in Mono and Combo groups - Efficacy population

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari), an oral selective Janus kinase 1/2 inhibitor, has shown clinical efficacy in patients (pts) with RA and an inadequate response to conventional synthetic DMARDs.¹ Baricitinib is approved for treating moderate-severe RA in over 40 countries. The two objectives of these analyses were to evaluate the percentage of pts, originally randomized to 2 mg or 4 mg in the Phase 3 RA-BUILD study, and rescued in the study and/or in RA-BEYOND (the long-term extension study); and to assess the clinical benefits post-rescue.

Methods: RA-BUILD was a 24-week study evaluating once daily bari 4 mg (N=227) and 2 mg (N=229) compared to placebo (N=228). Pts with <20% improvement in tender joint count or swollen joint count (SJC) at Weeks 14 and 16 compared to baseline were rescued to bari 4 mg at Week 16; at Week 20, rescue was based on investigators' decision. Pts not rescued continued blinded treatment in RA-BEYOND and those with Clinical Disease Activity Index (CDAI)>10 at or after 3 months in RA-BEYOND were eligible for rescue to bari 4 mg, but not required. Once rescued, change in background medications was allowed. In RA-BEYOND, unrescued pts achieving sustained CDAI ≤10 were randomized to bari 2 mg or maintained at 4 mg. Descriptive longitudinal data analysis was based on observed data from pts randomized to bari 2- or 4-mg in RA-BUILD, including data up to 1 April 2017 in RA-BEYOND. Percent rescued and overall response rates in achieving CDAI ≤10, and pain (visual analogue scale ≤10, 20 or 40 mm), were evaluated from time of original randomization to bari 4 mg and 2 mg in RA-BUILD. Median change over time in CDAI, HAQ, SJC28 and pain after rescue from 2 to 4 mg was evaluated using pt data at time of rescue (reset as Week 0).

Figure 1. Median CDAI (A) and Median Pain (B) after rescue in patients rescued from bari 2 mg to 4 mg. Observed values. Numbers are indicated for each data point. RA-BUILD dataset includes patients rescued only in RA-BUILD and those rescued in both RA-BUILD and RA-BEYOND. RA-BEYOND data set includes patients rescued only in RA-BEYOND.

Table. Mean and median clinical outcome values in patients originally on bari 2 mg rescued to bari 4 mg in RA-BUILD or RA-BEYOND								
	CDAI		HAQ-DI		Pain (VAS)		SJC28	
	Mean	Median	Mean	Median	Mean	Median	Mean	Median
RA-BUILD¹								
At time of rescue (N=21)	30.99	30.76	1.38	1.38	52.10	49.00	10.48	10.00
Week 128 after rescue ² (N=15)	13.96	14.50	1.04	1.13	35.53	34.00	2.80	2.00
RA-BEYOND³								
At time of rescue (N=97)	19.97	17.70	1.14	1.12	45.26	42.00	4.11	3.00
Week 120 after rescue ² (N=45)	10.47	8.60	1.02	1.00	35.56	30.00	1.90	2.00

¹Includes patients rescued only in RA-BUILD and those rescued in both RA-BUILD and RA-BEYOND.
²Includes patients rescued only in RA-BEYOND.
³15 of the patients achieved CDAI≤10 after rescue to bari 4 mg in RA-BUILD.
⁴15 of the patients achieved CDAI≤10 after rescue to bari 4 mg in RA-BEYOND.
CDAI = Clinical Disease Activity Index; HAQ-DI = Health Assessment Questionnaire; VAS = Visual Analogue Scale; SJC28 = Swollen Joint Count based on 28 joints; VAS = visual analogue scale.

Results: The percentage of pts on bari 4 mg “rescued” in RA-BUILD was 36% compared to 52% in pts originally assigned to bari 2 mg. In RA-BEYOND, 7% of pts originally randomized to 4 mg were rescued after dose tapering to 2 mg. Clinically meaningful response rates in CDAI (≤ 10) and pain improvement increased and stabilized over time in the bari-treated population. Pts rescued in RA-BEYOND, after being treated with bari in RA-BUILD had less disease activity compared to pts rescued in RA-BUILD at the time of rescue (Table). Pts on 2 mg rescued to bari 4 mg in RA-BEYOND demonstrated improved disease control with the majority achieving CDAI ≤ 10 and pain reduction (Figure).

Conclusion: Fewer pts originally assigned to bari 4 mg in RA-BUILD required rescue compared to pts assigned to 2 mg. Disease activity assessed by CDAI and patient-reported pain improved in many pts after rescue from 2 to 4 mg of bari.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) may discontinue their biologic disease modifying antirheumatic drug (bDMARDs) due to non-response, loss of response or adverse events. However, time to discontinuation may be related to mechanism of action. We aimed to compare drug survival of tumor necrosis factor inhibitors (TNFi) versus non-TNFi/TOFA in patients initiating bDMARD treatment in a Canadian (Ontario) observational cohort.

Methods: Patients enrolled in the Ontario Best Practice Research Initiative (OBRI) who started their first bDMARD therapy within 30 days before or any time after OBRI enrolment were included. Patients were excluded if they had less than 2 visits during this period of time. Patients were followed from bDMARD start until discontinuation/switching, death, lost to follow-up, or last visit, whichever came first. Time to discontinuation of bDMARD due to (1) any reason, (2) non-response, physician, and patient decision, (3) non-response, and (4) adverse events (AEs) were assessed using Kaplan-Meier survival analysis for TNFi versus Non-TNFi/TOFA users. Cox proportional hazards regression model was also used to compare TNFi versus Non-TNFi/TOFA users adjusting for the effect of potential confounders. To deal with missing data, multiple imputation by chained equations was performed.

Results: A total of 796 patients were included of whom 130 (16.3%) received non-TNFi and 756 (83.7%) received TNFi (Table 1). TNFi included: Etanercept, Adalimumab, Certolizumab, Golimumab, and Infliximab. Non-TNFi/TOFA and Tofa

included: Abatacept, Rituximab, Tocilizumab, and small molecule Tofacitinib. Mean (SD) age and disease duration were 56.2 (12.8) years and 8.3 (9.0) years, respectively, and the majority were females (79.8%).

Over a mean (SD) follow-up of 2.4 (2.0) years, bDMARD discontinuation was reported for 291 (36.6%) due to any reason, 229 (28.8%) due to non-response, AEs, physician, and patient decision, 110 (13.8%) due to non-response, and 81 (10.2%) due to AEs, respectively.

There was a significant difference in time to discontinuation due to any reason (Logrank $p=0.0002$); non-response, AEs, physician, and patient decision (Logrank $p=0.04$) between TNFi and non-TNFi/TOFA users. However, there was no significant difference in bDMARD discontinuation due to non-response (Logrank $p=0.36$) and AEs (Logrank $p=0.06$). After adjusting for potential confounders, difference in discontinuation remained significant between the TNFi and non-TNFi/TOFA group for any reason [HR: 0.62 (0.46-0.84)] and non-response, AEs, physician, and patient decision [HR: 0.67 (0.47-0.94)].

Conclusion: The analysis demonstrates that patients initially started on non-TNFi/TOFA therapy are significantly more likely to discontinue their therapy earlier for any reason and due to non-response, AEs, physician and patient decision compared to TNFi therapy. Lack of response is likely not driving this, however AEs and, to an even greater degree, patient and physician preference likely influenced the results.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: HOPEFUL-1 trial showed efficacy of combination therapy with adalimumab (ADA) plus methotrexate (MTX) in MTX naïve patients with active early rheumatoid arthritis (eRA). In that trial, early introduction of ADA significantly reduced the joint destruction. However, although the biological disease-modifying antirheumatic drugs (bDMARDs) are the most effective treatment of RA, the costs are much higher than those of conventional synthetic DMARDs (csDMARDs). In recent years, HOPEFUL-2 trial and HIT-HARD trial showed the possibility of successful bio-free in patients with eRA. / To analyze efficacy of early introduction of ADA and bio-free condition in RA patients in real world.

Methods: Among 172 patients (M35, F137) who received ADA, 44 patients (M12, F32) started ADA as an early introduction. In this study, the definition of early introduction was within 3 months from the start of MTX. Four patients switched to tocilizumab due to inefficacy and 3 patients achieved clinical remission (CR). Four patients discontinued ADA due to side effects. We analyzed 30 patients who were followed up more than 52 weeks with the mean age of 54.0 ± 14.9 years old, the mean disease duration of 11.8 ± 22.7 months.

Results: The mean DAS28-CRP decreased from 4.67 ± 1.38 to 1.73 ± 0.48 ($p<0.001$) after initiation of ADA. Twenty six patients achieved CR (86.6%), and 16 patients (53.3%) achieved bio-free condition. One patient relapsed and re-started ADA. After achieving CR again, the patient wanted bio-free condition with the adjustment of csDMARDs. Therefore, tacrolimus was raised from 1.5mg/day to 3mg/day and ADA was discontinued again. The mean duration of bio-free condition was 20.9 ± 14.7 months. MTX (mg/week) was significantly increased from 7.3 ± 1.9 to 8.8 ± 3.2 ($p<0.001$). The number of csDMARD other than MTX were changed from 0.9 ± 0.6 to 1.3 ± 0.9 ($p=0.008$). One patient discontinued bucillamine due to proteinuria. Prednisolone dose (mg/day) was decreased from 6.1 ± 3.5 to 2.9 ± 1.8 ($p<0.001$). Six patients with CR did not want bio-free condition. Six patients with sustained CR wanted bio-free condition and discontinuation of ADA was already scheduled.

Conclusion: Early introduction of ADA was effective and subsequent bio-free condition might be a good choice in terms of medical cost.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although biologics represent a major advance in rheumatoid arthritis (RA), many patients fail to achieve adequate responses to these agents. As previous studies have suggested that individual autoantibodies may selectively predict treatment response, we examined whether combined positivity to three well-characterized RA-related autoantibodies predicts treatment response among RA patients initiating biologics.

Methods: We examined data and banked serum from the Comparative Effectiveness Registry to study Therapies for Arthritis and Inflammatory Conditions (CERTAIN), a prospective RA cohort study. We examined a subset (n=1224) of enrolled patients including: biologic naïve anti-TNF initiations (35%), biologic exposed rituximab (10%) and tocilizumab (24%) initiations, and abatacept (31%) initiations regardless of previous biologic exposure. RF, anti-CCP and IgG antibodies to malondialdehyde-acetaldehyde (MAA) were measured centrally using banked enrollment serum. RF and anti-CCP positivity were defined per the manufacturer while anti-MAA positivity was defined as values >33rd percentile (to approximate the frequency of positivity for RF/anti-CCP). Response to therapy was evaluated at 6 months post biologic initiation. The relationship between the number of baseline autoantibodies (Abs) positive (range 0 to 3) with treatment response was examined using linear (DAS28 change) and logistic regression (>1.2 DAS28 change) accounting for age, sex, race/ethnicity, education, smoking, body mass index, concomitant DMARDs, baseline DAS28, and prior biologic use.

Results: Patients (n=1224) were predominantly Caucasian (89%) and female (79%) and had a mean age of 57 yrs. Most were RF (60%) or anti-CCP positive (55%) and biologic naïve (59%). Compared to those with no Abs positive, those positive for Abs achieved a significantly greater response (Figure). In separate univariate analyses, all 3 Abs were associated with DAS28 improvement with similar effects (β coef 0.29-0.31). After adjusting for covariates, patients positive for all 3 Abs had an average improvement in disease activity of 0.48 units (95% CI 0.26-0.70) compared to those with no Abs (A). Likewise, those with 3 positive Abs were 2.35 times more likely (95% CI 1.57-3.51) to achieve an improvement >1.2 DAS28 units during treatment (B). Associations between Ab positivity and treatment response were dose-dependent (trend $p < 0.001$ in both models) and did not differ substantially across biologics.

Conclusion: An expanded Ab profile appears to significantly predict RA treatment response to biologic treatment in a dose-dependent fashion. Additional work that incorporates these serologic profiles with additional biomarkers or other

informative patient characteristics could allow for the accurate prediction of treatment response, thus providing an opportunity to personalize RA management.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) efficacy and safety in rheumatoid arthritis (RA) have been well established by numerous phase 3 and 4 studies and observational studies. The purpose of the present analysis was to explore the extent to which disease duration, inflammation, disease burden, and other baseline factors explain variations in outcomes in studies of RA patients treated with TCZ.

Methods: This was a pooled analysis of methotrexate-inadequate responding (IR)/conventional synthetic (cs) DMARD-IR patients with RA allocated to TCZ (intravenous or subcutaneous, monotherapy + combination therapy) in phase 3 and 4 studies. Endpoints were change from baseline to week 24 in Clinical Disease Activity Index (CDAI) and quality of life

(Health Assessment Questionnaire–Disability Index [HAQ-DI]) and week 24 ACR50 and CDAI remission (≤ 2.8). Using a combination of clinically informed and mathematically driven variable selection techniques, models (with study included as a random effect to account for intracorrelation of observations within each study) were built to optimize fit and explain outcome variance. Analysis of covariance and logistic regression were used for CDAI/HAQ-DI change from baseline and for ACR50/CDAI remission, respectively.

Results: The analyses were performed on 5462 patients from 12 studies. Analysis of baseline characteristics (before TCZ administration) revealed that patients with longer disease duration had been exposed to more cs DMARDs and had worse HAQ-DI than patients with shorter disease duration. Statistical modeling of clinical outcomes showed that disease duration accounted for <2% of the variation in HAQ-DI and CDAI change from baseline. Baseline CDAI explained 32% of the variation in CDAI change from baseline. Patients with higher baseline values tended to have greater improvements, likely due to having more “room” for improvement and to a higher risk for regression to the mean resulting from the fact that inclusion criteria for most trials required defined thresholds of disease activity, including joint counts. Baseline HAQ-DI, neither an inclusion criterion itself nor influenced by other inclusion criteria, explained 15% of the variation in HAQ-DI change from baseline. The odds of achieving ACR50 decreased by 9.2% if disease duration was doubled. The odds of achieving CDAI remission decreased by 15% per 5 additional years of disease duration and decreased by 22% per 10 additional score units of CDAI at baseline.

Conclusion: In this pooled analysis of TCZ-treated RA patients, disease duration explained statistically significant but practically small variations in clinical outcomes. These findings support that TCZ treatment outcomes are not heavily influenced by disease duration or other baseline characteristics.

Changes in DNA Methylation Identify Response to Treatment with Methotrexate and TNF Inhibitors Among RA Patients

Cameron Adams¹, Katie Marker¹, Melissa Krueger², Lisa Barcellos¹ and Lindsey A. Criswell³, ¹School of Public Health, UC Berkeley, Berkeley, CA, ²UC San Francisco, San Francisco, CA, ³University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Epigenetic modifications including DNA methylation are implicated in the development and progression of autoimmune diseases, such as rheumatoid arthritis [MIM 180300]. Evidence indicates that exogenous exposures, such as smoking, diet, and medications can change DNA methylation and that changes in DNA methylation contribute to immune cell autoreactivity. Methotrexate (MTX) and anti-TNF agents (a-TNFs) are effective treatments for RA. It is believed they reverse epigenetic modifications that cause T-cell autoreactivity, improving RA symptoms among some patients. Changes in DNA methylation associated with response to these treatments are potential biomarkers for prediction of treatment response.

Methods: We conducted a study to identify DNA methylation profiles that may serve as biomarkers of response to treatment with MTX and a-TNFs for RA. Blood samples, clinical data, and disease severity scores (DSS) were collected from 30 treatment naive individuals with RA at baseline and after 3-6 months of treatment with: MTX (n=10), a-TNFs (n=10), or MTX and a-TNFs (n=10). DSS included the Simple Disease Activity Index, Clinical Disease Activity Index, and the C-reactive protein and Erythrocyte Sedimentation Rate Disease Activity Scores. Genome-wide methylation profiles were generated using Illumina's Infinium Human Methylation EPIC BeadChip from PBMC samples. Quantile normalization and background subtraction with dye-bias normalization were performed using minfi and CpGs with high detection p-values and cross-reactive probes, and CpGs measuring SNPs were excluded. Treatment response was defined as difference in DSS from baseline to post treatment measurements. Differentially methylated positions (DMPs) and differentially methylated regions (DMRs) associated with, i) treatment, and ii) treatment response, were identified with limma and bumpHunter, respectively, using surrogate variables to adjust for blood cell proportions, batch effects, and genetic ancestry. Next, due to small sample size, baseline methylation levels in the top 1000 DMPs and 100 DMRs (by p-value, no multiple testing correction) identified in pre- and post-treatment analyses were used to predict observed treatment response. Principal component analysis (PCA) was done with the top DMPs and DMRs to identify treatment and treatment response clusters.

Results: Preliminary results found 38 DMPs associated with treatment ($p < 0.0001$), 28 of which were hypomethylated. PCA found distinct clusters for study subjects pre- and post-treatment. Additionally, subjects clustered by treatment arm using baseline methylation only.

Conclusion: These results indicate that treatment with MTX and a-TNFs alter DNA methylation and may be used as biomarkers treatment response. Further research is needed with larger sample size.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA, originally approved at 5 mg twice daily (BID). In 2016, an extended-release (XR) dose of tofacitinib 11 mg once daily (QD) was approved. Limited clinical or real-world data exist comparing efficacy outcomes between 11 mg QD and 5 mg BID doses. We aimed to compare the efficacy of these formulations.

Methods: Treatment effectiveness at 6 (± 3) months(mos) after initiation (baseline) was evaluated in an observational cohort of patients(pts) initiating tofacitinib 5 mg BID or 11 mg QD between February 2016 and March 2018, identified from the Corrona US RA Registry. The primary outcome was achievement of a minimum clinically important difference (MCID) in Clinical Disease Activity Index (CDAI) improvement at approximately the 6-mo visit following initiation. The MCID was dependent on baseline disease activity (≥ 2 if low baseline CDAI [≤ 10], ≥ 6 if moderate baseline CDAI [$10 < \text{CDAI} \leq 22$], and ≥ 11 if high baseline CDAI [> 22]). Secondary outcomes included: CDAI change from baseline to 6-mo visit, Pt Pain, and Pt Fatigue; achievement of low disease activity (LDA; CDAI ≤ 10) in pts without baseline LDA, or remission (CDAI ≤ 2.8) in pts without baseline remission, at 6 mos; and improvement \geq MCID in HAQ (≥ 0.22) at 6 mos. Outcomes were compared between groups in unadjusted analyses and adjusted linear and logistic regression models (covariates: age, sex, baseline CDAI, duration of RA [apriori decision], and additional covariates with standardized

Table 1. Patient baseline characteristics, and unadjusted and adjusted 6-month primary and secondary outcomes, of patients initiating tofacitinib 11 mg QD and 5 mg BID in the Corrona US RA Registry

	Tofacitinib 11 mg QD (N=196)	Tofacitinib 5 mg BID (N=138)	p value*

*p value for primary outcome from adjusted logistic regression model; p values for binary secondary outcomes from chi-squared tests; ^bLine of therapy: 1st-line patients naïve to csDMARDs and all biologic DMARDs; 2nd-line patients naïve to biologic DMARDs, but not csDMARDs; 3rd-line patients exposed to one prior biologic DMARD; 4th-line+ patients exposed to more than one prior biologic DMARD; ^cAdjustment covariates were age, gender, duration of RA, CDAI, prior number of non-TNFi, and prior number of biologic DMARDs; ^dFor continuous outcomes, the LSM (95% CI) are from an adjusted linear regression model; ^eDefined from 0 (no problem) to 100 (major problem); ^f6-month CDAI ≤10 among those without LDA at baseline (CDAI >10); ^g6-month CDAI ≤2.8 among those without remission at baseline (CDAI >2.8); ^hImprovement in HAQ calculated only for patients with baseline HAQ ≥0.22 (N=79 11 mg QD; N=87 5 mg BID)

BID, twice daily; csDMARD, conventional synthetic disease-modifying antirheumatic drug; CDAI, Clinical Disease Activity Index; CI, confidence interval; HAQ, Health Assessment Questionnaire; LDA, low disease activity; LSM, least squares mean; MCID, minimum clinically important difference; OR, odds ratio; QD, once daily; RA, rheumatoid arthritis; SD, standard deviation; TNFi, tumor necrosis factor inhibitor

differences>0.2). An exploratory analysis (limited sample size) was conducted to examine 6-mo outcomes in pts who switched to 11 mg QD after 5 mg BID initiation.

Results: 791 pts initiated tofacitinib (11 mg QD: n=460; 5 mg BID: n=234), of whom 334 pts (11 mg QD: n=196; 5 mg BID: n=138) had a registry visit and thus CDAI data at 6 mos after initiation. Baseline characteristics are shown in the Table. There were no significant differences in the proportion of pts with CDAI improvements ≥MCID between formulations with and without adjustment (23.5% vs 21.0%; oddsratio 1.23; 95% confidence interval 0.70, 2.15; covariates added in the model were prior number of non-TNF inhibitors and biologic DMARDs). There were no significant differences in the odds of achieving LDA, remission or improvement in HAQ ≥0.22 between formulations with adjustment (Table). Similar proportions of pts initiating 11 mg QD and 5 mg BID remained on tofacitinib at 6 mos (61.2% vs 67.4%; p=0.43). There were 135 switchers (5 mg BID to 11 mg QD); their post-6-mo outcomes were similar to those at the time of switch.

Conclusion: Results suggest that pts with RA who initiated treatment with tofacitinib 11 mg QD achieved comparable efficacy outcomes with pts who initiated with 5 mg BID. Although currently available person years of exposure is limited, data do not suggest the emergence of any new or unexpected safety risks for the XR formulation.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA, in combination with MTX or other non-biologic (nb)DMARDs, or as monotherapy. Two pooled open-label long-term extension studies previously showed that patients (pts) discontinuing concomitant MTX or glucocorticoids (GC) could maintain favorable treatment response.¹This analysis of real world data assessed characteristics of pts who discontinued MTX after tofacitinib treatment.

Methods: This retrospective cohort study included pts aged ≥18 years in the Truven MarketScanTM US Commercial and Medicare Supplemental claims database with ≥2 tofacitinib claims (first = index) with <60-day gap between 1/1/2014–1/31/2017, ≥2 oral MTX claims (one ≤90 days post-index) with <60-day gap, and an RA diagnosis on or within 12 months pre-index. Pts were continuously enrolled for ≥12 months pre-/post-index with no prior claim for tofacitinib 12 months pre-index. Pts were assigned to mutually exclusive cohorts for analysis by 12-month post-index MTX persistence: “persistent” (MTX-P; ≤60-day gap), “discontinued” (MTX-D; >60-day gap) and “interrupted” (MTX-I; >60-day gap with ≥1 subsequent MTX claim 12 months post-index). Outcomes at 12 months post-index were tofacitinib persistence (<60-day gap), adherence (proportion of days covered), effectiveness (composite measure; defined in Table)^{2,3} and RA-related costs. Two sample tests (t-test, chi-squared) were applied separately to MTX-P vs combined MTX-D and MTX-I, and pair-wise among the 3 cohorts, with no adjustment for multiple comparisons or imbalances in baseline covariates.

Results: 479 pts met inclusion criteria (MTX-P: 337 [70%]; MTX-D: 94 [20%]; MTX-I: 48 [10%] in the 12-month post-index period). Demographic and baseline clinical characteristics were similar among cohorts, aside from differences in the proportion of males and all-cause out-of-pocket costs (p<0.05; Table).

Table. Baseline demographics and clinical characteristics, and outcomes of patients with RA treated with tofacitinib and MTX during the 12-month post-index period

	MTX-P (N=337)	MTX-D (N=94)	MTX-I (N=48)

Tofacitinib persistence, adherence and effectiveness over 12 months were similar between MTX-D and MTX-P. RA-related total and pharmacy costs were lower in MTX-D vs MTX-P ($p<0.001$ and $p<0.05$, respectively).

Conclusion: This analysis of US-based claims data showed that pts who initiate tofacitinib with oral MTX can discontinue MTX with similar persistence, adherence and effectiveness, and lower RA-related total/pharmacy costs 12-months post-index vs MTX-persistent pts. Further analysis with a larger sample size is needed to confirm the robustness of these findings; further investigation is also needed regarding the MTX-I group as interpretation of this group is limited by the small sample size. Findings are limited by the use of claims data which may reflect MTX discontinuation/interruption related to pt choice without physician knowledge.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Point of care tailored treatment strategies are of value to improve rheumatoid arthritis (RA) patient outcomes. Musculoskeletal ultrasound (MSUS) is increasingly used as a modality by which rheumatologists diagnose and monitor the progression of RA. The multi-biomarker disease activity (MBDA) blood test is a commercially available assay that measures twelve inflammatory biomarkers to score RA disease activity on a scale of 1-100. This pilot study evaluated whether baseline MSUS and MBDA scores or their early changes, are predictive of 12-week clinical response in RA patients treated with tofacitinib.

Methods: 25 RA patients who met entry criteria (including baseline disease activity score using ESR [DAS28]>3.2 and power Doppler US [PDUS] score >10) were treated with open-label tofacitinib at the approved dose of 5 mg PO BID and assessed at baseline, 2 weeks and 12 weeks. MSUS was performed at each visit scoring 34-joints for PDUS and GSUS. Other metrics examined were MBDA score, clinical disease activity index (CDAI), disease activity score (DAS28). Associations between MBDA score /PDUS/GSUS at baseline or their changes from baseline to 2 or 12 weeks, and the change in DAS28/CDAI from baseline to 12 weeks, were assessed using Pearson correlation coefficients.

Results: Mean age was 52 years, mean disease duration 10.4 years, 88% of patients were female, 40% Caucasian, and 96% were RF/CCP positive. At baseline, the mean (SD) DAS28 was 6.26 (1.2) and CDAI was 40 (13.2). There was significant improvement in PDUS, GSUS, MBDA score, DAS28, and CDAI over 12 weeks (all $p<0.0001$). Correlations of 12-week changes in MBDA score or MSUS with 12-week changes in CDAI or DAS28 were all significant (correlation coefficients 0.44-0.58), except for GSUS with DAS28 (Table 1). Changes from baseline to 2 weeks in PDUS or GSUS were associated with significant DAS28 response at 12 weeks (Table 1). Baseline PDUS, GSUS and MBDA score were significant predictors of 12-week CDAI or DAS28 responses, except for GSUS with DAS28 response (Table 1).

Conclusion: This study showed that RA patients treated with tofacitinib for 12 weeks demonstrated significant responses with clinical, imaging, and biomarker end-points. In addition, baseline PDUS and MBDA score were predictive of the

Table 1: Correlations coefficients for associations of Biomarker or Imaging Measures with 12-Week Changes (Δ) in Clinical Disease Activity Measures

Associations of 12-Week Δ MBDA score/MSUS with 12-Week Δ CDAI/DAS28		
	CDAI (0-12 week)	DAS28 (0-12 week)
PDUS (0-12 week)	0.56**	0.56**
GSUS (0-12 week)	0.47*	0.34
MBDA score (0-12 week)	0.44*	0.59**
Associations of 2-Week Δ MBDA score/MSUS with 12-Week Δ CDAI/DAS28		
	CDAI (0-12 weeks)	DAS28 (0-12 weeks)
PDUS (0-2 weeks)	0.37	0.42*
GSUS (0-2 weeks)	0.44*	0.42*
MBDA score (0-2 weeks)	0.22	0.29
Associations of Baseline MBDA score/MSUS with 12-Week Δ CDAI/DAS28		
	CDAI (0-12 weeks)	DAS28 (0-12 weeks)
PDUS Baseline	0.55**	0.46*
GSUS Baseline	0.47*	0.25
MBDA score Baseline	0.44*	0.50*

*p<0.05, **p<0.01

DAS28 and CDAI response at 12 weeks. This is the first study to evaluate early MSUS and MBDA changes as predictors of clinical response in RA patients treated with tofacitinib.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Among the best known disease-modifying antirheumatic drugs, Methotrexate (MTX) is one of the most effective and widely used medications. It is used as a general first-choice drug in rheumatoid arthritis (RA), although some patients will not respond to this treatment and it is not free from side effects. The purpose of this work is to identify circulating proteins that could be useful to predict the patient's response to MTX.

Methods: Serum samples from patients enrolled in the Pathobiology of Early Arthritis Cohort (PEAC) were collected before treatment with MTX. Response to therapy was determined after 6 months by calculating the initial and final DAS28 of the patients. Their classification was performed following the EULAR response criteria. Sixty samples at baseline from this cohort (30 good responders and 30 non-responders) were depleted from the 14 most abundant proteins by affinity chromatography to remove background. Then, they were analysed by reversed-phase nanoliquid chromatography coupled to mass spectrometry using a SWATH strategy in a tripleTOF MS (Sciex). The quantitative data obtained in this proteomic analysis were processed using the ProteinPilot 5.0.1 and PeakView 2.1 software (Sciex). Machine learning analyses were performed on a train set of 30 samples (15 responders and 15 non-responders) via support vector machine (SVM) using the Classyfire, e1071 and caret R packages. Results were verified in an independent set of 24 samples by a two-stage support vector machine (TSSVM) with RBF kernel and 10 cross-fold validation for each meta-model.

Results: The proteomic analysis led to the identification and quantification of 229 proteins that were common between the screening and validation sets. Independent screening and validation data sets were pre-processed by PCA for dimension reduction. Then, results were analyzed by machine learning tools, leading to the definition of a panel of 8 proteins (one of them involved in MTX metabolism and two in the regulation of the immune response) that classifies at baseline the groups of responders and non-responders to MTX with strong agreement (Kappa>0.80), very high accuracy and good relevant metrics (Table 1).

Conclusion: We have defined a panel of circulating proteins useful to predict the response to MTX therapy in rheumatoid arthritis patients.

Table 1. Metrics of the classification performance of the 8-protein panel identified in this work to predict response of the patient to MTX. Cut-off for significance was p-value < 0.05.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors (TNFi) are widely used for the treatment of rheumatoid arthritis (RA). This study aims to analyse the profile of peripheral blood mononuclear cells (PBMC) after 6 months (m) of treatment with TNFi in order to find cellular biomarkers of response.

Methods: This was a prospective bi-center pilot study including 50 RA patients under TNFithrapy. PBMC were isolated from patients at baseline and 6m of treatment, andflow-cytometry analysed. Clinical activity at baseline and 6m of TNFi

treatment was assessed by DAS28. Clinical remission (DAS28^{2.6}) after 6m of treatment was considered as optimal response. The association between clinical remission and the percentage of change (Δ ,6m-0m) within each PBMC subset was analysed through multivariate log-regression model (odds ratio; 95% CI). All the analyses were adjusted by sex, age, concomitant-methotrexate, rheumatoid-factor and baseline-DAS28.

Results: Increased percentage of CD4+ T cells (Δ CD4+) was found after 6m of TNFi treatment in optimal responders; while suboptimal responders showed decreased percentage of this cell population (OR: 1.08; 95% CI: 1.01-1.16; p: 0.017). In addition, the percentage of B cells after 6m of TNFi treatment (Δ CD19+) decreased in optimal responders (OR: 0.7; 95% IC: 0.54-0.96; p: 0.024). This effect was essentially promoted by naïve B cells (OR: 0.7; 95% IC: 0.47-0.93; p: 0.017). The other PBMC subsets (monocytes, NK and CD8+ T cells) did not show statistical differences.

Conclusion: Our results demonstrate that CD4+ T and B cells may be useful as cellular biomarkers of response to TNFi in RA patients.

Funding: ISCIII (PI16/00474; PI16/01092)

Figure Legend: Percentage of change of CD4+ T cells and CD19+ B cells after 6m of TNFi treatment according to clinical remission achievement (DAS28^{2.6}). The U Mann-Whitney test was applied considering p-value < 0.05 as significant difference.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Low dose methotrexate (MTX) is one of the most commonly used disease-modifying anti-rheumatic drug for rheumatoid arthritis (RA) with excellent efficacy and safety profile. However, it is implicated in significant inter-patient clinical response variability. Genetic polymorphisms have been suggested to play a role in this clinical response variations. In this study we investigated the association between key pharmacogenetics of methotrexate [ABCB1, DHFR] genes and the efficacy /tolerability of the drug among patients with RA at a tertiary center in Saudi Arabia, which may aid in an individualized risk assessment and prediction of treatment outcomes.

Methods: A total of hundred patients with RA who received low-dose MTX therapy for at least six months were selected. Clinical and demographic characteristics were collected, Red blood cell MTX PG concentration were measured and

common polymorphisms in folate pathway enzymes were performed through genotyping procedure. The efficacy of MTX in treating RA was measured by counting the number of tender, swollen joints, scoring the visual analogue scale (VAS), scoring modified Health Assessment Questionnaire (mHAQ).

Results: The allelic frequencies of rs1045642 were 76.8 % for C, 6.0% for T, and 17.2 % for C/T, while, the allelic frequencies of rs1232027 were 50.9 for G/A, 32.5 % for G, 16.6 % for A. The study did not demonstrate any association between the polymorphism in ABCB1 gene and either toxicity or efficacy of MTX, while revealed an association between (rs1232027) polymorphism in the DHFR gene and certain adverse effects which are; nausea, lung infection, skin nodules, menstrual irregularities, oral ulcers in patients with RA ($P < .05$). In this study, we did not find a correlation between MTX dose and plasma level. Moreover, MTX plasma level was not correlated with toxicities detected in patients on MTX. On top of that, ABCB1 (rs1045642) and DHFR Gene (rs1232027) polymorphism were not associated with the risk of delayed elimination of MTX.

Conclusion: The ABCB1 gene polymorphism is not a predictor of either toxicity or efficacy of MTX treatment in RA patients. while DHFR gene polymorphism might be a reliable predictor of toxicity to MTX treatment. Sofar, published data still inconsistent between variable studies. Further meticulously designed studies that include more genetic polymorphisms and larger sample size are needed for more accurate results that lead to further integration of pharmacogenetics into clinical practice and better outcomes.

Toxicity	GG	GA	AA	Pearson Chi-Square
Nausea	71.4%	14.3%	14.4%	0.029
Hair loss	48.1%	30.4%	21.4%	0.162
Photosensitivity	55.6%	22.2%	22.2%	0.209

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor approved for the treatment of RA. Efficacy and safety of tofacitinib have been shown in several randomized clinical trials. Aim of the study presented here was to assess the clinical tolerability and effectiveness of tofacitinib among RA patients in real life.

Methods: Consecutive patients between June 2013 and April 2017 with RA who fulfilled the ACR/EULAR 2010 criteria were included in a prospectively designed analysis of retrospective data. Patients were initiated on tofacitinib 5mg bid. The primary objective was to analyze the safety of tofacitinib in a real-life cohort. Safety was assessed by the reasons to stop tofacitinib during follow up and changes of liver enzymes, hemoglobin, and creatinine. The secondary outcome was to analyze the frequency of and time to achieve low disease activity (LDA) and remission as defined by DAS28. Patients were stratified according to previous treatment with biologic agents (bio-naïve versus bio-experienced).

Results: Overall, 144 patients were treated with tofacitinib. 83.9% of patients were pre-exposed to at least one biologic agent. The average DAS28 at the initiation of tofacitinib was 4.42. 50.4% were rheumatoid factor and 49.0% were ACPA positive. The mean follow up was 1.22 years (range 4d – 3.7 years). 89 (61.8%) patients remained on tofacitinib during follow-up. The median time to stop tofacitinib was 95 days (range 4-1106). Reasons to stop tofacitinib were: insufficient response (n=23), gastrointestinal symptoms (n=18), infection (n=5), myalgia (n=2), remission (n=2), headache (n=2), cough, blue finger syndrome, intolerance, heartburn, psoriasis, and increased liver enzymes (all n=1). Increased ALAT or ASAT > 2x ULN were detected in 3.3% and 4.4%, respectively. These elevated transaminase levels were transient in 50 and 60% of the cases, respectively. Hemoglobin decrease of >10% was detected in 15.1% of the patients and decreased lymphocytes < 500/μl in 3.4%. An increase of creatinine >20% was detected in 9.4%. 58.2% and 49.5% of all patients achieved LDA or remission after a median survival time of 319 and 645 days, respectively. These rates were significantly higher in patients naïve to biologic agents as compared to patients pre-exposed to biologics (LDA: naïve 100% after mean 92d, pre-exposed 34.8% after 434d, p <0.001; remission: naïve 83.3% after 132d, pre-exposed 44.9% after 692d, p=0.001).

Conclusion: Tofacitinib is a safe and effective treatment option for patients with RA. Tofacitinib may induce high rates of LDA and remission in patients with active disease, even after use of one or more biologics, though the rate is significantly higher in patients naïve to biologics. Tofacitinib may be a valuable option in a treat to target approach. Our data point to benefits of an early use of tofacitinib in the therapeutic strategy.

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

The superiority of a treat to target strategy over conventional treatment with fixed csDMARD and corticosteroids: a multi-centre randomized controlled trial in RA patients with inadequate response to conventional synthetic DMARDs, and anew therapy with certolizumab pegol.

Ruediger B. Mueller^{1,2}, Michael Spaeth³, Cord von Restorff⁴, Christoph Ackermann⁵, Johannes von Kempis¹

² Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Ludwig-Maximilians-University Munich

³ Division of Rheumatology, Spital Linth, Uznach, Switzerland

⁴ Private rheumatologic practice, Männedorf, Switzerland

⁵ Private rheumatologic practice, Triesen, Liechtenstein

Background/Purpose: Treatment of rheumatoid arthritis (RA) includes the use of conventional (cs), biologic (b) disease-modifying anti-rheumatic drugs (DMARDs) and oral or intraarticular (IA-) glucocorticoids (GCs).

To analyse whether a treat to target (T2T) strategy optimizing csDMARD, oral and IA-GC treatment as an adjunct new therapy to a new certolizumab pegol (CZP) therapy in RA patients improves effectivity in RA patients.

Methods: 43 patients with active RA (≥ 6 tender, ≥ 6 swollen joints, ESR ≥ 20 mm/h or CRP ≥ 7 mg/l) despite csDMARD treatment for ≥ 3 months and naïve to bDMARDs were randomized to CZP (200 mg/2 weeks after loading with 400 mg at weeks 0-2-4) plus a treat to target strategy (T2T, n=21) or to CZP added to the established csDMARD therapy (fixed regimen, n=22). The T2T strategy consisted of changing the baseline csDMARD therapy (1) SC-methotrexate (dose: 15 \Rightarrow 20 \Rightarrow 25 mg/week, depending on the initial dose) \Rightarrow leflunomide (20 mg/d) \Rightarrow sulfasalazine (2x1000 mg/d) plus (2) oral GCs (20-15-12.5-10-7.5-5-2.5-0 mg/d tapered every 5 days) and (3) injections of ≤ 5 affected joints with triamcinolone. DMARD modification and an addition of oral GCs were initiated depending on the achievement of low disease activity (DAS28 < 3.2). The primary objective was defined as the ACR50 response at week 24.

Results: ACR 50 was achieved in 76.2% of the T2T as compared to 36.4% of the fixed regimen patients (p=0.020). ACR 20 and 70 responses were achieved in 90.5% and 71.4% of the T2T patients and 59.1% and 27.3% of the fixed regimen patients, respectively (p=0.045 and p=0.010, resp.). The adverse event rate was similar for both groups (T2T n=51; fixed regimen n=55).

Conclusion: Treat to target management with optimization of csDMARDs, oral and IA-GCs of RA patients in parallel to a newly established CZP treatment was safe and efficacious in comparison to a fixed regimen of csDMARDs background therapy. UCB Pharma funded this study. Gebro Pharmaceuticals provided the csDMARDs and GCs for the study.

Acr Hybrid Analysis: Blinded Data from the Ongoing Phase IIb Trial with the EP4 Receptor Antagonist CR6086 in DMARD-Naïve Patients with Early Rheumatoid Arthritis

Cristina Vitalini, Beatrice Barbetta, Giampaolo Giacomelli, Nadia Brambilla, Massimo D'Amato, Federica Girolami and Lucio C. Rovati, Clinical Research Department, Rottapharm Biotech, Monza, Italy

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR Hybrid, officially recommended by the ACR as a revision to the ACR20/50/70 response criteria, combines the ACR20/50/70 scores with the mean percent change in all 7 ACR core components, thus providing a percent improvement from baseline on a continuous scale. Despite the demonstrated higher sensitivity to patient-reported improvement than the ACR20 criterion [1], its application is still limited in clinical trials [2], possibly because the scientific community is not yet familiar with its use. Data from an ongoing drug trial in DMARD-naïve patients with early rheumatoid arthritis (RA) were used to compare the ACR Hybrid scores versus the traditional efficacy measures (ACR20/50/70) and DAS28.

Methods: To assess the validity of the ACR Hybrid measure, we used blinded data from the ongoing trial with the EP4 receptor antagonist CR6086 in early rheumatoid arthritis, DMARD-naïve patients (the CREATIVE study). This is a randomized, placebo-controlled, double-blind, dose response, Phase IIb, multicentre trial of CR6086 administered for 12 weeks in combination with methotrexate (NCT03163966). The study consists of a baseline evaluation and 4 post-baseline visits at the following time-points: weeks 3, 6, 9 and 12. The ACR Hybrid score was obtained calculating the mean percent change from baseline across the 7 ACR core set measures for each patient/visit and determining whether patients achieved ACR20, 50, or 70 responses at that visit. The ACR Hybrid scores were compared with ACR20/50/70 outcomes and DAS28 calculated at each post-baseline visit. Missing data were not imputed. Results are presented as number of visits, regardless of patients and time-points.

Results: A total of 146 patients newly diagnosed with RA by the 2010 ACR/EULAR classification criteria had been randomized in EU/non-EU countries at the time of the data cut-off (May 2018). Overall, 376 post-baseline visits were available for the analyses. ACR20 response was achieved in 157/376 (42%) visits, while mean percent changes in ACR core measures $\geq 20\%$, and therefore positive ACR Hybrid scores, were observed in 250 visits (i.e. 66% of total) (Table). Similarly, ACR50 response was achieved in 66/376 (18%) visits, while mean improvements in ACR core measures $\geq 50\%$ were observed in 87 visits (i.e. 23% of total). ACR Hybrid scores and percent change from baseline in DAS28 were highly correlated (Spearman's correlation -0.85).

Conclusion: Analysis of blinded data from an ongoing Phase IIb drug trial in early RA, DMARD-naïve patients encourages the use of the ACR Hybrid score and supports its role as a valuable endpoint in clinical trials. By increasing the sensitivity of the analysis, this new measure of RA response might facilitate the demonstration of differences between treatments.

Table. Number of visits by ACR Status and mean percent change in ACR core set measures

ACR Status	Mean percent change in ACR core set measures			
	<20	$\geq 20, < 50$	$\geq 50, < 70$	≥ 70
Not ACR20	122	91	6	0
ACR20 but not ACR50	4	66	20	1
ACR50 but not ACR70	0	6	22	4
ACR70	0	0	8	26

DAS28-CRP Versus DAS28-ESR and Thresholds for Disease Activity Category: Blinded Data from the Ongoing Phase IIb Trial with the EP4 Receptor Antagonist CR6086 in DMARD-Naïve Patients with Early Rheumatoid Arthritis

Cristina Vitalini, Beatrice Barbetta, Giampaolo Giacobelli, Nadia Brambilla, Massimo D'Amato, Federica Girolami and Lucio C. Rovati, Clinical Research Department, Rottapharm Biotech, Monza, Italy

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In most patients with rheumatoid arthritis (RA) the 28-Joint Disease Activity Score (DAS28) values calculated using C-reactive protein (CRP) are lower than those calculated using erythrocyte sedimentation rate (ESR). Since validated thresholds for categorizing disease activity are available for DAS28-ESR only, their application for DAS28-CRP has become common in clinical practice and clinical trials. Recently, Fleischmann et al. proposed new DAS28-CRP cut-offs for definition of remission, low and high disease activity [1, 2]. We aimed to evaluate here the use of the newly proposed thresholds for categorizing disease activity in relation to the validated DAS28-ESR cut-offs in DMARD-naïve patients with early RA.

Methods: We used blinded data from the ongoing trial with the EP4 receptor antagonist CR6086 in early rheumatoid arthritis, DMARD-naïve patients (the CREATIVE study). This is a randomized, placebo-controlled, double-blind, dose response, Phase IIb, multicentre trial of CR6086 administered for 12 weeks in combination with methotrexate (NCT03163966). The study consists of a baseline evaluation and 4 post-baseline visits at the following time-points: weeks 3, 6, 9 and 12. DAS28-CRP and DAS28-ESR were determined at each visit and their correlation was analysed using Spearman's coefficient. Agreement between the newly proposed DAS28-CRP thresholds for remission (<2.4), low (≤ 2.9) and high disease activity (>4.6) and the validated DAS28-ESR cut-offs (<2.6 , ≤ 3.2 and >5.1 , respectively) was determined by κ coefficient, sensitivity and specificity. Results are presented as number of visits, regardless of patients and time-points.

Results: A total of 146 patients newly diagnosed with RA by the 2010 ACR/EULAR classification criteria had been randomized in EU/non-EU countries at the time of the data cut-off (May 2018). Overall, data for the analyses were available for 527 visits. DAS28-CRP values were generally lower than DAS28-ESR values, but the 2 measures were highly correlated (Spearman's correlation 0.94). Based on the validated DAS28-ESR cut-offs, remission was determined in 17 visits, low disease activity in 22 visits, moderate disease activity in 202 visits, and high disease activity in 286 visits. The corresponding values obtained applying the newly proposed DAS28-CRP thresholds were 18, 27, 181 and 301 visits, respectively. A good agreement was reached against the validated DAS28-ESR cut-offs ($\kappa=0.67$) and sensitivity was particularly high for the high disease activity category (90%).

Conclusion: Analysis of blinded data from the ongoing Phase IIb trial with CR6086 indicated that the newly proposed DAS28-CRP thresholds for remission, low and high disease activity are consistent with the validated DAS28-ESR cut-offs, thus supporting their use in clinical trial and clinical practice.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the last two decades the treatment in patients with rheumatoid arthritis(RA) has undergone major advances, especially due to the appearance of new therapies, the use of the “treat to target” strategy and a better understanding of the “window of opportunity” concept. However, data from clinical practice confirming the benefits of using these strategies are scarce. Our purpose was to investigate whether the proportion of patients (pts) with RA in maintained remission (R) or low disease activity (LDA) after starting a first biological agent has increased over time and which factors are associated with this change.

Methods: Analysis of a database from a prospective cohort including 365 pts with RA starting a 1st biological agent (BA) (TNF inhibitor, abatacept or tocilizumab) in a tertiary hospital between 2000-2014. Demographic, clinical and analytical data were collected at the beginning of treatment and clinical activity (DAS28) was measured every 6 months. For this study, 3 groups were established according to BA initiation date: interval 1 (i1) (between 2000-2004), (i2) 2005-2009 and (i3) 2010-2014, with a minimum follow-up of 2 years at all pts. For each interval, the percentage of pts achieving maintained (at least 3 consecutive visits) R (DAS28 <2.6) or LDA (DAS28 <3.2) was determined. In addition, all variables collected were compared between groups by ANOVA and chi-square test.

Results: Out of the 365 pts initiating a 1st BA, 133 started in i1, 122 in i2 and 110 in i3. Of these, 38% (n=137) achieved maintained R/LDA. This percentage increased significantly in successive intervals (31% in i1 vs, 38% in i2 vs 45% in i3, p=0.02). Baseline characteristics of pts achieving R/LDA are shown in table 1A. For patients in i2 and i3, compared to the previous interval (i1 and i2 respectively), a significant higher frequency of use of BA with different mechanisms of action (0% in i1 vs 2.2% in i2 vs 34% in i3, p <0.001), women (56% in i1 vs 76% in i2 vs 84% in i3, p = 0.01) and concomitant methotrexate (56% in i1 vs 74% in i2 vs 81% in i3, p=0.03) was found. On the other hand, the percentage of optimized pts increased significantly over time (13% in i1 vs 32% in i2 vs 56% in i3, p <0.001; table 1B).

Conclusion: The percentage of pts with RA achieving maintained R/LDA after initiating a 1st BA has progressively increased over time. This is probably related to a greater use of BAs with different mechanisms of action and concomitant methotrexate. The sustained control of disease activity may allow using more frequently optimized doses of BA.

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients (Pts) with Undifferentiated Arthritis (UA), positive for ACPA antibodies are at high risk of progressing to Rheumatoid Arthritis (RA). TNF play a key role in the pathogenesis of RA. Very early treatment with the combination of Methotrexate and Infliximab (IFX) in a small cohort of UA showed a benefit in clinical symptoms and reduction of MRI evidence of synovitis and erosions. We assess whether IFX as a monotherapy is more effective than placebo (Pbo) in UA Pts positive for ACPA. Here we evaluate the clinical response, the MRI RAMRIS score and the risk to develop RA.

Methods: This was a randomized, double-blind, Pbo-controlled, two-arm parallel design study of 12 months to the primary endpoint (proportion of Pts who developed RA by ARA 2007 criteria). Pts with UA and symptomatic clinical synovitis of ≥ 1 joints and ACPA positivity were randomized 1:1 to IFX (3 mg/kg) or Pbo at week 0, 2, 6, 14 and 22, after which treatment was terminated. NSAIDs/stable low-dose oral corticosteroids (≤ 5 mg/day) were permitted but no DMARDs. Disease activity measures (DAS28CRP) were evaluated at BL, Wks 2 and 4, and every 4 Wks until Wk 52. OMERACT RAMRIS scores (components: erosion, osteitis, synovitis, tenosynovitis) and peritendinitis scores were evaluated at BL and Mth 4. Pts who developed RA at any time were discontinued and could receive standard of care.

Results: 28 Pts were randomized (mean age: 48 +/- 12 yrs; mean UA duration: 0.34 +/- 0.53 yr; mean CRP: 1.67 +/- 2.23 mg/dL). By 1 yr, 11/15 (73%) Pts treated with IFX developed RA vs 10/15 (67%) Pbo-treated Pts (Kaplan Meier, log rank $p=0.868$). At Wk 14, ACR 20, 50, 70 responses were observed respectively in 71.4%, 42.9%, 28.6% Pts treated with IFX vs 21.4%, 0%, 0% treated with Pbo. Remission DAS28CRP rate was observed in 50% in the IFX group vs 21.4% in the Pbo group. Pts in the IFX arm experienced significantly greater improvements in RAMRIS score versus Pbo at Wk 16 (graph). Furthermore, the difference in the RAMRIS score observed at Wk 14 was statistically different in the group of Pts who did not develop RA after 1 yr.

Conclusion: In this small randomized cohort of UA ACPA positive Pts, we noted a significant difference in the RAMRIS scoring after 4 months in the IFX group vs Pbo. This is the first study to report a worsening of disease activity based on the RAMRIS scores in the Pbo group but changes were minimal and not observed in all Pts. IFX has higher efficacy but did not prevent the progression to definite RA. Further analyses are ongoing to determine MRI predictors for severity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although treatment of rheumatoid arthritis (RA) has significantly improved during the past decades, many patients do not adequately respond or become resistant to current treatments. It is currently unknown why some patients respond well and others do not, and how the response rate could be improved. Vitamin D has strong immunomodulatory properties and it has been shown RA patients have a lower serum 25(OH)D level than healthy individuals. Moreover, vitamin D levels are correlated with disease severity. Interestingly, in vitro studies have shown that vitamin D augments the suppressive effects of etanercept in a simplified model for synovial inflammation. This suggests that vitamin D could improve the therapeutic response to etanercept in RA patients. Therefore we studied if etanercept response is related to serum vitamin D (25(OH)D) levels in RA patients.

Methods: For this study, data were used from the tREACH trial, a multicenter stratified single blinded randomized clinical trial. RA patients, according to the 2010 classification criteria, who started with etanercept within the first 12 months of the study were included in the analysis. Serum vitamin D (25(OH)D) levels were determined at the start of treatment (Tstart) and 3 months later using the LIAISON® 25 OH Vitamin D TOTAL assay. Correlation coefficients between vitamin D levels and the disease activity score (DAS) were calculated. Treatment response was determined with the EULAR response criteria, and difference in response rates was assessed using Chi-Square tests.

Results: 91 patients started etanercept in the first 12 months of the study, of which 24 did not have serum for 25(OH)D measurements at start of treatment and three months later. A total of 67 patients was included, of which 82% was female. At baseline, 45 (67%) and 48 (73%) were positive for rheumatoid factor and anti-citrullinated protein antibodies, respectively. DAS after etanercept treatment was weakly inversely correlated with serum 25(OH)D after treatment ($r=-0.29$, $p=0.02$) and the change in 25(OH)D during treatment ($r=-0.25$, $p=0.04$). After correcting for DAS and serum 25(OH)D at the start of treatment the aforementioned correlations were still found. Importantly, EULAR response rate was significantly lower in patients who were vitamin D-deficient at the start of treatment (34.6% vs 59.4%) and in patients with decreasing 25(OH)D levels during treatment (39.2% vs 57.7%).

Conclusion: RA patients with a serum 25(OH)D level below 50 nmol/L at the start of etanercept treatment or decreases during treatment have a lower EULAR response rate. Therefore, increasing serum 25(OH)D level in vitamin D deficient patients may be important to achieve optimal effects of TNF α blocking therapy.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recommendations and guidelines for the management of Rheumatoid Arthritis (RA) and spondyloarthritis (SpA) with bDMARD include dose-tapering as an adequate option for patients on persistent remission. Although data regarding these strategies has increased in recent years, there is scarce evidence about their long-term effectiveness.

Our aim was to analyze the persistence of bDMARD dose-reduction in clinical practice and evaluate its predictors in patients with inflammatory arthritis with up to seven years of follow-up.

Methods: Prospective longitudinal study from June 2011 to April 2018. From a cohort of 153 patients with chronic inflammatory arthritis treated with bDMARD (TNF inhibitors, rituximab, tocilizumab, and abatacept) we recruited those with RA and SpA receiving reduced-dose regimens.¹

Variables analyzed were: persistence of bDMARD dose-reduction, outcomes of patients requiring its withdrawal, predictors of persistence reported in the literature such as glucocorticoid (GC) and previous bDMARD use, disease activity and duration of disease at dose reduction as well as demographic and clinical features. A logistic regression model was used to identify factors associated with persistence on reduced-dose regimen after 7 years of follow-up

Results: 56 patients (RA:33; SpA:23) on tapered bDMARD (etanercept 51.8%, adalimumab 32.1%, Infliximab 3.6% and tocilizumab 12.5%) at study entry were included. Their clinical and laboratory features are shown in table 1.

After a mean follow-up on tapered-dose of 4.4 ± 2.6 years, 42.9% of subjects overall remained treated with this strategy (RA: 36.4%; SpA: 52.2%).

From those who required discontinuation of the step-down regimen, 15 (48.4%) achieved the therapeutic objective and 7 (22.6%) failed after returning to standard dose respectively. bDMARD were discontinued in 4 (12.9%) patients due to sustained disease remission (RA=3; SpA=1), 3 (9.7%) due to adverse events and 2 (6.4%) due to other reasons.

No significant differences in the different variables analyzed were found between patients continuing vs discontinuing reduced-dose regimens. Only disease duration at dose-reduction was associated with persistence of bDMARD step-down strategy overall (AOR: 1.13; 95% CI 1.01-1.26; p 0.02) in multivariate analysis.

Conclusion: A significant proportion of patients with RA and SpA (36.4% and 52.2% respectively) can be maintained with reduced doses of bDMARD after a long-term follow-up. Disease duration was the only predictor of dose-tapering persistence overall.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To cilizumab, anti-interleukin 6 receptor (IL-6R) therapy, is an effective treatment of rheumatoid arthritis (RA). However, a significant amount of patients do not respond adequately long term and would most likely benefit from changing treatment at an early time point. Biomarkers reflecting joint tissue degradation (e.g. C1M) are direct measures of joint health and have been shown to be prognostic of structural progression, as well as pharmacodynamics markers of tocilizumab response. We investigated whether lack of early changes in biomarkers, in response to tocilizumab, were predictive of lack of long-term(52 week) clinical benefit.

Methods: Pooled biomarker data from the two treatment arms (4 and 8 mg/kg tocilizumab + MTX) were included in this reanalysis of the LITHE (a phase III randomized placebo controlled study, NCT00106535) biomarker study (N=380). Patients had moderate-severe RA and were DMARD-IRs. Biomarkers reflecting tissue degradation were selected; type I, II, III, IV and VI collagen metabolites C1M, C2M, C3M, C4M and C6M. Missing biomarker data(<5%) were imputed using KNN. Patients were dichotomized into quartiles using 16-week %-suppression in the biomarkers. Long-term clinical benefit was assessed by ACR20 and ACR50 at week 52. Escape patients were annotated as ACR non-responders. Mann-Whitney was used to compare level of biomarker suppression between responders and non-responders. Logistic regression was used to predict lack of response, adjusting for age, sex, BMI and baseline biomarker level.

Results: There were a total of 196 (50.5%) ACR20 and 266 (70.0%) ACR50 non-responders at week 52. There were significant differences in the median levels of biomarker suppression between ACR non-responders and responders: i) C1M; ACR20, 28 vs. 47% (p=0.0004), ACR50, 34 vs. 45% (p=0.02), ii) C2M; ACR20, 7 vs. 13%(p=0.007), ACR50, 8 vs. 13% (p=0.02), iii) C3M; ACR20, 14 vs. 28% (p=0.0008),ACR50, 17 vs. 30% (p=0.009), iv) C4M; ACR20, 20 vs. 30% (p=0.0001), ACR50, 22 vs. 29% (p=0.04), and v) C6M; ACR20, 36 vs. 53% (p=0.0004), ACR50, 37 vs. 56%(p=0.004). C1M was the best marker for prediction of whom would not respond totocilizumab. Patients with a 38 to 60% suppression in C1M were 2.0 times more likely to achieve an ACR50, whereas patient with less than a 38% suppression were 3.2 to 3.7 more likely not to achieve an ACR50 response and 3.7 to 5.6 more likely not to achieve an ACR20 response (table). The remaining markers could predict lack of ACR50 with ORs from 1.9 to 2.9 and ACR20 with ORs from 2.4 to 3.0, if the marker actually increased from baseline to 16 weeks (Q4, table).

	ACR20				ACR50

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) is directed against CD20 antigens in B lymphocytes (BL), producing selective depletion of BL, not affecting mature plasmatic cells, without immediate effect on immunoglobulin (Ig) levels.¹ RTX retreatment decrease serum Ig levels which could increase infection risk.² Current guidelines recommend optimization of biologic therapy once remission has achieved in rheumatoid arthritis (RA) patients. A serum biomarker able to predict what patients would maintain remission after optimization in RTX treated RA patients is lacking. In previous studies, RA patients with good response to RTX show significant decreases in DAS28 scores associated to maintained BL depletion.³ Purpose: to analyze the predictive value of CD19 serum level prior to RTX infusion for the long term maintenance of therapeutic response, and it's utility as a biomarker for optimization in RA patients treated with RTX.

Methods: all RA patients treated with RTX in our center during 2016 and 2017 for at least 6 months, and with 12 months follow-up, were included. Demographic data, clinical data related to RA, including activity parameters (DAS28, HAQ, ESR, RCP), number of infections, optimization and serum levels of lymphocytic subpopulations (CD19, CD3 and CD56) and immunoglobulins (Ig) prior to each RTX cycle were collected. Optimization was defined as any dose decrease (lower dose for cycle and/or increase interval between cycles). Recurrent infections were defined as three or more infections per year. Descriptive statistics, correlation between basal levels of CD19, CD3 or CD56, and activity parameters or Ig levels at 6, 12 and 18 months, and association studies between lymphocyte subpopulations and optimization or recurrent infections were performed.

Results: Thirty patients (25 females, 55±11 years) with RA (24 RF/aCCP +, 13±9 years from disease onset), were included. At RTX initiation, DAS28 was 5.4±1.2, 28 patients (93%) were treated with any DMARD, 25 (83%) with prednisone (5±2 mg/d), and 19 (63%) had received previous biologic therapy. After 57±39 months of RTX (accumulated dose 14±10g), 22 patients had been optimized (at 37±32 months, DAS28 3.2±1.4) and 6 had stopped RTX. CD19 levels were lower than 2% in 22 patients (79%), including 9 with undetectable levels. CD19 levels (cells/mm³) were lower in optimized patients (21 vs 4, p=.02), and were correlated with DAS28 6 and 12 months later (r=0.4; p=.02), and with ESR 6 months later (r=0.6; p=.002). CD19 levels did not correlate with Ig levels, and were not associated with recurrent infections. CD3 and CD56 levels did not show any relevant association.

Conclusion: In RA patients treated with RTX for more than 12 months, CD19 levels correlate with long term therapeutic response, being low or undetectable levels predictors of good outcome, without association with Ig levels or increased infections. Our results suggest that CD19 levels before every RTX cycle might be a useful biomarker to select candidate patients for optimization with this therapy.

Combination of Intra-Articular Steroid Injection and Tofacitinib More Effective Than Tofacitinib in Rapid Radiographic Progression Patients with Rheumatoid Arthritis

Kensuke Kume¹, Kanzo Amano¹, Susumu Yamada², Toshikatsu Kanazawa² and Kazuhiko Hatta³, ¹Rheumatology, Hiroshima Clinic, Hiroshima, Japan, ²rheumatology, hiroshima clinic, hiroshima, Japan, ³Rheumatology, Hatta Clinic, Kure, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) should aim at full remission. However, we experienced that rapid radiographic progression (RRP) existed despite initial tofacitinib and methotrexate combination therapy in early RA (unpublished data). In RRP, initial tofacitinib and methotrexate might be inadequate. To compare remission and radiographic non-progression in RRP patients treated with tofacitinib or with tofacitinib plus intra-articular steroid injection.

Methods: We designed a single-blind(X ray reader and assessment physician), randomized controlled trial. We screened 48 RRP (CRP> 10 mg/L, RF +, and ACPA+) early (disease duration<6 months) RA patients for inclusion. 39 were randomly allocated tofacitinib group (T group) or tofacitinib plus intra-articular steroid injection group (T plus I group). All patients were taking methotrexate (from 10 to 22mg a week). For T plus I group, palpate examinations of both MP and PIP joints, wrists, elbows, shoulders, and knees were performed every 4 weeks. If swollen joints were existed, intra-articular steroid injections were intensified in each swollen joints. Co-primary endpoints were proportion of patients showing clinical remission (SDAI <3.3) and radiographic non-progression (Δ modified total Sharp score ≤ 0.5) at 52 weeks. Analysis was by intention-to-treat with last observation carried forward to missing data.

Results: The characteristics of each group at baseline were not significantly different. Clinical remission at 52 weeks was achieved by more patients in the T plus I group (29.2%) than in the T group (21.3%) ($p<0.05$). Radiographic non-progression at 52 weeks was achieved by more patients in the T plus I group (33.4%) than in the C group (23.7%) ($p<0.05$).

Conclusion: Results of this reveal that combination of intra-articular steroid injection and tofacitinib can achieve a high clinical and radiological remission rate in early RRP RA.

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologics in combination with methotrexate (MTX) are being incorporated earlier in rheumatoid arthritis (RA) therapy to prevent long-term damage and maintain patient function. While some patients transition off TNF inhibitor (TNFi) + MTX combination therapy (Combo) to monotherapy (TNFi mono or MTX mono), differences in patient characteristics and attainment of disease control for the Combo and monotherapy groups are unclear.

Methods: Data were obtained from a prospectively collected cohort at a single academic medical center from 2003 to 2016. At study visits every 6 months, a range of patient and treatment variables were recorded. This analysis included patients who received Combo while in the cohort and were followed; patients were categorized into three groups: continued Combo, switched to TNFi mono, or switched to MTX mono. Baseline was the date of first recorded use of Combo or following entry to the cohort. Index was the date a patient switched to monotherapy, or for continuing Combo patients, baseline + 24 months (based on average time to switch in monotherapy groups). Predictors of disease activity scores at index were analyzed with ANCOVA.

Results: TNFi + MTX was used by 341 patients, with 46% remaining on Combo and 31% and 23% switching to TNFi mono or MTX mono, respectively. Half (51%) of the switches to monotherapy occurred in the first year after baseline, with an average time to switch of 23.4 months. Patient characteristics at index were significantly different across groups for mean age (older for switch to MTX mono) and biologic initiation era (less in late era for switch to MTX mono); nonsignificant trends were seen for gender and disease status (Table 1). Disease Activity Score 28-joint with C-reactive protein (DAS) at index was predicted by early TNFi initiation era ($p=0.0072$), longer disease duration ($p<0.0001$), and higher baseline DAS score ($p<0.0001$), but not by treatment group (Table 2). Other disease activity measures had similar predictors at index, except Rheumatoid Arthritis Disease Activity Index (RADAI), which was predicted by higher baseline RADAI score ($p=0.0004$) and marginally by treatment group ($p=0.0503$) (Table 2).

Conclusion: Over half the patients on Combo transitioned to TNFi mono or MTX mono, a majority during the first year of combo therapy on study. Patients switching to MTX mono were older than patients continuing Combo or switching to TNFi mono, but not much different in disease activity or time on therapy. Disease duration and baseline disease activity had the greatest influence on disease activity at the time of medication change.

Table 1. Demographic and Disease Characteristics at Index (Date of the Switch)

Characteristic at index*	Continued Combo TNFi + MTX (n = 157)	Switched to TNFi Mono (n = 105)	Switched to MTX Mono (n = 79)	p†
Age (years)	61.17 ± 11.83	59.36 ± 15.07	64.9 ± 12.92	0.0256

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Certolizumab-pegol (CZP) is a sixth antitumor necrosis factor inhibitor for rheumatoid arthritis (RA) in Japan. Several clinical trials were conducted to evaluate the efficacy and safety of CZP, such as J-RAPID, HIKARI and C-OPERA study. They clarified the efficacy and safety of CZP for RA. However, the target population of most clinical trials is limited by the inclusion and exclusion criteria of the studies. Thus, the target populations are different between those in clinical trials and in daily practice. We investigated the effectiveness and safety of CZP for RA in daily practice.

Methods: Patients who started CZP after April 1, 2013 were investigated in this retrospective study. Retention rate, change in disease activity and safety of CZP obtained through medical records and the data from Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort were analyzed. The missing data were complemented by using the last-observation-carried-forward (LOCF) method. Effectiveness was assessed by 28-joint Disease activity score (DAS28) and the factors associated with therapeutic response at 12 weeks with CZP by using logistic regression analysis. Retention rate was assessed by Kaplan-Meier method. Patients were followed until August 31, 2017.

Results: Consecutive 143 RA patients who started CZP at our institute were enrolled. Women were 93%. The median (interquartile range) age was 48 (36-59). Disease duration was 7 (3-14) years, and treatment periods were 39 (15-100) weeks. DAS28 was 3.7 (2.8-4.3) at baseline. Bio-naïve patients were 42%. Methotrexate (MTX) was used in 68% and the median dose was 10 (8-12) mg/week. Prednisolone was used in 39% and the median dose was 5 (4.0-8.8) mg/day at baseline. Patients who wanted to be pregnant were 42 (31% among women). The number of patients who could not continue CZP was 89 (62%), due to lack of effectiveness 51, marked effectiveness 2, pregnancy 5 and side effects 13. The DAS28 at 12 weeks was decreased from 3.6 to 2.9 ($p<0.01$). The DAS28 at 12 weeks was more decreased in bio-naïve subset than bio-switch subset significantly ($p<0.01$) and same tendency was detected in patients with MTX subset than without MTX ($p<0.01$). Bio-naïve might be the factor for achieving good response at 12 weeks (χ^2 2.2, $p=0.08$). The retention rate was 80% at 12 weeks and 47% at 52 weeks. A greater percentage of patients in bio-naïve subset adhered to CZP than that of patients in bio-switch subset ($p=0.04$). Similarly, the retention rate of CZP with MTX subset was significantly higher than that without MTX subset ($p=0.03$).

Conclusion: Patients who wanted to be pregnant was over 30% among women who used CZP. CZP was more effective in patients with bio-naïve and patients treated with CZP concomitant with MTX. The fact that seen in trial was ascertained in daily practice.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In Phase 3 trial (RA-BEGIN), baricitinib (BARI) monotherapy demonstrated superiority to MTX in pain reduction and HAQ-DI improvement in treatment of csDMARD-naïve active RA patients.¹ No prospective head-to-head(H2H) trial data are available comparing BARI monotherapy vs. bDMARD monotherapy in csDMARD-naïve RA patients.

The objective was to assess pain and HAQ-DI for BARI monotherapy from a randomized, MTX-controlled trial vs adalimumab (ADA), tocilizumab (TCZ), and tofacitinib (TOFA) monotherapy from similar randomized, MTX-controlled trials in csDMARD/bDMARD naïve RA patients using matching-adjusted indirect comparison (MAIC).

Methods: Individual patient data from the RA-BEGIN BARI 4 mg arm were weighted to match baseline characteristics of the ADA arm from PREMIER,² TOFA 5 mg arm from ORAL-START,³ and TCZ 8 mg/kg arm from combination of AMBITION and FUNCTION,^{4,5} respectively; MTX arms were also matched between trials. Method of moments was used to determine weights for age, gender, baseline disease scores, and baseline values of the outcome variable. Mean change on pain VAS and HAQ-DI at Week 24 for BARI were adjusted for the above baseline characteristics with the weighted linear model, and then indirectly compared vs. respective published results for Week 24 TCZ and TOFA and for Week 26 ADA data. Statistical significance of the weighted treatment effect was assessed with the bootstrap method. Sensitivity analyses included MAIC with study level matching⁶, Bucher's method without matching adjustment⁷, and inclusion of disease duration as an additional matching variable.

Results: Across trials, the mean baseline pain VAS ranged from 58.7 to 65.2 with a 6-month mean change in pain of -28.3 to -33.5 for the MTX arm, indicating comparability between trials. Similar HAQ-DI and changes in HAQ-DI for the MTX arm were observed. At Week 24, BARI showed numerically greater improvement over MTX in pain than that for TCZ, ADA, and TOFA; statistically significant pain improvement were observed for BARI vs ADA and TCZ with all 3 matching methods but only with the Bucher method for TOFA (Figure). BARI-treated patients showed significantly greater improvement in HAQ-DI at Week 24 than TCZ and ADA but not TOFA (Figure). Sensitivity analyses showed consistent results.

Conclusion: This indirect comparison of different studies in cs/bDMARD-naïve RA patients, after adjusting for differences in baseline characteristics, suggest a greater pain reduction and improved physical function for BARI monotherapy vs. TCZ and ADA monotherapy. There is suggestion of greater pain reduction for BARI monotherapy vs. TOFA monotherapy, but no differences in improved physical function between the JAK inhibitors. A H2H clinical trial would be needed to confirm these results.

Early Versus Delayed Treatment in Patients with Rheumatoid Arthritis (RA) in Routine Care at a Single US Academic Center: Better Response According to MDHAQ (MultiDimensional Health Assessment questionnaire) for Patients Starting Treatment in the Initial 6 Months

Jacquelin R. Chua, Mariam Riad, Sobia Hassan, Najia Shakoar, Joel A. Block and Isabel Castrejón, Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Delay in initiation of disease-modifying anti-rheumatic drug (DMARD) therapy may be a major contributing factor toward poor outcomes in patients with rheumatoid arthritis (RA). Many patients, however, undergo delay in diagnosis and treatment initiation in routine care regardless of rheumatologists' awareness. In this study, we aim to evaluate improvement according to multidimensional health assessment questionnaire (MDHAQ) scores in DMARD-naïve RA patients with and without delay in initiation of treatment.

Methods: We retrospectively reviewed all DMARD-naïve RA patients seen at a single academic site from 2011/16 who had an MDHAQ form at baseline visit and 6-month follow-up MDHAQ. Disease duration was derived from symptom onset to the time of first visit at our rheumatology clinic. We classified patients as "no delay" (<6 months) or "delay" (>6 months) to treatment according to the ACR definition ¹. Demographic, clinical data and the change from baseline to follow-up were compared in no delay versus delay groups using t-tests; %change from baseline in each group was also calculated. Mean change in MDHAQ scores in each group were compared with minimal clinically important improvement (MCII) ².

Results: Seventy-four patients were included; 33 (45%) with no delay and 41 (55%) with delay. By definition, median symptom duration at the first visit was significantly higher for the delay group (23 vs 2.2 months). No significant differences were seen in age, gender, ethnicity, rheumatoid factor, anti-cyclic citrullinated peptide antibody, type of DMARD initiated, and glucocorticoid dosage for both groups. Median interval from baseline to follow-up was not significant in both groups (6 months). Routine assessment of patient index data (RAPID3) and component scores improved in both groups at follow-up, greater improvement was noted in no delay vs delay (RAPID3 % change: -39% vs -29%, respectively. RA disease activity index (RADAI) self-reported joint counts of 48 joints also improved in both groups at follow-up with greater improvement in no delay vs delay (-46% vs -31%). Mean change in RAPID3, physical function and patient global assessment scores from baseline to follow-up in each group met the minimal clinically important improvement thresholds, but not pain (table).

Table. Changes in patient reported clinical variables included in the MDHAQ

	Early Treatment (<6m) N=33	Delayed Treatment (>6m) N=41	MCII threshold
RAPID3 (0-30)			3.8
Baseline	14.5 (5.7)	15.6 (6.7)	
Change at 6 months	-5.6 (6.4)	-4.6 (6.3)	
% Change from baseline	-39%	-29%	
MDHAQ-Function (0-10)			0.375 (HAQ)
Baseline	2.8 (2.0)	2.9 (2.3)	
Change at 6 months	-1.3 (2.0)	-0.9 (1.9)	
% Change from baseline	-46%	-31%	
MDHAQ-Pain (0-10)			2
Baseline	6.6 (2.5)	6.9 (2.6)	
Change at 6 months	-2.6 (2.8)	-1.8 (2.7)	
% Change from baseline	-39%	-26%	
MDHAQ-PATGL (0-10)			1.8
Baseline	5.9 (2.4)	6.4 (2.7)	
Change at 6 months	-2.6 (3.3)	-2.1 (3.2)	
% Change from baseline	-44%	-33%	
RADAI self-reported joint counts (0-48)			na
Baseline	13 (9)	16 (12)	
Change at 6 months	6 (10)	5 (10)	
% Change from baseline	-46%	-31%	

Data presented as mean (SD) and percentage (%) change from baseline comparing results between groups. MCII; minimal clinically important improvement; RAPID3, routine assessment of patient index data 3; PATGL, patient global assessment.

Conclusion: A clinically significant improvement was seen in all DMARD –naïve RA patients after treatment initiation, according to MDHAQ questionnaire. However, greater improvement was seen when treatment was initiated <6 months of symptom onset, emphasizing the importance of early referral and initiation of DMARD. Further studies confirming these results in other larger cohorts are needed. MDHAQ is useful in detecting meaningful clinical changes in early RA patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: MTX is considered as a cornerstone in RA treatment since the 1990s and its injectable forms have proven their enhanced clinical and pharmacological efficacy and safety in case of insufficient response or poor tolerance of oral formulations. Few data are available considering the timepoint at which the formulation switch is performed in current practice.

The objective of this work was to investigate across 3 independent trials if there was a consistency in patterns of MTX oral -> injectable switches in terms of RA characteristics, MTX dosages (before and after the switch) and reasons of passage.

Methods: Three trials were considered for this work: 1/ STRATEGIE (observational study designed to investigate the therapeutic strategies used in current practice in RA patients insufficiently responding to initial MTX monotherapy), 2/ APRiM (observational study aimed to investigate the treatment adherence of RA patients switching from oral to injectable MTX or between two different MTX prefilled syringes) and 3/ SELFi (phase III randomized trial aiming to compare a new MTX autoinjector to the historical MTX prefilled syringe in terms of treatment adherence and functional capacity in RA patients at 6 months). In all three studies we selected baseline data concerning patients switching from oral to injectable MTX at the inclusion visit.

Results:

	STRATEGIE N = 151	APRiM N = 270	SELFi N = 98
RA duration, years (mean ± SD)	4.9 ± 6.1	6.6 ± 8.1	4.5 ± 5.9
(median (min;max))	2.8 (0.0; 29.0)	3.0 (0.0; 40.0)	2.0 (0.2; 30.5)
MTX treatment duration, years (mean ± SD)	3.6 ± 4.5	3.3 ± 4.2	2.5 ± 2.8
(median (min;max))	1.9 (0.0; 24.3)	1.4 (0.0; 23.6)	1.4 (0.1; 15.4)
DAS28 (mean ± SD)	4.4 ± 0.9	3.9 ± 0.9	3.5 ± 1.2
MTX oral dosage at V0, mg/wk (mean ± SD)	15.3 ± 3.7	15.0 ± 4.1	14.8 ± 3.8
MTX injectable dosage at the end of V0, mg/wk (mean ± SD)	17.0 ± 4.0	16.3 ± 3.8	17.0 ± 4.0
Distribution MTX dosage unchanged / raised / reduced	50% / 45% / 5%	62% / 34% / 4%	51% / 42% / 7%

Conclusion: Our work showed a consistent pattern across 3 independent trials concerning the oral/injectable MTX switch. It generally occurs at 15mg/wk, the new injectable dosage being either unchanged or very slightly raised as compared to the last oral one. Surprisingly, the MTX route of administration seems to be modified mostly for efficacy reasons, safety issues being anecdotal.

Individualised Infliximab Treatment: A Treatment Strategy Based on Therapeutic Drug Monitoring

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose is to develop an individualised treatment strategy based on Therapeutic drug monitoring (TDM) in order to optimise efficacy of Infliximab (INX) treatment. Targeted therapies have greatly improved the treatment of patients' inflammatory joint diseases, but a significant proportion of patients either do not respond sufficiently to therapy or lose efficacy over time. An extensive individual variation in serum drug concentrations suggests both under- and overtreatment of a substantial proportion of patients. Many patients develop anti-drug antibodies (ADAb) during therapy, contributing to reduced drug levels, inefficacy and adverse events. TDM can probably increase effectiveness of treatment with INX and other biological drugs.

Serum (MIL) low (ng/ml)	<2.0 and high ADRs (≥ 10 ug/L)	<2.0	2.1 – 2.9	3.0 – 6.6	6.7 – 10.0	>10.0
Action	Switch to oral hydrocortisone (200)	Increase dose of prednisone based on weight (200 mg/d)	Consider increasing dose	Random	Consider decreasing dose	Decrease dose
Guideline for action		Increase the dose by increasing the dose by 2-2.5 mg/kg to a max dose of 32 mg/kg or by decreasing the dose interval by 2 weeks to a min of 4 weeks	Consider increasing the dose based on clinical judgement and the patient's factors given below*	Within target range Continue with the same dose and dosing interval	Consider to decrease the dose based on clinical judgement and the patient's factors given below*	Decrease the dose by increasing the dose interval by 2 weeks to a min of 3 weeks or by decreasing the given dose by 2-2.5 mg/kg

*Patient factors to be considered when making the treatment decisions in the yellow boxes:
Disease activity and trend (disease activity, the trend of the trough level over time, previous drug interval changes, availability of alternative drug, diagnosis (RA patients are expected to have lower trough levels due to lower recommended dosing)

Methods: The treatment strategy has been developed by the steering committee of the NORwegian DRUG Monitoring study (NOR-DRUM), based on a systematic literature research (SLR), unpublished data and expert opinion. A SLR was performed in May 2016. In Norway neutralising ADAb are measured with an “in house” assay. For this assay, ADAb levels >50 µg/L are defined as “high”. This cut-off is based on own s-INX and ADAb data (Diakonhjemmet Hospital during 2015-2016) and clinical experience. The proposed strategy has been developed through a series of meetings in the project group consisting of national leading experts in this field (both clinicians experienced with TDM and laboratory physicians) and with additional input from international key experts in the scientific advisory board of the NOR-DRUM study.

Results: The treatment strategy from infusion number 4 onwards is depicted in the Figure. The therapeutic range for serum INX (through levels) is defined as 3-8 µg/ml (Figure, green zone). During the induction phase (infusion 1-3) the recommendation is to keep the level >20 µg/ml at infusion 2 and >15 µg/ml at infusion 3. A guideline for action according to levels outside the therapeutic range is given in the Figure. If the patients develop high levels of ADAb the recommendation is to switch therapy.

Conclusion: An individualised treatment strategy based on TDM has the potential to optimise therapy with infliximab and other biological drugs by: 1) prevention of treatment failure by identification of patients with drug levels below the therapeutic range, 2) reduction of overtreatment, which predispose to side effects and increase costs, and 3) early identification of ADAb development, with the possibility to detect treatment failures prior to a clinical flare and to prevent hypersensitivity reactions. The real life efficacy of this strategy is being investigated in an ongoing randomised clinical trial, NOR-DRUM (NCT03074656).

Rheumatologists Beliefs in the Effectiveness of Other Methotrexate-Based Treatment Approaches May Explain the Low Use of Triple Therapy: A Bayesian Belief Elicitation

Gyanendra Pokharel¹, Rob Deardon¹, Sindhu Johnson², George A. Tomlinson³ and Glen Hazlewood⁴, ¹Department of Mathematics and Statistics, University of Calgary, Calgary, AB, Canada, ²Rheumatology, Mount Sinai Hospital and University Health Network, Toronto, ON, Canada, ³Medicine, Mount Sinai Hospital, Toronto, ON, Canada, ⁴Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Triple therapy (MTX, sulphasalazine (SSZ), hydroxychloroquine (HCQ)) has evidence to support its use from randomized trials (RCTs) but is not commonly used. The objective of this study was to quantify rheumatologists' beliefs about the effectiveness of common initial MTX-based treatment approaches for early rheumatoid arthritis (RA).

Methods: Rheumatologists completed a Bayesian belief elicitation exercise using a validated approach. In 1-on-1 interviews, each rheumatologist was asked to consider the probability that a typical patient with moderate-severe early RA would have an ACR50 response within 6 months, with each of 4 treatments: oral MTX, subcutaneous (sc) MTX, MTX + HCQ, or triple therapy. Rheumatologists were asked to think how they would typically use these treatments in practice, including their preferred dosing and use of any additional treatments (steroids, NSAIDs). In the belief elicitation exercise, participants were given 20 chips, each representing 5% of their total weight of belief. They were asked to distribute the 20 chips across a grid of possible values of the probability of an ACR50 response, placing more chips on values they believed more likely. The parametric distributions best fitting the chip counts were used to calculate pairwise relative risks for each participant. These distributions were averaged for the overall group and separately for subgroups that had optimistic or pessimistic beliefs regarding the relative effect of triple therapy to oral MTX (top and bottom quartiles).

Table 1: Pairwise treatment effects of the elicited distributions

Intervention	Comparator, relative risk, median (95% credible interval)			
	Oral MTX	Subcutaneous MTX	Dual therapy (MTX + HCQ)	Triple therapy
<i>Overall group</i>				
Oral MTX	1	—	—	—
Subcutaneous MTX	1.38 (0.82, 5.89)	1	—	—
Dual therapy (MTX + HCQ)	1.61 (0.87, 6.21)	1.16 (0.68, 3.7)	1	—
Triple therapy (MTX + HCQ + SSZ)	1.87 (0.74, 6.54)	1.29 (0.45, 3.74)	1.11 (0.34, 1.79)	1
<i>Triple therapy optimistic subgroup</i>				
Oral MTX	1	—	—	—
Subcutaneous MTX	1.52 (0.94, 6.22)	1	—	—
Dual therapy (MTX + HCQ)	1.90 (1.19, 6.33)	1.24 (0.72, 3.8)	1	—
Triple therapy (MTX + HCQ + SSZ)	2.35 (1.47, 6.84)	1.45 (0.96, 3.87)	1.14 (0.85, 1.87)	1
<i>Triple therapy pessimistic subgroup</i>				
Oral MTX	1	—	—	—
Subcutaneous MTX	1.20 (0.66, 2.05)	1	—	—
Dual therapy (MTX + HCQ)	1.25 (0.71, 2.67)	1.08 (0.60, 1.54)	1	—
Triple therapy (MTX + HCQ + SSZ)	1.26 (0.34, 2.05)	1.09 (0.18, 1.65)	1.05 (0.13, 1.57)	1

Results: The 38 rheumatologists who completed the belief elicitation exercise were from a variety of practice types (50% academic, 26% community, 24% both). The practice duration ranged from 1-42 years and 58% were female. The overall pooled RR for was highest for triple therapy vs. MTX (Table 1): relative risk (RR), median (95% credible interval): 1.87 (0.74-6.54). Triple therapy, however, was similar in perceived effectiveness to MTX + HCQ [RR 1.11 (0.34-1.79)]. For the optimistic subgroup, both triple therapy and MTX + HCQ were perceived as statistically superior to oral MTX [RR for triple therapy: 2.35 (1.47-6.84); RR for MTX+HCQ: 1.90 (1.19-6.33)], and similar to each other [RR triple therapy vs MTX+HCQ: 1.14 (0.85-1.87)]. Subcutaneous MTX was perceived as more effective than oral MTX, although the credible interval was wide. The pessimistic subgroup perceived all treatments to be similar.

Conclusion: There is variation in rheumatologists' beliefs regarding MTX-based DMARD treatments. Many consider triple therapy to be effective, but similar to other treatments, particularly MTX + HCQ, for which little RCT evidence exists. This may explain the low use in practice, and supports a randomized trial evaluating these treatments.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission is the goal of rheumatoid arthritis (RA) treatment, but ACR responses are more commonly measured in clinical trials. As such, data on remission are lacking for some treatments, or may be imprecise. The objective of this study was to jointly estimate remission and ACR50 responses for methotrexate (MTX)-based treatment options in early RA.

Methods: We conducted a Bayesian bivariate network meta-analysis (NMA) to compare methotrexate monotherapy and methotrexate-based DMARD combinations for RA. The correlation between the outcomes was derived from an observational study (CATCH cohort), whereas the treatment outcomes were derived from randomized trials that formed the connected network of evidence. The analyses were conducted separately for MTX-naïve and MTX-inadequate response populations in a Bayesian framework with uninformative priors. Comparisons were made to a univariate NMA that estimated each outcome separately.

Results: From the incident RA cohort study, the correlation between ACR50 response and DAS28 remission at 6 months was moderate (Pearson correlation coefficient 0.58) for the 900 patients in the CATCH cohort who had moderate-high disease activity at baseline. For MTX-naïve patients, the NMA included 74 trials in total; 39 measured both outcomes, whereas 64 and 49 measured only ACR50 response or remission respectively. Two treatments that were not statistically superior to methotrexate alone for remission in the univariate NMA, were in the bivariate model [Figure 1: bivariate odds ratio (OR) (95% credible interval (CrI)): MTX +infliximab 2.0 (1.2, 3.7), MTX + tofacitinib 2.7 (1.0, 6.2)]. Six treatments had no data for remission in the univariate model, but could be estimated in the bivariate approach. Of these, only triple therapy (MTX + sulphasalazine +hydroxychloroquine) was superior to MTX alone for remission (OR (95%CrI): 2.5(1.0, 6.1)). In the MTX-IR analysis, all 16 treatments were superior to MTX alone for both ACR50 response and remission in both the univariate and bivariate models, but the CrI were usually more precise in the bivariate approach and remission could be estimated for several treatments not possible in the univariate model, including triple therapy (OR (95%CrI): 17.5 (6.8,46.1)).

Conclusion: By borrowing the strength across treatments and outcomes, a bivariate NMA allowed the estimation of both ACR50 response and remission for all treatment comparisons. In particular, our results add data on remission for several

MTX-based DMARD combinations (including triple therapy and biologic combinations) not demonstrated in the univariate NMA model.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Golimumab (GLM) has demonstrated efficacy and safety in patients (pts.) with active RA after treatment with at least one TNFi in a RCT. However, data on effectiveness and patient-reported outcomes (PROs) under daily clinical practice conditions are required.

The aim is to assess the effectiveness of GLM as second line bDMARD therapy in patients with established RA, PsA or AS who had received TNFi pretreatment.

Methods: Subanalysis of the non-interv., prospective, 24-month (24 mo) study GO-NICE in pts. with established RA, PsA or AS starting with GLM 50mg SC once monthly as second line TNFi after one previous TNFi in a real life setting in Germany (158 sites). Disease activity was assessed with DAS28, PsARC and BASDAI. PROs included QoL (EQ-5D-3L), functionality (FFbH), and fatigue (FACIT-F).

Results: 358 pts. were eligible. They had previously received ADA (177), CZP (3), ETA (119), or IFX (59). 147 pts. (41.1%) completed the study until month 24.

RA pts. (n=98): Mean age 55.6 yrs., 73 (74.5%) patients were female, 67 (68.4%) were rheumatoid factor (RF) positive, and 71 (74.0%) had anti ccp-antibodies at BL. DAS28 score at BL dropped significantly from 5.0 to 4.2 after 3 months (m3) to 2.8 points (m24) (p<0.0001 vs. BL), (in bDMARD-naïve patients: 5.0, 3.6 to 2.9). After 3m of treatment, 47.4% of pts. had LDA or were in remission (DAS28 ≤3.2), after 24 mo 62.5%.

PsA pts. (n=134): Mean age 50.8 yrs., 68 (50.7%) were males, 120 pts. (89.6%) had extra-articular manifestations at BL. The proportion of pts. achieving a response (PsARC) was 51.3% at m3, and 52.1% at m24, respectively, (bDMARD-naïve: 64.0%, and 77.7%).

AS-pts. (n=126): Mean age 45.2 yrs., 79 (62.7%) were males, 101 (80.2%) were HLAB27+, 44 pts. (35.5%) had extra articular manifestations at BL. The BASDAI dropped significantly from 4.9 at BL to 3.1 (m3) to 2.9 within 24 months (p<0.0001 vs. BL), (bDMARD-naïve: 5.0, 2.5 to 2.0).

An improvement of quality of life (QoL) was seen after 6 months and was maintained over 24 months: The pts.' health status (EQ VAS) improved significantly ($p<0.001$ vs. BL) from 48.4 to 64.4 (RA), from 47.8 to 62.9 (PsA) and from 45.5 to 60.8 (AS). The functional ability (FFbH) improved significantly ($p<0.05$ vs. BL) from 63.4 to 73.5 points (RA), and from 67.4 to 76.2 (AS), changes at m24 vs. BL in pts. with PsA were n.s. The mean fatigue score (FACIT-F) increased significantly ($p<0.003$ vs. BL) from 30.8 to 38.2 points (RA), and from 28.8 to 34.4 points (AS), changes at m24 vs. BL in pts. with PsA were n.s. No new safety signals were detected.

Difference BL to m24 [STD] p	RA: DAS28	AS: BASDAI
(2 nd line, after one TNFi)	-2.23 \pm 0.30 [-2.82, -1.64] <.0001	-2.02 \pm 0.32 [-2.65, -1.39] <.0001
(bDMARD-naïve)	-2.10 \pm 0.15 [-2.39, -1.81] <.0001	-2.89 \pm 0.20 [-3.29, -2.49] <.0001

Conclusion: GLM 50 mg SC once monthly as second-line TNFi in pts. with RA, PsA or AS who had previously received pretreatment with another TNFi was also effective and showed remarkable improvements in clinical parameters, patient-reported quality of life, functionality, and fatigue parameters within 3 (and 6) months. These effects were maintained over 24 mo. Overall results were consistent with those in patient who received GLM as first TNFi.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib, a JAK3 inhibitor has been used to treat patients with rheumatoid arthritis (RA) in Turkey since 2015. The aim of this study was to investigate the drug survival, its efficacy and safety in patients with RA based on the database from the Turkish TURKBIO registry.

Methods: A total of 180 patients (152 female, median age: 54.5 years) were treated with tofacitinib for RA. Drug survival was assessed. In 118 patients with available data, treatment response was evaluated using the number of sensitive and swollen joints, VAS values, DAS28, HAQ scores and CRP levels at weeks 12, 24, 48 and 60.

Results: At baseline, RA patients had a median (Q1-Q3) disease duration of 14 (8-19) years. 75 patients (42%) had used ≥ 1 biologics previously. The other demographic and clinical features of the patients were shown in Table 1. Median (Q1-Q3) follow-up period was 137 weeks. After 48 and 137 weeks, 75% and 48% of the patients respectively, maintained tofacitinib (Figure 1). The most common reason for drug discontinuation was ineffectiveness of treatment (63%), followed by adverse events (23%). After 12 weeks, all disease activity parameters were reduced significantly compared to the baseline and most of them continued to be reduced until week 60. No difference was observed in disease activity

parameters between the groups with and without previous ≥ 1 biologics at weeks 0, 12 and 24 (Table 2). Remission rate was (43%) at week 60 (observed data), (Table 2).

A total of 9 adverse events (4 infection, 3 allergic reaction, 2 rash) were observed during the follow-up period.

Conclusion: The results of this long-term observational study suggest that tofacitinib might be an effective and safe treatment option in RA patients. Treatment with this drug may provide good response rates in RA patients refractory previous biologics.

Clinical and Functional Response to Tofacitinib and Adalimumab in Patients with Rheumatoid Arthritis: Probability Plot Analysis of Results from the ORAL Strategy Trial

Tsutomu Takeuchi¹, Josef S. Smolen², Roy Fleischmann³, Noriko Iikuni⁴, Haiyun Fan⁵, Koshika Soma⁶, Ermeg Akyzbekova⁷ and Tomohiro Hirose⁸, ¹Keio University, Tokyo, Japan, ²Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria, ³Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, ⁴Pfizer Inc, New York, NY, ⁵Pfizer Inc, Collegeville, PA, ⁶Pfizer Inc, Groton, CT, ⁷IQVIA, Durham, NC, ⁸Pfizer Japan Inc, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. ORAL Strategy (NCT02187055), a 12-month, global, Phase 3b/4 study, demonstrated that in patients with RA and an inadequate response to MTX, tofacitinib + MTX was non-inferior to adalimumab + MTX, while tofacitinib monotherapy was not non-inferior to either combination based on American College of Rheumatology (ACR) 50 response rates at Month 6.¹ This post hoc analysis aimed to assess the clinical and functional efficacy across treatments in the ORAL Strategy trial using cumulative probability plots.

Methods: Efficacy was evaluated between patients who received tofacitinib 5 mg twice daily (BID) as monotherapy (N=384), tofacitinib 5 mg BID + MTX (N=376), and adalimumab 40 mg subcutaneously once every 2 weeks + MTX (N=386) based on ACR responses and changes from baseline in Health Assessment Questionnaire-Disability Index (ΔHAQ-DI) at Month 12. Cumulative probability plots for ACR-n (where ACR is the % improvement from baseline in ACR components, and n represents the minimum % achieved by each patient) and ΔHAQ-DI are presented. The area under the curve (AUC) was calculated for ACR-n up to Month 12 (in months), and an analysis of covariance model was used to assess treatment effects in terms of the AUC of ACR-n at Month 12; there was no adjustment for multiplicity for this post hoc analysis.

Results: The cumulative probability plots of ACR responses at Month 12 indicated that the proportion of patients who achieved responses of ACR20, ACR50, and ACR70 was similar for tofacitinib + MTX and adalimumab + MTX, but was numerically smaller for tofacitinib monotherapy (Figure A). Responses of approximately \geq ACR80 were achieved by a similar proportion of patients in each treatment group. Least squares mean (standard error) AUC of ACR-n up to Month 12 (in months) was similar for tofacitinib + MTX (437 [35]) and adalimumab + MTX (402 [35]), but was smaller for tofacitinib monotherapy (319 [35]; $p < 0.05$; data not shown). The cumulative probability plots of Δ HAQ-DI suggested that, in general, reductions from baseline in HAQ-DI were similar across treatment groups (Figure B), although a slightly higher proportion of patients who received tofacitinib monotherapy reported an increase in HAQ-DI vs other treatments.

Conclusion: These data support the primary ORAL Strategy findings,¹ indicating that in patients with RA, clinical efficacy, based on ACR response, was generally similar for tofacitinib + MTX and adalimumab + MTX, while a smaller proportion of patients who received tofacitinib monotherapy achieved ACR response in general, and particularly for $<$ ACR80. Functional efficacy, based on Δ HAQ-DI, was generally similar across all treatment groups. Cumulative probability analyses for CDAI will be further evaluated.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, it is recommended that tapering csDMARDs could be considered if a patient is in persistent remission. However, the methods of tapering csDMARDs including MTX without RA flare is not established. In this study, we determine whether half dose reduction of MTX in RA patient who achieved clinical remission is possible without flare by using clinical disease activity and MRI images of hand.

Methods: Out patient of department of Rheumatology on our hospital were included in this study. Inclusion criteria was the following: diagnosis of RA was based on 2010 ACR/EULAR classification criteria; achieving clinical remission defined by DAS28-CRP over 4 weeks; been treated with methotrexate and was reduced by half according to the patient wishes; MRI images of hand was available at reduction of MTX. The exclusion criteria were as follows: been treated leflunomide or tacrolimus, tsDMARDs and bDMARDs; oral prednisolone more than 5mg/day. In this study, disease flare was defined as DAS28-CRP of ≥ 2.3 at two sequential visits, dose increase of MTX and add-on other DMARDs. MRIs of the patient's dominant wrist and 2nd–5th metacarpophalangeal (MCP) joints were obtained using 1.5 T whole-body MRI unit (Achieva 1.5T, Philips Healthcare, Best, The Netherlands) with contrast enhancement. The MR image sets were assessed for bone erosions, synovitis and bone marrow edema according to the original OMERACT RAMRIS.

Results: Fifteen patients were enrolled in this study (10 female). The mean (\pm SD) age, disease duration, MTX dose before reduced and DAS28-CRP at baseline was 66.6 ± 9.8 y, 6.0 ± 3.6 y, 8.8 ± 3.4 mg/w and 1.32 ± 0.26 . Thirteen patients were positive for anti-CCP antibody and RF. Subclinical MRI inflammation was detected in all patients. The median (range) synovitis, bone edema and bone erosion score were 2(0-7), 0(0-4) and 7(1-22). Two patients experienced disease flare at week 16 and these patients had significantly higher MRI synovitis score (4.5 vs. 1.9 $p < 0.05$). Higher score of DAS28-CRP at baseline independently predicted higher MRI synovitis score ($\beta = 4.454$, 95% CI 0.930-7.988, $p < 0.05$). Analysis of the ROC curve identified the most sensitive and specific cut-off value for MRI synovitis score to be 5 (AUC = 0.923, 95% CI 0.077-1.000, $p < 0.05$).

Conclusion: Baseline DAS28-CRP could predict baseline MRI synovitis score. However, even if in clinical remission, it is reported subclinical remission would remain and depending on degree of it, radiographic progression can progress. Hence, not only clinical evaluation but also MRI evaluation is important before reduction of DMARDs. We conclude that half dose reduction of MTX for the RA patient who achieved clinical remission and had low grade MRI synovitis score might be a beneficial option of tapering MTX.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic DMARDs (bDMARDs) have proven efficacy in rheumatoid arthritis (RA) however, some patients inadequately response to multiple bDMARDs. This study aims to determine the risk factors for ≥ 2 switches between bDMARDs in RA patients.

Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a monocentric registry of bDMARDs including 1609 RA patients by May 2018. The recorded bDMARDs in HUR-BIO were anti-TNF treatments (adalimumab, etanercept, infliximab, golimumab, certalizumab), rituximab, abatacept, tocilizumab, and tofacitinib. Demographic, clinical data and baseline disease activity (DAS-28, swollen and tender joint counts (28 joints)), and functional status were assessed. Six hundred and ninety-four patients with at least 3 control visits were enrolled to analyze. Flow-chart of switching among bDMARDs was shown in Figure. Baseline demographic and clinical risk factors for ≥ 2 switches of bDMARDs were analyzed by using univariate and multivariate analyses.

Results: One hundred and fifty-eight (22.7%) patients had ≥ 2 switches between bDMARDs for any reason. Among this group, 40.5%, 39.2%, 15.1%, 3.8%, 0.6% of patients were treated with 3,4,5,6 and 7 bDMARDs, respectively. Baseline demographic, clinical and laboratory data of patients were shown in Table 1. In multivariate analysis, longer follow-up duration (OR: 1.21, 95%CI: 1.06-1.37) and rheumatoid factor (RF) negativity (OR: 2.10, 95% CI: 1.13-3.89) was found as independent risk factors for ≥ 2 switches of bDMARDs. The analyses were performed again in a subgroup of patients including patients with ≥ 2 switches due to primary or secondary inefficacy (n=85) and patients without any switches (n=336). Patients with ≥ 2 switches were younger (46.2 (11.3) vs 49.5 (11.9), $p=0.02$), had higher number of swollen joint counts (3.8 (2.5) vs 2.9 (2.5), $p=0.04$), and longer follow-up duration (6.3 (3.9) vs 4.0 (2.6), $p<0.001$). Multivariate analysis failed to demonstrate any risk factor in this subgroup.

Conclusion: High prevalence of more than two switches among bDMARDs in our cohort implicates that there is still an unmet need in the treatment of RA patients. Multi-biologic usage of bDMARDs may be related with RF seronegativity.

Table 1. Baseline features of RA patients according to numbers of bDMARDs switching

	≥ 2 switching (n=158)	< 2 switching (n=536)	p

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Once sustained clinical remission is achieved under treatment with biological therapies, the most efficient strategy is optimization. Searching for the lowest effective dose for each patient could minimize the risk of adverse effects related to biologics and improve the cost-effectiveness of RA treatment.

Our objectives are 1) to prove that an optimization strategy in patients with RA and sustained clinical remission under biological treatment maintains the proportion of patients with DAS28^{2,6} after 4 years, 2) to assess the maintenance of the effectiveness of the optimization at 4 years and 3) to analyze the time until relapse.

Methods: Open observational prospective study that included 70 patients with RA (CREATE registry) in clinical remission at least for 6 months, under treatment with tapered dose of biological therapy (TNF- α inhibitors, abatacept and tocilizumab). Treatment effectiveness was assessed with the main variable DAS28^{2,6}.

Statistical analysis included a descriptive study of variables and a confidence interval of 95% (95% CI) was estimated. For bivariate analysis, we used Student t-test for independent samples, repeated measures analysis of variance and mixed analysis of variance, and as a post-hoc contrast, Sidak adjustment. The log-rank test was used to compare the time until relapse according to the biological therapy.

Results: The mean age of the patients was 56,9 (13,7) years, 78,6% were women, 68,8% were RF positive and 66,7% ACPA positive; the mean DAS28 at the beginning of the optimization was 2,24 (0,73).

After 4 years, 27,7% (95%CI:16,82%-38,58%) of patients maintained clinical remission with the optimized dose, with a DAS28 2,15 (0,81). Through the first year, the percentage of relapses was 15,71%, in the second year, 7,35% and 4,61% relapsed during the third year.

	DAS28 at baseline Mean (SD)	DAS28 at 1 year Mean (SD)	DAS28 at 2 years Mean (SD)	DAS28 at 3 years Mean (SD)	DAS28 at 4 years Mean (SD)	P
Global (n=62)	2,24 (0,73)	2,54 (0,83) ^a	2,44 (0,7)	2,43 (1,14)	2,56 (1,14)	NS
No relapse (n=22)	2,05 (0,87)	2,43 (0,73)	2,2 (0,71)	1,7 (1,02)	2,15 (0,81)	NS
Relapse (n=40)	2,34 (0,62)	2,59 (0,88)	2,53 (0,68) ^b	2,72 (1,06) ^c	2,76 (1,22)	NS

Statistically significant differences with: a) DAS28 at baseline (p=0,047); DAS28 at 2 years from the group no relapse (p=0,028); (c) DAS28 at 3 years from the group no relapse (p=0,025)

The median time of optimization strategy until relapse was 13,83 (3,18) months (95%CI:7,6-20,06). No significant differences were found at comparing the survival curves of the optimized patients until relapse for 4years according to the biological therapy (TNF-_α inhibitors vs. no TNF-_α inhibitors) (log-rank test:0,865, p:0,352).

Conclusion: At the end of the study, most of the patients maintained DAS28 levels of low disease activity and half of them reached clinical remission, including those who had suffered a relapse and had turned back to the previous dose of biologic treatment. In view of this outcomes, optimization strategy in real clinical practice is possible and effective in patients with persistently controlled RA, in order to keep the therapeutic goal.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: After the introduction of Biological Disease-Modifying Anti-Rheumatic-Drugs (bDMARDs) for the treatment of patients with active rheumatoid arthritis (RA), clinical remission has become an achievable and realistic therapeutic goal. In clinical trials, remission rates in patients receiving bDMARDs are assessed under a fixed-dose regimen of steroid and/or methotrexate (MTX). However, in daily practice, the dose of concomitant MTX and/or steroid is often titrated according to the patient's response to therapy; thus, remission rates might be influenced by this titration. To examine usage situation of concomitant MTX and steroid use and remission rate in RA patients receiving bDMARDs in daily practice.

Methods: We have established a large observational cohort of RA patients, IORRA (Institute of Rheumatology, Rheumatoid Arthritis), in our institute since October 2000. Essentially all RA patients who attend our clinic are asked to complete questionnaires every 6 months. Clinical information, including physician's evaluations and laboratory data, is collected biannually (April and October). As a result, more than 5000 RA patients were registered. All RA patients who commenced treatment with bDMARDs from 2012 to 2016 were extracted from the IORRA database. The 28-joint Disease Activity Score (DAS28), remission rate based on the ACR/EULAR remission criteria, and frequencies of use and doses of MTX and steroid before treatment and 2 years after initiation of each bDMARDs were calculated.

Results: Average DAS28 before and 2 years after the initiation of infliximab (IFX: n=39), etanercept (ETN: n=199), adalimumab (ADA: n=101), tocilizumab (TCZ: n=261), abatacept (ABT: n=123), golimumab (GLM: n=128) and certolizumab pegol (CZP: n=87) were 3.5/2.7, 3.4/2.7, 3.5/2.8, 3.8/2.4, 3.8/3.3, 3.7/2.8, and 3.6/2.9, respectively. The DAS28 remission rates were 56.4%, 57.3%, 53.3%, 64.0%, 23.6%, 50.1%, and 46.0%, respectively. The proportion of patients taking MTX decreased among ETN (78.4% to 59.3%) and TCZ (73.2% to 61.3%) users, while that and MTX dose increased among IFX (79.5% [9.0mg/week] to 84.6% [11.1mg/week]) and ADA (78.7% [9.8mg/week] to 85.3% [12.2mg/week]) users. The frequencies of use and average dose of steroid in patients treated with bDMARDs (n=912) before treatment and 2 years after initiation of bDMARDs were 43.1% (3.9 mg/day) and 42.0% (3.7 mg/day), respectively. The proportion of patients taking steroid did not change over time except for ETN user, and 42.0% of bDMARD users were still treated with steroid.

Conclusion: MTX and steroid use and doses in daily practice were well adjusted after the initiation of bDMARDs, with adjustment varied depending on the bDMARD. Despite increasing remission, our study revealed steroids have been used approximately 42.0%.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A reduced clinical response in patients taking TNF-alpha inhibitors is influenced by their immunogenicity and therefore the importance of therapeutic drug monitoring has been increasingly recognized in the recent years. Many different methods used in routine analysis of anti-drug antibodies (ADA) differ in their reported levels and types of the detected antibodies. Bridging ELISA (bELISA), mostly used in routine analysis, cannot differentiate between neutralizing and non-neutralizing ADA and cannot detect IgG4, which is possible with competitive ELISA (cELISA) and Reporter Gene Assay. The latter is costly and labour-intensive, while cELISA is only emerging. It has been clinically observed that many patients with negative bELISA lose response over time despite dose optimisation.

We aimed to test whether cELISA detects anti-adalimumab (anti-ADL) antibodies in patients negative in bELISA and if anti-ADL antibodies, as detected by cELISA, can better predict a subsequent loss of response compared to bELISA.

Methods: Sera of patients with inflammatory bowel or chronic rheumatic diseases treated with ADL, having undetectable ADL levels and negative anti-ADL levels in bELISA, were collected and tested with *in-house* cELISA (sampling time). Only samples from patients who continued with the therapy were included, meaning they had received at least one more application of the drug after sampling time (n=16).

In cELISA, samples were incubated with a fixed amount of added drug and the neutralizing capacity of the samples was determined using a plate with pre-coated TNF-alpha. Kaplan-Meier analysis and Log Rank test were performed in order to make a comparison between the group of samples negative in both assays and the group of samples negative in bELISA, but positive in cELISA, according to clinical status on follow-up (observation time).

Results: The samples negative in bELISA were all subsequently tested by cELISA whereby 5/16 were detected as positive and 11/16 as negative samples. Follow-up of patients revealed an 80% loss of response in patients with negative bELISA and positive cELISA, and a 45% loss of response in patients negative for both ELISAs. The Kaplan-Meier analysis and Log Rank test both showed statistically significant differences between the group of samples negative in both assays and the group of samples negative in bELISA, but positive in cELISA ($p=0.024$). Patients with positive cELISA experienced a shorter time period before treatment failure compared to patients negative in both assays.

Conclusion: Positive anti-ADL antibodies in cELISA can predict treatment failure in patients taking ADL, who had undetectable levels of ADL and negative anti-ADL antibodies, as detected by bELISA. Thus, cELISA shows clear benefit for clinical utility over bELISA alone.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the baseline characteristics, patient and physician preferences of rheumatoid arthritis patients treated with biologics or targeted therapies in a real world setting.

Methods: This is an interim analysis of a multicenter, prospective, observational study. We have recruited patients who were prescribed advanced RA treatments for the first time (bio-naïve) or needed a switch in their current advanced treatments (bio-experienced). The patients were classified as RA, according to ACR 2010 criteria. The patients will be followed for 12 months and will be evaluated with EQ-5D (EuroQol 5 Dimension), HAQ, DAS28-4(ESR), CQR-19 (Compliance Questionnaire for Rheumatology) and WPAI (Work Productivity and Activity Impairment) every three months. Target recruitment is 590 patients. For this analysis, database was locked by March 2018 with 370 patients.

Results: We have included the data from the baseline visits of 370 moderate to severe RA patients in this analysis. Baseline patient characteristics for demographic findings, disease state and compliance (CQR) are shown in Table 1. Among the bio-naïves, 58% declared that they would prefer using advanced treatments orally after the failure of conventional synthetic DMARDs, while 24% of them preferred SC and 17% IV infusion. Among the bio-experienced

patients 46% (n=39) preferred oral intake, 31% (n=26) SC injection and 23% (n=19) IV infusion. In 54.0% of the cases, the drug administration routes in the physicians' prescriptions were in concordance to the patients' preference, whereas in 38.4% physicians prescribed drugs with different routes of administration. In 7.6% of the cases, patient preference is not known. In binary logistic regression analyses, patient and physician preferences for the route of administration were independent of baseline characteristics (Table 2).

Conclusion: Oral drug intake is the preferred route of administration for patients and physicians in advanced rheumatoid arthritis treatment. Patient and physician preferences for the route of administration were not related to the demographic or clinical variables.

Table 1: Baseline patient characteristics for demographic findings and disease activity scores.

Disease Activity One Year after Addition of Bucillamine or Sulfasaladine to Methotrexate in Japanese Patients with Rheumatoid Arthritis : Propensity Score Analysis

Genki Kidoguchi¹ and Kenichiro Tokunaga², ¹General internal medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan, ²Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bucillamine (BUC) is a small-molecule disease-modifying antirheumatic drug (DMARD) developed in Japan. The efficacy of combination therapy with BUC and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfasalazine (SSZ) has not been elucidated.

Purpose: To assess the disease activity at 1-year after addition of BUC in comparison with SSZ to MTX in typical clinical practice.

Methods: We analyzed data from 16,988 cases of clinically diagnosed RA registered in a large database (NinJa: National Database of Rheumatic Diseases by iR-net inJapan) from April 2012 to March 2017 (1). The dataset was clinical information at a certain point within each year, and the point was any point selected by a registered physician. In this

Table1: Patients' Characteristics in Full and Propensity-Score Matched Cohorts

according to Initiation of bucillamine or sulfasalazine

Characteristics	Full cohort			Propensity Score-Matched Cohort

CRP: C-reactive protein; BUC: bucillamine; HASQ: The modified Health assessment questionnaire

MTX: methotrexate; PGA: patients' global assessment; PSL: prednisolone

SD: standard deviation; ESCR: erosive joint count; SSZ: sulfasalazine; TJC: tender joint count

study, we compared two groups of patients who received BUC or SSZ in addition to MTX in the earlier year. We excluded patients who started receiving biological DMARDs, and BUC or SSZ the year prior to the study period, and those whose regimens were changed to other DMARDs such as tacrolimus. Baseline characteristics were compared using the *t* test, Wilcoxon test, or chi-square test. Chi-square analysis was conducted for outcomes. The predicted probability of BUC treatment was calculated by fitting a logistic regression model by using all clinically relevant variables as presented in Table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of the patients with propensity-score matching by using the following algorithm: 1:1 optimal match with a 0.2 caliper and no replacement. We used the standardized difference to measure covariate balance, whereby a standardized mean difference of >0.1 represents meaningful imbalance. The outcome was remission rate with disease activity score in 28 joints based on C-reactive protein level (DAS28-CRP) in the year after initiation of BUC or SSZ therapy.

Results: The groups that received BUC and SSZ in addition to MTX included 134 and 169 patients, respectively. Table 1 shows the results of the pre- and post-propensity score matching of the patients characteristics. In each group, 117 patients were compared after score matching. The remission rates of DAS28-CRP in the following year were 48.7% (57/117 patients) and 51.3% (60/117 patients; *P* =0.79), and the drug use frequency rates in the following year were 74.4% (87/117 patients) and 71.8% (84/117 patients; *P* =0.93), in the BUC and SSZ groups, respectively.

Conclusion: Combination therapy with BUC or SSZ and MTX for rheumatoid arthritis did not show a significant difference in disease activity. Further studies are needed.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Since 2003 in Japan, biologic agents have become widely used for RA patients in whom csDMARDs were ineffective. Tocilizumab (TCZ) was approved for marketing for use in patients with RA in Japan ahead of other countries in 2008. Randomized controlled trials have been shown the efficacy and safety of TCZ in patients with RA. Infliximab (IFX) is the first approved TNF inhibitor in Japan and it has abundant evidences for RA treatment. There have been few reports about the head to head comparison between IL-6 inhibitor and TNF inhibitors in patients with RA. We investigated the efficacy, safety, and adherence in RA patients treated with TCZ or IFX in real clinical practice.

Methods: One hundred sixty-one patients with RA treated with TCZ or IFX were retrospectively observed for 12 months in Saitama Medical University Hospital since 2008 to 2016. We compared the baseline characteristics, disease activity, physical disability, drug continuation rate, and adverse events between the patients treated with TCZ or IFX.

Results: In TCZ group (n=89) compared with IFX group (n=72), we found longer disease duration (TCZ vs. IFX: 9.8 vs. 6.4years p=0.001), lower rate of biologic-naïve patients (27.0% vs. 94.4% p<0.001), fewer MTX-users (66.3% vs. 100% p<0.001), and lower dose of MTX (5.8 vs. 8.5mg/week p<0.001). Age of disease onset, rate of female, DAS28-ESR4, HAQ-DI, RF, MMP-3, and daily dose of PSL were similar between the groups. DAS28-ESR4 and HAQ-DI significantly decreased for one year in both groups. The patients who achieved remission or low disease activity in CDAI were more in TCZ group than IFX group (83.8% vs. 62.5% p=0.016). There was no significant difference in the drug continuation rate (80.9% vs. 75.0%). In the patients who discontinued TCZ or IFX during one year of observational period, the rate of adverse events or lack of efficacy was not significantly different between the groups. We also investigated the efficacy, safety and drug continuation rate of TCZ (n=24) or IFX (n=68) as a first biologic for RA. The prevalence of patients who achieved remission or low disease activity in CDAI were more in TCZ group than IFX group (95.0% vs. 61.7% p=0.007), and there was no significant difference in the drug continuation rate (83.3% vs. 77.9%). The rate in lack of efficacy was lower in TCZ group than IFX group (0% vs. 10.3%) and there was no difference in adverse events between the groups (16.7% vs. 11.8%).

Conclusion: TCZ-treated patients, who, despite, had longer disease duration, were less biologic-naïve, and fewer MTX-users, showed equivalent or greater efficacy, drug continuation rate, and safety comparing with those treated with IFX.

Supplementation of Methotrexate (MTX) with Ticagrelor Therapy Suppresses Disease Activity in Patients with Moderate to Very Active Ra; Further Evidence That Adenosine and Its Receptors Mediate the Anti-Inflammatory Activity of MTX

Pamela B. Rosenthal¹, Jeffrey S. Berger² and Bruce N. Cronstein¹, ¹Rheumatology, New York University School of Medicine, New York, NY, ²Medicine, Division of Cardiology, New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Low dose weekly MTX remains the anchor drug for treatment of Rheumatoid Arthritis. The principal mechanism by which MTX suppresses inflammation in Rheumatoid Arthritis is thought to be enhanced adenosine release from cells which suppresses inflammation by stimulating adenosine receptors on T cells, macrophages and other inflammatory cells (Nature Rev Rheumatol 13:41, 2017). Many patients do not respond to low dose MTX and studies in mice suggest that MTX resistance may be due to inadequately increased adenosine release (Clin Exp Rheumatol 31:433, 2013). Because adenosine is primarily taken up by cells from the extracellular space via the nucleoside transporter ent1 we asked whether an agent that blocks adenosine uptake could enhance the effect of MTX in the treatment of RA. We therefore carried out an open label 1 month study, adding an inhibitor of adenosine uptake via ent1, ticagrelor (a P2Y12 inhibitor that is approved for inhibition of platelet aggregation to prevent severe cardiovascular events) (Nat Rev Cardiology12:156,2014), to patients who were poorly controlled with low dose methotrexate therapy for RA. (NCT02874092)

Methods: Patients (5 female/1 male, mean age 49.6 years) who all met ACR criteria for RA and had active disease, as defined by DAS28 (ESR) > 3.6 and who were on stable doses of MTX monotherapy (for a minimum of 12 weeks), were recruited from the Bellevue Hospital Center Arthritis Clinic. Patients had no known contraindication to ticagrelor and had no history of coronary artery disease. After giving informed consent patients entered an open label protocol in which they were administered Ticagrelor (90mg) twice daily for one month in addition to their stable dose of MTX. Disease activity was reassessed and change in activity from the start of the trial was noted. This study was approved by the NYULMC-Bellevue IRB.

Results: Five of six patient achieved an improvement in their DAS28(ESR) >0.6. Half of the patients (3 patients) achieved a reduction in DAS28 (ESR) >1.2, 2 patients achieved a reduction in DAS28 (ESR) >0.6 but less than 1.2 and 1 patient showed no improvement. Four of six patients had a reduction in their tender joints and all had a reduction in swollen joints. No patients reported any adverse reactions, including excessive bleeding.

Conclusion: The results of this small open label trial suggest that treatment with ticagrelor enhances the effect of MTX on RA and may be a useful addition to the therapeutic armamentarium. Moreover, these results offer further support for the hypothesis that enhanced adenosine release at inflamed sites mediates the anti-inflammatory effects of MTX therapy. The limitations of this trial include the fact that it was an open label trial in a small group of patients but the results support further study of ticagrelor in combination with MTX.

Subject	Baseline DAS	Baseline Tender Joints	Baseline Swollen Joints	Baseline ESR	One Month DAS	One Month Tender Joints	One Month Swollen Joints	One Month ESR

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab is an effective treatment for rheumatoid arthritis (RA). Data on long-term outcomes following rituximab treatment are limited. The aim of this study was to evaluate the long-term efficacy of, and identify predictors of response to, rituximab in our centre.

Methods: We conducted an observational study of RA patients treated with rituximab from 2003-2016. Demographic and clinical characteristics, including response to treatment, were assessed with tender joint count, swollen joint count, erythrocyte sedimentation rate, and C-reactive protein. Arthroscopy was performed in patients where clinically indicated. Univariate and multivariable logistic regression models were established to evaluate baseline predictors of treatment response. Remission was defined as DAS28-CRP <2.6 or meeting the 2011 ACR/EULAR remission criteria.

Results: 114 RA patients were treated with rituximab. Mean (range) age was 62 (49-75) years. 73% were female, 85% were rheumatoid factor (RF)+, 64% anti-citrullinated protein antibody (ACPA)+, 59% RF+ and ACPA+. Median (IQR) disease duration was 13.5 (7,24.3) years and number of prior conventional synthetic DMARDs (csDMARDs) was 1 (0,2) and biologic DMARDs was 1 (0,2). Baseline characteristics of patients are shown in Table 1. 34 were receiving rituximab monotherapy, 80 were receiving combination therapy with a csDMARD. At last follow-up median (IQR) duration of rituximab treatment was 3.1 (1.8, 6.1) years. 68 (60%) patients maintained remission, 14 (12%) were primary non-responders (7% RF-, 50% ACPA-, 7% RF-ACPA-), 25 (22%) secondary non-responders (24% RF-, 40% ACPA-, 12% RF-ACPA-), and 7 (6%) stopped rituximab due to adverse events (3 hypersensitivity reactions, 2 recurrent LRTIs, 1 neutropenia, 1 severe herpes zoster). Of the 68 patients in remission, 26 (38%) were on rituximab monotherapy and 42 (62%) were receiving combination therapy with a csDMARD. Of the 39 biologic naïve patients, 24 (62%) were in remission and 15 (38%) were not; rituximab achieved equally good outcomes in patients who had previously failed a biologic. No significant baseline predictors of treatment response were identified using logistic regression modelling. In the 44 patients who had an arthroscopy, baseline ESR ($p=0.312$), CRP ($p=0.590$), patient global assessment ($p=0.934$), DAS28-CRP ($p=1$), TJC ($p=0.750$), SJC ($p=0.848$), macroscopic synovitis ($p=0.490$), macroscopic vascularity ($p=0.936$), and histologic inflammation ($p=0.146$) did not predict response to rituximab.

Conclusion: Rituximab is an effective long-term treatment, with 60% remission, for many of our RA patients, including those who have previously failed a biologic. In this cohort, no baseline demographic, clinical, or serological characteristics accurately predict response to rituximab.

Table 1: Baseline characteristics of 114 rituximab treated patients

N=114	
Age, years, mean (+SD)	62 (+13)
Female, n (%)	83 (73)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors (TNFi) are the most common biological agents used as disease-modifying treatment in rheumatoid arthritis (RA). Although these drugs have contributed to change the natural history of RA, approximately 30-50% of patients do not respond to this therapy. Early identification of optimal responders is crucial in the clinical setting. We aimed to study if baseline percentages of different leukocyte subsets in peripheral blood (PBMCs) can contribute to identify RA patients who will respond to TNFi.

Methods: This was a prospective bi-center pilot study including 50 RA patients under TNFi therapy. Clinical activity was assessed at baseline and 6 months of treatment by disease activity score 28 (DAS28), considering optimal responders if they reached remission at 6 months ($DAS28 \leq 2.6$). PBMCs were obtained before treatment and different leukocyte subsets were evaluated by flow cytometry in a FACSCantoII instrument. All the analyses were adjusted by sex, age, concomitant methotrexate, baseline DAS28 and rheumatoid factor through a multivariate log-regression model (odds ratio; 95% CI).

Results: Optimal responders showed higher percentage of B cells (OR=1.28;95%; CI:1.06-1.54;p=0.011) and naive B cells (Bn; OR=1.50; 95%; CI:1.11-2.04;p=0.009) at baseline. We established cut-off values by ROC curves and analyzed the ability of both variables in predicting clinical response. Best results were obtained with Bn. Showing more than 2.55% of these cells associated with optimal response.

Conclusion: Our results suggest that basal Bn percentages may contribute to identify optimal responders to TNFi in RA. Although our data should be validated in larger cohorts.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluate the survival of the 2nd biological disease modifying drug (bDMARD) and to determine the causes of suspension of the 2nd bDMARD.

Methods: Patients ≥ 18 years of age who met ACR/EULAR 2010 criteria for Rheumatoid Arthritis (RA) and who had started their first biological disease modifying antirheumatic drug (bDMARD) between 01/2006 and 12/2017 were included. Socio-demographic variables, comorbidities, smoking status, date of onset of symptoms, the time elapsed between the interruption of the first bDMARD and the start of the second and the response to it. Variables were compared with Chi2, Student's T test and ANOVA. Cumulative survival was evaluated using Kaplan Meier curves and their comparisons using log rank.

Results: 347 patients were included, with a median age of 57.8 years (IQR: 48-65), 89.6% were women, 96.5% had positive RF and 60.8% positive anti-CCP. 70.6% had health coverage, 16.3% were smokers and 51.2% had comorbidities. 53.9% discontinued the 1st bDMARD of which 27.6% started a 2nd one (Abatacept 41.2 %, Etanercept 25%, Adalimumab 16.7%, Tocilizumab 14.6%, Certolizumab 6.3% and Rituximab 1%). The mean time between 1st bDMARD discontinuation and initiation of the 2nd was 9.5 months. 41.3% discontinued the 2nd bDMARD, being the causes of discontinuation: inefficacy 35.9%, lack of provision 30.8% and adverse events (AE) 20.5%. The median survival time of the 2nd bDMARD was 11 months (95% CI: 4-17.9), with no significant difference between the different drugs. In patients who had a TNF inhibitor agent as 1st bDMARD and the cause of discontinuation was lack of provision, 86.9% of them restarted a TNF inhibitor, while a change in mechanism of action was preferred in patients who discontinued due to AE (69.2%) or due to inefficacy (77.7%). There was no difference in the survival of the 2nd bDMARD to its use in monotherapy or combined with csDMARD. When the cause of suspension of the 1st bDMARD was AE, the survival of the 2nd bDMARD was significantly lower

(mean: 3.6 months) compared to those who stopped the 1st bDMARD due to inefficiency (mean 21.5 months) or due to lack of provision (mean:20.5 months), (Log Rank test: $p = 0.03$).

Conclusion: The survival of the 2nd bDMARD was 11 months, with no differences between drugs. The most frequent cause of suspension of treatment was inefficacy. The only factor associated to a decreased survival of the 2nd bDMARD was the discontinuation of the 1st bDMARD due to adverse event.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The response rate of TNFi in RA is variable and to some extent unpredictable, making treatment decision-making quite complex. Some insurance carriers require RA patients to have failed 2 different TNFi agents prior to a trial of a biologic agent with an alternate mechanism of action (MOA). This study retrospectively analyzed our 4282 RA patient database to evaluate patients who failed to respond adequately to an initial TNFi and look for clinical predictors of response to a 2nd TNFi.

Methods: A retrospective manual chart review of the electronic health record (EHR) was performed on 322 RA patients seen over the course of four years who were noted to have been prescribed more than one TNFi. Age, gender, body mass index (BMI), insurance provider, RA diagnosis length, cyclic citrullinated peptide antibody (CCP) and rheumatoid factor (RF) positivity, concomitant disease modifying anti-rheumatic drug (DMARD) therapy, length of time between diagnosis of RA and start of 1st and 2nd TNFi, efficacy of 1st and 2nd TNFi as evidenced by sustained or transient reduction in clinical disease activity index (CDAI) or impression of the treating rheumatologist, and reason for discontinuation were recorded. Patients who did and did not respond to their 1st and 2nd TNFi were compared using Pearson's chi-square or Fisher's exact tests and Student's t-tests or Wilcoxon rank-sum tests. Comparisons of responses to 1st and 2nd TNFis were made with McNemar's tests. A multivariable logistic regression model that included age, BMI, and statistically significant characteristics from the bivariate analysis was used to model response to a 2nd TNFi.

Results: Whether there was no response or transient achievement of response to a 1st TNFi as measured by CDAI or treating rheumatologist is displayed in Table 1. RF positive patients were more likely to respond than RF negative patients. Whether there was a transient response or not could not be determined in 5 patients (1.6%). Response rates to the 2nd TNFi are displayed in Table 1. Response to the 2nd TNFi could not be determined in 24 patients (7.5%). Response rates to the 2nd TNFi were greater in females vs males and in RF positive vs. RF negative patients. The predilection for female response was independent of age, BMI, and seropositivity. If the time to 1st TNFi was three months or less from initial diagnosis of RA, sustained response to 2nd TNFi was more likely compared to longer times.

Conclusion: In RA patients who failed to achieve or sustain a clinical response to an initial TNFi, female patients, patients with +RF, and patients whose diagnosis of RA was within three months of 1st TNF initiation were more likely to have a clinical response to a 2nd TNF agent. In the absence of these criterion, our data suggest a significantly reduced response to a 2nd TNFi. In these individuals, a stronger consideration for choosing a biologic with alternative MOA could be given.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Short-term glucocorticoids (GCs) along with methotrexate (MTX) has been recommended for newly onset patients with rheumatoid arthritis (RA) in EULAR recommendation 2016. However, it is not always easy to taper or stop oral GCs in clinical practice due to patients' fear of relapsed pain or fatigue. As well, some patients disagree to increase MTX dose for fear of adverse events. This study was conducted to clarify whether GCs could be reduced without impaired disease control by optimizing MTX dose in RA patients with stable medication in Japanese clinical practice setting.

Methods: Seventy patients with RA who regularly visit our outpatient clinic for ≥ 1 yr with stable medication were enrolled during Sep.-Oct. 2016. Clinical characters, disease activity, and medications at entry and 1 year after were collected. Therapeutic strategy was to increase MTX up to 16mg/w with reducing prednisolone (PSL) as much as possible based on patient's consent. Using biological or targeted synthetic DMARDs was permitted in case of uncontrollable disease. Wilcoxon's signed-rank test and chi-square test were used for statistics.

Results: Clinical characters (median [IQR]) were; age 62 [51, 68] yrs; female 69%; disease duration 6.8 [3.4, 13.7] yrs. Rate of MTX was elevated from 57 to 62%, and dose (mean \pm SD) was increased from 9.8 \pm 3.2 to 11.6 \pm 3.7 mg/w ($p < 0.0001$) for users only, whereas PSL users was decreased from 56 to 26%, and decreased from 2.0 \pm 3.1 to 0.8 \pm 1.8 mg/d ($p = 0.0004$) for all patients. Biological or targeted synthetic DMARDs were used for 16 patients, and newly started for 2 patients (tocilizumab and tofacitinib). Median CDAI, SDAI, and DAS28 were suppressed from 5.7 to 3.8, 6.2 to 3.9, and 2.92 to 2.77, and remission rate were increased from 24 to 39%, 27 to 41%, and 36 to 41%, respectively.

Conclusion: Oral GCs were successfully reduced or withdrawn without deteriorated disease control of RA with optimized MTX dose. However, use of oral GCs might delay clinical decision-making of starting biological or targeted synthetic DMARDs.

	Baseline	1-Year	p-value
%MTX	57%	67%	0.2226
MTX[mg/w] for users	9.8 \pm 3.2	11.6 \pm 3.7	<0.0001
%PSL	56%	26%	0.0003
PSL[mg/d] for all patients	2.0 \pm 3.1	0.8 \pm 1.8	0.0004
CDAI value	6.9 \pm 5.9	5.3 \pm 5.3	0.0177
CDAI remission	24%	39%	0.0687
SDAI value	7.8 \pm 7.0	5.7 \pm 5.8	0.0038
SDAI remission	27%	41%	0.075
DAS28 value	3.19 \pm 1.15	2.97 \pm 1.13	0.0837
DAS28 remission	36%	41%	0.4874

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The efficacy and safety of certolizumab pegol (CZP) in the treatment of adult patients with moderate to severe rheumatoid arthritis (RA), when administered either in combination with methotrexate (MTX) or as monotherapy, has been previously shown in several controlled clinical trials. However, a detailed assessment of CZP in combination with a wide range of non-biologic disease-modifying drugs (nbDMARDs) used in clinical practice compared to switching to monotherapy after achieving a response when added to nbDMARD(s) is lacking. The objective of this trial was to compare the effectiveness and tolerability of CZP given as add-on to nbDMARDs, including MTX and others, or as monotherapy after achieving a DAS28 (ESR) improvement of ≥ 1.2 .

Methods: RA patients who had CZP added in clinical practice to their existing DMARD regimen due to inadequate response to their nbDMARD(s) were eligible. At 3 or 6 months, those patients who achieved a change in DAS28 of ≥ 1.2 were randomized to continue combination therapy (Combination group) or withdraw nbDMARD therapy (Monotherapy

group) and be followed up to 18 months. A sample size of 125 randomized patients was estimated to be required to have 100 randomized (50 per group) to detect a difference of 15% in response.

Results: A total of 124 patients were enrolled, of whom 81 were randomized to continue combination therapy (n=37) or withdraw nbDMARDs (n=44). No significant differences were observed between-groups in baseline age (58.4 vs. 54.2 years), gender (84% vs. 71% female), race (87% vs. 91% Caucasian), rheumatoid factor status (58% vs. 60% positive), or prior biologic experience (16% vs. 11%).

At 18 months, upon adjusting for baseline scores, similar improvements were observed between groups in DAS28 (ESR) (-2.1 vs. -2.1) (Figure 1). Furthermore, the odds of achieving DAS28 LDA (OR [95%CI]: 1.08 [0.36-3.23]), Δ DAS28 \geq 1.2 (1.59 [0.51-4.89]), LDA and/or Δ DAS28 \geq 1.2 (1.36[0.43-4.36]), and remission (1.00 [0.35-2.89]) were not different between the Combination and Monotherapy groups. Similarly, no differences were observed between groups at 12 months of treatment with respect to these outcomes.

Conclusion: The results suggest that, among RA patients achieving a therapeutic response when on combination therapy with certolizumab pegol and nbDMARDs, nbDMARDs could be withdrawn without significant impact on treatment effectiveness over the next year.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the Care in early RA (CareRA) trial, COBRA Slim, a combination of methotrexate (MTX) with a moderate-dose prednisone step-down-bridge scheme, showed a positive efficacy/tolerability balance in so-called low risk patients (Verschueren et al., 2015). The purpose of this piggy back study is to perform an economic evaluation on the 2 year data of CareRA.

Methods: Patients with early RA (≤ 1 year) naïve to DMARDs were stratified based on classic poor prognostic factors (RF/ACPA +, high disease activity, erosions), into high and low risk. Low risk patients were randomized to MTX with a step down bridge glucocorticoid (GC) scheme (COBRA Slim) or MTX without GC (Tight Step Up –TSU-). The treat to target principle was applied, with a low disease activity (DAS28CRP ≤ 3.2) threshold. Clinical and patient-reported data were collected at each visit (≥ 10 times in 2 years).

For cost-effectiveness analysis, direct costs of consultations, RA medication (systemic GCs, cs- and bDMARDs, analgesics) and hospitalization costs for serious adverse events over 2 years were considered. As benefits, proportion of patients with DAS28CRP < 2.6 at year 2 and area under the curve (AUC) DAS28CRP over 2 years were used. Missing data were imputed per item with expectation maximization.

For cost-utility analysis, utilities were calculated using a validated mapping algorithm (mixed adjusted censored model) for reconstructing EQ-5D scores based on age, sex, HAQ and VAS pain at relevant study visits. Quality-adjusted life years (QALYs) were determined as the time-weighted average of all available EQ-5D scores.

Incremental cost-effectiveness ratios (ICERs) were calculated to compare both treatment strategies. Bootstrapping corrected for bias with 1000 replications was used.

Results: From the initial CareRA cohort (n=379), cost/benefit data for a 2 year economic analysis of 326 patients was available and of these patients 75 belonged to the Low Risk group: 41 TSU and 34 COBRA Slim. Number of consultations were comparable (± 12). Hospitalization costs were > 2 times higher in TSU than in COBRA Slim. The mean hospitalization cost for COBRA Slim was 445.32 (CI 213.09-720.53) and 1067.12 (CI 242.34-2273.66) for TSU. There was an outlier in TSU accounting for 26318.43.

Numerically COBRA Slim (79.4% DAS28CRP < 2.6) showed a better effectiveness than TSU (75.6%). The cost-effectiveness analysis showed a dominating ICER for COBRA Slim compared to TSU (mean -167.85/1% remission gained, mean -2195.16/unit improvement of DAS28CRP AUC over 2 years).

More QALYs were gained with COBRA slim (1.72) compared to TSU (1.59), with significant differences in time (p < 0.05). Cost-utility analysis resulted in an ICER of -3938.54 per QALY.

A sensitivity analysis, leaving out the outlier, resulted in a mean ICER of 0.99/1% remission gained, 12.88/unit improvement of DAS28CRP AUC over 2 years and 23.12 per QALY.

Conclusion: COBRA Slim, a combination of MTX with a step down bridge GC scheme, seems more effective and results in a better quality of life than a tight step up approach. Based on this economic analysis, intensive step down remission induction strategies such as COBRA Slim should also be considered in patients with early RA lacking classical poor prognostic factors.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Prescribing biologics for patients with rheumatoid arthritis (RA) may be restricted by many factors other than the physician's clinical judgment. In Kuwait, patients with RA have a free and a rapid access to biologics as they are provided within a week after being prescribed by their treating rheumatologists. The cost of treatment is fully covered by The Ministry of Health for Kuwaiti patients (KP) while non-Kuwaiti patients (NKP) have to follow a strict and a long protocol and if approved, biologic treatment will then be partially covered by a charity organization. The purpose of this study is to evaluate whether accessibility to treatment affects the rate of biologic prescription and whether this has an impact on disease activity and quality of life in patients with RA.

Methods: Data were extracted from The Kuwait Registry for Rheumatic Diseases (KRRD). Adult patients who satisfied the ACR classification criteria for RA from four major hospitals in Kuwait were evaluated from February 2013 through May 2018. All KP were selected. Demographic data, treatment agents, disease activity tools and HAQ-DI scores were studied and were compared with NKP using appropriate statistical methods.

Results: A total of 1,511 RA patients were included with 7,893 hospital visits. 795/1,511 (52.6%) were KP. Among KP 555/795 (69.8%) were females with a mean age of 54.5±13 years and a disease duration of 8.9±7.5 years (0-52). 73.5% had a positive rheumatoid factor and 58.9% had positive anti-citrullinated protein antibodies. 446 (56.1%) were on methotrexate and 53 (6.7%) were on steroid therapy. 389/795 (48.9%) were on biologic treatment, and 124/389 (31.9%) used them as monotherapy. For the total KP the mean values for DAS28 was 2.67±1.2, CDAI 4.03±5.6, SDAI 7.75±5.4, VAS pain 1.67±2.4, tender joints 2.95±5.5, swollen joints 0.41±1.8, ESR 28.4±22.4, CRP 5.52±4.9 mg/dL and HAQ-DI 0.88±0.77. Comparing KP with NKP, NKP had lower prescription for biologic therapy (8.9% vs 48.9%, $p<0.001$, higher methotrexate (74.9% vs 56.1% $p<0.001$) and higher steroid therapy (14% vs 6.7%, $p<0.001$). With regard to RA activity, NKP had higher DAS28 ($p=0.004$), higher ESR ($p=0.014$), more swollen joints ($p<0.001$) and higher HAQ-DI ($p<0.001$).

Conclusion: In the setting of easy accessibility to treatment, biologics were prescribed by rheumatologists in a much higher rate than when approval is preceded by a strict and a long protocol. This may explain the lower disease activity and the lower rate of steroid use and its positive impact on physical function.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have demonstrated that Rheumatoid Arthritis (RA) patients achieving low disease activity or remission are able to taper biological disease-modifying antirheumatic drugs (bDMARDs). The aim of this study is to evaluate the proportion of patients in whom the bDMARD can be tapered in daily practice and to analyse the characteristics of these patients. Another objective is to determine which bDMARDs are more adapted to dose reduction and the cost saving.

Methods: Inclusion criteria were RA patients from our Brussels UCL cohort treated with a bDMARD for at least one year. A dose reduction was proposed by the senior physician when sustained low disease activity or remission was achieved. Patient characteristics and baseline features before the introduction of the current bDMARD were collected as well as flares if happened. We also calculated, for each bDMARD, the proportion of patients who received a decreased dose and the annual cost.

Results: Data from 332 eligible RA patients were collected, 140 patients (42,1%) had a tapered regimen and 192 received a full dose of bDMARD. In the decreased dose group, age at diagnosis (43.1 vs 38.7 years, $p=0.004$), HAQ (1.3 vs 1.5, $p=0.048$), RF (83.3 vs 72.9%, $p=0.026$) and disease duration at the bDMARDs introduction (9.7 vs 12.1 years, $p=0.034$) were statistically different. As expected, the current DAS28-CRP was lower (2.26 vs 2.64, $p=0.001$) in the decreased dose group and interestingly, more patients receiving a decreased dose were treated with a combination of methotrexate when the bDMARD was introduced (86.7% vs 73.8%, $p=0.005$). No difference between groups was observed for gender, ACPA, erosion, number of previous bDMARDs, time to first conventional synthetic DMARD and biological DMARD, baseline DAS28-CRP and use of glucocorticoids. In our cohort, anti-TNF agents were the most commonly prescribed medications (anti-TNF 68%, tocilizumab 15%, rituximab 10%, abatacept 7%). Only 15 patients experienced a flare during the follow-up. Adalimumab, etanercept and rituximab were the most frequent decreased bDMARD and were associated with the most important reduction of annual cost. Figure: Proportion of patients with decreased dose for each bDMARD

Conclusion: In daily practice, tapering of bDMARDs in RA patients with low disease activity or remission is an achievable goal in a large proportion of patients, thereby reducing annual drug cost. The combination with methotrexate could be a positive predictive factor for the success of bDMARD tapering but further prospective research in daily practice are needed to confirm this result.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Data on patient-reported functional ability to evaluate the optimal strategy for patients who have failed to first TNFi is scarce. Patient-reported outcomes are a critical component of assessing whether clinicians are improving the wellbeing of patients. We conducted a systematic review and meta-analysis to evaluate the comparative effectiveness of two strategies, cycling versus swapping, on patient-reported functional ability and other patient-reported outcomes.

Methods: Four electronic databases were searched (MEDLINE, EMBASE, Cochrane Library, and Web of Sciences). Sources of gray literature (unpublished records) were searched through clinicaltrials.gov and other websites. The selection process, risk of bias assessment, and data extraction were performed by two independent reviewers. We included controlled trials evaluating patient reported outcomes in patients either cycling to a second TNFi or swapping to a targeted drug with an alternative mechanism of action. Other outcomes reported included pain, patient global assessment, fatigue, and quality of life.

Results: We included 13 studies reporting data on 4,394 patients. The reported cycling strategies were adalimumab, certolizumab, etanercept, golimumab, or infliximab; swapping strategies were abatacept, rituximab, tocilizumab, or tofacitinib. For the individual comparisons, TNFi versus disease modifying antirheumatic drug (DMARD), there was a statistically significant increase in functional ability from baseline to 14 weeks, favoring those patients receiving the cycling strategy (Mean Difference (MD) -0.20, 95% CI -0.34 to -0.06; scores ranging from 0 to 3). Differences favoring cycling when compared to a DMARD were also observed for pain, fatigue, and patient global assessment. Similarly, when comparing nonTNFi versus DMARD, there was a statistically significant increase in functional ability from baseline to 24 weeks, favoring those patients receiving the swapping strategy (MD -0.31, 95% CI -0.35 to -0.27; scores ranging from 0 to 3). Differences favoring cycling when compared to a DMARD were also observed for pain, sleep, fatigue, patient global, and quality of life (SF-36 physical and mental components). Three RCTs directly compared the two strategies. There was no statistically significant differences in the functional disability reported between those patients assigned to the cycling strategy compared with those assigned to the swapping strategy at 12, 24, 36 or 52 weeks (MD at 52 weeks -0.05, 95% CI -0.18 to 0.09; score ranging from 0-3).

Conclusion: Although evidence from previous reports suggest that swapping may be more effective than cycling when evaluating some clinical outcomes our results suggest that with the current evidence both strategies are equally effective in improving functional disability and other patient-reported outcomes.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory, systemic autoimmune disease that causes several health problems, such as pain, joint destruction and loss of function. Thanks to the quick anti-inflammatory effects of the Glucocorticoids (Gc), Gc are the most common remedy used for the patients who suffer from RA. The present study aims to elucidate the effects of corticosteroid usage before the initiation of biologic disease-modifying antirheumatic drugs (DMARDs) to inform clinicians regarding the proper use of the required medications.

Methods: TReasure is a multicenter, web-based registry of RA where the information concerning spondyloarthritis patients who receive the targeted treatments could be found. As of May 2018, in the context of the present study, 1,209 RA patients were recorded. Age, sex, smoking habits, disease duration, BMI, initial bDMARDs, acute phase reactants, swollen and tender joint counts (28 joints), patient global assessment of disease activity, pain VAS, DAS-28, CDAI, and SDAI were recorded before patients started to use bDMARDs. In this study, corticosteroid doses were classified as follows: low as < 2.5, medium as 2.5 to 7.5 and high as ≥ 7.5 mg/day.

Results: 1,209 RA patients in the TReasure database used steroid therapy (Table 1). 420 (34.7%) of the patients discontinued steroid treatment after 90 ± 84.62 months (30-120) of follow-up. No statistically significant difference was found in the initial clinical characteristics of the patients who used or did not use Gc were evaluated (except the patients who were older or who had a lower ESR). The mean age of the patient who took Gc was 55 (45-62), RF positivity was 71.8%, CCP positivity was 64.9% and disease duration was nine years. Initially, low dose corticosteroids was used in 3.7%, medium dose corticosteroids in 61.7% and high dose in 34.6% of the patients. On the final treatment, low dose corticosteroids were used in 11.3%, medium dose corticosteroids in 64.3% and high dose in 24.4% of the patients (Figure 1, Table 2).

Conclusion: In the biologic registry, the administration of the Gc was stopped approximately in 35% of the patients. When the doses of the steroids usage were scrutinized, patients who received biologic DMARDs used fewer steroid dose. In 1/3 of the patients, Gc treatment was initiated with above 7.5 mg. In approximately 20% of the patients, the dose was reduced to 2.5 mg. However, 60% of the patients were using 2.5-7.5 mg Gc. Gc is frequently used as a bridge therapy because of its quick anti-inflammatory effects until the effects of DMARDs occur. However, it is notable that the corticosteroid usage was associated with more comorbidities before the initiation of biologic DMARDs among patients with RA. Our findings suggest that low and moderate doses of steroids are preferred more.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: For patients with Rheumatoid Arthritis (RA) who do not achieve adequate clinical response with combined conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), the next step in goal-directed therapy is initiation of either biologic DMARDs (bDMARDs) or targeted synthetic DMARDs (tsDMARDs). bDMARDs include tumour-necrosis factor inhibitors (TNFi) or non-TNFi classes. Since inception of Ontario Best Practice Research Initiative (OBRI), new treatment options have become available. We aimed to describe the evolution of relative use of non-TNFi vs. TNFi in Ontario-based practices from 2008-2017.

Methods: Adult patients with RA enrolled in the OBRI who started therapy with bDMARDs or tsDMARDs anytime during, or up to 30 days before, enrollment were included. Using descriptive analysis of data from each year between 2008 and 2017, the relative proportion of the population treated with TNFi and non-TNFi therapy was measured for (i) all patients and (ii) those initiating their first bDMARD/tsDMARD. TNFi included: Etanercept, Adalimumab, Certolizumab, Golimumab, and Infliximab. Non-TNFi included: Abatacept, Rituximab, Tocilizumab, and Tofacitinib.

Results: A total of 1,057 patients were included of whom 653 were bDMARD/tsDMARD naïve. In 2008, the relative non-TNFi use was 3/56(5.4%) in all patients and 0/31 (0%) in treatment-naïve patients. By 2013 the proportion non-TNFi use increased to 135/562 (24%) in all patients and 11/92(12.0%) in treatment-naïve patients. This increasing trend in relative non-TNFi utilization continued in both groups until 2016 when relative use was 224/679(33.0%) in all patients and 17/56 (30.4%) in treatment-naïve. This was followed by 144/426 (33.8%) and 4/15 (26.7%), respectively in 2017.

Conclusion: This descriptive analysis of data from the OBRI cohort shows an increase in the use of non-TNFi therapies. The overall trend towards greater use of non-TNFi therapies as first line agents after combined csDMARDs may be partially explained by the presence of guidelines that allow clinicians to select any of the above options as first line advanced therapies. Future analyses evaluating patient-, disease- and concomitant drug use-specific determinants of physician decision-making will be conducted.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I: Strategy and Epidemiology

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Tofacitinib was approved in December 2014 for RA under Taiwan's National Health Insurance (NHI) reimbursement system. A drug-based registry (XTRA; established July 2016) collects real-world short- and long-term effectiveness, safety, treatment patterns, and persistence in RA patients newly prescribed tofacitinib or a TNF inhibitor (TNFi).

Methods: This observational study within the XTRA Registry comprises a 24-month enrollment plus 36-month follow-up period (August 2016 to August 2021). Patients receive standard care for RA according to the treating rheumatologists and NHI reimbursement criteria (Disease Activity Score 28-ESR [DAS28-ESR]>5.1; failure of 2 DMARDs including MTX; no tuberculosis). The tolerance and effectiveness of tofacitinib were assessed using Work Productivity and Activity Index-RA (WPAI-RA), HAQ-DI, DAS28-ESR, and Clinical Disease Activity Index (CDAI) scores at baseline and 24-week intervals. Comparisons with TNFi used Chi-square test for categorical variables and Student's t test for continuous variables, with no adjustment for multiplicity.

Results: As of January 2018, 211 patients were enrolled in the registry (n=113 tofacitinib; n=98 TNFi [etanercept, adalimumab, or golimumab]). Demographic characteristics were similar between tofacitinib initiators and TNFi initiators. TNFi initiators had higher baseline median DAS28-ESR and CDAI scores (6.16 and 36.6, respectively) vs tofacitinib initiators (5.74 and 28.7, respectively) (p<0.05). Tofacitinib initiators comprised 69.9% who had not previously received TNFi. More tofacitinib initiators (30.1%) than TNFi initiators (2.0%) received ≥1 previous TNFi (p<0.05). Persistence at the end of the first year was similar for tofacitinib initiators (88.5%) and TNFi initiators (90.8%). Numerically decreased functional impairment and improved productivity over time measured by WPAI-RA were seen for both tofacitinib and TNFi initiators. At Week 24, a similar proportion of tofacitinib initiators (23.3%) achieved CDAI low disease activity (LDA; 2.8<CDAI≤10) vs TNFi initiators (20.8%); similar effectiveness was also shown for tofacitinib in terms of DAS28-ESR<3.2 (LDA; 20.7% vs 18.0%). At Week 48, TNFi initiators and tofacitinib initiators achieved CDAI LDA (37.0% and 31.8% of patients), DAS28-ESR<2.6 (remission; 7.4% and 4.2%), and DAS28-ESR LDA (29.6% and 16.7%), respectively. The incidence rate of all-cause adverse events (AEs) was numerically higher in tofacitinib initiators vs TNFi initiators (44.9 vs 33.1 events/100 patient-years).

Conclusion: This drug-based registry is an effective tool for collecting real-world data from RA patients. Preliminary data showed meaningful effectiveness and patient-reported outcomes in both tofacitinib and TNFi initiators. The incidence and types of AEs in this real world setting under the same reimbursement criteria in the 6 medical centers across Taiwan were comparable with the known safety profile of tofacitinib. Additional data from this registry will provide pertinent information on these advanced therapies among patients with severe RA.

Is Treatment Adherence of RA Patients to Injectable MTX Influenced By Previous MTX Route of Administration?

René-Marc Flipo¹, Eric Senbel², Sonia Tropé³, Elena Zinovieva⁴, Agnès Courbeyrette⁵ and Hélène Herman-Demars⁴, ¹Hôpital Roger Salengro, Lille, France, ²Rheumatology office, Marseille, France, ³149 avenue du Maine, ANDAR, Paris, France, ⁴Medical Department Nordic Pharma, Paris, France, ⁵Medical Department, Nordic Pharma, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster I – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown, that switching from oral to subcutaneous (SC) MTX can lead to improved efficacy and bioavailability (especially for doses $\geq 15\text{mg/wk}$) as well as to a decreased frequency of adverse gastrointestinal effects in patients with RA. Furthermore, some reports consider that this switch may improve treatments adherence and persistence [1]. The purpose of the present study was to investigate the treatment adherence of RA patients switching from oral to injectable MTX or between two different MTX prefilled syringes.

Methods: APRiM is a prospective, observational, multicenter study, which included adult patients with confirmed RA diagnosis (ACR/EULAR 2010 criteria) already treated by either oral MTX and requiring route modification (Gr1), or SC MTX in prefilled syringe (PFS) and eligible for a device switch (to an other PFS) (Gr2). The main objective of the study was to estimate at 6 months the proportion of patients with strong or improved to maximum treatment adherence evaluated by Morisky self-assessment (8: strong/maximum adherence, 6-7: medium adherence, <6 : poor adherence) in both groups.

Results: Between June 2016 and June 2017, 110 rheumatologists, at 90% with private practice, included 466 pts, 433 of which composed the analyzable baseline set. Pts baseline characteristics Gr1/Gr2 were [mean (SD)]: age: 59.2 (13.0) / 61.5 (12.2) yrs; RA duration: 6.5 (7.9) / 9.9 (10.5) yrs; MTX use duration: 3.6 (4.6) / 6.0 (5.1) yrs; DAS28: 3.9 (0.9) / 3.2 (1.2); Erosive RA: 37% / 53%. All pts were receiving MTX at a mean (SD) dose of 15.1 (4.0) / 15.6 (4.0) mg/wk. Mean (SD) Morisky's scores were 6.5 (2.0) / 6.6 (1.8) for respectively Gr1 / Gr2 at baseline, they improved up to 6.9 (1.8) / 7.0 (1.5) at 6 months. Treatment adherence remained strong or improved to max for 48% of patients in both Gr1 and Gr2. Interestingly, when rheumatologists were asked to estimate their patients' adherence, they reported respectively 77% and 84% [Gr1 / Gr2] of patients with "no missed injections". No new safety signals were identified during this study.

Conclusion: The results of the observational study APRiM revealed that less than 50% of patients are perfectly adherent to injectable MTX treatment, irrespectively of whether was their previous MTX way of administration. Though, this proportion seems to be highly overestimated by the rheumatologists. This underlies the importance of patient/physician effective communication.

Session Title: Rheumatoid Arthritis – Treatments Poster I – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Moderate-to-vigorous physical activity (MVPA) is recommended for the treatment and management of physical and psychological health in Rheumatoid Arthritis (RA). However, most people living with RA are insufficiently active to accrue health benefits. Interventions are therefore required to support physical activity (PA) behaviour change in this population.

Using theory to develop interventions, can inform what may be the strategies undergirding behavioural change, and provide a framework for testing the efficacy of the theory post-intervention in terms of hypothesised mechanisms. Self-determination theory (SDT) suggests that social environments which foster autonomous motivation toward a behaviour (i.e., intrinsic and personally identified reasons), will promote better uptake and maintenance of the behaviour. This study reports the theoretical process evaluation of an SDT-based exercise intervention for people with RA, which aimed to increase MVPA engagement and optimise psychological well-being.

Methods: Patients with RA (n = 115) were randomised to an SDT-based psychological intervention + RA exercise programme (experimental group, n=59), or a RA exercise programme only (control group, n =56), delivered over 3-months. The SDT-based psychological intervention involve done-on-one consultations with a PA advisor, trained in strategies to promote autonomous motivation for PA (Table 1). Validated questionnaires assessed autonomous and controlled motivation for PA (Behavioural Regulation in Exercise Questionnaire-2), psychological well-being (Subjective Vitality Scale), and daily MVPA (International Physical Activity Questionnaire). Assessments were conducted at baseline (T1) and the end of the exercise programme (T2). Path analyses examined the hypothesised theoretical process model (Figure 1).

Results: Participants were excluded from analyses due to missing baseline data (n = 36), or as extreme outliers (n = 6). The hypothesised model (n = 73), demonstrated an excellent fit to the data [χ^2 (26) = 34.10, p = .13, CFI = .96, RMSEA = .07]. The intervention promoted higher autonomous motivation and lower controlled motivation for PA at T2. In turn, changes in autonomous motivation from T1 to T2, significantly positively predicted changes from T1 to T2 in MVPA and subjective vitality. Controlled motivation did not significantly predict either outcome.

Conclusion: An SDT-based psychological intervention providing support for PA, may promote MVPA and more optimal psychological functioning in RA patients who are engaged in a tailored exercise programme.

Figure 1. Theoretical process model

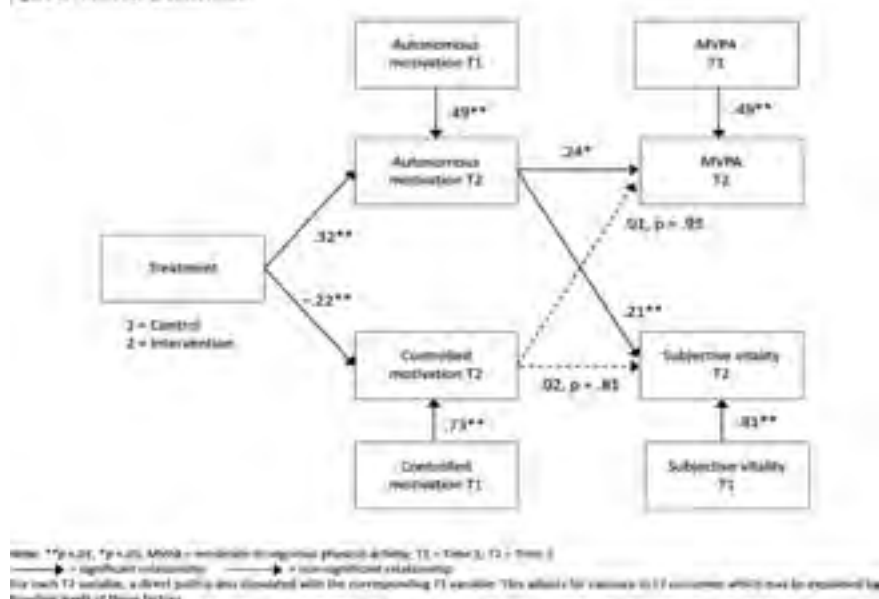

Table 1 Psychological intervention content for each contact with participants

Consultation	Contact	Duration	Behaviour change techniques
Baseline	Face-to-face	60 mins	<ul style="list-style-type: none"> • Elicit and acknowledge positive and negative experiences and emotions towards physical activity • Clarify the patient's knowledge regarding the benefits associated with increasing physically active behaviour specific to RA; gear discussions of these benefits to what is personally meaningful to the patient • Provide additional information requested by the patient • Encourage reflection on the links between physically active behaviour and personally meaningful life goals or events • Decisional balance • Patient centred goal setting
1 month	Telephone	10 mins	<ul style="list-style-type: none"> • Support attempts to change behaviour • Normalise failed attempts to be physically active • Problem solve to formulate strategies for enhancing self-efficacy • Elicit solutions to PA barriers • Review goals
2 month	Telephone	10 mins	<ul style="list-style-type: none"> • Encourage attempts made to be physically active • Brainstorm solutions to PA barriers • Discuss patient goals for last period of programme
3 month	Face-to-face	30 mins	<ul style="list-style-type: none"> • Recognise the institutionalisation of individual's PA participation • Have patients verbalise feelings towards physical activity • Discuss plans to be physically active in the future • Information regarding where it is possible to be physically active
5 month	Telephone	10 mins	<ul style="list-style-type: none"> • Discuss successful and failed attempts to maintain PA behaviour post exercise programme

Note: RA = Rheumatoid Arthritis; PA = physical activity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatments targets in psoriatic arthritis (PsA) are remission (REM) or Low Disease Activity (LDA) which are usually defined based on objective disease activity but also patient-reported outcomes (PROs). The objective was to analyze if there was a gender difference for PROs in PsA, a real-life setting and if this difference was associated with disease activity.

Methods: ReFlap (NCT03119805) is a cross-sectional study in 14 countries of consecutive adult patients with definite PsA and more than 2 years of disease duration. Each patient underwent articular, enthesal and skin assessment and composite measures i.e. clinical Disease Activity in Psoriatic Arthritis (cDAPSA) and Minimal Disease Activity (MDA) were assessed. PROs were collected: Patient Global Assessment (PGA) (range 0-10), Health Assessment Questionnaire, HAQ-DI (0 - 3) and the Psoriatic Arthritis (PsA) Impact of Disease questionnaire (PsAID12) (comprising 12 questions including pain and fatigue with a final 0 – 10 score where 0 is perfect). Differences in scores between men and women were calculated and p-values were computed.

Results: Of 466 patients, 451 could be analyzed: 226 (50.1%) were men, mean age (standard deviation) was 53.1 (12.7) years, mean disease duration was 11.1 (8.2) years, 62.9% were taking conventional synthetic DMARDs and 60.6% a biologic. Disease activity was moderate: 9.5% had a Body Surface Area of psoriasis (BSA) $\geq 5\%$, mean Tender Joint Count (TJC 0-68) was 4.6 (9.4), mean Swollen Joint Count (SJC 0-66) was 2.1 (6.3). Overall, 62.1% patients had cDAPSA levels ≤ 13 and 37.9% fulfilled MDA5/7 (i.e. remission and low disease activity). Concerning PROs, mean PGA was 4.1 (2.9), mean HAQ-DI was 0.66 (0.67) and mean PsAID12 was 3.4 (2.5). According to gender, PROs were significantly higher in women: 4.7 (2.8), 0.86 (0.69) and 4.1 (2.5) in females versus 3.4 (2.9), 0.46 (0.60) and 2.7 (2.3) in males for PGA, HAQ-DI and PsAID12, respectively (all $p < 0.001$). When comparing components of PsAID12 scores, they were systematically higher in women (all $p < 0.01$) except skin problems (2.9 (3.0) females, 2.5 (2.6) males, $p=0.23$). Conversely, objective measures of disease activity didn't differ by gender: SJC 2.1 (5.7) females, 2.0 (6.8) males, $p=0.14$; BSA $\geq 5\%$: 8.4% females, 10.6% males, $p=0.49$, except for TJC: 5.4 (9.2) females, 3.8 (9.5) males, $p<0.001$ and CRP $>5\text{mg/L}$: 38.7% females, 30.1% males, $p=0.045$. MDA5/7 was less often reached in women: 25.8% females versus 50.0% males, $p<0.001$.

Conclusion: A significant gender difference was observed in this cross-sectional analysis of unselected PsA patients from 14 countries, with females reporting worse symptoms although musculoskeletal and skin disease activity was similar. This gender difference has to be taken into account when targeting remission or low disease activity, and in the overall management of PsA activity and impact.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In a Ph2 study, GUS was shown to be safe & effective in pts w/active PsA. We evaluated effect of GUS on dactylitis in subset of pts w/dactylitis at baseline (BL) from Ph2 GUS PsA study.

Methods: Pts w/active PsA & $\geq 3\%$ BSA of plaque PsO, despite current or previous treatment, were randomized 2:1 to 100mg SC GUS at wks0,4 then q8w or PBO during a 24wk double-blind treatment (tx) period. At wk16, pts w/ $<5\%$

Figure. Proportion of Patients with Dactylitis Resolution over Time

improvement in swollen & tender joint counts (SJC/TJC) early escaped (EE). At wk24, PBO group (grp) crossed over to GUS (wks24, 28→ q8w) (PBO→GUS) & GUS grp continued GUS (GUS→GUS)) thru wk44. Dactylitis was assessed by scoring each digit from 0-3(0=absent, 1=mild, 2=mod, 3=sev), for combined score of 0-60. Sensitivity analysis of change from BL thru wk24 in dactylitic digits was performed(combined score 20). Dactylitis scores during 24wk double-blind tx was analyzed using LOCF imputation for missing data & EE. Dactylitis after wk24 was evaluated using observed data.

Results: Of 149 pts,81 presented w/dactylitis at BL(PBO N=23,mean[SD]=3.9[3.01];GUS N=58, mean[SD]=6.5[6.15]) & 66 continued to active tx period(PBO→GUS N=16;GUS→GUS N=50).The dactylitis subset was similar to overall population in BL characteristics except for higher median values for # of SJC, # of TJC,&CRP. At wks16&24, GUS grp had significantly greater reduction in dactylitis score (wk24 mean [SD] change from BL, PBO:-0.4[6.06]; GUS:-3.8[4.93]; p=0.006)&a greater % of pts w/dactylitis resolution vs PBO grp(Figure). Consistent results were obtained w/# digits w/ dactylitis (wk24 mean [SD] change from BL, PBO:-0.2[3.04];GUS:-2.1[2.21];p=0.003). Improvement in dactylitis seen at wk24 was maintained in GUS→GUS grp(wk56:mean[SD] change from BL=-5.5[4.84],75% of pts w/resolution)& the values for the PBO→GUS grp(wk56:mean[SD]change from BL=-4.4[3.50],93.7% of pts w/resolution)approached those of GUS→GUS grp. Improvement in dactylitis was greater in ACR20/ACR50 responders vs non-responders in GUS-txd pts (Table) &was significantly correlated with improvement in TJC(R=0.38,p=0.004),SJC(R=0.50,p<0.0001),&HAQ-DI score(R=0.33, p=0.013).

Conclusion: GUS is efficacious in resolving symptoms of dactylitis in pts w/active PsA. This effect on dactylitis is correlated with improvement in joint symptoms & physical function.

Table 1. Change in Dactylitis Score in ACR20/50 and PASI75 Responders and Non-responders

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Spinal mobility has been mostly investigated in cohorts of patients with established AS. However, it was scarcely studied in the early phases of the disease and how the impairment in mobility across different measures behaves as compared to normal subjects. The purpose of this study was to investigate 1) which spinal mobility measures (SMMs) are most frequently impaired and in which order; 2) which SMMs are most discriminative of activity and severity in early axial Spondyloarthritis (axSpA).

Methods: All SMM measurements of patients from the DESIR (5-year data) and SPACE (data from Leiden University Medical Center, 2.6 (1.9) years of follow-up) cohorts and with a clinical diagnosis of axSpA (level of confidence $\geq 7/10$) were analyzed. SMMs were considered impaired when falling below pre-defined cut-offs, derived from normal individuals¹. The proportion of patients with each of the SMMs impaired was calculated, for both baseline and all observations. The BASMI, being a composite index, was not considered in the ranking of impairment of spinal mobility and only the level of impairment is presented. The same analysis was conducted in subgroups to contrast patient and disease characteristics potentially influencing spinal mobility, like treatment with biologics (ever/never), disease activity (with/without low disease activity over time, i.e., ASDAS <2.1 in $\geq 2/3$ of visits) and the presence of baseline syndesmophytes (yes/no).

Results: We included 328 (54% males, mean (SD) age of 32 (8) years) and 148 (64% females, mean (SD) age of 30 (9) years) patients from the DESIR and SPACE cohorts, respectively. No strict and fixed order of impairment in SMMs was seen in both cohorts. Considering patients in whom all SMMs were assessed, in DESIR, the most frequently impaired SMM (below 2.5th percentile) was mSchober (42%), followed by Lateral Spinal Flexion (LSF; 37%), Tragus-to-wall (16%), Cervical rotation (16%) and Chest expansion (11%). In SPACE, the order of impairment was: LSF (36%), mSchober (14%), Chest expansion (13%), Cervical rotation (11%) and Tragus-to-wall (3%). LSF and mSchober captured the

Table 1. Impairment of each of the spinal mobility measures and of the BASMI score in patients with early axSpA from the DESIR cohort, stratified by subgroups to contrast patient and disease characteristics potentially influencing spinal mobility ‡

	Without ASDAS ≥ 2.1 in $\geq 2/3$ of visits (n=118)	Ever treated with biologics (n=321)	With syndesmophytes at baseline (n=62)
mSchober (cm)	485 (42)	589 (36)	76 (37)
Lateral Spinal Flexion (cm)	460 (37)	563 (44)	57 (36)
Tragus-to-wall (cm)	171 (16)	150 (16)	22 (37)
Cervical rotation (degrees)	177 (16)	142 (17)	18 (29)
Chest expansion (cm)	169 (11)	151 (11)	11 (18)
BASMI-modified (0-10) †	451 (42)	378 (43)	29 (45)
	With ASDAS <2.1 in $\geq 2/3$ of visits (n=65)	Never treated with biologics (n=53)	Without syndesmophytes at baseline (n=64)
mSchober (cm)	304 (51)	481 (33)	46 (34)
Lateral Spinal Flexion (cm)	343 (27)	346 (28)	232 (34)
Tragus-to-wall (cm)	74 (11)	86 (15)	73 (11)
Cervical rotation (degrees)	39 (8)	75 (8)	63 (13)
Chest expansion (cm)	75 (15)	78 (11)	11 (7)
BASMI-modified (0-10) †	154 (24)	227 (25)	234 (38)

Legend: mS: spinal mobility measure (SMM) most frequently impaired; orange: 2nd SMM most frequently impaired; yellow: 3rd SMM most frequently impaired; light green: 4th SMM most frequently impaired; dark green: SMM least frequently impaired.
 † Impairment was defined as a value below the 2.5th percentile in normal individuals, and is presented at the observation level (n (%)) of all 5-year observations.
 ‡ BASMI-modified: calculated with cervical rotation in sitting position and 10-cm Schober's test, using the linear method (sum of the five scores: Lateral Spinal Flexion, 10-cm Schober's test, Cervical rotation, intermammary distance and Tragus-to-wall distance).

majority of patients with ≥ 1 SMM impaired (86% and 78% for DESIR and SPACE, respectively). LSF and BASMI best discriminated between subgroups of patients, with higher impairment in patients ever treated with biologics, with higher disease activity and presence of baseline syndesmophytes (Table 1, data from DESIR). Similar results were obtained in the SPACE cohort.

Conclusion: LSF and mSchober are the most impaired SMMs, together allowing the identification of the majority of patients with impaired spinal mobility in early axSpA. LSF and BASMI discriminate best between subgroups of patients, reflecting a worse spinal mobility in patients with more active and severe disease.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Figure 1. Measurements of 10-cm Schober's test and Lateral Spinal Flexion in DESIR cohort axSpA patients in function of age: A) 10-cm Schober's test in all axSpA patients; B) 10-cm Schober's test in axSpA patients with low disease activity in at least 2/3 of visits; C) Lateral Spinal Flexion in all axSpA patients; D) Lateral Spinal Flexion in axSpA with low disease activity in at least 2/3 of visits. The dotted lines represent the percentile curves derived from the normal individuals (percentiles indicated) and also the help-lines (a' to d'), derived to accommodate impaired values of patients with axSpA. The colored lines represent all the real measurements of Schober's test and Lateral Spinal Flexion, for each patient, over time.

Background/Purpose: The use of spinal mobility measures (SMMs), at the individual level and in the follow-up of patients with early axSpA has not yet been studied. The purpose of our study was to investigate the longitudinal use of SMMs and the relation with mobility curves of healthy individuals in patients with early axSpA.

Methods: All SMMs of patients from the DESIR (5-year data) and SPACE (data from Leiden University Medical Center, 2.6 (1.9) years of follow-up) cohorts and with a clinical diagnosis of axSpA (level of confidence $\geq 7/10$) were analysed. All available SMMs were plotted for each patient in function of age, and together with the percentile curves derived for healthy volunteers, the mobility curves¹. A subgroup analysis was performed in patients with low disease activity over time (ASDAS < 2.1 in $\geq 2/3$ of visits), in order to control for the influence of disease activity on spinal mobility. Intra- and inter-observer reliability were analyzed using Intraclass Correlation Coefficients (ICC) and the Smallest Detectable Change (SDC) in the SPACE cohort.

Results: We included 328 (54% males, mean (SD) age of 32 (8) years) and 148 (64% females, mean (SD) age of 30 (9) years) patients from the DESIR and SPACE cohorts, respectively. The mean number of observations with assessment of SMMs was 7 (1.1) and 4 (1.7) per patient in DESIR and SPACE cohorts, respectively. A high variability in SMMs within the same patient over time was observed, with very discrepant values for the same SMM from visit to visit, even when restricting the analysis to patients with low disease activity over time. Figure 1 shows the results for 10-cm Schober's test and Lateral Spinal Flexion (LSF) in the DESIR cohort. The results were strikingly similar for all the SMMs and in both cohorts. The reliability of SMMs was only "fair" to "good" (inter-reader ICC (2,1): 0.55-0.84; intra-reader ICC (2,1): 0.49-0.72). The obtained SDCs reflect that large variations in SMMs are needed to capture a true change beyond measurement error (e.g. 1.4 cm for 10-cm Schober's test; 5.1 cm for LSF; 2.2 cm for Chest expansion and 12.2 degrees for Cervical rotation).

Conclusion: There is a high variation of SMMs from visit to visit, which impairs the use of spinal mobility measures, at the individual level in the follow-up of patients with axSpA. It should be tested if reliability can be improved to reduce at least part of the variability.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The link between treatment recommendations for PsA (to aim for a state of remission or low disease activity (LDA))^{1,2} and patient-important outcomes has been little explored. The objective of this analysis was to investigate the potential of remission or LDA according to the clinical Disease Activity Index for PsA (cDAPSA) and achievement of very low/minimal disease activity (VLDA/MDA) during treatment with ustekinumab (UST) or TNF inhibitor (TNFi), as well as the association between these outcomes and health-related quality of life (HRQoL).

Methods: PsABio (NCT02627768) is an ongoing real-world observational study in eight European countries where PsA patients receive 1st-, 2nd- or 3rd-line biologics (either UST or TNFi). Of 563 UST- or TNFi-treated patients enrolled Dec 2015 – Aug2017, 303 had data available at 6 months and were analyzed here. Disease states were defined using cDAPSA ≤ 4 for remission and ≤ 13 for LDA (data available for 250 patients) and VLDA 7/7 and MDA 5/7 criteria (data available for 206 and 260 patients, respectively), and HRQoL using EQ5D (data available for 249 patients with MDA availability). Available observed data are presented, with no imputation of missing data.

Results: For the 303 patients analyzed, mean age was 49.7 (standard deviation, SD 12.8) years, mean disease duration was 7.2 (SD 8.2) years, and 50.5% were women. The table shows data at 6 months for cDAPSA remission, cDAPSALDA, VLDA, and MDA in UST- and TNFi-treated patients. cDAPSA remission/LDA and VLDA/MDA achievement (Yes vs No) were associated with better HRQoL based on mean (95% confidence interval, CI) EQ5D visual analog scale (VAS) at 6 months, as shown by non-overlapping CIs in the figure. Assessment of Psoriasis Skin Disease (68/299=22.7%) was the most frequently missed MDA component, while enthesitis was the least frequently missed (6/299=2.0%). The other five components were all missed with equal frequency (8–9%).

	UST-treated patients n/N (%)	TNFi-treated patients n/N (%)
cDAPSA remission (cDAPSA ≤ 4)	25/126 (19.8)	25/124 (20.2)
cDAPSA LDA (including remission) (cDAPSA ≤ 13)	64/126 (50.8)	66/124 (53.2)
VLDA	11/102 (10.8)	12/104 (11.5)
MDA (including VLDA)	38/132 (28.8)	38/128 (29.7)

Conclusion: Remission and/or LDA appeared to be reachable outcomes in this real-world study, since among patients treated with UST or TNFi for 6 months, cDAPSA remission/LDA was achieved by approx. 50% of patients, and VLDA/MDA by approx. 30% of patients, irrespective of the type of therapy. Furthermore, these disease states were associated with improved HRQoL, making these outcomes patient-relevant.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission (REM) or minimal/low disease activity (LDA) is the treatment goal in Psoriatic Arthritis (PsA). There is no consensus on definitions of REM/LDA. Recently, composite measures of disease activity have been compared but this comparison did not address the patient's perspective (ref).

The objectives were to assess frequency of REM/LDA using different definitions, and agreement between these definitions according to the patient's and physician's perspectives.

Methods: ReFlap (NCT03119805) is a cross-sectional study in 14 countries of consecutive adults with definite PsA and more than 2 years of disease duration. REM and LDA were defined using Very Low Disease Activity (VLDA), Minimal

Figure 1 Prevalence of REM/LDA according to different definitions in 419 patients with PsA

REM: Remission; LDA: Low Disease Activity; VLDA: Very Low Disease Activity; MDA: minimal disease activity; DAPSA: Disease Activity Index for Psoriatic Arthritis; cDAPSA: clinical DAPSA; Physician's REM/LDA: physician's single question for REM/LDA; Patient's REM/LDA: patient's single question for REM/LDA; PGA: patient global assessment; PASS: Patient Acceptable Symptom Status.

Figure 2 Venn diagram representing the number of patients meeting different REM criteria among 419 PsA patients.

Disease Activity (MDA), Disease Activity in Psoriatic Arthritis (DAPSA), clinical DAPSA (cDAPSA) and Patient Global Assessment (PGA). Furthermore, REM and LDA were assessed using specific single questions for the physician and the patient (Figure 1: physician and patient REM/LDA).

Proportions achieving each REM/LDA criterion were calculated. The agreement between the tested definitions was assessed by Venn diagram and calculation of kappa and prevalence-adjusted and bias-adjusted kappa (PABAK).

Results: Of 466 patients, 419 had data available for all definitions of REM/LDA: 212 (51.3%) were male, mean age was 53.9 ± 12.6 years and mean disease duration 11.3 ± 8.4 years, 59.0% were taking a biologic. Disease activity was moderate: 9.5% had a Body Surface area of psoriasis $\geq 5\%$, mean Tender and Swollen Joint Counts were respectively 4.9 ± 9.7 and 2.3 ± 7.2 . The frequency of REM varied from 12.2% (VLDA) to 21.0% (Physician REM question) and of LDA from 25.1% (MDA) to 46.3% ($\text{PGA} \leq 3$) (Figure 1). Agreement was moderate between the composite scores for REM (kappa DAPSA/VLDA 0.57, cDAPSA/VLDA 0.59). Agreements were lower for LDA whatever the definition used. Agreement between patient-defined REM/LDA and composite scores was only moderate. In particular, 36/88 (40.9%) of patients in patient-perceived REM were not in REM according to any composite score. Moreover, agreement between patient and physician REM occurred in 58/148 (39.0%) patients (Figure 2).

Conclusion: In this unselected population, REM/LDA was frequently attained. VLDA/MDA was a more stringent definition than DAPSA-based REM/LDA. Patient-assessed REM/LDA was similar in terms of prevalence to DAPSA, though agreement between patients and composite scores was only moderate. Further studies of patients' expectations are needed.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease associated with a long diagnostic delay (DD); however, recent data suggests improvements¹. The purpose was to assess the evolution of DD over time as reported by European axSpA patients and to identify factors associated with DD.

Methods: Between July 2017 and February 2018, 2846 axSpA patients participated in the European Map of Axial Spondyloarthritis (EMAS) survey across 13 countries. DD was patient-reported and defined as the time between symptom onset and formal diagnosis. Socio-demographics (gender, country, education, and relationship status), disease characteristics (report of extra-articular manifestations, HLA-B27 positive and axSpA subtype) and year of onset were assessed using bivariate Mann-Whitney and Kruskal-Wallis homogeneity tests and Pearson correlation coefficient. Moreover, a stepwise forward linear regression was conducted using variables that were significantly associated with DD.

Results: Of the 2846 patients, 61.4% were female. The mean age was 43.9 (SD 12.3) years. 85.5% self-reported having AS (n=2394/2800), 73.9% were HLA-B27 positive (n=1282/1735), and 50.7% had received biologic treatment (n=953/1880). The mean DD was 7.4 (SD 8.4) years with a median of 4.0 years. The bivariate analysis showed that DD was associated with the female gender, participant's country and year of onset but not associated with educational level, relationship status or disease characteristics (Table 1). Stepwise forward regression also showed that all the variables with bivariate association had significant explanatory power over DD. There was a significant correlation between year of onset and DD; the more recent the disease onset, the shorter the DD (Pearson correlation -0.55; p<0.001) (Figure 1).

Conclusion: Despite recent progress in the field of axSpA, DD remains high in Europe (7.4 years). However, EMAS results show that DD is decreasing over time. The strongest factors associated with a longer DD were in order: female gender, country and earlier year of onset. Increased understanding of the factors associated with DD is needed to support earlier diagnosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Good response to NSAIDs is a SpA feature included in classification criteria for axial spondyloarthritis (axSpA). Among patients eligible for a TNF inhibitor (TNFi), some patients may have never responded to NSAIDs (NSAIDs non-responders) while others primary responded before secondary failure (NSAIDs responders). Our aim was to determine if the primary NSAIDs response is an independent predictive factor of a subsequent good response to the first TNFi in patients with early axSpA.

Methods: *Patients:* Subjects from the prospective observational DESIR cohort of early axSpA cohort who started a TNFi over the 5 years of follow-up.

NSAIDs response and TNFi response definitions: NSAIDs response was defined by the item “good response to NSAIDs according to Amor’s criteria” at the inclusion visit. TNFi response was defined by the BASDAI50 response between the “baseline” visit (last cohort visit before TNFi initiation) and the “follow-up” visit (visit taking place after at least 8 weeks of TNFi treatment).

Analysis

We compared the characteristics of the NSAIDs responder to the non-responders and their response to the first TNFi. We performed a multivariate logistic regression modeling the impact of an NSAID response to the TNFi response. We included known predictive factors of TNFi response in this model (age, gender, HLAB-B27, activity of the disease [ASDAS-CRP], CRP, X- ray and MRI sacroiliitis). To account for selection bias and for confirmation purpose, we applied a propensity score with Inverse Probability Weighting (IPW) method to predict TNFi response (SAS, version 9.2).

Results: Among the 708 patients of the cohort, 236 were included in the analysis. At baseline, the main characteristics were the following: 106 (44.9%) males, mean age 33.9 ± 8.9 years, mean BASDAI 54.4 ± 17.3 and 202 (85.6%) were NSAIDs responders. The NSAIDs responder and non-responder groups were comparable at M0 except for HLA-B27 positive status: 59.9% vs 41.2%, $p = 0.041$, history of psoriasis: 17.8% vs 35.3%, $p = 0.019$ and BASDAI: 53.0 ± 18.1 vs 61.8 ± 13.2 , $p = 0.001$, in responder and non-responder patients, respectively. The percentage of TNFi responders was 32.2% (65/202) and 23.5% (8/34) in the NSAIDs responder and non-responder groups, respectively (univariate analysis (OR 1.5 [IC95%: 0.7-3.6], $p = 0.313$).

The multivariate logistic regression found the following independent factors of the TNFi response: gender [adjusted OR (aOR) = 2.9 [CI95%: 1.4–6.0], $p=0.004$], age [aOR = 0.9 [CI95%: 0.91-0.99], $p=0.026$], HLA-B27 status [aOR = 2.5 [CI95 %: 1.2–5.3], $p = 0.02$], ASDAS-CRP score [aOR=1.6 [CI95 %: 1.1–2.4], $p = 0.016$], and MRI sacroiliitis [aOR = 2.0 [CI95 %: 1.0–4.2], $p = 0.054$]. Response to NSAIDs was not significantly associated to the response to the TNFi [aOR = 1.93 [CI95 %: 0.6-6.3], $p = 0.275$]. The IPW aOR confirmed the non-association between NSAIDs good response and TNFi good response: 1.60 [CI95%: 0.7–3.3], $p = 0.20$.

Conclusion: NSAIDs good response, according to the Amor’s criteria, does not seem to be an independent predictive factor of the subsequent TNFi response in early axSpA patients.

Increasing Rates of Arthroplasty for Psoriatic Arthritis in the United Kingdom between 1995 and 2010

Ryan Lewinson¹, Isabelle Vallerand², Jeremy LaMothe³, Laurie Parsons¹, Alexandra Frolkis⁴, Mark Lowerison², Scott Patten² and Cheryl Barnabe^{2,5}, ¹Dermatology, University of Calgary, Calgary, AB, Canada, ²Department of Community Health Sciences, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, ³Orthopaedic Surgery, University of Calgary, Calgary, AB, Canada, ⁴Internal Medicine, University of Calgary, Calgary, AB, Canada, ⁵Division of Rheumatology, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthroplasty requirements among patients with psoriatic arthritis (PsA) are not well known. This information is of importance to clinical and policy stakeholders for health system planning, and may serve as a surrogate for estimating the efficacy of disease-modifying therapy. Moreover, arthroplasty rates may be used as a proxy measure of how advanced medical therapy has contributed to the prevention of advanced-stage disease, as has been done previously for rheumatoid arthritis.

Methods: We utilized The Health Improvement Network (THIN), a large general practice medical records database in the United Kingdom to assess rates of first primary total arthroplasty among patients with PsA and the general population between the years 1995 and 2010. Linear regression was used to estimate arthroplasty rates for the two cohorts over the study period, and Poisson regression was used to determine incidence rate ratios (IRRs) between the PsA and general population cohorts, adjusted for age and sex. Chi-square tests were used to compare incidence rates across years between the two cohorts.

Results: We identified 5,619 patients with incident PsA and 5,090,814 eligible patients from the general population between 1995 and 2010. In total, 187 first primary total arthroplasties were documented in patients with PsA, and 80,165 first primary total arthroplasties were documented in the general population. A trend of increased arthroplasty rates were observed for both the PsA ($R^2=0.809$, $p<0.0001$) and general population ($R^2=0.890$, $p<0.0001$) cohorts over the study period. After adjustment for age and sex, PsA patients had a first arthroplasty incidence rate twice that of the general population (IRR=2.01, 95%CI 1.73-2.34, $p<0.0001$), notably beyond year 2003 when biologic therapies were introduced (Fig. 1).

Conclusion: Both general population and PsA patients have experienced increased rates of first arthroplasty from 1995 to 2010, although the overall incidence rate was significantly higher for those with PsA. There are a number of possibilities that could explain this finding such as patients living longer with PsA, or new biologic therapies making PsA patients better surgical candidates. Further research exploring these possibilities will be needed in the coming years.

Figure 1. Incidence rates (with 95% Confidence intervals) of first arthroplasty are shown for both the psoriatic arthritis cohort (blue circles) and the general population cohort (orange squares). The incidence rate of arthroplasty has increased for both groups from 1995 to 2010. *indicates significant difference in incidence rates by Chi-square test. Evaluation of the overall incidence rate ratio (IRR) revealed PsA patients had an incidence rate of first arthroplasty twice that of the general population (IRR 2.01, 95%CI 1.73-2.34, $p<0.0001$).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Joint counts are central to the measurement of musculoskeletal disease activity in psoriatic arthritis (PsA). Few studies have addressed whether the three most commonly used joint counts: 66/68-Swollen and Tender Joint Counts (SJC66/68TJC), SJC28/TJC28 and SJC76/TJC78, are valid for the measurement of musculoskeletal disease activity. To test the construct validity of the joint counts, we examined the correlations between the joint counts and other variables associated with MSK disease activity. We hypothesized that joint counts would be strongly correlated (ρ 0.8-1) with each other, moderately correlated (ρ 0.6-0.8) with the physician global assessment (PhGA), and mildly correlated (ρ 0.4-0.6) with patient global assessment (PtGA), pain, health assessment questionnaire disability index (HAQ-DI) and C-reactive protein (CRP).

Methods: Data were requested from 8 phase III randomized controlled trials (RCTs) and the Tight Control of Psoriatic Arthritis (TICOPA) trial. A priori, a standardized protocol was designed to study construct validity. Spearman's correlation coefficients were calculated (all data were skewed/nonparametric) at baseline and the primary endpoint (12-16 weeks for most RCTs, 24 weeks for TICOPA) between the following variables: TJC28, TJC68, TJC78, SJC28, SJC66, SJC78, PtGA, pain, PhGA, HAQ-DI and CRP. We also calculated Spearman's correlation coefficients between changes in each of the variables from baseline to follow up.

Results: The SJC28 was moderately to strongly correlated with SJC66 and SJC76 at baseline and follow up and changes in SJC28, SJC66, and SJC76 were moderately correlated (Table). Similarly, the TJC28 was strongly correlated with TJC68 and TJC78 at both time points as well as among changes in the joint counts between baseline and follow up. There were mild-to-moderate correlations between SJC and TJC at both time points and similarly changes in joint counts were moderately correlated. The joint counts had low to moderate correlations with PhGA in all three scenarios and correlations with PtGA and pain were low to moderate, depending on the RCT. Finally, correlations between joint counts and CRP were low in all three scenarios.

Conclusion: These results indicate that SJC and TJC have construct validity and replicated most of the pre-hypothesized relationships with other variables of importance in RCTs. While good correlation between TJC and SJC subsets were

Table. Correlation among disease activity measures at baseline, follow up and change in disease activity measures between baseline and the primary endpoint.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumour necrosis factor- α inhibitors (TNFi) are an effective but rather expensive treatment option in axial spondyloarthritis (axSpA) patients who fail conventional treatment. The aim of this study was to analyse the changes in the cost of illness after initiation of TNFi in patients with axSpA.

Methods: Patients with axSpA newly exposed to TNFi between 2011 and 2015 were identified from claims data of a large statutory health insurance fund (BARMER). Direct healthcare costs and productivity costs were analysed the year before (baseline period) and the year after (follow-up period) the first initiation of TNFi. Direct healthcare costs comprised costs for outpatient care, i.e. costs for services performed in an outpatient setting (visits to physicians, laboratory visits, visits to physical therapists, emergency department visits, outpatient hospital services), inpatient care, i.e. cost for performed services and administered drugs during inpatient hospital stays, and pharmacotherapy, i.e. costs for drug prescriptions in the outpatient setting.

Productivity costs comprised costs due to absence from paid work and were calculated using the friction cost method (FCM) and the human capital approach (HCA).

Results: Data from 1,452 persons were included in the analyses. The mean age was 44.6 years and 47.9% were female. AxSpA-related pharmacotherapy use (Fig. 1) and admissions to hospital as well as duration of inpatient treatment (Tab. 1) significantly decreased in the follow-up period compared to the baseline period. Mean total costs increased from 8,072 to 29,959 using the HCA and from 6,377 to 28,162 using the FCM (Tab. 2). Excluding costs for TNFi, total costs decreased by 15% to 6,876 or by 20% to 5,080 based on whether the HCA or the FCA was used.

Conclusion: Overall healthcare resource utilisation and productivity cost decreased in axSpA patients after initiation of TNFi. The increase in pharmacotherapy costs driven by TNFi was partly offset by significantly lower costs for outpatient and inpatient care, as well as significantly lower productivity costs. However, the effect of TNF-blocker therapy on the patient's disease activity, function or quality of life could not be assessed in this analysis.

Remission in Psoriatic Arthritis: Definition and Predictors

Samar AlHarbi¹, Justine Y. Ye², Ker-Ai Lee³, Vinod Chandran², Richard J. Cook³ and Dafna D Gladman¹, ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ³Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: No validated definition of remission exists for psoriatic arthritis (PsA) to date. We previously identified 17.6% of our patients as having remission (no actively inflamed joints for 12 months). However, we did not take into account the other domains of the disease. We aimed to test the concept of remission as the absence of disease manifestations in PsA, determine the frequency of remission in our PsA cohort, and identify predictors for remission.

Methods: Patients followed at the PsA clinic between 2000 and 2015 were included. Patients are assessed at 6- to 12-month intervals according to a standard protocol, which includes the information necessary for minimal disease activity (MDA) assessment. Remission was defined as a visit that patients had no tender or swollen joints, no inflammatory back pain, no tender enthesal sites, minimal skin involvement with BSA<1%, patient pain on visual analog scale (VAS) score of

<15, patient global disease activity VAS score of <20, Health Assessment Questionnaire (HAQ) score <0.5. We used imputation to determine remission status for each patient and did a sensitivity analysis including only visits with all information available. We fit a Weibull regression model with interval/right censored and left truncated data adjusted for sex and disease duration at baseline. Both multivariable full model and reduced model with Hazard Ratio (HR), 95% confidence interval (CI) estimates, and p-value are provided in Table1.

Results: 985 patients (57% males, mean age 47.4 yrs Table) were included. Using imputation 175 (18.2%) patients had remission at least once and 107 (10.9%) achieved sustained remission. For the sensitivity analysis, using only patients who had complete data, 109 (10.9%) patients achieved remission at least once, and 48(4.9%) sustained remission for 2 consecutive visits. Using baseline variables with imputation, only BMI was significant and lowered the chance of remission. In the sensitivity analysis no baseline variables were significant. Using a model with time varying covariates higher BMI lowered the chance of remission, while use of biologics increases the chance of remission. Similar results were obtained with the sensitivity analysis.

Conclusion: We defined remission as a state of no clinical activity. Remission occurred in 18% of patients with PsA at least once and was sustained in 11%. High BMI reduced and use of biologic agents increased the chance of sustained remission.

Influence of Inflammation and Structural Damage on Global Functioning in Patients with Axial Spondyloarthritis – Using the ASAS Health Index in Routine Care

Uta Kiltz¹, Thomas Wiatr², Xenofon Baraliakos¹, Kirill Fedorov² and Jürgen Braun³, ¹Rheumatology, Rheumazentrum Ruhrgebiet, Herne, and Ruhr University Bochum, Herne, Germany, ²Rheumazentrum Ruhrgebiet, Herne, Germany, ³Ruhr-University Bochum, Bochum, Germany

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the relationship between spinal mobility and self-report global functioning as assessed by the ASAS Health Index (ASAS HI), and to study the influence of structural and inflammatory spinal changes on global functioning.

Methods: Patients from the outpatient clinic of our hospital suffering from axial or peripheral SpA completed questionnaires assessing disease activity and functioning (ASAS HI, pain, BASDAI, ASDAS, BASFI). Axial inflammation as detected by magnetic resonance imaging (MRI) was assessed by the Berlin score, structural damage by the modified Stokes ankylosing spondylitis (AS) Spine Score (mSASSS) and spinal mobility by the Bath AS Metrology Index (BASMI). Imagings were scored by two independent readers. Correlations between the ASAS HI and other health outcomes were analysed by Spearman's test. Logistic regression analyses were performed to investigate the association between functioning and other clinical characteristics.

Results: A total of 203 patients (76 non-radiographic (nr)-axSpA, 115 AS patients, and 12 with peripheral SpA (pSpA) were included: 63.5% male, mean (SD) age 46.6 (14.1), symptom duration 18.8 (12.8) years, and 76.4% HLA-B27 positive. The mean values of clinical assessments were ASAS HI 7.9 (4.0), BASDAI 5.0 (2.2), ASDAS 2.8 (1.1), BASMI 3.3 (1.8), pain 6.0 (2.6), and BASFI 5.0 (2.6). Elevated CRP levels were found in 37.4% of the patients, while 59.1% of the AS patients had syndesmophytes and 11.3% a bamboo spine. The median (IQR) mSASSS value was 3.8 (IQR 1.0-22.1) in AS und 0.0 (IQR 0.0-1.4) in nr-axSpA patients. The mean Berlin Score for patients with axSpA was 5.3 (SD 7.1). Patients received a treatment with NSAIDs (62.7%), DMARDs (20.9%) and/or biologics (49.4%). A significant correlation of the ASAS HI was found for BASMI ($r=0.5$), BASDAI ($r=0.7$), ASDAS ($r=0.5$), BASFI ($r=0.8$), BMI (0.3) and Berlin Score (0.3). ASAS HI did not correlate with radiographic damage (mSASSS $r=0.2$, presence of bamboo spine $r=0.2$) and CRP ($r=0.07$). Stratifying patients by symptom duration (cut-off 3 years) did not affect these results. Logistic regression showed influence of obesity but not of inflammation or structural damage on global functioning (Table 1).

Table 1: Association between clinical characteristics of patients with SpA and functioning status

	Univariable		Multivariable	
	OR (CI)	p	OR (CI)	p
Age	1.04 (1.02-1.06)	0.001	-	NS
Male sex	0.47 (0.24-0.93)	0.003	0.09 (0.01-0.71)	0.022
BMI	1.10 (1.03-1.18)	0.006	1.24 (1.05-1.48)	0.013
BASDAI, 0-10	1.35 (1.17-1.57)	<0.001	-	NS
ASDAS	2.51 (1.76-3.57)	<0.001	-	NS
BASFI, 0-10	2.03 (1.66-2.48)	<0.001	1.85 (1.19-2.87)	0.006
BASMI, 0-10	2.0 (1.56-2.54)	<0.001	-	NS
mSASSS, 0-72	1.02 (1.00-1.05)	0.089	-	NS
Berlin Score, 0-72	0.98 (0.91-1.04)	0.490	-	NS

Conclusion: The influence of obesity on functioning is remarkable in patients with SpA. In contrast, the influence of structural damage and spinal inflammation on functioning was limited in this study, probably due to the relatively low mSASSS and MRI scores. Further studies with inclusion of more severely affected patients are needed to study the association of functioning, spinal mobility, obesity and radiographic damage over a broader range of affected patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) may suffer from extraarticular (EA) manifestations (uveitis, psoriasis) and have higher rates of comorbidities like cardiovascular diseases (CVD) and depression than the normal population. Comorbidities should be kept in mind when managing patients with PsA and AS, as they can contribute to increased mortality and influence disease activity¹. The aim of this interim analysis is to evaluate the incidence of selected EA manifestations and comorbidities at baseline and the impact of secukinumab on the status of these attributes compared to baseline.

Methods: The presence and severity of uveitis and psoriasis as well as coronary heart disease (CHD), stroke, heart insufficiency, and depression were documented according to clinical routine at baseline and at week 4, 16, 24 and 52 under treatment with secukinumab. Depressed mood has been evaluated by Becks Depression Inventory (BDI-II), plaque psoriasis via PASI score. At baseline 486 patients were included and observed up to 52 weeks, at the time of analysis not all patients have already reached the end of the study, therefore the results are presented as observed.

Results: As expected, plaque psoriasis was very frequent in PsA patients (63.3%), but also present in AS patients (11.5%) at baseline. For PsA patients, median PASI improved from 5.0 at baseline to 0.0 at week 52. Half of patients with available PASI achieved clear skin at week 52 (Tab 1).

Uveitis was more frequent in AS patients than in PsA patients (6.2% vs 0.9%). Only 1 AS patient and 2 PsA patients experienced new onset of uveitis.

At baseline, the following patients reported previous CHD (PsA 8.9%, AS 3.5%), heart failure (PsA 3.3%, AS 0.7%) and stroke (PsA 2.4%, AS 0.0%). Of these cardiovascular comorbidities none worsened (as observed at each scheduled visit) with secukinumab treatment for all patients observed up to 52 weeks. During the study two PsA patients were newly diagnosed with CHD and heart insufficiency throughout week 52. No new stroke occurred.

Depression was common in both populations (PsA 15.4%, AS 12.2%) at baseline. Up to week 52 median BDI-II improved from 12.0 to 6.0 (AS patients) and from 9.0 to 6.0 (PsA patients [Tab 1]).

Conclusion: Incidence of CVD and depression in PsA and AS patients is generally comparable to the published literature^{2,3}. However, in contrast to other studies⁴, previous uveitis was less frequently reported in SpA patients, particularly in the AS group. Cardiovascular comorbidities remained overall stable under secukinumab up to wk 52. Plaque psoriasis and depressive mood improved with secukinumab treatment.

	Baseline	Week 4	Week 16	Week 28	Week 40	Week 52
PASI 100 n(%)	0 (0.0)	7 (13.0)	23 (34.3)	28 (47.5)	18 (41.9)	15 (50.0)
PASI 75 n(%)	0 (0.0)	9 (16.7)	26 (38.8)	33 (55.9)	21 (48.8)	18 (60.0)
BDI-II (AS patients)	12.0	9.0	8.0	8.0	7.5	6.0
BDI-II (PsA patients)	9.0	8.0	7.5	8.0	7.0	6.0

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Assessment of SpondyloArthritis international Society (ASAS) defines a positive family history (PFH) of spondyloarthritis (SpA) as presence of ankylosing spondylitis (AS), acute anterior uveitis (AAU), reactive arthritis (ReA), inflammatory bowel disease (IBD), and/or psoriasis in first (FDR)- or second (SDR)-degree relatives. In two European cohorts (SPACE and DESIR) a PFH of AS and AAU, but not other subtypes, were associated with HLA-B27 carrier ship in patients suspected of axial SpA (axSpA)¹. As the importance of ethnicity or degree of family relationship is unknown, we investigated the influence of ethnicity, FDR or SDR on the association between a PFH and HLA-B27 carrier ship in patients suspected of axSpA.

Methods: Univariable analyses were performed among patients suspected of axSpA in the ASAS cohort at baseline. Each disease (AS, AAU, psoriasis, IBD, ReA) in a PFH according to the ASAS definition was a determinant in separate models with HLA-B27 carrier ship as outcome. Analyses were stratified for self-reported ethnicity (white, Asian, and other), FDR, and SDR. Analyses were repeated in multivariable models to investigate independent associations.

Results: In total, 594 patients were analysed. Patients had a mean (SD) age of 33.7 (11.7) years, 46% were male; 52% was HLA-B27+, 59% were white, 36% were Asian, and 5% had another ethnicity. A PFH was reported by 23% of the patients; a PFH of AS was the most (15%) and PFH of AAU (1%) the least often reported family history among all patients. A PFH in first-degree relatives was reported in 19% of patients and in second-degree relatives in 4%. A PFH was associated with HLA-B27 carrier ship in patients with a white (OR:2.3, 95%CI:1.4-3.9) or Asian ethnicity (OR:3.1, 95%CI:1.6-5.8) and with a PFH in FDR (OR:2.9, 95%CI:1.8-4.5), but not with a PFH in SDR (OR:1.7, 95%CI:0.7-3.8) or in other ethnicities (Table 1). A PFH of AS was positively associated with HLA-B27 carrier ship in all subgroups (white OR:7.1, 95%CI:2.9-17.1; Asian OR:5.7, 95%CI:2.5-13.2; FDR OR:7.8, 95%CI:3.8-16.0; SDR OR:3.7, 95%CI:1.2-11.6). A PFH of AAU, ReA, IBD, or psoriasis was never positively associated with HLA-B27 carrier ship. In the multivariate analysis, similar results were found.

Conclusion: In the international ASAS cohort, a PFH of AS, but not of AAU, ReA, IBD, or psoriasis, was associated with HLA-B27 carrier ship irrespective of ethnicity or degree of family relationship. These data, in combination with data from two European cohorts, show that a PFH of AS and possibly a PFH of AAU can be used to identify patients who are more likely to be HLA-B27 positive and therefore have an increased risk of axSpA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Spinal mobility is a major problem for people with axial spondyloarthritis (axSpA). The BASMI has been widely used for measuring spinal mobility but it lacks responsiveness to change and requires clinical expertise to perform. Inertial Motion Unit (IMU) sensors are now available to measure spinal movement without requiring significant operator expertise. Our objective in this study was to test the reliability of these new tools in patients with axSpA and to develop a composite measurement tool analogous to the BASMI.

Methods: The study included 40 patients with axSpA fulfilling ASAS classification criteria (12 females, 28 males) with a mean age of 48 (27-41). Subjects had a wide range of severity of axSpA. ViMove IMU sensors (DorsaVi©) were used to obtain ROM measurements at the cervical and lumbar spine. Intra-rater and inter-rater reliability of BASMI and IMU tests were assessed by intraclass correlation coefficients (ICC) (two-way model, single measure, absolute agreement) with a 95% CI. Based on these observations we developed a novel scoring system named 'IMU-ASMI'. It includes four measurements of maximum ROM (degrees) carried out in both lumbar and cervical regions: flexion, extension, averaged L/R values for lateral flexion and rotation. Maximum spinal ROM values in normal subjects taken from an earlier criterion validity study are taken as reference in the composite IMU-ASMI score calculation.

Results: The mean BASMI was 5.0 (range 0.7 to 8.2, SD 1.9). The mean IMU-ASMI was 5.1 (range 0.4-8.9, SD 2.1). The mean difference between the two scores was 0.04, SD 0.17.

The ICC results demonstrate that a sensor based IMU-ASMI has excellent reliability (table). The R^2 on the regression analysis was 0.97, indicating a close relationship between the BASMI and IMU-ASMI (Figure).

	BASMI		IMU-ASMI	
	ICC (2,1)	95% CI	ICC (2,1)	95% CI
Intra-rater	0.97	0.95-0.99	0.95	0.91-0.96
Inter-rater	0.95	0.91-0.98	0.93	0.85-0.98

Conclusion: IMU sensors can be used to accurately and reliably measure spinal mobility in patients with axSpA. We present a novel IMU-ASMI score based on combining sensor data on spinal mobility including an assessment of lumbar rotation. The score compares favorably with the BASMI linear scale, and the sensor technology on which it is based on will allow tests of spinal mobility to be carried out by non-experts in the community setting. Further studies are planned to test the sensitivity to change of the IMU-ASMI compared to BASMI.

Acknowledgements: This study was funded by FOREUM (<http://www.foreum.org/>). Physiotherapist Stephanie Keys also performed spinal mobility tests during this study.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnostic delay in axial spondyloarthritis (axial SpA) has been reported to be 9 years and still remains unacceptably high. One of the major reasons for this delay is a late referral of patients with suspicion of axial SpA by primary care (PC) physicians, dealing with patients with chronic back pain (CBP). Physician-based referral programs have performed well in recognition of patients with high probability of axial SpA among CBP patients. However, there is still an unmet need for patients who do not receive a referral recommendation to a rheumatologist because of lack of awareness on the PC level. The objective of this study was to develop and evaluate an online self-referral tool for CBP patients with suspicion of axial SpA.

Methods: Patients with CBP were included in the Identification of the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) Study and assessed by a rheumatologist if they either 1) were referred by a physician using the Berlin referral tool (CBP > 3 months and CBP onset < 45 years of age + at least 1 of the following 3 parameters: inflammatory back pain (IBP), HLA-B27 positivity, sacroiliitis on imaging), or 2) completed an online self-referral and indicated the presence of CBP > 3 months with onset < 45 years of age + at least 1 additional SpA parameter. Rheumatologist then performed a structured assessment of SpA features and made the diagnosis of axial SpA/non-axial SpA.

Results: A total of 362 patients were included in the study on a 1:1 ratio either referred by a physician using the Berlin referral tool or via the online self-referral tool. A total of 71 patients (39.9%) in the physician-referral group and 35 patients (19.3%) in the self-referral group were finally diagnosed with axial SpA ($p < 0.001$). Patients who were included via the online referral tool had a longer symptom duration, were more often females, less often HLA-B27 positive and had less often elevated CRP as compared to physician-referred patients (table 1a).

In patients diagnosed with axial SpA the patients referred by a physician were more often male ($p = 0.041$), HLA-B27 positive ($p < 0.001$) and showed more often advanced radiographic changes in the sacroiliac joints leading to the diagnosis of radiographic axial SpA (=ankylosing spondylitis) ($p = 0.033$). All other demographic and clinical characteristics did not differ between the two groups (table 1b).

Conclusion: The self-referral strategy resulted in the diagnosis of axSpA in 19% of the patients as compared to 40% with a referral done by a physician. However, the proportion of axSpA among self-referred patients was clearly higher than the expected 5% prevalence of axSpA in patients with CBP. The online self-referral tool can be used, therefore, in addition to a physician based referral program to improve the early diagnosis and to increase awareness of axSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Figure. Comparison of the disease activity state ascertainment by ASDAS-routine-CRP vs. ASDAS-quick-CRP (A) and ASDAS-routine-CRP vs. ASDAS-ESR (B).

A

		ASDAS-quick-CRP (n=50)			
		Inactive disease (<1.3)	Low Disease Activity (1.3 - <2.1)	High disease activity (2.1 - <3.5)	Very high disease activity (>3.5)
ASDAS-routine-CRP	Inactive disease (<1.3)	4 (8%)	1 (2%)	0	0
	Low Disease Activity (1.3 - <2.1)	1 (2%)	10 (20%)	0	0
	High disease activity (2.1 - <3.5)	0	0	24 (48%)	2 (4%)
	Very high disease activity (>3.5)	0	0	0	8 (16%)

B

		ASDAS-ESR (n=48)			
		Inactive disease (<1.3)	Low Disease Activity (1.3 - <2.1)	High disease activity (2.1 - <3.5)	Very high disease activity (>3.5)
ASDAS-routine-CRP	Inactive disease (<1.3)	2 (4.2%)	3 (6.3%)	0	0
	Low Disease Activity (1.3 - <2.1)	0	8 (16.7%)	3 (6.3%)	0
	High disease activity (2.1 - <3.5)	0	1 (2.1%)	17 (35.4%)	6 (12.5%)
	Very high disease activity (>3.5)	0	0	2 (4.2%)	6 (12.5%)

Background/Purpose: The Ankylosing Spondylitis Disease Activity Score (ASDAS) is a composite index to assess disease activity in patients with axial spondyloarthritis (axSpA). According to the treat-to-target (T2T) recommendations for SpA, and the ASAS/EULAR management recommendations for axSpA, the C-reactive protein (CRP)-based ASDAS is the preferred instrument for the assessment of disease activity in the process of making decision on modification of axSpA treatment in clinical routine. Currently, measurement of CRP by routine lab methods takes hours to days what challenges the feasibility of T2T approaches in clinical-routine and studies. The objective of this study was to compare the performance of the ASDAS based on a quick CRP assay (ASDAS-quick-CRP) with the ASDAS-routine-CRP and with the erythrocyte sedimentation rate (ESR)-based ASDAS in the assessment of disease activity in patients with axSpA.

Methods: This cross-sectional study was performed in patients referred with a suspicion of axSpA as part of the OptiRef study. Briefly, referred patients underwent an assessment of SpA features by a rheumatologist. CRP was measured in the central lab (routine turbidimetric assay, lowest detection level: 0.3mg/l) and locally by ESR and a quantitative quick-CRP test (QuickRead go®, Orion Diagnostica Oy, lowest detection level: 5mg/l, test duration approx. 2 min.). If the quick-CRP was below the limit of detection, the value of 2mg/l was used. In patients with the final diagnosis of axSpA, ASDAS-routine-CRP, ASDAS-quick-CRP and ASDAS-ESR were calculated.

Results: A total of 137 patients had available routine and quick CRP levels; 50 patients of them were diagnosed with axSpA. Mean±SD routine / quick CRP serum levels were 3.6±7.0 mg/l and 5.0±7.2 mg/l, respectively, in the entire group, and 6.2±8.3 mg/l and 7.4±8.4 mg/l, respectively, in patients with axSpA. There was no significant difference ($p=0.11$) in the mean values of ASDAS-CRP (2.7 ± 1.0) and ASDAS-quick-CRP (2.8 ± 1.0), while the ASDAS-ESR (2.9 ± 1.0) was significantly higher than ASDAS-routine-CRP ($p=0.02$). In 46 of the 50 cases of axSpA (92%) the status scores for disease activity showed no difference between ASDAS-routine-CRP and ASDAS-quick-CRP – figure. For ASDAS-ESR compared to ASDAS-routine-CRP, only 33/48 patients (68.8%) were assigned to the same DAC.

Conclusion: ASDAS-quick-CRP performed similarly well to ASDAS-routine-CRP with an agreement on the status score for disease activity of 92%, that was clearly better than the agreement of 68.8% between ASDAS-ESR and ASDAS-routine-CRP. With a duration of approximately 2 minutes the quick-CRP test is, therefore, feasible for immediate decision making as a part of clinical routine or clinical trials.

Acknowledgements: The OptiRef project was supported by an unrestricted research grant from Novartis. The “QuickRead go” was provided free of charge by Orion Diagnostica Oy.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many registries routinely collect only 28 joint count, although 66/68 joint count has higher face validity in PsA. We aimed to compute and test the validity of a simplified Disease Activity index for Psoriatic Arthritis (DAPSA) using 28 instead of 66/68 joint count.

Methods: We included PsA patients from the Danish national quality registry DANBIO, divided into examination (n=3157 patients, 24160 visits) and validation cohorts (n=3154 patients, 24160 visits) according to odd/even IDs. We defined: $DAPSA_{28} = (28TJC \times \text{conversion factor}_1) + (28SJC \times \text{conversion factor}_2) + \text{patient global [0-10VAS]} + \text{pain [0-10VAS]} + \text{CRP [mg/dL]}$. Identification of conversion factors was performed by Generalized Estimating Equations in the examination cohort, and *criterion, correlational and construct validity* explored in the validation cohort.

Results: Mean (SD) age: 52.0 (13.8) years, 54.4% females. *Conversion factor*₁ = 1.6, 95%CI(1.6-1.7), *conversion factor*₂ = 1.6, 95%CI (1.5-1.6), leading to:

$DAPSA_{28} = (28TJC + 28SJC) \times 1.6 + \text{patient global [0-10 VAS]} + \text{pain [0-10 VAS]} + \text{CRP [mg/dL]}$. *Criterion validity:* Physician's global and DAPSA/DAPSA₂₈ were similarly correlated ($r=0.63/r=0.61$, $p<0.001$). DAPSA/DAPSA₂₈ had comparable discriminative power, expressed as standardized mean difference (DAPSA, 0.90; DAPSA₂₈, 0.93) to distinguish between patients in high (starting bDMARD) and low (not starting/changing s/bDMARD for ≥ 60 days) disease activity. Agreement between DAPSA/DAPSA₂₈ disease activity states was best for remission/low disease activity (Table).

		DAPSA(n=6421) n(%) stratified by DAPSA disease activity states			
		DAPSA≤4	DAPSA>4 and ≤14	DAPSA>14 and ≤28	DAPSA>28
DAPSA28 (n=6421)	DAPSA28≤4	1135(98.4)	126(5.6)	4(0.2)	0(0)
	DAPSA28>4 and ≤14	18(1.6)	2073(91.5)	345(17.8)	14(1.3)
	DAPSA28>14 and ≤28	0(0)	66(2.9)	1509(77.9)	248(23.3)
	DAPSA28>28	0(0)	0(0)	80(4.1)	803(75.4)

Kappa with quadratic weighting of DAPSA/DAPSA28 disease activity states was high; 0.92 95%CI (0.92-0.92). Standardized response means for DAPSA/DAPSA28 were -0.96/-0.92 (n=572) for visits after bDMARD start. *Correlational validity:* Baseline DAPSA/DAPSA28 had strong correlation with DAS28 (r=0.87/r=0.93), SDAI (r=0.92/r=0.99), p<0.001. Bland-Altman plot showed better agreement between DAPSA/DAPSA28 for low than high disease activity (figure). *Construct validity:* DAPSA/DAPSA28 were similarly correlated to HAQ; r=0.60/0.62, p<0.001. DAPSA/DAPSA28 discriminated patients reporting their symptom state acceptable (n=1140) vs. not acceptable (n=1045) equally well: mean (SD) 9.1(8.7)/8.4(8.0) and 24.2(14.9)/22.5(13.8), respectively.

Conclusion: DAPSA28 showed good criterion, correlational and construct validity. Agreement between DAPSA and DAPSA28 was better for low than high disease activity levels. The original DAPSA should be preferred in PsA. However, data sets with only 28 joint counts available can be used to calculate DAPSA28.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Classification of axial spondyloarthritis (axSpA) by the imaging arm of the ASAS criteria relies partly on the detection of a bone marrow edema (BME) in the magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) suspicious of SpA. Here we evaluate different types of MRI changes possibly relevant for a diagnosis of axSpA as judged by radiologists taking the rheumatologist's diagnosis as gold-standard.

Methods: Consecutive patients <45 years were included if they presented with chronic low back pain (duration >3 months) and underwent complete diagnostic workup including SIJ-MRI. All clinical and laboratory information including images but no radiological reports was available for experienced rheumatologists to make a diagnosis of axSpA or non-axSpA. In parallel, two experienced musculoskeletal radiologists, blinded to patients' demographics and symptoms (except for back pain) evaluated all MR images without knowledge of the rheumatologist's diagnosis, by quantification of BME, fat metaplasia, erosions, sclerosis and ankylosis based on the Berlin SIJ score. The radiologists also stated whether the patient is likely to have axSpA or not, solely based on MRI findings.

Results: A total of 100 patients were recruited. The rheumatologist diagnosed axSpA in 54 patients (mean age 31.5±8.0 years, 77.8% HLA-B27+, mean symptom duration 36.4±42.0 months), while 46 patients were diagnosed as non-specific back pain (age 33.6±7.1 years, 17.4% HLA-B27+, mean symptom duration 25.5±31.6 months). According to the radiologists, 38 patients were identified as axSpA, 34 of which were also diagnosed as axSpA by the rheumatologist (overall agreement with the clinical diagnosis: 63%), and 4 patients were thought to have axSpA by the radiologist but not

by the rheumatologist (disagreement with the clinical diagnosis: 8.7%). Similarly, the quantification of MRIs showed higher scores in patients diagnosed as axSpA by the rheumatologist. Only few patients had sclerosis or ankylosis. From the radiologist's perspective, the calculated odds ratio (OR) for identification of axSpA by MRI only was 3.1 (95% CI:1.4-7.1) for the presence of BME, 3.5 (95% CI:1.4-9.0) for fat metaplasia, 2.8 (95% CI:1.1-7.0) for erosions, 2.0 (95% CI:0.7-5.5) for ankylosis. For the combination of BME and any structural change, the OR was 3.7 (95% CI:1.6-8.5).

Conclusion: This study reveals a discrepancy between the rheumatologist's and the radiologist's identification of axSpA, confirming that a diagnosis of axSpA in daily practice should not rely on imaging findings only. Nevertheless, the overall specificity of the radiologists was acceptable, although the sensitivity was relatively low. These data suggest also that not only BME but also fat metaplasia and erosions are of value to diagnose axSpA, beyond classification. The combination of MRI changes seems to enhance the discriminative diagnostic performance. Finally, it will be important to define clinically relevant cut offs for the MRI scores.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal changes precede the onset of psoriatic arthritis (PsA). A subset of psoriasis patients is characterized by arthralgia as well as inflammatory changes in the joints visible by MRI assessment. These patients have a high risk to progress into PsA. The objective of the study was to test the concept of a very early intervention in PsA we exposed psoriasis patients with subclinical joint inflammation to the anti-interleukin (IL)-17A antibody secukinumab. We hypothesized that IL-17A inhibition disrupted the early link between skin and joint disease in Psoriasis.

Methods: Psoriasis (but not PsA) patients were included in the open prospective 24-weeks “Interception in Very Early PSA” (IVEPSA) study. To fulfill the inclusion criteria patients had to have a PASI score greater than 6 or nail or scalp involvement as well as inflammatory or erosive changes in MRI or high-resolution peripheral quantitative computed tomography (HRpQCT) at baseline. Patients received treatment with secukinumab 300 mg sc. for 24 weeks. MRI scans and HRpQCT of the dominant hand were performed at baseline and at 24 weeks. MRI was scored according to PsAMRIS. HRpQCT evaluated for erosions and enthesophytes.

Results: 20 patients (median age 49.5 years (IQR 42.8, 59), 70% males) with a median disease duration of 14 years (IQR 5, 20), were included into the study. At baseline, 85% reported arthralgia assessed by a Visual Analogue Scale (VAS) and 40% had tender joints on examination (TJC78). 83.3% had at least one inflammatory lesion in the MRI, 66.7% synovitis, 55.6% tendinitis/enthesitis, 27.8% osteitis and 16.7% periarticular inflammation. Erosions were present in 72.2% and 58.8% in the MRI and HRpQCT, respectively, while enthesophytes were found in 33.3% and 41.2%. One patient was discontinued early due to lack of improvement (wk12) and one patient was unable to perform the follow-up MRI. Psoriatic skin disease (total PASI and BSA) significantly improved (both $p < 0.05$) and also arthralgia (VAS pain, tender joint count) significantly declined after secukinumab treatment (both $p < 0.05$). Total PsAMRIS score and synovitis subscore significantly improved at wk24 ($p = 0.005$ and $p = 0.008$, respectively). Importantly, improvement in total PsAMRIS score significantly correlated with the improvement in arthralgia ($p < 0.05$). Finally, neither erosions nor enthesophytes in MRI and HRpQCT progressed during the 24 weeks of treatment. There was no new safety signal in the study.

Conclusion: IL-17 inhibition by secukinumab over 24 weeks led to resolution of inflammation and no progression of bone changes in the joints in psoriasis patients with subclinical peripheral joint involvement. These data suggest that very early disease interception in PsA is a feasible approach. IVEPSA also provides the guide for further very early interventions in PsA providing concepts for imaging-based identification and the sensitivity to change of subclinical inflammation to biological disease modifying anti-rheumatic drug therapy.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The diversity of MRI lesions in the sacroiliac joints of patients with axial spondyloarthritis (axSpA) has only recently been appreciated and consistent terminology, descriptions, and definitions have not yet been internationally accepted. The ASAS MRI group has generated updated consensus lesion definitions (ASAS_MRI_defⁿ) and these now require validation to support widespread adoption for clinical practice and research. We aimed to assess the distribution by diagnosis, reliability of detection, and construct validity of active and structural lesions as defined by the ASAS-MRI group (ASAS_MRI_defⁿ) on MRI scans from the ECHOSPA cohort.

Methods: Consecutive outpatients with age <50 years and symptoms >3 months suggestive of SpA were enrolled in the French ECHOSPA cohort study. MRI scans from 412 of the 470 recruited cases were available for evaluation by 2 readers and an adjudicator. ASAS_MRI_defⁿ were recorded in an ASAS consensus-derived eCRF that comprises global assessment (active and/or structural lesion typical of axSpA present/absent) and detailed scoring of individual lesions (SPARCC SIJ inflammation, SPARCC SIJ structural). Definite lesions were defined according to confidence ≥ 3 (0-4 scale). Reliability of detection of lesions assessed as present/absent by global assessment was analyzed using kappa and detailed scoring of SIJ quadrants by intra-class correlation coefficient (ICC). For construct validity we calculated optimal cut-offs for bone marrow edema (BME) and erosion that defined active and structural lesion typical of axSpA, respectively.

Results: At baseline, mean age of the 412 cases with MRI scans was 39.3 years, mean duration of symptoms was 2.5 years, 41.3% were HLA-B27 positive, and 63.2% were female. Active and structural lesions typical of axSpA were present in 9.7% and 10.8%, respectively, and ASAS positive MRI in 9.3%. Subchondral BME (13.6%) and erosion (9.4%) were the most frequent active and structural lesions, respectively. Active but not structural lesions were present in 3.0% while the converse was evident in 4.0%. Both active and structural lesions were present in 6.9% while either active or structural lesions were present in 13.8%. AxSpA was diagnosed at baseline in 88.1% and all categories of active and structural lesions were higher in those with axSpA. Substantial κ values (95%CI) were evident for detection of these lesions with comparable reliability for active and structural lesions: active lesion (0.76(0.65-0.88)), ASAS positive MRI (0.78 (0.66-0.89)), structural lesion (0.76(0.65-0.87)). Detailed scoring per SIJ quadrant that reflect expert opinion as to what constitutes an active or structural lesion typical of axSpA are provided in the Table.

Conclusion: SPARCC BME score of ≥ 3 and Erosion Score ≥ 2 may optimally reflect active and structural lesions typical of axSpA, respectively. MRI lesions defined by the ASAS-MRI group can be reliably detected.

Table.

Number of SIJ Quadrants	Active Lesion Typical of AxSpA	
	Sensitivity	Specificity
BME Score ≥ 2	100%	90.27%
BME Score ≥ 3	100%	95.14%
BME Score ≥ 4	97.5%	96.76%

	Structural Lesion Typical of AxSpA	
	Sensitivity	Specificity
Erosion Score ≥ 2	84.09	99.15
Fat metaplasia ≥ 2	27.27	98.02
Backfill ≥ 2	11.36	100
Ankylosis ≥ 2	4.55	99.72

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been substantial progress in the characterization of MRI lesions in the sacroiliac joints (SIJ) and spine in axial spondyloarthritis (axSpA) since the last consensus-based reports from ASAS^{1,2}. In particular, new data have emerged regarding structural lesions and the considerable evolution in their appearance according to the degree of inflammation. There is as yet a lack of international consensus on standardized definitions of all the lesions reported to date. Consequently, the ASAS MRI group was convened to evaluate the literature describing the spectrum of MRI lesions in axSpA and to generate a consensus update on standardized definitions for MRI lesions.

Methods: The literature pertaining to MRI lesion definitions in axSpA was discussed at 3 meetings of the ASAS MRI group attended by 26 investigators (21 rheumatologists, 5 radiologists). The group reviewed the literature for MRI lesion definitions and decided by consensus which definitions would be retained, which required modification, and which required a new definition. The group also agreed on a set of reference images, a study design (ASAS MRImagine) for multi-reader assessment of lesion definitions using MRI scans from the ASAS classification cohort, a PowerPoint-based reader calibration module, and a study-specific interactive eCRF incorporating links to reference images for recording MRI data.

Results: For definitions denoting signs of activity in the SIJ, there are no revisions to the most current ASAS definition of a positive MRI and for subchondral bone marrow inflammation¹. Definitions for capsulitis and enthesitis are revised. A new definition, *joint space enhancement*, denotes increased signal on contrast-enhanced images in the joint space of the cartilaginous portion of the SIJ. This replaces the term 'synovitis' and a separate definition describes what constitutes joint

space fluid. For signs of structural change in the SIJ, the definition for sclerosis unchanged. A revised definition for a fatty lesion incorporates characteristics typical of axSpA, and for erosion requires both loss of cortical bone as well as adjacent marrow matrix on a T1W image. A new definition, *fat metaplasia in the joint space* (*'backfill'*), denotes the reparative change on aT1W image at the site of erosion when signs of activity recede. The new definition for ankylosis stresses the continuity of bright marrow signal across the joint space on a T1W image while for bone bud, the signal does not bridge the joint. Spinal lesion definitions are divided into those that occur in defined central and lateral sagittal slices. The revised definition of a vertebral corner inflammatory lesion divides this into a regular (type A) and dimorphic (type B) lesion. A new definition for corner erosion requires both loss of cortical bone as well as adjacent marrow matrix. New definitions for new bone growth require bright signal on T1W images extending from the vertebral corner marrow or endplate, which may (ankylosis) or may not (bone spur) be continuous with the adjacent vertebra.

Conclusion: The ASAS MRI group has generated a consensus-based update on MRI lesions in axSpA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The ASAS MRI group has generated updated consensus lesion definitions (ASAS_MRI_def^m) for the spectrum of MRI lesions in the SIJ. Their relative performance as diagnostic indicators requires assessment to understand their value in clinical practice when assessing patients referred with undiagnosed back pain. We aimed to determine optimal quantitative SPARCC cut-offs for specific MRI lesions reflecting diagnosis of axSpA in patients with undiagnosed back pain recruited to the ASAS Classification Cohort (ASAS-CC)¹ and diagnosed by local rheumatologist expert opinion.

Methods: ASAS_MRI_def^m were recorded in an eCRF that comprises global assessment (active or structural lesion typical of axSpA present/absent), links to reference images, and detailed scoring of lesions per SIJ quadrant (SPARCC SIJ inflammation, SPARCC SIJ structural). MRI images were available from 278 of the 495 cases that had MRI performed in the ASAS-CC and were evaluated by 7 experienced readers from the ASAS-MRI group. Detailed SPARCC scoring data was based only on assessment of images in DICOM format. We calculated sensitivity and specificity for varying numbers of SIJ quadrants with bone marrow edema (BME), erosion, and fatty lesions for diagnosis of axSpA as determined by the local rheumatologist at baseline and after a mean 4.4 years of follow up. Lesion cut-offs were tested according to data based on majority agreement ($\geq 4/7$ readers) and from any 2 central readers.

Results: Lesion cut-offs based on BME were most sensitive for diagnosis at baseline and follow up but erosion- and fatty-lesion based cut-offs were more specific (Table). There was a consistent improvement in the sensitivity and specificity

performance of cut-offs based on erosions and fatty lesions according to diagnosis at baseline and then at follow up after 4.4 years but not for cut-offs based on BME. This improvement was also consistently observed in data based on majority agreement of central readers. Sclerosis based cut-offs performed least well but specificity was still 90% at follow up.

Conclusion: The ASAS consensus definitions for active and structural lesions and scoring cut-offs based on the presence of these lesions in 2-3 SIJ quadrants have comparable diagnostic performance. However, diagnostic performance consistently improves for erosion and fatty lesion based cut-offs after follow up.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been no central reader evaluation of MRI scans from the ASAS Classification Cohort (ASAS-CC)¹ to compare detection of lesions between central and ASAS-CC local site readers. Local readers reported active MRI lesions typical of axSpA in the SIJ of 61.6% and 2.2% of patients diagnosed with axSpA and non-axSpA back pain, respectively. Structural lesions were recorded but not reported. We aimed to compare the frequencies of active and structural lesions from the ASAS-CC according to diagnostic category and agreement for their detection between ASAS-CC local site readers and central readers from the ASAS-MRI group.

Methods: MRI lesions were recorded in an eCRF that included wording of lesions defining active and structural lesions typical of axSpA that was exactly the same as in the original ASAS-CC eCRF permitting comparisons between central and local site readers. In addition, lesions that met the criteria for an ASAS positive MRI were recorded by central readers. MRI images were available from 276 of the 495 cases who had MRI performed in the ASAS-CC and also had a local rheumatologist expert opinion diagnosis. Image quality was considered sufficient to record global data by 7 central readers in all cases. Lesion frequencies were assessed descriptively according to majority agreement ($\geq 4/7$) of central reader data and also any 2 central readers. Agreement for detection of MRI lesions was compared using the kappa coefficient.

Results: Significant differences in lesion frequencies were observed according to diagnostic category (Table 1). However, the frequency of active lesions reported by local readers (61%) was greater than for central readers (43.2%). Structural lesions were also more frequently reported by local readers (42.1%) compared to central readers (34.7%) but less so than active lesions. Agreement for detection of active lesions was good but poor for structural lesions (Table 2).

Conclusion: Local readers may have overestimated the presence of MRI lesions in the ASAS-CC, particularly active lesions. Agreement for detection of structural lesions was limited. The impact on diagnosis by the local rheumatologist cannot be deduced.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The diversity of MRI lesions in the sacroiliac joints of patients with axial spondyloarthritis (axSpA) has only recently been appreciated and consistent terminology, descriptions, and definitions have not yet been internationally accepted. The ASAS MRI group has generated updated consensus lesion definitions (ASAS_MRI_defⁿ) and these now require validation to support widespread adoption for clinical practice and research. We aimed to assess the reliability of detection of active and structural lesions as defined by ASAS_MRI_defⁿ on MRI images from the ASAS Classification Cohort (ASAS-CC) by 7 experts in MRI interpretation from the ASAS-MRI group.

Methods: ASAS_MRI_defⁿ were recorded in an eCRF that comprises global assessment (lesion present/absent), links to reference images, and detailed scoring (SPARCC SIJ inflammation, SPARCC SIJ structural). MRI images were available from 278 of the 495 cases that had MRI performed in the ASAS-CC. MRI images were available in a variety of formats (DICOM(n=175), JPEG (n=71), DICOM film (n=32)) and sequences, axial and semicoronal orientations, from 278 of the 495 cases who had MRI performed in the ASAS-CC. Image quality was considered sufficient for global assessment in all cases by all readers. Detailed SPARCC scoring data was based only on assessment of images in DICOM format (n=175). Detection of lesions assessed as present/absent by global assessment was analyzed using kappa. Reliability of detailed scoring was analyzed by intraclass correlation coefficient (ICC).

Results: Reliability of detection of active lesions was comparable irrespective of image format but structural lesions were detected more reliably on DICOM images (Table). In particular, the most frequently detected structural lesion, erosion, was detected to a comparable degree of reliability on DICOM images as the most frequently detected active lesion, subchondral inflammation. Fat metaplasia in the joint space (backfill) and ankylosis were also reliably detected despite low frequency of occurrence in this cohort. For detailed scores based on SPARCC methodology, mean (SD) was BME4.0(9.9), erosion 2.0(2.2), fatty lesion 1.1(3.3), backfill 0.4(3.2), ankylosis 0.05(0.2). Mean ICC was BME-0.84, Erosion-0.55, Fatty lesion (any)-0.61, Fatty lesion (>1cm depth)-0.55, Sclerosis-0.73, Fat metaplasia in joint space-0.36, Ankylosis-0.97.

Conclusion: The reliability of the ASAS_MRI_defⁿ was substantial for the most frequently detected lesions and comparable between active and structural lesions.

Table. Kappa values for detection of MRI lesions in the SIJ of patients in the ASAS-CC by 7 central readers.

	All images (n=278) Mean kappa of all reader pairs (95% CI)	DICOM images only (n=175) Mean kappa of all reader pairs (95% CI)
Active lesions typical of axSpA	0.74 (0.65-0.82)	0.70 (0.58-0.82)
Active lesions typical of axSpA (confidence ≥3) (-4(not SpA) to +4 (SpA) NRS scale)	0.77 (0.68-0.86)	0.80 (0.69-0.92)
ASAS positive MRI	0.75 (0.66-0.83)	0.73 (0.61-0.84)
ASAS positive MRI (confidence ≥3) (1-4 scale)	0.77 (0.68-0.86)	0.79 (0.67-0.90)
Structural lesions typical of axSpA	0.64 (0.54-0.75)	0.71 (0.59-0.83)
Structural lesions typical of axSpA (confidence ≥3) (-4(not SpA) to +4 (SpA) NRS scale)	0.62 (0.50-0.74)	0.75 (0.62-0.88)
Subchondral inflammation	0.65 (0.56-0.74)	0.60 (0.49-0.72)
Inflammation in erosion cavity	0.30 (0.13-0.47)	0.37 (0.15-0.58)
Capsulitis	0.40 (0.14-0.66)	0.55 (0.18-0.90)
Joint fluid	0.36 (0.21-0.50)	0.41 (0.23-0.59)
Enthesitis	0.21 (0.05-0.37)	0.23 (0.03-0.45)
Sclerosis	0.43 (0.30-0.55)	0.48 (0.33-0.63)
Erosion	0.55 (0.44-0.66)	0.61 (0.47-0.75)
Fatty lesion (any)	0.59 (0.47-0.71)	0.61 (0.46-0.76)
Fatty lesion >1cm	0.59 (0.43-0.75)	0.66 (0.47-0.84)
Fat metaplasia in joint space	0.46 (0.27-0.66)	0.50 (0.26-0.74)
Bone bud	0.13 (-0.05-0.30)	0.11 (-0.06-0.29)
Ankylosis	0.53 (0.21-0.83)	0.58 (0.25-0.89)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The 10-item SIMPLE screening questionnaire for axSpA is a patient self-report standardized questionnaire developed by rheumatologists from the Spondyloarthritis Research Consortium of Canada and patient consumers. It elicits responses to domains comprising inflammatory back pain (IBP). We aimed to test the construct validity of the items comprising this questionnaire by comparing responses with those elicited independently by rheumatologists and by evaluating their association with severity of back pain and diagnosis of axSpA.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA in consecutive patients presenting with undiagnosed back pain to the rheumatologist. Consecutive patients ≤ 45 years of age with ≥ 3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis undergo routine clinical evaluation by a rheumatologist for axSpA. Patients first complete the SIMPLE questionnaire and then the rheumatologist independently of any patient data determines the presence or absence of a diagnosis of axial SpA. Agreement between patient and physician reporting of questions reflecting IBP domains was analyzed using the kappa statistic. Proportions of patients reporting to the various IBP domain questions were compared according to back pain score ≥ 5 or < 5 (0-10NRS) using the chi-square. Associations between patient responses for different IBP domain items and a diagnosis of axSpA were analyzed by regression.

Results: 234 patients (51.3% male, mean age 34.6years, mean symptom duration 7.0 years, mean back pain duration 7.1 years, B27+36.3%) were referred with AAU (29.9%), psoriasis (18.8%), Crohn's colitis (32.1%), ulcerative colitis (19.2%). Patients responded to SIMPLE items reflecting stiffness, nocturnal awakening, improvement with exercise, and response to NSAID significantly more frequently when back pain score was ≥ 5 . Agreement between patient and physician reporting for IBP domains was substantial for duration of stiffness ($\kappa=0.57$) and nocturnal awakening ($\kappa=0.63$), but less for effect of exercise ($\kappa=0.30$), effect of rest ($\kappa=0.44$), and response to NSAID ($\kappa=0.31$). Most of the SIMPLE items were significantly associated with diagnosis of axSpA with the exception of items describing alleviation of symptoms by exercise and NSAID therapy (Table).

Conclusion: Patient reporting to IBP domains of stiffness and nocturnal pain are congruent with physician reporting and associate strongly with final diagnosis of axSpA. Reporting of impact of exercise and NSAID is variable and dependent on level of back pain.

Table.

SIMPLE ITEM	Odds Ratio (95%CI)	P value
Back stiffness yes and most noticeable - When I get out of bed	2.07 (1.20, 3.64)	0.01
Amount of Stiffness - 60 min or more duration	2.92 (1.60, 5.37)	0.00053
Nocturnal Awakening - Often	4.00 (2.26, 7.20)	0.00000024
Nocturnal Awakening - After several hours of sleep	2.50 (1.44, 4.38)	0.0012
Time of Day Symptoms are worst - Morning	2.72 (1.57, 4.77)	0.00042
Effect of Rest – Makes it worse	2.46 (1.39, 4.36)	0.0019

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of the study was to compare magnetic resonance imaging (MRI) and conventional radiography of the sacroiliac joints (SIJs) for detection of structural lesions typical for axial spondyloarthritis (axSpA) in an international multireader exercise with central reading of images in the ASAS cohort.

Methods: Patients with symptoms suggestive of SpA from the international ASAS Cohort who had both radiographs and T1-weighted MRIs of SIJs available for central reading were included in the study. MRI scans were assessed for structural changes compatible with axSpA (global statement) and separate changes such as erosion, sclerosis, fat metaplasia and ankylosis, by 7 central readers. Structural changes were considered as present if recorded by the majority of readers (at least 4 out of 7). Similar to MRIs, radiographs of the SIJs were scored by 3 different central readers according to the grading system of the modified New York (mNY) criteria. At the patient level, presence of definite structural damage on radiographs was defined as fulfillment of the radiographic criterion of the mNY criteria (sacroiliitis of at least grade 2 bilaterally or at least grade 3 unilaterally); at the single joint level, radiographic structural damage was defined as presence of sacroiliitis grade 2 in the opinion of at least 2 readers. Absolute agreement (percentage of patients / joints with or without structural changes on both MRI and radiography) and Kappa coefficient of agreement between MRI and radiography were determined.

Results: Overall, 199 patients (contributing 398 joints) were included. 149 (74.9%) had a diagnosis of axSpA by a local rheumatologist. Based on central reading, 102 (51.3%) had definite radiographic sacroiliitis according to them NY Criteria,

while 65 (32.7%) had structural changes suggestive of SpA on MRI according to the global assessment. The absolute agreement between MRI and radiographic assessment was 69.3% and kappa was 0.39 (Table 1). Structural lesions scored positive on x-rays could not be confirmed in a relative high percentage (48.1%) on MRI. At the single joint level, the absolute agreement between MRI and radiography was 70.4% and kappa was 0.39 (Table 2). Among structural lesions, erosions on MRI showed the best discriminative capacity regarding the structural damage on radiographs (Tables 1 and 2).

Conclusion: There was only modest agreement between MRI and conventional radiography in terms of detection of structural changes typical for SpA in the SIJs. Erosions on MRI showed the best agreement with the presence of definite structural damage on radiographs.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is known that radiographic progression of sacroiliitis in axial spondyloarthritis (axSpA) is quite slow, with only few predictors of such progression identified. An analysis of data from the Assessment of Spondyloarthritis International Society (ASAS) Cohort, based on local assessment of radiographs, revealed surprisingly high rate of regression from radiographic axSpA (r-axSpA) to non-radiographic axSpA (nr-axSpA). The objective of the study was to analyze the rates and predictors for radiographic progression of sacroiliitis in patients with axSpA from the ASAS Cohort, based on the central reading of radiographs.

Table. Factors associated with progression from non-radiographic axial spondyloarthritis to radiographic axial spondyloarthritis in the ASAS cohort after central reading.

Parameter at baseline	Univariable analysis OR (95% CI)	Multivariable model 1 OR (95% CI)	Multivariable model 2 OR (95% CI)	Multivariable model 3 OR (95% CI)
Male sex	3.85 (0.60 to 23.83)	-	-	-
Age at baseline, years	0.85 (0.75 to 0.96)	-	-	0.88 (0.76 to 1.05)
HLA-B27 status	4.24 (0.76 to 23.57)	-	-	-
Active lesions on MRI*	15.08 (1.68 to 135.54)	28.55 (1.85 to 441.70)	21.99 (1.31 to 360.13)	7.82 (0.37 to 168.14)
Chronic lesions on MRI*	5.83 (1.14 to 29.90)	-	1.99 (0.19 to 21.14)	4.90 (0.27 to 88.61)
Elevated CRP (local lab)	2.15 (0.46 to 9.99)	-	-	-
Sacroiliitis sum score	16.81 (2.29 to 123.66)	35.08 (2.32 to 530.99)	31.80 (2.15 to 470.16)	18.96 (1.15 to 312.11)

*MRI was assessed by local rheumatologists. ASAS - The Assessment of Spondyloarthritis

International Society, OR = odds ratio, CI = confidence interval, HLA-B27 = human leukocyte antigen B27, MRI = magnetic resonance imaging, CRP = C-reactive protein

Methods: A total of 205 patients included in the ASAS Cohort and diagnosed with axSpA by local rheumatologists, with baseline pelvic radiographs available for central reading, were included in the current study. Among them, 106 patients had a pelvic radiographs available at follow-up (mean follow-up time 4.4 ± 0.8 years). Images were independently assessed by 2 central readers (MP, FP), blinded for the chronology of the radiographs, according to the grading system of modified New York criteria (grade 0-4). In case of discrepancy in classification (nr-axSpA or r-axSpA), the final classification was defined by adjudicator (DP). Sacroiliitis sum score (0-8) was calculated based on scoring results of all readers as the sum of the mean scores of all readers for both joints. The primary outcome was the proportion of patients progressing from nr-axSpA to r-axSpA at follow-up. Predictors of progression were investigated in univariable and multivariable logistic regression analyses.

Results: Among 106 patients, 49 (46.2%) were classified as nr-axSpA, 57 (53.7%) as r-axSpA at baseline. The agreement between primary readers in classification (nr-axSpA or r-axSpA) was moderate to substantial ($\kappa=0.54$ – baseline, $\kappa=0.63$ – follow-up); between local and central readers – poor to moderate ($\kappa=0.18$ – baseline, $\kappa=0.58$ – follow-up). At follow-up, 8 (7.5%) patients progressed from nr-axSpA to AS, 6 (5.7%) were reclassified from AS to nr-axSpA. The sacroiliitis sum score increased in 43 (40.6%) patients, decreased in 21 (19.8%) and did not change in 42 (39.6%). Logistic regression analysis showed an association of active and chronic changes on baseline MRI, existing structural damage in sacroiliac joints at baseline and younger age with higher odds for progression from nr-axSpA to r-axSpA.

Conclusion: There was a low but still detectable progression from nr-axSpA to r-axSpA in the ASAS cohort over 4.4 years of follow-up. Active and chronic changes on MRI, initial structural damage on radiographs, and younger age at baseline were associated with higher odds for progression from nr-axSpA to r-axSpA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis(axSpA) is diagnosed an average of 9 years after symptom onset (1), partly because inflammatory back pain (IBP) can be difficult for primary care providers to differentiate from mechanical back pain (MBP). Untreated, axSpA can result in irreversible structural damage, functional loss and reduced quality of life. We evaluated a stratified screening process for early axSpA identification. Objectives: 1) measure time to diagnosis by a rheumatologist; 2) measure referral wait times from primary care physician (PCP) to rheumatology screening; 3) determine the incremental precision and accuracy of a stratified screening process from primary to rheumatology care.

Methods: Adults (18+ years) with low back pain visited their PCP or a dedicated interprofessional back pain model of care (www.isaac.org) and underwent primary screening, consisting of a standardized clinical assessment that incorporated ASAS criteria for IBP. At the primary care level, patients with back pain >3 months duration, onset age <50 years, with at least one other IBP feature were referred for a secondary screen by a physiotherapist with advanced rheumatology training. This screen included standardized history, physical examination and baseline investigations. The likelihood of axSpA risk (vs MBP) was determined at each screening level and defined as low, medium, or high. Precision and accuracy of primary and

secondary screens were measured against the clinical judgement of a rheumatologist with axSpA expertise. The utility of HLA-B27 was assessed as an independent screen. Sensitivity, specificity and predictive values were calculated.

Results: 410 patients underwent primary and secondary screening over a 3-year period. Mean age: 36.9 years (± 9.8); 55% female; average back pain duration 7 years (± 7.2). HLA-B27 was present in 14.4% of patients. Meantime from onset of back pain to diagnosis for patients with medium or high risk (as per rheumatologist) was 6 years (± 6.3), with a median delay of 3 years. Median wait time from primary to secondary screen was 22 days. AxSpA risk assignment by rheumatologist was: 63.6% MBP or low risk and 36.4% medium or high risk, with 18.0% of all patients receiving a final diagnosis of axSpA. HLA-B27 performed poorly as an independent screen (28% sensitivity). The best combination of sensitivity, specificity, and predictive values was found with the secondary screen (see table 1).

Conclusion: The inclusion of a secondary screening process utilizing a stratified inter professional model can shorten time to diagnosis, with high precision and accuracy in patients with axSpA. Findings provide a platform to bridge the gap between onset of back pain and diagnosis and thereby improve long-term outcomes in this patient population.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE), an IL-17A antagonist, was shown to be superior to placebo (PBO) in inhibiting the progression of structural joint damage in patients (pts) with PsA treated for 24 weeks (wks).¹ We assessed the progression of structural joint damage in PsA patients with IXE for up to 3 years

Methods: SPIRIT-P1 (NCT01695239) is a Phase3 clinical trial investigating IXE treatment in biologic DMARD-naïve pts with active PsA. Pts must have had ≥ 1 joint erosion on the hand and foot radiographs confirmed by central reading *or* had a C reactive protein level > 6 mg/L at screening. 417 pts were randomized to 80 mg IXE every 2 (Q2W; N=103) or 4 wks (Q4W; N=107) following a 160 mg initial dose, PBO (N=106), or 40 mg adalimumab Q2W (ADA; active reference arm; N=101) for 24 wks. PBO and ADA pts were re-randomized (1:1) to IXEQ2W or IXEQ4W at Wk 16 (inadequate responders) or 24. Analyses are presented for either only pts who entered the long-term extension (LTE; wks 52-156) or

were intent-to-treat (ITT; wks 0-156). Radiographs were scored independently by 2 readers blinded to time point and clinical data. All pts were assessed for structural joint damage using the van der Heijde modified PsA Total Sharp Score (mTSS, 0-528 scale, average of readers). For LTE patients, data is presented as linear extrapolation or as observed. For linear extrapolation, any missing post-baseline data were imputed if pts had a baseline and ≥ 1 post-baseline value (i.e. Wk 52, 108, or 156). For ITT patients, post-hoc data is presented from a mixed model for repeated measures (MMRM).

Results: Of pts initially randomized (N=417), 300 pts (72%) entered the LTE (Wks 52-156) and 243 pts completed SPIRIT-P1 (58%). Adverse events and lack of efficacy were the primary reasons for discontinuation. 260 LTE pts had radiographs. Of LTE pts, mean mTSS change from baseline values at Wk 52, 108, and 156 for all 6 treatment groups are presented (Table). Wk 156 mean (SD) mTSS change from baseline values (linear extrapolation) were 1.7 (6.6) and 1.0 (3.2) for pts initially randomized to IXEQ4W and IXEQ2W. The Wk 156 cumulative probability plot is presented (Figure 1). For ITT patients, Wk 156 least squares mean (SE) mTSS change from baseline values (MMRM) were 1.9 (0.4) and 0.9 (0.4) for pts initially randomized to IXEQ4W and IXEQ2W. For LTE pts initially randomized to IXE, the majority of pts had Wk 156 mTSS change from baseline values (linear extrapolation) ≤ 0 (IXEQ4W: 67%; IXEQ2W: 62%) or ≤ 0.5 (IXEQ4W: 74%; IXEQ2W: 70%).

Conclusion: Over a 3 year period, minimal changes in mTSS were observed in the majority of PsA pts treated with IXEQ2W or IXEQ4W.

Relative Contributions of Improvements in the Psoriasis Area and Severity Index (PASI) and Disease Activity Index for Psoriatic Arthritis (DAPSA) to Improvements in Quality of Life and Function in Patients with Psoriatic Arthritis

Alexis Ogdie¹, Prashanth Sunkureddi², Baojin Zhu³, Aubrey Spraberry⁴, William Malatestinic⁴, Yan Dong⁴ and David Shrom³, ¹University of Pennsylvania, Philadelphia, PA, ²Rheumatology, Clear Lake Rheumatology Center, Nassau Bay, TX, ³LRL, Eli Lilly and Company, Indianapolis, IN, ⁴Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous inflammatory condition characterized by the clinical domains of arthritis, enthesitis, dactylitis, spondylitis, and psoriasis. While it is known that both psoriasis and articular/periarticular symptoms have a meaningful impact on lives of PsA patients, it is not known the degree to which improvements in these symptoms independently contribute to improvements in quality of life (QoL) or function. This analysis quantifies the contributions of improvements in joint related symptoms (Disease Activity Index for PsA [DAPSA]) and skin related symptoms (Psoriasis Area and Severity Index [PASI]) to improvements in function(Health Assessment Questionnaire and Disability Index [HAQ-DI]) and skin-related quality of life (Dermatology Life Quality Index [DLQI]) using a multi-mediator analysis.

Methods: This analysis included data from a Phase 3 randomized clinical trial (SPIRIT-P1; NCT01695239) in biologic DMARD-naïve patients who met criteria for PsA who were randomly assigned to treatment groups (ixekizumab 80 mg

every 4 weeks [IXEQ4W, N=107], every 2 weeks [IXEQ2W, N=103], adalimumab [ADA, N=101] or placebo [PBO, N=106]). In this analysis, a multiple mediation model¹ was employed to assess the 'direct' and 'indirect (mediation)' effects of treatment on the DLQI and HAQ-DI at week 16 using percent improvement in DAPSA and PASI as the mediators. In the model, the indirect effects represent how much of the improvements in HAQ-DI or DLQI can be attributed to improvements in PASI or DAPSA. The direct effects represent the mean improvement in HAQ-DI or DLQI that cannot be accounted for by DAPSA or PASI improvements. Analyses were conducted on the intent-to-treat population and in patients with $\geq 3\%$ and $\geq 10\%$ body surface area (BSA) psoriasis involvement. Missing data was imputed using the last observation carried forward.

Results: The relative contributions of DAPSA or PASI improvements to improvements in HAQ-DI and DLQI for each treatment arm over placebo are shown in the Figure. Improvements in DAPSA accounted for the majority of improvements observed in HAQ-DI, and improvements in PASI accounted for the majority of improvements in DLQI. In patients with moderate (BSA $\geq 3\%$) or severe (BSA $\geq 10\%$) psoriasis, PASI had higher levels of contribution to both HAQ-DI and DLQI.

Conclusion: These results indicate that improvements in both joint and skin symptoms play a role in improving different aspects of function and QoL for PsA patients. While DAPSA was the most substantial contributor to improvements in HAQ-DI, the skin also plays a role, potentially through the effect of skin symptoms such as itching and skin pain on some domains of the HAQ-DI such as grooming or hygiene.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral manifestations (arthritis, enthesitis and dactylitis) can be observed in patients with Spondyloarthritis (SpA), but the factors associated with their presence are not well known. Studies are needed in order to thoroughly evaluate these symptoms. For this, we conducted an analysis aiming to: a) describe the prevalence of peripheral manifestations in patients with SpA in a world-wide population; b) determine the factors associated with the presence of these manifestations.

Methods: Data from the ASAS-COMOSPA study were analysed. The prevalence of each peripheral manifestation was evaluated with regard to the criteria fulfilled by the patient (ASAS axial, ASAS peripheral, CASPAR) and with regard to the time of occurrence of axial symptoms (before/concomitant/after). Factors associated with the presence of these peripheral manifestations were also explored by univariate and multivariate logistic regression.

Results: Out of the 3984 patients included in ASAS-COMOSPA, 2562 (64.3%) reported, at least, one peripheral manifestation. Among these, 2051 patients (51.5% from the total database) had current or past history of peripheral arthritis, being more frequent among patients who met CASPAR and Peripheral ASAS criteria (see Figure 1). Involvement was more frequently oligoarticular (40.2%) and appearing after axial symptom onset (48.9%). Multivariate analysis showed that patients from South America [OR 2.01, (95%CI 1.54 – 2.64)], the presence of enthesitis [OR 2.48, (95%CI 2.13 – 2.88)], dactylitis [OR 6.62, (95%CI 4.09 – 8.93)], skin psoriasis [OR 3.79, (95%CI 2.90 – 4.96)], HLAB27+ [OR 0.81, (95%CI 0.69 – 0.94)] and inflammatory back pain (IBP) [OR 0.81, (95%CI 0.69 – 0.94)] were associated with peripheral arthritis.

A total of 1506 (37.8%) and 618 (15.6%) patients reported enthesitis and dactylitis, respectively. Both occurred after axial symptoms onset in 58.3% and 60.8% of the patients, respectively. Similar results than peripheral arthritis were obtained in

the multivariate analysis regarding these two peripheral manifestations, with exception of IBP and HLAB27+, which were not associated with enthesitis.

Conclusion: Peripheral manifestations appear in 64% of patients with SpA and in more than 50% after axial symptoms onset. Peripheral arthritis, were more frequently mono- or oligo- rather than poly-articular, and the presence of psoriasis or any of the three peripheral manifestations acts as risk factor for the development of other peripheral symptoms.

Abstract Number: 665

Impact of Peripheral Manifestations on Patient-Reported Outcomes (PROs) and Treatment in Spondyloarthritis. Data from ASAS-Comospa

Clementina López-Medina¹, Anna Molto² and Maxime Dougados³, ¹Rheumatology Department, Cochin Hospital, Paris, France, ²Hôpital Cochin, Department of Rheumatology, Paris Descartes University, Paris, France, ³Department of Rheumatology, Paris Descartes University and Cochin Hospital, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral manifestations (arthritis, enthesitis and dactylitis) are frequent in patients with Spondyloarthritis(SpA). However, little is known regarding the impact of these manifestations on patients' disease perception and treatments. In this analysis, we aimed to evaluate the impact of the presence of peripheral manifestations on patient-reported outcomes (PROs) and treatment.

Methods: Data from the ASAS-COMOSPA study were analysed. Patients who reported peripheral arthritis were divided into three groups: current, past history and no history. The impact of the presence of peripheral arthritis on VAS-G (Global Visual Analogue Scale), BASDAI (Bath Ankylosing Spondylitis Activity Index), BASFI (Bath Ankylosing Spondylitis Functional Index), work and activity impairment was evaluated through the use of the ANOVA one factor test. Finally, NSAIDs, corticosteroids and DMARDs intake were compared among patients with and without peripheral articular involvement.

A similar statistical analysis was performed for enthesitis and dactylitis.

Results: Among the 3984 patients included in the ASAS-COMOSPA study, 1333 (33.5%), 718 (18%) and 1933 (48.5%) patients had current, past history and no history of peripheral arthritis, respectively. Patients with current peripheral arthritis showed higher levels in VAS-G, BASDAI, BASFI, as well as in work and activity impairment, in comparison to the other two groups, being these differences statistically significant ($p < 0.01$). Patients with peripheral articular involvement at the time of the visit showed higher mean scores in all questions of the BASDAI questionnaire, in contrast to those with past history and/or no history ($p < 0.001$). Impact on treatment is shown in table 1. Regarding enthesitis, 642 (16.1%), 864 (21.7%) and 2478 (62.2%) patients had current, past history and no history of enthesitis, respectively. Patients with current enthesitis showed significant higher levels in all PROs against the other two groups of patients ($p < 0.05$), as well as higher scores in all the BASDAI questions ($p < 0.001$).

	Current or past history of arthritis			Current or past history of enthesitis			Current or past history of dactylitis		
	Yes = 2051 n (%)	No = 328 n (%)	p-value	Yes = 1506 n (%)	No = 2478 n (%)	p-value	Yes = 618 n (%)	No = 3366 n (%)	p-value
% of patients using NSAIDs	1858 (90.6)	1690 (87.4)	<0.001	1402 (93.1)	2146 (86.6)	<0.001	568 (91.9)	2980 (88.5)	0.013
% patients using csDMARDs	1581 (77.1)	790 (40.9)	<0.001	1062 (70.5)	1309 (52.8)	<0.001	492 (79.6)	1879 (55.8)	<0.001
% patients using bDMARDs	987 (48.1)	755 (39.1)	<0.001	750 (49.8)	992 (40.0)	<0.001	330 (53.4)	1412 (41.9)	<0.001
% patients using corticosteroids	1048 (51.1)	475 (24.6)	<0.001	738 (49.0)	785 (31.7)	<0.001	330 (53.4)	1193 (35.4)	<0.001

Finally, 171 (4.3%), 447 (11.2%) and 3366 (84.5%) patients had current, past history and no history of dactylitis, respectively. The same results as the other two peripheral manifestations were obtained regarding impact on PROs and BASDAI questions

Conclusion: The presence of any of the three peripheral manifestations at the time of the visit was associated to higher scores in all PROs. Patients with peripheral involvement showed greater use of NSAIDs, corticosteroids and DMARDs than those without peripheral manifestations.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The effect of MRI-detected inflammation on the development of radiographic damage at the sacroiliac joints (SIJ) level in patients (pts) with axial SpA (axSpA) has been previously shown when images were scored by trained central readers¹. Central reading decreases measurement error, but does not translate easily to what is usually done in clinical practice. We aimed to test the possible effect of MRI-SIJ inflammation on structural damage in X-SIJ, when both are assessed by local readers as in daily clinical practice.

Methods: Pts with axSpA from both the ASAS and DESIR cohorts were included. MRI-SIJ and X-SIJ were obtained at baseline (BL), and X-SIJ at follow-up (ASAS: mean 4.4years; DESIR: 5 years) and scored by local readers (rheumatologists/radiologists). Images were taken unblinded to other imaging information and clinical characteristics.

Figure. Net progression from mNY-negative to mNY-positive according to baseline objective inflammatory markers in the ASAS (A) and DESIR (B) cohorts (ASAS: N=125; 25 patients miss baseline MRI-SIJ; DESIR: N=398; 6 patients miss baseline MRI-SIJ and 17 patients miss baseline CRP).

Table. Effect of inflammation on MRI-SIJ at baseline on X-SIJ structural damage at follow-up.

Predictor	Outcome	mNY
		OR (95% CI)
Sacroiliitis on MRI-SIJ (ASAS-cohort)		3.1 (1.3; 7.9) *
Sacroiliitis on MRI-SIJ (DESIR-cohort)		7.4 (4.3; 12.7) *

* Adjusted for gender, HLA-B27, CRP, symptom duration.

Readers had the option to view the BL image when scoring the follow-up image. Bone Marrow Edema (BME) at MRI-SIJ was assessed either without a formal definition (ASAS) or according to the ASAS definition (DESIR). Structural damage in the X-SIJ was defined according to the mNY criteria. The % of structural net progression (number of ‘progressors’ minus the number of ‘regressors’ divided by the total number of pts) was assessed in subgroups according to CRP and BME status at BL. The effect of BME on MRI-SIJ on X-SIJ damage was evaluated in logistic regression models adjusted for potential confounders selected *a priori* on clinical grounds (gender, HLA-B27, CRP, symptom duration, variables available in both cohorts).

Results: In total, 125 (ASAS-cohort) and 415 (DESIR-cohort) pts had complete 5-year X-SIJ data available. Remarkably, but not unexpectedly, the % of ‘improvements in X-SIJ’ was impressive both in the ASAS and DESIR cohorts (8.8% and 5.5% respectively), yielding a total % of net progression that was higher in the former than in the latter (19.2% and 6.3%). Net progression in X-SIJ ranged from 0.0% to 33% and from 0% to 17.4% according to the presence of objective signs of inflammation at BL in the ASAS- and DESIR-cohorts, respectively (figure). In the multivariable analysis, the presence of baseline BME at MRI-SIJ both in the ASAS (OR=3.1 [95%CI: 1.3-7.9]), and DESIR cohorts (OR=7.4 [95% CI: 4.3-12.7]) was highly associated with X-SIJ structural progression at follow-up (table).

Conclusion: Our results, obtained in two independent cohorts, show that despite the expected increased ‘noise’ (measurement error) invoked by local reading, inflammation on MRI-SIJ still clearly associates with the development of radiographic damage in axSpA.

Assessment of Radiographic Sacroiliitis on Antero-Posterior Lumbar Radiographs As Compared to Conventional Pelvic Radiographs in Patients with Axial Spondyloarthritis

Valeria Rios Rodriguez¹, Maria Llop Vilaltella¹, Mikhail Protopopov¹, Joachim Sieper², Hiltrun Haibel¹, Martin Rudwaleit³ and Denis Poddubnyy⁴, ¹Charité Universitätsmedizin Berlin, Berlin, Germany, ²University Clinic Benjamin Franklin, Berlin, Germany, ³Department of Internal Medicine and Rheumatology, Klinikum Bielefeld, Bielefeld, Germany, ⁴Charité Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR guidelines consider conventional radiograph of sacroiliac joints (SIJs) as the first recommended imaging method in case of suspected axial spondyloarthritis (axSpA). However, it is not clear whether sacroiliac joints can be reliably assessed on anteroposterior (AP) lumbar radiographs, which are often performed as a part of the diagnostic work-up in patients presented with back pain. The aim of the study is to investigate reliability and validity of radiographic sacroiliitis assessment on AP lumbar radiographs as compared to conventional pelvic radiographs in patients with axSpA.

Methods: Patients from the GERman SPondyloarthritis Inception Cohort (GESPIC) were selected based on the availability of sets of pelvic and AP lumbar radiographs with visible SIJs at baseline and after 2 years of follow-up. Two trained readers (ML and VR) scored the images independently and in a random order according to the radiographic system of the modified New York (mNY) criteria (grade 0 to 4). The sacroiliitis sum score (0-8) was calculated as a sum of the mean grades of 2 readers for the right and left SIJ. We assessed intra- and inter-reader reliability using intraclass correlation coefficients (ICC) of the sacroiliitis sum scores.

Figure. Classification as non-radiographic or radiographic axial spondylarthritis based on sacroiliitis assessment on conventional pelvic and anteroposterior lumbar radiographs.

Results: A total of 226 sets radiographs were scored from 113 patients included in the present study. The intra-observer agreement was good to excellent for the sacroiliitis sum score of pelvic vs. AP lumbar radiographs at baseline (ICC 0.80 for ML and 0.74 for VR) and at year 2 (ICC 0.81 for ML and 0.77 for VR). The inter-observer agreement for pelvic and AP lumbar radiographs was also good to excellent: ICC at baseline: 0.81 and 0.73, respectively, at year 2: 0.76 and 0.79, respectively.

A total of 62 (54.9%) and 55 (48.7%) patients were classified as r-axSpA at baseline based on evaluation of pelvic and AP lumbar radiographs, respectively. The absolute agreement on the classification was 84.9% (figure). A total of 17 patients (12 (10.6%) with nr-axSpA and 5 (4.4%) with r-axSpA) were classified differently based on assessment of AP lumbar as compared to conventional pelvic radiographs (figure).

After 2 years of follow-up, progression from nr- to r-axSpA occurred in 7 patients (6.2%) and 8 patients (7.1%) classified as nr-axSpA at baseline based on pelvic or AP lumbar radiographs assessment, respectively. Regression from r- to nr-axSpA occurred in 4 patients (3.5%) and 3 patients (2.7%) on pelvic or AP lumbar radiographs, respectively, giving respective net progression rates of 2.7% and 4.4%.

Conclusion: Radiographic sacroiliitis can be assessed on AP lumbar radiographs with a similar reliability as on conventional pelvic radiographs.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial psoriatic arthritis (axPsA) lacks a universally accepted definition. Initial studies required \geq unilateral grade 2 sacroiliitis (Uni2SI) but recent studies have required the modified radiographic New York ankylosing

spondylitis criteria (NYC) (bilateral grade 2 or unilateral grade 3 or 4 sacroiliitis). Our aims were: 1) assess the prevalence of axial involvement in a PsA cohort according to “at least Uni2SI”, 2) assess the radiographic progression of Uni2SI, 3) identify risk factors associated with progression, 4) define axPsA.

Methods: PsA patients participating in a prospective observational cohort were classified according to their worst sacroiliitis ever observed during their follow-up. The baseline features of patients with only uni2SI were compared to patients with NYC. The progression of Uni2SI was assessed in a sub-group of patients with: uni2SI on one of their radiographs and following x-rays. A comparison was made between the “non-progressors” and “progressors” (=patients who developed NYC over time). T-test, Wilcoxon rank sum test and Chi-square tests were used for descriptive analyses. Logistic regression identified risk factors associated with NYC compared to Uni2SI. Risk factors associated with radiographic progression of Uni2SI were identified in a survival analysis with interval censoring. P<0.05 was considered statistically significant.

Results: At least Uni2SI was detected in 612/1354 patients (45%). NYC sacroiliitis was observed in 477 patients (35%). Radiographic progression of Uni2SI was assessed in 154 patients, 80 (52%) progressed to NYC sacroiliitis within 5.5 years. The progressors were diagnosed at a younger age (35.6, 38.9, p=0.05), had less degenerative disc disease (DDD) (OR= 0.47, p=0.02), worse peripheral radiographic damage (OR=1.02, p=0.03) and psoriasis (OR=1.09, p=0.01) compared to non-progressors. Other demographic, clinical and radiographic variables were not associated with NYC sacroiliitis (table). In a survival analysis, patients with an elevated erythrocyte sedimentation rate (ESR) were more likely to progress (HR = 1.83, p=0.02), while patients with longer disease duration were less likely to progress (HR=0.95, p=0.02).

Patients with NYC vs “non-progressors” (unilateral grade 2 as reference group) Regression Analysis

Variable at baseline	Univariate			multivariate		
	OR	95% CI	P value	OR	95% CI	P value
Age of diagnosis	0.98	0.96-1	0.05			
Age at x ray *	0.99	0.97-1	0.23	0.99	0.97- 1.01	0.45
Male sex*	1.54	0.93-2.54	0.09	1.67	0.94- 2.95	0.08
HLA-B*27 positivity	1.11	0.59-2.09	0.75			
Smoking	0.93	0.56-1.54	0.78			
Tender and swollen joints	1	0.98-1.03	0.86			
Clinically damaged joints	1.01	0.98-1.04	0.33			
Modified Steinbrocker score	1.01	1-1.02	0.03	1.02	1- 1.03	0.03
Inflammatory back pain	1.29	0.59-2.81	0.53			
Syndesmophytes	1.46	0.87-2.45	0.15			
Degenerative disc disease	0.47	0.28-0.79	0.004	0.47	0.25- 0.87	0.02
SPARCC enthesitis score	0.83	0.64-1.09	0.19			
PASI	1.07	1.02-1.13	0.01	1.09	1.02- 1.17	0.01
Nail disease	0.86	0.48-1.53	0.61			
Elevated ESR	1.48	0.9-2.45	0.12			
Biologics	1.86	0.78-4.46	0.16			
NSAIDS	1.06	0.62-1.82	0.82			

* adjusted variables

PASI=psoriasis area severity index; ESR=erythrocyte sedimentation rate; SPARCC=spondyloarthritis Research Consortium of Canada; NSAIDS=non-steroidal anti-inflammatory drugs

Conclusion: Only half of patients with Uni2SI progressed to NYC sacroiliitis. Young patients with a short disease duration elevated ESR and with less DDD are at increased risk of progressing. Therefore, we recommend using the NYC for the definition of axPsA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute anterior uveitis (AAU) can be associated with axial spondyloarthritis (axSpA). Previous studies even described undetected axSpA in 40% of the patients with noninfectious AAU. Currently, axSpA patients still suffer an important diagnostic delay. The objective was to investigate whether referral of all patients with AAU and chronic back pain results in a high prevalence of newly diagnosed axSpA patients.

Methods: In April 2017 the prospective (ongoing) observational Sp-EYE study was started to include all patients with noninfectious AAU and chronic back pain (≥ 3 months, started $<$ age of 45 years) who were referred from nine Ophthalmology clinics to the Rheumatology department of the VU university medical center. Exclusion criteria were: history of a rheumatic or other known systemic disease associated with uveitis. At the Rheumatology department sociodemographic, clinical (e.g. duration of back pain, extra-articular manifestations, BASMI), laboratory (HLA-B27, C-reactive protein) and radiographic parameters were collected, as well as patient reported outcome parameters (e.g. BASDAI, ASDAS, ASAS Health Index). The diagnosis of axSpA was made by the rheumatologist. According to the ASAS criteria, diagnosed patients were classified into radiographic or non-radiographic axial spondyloarthritis.

Results: In the first year, 42 patients were referred to the Rheumatology department, of whom 32 (median age 35 years; 47% female) met all the inclusion criteria. See also table 1. At referral, 63% of the patients already had a history of more than one AAU and the median back pain duration was 11 years (table 1). AxSpA was diagnosed in 10 patients (31%, all HLA-B27 positive), of whom four fulfilled the criteria for radiographic and six for non-radiographic axSpA. Another 11 patients (34%, six HLA-B27 positive) were considered to be suspicious for early axSpA. An ASDAS-CRP score corresponding to a high disease activity ($\text{ASDAS} \geq 2.1$) was found in 57% of the patients with a new diagnosis or a suspicion for axSpA. Treatment was started in 20 patients, mostly with nonsteroidal anti-inflammatory drugs (in 18). In one patient a tumor necrosis factor alpha inhibitor was started shortly after diagnosis, because of the severity of the axSpA.

Conclusion: In this study the referral of noninfectious AAU patients with chronic back pain led to a notably high number of new diagnoses of axSpA (31%). Another third of the patients was considered to be suspicious for beginning axSpA, requiring further follow up. These results stress the importance of systematic referral of AAU patients from the ophthalmologist to the rheumatologist in order to improve early recognition of axSpA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal antibody that neutralizes IL-17A, improved signs and symptoms of ankylosing spondylitis (AS) in patients (pts) in the MEASURE 1 core trial at 2 years and through 4 years in the extension study.^{1,2} A low radiographic progression rate was also reported through 2 years (Δ mSASSS at Year 2=0.3).¹ Comparison of anti-TNF agents with historical NSAID-treated cohorts have not shown a significant benefit at 2 years in reducing radiographic progression.^{3,4} This retrospective analysis compared spinal radiographic progression over 2 years in the MEASURE 1 cohort of secukinumab-treated AS pts (C1; NCT01358175) vs a historical cohort of biologic-naïve AS pts (ENRADAS [C2; NCT00715091]).⁵

Methods: Baseline (BL) and 2-year X-ray data from the 2 cohorts were compared. Only data from pts with X-rays at BL (up to Day 30) and Year 2 (Days 31–743) were included (n=168 [C1], n=69 [C2]). X-rays were independently re-evaluated using the mSASSS by 2 reviewers (and an adjudicator for the top 10% of cases with the highest difference in Δ mSASSS between readers) who were blinded to sequence and treatment; averaged values (or the adjudicated score) were analysed.

Radiographic status at Year 2			
	C1 (MEASURE 1) N=168	C2 (ENRADAS) N=69	Odds ratio (95% CI), p-value
BL mSASSS, Mean (SD)	9.55 (14.14)	9.85 (13.78)	
mSASSS at Year 2, Mean (SD)	10.15 (14.70)	10.35 (14.65)	
Δ mSASSS over 2 years, LS mean (SE)	0.55 (0.14)	0.50 (0.22)	p=0.185
No progression (Δ mSASSS ≤ 0), %	61%	50%	1.43 (0.78, 2.60), p=0.243
No progression (Δ mSASSS < 0), %	62%	73%	1.84 (0.60, 5.77), p=0.593
Sensitivity analyses			
	MEASURE 1 (N=201; ENRADAS (N=122) n (% of N)	LS mean change (SE) from Baseline in mSASSS	Difference in LS means (SE) (MEASURE 1 vs. ENRADAS) p-value
Sensitivity analysis set 1 (BL to Day 30-817)	M: 178 (89%) E: 62 (51%)	M: 0.66 (0.153) E: 0.72 (0.225)	-0.03 (0.272) p=0.9175
Sensitivity analysis set 2 (All patients)*	M: 201 (100%) E: 122 (100%)	M: 0.64 (0.165) E: 1.06 (0.212)	-0.43 (0.280) p=0.1140
Sensitivity analysis set 3 (All patients, time-adjusted)*	M: 201 (100%) E: 122 (100%)	M: 0.66 (0.168) E: 0.99 (0.217)	-0.31 (0.280) p=0.2636
LS, least squares; CI, confidence interval; E, ENRADAS; LS, least squares; M, MEASURE 1; SE, standard deviation; SD, standard deviation			

The primary outcome was to compare the % pts with no radiographic progression (Δ mSASSS at Year 2 ≤ 0) in C1 vs C2. The difference between C1 and C2 was analysed using a logistic regression with cohort as a factor and BL mSASSS as a covariate. Sensitivity analyses were performed to assess the robustness of the comparison between the two cohorts using sensitivity analysis set 1 (BL to Days 640–819) and sensitivity analysis set 2 (all subjects with BL and post-BL X-rays [time-adjusted and unadjusted]).

Results: BL demographics were comparable across cohorts, with mean age 40.9 vs 42.6 years, and gender 72.8% vs 66.7% male in C1 vs C2, respectively. Over 2 years, least squares (LS) mean Δ mSASSS was 0.55 for C1 vs 0.89 for C2 ($p=0.185$) and % pts with no radiographic progression (Δ mSASSS at Year 2 ≤ 0) was slightly higher in C1 vs C2. Mean changes from BL in mSASSS were numerically lower in the MEASURE 1 vs ENRADAS cohorts across all the analyses performed (Table).

Conclusion: Over 2 years, a numerically lower rate of progression was seen in secukinumab-treated pts vs a control cohort of biologic-naïve AS pts. Further research is needed to understand the impact of IL-17A inhibition with secukinumab on spinal disease progression in AS pts; SURPASS (NCT03259074), an ongoing H2H study powered to compare differences in spinal radiographic progression with secukinumab vs biosimilar adalimumab, will help answer these questions.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There are many scores available to measure radiographic joint damage in patients with PsA, but most of them were developed for RA and then modified for PsA. These scores don't evaluate juxtaarticular bone proliferation, which is included as an item in the CASPAR criteria. The aim of our study was to validate the Reductive X-Ray Score for Psoriatic Arthritis (ReXSPA) score in a cohort of patients with PsA.

Methods: A cross-sectional study was carried out, patients ≥ 18 years old with PsA according to CASPAR criteria were included. Sociodemographic data, comorbidities, clinical characteristics, morning stiffness, pain and patient and physician global assessments (by NVS), joint count (66/68), dactylitis, enthesitis (MASES), cutaneous psoriasis (PASI), ESR and CRP were consigned. The self-questionnaires HAQ-A, BASDAI, BASFI, PsAQoL and DLQI were administered. The composite DAPSA and CPDAI indices were calculated and the presence of MDA was assessed. All patients underwent X-

rays of the hands and feet in the anteroposterior view. Two blind readers for the clinical characteristics of the patients and previously trained, scored them by Sharp van der Heijde modified for PsA (PsA-SvdHm) and ReXSPA indexes (ICC>0.94). The ReXSPA score evaluates a total of 22 joints in hands and feet. It values joint narrowing and erosion according to PsA-SvdHm and proliferation by Ratingen score. Time to read and calculate both scores were measured. *Statistical analysis:* Student T and Chi² test. Spearman correlation. Lineal regression analysis.

Results: A total of 66 patients were included, half of them were female, median (*m*) age of 56 years (IQR 43-62.3) and *m* disease duration of 8 years (IQR 4-14.3). 132 X-Rays were scored according to PsA-SvdH [*m* 35 (IQR: 16.3-72.5)] and ReXSPA [*m* 22 (IQR: 7-46.3)]. Time to read them was significantly shorter with ReXSPA than PsA-SvdH (mean 5.8±2.1 vs 7.5±2.5 minutes, *p*<0.0001), as well as, time to calculate them (mean 26.5±14.7 vs 55.3±38.3 seconds, *p*<0.0001), respectively. The correlation between both indexes was excellent (Rho: 0.93). In the multivariate analysis, using both radiographic scores as dependent variable, the association with disease duration remained significantly associated with both of them, and in the case of ReXSPA also with age.

Conclusion: The ReXSPA index has shown validity and a very good correlation with PsA-SvdH. It is quicker to read and calculate. Subsequent longitudinal evaluations will allow to demonstrate the validity of these findings and to determine if the evaluation of bone proliferation adds an additional advantage.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: NLRP3 inflammasome is a molecular platform triggering activation of inflammatory cytokines including interleukin-1b (IL-1b). This study aimed to assess the expression of NLRP3 inflammasome complex and pro-inflammatory cytokines in patients with ankylosing spondylitis (AS).

Methods: Peripheral blood mononuclear cells (PBMCs) and serum from 23 male patients and gender-matched 30 healthy controls were consecutively collected. The mRNA expression for target genes including NLRP3, caspase-1, IL-1b, IL-17A, and IL-23 from PBMCs were evaluated by quantitative real-time polymerase chain reaction (qRT-PCR). Clinical information related with AS patients were collected including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), peripheral arthritis, enthesitis, and extraarticular manifestations. Statistical analyses were performed using Spearman's correlation coefficient and Mann-Whitney *t* test.

Results: Higher mRNA expression of NLRP3, caspase-1, IL-1b, IL-17A, and IL-23 in AS was noted than those in controls (*p* = 0.010, *p* = 0.029, *p* = 0.005, *p* = 0.046, and *p* = 0.002, respectively). Patients treated with biological diseases modifying antirheumatic drugs (bDMARDs) showed significantly lower caspase-1, IL-1b, and IL-17A mRNA levels than those without bDMARDs, but not in IL-23 and NLRP3. NLRP3 mRNA levels were significantly associated with IL-23, IL-17A, caspase-1, and IL-1b (*p* < 0.05 of all). Increased NLRP3, caspase-1, IL-1b, IL-17A, and IL-23 mRNA expression in PBMC cultured with LPS was marked attenuated by antioxidants.

Conclusion: This study suggests that inflammatory response by activation of NLRP3 inflammasome might be involved in the pathogenesis of AS.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We examined first degree relatives (FDRs) of patients with ankylosing spondylitis (AS) patients with chronic inflammatory back pain (CIBP), non-inflammatory CBP (NICBP) and no CBP for clinical features (comparing those with and without CIBP and with people participating in NHANES 2009-2010 with CBP. We examined HLA-B27 alleles and persistence of IBP over time in those with CBP.

Methods: 548 FDRs of 302 AS probands were divided into 3 groups, excluding those with a diagnosis of AS at baseline visit and, within each group, blood relatives: 1) No CBP (only subjects > 40 years of age at study visit who never had CBP) (n=159); 2) NICBP (n=79), and 3) CIBP (n=152). The white FDRs with CBP between ages 20 and 69 years were compared with 772 participants in NHANES 2009-2010 with CBP, to whom the same questionnaire was administered. HLA-B allele typing was carried out by single stranded conformation polymorphism analysis. FDRs were invited to return for a second visit either by mail or by repeat clinical evaluation.

Results:

1) FDRs with CIBP were younger than those with NICBP (45.1 years versus 55.6 years, $p=0.0002$), and had higher frequency of heel pain (52.7% versus 43.4%, $p=0.005$). HLA-B27 occurred in 57% of FDR's with CIBP compared 49.4% with NICBP ($p=n.s.$) and 39.6% of those >40 years of age at assessment with no CBP ($p=0.005$, OR=1.9).
2) Comparing 206 unrelated white FDRs (there were too few nonwhite FDR's available for meaningful analysis) with 772 white participants in NHANES 2009-2010 with CBP, there were no significant differences in features of IBP, in fact some features (pain improving as the day progresses, AM stiffness, awakening the second half of the night) were less common in FDRs with CBP compared with the general population (Table 1). On the other hand, other features of SpA (earlier age at CBP onset, uveitis, psoriasis) were more frequent in FDRs of AS patients.

Variable	AS-FDR with CBP% (N=206)	NHANES with CBP% (N=772)	*p	**p
Male	40.5	45.9	0.19	0.20
Morning stiffness >30 minutes	44.3	48.6	0.0008	0.0042
Back pain decreases as the day progresses	19.4	22.7	<0.0001	<0.0001
Back pain awakens after 4 hours sleep	57.2	74.8	<0.0001	<0.0001
Heel pain > 2 weeks	35.5	19.6	<0.0001	<0.0001
Iritis/uveitis	4.5	0.59	<0.0001	0.0005
Psoriasis	9.6	5.3	0.026	0.029
Age at CBP onset (years)	29.0+/-13.8	32.7+/-14.1	0.0006	0.0038

*p-value based on univariable model ** p-value based on multivariable model (adjusted for age and gender)

3) Of 23 patients with CIBP at baseline seen again 67.04+/- 31.02 months later, 16 (73%) still had CIBP, whereas only four (33%) of 13 NICBP patients (31%) seen 61.23 +/- 31.84 months later were still symptomatic. Of the remaining nine, three (23%) developed CIBP and six (46%) had symptoms resolve. Of the 13 without CBP at baseline seen 75.5 +/- 29.9 months later, 11(85%) remained asymptomatic, two (15%) developed CIBP and none developed noninflammatory CBP.

Conclusion: These data suggest FDRs of AS patients with CIBP have a younger age at onset, a higher frequency of heel pain, and higher frequency of HLA-B27 than those FDRs who do not develop CBP and compared to the general US population (though other features of CIBP were not more frequently seen). CIBP in FDRs of AS patients remains stable and chronic over time in most, suggesting a need for long term diagnostic and treatment approaches in this group.

Abstract Number: 674

Defining the Therapeutic Target in Psoriatic Arthritis: MDA Versus Dapsa

Andrea Lujan Coronel Ale¹, Osvaldo Luis Cerda¹, Marina Natalia Fornaro², Carolina Ayelen Isnardi³, Emilce E Schneeberger⁴ and Gustavo Citera¹, ¹Rheumatology Section, Instituto de Rehabilitación Psicosfísica, CABA, Argentina, ²Section of Rheumatology, Instituto de Rehabilitación Psicosfísica, buenos aires, Argentina, ³Reumatology, Instituto de Rehabilitación Psicosfísica, CABA, Argentina, ⁴Instituto de Rehabilitación Psicosfísica, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: T2T guidelines for psoriatic arthritis (PsA) propose using DAPSA or MDA to define the therapeutic target, but with differences in preference among experts. Objective: To determine the performance of MDA and DAPSA in the evaluation of disease activity in PsA patients.

Methods: Patients with PsA according to CASPAR criteria ≥ 18 years old were included. Sociodemographic data, comorbidities and current treatment were registered. Morning stiffness, pain, patient's (PtGA) and physician's global assessment (PGA) were consigned. Joint count (66/68), dactylitis, enthesitis (MASES), Psoriasis (PASI) and axial mobility (BASMI) were evaluated. ESR (mm/h) and CRP (mg/dl) were determined. Self-questionnaires were performed to assess: quality of life (PsAQoL, ASQoL), functional capacity (HAQ, BASFI) and disease activity (BASDAI). The composite indices were calculated: DAPSA, DAPSA-ESR, DAS28, CDAI, SDAI, CPDAI, and minimal disease activity (MDA). *Statistical analysis:* Descriptive statistics. Student's T test and ANOVA. Chi² test, Fisher exact test.

Results: 129 patients were included, 52.7% were male, with a median age of 56 years (IQR: 44-65). The median disease duration was 12 years (IQR: 7-18) and the median psoriasis duration was 21 years (IQR: 14-30). 58.9% had peripheral joint involvement, 2.3% axial involvement and 38.8% presented mixed involvement. The median of DAPSA was 13.3 (IQR: 7.4-21.7) and according to its cut-off values 3.9% of the patients were in remission, 26% in low disease activity, 55.8% in moderate and 14.3% in high disease activity. 31 patients (24%) met the MDA criteria. The cohort was dichotomized according to DAPSA: in those in remission and low activity, T2T group (10 and 56 respectively, total 66 patients) and in those with moderate and high disease activity, no T2T group (43 and 20 respectively, total 63 patients). We observed that 100% of patients who met MDA criteria were in remission and low disease activity categories by DAPSA. On the other hand, among patients who did not meet the MDA criteria, 46% had moderate and high disease activity according to DAPSA, while 35% (34 patients) were in low disease activity. The main reasons because of these patients did not meet MDA criteria, were: pain ≥ 15 mm (100%), PtGA ≥ 20 mm (79%) HAQ-A ≥ 0.5 (62%) and PASI ≥ 1 (56%). Of the 34 MDA/DAPSA discordant patients, a therapeutic change was made only in 11 of them, and they were: change of pharmacological treatment (55%), joint infiltration (27%) and consultation with the dermatologist due to skin disease activity (18%). The only variable associated with a therapeutic change was higher joint tender count in the univariate analysis, however, it did not remain significant in multivariate analysis, after adjusting for confounding variables.

Conclusion: The agreement of MDA and DAPSA was good in our cohort of PsA patients. In 60% of the discordant patients, treatment was not modified. It seems that both composite indexes are effective for monitoring T2T in daily clinical practice.

Quantitative Ultrasound of the Calcaneus Has a Role to Play in Detecting Low Bone Mineral Density in Axial Spondyloarthritis Patients

Gillian Fitzgerald^{1,2}, Tochukwu Anachebe³, Ronan Mullan⁴, David Kane⁵, Kevin McCarroll⁶ and Finbar O' Shea², ¹School of Medicine, Trinity College Dublin, Dublin 2, Ireland, ²Rheumatology, St. James's Hospital, Dublin 8, Ireland, ³Department of Rheumatology, St. James's Hospital, Dublin 8, Ireland, ⁴Department of Rheumatology,, Tallaght Hospital, Dublin, Ireland, ⁵Department of Rheumatology, Tallaght Hospital, Dublin 24, Ireland, ⁶Department of Medicine for the Elderly, St. James's Hospital, Dublin 8, Ireland

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) patients have an increased risk of developing osteoporosis compared to matched controls. Dual energy x-ray absorptiometry (DXA) is the technique of choice to detect low bone mineral density (BMD). Quantitative ultrasound (QUS) of the calcaneus measures 3 parameters of bone: speed of sound (SOS), broadband ultrasound attenuation (BUA) and stiffness index (SI; composite of SOS and BUA) and can predict fragility fractures in postmenopausal women. QUS is cheap, portable and does not use any ionising radiation. It also provides information on bone microarchitecture, as well as bone mineral density (BMD). Few studies have investigated the use of QUS in axSpA. We aimed to investigate relationships between DXA and QUS in a well characterised axSpA cohort.

Methods: Patients fulfilling modified New York (mNY) or Assessment of Spondyloarthritis International Society (ASAS) criteria were consecutively recruited from rheumatology clinics in this twin-centre cross-sectional study. DXA assessed BMD at the spine, hip and radius. QUS of the calcaneus generated SOS, BUA and SI. Patients had a detailed assessment that included demographics, clinical exam, laboratory assessment and validated measures of disease severity (BASDAI, ASDAS-CRP, BASMI, mSASSS) collected. SPSS was used for statistical analysis.

Results: A total of 107 patients were included: 76% male, 81% mNY criteria, median (IQR) age 51.5 (17.8) years, disease duration 23.5 (20.4) years, BASDAI 3.9 (3.6), ASDAS-CRP 2.1 (1.5) and BASMI 4.1 (3.2). Fragility fracture prevalence was low (6%).

Using DXA, 16.3% had osteoporosis, 41.3% of the cohort had osteopenia and 42.3% had normal BMD as per WHO criteria. Using QUS, 2.9% of the cohort had osteoporosis, 33.7% had osteopenia and 63.5% had normal BMD. Sensitivity of the QUS was 72% in detecting low BMD, specificity was 51%, positive predictive value was 71% and negative predictive value was 53%.

There was no difference in QUS parameters in the fractured versus non-fractured group; however fragility fractures occurred uncommonly in this cohort.

Each QUS parameter (BUA, SOS, SI) was compared with DXA measurements: BUA correlated significantly ($p<0.05$) with all DXA sites (spine $r=0.39$, femoral neck $r=0.33$, total hip $r=0.37$, radius $r=0.34$), as did SI (spine $r=0.32$, femoral neck $r=0.36$, total hip $r=0.35$, total forearm $r=0.37$). There was no correlation between SOS and DXA measurements.

In univariate regression analysis, age, gender, BMI, and QUS parameters BUA and SI were independently associated with BMD by DXA. In multivariate regression models, when controlling for age, gender and BMI, both BUA and SI remained independent predictors of BMD at all DXA sites.

Conclusion: Quantitative ultrasound of the heel is independently associated with DXA measurements of BMD in this axSpA cohort. To become clinically useful, more research is needed to determine the subgroup of patients it performs most accurately in, as well as its association with fracture risk. However, QUS of the calcaneus is a promising tool which may be incorporated in assessment for low BMD in axSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis that occurs in about 30% of patients with Psoriasis (Ps). Recently, a new Patient Reported Outcome Measure (PROM), Psoriatic Arthritis Impact of Disease (PsAID) was specifically developed for PsA Patients. The two versions of the PsAID, PsAID-9 and PsAID-12, are scored on a Numeric Rating Scale (NRS) of 0-10. The Minimal Disease Activity (MDA) is a composite outcome measure for PsA patients, which uses the Health Assessment Questionnaire (HAQ) as one criterion. However, the HAQ does not correlate well with measures of disease activity as PsA disease duration increases, and its use in the assessment of disease activity has been questioned.

Our objectives were to 1) validate the PsAID within our patient cohort, 2) determine if the PsAID can replace any of the other PROMs administered in the clinic, and 3) determine if the PsAID can replace the HAQ in the MDA.

Methods: Patients were recruited from a single psoriatic arthritis clinic. All patients completed the PsAID and 10 other PROMs. Various measures of disease activity were recorded by a physician at each visit. Descriptive statistics (mean, median, SD, min, max) were calculated for all PROMs. PsAID cut-offs for use in the MDA were generated based on Remission (REM) and Low Disease Activity (LDA) disease states in the Clinical Disease Activity for Psoriatic Arthritis Index (cDAPSA).

Results: 115 patients completed the PsAID. There were 70 males, 45 females, with a mean PsA duration of 18.7 (± 11.6) years. Mean scores of PsAID-9 and PsAID-12 were 3.4 (± 2.4) and 3.2 (± 2.3) respectively. The PsAID correlated moderately well with 9 of the PROMs administered in the clinic ($R^2 = 0.51-0.78$). Four PsAID cutoffs were generated for use in the MDA: REM PsAID-9, REM PsAID-12, LDA PsAID-9, and LDA PsAID-12. All four versions of the PsAID MDAs had a sensitivity greater than 85% with the HAQ MDA, and three versions of the PsAID MDA had a specificity greater than 85% with the HAQ MDA.

Conclusion: Our cohort had lower mean PsAID scores than previously reported series suggesting that our patients are monitored carefully. The only moderate correlations with other PROMs suggest that the PsAID cannot replace any of these PROMs. The high sensitivity and specificity of the PsAID MDA with the HAQ MDA suggest that the PsAID is an effective replacement for the HAQ in the MDA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Structural damage is a major cause of poor outcomes in patients with ankylosing spondylitis(AS). In China, structural damage characteristics of AS are rarely reported. We evaluated radiographic changes in sacroiliac (SI), spine and hip joints in Chinese AS patients, and compared structural damage with other races.

Methods: This study included 283 AS patients per the modified New York criteria. Computed tomography (CT) scans and lumbar/cervical X-rays were used to detect structural damage in SI joint and spine. Disease severity was assessed by BASRI-SI, BASRI-spine and BASRI-hip scored by a trained rheumatologist and a musculoskeletal radiologist where the inter-rater reliability (average kappa: 87.3%) was excellent. Adjusted median BASRI spine score per severity of hip arthritis was calculated using median regression.

Results: There were respectively 94 (33.2%), 98 (34.6%) and 91 (32.2%) patients with mild (BASRI-SI average: 2), moderate (2.5-3.5) and severe (4) structural damage of SI joint. 91.2% and 90.1% patients displayed bilateral symmetric sacroiliitis in the first decade and the whole duration, respectively. In patients with asymmetric sacroiliitis, more injuries were detected in left sacroiliac joints than the right. In early AS, more cervical and lumbar involvement was separately detected in 10.2 % and 21.8 %patients. In the whole duration, 68.9% patients had equal lumbar and cervical involvement. Median BASRI-spine was 4. 28 (9.8%) patients progressed to complete spinal fusion. The frequency of hip joint involvement was 41.2%. Higher hip scores were associated with worse BASRI-spine scores. Compared with the results from US AS patients (n=769) [PMID:20971774], our patients had more symmetric structural damage in SI joints and more cervical involvement in early disease. Comparing hip involvement with other races (24% for Spanish, 29% for Belgian, and 36% for Ibero-American) [PMID:19605374] revealed Chinese AS patients (41.2%) had more hip structural damage.

Table 1. Symmetric and Asymmetric Sacroiliac Involvement by AS Duration

Duration of Symptoms (years)	Symmetric Involvement	One-Grade Difference	Two-Grade Difference
	N (%)	N (%)	N (%)
0-9.9	134 (91.1)	13 (9.0)	0
10-19.9	85 (90.4)	9 (9.6)	0
20-29.9	37 (86.4)	4 (10.6)	1 (2.7)
30-39.9	3 (75)	1 (25)	0
≥ 40	1 (100)	0	0
All	233 (90.1)	27 (9.5)	1 (0.3)

Table 2. Comparison of Equal, Greater or Lesser Cervical- and Lumbar- Involvement by AS

Duration of Symptoms (years)	Cervical Equal Lumbar	Cervical > Lumbar Involvement	Lumbar > Cervical Involvement
	N (%)	N (%)	N (%)
0-9.9	100 (68)	13 (10.2)	32 (21.8)
10-19.9	58 (37.4)	9 (9.5)	31 (30)
20-29.9	20 (54.1)	8 (16.2)	14 (29.7)
30-39.9	2 (50)	1 (25)	1 (25)
≥ 40	1 (100)	0	0
All	195 (68.5)	31 (11)	77 (26.5)

Table 3. Median BASRI Spine Scores and Median Difference in BASRI Spine Scores per Score of Worst Hip

Hip Score	No. of Patients	Median BASRI Spine Score	Unadjusted Difference	Difference Adjusted for Disease Duration	Difference Adjusted for Disease Duration, Sex and Age of Onset
0	138	4 (1, 12)	Reference case	Reference case	Reference case
1	97	5.3 (2.5, 7)	+1.3 (-0.66, 3.6)	+1.36 (0.62, 2.09)	+1.66 (0.31, 2.77)
2	21	8 (5, 11)	+4 (1.65, 6.37)	+3.24 (1.88, 4.28)	+3.77 (1.75, 5.38)

Note: Data in parentheses are 95% confidence intervals. Hip score according BASRI-hip modified (0: normal, 1: nonsymmetric/oligoarticular, 2: severe, 3: complete joint fusion, 4: joint replacement).

Conclusion: Chinese AS patients had more symmetric structural damage in SI joints, more cervical involvement in early disease and more hip structural damage than reported in patients of other races. Using a more sensitive method of detection of SI and hip joint severity (CT scans) may explain part of these results.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Along with emergence of the term of ‘non-radiographic axial SpA’ (nr-AxSpA), studies comparing AS and nr-AxSpA in terms of genetic, epidemiologic, and clinical issues have accrued. The aim of this study is to evaluate the achilles tendon enthesopathy with ultrasound (US) in AS and nr-AxSpA patients and controls. We also aimed to compare these groups in terms of associations between disease activity parameters and ultrasonographic achilles enthesitis signs.

Methods: A total of 24 AS and 20 nr-AxSpA patients fulfilling the ASAS (Assesment of Spondyloarthritis International Society) criteria for AxSpA, and 30 controls were enrolled. All SpA patients were newly diagnosed and on NSAID treatment. Demographic characteristics and ESR, CRP, HLA-B27, and indices of BASDI BASFI, BASMI, MASES (Maastricht Ankylosing Spondylitis Enthesitis Score), ASDAS-CRP, and mSASSS (Modified Stoke Ankylosing Spondilitis Spinal Score) scores were noted. Ultrasonographic evaluation of achilles tendon was performed in prone position by two rheumatologists blind to patients’ clinical data. For the distribution of the categorical data, chi square and Fisher’s exact test were used. For comparison of mean or median values of continuous values Mann Whitney U and ANOVA tests were used. Kruskal-Wallis Test was used for comparison of non-parametric data. Spearman’s correlation analysis was applied for determination of correlations between clinical and US parameters.

Results: The mean age and body mass index were similar between AS and nr-axSpA groups. However, the mean age of the control group was lower. HLAB27 positivity, extra-articular and peripheral involvement, disease activity, functional status, mean mSASSS, ultrasonographic gray scale (GS) and total scores (TS) were similar between AS and nr-axSpA groups. In GS, tendon echotexture scores were significantly different across all groups (0.81 ± 0.38 in AS, 0.58 ± 0.47 in nr-axSpA, 0.17 ± 0.91 in controls; $p=0.000$). Enteseal calcification and bone profile scores were similar in AS and nr-axSpA groups but higher than controls ($p:0.01$). When the correlations between US findings and disease activity and functional status were considered, Power Doppler (PD) score and MASES total scores were positively correlated in AS group ($p=.045$; $r: 0.41$).

Conclusion: In this study, AS and nr-axSpA patients were found to be similar in various clinical, functional, and radiologic aspects indicating that these two entities are different phenotypic reflections of the same disease spectrum rather than two distinct diseases. The positive correlation between PD and MASES scores in AS patients substantiate the performance of MASES in evaluation of enteseal activity.

Table 1: Ultrasound findings of AS and nr-axSpA patients and controls

		n	Mean	SD	Median	Min.	Max.	p

* Adjusted by height and body weight

Background/Purpose: Although skin lesion is the most typical findings in patients with psoriasis (PsO), nail psoriasis is also one of the important clinical manifestation. Moreover, nail disorders in PsO are known as a risk factor for psoriatic arthritis (PsA). However, pathological feature and the relationship with inflammation of the soft tissue around the nail is unknown. The aim of this study was to compare the soft tissue thickness around the nail in patients with PsO, PsA and healthy control or other rheumatic diseases by using ultrasonography. The relationship between nail disorders and peripheral arthritis or enthesitis in patients with psoriasis was also analyzed.

Methods: Ultrasonographic assessment was performed in 25 PsO · 35 PsA · 15 healthy control · 23 rheumatoid arthritis (RA) · 28 ulcerative colitis (UC) and 13 Crohn's disease (CD) patients and included in this analysis. Ultrasonographic examination was performed by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18-6 MHz) and the gray scale (GS) and power Doppler (PD) findings were assessed. The distance between the proximal nail fold on the dorsal side of the nail matrix and the nail bed on the volar side of the nail matrix was measured by electric caliper. The soft tissue thickness around nail was compared between groups and the relationship between nail disorders and peripheral arthritis or enthesitis in patients with psoriasis was also analyzed.

Results: The distance between the proximal nail fold and the nail bed was 2.58 ± 0.56 mm in PsA and 2.55 ± 0.58 mm in PsO patients ($p=0.603$). Among the 60 patients who combined PsO and PsA patients, 41 patients with nail psoriasis and 19 patients without nail psoriasis was compared. The distance was 2.68 ± 0.62 mm in patients with nail psoriasis and 2.30 ± 0.41 mm in without nail psoriasis ($p<0.001$), which was also swelling compared with control, RA, UC and CD group. The relationship between nail disorders and peripheral arthritis or enthesitis was not found in patients with psoriasis and psoriatic arthritis.

Conclusion: Soft tissue thickness around the nail in patients with PsO and PsA was compared with other rheumatic diseases by ultrasonographic assessment. In patients with PsO and PsA with nail psoriasis, soft tissue swelling around nail was observed. However, the relationship between nail disorders and peripheral arthritis or enthesitis was not found in patients with psoriasis and psoriatic arthritis.

Unmet Needs in the Treatment of Ankylosing Spondylitis. a Long-Term Observational Study from a Single University Center

Eleftherios Pelechas¹, Evripidis Kaltsonoudis², Paraskevi V. Voulgari³ and Alexandros Drosos⁴, ¹Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Fellow in Rheumatology, Ioannina, Greece, ²Rheumatology Clinic, Department of Internal Medicine, Rheumatologist, Ioannina, Greece, ³Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, 45110, Professor of Rheumatology, Ioannina, Greece, ⁴Rheumatology Clinic, Department of Internal Medicine, Medical School University of Ioannina, Ioannina, Greece, Professor of Medicine/Rheumatology, Ioannina, Greece

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the progress in the treatment of ankylosing spondylitis (AS), a significant number of patients does not achieve low disease activity (LDA). The aim of this study was to estimate the size of unmet needs in the treatment of AS, using non-steroidal anti-inflammatory drugs (NSAIDs), and/or anti-cytokine therapy, in a long-term observational study.

Methods: Between January 2003 and December 2017, 220 patients with AS were diagnosed and followed-up in a tertiary outpatient rheumatology clinic. All patients fulfilled the 1984 modified New York criteria for AS. They were followed-up at predefined times and were naïve to biological treatment with anti-tumor necrosis factors (anti-TNFs) and interleukin (IL)-17 inhibitors. The patients were treated according to the European, United States and Canadian guidelines for AS. More specifically, NSAIDs including selective inhibitors of cyclooxygenase-2 were introduced. In addition, the following anti-TNFs were used: adalimumab (ADA), certolizumab, etanercept (ETN), golimumab and infliximab (INF). We also used secukinumab. During follow-up, clinical and laboratory findings, as well as treatment decisions and strategies, adverse drug reactions, reasons of termination or changing therapy, disease complications and comorbidities were all recorded. Disease activity was measured using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS), using the C-reactive protein.

Results: All patients had an active disease (BASDAI>4 and ASDAS> 2.1) and received at least two NSAIDs for 3 months. The anti-TNF of first choice was INF (51%), followed by ADA (27%) and ETN (22%). During the follow-up period, 18 patients were lost and 4 never received anti-TNF therapy due to various comorbidities. Thus, the final results are referred to 198 patients. Among them 12 (6%) continued receiving NSAIDs with significant clinical improvement and sustained LDA. However, 4 patients from this group never achieved LDA neither received anti-TNF therapy because they refused such treatment. On the other hand, 186 (94%) were treated with anti-TNFs. The majority of them demonstrated sustained LDA for a long period of time. However, from this group, 16 patients never achieved LDA despite they received 2 or 3 anti-TNFs or IL-17 inhibitors. Thus a total of 20 (10.1%) patients in our study never achieved LDA.

Conclusion: This is the first study aiming to estimate the gap and the size of unmet needs in AS patients using the international guidelines and recommendation for AS treatment. We found that the size of gap and unmet needs for AS treatment is 10%.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease that affects the skin, joints, and soft tissues. No metrics exist to indicate whether an untreated patient is unlikely to respond to oral therapies and will require therapy with a biologic. The objective of this study was to predict TNFi prescription among treatment naïve patients initiating methotrexate. We further aimed to identify subgroups of patients at baseline that would likely need a TNFi.

Methods: Data from the Tight Control of Psoriatic Arthritis (TICOPA) trial was used. In TICOPA, patients with at least one tender and swollen joint who were treatment naïve were randomized into one of two arms: intensive management and standard of care. We used all available baseline data to build models to predict the need for a subsequent TNFi within the 48 week study. We first applied a standard prediction modeling approach using stepwise Cox regression models. However, because of correlation among baseline variables (i.e., collinearity) and instability of the models, we decided to apply novel “machine learning” methods (e.g., tree-based classification, clustering methods, and latent class analysis, LCA) using R 3.4.4 with imported packages. Target categorical variables were cut from continuous variables after graphical exploration and trial analyses.

Results: Among the 188 participants who agreed to share data for additional studies, 44 initiated a TNFi during the 48-week study period. Exploration with comparison tests, stepwise regression, and tree-based models identified the PsAQoL score and the Patient Global Assessment (PtGA) as valuable predictors of TNFi prescription. Using LCA, we were able to define a two-class model (Figure 1A) that classified patients who were more and less likely to require a TNFi. In addition to receipt of a TNFi, these classes were defined by a CRP ≥ 25 , PsAQoL ≥ 7 , and TJC ≥ 10 (the most predictive and non-redundant set of variables). We termed the classes “Less Inflamed” and “More Inflamed” for simplicity. Importantly, PtGA was a strong predictor of being in one of these classes; as PtGA increased, the likelihood of being the “more inflamed” class increased. Dividing PtGA into Low (≤ 40), middle (40-70), and high (≥ 70) categories accurately predicted class membership (Figure 1B). In summary, PtGA was single best predictor of requiring a TNFi; baseline PtGA ≥ 70 has a HR of 2.62 (1.42-4.80) for requiring a TNFi and correctly classifies 76% of patients.

Conclusion: At baseline, participants in the TICOPA trial could be classified into two groups, “more inflamed” and “less inflamed” based on three variables and patient global was the single best predictor of class and receipt of a TNFi. The

baseline patient global assessment of treatment naïve patients with PsA yields valuable prognostic information and is an important tool for clinical decision-making in this population.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular morbidity and mortality are increased in Ankylosing Spondylitis (AS). Nonsteroidal anti-inflammatory drugs (NSAIDs) are the first line pharmacological therapy in AS; however, their propensity to increase blood pressure and potentially increase cardiovascular burden may limit their long-term use in an already at-risk population. Our objective was to determine the association of NSAID use and hypertension in AS.

Methods: We included 1069 adults with AS meeting the modified New York criteria from a longitudinal cohort with available NSAID and antihypertensive medication use data. Hypertension was defined by antihypertensive medication use. NSAID use was defined by the validated NSAID index and categorized according to no use or low vs. high NSAID use (index < 50 vs. ≥50). We conducted a comparison of baseline characteristics for patients with and without hypertension, using a chi-square test for categorical variables and Student's t-test or its nonparametric counterpart, as appropriate, for continuous variables. We assessed the association between NSAID use and hypertension at baseline with a multivariable logistic regression analysis.

Results: At baseline, the cohort was 74.1% male, 80.4% white, with a mean age 43.2 ± 14.2 years, and median disease duration of 16.0 years (interquartile range (IQR) = [8,27]) (Table 1). At baseline, 22.8% of patients had hypertension. After adjustment for age, gender and other covariates, the multivariable results found high compared to low dose NSAID use (adjusted OR 2.1, 95%CI 1.1-3.8) was associated with hypertension at baseline.

Conclusion: Compared to AS patients without hypertension, those with hypertension were significantly older, had longer disease duration, and more cardiovascular disease. Although there was no significant difference between any NSAID use versus no use, the multivariable analysis found a significant association between hypertension and high compared to low NSAID use. These data suggest a relationship between NSAID use and comorbid hypertension in AS, which may be dose-dependent and conditional upon the decision to initiate treatment.

Table 1 –Baseline characteristics of patients with and without hypertension

Variables	All patients N=1069	Hypertension (-) n=825 (77.2%)	Hypertension (+) n = 244 (22.8%)	p value

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PSA) is preceded by the presence of cutaneous psoriasis (PS) in approximately 80% of the cases. We consider relevant to have tools that allow the detection of PSA in that population. The aim of this study was to evaluate the validity and performance of an adapted version of the GEPARD questionnaire in Spanish (GEPARDa) in a group of Argentinean patients with PS.

Methods: Adults >18 years who were able to read and understand Spanish were included. The questionnaire was translated from the original language (German) by two independent translators and retranslation into Spanish was made by another two translators. The performance of the questionnaire was evaluated in its new version (GEPARDa) as a diagnostic test.

Results: 83 patients were included, 55 (66.3%) were women, with a mean age of 50.7 (SD 6.3). Of the patients evaluated, 29 (34.9%) had PSA, 15 (18%) were diagnosed with PSA after referral by dermatology, 18 (21.6%) had PS without joint involvement, 6 patients had PS associated with osteoarthritis (OA) (7.22%) and 15 (18%) were diagnosed with OA. The differences in the means of the GEPARD questionnaire among the different groups were statistically significant between patients with known PSA and patients with PS, PS and OA and OA. There were no differences between patients with PSA and newly diagnosed PSA (Table 1). The area under the curve, considering as the gold standard the CASPAR criteria, was 0.9554 DS 0.01 (95%CI 0.91-0.99). A score of 6 was determined to be the better cut-off point for distinguishing PSA from non- PSA. With this value, sensitivity was 88.64%, specificity of 89.74%, LR + of 8.6 and LR - 0.12. Five false negatives were found. 4 patients had a false positive diagnosis. Table 2 shows the relationship of the variables studied and the positivity of the GEPARDa questionnaire. After the multivariate analysis, the variable that was associated with the positivity of the questionnaire was the DAS28 (OR 2.93, 95%CI 0.13-0.91, p: 0.03).

Conclusion: The GEPARDa version is an excellent tool for the detection of PSA in argentine patients with PS.

TABLE 1. Differences of GEPARDa in the evaluated groups.

Variables	PSA	PSA new diagnosis	PS	PS + OA	OA
Median (IQR)	9 (7-10.5)	8 (5-12)	1 (0.2.75)	4 (3-5)	4 (3-5)
p-value (vs APS)		1	<0.001	0.60	<0.001
mean (SD)	8.9 (2.3)	8.6 (3.11)	1.78 (2.4)	4 (1.09)	4.13 (1.4)
p-value (vs PSA)		0.99	<0.001	<0.001	<0.001

TABLE 2. Associations between GEPARDa ≥ 6 and studied variables.

Variables	GEPARDa ≥ 6	GEPARDa <6	p -value

Results are expressed as proportions of patients in the intent-to-treat population calculated using non-responder imputation. *P*-value for differences between ixekizumab and placebo by Chi-square tests or Fisher's exact tests.

Abbreviations: ACR20/50/70=20/50/70% improvement from baseline in ACR criteria; ACR=American College of Rheumatology; DAPSA=Disease Activity Index for PsA; INV=investigators; ITT=intent-to-treat; LDA=low disease activity; LDI-B=leeds dactylitis index-basic; LEI=leeds enthesitis index; MDA=minimal disease activity; NRI=non-responder imputation; PASI=psoriasis area severity index; PsA=psoriatic arthritis; SJC= swollen joint count; TJC=tender joint count.

inadequate response or intolerance to TNF inhibitors (SPIRIT-P2) were randomized to IXE Q4W (N=122) or Q2W (N=123), or to PBO (N=118). Patients fulfilled the Classification Criteria for Psoriatic Arthritis (CASPAR) criteria and had active disease with ≥ 3 TSJ and ≥ 3 SJC. Patients were classified according to the following phenotypes of PsA¹: polyarthritis (≥ 5 TJC and/or ≥ 5 SJC), oligoarthritis (< 5 TJC and < 5 SJC), DIP joint only, enthesitis and dactylitis according to either the investigator's judgment or a scale-based definition. In each phenotype ACR 20, 50 and 70 response criteria, Minimal Disease Activity Psoriasis Area Severity Index (MDA_{PASI}), and Disease Activity Psoriatic Arthritis (DAPSA) remission and low disease activity (LDA) response criteria were assessed to evaluate IXE effect at week 24 combining both doses. For each phenotype with a sufficient sample size, the IXE- and PBO-treated patients' baseline characteristics were assessed. Treatment effects of IXE and PBO were compared using Chi-square tests (or Fisher's exact tests if appropriate) within each phenotype.

Results: The most frequent phenotypes were: polyarthritis (N=662), enthesitis (investigator: N=459; LEI>0: N=403), and dactylitis (investigator: N=220; LDI-B>0: N=155). Too small sample sizes due to inclusion criteria^{2,3} or low frequency were observed for "DIP joint only", oligoarthritis and arthritis mutilans phenotypes (N=22, N=17 and N=15; respectively). Baseline patient characteristics were generally balanced between treatment arms and similar between the 3 most frequent phenotypes, with no difference in disease activity and duration. Efficacy of IXE was consistent across the different phenotypes for various outcomes at week 24: ACR20/50/70, MDA_{PASI}, DAPSA remission and DAPSA-LDA in SPIRIT trials irrespective of previous biologic DMARD use (Tab.1). Response rates were consistent to overall efficacy reported with IXE in SPIRIT trials²⁻⁴.

Conclusion: Treatment responses with IXE at week 24 were consistent regardless of the phenotypes.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA) and rheumatoid arthritis (RA). In most countries where tofacitinib is approved, 5mg twice daily (BID) is the only recommended dose for PsA and RA. An important component of any product labeling is information on the need for laboratory monitoring. This post hoc analysis aimed to provide information on the effect of tofacitinib 5 mg BID on laboratory values in PsA and RA patients (pts).

Table 1. Changes in essential aminoacids and total levels, for 1996 year and 1997 year, among those and some countries, based on Health CT is the average information of all RCD group studies conducted in

[illegible]

Further studies are necessary to assess the role of individual

Smoking is the "most preventable cause of death and disability," and tobacco causes about 44% of all deaths in the United States.

Chemical-induced T_H1 and T_H2 profiles assigned to respectively T_H1 and T_H2 as assessed from pleural to peritoneal T_H1 and T_H2 in the spleen section, where Day 1 is the first day of infection; T_H1 and T_H2 cells were from L.TE, spleen which express in spleen section in 1:12 months.

Abbreviations: AIT, agitated intravenous infusion; BIA, twice daily; BI, baseline; CYP, C-reactive protein; HD, *in*-high-dose (aggravated-inflamed); LD, *in*-low-dose (aggravated-inflamed); LTZ, long-term treatment; M, month; N, number of patients included in the analysis. Stated as percent for each laboratory parameter at each time point to show that if due to missing values. PNA, patients' infection; RA, rheumatoid arthritis; SE, standard error; TO, toxyphoid.

Methods: For analysis of pts with active PsA treated with tofacitinib 5 mg BID, data were pooled from 2 Phase 3 studies and an ongoing long-term extension (LTE) study (data cut-off, January 25, 2017; database not locked; data may change). For analysis of pts with moderate or severe RA treated with tofacitinib 5 mg BID, data were pooled from 8 Phase 2, 7 Phase 3, and 1 LTE studies (data cut-off, March 2, 2017 for LTE; database not locked; data may change). All PsA and most RA pts received a background conventional synthetic DMARD. Data (to Month 12) for pts receiving constant tofacitinib 5 mg BID were evaluated, comprising pts who received tofacitinib 5 mg BID across studies, either at randomization or following switch from placebo. Pts in the placebo groups who switched to tofacitinib 5 mg BID at Month 3 were included from the time they first received tofacitinib. Pts who switched tofacitinib dose were excluded. Change from baseline in hematologic (hemoglobin, neutrophils, lymphocytes) and lipid (LDL-cholesterol, HDL-cholesterol, total cholesterol, triglyceride) levels and key liver tests (bilirubin, ALT, AST) were analyzed. Although not addressed in the product labeling, creatine kinase, creatinine, and C-reactive protein levels were also assessed. Pts meeting protocol-defined discontinuation criteria for laboratory values were evaluated.

Results: The constant tofacitinib 5 mg BID group comprised 348 PsA pts and 3,040 RA pts. Table 1 presents mean/percentage changes (SE) from baseline for laboratory values. Following initial increases/reductions, key laboratory values remained stable to Month 12 in both PsA and RA, except for a reduction in lymphocyte levels, which stabilized at later time points (data not shown). In both PsA and RA, $\leq 3.0\%$ of patients met discontinuation criteria for any laboratory values (Table 2).

Conclusion: In this post hoc analysis of laboratory data with tofacitinib 5 mg BID, changes in key laboratory values were similar for PsA and RA, and discontinuations due to protocol criteria being met for laboratory values were infrequent. These results provide further information on the effect of tofacitinib on laboratory values in PsA and RA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term apremilast (APR) efficacy and safety were evaluated for up to 5 yrs in adults with active PsA in the phase III PALACE 1-3 studies.

	Outcomes at Wk 260	
	APR30 n=329*	APR20 n=304*
ACR20, n/m (%)	215/320 (67.2)	202/298 (67.8)
ACR50, n/m (%)	144/324 (44.4)	142/287 (47.8)
ACR70, n/m (%)	86/325 (27.4)	75/300 (25.3)
Swollen joint count (0-76), mean % change from BL	-82.3	-86.0
Tender joint count (0-76), mean % change from BL	-72.7	-73.1
MASES [‡] of 0, n/m (%)	136/218 (62.4)	117/182 (64.3)
Dactylitis count [‡] of 0, n/m (%)	114/141 (80.9)	114/131 (87.0)
cDAPSA (0-154) ≤13, n/m (%)	108/328 (60.4)	106/302 (64.9)
HAQ-DI (0-3), mean change from BL	-0.42	-0.37
HAQ-DI MCI of ≥0.35, n/m (%)	173/329 (52.6)	148/303 (48.2)
PASI-50 [§] , n/m (%)	98/149 (65.8)	76/138 (55.9)
PASI-75 [§] , n/m (%)	65/149 (43.6)	59/136 (41.2)

Data as observed. *The n reflects the number of subjects with data available at Wk 260, regardless of when subjects started taking APR (BL, Wk 16, or Wk 24); actual number of subjects having data available for each end point may vary. †Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Examined among subjects with enthesitis at BL and having data at Wk 260. ‣Examined among subjects with dactylitis at BL and having data at Wk 260. ․Examined among subjects with psoriasis involvement of the body surface area ≥3% at BL and data at Wk 260. n/m=number of responders/number of subjects with sufficient data for evaluation. MASES=Maastricht Ankylosing Spondylitis Enthesitis Score. cDAPSA=Clinical Disease Activity in Psoriatic Arthritis. MCI=minimal clinically important difference. PASI-50/75=≥50/≥75% reductions from BL. Psoriasis Area and Severity Index.

Methods: Subjects were randomized (1:1:1) at baseline (BL) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). PBO subjects were re-randomized (1:1) to APR30 or APR20 at Wk 16 (early escape) or Wk 24. Double-blind APR treatment continued to Wk 52; subjects could continue APR during an open-label, long-term treatment phase for up to an additional 4yrs. Efficacy and safety were assessed and reported as observed.

Results: A total of 1,493 subjects were randomized and received ≥1 dose of study medication (PBO: n=496; APR30: n=497; APR20: n=500). Of those randomized to APR30 at BL, 44.5% (221/497) completed 260 wks of treatment. Among APR30 subjects entering Wk 52, 63.2% (331/524) completed 260 wks, regardless of when APR was started (BL, Wk 16, or Wk 24). At Wk 52, ACR20/50/70 response rates were 55.3%/26.1%/11.9% for APR30 subjects. Sustained response rates were observed with continued APR30 treatment at Wk 260 (Table). Marked swollen joint count improvements were seen, with a mean percent reduction of 82.3% at Wk 260; tender joint count reduction was 72.7%. At Wk 260, 62.4% (136/218) of APR30 subjects with BL enthesitis achieved a Maastricht Ankylosing Spondylitis Enthesitis Score of 0; 80.9% (114/141) with BL dactylitis achieved a dactylitis count of 0. A HAQ-DI minimal clinically important difference of ≥0.35 was achieved by 52.6% of APR30 subjects at Wk 260; 60.4% achieved low disease activity or remission, defined as a Clinical Disease Activity in Psoriatic Arthritis score ≤13. Sustained improvements in psoriatic skin involvement were observed with continued treatment at Wk 260 in APR30 subjects with ≥3% BL body surface area involvement, with 65.8% (98/149) and 43.6% (65/149) of subjects, respectively, achieving ≥50%/≥75% reductions from BL Psoriasis Area and Severity Index score. APR 20 results were similar (Table). Consistent efficacy results were seen across the individual studies. During the 0- to ≤52-wk APR-exposure period, adverse events (AEs) occurring in ≥5% of APR30-exposed subjects were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis. Most diarrhea and nausea AEs were reported within the first 2 wks of treatment and usually resolved within 4 wks; gastrointestinal AE frequency decreased with longer APR30 exposure, and frequency of other common AEs decreased/remained stable with prolonged exposure. Serious AE rate during Wks >208 to ≤260 was 5.8%, consistent with earlier periods.

Conclusion: APR demonstrated sustained, clinically meaningful improvements in PsA signs/symptoms, physical function, and associated psoriasis in the subjects continuing treatment over 5 yrs. APR continued to demonstrate a favorable safety profile and was generally well tolerated at 5 yrs.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To delineate clinical characteristics of patients with spondyloarthritis (SpA) in Japan in comparison to other areas of the world.

Methods: Utilizing the COMOSPA data, an international cross-sectional observational study of SpA patients we analyzed information on demographics, disease characteristics, comorbidities, and risk factors. Patients were classified by region: Japan, other Asia (China, Singapore, South Korea, and Taiwan), and non-Asian countries (Europe, Americas, and Africa); patient characteristics, including diagnosis and treatment, were compared.

Results: Among 3984 patients included in the study, 161 were from centers in Japan, 933 from other Asian countries, and 2890 from other regions. Of SpA patients in Japan, 28.6% had peripheral SpA, whereas presenting symptoms were more predominantly axial in other Asian countries. This trend was explained by the predominance of PsA patients among Japanese SpA patients. In contrast to the relatively low number in Japan, 54% of patients from other Asian countries had pure axial SpA without peripheral features. HLA B27 testing, which is considered an integral part of the classification of axial SpA, was only performed in 62% of Japanese axial SpA patients. More than half of Japanese axial SpA patients were classified using imaging criteria.

Conclusion: There is substantially more peripheral SpA in Japan compared to other parts of Asia, and other regions of the world. Aside from ethnic differences, increasing recognition of PsA, as well as a potential under-diagnosis of axial SpA due to the insufficient use of HLA B27 testing in Japan, may partly explain regional discrepancies.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of synthetic DMARDS (sDMARDS) in spondyloarthritis (SpA) has been increasingly questioned and restricted to peripheral disease, on the other hand, the use of immunobiological agents for the treatment of SpA has been further improved by anti-TNF and the release of new drugs with other mechanisms such as secukinumab (anti-IL17, SEC) and ustekinumab (anti-IL12/23, UST). The objective of our study is to describe clinical and treatment data of a SpA patients cohort followed at the outpatient clinic of a Brazilian single center.

Methods: 516 SpA patients evaluated from January 2017 to January 2018. Data from electronic medical records were assessed including diagnosis, disease characteristics, treatment and disease activity at the last visit.

Results: Among all patients, 195 (37.8%) were classified as Ankylosing Spondylitis (AS), 198 (38.3%) as psoriasis arthritis (PsA), 66 (12.8%) as axial non-radiographic or peripheral SpA, 42 (8.1%) as SpA related to inflammatory bowel disease and 15 (3.0%) as reactive arthritis patients. From all SpA patients 190 (36.8%) have no axial disease, with isolated peripheral arthritis. Regarding treatment, 321 (62.2%) patients were under sDMARDS as monotherapy or in association [156/321 (48.6%) methotrexate (MTX); 125/321 (38.9%) sulfasalazine (SSZ)]; 298 (57.7%) patients used NSAIDs. Concerning biological therapy 204 (39.5%) patients received biological DMARDS (bDMARDS) [68 infliximab (IFX), 59 adalimumab (ADA), 35 etanercept (ETA), 6 golimumab (GOL), 2 certolizumab pegol (CTZ), 23 secukinumab (SEC), 10 ustekinumab (UST), 1 rituximab (RTX)]. Patients with isolated peripheral involvement presented higher frequency of sDMARD use (78.4% vs. 51.4%, $P < 0.001$) compared to patients with axial disease, but with similar use of biological drug (37.1% vs. 45.7%, $P = 0.13$) and combined treatment of bDMARD and sDMARD (26.7% vs. 25%, $P = 0.73$). Forty-three AS patients (43/52, 82.7%) were HLA-B27 positive; 152/195 (77.9%) received NSAIDs; 95/195 (48.7%) used sDMARDS (23.1% MTX and 72.6% SSZ) and 79/195 (40.5%) used bDMARDS (31 INF, 22 ADA, 19 ETA, 3 GOL, 3 SEC, 1 UST). Among the 198 PsA patients, 148/198 (74.7%) have isolated peripheral disease; 146/198 (73.7%) used sDMARDS (78.8% MTX and 26.7% LNF) and 77/198 (38.9%) received bDMARDS (24 IFX, 18 ADA, 10 ETA, 19 SEC, 6 UST, 1 RTX). In relation to disease activity, 25/125 (20%) of AS patients had ASDAS ≥ 2.1 and 42/198 (21%) of PsA patients presented active arthritis in the last visit.

Conclusion: The description of epidemiological and clinical data of this cohort reinforces high prevalence of peripheral disease in Brazilian SpA patients. This fact could explain the wide use of sDMARDS in these patients. The frequency use of bDMARDS is in parallel with literature data including non-antiTNF drugs as SEC and UST.

Association of Kinesiophobia, Aerobic Exercise, Functional Impairment and Disease Activity of Patients with Rheumatoid Arthritis and Spondyloarthritis

Daniele Peres¹, Nicolas Tordi², Daniel Wendling³, Yoshimasa Sagawa⁴ and Clément Prati⁵, ¹EA 4267 PEPITE (FHU INCREASE) – Plateforme EPSI, Université de Bourgogne Franche-Comté, Besançon, France, ²PEPITE EA 4267, Bourgogne Franche-Comté University, Besançon, France, ³Rheumatology, University Hospital - Bourgogne Franche Comté University, Besançon, France, ⁴Laboratoire de l'Exploration Fonctionnelle et Clinique du Mouvement (LEFCM), BESANCON, France, ⁵Rheumatology, University Hospital - Bourgogne Franche Comté University, Besançon, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and spondyloarthritis (SA) are the most common chronic inflammatory rheumatism, leading to functional disability, but also cardiovascular mortality. Aerobic exercise (AE) is one of the most effective non-pharmacological resources for cardiovascular rehabilitation while the patients RA and SA have difficulty to join the practice of physical exercise. It can be explained by the presence of kinesiophobia, fear that the movement exacerbates the pain and disease. The objective was to compare the level of AE of patients with RA and SA with healthy subjects and to verify the association between kinesiophobia, the level of activity of the disease and the functional disability.

Methods: Fifty RA patients and fifty SA patients followed by the rheumatology department of the University Hospital of Besancon and fifty healthy age-matched subjects were included. The main inclusion criteria: between 18 and 80 years old and without orthopedic surgery <1 year. The disease activity (DAS-28 and ASDAS), the functional disability (HAQ and BASFI), the level of AE (SQUASH questionnaire) and kinesiophobia (TSK questionnaire) were evaluated. The control group answered to the SQUASH questionnaire. The t-test was used to compare inflammatory rheumatism groups with the control group (healthy subjects). The Pearson Correlation Test for each group (RA and SA) was used to verify the associations between variables.

Table 1: Demographic Characteristics of Patients with RA and SA and Healthy Subjects.

	RA	SA	Healthy Subjects
Age (years)	62.8 (10.8)	47.3 (12.7)	55.7 (13.4)
Height (m)	1.66 (0.10)	1.70 (0.1)	1.70 (0.1)
Weight (Kg)	72.4 (16.5)	71.8 (14.7)	71.7 (14.8)
Aerobic Exercises (SQUASH)	3706.9 (2958.3)	5448.0 (3655.6)	5503.5 (3095.9)
Kinesiophobia (TSK)	42.7 (7.8)	40.6 (7.5)	-
Functional disability (HAQ/BASFI)	1.0 (0.6)	4.3 (2.4)	-
Disease activity (DAS28/ASDAS)	3.0 (1.1)	1.6 (1.1)	-

Results: The level of AE is significantly higher in healthy subjects ($p = 0.022$). In the RA group, kinesiophobia is associated with disease activity, functional disability and level of AE. In the SA group, kinesiophobia is associated only with the functional disability.

Table 2: Results of Pearson Correlation Test between variables

		Aerobic Exercise	Kinesiophobia	Functional Disability	Disease Activity
RA	Aerobic Exercise	-	$r = -0.280^*$	$r = -0.414^{**}$	$r = -0.149$
	Kinesiophobia	$r = -0.280^*$	-	$r = 0.522^{**}$	$r = 0.327^*$
	Functional Disability	$r = -0.414^{**}$	$r = 0.522^{**}$	-	$r = 0.531^*$
SA	Aerobic Exercise	-	$r = -0.165$	$r = -0.40$	$r = -0.064$
	Kinesiophobia	$r = -0.165$	-	$r = 0.345^*$	$r = 0.224$
	Functional Disability	$r = -0.040$	$r = 0.345^*$	-	$r = 0.737^{**}$

* $p < 0.005$; ** $p < 0.005$

Patients have a low level of AE compared to healthy subjects. However, only the RA group has an association between kinesiophobia and AE. In the SA group, functional disability appears to be a factor limiting the practice of AE.

Conclusion: RA and SA patients need to be encouraged and better informed about the benefits of physical exercise.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab (SEC), a fully human anti-interleukin-17A monoclonal antibody, significantly improved signs and symptoms and inhibited radiographic progression versus placebo (PBO) at Week (Wk) 24 in patients (pts) with psoriatic arthritis (PsA) in the FUTURE 5 (NCT02404350) study.¹ Here, we report the effects of SEC on radiographic progression, additional efficacy endpoints and safety through 52 wks in the FUTURE 5 study.

Methods: Pts (N=996) with active PsA, were randomized (2:2:2:3) to subcutaneous (sc) SEC 300mg with loading dosage (LD; n=222), 150mg with LD (n=220), 150mg without LD (n=222), or PBO (n=332). All groups received SEC or PBO at baseline (BL), Wks 1, 2, 3, and 4, and then every 4 wks. At Wk 16, PBO non-responders were switched to SEC 300mg or 150mg; remaining PBO pts were switched at Wk 24. Radiographic progression, as assessed by mean change in van der Heijde-modified total Sharp score for PsA (mTSS), was based on hand/wrist/foot radiographs obtained at BL, Wk 16 (non-responders), Wk 24 and Wk 52, assessed by two blinded readers (plus an adjudicator if required). Pts were stratified based on anti-TNF status (naïve/inadequate response [IR]). Radiographic data was analyzed by linear extrapolation at Wk 24 for all PBO non-responders and for all other pts with missing Wk 24 radiographs; Wk 52 radiographic data are based on observed data. In addition, radiographic data for the overall population was analyzed by linear mixed effects model at Wk 24. Additional assessments at Wk 52 included ACR20/50, PASI75 and resolution of dactylitis and enthesitis. Statistical analyses used non-responder imputation for these clinical variables. Safety analyses included all pts who received ≥ 1 dose of SEC.

Results: 91.9% (204/222; 300mg LD), 91.4% (201/220; 150mg LD) and 86.9% (193/222; 150mg No LD) pts completed 52 wks of treatment. Inhibition of radiographic progression was sustained through 52 Wks (Table). Proportions of pts with no radiographic progression (change from BL in mTSS ≤ 0.5) with SEC at 52 Wks were 92% (300 mg LD), 85% (150 mg LD), and 87% (150 mg No LD). Mean changes from baseline in mTSS by linear mixed effects model at Wk 24 were 0.03 (P<0.01; 300mg LD), 0.14 (P<0.05; 150mg LD) and -0.10 (P<0.001; 150mg No LD) vs. 0.51 (PBO). Clinical responses were also sustained or improved through 52 Wks (Table). Over the study (mean SEC exposure of 309.0 days), exposure adjusted incidence rates with SEC for selected AEs were: serious infections (1.6), *Candida* infections (2.2), crohn's disease (0.2), ulcerative colitis (0.1), major adverse cardiovascular event (0.2) and malignant/unspecified tumors (0.5).

Conclusion: Secukinumab provided sustained inhibition of radiographic progression through 52 wks. Clinical responses were also sustained or improved through 52 wks. The safety profile was consistent with that previously reported.¹

A Service Evaluation of Reporting Standards of Computer Tomography Defined Sacroiliitis Suggestive of Axial Spondyloarthritis in Inflammatory Bowel Disease Patients Imaged for Non-Musculoskeletal Indications

Chong Seng Edwin Lim¹, Samantha Bee Lian Low², Baljeet Dhillon², Shin Azegami², Andoni Paul Toms² and Karl Gaffney¹, ¹Rheumatology, Norfolk and Norwich University Hospital, Norwich, United Kingdom, ²Radiology, Norfolk and Norwich University Hospital, Norwich, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A combined service evaluation by the rheumatology and radiology department was undertaken to understand the frequency and reporting standards of Computer Tomography-defined Sacroiliitis (CTSI) in patients with Inflammatory Bowel Disease (IBD) imaged for non-musculoskeletal indications.

Methods: CT scans of the abdomen and pelvis were identified retrospectively from the radiology imaging system (RIS) between January 2010 and December 2017. The results were then filtered to ages between 18 to 55 year olds, which is commonly considered to be the population with the highest diagnostic yield for axial spondyloarthritis (axSpA). Only scans of patients with confirmed IBD (Crohn's disease (CD) or Ulcerative Colitis (UC)) were evaluated. For patients who have undergone multiple scans, the most recent CT scan was used as the index scan. CT scan evaluation was undertaken by 3 radiology trainees (trained and under supervision of a senior musculoskeletal radiologist) in order to identify incidental CTSI, highly suggestive of axSpA^(1,2).

Results: A total of 301 unique scans of confirmed IBD patients (mean age 36; male 49.2%) were evaluated. The frequency of CTSI using the maximum sensitive criterion of a validated CT screening tool⁽¹⁾ was 19.9% (60/301). In 53 UC and 248 CD patients, the percentage of CTSI were 17.0% UC (9/53) and 20.6% CD (51/248) respectively. Of the 60 positive scans, 15/60 were reported as sacroiliitis but no reference was made for further rheumatological assessment; of these 15, seven had no previous diagnosis of axSpA. Of the remaining 45 CTSI; 26 were unidentified despite a bone evaluation having apparently been undertaken, 17 did not mention a bone evaluation, 2 were unidentified despite the SI joints having been reviewed.

Conclusion: An estimated 20% of selected IBD patients' scans have sacroiliitis indicative of possible underlying axSpA diagnosis but these were not reported in 75% of cases. There is a need to raise the awareness of this association and perhaps the utilisation of a validated CT tool may advance reporting excellence. Further assessment of this select group may help differentiate between asymptomatic sacroiliitis and a potential hidden burden of axSpA among IBD patients undergoing CT scanning for non-musculoskeletal indications.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with axial spondyloarthritis (axSpA) who have achieved a stable disease state and are undergoing treatment with tumour necrosis factor inhibitor (TNFi) therapy may opt for a dose reduction. Lowering the standard dosing regimen presents several potential risks including disease relapse. We investigated the efficacy of adjusting (reducing or withdrawing) the standard TNFi dose for the treatment of axSpA.

Methods: CENTRAL, Embase, and MEDLINE databases were searched (up to February 2018) along with trial registries and reference lists of relevant articles^{1,2}. All randomized controlled trials (RCTs) evaluating a method of TNFi dose adjustment were assessed for eligibility. Data were pooled in RevMan 5.3 using a random-effects model for the following outcomes: Assessment of SpondyloArthritis international Society 40% (ASAS40) improvement criteria, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), C-reactive protein (CRP), remission, relapse and quality of life (QoL).

Results: 297 full-texts were reviewed for eligibility and 6 RCTs (737 participants) were included in the meta-analysis. There were higher ASAS40 rates with standard TNFi treatment as compared to an adjusted dose (risk ratio [RR] 0.63; 95% confidence interval [CI] 0.51 to 0.78; 3 studies; 538 participants; moderate quality evidence). There were no differences in the mean BASDAI (mean difference [MD] 0.40; 95% CI -0.11 to 0.91; 4 studies; 319 participants; moderate quality evidence) and mean CRP (MD 0.68; 95% CI -1.49 to 2.85; 4 studies; 319 participants; low quality evidence) between the standard and adjusted doses. There were higher rates of remission in the standard dose as compared to the adjusted dose (RR 0.65; 95% CI 0.56 to 0.77; 5 studies; 694 participants; low quality evidence). There were fewer events of disease relapse (i.e. BASDAI >4) in the standard versus adjusted dose (RR 1.20; 95% CI: 0.58 to 2.48; 2 studies; 156 participants; low quality evidence). QoL was not pooled due to clinical heterogeneity.

Conclusion: To our knowledge, this is the first review to incorporate a meta-analysis on TNFi dose adjustment in an axSpA population. Overall, this review found that axSpA patients who have achieved stable disease might experience little benefit or harm from TNFi withdrawal or reduction. The published data to date leave unclear the risk/benefit ratio of withdrawing treatment. Individualizing this decision is an important research question for future studies.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a musculoskeletal inflammatory condition associated with psoriasis. It has a heterogeneous set of clinical manifestations which include peripheral arthritis, axial involvement, enthesitis, dactylitis, skin, and nail disease. In current practice, the treatment of PsA involves initiating a conventional synthetic DMARD (csDMARD), usually followed by an initial Tumor Necrosis Factor inhibitor (TNFi) and then a second TNFi before considering other classes of biological DMARD (bDMARD). The efficacy of TNFi in patients with PsA has been documented in randomized clinical trials (RCTs) for several of these agents, including adalimumab (ADA), etanercept, infliximab, adalimumab, golimumab, and certolizumab, compared with placebo. However, little is known about the utility of combining a TNFi with MTX (C) versus TNFi monotherapy (M) in psoriatic arthritis and studies to this day show conflicting results. We evaluate here the comparative sustainability of ADA used in first or second intention in patients with PsA initially treated in C or M.

Methods: Data from all RHUMADATA® patients with PsA prescribed ADA either as an initial or second TNFi was analyzed. Patients were followed until treatment discontinuation, loss to follow-up or February 21st, 2018. Only patients who were treated for at least six months were included. The characteristics of selected patients were tabulated, and the ADA discontinuation rates of patients who initiated C and M were compared using Kaplan-Meier estimates and multivariate Cox models adjusting for potential confounders.

Results: A total of 247 patients with PsA received ADA in first or second intention. Of those, 105(42.5%) and 142(57.5%) received treatment without and with MTX respectively. There was a statistically significant difference in populations in table 1 for the age at diagnosis (M:39.8±11.7; C: 43.5±11.4; p=0.012). No significant differences in retention rates between M and C therapy were observed (see figure below). Mean retention time for M and C therapy were respectively 5.06 (SE=0.29) and 6.82(SE=0.35). Subanalysis looking at ADA in first and in second intention showed similar results.

Conclusion: Combining MTX to ADA does not improve sustainability in patients with PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a musculoskeletal inflammatory condition associated with psoriasis. It has a heterogeneous set of clinical manifestations which include peripheral arthritis, axial involvement, enthesitis, dactylitis, skin, and nail disease. In current practice, the treatment of PsA involves initiating a conventional synthetic DMARD (csDMARD), usually followed by an initial Tumor Necrosis Factor inhibitor (TNFi) and then a second TNFi before considering other classes of biological DMARD (bDMARD). The efficacy of TNFi in patients with PsA is documented in randomized clinical trials (RCTs) for several of these agents, including etanercept (ETA), infliximab, adalimumab, golimumab, and certolizumab, compared with placebo. However, little is known about the utility of combining a TNFi with MTX (C) versus TNFi monotherapy (M) in psoriatic arthritis and studies to this day show conflicting results. We evaluate here the comparative sustainability of ETA used in first or second intention in patients with PsA initially treated in C or M.

Methods: Data from all RHUMADATA® patients with PsA prescribed ETA either as an initial or second TNFi was analyzed. Patients were followed until treatment discontinuation, loss to follow-up or February 21st, 2018. Only patients who were treated for at least six months were included. The characteristics of selected patients were tabulated, and the ETA discontinuation rates of patients who initiated C and M were compared using Kaplan-Meier estimates and multivariate Cox models adjusting for potential confounders.

Results: A total of 195 patients with PsA (according to CASPAR criteria) received ETA in first or second intention. Of those, 102 (52.3%) and 93 (47.7%) received treatment without and with MTX respectively. There were statistically significant differences in populations in table 1 for the BASDAI (M: 5.8 ± 2.8 ; C: 3.9 ± 2.3 ; $p=0.03$) and BASFI (M: 5.0 ± 3.0 ; C: 2.8 ± 2.0 ; $p=0.011$) scores, both being higher in the M group. No significant differences in retention rates between M and C therapy were observed (see figure below). Mean retention time for M and C therapy were respectively 7.12 (SE=0.42) and 8.25 (SE=0.68) years. The main reason for treatment cessation was inefficacy, followed by adverse events. There were more adverse events in the C group (26.1% vs 9.3%). Sub-analysis looking at ETA in first and in second intention showed similar results.

Conclusion: Combining MTX to ETA does not improve sustainability in patients with PsA.

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although tumor necrosis factor inhibitors (TNFi) have favorably altered the treatment landscape for patients with axial spondyloarthritis (AxSpA), permanent therapy is infrequent. Further, the extent to which patients continue individual TNFi agents is uncertain and the reasons for discontinuation of TNFi remain obscure.

Objective: To determine TNFi persistence and reasons for discontinuation in patients with axial spondyloarthritis

Methods: A retrospective cohort analysis was performed of US veterans enrolled from 2007 to 2017 in the Department of Veterans Affairs (VA) Program to Understand the Long term outcomes in SpondyloArthritis Registry (PULSAR), who met ASAS criteria for AxSpA and were treated with TNFi. Enrollment sociodemographic variables, HLA-B27 status,

Figure 1: TNFi Persistence estimates in AxSpA Cohort

Figure 2: Reasons for TNFi Discontinuation in AxSpA cohort

erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were collected. Corporate Data Warehouse Pharmacy files provided courses of injectable TNFi agents (etanercept, adalimumab, certolizumab, and golimumab). Individual TNFi persistence was first compared with unadjusted Kaplan-Meier plots, and then multivariable Cox proportional hazards regression applied, including a term for the course sequence (accounting for the order of the TNFi, [STATA]). Reasons for discontinuation (primary non-response [< 6 months TNFi exposure], secondary [> 6 months TNFi exposure] loss of efficacy (LOE), adverse event, patient averseness, financial/access, minimal disease, non-adherence) were obtained by physician chart review.

Results: The cohort of 229 patients were of mean age 53.2 years, and mainly white (69%) men (93.8%). HLA-B27 was positive in 73.4%, with mean CRP of 1 [1.4] mg/dl and ESR 17.9 [17.8] mm/hr. Individual TNFi persistence was highest for etanercept ($p < 0.05$), accounting for TNFi sequence. At approximately 3 years, persistence for any TNFi was $< 25\%$ (Figure 1). Secondary LOE was the most common reason for discontinuation, accounting for nearly half of all courses. In 20% of instances, primary non-response and adverse events accounted for TNFi discontinuation (Figure 2), while patient risk averseness, non-adherence and drug access were infrequent ($< 5\%$) reasons.

Conclusion: Etanercept has the best TNFi persistence among VA AxSpA patients, but discontinuation is common, mainly due to loss of efficacy. The contributing factors for discontinuation, including specific administration guidelines, comorbidities or anti-drug antibodies are potential areas for further inquiry

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many targeted synthetic DMARD (tsDMARD) and biological DMARD (bDMARD) were recently approved for treatment of active psoriatic arthritis (PsA), but their comparative efficacy and safety remain unknown. This study aims to compare the efficacy and safety of recently generated tsDMARD and novel bDMARD in active PsA.

Methods: Randomized clinical trials (RCT) evaluating the efficacy and safety of tsDMARD including tofacitinib (TOF) and apremilast (APR), and bDMARD such as ustekinumab (UST), secukinumab (SEC), ixekizumab (IXE), clazakizumab (CLA), and abatacept (ABA) for active PsA, who received a diagnosis of PsA at least 6 months previously, fulfilled the Classification Criteria for Psoriatic Arthritis, and had active plaque psoriasis and active arthritis (≥ 3 swollen and ≥ 3 tender or painful joints) at screening, were identified by comprehensive systemic literature review. Pairwise meta-analysis and Network meta-analysis (NMA) using a random effects model were performed to estimate pooled odds ratios (ORs) and 95% confidence intervals (CIs) of attaining 20% or 50% improvement in ACR criteria (ACR20 or ACR50) and 75% improvement in psoriasis area and severity index (PASI75), any adverse events (AE) and serious adverse events (SAE) across trials.

Results: We deemed 15 RCT eligible, including 6004 participants and 17 treatments. For efficacy, pairwise meta-analysis showed that all treatments except CLA 200mg/25mg monthly were superior to placebo in achieving ACR20, all except CLA 200mg monthly and ABA 125mg weekly were superior in achieving ACR50, and TOF, APR 30/20mg twice daily, UST, SEC 300mg/150mg monthly and IXE were superior in achieving PASI75. For safety, TOF 10mg twice daily, APR 30mg/20mg twice daily, and IXE were more likely to have any AE, but no significant differences were seen for pooled SAE among the various treatments. NMA showed SEC 300mg monthly to be more efficacious in achieving ACR20 and ACR50, whereas UST 90mg 12 weekly had the highest efficacy in achieving PASI75. SEC 75mg monthly and UST 90mg 12 weekly had the lowest probability of pooled AE and SAE, respectively. Regarding the overall efficacy in both articular and cutaneous aspects and overall risk-benefit profile, SEC and UST ranked higher than other interventions.

Conclusion: Secukinumab and Ustekinumab may be the safest and most efficacious (for arthritis and psoriasis, respectively) for active PsA among the new targeted synthetic and biological DMARD.

Figure 1: Clustered ranking plot for efficacy and safety

Each color represents a group of treatments that belong to the same cluster. Treatments lying in the upper right corner are more effective or/and safer than the other treatments. (Efficacy= 50% ACR20 response and 50% PASI75 response; Safety= 50% AE and 50% SAE). QD: daily; BID: twice daily; QW: weekly; Q2W: every 2 weeks; Q4W: every 4 weeks; Q12W: every 12 weeks; PLA: placebo.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We consider multidisciplinary management necessary, especially in a subgroup of patients with Psoriatic Arthritis (PsA) for complexity, cutaneous and / or joint involvement. Despite the limited evidence of efficacy of methotrexate (MTX) and other classical synthetic DMARDs (csDMARDs) in these patients, they are commonly prescribed in our multidisciplinary unit (following the recommendations of experts, in peripheral PsA). Objective: To assess joint and cutaneous involvement in patients with peripheral psoriatic arthritis not receiving biologics in our multidisciplinary unit (visited for at least 6 months)

Methods: We review clinical the records of 199 PsA patients visited in our multidisciplinary unit and select 74 patients with the above mentioned criteria; we collect epidemiological and clinical data, and joint and skin activity evaluation by DAPSA, PASI, BSA and PGA (in plaque psoriasis) and proportion of patients that achieve MDA (minimum disease activity) as a therapeutic goal. Data were analyzed using SPSSv23.

Results: 74 patients, 63.5% males, aged mean (SD) 54.8(14.0) years. 56 peripheral PsA and 18 mixed (peripheral predominance); with mean 94.9(92.4) months of disease; 35.1% with previous clinical enthesitis and 37.8% previous dactylitis. Cutaneous disease consisted mainly (82.4%) in plaque psoriasis, 9.5% affecting folds, 4.1% onychopathy. 52.7% have received a previous DMARD of (31.1% MTX, 9.5% leflunomide) and 23.0% PUVA; 4.1% have received previous biological treatment. Current treatment: 83.8% DMARDs (68.9% MTX and 5.4% leflunomide) with a mean follow-up of 60.6(55.0) months. Disease activity: Skin plaque psoriasis was mainly controlled: 73.4% low PASI level (23.4% moderate) median PASI 3.0 [1.5-5.0]; 50.0% mild BSA, median BSA 3.0[1.0-6.0]. 73.1% PGA of very mild or mild-moderate disease. 87.0% of patients met DAPSA criteria of remission-low disease activity (DAPSA median 3.15[1.34-6.71]; 55.9% achieved DAPSA <4); 75.7% were in low activity / remission according to medical judgement. Overall 63.9% of patients achieved MDA; 15.3% (10 patients) had relative” contraindications” to biological therapy (6 cases of recent cancer, 2 HBV infection).

Conclusion: Over half of PsA patients from our multidisciplinary unit achieve low cutaneous and articular disease activity under csDMARDs, mainly Methotrexate. The use of targeted DMARDs such as apremilast in this scenario before biological therapies may improve disease outcomes in a subgroup of patients, corresponding with the efficacy shown in different domains of the psoriatic disease. Further research is needed to compare clinical results between csDMARDs and Apremilast.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate and TNF inhibitors (TNFi) are commonly used in the treatment of RA, PsA, and other SpA. While MTX is a mainstay of RA treatment, its efficacy and tolerability have not been as well studied in spondyloarthritis. Our aims were 1) to assess the rates of MTX and TNFi discontinuation in patients with PsA and ankylosing spondylitis (AS) compared to patients with RA, hypothesizing that MTX discontinuation, but not TNFi discontinuation, would occur sooner in patients with PsA or AS; and 2) to determine whether concomitant methotrexate use was associated with later TNFi discontinuation in PsA and AS.

Table: Rates of MTX and TNF inhibitor discontinuation by disease and results of adjusted models

Methotrexate discontinuation								
	N	PY	Time to discontinuation		Early discontinuation (within 90 days)		Late discontinuation (after 90 days)	
			Median persistence (years)	aHR (95% CI)	N (%)	aOR (95% CI)	Median persistence (years)	aHR (95% CI)
RA	28812	24271	1.10	Ref	6783 (23.5%)	Ref	1.84	Ref
PsA	3021	2528	0.92	1.10 (1.05-1.16)	739 (24.4%)	1.00 (0.97-1.16)	1.59	1.13 (1.06-1.21)
AS	2019	1496	0.70	1.30 (1.23-1.38)	632 (30.8%)	1.41 (1.28-1.56)	1.36	1.27 (1.18-1.38)
TNF inhibitor discontinuation								
	N	PY	Time to discontinuation		Early discontinuation (within 90 days)		Late discontinuation (after 90 days)	
			Median persistence (years)	aHR (95% CI)	N (%)	aOR (95% CI)	Median persistence (years)	aHR (95% CI)
RA	24594	24106	1.27	Ref	4442 (17.4%)	Ref	1.81	Ref
PsA	6946	6734	1.50	0.96 (0.92-0.99)	1121 (16.1%)	0.98 (0.87-1.01)	2.04	0.97 (0.93-1.02)
AS	3978	3506	1.14	1.11 (1.05-1.16)	758 (19.0%)	1.17 (1.07-1.28)	1.75	1.09 (1.02-1.16)

Adjusted hazard ratio (aHR) and adjusted odds ratio (aOR) from multivariable Cox or logistic regression models adjusted for age, sex, and year. TNF inhibitor models also adjusted for which TNF inhibitor patients received. RA = rheumatoid arthritis, PsA = psoriatic arthritis, AS = ankylosing spondylitis, PY = person-years

Methods: This retrospective study using OptumInsight administrative data 2000-2014 evaluated adults with RA, PsA, or AS (based on two diagnosis codes and DMARD use) with no prior biologic use who received a first ever MTX prescription or first ever TNFi prescription or infusion, requiring 6 months of preceding data (baseline) and at least 90days of follow up. Cox proportional hazards were used to compare time to medication discontinuation over the next two years between patients with RA, PsA, or AS, adjusting for age, sex, and calendar year. We also assessed rates of early discontinuation (within 3 months) and late discontinuation (after 3months).

Results: We identified 33,882 patients initiating MTX and 36,518 initiating a TNFi. Median MTX persistence was 1.05years and 24% of patients discontinued MTX within 90 days. Discontinuation occurred sooner in patients with PsA [aHR 1.10 (1.05-1.16)] and AS [aHR 1.30(1.23-1.38)] vs. RA (Table). Early MTX discontinuation was more common in AS, and late discontinuation was more common in both PsA and AS (Table). Median TNFi persistence was 1.29 years and 17% of patients discontinued within 90 days. TNFi discontinuation occurred sooner in patients with AS [aHR 1.11 (1.05-1.16)] but later in patients with PsA [aHR 0.96 (0.92-0.99)] vs. RA (Table). Associations between AS and sooner TNFi discontinuation, however, were attenuated and no longer significant after adjustment for concomitant medications, comorbidities, and healthcare utilization (not shown). Among TNFi initiators, concomitant use of MTX was associated with longer TNFi persistence in RA, PsA, and AS (all $p < 0.001$, p for interaction 0.85). Depression, anxiety, chronic pain, opioid use, and greater comorbidity burden were associated with sooner discontinuation of MTX and TNFi in all groups.

Conclusion: TNFi and especially MTX discontinuation are common, with greater discontinuation in patients with mental health disorders, comorbidities, and chronic pain. Patients with PsA and AS discontinue MTX sooner than patients with RA but continue TNFi at similar rates, possibly indicating poorer tolerability or efficacy of MTX in spondyloarthritis. Use of MTX, however, is associated with less TNFi discontinuation in all disease groups.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vedolizumab (VDZ) is a monoclonal antibody approved for inflammatory bowel disease, with a gut-specific mechanism of action, binding to $\alpha 4\beta 7$ integrin expressed on gut-homing T lymphocytes. Few cases of flare or new occurrence of rheumatic disorders in patients treated with VDZ were reported in literature (1-2). A small cohort study (3) did not report new induction or flare of arthritis and/or sacroiliitis and some patients with active SpA showed some improvement in symptoms after VDZ. Our purpose is to observe the possible role of VDZ in new onset/recurrence of rheumatic manifestations.

Methods: Observational study of a series of 7 patients with IBD who developed inflammatory arthralgia after treatment with VDZ.

Results: Four out of 7 patients were women and 6 patients had been diagnosed with Crohn's disease (CD), 1 with ulcerative colitis (UC). The mean duration of IBD was of 14 years. The mean age was 49.8 years (range 24-63). None of the patients had previous history of arthritis/spondyloarthritis. One patient who was previously treated with Infliximab and Mesalazine, during the course of the treatment suffered from an episode of arthritis with spontaneous remission, 9 years before starting VDZ. Six patients out of 7 had previously been treated with biologic therapy, in 2/6 patients VDZ was the 2nd-line biologic therapy and in 4/6 patients the 3rd-line. Six patients fulfilled the ASAS criteria for spondyloarthritis (4-5), 1 was classified as unspecified inflammatory arthralgia. The mean number of infusions of VDZ received before the onset of symptoms was 3 (range 1-6) and the mean time of exposure to VDZ was 11 weeks (range 1-32). Five patients had high levels of inflammation with mean CRP of 15.6 mg/L (range 0.6-42.2). Three patients with back pain performed a MRI that showed sacroiliitis. In 2 cases HLA-B27 was investigated with negative result. Four patients discontinued VDZ, 3 restarted the previous biologic therapy with Adalimumab and 1 was started on Infliximab.

Conclusion: This is the longest series collected so far regarding rheumatic manifestations developed after onset of VDZ treatment for IBD. Further studies are needed to investigate the role of VDZ in rheumatic diseases.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The NOR-SWITCH study was funded by the Norwegian government to investigate switching from originator infliximab (INX) to biosimilar CT-P13, in spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA), plaque psoriasis (Ps), Crohn's disease (CD) and ulcerative colitis (UC). Previously, the primary analyses of the pooled indications have been published¹. Anti-drug antibodies (ADAb) are associated with treatment failure and have been a concern in switching. Here, we investigate immunogenicity of infliximab in patients treated with originator INX vs patients switched to CT-P13; between patients with different inflammatory diseases; and the epitope specificities of ADAb.

Methods: The study was a 52-week randomized, double-blind, non-inferiority, phase IV trial and included adult patients with SpA, RA, PsA, UC, CD or Ps on originator INX. Patients were randomized 1:1 to either continued INX or switch to CT-P13 treatment. Assays for drug serum levels and neutralizing ADAb are fully automated on the AutoDELFIATM (PerkinElmer, Waltham, MA) immunoassay platform. Immunogenic infliximab-epitopes were identified by ELISA and comparison of sera from patients with CD, UC, SpA, RA, PsA or Ps was performed.

Results: 20 patients entered the study with detectable ADAb (9 in INX arm, 11 in CT-P13 arm). 36 patients (17 in INX-arm, 19 in CT-P13 arm) developed incident ADAb during the 52-week main study period with no consistent difference between diseases though numbers are small. 36 patients' and 15 control sera were tested for epitope specificity. No Ps patients developed ADABs in our study. All anti-CT-P13 and anti-INX sera were cross-reactive with INX and CT-P13, respectively. ADAb concentrations against INX or CT-P13 were strongly correlated (r values 0.92 - 0.99, $p < 0.001$ for all experiments, Spearman's correlation test). ADAb-negative controls (10 healthy individuals, 5 patients with RA) were negative for both INX and CT-P13. Recognition of 5 different batches of CT-P13 and INX by IgG4 ADAb were similar between all tested sera. ADAb in 60%-79% of patients recognized 7 synthetic peptides, with no significant differences between CT-P13 and INX ADAb. However, two epitopes were specifically recognized in UC and CD but not in rheumatic patients. Patients with detectable ADAb at any time were more likely to discontinue study drug treatment (7/26 (26.9 %) in INX arm, 5/30 (16.7 %) in CT-P13 arm) than patients without detectable ADAb (17/214 (7.9 %) in INX arm, 13/210 (6.2 %) in CT-P13 arm) ($p = 0.001$).

Studies on a possible association between HLA and ADAb responses are ongoing.

Conclusion: ADAb occurred to a similar degree in the two study arms and ADAb to originator INX also recognized CT-P13. The majority of patients show no consistent difference in epitope specificity between RA, SpA, PsA, UC and CD patients. However, two specific minor epitopes are only recognized by IBD patients which might reflect the importance of HLA background for ADAb response.

Table 1. ACR 20/50/70 and PASI 75/90 response rates at Week 24 among biologic-naïve PsA patients¹

	ACR response rates			PASI response rates	
	ACR 20	ACR 50	ACR 70	PASI 75	PASI 90
PBO	21.7% (19.8%, 23.7%)	7.4% (6.1%, 8.8%)	2.9% (2.2%, 3.9%)	7.8% (5.4%, 11.0%)	3.0% (1.9%, 4.7%)
ABA	43.6% (28.1%, 61.0%)	13.4% (6.4%, 26.3%)	4.1% (1.5%, 11.6%)	12.3% (6.5%, 21.3%)	5.3% (2.4%, 10.6%)

TOF	47.5% (34.9%, 60.5%)	30.8% (19.4%, 45.4%)	13.0% (6.1%, 26.4%)	32.0% (20.6%, 44.9%)	17.9% (10.1%, 28.2%)
UST 45	41.6% (32.3%, 51.7%)	21.8% (13.3%, 34.4%)	14.8% (6.2%, 35.6%)	51.7% (38.6%, 65.0%)	34.2% (22.8%, 47.4%)
UST 90	47.7% (38.0%, 57.8%)	24.6% (15.3%, 38.0%)	17.2% (7.5%, 39.6%)	58.8% (45.3%, 71.4%)	40.8% (28.3%, 54.6%)

[1] PASI 75 and PASI 90 responses for APR and CZP were not reported among biologic-naïve population.

Methods: A systematic literature review was conducted to identify Phase 3 randomized controlled trials (RCTs) for TIMs approved for the treatment of active PsA in the US, including tumor necrosis factor- α inhibitors (adalimumab [ADA], certolizumab pegol [CZP], etanercept [ETN], golimumab [GOL], and infliximab [INF]), interleukin-17 inhibitors (secukinumab [SEC] and ixekizumab [IXE]), an interleukin-12/23 inhibitor (ustekinumab [UST]), a phosphodiesterase-4 inhibitor (apremilast [APR]), a selective T cell costimulation modulator (abatacept [ABA]), and a Janus kinase inhibitor (tofacitinib [TOF]) in active PsA. Joint (ACR 20/50/70) and skin (PASI 75/90) responses at Week 24 were estimated via a Bayesian network meta-analysis (NMA) among biologic-naïve patients. Treatment costs were based on Wholesale Acquisition Cost as of April 18, 2018 and included drug acquisition and administration costs. Incremental costs per responder relative to placebo were calculated as incremental treatment costs during 24 weeks divided by response rate difference vs. placebo.

Results: Fourteen RCTs that reported ACR and/or PASI responses at Week 24 among biologic-naïve PsA patients were included. INF, ETN, and GOL had higher ACR 50 response compared with other TIMs (Table 1). In terms of ACR 20 and ACR 70, GOL, INF, and SEC 150 mg had higher efficacy than other TIMs. With respect to PASI responses, INF, GOL, and IXE had higher efficacy than other TIMs. In terms of cost-effectiveness, when considering skin and joint responses together, INF (\$47,899 for ACR 50/\$42,522 for PASI 90), GOL (\$79,982/\$50,238), and ADA (\$111,259/\$96,149) were associated with lower incremental costs per additional ACR 50 or PASI 90 responder than other TIMs (Figure 1).

Conclusion: At Week 24, INF, GOL, and ADA had the lowest incremental cost per responder for joint and skin outcomes among all TIMs approved for PsA in biologic-naïve patients.

Effect of Biologics on Radiographic Progression of Peripheral Joints in Patients with Psoriatic Arthritis: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Dongze Wu¹, Priscilla Wong¹, James F Griffith², Jiang Yue¹ and Lai-Shan Tam³, ¹Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China, Hong Kong, China, ²Department of Imaging and Interventional Radiology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China, ³Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong

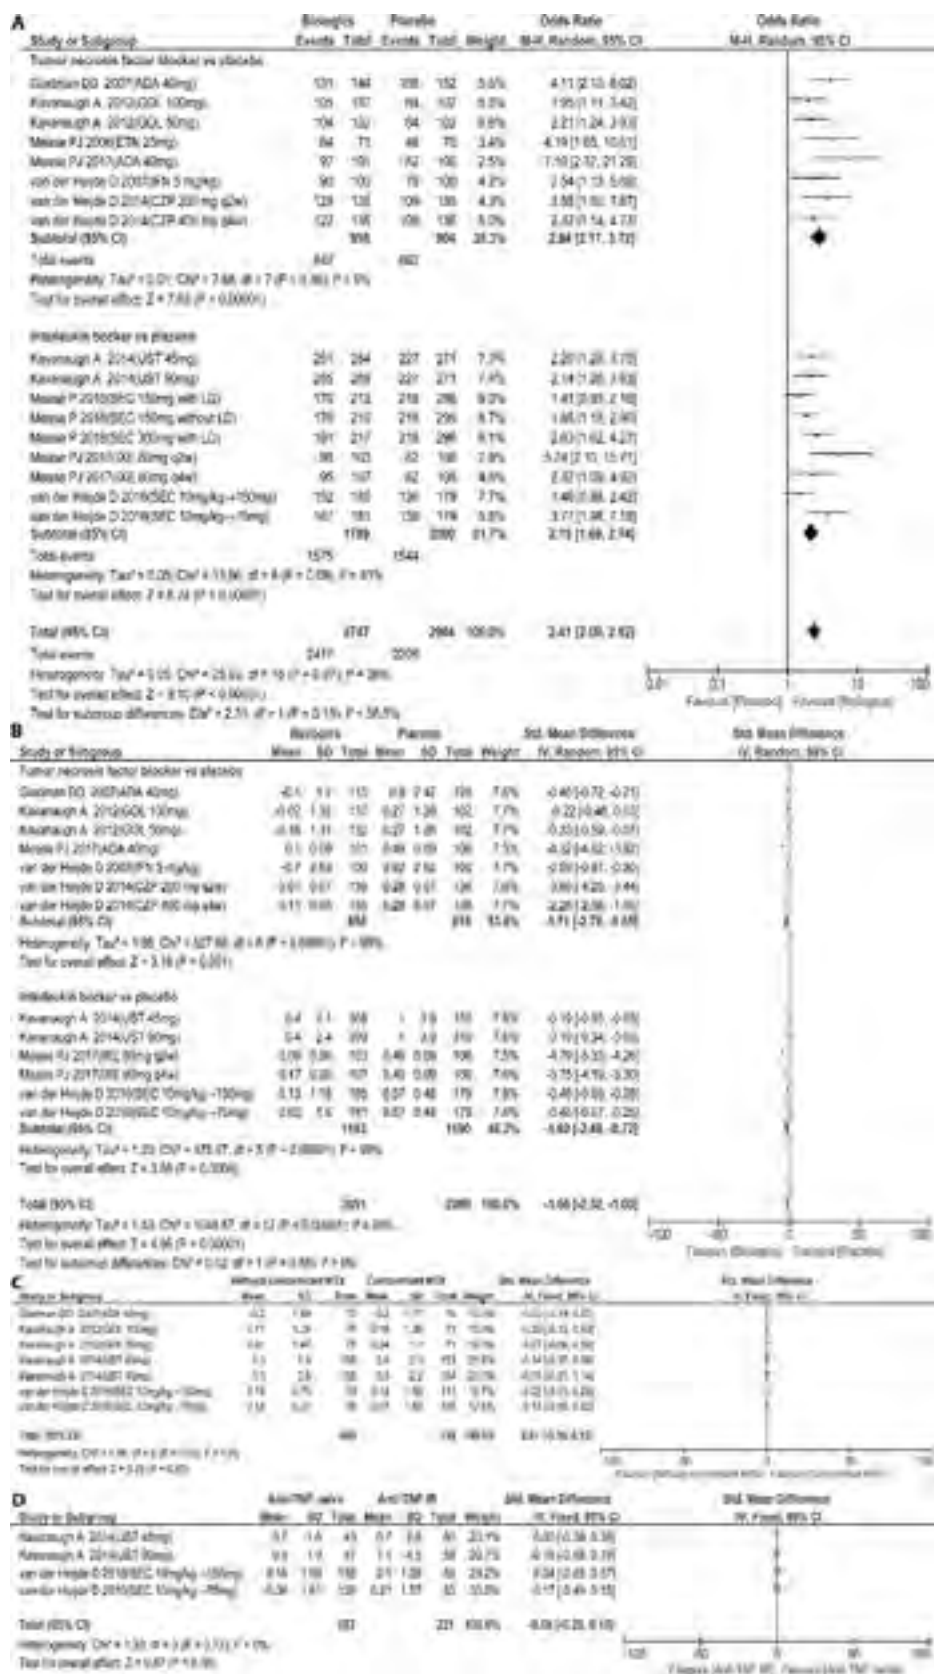

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) often leads to structural damage with resultant disability and reduced quality of life. Biologic disease modifying anti-rheumatic drugs (bDMARDs), including tumor necrosis factor alpha (TNF- α), interleukin (IL), phosphodiesterase type 4 (PDE-4) and Janus kinase (JAK) antagonists have shown clinical efficacy in PsA.

The aims of this study are to determine the efficacy of the following drug combinations in preventing radiographic progression in peripheral joints of PsA patients, namely 1) bDMARDs versus placebo 2) concomitant methotrexate (MTX) versus bDMARD monotherapy 3) IL blockers in anti-TNF-naïve patients versus anti-TNF-failure patients.

Methods: Systematic review of articles published up to May 2018 in Medline and Web of Science, and abstracts from the two last European League Against Rheumatism (EULAR) and American College of Rheumatology (ACR) meetings. Primary endpoint was the proportion of patients without radiographic progression (non-progressors) at week 24. Secondary endpoint was the mean change in total radiographic score [modified total Sharp score (mTSS) or modified van der Heijde-Sharp score (mvdH-SS)] at week 24. Odds ratio (OR) and standardized mean difference (SMD) with 95% CIs across studies were synthesized. Subgroup analyses were performed on pre-specified study-level characteristics. We assessed the quality of evidence using the GRADEpro. This study was registered with PROSPERO, number CRD42018095272.

Results: Nine studies (10 RCTs, 4,478 patients), 8 drugs (adalimumab, etanercept, infliximab, certolizumab pegol, golimumab, secukinumab, ustekinumab, ixekizumab) and 16 treatments were evaluated. Tofacitinib and apremilast were not included as complete radiographic data was not available. (1) Patients treated with bDMARDs were more likely to achieve radiographic non-progression compared with placebo (OR for pooled: 2.41, 95% CI: 2.00, 2.92; OR for TNF blocker: 2.84, 95% CI: 2.17, 3.72; OR for IL blocker: 2.15, 95% CI: 1.69, 2.74; Figure 1A), and have significantly lower radiographic progression (SMD for pooled: -1.66, 95% CI: -2.32, -1.00; SMD for TNF blocker: -1.71, 95% CI: -2.76, -0.65; SMD for IL blocker: -1.60, 95% CI: -2.49, -0.72; Figure 1B). (2) In patients receiving bDMARDs, concomitant MTX use was not superior to monotherapy (SMD: 0.01, 95% CI: -0.09, 0.12; Figure 1C). (3) The effect of IL blockers (ustekinumab, secukinumab) on radiographic progression were not influenced by prior anti-TNF therapy (SMD: -0.08, 95% CI: -0.25, 0.10; Figure 1D).

Conclusion: Biologic DMARDs can retard radiographic progression in PsA compared with placebo. Concomitant MTX treatment does not improve this effect. Prior anti-TNF therapy does not influence the radiographic efficacy of IL blockers.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Imaging, Clinical Studies, and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vedolizumab is a humanised IgG1 monoclonal antibody anti- $\alpha 4\beta 7$ integrin agent used in inflammatory bowel disease (IBD). It modulates gut inflammation by preventing leukocyte migration to gastro-intestinal mucosa. Vedolizumab is effective on IBD but has been incriminated in occurrence of articular manifestations. Our study aimed at describing rheumatic manifestations and their risk factors occurring in IBD patients treated by vedolizumab.

Methods: In this retrospective monocentric study, we identified through a systematic electronic search all IBD patients treated by vedolizumab in rheumatology and gastroenterology of our hospital. We collected all the cases of incident articular manifestations occurring in the follow-up of these patients. Characteristics of articular manifestations were

analyzed and classified as inflammatory or not, and characteristics of patients who presented inflammatory articular manifestations were compared to those of patients without.

Results: Between february 2013 and june 2017, we indented 112 patients treated by Vedolizumab (56 women, mean age 39.9 ± 16 years, mean disease duration = 9.1 ± 7.8). The IBD was Ulcerative Colitis (UC) in 59 (52.7%), Crohn's disease (CD) in 49 (43.8%), and undetermined colitis in 4 (3.6%). Only 4 (3.6%) had a history of spondyloarthritis and 14 (12.5%) of peripheral arthralgias associated with IBD. 102 (91.1%) patients previously received anti-TNF : one in 49.1%, two in 35.7% and three lines or more in 6.3%). At initiation of vedolizumab, 55 (49.1%) received a DMARD (azathioprine in 19.6%, purinethol in 11.6%, methotrexate in 7.1%).

After a mean follow up duration of 11.4 ± 8.6 months, 32 (28.6%) of the patients presented articular manifestations (figure).

We studied several risk factors for developing articular symptoms. Among them, only the previous history of articular manifestation was associated with an increased risk of occurrence of inflammatory manifestations (4.8% vs. 12.5%; $p=0.007$). The use of corticosteroids or methotrexate was not significantly associated with a lower incidence of articular manifestations.

Conclusion: Occurrence of articular manifestations in patients treated with vedolizumab for IBD is quite infrequent. Half of the manifestations were not of inflammatory origin. About 5% of the patients presented early reversible inflammatory arthralgias that did not require treatment discontinuing. Only 10% of the patients present persistent inflammatory rheumatic manifestations that evolved in most of cases in parallel to IBD, but were considered as occurring paradoxically in only 3 patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients present a higher prevalence of insulin resistance (IR) and metabolic syndrome (MetS) than age- and sex-matched healthy controls. Advances in technology are enabling evaluation for the prevention and early detection of those morbidities. Quantose IR is a simple test for IR based on a single fasting blood sample and may have value as an early indicator of risk for the development of prediabetes and type 2 diabetes mellitus (T2DM). The objective of this study was to evaluate IR in non-diabetic SLE women using metabolite markers identified using high-throughput metabolomic techniques.

Methods: SLE patients were consecutively enrolled in a cross-sectional study. A metabolomic approach using ultra-high performance liquid chromatography coupled with high-resolution mass spectrometry (UHPLC-HRMS) was developed in serum samples from non-diabetic SLE women. Activity (SLEDAI-2K) and damage (SLICC) index scores, as well as carotid intima-media thickness (IMT), were determined in SLE patients. Patients with a Quantose IR score of ≥ 63 were defined as IR. MetS was evaluated according to the NCEP-ATP III criteria.

Results: We enrolled 70 SLE patients with a mean \pm SD age of 39.3 ± 10.6 years and median disease duration of 11 years (IQR: 8-14). Forty-five of 70 (64.2%) and 27 (38.5%) SLE patients were found to have IR and MetS, respectively. The median Quantose IR score was 69 (IQR 52.7-80.0). Patients with IR had a higher body mass index (BMI) than those without IR (27 vs. 23.7; $p = 0.001$). Hypertension was more frequently found in patients with IR (33.3% vs. 8.0%; $p = 0.02$). The SLICC index and disease activity were not associated with the Quantose IR Score. The prevalence of a Quantose IR score ≥ 63 was higher in patients with MetS (81.5% vs. 53.5%; $p = 0.02$). Quantose IR score also correlated with the number of metabolic syndrome criteria ($r = 0.35$, $p = 0.003$). Carotid IMT values were not correlated with the IR index.

Conclusion: In non-diabetic SLE women, the prevalence of IR based on Quantose IR was 64.2% using UHPLC-HRMS. Although, some traditional IR factors, such as BMI and hypertension were associated with IR in these patients, SLE-related factors were not. Moreover, Quantose IR score may be related to MetS in those patients.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Human papillomavirus (HPV), a common sexually-transmitted infection, is considered a necessary cause of cervical cancer.

The objectives of this systematic review and meta-regression were: 1) to compare the prevalence of cervical HPV infection between SLE patients and healthy controls and 2) to evaluate the relationship between cervical HPV infection and traditional and SLE-related risk factors for cervical HPV infection in these patients.

Methods: We conducted a systematic literature review (PubMed, Cochrane library, Embase, Virtual Health Library and SciELO databases) following PRISMA guidelines and meta-regression to investigate the pooled prevalence of cervical HPV infection in adult women with SLE. The included articles were independently evaluated by two investigators who extracted information on study characteristics, defined outcomes, risk of bias and summarized strength of evidence [Quality of evidence using the Oxford Centre for evidence-based medicine (EBM) Levels of Evidence] Using meta-regression, we further analyzed whether factors such as multiple sexual partners and immunosuppressive therapy were associated with HPV prevalence. We evaluated the quality of evidence included using the Oxford Centre for evidence-based medicine (EBM) levels of evidence. Pooled odds ratios (ORs) and 95% confidence intervals (CIs) were calculated for studies providing data on HPV prevalence in women with SLE and in healthy controls.

Results: A total of 687 articles were identified; 9 full-text articles examining the prevalence of cervical HPV infection in SLE women were included, comprising 751 SLE women. Eight studies employed PCR using general primers. The HPV prevalence varied from 3.1% to 80.7%. From the random effects meta-analysis, the pooled prevalence of cervical HPV infection in SLE vs. controls was 34.15% (95% CI: 19.6%-52.5%) vs. 15.3% (95% CI 0.79-27.8%), OR = 2.87 (CI 95% 2.20-3.76) $p < 0.0001$ (Fig. 1), with large between-study heterogeneity ($I^2 = 95.4\%$). When only SLE women were evaluated, meta-regression showed no significant differences between patients with and without a background of multiple sexual partners and any immunosuppressive therapy. In addition, the prevalence of cervical HPV infection did not significantly differ between SLE patients on azathioprine or cyclophosphamide.

Conclusion: This meta-analysis suggests that the prevalence of cervical HPV infection was higher in SLE women than in healthy controls. However, multiple sexual partners and any immunosuppressive therapy or specific immunosuppressive treatment (azathioprine and cyclophosphamide) were not associated with cervical HPV infection prevalence in these patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Resistant hypertension (RHTN) is associated with increased risk of cardiovascular events in the general population. Patients with systemic lupus erythematosus (SLE) have increased cardiovascular risk, but little is known about RHTN in patients with SLE. We first compared the risk of RHTN in SLE patients and matched controls, then defined factors associated with RHTN in SLE, and finally calculated the risk of mortality associated with RHTN in SLE.

Methods: We used a validated algorithm (94% PPV) to identify adults with SLE from de-identified electronic health records at an academic medical center. We established a control cohort matched by age, race, and sex, with a 5:1 control-case ratio. Follow-up began with first SLEICD9 code (cases) or first ICD9 code (controls) and continued until RHTN or last visit. A RHTN diagnosis required simultaneous use of 3 antihypertensives including a thiazide diuretic and a mean outpatient blood pressure $\geq 140/90$ in the 6 months after therapy, or simultaneous use of ≥ 4 antihypertensives. We extracted demographic and comorbid variables using computer programming and included values closest to a patient's first relevant ICD9 code. We defined end-stage renal disease (ESRD) by an ESRD ICD9 or dialysis CPT code. We ascertained mortality by Social Security death files and hospital records. We used Cox proportional hazards models to compare risk of RHTN between groups, in incident cases only.

Results: We studied 1044 SLE patients and 5241 control subjects (Table). RHTN developed in 106 SLE patients (10%) and 278 controls (5%), with an incidence rate of 14.7 cases/1000 person-years in SLE compared to 7.4 in controls [HR 1.66, 95% CI, 1.26-2.21] (Figure). Patients with SLE had a higher risk of RHTN after adjustment for age, sex, race, calendar year, creatinine, and ESRD [HR 1.50, 1.12-2.00]. Among these patients, black race [HR: 3.20 CI: 2.48-4.12] and ESRD [HR: 5.76 95% CI: 3.85-8.62] were associated with RHTN. Finally, 25% of SLE patients with RHTN died compared to 10% of SLE patients without RHTN; this association remained significant after adjustment for age, sex and race [HR 2.83 CI: 1.65-4.87].

Conclusion: SLE Patients have a 1.7-fold higher risk of developing RHTN compared to frequency-matched controls. RHTN is an important comorbidity for clinicians to recognize in SLE, as it is associated with a 2.8-fold higher mortality risk.

Table. Baseline Characteristics

	N	Patients with SLE (N=1044)	Matched Controls (N=5241)	p value
Demographics				
Age at first ICD9 code (years)	6285	41 [30-53]	42 [31-54]	0.15
Female (%)	6285	941 (90.1)	4728 (90.2)	0.94

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that cardiovascular diseases (CVD) are a major contributor of death in systemic lupus erythematosus (SLE) as well in other rheumatic illness. In the last decades, there has been a growing development of different methodologies with the purpose of early detection of CVD. The aim of this study is to correlate the usefulness of subclinical parameters of vascular aging and QRISK3-2017 score for early detection of CVD in SLE.

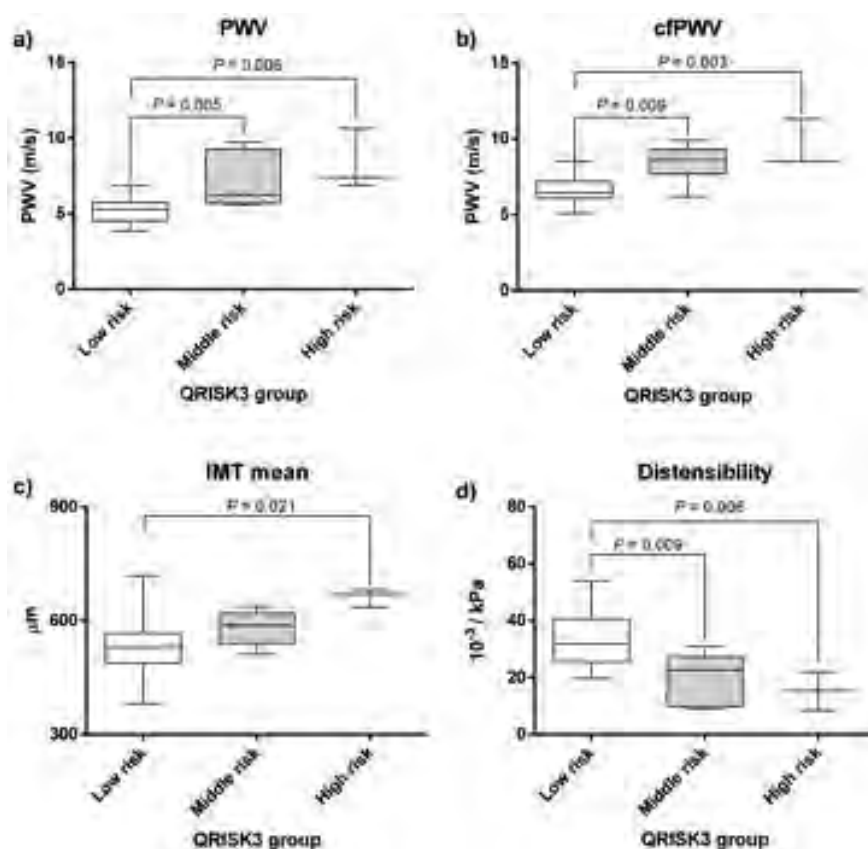

Table 1. Clinical and demographic characteristics in lupus and control subjects

Variable	Study group		P
	Lupus n = 50	CS n = 82	
Age (years)	33.6 ± 12.4	37.6 ± 12.9	0.076
Male / Female (n)	41 / 9	59 / 23	0.215
BMI, kg/m ²	25.6 ± 4.0	27.4 ± 5.0	0.026
Disease duration (years)	6.4 ± 4.8	—	—
SLEDAI	5.9 ± 4.2	—	—
SLICC	1.0 ± 1.2	—	—
Scholarship			
Basic (n, %)	22 (44%)	—	—
Upper secondary (n, %)	16 (32%)	—	—
Higher (n, %)	12 (24%)	—	—
Alcoholism (n, %)	0	0	N.S.
HT (n, %)	5 (10%)	0	0.007
DM2 (n, %)	3 (6%)	0	N.S.

Anti-dsDNA (n, %)	22 (44%)	—	—
Complement			
C3 (mg/dL, \bar{x} ± SD)	83.6 ± 21.3	—	—
C4 (mg/dL, \bar{x} ± SD)	20.3 ± 11.8	—	—
Carotid plaque (n, %)	0	0	N.S.
cIMT mean (μm)	519 ± 89	542 ± 113	N.S.
PWV (m/s)	5.5 ± 1.5	5.8 ± 1.3	N.S.
cfPWV (m/s)	7.1 ± 1.3	7.0 ± 1.2	N.S.
Distensibility, (10 ⁻³ / kPa)	32.0 ± 12.2	32.1 ± 13.0	N.S.

Methods: Clinical assessment including systemic lupus erythematosus disease activity index (SLEDAI) and systemic lupus international collaborating clinics/ american college of rheumatology damage index (SLICC/ACR DI), laboratory measurements, carotid ultrasound examination, carotid intima media thickness(cIMT) measurement, carotid distention and diameter analysis, arterial stiffness measurement measured by tonometry and QRISK3-2017 were done. All results were analyzed by SPSS 24 software.

Results: We observed correlation between QRISK3 and mean cIMT ($r_s = 0.651$, $P < 0.001$), PWV ($r_s = 0.627$, $P < 0.001$), cfPWV ($r_s = 0.651$, $P < 0.001$) and distensibility($r_s = 0.555$, $P = 0.001$). Consistent with above, SLE patients in middle and high risk QRISK3-2017 showed increased arterial stiffness versus low risk group.

Conclusion: We encourage to the rheumatology community to assess cardiovascular risk in SLE patients with QRISK3-2017 risk calculator as an alternative method at the outpatient clinic along a complete cardiovascular evaluation when appropriate.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an inflammatory, chronic and multisystemic disease, which can be related with a long range of neuropsychiatric manifestations, including cognitive impairment. Cognitive evaluations based on screening tests in SLE, might identify early cognitive alterations. Objective. The aim of this study was to evaluate and to compare the efficacy of three screening test for cognitive impairment, Montreal Cognitive Assessment (MoCA), Mini Mental State Examination (MMSE), Cognitive Symptom Inventory (CSI) against the gold standard (neuropsychological battery), and identify the most efficient screening test, in a group of patients with SLE.

Methods: This is an observational cross-sectional study that recruited 44 patients from august to December 2017, diagnosed with SLE according to Systemic Lupus International Collaborating Clinics (SLICC) criteria 2012, without medical or psychiatric comorbidities, evaluated by MoCA, MMSE, CSI and the gold standard. These evaluations were performed to detect the presence and degree of cognitive impairment. Statistics were done using SPSS software.

Results : The MoCA test showed the highest correspondence (AUC = 99.4% $p < 0.001$), sensitivity(84%) and specificity (100%) with the gold standard. Followed by MMSE (AUC = 92.6%, $p < 0.001$) sensitivity (54.8%), specificity (100%), and finally, CSI(AUC = 30.6%, $p < 0.05$) had the lowest sensitivity (54.8%) and specificity(30.76%).

Conclusion: The MoCA is a brief, easily applicable screening test, highly effective for detecting cognitive impairment in SLE patients. It could be useful in the clinical follow-up as a tool for early detection of cognitive alterations, and could facilitate a timely diagnosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psychiatric manifestations are relatively common in patients with systemic lupus erythematosus (SLE). Since there are a number of factors causing psychiatric manifestations other than SLE, the diagnosis of lupus psychosis (LP) is often difficult. Especially, it has been sometimes challenging to discriminate steroid psychosis (SP) from LP, since LP usually occurs after the initiation or increase of steroid. The current studies were therefore designed to clarify the differences in clinical features between LP and SP.

Methods: Multicenter retrospective cross-sectional study was performed with 51 SLE patients who presented psychiatric manifestations between 1992 and 2001. The diagnosis of LP and SP was confirmed by retrospective review of the clinical records. Demographic features, clinical manifestations, serum autoantibodies and cerebrospinal fluid IL-6 were compared between LP and SP.

Results: Thirty-one and 20 patients were judged by review of the clinical records as LP and SP, respectively, in the retrospective study. There were no significant differences in age and gender between the 2 groups. However, the prevalence of acute confusional state was significantly higher in LP, whereas the prevalence of mood disorder was predominant in SP (Figure 1). Eleven of the 31 patients with LP were complicated with seizure disorders, whereas no patients with SP presented seizure. Of note, CSF IL-6 levels were elevated above the cut-off value of 4.3 pg/ml in 27 of 31 patients with LP, but in none of 7 patients with SP. Finally, serum anti-Sm antibodies, but not anti-DNA or anti-phospholipid antibodies, were significantly elevated in 31 patients with LP compared with 20 patients with SP (Figure 2).

Conclusion: These results in the current studies highlight the differences in clinical and laboratory features between LP and SP. Thus, acute confusional state and complication of seizure are characteristic of LP, whereas the most prevalent manifestation of SP is mood disorder. Moreover, the data also suggest that CSFIL-6 as well as serum anti-Sm antibodies might be effective tools for differential diagnosis of LP from SP.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with increased risk of diffuse large B-cell lymphoma (DLBCL). DLBCL is routinely classified by cell-of-origin (COO), with non-germinal centre B-cell (GCB) indicating poorer prognosis in the general population. We studied COO subtyping in SLE patients diagnosed with DLBCL, and overall survival.

Methods: We evaluated 20 cases of SLE with DLBCL. In tissue microarrays, immunohistochemistry analysis was performed (BCL2, MYC, BCL6, CD10, CD20, FOXP1, GCET1, MUM1). We examined associations between molecular and clinical features, including overall survival (time to death, all-cause).

Results: Of the 20 DLBCL SLE cases (Table 1), 12/20 cases (60%) were classified as non-germinal centre B-cell (GCB) whereas 8/20(40%) were classified as GCB using Hans or Choi algorithms. MYC and BCL2 protein expression was positive in 6/20 (30%) and 8/20(40%) SLE cases, respectively with 2/20 (10%) co-expressing both markers. The median survival for all 20 cases was 39 (mean 64) months. As expected, non-GCB cases had worse survival. In both univariate and multivariable Cox proportional hazards models, both non-GCB type and nodal status (any nodal involvement versus none) were associated with lower survival (Table 2). Stratification of cases by nodal status revealed that SLE duration at DLBCL diagnosis was much longer in cases presenting with nodal-only involvement and that BCL2 expression tended to be greater in patients presenting with extra-nodal involvement only. We were unable to detect any molecular or clinical features differing by COO subtype. SLE patients presenting exclusively with extranodal DLBCL were associated with better survival despite higher BCL2 protein expression (which normally indicates poor prognosis).

Conclusion: We present novel data characterizing DLBCL in SLE. Sixty percent of the DLBCL in SLE patients were non-GCB. The nodal and extranodal distribution was similar between patient with SLE and the general population, but extranodal disease occurred more often with short SLE duration and was associated with longer over-all survival. Since non-GCB DLBCL rely on the activation of the NF- κ B and JAK-STAT pathways, future assessments of the links between SLE and DLBCL could focus on genetic factors related to the TNF superfamily (TNFSF4), TNF- α , TNF Alpha Induced Protein 3, and other related pathways.

Table 1. Descriptive features of the SLE-DLBCL (n=20) subjects

Variable	Median [IQR]
Sex (female)	2/20 (90)
Age at SLE Diagnosis	45 [36-54]
Age at time of DLBCL diagnosis	58 [48-66]
SLE duration at DLBCL diagnosis	11 [5-18]
Variable	N (%)
Diagnosed after 1991	12 (60)
Nodal-only involvement	10 (50)
Only extranodal involvement	7 (35)
MYC positive	6 (30)
BCL2 positive	8 (40)
BCL6 positive	7 (35)
Dual positive, MYC and BCL-2	2 (10)
Non-germinal B-cell origin (Hans)	12 (60)

Table 2. Cox proportional hazards ratio (HR) for survival in SLE-DLBCL (n=20).

Variable (reference)	Unadjusted HR (95%CI)	Adjusted* HR (95%CI)
Sex (female)	2.64 (0.95-7.37)	4.49 (1.06-19.0)
Year of DLBCL diagnosis (years)	0.97 (0.92-1.02)	0.94 (0.88-1.01)
Any nodal-involvement	0.29 (0.10-0.98)	0.09 (0.03-0.26)
Non-germinal B-cell origin cell type(Hans)	0.28 (0.08-0.93)	0.08 (0.02-0.43)

Recurrence of Lupus Nephritis in Renal Transplant Recipients

Debendra Pattanaik¹, Joseph Green², Manish Talwar³, Miklos Molnar³ and Syed Hasan Raza¹, ¹Rheumatology, University of Tennessee Health Science Center, Memphis, TN, ²rheumatology, University of Tennessee Health Science Center, Memphis, TN, ³University of Tennessee Health Science Center, Memphis, TN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recurrence of lupus nephritis in the graft is a concern in lupus patients with end stage renal disease who undergo renal transplantation. The recurrence of lupus nephritis has been variable among different studies depending on the patient characteristics, immunosuppressive regimens and indications of renal biopsy. One of the major change is the use of posttransplant immunosuppressive regimen consisting of tacrolimus and mycophenolate mofetil instead of cyclosporine and azathioprine in addition to prednisone. Many of the previous studies reported the recurrence of lupus nephritis where cyclosporine and azathioprine were used as posttransplant regimen. We investigated the recurrence of lupus nephritis among our patients to see if the new posttransplant regimen has impacted the recurrence.

Methods : All recipients, who were transplanted between 2006-2017 in our center, with end stage renal disease secondary to lupus nephritis have been included in the study (n=38). Medical records of all 38 patients were reviewed retrospectively in the electronic medical record and information from the United Network for Organ Sharing Network (UNOS) were also reviewed retrospectively. Demographic information, transplant and dialysis related information have been recorded including kidney biopsy, graft loss and survival. The result of the indication biopsies has also been recorded. Association between recurrent lupus nephritis and survival and graft loss were examined using survival models.

Results : The overall mean \pm SD age at baseline was 42 \pm 13 years; 89% were female; 89% were African-American; the previous time on dialysis was median of 4 years (IQR: 2-8 years), 80% received hemodialysis and 31% received living donor transplantation in the cohort. All our patients received the standard immunosuppressive regimen consisting of prednisone, tacrolimus and mycophenolate mofetil. Four (11%) of the 38 patients had biopsy proven lupus nephritis recurrence. Total of 10 patients (26%) had graft loss or death during the median follow up time was 1,230 days (IQR: 460-2,227 days). Patient with recurrence showed trend for increased risk for graft loss or death (Hazard Ratio: 3.14, 95% Confidence Interval: 0.65-15.24) compared to the recipient without recurrence in our unadjusted proportional Cox regression model.

Conclusion: Recurrence rate of lupus nephritis in our patient population is much lower compared to previous data from different immunosuppressive era. Patient with recurrent disease showed trend for increased risk for graft loss or death. The current standard of posttransplant immunosuppressive regimen may have played role in lower relapse rate.

patients with SLE have not been fully investigated. The aim of this study was to evaluate the effects of corticosteroid and immunosuppressants on the prognosis of TB in SLE patients.

Methods: This retrospective cohort study was conducted by reviewing the medical records between January 1, 2006 and December 31, 2016. SLE patients with TB infection were screened via ICD codes. Only those fulfilled the ACR 1997 classification criteria of SLE and presented with microbiological or typical histological evidence of TB were enrolled. Patients with history of organ transplantation, HIV, incomplete history of immunosuppressive agents, and those without taking anti-TB regimen were excluded. The primary outcome was mortality during TB treatment.

Results: 5388 patients with ICD codes of SLE were screened, and 88 patients with ICD codes of TB were identified. After review of the medical records, 32 patients and 33 episodes fulfilled the inclusion criteria and were enrolled. The mortality during TB treatment was 21.2% (7/33). In comparison with the patients in the survival group (n=26), the patients in the mortality group (n=7) had younger age at diagnosis (44.0 vs 57.5, $p=0.0384$), higher average prednisolone dose 30 days before TB diagnosis (55.3 mg/day vs 15.6 mg/day, $p=0.0010$), higher average prednisolone dose during TB treatment (56.3 mg/day vs 11.7 mg/day, $p=0.0001$), more steroid pulse therapy 6 months before the TB diagnosis (4/7, 57.1% vs 4/26, 15.4%, $p=0.0418$), and more cyclophosphamide pulse therapy 6 months before the TB diagnosis (6/7, 85.7% vs 3/26, 11.5%, $p=0.0005$). There was no significant difference between the two groups in SLEDAI-2K (7 vs 4, $p=0.1261$). The multivariate analysis by Cox proportional hazard model revealed that average dose of prednisolone more than 0.5 mg/kg/day during TB treatment (HR 33.18, 95% CI 1.63-674.28, $p=0.0227$) and cyclophosphamide 6 months before the diagnosis of TB (HR 34.05, 95% CI 1.80-642.96, $p=0.0186$) were associated with higher mortality during TB treatment.

Conclusion: This retrospective cohort study finds that the mortality during TB treatment correlates with prednisolone dose during TB treatment and cyclophosphamide use 6 months before TB diagnosis.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Subclinical myocardial dysfunction has been reported to occur early in SLE. The pathogenesis and prognosis of this finding is not clear. The study aims to search for biomarkers of subclinical myocardial dysfunction which may serve for early detection and better understanding of myocardial dysfunction pathogenesis in SLE.

Methods : A cross sectional study of 57 consecutive patients with SLE and 18 controls was performed. Demographic, clinical and cardiovascular risk factor data were obtained by questionnaires and review of patient charts. Serum samples were obtained to determine serum soluble ST2 (sST2), CXCL-10 and high sensitivity troponin (hs-troponin) levels. All participants underwent an Echo Doppler study including comprehensive diastolic function assessment.

Results: Cardiovascular risk factors were more frequent in the SLE group including hypertension, hyperlipidemia, chronic renal failure and smoking. SLE disease activity (SLEDAI) positively correlated with sST2, CXCL-10 and hs-troponin levels ($p=0.001$; $p<0.001$; $p=0.008$, respectively). Disease damage, measured by the SLE damage index (SDI) positively correlated with sST2 and CXCL-10 levels ($p=0.002$; $p<0.001$, respectively). Looking at tissue echo-Doppler, several measures of diastolic dysfunction negatively correlated with log CXCL-10: including E/A; E/e'_{lateral} and E/e'_{septal} ($p=0.04$, $p=0.003$, $p=0.029$, respectively) while E/e' positively correlated with CXCL 10 ($p=0.001$). Diastolic dysfunction parameters also correlated with log sST2 levels, a negative correlation was seen with E/e'_{lateral} and a positive correlation was seen with E/e' ($p=0.001$, $p=0.006$ respectively). Systolic dysfunction parameters positively correlated with hs-troponin: LVED, LVES, IVS, LVMASS and LVMASS index ($p=0.007$, $p=0.002$, $p=0.002$, $p=0.001$, $p=0.001$ respectively). In a multivariate analysis, log sST2 and log CXCL-10 were significantly different in SLE patients as compared to controls, independent of cardiovascular risk factors ($p=0.005$; $p=0.004$ respectively) and independent of each other ($p=0.003$, $p=0.018$, respectively).

Conclusion: Soluble ST2 and CXCL-10 levels were found to correlate with disease activity and accrued damage in SLE and may serve as sensitive biomarkers for early detection of diastolic dysfunction, independent of traditional cardiovascular risk factors, supporting the hypothesis that disease activity has an independent role in the development of myocardial dysfunction in SLE.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have multiple innate and adaptive immune response abnormalities. It is unknown whether they play a key role in the development of infections, which was the aim of the present study. Until now, a tool to predict infections that encompasses the clinical and immunological features characteristic of SLE patients was lacking.

Methods: A prospective cohort study of 55 SLE patients with less than 5 years since diagnosis was undertaken in a tertiary care center. Patients were prospectively followed up during a twelve-month period, looking for the primary outcome that was the development of infection, defined as the presence of characteristic clinical features with response to antibiotic treatment, with or without microbiological isolation. Severe infections were defined as those requiring hospital admission for at least 72 hrs, IV antibiotic treatment or causing death. We registered relevant clinical data and performed immunophenotyping by flow cytometry. We analyzed the number of neutrophil extracellular traps (NETs) and their LL-37 expression by confocal microscopy. Repeated measure analysis for the immunosuppressive therapy, mean adjusted SLEDAI score for disease activity. Relative risks (RR) for infection adjusted for clinical and immunological features. The study was approved by the institutional ethics and research committees.

Results: During 12 months of follow-up, 18 patients (32%) presented 19 infectious events in a median time of 21.5 weeks (IQR 4-24), 12% were severe. The main causes of infection were community-acquired pneumonia (23%), superior respiratory tract (23%) and urinary tract infections (17%), herpes zoster virus (17%), gastroenteritis (11%) and cellulitis (5%). In comparison to their baseline immunological parameters, there was a higher expression of LL-37 in LPS induced NETs and a higher amount of LDGs during the infectious events. After univariate and multivariate analysis, we developed an index to predict infection in SLE patients assigning a score according to the RR absolute values. The index parameters were cyclophosphamide use, absolute numbers of B cells, total Th17 lymphocytes and expression of TLR2 in monocytes measured with multi-parametric flow cytometry. We validated the index retrospectively in a nested case-control study and at baseline. In the case-control analysis, a score ≥ 2 was able to predict infection in the following 3 months (AUC= 0.79; likelihood ratio = 2.22, P=0.015). The same cutoff point at baseline predicted infection in the following year (AUC= 0.84; likelihood ratio = 2.0, P=0.012).

Conclusion: Our compound clinical-immunological index is able to predict the development of infection in SLE patients, taking into account the use of cyclophosphamide, absolute numbers of peripheral Th17 and B cells as well as TLR2 expression in monocytes. By alerting clinicians about patients who are more prone to develop infections, there could be a closer follow-up of these patients, with a targeted, multidisciplinary approach.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Infection is a leading cause of death and ICU admission in systemic lupus erythematosus (SLE) patients. Our aim was to investigate the outcome and costs of septic shock among SLE patients and to evaluate the main determinants of mortality.

Methods: We performed a retrospective analysis of all SLE patients hospitalized with a first episode of septic shock in France from January 1st, 2010 to December 31st, 2015 by extracting data from the PMSI database (*Programme de Médicalisation des Systèmes d'Informations*) which compiles all data concerning hospital discharges in France. SLE and septic shock diagnoses were based on ICD10 classifications. We assessed the lupus phenotype with diagnostic codes used before or during septic shock hospital stays. Severity of ICU stay was assessed by Simplified acute Physiology score (SAPS II) and procedure use were systematically recorded. Healthcare use and hospital costs were assessed at 1-year for septic shock survivors. Factors associated with 30-day and 1-year in-hospital mortality were studied using Cox regression models.

For multivariate analysis, we used sex, chronic kidney disease (CKD) and all variables that had a significance level < 0.20 as covariates.

Results: One thousand sixty eight (1,068) first ICU stays for septic shock were extracted from 130,150 hospital stays of SLE patients. In oonstrictors (epinephrine, norepinephrine) were used in 913(85.6%) patients, invasive mechanical ventilation for 369 (34.6%) and dialysis for 342 (32.0%). Thirty-day and 1-year post admission mortality rates were 30.9% (n=330) and 43.4% (n=463), respectively. Within one year, 30-day post septic shock survivors (n=738) were re-admitted (mean [SD]) 6.42[17.3] times for 64.1[48.9] days with a total cost of 14 431€ [20 444€] and 12 (1.6%) required chronic hemodialysis. Factors associated with death are shown in Table 1. At1-year, the main determinants of death were (HR [IC95]) Simplified Acute Physiology Score (SAPS II) (1,022 [1,017-1,026]), Charlson-age adjusted comorbidity index (1,166 [1,106-1,228]), an associated Goujerot-Sjögren syndrome(1,392 [1,021-1,899]) and fungal infection (1,371[1,056-1,781]).

Conclusion: For SLE patients septic shock is associated with poor short- and long-term outcomes and heavily increased healthcare use at 1-year. We found that independently of severity of the acute illness, Goujerot-Sjögren associated syndrome is a main determinant of 1-year death. Other characteristics of the SLE phenotype were not associated with short and 1-year prognosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our study aimed to determine whether sCD163, a soluble macrophage marker upregulated in numerous inflammatory disorders, might be predictive of accelerated atherosclerosis associated with SLE.

Methods: The presence of carotid plaques was prospectively assessed by repeating ultrasound analysis in 63 consecutive SLE patients asymptomatic for cardiovascular disease (CVD) and 18 volunteer health-workers (controls). Ultrasound was performed at baseline and during follow up by a single investigator. Serum level of sCD163 was determined at baseline using ELISA. The primary outcome was the presence of a carotid plaque. Factors associated with carotid plaques were identified through multivariate analysis.

Results: Despite a low risk for cardiovascular events according to Framingham score in both groups ($2.1\% \pm 3.8$ in SLE vs $2.1\% \pm 2.9$ in controls; $p=0.416$), ultrasound study at baseline showed a carotid plaque in 23 (36.5%) SLE patients versus 2 (11.1%) controls ($p=0.039$). Multivariate analysis showed that SLE status increased the risk for carotid plaque by a factor of 9 ($p=0.017$). In SLE patients, sCD163 level was high ($483.7 \text{ ng/ml} \pm 260.8$ versus $282.1 \text{ ng/ml} \pm 97.5$ in controls; $p<0.001$) and independently associated with carotid plaques as assessed by stratification based on sCD163 quartile values ($p=0.009$), receiver operating characteristic (ROC) ($p=0.001$) and multivariate analysis ($p=0.015$). Eventually, sCD163 at baseline was associated with the onset of carotid plaque during follow up (3 ± 1.4 years) in SLE patients who had no carotid plaque at first evaluation ($p=0.041$).

Conclusion: Since sCD163 is associated with developing carotid plaque in SLE, it may be a useful biomarker for accelerated atherosclerosis in SLE patients at apparent low risk for CVD

1. Serum level of sCD163 in SLE patients (black rounds) and controls (white rounds).

2. Percentage of SLE patients (black bars) with carotid plaque according to serum level of sCD163 divided by quartile values

3. ROC curves of sCD163 for prediction of carotid plaque in SLE patients. AUC, area under the curve; CI, confident interval

4. Serum level of sCD163 measured at baseline in SLE patients with or without carotid plaque at first vascular assessment (black rounds, top). Serum level of sCD163 measured at baseline in SLE patient who had no carotid plaque (square box) at first assessment and in whom carotid plaque did or did not occur during follow up (black round, bottom).

The Burden of Chronic Kidney Disease in Systemic Lupus Erythematosus (SLE): A Nationwide Epidemiologic Study

Arthur Mageau¹, Jean Francois Timsit¹, Anne Perozziello¹, Stephane Ruckly¹, Claire Dupuis¹, Lila Bouadma¹, Thomas Papo¹ and Karim Sacre², ¹Université Paris-Diderot, Paris, France, ²Bichat Hospital, Paris Diderot University, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis occurs in about 50% of SLE patients. We aimed to analyze the impact of chronic kidney disease (CKD) on major clinical outcomes in SLE by using a nationwide medico-administrative database.

Methods: We performed a retrospective cohort study to analyse hospital stays' characteristics of SLE population in France from January 1st, 2009 to December 31st, 2015. We extracted data from the PMSI database (Programme de Médicalisation des Systèmes d'Informations) which compiles hospital discharges of all French healthcare facilities. PMSI uses International Classifications of Diseases 10th revision (ICD-10) to encode diagnosis. All the diagnosis and procedures performed during hospital stays associated with or following a "M32" diagnosis code, which defines the SLE population, were identified. Factors associated with major clinical outcomes such as death, end-stage renal disease (ESRD), septic shock, and cardiovascular event were assessed. Kaplan-Meier method was used to represent survival without major clinical outcomes according to the presence of CKD (eGFR <60mL/min/1.73m²) at first stay.

Results: From 2009 to 2015, 145 794 hospital stays associated with SLE diagnosis corresponding to 26 320 unique SLE patients were identified. Mean age [SD] at first stay was 46.7 [+/-17.2] and 85.6% were female. Among patients with kidney disease at first stay, 20.8% developed end-stage renal disease (ESRD) during follow up. Overall, from 2009 to 2015, death, septic shock, and cardiovascular event occurred in 6.7%, 4.5% and 10.5% of SLE patients, respectively. CKD identified at first stay in 2009 was significantly associated with the occurrence of death (RR 2.4 [2.0-2.9]), ESRD(RR 4.02 [2.86-5.65]), septic shock (RR 3.1 [2.3-4.2]), and cardiovascular event (RR 1.9 [1.6-2.3]) between 2009 and 2015.

Conclusion: Our results confirm at a nationwide level that CKD is a major risk factor for overall morbidity and mortality in SLE patients, highlighting the need for early pre-CKD lupus nephritis diagnosis. Occurrence of death (A), ESRD (B), cardiovascular event (C) and septic shock (D) between 2009 and 2015 according to CKD status (eGFR <60mL/min/1.73m²) at first stay in 2009. Blue lines represent the outcome in patients without CKD at first stay. Red lines represent the outcomes in patients with CKD at first stay

Assessing Dyspnea in Patients with Systemic Lupus Erythematosus

Chia-Chi J. Lee¹, Lindsay J. Forbess², Daniel J. Wallace², Caroline Jefferies² and Mariko Ishimori³, ¹Cedars-Sinai Medical Center, Los Angeles, CA, ²Division of Rheumatology, Cedars-Sinai Medical Center, Los Angeles, CA, ³Medicine, Division of Rheumatology, Cedars-Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lungs can be affected in up to 50% of systemic lupus erythematosus (SLE) patients. Our aim was to assess the prevalence and degree of dyspnea in a SLE cohort using questionnaires and to see if they correlate with lung involvement.

Methods: Consecutive patients with SLE by 1997 ACR criteria in the Lupus Clinical Repository at a single academic center were given the UCSD Shortness of Breath Questionnaire (UCSD SOBQ) and the Dyspnea-12 Index (D-12). These questionnaires have been validated in connective tissue disease-related interstitial lung disease (ILD) cohorts but not in SLE. UCSD SOBQ is a 24-item tool (scores 0-120) assessing dyspnea severity with activities of daily living and its psychological impact. D-12 is a 12-item scale (scores 0-36) incorporating “physical” and “affective” aspects of dyspnea severity. Scores >50 were considered high for UCSD SOBQ and >12 for D-12. Demographics and SLE disease characteristics were recorded. Lung involvement was ascertained with medical record review by two rheumatologists. Correlation between dyspnea scores and lung involvement was determined using the Spearman’s Rank Order Correlation or Wilcoxon rank sum test, as appropriate, with SAS 9.4. A p value of <0.05 was considered significant.

Results: 50 SLE patients completed questionnaires (95% female, mean age 44 ± 14 years, mean disease duration 18 ± 10 years). 42% were White, 16% Latino, 12% Black, 10% Asian, and 20% other. Mean ±SD SLE disease activity (SLEDAI-2K) was 3.8±4. 98% of subjects were ANA positive, with about 1/3 positive for anti-dsDNA (27%), anti-RNP (33%), and anti-Smith (33%). Fewer were positive for Anti-Ro(17%), anti-La (6%) and anti-centromere (4%). 48/50 (96%) of subjects had abnormal UCSD SOBQ scores consistent with some degree of dyspnea. 37/50 (74%) had both abnormal UCSD SOBQ and D-12 scores. The median score was 24 (8-52) for UCSD SOBQ and 3 (0-8) for D-12. 13 had high UCSD SOBQ (score > 50), 10 had high D-12 (score > 12), and 8 had high scores on both indexes. 8 had lung involvement (7 ILD, 1 pleurisy) with all but 1 having a high UCSD SOBQ score, and 5 of them having both high UCSD SOBQ and D-12 scores. 3 had high scores on both indexes without SLE related lung involvement (2 heart failure, 1 unidentifiable cause). 3 had high UCSD SOBQ without high D-12 scores and no SLE related lung involvement (1 asthma, 2 unidentifiable cause). 2 had high D-12 without high UCSD SOBQ scores and no SLE related lung involvement (1 asthma, 1 unidentifiable cause). High UCSD SOBQ (p = 0.002) and D-12 scores (p = 0.004) were strongly associated with SLE lung involvement. High UCSD SOBQ scores correlated with higher SLE disease activity (SLEDAI-2K) (p = 0.03) and high D-12 scores with positive anti-dsDNA (p = 0.03). There were no significant associations with age, sex, SLE disease duration, or other autoantibodies.

Conclusion: Dyspnea was prevalent in our SLE cohort. UCSD SOBQ and D-12 questionnaires captured the majority of SLE patients with known lung involvement, with UCSD SOBQ being potentially more sensitive than D-12. These questionnaires may be useful tools to screen for dyspnea and possibly identify subclinical shortness of breath in SLE patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Whereas SLE is uncommon in men, the disease is usually more severe and requires more aggressive immunosuppression in male patients. There are multiple studies regarding sexual aspects in women with SLE, but information about sexual function in male patients is quite scant. The impact that the SLE-associated physical and psychological aspects have in these patients has not been previously addressed.

Methods: We performed a transversal study in a third-level referral center in Mexico City (between January and May 2018). We included men aged ≥ 16 years who fulfilled ACR criteria for SLE and who were sexually active in the previous six months. Patients with other autoimmune diseases (except for APS) or chronic viral infections were excluded. All subjects answered the International Index of Erectile Function-15 (IIEF-15) and the SF-36 (which determines generic health-related quality of life) questionnaires. Other clinical, serological and demographic variables were measured. Oxidized LDL was quantified by ELISA.

Results: We included 73 male SLE patients. Mean age was 37.8 ± 2.7 years and disease duration was 9.0 ± 7.3 years. SLEDAI score at the time of the study was 4.3 ± 4.1 points; most patients (87.7%) were taking immunosuppressive therapy. Comorbidities were present in 54.7% of subjects, with dyslipidemia and hypertension being the most prevalent (31.5% each).

Global IIEF-15 score was 56.4 ± 15.2 (range 5-75 points) and global SF-36 score was 70.1 ± 12.9 (range 0-100 points). There was a positive correlation between both scores (see Fig. 1). There was also a weak correlation between oxidized LDL levels and global IIEF-15 ($r=0.321$, $p=0.036$). Regarding erectile function, 37 subjects (50%) had some degree of dysfunction. These patients were older (34.7 ± 12.1 vs 40.9 ± 12.7 years, $p=0.037$), had a lower education degree ($p=0.002$) and a higher prevalence of type 2 diabetes mellitus ($p=0.016$) than those without erectile dysfunction. The rest of the variables are shown in Table 1.

Interestingly, 86% of patients said they would be willing to consult a specialist if any degree of sexual dysfunction was detected.

Conclusion: Global sexual function, and especially erectile function, is impaired in men with SLE. Most patients with sexual dysfunction are young and sexually active, and this should be considered by their rheumatologists, in order to inquire about this issue in regular visits. Further research is required to determine the physiopathogenic mechanisms underlying this condition, but endothelial damage and SLE-associated neuropsychological features could play a role.

Table 1

Variable	Mean \pm SD
Demographic	
Age (years)	37.8 \pm 12.7
Body mass index (m ² /kg)	26.6 \pm 4.8
Less than 10 years of schooling (n, %)	17/73 (23.2)
Time since SLE diagnosis (years)	9.0 \pm 7.3
Clinical Features	
Total score IIEF-15 (reference interval: 5-75 points)	56.47 \pm 15.2
Erectile function (reference interval: 1-30 points)	22.68 \pm 7.6
Intercourse satisfaction (reference interval: 0-15 points)	10.4 \pm 3.6
Orgasmic function (reference interval: 0-10 points)	7.7 \pm 2.9
Sexual desire (reference interval: 2-10 points)	7.4 \pm 1.8
Overall satisfaction (reference interval: 2-10 points)	8.1 \pm 1.6
Total score SF-36 (reference interval: 0-100 points)	70.14 \pm 12.9
Physical component summary score (reference interval: 0-100 points)	72.2 \pm 17.6
Mental component summary score (reference interval: 0-100 points)	68.0 \pm 11.2
Secondary antiphospholipid syndrome (n, %)	22/73 (30.1)
SLEDAI score (points)	4.3 \pm 4.1
Others comorbidities (n, %)	40/73 (54.7)
Laboratory features	
Hemoglobin (mg/dl)	15.4 \pm 2.43
Leukocytes (mm ³) (x10 ³)	5.69 \pm 2.2
Absolute lymphocyte count (mm ³)	1333.5 \pm 760.6
Absolute neutrophil count (mm ³)	3661.3 \pm 1759.4
Neutrophil-to-lymphocyte ratio	3.9 \pm 5.7
Platelets (cells/μl) (x10 ³)	216.3 \pm 77.2
Serum creatinine (mg/dl)	1.4 \pm 1.7
C3 levels (reference interval: 87-200 mg/dl)	104.9 \pm 32.8
C4 levels (reference interval: 19-52 mg/dl)	19.5 \pm 11.6
Anti-dsDNA antibodies (reference interval: \leq 9.6 UI/ml)	249.1 \pm 796.0
Use of immunosuppressive treatment (n, %)	64/73 (87.7)
Prednisone (n, %)	41/73 (56.2)
Current dose (mg/day)	5.30 \pm 7.9
Azathioprine (n, %)	26/73 (35.6)
Current dose (mg/day)	36.3 \pm 54.8
Antimalarial (n, %)	48/73 (65.8)
Current dose (mg/day)	150.3 \pm 123
Mycophenolate mofetil (n, %)	27/73 (37)
Current dose (mg/day)	616.4 \pm 887.9
Cyclophosphamide exposure previous 6 months (n, %)	7/73 (9.5)
Cumulative dose (previous 6 months) (mg)	417 \pm 1466
Anticoagulation (n, %)	11/73 (15.0)
Non-immunosuppressive treatment (n, %)	56/73 (76.7)

Interleukin-6 Level in Cerebrospinal Fluid As a Biomarker for Systemic Lupus Erythematosus Patients with Longitudinally Extensive Transverse Myelitis like Neuromyelitis Optica Spectrum Disease

Yasuhiro Hasegawa¹, Yoshiyuki Arinuma¹, Kazuma Ino¹, Takumi Muramatsu¹, Junichi Kondo¹, Yu Matsueda¹, Takayuki Hoshiyama¹, Toshihiro Tono¹, Tatsuhiko Wada¹, Tatsuo Nagai² and Sumiaki Tanaka¹, ¹Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Sagamihara, Japan, ²Kitasato University, Department of Rheumatology and Infectious Diseases, Sagamihara, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Background/Purpose: Demyelinating syndrome in NPSLE includes the wide range of lesions similar to multiple sclerosis (MS). Recently, the diagnostic criteria for neuromyelitis optica spectrum disease (NMOSD) has been established, independently of MS. Clinically, longitudinally extensive transverse myelitis (LETM) as is described in the definition of NMOSD can be observed even in patients with SLE. IL-6 in cerebrospinal fluid (CSF) has been reported as one of biomarkers in NMOSD, but in lupus patients with LETM, the utility of CSF IL-6 for a diagnosis and as a surrogate marker after treatment has not been demonstrated. The aim of this study is to reveal the characteristic of lupus patients with NMOSD-like lesions, especially focusing on CSF IL-6.

Methods: SLE patients who had admitted to Kitasato University hospital due to a diagnosis and a treatment for NPSLE since 2004 to 2018 were exhaustively collected. Of collected NPSLE patients, patients who were classified as demyelinating syndrome were recruited for this analysis. To be compared with characteristics of patients with NMOSD not involving other autoimmune diseases, these patients were divided into two groups according to the lesions by magnetic resonance imaging: patients with LETM as is defined in international consensus diagnostic criteria for NMOSD and patients with brainstem and/or spinal cord lesions other than LETM. Clinical data including CSF IL-6 based on their medical charts were reviewed. The IL-6 levels in CSF were compared with non-parametric tests.

Results: Total 77 NPSLE patients admitted for 14 years. Of 77 patients, 12 patients (15.6%) had some brainstem and/or spinal cord lesions like demyelinating syndromes in NPSLE. 7 patients had LETM and of 7 patients with LETM, 2 patients were positive for anti-aquaporin 4 antibody. Of remained 5 patients, 1 patient had as small and punctuated lesion in brainstem and 4 patients had spinal cord lesion unlike LETM. The median level in CSF IL-6 in these 12 patients was 29.10 pg/ml, which was significantly decreased to 3.75 pg/ml ($p=0.008$) after treatment (Figure 1A). In patients with LETM, the median level of CSF IL-6 was 18.7 pg/ml, which tended to be decreased ($p=0.065$) after treatment (Figure 1B). Interestingly, patients with LETM positive for anti-Sm antibody had higher CSF IL-6 level (Figure 1B).

Figure 1 The change of IL-6 levels in CSF by treatment

Conclusion: IL-6 in CSF could be one of biomarkers in SLE patients with LETM, presumably depending on causes of LETM including autoantibodies.

Bartels⁴, ¹Rheumatology/ Medicine, University of Wisconsin - Madison, Fitchburg, WI, ²Nephrology/ Medicine, University of Wisconsin, Madison, WI, ³Nephrology/ Pediatrics, University of Wisconsin, Madison, WI, ⁴Rheumatology/Medicine, University of Wisconsin - Madison, Madison, WI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is significantly accelerated in young systemic lupus erythematosus (SLE) patients including those with lupus nephritis (LN). Despite literature suggesting that renal arteriosclerosis is an early predictor of CVD, presence of arteriosclerosis often overlooked in LN biopsies. Hence, we aimed to examine the prevalence of renal arteriosclerosis in kidney biopsies of LN patients by age group and in comparison to published rates in healthy adult kidney donors. We hypothesized that renal arteriosclerosis burden will be greater and will accelerate at a younger age in LN patients compared to healthy donors.

Methods: Our cohort study identified all consecutive LN patients who underwent kidney biopsy between 1994 and 2017 at an academic center. Data were abstracted from a comprehensive native renal biopsy database including sociodemographics and reported details regarding the first biopsy in SLE patients. SLE diagnosis was validated using SLICC 2012 and SLE duration was recorded from electronic health records. Biopsy reports were reviewed for LN class and chronicity as classified per International Society of Nephrology guidelines. The primary outcome of interest, renal arteriosclerosis (without arteritis or thrombi) was classified into four categories based on BANFF criteria for donor kidney biopsies: none, mild, moderate, severe. Prevalence of (A) any renal arteriosclerosis and (B) moderate-severe arteriosclerosis was calculated. Further, we compared predictors of the presence of any renal arteriosclerosis (vs. absence) using multivariate logistic regression.

Results: Among 189 incident LN patients with kidney biopsies, 78% were female, 78% white and median age was 25 years (2-79 years). Prevalence of any renal arteriosclerosis and moderate-severe renal arteriosclerosis was 31.8% and 7.4% respectively in LN patients (Table 1). Respective rates of 51.7% (any) and 10.8% (mod-severe) in ages 40-49 were comparable to healthy kidney donors ages 70-79.

Univariate analysis in LN patients showed that age, chronicity and ever smoking were positive predictors of renal arteriosclerosis. Multivariate analysis showed a peak of 11 times greater odds of renal arteriosclerosis in LN patients ages 40-49 compared to younger patients (OR 11.7, CI 1.6, 246.0), and chronicity predicted nearly three times greater odds of arteriosclerosis (OR 2.9, CI 1.2, 7.1). LN class and SLE duration were not predictors of arteriosclerosis.

Conclusion: Findings showed significantly greater burden of renal arteriosclerosis in LN patients two to three decades earlier than in healthy kidney donors. Quantifying renal arteriosclerosis burden in LN is important as a potential early predictor of CVD in SLE. Future work will compare prevalence and predictors of renal arteriosclerosis in SLE, vasculitis and non-glomerulonephritis biopsies and long-term CVD outcomes.

Table 1. Prevalence of Any or Moderate-Severe Arteriosclerosis in LN by Age Groups

Age groups	Prevalence Any arteriosclerosis	Prevalence Moderate-severe	Control Prevalence* (Any, Moderate-severe)
Overall (n=189)	31.8%	7.4%	(32%, 3.3%)
0-9 years (n=16)	6.3%	6.3%	NA
10-19 years (n=66)	22.2%	0	NA
20-29 years (n=33)	17.9%	0	(10%, 0%)*
30-39 years (n=17)	35.3%	11.8%	(19%, 2%)
40-49 years (n=29)	51.7%	10.8%	(37%, 2.3%)
50-59 years (n=12)	59.0%	25.0%	(44%, 7%)
60-69 years (n=12)	66.7%	33.3%	(51%, 6.5%)
70-79 years (n=4)	50.0%	25.0%	(82%, 9.1%)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Table: Factors associated with blood pressure variability in patients with SLE

Variable	Spearman coefficient	p-value
Age	0.15	<0.001
Creatinine	0.14	<0.001
C-reactive protein	0.12	0.002
Charlson score	0.18	<0.001
C3	-0.05	0.13
C4	0.003	0.94
Body mass index	-0.007	0.84

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have increased mortality compared to the general population. As outcomes related to disease control have improved, this mortality difference has been explained increasingly by higher rates of cardiovascular and renal disease. Blood pressure visit-to-visit variability (BPV) has emerged as a risk factor for cardiovascular and renal outcomes in the general population but little is known about this relationship in SLE. We hypothesized that SLE patients have greater BPV than control subjects and that BPV is associated with higher comorbidity burden and increased mortality in SLE.

Methods: We identified a cohort of patients with SLE using a previously validated algorithm (PPV 94%) from a de-identified version of an academic medical center's electronic health record(EHR) and then frequency-matched (age, race, and sex) SLE patients to a control group in a ~5:1 control-case ratio. We excluded patients with fewer than three visits or age <18 years at the time of the first relevant ICD9 code (710.0 for SLE, any code for controls). We extracted demographic variables (age, race, and sex), ICD9 codes, laboratory results, and outpatient blood pressure values from the EHR. We compared BPV in SLE patients and controls. The primary outcome was systolic blood pressure coefficient of variation. Secondary outcomes included standard deviation, average real variation, and successive variation for both systolic and diastolic blood pressure. Second, we examined the association between BPV with clinical characteristics and mortality in patients with SLE.

Results: 899 patients with SLE and 4172 controls met inclusion criteria. Age, sex, and race were similar among the SLE and control groups. Patients with SLE had higher systolic BPV 9.7% [7.8-11.8] than the control group 9.2% [7.4-11.2], $p<0.001$ measured by coefficient of variation. All other measures of BPV were significantly higher in patients with SLE than in controls. In SLE patients, BPV correlated significantly with age, creatinine, C-reactive protein, and the Charlson comorbidity score; but not with C3, C4, and body mass index (Table). There was no statistically significant difference in BPV by sex, but Caucasian SLE patients [9.6%(7.9-11.4)] had lower BPV than SLE patients who were African-American [10.3%(7.9-12.9)] or patients from other races [10.4% (7.6-12.3)], $p=0.015$. Over a median follow-up of 6.5 years, 91 patients died. After adjustment for age, sex, race, and baseline Charlson comorbidity score, higher BPV was associated with death in patients with SLE [OR=1.24, 95%CI 1.16-1.33, $p<0.001$].

Conclusion: SLE patients had a higher BPV than the control group. In patients with SLE, higher BPV was associated with older age, higher creatinine, inflammation, comorbidity index, and mortality.

Patient-Reported Cognitive Screen Does Not Identify Cognitive Sub-Domains: Exploration of the Subscale Structure of the Perceived Deficits Questionnaire in a Systemic Lupus Erythematosus Cohort

Lisa Engel¹, Jiandong Su¹, Emily Nalder², Yael Goverover³, Monique Gignac⁴, Carmela Tartaglia⁵, Nicole Anderson¹ and Zahi Touma¹, ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Department of Occupational Science and Occupational Therapy, University of Toronto, Toronto, ON, Canada, ³Department of Occupational Therapy, New York University, New York, NY, ⁴Institutue for Work and Health, Toronto, ON, Canada, ⁵University of Toronto, Krembil Neurosciences Centre, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Identifying patients with Systemic Lupus Erythematosus related cognitive impairment (SLE-CI) is critical as SLE-CI can negatively affect employment, quality of life, and disease self-management. Evidence-based and resource-efficient SLE-CI screening instruments are needed. The patient-reported 20-item Perceived Deficits Questionnaire (PDQ-20) is a potential instrument. However, our previous analyses questioned the PDQ-20 purported four-factor structure: attention/concentration, retrospective memory, prospective memory, and planning/organization. The purpose of this study is to explore the PDQ-20 factor (subscale) structure in an SLE cohort.

Methods: This study used PDQ-20 data from consecutive patients aged 18-65 years who met the ACR classification criteria for SLE in a single Canadian rheumatology center. Exploratory factor analyses (EFA) included squared multiple correlations and the maximum likelihood method to extract factors, followed by a varimax (orthogonal) rotation. Subsequent confirmatory factor analyses (CFA) was completed on identified factor structures. The validity of the results was tested with the assumption that each item had one factor pathway, with factor correlations considered. The sample size met standards for EFA ($>5 \times \text{items}$) and was sufficient to perform CFA (power=0.99).

Results: Participants who did ($n=177$) and did not return ($n=31$) the PDQ-20 did not statistically significantly differ in age, age at SLE diagnosis, education or employment status. EFA without any restriction resulted in 5 factors. However, one factor included only one item (Q19. Forget to take your medication). The EFA scree-plot and eigenvalues (factor 1=119.38) provided strong support for a single factor model. Four factors had eigenvalues over 1, with each factor having 4-6 items, which pulled for examination of a new four-factor model. Overall hypothesis test rejected the assumption of no common factor (Tucker and Lewis coefficient = 0.94). CFA results indicated adequate model fit for the new four-factor model (standardized root mean square residual=0.04; root mean square error of approximation=0.08; Bentler comparative fit index=0.93; all item factor loadings statistically significant with standardized factor loading range 0.56-0.88). Lagrange Multiplier statistics in the CFA found alternate item-factor pathways that significantly improved the model by adding or removing pathways. Correlations between the new four factors were all statistically significant with high interrelatedness (range: 0.80-0.92).

Conclusion: Results indicate that the PDQ-20 has one factor. Some results support a four-factor model distinct from the original PDQ-20 subscales. However, this new model exhibits high correlations between factors and multiple item pathways, and it does not correspond with a theoretical cognitive conceptual structure. This may be due to the recruitment of multiple cognitive domains in items related to everyday living activities. Evidence from this analysis and our previous CFA of the original PDQ-20 factor structure indicates that the PDQ-20 has one factor and should be interpreted using the total score and not subscales.

Are Traditional Biomarkers of Lupus Associated with Renal Pathology in Lupus Nephritis?

Kelly Liang¹, Kimberly P. Liang², Yaming Li³, Alex Hurd³, Douglas Landsittel⁴ and Sheldon Bastacky⁵, ¹Medicine, Renal-Electrolyte Division, University of Pittsburgh, Pittsburgh, PA, ²Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, ³Biostatistics, University of Pittsburgh, Pittsburgh, PA, ⁴Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA, ⁵Pathology, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditional biomarkers for systemic lupus erythematosus (SLE) and lupus nephritis (LN) include serum creatinine (Cr), complement levels (C3/C4), double-stranded DNA antibody (dsDNA), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), urine red blood cells (uRBC), and urine protein/Cr ratio (uPCR). However, these clinical parameters have limited specificity for active LN and are inconsistent predictors of renal pathology. Whether these biomarkers are associated with LN class has important implications in therapeutic decision-making. The objectives of this study are: 1) to determine whether these biomarkers are associated with LN on renal biopsy; 2) to determine whether they can distinguish between LN classes; and 3) to assess correlation between these biomarkers and activity and chronicity indices on renal biopsy.

Methods: Using the University of Pittsburgh Health Sciences Tissue Bank (HSTB) and Renal Pathology Department stored biopsy specimens, we identified 37 cases of LN diagnosed on renal biopsy from 2010-2016. Using the electronic database, we obtained LN classes and biomarkers checked within a few days to a month of biopsy date for each sample. Descriptive summaries, correlations, Fisher's exact test, and rank-sum tests were used to evaluate the relationship between the biomarkers and LN.

Results: Of the 37 LN samples, 1 had class I, 3 had class II, 10 had class III, 15 had class IV, and 13 had class V (5 with isolated class V) LN. Excluding samples with missing data, 14 (47%) had Cr >1.3 mg/dL. There were 17 (56.7%) with low C3, 18 (60.0%) with low C4, and 16 (59.3%) with dsDNA positivity. Of the 11 samples negative for dsDNA, 8 had class III or IV, and 3 had class I, II, or V LN. Overall mean \pm SD ESR was 53.3 ± 35.6 mm/h and CRP was 1.2 ± 2.5 mg/dL. Hematuria was variably reported, but only 11 (37.9%) had >5 RBC/hpf on urinalysis. Mean \pm SD uPCR was 2.6 ± 2.9 mg/g Cr. Comparison of biomarkers between classes III and IV vs. other classes (I, II, V, and II+V) showed significantly greater proportion with low C3 (66.7% vs. 16.7%; $p=0.027$) and significantly higher activity index (7.2 ± 3.8 vs. 1.0 ± 0.7 ; $p=0.002$) in class III-IV vs. other classes. Comparison of biomarkers for class V only vs. classes III and IV with or without class V (III, IV, III+V, and IV+V) showed significantly lower proportion with low C3 (0.0% vs. 66.7%; $p=0.008$) and significantly lower activity index (0.5 ± 0.7 vs. 7.2 ± 3.8 ; $p=0.034$) in class V vs. class III-IV. There was no significant correlation between any biomarker and activity index. There was borderline significant correlation between CRP ($\rho -0.4$, $p=0.058$) and uPCR ($\rho 0.4$, $p=0.057$) and chronicity index.

Conclusion: Traditional biomarkers of SLE and LN are imperfect predictors of LN class on renal biopsy. Surprisingly, only C3 was significantly different between LN classes, and none were significantly correlated with activity and chronicity indices. Because clinical laboratory and urine biomarkers do not distinguish LN classes well, renal biopsy is necessary to reliably diagnose LN class. Given the lack of associations between traditional biomarkers and renal pathology, more specific LN biomarkers are urgently needed.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The extant epidemiologic data of primary discoid lupus erythematosus (DLE) and primary cutaneous lupus erythematosus (CLE) remains limited with few published estimates for the general population and scant data regarding racial/ethnic populations in the U.S. DLE is associated with considerable morbidity given it tends to occur on the face, scalp, and ears and is associated with scarring and permanent alopecia. The Manhattan Lupus Surveillance Program (MLSP) is a population-based registry comprised of patients with Systemic Lupus Erythematosus (SLE) and related diseases treated in New York County (Manhattan) that was developed to determine the incidence and prevalence of SLE among Manhattan residents. Leveraging MLSP data we provide estimates of the prevalence and incidence of DLE and CLE during 2007 and 2007-09, respectively, in Manhattan across the major racial/ethnic populations (Black, Latino, Asian, White).

Methods: MLSP cases were identified from hospitals and associated lupus clinics, rheumatologists, and state population databases. Case screening was performed using a Manhattan address and ICD-9 codes, including 695.4 for DLE. Charts were abstracted and final diagnosis coded. DLE was defined as a diagnosis of primary DLE. CLE was defined as either a diagnosis of DLE, subacute cutaneous lupus erythematosus (SCLE), lupus profundus, chilblain lupus, or lupus tumidus. All diagnoses required notation by a rheumatologist, dermatologist, or pathologist. Patients who met ACR criteria for SLE were excluded.

Results: There were 74 prevalent and 26 incident primary DLE cases, resulting in preliminary age-adjusted overall prevalence and incidence rates of 4.4 and 0.5 per 100,000 person-years. Overall age-adjusted prevalence and incidence rates were 2 and 8 times higher among women compared with men, respectively. The age-adjusted prevalence of DLE was significantly higher among Blacks (15.1) and Latinos (4.8) compared with Whites (0.6) and Asians (0.6). The age-adjusted incidence of DLE was significantly higher among Blacks (1.8) compared with Whites (0.1) and Latinos (0.4). Diagnoses of SCLE, lupus profundus, chilblain lupus, and lupus tumidus were rare and thus the age-adjusted overall prevalence and incidence rates of CLE were similar to DLE (4.5 and 0.6 per 100,000 person-years, respectively). CLE, with 77 prevalent and 31 incident cases, had similar gender and racial ethnic differences.

Conclusion: Using data from a large population-based registry revealed substantial racial/ethnic and gender disparities in DLE and CLE among Manhattan residents. These data are consistent with the evidence of similar disparities among SLE patients with DLE and suggest Blacks are disproportionately affected whether they have the systemic or primary form. These data also provide epidemiologic estimates for DLE and CLE for the major racial/ethnic populations in the U.S.

Table 1: Age-adjusted rates of DLE and CLE among Manhattan residents, overall and by sex and race/ethnicity

	Prevalent Cases, 2007 Rate per 100,000 person-years (95% Confidence Interval)	Incident cases, 2007-2009 Rate per 100,000 person-years (95% Confidence Interval)
Primary DLE		
Total	4.4 (3.4-5.5)	0.5 (0.3 -0.7)
Male	2.5 (1.5 -3.9)	0.1 (0.0 -0.3)
Female	5.9 (4.4-7.8)	0.8 (0.5-1.3)
Race/ethnicity		
Non-Latino White	0.6 (0.2-1.4)	0.1 (0.0-0.4)
Non-Latino Black	15.1 (10.4-21.1)	1.8 (0.9-3.2)
Latino	4.8 (2.9-7.5)	0.4 (0.1-0.9)
Non-Latino Asian	0.6 (0.0-3.5)	0.6 (0.1-1.7)
Primary CLE		
Total	4.5 (3.6-5.7)	0.6 (0.4 -0.8)
Male	2.5 (1.5 -3.9)	0.1 (0.0 -0.3)
Female	6.2 (4.4-8.1)	1.0 (0.7-1.5)
Race/ethnicity		
Non-Latino White	0.6 (0.2-1.4)	0.1 (0.0-0.4)
Non-Latino Black	15.1 (10.4-21.1)	1.8 (0.9-3.2)
Latino	5.7(3.5-8.6)	0.4 (0.1-0.9)
Non-Latino Asian	0.6 (0.0-3.5)	0.6 (0.1-1.7)

There were 77 CLE cases (31 incident) and 74 DLE cases (26 incident).

Rates are per 100,000 Manhattan residents. Denominator data is based on 2007-2009 intercensal population estimates from the NYC DOHMH Bureau of Epi Services (2000-2014 files).

Data are age adjusted to the US 2000 Standard Population.

Cases were assigned to one of five mutually exclusive race/ethnicity categories: non-Latino white, non-Latino black, non-Latino Asian, Latino, and non-Latino other. Non-Latino cases identified with more than one race were categorized as non-Latino other.

Anti-Retinoblastoma Protein Antibody Is Protective Against Lupus Nephritis

Jessica Li¹, Andreas Goules², Daniel Goldman¹, Antony Rosen³, Livia Casciola-Rosen⁴ and Michelle Petri¹, ¹Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ²Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ³Division of Rheumatology, The Johns Hopkins University School of Medicine, Baltimore, MD, ⁴Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Retinoblastoma protein (RB) regulates nucleosome/chromatin structures and is linked to tumor suppression. It regulates the cell cycle by repression of E2F transcription factor and stabilization of heterochromatin. Because SLE is the prototypic autoimmune disease with autoantibodies against the nucleosome and chromatin, the presence of anti-RB antibodies and the association with disease manifestations were examined.

Methods: 222 SLE patients from the Hopkins longitudinal cohort seen consecutively in clinic were studied (85% female, 94% Caucasian, mean age 51 years). Anti-RB antibodies were assayed by immunoprecipitation of ³⁵S-methionine-labeled protein generated by in vitro transcription and translation from full length human cDNA. Odds ratios and p-values for univariate analyses were calculated using Fisher's exact t-test. Exact logistic regression and odds ratios were calculated for the multi-variate model due to a cell frequency of zero for proteinuria ever and positive anti-RB antibody status.

Results: Anti-RB antibodies were present in 8.6% of these SLE patients, 6.3% with medium-high titer. Univariate associations with SLE manifestations for the medium-high titer positive patients are included in Table 1.

Table 1. Association of Anti-RB antibodies with SLE Manifestations

	Anti-Rb Positive (N=14)	Anti-Rb Negative (N=203)	p-value	OR (95% CI)
Vasculitis ever	0 (0.0%)	34 (16.8%)	0.1338	N/C
Proteinuria ever	0 (0.0%)	75 (37.0%)	0.0028	N/C
Hematuria ever	1 (7.1%)	43 (21.2%)	0.3103	0.29 (0.04, 2.25)
Renal SLE ever (Hematuria OR Proteinuria)	1 (7.1%)	81 (39.9%)	0.0145	0.12 (0.01, 0.9)
Stroke ever	2 (14.3%)	3 (1.5%)	0.0347	11.11 (1.69, 72.94)
Anemia ever	1 (7.1%)	124 (61.1%)	<0.0001	0.05 (0.01, 0.38)
Anti-Ro	4 (28.6%)	65 (32.2%)	1.0000	0.84 (0.25, 2.79)
Anti-La	1 (7.1%)	31 (15.4%)	0.6988	0.42 (0.05, 3.36)
Anti-RNP	1 (7.1%)	36 (17.7%)	0.4731	0.36 (0.05, 2.82)
Anti-Smith	1 (7.1%)	35 (17.2%)	0.4745	0.37 (0.05, 2.92)
Anti-dsDNA	6 (42.9%)	126 (62.1%)	0.1679	0.46 (0.15, 1.37)
RVVT	2 (14.3%)	69 (34.0%)	0.1525	0.32 (0.07, 1.49)
Anticardiolipin	9 (64.3%)	124 (61.1%)	1.0000	1.15 (0.37, 3.55)
Coombs	1 (7.1%)	33 (16.3%)	0.7021	0.40 (0.05, 3.13)

N/C=odds ratio was not calculated due to zero cell frequencies

Of note, medium/high titer anti-RB antibodies were never found in patients with proteinuria (p=0.0028). We next constructed a multi-variate model for proteinuria.

Table 2. Anti-RB antibodies Remain Negatively associated in a Multi-variate Model for Proteinuria

Variables	OR (95% CI)	p-value
Anti-RB	0.112 (0, 0.558)	0.016
Gender (Female)	0.417 (0.172, 0.999)	0.0498
Ethnicity (Caucasian)	0.288 (0.06, 1.144)	0.0833
Anti-dsDNA	1.806 (0.873, 3.808)	0.1192
Anti-Sm	1.273 (0.505, 3.154)	0.7127
Low complement	2.111 (1.04, 4.377)	0.0377

Conclusion: Anti-RB antibodies are a novel specificity not previously described in SLE. These antibodies are strongly negatively associated with lupus nephritis, even in multivariate models that include other variables (female gender, Caucasian ethnicity, anti-dsDNA, anti-Sm, and low complement). Intriguingly, anti-RB antibodies are positively associated with stroke in SLE. Additional studies are warranted to understand the mechanism of this finding.

Abstract Number: 727

Increased Risk of Coronary Artery Disease Among Patients with Class III Lupus Nephritis: A Retrospective Study of Patients at the University of North Carolina at Chapel Hill

Enid Y Sun¹, Carolina Alvarez² and Saira Z Sheikh³, ¹Internal Medicine, University of North Carolina, Chapel Hill, NC, ²Thurston Arthritis Research Center, Department of Medicine, University of North Carolina, Chapel Hill, NC, ³University of North Carolina at Chapel Hill, Chapel Hill, NC

Table 1. Odds Ratios and 95% CI of Coronary Artery Disease by Lupus Nephritis Class

LN class categories (n)*	OR (95% CI)
<i>Demographic + CAD + LN factors model with all classes**</i>	
Class 2 (n = 4)	2.90 (0.71, 11.9)
Class 3 (n = 18)	2.00 (0.98, 4.06)
Class 4 (n = 153)	1.31 (0.72, 2.37)
Class 5 (n = 97)	1.41 (0.75, 2.65)
Class 6 (n = 5)	2.76 (0.32, 23.8)
Classes 3 and 5 (n = 67)	2.45 (1.22, 4.90)
Classes 4 and 5 (n = 53)	1.58 (0.67, 3.76)
Classes 3 and 4 (n = 8)	0.86 (0.56, 26.5)
<i>Demographic + CAD + LN factors model with combined class III*</i>	
Any class 3 involvement (n=143)	2.35 (1.44, 3.86)
Other class involvement (n=333)	1.45 (0.87, 2.16)

* Three categories had n=1 and one category had n=0, however none of these patients had CAD. For these reasons, these subjects were not included in this analysis (n=9). 123 patients were missing LN class information.

** Adjusted for: **age, sex, 5-level race-ethnicity, HTN, DLP, DM, smoking history, steroid use, DMARDs use**. Model covariates—covariates in bold were independently significant with CAD at 0.05.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at an increased risk for developing coronary artery disease (CAD) compared to their cohorts without lupus. There have been several studies published that suggest that the presence of lupus nephritis (LN) is independently associated with CAD. However, none of these studies have looked at this association by class of LN. The purpose of our study was to define the characteristics of patients with SLE seen at the University of North Carolina Hospitals (UNCH); assess whether the presence of LN is independently associated with CAD; and evaluate whether this association varies according to specific LN classes.

Methods: A retrospective cross-sectional analysis was performed using medical records of patients 18 years and older with SLE at UNCH from April 4, 2014 to December 31, 2017. Subjects were identified using ICD-9 and ICD-10 codes specific for SLE. LN class was defined by ISN/RPS classification and determined based on review of renal biopsy and clinic notes. CAD was the outcome of interest and was defined by ICD codes for unstable angina, ST segment elevation myocardial infarction (STEMI), or non-STEMI. To determine the association between LN and CAD among SLE patients, logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI).

Results: The sample consisted of 3732 patients, 12% men with a mean (standard deviation) age of 48 (15.2) years; 43% White, 38% Black. Seventy percent had hypertension (HTN), 42% had dyslipidemia (DLP), 23% had diabetes mellitus (DM), and 38% had a history of smoking. Sixteen percent had LN (n=598) and 14% had CAD. When adjusting for age, sex, race/ethnicity, HTN, DLP, DM, smoking, steroid use, and disease-modifying antirheumatic drugs (DMARDs) use, the odds of having CAD were significantly higher for SLE patients with LN compared to patients without LN [OR 1.58, 95% CI (1.18, 2.14)]. In the LN analyses (Table 1), combined class III and V was significantly associated with CAD and class III alone was strongly associated with CAD. In several statistical models, class III was either strongly or significantly associated with increased risk of CAD. To better study the relationship between class III LN and CAD, all subjects with evidence of class III LN either alone or in combination were combined and the odds of CAD assessed. In this analysis any class III involvement was significantly associated with CAD compared to subjects without LN.

Conclusion: The results of our study confirm the findings of previous studies that LN is significantly associated with CAD after controlling for demographic, CAD, and lupus-specific factors. Ours is the first to study this association by LN class. We have shown that there may be an unexplored association between class III LN and CAD. We believe that our study reveals a critical area of further investigation and potential clinical intervention.

A Higher Activity Index at Initial Renal Biopsy Is Associated with Rapid Progression to Renal Failure in Patients with Refractory Lupus Nephritis

Shuwei Wang¹, Stacy Tanner², Teja Kapoor³, Thania Perez⁴, Vivette D D'Agati⁵, Anca Askanase⁴, Robert Winchester³ and Laura Geraldino-Pardilla³, ¹Rheumatology, Columbia University, College of Physicians & Surgeons, New York City, NY, ²Division of Rheumatology, Columbia University, College of Physicians & Surgeons, Winnipeg, DC, Canada, ³Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, ⁴Columbia University, College of Physicians & Surgeons, New York, NY, ⁵Pathology & Cell Biology, Columbia University, College of Physicians & Surgeons, New York City, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a major cause of morbidity and mortality affecting ~50% of systemic lupus erythematosus (SLE) patients. Up to 30% of patients with LN progress to end stage renal disease (ESRD). Blacks and Hispanics develop LN earlier and have worse prognosis compared with whites. It remains controversial whether a higher activity index (AI) at the initial renal biopsy correlates with poor renal outcomes. We sought to investigate the association between AI and progression to renal failure in refractory LN patients of predominantly black and Hispanic backgrounds.

Methods: This study included sixty-one SLE patients meeting 1997 SLE ACR classification criteria and followed at the Columbia University Lupus Center, with a first renal biopsy performed between 1994 and 2015, and at least one subsequent biopsy due to refractory disease. Demographics, clinical, laboratory, and histopathologic characteristics were ascertained. Renal failure was defined as ESRD requiring renal replacement therapy (dialysis or transplant). Logistic regression models were constructed using STATA/SE 13.0 to evaluate for predictors of progression to renal failure within 5 years.

Results: Of the 61 patients, 51 (84%) were female, 26 (43%) Hispanic, and 18 (30%) black. The mean age at SLE diagnosis was 26 ± 12 years (Table 1). Twenty-two patients (36%) progressed to renal failure. Fibrinoid necrosis on first renal biopsy was associated with renal failure in unadjusted [OR 4.13 (CI 1.21- 14.05), $p=0.024$] and multivariate analyses (adjusting for age, sex, race, and serum creatinine at time of first biopsy) [OR 4.21 (CI 1.18 – 15.05), $p=0.027$]. Among the 22 patients with renal failure, 11 progressed to renal failure in less than 5 years and the median time from first renal biopsy to renal failure was 4.8 years (3.5-7.9). AI on the first renal biopsy significantly predicted progression to renal failure within 5 years in unadjusted [OR 1.24 (CI 1.01- 1.51), $p=0.038$] and multivariate analyses (adjusting for age, sex, race, and serum creatinine at time of first biopsy) [OR 1.26 (CI 1.004 – 1.58), $p=0.046$]. Chronicity index was not significantly associated with rapid progression to renal failure.

Conclusion: In a predominantly Hispanic and black cohort of refractory LN patients, 36% progressed to renal failure with half of them progressing in less than 5 years. AI on the first renal biopsy was an independent predictor of faster progression to renal failure and should prompt aggressive therapy.

Abstract Number: 729

Atherosclerotic Vascular Events in SLE – an Evolving Story

Murray Urowitz¹, Jiandong Su¹ and Dafna D Gladman^{1,2}, ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Atherosclerotic vascular events(AVEs) are a major cause of mortality and morbidity in systemic lupus erythematosus (SLE) with a prevalence of 8-12%. We aimed to determine the changing pattern of AVE occurrence over the decades and to discern the effect of change in management of both classic risk factors for AVE and SLE.

Methods: Inception patients who entered the Lupus Clinic between 1975 and 1987 and followed to 1992 (Cohort 1) and between 1999 and 2011 and followed to 2016 (Cohort 2) were studied. AVEs (MI, angina, congestive heart failure, pace maker insertion, transient ischemic attack, stroke), attributed to atherosclerosis, and occurring during the 17 years, were identified. Lupus disease activity and therapy as well as hypertension, hypercholesterolemia, hyperglycemia and smoking were assessed. Analysis included descriptive statistics on baseline characteristics, traditional risk factors over the follow up, outcome rates by each 100 person years; Kaplan-Meier cumulative AVE curves, as well as competing risk Cox models adjusted by Inverse Probability Weights (IPW).

Results: There were 234 patients in Cohort 1 and 262 in Cohort 2. At enrollment the two cohorts were similar other than a greater number of Caucasians in Cohort 1 and more use of antimalarials and immunosuppressives in Cohort 2. Cohort 2 patients were more often treated with anti-hypertensives, lipid lowering therapy and smoking cessation and more often used antimalarials and immunosuppressives during the years of follow-up. 28(12%) of patients in Cohort 1 had an AVE compared with 10 of 262 (3.8%) in Cohort 2. The rate per 100 patient-years of follow-up was 1.9 in Cohort 1 and 0.44 in Cohort 2 (P < 0.0001) (Table). Percent of time with normal risk factors over the 17 year period was better in Cohort 2 (Table). The hazard ratio from IPW weighted model is 0.38 (95%CI: 0.22, 0.66) comparing cohort 2 to Cohort 1, a reduction of 62% in the risk for AVE in Cohort 2 (p = 0.0007).

Conclusion: The incidence of AVE in SLE in the modern era has declined in large part due to more effective management of classic coronary artery disease risk factors and SLE disease activity and treatment.

Table: Outcomes and management of risk factors and disease activity in SLE

Variable	Cohort 1 1975 - 1987	Cohort 2 1999 - 2011	P values
Number of patients	234	262	NA

Accrual of Atherosclerotic Vascular Events over 10 Years in a Multicentre Inception SLE Cohort

Murray Urowitz¹, Dafna D Gladman², Nicole Anderson² and Jiandong Su², ¹Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of atherosclerotic vascular events (AVE) in published literature of an inception cohort with SLE is 10%. We aimed to investigate the annual occurrence and the associated factors of AVE in a multinational multiethnic inception cohort of patients with SLE.

Methods: A large 33-centre multinational inception cohort of SLE patients was followed yearly according to a standardized protocol between 2000-2018. Patients entered the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Patients followed for at least 10 years were identified. AVEs are described and attributed on a specialized form. Diagnosis of AVE is confirmed using standard clinical criteria, relevant laboratory data and imaging. Attribution to atherosclerosis (AS) is made on the basis of SLE being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Analysis included descriptive statistics, rate of AVE's per 100 patient-years of follow-up and univariable and multivariable models.

Results: Of the 1847 patients enrolled in the cohort, 659 were followed for a minimum of 10 years (90.1% female, 46.3% Caucasian, 14.0% Black, 17.9% Asian, 18.4% Hispanic and 3.5% other). At enrolment mean age was 33.68 ± 12.75 years and SLEDAI-2K 5.75 ± 5.74. Disease duration at enrolment was 5.55 ± 4.21 months. The prevalence of AVEs, increases over time and is illustrated in table 1. The rate of AVEs per 100-patient years was 0.34. This was similar to the rate found in the entire cohort (N=1847) of 0.35. Associated univariate risk factors for AVE were older age at enrolment, male sex, Caucasian ethnicity, smoking, hypertension, and high cholesterol (Table 2). In multivariable analyses, associated risk factors for AVE were older age at enrolment [hazard ratio and 95% confidence interval [HR (95%CI)] [1.09 (1.06, 1.12)], smoking [1.03 (1.00, 1.06)] and steroid use [4.74 (1.08, 20.88)].

Conclusion: The prevalence of AVE in this study is much lower compared to previously published data. This may be due to more judicious use of glucocorticoids and improvements in treatment of cardiac risk factors. Although only a small number of classic risk factors showed positive associations in multivariable analysis all risk factors should be closely monitored and treated as they are in the general population.

Table 1. Cumulative annual prevalence of AVEs over time (n=659)

Follow-up	AVE
1	3 (0.46%)
2	4 (0.6 %)
3	8 (1.2%)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of peripheral neurological manifestations in Systemic Lupus Erythematosus (SLE) ranges between 5% and 27% and are a major cause of morbidity. The aim of this study is to compare clinical characteristics and neurophysiologic patterns of peripheral neuropathies (PNP) in patients with SLE.

Methods: A retrospective study was performed. We included patients with SLE (SLICC 2012 criteria), who presented a PNP associated to SLE according to ACR 1999 nomenclature, since January 2015 to December 2017. Patients were classified according to the neurophysiologic pattern by the Neuromuscular Clinic Disorders at our Institute in 3 groups: 1. Sensory or sensory motor axonal neuropathy (ANP). 2. Mononeuropathy single or multiplex (MNP), and 3. Demyelinating neuropathy (DNP). The medical records were reviewed by an expert rheumatologist. Demographic characteristics: gender, age, Body Mass Index (BMI), and comorbidities (Diabetes Mellitus [DM] and Hypertension [HT]) were compared. Lupus characteristics: SLICC criteria, time between SLE diagnosis and PNP, ACR / 2012 criteria, disease activity (SLEDAI-2K),

cumulative damage (ACR/SLICC-DI), and treatment were compared between the PNP groups. One year after the event, disease activity, cumulative damage, treatment, and a new neurophysiologic study performed, and death was reviewed. Statistical analysis: Continuous variables were compared using Mann-Whitney U, categorical variables were compared using Chi-squared test and Fisher exact test as appropriate. Kruskal-Wallis test for multiple comparisons.

Results: Forty one PNP were included, 17 (41.5%) ANP, 16 (39%) MNP, and 8 (19.5%) DNP. Patients with ANP had lower BMI than MNP and DNP ($p < 0.05$). Eleven patients had a comorbidity, DM in 3 (7.31%) and HT in 9 (21.9%). No difference was found between age, sex and time between SLE diagnosis and PNP. Patients with DNP presented more cutaneous manifestations (alopecia and chronic cutaneous lupus) compared with MNP (50% vs 12.5%, $p < 0.046$; 25% vs 0%, $p < 0.037$, respectively). Patients with MNP had more synovitis compared with ANP (100% vs 76.5%, $p < 0.038$). Disease activity was similar between the groups, the median SLEDAI 2-K was 6 (IQR 2.5-12.5). However, renal and pleuritis manifestations were more frequently present in the DNP group comparing with MNP and ANP ($p < 0.05$). Cumulative damage was similar between the 3 groups, the median SLICC-DI was 0 (IQR 0-1). Pulses of methylprednisolone, cyclophosphamide, and higher doses of prednisone were used in the MNP and DNP than in the ANP group ($p < 0.05$). One year after, 100% of patients were alive, SLEDAI-2K and SLICC-DI scores were similar between groups. DNP was more frequently revalued with a new neurophysiologic study than the other groups ($p < 0.05$).

Conclusion: ANP were the most frequent PNP. Patients with PNP have moderate disease activity at the time of presenting the PNP. The DNP and MNP were considered more severe and received more aggressive treatment than the ANP.

Impact of Disease Course on Atherosclerotic Vascular Events, Osteoporosis and Osteonecrosis in Systemic Lupus Erythematosus

Konstantinos Tselios, Dafna D Gladman, Zahi Touma, Jiandong Su, Nicole Anderson and Murray Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have shown that disease course over time in systemic lupus erythematosus (SLE) follows three distinct patterns (prolonged remission, relapsing remitting and persistently active). The impact of these patterns on the development of specific co-morbidities, such as atherosclerotic vascular events (AVEs), osteoporosis and osteonecrosis is not known. The aim of the present study was to assess the incidence of such co-morbidities in lupus patients in the long term.

Methods: The inception patients of our long-term longitudinal cohort (enrolled within 18 months of diagnosis), with at least 10 years of follow-up and no time interval >18 months between consecutive visits, were investigated. Prolonged remission (PR) was defined as a clinical SLEDAI-2K=0 [serology (anti-dsDNA antibodies and C3/C4 levels) excluded], achieved within five years since enrolment and maintained for ≥ 10 years after that. Relapsing-remitting (RR) pattern was defined based on ≥ 2 remission periods (one remission period equals two consecutive visits with a clinical SLEDAI-2K=0), while patients with no remission were categorized as persistently active (PA). Incidence rates for AVEs (angina, myocardial infarction, re-vascularization procedure, transient ischemic attack, stroke, peripheral vascular disease), osteoporosis (according to the WHO definition) and osteonecrosis (confirmed radiologically) were calculated at 10 years and at the end of follow-up (median 17.5 years).

Results: Of 267 patients who fulfilled the inclusion criteria, 27 (10.1%) achieved PR, 180 (67.4%) were RR and 25 (9.4%) PA. At enrollment, there were no significant differences in demographic, clinical, immunological and therapeutic characteristics among the groups. At 10 years, PA patients had received significantly more glucocorticosteroids [39.4 ± 24.3 g vs. 16.6 ± 10.7 g and 27.3 ± 18.4 g for the PR and RR groups, $p < 0.001$]. The incidence rates of AVEs, osteoporosis and osteonecrosis at 10 years and for the entire duration of follow up are given in Table 1.

Table 1. Incidence rates (/100 patient-years) of AVEs, osteoporosis and osteonecrosis in all patients

	PR (n=27)	RR (n=180)	PA (n=25)	<i>p</i>
Age at enrolment (mean±SD)	39.2 ± 14.1	35.2 ± 13.4	37 ± 13.9	0.142
At 10 years				
AVEs (incidence, n, %)	0	2.7	4.3	0.002
Osteoporosis (incidence, n, %)	0.4	7.6	8.5	<0.001
Osteonecrosis (incidence, n, %)	8.5	10.3	12.4	0.142
At the end of follow-up				
AVEs	0.75	6.4	8	<0.001
Osteoporosis	6.6	14.1	12.3	0.004
Osteonecrosis	10.7	16.5	18	0.001

P value from ANOVA (Analysis of Variance) for age and Cochran-Armitage trend test for all rates (between PR and the other groups). No differences were observed between the RR and PA groups.

Conclusion: Disease course had a significant impact on the rates of atherosclerotic vascular events, osteoporosis and osteonecrosis over time. Patients who had achieved prolonged remission developed significantly fewer such co-morbidities whereas the differences between the RR and PA patients were not statistically significant.

Abstract Number: 733

Advanced Chronic Kidney Disease in Lupus Nephritis: Factors Leading to Progression

Konstantinos Tselios, Dafna D Gladman, Jiandong Su and Murray Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Advanced chronic kidney disease (CKD) carries an increased risk for progression to end-stage renal disease (ESRD) and renal replacement therapy. However, the rate of progression and the predictors that drive the decline of renal function in lupus nephritis (LN) are not known. The aim of the present study is to define such factors in patients with LN and advanced CKD.

Methods: Patients with advanced LN-related CKD for two consecutive clinic visits were retrieved from our long-term longitudinal lupus cohort. Advanced CKD was defined according to the Kidney Disease Improving Global Outcomes as CKD stage 3b (eGFR=30-44ml/min/1.73m²) and stage 4 (eGFR=15-29ml/min/1.73m²), while ESRD was defined as eGFR<15ml/min/1.73m² or initiation of dialysis. All individuals were followed until the progression to ESRD or the last visit and were divided into two groups (“progressors” and “non-progressors”). Demographic, clinical, immunological and therapeutic variables were compared at baseline (the second visit of advanced CKD). Multivariable Cox regression analysis was performed for the identification of predictors for transition to ESRD. Statistical analysis was performed with SAS 9.4; *p*<0.05 was considered significant.

Results: One hundred eighteen patients (74 with CKD 3b and 44 with CKD 4) were included. Mean time from LN to advanced CKD was 5.6 years. There were no differences between groups at baseline, concerning demographic, clinical and immunological variables. Patients with CKD 4 more often had a proliferative LN (class III or IV) (50% vs. 29.7%, *p*=0.053). Rates of and time to progression are shown in Table 1.

Table 1. Rates and time to progression for all patients

Variable	CKD 3b (n=74)	CKD 4 (n=44)
Age at CKD	44.7±13.4	40.8±13.6
Progression to ESRD (% , n)	5.4% (4)	56.8% (25)
Time to ESRD (y, median)	4.5	3.1
Progression to CKD 4 (% , n)	21.6% (16)	Not applicable
Time to progression to CKD 4 (y, median)	4.8	Not applicable

Patients who did not progress (n=73, 61.9%) had a mean follow-up of 5.8 years (range 0-26.7). Their eGFR remained unaltered (from a median of 38.6 at baseline to 37.1ml/min/1.73m² at the last visit). Multivariable analysis for predictors of progression to ESRD is shown in Table 2.

Table 2. Predictors for transition to ESRD from CKD stages 3b and 4

	HR	Lower 95%CI	Higher 95%CI	p
Anti-dsDNA (+) at baseline	5.28	1.91	14.57	0.001
Glucocorticosteroids at baseline	4.17	1.01	17.15	0.048
Cumulative GCS dose (from LN to CKD)	1.01	1.00	1.02	0.04
Treated with IS (MMF or AZA) at baseline	0.21	0.07	0.60	0.004
CKD 4 (compared to CKD 3b)	27.5	2.9	96.3	<0.0001

GCS: glucocorticosteroids, IS: immunosuppressives, MMF: mycophenolate mofetil, AZA: azathioprine

Conclusion: Only 24.6% of our patients developed ESRD, while another 21.6% of the CKD 3b patients progressed to CKD 4. Risk factors for ESRD included abnormal anti-dsDNA antibodies at the time of CKD as well as treatment with glucocorticosteroids and higher cumulative dose (for the treatment of LN). Immunosuppressive treatment at the time of CKD was protective. Renal function remained stable in approximately 73% of the CKD 3b and 43% of the CKD 4 patients over 6 years of follow-up.

The Role of Micro-RNA 142-3p Expression in Lupus Nephritis in an Egyptian Cohort

Marwa Elkhailifa¹, Magdy Zehairy¹, Manal Tayel¹, Ahmed Elkeriaie², Dalal Elkaffash³ and Nahed Baddour⁴, ¹Internal medicine, Rheumatology, Faculty of medicine, Alexandria University, Egypt, Alexandria, Egypt, ²Internal medicine, Nephrology, Faculty of medicine, Alexandria University, Egypt, Alexandria, Egypt, ³Clinical and Chemical Pathology, Faculty of medicine, Alexandria University, Egypt, Alexandria, Egypt, ⁴Pathology, Faculty of medicine, Alexandria University, Egypt, Alexandria, Egypt

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Micro-RNAs play an important role in regulating gene expression at the posttranscriptional level. Recent data have shown that microRNAs are critical for the development and function of immune system, both innate and adaptive immunity.^(1,2) MicroRNAs are differentially expressed in patients with systemic lupus erythematosus (SLE), especially in association with lupus nephritis.^(3,4) The heterogeneity of patient ethnicity and variety in detection method may in part explain some of the discrepancies of positive micro-RNA list in SLE patients in different studies. Testing serum or urine microRNA expression would offer a promising tool to illustrate the pathogenesis of SLE, provide novel biomarkers and potential therapeutic option.⁽⁵⁾

Methods: Expression levels of micro-RNA-142-3p extracted from peripheral blood mono-nuclear cells determined using quantitative reverse transcription–polymerase chain reaction assay. A total of 90 plasma samples were obtained from 30 SLE patients without clinical and laboratory evidence of lupus nephritis, 30 SLE patients with lupus nephritis and 30 healthy control subjects.

Results: The expression of micro-RNA-142-3p in SLE patients was significantly lower than the expression in normal healthy control, p<0.001. In addition the Roc curve of micro-RNA-142-3p showed that micro-RNA-142-3p expression levels can significantly discriminate between lupus patients with and without lupus nephritis at a cut off level $\leq 5.7 \times 10^{-6}$ with a sensitivity of 83.33% and specificity of 90%. We also found a significant correlation between micro-RNA-142-3p expression levels and the pathological activity index of renal biopsy, while there was no significant correlation between micro-RNA-142-3p expression level and the pathological chronicity index.

Conclusion: The expression level of micro-RNA-142-3p could be considered a diagnostic marker of SLE. Also, the expression level of micro-RNA-142-3p could be considered a potential biomarker for recognition of renal involvement in SLE patients.

Serum Albumin at One Year Predicts Long-Term Renal Outcome

Vinicius Domingues¹, Daniel Goldman², Laurence S Magder³ and Michelle Petri², ¹Medicine, New York University School of Medicine, New York, NY, ²Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ³Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis remains a major cause of morbidity/mortality in SLE. Our cohort has shown that 20% of SLE patients with lupus nephritis onset in the first year will have end-stage renal disease (ESRD) by year ten. Population studies have shown no improvement in lupus nephritis outcomes in the last decades. Clinical trials of lupus nephritis cannot address long-term renal outcomes. We addressed whether serum albumin at 12 months after renal biopsy predicted long-term renal outcome.

Methods: 87 patients with biopsy-proven lupus nephritis were included in the analyses. Of the 87 patients, 79 (91%) were female, 49 (56%) were African American, 24 (28%) were Caucasian, and 14 (16%) were “other”. At the time of biopsy, 33 (38%) were under 30 years of age, 38 (44%) were from 30-44, and 16 were 45 years of age or older. The median age was 32.9. The median values of albumin at biopsy and 1-year post were 3.7 and 3.9 respectively. ISN/IRP class was 24% III, 23% IV, 23% V, and 30% mixed. Albumin levels were classified as low (<3.4g/dL), medium(3.5-4.3g/dL) and high (>4.3g/dL).Kaplan-Meier curves were plotted to assess the association between albumin levels and risk of developing renal event. Renal outcomes were 1 ESRD, 6 renal insufficiency, and 14 doubling creatinine.

Results: Serum albumin at 12 months post renal biopsy was associated with poor renal outcomes during follow-up ($p = 0.0098$). Among those with low serum albumin one year after biopsy, an estimated 43% will progress to renal failure, renal insufficiency, or a doubling of creatinine within 5 years (95% confidence interval 16%-71%). In contrast, among those with high serum albumin, an estimated 13% will progress (95% CI 1%-29%).

Figure 1: Plot of the probability of remaining renal-event free, by albumin levels one year after biopsy

	SLE cohort (N=76,354)				LN cohort (N=11,068)				IRR compared with SLE	
	Event	PT	Incidence per 100PY	95% CI	Event	PT	Incidence per 100PY	95% CI	Incidence rate ratio	95% CI
Herpes zoster	4,784	763,208	1.6	1.6 1.7	955	17,557	2.4	2.4 2.7	1.6	1.5 1.7
Disseminated zoster	582	375,582	0.3	0.2 0.2	157	89,352	0.4	0.3 0.5	1.9	1.6 2.3

Conclusion: Serum albumin 12 months post biopsy predicted good renal outcome in a linear fashion. This surrogate for renal outcome is readily available from lupus nephritis randomized clinical trials (and from some large databases, as well). Serum albumin should be added to urine protein/crds validated surrogates for long-term renal outcome in lupus nephritis.

Herpes Zoster and Disseminated Zoster in Systemic Lupus Erythematosus and Lupus Nephritis: Incidence Rates in Real-World Claims Data

Katherine Belendiuk¹, Yingjie Ding², Devika Chawla¹ and Matthew Cascino¹, ¹Genentech, Inc., South San Francisco, CA, ²Genesis Research, Hoboken, NJ

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disseminated zoster is a highly morbid complication of varicella zoster reactivation (herpes zoster) that is typically associated with immunosuppression. Systemic lupus erythematosus (SLE) and lupus nephritis (LN) are associated with increased risk of herpes zoster [1,2] but rates of disseminated zoster in these populations have not been described. The objective of this study was to compare the rates of herpes zoster and disseminated zoster infections in patients with SLE and LN using population-based claims data.

Methods: We conducted a retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database between 2000 and 2014. Patients with SLE (SLE cohort) and SLE and LN (LN cohort) were identified using modifications to validated algorithms using claims data [3,4]. All patients received medical care in the U.S. and had 6 months of continuous medical and drug coverage ± index date. End of study was the first of end of enrollment or end of database. Incident herpes zoster cases were identified using ICD-9 codes 053.xx. Incidence rate ratios (IRR) and 95% confidence intervals (CI) were calculated.

Results: SLE and LN cohorts included 76,354 and 11,068 patients, respectively. Mean age was 48.1 and mean enrollment duration was 6.3 years. For patients in the SLE cohort there were 4284 incident cases of herpes zoster, of which 582 (14%) were considered disseminated. The LN cohort had increased rates of herpes zoster (IRR 1.6, 95% CI 1.5 to 1.7) and disseminated zoster (IRR 1.9, 95% CI 1.6 to 2.3) compared with the SLE cohort (Table 1).

Conclusion: In this population-based analysis of claims data, the rate of herpes zoster in SLE was consistent with prior reports [1] and the presence of LN was associated with increased risk of herpes zoster and disseminated zoster compared with SLE. A substantial minority of herpes zoster cases were associated with dissemination. Further characterization of the relative contributions of age, immunosuppressive therapies, and disease factors is warranted.

Atherogenic Index of Plasma in Women with Systemic Lupus Erythematosus and Rheumatoid Arthritis: A 10-Year Potential Predictor of Cardiovascular Disease

Nevin Hammam^{1,2} and Tamer A Gheita³, ¹University of Alberta, Edmonton, AB, Canada, ²Rheumatology and Rehabilitation Department, Assiut University, Assiut, Egypt, ³Rheumatology Department Faculty of Medicine, Cairo University, Cairo, Egypt

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are characterized by an increased frequency of cardiovascular diseases (CVD). Early diagnosis of these complications can reduce morbidity and mortality. Atherogenic index of plasma (AIP) is a new parameter in assessing the CVD risk¹. Previous work supports the utility of AIP and demonstrates that it is more closely associated with CVD risk than individual cardio-metabolic factors. However, no research yet has evaluated the relationship between AIP and the long term CVD risk in SLE and RA patients. The purpose of this study was to investigate whether AIP is associated with long term CVD risk among women with SLE and RA and to further determine its predictive value.

Methods: This was a cross-sectional study of 59 SLE and 99 RA women diagnosed according to the ACR criterion and carried out in the rheumatology department. For each patient, long-term risk of CVD was calculated using the Framingham risk score (FRS); AIP was derived according to the logarithmic (triglycerides/high-density lipoproteins cholesterol). At the same time, clinical, and biochemical data were obtained and disease activities were calculated. The relationship between FRS as a dependent variable and the AIP as an independent one was examined using linear regression analysis.

Results: The mean age of the SLE patients was 36.7 ± 9.1 years and of the RA was 47.9 ± 8.8 years. The mean disease duration for SLE and RA was 5.2 ± 3.8 and 8.4 ± 7.8 years, respectively. The mean body mass index for both groups was over 27.8 kg/m^2 . Nearly 70% of SLE patients were using prednisone with a mean daily dose of 9.1 mg; 29% of RA patients were receiving prednisone with a mean daily dose of 5.1 mg. The mean FRS% in SLE was 4.8 ± 4.5 , while in RA women was 6.4 ± 5.6 . 8.6% of SLE and 23.2% of RA patients were at a moderate to high risk of CVD. In SLE, mean AIP was 0.02 ± 0.27 while in RA it was 0.00 ± 0.4 . Among SLE patients, AIP showed significant association with FRS ($r=0.45$; $p<0.01$), triglyceride ($r=0.46$; $p<0.01$) and mild positive association with disease activity score ($r=0.29$; $p=0.03$), while FRS was significantly linked to uric acid level ($r=0.49$; $p<0.01$). In RA, AIP was associated with FRS ($r=0.26$; $p=0.01$), waist circumference ($r=0.27$; $p<0.01$), triglyceride and total cholesterol ($r=0.66$, $p<0.01$ and $r=0.38$, $p<0.01$; respectively). Serum uric acid was significantly associated with both FRS ($r=0.43$; $p<0.01$) and AIP ($r=0.27$; $p<0.01$) in women with RA. In multivariate regression analysis, an independent relationship between AIP and risk of CVD in both SLE ($\beta=6.0$, 95% CI: 1.87–10.13; $p<0.01$) and in RA ($\beta=1.64$, 95% CI: -0.64–3.93; $p=0.01$) was detected. SUA remained significant CVD predictor in both SLE and RA ($p=0.03$ and $p=0.01$; respectively).

Conclusion: Higher atherogenic index of plasma was potentially and strongly associated with risk of long term CVD risk among women with SLE and RA patients. AIP level can be a good marker for the CVD risk, thus control and monitor of AIP can improve the outcome in these populations.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe complication of systemic lupus erythematosus (SLE), which is the most common underlying disease of CTD associated PAH. However its pathogenesis is still unknown. Both inflammatory mechanisms and endothelial dysfunction are involved. According to the guidelines, immunosuppressive therapy and pulmonary vasodilators were two common strategies in our clinical practice, but the responses to two therapies vary in different reports, indicating different underlying mechanisms in different patients. In order to identify homogeneous groups of SLE-PAH patients, we conducted this retrospective study.

Methods: From 2011 to 2016 in Ren Ji Hospital, SLE-PAH patients were identified based on right heart catheterization (mPAP \geq 25 mmHg at rest, PAWP $<$ 15 mmHg and PVR $>$ 3 WU) or echocardiography (peak tricuspid regurgitation velocity (TRV) $>$ 3.4 m/s) excluding pulmonary hypertension due to left heart disease and pulmonary thrombosis. We distinguished two clusters according to multiple correspondence analysis and k-cluster analysis, which were defined as Vasculitic and Vasculopathic type. Kaplan-Meier survival curve of two clusters were made. Multivariate logistic regression was performed to identify predictors of clusters. Prediction model was established and ROC curve was made to find the optimal cut-off value.

Results: In a total of 108 SLE-PAH patients, two clusters with homogenous clinical features were identified. The Vasculitic Cluster were more likely to have pericarditis, LN, NPSLE, anemia, thrombocytopenia, as well as higher disease activity, and receiving higher doses of prednisone together with immunosuppressants, while the Vasculopathic type tended to have less systemic manifestations with lower disease activity, and were more likely given vasodilators in clinical practice. Overall, it seemed that the Vasculitic subtype was more severe with poorer outcome than the other subtype evidenced by the significantly higher mortality in survival curve (37.8% vs 18.3%, $p=0.026$) (Figure 1). Upon multivariate logistic regression, three predictors (SLEDAI $>$ 9, hypertension and early onset of PAH $<$ 2.99 years since SLE) were identified to distinguish Vasculitic SLE-PAH patients. Prediction model with these three factors were built, and ROC curve identified that score \geq 2 had a prediction rate of 89.5% with sensitivity of 91.9% and specificity of 94.4% (AUC 0.949, $p<0.0001$).

Conclusion: In this retrospective cohort study, two clusters with different prognosis were identified. The Vasculitic type had more systemic manifestation and higher disease activity as well as poorer outcome than the Vasculopathic type. The prediction model combining three factors established in our study might help stratify the patients and guide the therapy in clinical practice.

Figure 1. Survival Curve of 108 SLE-PAH in two distinct clusters.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated levels of sTREM-1 have been previously found in patients with SLE. A prospective, case-control, longitudinal study aimed to assess the value of urinary and plasma levels of sTREM-1 in evaluating disease activity in patients with active renal and non-renal SLE.

Methods: 15 patients with active renal lupus (ARL), 15 patients with active non-renal lupus (ANRL), and 30 patients with inactive lupus (IL), defined by baseline score of Safety of Estrogen in Lupus National Assessment-Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) \geq or $<$ 6 and renal-SLEDAI \geq 4 or 0. Urine and plasma samples were collected and kept at -70°C until assayed for sTREM-1 levels using commercial ELISA. Urinary values were normalized for creatinine (Cr.) excretion. Plasma and urine samples of healthy individuals served as healthy control (HC).

Results: Compared to HC (urine: $n=13$; plasma: $n=72$), baseline mean urine sTREM-1 level (UsTREM-1) was significantly higher in ARL ($62.38 \pm 85.14 \text{ pg/mg Cr.}$ vs. $3.05 \pm 7.19 \text{ pg/mg Cr.}$, $p=0.0015$) but not in ANRL, whereas plasma sTREM-1 (PsTREM-1) was significantly higher in patients with ANRL ($361.47 \pm 187.79 \text{ pg/ml}$, 312.15 pg/ml vs. $228.76 \pm 85.23 \text{ pg/ml}$, $p=0.009$) and not in the ARL group. Moreover, UsTREM-1 level significantly discriminated between ALN and ANRL or IL ($p=0.0056$) as well as the ratio of urine-to-plasma sTREM-1 ($p=0.0083$), whereas PsTREM-1 was significantly higher in ANRL compared to ARL or IL ($p=0.014$). Baseline SELENA-SLEDAI score correlated with UsTREM-1 ($p=0.0005$) and PsTREM-1 ($p=0.006$) while renal-SLEDAI correlated only with UsTREM-1 ($p=0.013$). Elevated UsTREM-1 level positively correlated with higher ESR ($r=0.35$, $p=0.03$), serum anti-dsDNA antibody titer ($r=0.39$, $p=0.006$), SELENA-SLEDAI and renal-SLEDAI scores ($r=0.48$, $p=0.0005$ and $r=0.36$, $p=0.013$, respectively) and inversely correlated with lower serum C3 level ($r=-0.39$, $p=0.005$). Elevated PsTREM-1 level positively correlated with age ($r=0.25$, $p=0.005$), serum creatinine ($r=0.33$, $p=0.0006$), higher ESR ($r=0.4$, $p=0.007$), serum anti-dsDNA antibody ($r=0.59$, $p<0.0001$) and SELENA-SLEDAI score ($r=0.38$, $p=0.006$) but not with renal-SLEDAI score and serum C3 and C4 levels. Receiver operating characteristic (ROC) curves analysis of the area under the curve (AUC) displays that PsTREM-1 level differentiates between overall active SLE and IL: $\text{AUC} = 0.74$, $95\% \text{CI } 1.001 - 1.010$, $p=0.01$.

Conclusion: Our data suggest that UsTREM-1 level correlates with ARL while elevated PsTREM-1 correlates with ANRL. Urine and plasma sTREM-1 might be clinically used as a biomarker for the assessment of renal and non-renal disease activity in SLE. We suggest that renal innate immune activation and particularly TREM-1 play a role in the pathogenesis of lupus nephritis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus Nephritis one of the commonest manifestations of SLE. Despite being the gold standard in Lupus nephritis, renal biopsy is an invasive procedure with potential complications and difficult to repeat. Current treatment guidelines prioritize the histological class of lupus nephritis. Monocyte chemo-attractant Protein-1(MCP-1) a chemokine produced locally during active nephritis was shown in many previous studies as a promising biomarker for activity. This study investigates its usefulness to define histological classes.

Methods: This is a case-control study conducted at a tertiary care center in North India. Cases were patients of SLE satisfying the criteria for active lupus nephritis, defined as proteinuria > 1 gm/24 hours and/or active sediments in the form of hematuria [RBC > 5/hpf] or presence of cellular casts and undergoing kidney biopsy (n=36). Controls were patients of SLE without active LN (less than 500 mg/24 hours proteinuria and no active sediments. These were further divided into Control group I, those who had previously had lupus nephritis and were treated (n=11) and Control group II, those who never had nephritis (n=15)]. Urinary MCP-1 measurement was done using Sandwich ELISA kit. This was normalized for urinary creatinine excretion(pg/mg).

Results: Mean age in cases was 31.1 ± 10.2 years and in control-I was 34.6 ± 8.0 and control II was 36.3 ± 10.4 yrs respectively ($p=0.3$). Urinary MCP-1 values in cases (1214 ± 1467.1 pg/mg) were significantly higher compared to controls (184.5 ± 186.8 pg/mg, $p<0.001$). However, no significant difference was observed between control group I (170.5 ± 150.8) and control group II (194 ± 214 , $p=0.7$). Urinary MCP-1 levels showed significant correlation when compared with classical disease markers like 24-hour proteinuria, 24-hour PCR, Spot PCR and SLEDAI. A cut off value of MCP-1 of 339 pg/mg on ROC curve has sensitivity and specificity of 80% and 92% respectively for differentiating active from inactive nephritis. However, there was no significant difference of Urinary MCP-1 levels among different classes of nephritis ($p=0.593$) (Figure 1). Urinary MCP-1 levels did not show significant correlation with Renal activity index calculated on renal biopsy.

Conclusion: Urinary MCP-1 was not associated with different histological classes of lupus nephritis.

Figure 1: Box-plot depicting Urinary MCP-1 (normalized to urinary creatinine) across various histological classes. Box-plots show median and interquartile range, whiskers denote 1.5xIQR

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with an increased in the prevalence of atherosclerosis. Composite scores of cardiovascular risk factors in patients with SLE have been found to underestimate cardiovascular risk. Besides, ultrasound of the carotid arteries has been proposed as a reclassification risk tool in inflammatory diseases. The main purpose of our study was to analyze the impact of ultrasound carotid assessment in the cardiovascular risk stratification of patients with SLE.

Methods: This cross-sectional study encompassed 276 SLE patients. Lipid profile, SCORE risk calculation, and disease activity (SLEDAI), severity (Katz), and damage (SLICC) indexes were assessed. Carotid intima-media thickness (cIMT) and carotid plaques were determined through ultrasound evaluation. Reclassification of SCORE after ultrasound carotid assessment was performed. A multivariable regression analysis, adjusted for classic cardiovascular related factors, was performed to evaluate how risk reclassification is influenced by disease characteristics in SLE patients and to describe potential predictors of this risk reclassification.

Results: Patients had a mean \pm SD age of 51 ± 12 years. The median SLE disease duration was 18 ± 10 years and SLICC and Katz indexes were, respectively, 1 (interquartile range –IQR- 0-2) and 2 (IQR 1-4). Thirty-four percent of the patients were categorized as having no activity based on the SLEDAI index, while 31%, 17%, and 8% were classified, respectively, in the mild, moderate, and high or very high categories. According to the SCORE risk stratification system, 184 (67%) and 73 (27%) patients were respectively in low and moderate categories. Additionally, only 16 (6%) patients were considered in high or very high risk categories. However, after carotid ultrasound assessment, 37% (100) of the patients were considered to be in the very high risk category. Exactly, 64 patients, 43 in both the low and moderate category, moved into very high category. Patients that experienced reclassification compared to those that did not were older (48 ± 11 vs. 57 ± 9 years, $p=0.000$) and had more hypertension (31 vs 56 %, $p=0.000$). Gender, BMI, waist circumference and the presence of dyslipidemia, smoking or diabetes did not shown differences. Lipid profile disclosed no differences between reclassified or non reclassified subjects. Disease duration was related to reclassification after multivariable analysis (OR 1.04 [95% CI 1.00-1.07], $p=0.025$). Similarly, a SLICC higher or equal to 1 (OR 2.48 (95% CI 1-15-5.34), $p=0.020$) and *log* SLICC (OR 1.63 (1.01-2.64), $p=0.045$) disclosed statically significant relation to reclassification after multivariable adjustment. These relations were also found when SLICC was used without the cardiovascular item that its contains although in the case of *log* SLICC the significant was not completely found (OR 1.56 (95% CI 0.95-2.64), $p=0.077$).

Conclusion: Reclassification into very high SCORE category is frequent after carotid ultrasound assessment in SLE patients. This reclassification can be independently explain by the damage produced by the disease and makes candidates for more intensive preventive interventions to one out of every three patients evaluated.

Abstract Number: 742

Moderate to Severe Depression in Patients with Systemic Lupus Erythematosus

Nathalie Chalhoub and Michael Luggen, Division of Immunology, Allergy, and Rheumatology, University of Cincinnati College of Medicine, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression is among the most common neuropsychiatric manifestations in SLE with a prevalence reported to be up to 75% in some studies. Depression in SLE patients has been shown to adversely affect health-related quality of life and increase work disability. The causes of depression in SLE are unclear and various sociodemographic and disease-specific factors have been identified. However, conflicting results have been reported in part because of methodologic issues and failure to account for all potentially important covariates. In this study, we examined the association of moderate to severe depression with socioeconomic status, disease activity, disease severity, treatment, and cognitive performance in patients with SLE.

Methods: Patients with SLE fulfilling the American College of Rheumatology criteria were recruited. All patients had detailed sociodemographic data collected and were evaluated for depression with the Beck Depression Inventory (BDI), for disease activity (SLEDAI-2K), SLE damage with the SLICC Damage Index (SLICC-DI), pain (10 cm visual analogue scale), and cognitive function by the Automated Neuropsychologic Assessment Metrics (ANAM), a symbol-based computerized testing program measuring multiple cognitive domains. Prednisone and immunosuppressive use as well as use of other potentially psychoactive medications were captured as well.

Results: In total, 99 patients were evaluated. Mean age was 46.4 (± 12.1) years with a female preponderance (93% vs 7% men). BDI score ranged from 1 to 52 (mean 17 ± 12). Moderately or severely depressed patients, defined by a BDI score ≥ 20 or BDI ≥ 29 respectively, comprised 31.3% of patients; of these 13.1% had moderate and 18.2% severe depression. Cognitive dysfunction was identified in 24.5%. Mean SLEDAI-2K scores were 5.1 (± 4.7) and mean SLICC-DI scores were 2.4 (± 2.1). Low annual income defined as $< \$20,000/\text{year}$ was reported by 37% of patients and mean pain severity was 3.5/10 (± 2.4). Using logistic regression, SLEDAI-2K scores and pain severity were found to be independently correlated with moderate to severe depression in patients with SLE (p-values of 0.0078 and < 0.0001 respectively). Low annual income showed a potential association (p=0.0902) and, in multiple linear regression using the actual BDI scores, was significantly associated (p=0.04). No independent associations were found between cognitive dysfunction, SLICC-DI, demographic or treatment characteristics (including prednisone) and depression in our group of SLE patients.

Conclusion: Patients' pain severity, disease activity as measured by SLEDAI-2K and low-income level are associated with the development of moderate to severe depression in patients with SLE. The first two of these are potentially modifiable.

Abstract Number: 743

Outcome of Stroke in Patients with Systemic Lupus Erythematosus: A Nested Case-Control Study

Chi Chiu Mok, Lap Kiu Tsoi and Yat Pang Fu, Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the outcome of stroke in patients with systemic lupus erythematosus (SLE) in comparison with non-SLE patients.

Methods: Patients who fulfilled ≥ 4 SLICC/ACR criteria for SLE and had a history of cerebrovascular accident (stroke) were retrieved from our SLE database. The outcome of stroke in these patients was evaluated retrospectively and compared with a group of randomly selected age and gender matched non-SLE patients (in a 1:3 ratio) admitted to our stroke unit within the same time period. The type and pattern of stroke, atherosclerotic risk factors and previous history of stroke were compared between the two groups of patients. The primary outcome of interest was the 90-day functional outcome as assessed by the modified Rankin scale (mRS) (score 0-2 = functional independence; score 3-6 = functional dependence). Secondary outcomes included all-cause mortality, 30-day stroke mortality, stroke recurrence and stroke complications. Factors independently associated with a poor functional outcome (mRS 3-6) was studied by logistic regression.

Results: 40 SLE patients (age 53.7 ± 11.5 , 87.5% women) with stroke were identified (stroke prevalence 0.39/100 patient-year) and 120 non-SLE control patients (age 52.8 ± 14.8 , 87.5% women) with stroke were randomly selected. All were ethnic Chinese. The prevalence of atherosclerotic risk factors was similar between the two groups, except SLE patients had a higher atherogenic index (Log serum [triglyceride/HDL-cholesterol]). Ischemic stroke was more common in SLE than non-SLE patients (90% vs 63%; $p=0.001$). Among patients with ischemic stroke, SLE patients had more extensive infarction (defined as diffuse white matter lesions, multiple infarcts involving >1 major vascular territory or one single major vessel $>50\%$ involvement) than controls on CAT scan (69.4% vs 28%; $p<0.001$). Significantly more SLE patients had functional dependence (mRS score 3-6) at 90 days post-stroke than controls (32.5 vs 8.3 %; $p<0.001$; unadjusted OR 14.2). Logistic regression showed that SLE was an independent risk factor for a poor stroke outcome after adjustment for age, sex, history of stroke, various atherosclerotic risk factors and the type of stroke (ischemic vs hemorrhagic) (OR 10.1 [2.7–38.0]; $p=0.001$). In a subgroup of patients with ischemic stroke, SLE remained an independent factor for a poorer functional outcome after adjustment for the same covariates and the extent of stroke (OR 14.0 [2.0–96.2]; $p=0.007$). Although there was no significant difference in the 30-day stroke mortality between SLE and non-SLE patients (5% vs 2.5%; $p=0.43$), SLE patients had a higher incidence of post-stroke epilepsy (22.5% vs 3.3%; $p=0.001$). Upon a follow-up of 7.5 ± 5.2 years, SLE patients had a lower stroke recurrence free survival (59.5% vs 85.7%; $p<0.001$) and a higher rate of all-cause mortality (34.6% vs 15.1%; $p<0.001$).

Conclusion: Stroke in SLE patients is more likely to be ischemic in origin and more extensive than matched controls. Short-term functional outcome of stroke is poorer in SLE patients. Over 7.5 years, stroke recurrence, post-stroke epilepsy and all-cause mortality is significantly more frequent in SLE than non-SLE patients.

Hospital Universitario de Canarias, Tenerife, Spain

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease is one of the major causes of morbidity and mortality in patients with systemic lupus erythematosus (SLE). SLE patients are characterized by a lipid metabolism dysregulation. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease that regulates cholesterol metabolism through low-density lipoprotein (LDL) receptor degradation. PCSK9 has been linked to cardiovascular risk (CVR) in general population. The purpose of this study is to examine whether PCSK9 levels are related to disease activity, damage and severity scores; abnormalities in the lipid profile; and the subclinical atherosclerosis that occur in SLE patients. If this were shown to be the case, PCSK9 would be a link between the disease and the lipid metabolism dysregulation that occurs in SLE patients

Methods: Cross-sectional study that encompasses 195 SLE patients. PCSK9 and lipoproteins serum concentrations were assessed. Activity (SLEDAI), severity (Katz) and damage (SLICC) index scores, and carotid ultrasound sonography were evaluated. A multivariable analysis, adjusted for standard CVR factors, was performed to evaluate the association of PCSK9 with SLE related dyslipidemia, subclinical atherosclerosis and activity/damage status

Results: In the univariate analysis, body mass index (BMI), waist circumference, traditional CVR factors and triglycerides were strongly related with PCSK9 serum levels. On the contrary, HDL cholesterol and apolipoprotein A levels showed a negative association. LDL cholesterol exhibited a trend to a negative association (beta coeff. -0.30, 95% CI -0.67-0.069, p=0.11). The presence of carotid plaques and cIMT were not associated with PCSK9 levels although a trend was observed (beta coeff. 20.21, 95% CI -2.47 - 42.72, p=0.081 and beta coeff. 71.19, 95% CI -18.38 - 160.76, p=0.12 respectively).

Regarding SLE data, patients with longer disease duration (beta coeff. 1.25, 95% CI 0.15-2.35, p=0.026) and higher C reactive protein (CRP) levels (beta coeff. 1.42, 95% CI 0.61-2.22, p=0.00) disclosed higher PCSK9 levels.

Prednisone intake was positively associated with PCSK9 levels (beta coeff. 35.48, 95% CI 14.29-56.6), p=0.001), and patients that were taking any DMARD or hydroxychloroquine disclosed significant lower levels of PCSK9 (beta coeff. -27.91, 95% CI -54.5 - -1.32, p=0.040 and beta coeff. -39.21, 95% CI -62.21 - -16.21, p=0.001 respectively). Higher values of SLICC index (beta coeff. 9.66, 95% CI 4.47-14.84, p=0.000) and patients that were in the high/very high SLEDAI activity category (beta coeff. 62.98 95% CI 18.10-107.86, p=0.006) disclosed significant higher values of PCSK9.

When multivariate analysis was performed (adjusted by BMI, waist circumference, gender, hypertension, dyslipidemia, CRP levels and atherogenic index) these positive associations with both SLICC index and SLEDAI activity and the use of prednisone were maintained, as well as negative associations with LDL levels and the use of hydroxychloroquine.

Conclusion: PCSK9 serum levels are independently related to SLE activity and damage scores. This would imply that the mechanisms leading to lipid metabolism dysregulation in SLE patients may be mediated or be a consequence of PCSK9.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Abstract:

Background/Purpose: To study how many patients with Systemic Lupus Erythematosus (SLE) maintained remission in CSTAR(Chinese SLE Treatment and Research group) registry cohort, and further explore the influence of remission on organ damage accumulation and infection, which is the major cause of death in our cohort.

Methods: Patient recruitment started from April 2009 to February 2010. They were followed up yearly at clinic. Baseline data mainly included demography, clinical manifestations, activity (SLEDAI-2K), organ damages (SLICC/Damage Index). Logistic regression model was performed to study the effect of remission on damage and severe infection occurrence.

Results: A total of 687 patients were regularly followed up with intact data. Among them, 357 patients never experienced disease flare during follow-up. Finally, 74 (10.8%) patients developed into prolonged remission off steroids for at least 1 year, and 23(3.3%) patients of them were treated without steroids since enrolled. 137(19.9%) patients achieved persistent

remission with prednisone $\leq 5\text{mg/d}$ at the endpoint. Logistic regression analysis showed that disease flare was associated with new damage [OR 2.385, $p < 0.001$] and severe infection [OR 1.833, $p = 0.006$].

Conclusion: Prolonged remission should be a treating target for Chinese SLE patients and it can be achieved for nearly half of the patients now. To avoid disease flare may reduce the probability of new damage and severe infection. Appropriate strategies to maintain remission deserve more investigations in future.

Key words: Systemic lupus erythematosus, Remission, Organ damage, Infection

Table 1 Baseline Characteristics for Patients

	Remission with pred $\leq 5\text{mg/d}$ n=211 (%)	With flare N=330 (%)
Male	7.58	9.10
Serositis	21.8	16.4
Lupus nephritis	52.6	58.8

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Early cardiovascular disease is an important cause of mortality in SLE. Previous studies have shown that lupus nephritis (LN) was associated with an increased risk of cardiovascular events in SLE patients. The primary aim of the present study was to assess the role of nephritis in mortality of SLE patients hospitalized with acute myocardial infarction (AMI) in a nationally representative sample.

Methods: We used data from the National Inpatient Sample (NIS) for the period 2005-2015 with adult AMI as a primary diagnosis and SLE, nephritis, chronic kidney disease (CKD) and end-stage renal disease (ESRD) as secondary diagnoses using ICD-9 codes. There is no specific ICD-9 code for LN and its classes. The proportion who met ACR classification criteria cannot be determined with the NIS database.

We compared the characteristics of AMI hospitalizations in SLE patients with and without nephritis and used logistic regression to calculate the odds ratios for inpatient mortality from AMI in SLE patients with nephritis. We compared this to AMI in SLE patients with all kidney disease (AKD) (defined as having ESRD or CKD or nephritis) and without kidney disease. AKD in SLE population is most likely due to LN¹.

Results: We identified a total of 4810 AMIs from 2005-2015 in patients with SLE. Among these, 245 had a discharge diagnosis of nephritis and 837 had AKD.

AMI hospitalizations with SLE and nephritis were younger (50.3 vs. 61.3 years; $p < 0.01$) with a higher proportion of males (24.9% vs. 19%; $p < 0.05$) and a higher proportion of African-Americans (36.7% vs. 22.3%; $p < 0.01$) compared to patients with SLE without nephritis. The findings for SLE and AKD were similar: younger and with a higher proportion of males and African-Americans. The findings are summarized in the table.

The unadjusted inpatient mortality from AMI in SLE and nephritis was not statistically different from that in SLE patients without nephritis, even after adjusting for age, gender, race, comorbidities and invasive cardiac procedures (a OR=1.28; 95% CI=0.5-2.7; $p = 0.52$). The adjusted odds-ratio for inpatient mortality from AMI in SLE and AKD, however, was 1.84 (95% CI=1.27-2.67; $p < 0.01$).

Conclusion: Patients with SLE and nephritis presented with AMI at a younger age compared to patients with SLE and no nephritis. The former group of SLE patients did not have a statistically different inpatient mortality due to AMI. However, AMI hospitalizations with SLE and AKD were associated with an increased probability of inpatient mortality compared to the ones with SLE and no kidney disease. Given that the most kidney diseases in SLE patients appear to be related to LN¹, this study suggests that LN is an independent risk factor for inpatient mortality due to AMI.

Variables*	SLE with nephritis vs. SLE without nephritis	SLE with AKD vs. SLE without kidney disease
Mean age (years)	50.3 vs. 61.3 ($p < 0.01$)	57.6 vs. 61.4 ($p < 0.01$)
Female percentage	75.1 vs. 81.0 ($p < 0.05$)	75.9 vs. 81.7 ($p < 0.05$)
Hypertension (%)	80.8 vs. 68.6 ($p < 0.01$)	81.8 vs. 66.5 ($p < 0.01$)
Complicated diabetes mellitus (%)	15.5 vs. 4.3 ($p < 0.01$)	11.4 vs. 3.5 ($p < 0.01$)
Anemia (%)	45.3 vs. 22.7 ($p < 0.01$)	42.4 vs. 19.9 ($p < 0.01$)
Non-ST elevation MI (%)	75.9 vs. 70.5 ($p = 0.06$)	79.0 vs. 69.0 ($p < 0.01$)
Percutaneous coronary intervention (%)	33.5 vs. 41.8 ($p < 0.01$)	30.9 vs. 43.6 ($p < 0.01$)
Coronary artery bypass graft (%)	3.7 vs. 7.0 ($p < 0.05$)	6.6 vs. 6.9 ($p = 0.75$)
Mean length of stay (days)	6.2 vs. 5.0 ($p < 0.01$)	6.5 vs. 4.3 ($p < 0.01$)
Mean total charges (\$)	66717.7 vs. 66493.8 ($p = 0.96$)	73320.5 vs. 65069.4 ($p < 0.01$)
Unadjusted odds-ratio for inpatient mortality	1.24 (CI=0.72-2.12; $p = 0.43$)	1.45 (CI=1.06-1.97; $p < 0.01$)
Adjusted odds-ratio for inpatient mortality	1.28 (CI=0.59-2.77; $p = 0.52$)	1.84 (CI=1.27-2.67; $p < 0.01$)

Clowse¹, ¹Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC, ²Medicine, Division of Rheumatology, Duke University, Durham, NC, ³Department of Medicine, Duke University, Durham, NC, ⁴Division of Rheumatology & Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression occurs commonly among patients with SLE. In this study, we used two separate scales to assess depression and determined differences in clinical characteristics and patient-reported disease activity in patients with and without symptoms of depression.

Methods: Patients meeting ACR or SLICC criteria for SLE in a university rheumatology clinic were included. At each visit, patients completed a series of questionnaires: Systemic Lupus Activity Questionnaire (SLAQ), Patient Health Questionnaire (PHQ-9), and the ACR Fibromyalgia (FM) Diagnostic Criteria 2011. To meet criteria for FM, patients had (1) widespread pain score ≥ 7 and symptom severity score ≥ 5 or (2) widespread pain score ≥ 3 and symptom severity score

Table 1. Clinical characteristics of SLE patients with depression.

	PHQ-9*			SLAQ*		
	No Depression n=122 n (%)	Depression* n=53 n (%)	p-value	No/Mild Depression n=172 n (%)	Moderate/Severe Depression n=36 n (%)	p-value
Fatigue	68 (55.7%)	46 (86.8%)	<0.0001	92 (53.8%)	30 (83.3%)	0.001
Muscle Weakness	39 (32.0%)	32 (60.4%)	0.0007	54 (31.4%)	21 (58.3%)	0.004
Muscle Pain	48 (39.3%)	39 (73.6%)	<0.0001	72 (41.9%)	24 (66.7%)	0.01
Swollen Joints	38 (30.9%)	36 (67.9%)	<0.0001	56 (32.8%)	25 (69.4%)	<0.0001
Stiff Joints	62 (50.4%)	37 (69.8%)	0.02	85 (49.7%)	25 (69.4%)	0.04
Anxiety	14 (11.5%)	21 (39.6%)	<0.0001	12 (7.0%)	24 (66.7%)	<0.0001
Forgetfulness	30 (24.6%)	30 (56.6%)	<0.0001	39 (22.8%)	22 (61.1%)	<0.0001
Patient reported flare	60 (53.1%)	44 (89.8%)	<0.0001	85 (54.5%)	27 (81.8%)	0.004
Fibromyalgia	15 (12.1%)	29 (54.7%)	<0.0001	31 (18.0%)	14 (38.9%)	0.01
	Mean (SD)	Mean (SD)	p-value	Mean (SD)	Mean (SD)	p-value
Clinical SLEDAI	1.7 (2.4)	2.8 (2.9)	0.008	1.8 (2.5)	2.1 (2.3)	0.6
Full SLEDAI	3.8 (3.2)	5.3 (5.3)	0.02	4.2 (4.1)	4.5 (4.3)	0.7
PGA (0-3)	0.4 (0.5)	0.7 (0.6)	0.0004	0.5 (0.6)	0.6 (0.6)	0.2
Patient-reported disease activity (0-10)	3.9 (2.7)	6.3 (2.2)	<0.0001	3.8 (2.8)	6.0 (2.6)	<0.0001
SLAQ	10.1 (5.6)	18.3 (6.1)	<0.0001	10.1 (6.6)	18.0 (6.2)	<0.0001
Fibromyalgia Widespread Pain Score	3.4 (3.3)	7.0 (5.2)	<0.0001	3.7 (3.9)	5.6 (5.1)	0.01
Fibromyalgia Symptom Severity Score	3.7 (2.1)	6.5 (1.6)	<0.0001	3.6 (2.5)	6.0 (1.9)	<0.0001

*Depression defined as Patient Health Questionnaire (PHQ-9) score ≥ 10

†Depression defined as patient response of moderate or severe to the SLAQ item "feeling depressed" in the previous month

≥ 9 . Physician measures of disease activity collected at each visit included SLEDAI and physician global assessment (PGA). Depression was defined as PHQ-9 score ≥ 10 . As part of the SLAQ, patients were asked if they were “feeling depressed” in the prior month, with responses of none, mild, moderate, or severe. Differences in clinical characteristics and patient-reported disease activity in patients with and without depression were analyzed by Fisher’s exact test and t-tests.

Results: The analysis included 208 patients with SLE (92% female, mean age 45 years, 22% with FM). Of 175 patients who completed the PHQ-9, 30% met criteria for depression. Of the 208 patients who completed the SLAQ, 47% reported experiencing any depression (mild, moderate, or severe) in the previous month, while 17% reported moderate to severe depression.

Among patients with FM, 66% reported depression by PHQ-9, 33% reported mild depression by SLAQ and 31% reported moderate to severe depression. In contrast, among those without FM, 18% reported depression by PHQ-9, 20% reported mild depression, and 13% reported moderate or severe depression by SLAQ.

Patients with depression reported more fatigue, muscle weakness, muscle pain, swollen joints, stiff joints, anxiety, and forgetfulness (Table 1). Further, patients with depression had higher overall SLAQ scores, patient-reported disease activity, widespread pain scores, and symptom severity scores. Among patients who met PHQ-9 criteria for moderate-severe depression, clinical SLEDAI, full SLEDAI, and PGA scores were higher than patients without depression.

Conclusion: These data suggest that SLE patients with depression are more symptomatic and have higher perceived disease activity. They also demonstrate a strong association between depression, FM, and some SLE symptoms that often confounds trials and clinical care decisions. Together, these findings suggest that identifying methods to distinguish between these symptoms and target therapy to the underlying pathology will improve the quality of life for patients living with SLE and the comorbid symptoms of fibromyalgia and depression.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

FIGURE 1. Graft and patient survival.

Background/Purpose: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus, affecting up to 40% of patients. Unfortunately, about 20% of LN develop end stage renal disease (ESRD) and need replacement therapy. Renal transplantation (RT) may be required. However, concerns about LN recurrence after RT has been reported. In a series of patients with RT due to LN our aim was to assess a) long-term post-transplant survival and, b) comparison of post-transplant survival with a control group due to a non-autoimmune nephropathy, a polycystic kidney disease (PCKD).

Methods: We studied 2 groups of patients with first RT: a) LN and b) PCKD (control group). All these patients were transplanted in a single reference University Hospital. The main outcome variables were a) graft and patient survival up to 20 years and b) evolution of renal function (serum creatinine and proteinuria) in the first 5 years. Cumulative survival rates after RT were estimated by the Kaplan-Meier method and compared between groups using the log-rank test. Mann-Whitney test or chi²/Fisher's exact test were used to compare quantitative or qualitative variables, respectively.

Results: We included 53 patients with RT; a) LN group (21), b) PCKD group (32). No significant differences at baseline were observed between both groups regarding sex and cardiovascular risk factors. Significant differences were found in terms of age at RT, with a mean of 39.80±11.27 years in LN group and 46.59±5.01 years in PCKD group (p=0.004). Renal biopsy was performed in 16 LN patients: type II LN (25%), type III (25%) and type IV (50%), according to the World Health Organization and International Society of Nephrology/Renal Pathology Society classification. From 48 patients (of 53) in which a renal biopsy was performed during the first-year post-transplant, rejection was found in 21 cases (43.7%) with no significant differences between both groups (p=0.444). The evolution of serum creatinine and proteinuria after RT is shown in TABLE. Significant differences were found in creatinine levels at the 6th month post-transplant (p=0.032), not so in the rest of measurements. In LN group, 3 patients (14.3%) developed a lupus flare: 2 cases of extrarenal disease and only 1 case with histological recurrence in the graft. No significant differences were found in patient or graft survival between both groups in 20 years of follow-up (Figure 1).

Conclusion: RT may be a safe alternative therapy for ESRD in LN patients and can provide a long-term survival.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus Nephritis (LN) usually presents within 5 years of SLE diagnosis, however the minority of patients with late-occurring nephritis are poorly characterized. Factors associated with high risk for early nephritis include male gender, Hispanic and African American race, and childhood-onset SLE (Jacobsen et. al. 1998, Seligman et. al. 2002). Since proliferative nephritis is a more aggressive class of nephritis than membranous and mesangial nephritis, we hypothesized that female gender, Caucasian race, adult-onset SLE, and membranous pathology would be associated with a later or more insidious onset of nephritis.

Characteristic	Total (n = 278)	≤ 5 Years (n = 197)	> 5 Years (n = 81)	>10 Years (n = 45)	>15 Years (n = 22)
Female (n, %)	242 (87.05)	167 (84.77)	75 (92.68)	42 (93.33)	21 (95.45)
Race/Ethnicity (n, %)					
Black/African American	121 (43.53)	84 (41.12)	40 (49.38)	21 (46.67)	12 (54.55)

White/Caucasian	27 (9.71)	17 (8.63)	10 (12.35)	7 (15.56)	5 (22.73)
Asian	18 (6.47)	9 (4.57)	9 (11.11)	5 (11.11)	2 (9.09)
Age at SLE (median, IQR)	25.45 [19.12, 33.20]	25.84 [19.49, 39.03]	25.16 [18.31, 30.22]	24.36 [16.12, 39.34]	24.5 [19.19, 27.03]
Age at Lupus Nephritis (median, IQR)	29.78 [21.25, 39.43]	35.86 [20.49, 38.49]	58.24 [30.02, 44.78]	42.34 [33.06, 48.88]	45.38 [38.34, 51.75]
Histopathologic Class (n, %)					
I	35 (11.87)	24 (12.18)	9 (11.11)	6 (13.33)	5 (22.73)
II	65 (23.38)	45 (22.84)	20 (24.69)	14 (31.11)	7 (31.82)
III+IV	41 (14.75)	25 (12.69)	16 (19.75)	5 (11.11)	1 (4.55)
IV	54 (23.02)	48 (24.37)	15 (18.52)	7 (15.56)	3 (13.64)
IV+V	24 (8.63)	16 (8.12)	8 (9.88)	4 (8.89)	1 (4.55)
V	51 (18.32)	38 (19.29)	13 (16.05)	9 (20.00)	5 (22.73)
Proliferative (II, III+IV, IV, IV+V)	194 (69.78)	135 (68.53)	58 (72.84)	30 (66.67)	12 (54.55)

Table 1. Characteristics of the LN cohort. The initial group is the total cohort, followed by the cohort divided into ≤ 5 years between SLE and first LN biopsy and > 5 years. All >10 years patients are also included within the > 5 years group, and > 15 years patients are also in >5 years and >10 years groups. Time between SLE and biopsy was analyzed as a continuous outcome variable to prevent unnecessary loss of power.

Methods: A single large urban medical center was the source for retrospective record review of patients who underwent kidney biopsy between 1999 and 2015. Patients with biopsy-proven LN were evaluated to determine whether gender, race, age at SLE diagnosis, age at first biopsy, or histopathologic classification were associated with the time (years) between SLE diagnosis and first renal biopsy.

Results: 630 patients were screened. After elimination of duplicates, those without initial biopsy, biopsy findings other than lupus nephritis, and unknown date of SLE diagnosis, 293 subjects had adequate data available for analysis. Those with late onset SLE, diagnosis after age 50 (n=15), were excluded from further analysis due to known differences in this subgroup. The remaining 278 patients had characteristics shown in Table 1. Twenty-nine percent of patients in this cohort developed nephritis more than 5 years after initial SLE diagnosis, including 50% of Asian, 37% of Caucasian, 33% of African American, and 20% of Hispanic LN patients. Multivariable linear regression identified greater age at first biopsy and race as the strongest predictors of time between SLE diagnosis and first renal biopsy. Hispanic patients were more likely to present with LN earlier in their course and Asian patients were more likely to present later, with African American and Caucasian groups between them. The model accounts for 27% of the variability in the time elapsed between diagnosis and biopsy. Histopathologic class did not make a significant contribution, and proliferative nephritis was noted in similar numbers of patients who developed LN after 5 years (73%) and those in the early presenting group (69%, p=0.6).

Conclusion: Surprisingly, more than a quarter of known LN patients at this large US center present after 5 years of SLE, higher than expected based on low numbers of late onset nephritis in other cohorts. This appears to be more common in Caucasian and Asian subgroups. Older patients are more likely to develop nephritis later, but aggressive histopathology is not less likely in later presentations. The data underscore the importance of remaining vigilant about nephritis risk in patients of diverse demographics five years and more after diagnosis with SLE.

Positive Remodeling Index and Low Attenuation Non-Calcified Coronary Plaques: Markers of Vulnerable Coronary Plaques in Systemic Lupus?

George Stojan¹, Laurence Magder² and Michelle Petri³, ¹Division of Rheumatology, Johns Hopkins University, Baltimore, MD, ²Department of Epidemiology, University of Maryland, Baltimore, MD, ³Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE. Positive remodeling index and presence of low attenuation noncalcified plaque (<30 Hounsfield units) are characteristic vessel changes in unstable coronary plaques. We sought to characterize noncalcified plaque lesions in patients with systemic lupus erythematosus and to identify high risk lesions.

Methods: A total of 66 patients who met the ACR or SLICC classification criteria for SLE had CT angiogram studies. Of these, 30 patients had two CT angiogram studies. Coronary plaque area was measured by manual tracing for the difference between the area within the external elastic membrane and the area of the vessel lumen at the site of maximal luminal narrowing as observed on a cross-sectional coronary CT angiography image. Each noncalcified plaque detected within the vessel wall was evaluated with the minimum CT density and vascular remodeling index (RI). Total low density plaque volume per patient and low density/high density noncalcified plaque ratio were then compared by patient characteristics which included age, sex, ethnicity, BMI, smoking, SLEDAI, PGA, anti-dsDNA, low complement, current prednisone, current hydroxychloroquine, current NSAID use, history of cardiovascular event, hypertension, lupus anticoagulant, antidiolipin, hypercholesterolemia, and methotrexate use.

Results: All patients had at least one plaque with a positive remodeling index (>10%), and 83.1%(n=271) of total identified plaques had a positive remodeling index. Low density noncalcified plaque volume was associated with age ($p<0.01$) and body mass index ($p<0.01$). African Americans had significantly more ($p<0.05$) low density noncalcified plaque compared to patients of other ethnicities. The low density/high density noncalcified plaque ratio did not correlate with any patient characteristics and was on average 46% (SD=10). There were only 5 cardiovascular events in the studied group and there were no differences in remodeling index or low density noncalcified plaque observed in this group, but the number of events was small.

Conclusion: Positive remodeling index and low attenuation noncalcified plaques are common in patients with lupus and are significantly more likely to be seen among African American patients, patients with a BMI>30, and age over 60. These characteristic vessel changes, seen in unstable coronary plaques, may identify patients at need for more frequent noninvasive cardiac monitoring.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE. We sought to characterize non calcified and calcified plaque lesions in patients with systemic lupus erythematosus and to compare the findings with a group of healthy controls.

Methods: A total of 70 patients who met the ACR or SLICC classification criteria for SLE were included in the study. All patients underwent coronary CT angiography. A total of 100 non-matched healthy controls were included in the study. Coronary plaque area was measured by manual tracing for the difference between the area within the external elastic membrane and the area of the vessel lumen at the site of maximal luminal narrowing as observed on a cross-sectional coronary CT angiography image.

Results:

Table 1. Mean plaque volume (95% CI, in mm³) between study groups at baseline

	SLE group (N=70)	Control group (N=100)	p-value
Total plaque volume	1547.88 (1435.54, 1660.22)	432.96 (338.62, 527.29)	<0.0001
Calcified plaque volume	29.79 (-36.16, 95.74)	265.27 (209.89, 320.66)	<0.0001
Non-calcified plaque (NCP) volume	1518.09 (1427.73, 1608.45)	167.68 (91.81, 243.56)	<0.0001

Table 2. Mean(SD) of Calcified and Non-calcified Plaque, in each cohort, by age and sex

Sex	Age	Non-calcified Plaque					Calcified Plaque				
		JHU		UCLA		p	JHU		UCLA		p
		n	Mean(SD)	n	Mean(SD)		n	Mean(SD)	n	Mean(SD)	
Female	<44	18	1324.44 (464.69)	0	- (-)	-	18	0 (0)	0	- (-)	-
	45-59	25	1416.36 (429.85)	3	244.83 (125.38)	<.0001	25	2.00 (4.83)	3	138.50 (186.60)	0.3327
	60+	16	1562.06 (560.33)	21	111.04 (109.35)	<.0001	16	16.38 (28.54)	21	162.39 (165.96)	0.0007
Male	<44	2	1549.00 (548.71)	2	203.20 (287.37)	0.0916	2	0 (0)	2	122.20 (66.75)	0.2347
	45-59	4	1670.75 (290.82)	22	227.97 (268.13)	<.0001	4	0.50 (1.00)	22	250.30 (265.18)	0.0002
	60+	5	1919.60 (489.46)	52	215.31 (225.93)	0.0013	5	77.60 (69.37)	52	355.44 (400.42)	<.0001

Conclusion: SLE patients on average have a significantly higher burden of non calcified plaque (p<0.0001) compared to controls, while surprisingly, the calcified plaque burden is lower (p<0.0001). The limitation of our study is the comparatively older age of the control group as well as the gender discrepancy, with males being predominant among the controls. Nevertheless, this discrepancy even further highlights the burden of high risk non calcified plaque in SLE.

Prevalence and Predictors of Peripheral Vascular Disease in a Cohort of Systemic Lupus Erythematosus (SLE) Patients

Ida Dzifa Dey¹, Kelvin Acquaye², Alfred Yawson³, Kofi Agyabeng⁴, Ernest Yorke⁵, Vincent Boima⁶ and Charles Mate-Kole⁷, ¹Department of Medicine, Rheumatology Unit, School of Medicine and Dentistry, University of Ghana, Accra, Ghana, ²Department of Psychology, School of Medicine and Dentistry, Accra, Ghana, ³Department of Community Health, School of Medicine and Dentistry, Accra, Ghana, ⁴Department of Community Health, School of Medicine and Dentistry, University of Ghana, Accra, Ghana, ⁵Medicine, School of Medicine and Dentistry, University of Ghana, Accra, Ghana, ⁶School of Medicine and Dentistry, University of Ghana, Accra, Ghana, ⁷Department of Psychology, School of Medicine and Dentistry, University of Ghana, Accra, Ghana

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Low Ankle-brachial index (ABPI) < 0.9 demonstrating peripheral vascular disease (PVD), is a marker of subclinical cardiovascular disease and it is an inexpensive and easy method in which to assess peripheral vascular disease (PVD). Cardiovascular morbidity in systemic lupus erythematosus (SLE) is at least as frequent as in age- and sex-matched type-1 diabetes mellitus patients, making SLE a cardiovascular disease equivalent. Therefore, aggressive screening and management of cardiovascular risk factors should be performed to reduce this risk and improve long term mortality from vascular events.

Methods: The present study evaluated prevalence and risk factors for peripheral vascular disease in patients with SLE in a sub-Saharan country, Ghana. Secondly, it examined the correlates with disease characteristics, activity indices and traditional risk factors of atherosclerosis.

A prospective cohort of 77 Ghanaian female patients with SLE had clinical, laboratory parameters, disease activity, damage indices, treatment and traditional risk factors for atherosclerosis evaluated between those with and without PVD measured using ankle brachial pressure index (ABPI).

Results: The prevalence of PVD was 22.73% with a mean age of 30.94 (SD \pm 8.22) years (range: 20 – 60 years). Women with normal ABPI were older than those with abnormal ABPI, but this was not statistically significant (31.5 verses 28.5 years, $p = 0.192$).

From the multiple logistic regression model, prednisolone dosage, waist to height ratio (WHR), low density lipoprotein (LDL) as well as educational level were the statistically significant factors associated with higher prevalence of PVD ($p < 0.05$). A unit increase in WHR decreased the odds of developing PVD by 0.0013 (95% CI: 0.00 – 0.18). Increase in prednisolone dosage increases the patient's odds of developing PVD by 0.88 (95% CI: 0.79 - 0.99). Each one unit rise in patient's LDL increased their odds of getting PVD by 0.52 (95% CI: 0.27 - 0.98). Patients odds of being diagnosed with PVD increased by 0.85 (95% CI: 0.76 - 0.96) for each year after diagnosis. Higher educational level was associated with lower odds of developing PVD. Patients with tertiary education had 99% (AOR: 0.01, 95% CI: 0.00 - 0.47) lower odds of developing PVD.

Conclusion: There is an increase prevalence of PAD in this Ghanaian cohort of SLE patients compared to the general public but lower than other SLE cohorts, despite being younger than other SLE cohorts and female. Traditional cardiovascular factors as well as disease related factors like disease duration and prednisolone use are associated. Follow up studies would see the impact of this on disease outcome and organ damage, especially on their neurocognitive effect which has not been studied previously.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a leading cause of death in systemic lupus erythematosus (SLE). The coronary artery calcium (CAC) score is a surrogate for atherosclerosis that strongly predicts incident coronary artery disease and major CVD events, independent of traditional Framingham risk factors. The prevalence of CAC deposition in SLE patients over the age of 45 is higher compared to the Multi-Ethnic Study of Atherosclerosis (MESA) cohort; however, data on patients <45 years of age is limited. We evaluated CAC scores in younger SLE patients, compared to healthy controls from the Coronary Artery Risk Development in Young Adults (CARDIA) cohort.

Methods: We identified 45 SLE patients who met 1997 ACR classification criteria, with no known coronary artery disease, and who had a non-contrast chest CT performed as part of their routine clinical care with images retrievable for calculation of CAC using the Agatston score. Demographics, disease characteristics, and comorbidities were ascertained. Prevalence of any calcification - defined as CAC>0 - was reported and compared with data from the CARDIA cohort, a large biracial U.S. cohort of patients ages 33 to 45 at time of chest CT scan for CAC determination. Additionally, within our SLE cohort, we investigated the relationship between disease characteristics and presence of coronary artery calcification.

Results: The 45 SLE patients were 39±14 years old, 89% female, 38% Hispanic, and 38% African American, with a disease duration 9±7 years. Patients met on average 5±1 ACR-SLE classification criteria; all had positive ANA titers; and 58% had elevated dsDNA titers. The average SLE disease severity index¹ was moderate (5±3), 42% had lupus nephritis, and 36% tested positive for antiphospholipid (APL) antibodies. CAC>0 was noted in 47% of all patients, with 41% of patients age <45 and 56% of patients age ≥45 having positive CAC. Out of the patients with positive CAC, 81% of patients had CAC scores between 1 and 100 and 19% had CAC scores >100. When compared with the CARDIA subjects, more SLE patients aged<45 had a CAC>0 (41.4% vs 9.6%, p-value <0.00001). Additionally, 45% of SLE patients ages 18 to 32 and 5 years median SLE disease duration, had abnormal CAC scores; the youngest of whom was 21 years old. There were no significant differences in SLE disease duration, SLE severity index, lupus nephritis, APL positivity, BMI, smoking status, presence of hypertension or diabetes between patients with and without CAC.

Conclusion: Young SLE patients have significantly higher CAC scores compared with the general population. A positive CAC score was seen in 41% of SLE patients <45 year-old and 45% of SLE patients <32 years old. Our data suggest that subclinical atherosclerosis in SLE develops as early as the second decade of life, and warrants screening and cardio-protective interventions.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Factors associated with neuropsychiatric damage in SLE has been described. Yet, determinants of progression of small vessel related brain injury, and major neurocognitive disorder-vascular dementia (MCD) is not well understood. The purpose of this study is a case-control analysis that compare neuropsychiatric lupus (NPSLE) patients with MCD and those who have not developed MCD.

Methods: A nested case-control study of 24 NPSLE subjects with MCD out of the SLE cohort at the University of Maryland between 1995 and 2018, were identified according to the 2007 American College of Rheumatology proposed response criteria for severe neurocognitive impairment in SLE (> 2.0 SD below the mean compared to normative data) that interferes with daily functioning leading to loss of independence. For each NPSLE patient with MCD, 3 age- and gender- matched NPSLE subjects with no MCD were randomly selected from the same cohort, and assigned an index date of the NP events corresponding to the MCD group ($n = 72$).

Results: 24 NPSLE cases with MCD [mean age 48.8 ± 18.5 years, African American (71.0 %), mean level of education 11.7 years, mean SLE duration of 15 years] were compared to 72 NPSLE patients with no MCD [mean age 44.8 ± 17.1 years, African American (69.4 %), mean level of education 12.3 years, mean SLE duration of 13 years]. Baseline data including, severity of NPSLE events, structural neuroimaging findings of cortical and subcortical infarcts, hypo perfusion with watershed infarction, periventricular white matter hyper intensity, cardiovascular disease risk factors and Framingham risk score, cytotoxic or immune therapy, glucocorticoid, anticoagulation or aspirin use were not significantly different among both groups. Similarly, autoantibodies of phospholipid, ribosomal-P, anti-neuronal antibodies, NR2 and NMDA, were similar among both groups. Higher disease activity, glomerulonephritis and depression were more frequent among MCD group than in comparators. Independent predictors of MCD included baseline lacunar infarcts based in the caudate, thalamus, cerebellum, and peri-Sylvian regions (OR 5.0, 95% CI: 1.2-20.3, $P < 0.012$), regional volume loss (OR 20.0, 95% CI: 2.2-182.4, $P < 0.001$), and cerebral atrophy (OR 1.8, 95% CI: 1.2-2.7, $P < 0.001$). Medication non-adherence for SLE disease activity (OR 2.0, 95% CI: 1.1- 3.9, $p < 0.012$), uncontrolled dyslipidemia (OR 16.3, 95% CI: 2.9-91.8, $P < 0.001$), uncontrolled hypertension (OR 7.3, 95 % CI: 1.6-33.1, $P < 0.003$), and alcoholism (OR 4.4, 95% CI: 0.9-25.2, $p < 0.076$) were independent predictors of MCD progression. Hydroxychloroquine use was associated with slow progression of MCD (OR 3.0, 95% 1.4-6.7, $P < 0.001$).

Conclusion: Despite a similar prevalence of vascular risk factors at baseline, the risk of MCD is higher in NPSLE patients who do not adhere to medications related to SLE and control of cardiovascular risk factors than in matched comparable group. Understanding the complexity of medication non adherence in SLE need to be identified, and patient-tailored interventions focusing on patients' specific barriers to adherence are needed. This observation deserve further study to confirm the use of hydroxychloroquine as an intervention to slow progression of MCD.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Myocarditis is a severe manifestation of systemic lupus erythematosus (SLE). Ethnicity is believed to play an important role in influencing the outcome. We aimed to describe the clinical features and outcomes of lupus patients with myocarditis in a North Indian population.

Methods: Clinical records of SLE patients fulfilling 2012 SLICC criteria presenting to the Rheumatology Clinic and inpatient services (from November 2014 to November 2017) were screened for a clinical and laboratory diagnosis consistent with lupus myocarditis (LVEF <50%, absence of massive pericardial effusion, severe pulmonary artery hypertension, significant regional wall motion abnormality or primary valvular disease). Demographic data, clinical features and echocardiography findings were noted. Cardiac outcomes as well as survival were assessed using Kaplan Meier survival analysis and Cox regression analysis.

Results: 37 patients with SLE who had features consistent with lupus myocarditis were included. The median duration of follow up was six and half months. 12 patients (32%) presented with lupus myocarditis at first presentation; the median duration between the diagnosis of SLE and diagnosis of myocarditis was seven and half months. All patients received corticosteroids and hydroxychloroquine while 27 patients received additional cyclophosphamide. Ten deaths (27.7%) were noted, of these 9 died during the initial presentation while one patient died two months' later of disseminated varicella infection. The deaths were attributed to disease activity alone in 2 patients, activity with infection in 5 patients and infection alone in remaining 3 patients. Among the survivors, mean ejection fraction rose from $33 \pm 8\%$ at baseline to $48 \pm 11\%$ at last follow up in 70% of patients (n=20). Raised serum procalcitonin at presentation (> 0.9 ng/ml) ($p=0.049$), higher blood urea ($p=0.038$) and low serum complement C3 (< 50 mg/dl) (0.002) were associated with increased mortality. Patients with raised serum procalcitonin at presentation had reduced survival (mean survival 2.5 months, C.I. 0.1 to 4.8 months) as compared to those without (mean survival 49.2 months, C.I. 38.2 to 60.2 months) ($p=0.014$).

Conclusion: Lupus myocarditis is associated with high mortality in Indian SLE patients. Elevated serum procalcitonin at presentation is associated with reduced survival in these patients.

Table1 showing baseline characteristics of all patients with myocarditis.

	Results
Duration of symptoms in days	15 (71)
Time from diagnosis of SLE to myocarditis in months [median (range)]	7.5 (0-84)
Follow up in months [median (range)]	6.5 (0-60)
dsDNA positivity	26/37 (70.2%)
Crackles on auscultation	17/23
Anemia (<10 g/dl)	26/33
Thrombocytopenia ($<150 \times 10^9/L$)	10/33
Leucopenia ($<4 \times 10^9/L$)	6/33
Hypoalbuminemia (<35 g/L)	32/34
Proteinuria (>0.5 gm/24hr or dipstick $>2+$)	22/28
Raised serum creatinine (>1.4 mg/dl)	13/36
Raised procal (>0.9 ng/ml)	8/26
Low C 3 (50-150 mg/dl)	10/22
Low C4 (16-38 mg/dl)	16/22
SELENA-SLEDAI	N=30
No flare (≤ 3)	3
Mild or moderate flare (3-12)	14
Severe flare (>12)	13

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Systemic lupus erythematosus (SLE) are prone to bacterial infection owing to disease activity, abnormal immune function and long-term immunosuppressive therapy. Differentiating bacterial infection from disease relapse in SLE is challenging based on clinical signs and symptoms due to similar clinical presentation. Microbial culture is the gold standard for diagnosing bacterial infection, but it is time-consuming and the positive culture ratio is low. The role of several biomarkers including C-reactive protein (CRP), procalcitonin (PCT) and white blood cell count (WBC) for diagnosing bacterial infection is controversial. The study is aimed at evaluating the significance of neutrophil CD64 (nCD64) index, complement C3, complement C4, CRP, PCT, WBC, lymphocyte subsets, CD4⁺T subsets and their combination in differentiating bacterial infection from disease relapse in SLE.

Methods: Thirty-six hospitalized SLE patients with bacterial infection and 45 with lupus flare without infection were retrospectively studied. Bacterial infection was proven by positive cultures or typical clinical symptoms and signs combined with positive response to antibiotics. Lupus flare was considered as three points greater than the patient's previous SLEDAI. C3, C4, CRP and PCT were detected by immunoturbidimetry. Lymphocyte subpopulations, CD4⁺T subsets and nCD64 index were measured by flow cytometry. WBC was detected by blood cell analyzer.

Results: The levels of nCD64 index ($p=0.034$), CRP ($p=0.049$) and WBC ($p=0.028$) were significantly higher in the infected group and C3 ($p=0.001$), C4 ($p=0.016$) and B cells ($p=0.010$) were lower. The areas under the receiver operating characteristic (ROC) curves (AUC) for the above six biomarkers had no significant difference [nCD64 index: 0.619 (CI 0.504-0.724), CRP: 0.608 (CI 0.492-0.715), WBC: 0.625 (CI 0.510-0.730), C3: 0.658 (CI 0.540-0.764), C4: 0.646 (CI 0.526-

Figure 2 Comparison of ROC curves of C3, C4, CRP, nCD64 index, WBC and B cells as biomarkers in differentiating bacterial infection from disease relapse in SLE.

Figure 2 Distribution of the infected and the disease relapse SLE patients at bioscore range 0-6. One point was added once the value of C3, C4 or B cells was below the normal reference range of laboratory or the value of CRP, WBC or nCD64 index was above the cut-off value in the normal reference interval, with 0 being the minimum score and 6 being the maximum score. Six individuals were excluded due to some indicators were not detected. The value of patients with bioscore of less than 2 ($n=10$) were in the disease relapse group. Eleven (39.29%) of 28 patients with bioscore of 1 were infected. Thirteen (39.10%) of 33 patients with bioscore of 2 were infected. Thirteen (39.10%) of 33 patients with bioscore of 3 were infected. Eight (61.54%) of 13 patients with bioscore of 4 were infected. The whole of patients with bioscore of 5 ($n=2$) were infected.

Table 1 The demographic data and various markers of the infected group and the disease relapse group

	Infected group ($n=16$)	Disease relapse group ($n=45$)	<i>p</i>
Age	41.00 (28.25,56.75)	39.00 (26.00,46.50)	0.055
Gender			
female	4 (11.11%)	7 (15.56%)	0.400
male	32 (88.89%)	38 (84.44%)	
Weight (kg)	59.84 \pm 10.96	58.53 \pm 10.59	0.302
C3 (g/L)	0.46 (0.29,0.55)	0.56 (0.43,0.69)	0.001
C4 (g/L)	0.08 (0.03,0.12)	0.11 (0.06,0.17)	0.016
CRP (mg/L)	7.93 (3.35,23.15)	4.81 (2.02,10.48)	0.049
PCT (ng/mL)	0.19 (0.02,0.79)	0.09 (0.01,0.21)	0.160
nCD64 index	1.06 (0.75,3.13)	0.92 (0.73,1.17)	0.034
WBC ($\times 10^9/L$)	4.43 (3.42,8.01)	3.75 (2.46,6.72)	0.028
T cell (cell/ μ L)	727.50 (414.00,935.00)	722.68 (427.06,1141.00)	0.243
B cell (cell/ μ L)	89.56 (56.28,162.00)	130.00 (79.50,315.38)	0.010
NK cell (cell/ μ L)	58.50 (32.50,99.00)	49.00 (28.51,136.00)	0.470
Th cell (cell/ μ L)	263.50 (110.75,477.25)	276.00 (159.09,497.48)	0.213
Ts cell (cell/ μ L)	364.00 (193.25,506.43)	384.00 (234.50,543.30)	0.142
Th1 cell (cell/ μ L)	13.08 (11.72,84.63)	46.00 (15.53,95.60)	0.303
Th2 cell (cell/ μ L)	4.50 (2.40,8.07)	4.94 (2.48,9.20)	0.291
Th1/2 cell (cell/ μ L)	4.51 (2.27,7.31)	4.17 (2.08,9.30)	0.412
Treg cell (cell/ μ L)	13.49 (3.99,23.13)	12.46 (4.66,27.37)	0.492
Th1/Th2	3.00 (2.61,11.96)	8.22 (4.96,14.00)	0.274
Th1/2/Treg	0.30 (0.17,0.69)	0.40 (0.17,0.80)	0.434

Continuous variables were reported as Mean \pm standard deviation (M \pm SD) or median and interquartile range (IQR) and analyzed by the *t* test or Mann-Whitney U test for independent samples. Categorical variables were expressed as numbers and proportions and compared with Chi-square test.

0.754), B cells: 0.652 (CI 0.538-0.754)] and the best combination was nCD64 index, CRP, WBC, C3 and C4. The bacterial infection rate in patients with bioscore $\leq 2, 3, 4, 5$ and 6 were 0.00%, 39.29%, 59.10%, 61.54% and 100.00%, respectively.

Conclusion: The combination of nCD64 index, C3, C4, CRP, WBC and B cells in a bioscore is useful to diagnose bacterial infection in SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is one of the most common and severe manifestations of systemic lupus erythematosus (SLE). This study investigates urinary galectin-3 binding protein (G3BP) levels in LN patients and their association with renal disease activity both clinically and pathologically.

Methods: A total of 44 biopsy-proven active LN, 27 active non-nephritis SLE and 24 inactive SLE patients were recruited. All of them fulfilled the 1997 ACR classification criteria for SLE. 28 Age matched healthy controls were recruited. Urinary G3BP was tested by ELISA. rSLEDAI was the total score of the four kidney-related parameters in SLEDAI.

Results: Urinary G3BP levels were significantly increased in active LN patients, and discriminated LN patients (27.65 (12.68-62.04)) from active non-nephritis SLE (6.35 (1.84-14.25), Area Under the Curve (AUC): 0.81 ($P<0.001$)), inactive SLE (7.62 (3.58-23.57), AUC: 0.74 ($P=0.001$)), and healthy controls (1.89 (1.31-5.54), AUC: 0.89 ($P<0.001$)) (Tab.1 and Fig. 1). Urinary G3BP performed better in discriminating active LN from active non-LN nephritis SLE than conventional markers, such as C3 (AUC: 0.51), C4 (AUC: 0.59), and anti-dsDNA (AUC: 0.51). Correlation analysis showed a significant negative correlation between urine G3BP and hemoglobin ($r=-0.29, P=0.005$), positive correlation between urine G3BP and

Figure 1. Urinary G3BP level is significantly increased in active LN patients. A. Group comparison. B. Receiver Operating Characteristic (ROC) curve.

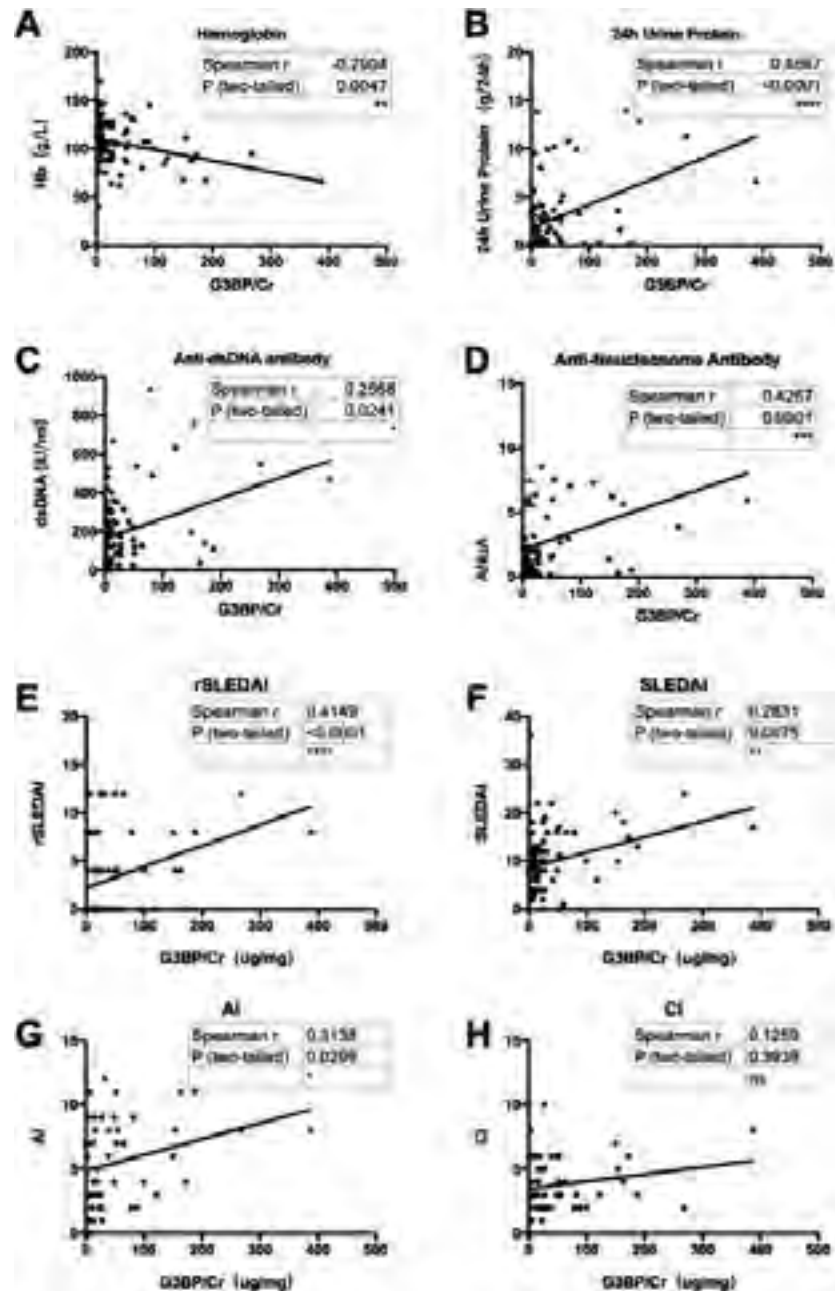

Figure 2. Correlation analysis between urinary G3BP and A. Hemoglobin; B. 24-hour urine protein; C. Anti-dsDNA antibody level; D. Anti-nucleosome antibody level; E. rSLEDAI; F. SLEDAI; G. Activity Index (AI); H. Chronicity Index (CI)

24-hour urine protein ($r=0.46$, $P<0.001$), anti-dsDNA antibodies ($r=0.26$, $P=0.02$) and anti-nucleosome antibodies ($r=0.43$, $P<0.001$) (Fig.2A-2D). Moreover, renal disease activity as assessed by rSLEDAI correlated with urine G3BP levels ($r=0.41$, $P<0.001$) (Fig. 2E). In 44 biopsy-proven active LN patients, urine was collected one day before the biopsy day. These previous concurrent samples revealed urinary G3BP levels were significantly elevated in Class III and Class IV LN over Class V LN (32.59 (15.75-80.46) vs 4.54 (3.83-19.09)). More importantly, urinary G3BP correlated with pathological renal activity index (AI), suggesting the measurement of G3BP levels in urine is useful in monitoring the progression of renal pathologies in patients with LN (Fig. 2G-H).

Conclusion: Our data suggest urinary G3BP as a biomarker for renal pathologies in patients with LN. These findings should be confirmed in a larger cohort to further validate the utility of urinary G3BP as a biomarker.

Cutaneous Lupus Erythematosus Patients with a Negative ANA Meeting ACR and/or SLICC Criteria for Systemic Lupus Erythematosus

Meera Tarazi¹, Carolyn Kushner², Rebecca Gaffney² and Victoria P. Werth³, ¹Department of Dermatology, University of Pennsylvania, Philadelphia, PA, ²Dermatology, University of Pennsylvania, Philadelphia, PA, ³Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a disorder that is heterogeneous and can be difficult to diagnose. One hallmark of the disease is the presence of anti-nuclear antibodies (ANA), a feature that has been incorporated into multiple classification criteria over the years. In this study, we use a database of cutaneous lupus erythematosus (CLE) patients to determine how many have a negative ANA and meet criteria for SLE using ACR and/or SLICC criteria.

Methods: We used a database of 454 CLE patients at the University of Pennsylvania that contained information including ANA status and the presence of features of SLE. The database was searched for patients who had a negative ANA and whether or not they met SLE criteria using the ACR and/or SLICC criteria.

Results: Of the 406 active patients with a known ANA, 147 had a negative ANA (36.2%) and 39 of all patients who had multiple ANAs checked (n = 114) had an ANA that fluctuated (34.2%). 30 ANA negative patients met SLE criteria (20.4%) and 19 patients with fluctuating ANA met SLE criteria (48.7%). Of all patients who had either a negative or a fluctuating ANA and met criteria for SLE (n = 49), 40 patients had involvement of at least 1 organ system other than skin (81.6%), and 22 patients had involvement of at least 2 organ systems other than skin (44.9%). Of the 40 patients with non-mucocutaneous organ involvement, 35 patients had arthritis, 14 patients had leukopenia, 9 patients had renal involvement, 4 patients had serositis, 3 patients had neurologic involvement, and 1 patient had thrombocytopenia.

Conclusion: Our results demonstrate that a positive ANA is not always present in patients with SLE involving non-mucocutaneous organ systems. If a positive ANA was a requirement for diagnosing SLE, many patients, who warrant treatment or should be included in clinical trials, would be excluded. This should be taken into consideration when devising SLE classification criteria to be used for clinical trials.

Comparison of Length of Stay and Total Hospital Charges for Hospitalizations for Sepsis in Patients with Systemic Lupus Erythematosus: A Study of National Inpatient Sample Database 2010 to 2014

Karan Chugh¹, Shraddha Jatwani², Karan Jatwani³ and Jasleen Kaur⁴, ¹Division of Pulmonary, Critical Care & Sleep, Wayne State University/Detroit Medical Center, Detroit, MI, ²Department of Internal Medicine, Division of Rheumatology, Henry Ford Allegiance Health, Jackson, MI, ³Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, New York, NY, ⁴Department of Internal Medicine, Wayne State University/Detroit Medical Center, Detroit, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sepsis is a systemic inflammatory response syndrome caused by an infection with at least one acute organ failure and is major public health concern.¹ Serious infectious diseases are recognized as major causes of morbidity and mortality in patients with systemic lupus erythematosus (SLE). Hospitalization of patients with SLE is a major cause of healthcare costs², but limited research is available examining cost differences of complications associated with lupus including severe infections and sepsis.

Methods: We analyzed hospitalizations for sepsis among adults in the Nationwide Inpatient Sample (NIS). Patients were stratified into two groups based on the status of SLE; using ICD-9 CM diagnostic codes. Descriptive statistics were represented as means/medians for continuous and as frequencies and percentages for categorical variables. A survey weighted multivariate regression analysis was used to adjust for confounders when calculating length of stay and total charges.

Results: There were an estimated 35475 adult hospitalizations for sepsis with secondary diagnosis of lupus, from 2010 to 2014. On univariate analysis, the average age of patients admitted with sepsis in the general population was 67.154 ± 0.064 years, whereas in the SLE population, the average age was 54.145 ± 0.225 years ($p < 0.0001$). Among the general population, 51.47% of all patients with sepsis were females; whereas among the SLE population, 87.79% of the population were females ($p < 0.0001$). Septic patients with secondary diagnosis of lupus had significantly higher length of stay and total cost per hospitalization. When adjusted for patient factors affecting population with SLE including age, gender and race, length of stay was still found to be significantly high by a coefficient of 0.27 (p value = 0.01). Similar results were noted in total hospital cost with average \$3541 increase in charges, for patients with sepsis and lupus, when adjusted for age, gender and race.

Conclusion: From our study, SLE is associated with higher cost burden and length of stay in patients admitted with sepsis. This may reflect decreased immune response from the disease itself as well as use of immunosuppressive drugs, resulting in longer stay in hospitals. Inpatient hospital charges associated with sepsis can be decreased with early and aggressive intervention. Rheumatology providers should have low threshold to screen patients for infections to prevent progression of infections to sepsis. This will help reduce healthcare utilization and costs in patients with underlying SLE.

Diagnosing SLE Arthritis with Dynamic Diffuse Optical Spectroscopy

George Danias¹, Youngwan Kim², Alessandro Marone³, Kayla Neville¹, Andrea Frantz¹, Teja Kapoor⁴, Laura Geraldino-Pardilla¹, Ioannis Kymissis², Andreas Hielscher^{2,3,5} and Anca Askanase¹, ¹Rheumatology, Columbia University Medical Center, New York, NY, ²Electrical Engineering, Columbia University, New York, NY, ³Biomedical Engineering, Columbia University, New York, NY, ⁴Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, ⁵Radiology, Columbia University Medical Center, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE arthritis is difficult to evaluate because of the sometimes-evanescent nature of the symptoms and limitations of physical exams and imaging studies. Dynamic diffuse optical spectroscopy (dDOS) can be used to assess changes in light absorption through tissues during transient venous occlusion. The optical signal reflects changes in blood perfusion and has diagnostic value in rheumatoid arthritis. The current study explored the use of dDOS in SLE arthritis.

Methods: 11 SLE patients (ACR criteria) with active arthritis and 4 controls were evaluated. A dDOS sensor module was developed (Fig. 1). Hemodynamic effects were obtained by inflating a BP cuff to 40 mmHg x 60 seconds. Light at 3 wavelengths ($\lambda = 530, 655, 940\text{nm}$) was used to illuminate joints at 8 different points. Transmitted light intensities

Fig. 1: Two dDOS sensor module bands (1a) wrapped around a PIP joint for measurement (1b). Each band contains 4 measurement heads (black dots). Each of the measurement heads includes 3 light-emitting diodes at three different wavelengths ($\lambda = 530\text{nm}$, 655nm , and 940nm , power = 2mW) and one Si-photodetector.

Fig. 2: Representative raw data for one healthy subject (blue) and one SLE arthritis subject (red). (1) and (2) are respectively the rise and the plateau times for a SLE patient, while (3) and (4) are respectively the rise and the plateau times for a healthy patient. It can be seen that SLE arthritis joints display a faster rise time (time needed to increase from 10% to 90% of the maximum value) and a longer plateau time than healthy joints.

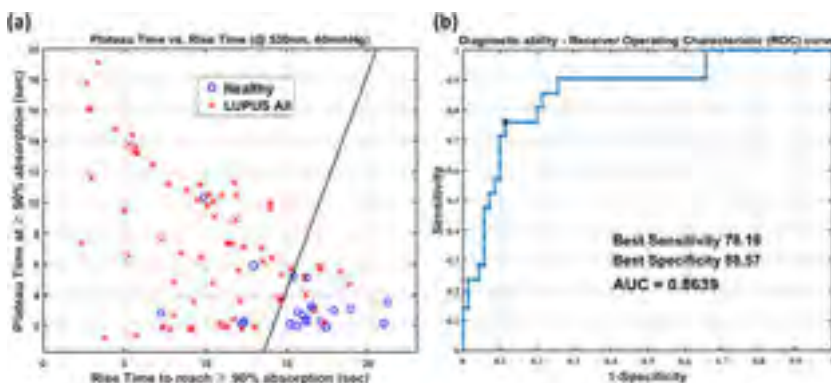

Fig. 3: Discriminant and ROC analysis which demonstrate the high specificity and sensitivity of dDOS when taking into account the rise time and the plateau time of the absorption signal (see Fig. 2).

were measured with Si-photodetectors at 8 other positions (total 8x8x3=192 signal traces). Swollen, tender and healthy joints were examined by the same assessor.

Results: SLE patients and normal controls dDOS data were available for analysis from 66 and 24 proximal interphalangeal (PIP) joints, respectively (PIPs 2-4). Best results were obtained at 530 nm with cuff inflation at 40 mmHg. A representative measurement of 3 SLE arthritis and 3 normal joints is shown in Fig. 2, highlighting differences in rise and plateau time. Given the pronounced effects at $\lambda = 530\text{nm}$, we speculate that altered vessel physiology paired with already-increased blood pooling in the affected inflamed joints resulted in quicker increase in light absorption (rise time) that is maintained longer (plateau time) compared to normal joints. The AUC for dDOS was consistent with excellent discrimination, AUC = 0.8639, sensitivity = 76.19, specificity = 88.57 (Fig. 3).

Conclusion: dDOS can evaluate SLE arthritis with high sensitivity and specificity. Rise and plateau time of the optical traces correlate strongly with swollen and tender joint count. The advantages of dDOS are non-invasiveness, objectivity (eliminates inter-rater variability and operator dependency), low cost, and high speed of performance (~5 min per area of scanning) compared to US and MRI. dDOS has the potential to bring much-needed objectivity to the quantification of SLE arthritis.

Protein/Creatinin Urinary Index Has Concordance with 24 Hour Urinary Proteinuria in Patients with Systemic Lupus Erythematosus

Eugenia Picco¹, Ricardo Vicente Juárez², Emilio Buschiazzi², Natalia Lili Cucchiaro³, Gustavo Rua⁴, Patricia Talocchino¹, Ivana Romina Rojas Tessel¹, Mariana Aciar³, Maria Veronica Lencina³ and Maria Elena Crespo Espindola⁵, ¹Hospital Señor del Milagro, Salta, Argentina, ²Rheumatology Section, Hospital Señor del Milagro, Salta, Argentina, ³Rheumatology, Hospital Señor del Milagro, Salta, Argentina, ⁴Biochemistry Section, Hospital Señor del Milagro, Salta, Argentina, ⁵Reumatología, Hospital Señor del Milagro, Salta, Argentina

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty-four hour proteinuria (24hp) has been the gold standard for the screening and follow up of glomerular disease. The use of protein/creatinin urinary index (PCI) in a spot urine sample, has been proposed as an alternative to 24hp due to its low cost and simple recollection of the sample. This method has been validated in patients with diabetic and non-diabetic nephropathy, with less data in patients with Systemic Lupus Erythematosus (SLE). The aim of this study was to measure the correlation and concordance between these two methods in patients with SLE

Methods: Paired samples of 24hp (in grams in 24 hours) and PCI (first urine sample, expressed in mg/g) in SLE diagnosed patients with or without lupus nephropathy, collected between June 2015 and May 2018, in Señor del Milagro's Hospital at Rheumatology Unit were included for the analysis. PCI value is 1000 times higher than 24hp. Walser's index (WI) which evaluates the quality of the collected sample on 24hp, calculated with estimated and measured urine creatinine, age and weight was performed. A WI between 0.75 and 1.25 reflects well collected 24hp. Qualitative data was expressed in frequency and percentages, quantitative data in medians and interquartile range (IQR) or media and standard deviation (SD) depending on its distribution. Spearman test was performed to assess correlation between 24hp and PCI was. In order to analyze concordance between PCI and 24hp, the PCI was multiplied by 1000. Interclass Concordance Coefficient (ICC), with (Cronbach's alpha) was calculated. Receiver operating curves (ROC) with under the curve area (UCA) were calculated for 24hp values of ≥ 0.3 , 0.5, 1 and 3.5 grams per 24 hours, in order to calculate IPC cut points. A p value < 0.05 was considered significant.

Results: 68 patients, 60 (88.2) female, median age 33 years (IQR: 27-48), and 187 paired urine samples were included. Spearman's correlation between the 2 methods was 0.84. ICC was > 0.9 for the whole sample, 0.92 when WI was acceptable (n=88) and only dropped to 0.88 in the context of "non-acceptable" WI (n=99). Considering only acceptable WI samples, ROC curves showed cut points of 333 mg/g, 407 mg/g, 984 mg/g and 3013 mg/g had good sensitivity and specificity (S 77, Sp 87 or higher) to predict 24hp of 0.3 g, 0.5 g, 1 g and 3.5 g.

Conclusion: In this sample of SLE patients, 24ph and PCI had a good ICC and correlation, considering an acceptable WI. The use of PCI could replace 24ph in the assessment of glomerular disease in SLE patients.

Aquaporin-4 Immunoglobulin G Antibody Positive Neuromyelitis Optica Spectrum Disorder and Systemic Autoimmune Diseases Overlap Syndrome: A Single Center Experience

Eduardo Martín Nares¹, Gabriela Hernandez-Molina¹ and Hilda Frago-Loyo², ¹Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ²Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México, Mexico

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The coexistence of neuromyelitis optica spectrum disorder (NMOSD) with other systemic autoimmune diseases is well recognized, especially with systemic lupus erythematosus (SLE) and Sjögren syndrome (SS). However, literature is scarce, limited to case reports and multicentric case series. The objective of this study is to describe the clinical and radiological characteristics and outcomes of patients with AQP4-IgG seropositive NMOSD coexisting with SLE and SS in a single center.

Methods: This was a retrospective study that included patients with concurrent diagnosis of AQP4-IgG seropositive NMOSD according to the 2015 International Consensus Diagnostic Criteria, and SLE according to the ACR revised criteria or SS according to the AECG criteria who regularly attended a tertiary referral center in Mexico City (2003-2018). We collected demographics, clinical (neurological events, number of relapses, remission, treatment, follow-up [date of last visit to a rheumatologist and/or neurologist] and disability according to the Expanded Disability Status Scale [EDSS]), laboratory (cerebrospinal fluid (CSF) analysis) and imaging data of NMOSD, as well as clinical and serological data of the overlapping autoimmune disease. We assessed disease activity in SLE and SS using SLEDAI-2K and ESSDAI respectively, and accrual damage with the SLICC/ACR-DI and SSDDI respectively.

Results: We included 11 patients, 10 (90.9%) women with a mean age at diagnosis of 36 ± 15 years. Seven (63.6%) had SLE and 4 (36.6%) primary SS. Five (45.5%) patients had also another systemic or organ-specific autoimmune disease. In 8 (72.7%) patients NMOSD followed SLE/SS onset, 2 (18.2%) had a simultaneous presentation, and in 1 (9.1%) NMOSD preceded SS diagnosis. The mean time from diagnosis of SLE/SS to the first neurological event was 54.6 months. The mean SLEDAI-2K and ESSDAI at first neurological event was 3.1 (mainly hypocomplementemia and high anti-dsDNA) and 14.3 points (mainly renal and peripheral nerve involvement) respectively. During follow-up, 10 patients (90.9%) experienced myelitis, 5 (45.5%) optic neuritis, 2 (18.2%) each experienced area postrema syndrome, acute brainstem syndrome and cerebral syndrome; being the median number of neurological events 4 (1-8). Three patients (27.3%) had antiphospholipid antibodies. None of the patients had pleocytosis or low CSF glucose and 3 had high CSF proteins. All patients had longitudinally extensive transverse myelitis on MRI, 3 (27.3%) optic nerve findings and 6 (54.5%) NMOSD-typical brain lesion patterns. Nine (81.8%) patients went into either total or partial NMOSD remission at a mean follow up of 6.5 ± 5.3 years. At last follow up the median EDSS, SLICC/ACR-DI and SSDDI was 2.5 (1-10), 2 (0-7) and 2 (0-3) points respectively; 4 (36.4%) patients had sequelae and 1 patient was death.

Conclusion: Patients with SLE or SS with clinical features of NMOSD should be tested for AQP4-IgG. In our cohort, AQP4-IgG seropositive NMOSD arose in the context of low SLE activity and in the context of SS with extraglandular features; and the disability and accrual damage at last follow up appeared to be mild.

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupusnephritis (LN) is a serious manifestation of systemic lupus erythematosus(SLE). Rarely, patients may present with LN alone and have no extra-renalclinical manifestations of lupus (isolated lupus nephritis, ILN). We aimed to describe the clinical characteristics of patients presenting with isolated LN and to study their treatment outcome and long term survival and its predictors compared to classic LN.

Methods: Subjects were identified by searching a pathologic renal biopsy database. Clinical records were reviewed for exclusion of infectious and secondary causes. Cases with isolated LN were defined per 2012 SLICC criteria; classic SLE patients had lupus nephritis along with extra-renal manifestations of lupus. Complete response (CR) was defined as proteinuria <0.5 g/24 h and serum creatinine(sCr) within 125% of the baseline value after the start of induction therapy. Partial response (PR) was defined as reduction of proteinuria of >50% (and at least <3.0 g/24 hours) plus sCr within 125% of the baseline value after the start of the induction therapy.

Results: 30 patients with isolated LN and 134 patients with classic LN were identified. The median age at the time of biopsy was 41 and 39 years, for the ILN and LN group, respectively. Majority were Caucasian; female to male ratio was 3:1 in ILN and 2:1 in the LN group. The median duration from renal symptoms to biopsy was 5.2 months for ILN and 1.2 for the LN group (p=0.013). Mean sCr was 1.7 mg/dl and 1.3 mg/dl and 24hour proteinuria 8.5 and 4.9 g, respectively. A greater percentage of patients with ILN had hypertension at onset (83% versus 35% in LN, p<0.001) and interstitial fibrosis in biopsies (97% ILN versus 69% LN, p=0.018). The outcomes and survival among 18 ILN and 72 LN patients of class 3, 4 or mixed are noted in Table.

	ILN	LN
Complete response (95% CI)		
12 mo	23 (10, 54)	42 (32, 55)
5 year	48 (29, 80)	67 (57, 80)
10 year	62 (39, 99)	70 (59, 83)
Complete and/or partial (95% CI) response		
12 mo	51 (32, 80)	58 (48, 71)
5 year	69 (50, 95)	82 (73, 92)
10 year	85 (64, 100)	88 (79, 98)
ESRD/Renal transplant (95% CI)		
12 mo	6 (0, 40)	4 (1, 13)
5 year	12 (3, 45)	17 (10, 30)
10 year	30 (13, 71)	27 (17, 44)
Survival (95% CI)		
12 mo	94 (84, 100)	99 (96, 100)
5 year	88 (74, 100)	94 (87, 100)
10 year	64 (40,100)	87 (77, 100)

Conclusion: The response rates and 10 year survival tended to be higher in the LN group compared to ILN. Possible late recognition and/or under treatment of this subset may be underlying the differences.

Cardiovascular Disease in SLE at One Center between 1981 and 2016. a Population-Based Study Highlighting the Importance of Disease Duration and Age at Diagnosis

Ola Nived¹, Ragnar F Ingvarsson¹, Anna Jöud², Petrus Linge¹, Helena Tydén¹, Anders A. Bengtsson¹ and **Andreas Jönsen¹**, ¹Rheumatology, Lund University, Department of Clinical Sciences, Lund, Sweden, ²Division of Occupational and Environmental Medicine, Lund University, Department of Laboratory Medicine, Lund, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Active inflammatory processes characterize early SLE disease, while later morbidity to a considerable extent consists of consequences of organ damage, particularly cardiovascular disease (CVD). In this study, we report on the frequency of acute myocardial infarctions and stroke in incident SLE cases in a defined population over an extended time.

Methods: The current study includes SLE patients followed at the Department of Rheumatology in Lund, Sweden, diagnosed 1981 through 2006. First, we compare incidence rates of acute myocardial infarctions (AMI) and cerebrovascular incidents (CVI) between all incident SLE cases within 8 counties, through the years 1998-2016, and the population. This time constraint is due to the availability of reliable electronic health care information for the population only from 1998 and forward. Second, we describe AMI and stroke incidence patterns in SLE patients 1981-2016 in an extended cohort. Only the first events of AMI and CVI respectively, both among SLE patients and in the population, were used for calculations.

Results: In all, 276 SLE patients were included in the study. From the defined 8 counties 175 SLE patients were studied and thus 101 patients from outside this region were included. Overall, 38 AMI and 44 CVI were recorded in 72 SLE patients, thus 10 patients had suffered both from an AMI and a CVI. The incidence rate-ratio for AMI was 3.0 in SLE overall (CI 1.3-6.9 (99.9%) $p<0.001$) compared with the population. Significantly increased rate-ratios of AMI were seen in women <40 and between 40-59 years of age, while for males only the age group 40-59 years had an increased incidence of AMI. SLE patients with a higher age at diagnosis (>54 years) had a shorter disease duration before suffering an AMI compared to SLE patients diagnosed at a younger age (median 7 years vs 18 years, $p<0.05$). The incidence rate-ratio for CVI in SLE overall was 3.2 (CI 1.6-6.6 (99.9%) $p<0.001$) compared to the population. An increased CVI incidence was only significant for women in the age group 40-59 years. Males were few and had only 2 events in the higher age group.

Conclusion: SLE patients are at risk of developing early myocardial infarctions and cerebrovascular incidents compared with the population. Patients with a younger age at SLE diagnosis may develop AMI after a longer disease duration compared to older patients.

Predictors of End-Stage Renal Disease in Lupus Nephritis

Mery Deeb¹, Konstantinos Tselios², Dafna D Gladman², Jiandong Su² and Murray Urowitz³, ¹Division of Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ³Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: End-stage renal disease (ESRD) is the most important complication of lupus nephritis (LN) and greatly affects mortality. Its incidence has been estimated at 11% at 5 years and 17% at 10 years after LN diagnosis. The identification of certain predictive factors is of importance for risk stratification and proper management. The aim of the present study was to define the factors associated with ESRD development in a defined cohort of LN patients.

Methods: Patients with LN (class II-V according to the International Society of Nephrology/Renal Pathology Society classification) were recruited from our long-term longitudinal cohort. Individuals with ESRD (estimated glomerular filtration rate, $eGFR \leq 15$ ml/min/1.73m²) at the first two clinic visits after enrolment were excluded. Patients were followed until the occurrence of ESRD (defined as two consecutive visits with an $eGFR \leq 15$ ml/min/1.73m² or initiation of dialysis) or last visit. They were divided in two groups (ESRD or not) and compared as per the demographic, histopathological, clinical and therapeutic variables. Statistical analysis was performed with SAS 9.0; $p < 0.05$ was considered significant. Time-dependent Cox regression analysis was performed for the identification of predictors.

Results: LN was diagnosed in 560 patients, 43 of whom developed ESRD (7.7%) after 7.5 ± 6.4 years of follow up. There were no differences in demographic variables at baseline. Concerning the histopathologic class, diffuse proliferative LN (class IV) was more frequent in the ESRD patients (51.2% vs. 28.4%, $p = 0.033$). Baseline serum creatinine was higher in the ESRD patients (152 ± 94 vs. 85 ± 41 mmol/L, $p < 0.001$); consequently $eGFR$ was lower (61 ± 37 vs. 93 ± 37 ml/min/1.73m² respectively, $p < 0.001$). Hypertension was more frequent in the ESRD patients (58.1 vs. 38.3%, $p = 0.015$). Concerning laboratory values, initial proteinuria was more severe in the ESRD patients (3.2 ± 2.5 vs. 1.9 ± 2.8 g/day, $p = 0.027$) whereas hemoglobin was lower (113 ± 18 vs. 120 ± 20 g/L, $p = 0.02$). There were no differences in therapeutic variables (dose of glucocorticosteroids, type and dose of immunosuppressives and antimalarials). Patients with ESRD were using angiotensin converting enzyme inhibitors or angiotensin receptor blockers more frequently (34.9 vs. 21.3%, $p = 0.04$). Multivariable Cox regression analysis revealed that hypertension (HR=10.1, 95%CI=4.34-23.8, $p < 0.001$), baseline serum creatinine (HR=1.009, 85%CI=1.008-1.01, $p < 0.001$) and initial prednisone dose (HR=1.016, 95%CI=1.001-1.031, $p = 0.03$) were associated with a higher probability for ESRD development. On the contrary, normal hemoglobin at baseline was protective (HR=0.97, 95%CI=0.95-0.99, $p < 0.001$).

Conclusion: Initial serum creatinine and hypertension were the most important predictors for the development of ESRD in patients with LN. These findings reinforce the importance of regular monitoring of serum creatinine even in asymptomatic patients as well as the need for strict control of hypertension in LN.

Neutrophil Extracellular Traps Are a Source of Extracellular High Mobility Group Box-1: Association with Clinical and Histopathological Features in Patients with Lupus Nephritis

Laura Patricia Whittall¹, Diana Gómez-Martín¹, Jiram Torres-Ruiz², Alejandro Zentella Dehesa¹, Miguel Tapia-Rodríguez¹ and Jorge Alcocer-Varela¹, ¹Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ²Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current evidence suggests that neutrophils play an important role in the pathophysiology of lupus nephritis (LN) mainly through the secretion of type I IFN and the production of Neutrophil Extracellular Traps (NETs). This type of cell death releases proinflammatory molecules, including High Mobility Group Box-1 (HMGB1). HMGB1 acts as an alarmin once released into the extracellular space and induces the synthesis of proinflammatory cytokines through its interaction with diverse receptors. Elevated levels of this protein have been associated with global disease activity as well as LN. However, the precise source of extracellular HMGB1 has not been addressed. The aim of this study was to analyze the expression of HMGB1 in NETs of patients with LN and its association with clinical and histopathological characteristics of the disease.

Methods: Twenty-three patients with LN confirmed by biopsy as well as 14 SLE patients with active disease (SLEDAI ≥ 6) and no evidence of LN were included. Clinical and laboratory features were obtained. NETs and the expression of HMGB1 were assessed by immunofluorescence and confocal microscopy. Besides, serum HMGB1 levels were measured by ELISA.

Results: 81% of the patients were women and the mean age was 30.6 years. Patients with LN were characterized by a higher expression of HMGB1 in NETs compared to patients without LN (Spontaneous: 57 vs 30.4, $p=0.027$; LPS: 55.8 vs 24.9, $p=0.005$), even though, we did not find differences in serum HMGB1 levels ($p=0.920$) nor the amount of NETs (Spontaneous: $p=0.230$, LPS $p=0.263$). Nonetheless, we found a positive correlation between serum HMGB1 and HMGB1 expression in LPS-induced NETs ($r=0.447$, $p=0.017$). The expression of HMGB1 in spontaneous NETs correlated with serum creatinine ($r=0.481$, $p=0.003$), proteinuria/creatinuria index ($r=0.34$, $p=0.039$), % of glomerular filtration rate descent ($r=0.543$, $p=0.001$), SLEDAI score ($r=0.508$, $p=0.001$), anti-DNAbs ($r=0.514$, $p=0.001$) and diverse histopathological findings of active LN in the renal biopsy as shown in Table 1.

Conclusion: Our findings support the hypothesis that NETs are a relevant source of extracellular HMGB1 in patients with LN. The positive correlation between HMGB1 from spontaneous NETs and histopathologic findings of active proliferative LN suggest the role of this alarmin in the pathophysiology of renal damage in SLE.

Table 1: Correlations between the mean fluorescence intensity of HMGB1 in spontaneous NETs and histopathological findings in renal biopsies.

Feature	Rho	p value
Activity Index	0.581	0.001

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Only a few studies have analyzed the influence of tobacco smoking in SLE in a quantitative way. Furthermore, scanty information exists regarding smoking and damage in SLE patients, considering the damage by organs, in a separate manner. The objective of this study was to carry out a cross-sectional analysis of the smoking habit in a well characterized, monocentric, cohort and to analyze the influence of tobacco on SLE phenotype, activity and specific damage. Additionally, we inquired about the degree of patient weakness regarding the impact of the tobacco use in SLE.

Methods: Consecutive SLE-patients (ACR-97 criteria) attendant our Lupus clinic throughout 2017 were included. At the time of the last visit, activity (S SLEDAI), cumulative clinical data and comorbidities were retrospectively collected and damage (SLICC/ACR damage index (SLICC/ACR DI) was calculated. To determine patients' smoking exposure, we used a standard model questionnaire and the pack-year (PY) was calculated. Patients ever smoking versus never smoking were compared, using only cumulative variables. A regression model was built to identify factors associated with retinal damage

Results: 216 patients included. Mean age 49 years (± 12.7), 93% females, median disease duration of 17 years (p25-p75: 9-25). 53% of the patients recognized to having ever smoked and 23% were active smokers. Medium PY: 13 (6-20.5). Sixty-one percent of all patients recalled being informed of the negative effects of smoking on their disease. However, only 54.8% of current smokers admitted to having been informed, compared to 83.3% of non-smokers ($p < 0.001$). In the bivariate analysis, a statistically significant association between tobacco any time and discoid lupus [$p = 0.002$; OR:3.5 (IC95% 1.5-8.9)] and photosensitivity [$p = 0.01$; OR:2.06 (IC95% 1.16-3.7)] was found. Regarding SDI, a trend was identified ($p = 0.08$) with a significant association with retinal damage, adjusted by age (OR 1.03, CI95% 1-1.07, $p = 0.04$) when the comparison was made considering the SDI organ by organ. Regarding comorbidity, the only one significant association that we found was peripheral arteriopathy ($p = 0.007$). When the comparison was carried out using PY, a statistically significant association was found with global SDI > 0 ($p = 0.002$) and retinal damage ($p = 0.02$), as well as with discoid lupus ($p = 0.01$), photosensitivity ($p = 0.03$) and peripheral arteriopathy ($p = 0.01$), suggesting a dose-response relationship. In a multivariate analysis exploring factors associated to retinal damage, just smoking ever and SDI remain statistically significant.

Conclusion: Smoking is associated to cutaneous manifestations and damage in SLE patients as well as peripheral arteriopathy, with a dose-response relationship. There is a specific association, not previously reported, between retinal damage and smoking. If confirmed, this association should be considered when planning the ophthalmologic monitoring for antimalarials use. It is imperative to optimize the patient education about the impact of tobacco consume in SLE.

Spinal Cord Syndromes Associated with Systemic Lupus Erythematosus: Differentiating Lupus Myelitis, Neuromyelitis Optica, and Multiple Sclerosis

Jessica Williams¹, Cameron Speyer¹, David Kreps¹, Karen Costenbader¹ and Shamik Bhattacharyya², ¹Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ²Neurology, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-infectious myelitis in SLE is caused by heterogeneous disease processes including SLE myelitis, comorbid multiple sclerosis (MS), or anti-aquaporin-4 antibody (AQ4) mediated neuromyelitis optica (NMO). These conditions with different treatments and prognosis are difficult to differentiate. We compared the demographic, clinical, laboratory, and radiographic characteristics of these 3 conditions in SLE patients at a large academic institution.

Methods: We searched the Brigham and Women's Hospital Lupus Center Registry comprised of 2,297 patients with ≥ 4 1997 ACR revised criteria for SLE. Neurologic diagnoses within this population were identified by text string searches within electronic medical records for the terms "myelitis", "NMO", "neuromyelitisoptica", and "multiple sclerosis" between January 1, 2000 and December 31, 2015. Each subject was then reviewed by an attending neurologist to confirm the diagnosis of myelitis, NMO, or MS. To be classified as NMO, subjects required a positive AQ4 antibody and a neurologic syndrome typical of NMO (myelitis +/- optic neuritis). To be classified as MS, subjects required 2 separate neurologic syndromes typical of MS with characteristic brain lesions. Demographic, clinical, laboratory, and radiographic data were extracted. Characteristics of these 3 groups were compared using Fisher's exact test for categorical variables and analysis of variance for continuous variables. Wilcoxon rank-sum test was used for SLEDAI-2K score, ESR, and CRP level as these values were not normally distributed.

Results: Fifteen subjects with SLE (0.7%) met criteria for a spinal cord syndrome: 7 had myelitis, 3 had NMO, and 5 had MS (Table). The median SLEDAI-2K score at time of neurologic syndrome presentation was higher in myelitis subjects (8, IQR 7-16) compared to subjects with NMO (6, IQR 0-14) or MS (2, IQR 0-4), $p = 0.02$. Subjects with myelitis were also more likely to have elevated anti-dsDNA antibodies at presentation (86%) compared to subjects with NMO (33%) or MS (0%), $p = 0.03$. In all 3 groups, 100% of subjects who had a repeat MRI of the spine ≥ 6 months after spinal disease onset had persistent lesions. One year after spinal disease onset, all subjects were either in American Spinal Injury Association Impairment Scale (AIS) category D (in complete motor loss, $\geq 4/5$ strength) or category E (normal function).

Conclusion: Compared to subjects with SLE + NMO and subjects with SLE + MS, subjects with SLE myelitis had higher SLE disease activity at myelitis onset as indicated by SLEDAI-2K scores and elevated anti-dsDNA antibody levels. Studies involving larger populations should be conducted to differentiate these 3 conditions.

Herpes Zoster in Systemic Lupus Erythematosus: Prevalence and Risk Factors

Hanan Al Rayes¹, Nicole Anderson², Dennisse Bonilla², Jiandong Su² and Zahi Touma², ¹Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Herpeszoster (HZ) commonly observed in the elderly and in immune-compromised patients. The prevalence of HZ is 3.6-19.9% in previously reported data. The higher prevalence of HZ in Systemic Lupus Erythematosus (SLE) patients is aggravated by the concomitant use of immunosuppressant and glucocorticoids (GCs). The objective of this study is to determine the prevalence and describe the characteristics of HZ in an SLE cohort.

Methods: A patient questionnaire was developed to examine HZ in SLE patients. It includes different questions on patient' demographics, the onset of HZ in relation the SLE onset, pain related to HZ, history of varicella zoster vaccine, anti-viral therapy for HZ, and several estimated risk factors for HZ. The survey was distributed to consecutive SLE

patients attending the Lupus Clinic from January 2016 to April 2018. All patients were evaluated according to a standard protocol which includes assessment of disease activity (SLE Disease Activity Index 2000 [SLEDAI-2K]). Analysis included descriptive statistics.

Figure 1. HZ Pain Severity as Reported by SLE Patients (N=123)

Results: Of 912 patients who visited the clinic within that period, 412 patients completed the survey. The prevalence of HZ was 127 (30.8%) at a mean age of 47.4 ± 13.7 years. Of these 127 patients, 32 (25.2%) patients experienced recurrent HZ event, occurring within 12.2 ± 12.1 years from the 1st HZ event. The demographic features of SLE patients with and without HZ are presented in Table 1.

HZ occurred in the first 5 years post SLE diagnosis in 43.1% of patients, 18.1% reported HZ from 6-10 years and 38.2% reported HZ occurrence ≥ 10 years post SLE diagnosis. Mean SLE duration at first HZ was 9.6 ± 9.8 years. Most (78.8%) of those who developed HZ were not vaccinated prior to HZ. 97.6% of HZ was confirmed by physician and 78% received anti-viral therapy. HZ pain, itching or tingling in the rash area was reported in 96.7% of patients. The majority of the patients reported pain (95.9%) and 74.0% scored between 7 and 10 (Fig. 1).

Eighty patients (62.9%) reported taking prednisone at the time of HZ. Of those, 32 patients reported a mean prednisone dose of 23.3 mg/day (range, 3–60 mg). Seventy-two patients (56.7%) were on immunosuppressant (Azathioprine 31.5%, Mycophenolate mofetil 14.17%, Methotrexate 6.3% and cyclophosphamide 4.72%).

Conclusion: The HZ prevalence of 30.8% was higher than previously published data in SLE. HZ can be an early comorbidity in SLE, with 43.1% of cases occurring within 5 years of SLE diagnosis and 57% after 10 years of SLE diagnosis.

Table 1. Demographic characteristic at study visit of patients with and without HZ

Characteristic	Patients who had HZ (N=127)	Patient who never had HZ (N=285)	P value

Cognitive Function Trajectories Are Associated with the Depressive Symptoms Trajectories in SLE over Time

Zahi Touma¹, Jiandong Su¹ and Patricia Katz², ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have shown that cognitive function followed particular trajectories over time in SLE, with some patients having persistently low scores and others normal scores. This study aims to: 1) describe the association between cognitive function trajectories and depressive symptoms trajectories and 2) identify baseline factors associated with trajectory membership.

Methods: Data were from the University of California San Francisco Lupus Outcomes Study, in which participants are followed longitudinally via annual telephone surveys. The Hopkins Verbal Learning Test-Revised (HVLTR; measures verbal memory) was administered in years 2-7, providing up to 6 of observation. Age- and education-stratified z-scores were derived for HVLTR delayed recall. The Center of Epidemiologic Studies Depression Scale (CES-D; score range 0–60; score ≥ 24 represents depression) was administered yearly.

Combined trajectory modelling for HVLTR and CES-D was performed. Models with up to 6 classes were assessed. The best model was determined by a combination of clinical plausibility and statistical criteria. Univariate/multivariable logistic regression analyses examined baseline (year 2) factors associated with class memberships, including sex, ethnicity, disease duration, treatments, fatigue, and self-reported disease activity.

Results: 755 patients (mean age 35 ± 13 years at SLE diagnosis) were studied. 4 latent classes were identified: 1-low CES-D scores and low cognitive scores (no depression + cognitive impairment; 20%), 2-lowest CES-D scores and highest normal cognitive scores (no depression + normal cognition; 48%), 3-highest CES-D scores and lowest cognitive scores (depression + cognitive impairment) (9%), and 4-high CES-D scores and normal cognitive score (depression + normal cognition; 23%) (Figure 1).

Figure 1. Cognitive function trajectories and the depressive symptoms trajectories in SLE

Table 1 shows the association between baseline variables and membership in classes 2 and 3. Caucasian ethnicity and education were associated with normal cognitive function. SLE disease activity and duration, fatigue, and methotrexate use (reflecting disease activity) were associated with cognitive impairment.

Conclusion: 4 distinct classes of combined cognitive function and the depressive symptoms were identified. Cognitive function was associated with depression status in 32% of patients (class 2 and 3). The results also confirmed that other factors predicted the latent class membership; such as ethnicity, education, disease activity and fatigue. These results highlight different aspects relevant for assessing and managing cognitive function over time in SLE.

Table 1. Baseline factors associated with normal cognitive function and absence of depression (comparing class 2 and 3 in univariate and multivariate analysis)

	HVLT-R delayed recall		P values
	Univariate	Multivariate	
Female	0.5 (0.2, 1.8)	---	
Caucasian	1.9 (1.1, 3.3)	5.9 (2.4, 14.7)	0.0001
Disease duration, year	1.0 (0.98, 1.02)	---	
Education	2.2 (1.8, 2.8)	2.3 (1.6, 3.1)	<0.0001
SLE activity	0.6 (0.5, 0.7)	0.7 (0.6, 0.8)	0.0004
Smoking, ever	0.8 (0.4, 1.2)	---	
Oral glucocorticoids	0.9 (0.5, 1.5)	---	
Methotrexate	0.6 (0.3, 1.7)	0.2 (0.06, 0.9)	0.03

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cognitive impairment (CI) is a common neurobehavioral manifestation of SLE. In our recent systematic review, the prevalence of CI was 38% (95% CI: 33-43%). Studies assessing CI in SLE are mostly cross-sectional and do not provide longitudinal data. Therefore, we aim to report the prevalence of CI and the change over-time in an SLE cohort using a comprehensive battery (CB) of tests.

Methods: Consecutive consenting SLE patients, aged 18-65 years, who attended a single centre (Jul 2016-Apr 2018) were recruited. Patients were administered the CB at baseline (T0), 6 months (T1) and 12 months (T2) which evaluates the following cognitive domains: simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory (visuospatial and memory), executive functioning (untimed and timed) and manual motor speed and dexterity. Patient scores were compared to a normative sample of age- and gender-matched healthy controls to obtain z-scores. CI was operationalized on the CB as a z-score of ≤ -1.5 (as compared to controls) on ≥ 2 domains. We determined the status of cognitive function based on the CB at T0, T1 and T2.

Results: Of the 220 patients (89.1% female), the mean age at SLE diagnosis was 28.3 ± 10.5 and disease duration at enrolment was 14.1 ± 10.4 years (Table 1). The prevalence of CI at T0 in 220 patients was 40.9%. Of the 220 patients, 124 had a 6 month follow-up with a CI prevalence of 29.8% and 71 patients had a 12 month follow-up with a CI prevalence of 35.2%. CI status over 6 months for T0 and T1: Of the 220 patients, 123 had both a T0 and T1 assessment. Sixty-two(50.4%) patients remained non-CI and 30 (24.4%) patients remained CI. Twenty-four(19.5%) patients transitioned from CI to non-CI at T1 and 7 (5.7%) patients transitioned from non-CI to CI at T1. CI status over 12 months for T0, T1 and T2: Of the 220 patients, 56 patients had 3 assessments at T0, T1 and T2. Of these, 41 (73.2%) patients remained stable across all three time points. Of the 41 patients, 30 patients remained non-CI and 11 patients remained CI over all three time points. Of 56, 15 (26.8%) patients changed CI status from CI to non-CI or vice versa (Table 2).

Conclusion: Cognitive function status in SLE patients fluctuates over time, with 26.8% of patients showing a change in status over a 12-month period. Our results advocate for close monitoring of cognitive function inpatients with SLE.

Table 1. Cohort characteristics at enrolment (n=220)

Characteristic	Value (N=220)
Gender (Female)	196 (89.1%)
Ethnicity:	
Asian	18 (8.2%)
Black	45 (20.5%)
Caucasian	128 (58.2%)
Other	25 (11.4%)
Age:	
18-29	38 (17.3%)
30-39	57 (25.9%)
40-49	55 (25.0%)
50-59	50 (22.7%)
60-69	20 (9.1%)
Education:	
Grade 8	9 (4.2%)
High School	39 (18.4%)
College	73 (34.4%)
University	91 (42.9%)
Age at SLE diagnosis (mean \pm SD)	28.3 ± 10.5
Age at enrolment (mean \pm SD)	42.4 ± 12.1
Disease duration at enrolment (mean \pm SD)	14.1 ± 10.3

Table 2. CI status at T0, T1 and T2 (N=56)

CI Status	Frequency (%)
Non-CI at all visits	30 (53.6)
CI at all visits	11 (19.6)
Transitioned from non-CI at T0 or T1 to CI at T2	6 (10.7)
Transitioned from CI at T0 or T1 to non-CI T2	9 (16.1)

Cytomegaloviral or Pneumocystis Jiroveci Pneumonia Increases Mortality Rate in Systemic Lupus Erythematosus Patients with Pulmonary Hemorrhage: Evidence from Bronchoalveolar Lavage Fluid Analysis

Chien-Chih Lai, Yi-Syuan Sun and De-Feng Huang, Allergy, Immunology, Rheumatology, Taipei Veterans General Hospital, Taiwan, Taipei City, Taiwan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the role of cytomegaloviral or Pneumocystic jiroveci pneumonia (CMV/PJP) in SLE patients with pulmonary hemorrhage (PH).

Methods: We retrospectively examined hospital records for 27 SLE patients with PH who received bronchoalveolar lavage fluid (BALF) analyses. Clinical profile and mortality rates were compared between groups with and without CMV/PJP. Risk factors for PH-related mortality were analyzed.

Results: Among 27 SLE patients with PH, 15 patients had pathogens from BALF samples, and eight patients had CMV/PJP (Table 1). Although CMV/PJP was treated, the 90- and 180-day mortality rates of SLE patients with CMV/PJP were higher than those without these infections (90-day: 62.5% vs. 10.5%, $p = 0.011$; 180-day: 75% vs. 10.5%, $p = 0.002$). Risk factors for 90- and 180-day mortality were presence of CMV/PJP (OR 14.2, 95% CI 1.83-109.9; OR 25.5, 95% CI 2.91-223.3) and use of pulse methylprednisolone for PH treatment (OR 12.0, 95% CI 1.48-97.2; OR 8.5, 95% CI 1.13-63.9). Factors increasing the 90-day mortality rate were duration of mechanical ventilation exceeding 14 days (OR 11.1; 95% CI 1.11-112.0) and use of aggressive immunosuppression close to PH onset (OR 7.56; 95% CI 1.09-52.4) (Table 2). Three of the seven patients receiving aggressive immunosuppression died with the presence of CMV/PJP.

Conclusion: Due to the high prevalence of CMV/PJP and its association with mortality, routine BALF analysis is recommended in all suitable SLE patients with PH. Use of aggressive immunosuppression does not benefit SLE patients with opportunistic infections during PH attack.

Table 1. Baseline characteristic of PH of SLE patients.

Parameter	CMV - PJP - (n = 19)	CMV or PJP + (n = 8)
Age at hospitalization, years	33.2 (28.3 iV 43.7)	34.2 (32.7 iV 56.0)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Infection is a major cause of mortality in all stages of disease in systemic lupus erythematosus (SLE). Several risk factors for infection have been identified in SLE such as immunosuppressive medications and prednisone. Yet these do not fully explain the increased risk for infection. We have recently identified a possible association between low immunoglobulin levels and infection risk. The aim of this study was to determine whether acquired low levels of immunoglobulins (Ig) increase the risk of clinically relevant infections within two years in adults with SLE.

Methods: SLE patients in a long term observational study are followed at 2-6 month intervals according to a standard protocol which includes demographics, clinical, laboratory and therapeutic information. Disease activity is measured by the SLEDAI-2K, and damage by the SLICC/ACR damage index (SDI). Ig are measured yearly with quantification of IgG, IgA and IgM. The Low Ig was defined as at least two consecutive or non-consecutive immunoglobulin levels below normal. Baseline was defined by the first visit when low Ig was detected. Controls were patients who never having low Ig levels. The outcome was clinically relevant infection defined as an infection requiring use of antibiotics within 2 years from baseline. Cases and controls in this cohort study were matched on age and decade and then adjusted for potential confounding using propensity score. Primary analysis was time to event using cox-regression model tested for proportional hazard assumption. Restricted cubic spline function was used to address non-linearity. Results were further confirmed using inverse probability weighted treatment (IPWT).

Results: We identified 437 in the exposure group (221 consecutive and 227 non-consecutive) and 656 matched controls. Baseline characteristics are presented in the following table:

Variables at Index	Unit	Non-Low immunoglobulins	Low immunoglobulins	P-value
Disease Duration	Mean \pm SD	7.6 \pm 8.0	11.2 \pm 9.1	0.0001
Ethnicity	Black	90 (13.7%)	58 (13.3%)	0.4
	Caucasian	436 (66.5%)	292 (66.8%)	
	Chinese	57 (8.7%)	50 (11.4%)	
	Others	73 (11.1%)	37 (8.5%)	
SLEDAI-2K	Mean \pm SD	5.9 \pm 5.9	6.2 \pm 6.3	0.02
SDI	Mean \pm SD	0.5 \pm 1.0	1.2 \pm 1.6	<.001
Had Lupus Nephritis before the index.	Yes (%)	117 (17.8%)	196 (44.9%)	<.001
Proteinuria	Yes (%)	74 (11.3%)	112 (25.6%)	<.001
Any Low complement	Yes (%)	274 (41.8%)	162 (37.1%)	0.27
Increase DNA binding	Yes (%)	315 (48.0%)	187 (42.8%)	0.25
Leukopenia	Yes (%)	21 (3.2%)	18 (4.1%)	0.36
Antiphospholipids Antibodies	Yes (%)	168 (26.2%)	62 (15.2%)	0.0001
Prednisone use	Yes (%)	349 (53.2%)	332 (76.0%)	<.001
Oral Prednisone dose (mg/day)	Mean \pm SD	15.3 \pm 14.6	16.8 \pm 16.8	0.06
Immunosuppressant use	Yes (%)	152 (23.2%)	201 (46.0%)	<.001
Biologics treatment	Yes (%)	1 (0.2%)	5 (1.1%)	0.10

All immunoglobulins showed evidence of non-linearity. Proportional hazard assumption was satisfied for immunoglobulins and propensity score. A total of 97 events (47 in exposure group and 50 in non-exposure group). IgG and IgA showed increased hazard at very low levels (1.2 g/l and 1.25 g/l respectively) after adjustment for propensity score or weighted using IPWT. All three Ig showed decreased hazard of infection for normal ranges after adjustment of propensity score.

Conclusion: Our data suggest that very low IgG and IgA are important risk factors for infection independently from all known confounders including prednisone and immunosuppressives. Acquiring low immunoglobulins in SLE patients usually occurs later in the disease and is more likely to be seen among active patients with proteinuria and history of lupus nephritis. We recommend incorporating immunoglobulins measurement in clinical care of adult patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tubulointerstitial damage (TID), defined as tubulointerstitial inflammation (TII) or interstitial fibrosis/tubular atrophy/ (IF/TA) is associated with poor renal outcomes in lupus nephritis (LN)¹. Glomerular damage is thought to initiate downstream changes that culminate in TID². However, some SLE patients with advanced TID have no significant renal impairment to prompt a renal biopsy, complicating their early recognition. Therefore, we studied whether patients with TID and either none or mild renal impairment at the time of biopsy differ from patients with TID and significant renal impairment. The objective was to identify potential factors that may aid in the early recognition of patients with TID before overt renal dysfunction.

Methods: We identified all patients who fulfilled ACR and/or SLICC criteria for SLE and had an index renal biopsy between 2005 and 2017 with moderate/severe TID. Moderate/severe TID was defined as IF/TA and/or TII involving $\geq 25\%$ of the biopsied tissue. Significant renal impairment was defined as glomerular filtration rate (eGFR) < 60 mL/min/1.73m² at the time of biopsy. The following variables were compared: SLE duration, LN class, history of diabetes, hypertension (HTN) and Sjogren's syndrome, medications (steroids, hydroxychloroquine, immunosuppressives, non-steroidal anti-

inflammatory drugs), demographics and laboratory data (complement, dsDNA, antiphospholipid antibodies, anti-Ro/La, anti-Sm/RNP).

Results: A total of 65 patients with moderate/severe T1D were included. Among these patients, 19 (29%) had moderate/severe T1I alone, 25 (38%) had moderate/severe IF/TA alone, and 21 (32%) had moderate/severe T1I accompanied by moderate/severe IF/TA. Among the 40 patients with moderate/severe T1I with or without accompanying IF/TA, 16 (40%) had eGFR ≥ 60 and 24 (60%) had eGFR < 60 . Compared to patients with eGFR < 60 , those with eGFR ≥ 60 had a longer disease duration [median (IQR): 55 (30, 68) vs 17 (3, 26) months, $p=0.002$], and were less likely to have anti-Ro/La antibodies (6% vs 35%, $p=0.04$). Among the 46 patients with moderate/severe IF/TA with or without accompanying T1I, 14 (30%) had eGFR ≥ 60 and 32 (70%) had eGFR < 60 . Compared to patients with eGFR < 60 , those with eGFR ≥ 60 were younger [28 (16, 33) vs 45 (30, 55) years, $p=0.002$] and had a higher proportion of Black patients (72% vs. 36%, $p=0.02$). In this group, patients were more likely to be on steroids at the time of biopsy (100% vs 70%, $p=0.03$) and HTN was seen less frequently (38% vs 74%, $p=0.03$). There was no association between eGFR ≥ 60 and LN class or routine serologic markers of disease activity among patients with moderate/severe T1I or IF/TA.

Conclusion: Moderate/severe T1I and/or IF/TA frequently occur in the absence of significant renal impairment and identifiable markers of early disease, hindering its timely recognition. At the time of biopsy, a large proportion of patients with eGFR ≥ 60 will already have moderate/severe T1D. New biomarkers to aid in the early identification of these patients are needed. Clinically, mild impairment in eGFR may aid the decision to biopsy earlier for prompt detection of tubular damage.

Endomyocardial Biopsies in the Diagnosis of Myocardial Involvement in Systemic Lupus Erythematosus

Laura Geraldino-Pardilla¹, Teja Kapoor², Thania Perez³ and Anca Askanase³, ¹Division of Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY, ²Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, ³Columbia University, College of Physicians & Surgeons, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Myocardial dysfunction is reported in over half of systemic lupus erythematosus (SLE) patients, yet the underlying pathogenesis remains poorly understood. Endomyocardial biopsies (EMBs) are considered the gold standard for diagnosing cardiac involvement and myocarditis in inflammatory conditions, including SLE. However, EMBs are rarely performed in clinical practice and most of the histopathology reports in the literature consist of post-mortem data. We sought to describe the histopathologic findings of EMBs in SLE patients with active cardiac symptoms.

Methods: A retrospective review of histopathology reports was performed on SLE patients at Columbia University Medical Center who underwent EMBs from 1994-2017. SLE patients were identified by ICD-9 & 10 codes. EMBs, performed for evaluation of unexplained low ejection fraction suspicious for myocarditis, were similarly identified by procedure codes for cardiac pathology. Out of 1,994 SLE patients identified by ICD codes, 59 had cardiac pathology reports. The diagnosis of SLE was confirmed in 41/59 patients by chart review using ≥ 4 revised 1997 ACR classification criteria or SLICC classification criteria. Eleven histopathology reports were EMBs and the remaining were valvular specimens. Demographics, SLE characteristics, and cardiovascular disease risk factors were ascertained by chart review.

Results: Data from eleven SLE EMBs patients was reviewed (Table 1). Mean age was 37 ± 17 ; 82% were female, and median disease duration was 2.5 years (0-25.5). Anti-dsDNA and anti-SSA/Ro antibodies were present in 64% and 45%, respectively. Forty-five percent had hypertension, 27% had coronary artery disease, 9% had hyperlipidemia, and 36% had end-stage renal disease; none had diabetes or smoked. One patient had antiphospholipid antibody syndrome on anticoagulation. Mean ejection fraction was 37%. On histopathology, 91% had mild interstitial fibrosis, 82% had myocyte hypertrophy, 27% had organized blood clots, and 27% had a mild infiltration of lymphocytes and macrophages without

clear evidence of myocarditis. None of the patients had vasculitis, endocarditis, ischemia, or amyloid deposition. Glycogen storage was observed in one patient.

Conclusion: EMBs are rarely performed in SLE. Inflammatory infiltrates were present in only 27% of all SLE EMBs and non-specific interstitial fibrosis and myocyte hypertrophy were the most common findings. These data suggest that EMBs have limited value in the diagnosis of cardiac involvement in lupus and support the need for alternative diagnostic approaches to SLE heart disease.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is one of the most serious complications of Systemic lupus erythematosus (SLE). Early diagnosis of renal impairment, combined with a strict follow-up of patients, is important to avoid morbidity and mortality. Yet, current conventional biomarkers (proteinuria, urinary protein/creatinine ratio, estimated glomerular filtration rate, serum anti-dsDNA antibody titers, serum complement levels) reflect systemic rather than renal activity of the disease, or, in the case of proteinuria, remain elevated as a consequence of chronic damage. The aim of this study was to identify new biomarkers reflecting intra-renal activation of immune cells and renal tubular cell damage, the main determinants of impaired renal function in LN.

Methods: Using transcriptomic data generated in LN versus control renal biopsies in the context of the PRECISESADS study, we identified candidate biomarkers that correlated with intra-renal infiltration by immune effectors or histological evidence of tubular damage, and were potentially secreted in the serum: IL34, MMP7, RANTES, SLA2, CXCL12, CCL19 and CCL21. We evaluated concentrations of these eight biomarkers in sixty-seven LN and in eight control sera. IL34, MMP7, RANTES and SLA2 were evaluated by ELISA and CXCL12, CCL19 and CCL21 using a Bioplex assay. Biological indices of disease activity were retrieved from the patients files.

Results: Serum IL34 (p value: 0.0288), MMP7, CXCL12, CCL19 and CCL21 (p values: <0.0001) concentrations were significantly higher in LN patients than in controls. Strikingly, serum MMP7 and CXCL12 concentrations were negatively correlated with eGFR (p values: 0.0135 and 0.0190 respectively), while this was not the case for anti-dsDNA antibody titers, serum C3 or urinary protein/creatinine ratio. Accordingly, serum MMP7 and CXCL12 concentrations were significantly higher in patients with an eGFR < 50 mL/min/1.73 m² compared to > 50 mL/min/1.73 m² (p values: 0.0020 and 0.0336, respectively).

Conclusion: Adequate management of LN will be served by the identification of biomarkers reflecting intra-renal rather than systemic inflammation. By opposition to conventional biomarkers, MMP7 and CXCL12, which are produced in the kidney itself, displayed a significant negative correlation with eGFR in LN. Confirmation of these results in independent cohorts of samples is pending.

Electrocardiographic Abnormalities Are Associated with the Occurrence of Strokes in Systemic Lupus Erythematosus

Thania Perez¹, Christopher Depender², Jianhua Li³ and Laura Geraldino-Pardilla⁴, ¹Columbia University, College of Physicians & Surgeons, New York, NY, ²Medicine/Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, ³Department of Biomedical Informatics, Columbia University Medical Center, New York, NY, ⁴Division of Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients have a 10-fold higher risk for myocardial infarctions and a 3-fold higher risk for congestive heart failure and strokes, making cardiovascular disease (CVD) the leading cause of death in SLE. In the general population, nonspecific ST-T and QTc abnormalities are strong predictors of CV mortality. Yet, studies exploring the value of the ECG in identifying SLE patients at increased risk for cardiovascular events (CVE) are lacking. Therefore, we investigated the association between electrocardiographic (ECG) abnormalities and CVE in SLE.

Methods: We retrospectively reviewed 12-lead ECG data preceding a diagnosis of cardiovascular event (defined as myocardial infarction, congestive heart failure, and/or stroke) in 81 SLE patients, compared with ECG data from 269 SLE patients lacking a diagnosis of CVE. Patients were identified by ICD-9 & 10 codes for SLE, and the diagnosis was ascertained by chart review confirming ≥ 4 revised 1997 ACR or SLICC classification criteria. CVE were similarly confirmed by chart review including cardiology notes, diagnostic tests, and procedure data confirming the events. Nonspecific ST-T abnormalities were defined by the Minnesota code, and the QT interval was calculated and adjusted for heart rate by Bazett's formula. Regression models were constructed to test the association of ECG abnormalities with CVE.

Figure 1. Association of ECG non-specific ST-T changes with Strokes in SLE.

Figure 2. Association of maximum QTc ≥440 with Strokes in SLE.

Results: The mean age was 47 ± 15 years, 90% were female, 43% Hispanic and 40% were black. Sixty-five percent had hypertension, 8% had diabetes, 16% had a history of smoking, and 17% had hyperlipidemia. Mean disease duration at the time of the CVE was $12 (\pm 10)$ years. Nonspecific ST-T abnormalities were seen in 65% and 48% of patients with and without CVE, respectively (OR=2.05, $p=0.006$). Mean QTc length was 435 and 431 ms in those with and without CVE, respectively ($p=0.0102$); and the maximum QTc length was 464 and 431 ms, respectively ($p=0.0207$). After adjusting for confounders, the association between any CVE and ECG abnormalities lost significance. However, strokes remained significantly associated with nonspecific ST-T changes (OR=2.45, 95% CI: 1.01, 5.98; $p=0.05$) and a maximum QTc ≥ 440 ms (OR= 3.05, 95% CI: 1.02, 9.10; $p=0.045$) after adjusting for hypertension (Figures 1 & 2).

Conclusion: ECG nonspecific ST-T abnormalities and a maximum QTc ≥ 440 ms were associated with a 2-3-fold higher risk for strokes in SLE patients. This study supports the use of ECG to identify SLE patients at risk for stroke.

Rates of Herpes Zoster Virus Infection in SLE Patients on Immunosuppression

Inessa Gendlina¹, Alejandra Londono Jimenez², Kimberly A. Lynch², Wenzhu B. Mowrey³, Yevgeniy Balagula⁴ and Anna R. Broder⁵, ¹Infectious Disease, Albert Einstein College of Medicine, Bronx, NY, ²Internal Medicine, Montefiore Medical Center, Bronx, NY, ³Albert Einstein College of Medicine, Bronx, NY, ⁴Medicine/Dermatology, Montefiore Medical Systems, Bronx, NY, ⁵Rheumatology-Forchheimer 701N, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased incidence of herpes zoster (HZ) has been reported in patients with autoimmune diseases. SLE in particular is known to be associated with a 2-fold increased risk of HZ compared with the general population.¹ ² Previously available live attenuated zoster vaccine was contraindicated in SLE patients on immunosuppression, or required significant treatment delay, resulting in relatively low vaccination rates. The recently approved recombinant zoster vaccine (RZV) can be safely administered to SLE patients on immunosuppression and recent immunization guidelines recommend RZV vaccination for patients with chronic medical conditions³. Therefore, it is important to define the HZ burden and to identify SLE patients who may benefit from HZ vaccination. We aimed to estimate HZ rates and to compare SLE patients with and without HZ.

Methods: Retrospective EMR chart analysis identified all patients with the new diagnosis of SLE, defined as having at least 2 ICD codes for SLE 1-6 months apart between 1/1/2006 and 12/31/2017 and no previous visits with SLE codes in our tertiary care center within 1 year prior. HZ infection was ascertained using ICD codes. HZ rates were calculated in subgroups stratified by SLE-specific medications. We used univariate analyses to compare patient demographics, laboratory parameters and SLE-specific medications between SLE patients with and without HZ.

Results: Out of 1646 patients who met inclusion criteria, 89 (5.4%) were diagnosed with HZ after the initial SLE diagnosis. There were no statistically significant differences between HZ+ and HZ- patients in demographics, baseline leukocyte cell counts, or ICD diagnosis codes for heart failure, cancer, lung disease or diabetes (Table). HZ+ patients were more likely to be on immunosuppressive medications, hydroxychloroquine (HCQ) and corticosteroids (CS). The rate of HZ among 307 patients on CS alone was 8%. The rate of HZ in 230 patients on HCQ +/- CS without other immunosuppressives was 4.8%. The rate of HZ among 161 patients on mycophenolate mofetil (MMF) +/- HCQ +/- CS without other immunosuppressives was 12%. The rate of HZ among 348 patients on non-MMF immunosuppressives +/- HCQ +/- CS without MMF was 4%.

Conclusion: This study demonstrates that among SLE patients treated with MMF, HZ rates were significantly higher when compared to patients receiving other immunosuppression, regardless of CS use. Therefore, HZ vaccination should be considered in all individuals with SLE on MMF.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current guidelines recommend that in suspected neuropsychiatric SLE (NPSLE), the initial diagnostic workup should be similar to that in non-SLE patients presenting with the same manifestations. We aimed to synthesize the current best evidence regarding whether any additional cerebrospinal fluid (CSF) biomarker could be particularly beneficial in diagnosing patients with suspected NPSLE.

Methods: We completed a comprehensive search within PubMed, Embase, and CINAHL. We used a highly-sensitive search strategy comprising 67 keywords representing NPSLE and its 19 syndromes as well as CSF biomarkers. We also carried out forward and backward citation checking of the included studies and the relevant reviews using the Web of Knowledge Science Citation Index. We included the studies of the diagnostic test accuracy of any CSF biomarker for diagnosing NPSLE among patients with SLE, in which they used the ACR case definitions or other validated tools as their reference standards. Two investigators (SFA, GZ) independently replicated data extraction by using a standard form, which included an assessment of study quality as well as participant-level data to populate 2×2 contingency tables (true positives, true negatives, false positives and false negatives).

Results: We screened 2851 records and eventually included the data from 30 studies. Among the investigated 46 CSF biomarkers, only anti-NR2 and anti-neuronal antibody were shown to be highly accurate by more than one study (Figure 1). Also, anti-Smith, anti-RNP, α -klotho, fibroblast growth factor, IFN- γ , and interleukins 2, 5, 15, and 17 were

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis(LN) develops in 50-60% of lupus patients. The consequence of this entity is renal failure, that can arise in 10-15% of patients and an increase of the hazard ratio for mortality (HR 2.28). Proliferative lupus nephritis is the most aggressive clinical form. The criteria for diagnosis of LN are easy to apply, but not specific for determine the class of LN.

The aim of the study was to find a metabolomic profile in the urine of lupus patients to diagnose proliferative and/or membranous classes of LN.

Methods: This was a cross-sectional study. We included lupus patients with and without proliferative and/or membranous lupus nephritis. We used urine samples for the detection of metabolites using mass spectrometry thru gas chromatography (coupled with electronic nose). For baseline characteristics we used t test or U Mann-Whitney depending on the distribution of the variables; and X2 for categorical variables. For the detection and selection of the metabolites we used principal component analysis and random forest.

Results: We included 73 lupus patients, 35 had lupus nephritis; in this group the most common class of LN was IV. The patients with lupus nephritis were younger and had higher SLE activity at baseline. Sex distribution between the groups were similar. Due to these variety of the disease more patients with LN received steroid and cyclophosphamide pulses.

In the preliminary results of metabolomics we found 242 metabolites, of which 15 were match lupus nephritis, and thus can be considered as a metabolomic fingerprint.

	Lupus with nephritis (n: 35)	Lupus without nephritis (n: 38)	p value
Age	28.5 (13.1)	35 (14.6)	0.04
Females (%)	32 (82.1)	35 (92.1)	0.31
Weight	60.1 (11.8)	65.4 (16.4)	0.1
SLEDAI	13.7 (8.1)	3.7 (2.6)	< 0.0001
Evolution median (IQR)	24 (50)	54 (102)	0.005
Prednisone	29 (74)	27 (71)	0.74
Dose of prednisone median (IQR)	5 (10)	5 (0)	0.055
Cyclophosphamide	23 (59)	0	< 0.0001
Methylprednisolone pulse,	21 (53.8)	0	< 0.0001

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies suggest that autophagy defects contributes to systemic lupus erythematosus (SLE) pathogenesis. Prolactin (PRL) is associated with active SLE and stimulates the immune cells by binding to receptor (PRL-R). Prolactin decreases the suppressor function exerted by Treg cells favoring an inflammatory microenvironment in SLE. The objective is simultaneously identify the expression of autophagy in Treg lymphocytes and PRL-R in B lymphocytes of SLE patients.

Methods: We included 40 patients with SLE (ACR criteria) divided into two groups: Group 1: patients with remission SLE (SLEDAI<4), Group 2: patients with active SLE (SLEDAI > 4). The affected organs and the treatments received were obtained. As a control group, we included healthy individuals. A fasting peripheral blood sample was taken from all patients and controls. The cells were separated and labeled with specific antibodies: Treg cells: CD25⁺, FoxP3⁺,

Atg14⁺ (autophagy marker), and B lymphocytes: CD19⁺, PRL-R⁺. Analysis was performed by flow cytometry. ANOVA test was used for statistical analysis.

Results: We included 40 patients, divided in 20 inactive, 20 active SLE patients and 20 healthy controls. 80% of our population were female. Evolution time in inactive SLE patients was 8.72 ± 1.16 years and inactive SLE patients was 5 ± 0.95 years. SLEDAI was higher in active SLE patients than inactive SLE patients. In both active and inactive SLE groups, kidney was the most affected major organ (55% and 25% respectively). Sixty percent of inactive SLE patients and 35% of active patients had Chloroquine. The expression of autophagy, Treg cells Prolactin receptors and B-lymphocytes are shown in Figures 1 and 2.

Conclusion: The increase of autophagy in Treg and PRL-R in B lymphocytes participate in active lupus glomerulonephritis. Autophagy and PRL-R may be new therapeutic targets in SLE. This results suggest that may be a connection between autophagy, PRL-R, Treg and B cells if any.

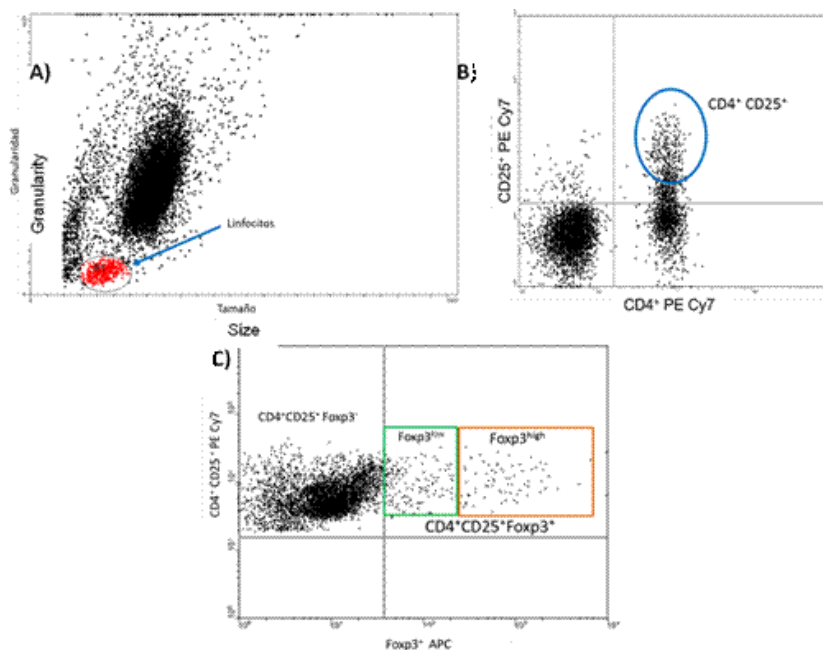

Fig.1: A) Dot plot in logarithmic scale of peripheral blood mononuclear cells (PBMC) of a SLE patient. B) Dot plot of the percentage of CD4 + CD25 + expression for Treg lymphocytes. C) Dot plot of the percentage of CD4 + CD25 + expression for Treg lymphocytes

Fig. 2: Left: autophagy (%) in Treg cells inpatients and controls: A: Healthy control vs. Inactive SLE: 7.44 vs 8.74 $p = >0.9999$ B: Healthy control vs. Active SLE: 7.44 vs 12.11 $p = <0.05$. Right: prolactin Receptor in Blymphocytes, in Active and Inactive patients and healthy controls: A:Healthy Controls vs Inactive SLE: 0.62 vs 3.56 $p = 0.7463$. SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are commonly affected by cognitive impairment (CI), with a meta-analysis finding a prevalence of 38%. Despite this high prevalence, there is limited data regarding the clinical impact of CI on patients with SLE. We hypothesize that the presence of CI is associated with a significant reduction in Health-Related Quality of Life (HRQoL) scores. Specifically we postulate effects on the domains of mental health, planning, and social functioning given the known effects of CI on these areas of function in other patient populations.

Methods: This single-center, cross sectional study of English-speaking SLE patients who presented in clinic from Ju 2016 to Apr 2017. Patients completed a comprehensive 2-hour neuropsychological battery, the Medical Outcomes Study Short Form 36 (SF-36) and Lupus Quality of Life (LupusQoL). CI was operationalized on the comprehensive battery as a z-score of ≤ -1.5 (as compared to controls) on ≥ 2 domains and/or $z \leq -2.0$ on ≥ 1 domain. Propensity scores were generated to balance covariates. Linear regression models were calculated for SF-36 and LupusQoL domain scores with respect to presence of CI.

Results: 171 participants were included in this study. 64 (37.4%) were found to have CI. Patient demographics are represented in table 1. Unadjusted patient characteristics by presence of CI are represented in Table 2. Linear regression models revealed that patients with CI showed statistically significantly lower scores in SF-36 Physical Component Summary score (PCS), SF-36 Mental Health, SF-36 Physical Functioning, SF-36 Social Functioning and LupusQoL Planning (Table 3).

Conclusion: Similar to previous studies, in our SLE cohort CI is prevalent, even with a high rate of post-secondary education. Our data demonstrate that CI is associated with significantly lower HRQoL scores. In addition to the expected decrease in Mental Health, Social Functioning, and Planning domains, a decrease in SF-36 PCS was also observed. This unexpected finding may be secondary to how patients interpret the PCS items, namely the effects of health on daily work activities. LupusQoL, a specific HRQoL measure for SLE, did not demonstrate a decrease in Physical Health scores but lower scores in Planning.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumonia is an important cause of death in patients with SLE. In general population, recommendations encourage the use of procalcitonin for management of pneumonia, however, evidence in patients with SLE is scant. The aim is to investigate the diagnostic and prognostic utility of procalcitonin and selected chemokines/cytokines in patients with SLE and pneumonia.

Methods: Cases: We studied 46 constitutive SLE patients (SLICC 2012 criteria) with pneumonia (respiratory symptoms + compatible image study) in a single tertiary care center, from Dec 2014 – Dec 2015. Patients were prospectively evaluated and samples for cultures and respifinder-22 (PCR for 18 viral + 4 bacterial pathogens) were obtained. Follow-up: 30 days after discharge. Basal procalcitonin determination on admission and in 42 (91%) patients a second sample 48-72 hrs later. Control groups: We included 27 active SLE and 24 inactive SLE patients (SLEDAI 2-K), without evidence of infection and a single procalcitonin measurement.

In 58 unselected patients (17 pneumonia, 23 active, and 18 inactive) we obtained serum for cytokines/chemokines determination by luminometry (IFN γ , IL-10, IL-12, IL-17, IL-1 β , IL-2, IL-21, IL-23, IL-5, IL-6, IL-8, TNF α , BAFF, IP-10, and CXCL-9).

Statistics analysis: Student-T test, Mann-Whitney U, Wilcoxon signed-rank test, Chi-squared test, Fisher exact test or Kruskal-Wallis test were used as appropriate.

Results: We included 97 patients, 83 women (86%). SLEDAI 2k: 1 ± 1.2 inactive vs 8.8 ± 4.5 active vs 8.2 ± 5.7 pneumonia. Patients with pneumonia had a shorter time from diagnosis (pneumonia 6 ± 8 years; $p < 0.001$; active 9 ± 6 years; inactive 14 ± 7 years).

Thirteen (28%) patients with pneumonia had a negative outcome (mechanical ventilation, shock or death). In 25 (54%) patients, a causal germ was identified. Patients with pneumonia had higher procalcitonin levels vs control groups ($p < 0.001$) whereas no differences were seen between active vs inactive patents. Thirty two patients (70%) with pneumonia had positive basal procalcitonin (> 0.5 $\mu\text{g/L}$) vs 0.0 $\mu\text{g/L}$ in control groups ($p < 0.001$); sensitivity 70% (95% CI: 54 - 82%), specificity 100% (95% CI: 93 - 100%). Twelve (38%) patients with positive basal procalcitonin had negative outcome vs one (7%) with procalcitonin ≤ 0.5 $\mu\text{g/L}$ ($p = 0.072$). Procalcitonin levels diminished in the second determination: median 0.95 (IQR 0.25 - 6.98) vs 0.36 (0.11 - 1.7), $p < 0.001$. In this determination, 16 patients had procalcitonin < 0.25 $\mu\text{g/L}$; two of them (12%) had negative outcome; 11 of 26 patients with procalcitonin > 0.25 $\mu\text{g/L}$ had a negative outcome (42%); $p = 0.084$.

Among the cytokines/chemokines evaluated, only CXCL9 was significantly higher in pneumonia vs control groups: median 1614 (IQR 905 - 2527) vs 641 (247 - 1096) active SLE and 313 (179 - 522) inactive SLE ($p < 0.001$).

Conclusion: Patients with SLE have a high rate of complications secondary to pneumonia. Procalcitonin is useful for diagnosis of pneumonia with a high specificity, even when comparing vs active SLE patients. CXCL9 is a potential biomarker for pneumonia in patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with SLE have an increased risk of serious infections, including nosocomial infections, which are associated with potentially modifiable adverse outcomes. Our objective is to develop a prognostic prediction model of hospital-acquired bacterial infections in patients with SLE.

Methods: A retrospective cohort of patients with SLE, classified according to the ACR criteria of 1987, with an age ≥ 16 years, hospitalized for ≥ 4 days for reasons other than bacterial infection in a university hospital between 2011 and 2016 was analyzed. Potential predictors were clinical and laboratory variables obtained during the first hours of hospitalization and selected by review of the medical literature. We compared the episodes in which at least one bacterial infection requiring intravenous antibiotics was diagnosed between days 3 and 15 of hospitalization with those who did not present this outcome. The significant variables in the univariate analysis and with absent data $\leq 20\%$ were included in a multivariate logistic regression model and finally the best performance prediction model was chosen with the most reasonable number of predictors.

Results: 579 hospitalizations were included, 12.4% ($n = 72$) developed the outcome, the most frequent nosocomial bacterial infection was bacteremia ($n = 24$), followed by urinary tract infections ($n = 19$) and pneumonia ($n = 13$). The main isolated bacteria were Escherichia coli ($n = 16$) and Staphylococcus aureus ($n = 15$). Table 1 presents the univariate analysis with selected independent variables. The variables incorporated in the final prediction model were: age, first neutrophil count of hospitalization, SLEDAI calculated on admission, use of central catheter in the first 72 hours, mean glucocorticoid dose in last month and use of antimalarial in last 3 months (table 2). By Receiver Operator Characteristic (ROC) analysis, it was demonstrated that the discrimination capacity of our model was acceptable (area under the ROC curve = 0.7475).

Conclusion: Our model predicts the risk of developing hospital-acquired bacterial infections in patients with SLE, using relatively simple clinical and laboratory data. One of the most important findings was that the use of antimalarials was associated with a significant reduction in the probability of nosocomial bacterial infection. External validation is required to corroborate the results and prospective studies are necessary to evaluate their clinical usefulness and impact.

Correlation between Nailfold Capillary Number and Blood Perfusion in Systemic Lupus Erythematosus Patients

Alberto Sulli¹, Barbara Ruaro¹, Carmen Pizzorni¹, Vanessa Smith², Sabrina Paolino³, Veronica Tomatis¹, Monica Pendolino¹ and Maurizio Cutolo¹, ¹Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy, Genoa, Italy, ²Department of Internal Medicine, Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium, Ghent, Belgium, ³Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy, Genova, Italy

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster I: Clinical Manifestations and Comorbidity

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Numerous articles have investigated peripheral microcirculation in primary Raynaud's phenomenon (RP) (1,2). Reports evaluating peripheral microcirculation in systemic lupus erythematosus (SLE) are scanty, but the interest is increasing (3). The aim of this study was to investigate possible correlations between morphological and functional aspects of microcirculation in different skin areas of the hands and face in SLE patients and to compare the results with primary RP (PRP) patients and healthy subjects (HS).

Methods: 14 SLE patients without RP (ACR criteria) (4) (mean age 53 ± 14 SD years, mean disease duration 7 ± 4 years), 14 PRP patients (LeRoy criteria) (5) (mean age 53 ± 17 years, mean RP duration 6 ± 5 years) and 14 HS (mean age 50 ± 17 years) were enrolled during the winter period, after informed consent. Nailfold video capillaroscopy (NVC) and laser speckle contrast analysis (LASCA) were performed in the three groups of patients. The absolute nailfold capillary number (CN) per linear millimeter at first distal row was assessed by NVC. Blood perfusion (BP) was detected by LASCA at the level of fingertips, periungual areas, dorsum and palm of both hands and face. The average BP was calculated as perfusion units (PU) (2). Patients were not taking vasodilator drugs since at least one month before study entry. Statistical analysis was performed by non parametric tests.

Results: SLE patients showed a positive correlation between nailfold CN and BP in all areas of hands ($p < 0.0001$), but no statistically significant correlation was observed between nailfold CN and BP at the level of face ($p = 0.10$). In both PRP and HS no statistically significant correlation was observed between nailfold CN and BP in all examined areas ($p = 0.70$ and $p = 0.20$, respectively). SLE patients showed a statistically significant lower nailfold CN than both PRP and HS (median 9.1 vs 10.3 vs 11.0, respectively, $p < 0.0005$). Conversely, no statistically significant difference of nailfold CN was observed between PRP and HS. PRP patients showed a statistically significant lower BP than both SLE and HS at the level of fingertip (median 90, 114, 187 PU, respectively; $p < 0.0001$), periungual (median 74, 100, 141 PU, respectively, $p < 0.0001$), dorsal (median 61, 72, 128 PU, respectively, $p < 0.0001$), and palm areas (median 76, 96, 124 PU, respectively, $p < 0.0001$). Conversely, PRP, SLE and HS patients showed similar BP values at the level of face (median 141, 139, 137 PU, respectively, $p = 0.30$).

Conclusion: This study demonstrates a correlation between morphological and functional microvascular features in SLE patients. SLE patients without RP have a subclinical microangiopathy, showing lower nailfold CN and BP than HS. Conversely, PRP patients show only a functional dysfunction, having a lower peripheral skin BP than both SLE patients and HS. The clinical value of this finding is undergoing further analysis, and open the door to new clinical insight.

Abstract Number: 786

Comparison of Nailfold Microvascular Damage in Mixed Connective Tissue Disease Versus Systemic Sclerosis Patients during a Three Year Follow-up

Alberto Sulli¹, Giorgia Ferrari¹, Carmen Pizzorni¹, Barbara Ruaro¹, Sabrina Paolino², Vanessa Smith³ and Maurizio Cutolo¹, ¹Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy, ²Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy, ³Department of Internal Medicine, Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic sclerosis (SSc), capillary abnormalities progress in a clearly defined sequence called the “scleroderma patterns” (Early, Active, Late) (1-3). On the contrary, characteristic nailfold capillary abnormalities are not present in mixed connective tissue disease (MCTD) (1,2). Until today, few studies described the main nailfold video capillaroscopy (NVC) changes in MCTD (4,5). The aim of this retrospective study was to compare nailfold capillary abnormalities in MCTD and SSc patients at first NVC visit, and to monitor MCTD capillary changes over a three year follow-up.

Methods: Ten patients (mean age 50 ± 19 years, mean disease duration 6.4 ± 4.2 years) affected by MCTD (Kasukawa’s criteria) who performed their first NVC were enrolled. Main capillary parameters (scores of capillary ramifications, enlarged capillaries, giant capillaries, microhemorrhages, number of capillaries, as well as absolute number of normal and total capillaries per linear millimetre) were evaluated in MCTD patients by NVC at baseline (T0, first NVC), and during a three year follow-up. Furthermore, NVC parameters were compared at T0 with 10 random SSc patients with the same disease duration (6.4 ± 4.2 years) and similar age (51 ± 17 years). Statistical analysis was performed by non parametric tests. The patients were receiving different immunosuppressive treatments.

Results: The scores of enlarged capillaries, giant capillaries and microhemorrhages were found significantly higher in patients with SSc versus MCTD patients at T0 (2.50 ± 0.5 vs 1.90 ± 0.6 $p=0.04$, and 1.63 ± 0.7 vs 0.70 ± 0.7 $p<0.02$, 1.25 ± 0.7 vs 0.70 ± 0.7 $p=0.05$, respectively). Moreover, the absolute number of total capillaries and normal capillaries were found significantly lower in SSc patients versus MCTD patients (5.8 ± 1.9 vs 7.6 ± 1.6 $p=0.04$ and 0.45 ± 1.0 vs 3.03 ± 2.9 $p=0.009$). On the contrary, no statistically significant difference was observed for the other capillary parameters (including capillary ramifications) between the two groups of patients. No statistically significant variation of the scores as well as of the absolute value of the above reported capillary parameters was observed during the 3 years of follow-up in MCTD patients. No statistically significant correlation was observed between capillary parameters and MCTD clinical aspects (Raynaud phenomenon, dysphagia, dyspnoea, sclerodactily, sicca syndrome, teleangiectasias and arthralgia) at first visit and during follow-up.

Conclusion: In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microangiopathy does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SSc is known for its heterogeneous disease course in which anti-topoisomerase I antibodies (ATA) are associated with dcSSc and interstitial lung disease and therefore regarded as marker for high-risk disease. In this study we aimed to describe disease course in ATA+ SSc patients.

Methods: Data of ATA+ patients included in the Leiden Systemic Sclerosis cohort (CCISS) between April 1st 2009 and May 1st 2016 were collected. Medsger Disease Severity Scale(DSS), providing a 0-4 score on 9 organ systems (0 normal to 4 severely affected; organ systems: general, peripheral vascular, skin, joint/tendon, muscle, GI tract, lung, heart and kidney) were calculated in all patients at baseline. Maximum disease score was determined, taking disease duration into account by stratifying the patients in 3 groups: 1. incident cases, 2. early disease, disease duration since first non-Raynaud ≤ 5 years,

Figure 1. Systemic Sclerosis maximum disease severity scores according to disease duration

Figure 2. Kaplan Meier curves for time to development of severe lung involvement (FVC or DLCO % predicted <50%) according to baseline lung disease severity scale

3. Prevalent disease, disease duration since first non-Raynaud > 5 years. Disease progression over time with specific focus on pulmonary involvement was assessed. For this purpose Kaplan Meier analysis assessing deterioration towards severe lung involvement (Lung DSS ≥ 3) was performed in patients with non-severe lung involvement (Lung DSS ≤ 2), with stratification for baseline severity score.

Results: Ninety-five patients were included in the current study. At baseline, median disease duration since first non-Raynaud symptom was 2.7 years (IQR 0.7-9.3). Evaluation of disease severity at baseline showed that mild / moderately severe disease (DSS scale 0, 1 and 2) was present among all subgroups including in 36% of patients with disease duration > 5 years (Figure 1). Longitudinal follow-up was available in 85 patients, with a median follow-up time of 3.2 years. Disease progression occurred in 48 patients (57%) and 2/49 lcSSc patients developed dcSSc over time. Of the 60 patients with non-severe pulmonary involvement at baseline, 9 (15%) developed severe pulmonary involvement over time, in which baseline Medsger Disease Severity Scale was a significant predictor (Figure 2).

Conclusion: ATA+SSc has a heterogeneous disease course, in which more than one-third of patients never develop severe organ involvement. Patients with normal lung function tests including FVC $\geq 70\%$ at baseline are unlikely to develop severe lung disease during follow-up. These data show that additional characteristics are needed to identify patients in need of therapy targeting SSc-related ILD.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac events are an important cause of mortality in Systemic Sclerosis (SSc), but its diagnosis remains challenging. Left ventricular global longitudinal strain is a novel parameter derived from speckle tracking echocardiographic analysis which has been proposed to identify patient at higher risk of cardiac events. We aimed to identify clinical and echocardiographic (including GLS) parameters associated with all-cause mortality and cardiovascular events in SSc patients.

Methods: 408 SSc patients (344 females, age 54±14 yrs.) were prospectively evaluated at baseline and follow-up (FU time 3.3 yrs. [IQR 1.8 to 5.5]). Cardiovascular events included: heart failure, cardiac infarction, coronary interventions, device implantation, arrhythmias, cerebral infarction, peripheral ischemic vascular disease.

Results: All-cause mortality (n=37) or cardiovascular events (n=57) occurred in 84 patients. At baseline, these patients were older (59±14 vs. 53±14 yrs., p<0.001), more often male (24 vs. 13%, p=0.018), more often had skin pigment changes (21 vs. 5%, p=0.011), coronary artery disease (11 vs. 3%, p=0.001), holter abnormalities (45 vs. 24%, p<0.001), increased ESR (24 [IQR 14 to 46] vs. 11 [IQR 6 to 25], p<0.001), worse NT-proBNP (151 [IQR 60 to 644] vs. 82 [IQR 51 to 145] ng/L, p<0.001), worse lung function test results (FVC 92±19 vs. 104±21%, p<0.001; DLCO 55±17 vs. 70±19%, p<0.001), worse left ventricular diastolic function (E/E-prime ratio 9.9 [IQR 6.7 to 10.2] vs. 7.8 [IQR 6.4 to 9.7], p<0.001), higher systolic pulmonary artery pressure (31±12 vs. 25±7mmHg, p<0.001) and lower GLS (-18.8 [IQR -20.3 to -19.5] vs. -21.1 [IQR -22.1 to -20.0]%, p<0.001). In a multivariate cox-regression analyses, age (HR 1.029, 95%CI 1.006 to 1.052), female sex (HR 0.527, 95%CI 0.302 to 0.922), NT-proBNP (HR 1.000, 95%CI 1.000-1.001), DLCO (HR 0.973, 95%CI 0.961-0.986) and GLS (HR 1.281, 95%CI 1.172-1.399) were independently associated with outcome. After dividing patients into groups according to median GLS (-20.9%) and elevated NT-proBNP (>200 ng/L), survival rates were lower and cardiovascular events increased when GLS was impaired and worsened when NT-proBNP was elevated (Log-rank p<0.001).

Conclusion: In SSc patients, next to age, DLCO and NT-proBNP, GLS strongly associates with all-cause mortality and cardiovascular events, indicating that these parameters reflect relevant cardiac involvement in SSc, and as such can contribute to risk stratification and patient management.

The Relationship between YKL-40 and Vascular Endothelial Growth Factor in Angiogenesis in Systemic Sclerosis Patients

Tetsuya Furukawa¹, Kiyoshi Matsui², Masayasu Kitano² and Naoto Azuma², ¹Division of Rheumatology Department of internal medicine, Hyogo College of Medicine, Nishinomiya, Japan, ²Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an intractable, connective tissue disease that causes fibrosis of the skin and organs and its prognosis is affected by pulmonary arterial hypertension (PAH). SSc presents with Raynaud's phenomenon as the initial set of symptoms and is often accompanied by nailfold capillary abnormality. SSc is thought to cause microvascular disorder from the early stage. The chitinase-like protein YKL-40 has been implicated in inflammation, tissue remodeling, and angiogenesis in malignant tumors. A previous study in our department demonstrated elevated blood levels of YKL-40 in Japanese SSc patients. Globally, there are no reports examining the relationship between YKL-40 and vascular endothelial growth factor (VEGF) in SSc patients. Immunohistochemical (IHC) staining has not shown a relationship between YKL-40 and SSc in detail. We examined the relationship between YKL-40 and VEGF, which has an important role in angiogenesis.

Methods: We conducted a retrospective analysis of 84 SSc patients who were referred to our institution for treatment between August 2014 and April 2017. We excluded infection and malignant tumor complications. Controls were 15 healthy individuals. We measured serum YKL-40 levels and VEGF levels by ELISA and examined the correlation between YKL-40 age percentile, which was age-corrected for serum YKL-40 levels, and VEGF levels. Additionally, skin biopsy tissues from 7 SSc patients and 7 healthy individuals were also subjected to IHC staining with anti YKL-40 antibody.

Results: Our patient group included 11 men and 73 women with a mean age of 63.1 ± 13.4 years and a mean disease duration of 9.6 ± 9.8 years. The modified Rodnan total skin thickness score was 6.4 ± 6.9. Diffuse cutaneous SSc was identified in 20 patients; limited cutaneous SSc was identified in the other 64 patients. The 15 healthy individuals included 2 men and 13 women with a mean age of 59.7 ± 14.7. YKL-40 age percentile and VEGF levels in SSc patients (56.3 ± 30.2 and 410.0 ± 307.3 pg/ml, respectively) were significantly higher than in healthy individuals (24.9 ± 17.4 and 295.0 ± 154.5 pg/ml, respectively). The correlation coefficient (0.41) showed a mild correlation between YKL-40 age percentile and VEGF levels in SSc patients. Furthermore, staining of the blood vessel wall of the superficial dermis was found in specimens obtained from all SSc patients.

Conclusion: YKL-40 appears to reflect regeneration after capillary injury in SSc patients, with capillary vessels of the superficial dermis staining with IHC. There is a correlation between serum YKL-40 and VEGF levels in SSc patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease affecting multiple organ systems including vascular, musculoskeletal, cardiac, renal, pulmonary, and gastrointestinal (GI). 90% of SSc patients experience GI impairment and severe complications including impaired digestion, emptying, absorption, and peristalsis. The role of diet in SSc is not clear with few studies demonstrating prevalence of fructose intolerance and higher prevalence of celiac disease in undifferentiated connective tissue disease with SSc like features. Currently no consensus on dietary interventions in SSc exists. We aim to examine the impact of diet on symptom burden and quality of life measures in SSc.

Methods: An international randomized controlled single-blind study (IRB #748566) compared effects of a 4-week intervention of gluten-free (GF) vs Mediterranean (M) vs low FODMAP (LF) diets with no restriction on portion/calories. Medication changes were controlled for during the intervention period. Inclusion required a negative celiac test and a checklist from the subject's rheumatologist confirming ACR/EULAR SSc criteria. Telephone counseling provided diet instruction and support. Patient reported outcomes measures (PROMs) included the Geissen SSc Gastrointestinal (GGI),

SSc Gastrointestinal Tract (GIT), SF-36 and adherence questionnaires and were completed via REDCap at 0, 4, and 8 weeks. Data was analyzed by repeated measures analysis and linear mixed model analysis.

Results: Enrollment is ongoing with 51 subjects enrolled and 29 reaching completion (8, 9 and 12, respectively in the GF, M, and LF groups). Of these 29, there were no differences in age, gender, race, or ethnicity. There were no differences between diet groups at 0, 4 or 8 weeks in GGI, GIT, or SF-36. Statistically significant improvements for all groups occurred in the GGI daytime heartburn ($p=0.04$), nighttime heartburn ($p=0.01$), difficulty swallowing ($p=0.01$), and constipation items ($p=0.006$); in the GIT bloating domain ($p=0.02$) and overall combined score ($p<0.005$); and in quality of life (QoL) SF-36 role physical ($p=0.02$) and vitality ($p=0.01$) domains. Largest improvements occurred immediately post-intervention (week 4) with waning at week 8 though still significant. Mean adherence was 78.3% with the GF group demonstrating higher adherence (97.2%) than the M and LF groups (73.7% and 72.4% respectively) ($p<0.005$).

Conclusion: Though no differences related to diet emerged, statistically significant improvements in GI and QoL PROMs occurred in all groups suggesting that increased awareness and purposeful nutrition selection may impact GI symptom burden and overall QoL. Further inquiry is needed with larger sample sizes to determine if premeditated/structured nutrition selection is a worthwhile application in SSc care.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies from our laboratory and others have shown thrombin to be a fibrogenic mediator implicated in the pathogenesis of ILD, including scleroderma-associated ILD (SSc-ILD). Thrombin activity is high in SSc-ILD bronchoalveolar lavage fluid (BALF), and normal lung fibroblasts transform to a myofibroblast phenotype upon exposure to thrombin. Dabigatran etexilate (Pradaxa[®]) is a selective thrombin inhibitor approved for the prevention of thromboembolic complications. On the basis of strong preclinical in vitro and animal data demonstrating that thrombin inhibition can ameliorate lung fibrosis, we have conducted a single-site, open-label study to establish the safety of Dabigatran etexilate in SSc-ILD patients.

Methods: Dabigatran etexilate was administered orally in a dose of 75 mg twice daily for 6 months to 15 patients with SSc-ILD having no contraindication to anticoagulant therapy (ClinicalTrials.gov Identifier NCT02426229). Safety and tolerability of Dabigatran etexilate were monitored by history, PE, questionnaires and laboratory studies during the treatment period. Plasma, BALF, skin and lung fibroblasts were obtained before and after treatment.

Results: 15 patients fulfilling the 2013 ACR/EULAR classification criteria have been enrolled: 13 have completed, 1 subject is still enrolled, and 1 subject was withdrawn due to noncompliance. Baseline characteristics are as follows: 13 females and 2 males; 6 African Americans and 9 Caucasians; 5 limited and 10 diffuse cutaneous SSc; age 47.5 ± 9.6 years (mean \pm SD); disease duration 4.1 ± 3.3 years; modified Rodnan Skin Score 16.0 ± 10.3 ; SSc Health Assessment Questionnaire 1.4 ± 0.6 ; UCLA SCTC GIT score 0.79 ± 0.58 ; Baseline Dyspnea Index 7.9 ± 3.1 ; FVC % predicted 70.6 ± 15.4 ; DLCO % predicted 54.3 ± 14.1 .

Overall, Dabigatran etexilate has been well tolerated. There have been no serious adverse events. Mild adverse events include: fatigue ($n=1$), epistaxis ($n=3$), menorrhagia ($n=2$) and cystitis ($n=1$). One moderate adverse event occurred in a subject with headache found to be unrelated to study medication. Monthly laboratory monitoring has shown no clinically significant change in CBC, CMP, PT/INR or PTT, but did show the expected prolongation of thrombin time (TT).

Exploratory analysis before and after Dabigatran etexilate treatment revealed that the most profound reduction in thrombin activity was observed in a patient having high BALF thrombin activity at baseline, and this patient also demonstrated the greatest reduction in collagen type I and α -smooth muscle actin in skin fibroblasts, as well as reduction of α -smooth muscle actin in lung fibroblasts.

Conclusion: Our data suggest that Dabigatran etexilate at a dose of 75 mg twice daily is safe and well tolerated in patients with SSc-ILD. Exploratory analysis suggests that SSc-ILD patients with high BALF thrombin activity may have the greatest potential to benefit from treatment with Dabigatran etexilate. A randomized controlled trial is warranted to establish safety and determine the efficacy of Dabigatran etexilate in patients with SSc-ILD.

Evaluation of Esophageal Dysmotility in Systemic Sclerosis: Clinical VALUE of Computed Tomography

Cristina Sobrino¹, Cristina Pijoan-Moratalla¹, Nicolás Almeida-Arostegui², Luis Gorospe-Sarasúa² and Carlos de la Puente-Bujidos¹, ¹Rheumatology Unit. Ramón y Cajal University Hospital, Madrid, Spain, ²Radiology Unit. Ramón y Cajal University Hospital, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Esophageal dysmotility is common in Systemic Sclerosis (SSc), affecting 50-80% of patients, usually associated with poor prognosis. SSc leads to atrophy and fibrosis of the smooth muscle of the esophagus, modifying peristaltic contractions and motility. Manometry is considered the gold standard for the diagnosis of esophageal motility disorders, but dilation can also be observed with computed tomography (CT), even if its diagnostic validity is still unknown. /Purpose: To compare esophageal dilation observed with CT to manometry, in patients with SSc and to confirm whether CT can be used in the assessment of esophageal dysmotility.

Methods: Forty six patients meeting the 2013 ACR/EULAR Classification Criteria for SSc, and 53 healthy controls were included and retrospectively studied. Patients with overlapping syndromes, active infections or with longstanding diabetes were excluded. Epidemiological and clinical data were collected from medical records. All patients and controls had undergone at least one manometry and one CT, requested in daily clinical practice for another purpose. The most recent exams were selected for the study. Esophageal involvement was assessed using manometry (aperistalsis, inefficient peristalsis, nonspecific dysmotility and normal peristalsis) and compared with the largest coronal esophageal luminal diameters proximally, near the carina, and distally observed by CT. Data analysis was performed by STATA. All patients signed written informed consent, approved by the Research Ethics Committee.

Results: The sample included 76 women (10 dcSSc, 28 lcSSc, 3 MCTD, 35 controls) and 23 men (3 dcSSc, 2 lcSSc, 18 controls). Esophageal dysmotility was seen in 40/46 patients with SSc (87%) by manometry (defined as inefficient peristalsis or aperistalsis). Esophageal dilation (≥ 10 mm) was present proximally in 23/44 patients (52.3%), distally in 35/46 patients (76.1%), and near the carina in 26/44 patients (59.1%). Esophageal dilatation at any level was statistically associated with esophageal dysmotility ($p < 0.05$). The areas under the ROC curves suggest that the esophageal proximal diameter in the coronal plane is good for detecting esophageal dysmotility (0.798, 95%CI 0.705-0.890), with the distal diameter (0.759, 95% CI 0.661-0.857) and the carinal diameter (0.712, 95%CI 0.607-0.816), being slightly lower. A proximal diameter ≥ 7.5 mm provides a specificity of 87.2% (95% CI: 76.7–96.7) and a sensitivity of 65.3% (95% CI: 51.9–78.6) for esophageal dysmotility, enabling correct classification of 75% of the patients. A distal diameter ≥ 12.9 mm provides a specificity of 76.6% (95% CI: 64.5–88.7) and a sensitivity of 71.2% (95% CI: 58.8–83.5), correctly classifying 73% of the patients.

Conclusion: CT, a less invasive technique than manometry, can be an acceptable diagnostic tool for esophageal dysmotility in SSc, when the maximum proximal or distal esophageal diameter are ≥ 7.5 mm and 12.9mm, respectively. CT done in the daily clinical practice could be exploited when manometry is not preferred in selected patients with SSc. More studies need to be carried out to confirm this results.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-nuclear antibodies (ANA) are present in approximately 90% of sera from systemic sclerosis (SSc) patients and play an important role in the diagnosis and prognosis of SSc. Besides the classical autoantibodies that are part of the classification criteria (anti-Scl-70, anti-centromere, anti-RNA Pol III), several other antibodies can be found in SSc, albeit with lower prevalence, some of which clearly associate with disease phenotypes. Anti-U11/12 Ribonucleoprotein (RNP) antibodies have been reported in a small portion of patients with pulmonary fibrosis. RNPC-3, also known as U11/U12 Small Nuclear Ribonucleoprotein 65 KDa Protein has been reported as an autoantibody target with strong association with malignancy in patients with SSc. Here we aimed to study the prevalence of anti-RNPC-3 antibodies in SSc and controls.

Methods: A total of 613 well characterized SSc patients from two different sites (Barcelona, n=225; and Milan, n=388) were used to establish sero-clinical associations. In addition, a variety of disease controls (rheumatoid arthritis, n=50; systemic lupus erythematosus, n=50; infectious disease, n=50; healthy individuals, n=50) were included to assess autoantibody specificity. All samples were tested on particles coated with recombinant RNPC-3 along with classical SSc markers (Scl-70, centromere, RNA Pol III) using a novel particle-based multi-analyte technology (PMAT, Inova Diagnostics, San Diego, USA). Disease subtype [limited (lcSSc) or diffuse SSc (dcSSc)] and clinical manifestations were retrieved from each site and included digital ulcers (39.2%), interstitial lung disease (ILD, 37.7%), scleroderma-related malignancy (16.7%), and calcinosis (22.7%).

Results: In the total cohort, anti-RNPC-3 showed a prevalence of 3.1% (n=19) in SSc with 99.5% specificity, while the prevalence in each SSc cohort was 4.9% and 2.1% in the Spanish and Italian sites, respectively. Anti-RNPC-3 antibodies were found at very high titers in SSc versus controls ($p<0.0001$) and the majority of the positives (13/19, 68.4%) were negative for the classical SSc markers (anti-Scl-70, anti-centromere, anti-RNA Pol III). When analyzing against clinical manifestations in SSc, anti-RNPC-3 antibodies showed a strong association with ILD both in prevalence (Fisher Exact $p=0.0062$) and antibody levels (Wilcoxon-Mann-Whitney, $p=0.0153$), however the marker was not significantly associated with the other manifestations analyzed (cancer, ulcers, calcinosis). Although the marker showed higher prevalence in dcSSc (6.5% vs. 3.1% in lcSSc), the difference did not reach significance.

Conclusion: Our study confirms the presence of anti-RNPC-3 autoantibodies in patients with SSc. In addition, this study of Spanish and Italian SSc patients confirms the association of anti-RNPC-3 with ILD as previously reported in a North American cohort. In contrast, we were unable to confirm the associations with cancer. Further studies are needed to verify the clinical utility of the marker and to further investigate the putative association with cancer.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-nuclear antibodies (ANA) are present in approximately 90% of sera from systemic sclerosis (SSc) patients and play an important role in the diagnosis and prognosis of that disease. Besides the classical autoantibodies that are part of the SSc classification criteria, several other antibodies can be found, albeit with lower prevalence, some of which clearly associate with disease phenotypes. Anti-U11/U12 Ribonucleo protein(RNP) antibodies have been reported in a small portion of patients with pulmonary fibrosis. RNPC-3, also known as U11/U12 Small Nuclear Ribonucleoprotein 65 kDa Protein has been reported as an autoantibody target with strong association with malignancy in SSc patients. The aim of this project was to analyze the B-cell epitopes of anti-RNPC-3 antibodies and to study the prevalence of anti-RNPC-3 antibodies in SSc and controls.

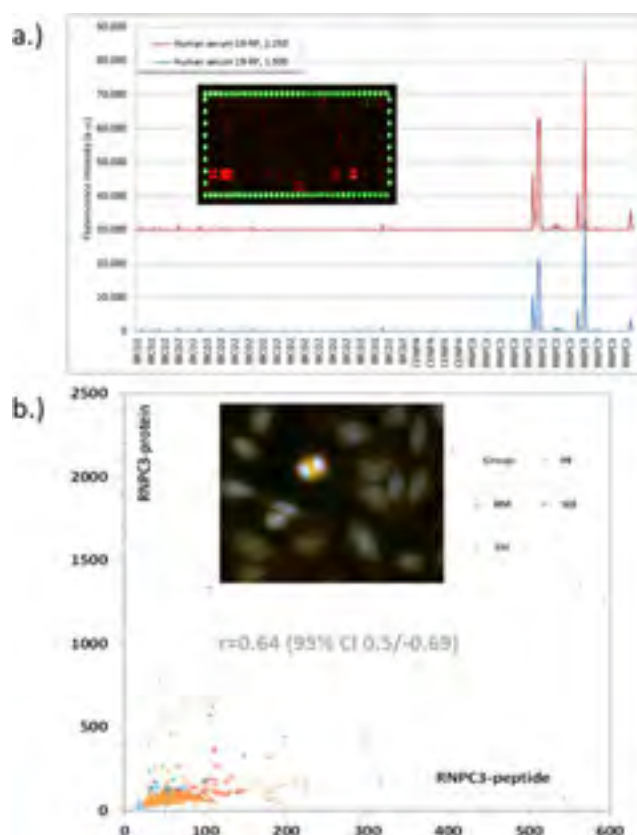

Figure1 Epitope mapping of RNPC-3 using solid phase peptide arrays (a) and correlation of peptide reactivity with RNPC-3 protein along with co-localized IIF pattern (b).

Methods: Two SSc sera with anti-RNPC-3 antibodies, assayed by an addressable laser bead-based immunoassay (ALBIA) with recombinant RNPC-3, were used for epitope discovery with peptide arrays covering the full-length aminoacid sequence of human RNPC-3. As controls, three samples with anti-centromere antibodies were included as well as peptides derived from CENP-A and BICD2. The identified candidate epitopes were subsequently utilized to synthesize synthetic,

biotinylated, soluble peptides for testing using a novel particle-based multi-analyte technology (PMAT). To analyze the marker in SSc, sera from 88 SSc patients were included where 32 cases had documented cancer. Sera from 64 systemic lupus erythematosus (SLE) patients, 65 idiopathic inflammatory myopathies (IIM), and 20 health individuals (HI) were included as a comparator group. Co-localization by indirect immunofluorescence (IIF) of human anti-RNPC3 with rabbit anti-RNPC3 (rabbit polyclonal) was performed.

Results: Epitope mapping revealed an immunodominant epitope in the C-terminus of the protein (see Figure). The reactivity to recombinant RNPC-3 (rRNPC-3) and to the RNPC-3 derived peptide (pRNPC-3) were highly correlated (Spearman's $\rho=0.64$, 95% Confidence interval 0.58-0.69; $p<0.0001$). Autoantibodies to both rRNPC-3 and pRNPC-3 tended to be higher in SSc and SLE compared to IIM and HI. When the cohort of patients with known history of cancer was compared with an unselected SSc cohort, no significant difference was found. Experiments performed by IIF confirmed the speckled pattern shown in previous studies.

Conclusion: Our study is the first to report a linear epitope on RNPC-3 as a target of autoantibodies in patients with SSc. Further studies are needed to validate the association of anti RNPC-3 antibodies with cancer as well as the utility of the novel RNPC-3 derived peptide.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Connective tissue diseases (CTDs) are characterised by specific autoantibodies which are useful for diagnosis. Rare antibodies have been described in CTDs in several case series. We assessed the frequency and clinical features of CTD patients attending our centre, positive for at least one of these antibodies (Jo-1, PCNA, XR, PL-4, PL-7, PL-12, SRP, Ku, Mi-2, EJ, SL, PmScl, rRNP, Th/To, NuMa-1, OJ and hnRNP). Rare antibody was defined as an antibody found in less than 5% of our patient population.

Methods: The immunology results for 5828 patients obtained over the past 17 years were analysed and patients with the rare antibodies were identified. Clinical data including diagnosis and frequency of organ involvement were obtained from medical records and patient review.

Results: 758 patients (12.5%) were positive for at least one rare antibodies. Clinical information confirming a diagnosis of a CTD was available for 514 patients. The most common rare antibody was PmScl (3.1%) and least common was OJ (0.01%). The majority of patients with rare autoantibodies demonstrated overlap syndromes (32.1%), the second most common diagnosis was scleroderma (SSc) (31.0%). The least common diagnosis was UCTD (1.1%). Further analyses of major organ involvement by antibody subtype revealed 82.4% of PL-7+ patients had interstitial lung disease (ILD). ILD was also frequently seen in PL12+ (75%), Jo-1+ (70.8%), SRP+ patients (66.7%) and Mi-2 (57%). PCNA, NuMa1, OJ and hnRNP were not associated with ILD. Pulmonary arterial hypertension (PAH) was most frequently seen in XR+ patients (31.8%), followed by Th/To+ (25%) and Jo-1 (15.3%) patients. None of our patients with PL-12 developed PAH. Inflammatory myositis (IM) was found in all Jo1+ and SRP+ patients, and in the majority of PL-7+ (88.2%) patients. Inflammatory arthritis was more commonly seen in hnRNP+ (100%), PCNA+ (57.1%), SL+ (38.3%),

and PL-12+ (33.3%) patients but not reported in EJ+, Mi-2+ and PL-4+ patients. Glomerulonephritis was reported in significant proportion of rRNP+ (60%), PCNA+ (42.9%), and PL-4+ (45.5%) patients. Scleroderma renal crisis was diagnosed in three (3.8%) SL+ patients.

Conclusion: Our data from a large cohort of patients with CTDs suggest that rare antibodies associate with characteristic features, in particular ILD and inflammatory myositis. A majority of these patients fulfil the criteria for overlap syndrome and SSc.

We noted some associations not reported in current literature between these antibodies and fibrotic and vascular features of CTDs. In contrast to previous findings, ILD was frequently reported in our Mi-2+ patients. Anti XR has not previously been associated with PAH or ILD, whereas we noted a frequency of 31.8% and 40.9% respectively.

Given the rarity of these antibodies, it is important to understand the clinical impact they may have in risk stratifying our patients at diagnosis especially given the high proportion of patients with overlap CTD features.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-U1RNP antibodies can be detected in patients with systemic sclerosis (SSc). However, their prevalence and clinical correlation with organ-specific complications have not been well characterized. The aim of the current study was to investigate the demographic and clinical features of SSc patients with anti-U1RNP antibodies using the European Scleroderma Trials and Research (EUSTAR) database.

Methods: SSc patients in the EUSTAR database with available data on anti-U1RNP antibodies were analyzed. Patients had to fulfill the 1980 American College of Rheumatology (ACR) or the 2013 ACR/European League Against Rheumatism (ACR/EULAR) classification criteria. Clinical characteristics were collected at the visit when the status of anti-U1RNP antibodies was first recorded.

Demographic and clinical parameters were compared between patients positive and negative for anti-U1RNP antibodies in univariate analysis followed by Bonferroni correction. Associations between anti-U1RNP status and involvement of multiple organs were tested in multivariate logistic regression models. Multiple imputation was used before regression analysis to handle missing values.

Results: A total of 8391 patients were eligible for this analysis, among which 408 (4.9%) patients were positive for anti-U1RNP antibodies. Of the 8391 patients, the majority was female (84.9%), the median age was 57.0 years (IQR: 46.0-66.0). The median disease duration was 7.0 years (IQR: 3.0-13.0). Thirty-one percent patients had diffuse cutaneous involvement.

In univariate analysis, SSc patients positive for anti-U1RNP antibodies were significantly younger at disease onset (mean 37.9 vs 46.6 years), had higher prevalence of synovitis (19.3% vs 13.4%), pulmonary hypertension assessed by

echocardiography (24.7% vs 15.9%), lung fibrosis diagnosed by chest X-ray or high-resolution computer tomography (53.1% vs 42.0%), proteinuria (12.6% vs 5.6%), erythrocyte sedimentation rate (ESR) >25mm/h (46.4% vs 31.4%) and hypocomplementemia (15.7% vs 7.1%) than those negative for anti-U1RNP antibodies.

By multivariate analysis, anti-U1RNP antibodies were confirmed to be independently associated with synovitis [odds ratio (OR) 1.47, 95% confidence interval (CI) 1.10 to 1.96], lung fibrosis (OR 1.36, 95% CI 1.06 to 1.76), pulmonary hypertension on echocardiography (OR 2.20, 95% CI 1.62 to 2.99), proteinuria (OR 2.27, 95% CI 1.56 to 3.31) and ESR>25mm/h (OR 2.11, 95% CI 1.65 to 2.71). In addition, there was a negative association with diffuse cutaneous involvement (OR 0.58, 95% CI 0.45 to 0.75).

Conclusion: This is the largest cohort of SSc patients positive for anti-U1RNP antibodies reported so far. It defines characteristic features associated with this specific subtype of SSc-patients. The detection of anti-u1RNP antibodies in SSc patients should be more emphasized and might be helpful for risk stratification during clinical practice.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of the present study was to investigate whether the imbalance of CD4⁺ T subsets can be corrected by supplementing low dose interleukin -2 (IL-2).

Methods: The PB samples from 21 patients with SSc as well as 30 healthy control subjects were analyzed for lymphocyte subsets using flow cytometry. Patients given a small dose of IL-2 (50WU) for a 5-day course based on standard treatment (including glucocorticoids, immunosuppressants, biologics, or combination). Using directly the percentages from flow cytometry combined with internal standard beads calculated absolute number of peripheral lymphocyte subsets and their ratio to Treg cells from the subjects in each group before and after IL-2 treatment.

Results: Notably, Treg cells rapidly increase after treatment with low doses IL-2. However, before treatment, the ratios of Th17/Treg($p<0.001$) and Th2/Treg($p=0.01$) were significantly higher. After treatment, although Th17 and Th2 cells increased, Treg cells increased more, so the ratios returned to normal. Similarly, after treatment, the numbers of Th1, CD8⁺ T, NK and B cells all increased to some extent, but the ratios of these T cells to Treg cells still were low i.e. they were balanced for the increase in Treg cells after treatment was more pronounced.

Conclusion: Short-term low-dose IL-2 treatment can promote the proliferation of Treg cells mainly and restore the balances of various cell subsets with Treg cells.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Skeletal myopathy in systemic sclerosis is poorly defined. The spectrum of muscle histopathology in systemic sclerosis has been previously studied and shown to be heterogeneous. There has been little data to describe the imaging findings in scleroderma muscle disease. The purpose of this study is to determine whether there are unique muscle magnetic resonance imaging (MRI) features of scleroderma associated myopathy.

Methods: This retrospective, cross-sectional study included 25 patients with SSc and biopsy proven fibrosing myopathy or inflammatory myopathy as previously described (1). These patients also had coronal and axial T1-weighted images and short tau inversion recovery (STIR images) of the thighs as part of routine clinical care. A small subset (n=15) also had axial diffusion weighted imaging (DWI) using 2 b-values (0 and 800 s/mm²) and apparent diffusion coefficient (ADC) mapping. Two musculoskeletal radiologists, blinded to histopathological finding, reviewed the MR studies in consensus and semi-quantitatively evaluated for the presence of intramuscular edema, fascial edema, fatty replacement and atrophy on all sequences using equidistant 4-point scoring system (0 = absence, 1 = mild, 2 = moderate, 3 = maximal) for 36 individual skeletal muscles in each patient. Pairwise comparisons for categorical variables between the fibrosing and non-fibrosing groups were made using χ^2 test.

Results: There were 12 patients with fibrosing myopathy and 13 patients with an inflammatory myopathy with available MRI data. On STIR sequences, patients with a fibrosing myopathy more often had mild intramuscular (48% (170/355) vs. 36% (176/485), p=.0005) but more prominent fascial edema (16% (46/294) vs. 9% (47/496), p=.0005) when compared with the inflammatory myopathy group. Whereas, on T1-weighted sequences, patients with an inflammatory myopathy more often had evidence of chronic muscle damage such as mild fatty replacement (36% (182/504) vs. 27% (82/306), p=0.008) and atrophy (44% (217/498) vs. 34% (104/306), p=0.005) when compared with a fibrosing myopathy. On DWI, patients with SSc-associated fibrosing myopathy more often had elevated signal for both low and high b-value images.

Conclusion: Thigh muscle MRI may be a useful imaging biomarker to distinguish fibrosing myopathy from inflammatory myopathy in systemic sclerosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) carries a high risk for interstitial lung disease (ILD). Patients with SSc-ILD are prone to develop progressive lung fibrosis, but there are no validated algorithms for early detection of these patients. We assessed the frequency of progressive fibrosis in patients with SSc-ILD in the EUSTAR database and parameters associated with progression of fibrosis over a 12-month follow-up.

Methods: Patients registered in the EUSTAR database since 2010 who were ≥18 years old; fulfilled SSc classification criteria; had recordings for disease duration, baseline and 12+/- 3 months follow-up for lung function, and radiographic assessments for ILD (on HRCT or x-ray) were eligible for this longitudinal study. Significant progressive fibrosis was defined as FVC decline >10% or FVC decline 5-10% and DLCO decline ≥15% from baseline to a follow-up visit at 12+/- 3

Figure: Characteristics associated with significant progressive fibrosis in SSc-ILD patients in (A) uni- and (B) multivariable logistic regression

Table: Demographic and clinical characteristics of SSc-ILD patients in subgroups by FVC change

	Significant progressive fibrosis (n=111, 13%)	Moderate progressive fibrosis (n=116, 13.6%)	Stable lung fibrosis (n=415, 48.7%)	Moderate improvement in lung fibrosis (n=200, 23.5%)
Age, yrs (SD)	59 (13.4)	55 (12.1)	55 (13.5)	58 (12.1)
Male, n (%)	18 (15.9)	17 (16.0)	81 (19.9)	34 (18.0)
Disease duration, yrs	9.2 (7.6)	9.6 (8.4)	10.2 (8.3)	9.0 (8.6)
Disease duration > 3 yrs, n (%)	27 (23.9)	27 (25.5)	70 (17.2)	50 (26.5)
Diffuse cutaneous SSc, n (%)	51 (45.1)	45 (42.5)	186 (45.6)	78 (41.3)
Limited cutaneous SSc, n (%)	58 (51.3)	43 (40.6)	180 (44.1)	81 (42.9)
Anti-topoisomerase I Ab, n (%)	48 (42.5)	35 (31.9)	221 (56.9)	93 (49.2)
Anti-centromere Ab, n (%)	19 (16.8)	20 (18.9)	60 (14.7)	40 (21.2)
FVC % predicted	95.7 (23.1)	89.2 (21.4)	85.2 (20.6)	85.1 (19.5)
DLCO % predicted	62.4 (17.8)	58.2 (16.5)	58.4 (19.5)	59.0 (16.8)
ΔFVC % predicted	-17.1 (8.0)	-7.0 (3.4)	0.3 (2.5)	11.0 (7.3)
ΔDLCO % predicted	-6.7 (16.6)	1.0 (10.0)	-0.4 (11.3)	2.4 (1.7)
mRSS	10.9 (8.0)	9.2 (8.3)	9.6 (7.6)	9.9 (8.9)
ΔmRSS	0.5 (4.2)	-0.4 (3.2)	-0.4 (4.6)	-1.2 (5.3)
ESR	29.3 (23.8)	23.1 (21.9)	26.0 (19.0)	23.9 (20.8)
GERD, n (%)	87 (77)	68 (64.2)	268 (65.87)	118 (62.4)
Immunosuppressant, n (%)	8 (7.1)	9 (8.3)	50 (12.3)	21 (11.1)

Values are mean (standard deviation) unless otherwise stated. yrs, years; Ab, Antibody; FVC, (forced vital capacity; mRSS, modified Rodan SSa score; ESR, erythrocyte sedimentation rate; GERD, gastro-esophageal reflux disease; Δ, difference between first assessment and 12-month follow up. Lung function assessments were assessed in diffuse cutaneous SSc patients.

months. Moderate progressive fibrosis was defined as FVC 5-10% decline without DLCO decline $\geq 15\%$ over this time period. Significant improvement in fibrosis was defined as improvement of FVC $> 10\%$, or improvement of FVC 5-10% and DLCO improvement $\geq 15\%$ from baseline to a follow-up visit at 12 \pm 3 months. Moderate improvement in fibrosis was defined as improvement in FVC ≥ 5 -10% without DLCO improvement $\geq 15\%$ over this time period. Stable lung fibrosis was defined as $< 5\%$ change in either direction. Lung function declines were assessed as absolute changes in % predicted. Candidate predictors of significant progressive fibrosis were selected by expert opinion and logistic regression was applied.

Results: A total of 826 SSc patients met the eligibility criteria including measurements for lung function after 12 \pm 3 months follow-up. Of these, 106(12.8%) showed significant progressive lung fibrosis, 113 (13.7%) moderate progressive lung fibrosis, 408 (49.4%) stable lung fibrosis, 189 (22.9%) moderate improvement in fibrosis and 10 (1.2%) significant improvement in fibrosis. Demographic and clinical characteristics by subgroup are shown in the Table. Baseline FVC, erythrocyte sedimentation rate (ESR), gastroesophageal reflux disease (GERD) and disease duration were significantly associated with the development of significant progressive fibrosis over 12 \pm 3 months in uni- and multivariable modeling (AUC 0.67) (Figure). Age, sex, antibody profile and SSc subtype were not associated with significant progressive fibrosis in SSc-ILD.

Conclusion: This study provides novel insights regarding progressive fibrosis in patients with SSc-ILD in the large EUSTAR database.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a chronic autoimmune disease characterized by fibrosis of skin and internal organs with an estimated worldwide prevalence of 110-430 cases/million. SSc involves the lung, with Interstitial Lung Disease (ILD) being the leading cause of death. The objective of this systematic literature review (SLR) was to review the available scientific evidence to guide decisions on screening; treatment initiation, change or escalation; disease progression and influence on subsequent treatment decisions in SSc-ILD.

Methods: The SLR was conducted according to NICE, CRD and IQWiG guidance for undertaking reviews in healthcare, and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology. To update on most recent developments, the search strategy covered literature published from 2016-2018. Population, Intervention, Comparator and Outcomes criteria (PICO) were used to select publications at title/abstract and full-text screening. Data was extracted in six categories: screening/risk stratification; current treatments; treatment initiation/escalation; disease progression; treatment algorithms and biomarkers for ILD in SSc. The quality of evidence extracted was assessed using GRADE 2007 criteria.

Results: After title and abstract screening of the initial 887 citations found, 260 publications were full-text screened and 163 included in the analysis.

Although evidence was most prolific in the screening/risk stratification category for SSc-ILD, the information extracted in the biomarkers category showed a higher grade of evidence (average medium/high vs medium/low). Although HRCT and

DLCO still remain as main screening tools, some biomarkers are already in use for diagnosis and prognosis of SSc-ILD. These include genetic- (ALOX5AP gene polymorphisms), cellular- (neutrophil/lymphocyte ratio), and plasma biomarkers (antibodies such as ATA, ACA, anti-CXT, or chemokines such as CCL18, KL6, CCL-2 or IL-10). Evidence on lung disease progression was also graded medium/low, and the lowest volume and weakest evidence was observed in the current treatment; treatment algorithms; and treatment initiation/escalation categories. Immunosuppressive drugs (mycophenolate mofetil, cyclophosphamide, azathioprine and rituximab) were used as the recommended therapeutic approach.

Conclusion: This SLR found that the identification, validation and application of biomarkers as the main field of interest in SSc-ILD research, reflecting progress for early diagnosis and subsequent prognosis of this disease. In contrast, there was a dearth of robust evidence and no clear consensus on therapeutic interventions, highlighting the need for further evidence to support treatment options.

Cardiac Autonomic Modulation at Rest and during Orthostatic Stress in Systemic Sclerosis Patients

Adriana Severino¹, Gabriel Dias Rodrigues², Chiara Bellocchi¹, Eleonora Tobaldini^{3,4}, Nicola Montano^{3,4} and **Lorenzo Beretta**¹, ¹Scleroderma Unit, Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, ²Department of Physiology and Pharmacology, Biomedical Institute, Fluminense Federal University, Niterói, Brazil, ³Department of Internal Medicine, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, ⁴Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autonomic dysfunction is a marker of myocardial involvement in systemic sclerosis (SSc) and heart rate variability (HRV) is impaired in SSc patients (1). The aim of the present study was to investigate autonomic HRV both at rest and during active standing in very early (EaSSc), limited (lcSSc) and diffuse cutaneous (dcSSc) patients.

Methods: Sixty-nine SSc patients (18M/51F, mean age 58 ± 12 yrs) and 36 age-matched healthy controls (HC) (13M/23F, age 57 ± 12 yrs) underwent recording of ECG and respiration in supine and orthostatic position. Spectral analysis of HRV identified different oscillatory components: total power (TP), index of global autonomic variability, low frequency (LF), marker of sympathetic modulation, and high frequency (HF), marker of vagal modulation. LF/HF was calculated as index of sympatho-vagal balance. Unpaired t-test and ANOVA were used to compare HRV parameters between the groups.

Results: Our case series included 12 EaSSc, 39 lcSSc and 18 dcSSc, aged 54 ± 8 , 59 ± 12 and 58 ± 12 yrs with a prevalence of anti-Topo-I/anticentromere antibodies equal to and 8/67%, 28/54% and 44/11%, respectively. SSc patients had a predominant sympathetic modulation and lower vagal control compared to HC at rest (low HF and high LF and LF/HF, Table 1). In SSc subgroups analysis in which parameters of HRV both at rest and in response to orthostatic stress (Δ ORT%), were significantly different in diffuse cutaneous (dcSSc) and limited cutaneous (lcSSc) patients compared to HC (Table 2).

Conclusion: SSc patients have a decreased vagal and an increased sympathetic modulation at rest as well as a blunted autonomic response to orthostatic challenge. These alterations were present in definite forms of SSc but not in EaSSc, suggesting that autonomic dysfunction follows the development of fibrosis. Further studies are needed to better establish the relationship between myocardial fibrosis and autonomic dysfunction.

Table 1. Comparison of HRV indexes at rest between SSc and age-matched healthy control group.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies (Ab) toward Bicaudal D homolog 2 (BICD2) can be found in 25% of Systemic Sclerosis (SSc) sera, mostly in association with anti-centromere (ACA) or anti-topoisomerase I (ATA)abs, but also in isolation. Anti-BICD2 single specificity has been associated with myositis and interstitial lung disease (ILD), however its prognostic significance is unclear. A retrospective-prospective study was conducted to evaluate disease evolution in anti-BICD2+ patients.

Methods: Serum samples from 288 SSc (ACR/EULAR 2013 criteria) collected between 2012 and 2014 were stored at -80° C and sent for Ab determination to Inova Diagnostics (San Diego, CA). Samples were tested using a novel particle-based multi-analyte technology (PMAT) and with CTD Essential (which includes DFS70, dsDNA, RNP, Sm, Ro60, Ro52, SS-B, Jo-1, Scl-70, Centromere, Ribo-P) and CTD Comprehensive (RNA Pol III, Th/To, Ku, BICD2, PM/Scl; both test research use only).

Clinical data regarding major organ complications were retrospectively collected; time of evolution from baseline to new clinical manifestations was recorded. For dcSSc subjects evolutions included death, new digital ulcers, worsening of lung function(forced vital capacity, FVC loss > 10% or diffusing capacity for carbonmonoxide, DLCO loss > 15%), progression

of ILD on high resolution computed tomography, HRCT, development of pulmonary hypertension (PAH); evolution for lcSSc included progression of skin thickening as well as dcSSc categories; evolution for definite SSc without skin fibrosis included the appraisal of skin fibrosis and the above categories. Survival analysis for interval-censored data with 1.000-fold permutations was used.

Results: Our cohort included: 30 (10.4%) definite non-cutaneous SSc, 216 (75%) lcSSc and 42 (14.5%)dcSSc, mostly females (95.5%), aged 60 ± 12.7 years and with disease duration of 14 ± 13 years. Anti-BICD2 Ab were found in 49 subjects (17%), in 10 (3.5%) as a single-specificity, in 8 (2.8%) in associations with ATA, in 31 with ACA (10.8%). Patients were followed for a median of 4.0 (interquartile: 2 – 5.1) yrs until the first sign of evolution. Single anti-BICD2 Ab positivity was associated with myositis (3/10 vs. 11/278, $p=0.0089$) and weakly with dcSSc (4/10 vs. 38/278, $p=0.045$). Ab specificity was associated with different pattern of progression (Figure): Anti-BICD2+ patients had shorter evolution times compared to anti-BICD2- patients ($p=0.03$), ACA+ subjects ($p=0.007$) but were similar to ATA+ subjects ($p=0.2$). Crude mortality trended to be higher in anti-BICD2+ than anti-BICD2- patients (3/10 vs. 27/278, $p=0.074$).

Conclusion: We confirm the association between anti-BICD2 Ab and myositis in SSc and its overall prevalence. Anti-BICD2+ patients have a worse prognosis and higher rates of disease progression compared to ACA+ subjects and behave similarly to ATA+ subjects.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Background/Purpose: Two randomized controlled trials showed modest but significant effects for oral (po) CYC (superior to placebo and equal to mycophenolate mofetil). A number of European centres seem to prefer intravenous (IV) CYC based on a presumed better safety profile. However, no direct comparisons of these two administration methods have been published. In this context, our goal was to compare the relative efficacy and safety of **po versus IV CYC(IV) for treating ILD and/or skin involvement in SSc.**

Methods: Patients were derived from the EUSTAR database and Scleroderma Lung Studies I and II, receiving ≥ 6 months of **po** or IVCYC ,all with 12 months follow-up. **Serious (SAEs) and non-serious adverse events (AEs) and efficacy (change in ppFVC, ppDLCO, mRSS) were analyzed at end of treatment (EoT) and at follow-up (FU).** Analysis included descriptive statistics and linear regressions

Results: Between the 149 po versus 153 IV CYC patients there were baseline statistical differences in ethnicity, previous DMARD exposure, previous and concomitant steroid exposure and dosage, current/previous smoking, digital ulcers and arterial hypertension (Table 1).

Efficacy: after adjusting for significant baseline **ppFVC, ppDLCO** and mRSS, at EOT vs baseline and at FU vs EOT, changes in **ppFVC, ppDLCO** and mRSS were similar for both groups (p=NS, Table 2). In a multivariate analysis, route of administration had no impact on efficacy.

Safety: there was more leukopenia (22.1% vs 1.3%, $p<0.001$), haemorrhagic cystitis (5.5% vs 0%, $p=0.011$) and alopecia (19.5% vs 1.3%, $p<0.001$) at EOT visit after po than IV CYC. In contrast, there were more SAEs and need for oxygen supplementation at FU in the IV vs po group (19.3% vs 9.4%, $p=0.025$, and 7.2% vs 2%, $p=0.049$). The median cumulative CYC dosage was significantly higher in the po group [39.4 mg vs 9.2 mg, $p<0.001$). No significant differences were found for deaths, anemia, **thrombocytopaenia, gastro-intestinal bleeding, serious infections, malignancies, need for total parenteral nutrition, new onset of cardiomyopathy or amenorrhea.**

CYC=cyclophosphamide, DMARD= disease modifying ant rheumatic drug, FVC=forced vital capacity, DLCO=lung diffusion of carbon monoxide, mRSS= modified Rodan skin score, IQR=inter-quartile range

Conclusion: This hypothesis generating study is limited by the different source data, patients' selection (i.e. presence of active ILD and absence of PAH for SLSI and SLS 2), post-treatment medications (higher dosage corticosteroids, more csDMARD and O2 in IV-CYC) and short follow-up duration. It showed similar efficacy of one year of oral versus IV CYC. AEs were more frequent with po CYC but more SAEs were noted for IV-CYC. Well-controlled studies are warranted to confirm and extend our data.

Prevalence of Echocardiographic Abnormalities in Patients with Systemic Sclerosis

Judit Lluch¹, Francisco Javier Narváez², Pablo Juárez¹ and Joan Miquel Nolla¹, ¹Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, ²Rheumatology Department, Hospital Universitario de Bellvitge, Idibell, Barcelona, Spain

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the prevalence of echocardiographic abnormalities and to identify associated clinical and laboratory features in a large systemic sclerosis (SSc) cohort.

Methods: The sample comprised 117 patients with SSc (ACR/EULAR 2013 criteria) treated at a tertiary university hospital that does not attend pediatric populations. In the routine clinical management of these patients, a transthoracic Doppler echocardiogram (TTE) is performed every 1 or 2 years. In each study, we investigated the presence of myocardial systolic dysfunction, diastolic myocardial dysfunction, valve disease, and pulmonary arterial hypertension (PAH) defined as a systolic pulmonary artery pressure (PAP) ≥ 40 mmHg and tricuspid regurgitation velocity (TRV) greater than 2.5 m/s.

Results: The sample included 104 women (89%) and 13 (11%) were men, with a mean age of 59 ± 15 years (mean ± standard deviation; range 19–86) and a median disease duration of 6.5 years (interquartile range [IQR], 25th-75th: 3–14 yrs). Twenty one patients (18%) had diffuse cutaneous scleroderma, eighty-nine (76%) had limited cutaneous involvement, 1 (0.8%) had a systemic sclerosis sine scleroderma, and six (5%) had prescleroderma.

The main TTE findings observed were:

- Left ventricular (LV) systolic dysfunction was present in 5.1% (6/117) of subjects, whereas LV diastolic dysfunction was present in 11.1% (13/117). Factors independently associated with LV diastolic dysfunction on multivariable analysis included arterial hypertension, disease duration, advanced age, and the limited cutaneous SSc subtype.

- Subclinical valve disease: 10.2% (12/117) of patients had valve dysfunction involving the mitral and/or the aortic valves. Valve dysfunction was mild or moderate in all cases, except in 3 patients (2.56%) who presented severe aortic stenosis. The age of these three patients were 52, 59 and 78 yrs. Antiphospholipid (APL) antibodies were positive in only 1 of these patients.
- TTE criteria for PAH: 11.1% (13/117). Right heart catheterization (RHC) confirmed the diagnosis of PAH in all cases except one (false positive). The median disease duration at PAH diagnosis was 6 years (IQR: 1.5 -14.5 yrs). Factors independently associated with PAH on multivariable analysis included the limited cutaneous SSc subtype and more severe peripheral vascular disease (Raynaud's phenomenon and digital ulcers).

Conclusion: In addition to the presence of PAH, it is also relatively common the presence of LV diastolic dysfunction (11.1%) and subclinical valve disease (10.2%).

The high frequency of severe aortic stenosis observed in our cohort (its prevalence in the general population is 0.3-0.5%) deserves a case-control study to investigate whether this complication is related or not to the activity of the disease.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma heart disease often goes unrecognized until severe clinical manifestations are present. Diastolic dysfunction (DD) may identify patients at risk for cardiac complications by identifying patients with myocardial fibrosis. The aims of this study were to 1) determine the prevalence of non-valvular DD in scleroderma, 2) assess risk factors for DD in scleroderma, and 3) evaluate the impact of DD on survival.

Methods: A total of 754 subjects with scleroderma seen between November 1st, 2007 through October 31st, 2017 were included in this retrospective cohort study. Echocardiograms were excluded if there was moderate to severe mitral or aortic valve disease, a primary cardiomyopathy, a recent myocardial infarction, or if subjects were admitted to an intensive care unit. The most recent analyzable echocardiogram for each subject was included. DD was defined according to the 2016 American Society of Echocardiography (ASE)/European Society of Cardiovascular Imaging (EACVI) guidelines. Univariable logistic regression assessed risk factors for DD, and a multivariable regression model was constructed of covariates with a p-value of ≤ 0.1 . Inclusion of all traditional DD risk factors in the multivariable model was planned a

*MMT= manual muscle testing

priori. A Kaplan-Meier curve evaluated for differences in survival among those with and without DD, and a log-rank test for equality of survivor functions evaluated for significance.

Results: The prevalence of DD was 18.8%. Mean age at time of echocardiogram was 67.4 years(STD 9.7). Traditional DD risk factors including age, hypertension, coronary artery disease (CAD), renal disease, ever smoker, COPD, and obesity ($\geq 30\text{kg/m}^2$) were significantly associated with DD on univariable analyses (Table 1). Disease duration, limited cutaneous disease, and presence of anti-Ro52 autoantibody were significantly associated with DD on univariable analysis (Table 1). Only age, CAD, obesity, and a positive anti-Ro52 autoantibody were associated with DD on multivariable model (Table 1). An increase in age-adjusted all-cause mortality was seen in subjects with DD compared to those with normal diastolic function ($p<0.0001$)(Figure 1).

Conclusion: Patients not only with traditional cardiac risk factors but also with a positive anti-Ro52 autoantibody are at higher risk for DD. Given the poor survival associated with DD in this population, aggressive control of modifiable risk factors as well as further investigation into treatments is warranted.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by excessive extracellular matrix deposition (ECM), leading to dermal and internal organ fibrosis. As in other autoimmune diseases, SSc is more prevalent in women. However, men have more severe disease. Considering the sex-based disparity in disease severity, estradiol (E2), an estrogen form with pro-fibrotic effects in different organs, may play a role in SSc pathogenesis. We previously reported that post-menopausal women with diffuse cutaneous (dc)SSc have higher serum E2 levels compared to healthy controls of similar age. Our objective was to examine serum E2 levels in dcSSc males in relation to disease characteristics (i.e. autoantibody profile and internal organ involvement) and its impact on survival.

Methods: We measured serum E2 levels in 83 dcSSc men >50 years old from the University of Pittsburgh Scleroderma Center and healthy controls of similar age. Using statistical modeling, we examined the associations between circulating E2 levels, internal organ involvement, autoantibody profiles, and survival.

Results: Male dcSSc patients had significantly higher serum E2 levels compared to healthy male controls. Male dcSSc patients also had higher serum E2 levels compared to dcSSc post-menopausal women of similar age. Male dcSSc patients with high serum E2 levels had significantly more heart involvement and worse survival. Using Cox regression modeling for risk of death, increasing serum E2 levels in anti-Scl-70 antibody positive dcSSc males were associated with an increased risk of death.

Conclusion: DcSSc male patients have higher levels of E2 compared to healthy controls and dcSSc post-menopausal women. Elevated serum E2 levels in dcSSc males >50 are associated with heart involvement and, if anti-Scl-70 antibody positive, worse survival. Our current study expands on our previous work, implicating E2 in the pathogenesis of SSc-associated fibrosis and extends our findings to an association between E2 levels, internal organ involvement, and overall survival. These data suggest an important role for estrogen imbalance in SSc.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The etiology and reasons underlying the ethnic disparities in systemic sclerosis (SSc) remain unknown. African-Americans (AA) are disproportionally affected by SSc, yet dramatically underrepresented in research. The role of DNA methylation in disease risk remains unclear. Previously, we conducted DNA methylation analysis in AA SSc patients and found 17 genes and 11 promoters showed significant differential methylation levels between cases and controls. In this study, we seek to determine expression differences in some of the candidate protein-coding and RNA genes previously identified.

Methods: RNA was isolated from cultured primary dermal fibroblasts isolated from 12 AA SSc cases and 14 AA controls. All patients met the 2013 ACR/EULAR classification criteria for SSc, most (93%) presenting with diffuse cutaneous SSc. Transcript levels of steady state RNA of 5 protein coding genes, 2 non-coding and 1 long-coding (lnc) RNAs were analyzed using QRT-PCR. Values were normalized to the house-keeping gene, β 2-microglobulin, to determine magnitude of fold change. Statistical differences were noted between the groups using the Mann-Whitney test.

Results: QPCR analysis revealed 2 of the 5 protein coding genes and the lncRNA had significant differences in transcript levels between primary dermal fibroblasts from AA SSc patients and healthy controls. Both protein coding genes *DLX5* and *TMEM140* were significantly increased, while the lncRNA *MGC12916* was significantly decreased in primary dermal fibroblasts from AA SSc patients compared to healthy controls.

Conclusion: Differential gene expression of *DLX5* and *TMEM140* has been reported in previous studies with SSc patients. Our current study shows that gene body hypermethylation in *DLX5* and promoter hypermethylation in *TMEM140* is correlated with its overexpression in AA SSc patients relative to healthy controls. However, gene body hypermethylation of lncRNA *MGC12916* is correlated with its under expression in AA SSc patients relative to healthy controls. While previous studies reported both differential methylation and gene expression in *DLX5* only, these results are the first to report both differential methylation and gene expression of *DLX5*, *TMEM140* and lncRNA *MGC12916* in AA SSc patients, prompting further research in determining their role regarding SSc susceptibility in this cohort.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold capillaroscopy (NFC) is essential in the evaluation and classification of systemic sclerosis (SSc). The mean number of capillaries is considered a promising tool for assessing vascular involvement in SSc, however there is no consensus yet over how many digits should be analyzed and how.

Objective: Investigation of the associations of the mean number of capillaries, measured by NFC, with disease activity (by the EScSG activity score) and vascular involvement (digital ulcers (DUs) or history of DUs) in a single-center cohort of SSc patients.

Methods: 68 SSc patients (mean (SD) age 52.9 (11.0) years, disease duration 9.2 (7.1) years and diffuse cutaneous involvement 22 (34.2%)) fulfilling the ACR/EULAR 2013 classification criteria, were included. NFC and extensive assessment per the recommendations of EUSTAR were performed in all patients. 54 patients had a follow-up at 6 months. 8 digits were examined (II to V of both hands) by NFC; 4 images for each finger were saved. The NFC images were assessed by 2 experienced raters independently, scoring the mean number of capillaries in all fingers (m_nr/pat), in the 3rd finger of the dominant hand (m_nr/3rd dom) and in the 4th finger of the non-dominant hand (m_nr/4th non-dom) for each patient. Moreover, 'early', 'active', 'late' Cutolo patterns were also recorded.

Results: 2176 images were scored at baseline and 1728 at FU. The m_nr/pat at baseline ranged between 3.4-9.1, mean(SD) 5.6(1.7) for rater 1, respectively 3.3-8.9, 5.2(1.4) for rater 2.

There was good to excellent correlation (Spearman's rho) at baseline and FU of the m_nr/pat with m_nr/3rd dom, m_nr/4th non-dom and Cutolo patterns, and fair correlation of m_nr/3rd dom with m_nr/4th non-dom and Cutolo patterns. We found significant differences of all mean scores of capillaries between patients with and without history of DUs (Mann Whitney U test) (table 1). Using linear regression adjusted for age, gender and history of DUs, mean number of capillaries was associated with disease activity at FU (table 2).

Table 1. Differences in mean number of capillaries in patients with and without history of DUs

	History of DUs min-max; mean (SD)	Without history of DUs min-max, mean (SD)	p*
m_nr/pat rater 1	3.4-8.6; 5.04 (1.4)	3.4-9.1; 6.4 (1.8)	0.016
m_nr/3 rd dom rater 1	2.5-9.8; 4.9 (1.79)	2.3-10.3; 6.2 (2.3)	0.033
m_nr/4 th non-dom rater 1	2.0-9.0; 4.8 (1.5)	2.5-11.5; 6.0 (2.1)	0.017

* Mann-Whitney U test

Table 2. Associations between mean number of capillaries at baseline and disease activity (ESSG score 2003) at FU (linear regression)

Predictors	B (95% CI)	p
m_nr/pat rater 1	-0.03 (-0.40, 0.34)	ns
m_nr/pat rater 2	-0.45 (-0.834, -0.07)	0.022
m_nr/3 rd dom rater 1	-0.23 (-0.47, 1)	0.056
m_nr/3 rd dom rater 2	-0.33 (-.62, -0.03)	0.032
m_nr/4 th non-dom rater 1	-0.11 (-0.34, 0.12)	0.346
m_nr/4 th non-dom rater 2	-0.27 (-0.57, 0.02)	0.070

Conclusion: The mean number of capillaries had a good association with the history of DUs and predicted disease activity at 6 months follow-up. The m_nr/pat performed better in our analysis than the m_nr/3rd dom and m_nr/4th non-dom, however these could be used alternatively in clinical practice as they are less time consuming.

This work is part of the QUANTICAP project.

The Lymphangiogenic Factors VEGF-C, CCL21 and Ang-2 Are Associated with Pulmonary Arterial Hypertension in Systemic Sclerosis

Henriette Didriksen¹, Havard Fretheim¹, Vyacheslav Palchevskiy², Arne K Andreassen¹, Torhild Garen¹, Oyvind Midtvedt¹, Einar Gude¹, John A Belperio³, Øyvind Molberg¹ and Anna-Maria Hoffmann-Vold¹, ¹Oslo University Hospital, Oslo, Norway, ²University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, ³University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Background/Purpose: Systemic sclerosis (SSc) is characterized by abnormalities in vascular pathways and lymphatic vessels with pulmonary hypertension as a major complication. Vascular endothelial growth factor C (VEGF-C), acting through its cognate receptor VEGFR3 is a major growth factor for lymphatic vessels under physiological conditions. Recent studies have shown that patients with SSc have altered levels of two VEGF-C regulating proteins; the angiogenic factor Ang-2 and the chemokine CCL21, also found to be associated with PAH development. We assessed the characteristics of VEGF-C in SSc patients and investigated serum levels of VEGF-C, CCL21 and Ang-2 segregated by pulmonary arterial pressure.

Methods: SSc patients from the Oslo University Hospital (n=371) and controls (n=100) were included; and sera analyzed for VEGF-C, CCL21 and Ang-2 by Luminex kits from Millipore. SSc patients with clinically suspect PH were referred to right heart catheterization. Mean pulmonary arterial pressure (mPAP) ≥ 25 mmHg in the absence of significant interstitial lung disease (ILD) was defined as PAH; mPAP of 20-24mmHg in the absence of significant ILD borderline PAH. Descriptive statistics and logistic regression analysis were performed and tested by the goodness-of-fit with area under the curve (AUC).

Results: The mean age of SSc patients was 54 ± 14.1 years, 80% were female and 74% had limited cutaneous SSc. Serum levels of VEGF-C were lower in SSc than in controls (2.0 ± 0.7 ng/ml vs. 2.4 ± 0.7 ng/ml, $p < 0.001$) (Table 1). In patients with low levels of VEGF-C (< 2.3 ng/ml) PAH was 3.5-fold more frequent than inpatients with high levels of VEGF-C (14.7 % vs 4.2 %, $p = 0.005$). 167 patients were assessed by RHC. Patients with PH-ILD (n=27), borderline PH-ILD (n=3) and post-capillary PH (n=14) were excluded from the study, while the remaining 123 patients were included in the investigation of lymphangiogenic factor expression; including 28 patients with PAH, 45 borderline PAH and 50 with no PAH. CCL21, Ang2 and VEGF-C levels in these groups are shown in Figure 1. VEGF-C (OR 0.99, 95%CI 0.997-0.998, $p = 0.001$, AUC=0.79), CCL21 (OR 1, 95%CI 1-1.003, $p = 0.050$, AUC=0.69) and Ang-2 (OR 1, 95%CI 1-1.0001, $p = 0.49$, AUC=0.67) were associated with PAH compared to no PAH patients.

Conclusion: VEGF-C is associated with ssc-PAH, making it a possible maker for the development of PAH. This study also demonstrates dysregulation of lymphangiogenetic factor expression of multiple targets in sera of SSc-PAH patients.

Table 1: Longitudinal clinical and demographic data

	OUPH (n=371)	PAH (n=28)	Borderline PAH (n=45)	No PAH (n=50)

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Impaired sexual function is common among women with chronic illnesses, including Systemic Sclerosis (SSc). Studies of sexual functioning among women with SSc have concluded that sexual impairment is common, according to comparisons with both the general population and women with other chronic diseases. There are no studies in our country that evaluate the impact of SSc in this area.

Objectives: To evaluate sexual impairment in women with SSc. To investigate sociodemographic, disease characteristics and psychological variables associated with sexual impairment in women with SSc.

Methods: Observational, analytical, cross-sectional study. We included women between 20 and 59 years of age diagnosed with SSc according to 2013 American college of rheumatology/European league against rheumatism classification criteria, from 5 public rheumatology centers of Argentina, between April 2017 and April 2018. We excluded patients with severe chronic diseases or other autoimmune rheumatologic diseases. Sexual impairment was assessed using the Spanish version of Female Sexual Function Index (FSFI) questionnaire, which has been validated among Latin American women aged 20 to 59 years. Higher subscale or total scores indicate better sexual function. A cutoff score of 26.55 is proposed as a criterion for impaired sexual function. We used Hospital Anxiety and Depression Scale (HADS) questionnaire to evaluate anxiety and depression. For the descriptive analysis, the continuous variables were reported as mean and standard deviation or median and interquartile range (IQR). The categorical variables were reported as percentage. A multiple linear regression model was performed, taking sexual dysfunction as the dependent variable, adjusted for possible confounders. The performance of the model was evaluated (assumptions, atypical observations, multicollinearity).

Results: We included 46 patients. The mean age was 44.78 years (+/- 9.84) and 39.13% were postmenopausal women. The mean FSFI score was 21.07 (+/- 8). Eighty percent presented sexual dysfunction and 13.04% of them correspond to sexually inactive patients due to the disease. The variables that showed significant association with sexual dysfunction in the univariate analysis were: dyspnea (β coefficient: -2.91. CI 95%: -5.79 to -0.04), VAS pain (β coefficient: -0.08. CI 95%: -0.15 to -0.005), VAS fatigue (β coefficient: -0.09. CI 95%: -0.17 to -0.01), body image satisfaction (β coefficient: 4.34. CI 95%: 0.80 to 7.88), age (β coefficient: -0.28. CI 95%: -0.51 to -0.05) and fibromyalgia (β coefficient: -14.73. CI 95%: -21.99 to -7.47). The variables that showed significant and independent association in the multivariate analysis were: body image satisfaction (β coefficient: 4.11. CI 95%: 1.10 to 7.13), age (β coefficient: -0.25. CI 95%: -0.45 to -0.05), fibromyalgia (β coefficient: -11.37. CI 95%: -18.26 to -4.48).

Conclusion: We found that sexual dysfunction is frequent between women with Systemic Sclerosis, and that is in concordance with other studies. According with our results, patients with greater body image satisfaction, younger and without fibromyalgia had better sexual function.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gastric Antral Vascular Ectasia(GAVE) is a vascular manifestation of systemic sclerosis (SSc) characterized by erythematous streaks and longitudinal rugal folds in the stomach on upper endoscopy. Estimates on the prevalence of GAVE in SSc patients range from 1-22%. GAVE can lead to iron deficiency anemia or acute gastrointestinal (GI) bleeding. Endoscopic laser therapy is effective in the treatment and prevention of GI bleeding related to GAVE. We aimed to identify risk factors for GAVE to improve early identification and treatment of these patients.

Term: PAH=pulmonary arterial hypertension; ILD=interstitial lung disease; GERD=gastroesophageal reflux disease; FVC=forced vital capacity; DLCO=diffusing capacity of the lung for carbon monoxide; RVSP=right ventricular systolic pressure

Methods: We performed a retrospective analysis of prospectively collected data on SSc patients with and without GAVE seen at Stanford between 2004 and 2018. All patients fulfilled 2013 ACR/EULAR classification criteria for SSc. We collected and compared data on demographics, clinical features, autoantibodies, and laboratory findings in those with and without GAVE. We used Fisher's exact test to compare categorical variables, and Wilcoxon rank-sum test for continuous variables. Multivariate logistic regression including variables with p-value less than 0.1 was performed to identify predictors of GAVE.

Results: A total of 323 patients with SSc were included in this study, of whom 17 (5.3%) had GAVE. GAVE was significantly associated with scleroderma renal crisis (SRC), negative ANA, positive anti-RNA Polymerase III antibody, lower aldolase, and a trend toward lower hematocrit (Table 1). Given the high correlation between SRC and anti-RNA Polymerase III, only the latter was included in the multivariate logistic regression model. ANA negativity (OR 4.76 (95% CI 1.43 - 15.82), p=0.01) and anti-RNA polymerase III positivity (OR 4.5 (95% CI (1.13 - 17.92), p=0.03) remained significant predictors of GAVE.

Conclusion: We found a prevalence of GAVE of 5.3% in our cohort. A negative ANA or positive anti-RNA polymerase III antibody increases the risk of GAVE by more than 4-fold. Further studies are necessary to determine whether patients with these antibody profiles should undergo screening endoscopies for GAVE.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated levels of C-reactive protein (CRP) in systemic sclerosis (SSc) have been linked to early inflammatory stages of the disease. This study has been set to investigate CRP levels in a longitudinal cohort of SSc patients and to correlate these findings with comorbidities and disease characteristics.

Methods: In this retrospective study patients with SSc were recruited from the outpatient clinic of the Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg. Only patients with at least three consecutive visits over at least one year were included in this study. CRP serum levels were measured at every visit and categorized as positive if CRP concentrations were ≥ 5 mg/l. Subjects with elevated CRP levels at more than 80% of visits were defined as inflammatory SSc. The longitudinal CRP profile was correlated to comorbidities and disease characteristics.

Results: A total of 1,815 consecutive visits of 131 SSc patients were analyzed. Over the observed time span (91 [136-56] months) 18.3% (n=24) of patients had continuously elevated CRP levels (inflammatory SSc), whereas in 29% (n=38) CRP levels were always in the normal range. There was no association between disease duration and CRP levels at first visit (p>0.5). Inflammatory SSc was associated (p<0.05) with anti-topoisomerase I-antibodies, diffuse cutaneous SSc (dcSSc), pulmonary fibrosis, rheumatoid arthritis, and cardiac arrhythmia (p<0.05). Moreover, patients with inflammatory SSc revealed higher modified Rodnan skin scores (mRSS), and lower FCV, TLC, and DLCO (p<0.001). Even treatment with cyclophosphamide (CYC) did not alter CRP levels (n=12, median dose 4.5 g (3-10), median CRP before CYC 18.0 mg/l, after CYC 17.7 mg/l, p=0.754).

Conclusion: Inflammatory SSc is characterized by a more severe disease phenotype and high morbidity. Even treatment with CYC does not alter CRP levels in these patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients frequently have upper gastrointestinal (GI) symptoms, with GI involvement being the leading cause of morbidity. Meanwhile, interstitial lung disease (ILD) and pulmonary hypertension (PH) are the leading cause of mortality in SSc. Reflux disease may play a role in ILD through chronic microaspiration and/or altered pulmonary mechanics in ILD can potentiate the impact of reflux. A potential causality between the two variables has yet to be established.

We investigated the prevalence of esophageal motility disorders and reflux in SSc patients and evaluated the relationship between GI characteristics and pulmonary outcomes.

Methods: This retrospective chart review was carried out at the University of California, Los Angeles (UCLA). Patients included in the study were diagnosed with systemic sclerosis and evaluated in SSc-GI clinic. Esophageal evaluation was carried out using at least one of the following modalities: high-resolution esophageal manometry (HREM), ambulatory pH testing and/or EGD. Data, collected within 1 year of the GI procedures, included: patient demographics, scleroderma characteristics, motility data, presence of ILD defined by HRCT, PH, oxygen requirement, and pulmonary function tests (PFTs) completed within one year of the index GI study. Statistical analyses included descriptive, ANOVA or Chi square testing as appropriate.

Results: Our study cohort included 122 patients, mean age \pm SD of 66 ± 9 at GI evaluation. 93% of patients were female, 68% had limited and 32% had diffuse cutaneous disease.

Most patients underwent HREM and EGD. Approximately 70% of the patients had absent contractility on manometry, while another 24% had ineffective esophageal motility. Hiatal hernia was found in one third of patients. Of those who underwent EGD, 37% had erosive esophagitis, while only 23% had a definitive diagnosis of GERD based on EGD. A portion of our cohort completed ambulatory pH testing, with 68% of studies demonstrating GERD. ILD was noted in 55% of patients.

We found no correlation between patient FEV1, FVC and/or DLCO and esophageal motility disorders based on HREM or the diagnosis of GERD based on EGD/pH studies. There were no significant differences in the PFTs and different HREM diagnoses, between patients with and without a diagnosis of GERD, or between patients with ILD with normal and abnormal motility. Our preliminary data did not reveal any correlation between esophagitis or hiatal hernia and ILD per HRCT findings.

Conclusion: Our study is one of the largest single-center cohorts of SSc patients characterizing esophageal motility, reflux and PFTs. The majority of our patients demonstrated abnormal motility, a finding believed to contribute to reflux. Over half of our cohort had lung involvement. There was no association found between esophageal dysmotility and/or GERD with PFTs. Similarly, preliminary data support a similar trend with HRCT findings of ILD. Given the lag time between discernable PFT changes and radiographic findings on HRCT, additional characterization of GI disease and early radiographic findings of ILD and PFT changes overtime is helpful and underway.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A higher prevalence of cancer has been described in patients with systemic sclerosis (SSc), but the magnitude of this risk and the type of cancer vary among reports. Risk factors predisposing the development of malignancies in SSc patients are not well defined. **The purpose** of our study was to analyze the frequency and risk factors associated with cancer in a large single cohort of patients with SSc.

Methods: All cases of cancer diagnosed in a cohort of 662 patients classified as SSc according to the ACR/EULAR criteria, attended in a single referral scleroderma outpatient clinic in Brazil between 2010 and 2017, were reviewed and evaluated regarding demographic, clinical and laboratory features. We used the Brazilian National Cancer Institute database to compare the cancer prevalence in SSc patients with the expected rate of cancer in the general population, and to estimate the risk of each cancer in this group, pairing by age. Taking into account that all sample proportions have an observed incidence higher than the general population, the one-tail proportion test was used to compare the cancer incidence in the sample and the population. A logistic regression model was performed to find risk factors for cancer. Statistical significance was considered when $p \leq 0.05$.

Results: ± 13.91 years; $p \leq \pm 9.24$ years; $p = 0.029$). When the frequency of cancer by gender in the SSc patients was compared with the predicted frequency of cancer in the Brazilian general population, it was found a significant association among female gender and cancer in general ($p < 0.001$), as well as with breast ($p < 0.001$), uterus ($p = 0.023$), lung ($p = 0.013$), colon ($p = 0.007$), esophagus ($p = 0.012$), stomach ($p = 0.042$), lymphoma/leukemia ($p = 0.007$), thyroid ($p = 0.004$) and melanoma ($p = 0.022$); male gender was only associated with cancer in general ($p = 0.013$). Multivariate logistic regression identified non diffuse SSc (OR 10.7, 95%CI 2.1-54.8, $p = 0.004$), Sjogren syndrome (OR 3.4, 95%CI 1.4-8.5, $p = 0.007$), peripheral neuropathy (OR 4.4, 95%CI 1.5-13.2, $p = 0.009$) and anti-RNAPolIII positivity (OR 5.1, 95%CI 1.2-22.7, $p = 0.032$) as significant risk factors for cancer occurrence.

Conclusion: This study confirmed a higher frequency of cancer in a large SSc cohort and pointed out that non diffuse SSc, peripheral neuropathy, concomitant Sjogren syndrome and anti-RNA polymerase III positivity represent risk factors for the development of cancer in SSc.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a common inflammatory rheumatic disease of the elderly whose diagnosis is usually based on clinical, analytical and ultrasound findings. However, sometimes patients who present symptoms resembling PMR donot complete fulfill the 2012 EULAR/ACR criteria. It is not well known if these atypical patients behave as those who fulfill criteria. In these cases, Positron Emission Tomography/computed tomography (PET/CT) could be a useful tool to assess if these patients have a similar pattern of 18F-FDG uptake to those who fulfill criteria.

Objectives: Our aims were: **a)**to compare clinical and analytical features in patients with classic PMR to a typical PMR, **b)** to asses if findings in PET/CT differ between both groups.

Methods: Retrospective study of 93 patients with PMR and their respective PET/CT scans from a single University referral center. We considered two groups: **a)** Classic PMR: patients who fulfilled the 2012 EULAR/ACR criteria; and **b)** A typical PMR: patients with symptoms resembling classic PMR but did not fulfill the 2012 EULAR/ACR criteria.

Results: We evaluated 93 patients (30 men/63 women) with a meanage±SD of 69.2±10.8 years. A PET/CT was performed in all of them. Eighty (86%) patients had classic PMR and 13 (14%)atypical PMR. The comparative study is shown in the **TABLE**. Both groups were receiving similar doses of Prednisone at the time of PET/CT performance. Patients with atypical PMR were younger and had shorter duration of symptoms. Pain in the pelvic girdle was more frequent in patients with atypical PMR (100% vs 65%)while shoulder girdle pain was higher in patients with classic PMR (23.1% vs72.5%). No significant differences were found in PET/CT findings between classic and atypical PMR, although large vessel involvement was slightly more frequent in patients with atypical PMR.

Conclusion: Patients with a typical PMR used to be younger with a shorter evolution of symptoms and had predominantly pelvic girdle affection. Despite these differences, the pattern of F-FDG uptake in PET/TC was similar in classic and atypical PMR.

TABLE

	Classic PMR (n=80)	Atypical PMR (n=13)	P
Sex (<i>women</i>), n (%)	55 (68.8)	8 (61.5)	0.61
Age (<i>years</i>), mean ± SD	70.9±9.8	58.3±10	< 0.01

Development of Thoracic Aortic Aneurysms in Patients with Polymyalgia Rheumatica: Under diagnosed Giant Cell Arteritis?

Nicolas Martin Marin Zucaro¹, Marina Scolnik², Florencia Beatriz Mollerach³, Valeria Scaglioni², Luciano Fernando Lo Giudice¹, Jose Maximiliano Martinez P⁴, John Fredy Jaramillo Gallego¹ and Enrique R Soriano⁵, ¹Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Capital Federal, Argentina, ²Rheumatology Unit, Internal Medicine Service, Hospital Italiano Buenos Aires, Argentina, Buenos Aires, Argentina, ³Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, ⁴Rheumatology, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, ⁵Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia Rheumatica (PMR) and Giant Cell Arteritis (GCA) are close-related entities. Imaging studies have suggested that subclinical inflammation of the large arteries is frequent in patients with apparently isolated PMR. Our objective was to compare characteristics of PMR patients who developed a thoracic aortic aneurysm (TAA) during follow-up with those who did not, in order to identify clinical features that may predict aortic involvement in clinical PMR patients.

Methods: All electronic medical records of PMR patients diagnosed after year 2000 (fulfilling ACR 2012 criteria) from a university hospital-based health management organization (HMO) were reviewed. Patients with a previous diagnosis of aortic aneurysm, those who developed clinical GCA or other rheumatic disease after PMR diagnosis and those lost in follow-up or without appropriate thoracic images after diagnosis, were excluded. A case-control study (PMR-TAA versus PMR without TAA) was performed and patients' characteristics were compared. A multivariate logistic regression analysis was performed to identify risk factors for TAA.

Results: 350 PMR patients were included (724 were excluded for the reasons mentioned in methods) and 50 (14.3%, 95% CI 10.9-18.4) developed a TAA during a median follow up of 5.4 years (IQR 2.9-7.9). 18 TAA were located at the aortic root and 32 at ascendant aorta, with a medium size at diagnosis of 4.3 cm (SD 0.33). No ruptures or dissections occurred but 5 patients (10 %, 95% CI 4.2-22.1) required surgery. Patients' characteristics are shown in Table 1. Traditional cardiovascular risk factors and clinical characteristics of PMR were similar across groups, except for less statins use and longer treatment with steroids in PMR-TAA group. In the multivariate logistic regression analysis, being a male (OR 4.4, CI 2.3-8.6, p <0.001) and months of corticosteroid treatment, (OR 1.02, 95% CI 1.01-1.03, p 0.01) were associated with an increased risk of TAA. Statins use seemed to be protective, although did not reach statistical significance (OR: 0.48, 95% CI 0.23-1.002; p=0.051).

Conclusion: 14.3 % of apparently isolated PMR developed a thoracic aortic aneurysm. Screening with thoracic images in PMR male patients and those PMR patients requiring a prolonged corticosteroid use may be advisable.

Table1. Demographic characteristics in PMR patients with and without thoracic aortic aneurysm.

	PMR with Thoracic aortic aneurysm (n=50)	PMR without aneurism (n=300)	P

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite recent advancements in the evaluation and management of vasculitis, patients with vasculitis continue to encounter diagnostic delays. These delays are often associated with substantial morbidity and mortality. This study sought to describe the diagnostic journey of patients with vasculitis from the onset of symptoms to diagnosis, and identify factors associated with time to diagnosis.

Methods: Patients enrolled in an online registry completed a two-stage mixed-methods study: Stage 1: Survey consisting of open-ended questions about patients' diagnostic journeys and the perceived factors associated with rapid or delayed diagnosis; and Stage 2: Survey with specific questions based on data from Stage 1 and additional investigator-identified factors. Multivariate linear regression analysis was used to identify factors associated with time to diagnosis. Factors were divided into patient-related factors and healthcare-related factors. Patient Research Partners participated in idea conception, study design, and patient-engagement.

Results: 375 patients with vasculitis participated in Stage 1 and 456 patients participated in Stage 2. The median age (IQR) was 59 (24). 72% were females and 94% Caucasians. The majority (74%) of patients sought medical attention within 3 months of their symptoms and 85% were seen by a health care provider within 3 months. The mean time to diagnosis of vasculitis (\pm SD) was 3.3 ± 7 years with IgA-vasculitis having the shortest time (0.3 ± 0.5 years) and Behcet's disease having the longest time (20.4 ± 15 years) (Table 1). 313/456 (73%) of patients were misdiagnosed initially (33% were diagnosed with infections, 29% with an autoimmune disease, and 11% with a "fake" illness). The median (IQR) number of misdiagnoses was 5 (3). 40% of diagnoses were made in a hospital setting (35% inpatient and 5% emergency room [ER]). Only 2% of diagnoses were made at a specialized vasculitis center. More than half of patients had at least 1 ER visit prior to diagnosis, with 5% of patients having > 10 ER visits. Unemployment, time to travel to a medical center greater than 1 hour, being initially misdiagnosed, and delays in seeing a specialist were all associated with longer times to diagnosis (Table 1). 373/456 (82%) of patients reported that a delayed diagnosis had negative consequences on their health: 55% of patients thought it made their condition worse, 16% lost their job, and 11% became disabled.

Conclusion: Patients with vasculitis encounter substantial delays in achieving an accurate diagnosis and these delays are associated with negative health consequences. Both patient-related factors and healthcare-related factors are associated with diagnostic delays. Future efforts should focus on mechanisms to address modifiable factors and shorten delays in diagnosis for patients with new-onset vasculitis.

Table 1. Time to diagnosis and factors associated with time to diagnosis of vasculitis

Time to diagnosis		
Disease type	Number of patients	Mean time to diagnosis (years \pm SD)
Behcet's disease	17	20.4 \pm 15
Central nervous system vasculitis	16	0.6 \pm 1
Cryoglobulinemic vasculitis	15	2.6 \pm 5
Eosinophilic granulomatosis with polyangiitis	60	5.0 \pm 8
Giant cell arteritis	23	1.7 \pm 6
Granulomatosis with polyangiitis	162	1.7 \pm 3
IgA-vasculitis	18	0.3 \pm 0
Microscopic polyangiitis	48	2.5 \pm 5
Polyarteritis nodosa	21	1.5 \pm 2
Takayasu's arteritis	24	2.0 \pm 4
Urticarial vasculitis	13	5.6 \pm 7
Other	39	7.3 \pm 16
Factors associated with time to diagnosis		
Factors	Coefficient (95% CI)	p-value
Patient-related factors		
Female gender	-1.5 (-4.0 - 0.5)	0.15
Caucasian race	-1.5 (-6.0 - 3.0)	0.54
Single or Divorced or Widow(er)	1.1 (-1.0 - 3.2)	0.29
Employed	-2.4 (-4.0 - -0.4)	0.02
Household income >\$50,000/year	-1.5 (-4.2 - 0.6)	0.18
Patient location (North America)	1.2 (-2.0 - 3.8)	0.76
Charlson score >1	-1.5 (-3.9 - 0.4)	0.12
Time to travel to healthcare site >1 hour	2.6 (0.6 - 4.5)	<0.01
Healthcare-related factors		
Specialist involved initially	-1.3 (-3.1 - 0.6)	0.18
Lab studies ordered initially	0.2 (-1.6 - 2.0)	0.80
Misdiagnosis	2.3 (0.1 - 4.5)	0.03
Referral delays due to insurance	-0.3 (-2.5 - 2.5)	0.98
Time to see a specialist > 1 month	2.4 (0.3 - 4.6)	0.03

A positive coefficient indicates a longer time to diagnosis and a negative one indicates a shorter time to diagnosis. CI: confidence interval; \$ are US dollars.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Under reporting of visual impairment attributable to GCA is likely; certificates of visual impairment do not include GCA as a category. Delayed presentation, recognition and treatment are in most cases the reasons that sight loss (SL) is still present in 15-25% of patients at diagnosis. A “Yellow card reporting system” enabled us to characterise the spectrum and severity of visual involvement (VI) attributable to GCA.

Methods: We recorded patients prospectively, with new or relapsing diagnosis of GCA who presented with or without VI over a period of 2 years. We collected demographic information, symptomatology at presentation, medical history, date/dose of initiation of steroids, response to treatment, laboratory results, confirmatory investigations as ultrasound of temporal arteries, biopsy or /and PET, presence of VI with or without loss of acuity, persistence of visual symptoms and findings from formal ophthalmology assessment. SL was defined as symptomatic loss of acuity, field of vision or diplopia ascribable to ischaemic complications of GCA. Patients with transient visual symptoms were not considered to have SL. Analyses were performed using chi-squared and rank sum tests

Results: 388 patients were enrolled from 19 sites. 135 (35%) presented with VI. Patients with VI had mean age of 75.9 (SD 9.3) years, were predominantly females 95 (70%) and all were Caucasian. Headache (84% vs 92%, $p=0.012$) and scalp tenderness (61% vs 75%, $p=0.005$) were less common, but jaw (57% vs 46%, $p=0.040$) and tongue claudication (13% vs 4%, $p=0.004$) were more common at presentation in patients with VI than in those without. Median duration of symptoms prior to diagnosis was 2.0 (IQR 1.0-4.0) weeks. Information was missing regarding type and severity of VI from 4 patients. 33/131 presented with diplopia, 51 with arteritic ischemic optic neuropathy (AION), 7 with central retinal artery occlusion (CRAO); changes were permanent in 36/58 and 5 patients experienced AION as manifestation of recrudescing disease. Headache (75% vs 92%, $p<0.001$) and myalgia/stiffness (25% vs 44%, $p=0.011$) were less common in patients who presented with AION/CRAO than those without. Patients with AION/CRAO were older [mean age 80.9 (SD 6.7) years] compared to those without [73.2 (SD 8.7) years, $p<0.001$]. History of hypertension was more common (70% vs 46%, $p=0.001$) and hemoglobin levels were lower (mean 119.9 mg/dl (SD 16.5) vs 124.4 (SD 15.4), $p=0.018$). Patients with SL presented quicker with median duration of symptoms of 2.0 (IQR 1.0-4.0) vs 3.0 (IQR 1.4-6.0) weeks ($p=0.016$). 44/92 patients who presented with SL had at least unilaterally reduced visual acuity: counting fingers (3), hand movements (4), no light perception (7), light perception (3), 1 reported as blind and 25 had variable severity of unilateral visual acuity loss (from 6/18 to 6/120 based on Snellen chart).

Conclusion: Visual symptoms often leading to SL in GCA require urgent management. Patients with VI were older, without 'typical symptoms' such as headache and polymyalgia but more likely to have ischaemic symptoms, such as jaw and tongue pain and hypertension. Recognition of VI associated features should be embodied in public and professional awareness programs to prevent permanent SL in GCA.

Abstract Number: 819

Use of Takayasu Arteritis Damage Score (TADS) to Measure Damage in Takayasu Arteritis

Sivakumar Mambakkam Rajappa¹ and Krishnamurthy Venkataraman², ¹Rheumatology and Immunology, GLB Hospitals, Chennai, India, ²Rheumatology, Apollo Speciality Hospitals, Chennai, India

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu Arteritis (TA) in India frequently present with complications, indicating the need for a specific damage index to capture the accumulation of disease-related scars over time. Takayasu Arteritis Damage Score (TADS) devised by us is a clinical index for use in these circumstances.

Methods: Disease extent in TA is assessed using the comprehensive tool, Disease Extent Index for Takayasu Arteritis (DEI.Tak). We modified this established score, using a large database of cases previously assessed by us. Items persisting for more six months, related to accumulating scars, were selected while omitting those used infrequently to produce a shorter form with 42 items focused on CVS, particularly pulse loss and vascular interventions. Drug-related damage were also included. This new TADS form was compared to Vasculitis Damage Index (VDI) and PGO using paper cases. It was then applied to analyze a cohort of 286 cases followed in one clinic over 2 decades.

Results: The increase in damage/scars over time correlated closely with disease duration, continuing to increase over 20 years. TADS also related to poor outcomes such as pulse loss. In a cohort of 286 TA patients, the mean age at onset of TA symptoms was 33.74 years (8-42). 142 vascular interventions were performed in 102 of this cohort (34 men, 68 women, mean disease duration 8.9 years). The procedures performed were: Carotid angioplasty + stenting - 29, vertebral angioplasty + stenting-6, grafts from ascending aorta to Carotids-4, subclavian angioplasty + stenting- 22, renal angioplasty + stenting-31, Aortic angioplasty + stenting - 15, coronary angioplasty + stenting- 22 and CABG Surgeries-14. The mean

follow up period was 144 months. Associated clinical features and drug therapy were recorded. Peri-operative complications included infections- 5.2%, Stroke- 8.8%, Myocardial infarction-4.6% and renal failure-4.8%. Drug toxicity and damage were seen in 30%. There were no deaths due to the procedures and TADS scores continued to rise. The patency of stents at 5 and 10 years were 92% and 83% respectively. In the majority (84.7%), drug therapy was also continuing. 32/286 patients died and the scores in fatal disease were higher than in non-fatal cases (7.4 Vs 4.8).

Conclusion: Damage is a significant factor in TA. Vessel occlusion is a major feature of TA, often requiring vascular interventions. Recording the new disease-specific damage score, TADS helps delineate features associated with pulse loss, long-term stent patency, drug induced damage and mortality.

Incidence And Seasonal Variation Of Biopsy-Proven Giant Cell Arteritis – Revisited: A 20-Year Population-Based Study From Sweden

Pavlos Stamatis¹, Carl Turesson², Jan-Ake Nilsson² and Aladdin Mohammad³, ¹Clinical Sciences, Rheumatology Lund, Lund University, Lund, Sweden, ²Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, ³Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the incidence rate and seasonal variation of biopsy-proven giant cell arteritis (GCA) in a well-defined population in southern Sweden.

Methods: The study area was the County of Skane with a total population of 1,324,565 as of December 2016 (37% aged ≥ 50 years). Patients who underwent temporal artery biopsy (TAB) between 1997 and 2016 and lived in Skane at time of TAB were identified using the database at the Departments of Pathology serving Skane. All pathology reports of all TABs performed in the region during the 20-year period were retrieved and reviewed. Only patients with TAB positive GCA were included. The study period was divided into 4 five-year periods to study possible fluctuation of the incidence over time. Date of TAB was used to study possible seasonal variations in the incidence of TAB+GCA. The seasons were defined as follow: winter (December-February), spring (March-May), summer (June-August) and autumn (September-November). Incidence rates per 100,000 persons aged ≥ 50 years are presented.

Results: A total of 5886 TABs were identified during the study time. Of these, 1202 patients (864 females, 72%) were found to have a positive TAB during the 20-year period. The mean age at diagnosis was 75.1 years (SD 8.0) for all patients, 75.4 years (SD 7.8) for women and 74.5 years (SD 8.5) for men. The annual incidence rate of biopsy-proven GCA per 100000 persons in the age group ≥ 50 years was estimated to 13.7 (95% CI 12.9-14.4) and was higher among women (18.4 vs. 8.2 for men, $p=0.04$). There was a decline in the incidence rate over time: 15.8 during period 1 (1997-2001) vs. 12.2 in period 4 (2012-2016), $p<0.01$ (Table 1). The incidence rate of performed TABs declined during the study period, 76.4 (95% CI 72.6-80.6) during period 1 vs. 58.4 (95% CI 55.4-61.5) during period 4, $p<0.01$. There was a seasonal variation in the diagnosis of GCA, with more patients diagnosed during spring and summer compared to autumn and winter (331 patients diagnosed during spring, 319 during summer, 282 during autumn and 270 during winter, $p=0.04$).

Conclusion: The incidence rate of biopsy-proven GCA decreased over time. Similarly, the number of performed TABs decreased during the study period. A possible explanation for this may be an increased use of imaging studies in diagnosing GCA. We also observed a seasonal variation, with more patients diagnosed during spring and summer, possibly due to season related exposures, e.g. infections.

	All	95% CI	Men	95% CI	Women	95% CI
Period 1 (1997–2001)	15.8	14.1 - 17.6	7.9	6.1 - 9.7	15.8	14.1 - 17.6

Comparison of Aortitis Vs Non-Inflammatory Aortic Aneurysms Among Patients Who Undergo Open Aortic Aneurysm Repair

Laarni Quimson¹, Bryan Rea² and Rennie L. Rhee³, ¹Internal Medicine, University of Pennsylvania, Philadelphia, PA, ²University of Pennsylvania, Philadelphia, PA, ³Rheumatology, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Distinguishing aortitis-induced aneurysms from more common non-inflammatory aortic aneurysms is difficult. Aortitis is often incidentally diagnosed upon histologic review after surgical repair of an aneurysm. Earlier detection of aortitis will allow for more prompt therapeutic intervention and possibly improve surgical outcomes. This study examined surgically diagnosed aortitis and identified patient characteristics and imaging findings associated with the disease.

Methods: This is a single-center, case-control study. Cases had biopsy-proven, newly-diagnosed, non-infectious aortitis following open aortic aneurysm surgical repair at the University of Pennsylvania Hospital System between 2012 and 2017. Controls were matched by year of open aortic aneurysm repair and lacked significant inflammation on pathology. Comorbidities, demographics, and laboratory prior to surgery were collected. Radiologic imaging (CT or MRI), including location of aneurysm, size, and rate of progression prior to surgery were also reviewed. The data was compared between aortitis and non-aortitis controls using Wilcoxon signed rank and chi-square or Fisher's exact tests. Backward stepwise logistic regression was used to determine factors independently associated with aortitis.

Table 1. Characteristics of Patients

Characteristic	Aortitis (n=20)	Control (n=11)	P-value
Age at time of surgery	67 (57, 79)	68 (58, 79)	0.78
Female	55%	31%	0.04
White Race	65%	77%	0.36
General Characteristics			
Co-morbidities			
Hypertension	85%	81%	0.74
Coronary artery disease	10%	57%	<0.01
Hyperlipidemia	50%	55%	0.79
Diabetes mellitus	15%	13%	0.96
Smoking history			0.66
Never	35%	47%	
Former	45%	47%	
Current	17%	7%	
BMI	28 (26, 30)	27 (25, 30)	0.89
Pre-surgical Imaging Findings (CT or MRI)			
Location of aneurysm that underwent repair			0.35
Ascending aorta	90%	73%	
Aortic arch	0%	9%	
Descending thoracic aorta	10%	13%	
Abdominal aorta, infrarenal or suprarenal	0%	3%	
Largest diameter of aneurysm, cm	5.7 (5.5, 6)	5.2 (4.9, 5.8)	0.01
Imaging abnormalities of aneurysm			
Wall thickening	15%	0%	0.07
Stenosis/Narrowing	4%	4%	0.98
Calcification or atheroma	17%	50%	0.03
Rate of change in aneurysm, mm/year	3.7 (1.6, 9.1)	-1.3 (-14.0, 1.2)	0.01
	N = 7	N = 7	
Values expressed as median (interquartile range) or percentage			

Table 2. Factors Independently Associated with Aortitis in Multivariate Analysis

	Odds ratio (95% CI)	P-value
Diameter of aneurysm, per cm	8.9 (2.5 – 31.9)	< 0.01
Calcifications and/or atheroma on imaging	0.1 (0.02 – 0.6)	0.01
Location of aneurysm in ascending aorta	76.4 (1.7 – 3393.6)	0.02

Results: 62 patients were included: 31 patients with aortitis and 31 controls (**Table 1**). Compared to controls, patients with aortitis were less likely to have a history of coronary artery disease prior to surgery (10% vs 58%, $p < 0.01$), calcification or atheroma on imaging (27% vs 58%, $p = 0.03$), and calcific atherosclerosis on pathology (35% vs 69%, $p < 0.01$). Aortitis patients had significantly larger aneurysmal diameters at the time of surgery and, among patients with serial imaging, a faster rate of growth of the aneurysm. Multivariable analysis revealed that aortitis is independently associated with a larger diameter of the aneurysm, absence of calcifications or atheroma on imaging, and location of aneurysm in the ascending aorta (**Table 2**).

Conclusion: The study revealed that among patients who undergo open surgical repair of an aortic aneurysm, those with a larger aneurysm diameter, no prior history of coronary artery disease, or absence of atherosclerosis on imaging are more likely to have histologic evidence of aortitis. Patients with these risk factors may benefit from referral to a rheumatologist for further evaluation and assistance with post-operative management.

Immuno-Inflammatory Markers and MR-Angiographic Imaging to Detect Disease Activity in Takayasu Arteritis

Andrea D. Gloor¹, Daniel Yerly², Jennifer L. Cullmann³, Sabine Adler¹ and Peter M. Villiger¹, ¹Department of Rheumatology, Immunology and Allergology, Inselspital, University Hospital of Bern, Bern, Switzerland, ²Department of Biomedical Research, University of Bern, Bern, Switzerland, ³Institute of Diagnostic, Interventional and Pediatric Radiology, Inselspital, University Hospital of Bern, Bern, Switzerland

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an unmet need for tools to quantify local disease activity in TAK.

Methods: Sera of 21 TAK patients, aged between 18 and 56 years and fulfilling the 1990 ACR criteria, were analyzed and compared with age/sex-matched controls (CTRL). Serum levels of 45 biomarkers were quantified using luminex technology. Vasculitis activity was scored in MR-angiography of 15 patients, which had MRA performed within 4 months to serum collection, from 0 (normal) to 3 (intense late enhancement). Disease activity was defined by the NIH criteria (1994).

Results: 4/21 patients showed active disease according to NIH criteria, and MRA signals of 10/15 TAK patients indicated vessel wall inflammation. Most serological molecules did not differ between the TAK cohort and the CTRL or remained undetectable in both cohorts. However, MMP-3 ($p=0.007$), sIL-6R ($p=0.010$), IL-11 ($p=0.021$) and APRIL ($p=0.001$) were elevated in the 22 TAK patients compared to CTRL. BAFF ($p=0.035$) and IFN α ($p=0.025$) directly correlated with MR-vasculitis activity, whereas YKL-40 (AUC=0.897), sILR2 (AUC=0.971) and CD163 (AUC=1) were associated with clinical disease activity. MRA signal intensity did not correlate with clinical disease activity ($p=0.51$).

Conclusion: Our data suggest that YKL-40, sILR2 and CD163 on one side and BAFF and IFN α on the other side may serve as biological mirrors of clinical disease activity and vessel wall inflammation, respectively. The clinical utility of these markers will have to be assessed in a prospective setting.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To correlate survival with clinical, laboratory and histopathological findings in a population based cohort of patients with biopsy-proven giant cell arteritis (GCA) living in the Reggio Emilia area during a 26 years period

Methods: In this population-based study, all patients living in the Reggio Emilia area who underwent temporal artery biopsy (TAB) for suspected GCA from January 1, 1986 to December 31, 2012 were identified. A pathologist with expertise in vasculitis and blinded to clinical data and final diagnosis reviewed all TABs. Based on the localization of the inflammation, positive TABs were classified into 4 categories: small vessel vasculitis (SVV), with inflammation limited to small periadventitial vessels devoid of muscular coat; vasa vasorum vasculitis (VVV), with inflammation surrounding the adventitial vasa vasorum; inflammation limited to adventitia (ILA), with inflammation spreading from vasa vasorum to the adventitia without extension to the media; transmural inflammation (TMI), with external elastic lamina disruption and extension of the inflammation to the media. Histopathologic features evaluated were: the severity of inflammation and intimal hyperplasia, both graded on a semiquantitative scale (mild=1, moderate=2 severe=3), the presence of intraluminal acute thrombosis, calcifications, giant cells, fibrinoid necrosis and laminar necrosis. Information about clinical manifestations, laboratory findings, treatment and disease course were collected. Patients were followed from GCA diagnosis to death, migration or December 2013. Survival was estimated with the Kaplan-Meier method. Univariate and multivariate Cox proportional hazards models were used to evaluate potential predictors of survival at diagnosis.

Results: 281 patients (206 female, 73.3%) with biopsy-proven GCA were identified in the study period. 120 patients (84 female, 70%) died during a median follow-up period of 96 (IQR 55, 143) months. At univariate analysis, the presence of polymyalgia rheumatica (PMR) (HR 0.54, 95% CI 0.37-0.79, p=0.002), higher level of hemoglobin (HR 0.84, 95% CI 0.74-0.96, p=0.011) at disease onset, long-term remission (HR 0.47, 95% CI 0.26-0.86, p=0.015) and ILA or VVV at TAB (HR 0.48, 95% CI 0.24-0.97, p=0.041) were associated with lower mortality, while the evidence of large vessel involvement at imaging studies performed at diagnosis was associated with increased mortality (HR 5.84, 95% CI 1.57-21.8, p=0.009). Multivariate analysis confirmed the association between lower mortality and PMR (HR 0.54, 95% CI 0.36-0.81, p=0.003), higher level of hemoglobin (HR 0.83, 95% CI 0.69-0.99, p=0.049) at disease onset, and ILA or VVV at TAB (HR 0.38, 95% CI 0.17-0.82, p=0.014), and between increased mortality and large vessel involvement at imaging studies performed at diagnosis (HR 5.31, 95% CI 1.39-20.26, p=0.014).

Conclusion: PMR at diagnosis and only adventitial inflammation at TAB seem to identify subsets of biopsy-proven GCA patients with more benign disease, while large vessel involvement at diagnosis a subset with reduced survival.

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate differences between childhood (cPAN)- and adult-onset polyarteritis nodosa (aPAN) patients.

Methods: cPAN patients' clinical findings at onset and outcomes were compared to those of aPAN patients from the French Vasculitis Study Group registry matched for year of enrollment and initial systemic versus cutaneous disease. Their information on medications, disease activity and damage were collected. Kaplan-Meier relapse-free survival curves and the log-rank test were used to analyze cPAN versus aPAN differences for predefined outcomes.

Results: Twenty-one children with systemic and 13 with cutaneous PAN were compared with 84 systemic- and 27 cutaneous-matched aPAN patients. Median follow-up exceeded 5 years for both groups. At study entry, mononeuritis multiplex was less frequent in systemic cPAN than systemic aPAN ($P=0.04$), and purpura and myalgias were less frequent in cutaneous cPAN than cutaneous aPAN ($P<0.03$). During follow-up, systemic cPAN relapsed more often than matched systemic aPAN ($P<0.0001$), while relapse rates were similar for cutaneous disease ($P>0.05$). Mostly minor relapses, predominantly involving the skin, occurred in all 4 groups. At last visit, damage accrual was comparable for cPAN and aPAN patients, but fewer systemic cPAN patients were treatment-free (15% versus 42%; $P=0.03$). Two (6%) cPAN and 8 (7%) aPAN patients died.

Conclusion: Systemic PAN is equally severe in children and adults and carries a higher risk of relapse. The main cutaneous PAN features seem not to be influenced by age at disease onset.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: IgA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. IgA Vasculitis is a predominantly pediatric vasculitis. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment. In this study, we aimed to evaluate the clinical characteristics, treatment, outcome and damage of patients with adult IgA Vasculitis.

Methods: We assembled a retrospective cohort of patients with adult IgA Vasculitis from tertiary Rheumatology Centers in Turkey. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.

Results: The study included 103 (male/ female: 67/36) patients with adult IgA Vasculitis. The mean age was 42.6 ± 17 years. Infection history within 6 weeks before presentation was present in 40 (38.8%) patients (32 upper respiratory tract, 3 urinary tract, 2 gastrointestinal, 3 others). Cutaneous manifestations and arthritis/arthralgia were the most common clinical manifestations (Table 1). Ninety-two (89.3%) patients were treated with oral glucocorticoids (GC). Pulse GC treatment was also given to 29 (28.1%) patients. As additional immunosuppressive agents, azathiopirine was given to 36 (34.9%) and pulse cyclophosphamide to 13 (12.6%) patients. Fifty-nine patients (58.2%) had follow-up of mean 35.6 months. Eleven (18.6%) patients relapsed during follow-up. While 5 relapses were major, six of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 7 (11.8 %) patients. The rate of chronic renal failure was 8.3 % (n=5). Mortality was 1.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.3 in the last visit. Twelve (20.3%) patients had at least one damage item at the end of follow-up period.

Conclusion: Our results showed that approximately one fifth of patients with adult IgA Vasculitis had relapses during follow-up and had at least one damage item at the end of follow-up. Although, 31% of patients had $\text{FFS} \geq 1$, the mortality rate was observed to be very low in the present study.

Table 1: Baseline clinical characteristics of patients with adult Henoch Schönlein Purpura

Adult Henoch Schönlein Purpura (n=103)	
Laboratory parameters	
Anemia (<12 mg/dl for female, <13 mg/dl for male) (n, %)	36 (35%)
Erythrocyte Sedimentation Rate (mm/hour) *	34.7 ± 22
C-reactive protein (mg/l) †	18 (1-297)
Proteinuria (>300mg/24 hours)	47 (45.6 %)
Creatinine (mg/dl)*	0.8 ± 0.3

Does Anti-Glomerular Basement (anti-GBM) Antibody Positivity Correlate with Relapse in Patients with Anti-GBM Disease?

Nicole Droz¹, Alexis Katz², John Sedor³ and Rula A Hajj-Ali^{1,4}, ¹Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, ²Cleveland Clinic Foundation, Cleveland, OH, ³Nephrology, Cleveland Clinic Foundation, Cleveland, OH, ⁴Rheumatic and Immunologic Disease, Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-GBM disease is characterized by rapidly progressive glomerular nephritis with or without pulmonary hemorrhage. It is usually monophasic in nature and disease severity correlates with antibody titer. The disease is mediated by pathogenic antibodies directed against the non-collagenous region of the $\alpha 3$ chain of type IV collagen. Despite the known pathogenicity of anti-GBM antibodies, and the correlation of disease severity with their titers, there is conflicting reports on whether anti-GBM antibody positivity correlates with disease relapse on long term follow up. The objective of this study was to assess for correlation of anti-GBM antibody positivity and disease relapse in patients with anti-GBM disease.

Methods: Patients seen in a single academic center between 1997 and 2017 were initially screened for the presence of anti-GBM disease by ICD 9/10 code for anti-GBM disease or Goodpasture's syndrome. 435 patients were identified. Patients were then included in the study if the diagnosis was confirmed by a board certified rheumatologist or nephrologist at our institution and had positive anti-GBM antibodies or biopsy results consistent with a diagnosis of anti-GBM disease. Relapsing disease was defined as recurrence of glomerulonephritis or pulmonary hemorrhage after the initial presentation that necessitated a change in therapy. The primary endpoint of this study was anti-GBM antibody positivity at the time of relapse. All charts were reviewed for baseline demographics, clinical manifestations, anti-GBM antibody and ANCA positivity at the time of initial presentation; these were compared between those with relapsing and non-relapsing disease. Results were analyzed using a two tailed standard t-test. These same characteristics were also examined in the relapsing cohort at the time of relapse.

Results: 40 patients were confirmed as having anti-GBM disease at our institution. Mean follow up from disease onset to the date of last follow up was 56.2 months. 8 patients had relapsing disease and 32 patients had non-relapsing disease. Baseline characteristics and clinical manifestations were similar between groups (Table1). Patients with relapsing disease had a statistically higher incidence of ANCA co-positivity as compared to non-relapsing patients (62.5% vs. 21.7% respectively p value- 0.03).

In patients with relapsing disease, only 14.7% (1/7 tested patients) had positive anti-GBM antibodies at the time of their relapse.

Conclusion: In this study, anti-GBM positivity did not correlate with disease relapse in patients with anti-GBM disease. Patients with relapsing disease had a higher incidence of ANCA positivity, consistent with previous investigations. In patients with newly diagnosed anti-GBM disease, ANCAs should be obtained to assess for the risk of relapse and to help guide long term follow up and treatment. Larger studies are needed to validate our results.

Table 1: Baseline demographics, clinical features and laboratory values at baseline and at the time of relapse of anti-GBM disease

		Non-relapsing anti-GBM disease (n=32)	Relapsing anti-GBM disease (n=8)	p-value

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid vasculitis (RV) is a rare systemic inflammatory process affecting small to medium sized blood vessels in patients with rheumatoid arthritis (RA). RV confers high morbidity and mortality, and evidence regarding safe, effective treatment options is lacking. Our study aims to characterize the indication, outcomes and adverse effects of rituximab treatment in a large single center cohort of RV patients.

Methods: Patients evaluated with systemic RV from 2000 to 2017 who were treated with rituximab were retrospectively identified through direct medical chart review. Patients who received rituximab for an indication other than RV, were treated at an outside institution, or for whom follow-up information was unavailable were excluded. Clinical characteristics, treatment, outcomes and adverse effects were analyzed.

Results: 17 patients with RV who were treated with rituximab were identified. Mean age at RV diagnosis was 59.2 (range:38-77), 59% were female, 94% were Caucasian and 76% had positive rheumatoid factor (RF). At time of initiating rituximab therapy, the median BVAS/RA was 4.0 (IQR, 2.0-7.5). RV presented in the skin in 9 patients (53%, ulcers and/or leukocytoclastic vasculitis), as mononeuritis multiplex in 2 (12%), inflammatory ocular disease in 2 (12%), and affected multiple organ systems in 4 (24%).

Rituximab was used as first-line induction therapy in 8 (47%) patients, first-line for relapse in 4 (24%), second-line in 2 (12%), and third- or fourth-line or in combination with another agent in 3 (18%). 15 patients had follow-up information recorded at 3 and 6 months from rituximab use. At 3 months, 2 (13%) had achieved complete remission (CR), and 10 (67%) had achieved partial remission (PR). At 6 months, 6 patients (40%) had achieved CR, 8 (53%) had achieved PR, and 1 patient had no response (NR). 8 of 13 patients with available records (62%) had CR at 12 months, and 5 patients (38%) had PR.

There were no significant differences in age, sex, smoking status, BMI, duration of RA, baseline RA characteristics, DAS28-CRP(3) or BVAS-RA baseline scores, RA treatments prior to development of RV, or type of RV presentation when compared between groups who did and did not achieve complete remission at 6 months.

10 (59%) of 17 patients experienced no adverse effects, 4 (24%) of 17 experienced mild adverse effects (infusion reaction, rash, infection requiring oral antibiotics) and 3 (18%) of 17 required hospitalization; 2 with infection requiring IV antibiotics and 1 with pneumocystis pneumonia. There were no deaths as a result of rituximab use.

Conclusion: Systemic RV is difficult to treat effectively. Complete remission of RV was achieved in 62% of patients and partial response in 38% within 12 months of rituximab use. Rituximab represents an effective treatment option for RV with an acceptable side effect profile. Further evidence is needed to inform treatment for patients with RV.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary systemic vasculitis, especially eosinophilic granulomatosis with polyangiitis and polyarteritis nodosa, can be associated with blood and tissue eosinophilia. Conversely, eosinophilia in the context of hypereosinophilic syndrome (HES) may involve various organs, including blood vessels. While HES-related superficial and/or deep venous thromboses have been extensively reported, little is known about its medium- and small-sized-vessel involvement.

Methods: This multicenter retrospective study concerned patients with medium/small-sized-vessel vasculopathy and eosinophilia $>1,000/\text{mm}^3$. Patients with cardiac embolism or preexisting thrombophilia and those with primary systemic vasculitis (as defined by the 2012 revised International Chapel Hill Consensus Conference) were excluded.

Results: Among 13 patients with eosinophilia and medium- and/or small-sized-vessel involvement, 1 had mononeuritis multiplex with biopsy-proven eosinophilic vasculitis and 1 had retinal vasculitis and coronary spasm. For the remaining 11 patients (median age: 43 (21–62) yr), clinical characteristics included distal ischemia (digital ischemia and/or necrosis for 9 and pulse abolition with paresthesia for 2), with splinter hemorrhages for 5, purpura for 2 and Raynaud's syndrome for 2. Eosinophilia had been detected before vasculopathy onset for 6 patients and concomitantly for 5. Their etiological work-ups for eosinophilia, including the search for the FIP1L1-PDGFR α fusion transcript and T-cell lymphoproliferative disorders, were unremarkable. At vasculopathy diagnosis, median eosinophil count was $5,500/\text{mm}^3$ ($2,500\text{--}9,000/\text{mm}^3$). Doppler ultrasonograms of 9 patients revealed arterial thrombosis in 5 and/or stenosis in 4. Magnetic resonance imaging, CT angiography or arteriography, obtained for 7 patients, showed thrombosis and/or vascular involvement. Two patients had histological evidence of small-vessel vasculitis. First-line therapies included glucocorticoids (GCs) for 9, antiplatelet drugs for 9, anticoagulants for 7, iloprost for 3, immunosuppressants for 2 and anti-eosinophil drugs for 2. Eight of the 11 patients entered remission but 3 of them relapsed and 1 required high-dose GCs. Seven (63%) patients received further-line treatments, including immunosuppressants for 4 and/or anti-eosinophil drugs (interferon- α , imatinib, hydroxycarbamide or cyclosporine) for 5. Despite initially severe disease, 10 patients had complete remissions when their eosinophil counts normalized and 1 required transmetatarsal amputation prior to remission. During follow-up, clinical status always corresponded to blood eosinophilia.

Conclusion: Medium- and small-sized-vessel vasculopathy associated with eosinophilia is a rare entity, frequently manifesting with distal ischemia that may not fulfill primary systemic vasculitis criteria but is consistent with HES. Despite initially severe disease, favorable outcomes were obtained for most cases with immunosuppressants and/or anti-eosinophil drugs.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Direct Acting Antiviral(DAA) agents were shown to be effective for treatment of HCV induced Cryoglobulinemic Vasculitis (HCV/CV+). Some reports showed failure of DAAs to reduce Hepatocellular carcinoma (HCC) development in HCV patients or the high risk of HCC. Although HCV replication results in hepatic stress which is associated with DNA damage, the impact of DAA on the host response to DNA damage is unknown. Our aim was to assess DNA damage and repair in CV patients treated with DAAs.

Methods: This study included 32 Egyptian patients with HCV/CV+ diagnosed according to the validated 2014 classification criteria of CV. We applied 3 DAA protocols: Sofosbuvir(SOF) plus Ribavirin (RBV) plus pegylated interferon (p-IFN) for 3 months (8 patients), SOF plus RBV for 6 months (13 patients) or SOF plus Daclatasvir for 3 months (11 patients). We measured DNA damage levels in peripheral blood cells as well as DNA repair genes (TOP1, TOP2A, TDP1, TDP2, XRCC1 and PARP1) in 3 groups: healthy individuals (n=9), HCV patients without CV (HCV/CV-) (n=13) and in HCV/CV+ patients: before and at end of treatment (EOT) (n=32), at 6 months; 3 months follow up from EOT (n=19) and at 12 months follow up (n=23). Data is reported as mean \pm SEM. *= $p<0.05$, **= $p<0.005$.

Figure 1: DNA damage levels: Healthy individuals (n=9), HCV-CV patients (n=13), HCV+CV at pretreatment (n=32), EOT (end of treatment) (n=32), 6 months (n=19) and 12 months (n=23).

Results: All patients showed viral clearance without recurrence, in all 3 protocols. All Patients improved clinically and serologically at EOT. After 12 months, only articular and constitutional manifestations as well as cryocrit % showed significant relapse (P value 0.009, 0.006, 0.002 respectively). HCV/CV+ patients showed increasing levels of double-strand breaks (DSBs) at EOT ($p < 0.05$) and at 6 months point ($p < 0.05$). However, at 12 months point, DSBs returned to pretreatment levels (**Figure 1**).

We found no studies investigating DNA repair genes during HCV infection. We report reduced expression of all tested DNA repair genes in HCV/CV+ patients compared to patients with HCV/CV- (**Figure 2**).

Figure 2: Repair genes expression levels: HCV-CV patients (n=13), HCV+CV at pretreatment (n=32), EOT (end of treatment) (n=32), 6 months (n=19) and 12 months (n=23).

Conclusion: The reported elevated levels of chromosomal breaks and the reduced expression of all tested DNA repair genes with DAAs in treating HCV/CV+ instigate deeper and more extended studies to understand the nature of our findings and evaluate the safety of these drugs.

Primary Central Nervous System Vasculitis with Tumor-like Presentation

Carlo Salvarani¹, Robert D. Brown Jr², Teresa J. H. Christianson³, Caterina Giannini⁴, John Huston III⁵ and Gene G. Hunder⁶, ¹Azienda USL-IRCCS di Reggio Emilia e Università di Modena e Reggio Emilia, Reggio Emilia, Italy, ²Department of Neurology, Mayo Clinic, Rochester, MN, ³Division of Biomedical Statistics & Informatics, Mayo Clinic, Rochester, MN, ⁴Division of Anatomic Pathology, Mayo Clinic, Rochester, MN, ⁵Mayo Clinic, Rochester, MN, ⁶Rheumatology, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to determine the frequency of ML in a large cohort of patients with PCNSV and compare the presenting clinical, laboratory, and imaging features in those with ML to those without.

Methods: We retrospectively studied a cohort of 191 consecutive patients with PCNSV who were seen at the Mayo Clinic, Rochester, MN over a 35- year period (1982-2017). The diagnosis of PCNSV was based on brain/spinal cord biopsy or

cerebral angiography. Cerebral biopsy specimens were reviewed by one pathologist (CG) without knowledge of clinical information. Comprehensive information about clinical manifestations at presentation and during the follow-up, laboratory investigations, radiological imaging, results of CNS biopsy or autopsy, type of, duration of, and response to treatment, number of relapses, functional status at last follow-up, and cause of death were recorded. We compared PCNSV patients with tumor-like presentation to those without.

Results: 13/191 (6.8%) patients had tumor-like presentation. In all 13 patients PCNSV diagnosis was established by cerebral biopsy (stereotactic in 10, open-wedge in 3). 4 patients had cerebral angiography, and vasculitis was suggested in one patient. A granulomatous inflammatory histologic pattern was found in 11 biopsies, accompanied by vascular deposits of β -amyloid peptide in 7. In the other 2 biopsies a lymphocytic vasculitis was observed. The 13 patients with tumor-like presentation were compared with the 178 patients without. The patients with ML were more frequently males (77% vs 44%, $p = 0.04$), were less likely to present with transient ischemic attacks (TIA) (0 vs 27.5%, $p = 0.023$) and more likely to present with seizures (46% vs 17%, $p = 0.022$). No significant differences in the CSF findings and ESR levels (normal in 100% and 82% of the patients, respectively) at diagnosis were observed in the two groups. Gadolinium-enhancing lesions were more frequently observed in patients with ML (77% vs 37%, $p = 0.007$). The frequencies of PCNSV recurrence (38% vs 29%), patients not requiring therapy at last follow-up (15% vs 25%), response to therapy (100% vs 74%), and poor outcomes (modified Rankin disability score ≥ 4) at last followup (8% vs 26%) were not significantly different in the two groups. No differences in survival were observed between the 2 groups ($p = 0.57$). Considering all 191 patients, univariate Cox proportional hazards modeling showed an increased mortality rate in those with increasing age (hazard ratio, HR, 1.4), cerebral infarction on initial MRI (HR 2.95), and angiographic large vessel involvement (HR 3.2), while mortality rate was lower in those with gadolinium-enhancing lesions on MRI (HR 0.3).

Conclusion: Tumor-like presentation represents a small subgroup of patients with PCNSV, and are often associated with vascular deposits of β -amyloid at biopsy, have seizures as presenting manifestation and gadolinium-enhancing cerebral lesions on MRI. As in PCNSV without ML, treatment response and prognosis was favorable in most patients.

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In addition to high antiviral efficacy, the new anti-HCV regimens (DAA) can improve most systemic manifestations of patients with HCV-mixed cryoglobulinemia vasculitis(HCV-CryoVas). However, 6 to 12 months after DAA, 50% to 61% of HCV-CryoVas patients still have detectable cryoglobulinemia and some of them still complain of CryoVas manifestations. The aim of the present study was to search for the presence of HCV RNA in serum and cryoprecipitate of HCV-CryoVas patients who had a sustained virological response after DAA and who remain cryoglobulin-positive.

Methods: Samples of patients who had systemic manifestations of CryoVas, including 15 HCV-infected and 4 HCV-noninfected patients were analyzed. All HCV-infected patients received all-or alinterferon-free combinations for 12 to 24 weeks. Cryoglobulins were precipitated during 7 days at 4°C, then cryoprecipitates were washed. Cryoglobulins were quantified by spectrophotometry and identified by immunofixation. HCV RNA viral loads were performed on sera and cryoprecipitates (after dilution) by the automated Roche Cobas® 6800 platform (limit of detection: 15 IU/mL).

Results: HCV-infected CryoVas patients were aged 59±10 yrs, 9 females, 44% cirrhotics, 69% genotype 1 and 30% treatment-naïve. Patients received DAAs, i.e. SOF/RBV (N=7), SOF/DACLA (n=6), SOF/SIME (n=2), and SOF/DACLA/RBV (N=1). Three groups of HCV patients were defined based on the presence of HCV RNA (in serum and/or cryoprecipitate) and clinical manifestations of CryoVas (**Table 1**). Group 1 included samples of 5 patients with symptomatic CryoVas before DAAs. They all showed HCV positive viral load in serum and cryoprecipitate. Other patients with either both positive cryoglobulin and symptomatic CryoVas (group 2, n=4) or positive cryoglobulin and no symptom of vasculitis (group 3, n=6) proved all negative for the presence of HCV RNA in serum and cryoprecipitate after sustained virological response to DAAs. In addition, 4 HCV-seronegative patients who had symptomatic CryoVas were all negative for the presence of HCV RNA in their serum and cryoprecipitate.

Conclusion: HCV-CryoVas patients who have a sustained virological response after DAA and who remain cryoglobulin-positive (symptomatic or not) do not have HCV RNA particles in their cryoprecipitate anymore. In such cases, the cryoglobulin production with or without vasculitis manifestations became autonomous and independent of HCV antigenic stimulation.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunoglobuline A (IgA) Vasculitis, formerly known as Henoch-Schönlein purpura, is a small-vessel leukocytoclastic vasculitis due to deposition of IgA1, a subclass of IgA. Although it is mainly a pediatric disease, it can

affect adults with an incidence rate of 1-8 cases/1000000 patients/year and it is reported to have a more aggressive course and worse renal outcome. There are scarce studies analyzing this association, and none in our region. The purpose of the study is to describe the different features of the disease (clinical, laboratory, treatment and prognosis) both in pediatric and adult patients, and evaluate the differences between these groups, especially regarding renal outcome.

Methods: We performed a retrospective review of the electronic medical records of all the patients with IgA vasculitis that were followed in a university hospital between 01/01/2000 and 05/01/2018. We included all patients that fulfilled the EULAR/PRINTO/PRES 2010 criteria (European League Against Rheumatism/Paediatric Rheumatology International Trials Organisation/Paediatric Rheumatology European Society), and collected and analyzed demographic, clinical, treatment and histopathologic information available on their medical records. We considered pediatric patients those who were under 20 years when they were diagnosed.

Results: One-hundred eighteen patients were included, being 107 pediatric and 11 adults.

Table 1 shows demographic information, clinical manifestations, predisposing factors, treatment used, relapses, kidney outcome and deaths in both groups.

In our cohort, the adult group had more renal involvement. Kidney biopsy was performed in 5/8 of the affected patients, with confirmatory histopathology for IgA vasculitis in all of them.

Since adults showed more severe clinical manifestations, significantly more corticosteroids and immunosuppressants were used in this group.

As a consequence of the vasculitis, 2 of the affected adults suffered from chronic kidney disease, one of them required kidney transplant. No pediatric patient presented chronic kidney disease.

Finally, 2 deaths were found, both in the adult group, but only one related to the disease.

Conclusion: In our cohort, adult patients with IgA vasculitis suffered a more aggressive disease, with more renal involvement and required more intense treatment.

Table 1.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a multi-system disease characterised by episodes of progressive inflammation and subsequent degeneration of cartilage and connective tissue throughout the body. RP can be associated with significant morbidity and increased mortality. Respiratory manifestations include large and small airway disease. Tracheobronchomalacia is one of the severe forms of respiratory involvement and can lead to sudden death due to collapse of the airways. RP is a rare condition with incidence of around 1 in a million. We present 11 patients who presented with severe airways disease, and subsequently were diagnosed as relapsing polychondritis from one centre in UK with catchment area of around 500,000.

Methods: The index case was diagnosed at Louise Coote Unit with RP on the basis of tracheobronchomalacia, bilateral auricular chondritis, nasal chondritis, costochondritis and inflammatory arthritis.

All patients had presented to the difficult airways clinic at University Hospital Coventry and Warwickshire NHS Trust (UHCW) in Coventry with severe breathlessness, cough and monophonic wheeze or been admitted as emergency with severe 'exacerbation of asthma'. RP was diagnosed using the McAdam criteria) and disease activity assessed using the Relapsing Polychondritis Disease Activity Index (RPDAI). Tracheobronchomalacia was usually initially suspected on clinical examination particularly the presence of fixed inspiratory or harsh monophonic inspiratory and expiratory wheeze. Diagnosis of tracheobronchomalacia was confirmed by a combination of lung function testing, inspiratory and expiratory CT and bronchoscopy.

Results: All patients had three or more of the six diagnostic clinical features described by McAdam et al. (1976). There was considerable delay from the onset of respiratory symptoms to the diagnosis of RP. Flow-volume loops demonstrated flattening of usually expiratory curves (intrathoracic). CT showed obvious dynamic major airway collapse on expiratory films in the majority. Other manifestations of autoimmunity, such as anti-phospholipid syndrome, or other autoimmune conditions were present in 5 patients.

Patients were initially treated with a combination of oral prednisolone and methotrexate or azathioprine. 3 patients were treated with IV Cyclophosphamide, although none responded. Five patients have been treated with continuous positive airway pressure (CPAP) to palliate airway collapse. Anti-TNF treatment was tried in 3 patients (Infliximab in one with good response, Etanercept in another 2 without response). One of these has now been switched to Abatacept, whilst the other is due to start Secukinumab.

Conclusion: Obstructive small or large airways disease is a common presentation for relapsing polychondritis which is contrary to previous reports.

Monophonic wheeze should encourage investigations for tracheobronchomalacia.

Koster¹, ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Health Sciences Research, Mayo Clinic, Rochester, MN, ³Rheumatology, Division of Rheumatology, Mayo Clinic College of Medicine, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis Poster I: Non-ANCA-Associated and Related Disorders

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Differences in both presentation and outcome based on age of diagnosis have been described in patients with IgA vasculitis (IgAV) but data are limited due to cohort size and follow-up duration. The aim of this study was to describe the clinical characteristics and outcome of a large single-institution cohort of biopsy-proven IgAV.

Methods: Patients with biopsy-proven IgAV from 1997 to 2016 were retrospectively identified. Clinical characteristics, laboratory parameters and outcomes were abstracted from direct medical chart review. Proteinuria was classified as non-nephrotic (≥ 0.2 g/d, ≤ 3.5 g/d) or nephrotic (> 3.5 g/d). Microscopic hematuria was defined as ≥ 5 RBCs/hpf or $\geq 2+$ on dipstick. Disease activity at each follow-up visit was categorized as complete response (normalization of all baseline abnormalities due to IgAV), partial response, non-response (lack of improvement of any abnormalities due to IgAV) or relapse (development of clinical signs of IgAV after a symptom-free period of at least one month). Prevalence of disease activity was estimated using multi-state models, which account for competing risks.

Results: A total of 243 IgAV patients were identified (97% Caucasian, 58% male). 174 patients were adults (> 21 years) and 69 were < 21 years. ACR criteria were met in 98% of adults and 100% of patients < 21 years. Compared to patients < 21 years, adults at baseline had more frequent ulcerative skin lesions (11% vs. 1%; $p=0.02$) and nephrotic-range proteinuria (22% vs. 3%; $p=0.007$) but less commonly had abdominal pain (34% vs. 61%; $p<0.001$), ischemic gastrointestinal involvement (10% vs. 20%; $p=0.04$) and arthralgias (38% vs. 61%; $p<0.001$). Frequency of baseline microscopic hematuria was similar between groups (47%). 8 adults, but no patients < 21 years, presented with end-stage renal disease. Oral (80%) and topical (23%) corticosteroids were the most common initial treatments used. Conventional immunosuppressive drugs were used at diagnosis in only 12% of patients.

Dialysis was required in 13 patients (8 adults) and renal transplant was performed in 4 cases (1 adult). Of 137 patients with hematuria during the study, 72% had complete resolution of hematuria by 1 year after onset, compared to 50% of 179 patients with proteinuria. The prevalence of disease activity state at each follow-up time point is shown in figure 1. During 389 person-years of follow-up, 29 deaths were observed. Five year survival rates (95% CI) for patients aged < 21 , 21-50, and 51+ years were 100%, 94% (87, 100) and 40% (26, 63), respectively ($p<0.001$). Standardized mortality ratio for patients aged 21-50 years at diagnosis was 5.62 (0.68, 20.3) and 7.60 (5.0, 11.1) for those 51 or older.

Conclusion: IgAV in adults is associated with more severe skin and kidney involvement, poorer renal outcome and increased mortality compared to patients diagnosed before 21 years of age.

Figure 1: Prevalence of IgA vasculitis disease state at each study time point during follow-up. Overall, patients spent 40% of time in complete response during the first 5 years after diagnosis, 20% in partial response, 6% in relapses, and 8% in non-response (nonresp). At 5 years after diagnosis 30% of the cohort was deceased.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: ACR Abstract: Plenary Session I

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: The diagnosis of ankylosing spondylitis (AS) is delayed by on average 8–11 years after the onset of symptoms, and there is increasing evidence that early intervention in the disease can lead to better outcomes for patients. Early diagnosis of AS is challenging and the performance is still imperfect, even with magnetic resonance imaging (MRI). Whilst genetic risk scores (GRS) utilising only genomewide-significant associated SNPs capture only a small proportion of total heritability and consequently have modest discriminatory capacity, polygenic risk scores involving hundreds to many thousand SNPs capture a higher proportion of overall disease heritability and have greater discriminatory capacity and accuracy in disease-risk prediction.

Methods: In this study, we developed two polygenic GRS, one for AS based on European-descent samples (7,742 AS patients and 14,542 controls), and a second based on East Asian-descent samples (6,001 AS patients and 4,943 controls). AS was defined according to the Modified New York Criteria and all the samples were genotyped using Illumina CoreExome microarrays involving ~270,000 SNPs after quality control. The European-GRS involved 3,947 SNPs and East Asian-GRS 8,659 SNPs. Validation was performed using 10-fold cross-validation in the originator population, and also tested in Turkish (873 patients and 961 controls) and Iranian case-control cohorts (430 AS patients and 761 controls). Genetic risk scores were calculated using the adaptive MultiBLUP algorithm (Speed and Balding, Genome Res, 2014). Discriminatory capacity was tested by receiver operating characteristic analysis, and reported as area under the curve (AUC), with sensitivity and specificity reported at the best Matthews correlation coefficient.

Results: For the European GRS the AUC was 0.92 (83% sensitivity, 92% specificity), compared with 0.87 by using imputed HLA-B27 status alone ($P=2.4 \times 10^{-10}$ vs GRS). In the East Asian cohort, the AUC is 0.95 (91% sensitivity, 95%

specificity). The risk score in AS patients is significantly higher than the score in controls in both cohort ($p < 2.2 \times 10^{-15}$). Both models showed moderate discriminant capacity in other ethnics groups (European model AUC 0.85, 0.85 and 0.78 in the Turkish, Iranian and East Asian cohorts respectively; East Asian model AUC 0.84, 0.87 and 0.88 in the Turkish cohort, Iranian and European cohorts respectively).

Conclusion: Our results indicate that in AS GRS has high discriminatory capacity and could be of clinical utility in early diagnosis. Given that the AUC for MRI imaging is currently thought to be 0.90, this data suggests that genetic test scoring performs at least as well as the current gold standard imaging procedure. Given the cost of a SNP microarray is <\$US50, this test is potentially far cheaper than MRI and less expensive than traditional HLA-B27 testing.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: ACR Abstract: Plenary Session I

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Rheumatoid arthritis (RA) patients have 2.75 fold increased risk of influenza and influenza-related illness than age-matched healthy controls. For this reason, RA patients are a priority group for annual vaccination. Although vaccination is currently the most effective intervention against influenza and its associated complications, vaccine induced antibody responses and protection in RA are low. It is unknown if the use of a high dose vaccine (high dose trivalent inactivated influenza vaccine: HD-TIV) can improve protection over that conferred by the standard vaccine (standard dose quadrivalent inactivated influenza vaccine: SD-QIV) in RA.

Methods: We conducted a treatment-stratified, randomized, modified double-blind, active-controlled trial in adult seropositive RA patients (rheumatoid factor and/or anti-cyclic citrullinated peptide antibodies) to assess antibody responses to either SD-QIV (15 µg of hemagglutinin (HA) per strain) or HD-TIV (60 µg of HA per strain) (NCT02936180). Subjects were recruited at a tertiary care center during the 2016–2017 (year 1) and the 2017–2018 (year 2) Northern-Hemisphere influenza seasons. They were stratified by the treatment received for 3 months prior to enrolment and during the study: DMARDs (Group 1-G1), anti-cytokine therapy (G2), anti-B-cell therapy and small molecules (G3). Seroconversion (SC) and seroprotection (SP) rates were assessed using pre- (Day 0 – D0) and post-vaccine (D28) serum hemagglutination inhibition (HI) titers. SC was defined as at least a four-fold HI antibody increase from D0. SP rate was defined as percent with HI titres $\geq 1:40$ at D28. Vaccine strains were A/HongKong/4801/2014(H3N2), B/Brisbane/60/2008 in Y1/2 with A/California/7/2009(H1N1) in Y1 and A/Michigan/45/2015(H1N1) in Y2.

Results: A total of 279 seropositive RA patients were enrolled. 140 (50.2%) received SD-QIV and 139 (49.8%) received HD-TIV. The mean age (\pm SD) was 61.0 ± 12.9 and 80% were female. According to treatment, 138 (49.5%) patients were in G1; 92 (33%) in G2 and 49 (17.6%) in G3. SP rates pre-vaccine were comparable between HD-TIV and SD-QIV groups. Overall responses to vaccination were consistently higher with the HD-TIV. SC (H3N2 22.3% vs 8.6%; B/Bris 44.6% vs 28.6%; H1N1 51.1% vs 30.0%) and SP rates (H3N2 48.5% vs 30.9%; B/Bris 60.9% vs 50.7%; H1N1 80.4% vs 73.5%) were seen in patients that received the HD-TIV compared to the SD-QIV. In logistic regression models including age, vaccine type, treatment (G1, G2 and G3); Charlson comorbidity index, and RA duration; vaccine dose and age were the only predictors of the influenza vaccine sero response. Patients that received HD-TIV were 2.8 times more likely to

H3N2 seroconvert (odds ratio 2.84; 95% confidence interval 1.38 - 5.87), 2 times more likely to B/Bris seroconvert (1.91; 1.15-3.17), and 2.3 times more likely to H1N1 seroconvert (2.33; 1.42-3.85).

Conclusion: In seropositive RA patients, the use of HD-TIV substantially improves the immune response to vaccination compared to SD-QIV. This is the first study documenting a successful intervention to enhance vaccine responses in immunocompromised hosts.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: ACR Abstract: Plenary Session I

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Interstitial lung disease (ILD) accompanied by anti-melanoma differentiation-associated gene 5 (MDA5)-positive dermatomyositis (DM) is often rapidly progressive and associated with poor life prognosis in Japanese patients. However, the standard treatment for such intractable cases had not been established, although some case reports have suggested possible efficacy of combined immunosuppressive therapy. Therefore, we evaluated the efficacy and safety of combined immunosuppressive regimen as a prospective trial for anti-MDA5-positive DM with ILD.

Methods: Anti-MDA5 was detected by protein-immunoprecipitation using ^{35}S -methionine-labeled HeLa cells. Newly onset adult Japanese anti-MDA5-positive DM patients with ILD were enrolled in multi-centers from July 2014 to September 2017. They were treated with combined immunosuppressive regimen of high-dose glucocorticoids (GC), tacrolimus, and intravenous cyclophosphamide. Plasmapheresis was also added if the patients got worse and needed oxygenation even after the regimen started. As the primary endpoint, their six-month survival was compared with a historical control of anti-MDA5-positive DM with ILD who received step-up treatment started with high-dose GC and gradually intensified by the addition of immunosuppressants. The alteration of serum ferritin level, anti-MDA5 titer (MESACUPTM anti-MDA5 test), and respiratory functions were also compared before and after treatment.

Results: The combined immunosuppressive regimen group (n=26) showed significantly better survival than the historical control (n=15) (6-month survival; 89% and 33%, respectively, $p<0.0001$) (Figure 1). At week 52, anti-MDA5-titer and serum ferritin level were decreased and %vital capacity was increased (Figure 2). During 52 weeks, cytomegalovirus reactivation was frequently observed in the combined immunosuppressive regimen group (90% vs 33%, respectively, $p=0.0002$). When the survived (18 cases) and the deceased (4 cases) in combined immunosuppressive regimen group were compared, frequency of skin ulcer (11% vs 75%, respectively, $p=0.01$), positivity of CRP (39% vs 100%, respectively, $p=0.01$), and serum ferritin level (468.3 ± 561.8 ng/mL vs 2050.3 ± 1772.8 ng/mL, respectively, $p=0.01$) before treatment were significantly higher in the deceased patients.

Conclusion: Early treatment with combination immunosuppressive therapy improves the survival of anti-MDA5-positive DM with ILD. Opportunistic infections such as cytomegalovirus reactivation should be carefully monitored and treated during the treatment.

Fibromyalgia Is Identified in Routine Care on Indices Derived from an MDHAQ (MultiDimensional Health Assessment Questionnaire) with Robust Agreement with 2011 Revised Fibromyalgia Criteria Questionnaire

Juan Schmukler, Jacquelin R. Chua, Mariam Riad, Isabel Castrejón and Theodore Pincus, Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: ACR Abstract: Plenary Session I

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Fibromyalgia (FM) generally is easily diagnosed, but maybe complex, particularly in patients who meet criteria for other rheumatic diseases. FM criteria have been revised in 2011, based entirely on a patient self-report questionnaire. However, these criteria generally are rarely used in routine clinical care because it is not feasible to use multiple patient questionnaires in busy clinical settings. An MDHAQ (multi-dimensional health assessment questionnaire) documents change in status in all rheumatic diseases in which it has been studied, and includes scales for pain, fatigue, symptom checklist, self-report painful joint count, and RAPID3 which are similar to the FM criteria questionnaire. We analyzed 5 indices based on MDHAQ scales for agreement with 2011 FM criteria in patients seen in routine clinical care.

Methods: All patients with all diagnoses complete an MDHAQ at all visits in routine care at one setting. The FM criteria questionnaire was added over a 3-month period to be completed by consecutive patients. The poly symptomatic distress (PSD) scale is derived from the FM questionnaire and indicates degree of FM symptoms. All MDHAQ scores were analyzed initially for agreement with FM Criteria questionnaire according to receiver operator characteristic (ROC) curves for area under the curve (AUC), and compiled into indices of 3 or 4 measures based on the highest results. The indices were then analyzed for AUC and cut points based on specificity and sensitivity identify to score 0 or 1 for a 0-3 index of 3 measures or 0-4 index of 4 measures, and correlations.

Results: Five different MDHAQ-FM indices were developed from the 5 MDHAQ scales with the highest AUC vs 2011. Criteria: symptom checklist, self-report painful joint count, fatigue, RAPID3, and pain scale. Three indices of 3 measures, termed MDHAQ-FM3, all included symptom checklist and self-report painful joint count; MDHAQ-FM3-P added a pain VAS, MDHAQ-FM3-F a fatigue VAS, and MDHAQ-FM3-R a RAPID3 score. Two MDHAQ-FM4 indices added fatigue VAS to symptom checklist and self-report painful joint count; MDHAQ-FM4-P included a pain VAS, MDHAQ-FM4-R RAPID3. The five different MDHAQ FM indices all agreed with the 2011 criteria with ROC AUC higher than 0.924 ($p=0.21$ for 5 indices), Correlations for 2011 criteria were all higher than 0.83 ($p<0.001$), and Agreement of the 5 indices with FM criteria was greater than 84.3% (table), these findings indicates robust capacity to identify FM similarly to the FM Criteria questionnaire.

	Contents:					Compared to 2011 FM Criteria		
	Pain VAS 0-10	Fatigue VAS 0-10	RAPID3 0-30	Symptom checklist 0-16	Self-report painful joint count 0-54	AUC for ROC Curves	Corre-lation With (PSD)	% Agreement
Cut-point for	≥6	≥6	≥16	≥16	≥16			
MDHAQ-FM3-P	+			+	+	0.924	0.832	84.3%
MDHAQ-FM3-F		+		+	+	0.937	0.854	86.6%
MDHAQ-FM3-R	+		+	+	+	0.928	0.839	84.5%
MDHAQ-FM4-P		+		+	+	0.927	0.852	85.9%
MDHAQ-FM4-R		+	+	+	+	0.932	0.849	86.9%

Conclusion: The MDHAQ identifies patients with FM similarly to the FM criteria questionnaire. Further longitudinal data will help to identify an optimal MDHAQ-FM index. Since MDHAQ also is useful in all rheumatic diseases in which it is been studied, it would appear a feasible and informative addition to routine clinical care in each patient at each visit.

The CCL21/CCR7 Axis Drives Vascular, Inflammatory and Destructive Remodeling in Rheumatoid Arthritis

Katrien Van Raemdonck^{1,2}, Karol Palasiewicz^{1,2}, Sadiq Umar^{1,2} and Shiva Shahrara^{1,2}, ¹Jesse Brown VA Medical Center, Chicago, IL, ²Medicine, Division of Rheumatology, University of Illinois at Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The synovial tissue of rheumatoid arthritis (RA) patients exhibits abundant expression of CCL21, produced excessively by RA fibroblasts and macrophages. While CCR7 mediates CCL21-driven T cell migration, we previously identified a novel angiogenic function of CCL21 in RA as well. We now reveal that in RA, macrophage expression of CCR7 is significantly increased, which further supports the importance of the CCL21/CCR7 pathway. In this study, we aim to determine the range of CCL21/CCR7 function and explore its activity on CCR7+ macrophages, contributing to the progression of inflammatory and destructive RA.

Methods: Expression of CCR7 on healthy (NL) versus RA immune cells was examined by flow cytometry and quantitative PCR. To evaluate CCL21-stimulated myeloid cell behavior, we performed monocyte chemotaxis, osteoclastogenesis assays and Western blot analysis for signaling. We also defined macrophage polarization through flow cytometry and ELISA. Intra-articular adenoviral delivery of CCL21 in mice was used to evaluate and confirm the arthritic effects of CCL21 in vivo.

Results: The percentage of double-positive CD14+CCR7+ is 2-fold higher in macrophages derived from RA compared to NL peripheral blood (NL: $19.38 \pm 2.7\%$; RA: $43.14 \pm 2.2\%$). We find that in vitro M1 polarized cells express higher levels of CCR7, which corroborates the high expression of CCR7 on macrophages isolated from RA synovial fluid. Confirming the clinical significance of CCL21/CCR7, monocyte chemotaxis induced by RA synovial fluid is considerably reduced in the presence of either anti-CCR7 or anti-CCL21 neutralizing antibody. Recombinant CCL21 stimulates RA monocyte chemotaxis dose-dependently, through CCR7 and activation of NF κ B, ERK and MAPK p38 signaling. CCL21 also affects myeloid cell differentiation and polarization. We observed an increase of M1 polarized macrophages upon CCL21 stimulation. Additionally, CCL21 ligation to CCR7 promotes osteoclast formation. Accordingly, local expression of CCL21 induces joint swelling and osteoclastic bone erosion in wild type mice, but not in CCR7-deficient mice. Histological analysis demonstrates that F4/80+ cell numbers are elevated in CCL21-treated arthritic joints. iNOS expression in the joint is increased 36-fold by CCL21. Elevated intra-articular production of M1-associated inflammatory factors confirms that local CCL21 expression promotes macrophage polarization to an M1 phenotype. We also noted that TRAP+ osteoclast numbers are 10-fold higher in CCL21 arthritic mice compared to the placebo non-arthritic group.

Conclusion: Our findings emphasize the diverse function of CCL21 and CCR7, increased even more by the pathogenic upregulation of CCR7 expression on RA macrophages. Given that CCL21/CCR7 activation potentiates RA joint inflammation, destruction and neovascularization, this pathway may be an attractive target for therapy.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Tumor necrosis factor- α (TNF), a potent proinflammatory cytokine, activates two receptors: TNFR1 and TNFR2. Anti-TNF biological agents neutralize TNF, thus preventing both TNFR1 and TNFR2 activation. These anti-TNF agents are used in treating inflammatory diseases including psoriasis and psoriatic arthritis. However, potentially life threatening adverse effects that include reactivation of tuberculosis and malignancies are associated with their long-term use. The adverse effects are associated with inhibition of TNFR1, not TNFR2, signaling. It is not clear whether inactivation of both TNF receptors is necessary for inhibiting psoriatic diseases. Here, we used a mouse model to identify the contributions of TNFR1 and TNFR2 in psoriasis.

Methods: We applied imiquimod (IMQ) (4 mg/day/mouse for 4 days) to 10-12-week-old wild type (WT), TNFR1 knockout (KO), and TNFR2KO mice ($n = 6$ each). Erythema, scaling, and thickness of the IMQ- or vehicle-treated area was assessed by PASI (Psoriasis Area and Severity Index). Epidermal thickness was measured using ImagePro software on H&E stained skin. We compared the psoriasis-related gene expression in the untreated vs. IMQ-treated skin using qPCR and immunohistochemistry. Fluorescence-activated cell sorting (FACS) was used to compare immune cell expansion in the lymph nodes.

Results: In WT, the cumulative score of skin inflammatory phenotype (erythema + scaling + thickness) peaked at day 5 with a cumulative score of 7.0 ± 1.3 . TNFR2 knock-out (TNFR2KO) did not show any sign of skin inflammation. TNFR1KO mice exhibited low level of inflammation with a cumulative score of 2.5 ± 0.8 . Histology revealed significant keratinocyte hyperplasia and leukocyte infiltration in the WT upon IMQ application. These inflammatory responses were significantly blunted in TNFR2KO, but not in TNFR1KO, mice. As expected, the IL-17 family of genes and genes encoding IL-22 and IL-23 are upregulated in IMQ-treated skin compared to untreated WT skin. Compared to WT mice, the IMQ induction of these genes was reduced significantly in TNFR2KO mice. Fold increases in mRNA levels upon IMQ: IL-17A (WT, 22.3 ± 4.1 vs TNFR2KO, 15.6 ± 2.3), IL-17C (WT, 31 ± 3.3 vs TNFR2KO, 11.2 ± 2.2), IL-17F (WT, 51.8 ± 3.8 vs TNFR2KO, 8.9 ± 1.7), IL-22 (WT, 33.6 ± 3.3 vs TNFR2KO, 9.4 ± 1.2) and IL-23 (WT, 101.8 ± 12.5 vs TNFR2KO, 14.2 ± 3.2). The effect of TNFR1 inactivation on IMQ induction of these genes was minimal. Importantly, our FACS analysis showed IMQ-induced CD11c⁺ and CD11b⁺ dendritic cell expansion, a critical component in T_H na \cdot ve cell to T_H17 differentiation, is inhibited in TNFR2KO, but not in TNFR1KO, mice. Immunohistochemistry studies showed reduced number of infiltrated T_H17 cells upon IMQ in TNFR2KO skin compared with WT or TNFR1KO mice.

Conclusion: Psoriatic inflammation in mice is critically dependent on TNFR2 via T_H17 cell expansion and IL-23/IL-17 induction. Selective inhibition of TNFR2 while retaining TNFR1 may block the psoriasis and psoriatic arthritis, as both share many common inflammatory pathways, and may lead to improved safety compared to the current anti-TNF therapy.

Abstract Number: 842

Interleukin 17 Receptor D (IL-17RD) Is Regulated By Pro-Inflammatory Cytokines and Plays a Role in the Development of Collagen-Induced Arthritis

M Molendijk¹, A Otten-Mus², P Asmawidjaja³, Dominique Baeten⁴ and Erik Lubberts⁵, ¹Rheumatology, Erasmus MC, Rotterdam, Netherlands, ²Rheumatology and Immunology, Erasmus MC, University Medical Center, Rotterdam, Netherlands, ³Rheumatology, Erasmus MC, University Medical Center, Rotterdam, Netherlands, ⁴Rheumatology and Clinical Immunology, AMC, Amsterdam, Netherlands, ⁵Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interleukin-17 Receptor D (IL-17RD) otherwise known as similar expression of fibroblast growth factor genes (SEF) is often described as an inhibitor of multiple signaling cascades. IL-17RD is a member of the IL-17 receptor family. In contrast to the other IL-17 receptors, IL-17RA, -RB, -RC and -RE, little is known about the ligand

and function of IL-17RD. We hypothesized that IL-17RD is a brake that needs to be removed in order to develop auto-immune arthritis. However, the functional role of IL-17RD in auto-immune arthritis is still unknown and is the purpose of this study.

Methods: Human synovial fibroblasts from Rheumatoid Arthritis (RA) patients were stimulated with tumor necrosis factor α (TNF α), interleukin 1 β (IL-1 β) or IL-17A for multiple time points. IL-17RD expression levels were measured via qPCR. Collagen induced arthritis (CIA) was induced in IL-17RD knockout mice and wildtype littermates. At days 1 and 21, mice were immunized intradermally with chicken collagen type II in complete Freund's adjuvant (CFA). Mice were scored 3 times a week for clinical disease defined as swollen joints with a maximum score of 8. Due to ethical reasons, mice were removed from the experiments when they reached a score of 6. CD4⁺ memory T cells, CD8⁺ memory T cells, CD19⁺ B cells and monocytes were isolated from WT spleens and analysed for IL-17RD expression. Blood neutrophil migration assays were performed in vitro using WT and IL-17RD deficient (IL-17RD KO) mouse synovial fibroblasts.

Results: We show that IL-17RD is regulated by pro-inflammatory cytokines and plays a role in the development of collagen-induced arthritis (CIA). IL-17RD expression was decreased in human synovial fibroblasts from rheumatoid arthritis (RA) patients upon stimulation with TNF α or IL-1 β but not IL-17A. Interestingly, CIA incidence was significantly reduced in IL-17RD knockout (IL-17RD KO) mice compared to wildtype littermates (C57BL/6N) without affecting CIA severity in mice developing clinical manifest disease. Besides very low or absent IL-17RD expression in immune cells, no altered cytokine production was observed in LPS stimulated monocytes or α CD3 and α CD28 activated CD4⁺ T cells from IL-17RD KO mice versus WT controls. However, lower production of CXCL2 was detected by IL-17RD deficient synovial fibroblasts when stimulated with TNF α and IL-17A. Additionally, less neutrophils were attracted by these IL-17RD deficient synovial fibroblasts.

Conclusion: These data show the downregulation of baseline IL-17RD expression by pro-inflammatory cytokines in synovial fibroblasts and how IL-17RD deficiency reduces CIA incidence. This indicates that IL-17RD is likely a brake that is removed in an inflammatory environment but contradictorily lowers the chance of developing auto-immune arthritis.

Localization of the Voltage-Gated Sodium Channel 1.7 in Peripheral Monocytes Contributes to Activation of BAFF Signaling in Monocytes of Patients with Primary Sjögren's Syndrome

Keiko Yoshimoto, Yumi Ikeda, Katsuya Suzuki and Tsutomu Takeuchi, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In our previous study, we have reported that IL-6 production was robustly increased in BAFF-stimulated peripheral monocytes of patients with primary Sjögren's syndrome (pSS) and was positively and significantly correlated with the expression level of BAFF-receptor (BR3). We also found that the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. In vitro analysis showed that IgG production by B cells was enhanced by co-cultured BAFF-stimulated monocytes probably through stimulation of B cells with IL-6 produced by the monocytes. These data collectively suggest that abnormal activation of monocytes is involved in the pathogenesis of pSS. It has been reported that the pathways via voltage-gated sodium channels in monocytic lineage are involved in production of inflammatory cytokines, such as IL-6 in inflammatory pain diseases. In this study, we investigated the localization and the expression level of ion channels, such as Nav1.7, a voltage-gated sodium channel, in peripheral monocytes in patients with pSS in an attempt to discriminate the disease from other autoimmune diseases, such as active RA and active SLE.

Methods: The expression level of Nav1.7 in peripheral monocytes was analyzed by FACS using whole blood samples from patients with pSS (n = 28), active RA (n = 15), active SLE (n = 37) and healthy controls (HC; n = 15). Monocytes were prepared from whole blood samples and stimulated with recombinant human soluble BAFF (sBAFF) in the presence or absence of an inhibitor against Nav1.7. The amount of IL-6 in the culture supernatants and the expression level of Nav1.7 in the cells were analyzed by ELISA and qPCR, respectively.

Results: FACS analysis revealed that the expression level of Nav1.7 in pSS monocytes was significantly higher than those of active RA ($p = 0.005$), active SLE ($p < 0.001$) and HC ($p < 0.001$). In addition, the expression level of BR3 in pSS monocytes was significantly higher than those of HC ($p = 0.048$), RA ($p = 0.037$) and SLE ($p = 0.024$). Interestingly, the expression level of Nav 1.7 in pSS monocytes was significantly and positively correlated with that of BR3 in the cells ($p = 0.02$). Moreover, a specific inhibitor against Nav 1.7 suppressed IL-6 production by sBAFF-stimulated peripheral monocytes in a dose dependent manner. In addition, qPCR analysis indicated that Nav 1.7 expression in pSS monocytes was induced upon stimulation with sBAFF.

Conclusion: Our results strongly suggest that the crosstalk between BAFF signaling and sodium channel is involved in activation of pSS monocytes and can be a therapeutic target for pSS.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Tumor Necrosis Factor (TNF) α exerts its pro-inflammatory or anti-inflammatory function. This study hypothesizes that TNF α has multi-function through binding the different receptor 1 and 2 (TNFR1 and TNFR2) and different signal pathways affect the development and function of induced regulatory T cells (Tregs) and Th cells.

Methods: iTreg and Th cells were differentiated *in vitro* and *in vivo* in the presence or absence of TNF. We also used TNFR1^{-/-} and TNFR2^{-/-} mice to investigate the requirement of TNFR1 or TNFR2 expression on these cells with differentiation, proliferation and function.

Results: TNF α facilitated iTreg differentiation and suppressive function *in vitro*. TNFR2 deficiency hampered iTreg differentiation, proliferation and function, while TNFR1 deficiency decreased the differentiation of inflammatory T cells such as Th1 and Th17 cells but maintained the regulatory capabilities of iTregs *both in vitro* and *in vivo*. Additionally, TNFR1^{-/-} iTregs expressed an increased level of TNFR2, while TNFR2^{-/-} iTregs expressed an elevated level of TNFR1. In human, Tregs from patients with multiple sclerosis (MS) and Rheumatoid Arthritis (RA) expressed an ascending level of TNFR1 but a decreased level of TNFR2.

Conclusion: TNF α may enhance the differentiation, proliferation and function of iTregs *via* TNFR2 signaling while promote Th cell *via* TNFR1. The expression of TNFR2 on Tregs might be downregulated in some autoimmune diseases, accompanied by an increased level of TNFR1. Thus, our results suggest that TNFR2 agonists or TNFR1-specific antagonists hold a potential promise for clinical application in treating patients with autoimmune diseases.

New Insights in Lupus Dermatitis: Differential Regulation and Roles of Tissue-Resident Dendritic Cell Subsets in the Pathogenesis of Autoimmune Skin Inflammation

Ram R. Singh, Miguel-Angel Gutierrez, Peter Kim, Darshan Randhawa, Rachael Philips, Jennifer K. King and Anna Eriksson, Autoimmunity and Tolerance Laboratory, Department of Medicine/Rheumatology, UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Cytokines and Cell Trafficking

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Acquired or self antigens in tissues are taken to lymphoid organs to elicit protective immunity or tolerance, respectively. This is accomplished by dendritic cells (DC) that reside in tissues. Here, we used the skin model of tissue-resident DC to investigate mechanisms of tissue-DC migration and its role in lupus dermatitis. Skin harbors at least three subsets of DC: Langerhans cells (LC) that reside in the epidermis, langerin-expressing dermal DC that reside in the dermis (LangdDC), and langerin⁻ dermal DC. Here, we investigated the roles of skin-resident DC subsets in lupus dermatitis.

Methods: 1. To evaluate skin DC migration in lupus-prone MRL-Fas^{lpr/lpr} (MRL-lpr) and MRL-Fas^{+/+} (MRL+/+) mice and control C3H, B10.BR and B6 mice, we: a) applied fluorophores (FITC/TRITC) to the skin of mice and detected FITC/TRITC⁺ cells in the skin-draining lymph nodes to track in vivo migration of skin-resident DC; b) verified in vivo migration of skin DC at the steady state (without any external manipulation) using langerin-driven eGFP knock-in mice in the lupus and control backgrounds; c) assessed in situ migration where skin explants were floated on a culture medium containing chemokines in a culture chamber, followed by staining and counting for DC in the epidermis (for DC that have not emigrated), dermis (for DC that are migrating through lymphatics), and in culture wells (for DCs that have migrated out). 2. We treated MRL mice with glycolipid α GalCer that ameliorates lupus dermatitis and determined its effect on skin DC migration. 3. We investigated mechanisms of skin DC migration using TCR $\gamma\delta^{-/-}$ and CD40L^{-/-} mice and respective blocking antibodies. 4. We used diphtheria toxin receptor knock-in MRL mice to conditionally ablate LC and/or LangdDC, and determined the effect on lupus disease.

Results: We found a reduced migration of LC but increased trafficking of LangdDC to skin-draining lymph nodes in lupus dermatitis-prone MRL-lpr and MRL+/+ mice as compared to control mice. Such altered pattern of migration of these two skin DC subsets was corrected by α GalCer treatment. However, α GalCer did not increase LC migration through its well-known target iNKT cells but increased epidermal $\gamma\delta$ T cells that were otherwise reduced in lupus mice compared to controls. Epidermal $\gamma\delta$ T cells increased LC migration in vitro. The role of $\gamma\delta$ T cells in modulating LC migration was confirmed using knockout animals as well as blocking antibodies. CD40L deficiency or antibody blockade abrogated the ability of $\gamma\delta$ T cells to enhance LC migration. Finally, conditional ablation of LC worsened lupus dermatitis; this effect was abrogated when both LC and LangdDC were ablated together. LC depletion or α GalCer treatment did not affect kidney or lung disease.

Conclusion: The two skin DC subsets play opposite, balancing roles in the pathogenesis of lupus dermatitis: LC protect and LangdDC harm. The two skin DC are also regulated differently: LC migrate less, but LangdDC traffic more, to skin-draining lymph nodes of lupus mice that also have less epidermal $\gamma\delta$ T cells. $\gamma\delta$ T cells regulate LC migration via CD40-CD40L interaction. α GalCer that corrects these defects ameliorates dermatitis.

CD14 Deficiency Dampens Osteoclastogenesis and Alters Bone Remodeling in a Murine Model of Osteoarthritis

Cheng Zhou^{1,2}, Vu Nguyen^{2,3}, Ryan Smalley², Nisha Sambamurthy^{1,2}, George R. Dodge^{2,4} and Carla Scanzello^{1,2}, ¹Division of Rheumatology, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, ²Translational Musculoskeletal Research Center, CMC Veterans Affairs Medical Center, Philadelphia, PA, ³University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, ⁴Department of Orthopaedic Surgery, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pathogenesis of osteoarthritis (OA) is accompanied by chronic inflammation evidenced by macrophage infiltration into the joint. CD14 is expressed by monocyte/macrophage lineage cells, and is a co-receptor that

facilitates Toll-like receptor (TLR) signaling. Upon binding, the CD14/TLR complex can activate cytokine production and promote chronic inflammation. Given that CD14 is expressed by osteoclast precursors, and TLR signaling influence osteoclast development and activation, we hypothesized that CD14 may play a role in bone remodeling after joint injury in a murine post-traumatic knee OA model.

Methods: 10-12 week old male mice from CD14^{-/-} and congenic C57BL/6 (WT) controls were subjected to destabilization of medial meniscus (DMM), sham surgery or left un-operated. Mice were sacrificed at 6 and 19 weeks post-surgery, knees isolated, and cartilage and bone histopathology evaluated with the modified OARS score. Micro-CT was used to measure subchondral bone mineral density (BMD) and trabecular thickness (TbTh). In separate experiments, bone marrow was isolated from tibias and fibulas of WT and CD14^{-/-} mice. Non-adherent cells were isolated after 24-hour initial culture, and then media containing M-CSF (35 ng/ml) and RANKL (100 ng/ml) was added to promote osteoclast differentiation. After 8 days, TRAP⁺ (tartrate-resistant acid phosphatase) staining was assessed, and mRNA expression of calcitonin receptor and cathepsin K were measured using quantitative PCR.

Results: 6 weeks after DMM surgery cartilage histology was similar in the two strains, but at 19 weeks degeneration was significantly less in CD14^{-/-} mice compared to WT (7.125 vs 16.22, p=0.0002). Micro-CT analysis showed age-related increases in BMD and TbTh in WT mice (12.8% increase at 19 weeks compared to baseline, p=0.006) but not in CD14^{-/-} mice. CD14^{-/-} mice were also protected from surgery-related increases in BMD, which were observed in WT mice 6 week post-DMM: (7.3% increase in WT BMD vs. naive, p=0.04; 2.0% increase in CD14^{-/-} BMD DMM vs. naive, p=ns). In response to M-CSF and RANKL, cells from CD14^{-/-} mice showed less TRAP staining, reduced numbers of multi-nucleated cells, and lower expression of calcitonin receptor and cathepsin K compared to WT mice (Fig 1).

Conclusion: CD14 deficiency protects mice from subchondral bone changes after joint injury, and reduces the capacity of precursors to differentiate into osteoclasts. Bone remodeling is dependent on both bone resorption and anabolism, therefore it is possible that the defect in osteoclastogenesis in this strain is related to the ability of subchondral bone to remodel in response to age and joint injury. Additional studies are underway to confirm this. This study brings attention to pathologic bone remodeling in osteoarthritis models, and these results suggest a possible new therapeutic target to explore.

Basic Calcium Phosphate Crystals Induce Osteoarthritis-Associated Changes in Chondrocyte Phenotype through Activation of Calcium/Calmodulin Kinase 2

Jing Rong¹, Bregina Pool², Mark Zhu³, Jacob Munro⁴, Geraldine M. McCarthy⁵, Jillian Cornish², Nicola Dalbeth¹ and Raewyn Poulsen³, ¹University of Auckland, Auckland, New Zealand, ²Department of Medicine, University of Auckland, Auckland, New Zealand, ³Medicine, University of Auckland, Auckland, New Zealand, ⁴Orthopaedics, Auckland City Hospital, Auckland, New Zealand, ⁵Mater Misericordiae University Hospital, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Basic calcium phosphate crystals (BCP) are frequently found in osteoarthritic joints. Whether BCP crystal deposition is a cause or consequence of osteoarthritis (OA) pathology remains contentious. In OA, chondrocytes undergo a phenotype shift resulting in increased production of cartilage degrading enzymes (particularly matrix metalloproteinase 13, MMP13) and production of abnormal extracellular matrix components (eg type X collagen, COL10), disrupting cartilage integrity and leading to cartilage loss. The purpose of this study was to determine whether BCP crystals can induce the OA-associated phenotype change in chondrocytes.

Methods: Primary human chondrocytes were exposed to 50µg/ml BCP crystals (equivalent to the concentration present in synovial fluid in patients with OA) for up to 48h. Chondrocyte phenotypic marker expression (*SOX9*, *RUNX2*, *IHH*, *MMP13*, *COL10A1*) was measured by RT-qPCR, ELISA and immunocytochemistry. BCP crystal-induced signalling pathway activation was identified using western blotting, pharmacological inhibitors and RNA interference. Intracellular calcium levels were measured using the calcium-sensitive dye, Fluo4.

Results: Exposure to BCP crystals resulted in changes in chondrocyte phenotypic markers indicating cells were adopting a more OA-like phenotype. Expression of *SOX9* was lower, and *RUNX2*, *IHH* and *MMP13* higher, in BCP crystal-exposed cells compared to untreated controls. COL10 (a late-stage marker of the osteoarthritic chondrocyte phenotype) was detected at both the RNA and protein level in BCP crystal-exposed but not in untreated cells. BCP crystal exposure resulted in a rapid increase in intracellular calcium levels that was abolished by co-treatment with an antagonist preventing the release of calcium from intracellular stores. The BCP-induced increase in intracellular calcium was dependent on free Ca^{2+} in the extracellular environment and activity of the extracellular calcium sensing receptor (CaSR, a receptor for calcium first messenger signalling and activator of calcium release from intracellular stores). Exposure to BCP crystals resulted in activation of the calcium-sensitive enzyme, calcium/calmodulin kinase 2 (CaMK2) by a mechanism dependent on CaSR activity and the release of calcium from intracellular stores. Inhibition of CaMK2 activity or knockdown of either of the CaMK2 isoforms expressed by human chondrocytes (δ and γ) mitigated the ability of BCP crystals to induce OA-associated changes in chondrocyte phenotype.

Conclusion: BCP crystal exposure results in OA-like changes in chondrocyte phenotype by CaSR-mediated activation of CaMK2. Increased CaMK2 activity has been observed in osteoarthritis and is implicated in the disease-associated change in chondrocyte phenotype. Our data indicate the presence of BCP crystals within osteoarthritic joints may contribute to the increased CaMK2 activation seen in disease and may promote OA progression by inducing disease-associated changes in chondrocyte phenotype.

A2A Adenosine Receptor Stimulation Switches TGF- β Signaling to Promote Chondrocyte Proliferation and Cartilage Regeneration

Carmen Corciulo¹, Cristina Castro², Samson Jacob³, David Fenyo³, Oran Kennedy⁴ and Bruce N. Cronstein⁵, ¹Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, ²Medicine, NYU School of Medicine, New York, NY, ³Institute for Systems Genetics, NYU School of Medicine, New York, NY, ⁴Department of Anatomy, Royal College of Surgeons, Dublin, Ireland, ⁵Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: We previously found that intra-articular injections of liposomal preparations of adenosine completely prevent progression and reverse cartilage loss in post-traumatic OA. TGF- β signaling plays dual and opposing roles in cartilage health and chondrocyte life depending on the signals activated downstream. Activation of downstream signaling pathways for TGF- β leading to localization of phospho-SMAD2/3 associated with maintenance of cartilage. In contrast nuclear localization of phospho-SMAD1/5/8 results in chondrocyte hypertrophy. Here we report that intraarticular

injections of liposomal adenosine and A2AR agonist reverse OA in a different OA model and explore the role of TGF β signaling in this phenomenon.

Methods: Obesity-induced OA model: C57Bl6 mice (5-6 for each group, 12 weeks old) were fed a 60% fat diet (HFF mice) for 3 months, after which received intraarticular injections (10 μ l) of empty liposomes (LIPO) or liposomes containing the A2AR agonist CGS21680 (LIPO-CGS) or LIPO-Adenosine into the knee every 10 days for 4 injections. PTOA was induced in Sprague Dawley rats following non-surgical rupture of anterior cruciate ligament (ACL). Four weeks later rats were injected in the knee with 100ul of saline, LIPO or LIPO-CGS every 10 days (6 injections). RNA was isolated from chondrocytes in knee cartilage of rats treated as described above (3 from each group X 3 replicates) and subjected to RNAseq analysis. TC28a2 human chondrocyte cell line was used for *in vitro* experiments.

Results: LIPO-CGS and LIPO-Adenosine reversed OA in the obesity-induced OA model. Mouse knees had an OARSI score of 5.17 ± 1.84 before treatment. Treatment with LIPO-Ado and lipo-CGS decreased OA severity (OARSI score 1.33 ± 0.81 and 1.83 ± 0.98 , respectively, $p < 0.001$ vs pre-treatment). RNAseq revealed an increase in aggrecan, TGF β 2 and 3 and TGF β receptor 2 expression in chondrocytes from knees treated with LIPO-CGS. TGF- β expression was increased in deep layers of cartilage in the Lipo-CGS-treated rats and there was notable nuclear localization of phospho-SMAD2/3 in these chondrocytes. In contrast, phospho-SMAD1/5/8 was expressed in the nuclei of chondrocytes in the saline and LIPO-treated rats but not in the LIPO-CGS treated rats. Identical changes were observed in the knees of obese mice. To determine whether the effect of A2AR stimulation on TGF β signaling was direct or indirect we studied the effect of CGS21680 on nuclear phospho-SMAD expression in TC28a2 cells and found that CGS21680 increased nuclear phospho-SMAD2/3 and reduced nuclear phospho-SMAD1/5/8, as detected by immunofluorescence.

Conclusion: Administration of an A2AR agonist to established OA knees reverses OA in rats and mice and shifts TGF β signaling from ALK1/SMAD1/5/8 to ALK5/SMAD2/3 in OA chondrocytes after activation of A2AR in 2 OA animal models. These findings suggest a novel approach to the treatment of OA with the potential to reverse the changes in cartilage that characterize OA.

Constructing a Macrophage Infiltration Timeline in a Murine Model of Osteoarthritis

Cheng Zhou^{1,2}, Vu Nguyen^{1,3}, Nisha Sambamurthy^{1,2}, Michael Dodge^{1,4} and Carla Scanzello^{1,2}, ¹Translational Musculoskeletal Research Center, CMC Veterans Affairs Medical Center, Philadelphia, PA, ²Division of Rheumatology, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, ³University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, ⁴Department of Orthopaedic Surgery, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

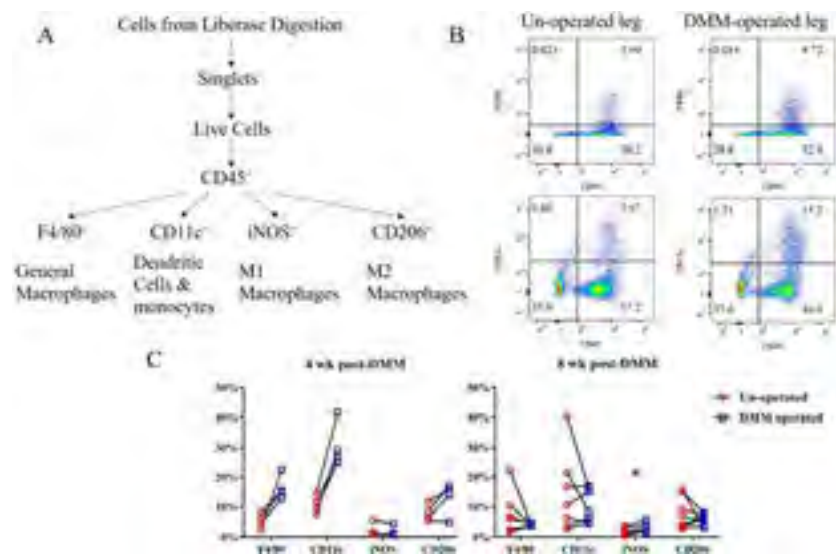

Session Title: Osteoarthritis and Joint Biology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Macrophage infiltration in synovium (SM) and intra articular fat pads (FP) is common in Osteoarthritis (OA), and can contribute to catabolic cytokine and protease production as well as symptoms. However, whether macrophages are targets for therapy in OA is unclear, as macrophages can also promote tissue repair. The purpose of this study is to characterize the timeline and subtypes of macrophages in SM and FP in a commonly used murine model of post-traumatic OA.

Methods: C57BL/6 male mice (10-12 wks old) were subjected to destabilization of medial meniscus (DMM) on the right leg. For gene expression analysis, groups of mice were sacrificed pre-DMM (baseline), and post-DMM at 1, 2, 4, 8 and 16 weeks. Anterior SM and FP (combined) was dissected. Tissues were pooled from 4-5 mice per sample to obtain adequate mRNA, cDNA synthesized by routine methods, and CD68 (a pan-macrophage marker) mRNA transcript number quantified using the QX200TM Droplet Digital PCR System (BioRad). Additional mice were sacrificed 4 and 8 weeks post-surgery and SM/FP dissected for cellular analysis. Tissues from 4 knees were pooled, cells isolated enzymatically, and stained with the Live/Dead™ Fixable Violet Dead Cell Stain Kit (Invitrogen) and the following antibodies: CD45-PerCP Cy5.5, CD11c-Super Bright 645,F4/80-APC, iNOS-Alexa Fluor 488, CD206-PE. Multicolor flow cytometry was performed

and data analyzed with FlowJo software (Version 10). Gating strategy is outlined in Fig 1A, and cells were expressed as percent of the CD45+ population.

Results: CD68 mRNA level increased in DMM-operated limbs compared to preoperative levels, peaking at 4 weeks (21.61 ± 3.02 , Baseline: 2.24 ± 0.42). Levels remained significantly elevated compared to the un-operated limb up to 16 weeks (DMM: 4.77 ± 0.31 , contralateral: 0.90 ± 0.26). Percentages of F4/80+ macrophages and CD11c+ cells (expressed by murine monocytes and dendritic cells) in SM/FP were increased at 4 weeks post- DMM but not at 8 weeks (Fig 1B & C). iNOS+ cells (primarily expressed on M1 macrophages) were slightly elevated compared to the un-operated side only at 8 weeks ($p=0.02$). Percentage of CD206+ cells (expressed on M2 macrophages) were similar in DMM and un-operated knees at either 4 or 8 weeks (Fig 1C).

Conclusion: Changes in macrophage populations can be detected in SM/FP tissues after DMM surgery by both gene expression and flow cytometry. CD68 gene expression was most pronounced early at 4 weeks, and paralleled changes in F4/80+ and CD11c+ cells. Flow cytometry of M1 and M2 markers suggested a slight increase in iNOS+ (M1-type) cells at 8 weeks and CD206 at 4 weeks. Additional work is being pursued to further characterize macrophage phenotypes, and confirm gene expression seen at the chronic stage (16 weeks). These observations will be used to plan timing of interventions to better understand the pathologic roles of macrophage subtypes in OA.

Long Term Efficacy of Cartilage Repair Induced By scSOX9 in Situ with Bone Marrow-Derived Mesenchymal Stem Cells

Xiaowei Zhang^{1,2}, Shili Wu³, Yong Zhu³ and Cong-Qiu Chu^{4,5}, ¹Oregon Health & Science University, Portland, OR, ²VA Portland Health Care System, Portland, OR, ³VivoScript, Inc, Costa Mesa, CA, ⁴Rheumatology, Oregon Health & Science University, Portland, OR, ⁵Rheumatology, VA Portland Health Care System, Portland, OR

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Microfracture induces fibrocartilage or fibro-hyaline cartilage both are biomechanically inferior to hyaline cartilage. We reported previously that a super positively charged SOX9 (scSOX9) improved the quality of microfracture induced cartilage repair by inducing mesenchymal stem cell differentiation into chondrocytes and promoting hyaline-like cartilage. Here we examined the long-term efficacy of cartilage repair induced by microfracture with scSOX9 by assessing biomechanical property of the repaired cartilage.

Figure 1. Mechanical property of repaired cartilage. (A) Thickness of reparative tissue in patellar groove. (B) Mechanical Young's modulus at 50 μ m indentation amplitude of representative control and treated patellar grooves. Data are presented for each region as the averaged of all control (n = 8) and all treated patellar grooves (n = 6-8). *p<0.05 and ***p<0.001 (compared with SOX9 group), # Not significant (compared with SOX9 group). Mem: collagen membrane only; A76E: scSOX9-A76E mutant; SOX9: super positively charged SOX9.

Methods: A cartilage defect was created at the right femoral trochlear groove in NewZealand female rabbits and microfracture was performed. scSOX9 was administered at the site of microfracture via a collagen membrane. Cartilage repair was assessed at 12 weeks by gross morphology, histology and matrix components. The distal femur was extirpated for biomechanical test.

Results: Cartilage defect in rabbits was treated with microfracture with collagen membrane only; with a SOX9 mutant, scSOX9-A76E or with scSOX9 respectively. Rabbits were observed for 12 weeks post-surgery. scSOX9 treated group induced hyaline-like cartilage while collagen-membrane only induced fibrocartilage and mutant scSOX9-A76E poorly induced cartilage repair. The cartilage matrix in scSOX9 treated group showed highly enriched proteoglycan content. The thickness of repaired cartilage induced by scSOX9 was comparable to that of normal cartilage in the same area. Whereas, collagen membrane only induced a thinner layer of cartilage, and scSOX9-A76E treated group showed even worse repaired tissue. In consistent with the histological data and the thickness of the repaired cartilage, the mechanical property of scSOX9 induced cartilage was also similar to that of normal cartilage (Figure1).

Conclusion: This long term *in vivo* study demonstrated that when administered at the site of microfracture, scSOX9 was able to induce reparative tissue with features of hyaline cartilage and near normal biomechanical properties. scSOX9 induced cartilage repair was enduring in long term. Together, this technology has potential to translate into clinical use for cartilage repair to prevent progression to osteoarthritis.

Integrin Mac-1 Potentiates Neutrophil Adhesion and NET Release in Antiphospholipid Syndrome

Gautam Sule¹, William J. Kelley¹, Srilakshmi Yalavarthi¹, Alison Banka¹, Andrew Vreede², Omolola Eniola-Adefeso¹ and Jason S. Knight³, ¹University of Michigan, Ann Arbor, MI, ²Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, ³., University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: While the role of antiphospholipid antibodies in activating endothelial cells has been extensively studied, the impact of these antibodies on the adhesive potential of leukocytes has received considerably less attention. Mac-1 is a heterodimeric beta-2 integrin primarily expressed by myeloid-lineage cells. In its activated state, Mac-1 mediates cell-cell interactions by engaging a variety of surface molecules, including the endothelium-expressed glycoprotein ICAM-1. Here, our goals were (1) to determine the extent to which APS neutrophils adhere to healthy, resting endothelial cells

under physiologic flow conditions, and (2) to identify potential therapeutic targets by elucidating the molecules required for that adhesion.

Methods: Primary APS patients (meeting Sydney criteria) and non-autoimmune controls were matched for age and gender. Freshly isolated human umbilical vein endothelial cells (HUVECs) were utilized within five passages. Samples were introduced into a flow channel via a programmable syringe pump, and perfused across a resting HUVEC monolayer. After 15 minutes of perfusion, the chamber was flushed, and the remaining adherent cells were quantified. Flow cytometry was used to identify differentially-expressed molecules on the surface of APS neutrophils. Neutrophil extracellular trap (NET) release was assessed in static neutrophil-HUVEC cultures.

Results: Pre-treating control neutrophils with APS plasma resulted in increased adhesion as compared with control plasma (>2.5-fold for n=12 plasma samples; p<0.05). This was true under both venous conditions (low shear) and conditions representative of the microvasculature (pulsatile flow and higher shear). Control neutrophils treated with APS plasma demonstrated upregulation of CD64, CEACAM-1, beta-2 glycoprotein I, and activated Mac-1 on the neutrophil surface, as well as shedding of L-selectin. Upregulation of activated Mac-1 and shedding of L-selectin were also triggered by IgG purified from APS plasma. For these changes to be meaningful clinically, we reasoned that they should be present on neutrophils in the peripheral blood of APS patients. Indeed, perfusion of anticoagulated blood through the flow chamber resulted in increased adhesion of patient neutrophils as compared with controls (>5-fold for n=18 patients; p<0.05). Similarly, patient neutrophils demonstrated upregulation of CD64, CEACAM-1, beta-2 glycoprotein I, and activated Mac-1 on the neutrophil surface. A monoclonal antibody specific for activated Mac-1 reduced the adhesion of APS neutrophils to HUVECs in the flow-chamber assay (>2-fold reduction for n=5 patients; p<0.05). Importantly, the same monoclonal antibody reduced NET release in neutrophil-HUVEC co-cultures.

Conclusion: APS neutrophils have an increased adhesive potential, which is dependent upon the activated form of Mac-1. This may lower the threshold for both neutrophil-endothelium engagement and NET release in patients, and thereby have implications for events such as venous thrombosis. Studies are underway to determine the extent to which Mac-1 is a viable therapeutic target in preclinical models of APS.

Antigenic Property of Prothrombin/HLA-DR Complex on Procoagulant Cells in Patients with Antiphospholipid Syndrome

Naoki Ohnishi¹, Yuichiro Fujieda¹, Ryo Hisada¹, Hiroyuki Nakamura¹, Masaru Kato¹, Kenji Oku¹, Toshiyuki Bohgaki¹, Olga Amengual¹, Shinsuke Yasuda¹, Hisashi Arase² and Tatsuya Atsumi¹, ¹Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, ²Department of Immunochemistry, Research Institute for Microbial Disease, Osaka University, Suita, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Antiphospholipid syndrome (APS) is characterized by thrombosis and/or pregnancy morbidity and the presence of antiphospholipid antibodies (aPL). Phosphatidylserine-dependent antiprothrombin antibodies (aPS/PT) recognize the phosphatidylserine/prothrombin(PS/PT) complex, and are highly associated with APS. Recently, it has been reported that misfolded beta2-glycoprotein I (beta2-GPI) are transported to the cell surface by human leukocyte antigen (HLA) class II molecules and are targeted by autoantibodies in patients with APS [1, 2]. APS patients with anti-beta2-GPI are highly likely to share the thrombophilic pathophysiology with those with aPS/PT, therefore we hypothesized that misfolded prothrombin(PT), likewise beta2-GPI, are transported to the cell surface by HLA class II molecules in procoagulant cells, consequently being targeted by aPS/PT.

Methods: 1) The interaction of PT with HLA-DR was analyzed by flow cytometry(FCM) using PT / HLA-DR overexpressed HEK293T cells. 2) PT synthesis from monocyte was investigated in phorbol-12-myristate-13-acetate (PMA) treated THP-1 cells by western blotting (WB) and FCM. 3) Cell surface transportation of synthesized PT with HLA-DR was evaluated by FCM in PMA-treated THP-1 cells.

Results: 1) PT protein in the presence of transcribed HLA-DR was detected on the cell surface and PT/HLA-DR complex was recognized by a mouse monoclonal aPS/PT (231D). 2) PMA treated THP-1 cells synthesized PT which showed stronger binding to 231D than to control monoclonal anti-PT antibody, the latter recognizes PT in the absence of phosphatidylserine (Fig). 3) 231D binding to PT/HLA-DR complex was confirmed in THP-1 cells co-stimulated with PMA and interferongamma. No binding was observed between control monoclonal anti-PT antibody and PT/HLA-DR complex.

Conclusion: Structurally altered PT is transported to the cell surface by HLA class II molecules in monocyte after PMA stimulation, indicating that PT/HLA-DR complexes may be targets for aPS/PT.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Primary antiphospholipid syndrome (PAPS) is an autoimmune vasculopathy mediated by autoantibodies with thrombosis as its main clinical manifestation. The presence of antiphospholipid antibodies, while relevant to confirm the diagnosis, does not seem to be sufficient to fully explain the pathophysiology and a second trigger is usually needed. Besides the hypotheses of viral infections and inflammatory insult as possible triggers, type II interferon (IFN) has been pointed as a possible protagonist. Recently, two studies have demonstrated that a relevant percentage of PAPS patients have an up-regulation of IFN genes in peripheral blood mononuclear cells (PBMC).However, 20% and 28%

Figure 1. Comparison of IFN-Score in PAPS patients, healthy controls and non-immune-mediated thrombophilia

of patients in these 2 cohorts, had anti-dsDNA positive antibodies, a highly specific Systemic Lupus Erythematosus (SLE) autoantibody. The aim of this study is to determine the prevalence of type I IFN signature in PBMC of patients with PAPS without specific SLE autoantibodies and search for it with clinical and laboratorial associations.

Methods: 53 PAPS patients (according to Sydney's criteria) were consecutively selected and age-matched with 50 healthy controls. A third group, with non-immune-mediated thrombophilia patients, was also included. The expression of 41 IFN induced genes was analysed using real time quantitative PCR (TaqMan Low Density Array). A principal component analysis (PCA) was used to determine which genes should compose the IFN signature and z-score was calculated. The IFN signature score cut-off was defined with a ROC curve, as the point that maximized both the specificity and sensitivity. Clinical and laboratorial features were analysed searching for associations with IFN signature.

Results: 11 IFN genes were highly expressed in primary APS patients. After PCA, 6 genes remained in the IFN signature: DNAJA1, IFIT5, IFI27, MX1, IFI6, TYK2. The type I IFN signature was present in 49% of patients with primary APS compared to 14.0% of healthy controls and 17% of non-immune-mediated thrombophilia patients ($p < 0.0001$). The mean IFN score was significantly higher in PAPS patients (4.0 fold higher, $p < 0.0001$) than in controls (**Figure 1**). A higher IFN signature was associated with a younger age at the first APS event ($p = 0.023$) and with the presence of obstetric events, especially with preeclampsia ($p = 0.032$). Treatment with statins was associated with lower levels of IFN scores ($p = 0.026$).

Conclusion: Our result indicates that PAPS patients, without lupus specific antibodies, have an enhanced type I IFN gene signature, not observed in non-immune mediated thrombophilia. We also provide novel data demonstrating that this overexpression of type I IFN-regulated genes is associated with an earlier onset of APS events and preeclampsia. Further studies are necessary to determine if this subgroup of patients will benefit of interventions targeting the type I IFN signalling pathway.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases (SAIDx). Previously, we reported the annual recurrent and first thrombosis risk in persistently aPL-positive patients as 2.63% and 1.68%, respectively (*Arthritis Rheumatol* 2017;69:sup10).

Methods: A web-based data capture system is used to store patient demographics and aPL-related history. The inclusion criteria are positive aPL based on the laboratory section of the Updated Sapporo APS Classification Criteria, tested ≥ 2 within 1 year prior to enrollment. Patients are followed every 12 ± 3 months and receive advice on cardiovascular disease and thrombosis prevention at each visit. Based on patients who completed 1, 2, 3, 4, and 5 year follow-up visits, we report the incident thrombosis risk in persistently aPL-positive patients with/without a history of thrombosis. We also compare the characteristics of patients with/without new thrombosis.

Results: As of 5/2018, 735 patients were included: aPL/APS without SAIDx: 472 (no APS: 87; thrombotic APS [TAPS]: 272; obstetric APS [OAPS]: 51; and TAPS+OAPS: 62); and aPL/APS with SAIDx: 263 [no APS: 72; TAPS: 136; OAPS: 19; and TAPS+OAPS: 36]. Of 735 patients, 572, 473, 396, 264, and 71 completed 1, 2, 3, 4, and 5 year follow-up visits, respectively. Mean follow up was 2.6 years (1308 patient-years [pt-y]) and 2.54 years (589 pt-y) for those with and without a history of thrombosis, respectively. Based on 45 recurrent events in 36 patients, and 9 initial events since the inception of the registry (Table), the incident thrombosis risk was 2.75 and 1.53 per 100 pt-y in patients with and without history of thrombosis, respectively. Demographics, concomitant lupus diagnosis, aPL-profile, medications, and non-aPL thrombosis risk factors were not different between APS patients with (n: 36) or without (n: 376) recurrent thrombosis, and between aPL-positive patients with (n: 9) or without (n: 184) initial thrombosis except: APS patients with recurrence (vs those without recurrence), were younger (40.6 ± 13.2 vs 45.71 , p 0.04) and more likely to receive direct oral anticoagulants (3/36 [8%] vs 9/376 [2%], p 0.04) or no antiplatelet/anticoagulants (6/36 [17%] vs 15/376 [4%], p 0.001).

Conclusion: Based on approximately 2000 patient years of follow-up, the incident thrombosis risk in persistently aPL-positive patients remains relatively low (2.75 and 1.53 per 100 pt-y in patients with and without history of thrombosis, respectively) and commonly associated with LA- and/or triple aPL-positivity as well as non-aPL thrombosis risk factors and sub-therapeutic international normalized ratios. Future cox proportional analysis of APS ACTION registry will better determine the risk of thrombosis in persistently aPL-positive patients based on different risk profiles.

Table: Clinical and Laboratory Characteristics of Patients with Recurrent and Initial Events Since the Inception of AntiPhospholipid Syndrome Alliance for Clinical Trials and InternatiOnal Networking (APS ACTION) Clinical Database and Repository ("Registry")

N (%)	# of APS Patients with Recurrent Events n: 36	# of aPL-positive Patients with Initial Events n: 9
Mean age (registry entry) (\pm SD)	40.58 ± 13.20	38 ± 14.47

SESSION INFORMATION

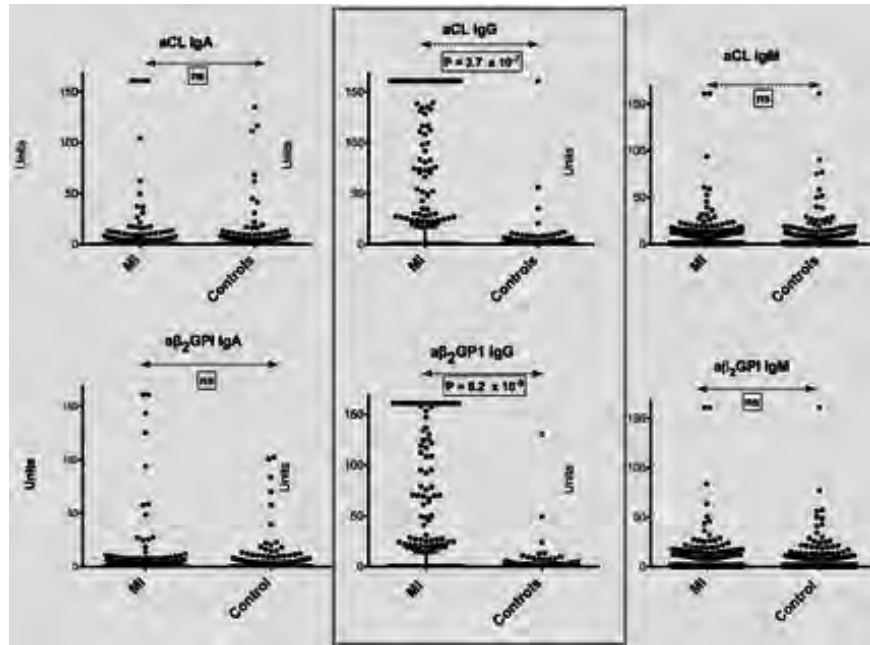

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The antiphospholipid syndrome (APS) is present when arterial, venous or microvascular thrombosis or obstetric morbidity concur with confirmed positive tests for antiphospholipid antibodies (aPL). Long-term anticoagulation prevents new thrombotic events in most APS patients. Information on the occurrence of pro-thrombotic

aPL in myocardial infarction (MI) is conflicting due to limited size, selected populations and/or non-standardized methods in previous studies.

Methods: 805 patients (age <75years; 6-10 weeks after a first MI) and 805 age- (mean 62 ± 8 years), sex- (male 81%) and area-matched controls, free from MI, were examined. Associations between a PL positivity [anti-cardiolipin (aCL) and anti- β_2 glycoprotein-I (anti- β_2 GPI), IgG, IgM and IgA] and MI were studied by paired statistical analyses (paired Student's t-test, McNemar's test). Additionally, aPL positive MI patients and 6 APS patients, defined according to the Sydney criteria, were tested on a peptide ELISA regarding reactivity to specific domains of the β_2 GPI protein.

Results: Positivity for IgG anti-CL and IgG anti- β_2 GPI was noted in 10.9% versus 0.9% [$p < 0.0001$] and in 10.4% versus 0.9% [$p < 0.0001$] among MI patients and controls respectively, and many MI patients had high IgG titers. aPL of IgM and IgA isotypes did not differ (figure). IgG positivity for anti-CL and anti- β_2 GPI was highly correlated ($r_{\text{Spearman}} = 0.85$) and these antibodies were therefore evaluated combined as aPL IgG positivity ($n = 88$). Using this definition aPL IgG positivity remained associated with MI after adjustment for traditional cardiovascular risk factors (present smoking, hypertension, diabetes and body mass index) [adjusted OR 8.9 (95% CI: 4.6-17.3)]. Anti- β_2 GPI antibodies from MI patients usually recognized one domain of the β_2 GPI protein, while antibodies from APS patients targeted several domains.

Conclusion: In a large representative cohort of patients with a first-time MI and matched controls, we report a strong independent association between IgG aPL positivity and MI, suggesting that IgG aPL could be an important risk factor for MI in the general population. If long-term cohort studies can confirm causality for IgG aPL, our results may alter handling, treatment and outcomes for many patients with MI.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: 1. To characterize the mRNAs and microRNAs transcriptomes of monocytes, key immune cells in the atherothrombotic pathology of Antiphospholipid Syndrome patients (APS). 2. To evaluate the role of antiphospholipid antibodies (aPL) in the regulation of these processes. 3. To investigate the short-term effects of *in vivo* ubiquinol (reduced coenzyme Q10 [Qred]) supplementation.

Methods: Monocytes from peripheral blood of 30 APS patients and 30 healthy donors were purified by negative immunomagnetic selection. Then, gene expression microarray (Agilent G4112F platform) and nCounter microRNA expression arrays (Nanostring) were performed. Functional categorization of altered genes and miRNAs was made using IPA software, and interaction networks were identified. Genes and miRNAs integrating the networks were validated in the whole APS cohort, as well as on a set of thrombotic non-autoimmune patients. Predicted miRNA-mRNA interactions were tested by microRNA over-expression experiments. The short-term effects of *in vivo* Qred supplementation on the monocyte transcriptomes profiles were further analyzed.

Results: Microarray identified 518 altered genes in APS monocytes. Relevant biofunctions on which these genes were involved included hematological and cardiovascular system development and function, inflammatory response, and embryonic development, among others. Gene alterations were validated in the whole cohort, demonstrated to be stable along the time, divergent of the gene profile in monocytes from non-autoimmune thrombotic patients, and associated to clinical parameters, including thrombotic recurrences and early atherosclerosis. Analysis of miRNA profiles showed altered expression of 22 miRNAs in APS monocytes. Fifty-four genes were inversely correlated and predicted as CVD-related target genes of 19 differentially expressed miRNAs. Association of these genes and miRNAs with the occurrence and type of thrombotic events, obstetric complications and presence of atheroma plaques were demonstrated. Transfection studies further confirmed the relationship between specific miRNAs and their identified target genes. *In vitro* studies demonstrated the specific modulation of several genes/miRNAs by aPLs. *In vivo* Qred supplementation of APS patients reversed the monocytes' altered gene/miRNA profiles.

Conclusion: 1. Gene and microRNA expression profiles allowed the identification of relevant genes and pathways altered in monocytes of APS patients, associated with the pathogenesis of the disease and modulated, at least partially, by aPLs. 2. Specific microRNA-miRNA regulatory networks control the biological processes and factors related to the CV pathology in APS and are modified by *in vivo* Qred supplementation.

An Interactive Rheumatology Curriculum for Interprofessional Teams Using a Novel Mobile App

Jennifer Mandal¹, Maria Dall'Era², Sebastian Andreatta² and Leslie Floren³, ¹Rheumatology, University of California, San Francisco, San Francisco, CA, ²University of California, San Francisco, San Francisco, CA, ³School of Pharmacy, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education

Figure 1: Students' Impressions of the Interprofessional Rheumatology Curriculum

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The demand for rheumatologic care far exceeds the current supply of rheumatology providers, and this gap is expected to increase. Early exposure to rheumatology cases is an important way to inspire interest in our specialty among trainees in various health professions. The ability to work effectively in interprofessional (IP) teams is a critical skill for the next generation of rheumatology providers. We created a novel curriculum that A) provides health professions students with early exposure to illustrative rheumatology cases using an innovative patient simulation app, and B) allows students to practice collaborating in IP teams.

Methods: In this pilot curriculum, 16 medical students and 16 pharmacy students collaborated in pairs over the course of 2 weeks on a virtual patient case of a young woman with lupus. The case was presented using PIVOT (Practice Improvement using Virtual Online Training) – an interactive mobile app that allows students to review case content (i.e. videos of the patient interview, radiographic images, and lab results), refine their clinical reasoning skills (with tools such as the differential diagnosis slider which allows students to rank diagnoses in order of likelihood), and communicate with their teammate via mobile chat to formulate several IP collaborative care plans. The plans were graded for accuracy and completeness, and students were able to review expert plans written by faculty rheumatologists and pharmacists. At the end of the case, students completed a feedback survey that included both quantitative (Likert scale) and qualitative (open-text) assessment of the curriculum. We calculated descriptive statistics for the Likert scale data, and performed structured thematic analysis of the open-text data to identify common themes.

Results: All 16 interprofessional teams successfully completed the case and submitted 3 collaborative care plans. All 32 students completed the post-curriculum survey, and Likert scale scores are summarized in Figure 1. Thematic analysis of the open-text questions revealed that students particularly valued 1) the opportunity to learn from their medical/pharmacy teammate's unique approach to the case, 2) the team chat platform which allowed them to communicate with their teammate in real time, and 3) the opportunity to learn from faculty expert care plans.

Conclusion: We successfully developed a novel IP rheumatology curriculum for medical and pharmacy students using PIVOT, an interactive mobile application. The curriculum was well-received by the students, who reported that it improved their understanding of lupus as well as their ability to communicate effectively in IP teams. Based on the success of this pilot, we plan to utilize the PIVOT platform to develop additional rheumatology cases and to involve more health professional trainees, including nursing and physical therapy students.

Measuring Cognitive Load during Arthrocentesis Training: Our Initial Experience

Erica Jaffe¹, Andrea Barker² and Michael J. Battistone³, ¹Internal Medicine, Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, ²Salt Lake City VAMC and University of Utah, North Salt Lake, UT, ³Division of Rheumatology, University of Utah Medical Center, Salt Lake City, UT

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Cognitive load theory is increasingly recognized as a meaningful construct in medical education and considers learning to be limited by availability of working memory. Demands on working memory are defined as cognitive load (CL), which is characterized as *intrinsic* (IL—related to the inherent difficulty of the task), *extrinsic* (EL—factors unrelated to the task), and *germane* (GL—deliberate cognitive processes used to acquire skills). Optimal learning conditions limit IL and EL, and increase GL. The Cognitive Load Inventory for Colonoscopy (CLIC) was developed as a tool to measure CL during procedural training in colonoscopy. The purpose of this study was to examine the initial experience with an adaptation of the CLIC to measure CL during arthrocentesis training.

Methods: From 2016 to 2018, 149 learners participated in a previously validated knee injection objective structured clinical examination (OSCE) during the MSK Education Week at the Salt Lake City VA. Immediately after the OSCE participants completed the CLIC adapted for arthrocentesis (Fig 1). 131 participants (3 fellows, 80 residents, 48 students) completed all activities and were used for data analysis. We used chi-squared analysis to compare CL to OSCE results. Only one question for EL (E5) was analyzed as other questions had no variance. We used unpaired T-test to compare different domains of cognitive load across fellows, residents and students.

Results: High IL (IL4) was associated with worse OSCE score ($p=0.04$). There was no association between internal distraction (E5) and OSCE score. High GL for no touch technique (G3) was associated with better scores for skin sterileprep ($p=0.01$) and sterility of procedure ($p=0.04$). High GL in controlling supplies (G4) was associated with better needle technique ($p=0.04$). Residents compared to fellows had significantly lower GL for controlling supplies (1.7 vs 2.9,

Figure 1. Cognitive Load Questionnaire

Intrinsic Load (IL)

1. How difficult was it to appropriately position the patient and manage their level of comfort?
2. How difficult was it to identify the relevant anatomy and landmarks?
3. How difficult was it to physically manipulate and control the needle and syringe?
4. Overall, how difficult was the procedure? (global)

Extrinsic Load (EL)

Effectiveness of teacher

1. How clear were your preceptor's instructions?
2. How effective was the manner in which my supervisor provided instructions or teaching?

External/Internal Distractions

3. How distracted did you feel by other people present in the room?
4. How distracted did you feel by the environment (ie, my pager going off, environmental noise, layout of the room)
5. How distracted did you feel by things on your mind unrelated to the procedure?

Germane Load (GL)

Preparation for procedure

1. How much mental effort did you invest learning how to position the patient and manage their level of comfort?
2. How much mental effort did you invest learning how to identify the relevant landmarks?

Performance of procedure

3. How much mental effort did you invest learning how to adequately disinfect the injection site and maintain the no-touch technique?
4. How much mental effort did you invest learning how to control or manipulate the needles and other supplies in this procedure?

Global

5. Overall, how much mental effort did you invest learning during this procedure?

Global (Glob)

During the procedure you've just completed, to what extent was your mind occupied by the following three activities?

1. The overall difficulty of the procedure? – I
2. Thoughts or distractions not essential to performing this procedure? – E
3. My efforts to understand learn knee aspiration/injection technique? – G

p=0.03) and significantly higher perception of global IL (2.3 vs 1.3, p=0.046), but not global EL or GL. There was no significant difference between residents and students in any domain.

Conclusion: We have adapted a previously validated tool to measure CL during arthrocentesis training. High IL was associated with worse performance and high GL with better performance on the OSCE which is consistent with cognitive load theory. IL and EL were likely lower than in the clinic as the OSCE took place directly following didactics and distractions were more limited than in a clinical setting. We would like to measure CL in the clinic setting to understand barriers to learning arthrocentesis.

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: With rapid rise in healthcare costs, there is increased emphasis to teach cost-conscious care in graduate medical education. Our objective was to develop online cases to teach high-value care and diagnostic evaluation of musculoskeletal (MSK) complaints to pediatric residents and rotating medical students.

Methods: Six online cases of common pediatric MSK complaints were developed utilizing a branched storyboard approach. Access and instructions on using the online modules were distributed during two scheduled lunchtime teaching conferences at University Hospitals Cleveland Medical Center.

Learners completed the modules in either one of two groups, those who saw the itemized costs of diagnostic tests and those who did not, to determine whether displaying costs would affect decision-making behavior and ability to arrive at a correct diagnosis. All learners completed a post-simulation survey. Measured outcomes included presumed diagnosis, cost of evaluation, diagnostic testing utilized, and perceptions towards the learning platform and high-value care. Simulation outcomes were assessed using paired t-tests. Survey data between the two groups were analyzed with Chi-squared tests. Outcomes separated by training year were analyzed using ANOVA and a post-hoc Tukey test.

Results: A total of 39 residents and medical students participated in the pilot and completed the survey. Learners were randomly assigned to complete the simulated cases with costs (n=19) or no costs (n=20) displayed next to orderable tests during the diagnostic workup. Overall, learners who were able to see costs of diagnosis spent less money on diagnostics (\$1511.11 mean per learner versus \$2311.35, p = 0.01). Arrival at the correct diagnosis was associated with lower costs in 3 of 6 cases (Table 1). When compared to the no cost group, learners in the group that had access to costs reported feeling more knowledgeable about the price of diagnostic tests post-simulation (p=0.04) and were more likely to factor costs into

Table 1: Costs vs. Correctness

Case	Correct diagnosis	Mean cost of work up	95% CI	Incorrect diagnosis	Mean cost of work up	95% CI	P-value
Rheumatic fever	17/39	\$701.29	\$559.13-\$843.46	22/39	\$599.55	\$404.45-\$794.64	0.30
Lyme arthritis	10/39	\$294.93	\$197.29-\$372.58	9/39	\$528.00	\$276.62-\$779.37	0.01*
Transient synovitis	24/39	\$237.83	\$134.22-\$341.44	15/39	\$520.80	\$311.82-\$727.77	<0.01*
Osgood-Schlatter	35/39	\$112.97	\$88.15-\$137.79	4/39	\$210.00	\$458.11-\$878.31	0.10
Anterior longitudinal ligament	33/39	\$410.33	\$250.60-\$560.01	6/39	\$277.33	\$133.98-\$468.68	0.75
Benign growth pain	36/39	\$66.72	\$36.66-\$96.79	3/39	\$201.67	\$14.28-\$389.06	0.01*

their practice moving forward ($p=0.03$). Third year residents demonstrated a statistically significant increase in number of cases diagnosed correctly as opposed to medical students.

Conclusion: Our data showed that those who made incorrect diagnoses often spent more money, stressing the need for proper clinical training to prevent wasted healthcare costs. Overall, learners expressed preference for using online cases as a learning tool and recognized high-value care as an important component of patient care after completion of the simulation. This suggests that simple interventions that challenge learners to integrate costs into decision-making can be the basis for changing future practice.

Efficacy of a Web-Based Module to Educate Internal Medicine Housestaff on Gout

Allan C. Gelber¹, Olive Tang¹, Uzma Haque², Amanda Bertram³ and Stephen Sisson³, ¹Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, ²Rheumatology, Johns Hopkins School of Medicine, Lutherville, MD, ³Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gout is a leading form of inflammatory arthritis. There is a paucity of data that examines the efficacy of teaching internal medicine (IM) residency trainees about the diagnosis and management of gout.

Methods: The Johns Hopkins Physician Education & Assessment Center was established to deliver an internet-based curriculum in Ambulatory Medicine to subscribing internal medicine residency training programs. A didactic module on the diagnosis and management of gout, including clinical manifestations, epidemiology, risk factors, pathophysiology and therapeutic approaches to gout care was added to the curriculum in 2017. This module included a pre-test and post-test, both consisting of 10 multiple-choice questions. We examined baseline (pre-test) and post-test scores after completing the gout module according to postgraduate year (PGY) of training, program size, and month of year the module was completed, for participating trainees in 2017 and 2018.

Results: A total of 3,612 trainees (PGY1 1334; PGY2 1273; PGY3 1005) at 148 IM residencies completed the gout module. Overall, mean score on the pre-test exam was 71% compared to 88% on the post-test exam ($p<0.001$). Aggregate pre-test scores did not differ, meaningfully or statistically, by PGY year. Further, scores were higher at the start of the academic year (i.e., July, August) than at its conclusion (i.e., April, May). While baseline knowledge of diagnosis and management of gout was not different between PGY1 and PGY3 trainees, PGY1 residents had higher baseline knowledge on the pathophysiology/epidemiology content area; mean PGY1 score was higher than the PGY3 score, at 53% compared to 50% ($p<0.05$), respectively. Both groups improved to a mean score of 85% on the post-test exam. Further, the figure

Table. Mean (SD) pre-test and post-test scores by content area according to PGY status.

	PGY-1	PGY-2	PGY3
Pre-test			
Pathophysiology/Epidemiology	53.0 (29.4)	51.1 (29.6)	50.1 (29.4)*
Clinical	72.7 (23.5)	71.4 (23.2)	73.1 (24.0)
Treatment	80.2 (25.3)	79.7 (26.9)	80.8 (28.2)
Post-test			
Pathophysiology/Epidemiology	84.9 (18.6)	84.8 (19.4)	84.9 (19.7)
Clinical	90.2 (18.7)	90.4 (18.6)	89.6 (18.8)
Treatment	89.5 (20.1)	91.3 (17.7)*	91.7 (18.3)**

* $p<0.05$ compared to PGY-1 as reference group

** $p<0.01$ compared to PGY-1 as reference group

and table below, demonstrate the ability of all trainees, regardless of PGY status, to increase their knowledge score after module completion, overall and in each content area.

Conclusion: This web-based gout curriculum is effective at increasing subject knowledge for all trainees, overall and by content-specific areas. Yet, inasmuch as baseline knowledge of gout was not higher at each successive year of training, this suggests a lack of effective training on the diagnosis and management of gout during IM residency training. Further, enrollment in the gout module earlier, rather than later, in residency training may enable earlier acquisition of gout knowledge, and improved patient outcomes in gout-related care.

Abstract Number: 861

Critical Appraisal Self-Efficacy and Learning Behavior in Rheumatology Trainees

Juliet Aizer¹, Michael D. Tiongson², Julie Schell³, Jessica R. Berman¹, Stephen A. Paget¹ and Lisa A. Mandl¹,
¹Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, ²Hospital for Special Surgery, New York, NY, ³The University of Texas at Austin, Austin, TX

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Critical appraisal self-efficacy, defined as confidence in one's ability to appraise the clinical literature, may impact trainees' ability to optimally use and incorporate literature in practice. Self-efficacy has been shown to influence behavior to engage in subsequent related tasks.¹ Little is known about critical appraisal self-efficacy in rheumatology trainees or how it relates to learning behaviors.

Methods: All ACGME-accredited rheumatology training programs were invited to enroll trainees in an online learning tool for epidemiology and biostatistics (epi/biostats): Hospital for Special Surgery Critical Literature Assessment Skill Support – Rheumatology (HSS CLASS-Rheum). Once enrolled, trainees completed a Baseline Questionnaire in order to access 10 educational modules. The Baseline Questionnaire included the 6 items most relevant to critical appraisal self-efficacy from the validated 92-item Clinical Research Appraisal Inventory (CRAI),¹ as well as 5 other critical appraisal self-efficacy items developed internally. Items ranged from 0 (no confidence) to 10 (total confidence). Analyses were performed with t-tests, Pearson correlations, and Cronbach's alpha.

Results: 33/150 programs enrolled in HSS CLASS-Rheum, and 118/125 trainees (94%) completed the Baseline Questionnaire: 63.6% female; 54.2% Caucasian, 31.4% Asian, 4.2% African American; 8.5% Hispanic/ Latino; 47.5% in 1st year of fellowship, 42.4% 2nd year; 55% had prior courses in epi/biostats.

The mean score of the 6 items from the CRAI was 4.28 (range 0.5-8.17; 10 highest possible score). These 6 items demonstrated internal consistency (Cronbach's alpha 0.95) and a strong correlation with our internally developed critical appraisal self-efficacy items ($r=0.84$; $p<0.001$). Trainees had significantly lower scores on the 6 CRAI items if they had no previous coursework in epi/biostats (3.6 vs. 4.8; $p<0.001$), rated their understanding of epi/biostats lower than their peers (3.3 vs. 4.9; $p<0.001$), reported being less likely to refer to studies to answer clinical questions (3.8 vs. 4.8; $p=0.002$), or were planning to enter private practice (3.9 vs. 4.6; $p=0.04$). Trainees who went on to complete at least 1 of the HSS CLASS-Rheum modules had higher baseline scores on these 6 CRAI items (4.5 vs. 3.6; $p=0.02$).

Conclusion: These data suggest that the 6 CRAI items may serve as a useful measure of critical appraisal self-efficacy in rheumatology trainees. Higher scores on these 6 items were associated with prior training in epi/biostats, better self-reported understanding of epi/biostats, as well as with positive learning behaviors including self-reported utilization of the medical literature and objective use of the HSS CLASS-Rheum learning tool. Prospective studies are needed to validate these items as a measure of critical appraisal self-efficacy, evaluate the effect of educational interventions on critical appraisal self-efficacy, and measure the impact of improved critical appraisal self-efficacy on learning behaviors.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The recent ACR Workforce Survey has projected that the current workforce shortage in pediatric rheumatology will worsen in the coming decades. Contributing to this shortage is lack of exposure to pediatric rheumatology in medical school and residency. In 2001, the American College of Rheumatology (ACR) established the annual Pediatric Rheumatology Residents Program to address this workforce shortage. This program introduces pediatrics and internal medicine-pediatrics residents to subspecialty rheumatology training by providing an opportunity for the residents to attend the ACR/Association of Rheumatology Health Professional (ARHP) annual meeting. The program focuses on residents who have an interest in pediatric rheumatology but are undecided about a subspecialty. The residents are paired with a pediatric rheumatology faculty mentor, attend special interactive sessions such as fellow/faculty panels and guided poster tours, and are recommended to attend pediatric rheumatology-specific sessions at the annual meeting. The goal of the program is to encourage residents to pursue pediatric rheumatology fellowship training. We were interested in learning how successful this program was at achieving its stated goals.

Methods: We reviewed data collected from resident applications and annual post-meeting electronic surveys for all program years to determine the number of residents who went on to pediatric rheumatology fellowship training. We also looked at how important individual sessions were to the residents' career decision-making.

Results: The inaugural program included 22 pediatric residents, 8 of whom pursued pediatric rheumatology fellowship training (36%). Over the subsequent 17 years, the program has sponsored 21-26 pediatric residents per year. The percentage of residents who pursued pediatric rheumatology training is shown in Figure 1 and varied between 13-73%.

End of program evaluations resident response rates were >95%. On program evaluations, residents noted that the faculty and fellow interactions were important and >90% of residents reported that faculty mentoring at the sessions was important in making decisions about the specialty.

Conclusion: The ACR Pediatric Rheumatology Residents Program has been successful in recruiting previously undecided residents to pursue fellowship training by providing opportunities for the residents to interact with pediatric rheumatologists and gain exposure to clinical and research sessions at the annual ACR/ARHP meetings. Continuation of this program is vital to address the deepening workforce shortage in pediatric rheumatology.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

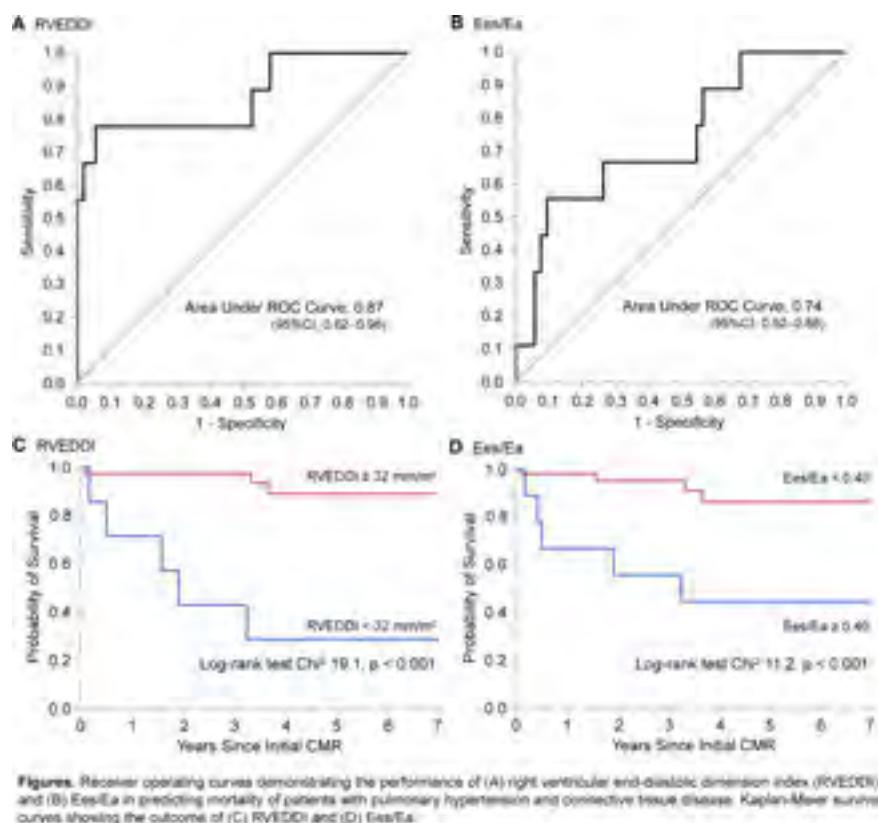

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pulmonary arterial hypertension associated with connective tissue diseases(CTD-PAH), particularly PAH associated with systemic sclerosis (SSc-PAH), has a poor prognosis compared with other PAH. The pathogenesis of CTD-PAH is complex, comprising not only pulmonary arteriopathy but also venous and interstitial involvements. In addition, recent studies have shown that right ventricular(RV) dysfunction is more pronounced in CTD-PAH than in other PAH despite similar or even lower pulmonary arterial (PA) pressure in CTD-PAH patients. The present study aimed to precisely evaluate RV function, including RV-PA coupling by combining cardiac magnetic resonance (CMR) and right heart catheterization(RHC) and to analyze its prognostic value in CTD patients with pulmonary hypertension (PH).

Methods: This is a single center retrospective analysis comprising 84 CTD patients, including SSc, systemic lupus erythematosus, and mixed connective tissue disease, who underwent both CMR and RHC from January 2008 to March 2018. End-systolic elastance (Ees, mPAP/RV end-systolic volume index), pulmonary arterial elastance [Ea, (mPAP-PAWP)/SV index], and Ees/Ea were calculated as load-independent parameters of RV systolic function, RV afterload, and RV-PA coupling metrics, respectively. The prognostic value of each parameter was evaluated by area under the ROC curves (AUCs) and Kaplan-Meier curves.

Results: Of 84 patients, 54 had PAH, 11 had non-PAH PH due to left heart disease, severe interstitial lung disease (ILD) and venous thromboembolic disease, and 19 did not have PH. Nine patients deceased during a median follow-up period of 25 months. In patients with PH (n=65), RV end-diastolic dimension (RVEDDI) and Ees/Ea strongly predicted the mortality with AUC of 0.87 and 0.74, respectively (Figure A and B). The 2-year overall survival rate was significantly lower in patients with either RVEDDI of >32 mm/m² or Ees/Ea of <0.40 compared with other patients (62% vs 98%, $p<0.001$) (Figure C and D). Notably, 2-year survival of patients with both RVEDDI of >32 mm/m² and Ees/Ea of <0.40 was only 20%. In multivariate Cox proportional hazards regression analyses using propensity score to control confounding factors including age, sex, PAH, SSc, and ILD, RVEDDI still significantly predicted the mortality (hazards ratio 11.1, 95% confidence interval 1.82-70.6). In SSc-PAH patients (n=24), compared with other CTD-PAH patients, RVEDDI was significantly higher ($p=0.004$), and Ees was significantly lower ($p=0.013$), indicating RV impairment in systolic function as well as diastolic function.

Conclusion: RV dimension and RV-PA coupling, which can be evaluated by combining CMR and RHC, strongly predicted the prognosis of CTD patients with PH. More pronounced impairment of these parameters observed in SSc-PAH patients is consistent with the less favorable outcome of those patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: MRI detected bone marrow edema (BME) plays a central role in the ASAS (Assessment of Spondyloarthritis International Society) classification criteria for axial spondyloarthritis (axSpA). However, several studies have shown that BME in the sacroiliac joints (SIJs) is also present in other conditions^{1, 2}. The aim of the study was to investigate the utility of the relation between MRI BME and different types of MRI lesions in the sacroiliac joint to separate patients with axSpA from persons with other conditions.

Methods: The MASH study is a prospective cross-sectional study of 204 participants, aged ≤ 45 yrs. The study included 41 patients with axSpA, 46 women with and 14 without pain related to pregnancy or postpartum within 12 months after delivery, 25 patients with lumbar disc herniation, 26 persons with hard physical labor (cleaning assistants), 23 long-distance runners (≥ 30 km/week) and 29 healthy men. Participants with pain should all have VAS pain > 2 (on a scale 0-10) for ≥ 2 months. Participants in the non-axSpA groups were not allowed to have any clinical SpA features or rheumatological conditions. All participants underwent clinical, laboratory and MRI examination including semi-coronal STIR and T1-weighted sequences of the SIJs. MRIs were evaluated for BME, erosion, fat, ankylosis, and sclerosis according to the SPARCCMRI definitions of lesions^{3,4} by two independent readers. In each of the nine slices of the cartilaginous compartment, the left and right SIJs were separately assessed for presence of BME in relation to each of the above mentioned structural lesions (range of total score per patient: 0-18).

Results: The table shows the clinical characteristics within each participant group, and MRI results based on the mean scores of the two readers. BME located adjacent to joint space, adjacent to erosions and adjacent to fat were more frequent in patients with axSpA, but these lesions were also seen in the other study groups, mainly women with postpartum pain. When increasing amounts of lesions were required (higher cut-offs), almost only AxSpA patients fulfilled the requirements (table). BME adjacent to sclerosis was most frequent in women with postpartum pain, whereas BME adjacent to ankylosis was only seen in patients with axSpA.

Conclusion: BME located adjacent to joint space, adjacent to erosion and adjacent to fat was most frequent, but did not exclusively occur in patients with axSpA, whilst BME adjacent to sclerosis was most frequent in women with postpartum pain. Detailed analysis of lesions and their anatomical location may help differentiate axSpA from other conditions.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Metacarpal head directly exposed to intra-articular inflammatory milieu, therefore may lead to abnormal bone remodeling (bone loss and new bone formation).

The aims of this study are to investigate the structural (bone erosion and enthesiophyte) and microstructural bone changes in patients with PsA at the second and third metacarpal head (MCH2&3) compared with controls.

Methods: 139 subjects (77 PsA, 62 control) underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) scanning at the MCH 2 and 3 and distal radius. Structural and microstructural bone changes at the MCH 2 and 3 were calculated (Figure 1) and compared between PsA patients and healthy controls.

Results: 15 patients with joint destruction were excluded from further analysis. 62 patients with PsA and controls were comparable in age, gender and body mass index (BMI). PsA patients had a significantly increased number (2.4 ± 1.4 vs 1.3 ± 1.1 , $p < 0.001$) and total enthesiophytes volume per person (8.75 ± 6.92 vs 4.36 ± 4.90 mm³, $p < 0.001$) compared to controls. Erosion number (2.9 ± 1.2 vs 2.7 ± 1.4 , $p = 0.408$) and total erosion volume per person (11.88 ± 7.82 vs 9.64 ± 5.96 mm³, $p = 0.076$) were similar in PsA patients compared with control. Regarding microstructure, PsA patients had a significantly decreased total volumetric bone mineral density (vBMD), cortical vBMD and cortical thickness at the distal radius; while a preferential bone loss at the trabecular compartment at the MCH was noticed compared to control. Regression model in PsA showed that advancing age, a higher BMI and C-reactive protein level were independent explanatory variables associated with a larger erosion volume. In contrast, older age and swollen joint count were independent explanatory variable associated with an increase in enthesiophyte volume.

Conclusion: Intra-articular trabecular bone loss and enthesal new bone formation was more prevalent in the MCH of patients with PsA.

Disclosures: This study has been partly presented at EULAR 2018.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gout is typically characterized as an acute monoarthritis involving the joints of the foot. However, polyarticular involvement develops, especially in advanced disease. Patterns of involvement of monosodium urate (MSU) crystal deposition such as symmetry and clustering in patients with gout has never been described. The aim of this study was to evaluate patterns of MSU deposition using dual-energy CT (DECT) among gout patients on urate-lowering therapy (ULT).

Methods: Using standardized acquisition protocols, DECT scans of the feet/ankles, knees, and hands/wrists were prospectively obtained in 153 patients with a known diagnosis of gout (all meeting 1977 ARA gout classification criteria) and on allopurinol at a dose of at least 300 mg daily for at least 3 months. MSU deposition was evaluated by 2 DECT radiologists at 12 sub-sites in the feet/ankles, 4 sub-sites in the knees, and 15 sub-sites in the hands/wrists. We calculated the number of subjects who would have 0, 1, 2, 3, 4, or 5+ joints with MSU deposition, assuming that its presence in different joints in a subject is independent. Clustering of MSU deposition in the 3 regions was assessed using a χ^2 -test. We then evaluated the patterns of MSU deposition at different joints with generalized estimating equations while adjusting for age, sex, and race.

Results: Our analysis included 153 patients (92% male) with gout (mean disease duration, 15 years) on allopurinol (mean duration of therapy, 5 years; mean daily dose, 333mg). MSU deposition was observed in a clustered manner at multiple joints of the hands/wrists, feet/ankles, and knees more frequently than would be expected by chance ($p < 0.001$ for all 3 regions). Presence of MSU deposition at a given joint was strongly associated with MSU deposition at the same joint of the opposite extremity (i.e., symmetric involvement), followed by other joints in the same ray of the hand or foot (i.e., multiple joints of one digit), followed by other joints in the same row of the hand or foot (i.e., same joint across multiple digits).

Conclusion: MSU deposition often affects multiple joints of the feet/ankles, knees, and hands/wrists in a clustered manner. MSU deposition tends to occur in a highly symmetric pattern in all three regions evaluated. In the hands and feet, MSU deposition is more likely to cluster by ray (i.e., multiple joints of one digit) than by row (i.e., same joint across multiple digits). These findings may shed light on pathophysiologic factors that lead to MSU deposition and may inform clinicians' decisions to obtain bilateral vs unilateral imaging of a target joint.

Table 1 – Pattern of MSU Deposition in Treated Patients with Gout

	Adjusted Odds Ratio* (95% CI)
Hand	
Same joint, other side	26.1 (2.6, 263.6)
Same ray, same side	15.0 (2.1, 107.8)
Same row, same side	14.9 (1.9, 114.3)
Foot	
Same joint, other side	46.9 (23.9, 92.2)
Same ray, same side	4.6 (2.0, 10.6)
Same row, same side	1.5 (0.7, 3.1)
Knee	
Same joint, other side	9.9 (5.9, 16.5)
Same row, same side	4.2 (2.5, 7.2)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Magnetic Resonance Imaging (MRI) bone marrow edema (BME)/osteitis and MRI synovitis have been identified as predictors of structural damage progression in rheumatoid arthritis RA^{1,2}. Targeting MRI remission may reduce inflammation and halt damage progression.

The purpose was to investigate whether a 2-year treat-to-target (T2T) strategy targeting MRI remission (defined as absence of BME) suppresses MRI-determined measures of disease activity and structural joint damage in RA patients in clinical remission.

Methods: In the two year investigator initiated, randomized, open label multicentre IMAGINE-RA study, 200 RA patients in clinical remission (defined as DAS28-CRP<3.2 and no swollen joints) receiving conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) were randomized 1:1 to a conventional DAS28-CRP guided T2T treatment strategy targeting DAS28<3.2 and no swollen joints or an MRI guided T2T treatment strategy applying the same clinical T2T strategy and in addition targeting absence of MRI BME. Patients were followed every 4 months over a 2-year follow-up period. In all patients contrast-enhanced MRIs of the 2nd-5th metacarpophalangeal (MCP) joints and wrist of the dominant hand were performed at baseline, 12 and 24 months. In the MRI T2T arm MRI was performed every 4 months ahead of the clinical visit and assessed for presence/absence of BME by one blinded evaluator so the result was available for the

investigator at the visit. In the conventional T2T arm MRI findings were blinded to the investigator. If treatment target was not met treatment was escalated according to a predefined treatment algorithm starting with increment in csDMARD and then adding biologic DMARDs. MRIs (0,12 and 24 months) were evaluated according to the RAMRIS scoring system, with known chronology by one blinded experienced reader. Pearson's chi-square statistics and repeated-measures logistic regression models were used to assess outcomes.

Results: MRI outcomes of inflammation and damage at 24 months are presented in the table. The MRI T2T arm showed statistically significant reductions at 24 months in all inflammatory endpoints (osteitis, tenosynovitis and total inflammation score, $p<0.018$), except synovitis, ($p=0.074$), compared to the conventional T2T arm. No differences between treatment strategies were seen in damage progression.

MRI outcomes at 24 months

	MRI T2T	Conventional T2T	Difference between groups (95% CI)	P value*
MRI				
Inflammation				
Change in osteitis (RAMRIS) score	-1.8 (0.6)	-0.1 (0.5)	-1.8 (-3.2 to -0.3)	0.018
Change in synovitis (RAMRIS) score	-0.5(0.3)	0.3 (0.3)	-0.8 (-1.8 to 0.1)	0.074
Change in tenosynovitis (RAMRIS) score	-0.9 (0.3)	0.3 (0.3)	-1.2 (-2.1 to -0.3)	0.007
Change in total inflammation (RAMRIS) score	-2.9 (1.0)	0.7 (1.0)	-3.6 (-6.4 to -0.8)	0.013
Damage				
Change in erosion (RAMRIS) score	0.5 (0.2)	0.6 (0.2)	-0.1 (-0.6 to 0.4)	0.663
Change in JSN (RAMRIS) score	0.1 (0.2)	0.4 (0.1)	-0.3 (-0.7 to 0.2)	0.236
Change in total damage (RAMRIS) score	0.6 (0.3)	1.0 (0.3)	-0.3 (-1.2 to 0.5)	0.395
No progression in erosion (RAMRIS), n (%)	59 (79.7%)	70 (75.3%)	OR, 1.06 (0.02 to 66.59)	0.976

95% CI, 95% confidence interval; JSN=joint space narrowing; MRI=Magnetic Resonance Imaging; RAMRIS=RA magnetic resonance imaging scoring system; T2T=treat-to-target; total damage score=sum score of MRI erosion and JSN; total inflammation score=sum score of MRI synovitis, osteitis and tenosynovitis. Data are presented as least square means (SE) unless otherwise stated. Analyses are based on full analysis set (patients having a baseline visit and at least one follow-up visit) with no data imputation to replace missing data. *P values are based on repeated-measures logistic regression models. For some of the variables, fewer patients were included in the analyses due to missing data in the MRI T2T arm (range 85-89) and in the conventional T2T arm (range 90-95).

Conclusion: An MRI T2T strategy, aiming to eliminate MRI BME, was more effective than a conventional T2T strategy in reducing MRI inflammation but not MRI damage progression. The reduced inflammatory load caused by the MRI T2T strategy may reduce long-term structural joint damage and improve patient-reported outcomes, but more than two years follow-up data are needed to clarify this.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases I: MRI and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Bone marrow lesion (BML) in hip osteoarthritis (OA) may be a determinant of prognosis and a target for emerging anti-inflammatory therapies. We developed the OMERACT Hip MRI Scoring System (HIMRISS) to maximize reliability & sensitivity to change. Innovations include electronic overlays (touch or mouse-click a region to identify BML), a web-based online interface, and real-time iterative calibration (RETIC) in which new readers perform a scoring exercise online, learning by observing their ICC vs. expert consensus displayed in real-time. Pre-specified minimum ICC must be achieved before becoming eligible to proceed with formal scoring. We tested feasibility, reliability, and responsiveness of HIMRISS for scoring BML in a large prospective cohort.

Methods: In HIMRISS, BML is scored as 0/1 (absent/present) in 100 regions on a web-based grid overlay slice-by-slice in coronal hip MRI. In the Edmonton Steroid Injection in Hip OA (STIHO) cohort, we had n=90 patients x 2 hips x 2 MRI: at baseline presenting for hip steroid injection, and at 8 weeks post injection. Coronal T1/STIR sequences were provided, blinded to time point, to 8 readers: 2 radiology fellows, 3 rheumatologists, 3 musculoskeletal radiologists. Each reader prepared by reviewing a comprehensive HIMRISS methodology module, then had to pass an online RETIC training module with proficiency (ICC 0.80 vs. experts) prior to formal scoring. Readers each scored HIMRISS BML in all 360 hips.

Results: Subjects were 56% male, age 59 ± 13 (mean \pm SD) years, symptom duration 4.4 ± 4.5 years, K-L OA grade 1/2/3/4 in 20%/28%/34%/18%. Reliability (ICC single measure, absolute agreement, 2 way model) was high for baseline BML status for all readers (0.83) and for 2 experts (0.88-0.92). Change was small, mean (SD) $2.1 \pm 10.0/100$. Despite this, ICC for change was (0.42-0.76) for all readers, (0.56-0.81) for experts.

Conclusion: HIMRISS reliably quantifies BML in hip OA at a single time point and can responsively discriminate small changes in BML. Novice readers trained via an online RETIC system achieved reliability close to that of experts. Future studies will assess performance of HIMRISS assessing inflammation in other arthropathies.

Reliability of HIMRISS BML Measurements	Baseline Status		Change	
ICC for BML	All readers	Experts	All readers	Experts
Femoral head	0.83 (0.65-0.91)	0.91 (0.87-0.94)	0.76 (0.65-0.83)	0.81 (0.72-0.87)
Acetabulum	0.83 (0.74-0.89)	0.88 (0.82-0.92)	0.42 (0.23-0.57)	0.56 (0.40-0.68)
Total	0.83 (0.55-0.92)	0.92 (0.88-0.95)	0.72 (0.60-0.81)	0.78 (0.68-0.85)

Change in BML, and HIMRISS Responsiveness	Scoring range	Change observed 0-8 wks; mean(SD)	Smallest detectable change SDC	Hips with change >SDC
Femoral head	0-65	2.2(9.2)	3.6	45%
Acetabulum	0-35	-0.1(2.3)	1.9	33%
Total	0-100	2.1(10.0)	4.6	36%

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gout is associated with an increased risk of cardiovascular events and death. It has been shown that both overall and risk of death are associated with increasing gout severity, as reflected by the number of tophi. It remains to be proven whether better control of gout through lowering of serum uric acid (sUA) confers a survival advantage. To determine the impact of achieving sUA less than 6 mg/dl (vs greater) on mortality risk among gout patients.

Methods: Analysis of data from a prospective follow-up cohort (1992 to 2017) of patients attending a gout clinic (85% of patients with microscope or ultrasound diagnosis) and with at least one follow-up visit. Mortality was confirmed from medical records, patients' families, or local death registries if needed. sUA levels were monitored during follow-up and the average sUA until sUA was stable was used as the primary exposure dichotomized as < 6 mg/dl (versus ≥ 6 mg/dl). Descriptive variables and potential confounders included: age, gender, body mass index, previous treatment with urate-lowering drugs (ULDs), number of joints affected at entry, presence of subcutaneous tophi, radiographic evidence of articular damage, number of gout flares in the year preceding evaluation, previous diagnosis of cardiovascular (CV) disease, loop diuretic use, alcohol intake, diabetes, hypertension, hyperlipidemia, and renal function impairment. In addition, the Kaiser Permanente stratification of comorbidity was further used to risk stratify patients from low to high risk of death. Univariate and multivariate Cox proportional hazards models were used to determine mortality risks expressed as hazard ratios (HR) and 95% Confidence Intervals (CI).

Results: The study cohort included 1,193 patients (92% men, mean age 60, 6.8 years disease duration, with an average of 3 to 4 flares in the previous year). Mean follow-up was 48 (median 30, IQR 12-66), with 4,830 patient-year observation. Mean sUA at baseline was 9.1 mg/dl and 16.3% of the patients maintained sUA levels ≥ 6 mg/dl despite treatment. A total of 158 deaths occurred (13% overall mortality), with loss to follow-up in 286 cases (24%). Overall crude mortality rate was 32.7 per 1,000 patient-years (95% CI: 28.0-38.2) and was significantly higher for patients with sUA ≥ 6 mg/dl, 80.9 per 1,000 person-years (95% CI 59.4-110.3) compared to patients with sUA < 6 mg/dl, 25.7 per 1,000 person-years (95% CI: 21.3-30.9). With adjustment for age, sex, previous CV events, and baseline sUA concentration, a sUA ≥ 6 mg/dl was associated with a HR of 2.39 (1.64- 3.50).

Conclusion: Failure to reach a target sUA level of 6 mg/dl is an independent predictor of mortality in gout patients. Control of gout with achievement of sUA target < 6 mg/dl should be considered in order to improve patient survival.

Patient-Reported Burden of Gout in 2017 from the United States

Puja P. Khanna¹, Douglas C.A. Taylor², An-Chen Fu² and Robert Morlock³, ¹University of Michigan, Ann Arbor, MI, ²Ironwood Pharmaceuticals, Inc., Cambridge, MA, ³YourCareChoice, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Total Flare Burden

- The total flare burden for US adults with gout is 6.5 flares per year
- 69.2% of flares are pretreated/prevented or suffered and not reported to doctors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gout is reported to impact 3.9% of the US adult population (Zhu. Arthritis Rheum 2011;63:3136-41). Treatment encompasses controlling acute attacks (flares) and, dependent on the degree of severity of joint involvement, long-term efforts to reduce urate levels and dissolve existing urate deposits, while preventing new crystal formation. Gout flares are often self-treated by patients, so it is hypothesized that the number of gout flares experienced is underreported to health care providers, leading to underestimation of the burden of gout. The aim of this study was to describe gout flares experienced and reported, unreported, and prevented per year by patients with gout in the United States.

Methods: A 2017 cross-sectional survey of US adults assessed health conditions, impact on health-related quality of life, and health care resource utilization. Participants aged ≥ 18 years were recruited using a random stratified sampling framework to ensure demographic composition representative of the US population. Participants with self-reported gout were asked to estimate the annual number of flares they experienced and reported to their physician, flares experienced and not reported, and flares prevented. Population level characteristics and outcomes are summarized using descriptive statistics.

Results: In 2017, 3.1% ($n=372$) of a representative sample of US adults ($n=12,146$) reported having gout. Patients with gout reported significantly lower physical health as measured with the Rand VR-12 Physical Component Subscale (41.1 vs 46.5; $P<0.05$). The total flare burden was 6.5 flares per year; 69.2% of flares were pretreated/prevented or suffered and not reported to any physician (Figure). On average, patients with gout told their physician they experienced 2 flares over the last 12 months. They reported another 1.3 flares experienced per year that they did not report to their physician and 3.2 flares per year that were alleviated with treatment of initial flare signs (eg, joint warmth and redness). Females were less likely to report all of their flares to their physician (32.4% of females vs 51.8% of males reported all flares; $P<0.05$). Younger patients were more likely to report all gout attacks to a physician (mean age 55.5 reporting all flares vs 63.1 years not reporting all flares; $P<0.01$). There was no difference in reporting flares by the number of comorbidities or use of a urate-lowering therapy.

Conclusion: Patients report only a third of their flares to physicians, resulting in suboptimal treatment of gout. Likewise, age and gender disparity in underreporting also reveals a missed window of opportunity that is essential to ensure optimal management in a large proportion of patients. Reliance on clinical documentation of physician-reported flares is insufficient to assess the true patient burden of gout.

Abstract Number: 871

Estimates of Diet Quality Explain Less Variability in Serum Urate Levels Than Genetic Factors

Tanya J. Major¹, Ruth Topless¹, Nicola Dalbeth² and Tony R. Merriman¹, ¹University of Otago, Dunedin, New Zealand, ²University of Auckland, Auckland, New Zealand

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Hyperuricaemia (elevated serum urate) is a central risk factor for gout, an acute inflammatory form of arthritis. The balance between the hepatic production of urate and the intestinal / renal urate excretion pathways determines an individual's serum urate levels and this balance can be modified by both genetic and environmental factors. This study aimed to evaluate the relative contributions of estimates of diet quality and inherited genetic variants in determining serum urate levels.

Methods: 16,760 American European individuals (8,414 men, 8,346 women) were used to test for associations between serum urate ($\mu\text{mol/L}$) and four composite dietary scores or a genetic risk score, adjusting for sex, age, body mass index, average daily calorie intake, years of education, exercise levels, smoking status, menopausal status, and genome-wide principal component vectors. Genetic heritability of serum urate in these individuals was also assessed.

Results: Three diet quality scores, constructed based on healthy diet guidelines (Healthy-Eating Pyramid, DASH Diet, and Mediterranean Diet), were inversely associated with serum urate (β (in $\mu\text{mol/L}$) = -0.72 , $P = 1.12 \times 10^{-6}$; $\beta = -0.73$, $P = 3.1 \times 10^{-10}$; $\beta = -0.38$, $P = 2.9 \times 10^{-4}$, respectively) and a fourth, data-driven diet quality score associated with raised serum urate ($\beta = 0.59$, $P = 2.3 \times 10^{-8}$). However, each explained $\leq 0.28\%$ of the cohort variance in serum urate. In comparison, a weighted serum urate genetic risk score, constructed from 30 variants previously associated with serum urate in Europeans (Köttgen *et al.* 2013), associated with raised serum urate ($\beta = 0.99$, $P = 2.2 \times 10^{-231}$) and explained 7.9% of the serum urate variance within the cohort. A genome-wide estimate of serum urate heritability explained 23.9% ($P < 1.0 \times 10^{-16}$) of the cohort variance in serum urate.

Conclusion: This study has identified an association between estimates of healthier dietary habits and reduced urate in people of European ancestry and suggests, in contrast to genetic contributions, diet explains very little variation in serum urate levels. Our results are important in demonstrating the relative contributions of overall diet and inherited genetic factors to the population variance of serum urate levels and challenge widely held community perceptions that hyperuricaemia is primarily caused by diet. This study directly shows, for the first time, that genetic variants have a much greater contribution to population-wide variance in hyperuricaemia than dietary habits.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Session Type: ACR Concurrent Abstract Session

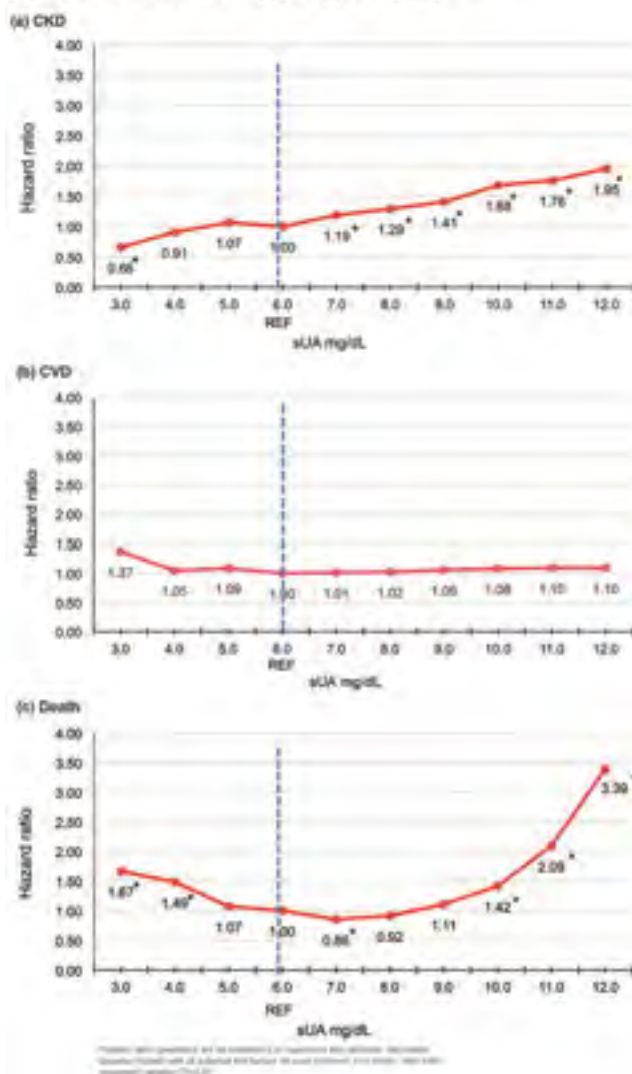

Session Time: 2:30PM-4:00PM

Background/Purpose: Many studies have found that serum uric acid (sUA) levels are associated with the incidence of chronic kidney disease (CKD), cardiovascular disease (CVD), and mortality; however, these associations have not been studied among gout patients. As lowering urate is the mainstay of gout care, these associations would have implications for gout care and future research.

Methods: We conducted a cohort study using data from Clalit Health Services (Israel, January 2006–December 2015). Incident cases of gout were included from 1/2006 to 12/2009 among members aged ≥ 25 years and with continuous enrollment for ≥ 1 year prior to and ≥ 5 years after the first qualified gout diagnosis (the index date). Gout cases were identified based on the following criteria: a) 1 diagnosis of gout from a hospital or specialist visit; or b) ≥ 2 diagnoses of gout from 2 different general practitioner visits and either an elevated sUA (>6 mg/dL) or dispensation of colchicine or allopurinol. Exposure was assessed during the follow-up as: (1) the mean sUA; and (2) a summary measure of sUA above the threshold of 6 mg/dL, and then categorized as either no exposure (sUA-T0) versus quartiles of exposure (sUA-T1 to sUA-T4). We examined the association between time-updated prior sUA levels using either exposure measure and the risk of CKD, CVD, and mortality using extended Cox proportional hazard regression models adjusted for risk factors. Hazard ratios (HRs) were calculated relative to the reference group inclusive of 6 mg/dL.

Results: A total of 12,234 gout patients (mean age at diagnosis=64 years; 76.1% male) were followed for an average of 6.9 years. The mean sUA during the follow-up period was 7.4 mg/dL with sUA category-specific means of sUA-T0=4.4, sUA-T1=6.2, sUA-T2=7.2, sUA-T3=7.8, and sUA-T4=8.7 mg/dL. For CKD endpoints, risks increased with greater UA exposure relative to a mean sUA of 6 mg/dL (Fig1a) and for threshold categories versus sUA-T1 ($HR_{sUA-T2}=1.23$, $HR_{sUA-T3}=1.34$, $HR_{sUA-T4}=1.93$; all $P<0.001$). For CVD endpoints, risks did not differ relative to mean sUA levels of 6 mg/dL (Fig 1b) or versus the thresholds UA-T1 (all $P>0.05$). For mortality, a U-shaped curve was observed for mean sUA exposure (Fig 1c) and for the low and high threshold categories versus sUA-T1 ($HR_{sUA-T0}=1.33$, $HR_{sUA-T4}=2.08$; all $P<0.001$).

Figure 1: Hazard ratio for sUA and (a) CKD, (b) CVD, or (c) Death*

Conclusion: These findings suggest a positive association between cumulative sUA burden above the target level of 6 mg/dL and CKD risk among gout patients. To that end, the sUA target of <6 mg/dL may provide reno-protective benefits among gout patients. Further, gout patients with extreme sUA levels are at risk for increased mortality.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The cardiovascular (CV) safety study CARES has the longest study duration of any randomized controlled trial in patients (pts) with gout and CV disease. In CARES, the proportion of pts with the primary endpoint (composite of CV death, nonfatal myocardial infarction, nonfatal stroke, and unstable angina with urgent revascularization) was non inferior between febuxostat (feb) and allopurinol (allo), but there was an imbalance in rates of CV mortality (4.3% and 3.2%, respectively).¹ We evaluated the general safety of feb and allo in CARES and the relationship between CV mortality and serum urate levels (sUA) or gout flares.

Figure 1. Change in mean sUA with febuxostat and allopurinol in the overall mITT population and CV mortality subgroups during the CARES study⁴

Modified intention-to-treat population (patients who were randomized to treatment and received at least one dose of study drug). At baseline, patient numbers for overall population were: feb n=3098, allo n=3092; CV mortality subgroup: feb n=134, allo n=100

*Number of patients in CV mortality groups with sUA data at Months 60 and 72 were too low (n<5) to allow meaningful interpretation of sUA at these timepoints

CV, cardiovascular; SD, standard deviation; sUA, serum urate levels

Figure 2. Gout flares requiring treatment (per patient-year of exposure) with febuxostat and allopurinol over 5-month intervals during the CARES study (<72 months)

Methods: Pts were randomly assigned to once-daily feb (40 or 80 mg, based on sUA at Week 2) or allo (dose titrated in 100 mg increments from 200–400 mg or 300–600mg, based on kidney function). The modified intention-to-treat population (mITT) comprised pts who were randomized and received treatment. Safety endpoints included treatment-emergent adverse events (TEAEs); key efficacy parameters were changes from baseline in sUA and gout flares. The sUA and flares (while on study drug) were evaluated in those pts with CV mortality versus those in the overall mITT.

Results: Randomized pts were treated with feb (n=3098) or allo (n=3092) over a median follow-up of 32 months (max 85 months); 57.3% and 55.9% of patients randomized to feb and allo, respectively, discontinued treatment early. In the feb and allo treatment groups (mITT), similar proportions of pts had TEAEs (83% vs 82%, respectively) or serious TEAEs (34% vs 32%); most common TEAEs were diarrhea (10% vs 9%) and arthralgia (8% vs 10%). Total incidences of rashes, eruptions, or exanthemas for feb and allo were 4% and 5%, respectively. A total of 13% pts in each group discontinued study drug due to TEAEs. Baseline sUA were higher in pts with CV mortality (feb: 9.3 mg/dL [n=134]; allo: 9.8 mg/dL [n=100]) versus the overall mITT (8.7 mg/dL with feb and allo), but comparable between treatment groups. In the overall mITT, sUA with feb were lower than with allo at Week 2 and Months 3, 6, 12, 24, 36, 48, 60 and 72; however, sUA were not consistently lower with feb in the CV mortality cohort (Figure 1). Gout flare rates were similar with feb and allo and decreased across the study period (Figure 2); flare rates within 3 months of CV mortality were low in both the feb (6%) and allo (2%) groups.

Conclusion: Feb and allo treatments had comparable safety and tolerability findings in pts with gout and CV disease. There were no distinct relationships between CV mortality and sUA or gout flares.

Preventing a Large Majority of Incident Gout Cases By Modifying Key Risk Factors: Findings from a Prospective Cohort of 44,629 Men over 26 Years

Sharan K. Rai^{1,2}, Na Lu³, Chio Yokose⁴ and Hyon K. Choi^{3,4}, ¹Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, ²Graduate School of Arts and Sciences, Harvard University, Cambridge, MA, ³Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA, ⁴Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Metabolic and Crystal Arthropathies: Comorbidities and Outcomes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Many modifiable risk factors have been found to be independently associated with the risk of developing gout, including dietary factors (e.g., intakes of red meat and fructose), adiposity, alcohol intake, and diuretic use. Conversely, healthy dietary patterns (e.g., the Dietary Approaches to Stop Hypertension [DASH]) and a high intake of vitamin C have been shown to be independently associated with lower gout risk. However, the potential combined impact of these factors on the risk of developing gout is unknown. We aimed to estimate the proportion of incident gout cases that could theoretically be avoided through the simultaneous adoption of multiple low-risk behaviors, including low body mass index (BMI), consumption of a DASH-style eating pattern, no alcohol intake, vitamin C supplementation, and no diuretic use.

Methods: From 1986 to 2012, we prospectively followed 44,629 men free from gout at baseline in the Health Professionals Follow-up Study. Lifestyle, anthropometric, and medical information was collected at baseline and updated biennially. Dietary data were obtained using validated food frequency questionnaires at baseline and approximately every 4 years during follow-up. We ascertained incident cases of gout using the American College of Rheumatology survey criteria for gout. We defined low-risk groups according to combinations of the following five factors: a low BMI ($<25\text{kg/m}^2$), adherence to a DASH-style diet, no alcohol intake, vitamin C supplementation ($\geq 1500\text{mg}$), and no diuretic use. Cox proportional hazard regression models were used to estimate the association of each risk factor with the development of gout and calculate the population attributable risk percent (PAR%).

Results: During 950,086 person-years of follow-up, incident gout developed in 1,687 participants. All five modifiable risk factors were independently associated with incident gout. Obesity was the single most important predictor of gout; all other risk factors were also associated with a statistically significant increased risk of gout, even after adjustment for BMI. As compared with the rest of the cohort, men in the low-risk group (comprised of all five low-risk factors; 4.4% of men) had a relative risk of gout of 0.30 (95% confidence interval [CI], 0.12 to 0.72) (Table). Accordingly, the PAR% for all five risk factors combined was 70% (Table). The PAR% for four and three risk factors was 64% and 50%, respectively (Table).

Conclusion: Five modifiable risk factors accounted for 70% of incident gout cases in this large prospective cohort of male health professionals. Assuming a causal relation, our findings support the hypothesis that the vast majority of cases of gout could be prevented by modifying key risk factors.

Table. Relative and Population Attributable Risks of Gout for Groups Defined by Combinations of Modifiable Risk Factors

	Percentage of Men (%)	Number of Gout Cases	Relative Risk (95% CI)	PAR%
3 factors in low-risk category a	11.0	24	0.49 (0.33, 0.74)	50
4 factors in low-risk category b	10.3	15	0.35 (0.21, 0.59)	64
5 factors in low-risk category c	4.4	5	0.30 (0.12, 0.72)	70

Abbreviations: BMI, body mass index. CI, confidence interval. DASH, Dietary Approaches to Stop Hypertension. PAR%, Population attributable risk percent.

Relative risks were adjusted for total energy intake, coffee intake, and histories of renal failure and hypertension.

^a Low BMI, highest quintile of DASH diet score, and no alcohol intake.

^b Low BMI, highest quintile of DASH diet score, no alcohol intake, and no diuretic use.

^c Low BMI, highest quintile of DASH diet score, no alcohol intake, no diuretic use, and vitamin C supplementation.

Anti-Calreticulin Antibody – a Novel Antibody in Patients with Idiopathic Inflammatory Myopathies and Its Association with Malignancy

He Chen^{1,2}, Guochun Wang³ and Xin Lu⁴, ¹Department of Rheumatology, China-Japan Friendship Hospital, Beijing, China, ²Graduate School of Peking Union Medical College, Beijing, China, ³China-Japan Friendship Hospital, Beijing, China, ⁴Rheumatology, China-Japan Friendship Hospital, Beijing, China

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies I: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: To investigate the occurrence of anti-calreticulin antibodies (anti-CRT Abs) and evaluate its association with malignancy in patients with idiopathic inflammatory myopathies (IIM).

Methods: In total, 211 patients with IIM were enrolled in our study and patients complicated with malignancy were separated into a single category. The levels of anti-CRT Abs were measured in serum samples from 106 with dermatomyositis (DM), 21 with polymyositis (PM), 34 with immune-mediated necrotizing myositis (IMNM), 50 IIM with malignancy and 40 healthy controls (HC) by an in-house enzyme-linked immunosorbent assay (ELISA) using recombinant full-length CALR. The clinical and laboratorial data were collected and compared between anti-CRT Abs positive and negative patients. Then 8 IIM patients were followed longitudinally whose changes in concentrations of anti-CRT Ab were assessed and variations in disease activity were measured by myositis disease activity assessment visual analog scales (MYOACT) scores. Receiver operating characteristic (ROC) curve analysis was performed to determine the value of anti-CRT Abs in distinguishing IIM with malignancy from those without malignancy.

Results: Serum levels of anti-CRT Abs were significantly higher in IIM [median 5.3 AU (IQR 2.5-11.6)] than in HC [median 3.8 AU (IQR 1.8-6.4), $P = 0.003$] and anti-CRT Abs were judged to be positive in 48 of 211 IIM patients (22.7%). Among the IIM subgroups, 17/106 (16.1%) DM, 2/21 (9.5%) PM, 7/34 (20.6%) IMNM and 22/50 (44%) IIM with malignancy were seropositive for anti-CRT Abs. Higher frequency of malignancy, heliotrope rash and gottron papules as well as elevated concentrations of immunoglobulin G (IgG) and anti-nuclear Abs (ANA) were present in IIM patients with positive anti-CRT Abs than in those negative. A positive correlation between serum anti-CRT Abs concentrations and MYOACT scores was shown by longitudinal study. ROC curve analysis revealed that the anti-CRT Abs had diagnostic value in distinguishing IIM with malignancy from those without malignancy, with an area under curve (AUC) value of 0.65 (95% CI 0.56 – 0.74, $P = 0.001$).

Conclusion: This is the first report to discover that anti-CRT Abs could be a novel autoantibody detected in IIM. The levels of anti-CRT Abs increased significantly and markedly high anti-CRT Abs levels could be a possible serological marker of malignancies in IIM patients.

Dermatomyositis Skin Shares Type I Interferon Overlap with Cutaneous Lupus but Displays Many Unique Expression Changes That May Serve As Biomarkers for Skin Disease

Tori Nault¹, Alex Tsoi², Tamra J. Reed³, Mehrnaz Gharaee-Kermani³, Lori Lowe⁴, Johann Gudjonsson⁴ and Michelle Kahlenberg³, ¹Internal Medicine, University of Michigan, Ann Arbor, MI, ²Departments of Dermatology and Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI, ³Internal Medicine, Rheumatology, University of Michigan, Ann Arbor, MI, ⁴Dermatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies I: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Dermatomyositis (DM) is a rare disease with both cutaneous and muscle pathophysiology. In the skin of DM patients, very little is known about the drivers of inflammation. In addition, the pathologic diagnosis of cutaneous DM is complicated by its morphologic overlap with cutaneous lupus erythematosus (CLE). Thus, it can be difficult to differentiate DM from CLE patients based on skin biopsy alone. We thus undertook this study to evaluate the gene expression changes in DM skin to understand the dysregulated genes in this disorder and to compare DM skin expression changes to our database of expression changes in CLE to determine unique and overlapping changes between the two diseases.

Methods: Thirty-six patient samples of DM skin biopsies were obtained through the University of Michigan Pathology Archives under IRB HUM72843. Validation of dermatomyositis was made via chart review for documented muscle disease, classic rash features such as Gottron's papules, and autoantibodies. RNA was isolated from formalin-fixed, paraffin-embedded tissue and subjected to microarray analysis via Affymetrix ST 2.1 chip. Differentially expressed genes in dermatomyositis were identified via linear model (*limma*). DM skin biopsies were stained for interferon (IFN) α , β , and κ via immunohistochemistry.

Results: For patients included in the DM cohort, the mean age was 55.5 (SD 16.7); 9 were male, and 27 were female. Race and ethnic distribution was as follows: 28 were Caucasian, 3 were African American, 2 were Hispanic, and 3 were unspecified. Thirteen had skin-only involvement, 22 patients had both muscle and skin involved. Principal component analysis demonstrated substantial differences between DM and healthy control skin. A total of 6,382 differentially expressed genes (DEGs; FDR \leq 10% and fold change (FC) \geq 2) were identified in DM skin. There was a strong correlation between SCLE and DM DEGs; however, DM patients had 4,550 unique DEG that showed limited dysregulation in SCLE. Of the genes in common between DM and SCLE, we identified a significant type I IFN signature, including *MX1*, *OASL*, and *IFIT1*. Interestingly, similar to our data from CLE skin, we identified IFN κ as the most significantly upregulated type I IFN in DM skin (FC=2, q=7.2E-06). IFN ϵ was the only other type I IFN upregulated by our array (FC=1.4; q=3.05E-02). Upregulation of IFN κ expression was confirmed by immunohistochemistry and displayed expression in the basal keratinocyte layer and in the dermis. Minimal IFN α and IFN β staining was seen. When genes unique to DM were subjected to GO analysis, functional enrichment in pathways involving vesicle transport (q= 2.03E-05), RNA splicing (q= 2.11E-05), and neutrophil degranulation (q= 5.18E-05) were noted.

Conclusion: DM skin displays a strong type I IFN signature and upregulation of IFN κ , similar to CLE, but there are distinct regulatory pathways that separate DM from CLE that may be useful biomarkers for early identification of DM. In addition, our data suggest that targeting type I IFN pathways in DM patients may be of benefit to skin lesions.

Abstract Number: 877

Serum Krebs Von Den Lungen-6 Is a Useful Biomarker for Assessing Activity of Myositis-Associated Interstitial Lung Disease

Satoshi Takanashi¹, Naoshi Nishina², Maho Nakazawa², Yuko Kaneko² and Tsutomu Takeuchi², ¹Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, ²Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies I: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interstitial lung disease (ILD) is one of serious organ involvements in idiopathic inflammatory myositis. Krebs von den Lungen-6 (KL-6) is an antigen produced primarily by regenerating type II pneumocytes and has been known as a biomarker in ILD, although whether it can be used to assess myopathy-associated ILD is unclear. The aim of this study is to elucidate the usefulness of KL-6 in myositis-associated ILD.

Methods: We reviewed consecutive patients with myositis-associated ILD in our institution between 2002 and 2017 and enrolled those with serum KL-6 at diagnosis available. We divided the patients into two groups who relapsed and did not (relapse group and non-relapse group), and compared serum KL-6 levels and its time-course changes during the observation period between 2 groups.

Results: Fifty-eight patients with myositis-associated ILD were included in the analysis. Median age at diagnosis was 51 years old, and female was 60%. Diagnosis consisted with 13 (22%) with polymyositis, 22 (38%) with dermatomyositis and

23 (40%) with clinically amyopathic dermatomyositis. Of those patients, 21 (36%) relapsed and 37 (64%) did not. Median period from diagnosis to the last visit in the non-relapse group was 27 months, and from diagnosis to the relapse in the relapse group was 26 months. Median KL-6 levels at diagnosis were significantly higher in the relapse group than the non-relapse group (1870 vs 935 U/mL, $p = 0.003$). A receiver operating characteristic curve identified baseline KL-6 of 1359 U/mL as a significant indicative level for futuristic relapse. When we followed the relapse group until the last visit (median period was 82 months), 6 patients experienced second or third relapse. The time-course change in serum KL-6 in the relapse group showed remarkable decrease at remission and increase at relapse in each time (Figure). The range of fluctuation of KL-6 levels was significantly wider in the relapse group than in the non-relapse group (866 vs 259 U/mL, $p < 0.001$), suggesting KL-6 levels in the non-relapse group was stable. The increase in KL-6 levels of 625 U/mL could be a cut-off level for relapse by receiver operating characteristic analysis.

Conclusion: Serum KL-6 is a useful biomarker for assessing activity of myositis-associated interstitial lung disease.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies I: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Inflammatory idiopathic myopathies (IIM) is a heterogeneous group of disorders ranging from muscle specific auto-immune diseases to systemic ones (dermatomyositis (DM), anti-synthetase syndrome (ASS), immune-mediated necrotizing myopathy (IMNM) and inclusion body myositis (IBM)). Recent insight into DM pathogenesis highlighted the role of type I interferon (IFN) and the level of IFN-pathway activity is linked to those of the disease. The aim of this study was to measure IFN- α seric level in the different groups of myositis using an ultrasensitive detection technology to evaluate IFN- α as disease activity biomarker.

Methods: IIM patients were enrolled in a monocentric prospective cohort. Clinical and biological data were prospectively collected as well as sera and peripheral blood mononuclear cells. Disease activity was assessed by calculating the Physician Global Activity (PGA) for each patient. To measure IFN- α level, sera were analyzed by single molecule array technology (SIMOA). The expression of IFN-stimulated genes (ISG) was detected by quantitative RT-PCR assays, and IFN scores were assessed by the median gene expression of the 5(ISG).

Results: One hundred and sixty-four patients (57 DM, 48 ASS, 35 IMNM and 24 IBM) and 35 age- and sex-matched healthy controls were included. Patient's characteristics were similar in all groups, but IBM patients were older (67.5 [63.5-78]) with a more severe weakness (Manual muscle testing 8 score was 120 ± 19) compared to DM (142 ± 7.6 , $p=0.001$) and to ASS patients (148 ± 12.4 , $p<0.001$).

IFN- α levels were higher in DM (0.05 ± 1.3 pg/ml, $p=0.005$) and ASS groups (0.06 ± 0.2 pg/ml, $p=0.005$) compared to controls (0.02 ± 0.06 pg/ml). IFN- α levels were similar in IMNM (0.03 ± 0.11 pg/ml), IBM (0.02 ± 0.07 pg/ml) and controls groups. As expected, anti-Jo1 antibody was associated with higher IFN- α level ($p=0.05$). IFN- α levels were correlated to disease activity in DM ($r=0.72$, $p<0.0001$) and ASS groups ($r=0.47$, $p=0.0009$).

Active (PGA >5) DM patients had a higher level of IFN- α (0.28 ± 1.9 pg/ml) compared to non-active patients (0.03 ± 0.05 pg/ml, $p<0.001$) and controls (0.02 ± 0.06 pg/ml; $p<0.001$). The accuracy of IFN- α level to discriminate active and non-active disease was excellent attested by an area of 0.92 under the ROC-curve (AUC). For an IFN- α level above 0.15 pg/ml, the sensitivity was 72.7% and specificity was 96.4%. Active ASS patients had also higher IFN- α level (0.16 ± 0.26 pg/ml) compared to non-active patients (0.04 ± 0.1 pg/ml, $p=0.003$) and controls ($p<0.001$). In ASS group, the accuracy of the test was also good (AUC=0.80) but the sensitivity and specificity were lower (52% and 87% respectively) for an IFN- α level cut-off at 0.29 pg/ml.

In naïve DM and ASS patients ($n=12$), IFN scores, considered as the gold standard to measure IFN activation, were assessed. The correlation between IFN score and IFN- α levels was very good ($r=0.76$, $p=0.005$).

Conclusion: IIM IFN- α level (assessed by SIMOA) is increased not only in DM but also in ASS patients. It is strongly correlated with disease activity especially in DM patients showing that it can be considered as biomarker of disease activity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies I: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Dermatomyositis (DM) is an inflammatory myopathy where itch is a major contributor to impaired quality of life. Previously, we have shown that a cytokine responsible for itch in other diseases, interleukin (IL)-31, is elevated in lesional skin of DM patients. We aim to i) demonstrate the correlation between IL-31 protein expression in lesional skin and clinical assessment tools of itch severity and disease activity; ii) investigate the relationship between IL-31

protein expression in DM responders vs. non-responders in terms of itch and disease activity; iii) identify the cellular source of IL-31 in DM.

Methods: IL-31 protein expression in skin was quantified using immunohistochemistry (IHC) analysis of lesional skin samples of 12 DM patients at two separate time points. The visual analog scale (VAS), and SKINDEX-29 Symptoms Score clinical assessment tools, and Cutaneous Disease and Activity Severity Index (CDASI) were used to evaluate itch and disease activity. IHC co-localization of CD4, IL-31, and either IFN-gamma (Th1) or IL-4 (Th2) was performed on baseline lesional skin samples from 5 DM patients to identify the cellular source of IL-31.

Results: IL-31 expression with respect to mean cell intensity in lesional skin was highly correlated with SKINDEX-29 Symptoms Score, SKINDEX-29 question 10, and VAS itch score ($r=0.85$, $p<0.001$; $r=0.77$, $p<0.01$; $r=0.68$, $p<0.05$ respectively). IL-31 expression with respect to area stained was highly correlated with CDASI ($r=0.78$, $p<0.01$). These correlations were maintained at visit 6 ($r=0.65$, $p<0.05$; $r=0.64$, $p<0.05$; $r=0.60$, $p<0.05$; $r=0.74$, $p<0.01$). Itch responders had a greater reduction of IL-31 relative to non-responders with respect to mean cell intensity ($p<0.05$). Disease responders had a greater reduction in IL-31 staining area relative to non-responders ($p<0.05$). IHC co-staining of IL-31 with Th1 and Th2 markers demonstrated strong co-localization of IL-31 with Th1 T-cells and relatively little Th2 production of IL-31.

Conclusion: IL-31 cell intensity in lesional skin correlates strongly with itch severity while IL-31 staining area is highly correlated with disease activity. The source of IL-31 in DM is likely to be from Th1 cells rather than Th2 cells.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The immune system plays a critical protective role in cancer (CA) development. Perturbations in immune signaling, including cytokine dysregulation, may disrupt this homeostatic balance. Recently, IL-1 β inhibition reduced lung cancer incidence and mortality in a large RCT. We have previously shown serum cytokines are predictive of CA mortality in RA. The goal of the current study was to examine whether circulating cytokines are associated with CA incidence.

Methods: We linked the Veterans Affairs Rheumatoid Arthritis (VARA) registry with the VA Central Cancer Registry (VACCR) and the National Death Index (NDI). VACCR captures >90% of CAs occurring in US Veterans. VARA participants with available cytokine data and without a history of CA prior to VARA enrollment were included in analyses. Serum cytokines and chemokines (CKs) were measured with a 17-plex bead based assay using banked serum collected at VARA enrollment. CK score, an overall measure of CK concentrations, was calculated from individual analytes. Associations of CK with incident CA (identified in VACCR and NDI) were assessed using multivariable Cox regression models adjusting for age, sex, race, smoking status, DAS28, MD-HAQ, RF titer, methotrexate, and biologic use. CK score and individual analytes were analyzed as log-transformed continuous values and in quartiles. Additional analyses were stratified by smoking status (current vs. former/never).

Results: We studied 1,216 US Veterans with RA (mean age 63 yrs, 89% male, 78% anti-CCP positive) with available CK data, all without a pre-enrollment history of cancer. During 10,034 pt-yrs of follow-up, 159 incident CAs occurred with a median time to cancer of 4.7 yrs (IQR 2.7-6.9). Lung CA was the most frequent site ($n=41$), followed by prostate ($n=26$),

lymphoproliferative (n=23), and skin (n=15). Log-transformed CK score was associated with an increased risk of incident CA (aHR 1.45, 95% CI 1.27-1.67). Higher concentrations of 13 analytes were associated with increased CA risk (Figure). The highest quartile of CK score was associated with a >2-fold increased risk of CA (aHR 2.40; 95% CI 1.21-4.76). The highest quartiles of 8 analytes were significantly associated with CA risk, with the strongest effect sizes for IL-2 (aHR 2.33; 95% CI 1.48-3.67), IL-17 (aHR 2.49; 95% CI 1.63-3.82), and MIP-1 β (aHR 2.32; 95% CI 1.24-4.35). In stratified analyses, CK score was significantly associated with incident CA in both current and former/never smokers, though greater in current smokers.

Conclusion: Serum CK concentrations are predictive of future CA in RA patients, even after adjustment for RA disease activity and smoking. In addition to suggesting a potential role of CK profiling in modeling CA risk in RA, these results suggest that disease control and “normalization” of systemic CK disturbances could be important strategies in CA prevention in RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Racial/ethnic disparities in comorbidity (CM) in rheumatoid arthritis (RA) may confound treatment and outcomes. Rheumatic Disease Comorbidity Index (RDCI) is a validated tool predicting disability and mortality in RA patients. We evaluated the association between RDCI and clinical outcomes within racial/ethnic subsets of RA patients

Methods: Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least one follow-up (FU) visit were analysed. RDCI was compiled from enrolment data. Clinical outcomes: tender joint count (TJC), swollen joint count (SJC), RAPID 3 and DAS28; medication use (recorded and aggregated as prednisone methotrexate, other DMARD, and biologic use), were recorded. Analysis of variance or chi-square tests were used to estimate enrolment differences between racial/ethnic groups. Generalized estimating equations and mixed model regression accounting for repeated measurements were used to estimate any differences between racial/ethnic groups during FU, and explore associations of RDCI on clinical outcomes and remission (DAS28<2.6), adjusting for enrolment age, gender, education, race/ethnicity and medication use.

Results: 1066 subjects with 3719 FU visits over 58 weeks were evaluated. Racial/ethnic disparities were seen in formal education, RAPID3, DAS28, TJC, SJC as well as CM. Additionally, racial/ethnic disparities were seen in length of FU and medication use (**Table**). Increased RDCI scores were significantly associated with increased enrolment RAPID3 (P=0.022) and DAS28 (P<0.001), adjusting for age, education, gender and race/ethnicity. Enrolment DAS28 was also significantly higher in Blacks (0.49, 95% CI [0.21, 0.78], P=0.001) and Hispanics (0.70, 95% CI [0.37, 1.03], P=0.001) compared to Whites. While increased RDCI significantly reduced improvement in both RAPID3 (P<0.001) and DAS28 (P<0.001), RDCI was not significantly associated with reducing odds of DAS28 remission. Blacks, however, were significantly less likely to have DAS28 remission than all other race groups (**Figure**). Additionally, biologic use increased odds of DAS28 remission (OR=1.53, 95% CI [1.01, 2.33], P=0.45), but was less with advanced age (OR=0.80, 95% CI [0.68, 0.95], P=0.009).

Conclusion: CM was associated with higher disease activity regardless of race/ethnicity or medication, with black patients having more CM and less odds of remission. Early access to care for management of comorbidities and disease in Black RA patients is necessary to improve outcomes

Kerr⁵, ¹Rheumatology, VA Pittsburgh HCS, Pittsburgh, PA, ²Division of Rheumatology, University Of Pittsburgh, Pittsburgh, PA, ³Lead Biostatistician, Medical Faculty Associates Clinical Professor, Dept. of Surgery, George Washington University School of Medicine & Health Sciences, Washington, DC, ⁴Division of Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, ⁵Rheumatology, Washington DC VAMC and Georgetown and Howard University, Washington, DC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chronic kidney disease (CKD) is a comorbidity that may affect patients with rheumatoid arthritis (RA). CKD restricts the use of disease modifying anti-rheumatic drugs (DMARDs) e.g. methotrexate, limiting the ability to control disease activity. We utilized the Veterans Affairs Rheumatoid Arthritis Registry (VARA), an observational chronic disease cohort at 11 Veterans Affairs (VA) medical centers where RA disease activity measures are recorded longitudinally to examine the frequency and progression of CKD in patients with RA..

Methods: VA patients enrolled in the VARA registry were eligible for analysis. This database was used to extract patient demographics and measures of RA disease activity and severity. Administrative data obtained from the VA corporate data warehouse (CDW) was collected for serum creatinine, weight, select comorbidities including ischemic heart disease (IHD), diabetes mellitus (DM) and hyperlipidemia. Creatinine clearance (CrCl) was calculated for each patient using the CKD-EPI creatinine equation and severity of CKD staged. Chi square and analysis of variance were used to compare categorical and continuous variables respectively between the stages of CKD. Longitudinal data from VARA and CDW were collected to examine the progression of CKD from stage II or better to Stage 3 or worse. A cox regression analysis was used to examine the effect of patient demographics and RA characteristics on the progression of CKD.

Results: There were 1577 RA patients available for study, 473 (30.1%) had CKD stages III to V, most, 399 (25.1%) had stage III. CKD was associated with male gender, older age and African American (AA) race (Table 1). There were no differences in the presence of RF, anti-CCP antibodies, radiographic changes or the use of DMARDs, however patients

with CKD were more likely to have subcutaneous (SC) nodules. Greater disease activity 28- C-reactive protein (DAS28-CRP) scores were reported in patients with stage IV and V CKD [4.0 (1.0) and 4.7 (1.4) respectively] compared with stage I and II [3.8 (1.2) and 3.6 (1.3) respectively] $p < 0.0001$. Comorbidities, DM, IHD and hyperlipidemia were independently associated with CKD ($p < 0.0001$). Predictors of progression of CKD included AA race HR= 2.0; CI = 1.48, 2.69, physician global assessment (PGA) HR = 1.36 (CI = 1.03, 1.80), DAS28-CRP, HR = 1.45 (CI = 1.10, 1.91) and IHD, HR = 1.63 (CI = 1.24, 2.16). Age, radiographic erosions, SC nodules and multi-dimensional health assessment questionnaire (MD-HAQ) were not associated with progression of CKD

Conclusion: CKD was not infrequent in US veterans with RA and was associated with older age, AA race, smoking, IHD, rheumatoid nodules and greater disability and disease activity. The predictors for the progression of CKD included AA race, PGA, DAS28-CRP and IHD. RA patients with early CKD should be monitored for disease progression and treatment of both CKD and RA optimized.

Table 1. Association of Patient and RA Characteristics with CKD* Stage

Evaluation of Fracture Risk and Osteoporosis in Males with Rheumatoid Arthritis

Kanchana Herath¹, Melissa Saul², Lei Zhu³ and Larry W. Moreland³, ¹Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, ²Department of Medicine, University of Pittsburgh, Pittsburgh, PA, ³Division of Rheumatology and Clinical Immunology, Division of Rheumatology, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Osteoporosis is an asymptomatic disease complicated by fractures and is associated with increased morbidity and mortality. Rheumatoid arthritis (RA) has been found to be a secondary cause for osteoporosis and it occurs more frequently in the RA population compared to the healthy population. There is a generalized consensus concerning osteoporosis screening in women, however, no such consensus exists for men due to insufficient available data. Current recommendations are to screen men ages 50-69 with increased risk and all men >70. However, with limited data available on appropriate screening guidelines, many with increased risk of osteoporosis are not being screened.

Objectives: The aims of this retrospective study were to assess if dual-energy x-ray absorptiometry (DEXA) scans are being obtained for males between the ages of 50-69, if these patients have decreased bone mineralization and if there is an increased risk of fractures in male patients with RA between the ages of 50-69.

Methods: A total of 1,970 male RA patients ages 50-69 were identified who were seen in an outpatient setting between the years of 2010-2017. Outpatient clinic notes, DEXA scans, radiology reports, laboratory results for rheumatoid factor (RF) and anti-cyclic citrullinated peptide (CCP), along with hospital medical record discharge abstracts for all patients were retrieved. Outcomes included DEXA scan results and frequency of fractures.

Results: 488 DEXA scan results were obtained with osteopenia reported in 231 patients and osteoporosis reported in 67 patients. Of the overall results, 61% had decreased bone mineralization. Serologies for RF and CCP were compared with DEXA scan results and fractures. Osteoporosis was seen significantly more in the RF positive group compared to the RF negative group (30 and 9 respectively, chi-square 0.0076). Osteoporosis was also seen significantly more in the CCP positive group compared to the negative group (18 and 7 respectively, chi-square 0.027).

Conclusion: Our preliminary data show that in men <70 years of age there is evidence of osteopenia and osteoporosis on DEXA scans, especially in those who are RF and CCP positive. DEXA scans are not being utilized enough in males with RA <70 years of age. Increased screening can help recognize those with decreased bone mineralization who may need treatment to help prevent future fractures.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Determining modifiable risk factors for interstitial lung disease (ILD) is crucial given its substantial morbidity/mortality. Treatment to target of remission/low disease activity improves articular RA outcomes, but the association with ILD is unclear. Prior studies correlated active RA with ILD, but were limited by cross-sectional designs with prevalent ILD. Therefore, we aimed to investigate RA disease activity and incident ILD risk.

Methods: We studied RA disease activity and incident ILD in a prospective cohort study at a single center (2003-2016). All subjects had RA according to ACR criteria. Disease activity score with 28 joints and C-reactive protein (DAS28-CRP3) and covariates were measured annually. Two pulmonologists and one radiologist adjudicated every clinically-indicated chest computed tomography (CT) scan. Cases were defined as consensus agreement with ILD diagnosis. We analyzed subjects with no clinically apparent ILD at baseline. We used Cox regression to estimate HRs and 95% CIs for ILD by DAS28-CRP3, adjusting for known ILD risk factors (age, sex, smoking, RA duration, and serostatus). We investigated DAS28-

Table: Hazard ratios for incident ILD among patients with RA according to category of DAS28-CRP3 (n=1,281).

	DAS28-CRP3 category				p for trend
	Remission (<2.6) HR (95%CI)	Low (2.6 to 3.2) HR (95%CI)	Moderate (>3.2 to 5.1) HR (95%CI)	High (>5.1) HR (95%CI)	
(Baseline)					
Unadjusted	1.00 (Ref)	0.92 (0.31-2.68)	2.57 (1.28-5.14)	3.09 (1.51-6.33)	0.0003
Multivariable*	1.00 (Ref)	0.87 (0.30-2.54)	2.31 (1.15-4.66)	2.27 (1.09-4.73)	0.001
Cumulative average updated					
Unadjusted	1.00 (Ref)	1.66 (0.71-3.92)	2.54 (1.28-5.02)	2.50 (1.05-5.92)	0.004
Multivariable*	1.00 (Ref)	1.50 (0.63-3.54)	1.97 (0.99-3.93)	1.59 (0.66-3.82)	0.09

There were 66 incident ILD outcomes during 13,141 person-years of follow-up in the baseline analysis. There were 65 incident ILD outcomes during 8,736 in the cumulative average updated analysis.

The cumulative average updated analysis accounted for all previous and current annual DAS28-CRP3 measures for each cycle predicting ILD risk in the subsequent year.

*Adjusted for age, sex, smoking pack-years, RA duration, and serostatus (+CCP and/or RF vs -CCP and/or RF).

CCP, cyclic citrullinated peptide; CI, confidence interval; DAS28-CRP3, disease activity score with 28 joints and C-reactive protein; ILD, interstitial lung disease; HR, hazard ratio; RA, rheumatoid arthritis; RF, rheumatoid factor.

CRP3 categories at baseline in the primary analysis. As a secondary analysis, we used cumulative average updated DAS28-CRP3, which took into account all previous disease activity measures to predict incident ILD in the subsequent year.

Results: Among 1,281 subjects at baseline, mean age was 56.0 years (SD 14.1), 82.1% were female, 69.6% were seropositive, median RA duration was 9 years, and 58.3% had high/moderate disease activity. During 13,141 patient-years (median follow-up 8 years), we identified 86 cases of incident clinically-apparent ILD. ILD risk significantly increased across baseline DAS28-CRP3 categories. The multivariable HR (95% CI) for ILD by DAS28-CRP3 categories were: 1.00 (reference) for remission, 0.87(0.30-2.54) for low, 2.31 (1.15-4.46) for moderate, and 2.27 (1.09-4.73) for high; *p* for trend=0.001). Compared to low/remission, moderate/high disease activity had HR for ILD of 2.41 (95% CI 1.37-4.25). When analyzing cumulative average updated DAS28-CRP3 with fewer ILD outcomes and shorter follow-up, there was a trend towards significance of active RA increasing ILD risk (*p*=0.09). Seropositivity was strongly associated with ILD risk (HR 2.69, 95% CI 1.38-5.27).

Conclusion: In this large prospective cohort using adjudicated ILD outcomes, active RA was associated with increased risk for clinically-apparent ILD. Replication studies in other prospective cohorts and clinical trials are needed to firmly establish the role of RA treat-to-target approaches and ILD risk, particularly for patients with seropositive RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: An increased incidence of herpeszoster (HZ) has been observed with Janus kinase inhibitors such as tofacitinib(TOF). However, among TOF users, a potentially additive or multiplicative risk of HZ associated with concomitant methotrexate (MTX) and glucocorticoid (GC) use is not clear. We evaluated HZ risk in TOF users with and without MTX and GC, to evaluate potential interactions.

Methods: Market Scan and Medicare data (2011-2016) was used to identify all rheumatologist-diagnosed RA patients initiating TOF (indexdate); demographics and covariates were evaluated in the 12 prior months(baseline); pts with HIV, malignancy or prior HZ (or anti-viral commonly used for HZ) in baseline were excluded. All 3 main drug exposures were time-varying with a 30 day extension. HZ was ascertained using ICD9/10 codes with anti-viral drug use (+/-7 days). Multivariable (MV) Cox regression was used to evaluate hazard ratios (HRs) for HZ in TOF users with and without MTX and GC, controlling for baseline covariates.

Results: A total of 8,030 new TOF users meteligibility criteria for analysis. Mean (SD) age was 60.3 (12.6) years, 83.3% women. The crude HZ incidence with TOF use was numerically lowest in the absence of GC (e.g. 3.4/100py with MTX and 3.7/100py without MTX, Table). An approximately two-fold increased crude incidence of HZ was observed for TOF users receiving either GCs alone (6.0/100 py) or both MTX and GCs (6.5/100py).After MV adjustment, the HR for HZ associated with TOF was unchanged when given with MTX but approximately double when TOF was given with GC. Based on the non-significant interaction *p* value, there was no indication of an interaction between MTX and GC. Among various covariates, older age was a significant albeit weak risk factor for HZ (adjusted HR = 1.05, 95% CI 1.03-1.18, per 5 year increment).

Conclusion: These analyses suggest that HZ risk in TOF users is doubled with GC exposure. Concomitant MTX did not confer increased risk.

Table: Herpes Zoster Risk Associated with Tofacitinib according to Concomitant Use of Methotrexate and Glucocorticoids

Concomitant Medications with TOF	Events	Incidence Rate per 100PY	Adjusted Hazard Ratio
No MTX; no GC	73/1986	3.7 (2.9-4.6)	1.0 (ref)
With MTX; no GC	27/791	3.4 (2.3-5.0)	1.00 (0.64, 1.55)
No MTX; with GC	82/1356	6.0 (4.9-7.5)	2.03 (1.42, 2.91)
With MTX; with GC	40/617	6.5 (4.8-8.8)	2.24 (1.47, 3.43)

PY = Patient-years; MTX = methotrexate; GC = glucocorticoid

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments I: JAK Inhibitors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Baricitinib (bari) is an oral JAK1/JAK2 inhibitor approved for the treatment of moderately to severely active RA in adults in over 40 countries, including European countries, the United States, and Japan. In the 52-week Phase 3 RA-BEAM study, bari 4-mg once daily (QD) showed clinical improvements compared with placebo (PBO) and with adalimumab (ADA) in MTX-inadequate-responder (IR) patients (pts).¹ The objective of this analysis was to evaluate efficacy, patient-reported outcomes (PRO), and safety in pts from RA-BEAM who switched treatment from ADA to bari after entering a long-term extension (LTE) study (RA-BEYOND).

Methods: In RA-BEAM (completed September 2015), 1305 pts were randomized 3:3:2 to PBO, bari 4-mg QD, or ADA 40-mg every 2 weeks (wks). At wk 52, pts could enter the LTE, where all pts received open-label bari 4-mg but remained blinded to randomized treatment in RA-BEAM. No ADA washout period was applied. Efficacy, PROs, and safety were evaluated in pts who were not rescued in RA-BEAM and entered the LTE ≥ 48 wks before the data cutoff of April 1, 2017.

Results: Among pts who completed RA-BEAM without rescue, 381/394 (97%) bari (continued bari), and 238/241 (99%) ADA (switched to bari) pts entered the LTE ≥ 48 wks before the cutoff date and were included in the analysis. Pts who switched from ADA to bari showed improvements in disease control through 24 wks post-switch in the LTE without evidence of worsening through the following 24 wks (Table 1) and showed further small improvements in PRO assessment of pain and physical function (HAQ-DI) through wk 48 (Figure 1). Of pts who were non responders (CDAI > 10) at the time of switch (107 and 74 in bari and ADA groups, respectively) approximately half reached low disease activity (CDAI ≤ 10) by wk 48 (54% and 50%, respectively). Exposure-adjusted incidence rates for treatment-emergent adverse events (TEAEs) and infections, including serious AEs, were similar for pts who switched from ADA to bari and those who continued bari (Table 2).

Conclusion: Switching from ADA to bari without ADA washout was associated with maintenance of disease control through 48 wks post-switch, with some non responders being able to achieve LDA as well. There was no increase in TEAEs or serious AEs or infections.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments I: JAK Inhibitors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Peficitinib (ASP015K), a novel oral JAK inhibitor, demonstrated efficacy as once-daily monotherapy in patients with moderate to severe RA in a phase 2b study (NCT01649999). In this phase 3 study (NCT02308163), we report efficacy and safety data for peficitinib alone or in combination with DMARDs in patients with RA who had an inadequate response to DMARDs.

Methods: This multicenter, randomized, double-blind, parallel-group, placebo (PBO)-controlled study was conducted in Japan, Korea, and Taiwan. All patients had RA diagnosed according to 1987 ACR or 2010 ACR/EULAR criteria. Patients

Table 1: Primary and selected secondary efficacy endpoints at week 12/ET

Result at 12 weeks/ET	PBO	Peficitinib 100 mg/day	Peficitinib 150 mg/day	Etanercept 50mg/week (open-label arm)
ACR20 ^a , n/N (%)	81/101 (80.7)	60/104 (57.7)***	76/102 (74.5)***	167/200 (83.5)
ACR50 ^a , n/N (%)	9/101 (8.9)	32/104 (30.8)***	43/102 (42.2)***	105/200 (52.5)
ACR70 ^a , n/N (%)	1/101 (1.0)	14/104 (13.5) ^{b,1}	28/102 (27.5)***	61/200 (30.5)
Mean (SD) CRP change from baseline, mg/dL	0.022 (1.498)	-1.056 (1.908)***	-1.734 (1.906)***	-1.207 (2.694)
Mean (SD) ESR change from baseline, mm/h	-1.96 (17.82)	-12.96 (21.51)***	-23.92 (21.26)***	-20.92 (21.66)

Mean (SD) DAS28-CRP change from baseline, n	-0.64 (1.20)	-1.63 (1.41)***	-2.17 (1.14)***	-2.42 (1.11)
Mean (SD) change from baseline in patient's assessment of pain, 100 mm VAS	-6.64 (24.61)	-23.78 (30.75)***	-30.85 (27.91)***	-30.82 (27.88)
SDAI remission (SDAI score ≤3.3) ³ , n/N (%)	0/100	9/102 (8.8) ²	9/101 (8.9) ²	37/200 (18.5)

Last Observation Carried Forward imputation method was used. Statistical testing was performed for ASP015K 100 mg and 150 mg, compared with PBO. ***p<0.001 vs PBO according to Wald's chi-square test for ACR20, ACR50, ACR70, DAS28-CRP <2.6, and SDAI remission, and analysis of covariance for CRP, ESR, DAS28-CRP and patient's assessment of pain. Closed testing procedure was used for multiplicity adjustment in the primary analysis.

^aBased on logistic regression model: Response (responder, non-responder) = treatment + the prior biologics (DMARD-10) (no, yes) + concomitant DMARD use (no, yes) + study region (Japan, Korea, and Taiwan).

^bNot estimable owing to the small number of responses.

¹In a post-hoc analysis, based on the logistic regression model in which the only independent variable was treatment, the odds ratio between PBO and peficitinib 100 mg for ACR70 was estimated and p=0.009.

SD=standard deviation; SDAI=simplified disease activity index; VAS=visual analog scale.

Table 2: Treatment-emergent adverse events

	PBO (N=101)	Peficitinib 100 mg/day (N=104)	Peficitinib 150 mg/day (N=102)	Peficitinib 100 mg/day + 150 mg/day (N=206)	Etanercept 50mg/week (open-label arm) (N=200)

Malignancy	0.0	2.3 (0.6, 9.1)	0.0	1.2 (0.4, 3.8)	0.5 (0.1, 3.6)

¹Severity or probability related to study drug, as assessed by risk investigator, or events where causation is obvious.

²Based on NCI-CTCAE grade 3–severe or medically significant, grade 4–life threatening, grade 5–death related to AE.

³Median years event from initial dose up to first occurrence of AE for patients who had at least one event; otherwise, the duration of the patient's last event is used.

⁴Includes AEs that occurred after initial peficitinib dosing, and after switching from PBO to peficitinib 100 mg/day or 150 mg/day.

⁵Defined as an AE belonging to the System organ class of "infections and infestations" and regarded as serious.

AE=adverse event; SAE=serious adverse event.

with active RA (defined as ≥ 6 tender and painful joints and ≥ 6 swollen joints, using 68 and 66-joint assessment respectively, and CRP >0.50 mg/dL) and inadequate response to DMARDs (administered for ≥ 90 days) were randomized in a 1:1:1:2 ratio to 52 weeks' treatment with PBO, peficitinib 100 mg/day, peficitinib 150 mg/day or etanercept 50 mg/week (open-label reference arm). At week 12, patients initially assigned to PBO were switched (under blinded conditions) to either peficitinib 100 mg/day or peficitinib 150 mg/day until end of treatment. Concomitant stable dose of DMARDs was permitted. The primary efficacy variable was ACR20 response rate at week 12/early termination (ET).

Results: In total, 507 patients were randomized and treated: PBO (n=101), peficitinib 100 mg/day (n=104), peficitinib 150 mg/day (n=102) and etanercept (n=200). Regarding efficacy at week 12/ET, significant differences were observed with peficitinib 100 mg/150 mg vs PBO ($p<0.001$) in the proportion of patients achieving ACR20, ACR50, ACR70 (150 mg/day dose only) and DAS28-CRP <2.6 , and for change from baseline to week 12/ET in DAS28-CRP (**Table 1**). Week 0–12 safety results were similar between treatment groups, while serious adverse events were more common with PBO than other study treatments (**Table 2**). For the overall study period, the incidence rate of serious infections per 100 patient-years was higher with peficitinib 100 mg/150 mg than PBO (**Table 2**). There were no deaths during the study.

Conclusion: In patients with RA who had an inadequate response to DMARDs, 100 mg/day and 150 mg/day peficitinib doses significantly reduced RA symptoms according to clinical and patient assessment scores. The proportion of patients achieving the primary efficacy variable (ACR20 at week 12/ET) was significantly greater for both peficitinib doses versus PBO. Peficitinib 100 mg/day and 150 mg/day showed acceptable safety and tolerability, with no new safety signals detected compared with other JAK inhibitors.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments I: JAK Inhibitors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Peficitinib (ASP015K), a novel oral JAK inhibitor, demonstrated efficacy as once-daily monotherapy in patients with moderate-to-severe RA in a phase 2b study (NCT01649999)¹. We report phase 3 efficacy and safety data for peficitinib–methotrexate (MTX) combination in patients with RA who had an inadequate response to MTX (NCT02305849).

Table 1: Primary and selected secondary efficacy endpoints at week 12/ET

Result	Week 12/ET			Week 28/ET		
	PBO	Peficitinib 100 mg/day	Peficitinib 150 mg/day	PBO	Peficitinib 100 mg/day	Peficitinib 150 mg/day

	PBO	Peficitinib 100 mg/day	Peficitinib 150 mg/day	PBO	Peficitinib 100 mg/day	Peficitinib 150 mg/day
Mean (SD) mTSS change from baseline ¹	3.37 (5.46)	1.62 (4.23)***	1.03 (2.86)***	6.27 (10.18)	2.12 (5.83)***	1.54 (4.11)***
Patients achieving mean mTSS change from baseline ≤0.5 ¹ , n/N (%)	70/153 (45.8)	110/164 (67.1)***	119/164 (72.6)***	65/153 (42.5)	105/164 (64.0)***	113/164 (68.9)***

Last Observation Carried Forward imputation method was used, except for mTSS. Statistical testing was performed for peficitinib 100 mg, and 150 mg, compared with PBO.

p<0.01 vs PBO; *p<0.001 vs PBO, according to Fisher's Exact test for ACR20, ACR50, ACR70, DAS28-CRP <2.6, SDAI remission, and mTSS change from baseline ≤0.5; analysis of covariance for CRP, ESR, DAS28-CRP, and patient's assessment of pain; and rank analysis of covariance for mTSS change from baseline. Closed testing procedure was used for multiplicity adjustment in the primary analysis.

¹For the calculation of mTSS, patients who discontinued at or before week 28 or were switched from PBO to peficitinib at week 12 due to lack of efficacy, week 28/ET mTSS was extrapolated using linear extrapolation method based on the mTSS at baseline and early termination or week 12 (day 85) (before switching). For patients who discontinued at or before Week 52 or switched to receive peficitinib instead of placebo at Week 12 or Week 28, mTSS at Week 52/ET was extrapolated using a linear extrapolation method based on mTSS at baseline and early termination, Week 12 (Day 85) or Week 28 (Day 197) (before switching).

mTSS=modified Total Sharp score; SD=standard deviation; SDAI=simplified disease activity index; VAS=visual analog scale.

Table 2: Treatment-emergent adverse events

¹Previously or potentially related to study drug, or caused by the intervention, or events which necessitate a report.

²Based on FDA CTCAE global grade 1 events or specifically specified grade 4–5 events occurring at the 5-week point for AE.

³Percentages of serious infections shown up to 12 of patients with RA for whom serious infection was reported at least one event; otherwise, the denominator for the denominator is the number of patients who were included in the study (N=348).

⁴Includes AE that occurred after initial enrollment, and after switching from PBO to peficitinib 100 mg/day or 150 mg/day.

⁵Based on the incidence rate per 100 patient-years of serious infections, and reported as events.

AE=adverse event; SAE=serious adverse event.

Methods: This multicenter, randomized, double-blind, parallel-group, placebo (PBO)-controlled study was conducted in Japan. Patients had RA diagnosed within the past 10 years (1987ACR or 2010 ACR/EULAR criteria), active disease (≥ 6 tender and painful joints and ≥ 6 swollen joints, using 68 and 66-joint assessment respectively; CRP ≥ 1.0 mg/dL; bone erosion; and ACPA or RF positivity) and inadequate response to MTX (administered for ≥ 90 days; ≥ 8 mg/week for ≥ 28 days prior to baseline). Patients were randomized 1:1:1 to 52-week MTX plus PBO, peficitinib 100 mg/day or peficitinib 150 mg/day. At week 12, inadequate responders in the PBO group ($<20\%$ improvement from baseline in tender and swollen joint counts) were switched (under blinded conditions) to peficitinib 100/150 mg until end of treatment. Remaining patients in the PBO group were switched (under blinded conditions) to peficitinib at week 28. Concomitant stable MTX dose (≤ 16 mg/week) was mandatory. Primary efficacy variables were ACR20 response rate at week 12/early termination (ET) and change from baseline in modified Total Sharp score (mTSS) at week 28/ET.

Results: 519 patients were treated: PBO (n=170), peficitinib 100 mg (n=175) and peficitinib 150 mg (n=174). At week 12, 75 PBO-treated patients were switched to peficitinib 100 mg (n=37) and 150 mg (n=38) due to inadequate response. At week 12/ET, peficitinib showed superior efficacy vs PBO with respect to symptoms and inflammatory markers (**Table 1**). At weeks 28 and 52, peficitinib significantly reduced the mean mTSS change from baseline vs PBO (**Table 1**). Week 0–12 safety results were similar for PBO and peficitinib (**Table 2**). For the overall study period, incidence rate of serious infections per 100 patient-years was higher with peficitinib 100 mg/150 mg than PBO (**Table 2**).

Conclusion: In patients with RA who had an inadequate response to MTX, peficitinib 100 mg/day and 150 mg/day demonstrated significant superiority vs PBO in reducing RA symptoms and suppressing joint destruction, according to primary efficacy variables (ACR response and change in mTSS). Peficitinib 100 mg and 150 mg showed acceptable safety and tolerability, with no new safety signals compared with other JAK inhibitors.

2. Genovese et al; 2017, Arth Rheum;69 S10

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor, showed efficacy in rheumatoid arthritis (RA) patients (pts) with an inadequate response to csDMARDs or bDMARDs on continuing stable csDMARD(s)^{1,2}. We assessed the safety and efficacy of switching to UPA 15 or 30mg monotherapy vs continuing methotrexate (MTX) as a blinded study drug was evaluated in pts with inadequate response to MTX (MTX-IR).

Methods: Pts with active RA (TJC \geq 6, SJC \geq 6, hsCRP \geq 3 mg/L) on stable MTX were enrolled and randomized 1:1:1 in a double-blind manner to once-daily (QD) UPA 15mg or 30mg monotherapy or to continue MTX (cMTX) at their prior stable dose. At BL, all pts discontinued prior MTX without washout and received PBO (for pts on UPA) or MTX at prior dose (cMTX) as blinded study drug. The primary endpoints at Week (Wk) 14 were the proportion of pts achieving ACR20, and the proportion achieving DAS28-CRP \leq 3.2 (NRI).

Results: 648 pts were randomized, all received study drug; 598 (92.3%) completed 14 wks. BL demographics and disease characteristics were generally similar across arms. Both primary endpoints were met ($p < .001$); at Wk 14, a significantly greater proportion of pts receiving UPA monotherapy (15mg and 30mg) vs cMTX achieved ACR20 (67.7% and 71.2% vs 41.2%), and DAS28-CRP \leq 3.2 (44.7% and 53.0% vs 19.4%) (**Table**). All key secondary endpoints also showed UPA 15 and UPA 30 monotherapy to be superior to cMTX, including ACR50 (41.9% and 52.1% vs 15.3%), ACR70 (22.6% and 33.0% vs 2.8%), DAS28-CRP \leq 2.6 (28.1% and 40.5% vs 8.3%), Δ HAQ-DI (-0.65 and -0.73 vs -0.32). Δ SF-36PCS and Δ Morning Stiffness data are also shown (**Table**). The proportion of pts achieving CDAI \leq 10 was significantly greater with UPA 15 and 30 vs cMTX (34.6% and 46.5% vs 24.5%).

Adverse events (AEs) were reported at similar frequencies across arms; serious AEs were numerically higher in UPA 15 but similar between cMTX and UPA 30 (**Table**). Numerically more infections were reported in cMTX and UPA 30 vs UPA 15. One serious infection each was reported in UPA 15 and cMTX, and none in UPA 30. Herpes zoster was more frequent in UPA 30 vs UPA 15 or cMTX. 3 malignancies (1 in cMTX and 2 in UPA 15) and 3 adjudicated MACE (1 in UPA 15 and 2 in UPA 30) were reported. One adjudicated pulmonary embolism was reported (UPA 15) in a pt with known risk factors (BMI 36; on estrogen therapy). One death (hemorrhagic stroke due to ruptured aneurysm) was reported in UPA 15. No TB, renal dysfunction or GI perforation was reported. Rates and types of laboratory abnormalities were consistent with prior UPA RA studies to date.

Conclusion: In this MTX-IR study population, switching to UPA as monotherapy at 15mg and 30mg QD showed significant improvements in RA signs and symptoms vs continuing MTX. Numerically higher responses were observed for UPA 30mg vs 15mg, particularly for more stringent efficacy criteria. Safety observations were similar to those in prior UPA studies.

Values are LS mean unless specified. Δ, Change from baseline; QD, once daily; ACR20/50/70, 20/50 or 70% improvement in ACR criteria; CR, Clinical remission; DAS28-CRP, 28-joint disease activity score using C-reactive protein; HAQ-DI, health assessment questionnaire disability index; JE, joint erosion; JSN, joint space narrowing; LDA, low disease activity; mTSS, modified total Sharp score; SF-36 PCS, short form 36-physical component score. Results are based on following analyses: binary endpoints, NRI; mTSS, ANCOVA with linear extrapolation; other continuous endpoints, ANCOVA with rescue handling via LOCF. *** p<.01 and .001 for UPA vs PBO. Δ, ** p<.05, .01 and .001 for UPA vs ADA. Black symbols indicate comparisons that were pre-specified for multiplicity control; lighter gray symbols indicate comparisons that were not pre-specified for multiplicity control.

Background/Purpose: To assess efficacy, including inhibition of radiographic progression, and safety with up adacitinib (UPA), aJAK1- selective inhibitor, vs placebo (PBO) and active comparator, originator adalimumab (ADA), in patients (pts) with active rheumatoid arthritis (RA) continuing on prior methotrexate (MTX).

Methods: In SELECT-COMPARE, pts with active RA despite MTX were randomized 2:2:1 to once-daily (QD) UPA 15mg, PBO, or ADA 40mg every other week (wk) in a double-blind manner, while continuing stable background MTX. Primary endpoints were ACR20 and the proportion of pts achieving DAS28CRP≤2.6(NRI) at Wk12. Key secondary endpoints included non-inferiority (and superiority) of UPA vs ADA at Wk12 (for ACR50, DAS28CRP≤3.2, change from BL (Δ) in Pain, and ΔHAQ-DI), and radiographic inhibition(ΔmTSS) for UPA vs PBO at Wk26. Pts with <20% improvement in TJC and SJC were rescued between Wks14- 26 (from PBO to UPA, UPA to ADA, or ADA to UPA).

Results: Of 1629 randomized pts, 91% completed Wk26 (including rescued pts). BL characteristics were similar across arms. All primary and key secondary endpoints were met. At Wk12, significantly more pts on UPA vs PBO achieved ACR20 (70.5% vs 36.4%) and DAS28CRP<2.6 (28.7% vs 6.1%) (**Table 1**). Superiority was met for UPA vs ADA at Wk12 for ACR50 (45.2% vs 29.1%), DAS28CRP≤3.2 (45.0% vs 28.7%), ΔPain (-31.76 vs -25.31) and ΔHAQ-DI (-0.60 vs -0.49). These differences were maintained through Wk26. At Wk26, pts on UPA vs PBO had significantly less radiographic progression (ΔmTSS, 0.24 vs 0.92), and significantly more pts had no radiographic progression (ΔmTSS ≤0)(83.5% vs. 76.0%). At Wk26, more pts on UPA vs PBO or ADA achieved low disease activity or remission by various criteria (nominal p<.001). Up to Wk26, the proportion of pts with adverse events (AEs) and serious infections, censored at rescue, was higher for UPA vs PBO but similar vs ADA (**Table 2**). The proportion of pts with SAEs and AEs leading to discontinuation for UPA was numerically higher vs PBO and lower vs ADA. Herpes Zoster was numerically higher in UPA vs ADA and PBO. Three malignancies, 5 major adverse cardiovascular events, and 4 deaths were reported, none on UPA. Six venous thromboembolic events (VTEs) were reported (1 on PBO, 2 on UPA and 3 on ADA). For pts who were rescued, no deaths, adjudicated MACE, or adjudicated VTE were observed between rescue and Wk26.

Table 2. Adverse Events Summary Through Week 26, n (%) (censored at treatment switch)

	PBO N=652	UPA 15MG QD N=650 ^a	ADA 40MG EOW N=327
Any Adverse Event (AE)	347 (53.2)	417 (64.2)	197 (60.2)
Serious AE	19 (2.9)	24 (3.7)	14 (4.3)
AE Leading To Discontinuation Of Study Drug	15 (2.3)	23 (3.5)	20 (6.1)
Deaths ^b	2 (0.3)	0	2 (0.6)
Infection	154 (23.6)	226 (34.8)	95 (29.1)
-Serious Infection	5 (0.8)	12 (1.8)	5 (1.5)
-Opportunistic Infection	4 (0.6)	4 (0.6)	1 (0.3)
-Herpes Zoster	3 (0.5)	5 (0.8)	1 (0.3)
Hepatic disorder	32 (4.9)	43 (6.6)	12 (3.7)
Gastrointestinal perforation ^c	0	2 (0.3)	0
Malignancy (including NMSC) ^d	2 (0.3)	0	1 (0.3)
MACE (adjudicated) ^e	3 (0.5)	0	2 (0.6)
VTE (adjudicated)	1 (0.2)	2 (0.3)	3 (0.9)
-PE	1 (0.2)	1 (0.2)	3 (0.9)
-DVT	0	1 (0.2)	0

AE, adverse event; NMSC, non-melanoma skin cancer; VTE, venous thromboembolic events; PE, pulmonary embolism; DVT, deep vein thrombosis.

^aOne patient (patient 1) in UPA received only PBO injection before discontinuing and is included in PBO group for safety assessments.

^bDeaths: PBO: 1 cardiovascular (CV) death and 1 death due to Pneumocystis (jirovecii) pneumonia; ADA: 1 death due to cranio-cervical injury and 1 CV death.

^cGastrointestinal perforation (identified using GI perforation MedDRA SMQ): not spontaneous perforations but 1 perforitis, and 1 anal abscess.

^dMalignancies: PBO: 1 cervical carcinoma, 1 basal cell carcinoma; ADA: 1 basal cell carcinoma.

^eMACE, major adverse cardiovascular events (adjudicated). PBO: 2 non-fatal myocardial infarctions and 1 CV death; ADA: 1 non-fatal stroke and 1 CV death.

Conclusion: UPA 15mg QD showed superiority on improvement in RA signs & symptoms vs PBO and ADA in this MTX-IR population. Radiographic progression was significantly lower with UPA vs PBO. Safety events were consistent with Ph 2 and 3 studies in RA to date.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments I: JAK Inhibitors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: To compare the clinical efficacy, including inhibition of structural damage, and safety of upadacitinib (UPA), a JAK1-selective inhibitor, as monotherapy, vs methotrexate (MTX) monotherapy, in MTX-naïve patients (pts) with moderate to severely active rheumatoid arthritis (RA).

Methods: In SELECT-EARLY, MTX-naïve pts with active RA who were positive for both RF and ACPA and/or had ≥ 1 joint erosion were randomized 1:1:1 to once-daily (QD) UPA at 15mg or 30mg, or weekly MTX (titrated by Wk8). Separate primary endpoints were ACR50 at Wk12 (FDA), or the proportion of pts achieving DAS28CRP < 2.6 at Wk24 (EMA). Secondary endpoints included mean changes from baseline (Δ BL) in modified Total Sharp Score (mTSS) and proportion of pts with no radiographic progression (mTSS ≤ 0) at Wk24.

Results: Of 947 randomized pts, 945 received study drug; 840 (88.7%) completed Wk24. ~50% had an RA diagnosis of < 6 months and RA symptoms < 2 years; Of the 945 pts, 874 (92.5%) had no prior MTX exposure; 706 (74.7%) had no prior csDMARD exposure. Both primary endpoints were met. Significantly more patients receiving UPA 15 and 30mg vs MTX achieved ACR50 responses at Wk12 (52.1% and 56.4% vs 28.3%) and DAS28CRP < 2.6 at Wk24 (48.3% and 50.0% vs 18.5%) (**Table 1**). All ranked secondary endpoints were met: ACR50 at Wk24, improvements in DAS28CRP, HAQ-DI, SF36-PCS, and the proportion of pts achieving DAS28CRP ≤ 3.2 at Wks12 and 24. At Wk24, mean Δ mTSS were 0.14 and 0.07 vs 0.67; significantly more pts had no radiographic progression on UPA 15 and 30mg vs MTX. LDA and remission by various criteria at Wks 12 and 24 were achieved in more pts on UPA vs MTX (nominal $p < .001$ for all).

Up to Wk24, treatment-emergent adverse events (AEs) and serious AEs were similar in the UPA 15mg and MTX arms, and slightly higher in the UPA 30mg arm (**Table 2**). AEs leading to discontinuation were similar across arms. A numerically higher proportion of pts on UPA 30mg reported serious infections vs MTX and UPA 15mg, and there were more cases of herpes zoster in the UPA vs MTX arms. Four malignancies, 4 major adverse cardiovascular events (MACE),

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The Ankylosing Spondylitis Quality of Life (ASQoL) is a readable and simple to complete questionnaire relating to health-related quality of life (HRQoL) in subjects with axial spondyloarthritis (axSpA). Although this tool has previously been used in various research settings over the last decade, the minimal clinically important difference (MCID) remains to be defined.

Methods: All subjects seen at the Spondylitis Clinic of the Toronto Western Hospital between July 2003 and January 2018 with a diagnosis of axSpA were included in this study. The ASQoL comprises 18 questions and answers are dichotomized into yes/no. The weighted score for each item is 1 and poorer HRQoL is associated with higher scores. The MCID for

Receiver operating characteristics curve (ROC) method to estimate MCID for ASQoL

MCID: Minimal clinically important change; AUC: Area under the receiver operating characteristic curve; ASQoL: Ankylosing spondylitis quality of life; PPV: Positive predictive value; NPV: Negative predictive value; HTI: Health transition index; GSRH: global self-rated health

ASQoL was determined by anchor-based methods using two instruments to anchor the change on the ASQoL. The first anchor was the Health Transition Index (HTI) of the Short Form 36 (SF-36): “compared to one year ago, how would you rate your health in general now?”. The answers to this question at the yearly follow-up visit were incorporated in a 5-point Likert scale: “much worse” (-2), “somewhat worse” (-1), “about the same” (0), “somewhat better” (+1) or “much better” (+2). The second anchor was the change in the global self-rated health (GSRH) question of the SF-36 : “In general, would you say your health is [...]”. The answers to this question are: “1- excellent”, “2- very good”, “3- good”, “4- fair” and “5- poor”. The level of change in GSRH between two consecutive visits was considered. A minimal change on the HTI was considered as anyone reporting better (+2 or +1) or worse (-2 or -1), and a minimal change on the GSRH was considered has those who had 1 level of improvement or worsening. The MCID for ASQoL was determined by plotting on receiver operating characteristic (ROC) curves the change in ASQoL that most accurately classified subjects based on optimal sensitivity/specificity ratio (improvement or worsening).

Results: The study consisted of a total of 1328 subjects with longitudinal data cumulated over 5607 visits. Based on ROC curve analyses (image), the MCID for improvement is -2: this had a sensitivity of 40% and specificity of 84% anchored on the HTI, and sensitivity of 43% and specificity of 79% anchored on the GSRH. The MCID for worsening is 1, having a sensitivity/specificity of 40%/84% anchored on the HTI and 43%/79% anchored on the GSRH. Larger cut-off values for ASQoL resulted in a linear increase in the positive predictive value (PPV) up to thresholds of -5 for improvement (PPV=71% anchored on the HTI and PPV=55% anchored on the GSRH) and 5 for worsening (PPV=57% anchored on the HTI and PPV=53% anchored on the GSRH).

Conclusion: This study gives values for MCID and further suggests that larger threshold values in ASQoL change may be applied to better classify subjects according to improvement or worsening in HRQoL. Defining cut-off values will enhance the utility of ASQoL in clinical and research settings.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Big data research in axial spondyloarthritis (axSpA) is limited by a lack of adequate methods for identifying axSpA patients, since there are no billing codes for most subtypes of axSpA. The objective of this study was to develop accurate axSpA identification methods to enable previously impractical observational research in axSpA.

Methods: The population included 600 Veterans with risk factors for axSpA in the Veteran Health Administration (January 1, 2005 through June 30, 2015). Clinical experts reviewed medical records to determine axSpA status. axSpA identification algorithms were developed in a subset of 451 patients (training set) and tested in the remaining 149 patients (testing set). Forty-nine variables anticipated by clinical experts to be predictive of an axSpA diagnosis were selected for algorithm development. The variables included demographics, billing codes, provider utilization patterns, medication dispensations, laboratory results, and affirmative language for key disease features (spondyloarthritis, sacroiliitis, and HLA-B27 positivity) that was extracted from the free text of documents with natural language processing (NLP). Three algorithms were developed: the Spond NLP Algorithm (NLP algorithm as a single variable), High Feasibility Algorithm (16 coded variables), and Full Algorithm (all coded and NLP variables). Random Forest, 5-fold cross validation, and Random Forest Gini Scores were used for algorithm development, testing, and variable prioritization.

Results: In the testing set, the sensitivity of the Spond NLP Algorithm was 95.0% and the specificity was 78.0%. For the High Feasibility Algorithm, the sensitivity was 85.0% and the specificity was 93.6%. For the Full Algorithm, the sensitivity was 87.5%, and the specificity was 91.7% (Figure 1). The areas under the curve with the receiver operating characteristic

analysis for the testing set were 0.86 for the Spond NLP Algorithm, 0.94 for the High Feasibility Algorithm, and 0.96 for the Full Algorithm (Figure 2).

Conclusion: Sensitive and specific algorithms were developed for identifying axSpA patients for big data research. These algorithms offer a range of performance and feasibility attributes that may be appropriate for a broad array of axSpA research.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Few studies have examined risk of cancer in ankylosing spondylitis (AS) since the end of the radiation therapy era. With greater use of biologics, establishing the baseline risk has become more important. The objective of this study was to assess the risk of organ specific cancer in a population-based sample of elderly patients with AS.

Table 1. Organ-Specific Cancer Incidence, Standardized Incidence Ratio

Site	Cancer Events		Standardized Incidence (95% CI) (per 100,000)		SIR (95% CI)
	AS	Control	AS	Control	
Upper Airways	150	3753	119.5	114.0	0.95 (0.80-1.11)
Esophagus	26	18604	19.3	19.3	0.58 (0.36-0.81)
Stomach	22	17195	17.0	30.4	0.55 (0.32-0.79)
Small Intestine	16	3707	12.2	6.5	1.87 (0.95-2.78)
Colorectal	248	132078	190.6	233.7	0.81 (0.71-0.91)
Liver, Gallbladder	18	25807	38.5	45.6	0.84 (0.61-1.07)
Pancreas	68	26932	51.3	47.6	1.07 (0.82-1.33)
Lung	262	168067	213.2	293.8	0.72 (0.64-0.81)
Female Breast	258	102472	569.4	517.6	1.10 (0.96-1.23)
Uterus	49	25044	108.5	126.5	0.85 (0.61-1.09)
Prostate	929	305498	1116.4	831.9	1.34 (1.25-1.42)

Continued: Table 1. Organ-Specific Cancer Incidence, Standardized Incidence Ratio

Site	Cancer Events		Standardized Incidence (95% CI) (per 100,000)		SIR (95% CI)
	AS	Control	AS	Control	
Kidney	160	46593	135.5	85.9	1.57 (1.34-1.80)
Bladder	208	74664	151.2	132.1	1.14 (0.98-1.30)
Thyroid	48	13586	34.5	24.0	1.43 (1.02-1.85)
Connective tissue, Bone	59	19218	44.1	40.2	1.29 (0.96-1.63)
Melanoma	179	48158	127.6	85.2	1.49 (1.27-1.71)
Brain, Eye, Nervous System	62	21491	46.3	38.0	1.21 (0.91-1.52)
Multiple Myeloma	66	22040	51.8	38.9	1.32 (1.01-1.64)
Non-Hodgkin's Lymphoma	251	76365	184.9	135.1	1.36 (1.19-1.53)
Hodgkin's disease	16	5263	12	9.3	1.29 (0.66-1.92)
Leukemia	189	54565	139.8	96.5	1.44 (1.24-1.65)

Methods: We reviewed Medicare databases from 1999 to 2013 for all beneficiaries 65 or older with a diagnosis of AS, excluding those with concomitant diagnosis of other rheumatic diseases. The reference population was a 30% stratified random sample of beneficiaries without a diagnosis of AS, matched on age and sex. New cancer diagnoses were identified in the AS and reference population when there were two identical International Classification of Disease-9 codes in visits at least thirty days apart. Those who developed cancer within the first year of observation were excluded. Patients were followed until 2015. Standardized incidence ratio (SIR) was defined as the ratio of observed to expected number of cancers in AS compared to the reference group, accounting for person-years at risk.

Results: A total of 13,305 AS (66% male, 91% white, median follow up 10 years) and 6,749,053 beneficiaries without AS (66% male, 85% white, median follow up 8 years) were included. AS patients contributed 130,841 person-years and beneficiaries without AS contributed 56,515,489 person-years of follow up. A total of 3322 cancers occurred in AS and 1,211,126 cancers occurred in beneficiaries without AS. SIR (95% confidence interval) for six sites were higher in AS: kidney cancer 1.57(1.34-1.80) melanoma 1.49 (1.27-1.71) thyroid cancer 1.43 (1.02-1.85) leukemia 1.44(1.24-1.65) non-Hodgkin's lymphoma 1.36 (1.19-1.53) and prostate cancer 1.34 (1.25-1.42). SIR for four sites were lower in AS: esophagus 0.58 (0.36-0.81) stomach 0.55 (0.32-0.79) colorectal 0.81 (0.71-0.91) and lung cancer 0.72 (0.64-0.81). (table 1)

Conclusion: Elderly patients with AS are at increased risk of hematological malignancies and kidney cancer but have lower risk of gastrointestinal and lung cancer. The relative protection from gastrointestinal and lung cancer and increased risk of kidney cancer is consistent with the pattern seen with chronic use of nonsteroidal anti-inflammatory drugs. Further study is required to distinguish disease from treatment related cancer risk in AS.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Recent studies have shown possible anti-inflammatory effects and a survival benefit with statin usage in ankylosing spondylitis (AS). The purpose of this study was to assess whether statin usage is associated with lower disease activity in a longitudinal cohort of patients with AS.

Methods: AS patients meeting modified New York Criteria with at least one year of clinical follow-up with statin usage were included in the analysis. Patients on statins were classified into high, moderate, and low intensity statins based on 2013 American Heart Association/American College of Cardiology Treatment of Cholesterol Guidelines [1]. We used a longitudinal negative binomial regression model to evaluate the effect of statin usage on the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) using generalized estimating equations controlling for age, sex, ethnicity, education, smoking status, cardiovascular comorbidities, CRP, exercise, antihypertensive, nonsteroidal anti-inflammatory drugs (NSAID) and TNFi usage. We further tested interactions to see whether NSAID usage modified the longitudinal association between BASDAI scores and statin usage.

Results: 814 AS patients, with at least one year of follow-up, were studied. 86 of these patients were on a statin at baseline. 10 patients, 65 patients, and 11 patients were on a low, moderate, and high intensity statin respectively. Follow-up median was 4.8 years, IQR of (2.3,7.1). Statin usage alone was not significantly associated with BASDAI when it was tested in additive models ($p=0.4$). NSAID usage alone was significantly associated with higher BASDAI score ($p<0.01$). In the interactive model, when the interaction effect between statin and NSAID usage in relation to BASDAI was assessed, of patients with an NSAID index $\geq 50\%$, BASDAI score was 32% lower for low intensity statin compared to no statin use ($p<0.001$) and 18% lower for high intensity statin compared to no statin use ($p=0.004$) (Table 1). ESR was collinear with CRP. When interactions of statin and TNFi usage were tested (data not shown), of the patients taking TNFi, statins were not significantly associated with lower BASDAI score. Of the patients not taking TNFi, statins were significantly associated with lower BASDAI scores for high intensity statins compared to no statin use ($p<0.01$).

Table 1: Effect of Statin Usage on BASDAI based on Multivariable Longitudinal Model

	Adjusted Rate Ratio (95% CI)	P-value
<u>Effect of Statin Usage on BASDAI per NSAID index group</u>		0.150
<i>(interaction between Statin and NSAID usage in relation to BASDAI)</i>		
when NSAID index \geq 50%:		
Statin Low Intensity vs no use	0.68 (0.57, 0.81)	<0.001
Statin Moderate Intensity vs no use	0.98 (0.89, 1.09)	0.703
Statin High Intensity vs no use	0.82 (0.72, 0.94)	0.004
Statin High Intensity vs Moderate Intensity	0.84 (0.73, 0.96)	0.009
when NSAID index < 50%:		
Statin Low Intensity vs no use	1.01 (0.88, 1.17)	0.848
Statin Moderate Intensity vs no use	0.94 (0.83, 1.05)	0.286
Statin High Intensity vs no use	1.01 (0.74, 1.38)	0.939
Statin High Intensity vs Moderate Intensity	1.08 (0.80, 1.45)	0.616
when NSAID not used:		
Statin Low Intensity vs no use	1.11 (0.92, 1.35)	0.275
Statin Moderate Intensity vs no use	1.00 (0.92, 1.08)	0.906
Statin High Intensity vs no use	0.94 (0.82, 1.08)	0.389
Statin High Intensity vs Moderate Intensity	0.94 (0.82, 1.09)	0.443
Education Level (college or higher) vs. other	0.78 (0.70, 0.87)	<0.001
White vs. other	0.93 (0.85, 1.03)	0.176
Male vs. female	0.87 (0.80, 0.94)	0.001
AGE \geq 40 years vs. < 40 years	1.12 (1.04, 1.22)	0.005
Ever Smoker vs. Nonsmoker	1.15 (1.06, 1.24)	0.001
Abnormal CRP vs. normal	1.16 (1.12, 1.21)	<0.001
Cardiovascular Diseases* (hypertension excluded) vs. other comorbidities	1.10 (0.96, 1.27)	0.171
Diabetes vs. other	1.23 (1.05, 1.44)	0.012
Exercise \geq 120 mins vs. < 120 mins	0.92 (0.89, 0.95)	<0.001
TNFi use	0.88 (0.83, 0.93)	<0.001
Antihypertensive Medication use	1.07 (1.01, 1.14)	0.031

* cardiac bypass surgery, angioplasty (percutaneous intervention), coronary artery disease, myocardial infarction, angina, valvular heart disease, or heart valve replacement.

Conclusion: Statins when taken with NSAIDs at anti-inflammatory doses were associated with a significant reduction in AS disease activity. TNFi may mask the anti-inflammatory effect of statins. Future studies will require more patients to confirm the effect.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: TNF blockers, have been widely used in immune-mediated diseases and many genetic variations predicting treatment response have been described. We applied previously published genetic variations relevant in response of TNF blockers of rheumatoid arthritis (RA) and spondyloarthritis (SpA) to predict treatment response and radiographic progression of ankylosing spondylitis (AS) patients.

Methods: We recruited 142 AS patients from three medical centers (Guanghua, Changhai and Zhongshan hospital in China). All patients have stopped treatment for more than 6 months before we recruited them or never been treated with TNF blockers. The response to etanercept or adalimumab was evaluated at 3-month and 6-month followup visits by different criteria (BASDAI 50, ASAS20, ASAS 40, ASAS5/6, partial remission and difference of ASDAS) and 62 of AS patients were evaluated for disease activity or progression with MRI (SPARCC) and radiographic imaging. Sixty-two genetic variations were collected by searching in PUBMED. Statistical analyses included Fisher's exact test and logistic regression analysis.

Results: Most of key loci identified belonged to genes in the Toll-like receptor signaling pathway and other immune-relevant loci. The results showed important differences between etanercept and adalimumab when associations between genetic polymorphisms and treatment response were examined. Genetic variations in *ARFGAP2* alleles showed significantly difference between responders and non-responders, especially in patients treated with etanercept (OR = 0.21, P-value = 0.0004). When ASDAS was performed as the response criterion, a *SLCO1C1* allele was highly associated with treatment response (OR = 12.72, P-value = 0.0004), and in the etanercept subgroup, none of the non-responders carried it (P-value = 0.008). In addition, genetic loci in *LRPAP1* had strong linkage with the variation of fat metaplasia and erosion. It was associated with the variation of erosion both in 3-month follow-up and 6-month follow-up. Genetic loci in *MYOM2* was associated with the variation of backfill after 6-month treatment. *IL10* were associated with ankyloses at baseline. *ACE* and *S100A8* are significantly associated with mSASSS score of sacroiliac and spine at baseline, respectively (Table 1).

Conclusion: Several genetic loci showed significantly differences between responders and non-responders to anti-TNF agents in AS and may also predict the MRI/radiographic inflammation and disease progression. This suggests an important role of pharmacogenomics profiling in predicting treatment response and disease progression.

Table 1 Genetic loci associated with Image progression

	Gene	β	P-value
MRI (N=65)			
sacroiliac joint inflammation	ARFGAP2	8	0.02
spine inflammation	TNF	-7.6	0.02
fat metaplasia	LRPAP1	-1.8	0.004
erosion	LRPAP1	1.1	0.006
backfill	MYOM2	-1.6	0.003
ankylosis	IL10	8.1	0.003
mSASSS (N=65)			
sacroiliac	ACE	0.66	0.04
spine	S100A8	11.2	0.01

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Magnetic resonance imaging (MRI) is crucial for classification and diagnosis of axial spondyloarthritis (axSpA). Characteristic MRI lesions of axSpA are bone marrow edema (BME) or structural fatty lesions

(FL) of the sacroiliac joints (SIJ) and spine. However, the specificity of these lesions has been questioned, since patients with chronic back pain but no axSpA may also have a positive MRI, as shown in recent cohort studies. In this study we investigate the prevalence of BME and FL on MRI of the spine and the SIJ in the general population.

Methods: Volunteers <45 years of the population based Study of Health in Pomerania (SHIP)^{1,2} underwent MRI examinations of the spine (sagittal orientation, T1 and T2 MRI sequences) and the SIJ (coronal orientation, STIR sequences), independently of clinical symptoms. Two trained readers blinded for age and gender of the examined persons evaluated the prevalence of BME (SIJ and spine) and FL (spine) suggestive of axSpA using the ASAS definitions: a lesion in the SIJ was considered positive if located periarticularly and in the middle part of the joint and a lesion in the spine was considered positive if detected at the edge of the vertebral body). Clearly degenerative lesions involving the vertebral endplate or being accompanied by abnormalities of the intervertebral disc (protrusion or prolapse) were not counted.

Results: A total of 802 complete MRI sets (spine and SIJ) of 394 male (49.1%) and 408 female volunteers (50.9%) was evaluated. The mean age of all patients was 37.5±6.2 years. BME in the SIJ suggestive of axSpA were found in 144 individuals (18%), with an equal distribution between males (n=74, 18.8%) and females (n=70, 17.2%). A similar pattern of BME was found in the spine, again with no differences between males and females. However, the location of the lesions was different: 9.5% had ≥1 lesion in the cervical, 18.6% in the thoracic and 7.4% in the lumbar spine. Overall, 88.6% male and 84.6% female volunteers were found to have ≥1 and 54.6% male and 46.1% female volunteers were found to have at ≥3 positive spinal lesions in any spinal region. In comparison, the prevalence of FL was higher (36.7% volunteers in the cervical, 72.4% in the thoracic and 52.7% in the lumbar spine). Overall, 86.5% volunteers were found to have ≥1 and 50.2% volunteers were found to have ≥3 positive spinal lesions in any spinal segment. Logistic regression analysis showed that age was the only demographic characteristic that independently contributed to the occurrence of both BME (RR=1.22, 95%CI 1.03-1.46, p<0.025) or FL ((RR=1.12, 95%CI 1.07-1.19, p<0.001).

Conclusion: In this large population-based study with healthy volunteers a relatively high prevalence of inflammatory and structural MRI lesions was found. Whether these lesions are to be explained by mechanical stress needs to be further studied. The high prevalence of BME and FL in the axial skeleton in the general population indicates a limited diagnostic value of these MRI findings. Thus, those should be interpreted with caution in relation to diagnosis, classification and assessment of disease activity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

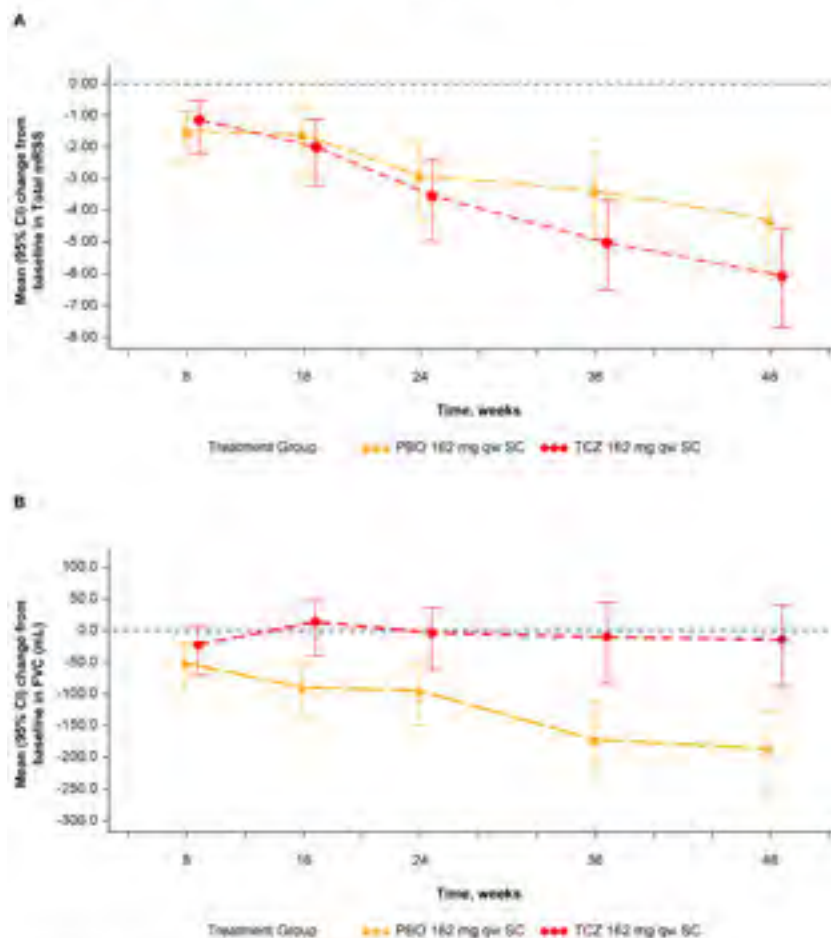

Session Time: 2:30PM-4:00PM

Background/Purpose: The anti-interleukin-6 (IL-6) receptor- α antibody tocilizumab (TCZ) demonstrated numeric improvement in skin thickening (modified Rodnan skin score [mRSS]) and clinically meaningful lung function preservation (forced vital capacity [FVC]) in patients with systemic sclerosis (SSc) in a phase 2 randomized controlled trial.^{1,2} Efficacy and safety of TCZ vs placebo (PBO) in patients with SSc are now reported from the double-blind period of a phase 3 trial (NCT02453256).

Methods: Patients with SSc were randomly assigned 1:1 to receive weekly double-blind injections of subcutaneous TCZ 162mg or PBO for 48 weeks. Patients could receive escape therapy from week 16 if they experienced declines in FVC or from week 24 if they experienced worsened mRSS or worsened SSc complications. The primary end point was difference in mean change in mRSS from baseline to week 48 for TCZ vs PBO. Key secondary end points were change from baseline in percent predicted FVC at week 48 and time to treatment failure (time from first study treatment to first occurrence of death, decline in FVC >10%, increase in mRSS >20% and mRSS \geq 5, or occurrence of predefined SSc-related complications).

Results: Among 212 randomly assigned patients, 81% were women; baseline mean values were age 48 years, SSc duration 23 months, mRSS 20.4, and percent predicted FVC 82.1% (210 patients were treated [PBO, 106; TCZ, 104]). At week 48, the primary end point (change in mRSS) was not met but improved numerically (PBO, -4.41; TCZ, -6.14; adjusted difference in least squares mean, -1.73 [95% CI: -3.78, 0.32]; $p = 0.098$) (Figure). Therefore, all other p values were considered nominal. The cumulative distribution of change from baseline to week 48 in percent predicted FVC favored TCZ over PBO (median [IQR]: PBO, -3.9 [-7.2, 0.6] vs TCZ, -0.6 [-5.3, 3.9]; van Elteren $p = 0.0015$). The difference in mean change from baseline in FVC at week 48 was 167 mL (95% CI: 83, 250) in favor of TCZ. Preservation of lung function with TCZ was shown by change from baseline in FVC over time (Figure). The hazard ratio (95% CI) for the time to treatment failure end point was 0.63 (0.37, 1.06) in favor of TCZ (Cox proportional hazards model; $p = 0.082$). Safety was consistent with known complications of SSc and with the safety profile of TCZ; serious adverse events were reported by 17% of PBO patients and 13% of TCZ patients; serious infections were reported by 7% and 2% of patients, respectively.

Figure. Change from baseline in mRSS (A) and FVC (B)

A mixed model for repeated measures analysis was implemented. The analysis included the fixed, categorical effects of treatment, visit, the stratification factor IL-6 level (<10; \geq 10 pg/mL) at screening, IL-6 level at screening-by-visit interaction, and treatment-by-visit interaction, as well as the continuous covariates of baseline score and baseline score-by-visit interaction.

Conclusion: The primary end point was not met; however, clinically meaningful and consistent differences in FVC were shown in 2 randomized controlled trials. Time to treatment failure is supportive of a clinical benefit of TCZ in SSc.
